ABSTRACT

If the number of runs in a (mixed-level) orthogonal array of strength 2 is specified, what numbers of levels and factors are possible? The collection of possible sets of parameters for orthogonal arrays with N runs has a natural lattice structure, induced by the “expansive replacement” construction method. In particular the dual atoms in this lattice are the most important parameter sets, since any other parameter set for an N -run orthogonal array can be constructed from them. To get a sense for the number of dual atoms, and to begin to understand the lattice as a function of N , we investigate the height and the size of the lattice. It is shown that the height is at most $\lfloor c(N - 1) \rfloor$, where $c = 1.4039\dots$, and that there is an infinite sequence of values of N for which this bound is attained. On the other hand, the number of nodes in the lattice is bounded above by a superpolynomial function of N (and superpolynomial growth does occur for certain sequences of values of N). Using a new construction based on “mixed spreads”, all parameter sets with 64 runs are determined. Four of these 64-run orthogonal arrays appear to be new.

1. Introduction

Although mixed-level (or asymmetrical) orthogonal arrays have been the subject of a number of papers in recent years (see Chapter 9 of Hedayat, Sloane and Stufken, 1999, for references), it seems fair to say that we know much less about them than about fixed-level orthogonal arrays (in which all factors have the same number of levels). For example, there is no analogue for mixed orthogonal arrays of one of the most powerful construction methods for fixed-level arrays, that based on linear codes (see Chapters 4 and 5 of Hedayat, Sloane and Stufken, 1999).

Again, there are many instances where the linear programming bound for fixed-level orthogonal arrays gives the correct answer for the minimal number of runs needed for a specified number of factors. There *is* a linear programming bound for mixed arrays (Sloane and Stufken, 1996), but it is less effective than in the fixed-level case — it ignores too much of the combinatorial nature of the problem (especially when the levels involve more than one prime number), and, though generally stronger than the Rao bound, does not give correct answers as often as in the fixed-level case.

A mixed orthogonal array $OA(N, s_1^{k_1} s_2^{k_2} \cdots s_v^{k_v}, t)$ is an array of size $N \times k$, where $k = k_1 + k_2 + \cdots + k_v$ is the total number of factors, in which the first k_1 columns have symbols from $\{0, 1, \dots, s_1 - 1\}$, the next k_2 columns have symbols from $\{0, 1, \dots, s_2 - 1\}$, and so on, with the property that in any $N \times t$ subarray every possible t -tuple of symbols occurs an equal number of times as a row. We usually assume $2 \leq s_1 < s_2 < \cdots$ and all $k_i \geq 1$. Except in Section 5, only arrays of strength 2 will be considered, and we will usually omit t from the symbol for the array.

We refer to $(N, s_1^{k_1} s_2^{k_2} \dots)$ as the *parameter set* for an $OA(N, s_1^{k_1} s_2^{k_2} \dots)$. We also allow the parameter set $(N, 1^1)$, corresponding to the trivial array consisting of a single column of N 0's. In this paper we consider the question: if N is specified, how many different parameter sets are possible?

Given an array $A = OA(N, s_1^{k_1} s_2^{k_2} \dots)$, other N -run arrays can be obtained from it by the *expansive replacement method*. Let S be one of the s_i occurring in A , and suppose B is an $OA(S, t_1^{l_1} t_2^{l_2} \dots)$. The expansive replacement method replaces a single column of A at S levels by the rows of B . For example, if $A = OA(16, 2^3 4^4)$ and $B = OA(4, 2^3)$, we obtain an $OA(16, 2^6 4^3)$. If B is a trivial array $OA(S, 1^1)$, we are simply deleting one of the S -level factors from A . E.g. taking $S = 2$, an $OA(24, 2^{20} 4^1)$ trivially produces an $OA(24, 2^{19} 4^1)$. The expansive replacement method also includes replacing a factor at s levels by a factor at s' levels, if s' divides s . For further details about the expansive replacement method see Chapter 9 of Hedayat, Sloane and Stufken, 1999.

Let A and B be parameter sets for orthogonal arrays with N runs. We say that B is *dominated*

by A if an orthogonal array with parameter set B can be obtained from an orthogonal array with parameter set A by a sequence of expansive replacements.

Using “dominance” as the relation, the parameter sets for orthogonal arrays with N runs form a partially ordered set, which we denote by Λ_N (Hedayat, Sloane and Stufken, 1999 p. 335).

Λ_N has a unique maximal element (N, N^1) (corresponding to the trivial array with one factor at N levels) and a unique minimal element $(N, 1^1)$. It is straightforward to verify that meet (\wedge) and join (\vee) are well-defined for this relation (we omit the proof), so Λ_N is in fact a *lattice* (cf. Welsh, 1976; Trotter, 1995).

If an $OA(N, s_1^{k_1} s_2^{k_2} \dots)$ exists, then necessarily we must have:

(C1) s_i divides N , for all i ,

(C2) s_i^2 divides N , if $k_i \geq 2$,

(C3) $s_i s_j$ divides N , if $i \neq j$,

(C4) the Rao bound holds:

$$N - 1 \geq k_1(s_1 - 1) + k_2(s_2 - 1) + \dots, \quad (1)$$

(C5) the linear programming bound holds (see Sloane and Stufken, 1996).

These conditions are certainly not sufficient for an array to exist, and it appears to be difficult to test if an orthogonal array does exist with a putative parameter set satisfying (C1)–(C5). A further difficulty is that in order to construct Λ_N it is necessary to know Λ_d for all proper divisors d of N .

To avoid these difficulties we define a second lattice, the *idealized lattice* Λ'_N : this has as nodes all putative parameter sets satisfying (C1) to (C4), with the dominance relation as before, except that in the expansive replacement method we may now make use of any of the nodes of any Λ'_d for d dividing N .

Constructing Λ'_N is much easier than constructing Λ_N , since essentially all we need to do is enumerate the solutions to (1). Of course Λ_N is a sublattice of Λ'_N .

To avoid having to repeat the adjective “putative”, from now on we will use “parameter set” to mean any symbol $(N, s_1^{k_1} s_2^{k_2} \dots)$ satisfying conditions (C1) to (C4). The parameter sets are precisely the nodes of Λ'_N . If a parameter set is also a node of Λ_N then it is implied that an $OA(N, s_1^{k_1} s_2^{k_2} \dots)$ does exist, i.e. that the parameter set is realized by an orthogonal array.

It is convenient to represent Λ_N and Λ'_N by their Hasse diagrams (cf. Welsh, 1976, p. 45). These diagrams are drawn “from the bottom up”, with $(N, 1^1)$ as the root node at the bottom

(Figure 1 shows Λ_{12} and Λ'_{12}). The *height* of a parameter set is the number of edges in the longest path from that node to the root. A node of height i appears on the i th level of the diagram. The height of the maximal element (N, N^1) will be denoted by $ht(N)$.

