Characterization of Unlabeled Level Planar Graphs

J. Joseph Fowler* and Stephen G. Kobourov*

Department of Computer Science, University of Arizona {jfowler,kobourov}@cs.arizona.edu

Abstract. We present the set of planar graphs that always have a simultaneous geometric embedding with a strictly monotone path on the same set of n vertices, for any of the n! possible mappings. These graphs are equivalent to the set of unlabeled level planar (ULP) graphs that are level planar over all possible labelings. Our contributions are twofold. First, we provide linear time drawing algorithms for ULP graphs. Second, we provide a complete characterization of ULP graphs by showing that any other graph must contain a subgraph homeomorphic to one of seven forbidden graphs.

1 Introduction

Simultaneous embedding enables the visualization of multiple graphs on the same set of vertices. In order to preserve the "mental map," graphs are overlaid so that corresponding vertices have the same location. The mapping between vertices may be fixed, or may not be given, or may change and dynamically evolve as in the case of colored simultaneous embeddings [1]. To accommodate this, we consider all possible 1-1 mappings between graphs. Embeddings that use no edge bends and in which no pair of edges of the same graph cross are known as simultaneous geometric embeddings [2].

Determining which graphs share a simultaneous geometric embedding has proved difficult. While Geyer et al. [7] have shown this cannot always be done for tree-tree pairs, the question remains open for tree-path pairs. Estrella et al. [5] partially answer this question by characterizing the set of trees that have a simultaneous geometric embedding with a strictly monotone path. We now extend those results by characterizing the set of all planar graphs that have a simultaneous geometric embedding with a strictly monotone path. The importance of this result lies in the fact that all positive results showing that certain pairs of graphs allow simultaneous geometric embeddings rely on reducing at least one of the graphs in the pair under consideration to a path which is realized in strictly monotone fashion. Thus, our result captures the largest possible class of graphs that can be embedded using this technique.

Rotating or stretching a drawing along a single direction does not affect crossings. As a result, we assume that the path will be drawn in a zig-zag fashion

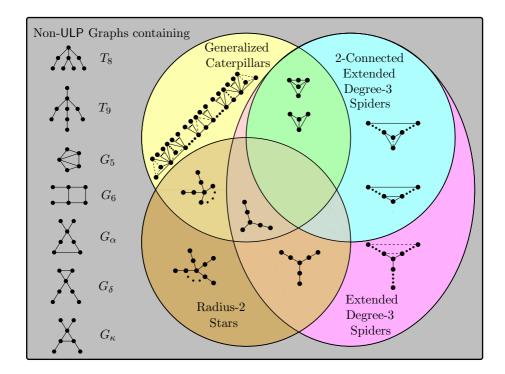

Fig. 1. A Venn diagram of the set of graphs characterized by the seven forbidden graphs T_8 , T_9 , G_5 , G_6 , G_α , G_δ , and G_κ in \mathcal{F} . Graphs that do not contain a subgraph homeomorphic to of any of these are generalized caterpillars, radius-2 stars, and extended degree-3 spiders.

with a difference of +1 between the y-coordinates of two successive vertices. This allows us to frame the problem of drawing the planar graph in terms of placing the vertices along a set of parallel horizontal lines, called tracks, with one vertex per track. For an n-vertex planar graph, we label the vertices from 1 to n in which the label is the y-coordinate. If a planar graph has a straight-line drawing without crossings for all n! permutations of the labels, then it has a simultaneous geometric embedding with a strictly monotone path for any mapping.

A related problem is that of level planarity [9]. Our labeling forms a partition of vertices into levels with one vertex per level. If we consider a graph in which the y-coordinate of each level is distinct and all the edges are y-monotone, then we have a level drawing. If the drawing is planar, then the graph is level planar for that labeling. If this holds for each of the n! labelings, then the graph is unlabeled level planar (ULP). ULP graphs are precisely those that have a simultaneous geometric embedding with strictly monotone paths for any labeling. Hence, we can also phrase our problem in terms of level planarity.

Any graph for which this cannot be done must have some subgraph homeomorphic to a forbidden graph, or obstruction, that will induce a crossing when drawn on tracks for a particular labeling. In this paper we show that ULP graphs

fall into three categories: radius-2 stars, generalized caterpillars, and extended degree-3 spiders. Furthermore, we show how to simultaneously embed any ULP graph with a monotone path in linear time. Finally, we complete the characterization in terms of a minimal set of seven forbidden graphs, $\mathcal{F} := \{T_8, T_9, G_5, G_6, G_{\alpha}, G_{\delta}, G_{\kappa}\}$; see Fig. 1.

2 Preliminaries

Two planar n-vertex graphs $G_1(V, E_1)$ and $G_2(V, E_2)$ have a simultaneous embedding with mapping if they can be drawn in the xy-plane with bijection $f: V \mapsto V$ in which v and f(v) have the same xy-coordinates while maintaining the planarity of each graph. If this can be done for some bijection f, then G_1 and G_2 are simultaneously embeddable. If edges of both E_1 and E_2 are drawn with straight-line edges, then G_1 and G_2 have a simultaneous geometric embedding.

Let an n-vertex graph G(V, E) have a labeling $\phi: V \mapsto [1..n]$ in which $\phi(u) \neq \phi(v)$ for all $(u, v) \in E$. A horizontal line $\ell_j = \{(x, j) \mid x \in \mathbb{R}\}$ for some $j \in [1..n]$ is $track\ j$. In a realization of G, each vertex $v \in V$ is placed along track $\phi(v)$ and each edge (u, v) is strictly y-monotone. Edge bends b_1, b_2, \ldots, b_k may naturally occur at any point edge (u, v) intersects a track provided $\phi(u) < \phi(b_1) < \cdots < \phi(b_k) < \phi(v)$ or $\phi(u) > \phi(b_1) > \cdots > \phi(b_k) > \phi(v)$ in which b_1 is adjacent to u, b_k is adjacent to v, and b_i lies between b_{i-1} and b_{i+1} for 1 < i < k.

A realization without crossings is a planar realization of G. A planar realization with one straight-line segment for each edge (u,v) is a straight-line planar realization of G. While any planar realization with bends can be "stretched out" in the x-direction to form a straight-line planar realization in O(n) time as shown by Eades et al. [4], the area of the realization can become exponential.

A level graph $G(V, E, \phi)$ is a directed graph with leveling $\phi : V \mapsto [1..k]$ that assigns every vertex to one of k levels so that $\phi(u) < \phi(v)$ for every edge (u, v). In a level drawing all vertices in a level have the same y-coordinate and each edge is y-monotone. If the level drawing can be drawn without crossings, then G is level planar. The level planarity of G for a given leveling is independent of its orientation: First take an n-vertex undirected graph G. Then label G with labeling $\phi : V \mapsto [1..n]$. Next orient each edge (u, v) of G so that $\phi(u) < \phi(v)$ to form the level graph $\tilde{G}(V, \tilde{E}, \phi)$ with the leveling ϕ on n levels with one vertex per level. Then ask is \tilde{G} level planar? If yes, repeat this process for all other labelings of G. If one never encounters a level nonplanar graph, the graph G is called unlabeled level planar (ULP). Hence, a ULP graph has a simultaneous embedding with a strictly y-monotone path for any labeling ϕ ; see Fig 2.

The vertices placed along a track correspond to the levels in a level graph. An undirected graph with a labeling ϕ has a "planar realization" if and only if the corresponding level graph is "level planar". These two terms are interchangeable only if edge bends do not matter. If we need a simultaneous geometric embedding we use the more restrictive term "straight-line planar realization".