Figure 1: (Left) Lattice Λ_{12} , showing all (true) parameter sets for 12-run orthogonal arrays. There are 23 nodes, four dual atoms (circled) and the height is 12. (Right) Idealized lattice Λ'_{12} , showing all (putative) parameter sets satisfying conditions (C1)–(C4). No arrays exist for the nine nodes marked \times . There are 32 nodes, four dual atoms (circled) and again the height is 12.

The *atoms* in Λ_N (those nodes just above the root) are precisely the parameter sets (N, p^1) for the primes p dividing N .

The *dual atoms* in Λ_N (those nodes just below the maximal element) are especially interesting, since they dominate all other parameter sets.

We can now state our main results.

Theorem 1. (i) For all N ,

$$ht(N) \leq \lfloor c(N - 1) \rfloor, \quad (2)$$

where

$$c = \sum_{i=0}^{\infty} \frac{1}{2^{2^i} - 1} = 1.4039 \dots \quad (3)$$

(ii) If $N = 2^{2^m}$ ($m \geq 0$) then $ht(N) = \lfloor c(N-1) \rfloor$.

Let $T(N)$ (resp. $T'(N)$) denote the total number of nodes in Λ_N (resp. Λ'_N).

Theorem 2. If $N = 2^n$,

$$\frac{1}{4}(\log_2 N)^2(1 + o(1)) \leq \log_2 T(N) \leq \frac{3}{8}(\log_2 N)^2(1 + o(1)). \quad (4)$$

Theorem 3. There is a constant c_1 such that for all N ,

$$\ln \ln T(N) \leq c_1 \frac{\ln N}{\ln \ln N} (1 + o(1)). \quad (5)$$

Remarks. (i) The bounds in (4) and (5) also apply to $T'(N)$.

(ii) Theorem 2 shows that when $N = 2^n$, $T(N)$ grows very roughly like $N^{a \log_2 N}$, for some constant a between $\frac{1}{4}$ and $\frac{3}{8}$. This is a “superpolynomial” function of N , meaning that it grows faster than any polynomial in N .

(iii) It appears (although we have not proved this) that the upper bound in (5) can be achieved by taking N to be a certain product of powers of the first m primes, where m is about

$$\frac{1}{2e} \frac{\ln N}{\ln \ln N}$$

(see Section 7). In other words, it appears that there is an infinite sequence of values of N for which $T(N)$ grows *very* roughly like

$$\exp(N^{c_2 / \ln \ln N}),$$

where c_2 is a constant. This is again a superpolynomial function of N , and is now close to being an exponential function, since $\ln \ln N$ grows slowly.

The above discussion has shown that there is an infinite sequence of values of N for which the number of nodes in Λ_N grows superpolynomially, while the height of Λ_N grows at most linearly. It follows that the size of the largest antichain must also grow superpolynomially. The data in Table 3 suggest the following conjecture.

Conjecture. *There is an infinite sequence of values of N for which the number of dual atoms grows superpolynomially in N .*

In fact it seems likely that if $N = 2^n$, a lower bound of the form in (4) (possibly with a different constant) applies to the logarithm of the number of dual atoms, and that for some sequence of values of N a lower bound similar to the upper bound on the right-hand side of (5) will hold. However, at present these are only conjectures.

In order to construct the orthogonal arrays needed to establish the lower bound in Theorem 2 we make use of what we call “mixed spreads”, generalizing the notions of “spread” and “partial spread” from projective geometry. Arrays that can be constructed in this way we call “geometric”. Many familiar examples of orthogonal arrays, for example arrays constructed from linear codes, are geometric. The construction is not restricted to strength 2 (and is one of the few general constructions we know of for mixed arrays of strength greater than 2). The construction will be described in Section 5.

In Section 6 we use this construction to determine the lattice Λ_{64} , and in doing so we find tight arrays with parameter sets

$$(64, 2^5 4^{17} 8^1), (64, 4^{14} 8^3), (64, 2^5 4^{10} 8^4), (64, 4^7 8^6),$$

which appear to be new.

When studying parameter sets of putative orthogonal arrays with N runs, it is convenient to be able to say that if the number of degrees of freedom of the parameter set $(N, s_1^{k_1} s_2^{k_2} \dots)$, that is,

$$k_1(s_1 - 1) + k_2(s_2 - 1) + \dots, \tag{6}$$

is small compared with $N - 1$, then an orthogonal array certainly exists.

To make this precise, we define the *threshold function* $B(N)$ to be the maximum number b such that every parameter set (satisfying conditions (C1) to (C4)) with at most b degrees of freedom is realized by an orthogonal array, but some parameter set (again satisfying (C1) to (C4)) with $b + 1$ degrees of freedom is not realized. If every parameter set satisfying (C1) to (C4) is realized, we set $B(N) = N - 1$.

Figure 1 shows that $B(12) = 6$, since there is no $OA(12, 2^5 3^1)$, but every parameter set with at most 6 degrees of freedom is realized.

We are not aware of any earlier investigations of $B(N)$.

Theorem 4. *If N is a power of a prime then*

$$N^{3/4} \leq B(N) .$$

In words, if the number of degrees of freedom in the parameter set does not exceed $N^{3/4}$, then an orthogonal array exists. This is certainly weak, but is enough to establish the lower bound of Theorem 2. It would be nice to have more precise estimates for $B(N)$.

A final remark. We *could* have considered the partially ordered set whose nodes are all the inequivalent orthogonal arrays with N runs, rather than just their parameter sets. However, the

number of nodes then becomes unmanageably large, even for small values of N (furthermore, it appears that “meet” and “join” are no longer well-defined, and so in general this partially ordered set would not be a lattice).

Consider $N = 28$, for example. Using Kimura’s (1994a, 1994b) enumeration of the Hadamard matrices of order 28, we have calculated¹ that there are precisely 7570 inequivalent $OA(28, 2^{27})$ ’s. This would be merely a lower bound on the number of dual atoms. On the other hand we know (see Table 1) that Λ_{28} has precisely four dual atoms, between 47 and 55 nodes, and height 28.

Figure 2: (a) Λ_p and (b) Λ_6 .

2. Examples of the lattices Λ_N and Λ'_N

There are a few general cases when we can describe Λ_N explicitly (and for which Λ'_N is the same as Λ_N).

If $N = p$ is a prime then $\Lambda_N = \Lambda'_N$ has two nodes, one dual atom and height 1, as shown in Fig. 2(a) (dual atoms are circled).

If $N = pq$ is the product of two distinct primes, $\Lambda_N = \Lambda'_N$ has five nodes, one dual atom and height 3. Λ_6 is shown in Fig. 2(b).

More generally, if N is the product of $u \geq 2$ distinct primes, it is not difficult to show that $\Lambda_N = \Lambda'_N$ has $2^{u-1} - 1$ dual atoms, height $2u - 1$, and β_{u+1} nodes, where

$$\{\beta_1, \beta_2, \beta_3, \dots\} = \{1, 2, 5, 15, 52, \dots\}$$

are the Bell numbers (see Sequence A110 of Sloane, 1999). Figure 3 shows Λ_{30} , illustrating the case $u = 3$.