A chain C of G is a simple path denoted $v_1-v_2-\cdots-v_t$. The vertices of C are denoted V(C). A vertex v of C is ϕ -minimal (or ϕ -maximal) if it has a

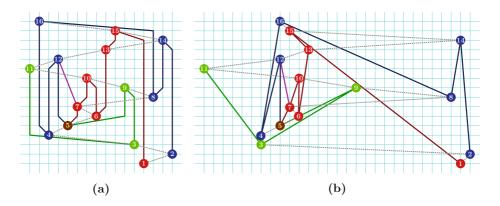

Fig. 2. Simultaneous embeddings of a path and a ULP tree with and without bends

minimal (or maximal) track number of all the vertices of V(C). Such a vertex is ϕ -extreme if it is ϕ -minimal or ϕ -maximal.

In a graph G(V, E), subdividing an edge $(u, v) \in E$ replaces edge (u, v) with the pair of edges (u, w) and (w, v) in E by adding w to V. A subdivision of G is a graph obtained by performing a series of subdivisions of G. A graph G(V, E) is isomorphic to a graph $\tilde{G}(\tilde{V}, \tilde{E})$ if there exists a bijection $f: V \mapsto \tilde{V}$ such that $(u, v) \in E$ if and only if $(f(u), f(v)) \in \tilde{E}$. A graph G(V, E) is homeomorphic to a graph $\tilde{G}(\tilde{V}, \tilde{E})$ if a subdivision of G is isomorphic to a subdivision of G. The distance between vertices G and G is isomorphic to a subdivision of G the form G is the length of the shortest path from G is isomorphic to a subdivision of G. The radius of a graph is the minimum eccentricity of any vertex.

A leaf vertex is any degree-1 vertex. A caterpillar is a tree in which the removal of all leaf vertices yields a path (the empty graph is a special case of a path). The remaining path forms the spine. A lobster is a tree in which the removal of all leaf vertices yields a caterpillar. A claw is a $K_{1,3}$, whereas, a star is a $K_{1,k}$ for some $k \geq 3$. A double star is a star in which each edge has been subdivided once. A radius-2 star (R-2S) is any subgraph of a double star with radius 2. A degree-3 spider is an arbitrarily subdivided claw. The following six types of "edges" in Fig. 3 allow us to generalize a caterpillar and to extend a degree-3 spider to include cycles.

Definition 1

- (a) A K_3 edge is the cycle u-v-w-u on vertices $\{u,v,w\}$
- (b) A C_4 edge is the cycle u-s-v-t-u on vertices $\{u,v,s,t\}$.
- (c) A kite edge is the cycle u-s-v-t-u with edge s-t on vertices $\{u,v,s,t\}$.
- (d) A K_3^* edge is set of cycles u-v-w'-u with edge u-v on vertices $\{u,v\} \cup W$ where $w' \in W$ for some possibly empty vertex set W.
- (e) A C_4^+ edge is set of cycles u-w-v-w'-u on vertices $\{u,v,w\} \cup W$ where $w' \in W$ for some non-empty vertex set W.
- (f) A K_4 edge is the complete graph on the vertices $\{u, x, y, z\}$.

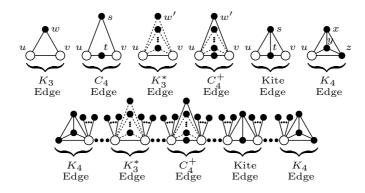

Fig. 3. The six types of H edges used to from a GC on the second line

Definition 2. A generalized caterpillar (GC) is a caterpillar in which each edge u'-v' along the spine can be replaced with a K_3^* , C_4^+ , or kite edge (and the two edges at the end of the spine can also be replaced by a K_4 edge) in which vertex u (and v if present) replaces vertex u' (and v'); see Fig. 3.

Definition 3

- (a) A 1-connected extended degree-3 spider (1-CE3-S) is a degree-3 spider with two optional edges connecting
 - (i) two of three vertices adjacent to the degree-3 vertex and
 - (ii) two of the three leaf vertices; see Fig. 4(a).
- (b) A 2-connected extended degree-3 spider (2-CE3-S) is a cycle or a cycle with one K_3 , C_4 or kite edge, see Fig. 4(b).
- (c) A extended degree-3 spider (E3-5) is either a 1-connected extended degree-3 spider or a 2-connected extended degree-3 spider.