If $N = p^2$ is the square of a prime, $\Lambda_N = \Lambda'_N$ has a single dual atom, $OA(p^2, p^{p+1})$, has height $p + 2$ and contains $p + 3$ nodes. If $N = p^3$ (p prime), $\Lambda_N = \Lambda'_N$ also has a single dual atom,

¹Using the method described on page 165 of Hedayat, Sloane and Stufken (1999).

Figure 3: The lattice Λ_{30} : there are $\beta_4 = 15$ nodes, three dual atoms (circled) and the height is 5.

$OA(p^3, (p)^{p^2}(p^2)^1)$, has height $p^2 + p + 3$ and contains $2p^2 + p + 4$ nodes. Λ_8 is shown in Fig. 4. If $N = p^4$ (p prime), $\Lambda_N = \Lambda'_N$ has two dual atoms, $OA(p^4, (p^2)^{p^2+1})$ and $OA(p^4, (p)^{p^3}(p^3)^1)$, has height $p^3 + 2p^2 + p + 3$ and contains

$$\frac{1}{2}(p^5 + p^4 + 5p^3 + 5p^2 + 2p + 10)$$

nodes.

For all values of N mentioned so far in this section, the threshold function $B(N) = N - 1$.

If N is not of one of the above forms then it seems necessary to consider each case individually. Table 1 summarizes the properties of Λ_N for some small values of N . Here $A(N)$ denotes the number of dual atoms in Λ_N . Most of the entries in this table can be deduced from the tables in Chapter 12 of Hedayat, Sloane and Stufken (1999), except for $N = 32$ and 64 , which are discussed in Section 6.

$N = 24$ is the smallest case when we do not know the complete lattice Λ_N . In Λ_{24} the maximal value of k that occurs in each of the parameter sets $2^k 3^1$, $2^k 3^1 4^1$, $2^k 4^1 6^1$ and $2^k 6^1$ is presently unknown. For $2^k 3^1$, for example, it is known only that an $OA(24, 2^{16} 3^1)$ exists, and an $OA(24, 2^{21} 3^1)$ is impossible by the linear programming bound. The number of dual atoms is in the range 4 to 7.

Figure 4: The lattice Λ_8 : 14 nodes, one dual atom, height 9.

It is possible to show that the height of Λ_{24} is 25, however: no chain can be longer than

$$24^1 - 2^{20}4^1 - 2^{23} - 2^{22} - 2^{21} - \dots - 2^1 - 1^1.$$

We also do not know Λ_N for $N = 28, 36, \dots$

The four sequences in Table 1 are Sequences [A39927](#), [A39930](#), [A39931](#) and [A48893](#) of Sloane (1999). The entries in that database will be updated as further values are determined.

We end this section with a remark about the nature of Λ_N as a lattice. Since not all maximal chains between two nodes need have the same length (see Fig. 1), Λ_N does not in general satisfy the Jordan-Dedekind chain condition (cf. Welsh, 1976). It follows that Λ_N is in general not distributive, not semimodular, nor is it the lattice of a matroid.

3. The maximum height of Λ_N

In this section we give the proof of Theorem 1.

Let σ denote a specification $s_1^{k_1} s_2^{k_2} \dots$ of factors at various levels, leaving the number of runs unspecified. Given σ , there is a smallest number of runs, N_0 say, for which an $OA(N_0, \sigma)$ exists. Let h be the height of the parameter set (N_0, σ) in Λ_{N_0} . Then if the parameter set (N, σ) occurs in any other lattice Λ_N , it also has height h . (E.g. the specification $\sigma = 6^1$ has height 3 in each of Figs. 1, 2(b) and 3.) We may therefore define $ht(\sigma)$ to be h , independently of the number of runs.

Table 1: For the lattice Λ_N of parameter sets of orthogonal arrays with N runs, the table gives the number of dual atoms $A(N)$, the height $ht(N)$, the total number of nodes $T(N)$ and the threshold function $B(N)$.

N	$A(N)$	$ht(N)$	$T(N)$	$B(N)$
1	0	0	1	0
2	1	1	2	1
3	1	1	2	2
4	1	4	5	3
5	1	1	2	4
6	1	3	5	5
7	1	1	2	6
8	1	9	14	7
9	1	5	6	8
10	1	3	5	9
11	1	1	2	10
12	4	12	23	6
13	1	1	2	12
14	1	3	5	13
15	1	3	5	14
16	2	21	61	15
17	1	1	2	16
18	2	10	26	15

The height of Λ_N , $ht(N)$, as defined in Section 1 coincides with $ht(\sigma)$ when $\sigma = N^1$. The height function has the following additivity property.

Lemma 5.

$$ht(s_1^{k_1} s_2^{k_2} \dots) = k_1 ht(s_1) + k_2 ht(s_2) + \dots \quad (7)$$

Proof. If there is a single factor on the left-hand side, say $s_1 = s$, $k_1 = 1$, then (7) just says that $ht(s^1) = ht(s)$, repeating the assertion made above. Otherwise, more than one factor occurs in the specification σ on the left-hand side of (7). Suppose the parameter set (N, σ) occurs as a node in some Λ_N . The portion of Λ_N consisting of this node and all nodes dominated by it is the product in an obvious sense of k_1 copies of Λ_{s_1} , k_2 copies of Λ_{s_2} , etc. The height of (N, σ) is the sum of the heights of all these sublattices, and (7) follows. ■

Lemma 5 reduces the calculation of $ht(s_1^{k_1} s_2^{k_2} \dots)$ to the calculation of the values of $ht(s_1)$, $ht(s_2), \dots$. To determine the latter we must consider exactly which orthogonal arrays exist with a specified number of runs. For this we can apply the following lemma.

Table 1 (cont.)

N	$A(N)$	$ht(N)$	$T(N)$	$B(N)$
19	1	1	2	18
20	4	20	35	11
21	1	3	5	20
22	1	3	5	21
23	1	1	2	22
24	4 – 7	25	119 – 133	18 – 22
25	1	7	8	24
26	1	3	5	25
27	1	15	25	26
28	4	28	47 – 55	15
29	1	1	2	28
30	3	5	15	29
31	1	1	2	30
32	2	42	320	29
33	1	3	5	32
34	1	3	5	33
35	1	3	5	34
...
64	7	86	3037	57
...

Lemma 6.

$$ht(N) = 1 + \max \sum_i k_i ht(s_i) , \quad (8)$$

where the maximum is taken over all parameter sets $(N, s_1^{k_1} s_2^{k_2} \dots) \neq (N, N^1)$ for which an orthogonal array exists.

Proof. The height of Λ_N is one more than the maximal height among the dual atoms. (8) follows by applying Lemma 5 to the parameter set of such a dual atom. ■

We can now use linear programming to obtain an upper bound on $ht(N)$, by maximizing

$$1 + \sum_i k_i ht(s_i) \quad (9)$$

over all choices of $s_1, k_1, s_2, k_2, \dots$ that satisfy (C1) to (C4).

We first consider the case when $N = 2^n$ for some n .

The case $N = 64$ will illustrate the method. If there is a factor 32^1 then linear programming shows that (9) is maximized by $2^{32} 32^1$, giving height 75. If there is a factor 16^1 then there is a unique parameter set that maximizes (9), $4^{16} 16^1$, giving height 86. Otherwise, if only factors

$2^{k_1}4^{k_2}8^{k_3}$ occur, the height does not exceed 85. Since an $OA(64, 4^{16}16^1)$ exists, we conclude that $ht(64) = 86$. We will return to the case $N = 64$ in Section 6.

In this way we obtain the values of $ht(N)$, $N = 2^n$ shown in Table 2.

Table 2: Height of Λ_N for $N = 2^n$.

n	1	2	3	4	5
$N = 2^n$	2	4	8	16	32
$ht(N)$	1	4	9	21	42
$ht(N)/(N - 1)$	1	1.3333...	1.2857...	1.4	1.3548...

n	6	7	8	9	10
$N = 2^n$	64	128	256	512	1024
$ht(N)$	86	171	358	715	1431
$ht(N)/(N - 1)$	1.3650...	1.3465...	1.4039...	1.3992...	1.3988...

Consider the general problem of maximizing (9) for $N = 2^n$. Comparing (1) and (9), we see that an s -level factor contributes $ht(s)$ to the height but uses up $s - 1$ degrees of freedom. If we ignore the constraints of integrality then the value of the expression in (9) would be maximized by a term s^k where s is chosen to maximize $ht(s)/(s - 1)$. This suggests that we should investigate this quantity in order to prove Theorem 1. The data in Table 2 suggest that the ratio $ht(s)/(s - 1)$ is maximized if s is of the form 2^{2^i} and is as large as possible. That this is indeed so is established by the next three lemmas.

Lemma 7. *Given positive real numbers α_r, β_r ($r = 1, \dots, m$), γ , the maximal value of*

$$\sum_{r=1}^m \alpha_r x_r$$

subject to the constraints

$$\sum_{r=1}^m \beta_r x_r = \gamma,$$

$$x_r \geq 0 \quad (r = 1, \dots, m)$$

is

$$\gamma \max_{r=1 \dots m} \frac{\alpha_r}{\beta_r}.$$

We omit the straightforward proof.

Lemma 8. Given positive real numbers α_r, β_r ($r = 1, \dots, m+n$), γ, γ' with $\gamma' \leq \gamma$, the maximal value of

$$\sum_{r=1}^{m+n} \alpha_r x_r \quad (10)$$

subject to the constraints

$$\sum_{r=1}^{m+n} \beta_r x_r = \gamma, \quad (11)$$

$$\sum_{r=m+1}^{m+n} \beta_r x_r \leq \gamma', \quad (12)$$

$$x_r \geq 0 \quad (r = 1, \dots, m+n) \quad (13)$$

is

$$\max \left\{ \gamma \max_{r=1\dots m} \frac{\alpha_r}{\beta_r}, (\gamma - \gamma') \max_{r=1\dots m} \frac{\alpha_r}{\beta_r} + \gamma' \max_{r=m+1\dots m+n} \frac{\alpha_r}{\beta_r} \right\}. \quad (14)$$

The maximum is given by the first expression if and only if

$$\max_{r=1\dots m} \frac{\alpha_r}{\beta_r} \geq \max_{r=m+1\dots m+n} \frac{\alpha_r}{\beta_r}.$$

Proof. Let $\sigma, 0 \leq \sigma \leq \gamma'$, denote the value of the left-hand side of (12). Then by Lemma 7 the maximal value of the sum in (10) is equal to

$$(\gamma - \sigma) \max_{r=1\dots m} \frac{\alpha_r}{\beta_r} + \sigma \max_{r=m+1\dots m+n} \frac{\alpha_r}{\beta_r}.$$

This is a linear function of σ and so its maximal value is taken at one of the two endpoints, leading to (14). ■

We can now give an upper bound on the height $ht(N)$ for $N = 2^n$. Let

$$\rho_n = \frac{ht(N)}{2^n - 1}, \quad N = 2^n.$$

Lemma 9.

$$\rho_n < c \quad \text{for all } n,$$

where c is the constant

$$\sum_{i=0}^{\infty} \frac{1}{2^{2^i} - 1} = 1.4039\dots$$

Proof. We use the induction hypothesis that, for $m \geq 0$,

$$\rho_{2^m} > \rho_x \quad \text{whenever} \quad 1 \leq x < 2^{m+1}, \quad x \neq 2^m. \quad (15)$$

This is trivially true when $m = 0$. We first compute ρ_{2^m} . From the Rao-Hamming construction, for $N = 2^{2^m}$, an $OA(N, (\sqrt{N})^{\sqrt{N}+1})$ always exists, and we find that

$$\rho_{2^m} \geq \rho_{2^{m-1}} + \frac{1}{2^{2^m} - 1}.$$

On the other hand, we obtain an upper bound on ρ_{2^m} from the linear program: choose nonnegative integers k_1, k_2, \dots so as to maximize

$$1 + \sum_{r=1}^{2^m-1} ht(2^r)k_r$$

subject to the constraint

$$\sum_{r=1}^{2^m-1} (2^r - 1)k_r = 2^{2^m} - 1.$$

From Lemmas 6 and 7 we have

$$\begin{aligned} \rho_{2^m} &\leq \frac{1}{2^{2^m} - 1} + \max_{r=1 \dots 2^m-1} \rho_r \\ &= \frac{1}{2^{2^m} - 1} + \rho_{2^{m-1}}. \end{aligned}$$

Since the two bounds agree,

$$\rho_{2^m} = \rho_{2^{m-1}} + \frac{1}{2^{2^m} - 1}. \quad (16)$$

We now complete the proof of the induction step. For $1 \leq x < 2^m$, we have

$$\rho_{2^m} > \rho_{2^{m-1}} \geq \rho_x,$$

as required. Suppose $2^m < x < 2^{m+1}$. Then ρ_x is upper-bounded by the solution to the linear program: maximize

$$\left(1 + \sum_{r=1}^{x-1} ht(2^r)k_r \right) / (2^x - 1)$$

subject to the constraints

$$\begin{aligned} \sum_{r=1}^{x-1} (2^r - 1)k_r &= 2^x - 1, \\ \sum_{r=2^m}^{x-1} (2^r - 1)k_r &\leq 2^{x-1} - 1. \end{aligned}$$

(The second constraint is implied by the requirement that there can be at most one factor which has more levels than the square root of the number of runs.) By Lemma 8 and induction on x , we obtain

$$\begin{aligned} \rho_x &\leq \frac{1}{2^x - 1} (1 + 2^{x-1} \rho_{2^{m-1}} + (2^{x-1} - 1) \rho_{2^m}) \\ &= \rho_{2^m} - \frac{1 + 2^{x-1} - 2^{2^m}}{(2^{2^m} - 1)(2^x - 1)} \\ &< \rho_{2^m} . \end{aligned}$$

This completes the induction step.