These definitions allows us to make the following observation.

Observation 4. Every spanning tree of a GC is a caterpillar. Every spanning tree of a E3-S is a degree-3 spider or a path.

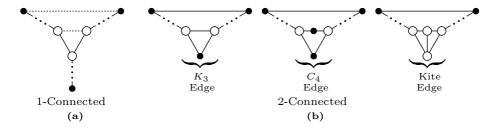

Fig. 4. A extended degree-3 spider is either (a) a 1-CE3-S or (b) a 2-CE3-S

3 Graphs with Planar Realizations on Tracks

In this section we show that radius-2 stars (R-2S), generalized caterpillars (GC), and extended degree-3 spiders (E3-S) are level planar for any labeling. We do this by presenting linear time algorithms for straight-line, crossings-free drawing of any such graph on the tracks determined by its labeling. More formally, we show that $\mathcal{P} = \{G: G \text{ is a R-2S, GC, or E3-S}\}$ is ULP.

The next lemma from [5] shows this for a R-2S.

Lemma 5 (Lemma 4 of [5]). An n-vertex radius-2 star can be straight-line planarly realized in O(n) time on a $(2n+1) \times n$ grid for any labeling.

The following lemmas show how a GC and the two types of a E3-S also have compact planar realizations on tracks. We give a proof sketch for the next lemma; the full proof can be found in [6].

Lemma 6. An n-vertex generalized caterpillar can be straight-line planarly realized in O(n) time within an $n \times n$ grid for any labeling.

Proof Sketch: We obtain the cut vertices of the GC using the vertices of its spanning tree, which must be a caterpillar by Observation 4, as candidates. With these we can draw each incident K_3^* , C_4^+ , kite, and K_4 spine edge using at most $4 \times n$ space for each one proceeding left to right along the spine; see Fig. 5. If we were not constrained to an integer grid, one could place all the incident edges with leaf vertices in a sufficiently narrow region above and below each cut

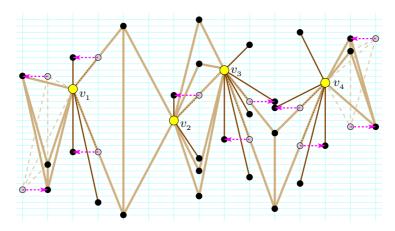

Fig. 5. The gray vertices are initial locations of vertices in a straight-line planar realization of a GC on a 14×32 grid. The arrows avoid crossings or overlapping edges. A leaf is initially placed to the right of its cut vertex except for the last one with its leaves placed to the left. Overlaps are eliminated by moving leaves left and right, e.g., the leaves between v_3 and v_4 . The K_4 edges incident to v_1 and v_4 show initial locations with dashed edges leading to crossings that are eliminated by switching the location of the two incident vertices.

vertex. Being restricted to integer coordinates, we shift the endpoint of a leaf vertex left or right by one space as needed to avoid overlapping edges. \Box

Lemma 7. An n-vertex 1-connected extended degree-3 spider can be planarly realized in O(n) time on an $n \times n$ grid for any labeling.

Proof. We show how to draw G on tracks with at most one bend per edge for a labeling ϕ . We first draw a subgraph that is a degree-3 spider T with an extra edge in G between two of three vertices adjacent to the root vertex r (the unique degree-3 vertex) of T. Next, we accommodate an extra edge in G connecting two leaf vertices of T.

Let T' be portion of the T drawn so far. We maintain two invariants:

- (1) two of the leaf vertices v_{\min} and v_{\max} of T' are ϕ -extreme and
- (2) T' only intersects the track of the third leaf vertex v_{mid} either to the left or right of v_{mid} .

Provided these invariants hold, we keep placing the next vertex v adjacent to $v_{\rm mid}$ in T-T' one space to the left or right of T' at x-coordinate v_x depending on which side of the track of $v_{\rm mid}$ that T' intersects. By (2), T' does not intersect one side of the track of $v_{\rm mid}$. Whenever we draw from v to w (in this case $w=v_{\rm mid}$), we bend the edge at $(v_x, \phi(w)-1)$ if $\phi(v) < \phi(w)$ and at $(v_x, \phi(w)+1)$ otherwise. We keep doing this until v becomes ϕ -extreme. Either $v_{\rm min}$ or $v_{\rm max}$ becomes $v_{\rm mid}$. Since that vertex was previously ϕ -extreme by invariant (1), T' now only intersects its track either to the left or right, maintaining invariant (2).

We start drawing T until both invariants hold for T'. Place r at $(0, \phi(r))$. Let $\{u, v, w\}$ be the neighbors of r in T. Let v_{\min} , v_{\min} and v_{\max} be these vertices such that $\phi(v_{\min}) < \phi(v_{\min}) < \phi(v_{\max})$. If $\phi(v_{\min}) < \phi(r) < \phi(v_{\max})$, drawing edges from r to vertices at $(-1, \phi(v_{\min}))$, $(1, \phi(v_{\max}))$, and $(2, \phi(v_{\min}))$ satisfies both invariants. In this case, we can also add a straight-line edge between any one pair of $\{u, v, w\}$. Otherwise, suppose w.l.o.g that $\phi(r) < \phi(v_{\min})$. Let $\{a, b, c\}$ be the ϕ -maximal vertices of the portions of the chains in T from r to the point each chain crosses the track of r such that $\phi(a) > \phi(b) > \phi(c)$. Assume w.l.o.g. that u is first vertex of the chain with a. There are two cases:

- (i) If edge (v, w) is not in G, assume w.l.o.g. edge (u, w) is in G. Extend the chain starting with u to the right of r until it reaches a becoming v_{max} . Place v one right of a with an edge bend at $(v_x, \phi(r) + 1)$.
- (ii) If edge (v, w) is in G, then assume w.l.o.g. v is the first vertex of the chain with b. Extend this chain to the right until it reaches b. Place u one right of b with an edge bend at $(u_x, \phi(r) + 1)$ and continue to extend the chain to the right until it reaches a becoming v_{max} .

Place w at $(-1, \phi(w))$ and extend the chain to the left until it becomes v_{\min} . Edge (u, w) or (v, w) can be drawn with a straight-line edge since u or v is one right of r. In both cases, invariants (1) and (2) hold; see Fig. 6.

If an edge connects two leaf vertices to form a cycle C in T, we first draw subtree \tilde{T} in which two leaf vertices c_{\min} and c_{\max} of \tilde{T} are the ϕ -extreme vertices

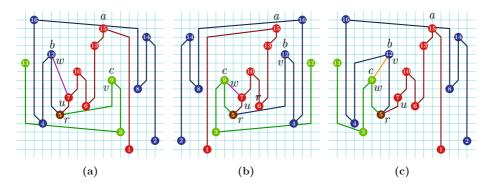

Fig. 6. Examples of three 1-CE3-Ss on 16×16 grids. The only difference is the edge between one pair of the three vertices adjacent to the root. If this edge is incident to u, the first vertex along chain with the vertex a, case (i) applies as in (a) and (b). Otherwise, case (ii) applies as in (c).

of C. The above algorithm ensures the other chain of \tilde{T} only intersects the tracks of c_{\min} and c_{\max} to the right or left, blocking one direction, but not both. Whichever c_{\min} or c_{\max} is leftmost or rightmost of \tilde{T} , say that c_{\min} is rightmost, we extend the rest of C from c_{\min} right until reaching v adjacent to c_{\max} . Then we draw an edge from v to c_{\max} with a bend at $(v_x, \phi(c_{\max}) - 1)$.

We next give a similar realization of a 2-C E 3-S with bends—the difference being that most edges are straight except for one or two edges that might require a bend.

Lemma 8. An n-vertex 2-connected extended degree-3 spider can be planarly realized in O(n) time on an $n \times n$ grid for any labeling.