To complete the proof of Lemma 9, by the induction hypothesis it suffices to prove that $\rho_{2^m} < c$ for all m . But from (16) it follows that

$$\rho_{2^m} = \sum_{i=0}^m \frac{1}{2^{2^i} - 1} < c ,$$

and that $\rho_{2^m} \rightarrow c$ as $m \rightarrow \infty$. ■

If N is not a power of 2 then similar arguments show that the height is (considerably) less than cN . This completes the proof of Theorem 1.

4. Upper bounds on the number of parameter sets

In this section we establish the upper bounds in Theorems 2 and 3. We will bound $T'(N)$, the number of nodes in Λ'_N . Since Λ_N is a sublattice of Λ'_N , this is also an upper bound on the number of nodes in Λ_N . Suppose first that $N = 2^{2^r}$.

We start by considering parameter sets $(N, 2^{k_1} 4^{k_2} 8^{k_3} \dots (2^r)^{k_r})$, containing no level exceeding \sqrt{N} . From (1),

$$N - 1 \geq k_1 + 3k_2 + 7k_3 + \dots + (2^r - 1)k_r . \quad (17)$$

Let γ be the number of nonnegative integer solutions (k_1, k_2, \dots, k_r) to this inequality. Then $\gamma/(N - 1)^r$ is the Riemann sum approximating the volume of the simplex bounded by the hyperplanes

$$\begin{aligned} 1 &\geq x_1 + 3x_2 + 7x_3 + \dots + (2^r - 1)x_r , \\ x_1 &\geq 0, \quad x_2 \geq 0, \dots, x_r \geq 0 \end{aligned}$$

in \mathbb{R}^r . For large N this yields

$$\gamma = \frac{N^r}{r! \prod_{i=1}^r (2^i - 1)} (1 + o(1)) . \quad (18)$$

The product in the denominator approaches $c_3 2^{r(r+1)/2}$, as $r \rightarrow \infty$, where $c_3 = 0.2887\dots$

Now suppose the parameter set contains a factor at 2^i levels, where $r + 1 \leq i \leq 2r - 1$. There can be at most one such factor, and the number of such parameter sets in each case is at most γ . The total number of parameter sets is therefore at most $r\gamma$, and setting $r = \frac{1}{2} \log_2 N$ we find that

$$\log_2(r\gamma) \leq \frac{3}{8}(\log_2 N)^2(1 + o(1)) .$$

This establishes the upper bound in Theorem 2 for $N = 2^{2r}$. It also implies the upper bound for $N = 2^{2r+1}$, after noting that $T'(N) \leq T'(2N)$.

We now give a sketch of the proof of Theorem 3, omitting many tedious details. To simplify the analysis we will neglect terms on the right-hand side of (1) that correspond to factors with a level greater than \sqrt{N} . Suppose first that N is a large number of the form $2^{2a_1} 3^{2a_2}$. Pretending for the moment that a_1 and a_2 are allowed to be real numbers, not just integers, we may consider what choice of a_1 and a_2 maximizes the number of solutions to (1) for a given value of N . The number of terms on the right-hand side of (1) is now $(a_1 + 1)(a_2 + 1) - 1$. The arguments used to establish the upper bound of Theorem 2 show that the number of solutions to (1) is maximized if 2^{2a_1} is approximately equal to 3^{2a_2} .

Now suppose that N is of the form

$$p_1^{2a_1} p_2^{2a_2} \dots p_m^{2a_m} , \tag{19}$$

where $p_1 = 2, p_2 = 3, \dots$ are the first m primes. We find that the number of solutions to (1) is maximized when the numbers $p_i^{2a_i}$ are all approximately equal, and we will therefore assume that $p_i^{2a_i} = N^{\frac{1}{m}(1+o(1))}$, i.e. that

$$a_i = \frac{1}{2m} \frac{\ln N}{\ln p_i} (1 + o(1)), \quad i = 1, \dots, m .$$

The Rao bound contains a term for every possible level

$$s = p_1^{i_1} p_2^{i_2} \dots p_m^{i_m}$$

in which $0 \leq i_\nu \leq a_\nu, 1 \leq \nu \leq m$, where not all the i_ν are equal to 0. The number of such terms is

$$\delta := (a_1 + 1)(a_2 + 1) \dots (a_m + 1) - 1 = \frac{1}{(2m)^m} \frac{(\ln N)^m}{\prod_{j=1}^m \ln p_j} (1 + o(1)) . \tag{20}$$

The product of the coefficients of all the terms on the right-hand side of the Rao bound is

$$\zeta := p_1^{a_1^2 a_2 \dots a_m / 2} p_2^{a_1 a_2^2 a_3 \dots a_m / 2} \dots p_m^{a_1 \dots a_{m-1} a_m^2 / 2} (1 + o(1)) .$$

This implies

$$\ln \zeta = \frac{\delta}{4} \ln N(1 + o(1)) .$$

Again using γ to denote the number of solutions to the Rao inequality, we have

$$\gamma = \frac{N^\delta}{\delta! \zeta} (1 + o(1)) ,$$

hence

$$\begin{aligned} \ln \gamma &= \frac{3}{4} \frac{(\ln N)^{m+1}}{(2m)^m (\ln m)^{m(1+o(1))}} - \frac{1}{(2m)^m} \frac{(\ln N)^m}{(\ln m)^{m(1+o(1))}} (m \ln \ln N - m \ln m) \\ &\quad + \text{smaller terms} . \end{aligned}$$

This expression is maximized if we take

$$m = \frac{1}{2e} \frac{\ln N}{\ln \ln N} (1 + o(1)) ,$$

and then we find that the leading term in the expression for $\ln \gamma$ is

$$\frac{3}{4} \ln N N^{\frac{1}{2e} \frac{1}{\ln \ln N}} .$$

We conclude that

$$\ln \ln \gamma \leq \frac{1}{2e} \frac{\ln N}{\ln \ln N} ,$$

which establishes Theorem 3.

5. Geometric orthogonal arrays

We consider subspaces V of the vector space $GF(q)^n$ over $GF(q)$, where q is a power of a prime. By the dimension of V , $\dim V$, we mean the vector space dimension over $GF(q)$ (rather than the projective dimension, which is one less). The following notion was suggested by the notions of spread and partial spread in projective geometry (cf. Thas, 1995).

Definition. A *mixed spread of strength t* is a collection $\mathcal{V} = \{V_1, V_2, \dots, V_k\}$ of subspaces of $GF(q)^n$ such that for all choices of $\tau \leq t$ indices i_1, i_2, \dots, i_τ (with $1 \leq i_1 < i_2 < \dots < i_\tau \leq k$) the dimension of the span of $V_{i_1}, \dots, V_{i_\tau}$ is equal to $\dim V_{i_1} + \dots + \dim V_{i_\tau}$.

An equivalent condition is that the span of $V_{i_1}, \dots, V_{i_\tau}$ is the direct sum $V_{i_1} \oplus \dots \oplus V_{i_\tau}$ for all choices of $\tau \leq t$ indices i_1, \dots, i_τ with $1 \leq i_1 < \dots < i_\tau \leq k$.