Proof. Let ϕ be a labeling of a 2-CE3-S G. If G is merely a cycle C, then C can be planarly realized on an $n \times n$ grid with one edge bend. Begin with the ϕ -maximal vertex v_1 at the first position and proceed left to right placing each subsequent vertex in the cycle one to the right of the previous one until reaching the last vertex v_k that is also adjacent to v_1 . The edge v_1 - v_k requires only one bend directly above v_k routing the edge above all the other vertices.

By Definition 3, a 2-C E 3-S is at worst a cycle with a kite edge between u and v with common neighbors $\{s,t\}$ connected by edge s-t such that $\phi(s) > \phi(t)$. If s and t are ϕ -extreme, then we can draw the cycle without t starting from s and ending with v as above and place t below s drawing the straight edges s-t and t-u. Then we draw t-v with a bend directly below v and route the edge below all the others; see Fig. 7(a). Otherwise, either s or t is not ϕ -extreme in which case the other ϕ -extreme one is used to draw the cycle so as to not end with u or v; see Fig. 7(b). Suppose that s is not ϕ -maximal, then t can be placed directly below s and the three additional edges can be added as straight edges.

We can remove the bends on the edges by stretching the layout which yields the next corollary; the full proof can be found in [6].

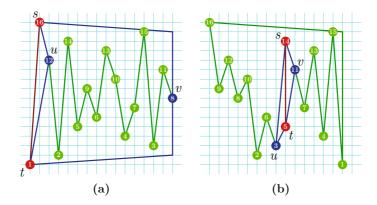

Fig. 7. Planar realizations of two 16-level 2-C E 3-Ss on 16×16 grids illustrating the two cases in which s and t are ϕ -extreme

Corollary 9. An n-vertex 1-connected extended degree-3 spider with radius r can be straight-line planarly realized in O(n) time on an $O(r! 3^r) \times n$ grid for any labeling, whereas, an n-vertex 2-connected extended degree-3 spider can be straight-line planarly realized in O(n) time on an $n^2 \times n$ grid for any labeling.

Combining Lemmas 5, 6, 7, 8, and Corollary 9, we have our first theorem.

Theorem 10. Any graph from \mathcal{P} has a simultaneous geometric embedding with a strictly monotone path for any labeling.

4 Forbidden Graphs

We give seven forbidden graphs $\mathcal{F} := \{T_8, T_9, G_5, G_6, G_{\alpha}, G_{\delta}, G_{\kappa}\}$ that do not always have a simultaneous geometric embedding with a strictly monotone path; see Fig. 8. For each we provide a labeling that forces self-crossings. As noted previously for a given labeling, a graph has a straight-line planar realization if and only if it also has a planar realization that allows edge bends provided the edges remain strictly monotone [4]. Hence, it suffices to only consider straight-line edges in this section.

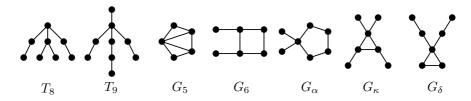

Fig. 8. The seven forbidden graphs of \mathcal{F}

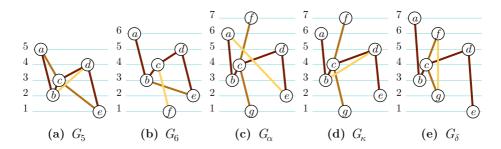

Fig. 9. Labelings that force self-crossings for G_5 , G_6 , G_{α} , G_{κ} , and G_{δ}

Lemma 11. There exist labelings that prevent each graph in \mathcal{F} from having planar realizations on tracks.

Proof. The labelings of T_8 and T_9 were shown not to have planar realizations in [5]. We need to do the same for the labelings of the remaining five graphs in \mathcal{F} given in Figure 9.

Let C denote the chain a-b-c-d-e, which is highlighted in each of the graphs in Figure 9. Observe that $\phi(a) > \phi(d) > \phi(c) > \phi(b) > \phi(e)$ in which C forms an backwards 'N'. If the rest of C intersects the track of c only on the left or right of c, then some part of the chain a-b-c must cross the chain c-d-e. Hence, we only need to consider embeddings in which c lies between the edge a-b and d-e, i.e., one of those edges intersect the track of c to the left, while the other intersects on the right. To avoid a self crossing of C, a-b must intersect the tracks of c and d on the same side of both vertices. The same goes for the d-e intersecting the tracks of c and d to the same side. So we can assume w.l.o.g. that a-b intersects the tracks of c and d to the their left while d-e intersects the tracks of b and c to the their right as is the case in all the figures.

For G_5 , c and d being on the same side of a-b means that the edge b-d must also lie between the two edges. The only question is whether b-d intersects the track of c to the left or right. If it is to the left, then b-d must cross a-c, otherwise, it must cross c-e as in Fig. 9(a).

For G_6 , from the assumptions, the edge c-f either crosses

- (i) a-b if it intersects the track of b to the left since c is right of a-b,
- (ii) d-e if it intersects the track of e to the right since c is left of d-e,
- (iii) b-e otherwise since it must intersect the track of b to the right and e to the left as in Fig. 9(b).

In G_{α} , G_{δ} and G_{κ} for c-f and c-g to avoid crossing C, c-f must intersect the track of d to the left while c-g must intersect the track of b to the right. Since $\phi(f) > \phi(a) > \phi(e) > \phi(g)$ in G_{α} and G_{κ} , c-f must intersect the track of a to the right while c-g must intersect the track of e to the left. However, in G_{δ} $\phi(a) > \phi(f) > \phi(g) > \phi(e)$ so that a-b must intersect the track of f to the right while d-e must intersect the track of g to the left.

This means in G_{α} for a-e to avoid crossing C, as in Fig. 9(c), it must either intersect the track of d to the right in which case it must cross c-f or b to the left in which case it must cross c-g.

This also means in G_{κ} if b-d intersects the track of c to the right as in Fig. 9(d), it will cross c-g. Otherwise, b-d will cross c-f.

Finally, in G_{δ} if f-g intersects the track of c to the right as in Fig. 9(e), it will cross c-d-e. Otherwise, f-g will cross a-b-c.

Corollary 12. A graph containing a subgraph homeomorphic to a graph in \mathcal{F} does not have a simultaneous geometric embedding with a strictly monotone path for all labelings.

Proof. We provide a labeling ϕ of a graph G containing a subgraph homeomorphic to a graph $\tilde{G} \in \mathcal{F}$. Let h be the homeomorphism that maps an edge in \tilde{G} to a path in G and a vertex in \tilde{G} to the endpoint of such a path in G. Label the vertices of \tilde{G} using the appropriate labeling ϕ' from Lemma 11 that forces a self-crossing in \tilde{G} . We maintain the same relative ordering of the labels in G as in \tilde{G} . In particular, we want $\phi(h(u)) < \phi(h(v))$ if and only if $\phi'(u) < \phi'(v)$ for each edge (u, v) in \tilde{G} . For each path $h((u, v)) = p_{(u, v)} = v_1 - v_2 - \cdots - v_k$ in G that corresponds to an edge (u, v) in \tilde{G} , we want $\phi(v_1) < \phi(v_2) < \cdots < \phi(v_k)$ if $\phi'(u) < \phi'(v)$. We can assign the other vertices of G not in the image of h arbitrary labels. Then every edge (u, v) in \tilde{G} corresponds to a strictly monotone path $p_{(u,v)}$ in G preserving the nonplanarity of the realization of \tilde{G} .

5 Completing the Characterization

The next lemma shows that the seven forbidden graphs of \mathcal{F} are minimal; the removal of any edge from any of the seven yields a graph from \mathcal{P} .

Lemma 13. Each forbidden graph is minimal, in that the removal of any edge yields one or more GCs, R-2Ss, or E3-Ss.