Any collection \mathcal{V} of subspaces has strength 1. \mathcal{V} has strength 2 if and only if every pair $V_i, V_j \in \mathcal{V}, i \neq j$, intersect just in the zero vector. \mathcal{V} has strength 3 if and only if it has strength 2 and for any triple of distinct subspaces each one meets the span of the other two just in the zero vector.

If V is a d -dimensional subspace of $GF(q)^n$ we denote by V^* the dual space, the space of linear functionals on V (see for example Hoffman and Kunze, 1961), and we fix a labeling $f_0, f_1, \dots, f_{q^d-1}$ for the elements of V^* .

Given a mixed spread of strength t , $\mathcal{V} = \{V_1, V_2, \dots, V_k\}$, where the V_i are subspaces of $GF(q)^n$, we obtain an orthogonal array $OA(\mathcal{V})$ with q^n runs as follows. The columns of the array are labeled V_1, V_2, \dots, V_k and the rows are labeled by the linear functionals $f \in (GF(q)^n)^*$. If f restricted to V_i , $f|_{V_i}$, is the j th linear functional in V_i^* , the (f, V_i) -th entry in the array is j . The symbols in column i are therefore taken from $\{0, 1, \dots, q^{\dim V_i} - 1\}$.

We will say that an orthogonal array constructed in this way is *geometric*.

Theorem 10. *The orthogonal array $OA(\mathcal{V})$ has strength t if and only if the mixed spread \mathcal{V} has strength t .*

Proof. Suppose $OA(\mathcal{V})$ has strength t . Consider for example the first t columns. In the projection of the array onto these columns we see

$$\prod_{i=1}^t q^{\dim V_i} = q^{\sum_{i=1}^t \dim V_i}$$

different t -tuples of symbols. Since these depend only on the restrictions of the $f \in (GF(q)^n)^*$ to the span of V_1, \dots, V_t , the dimension of that space must be at least the sum of the dimensions of V_1, \dots, V_t , and clearly it cannot have a higher dimension. So \mathcal{V} is a mixed spread of strength t .

Conversely, suppose \mathcal{V} is a mixed spread of strength t . We can write

$$GF(q)^n = V_1 \oplus \dots \oplus V_t \oplus X$$

where X is the complementary space to the V_i . Since the dual of a direct sum is canonically isomorphic to the direct sum of the duals, we immediately find that as we run through the linear functionals on $GF(q)^n$, every tuple $(f|_{V_1}, \dots, f|_{V_t}, f|_X)$ of restrictions occurs precisely once. Ignoring the last component, we see that every tuple $(f|_{V_1}, \dots, f|_{V_t})$ occurs precisely $|X|$ times. Hence $OA(\mathcal{V})$ has strength t . ■

Lemma 11. *Any geometric array of strength 2 can always be extended to a tight array (i.e. one meeting the Rao bound) by adding q -level factors.*

Proof. We simply group any unused points into 1-dimensional subspaces. ■

Examples. (i) The 1-dimensional subspaces of $GF(q)^n$ form a mixed spread of strength 2. The corresponding array is the familiar

$$OA(q^n, q^k), \quad k = (q^n - 1)/(q - 1),$$

of the Rao-Hamming construction.

(ii) More generally, a classical a -spread in $PG(b, q)$ is a mixed spread of strength 2 in our sense. This is a set of subspaces of $PG(b, q)$ of projective dimension a which partitions $PG(b, q)$ (Thas, 1995), and exists if and only if $a + 1$ divides $b + 1$. From Theorem 10 we obtain an

$$OA(q^{b+1}, (q^{a+1})^k), \quad k = (q^{b+1} - 1)/(q^{a+1} - 1),$$

which of course is also given by the Rao-Hamming construction.

We could also have obtained example (ii) directly from example (i), by remarking that a mixed spread of strength t over $GF(q)$, $q = p^\beta$, is also a mixed spread of strength t over $GF(q')$, $q' = p^\alpha$, if q' divides q . The dimensions of the subspaces are multiplied by β/α .

(iii) Provided $a \geq b/2$, there exists a mixed spread of strength 2 in $GF(q)^b$ consisting of a single subspace $GF(q)^a$ and a partitioning of the remaining points into q^a subspaces $GF(q)^{b-a}$. This can be proved directly, or alternatively is equivalent to Lemma 2.1 of Eisfeld, Storme and Sziklai (1999). From Theorem 10 we obtain a geometric

$$OA(q^b, (q^{b-a})^{q^a} (q^a)^1)$$

whenever $a \geq b/2$. Orthogonal arrays with these parameters were already known from the difference scheme construction (Hedayat, Sloane and Stufken, 1999, Example 9.19), but the present construction also shows that they are geometric.

(iv) The classical “partial a -spread” constructed in Lemma 2.2 of Eisfeld, Storme and Sziklai (1999) translates in our language into a mixed spread of strength 2 consisting of k b -dimensional subspaces ($b \geq 2$) of $GF(q)^n$, where $n = ib + r$, $0 \leq r < b$, and

$$k = q^r \frac{q^{ib} - 1}{q^b - 1} - q^r + 1.$$

This produces a geometric $OA(q^n, (q^b)^k)$ (again arrays with these parameters were known from the difference scheme construction), which by Lemma 11 can be extended to a tight

$$OA(q^n, (q^1)^l (q^b)^k), \tag{21}$$

where $l = q^b(q^r - 1)/(q - 1)$. The orthogonal arrays constructed by Wu (1989) are a special case of (21), but in general these arrays may be new.

(v) Generalizing examples (i) and (ii), any orthogonal array formed from the codewords of a projective linear code (one for which the columns of a generator matrix are nonzero and projectively distinct) is geometric.

(vi) The $OA(256, 2^{16})$ of strength 5 formed from the Nordstrom-Robinson code (see Hedayat, Sloane and Stufken, 1999, Section 5.10) is not geometric, and no geometric $OA(256, 2^{16})$ of strength 5 exists.

We shall see other examples in Section 6.

Remarks. An unmixed geometric orthogonal array is always linear, in the sense of Hedayat, Sloane and Stufken (1999), Chapter 3. In general a mixed geometric orthogonal array is additive but not necessarily linear² over each of the fields involved.

If the strength is 2, the number of degrees of freedom in the parameter set for $OA(\mathcal{V})$ is equal to the total number of nonzero points in all the subspaces V_i .

Finally, the following is a recipe for constructing the orthogonal array from a mixed spread $\mathcal{V} = \{V_1, V_2, \dots, V_k\}$ of subspaces of $GF(q)^n$ in the case when q is a prime. Let $v_1^{(i)}, \dots, v_{d_i}^{(i)}$ be a basis for V_i , where $d_i = \dim V_i$, $1 \leq i \leq k$. Let w_0, \dots, w_{q^n-1} be the vectors of $GF(q)^n$. Then the i th entry of the j th row of the orthogonal array, for $1 \leq i \leq k$, $0 \leq j \leq q^n - 1$, is the number

$$\sum_{r=1}^{d_i} w_j \cdot v_r^{(i)} q^{r-1} .$$

(This is a number in the range $\{0, \dots, q^{d_i} - 1\}$.)