Proof. Showing that the removal of any edge from T_8 or T_9 yielded a caterpillar, radius-2 star, or degree-3 spider, all members of \mathcal{P} , was done in [5]. For G_5 in which a-b-d-e-c-a, a-b-c-a, b-c-d-b, c-d-e-c all form cycles shown in Fig. 9(a), the removal of edges b-c or c-d forms a 2-CE3-S, while removing of any other edge forms a GC. For G_6 in which b-e-d-c forms a 4-cycle shown in Fig. 9(b), the removal of any edge leaves a GC. For G_α shown in Fig. 9(c), the removal of c-f or c-g leaves a E3-S. Removing any other edge yields a GC. For G_κ in which b-c-d-b forms a 3-cycle shown in Fig. 9(d), the removal of c-f or c-g leaves a 1-CE3-S, while removing any other edge leaves a GC. For G_δ in which c-f-g-c forms a 3-cycle shown in Fig. 9(e), the removal of c-b or c-d leaves a GC and a lone edge. Removing a-b, d-e, or f-g leaves a GC, and removing c-f or c-g leaves a degree-3 spider.

Finally, the next theorem completes our characterization.

Theorem 14. Every connected graph either contains a subgraph homeomorphic to one of the seven forbidden graphs of \mathcal{F} , or it is a generalized caterpillar, radius-2 star, or a extended degree-3 spider, which form the collection of graphs \mathcal{P} that have simultaneous geometric embeddings with strictly monotone paths for any labelings, the set of ULP graphs.

Proof Sketch: We sketch out the proof here; the complete proof can be found in [6]. The high-level proof idea is to use induction on the number of edges in which we have as an inductive hypothesis that any connected graph with fewer than m edges that does not contain one of the seven forbidden subgraphs of \mathcal{F} is a GC, a R-2 S, or a E 3-S. As a base case are all connected graphs with two edges, which is only the path of length 2, which is clearly a GC. Let G(V, E) be some connected graph then with m edges. Remove a single edge e to form $G' = G - \{e\}$ and the inductive hypothesis holds for G'. We then need to consider all the ways of adding back in the edge e to form G'' showing that no matter what G'' is a GC, a R-2 S, or a E 3-S or contains a copy of one of the seven graphs of \mathcal{F} .

6 Previous and Future Work

Level planar graphs are historically studied in the context of directed graphs, which restricts the types of levelings that can be assigned. Additionally, they are generally considered in the context of a particular leveling such as ones given by hierarchical relationships with an emphasis on minimizing the number of levels required to maintain planarity. In contrast, our application of level planarity has been in terms of the underlying undirected graph with one vertex per level with no consideration given to minimizing levels.

Many of the problems regarding level planarity have been addressed, including the ability to recognize a level planar graph and produce an embedding in linear time [9,10]. However, all of these results are for a particular leveling and do not generalize to the context of considering the level planarity of all the level graphs induced by all possible n! labelings of a given undirected graph. Running either of these linear time algorithms for each possible level graph leads to an exponential running time. Using our approach we achieve this in linear time.

We gave a characterization of ULP graphs akin to Kuratowksi's characterizations of planar graphs [11]; we provided a forbidden set of graphs \mathcal{F} that play the same role with respect to ULP graphs that K_5 and $K_{3,3}$ play with respect to planar graphs. Just as Kuratowksi's theorem states that a graph is planar if and only if it does not contain a subgraph that is a subdivision of K_5 or $K_{3,3}$, we show a graph is ULP if and only if it does not contain a subgraph homeomorphic to a forbidden graph of \mathcal{F} .

The analogue of Kuratowksi's theorem for level planar graphs are minimum level non-planar patterns [8]. These are based on the characterization of hierarchies by Di Battista and Nardelli [3]. Unlike our characterization, these patterns are not solely based upon the underlying graph, but also upon the given leveling. The same graph with two different levelings that is level non-planar for each may

very well match two distinct patterns since the reasons that a crossing is forced in each can be entirely different.

Estrella *et al.* [5] presented linear time recognition algorithms for the class of ULP trees. Providing the equivalent algorithms for general ULP graphs remains for future work.