6. If the number of runs is a power of 2

In this section we consider the case $N = 2^n$, $n = 1, 2, \dots$. We have already discussed $ht(N)$ in Section 3 (see Table 2). With the assistance of Michele Colgan, we used a computer to determine the number of dual atoms $A'(N)$ and the total number of nodes $T'(N)$ in the idealized lattice Λ'_N for $n \leq 9$. The results are shown in the second and third columns of Table 3. Note in particular the extremely rapid growth from $N = 256$ to $N = 512$. We regard this as convincing evidence that when $N = 2^n$, $A'(N)$ (and therefore presumably $A(N)$) grows faster than any polynomial in N .

As to the lattice Λ_N itself, for $n \leq 4$ this is covered by the results in Section 2. For $N = 32$ there are precisely two parameter sets in Λ'_{32} which do not exist, $(32, 4^{10})$ and $(32, 2^1 4^{10})$. These can be ruled out either by the linear programming bound or by the Bose-Bush bound (Hedayat,

²For the distinction between additive and linear sets in the context of coding theory see Calderbank et al. (1998).

Table 3: Dual atoms and total number of nodes in idealized lattice Λ'_N ($A'(N)$ and $T'(N)$) and in lattice Λ_N ($A(N)$ and $T(N)$).

N	$A'(N)$	$T'(N)$	$A(N)$	$T(N)$
1	0	1	0	1
2	1	2	1	2
4	1	5	1	5
8	1	14	1	14
16	2	61	2	61
32	3	322	2	320
64	11	3058	7	3037
128	21	33364		
256	72	789085		
512	144521	18614215		

Sloane and Stufken, 1999, Theorem 2.8). All other parameter sets in Λ'_{32} are realized. It follows that Λ_{32} contains exactly two dual atoms, $OA(32, 2^{16}16^1)$ and $OA(32, 4^88^1)$.

Before considering Λ_{64} we give a lemma that will be used to construct new arrays.

Lemma 12. *Suppose V_1, V_2, V_3 are three r -dimensional subspaces of $GF(2)^{2r}$ such that $V_i \cap V_j = \{0\}$, $i \neq j$. Then their union can be replaced by $2^r - 1$ two-dimensional subspaces, any pair of which meet just in the zero vector.*

Proof. Since $V_1 \cap V_2 = \{0\}$, V_1 and V_2 span the space $GF(2)^{2r}$. Let π_1, π_2 be the associated projection maps from $GF(2)^{2r}$ to V_1, V_2 respectively. Then $i_1 = \pi_1|_{V_3}: V_3 \rightarrow V_1$ and $i_2 = \pi_2|_{V_3}: V_3 \rightarrow V_2$ are both isomorphisms. It follows that V_3 is the set

$$\{v + i(v) : v \text{ in } V_1\}, \quad i = i_2 i_1^{-1}.$$

But then we need simply take the planes $\{0, v, i(v), v + i(v)\}$ for $v \in V_1$ to establish the lemma. ■

The lemma implies that if a geometric $OA(2^{2r}, \dots)$ exists then so does the array obtained by replacing $(2^r)^3$ in the parameter set by 4^k , $k = 2^r - 1$. In particular, in a geometric $OA(64, \dots)$ we can replace 8^3 by 4^7 .

Theorem 13. *The lattice Λ_{64} contains precisely seven dual atoms, with parameter sets*

$$\begin{aligned} &(64, 2^5 4^{17} 8^1), (64, 4^{14} 8^3), (64, 2^5 4^{10} 8^4), \\ &(64, 4^7 8^6), (64, 8^9), (64, 4^{16} 16^1), (64, 2^{32} 32^1). \end{aligned} \tag{22}$$

A geometric orthogonal array exists for each of these parameter sets.

Proof. As an intermediate step, we use mixed spreads of strength 2 to construct orthogonal arrays with the following parameter sets:

$$\begin{aligned}
& (64, 4^{21}), (64, 2^5 4^{17} 8^1), (64, 2^4 4^{15} 8^2), (64, 4^{14} 8^3), \\
& (64, 2^5 4^{10} 8^4), (64, 2^4 4^8 8^5), (64, 4^7 8^6), (64, 2^8 4^2 8^7), \\
& (64, 2^4 4^1 8^8), (64, 8^9), (64, 4^{16} 16^1), (64, 2^{32} 32^1).
\end{aligned} \tag{23}$$

On the other hand, linear programming shows that orthogonal arrays do not exist with parameter sets

$$(64, 4^{18} 8^1), (64, 4^{16} 8^2), (64, 4^{11} 8^4), (64, 4^9 8^5), (64, 4^3 8^7), (64, 4^2 8^8). \tag{24}$$

We then check that every parameter set with 64 runs either dominates one of (24) (and so is not realized), or is dominated by one of (23) (and is realized). Furthermore, the parameter sets in (22) dominate all of (23).

It remains to construct the arrays mentioned in (22). The last two follow from Example (iii) of Section 5. Also $(64, 8^9)$ comes from Example (i), and $(64, 4^7 8^6)$ and $(64, 4^{14} 8^3)$ follow from Lemma 12.

To construct an $OA(64, 2^5 4^{10} 8^4)$ we proceed as follows. We begin by constructing an explicit example of an $OA(64, 8^9)$ from Theorem 10, by using an extended Reed-Solomon code of length 9, dimension 2 and minimal distance 8 over $GF(8)$. This gives a decomposition of $GF(2)^6$ into 9 copies of $GF(2)^3$ meeting only in the zero vector. These 9 subspaces are spanned by the following nine triples of columns:

$$\begin{array}{cccccccccc}
0 & I & I & I & I & I & I & I & I & I \\
I & 0 & I & A & A^2 & A^3 & A^4 & A^5 & A^6 &
\end{array} \tag{25}$$

where

$$0 = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix}, \quad I = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}, \quad A = \begin{bmatrix} 0 & 1 & 0 \\ 1 & 0 & 1 \\ 0 & 1 & 1 \end{bmatrix},$$

and $A^7 = I$.

We may replace the first four subspaces and the last subspace (which together contain 35 nonzero points) by ten two-dimensional subspaces with five single points left over. One choice for the ten two-dimensional subspaces is shown in Table 4. This gives a mixed spread of strength 2 consisting of four 3-dimensional subspaces, ten two-dimensional subspace and five points, and so by Theorem 10 corresponds to an $OA(64, 2^5 4^{10} 8^4)$. Finally, Lemma 12 produces an $OA(64, 2^5 4^{17} 8^1)$. ■

Remark. Geometric orthogonal arrays with parameter sets of the form $(64, \dots 8^k \dots)$ involve selecting k disjoint (except for the zero vector) copies of $GF(2)^3$ inside $GF(2)^6$. It is simpler to

Table 4: Ten pairs of columns each spanning a two-dimensional subspace of $GF(2)^6$.

01	01	00	00	01	01	00	01	10	01
00	01	01	00	01	11	01	00	01	11
01	00	10	01	00	11	00	00	01	01
00	11	00	00	10	01	10	10	01	10

11	10	10	10	10	01	00	00	00	10

work projectively, and then we must choose k disjoint copies of $PG(2, 2)$ inside $PG(5, 2)$. Equation (25) then gives a decomposition of $PG(5, 2)$ into nine copies of $PG(2, 2)$.

With the help of Magma (Bosma and Cannon, 1995; Bosma, Cannon and Mathews, 1994; Bosma, Cannon and Playoust, 1997), we showed that if $1 \leq k \leq 4$ there is a unique way to choose k disjoint $PG(2, 2)$'s in $PG(5, 2)$, and these are equivalent to a subset of (25). For $k = 5$, there are precisely two ways, one of which is equivalent to a subset of (25) while the other contains no $PG(2, 2)$ in its complement, and so cannot be extended to $k = 6$. For $k = 6, \dots, 9$, there is again a unique way to choose k disjoint planes. In particular the decomposition into nine planes shown in (25) is also unique.

An example of a maximal set of five $PG(2, 2)$'s in $PG(5, 2)$ is shown in Table 5. This corresponds to a geometric $OA(64, 8^5)$ that cannot be extended to a geometric $OA(64, 8^6)$. It would be interesting to determine if it can be extended to *any* $OA(64, 8^6)$.

Table 5: A set of five disjoint $PG(2, 2)$'s in $PG(5, 2)$ that is not contained in a set of six. Each triple of columns spans one of the subspaces.

7. The existence of orthogonal arrays with certain parameter sets

In this section we prove Theorem 4, the lower bound in Theorem 2, and also give some other conditions which are sufficient to guarantee that a parameter set can be realized by an orthogonal array.

Lemma 14. *Suppose $N = p^m$ is a power of a prime and $(N, s_1^{k_1} s_2^{k_2} \dots)$ is a parameter set with $k = \sum_i k_i$ factors. If $k \leq p^{\lfloor (m+1)/2 \rfloor} + 1$ then this parameter set is realized by a geometric orthogonal array.*

Proof. Suppose first that the parameter set contains a factor with $s = p^n > \sqrt{N}$ levels. If m is even then a geometric $OA(p^m, (p^{m-n})^{p^n} (p^n)^1)$ exists by Section 5, and p^{m-n} is the largest number of levels other factors can have if there is an s -level factor. Since there are p^n factors with p^{m-n} levels, the existence of any array with one s -level factor and at most $p^{m/2}$ factors with $\leq p^{m-n}$ levels follows immediately. The case that m is odd follows similarly.

We now assume that all $s_i \leq \sqrt{N}$. If m is even, $N = p^{2r}$, then a geometric

$$OA(p^{2r}, (p^r)^{p^r+1}) \quad (26)$$

exists by Section 5. Any parameter set with all $s_i \leq p^r$ and $k \leq p^r + 1$ is dominated by (26) and so is realized. If m is odd, $N = p^{2r+1}$, then a geometric

$$OA(p^{2r+1}, (p^r)^{p^{r+1}+1}) \quad (27)$$

also exists by Section 5. Any parameter set with all $s_i \leq p^r$ and $k \leq p^{r+1} + 1$ is dominated by (27) and so is also realized. ■

Since the number of factors in a parameter set is less than or equal to the number of degrees of freedom (6), Lemma 14 immediately implies that any parameter set $(N = p^m, s_1^{k_1} s_2^{k_2} \dots)$ with at most $p^{\lfloor (m+1)/2 \rfloor} + 1$ degrees of freedom is realized by an orthogonal array. However, Theorem 4 is much stronger.

Proof of Theorem 4. We will show that any parameter set $(p^m, p^{k_1} (p^2)^{k_2} (p^3)^{k_3} \dots)$ satisfying

$$\sum_{i \geq 1} k_i (p^i - 1) \leq p^{3m/4} \quad (28)$$

is realized by a geometric orthogonal array, where p is any prime. To simplify the notation we assume $m = 4r$ is a multiple of 4. The arguments in the other three cases require only minor modifications and are left to the reader.

From (28) we have

$$k_{r+1} + k_{r+2} + \dots + k_{4r-1} \leq p^{2r} + 1, \quad (29)$$

and so by Lemma 14 a geometric

$$OA(p^{4r}, (p^{r+1})^{k_{r+1}} (p^{r+2})^{k_{r+2}} \dots (p^{4r-1})^{k_{4r-1}})$$

exists.

We now proceed by induction. Let H_n be the hypothesis that every parameter set

$$(p^{4r}, p^{b_1}(p^2)^{b_2} \dots (p^r)^{b_r}(p^{r+1})^{k_{r+1}} \dots (p^{4r-1})^{k_{4r-1}}) \quad (30)$$

with $b_i \leq k_i$ for $1 \leq i \leq r$ and

$$b_1 + b_2 + \dots + b_r = n$$

can be realized by a geometric orthogonal array constructed using disjoint subspaces of $PG(4r - 1, p)$. We have shown that H_0 holds. Suppose H_n holds with

$$n < k_1 + k_2 + \dots + k_r .$$

We will show that we can increase b_r by 1 and still realize the parameter set, thus establishing H_{n+1} .

To show this, note that the number of projectively distinct nonzero points in all the subspaces in (30) is at most

$$\sum_{i=1}^{4r-1} k_i \frac{p^i - 1}{p - 1} - 1 \leq \frac{p^{3r}}{p - 1} - 1 .$$

However, by Theorem 1 of (Thas, 1995), Section 7, if a subset of $PG(4r - 1, p)$ contains fewer than

$$(p^{3r+1} - 1)/(p - 1) \text{ points ,}$$

there is a subspace $PG(r - 1, p)$ disjoint from it. Since

$$\frac{p^{3r}}{p - 1} - 1 < \frac{p^{3r+1} - 1}{p - 1} ,$$

such a subspace exists and we can use it to augment b_r by 1.

By induction, we can realize the parameter set $(p^{4r}, p^{k_1}(p^2)^{k_2} \dots (p^{4r-1})^{k_{4r-1}})$, as required. ■

Proof of lower bound of Theorem 2. First suppose $N = 2^{2r}$. From Theorem 4, every parameter set

$$(2^{2r}, 2^{k_1} 4^{k_2} 8^{k_3} \dots (2^r)^{k_r})$$

with at most $2^{3r/2}$ degrees of freedom can be realized. The lower bound of Theorem 2 now follows in the same way that we proved the upper bound in Section 4. If $N = 2^{2r+1}$ we use the previous case together with $T(N) \geq T(N/2)$. ■

It would be nice to have analogues of Theorem 4 and Lemma 14 when N is not a prime power!

Acknowledgments

We thank Michele Colgan for computing the properties of the lattices Λ'_N shown in Table 3. The research of John Stufken was supported by NSF grant DMS-9803684.
