ENVIRONMENTAL, SOCIAL AND GOVERNANCE DISCLOSURE, INTEGRATED REPORTING, AND THE ACCURACY OF ANALYST FORECASTS

ABSTRACT

The International Integrated Reporting Council advocates that integrated reporting (IR) should become the worldwide norm for corporate reporting aimed at serving the needs of investors. Nonetheless, only in South Africa has IR been mandated. We study the impact of the reporting regime change in South Africa on analyst forecast accuracy over the period 2008 to 2012, as a way of evaluating users' perceptions of the usefulness of IR. We theorise that any effects of IR will be greater the greater is the level of disclosures of environmental, social and governance performance. We find results consistent with those who support IR and our theory that the level of environmental, social and governance disclosures is a mediating variable in determining the effectiveness of IR. The results are driven by the levels of environmental disclosure and, to a lesser extent, governance disclosure. Our results provide some support for those who advocate the virtues of integrated reporting.

Key words: integrated reporting; environmental, social and governance disclosures; analyst forecasts

1 INTRODUCTION

The idea that corporations have responsibilities to not only their shareholders but also to society overall has been around for centuries (Carroll and Shabana, 2010). In this context, a criticism of financial reporting is that it does not adequately satisfy the informational needs of all stakeholders who wish to assess a company's past and future performance. This is because it only provides a partial account of business activities, ignoring the social and environmental impact made by an entity (Flower, 2015). As a consequence, there have been calls for enhanced reporting on corporate social responsibility (CSR), as well as for any additional information that can potentially impact on business performance. Subsequently, the number of companies disclosing their initiatives and performance with respect to environmental and social activities has grown. The preferred format for such disclosures has typically been a stand-alone report.¹

A concern with stand-alone reports related to environmental and social activities is that they provide non-financial information which is non-integrated and compartmentalised. Therefore, they are not capable of providing stakeholders with the required links and connections that are fundamental to effectively evaluating business performance, strategy and potential for future value creation (Wild and van Staden, 2013, p.6). Integrated Reporting (IR) is seen as a response to this criticism. The International Integrated Reporting Council (IIRC) states that the purpose of IR is to provide '... information about an organisation's strategy, governance, performance and prospects in a way that reflects the commercial, social and environmental context within which it operates' (IIRC, 2011, p.2). The IIRC has

¹ We use the term 'stand-alone report' to describe a number of differently titled reports. These titles include 'Sustainability Report', 'Corporate Social Responsibility Report', 'Sustainable Development Report' and 'Triple Bottom Line Report'. The common characteristic of these reports is a focus on the environment and/or society.

1 established a network of companies experimenting with IR. Further, the IIRC advocates that
2 IR should become the worldwide norm for corporate reporting to investors.
3
4
5
6

7 Research on the usefulness of IR is relatively sparse and impeded by two factors. First, only
8 in South Africa has IR been mandated, with South African listed firms with financial years
9 ending after February 28, 2011 required to publish an integrated report on an ‘apply or
10 explain’ basis. As a consequence, the study of IR in other jurisdictions involves firms that
11 adopt IR voluntarily. Second, as Pope and McLeay (2011) point out, the study of firms that
12 voluntarily adopt particular reporting practices does not necessarily produce results that are
13 generalisable to all companies. This is because the firms studied could have reason to adopt
14 the practices other than for reasons of good citizenship and a belief in transparency.
15 Consequently, adopting firms might be different from non-adopting firms in ways that bias
16 the results of tests of usefulness. Second, the number of firms voluntarily adopting IR around
17 the world is relatively small.

36 Given these arguments, studying South African firms has interest. Our analysis investigates
37 South African firms covering the period 2008-2012. Therefore, we cover firms which are
38 mandated to implement IR on an ‘apply or explain’ basis in the later part of the period
39 investigated. We study the impact of the reporting regime change on analyst forecast
40 accuracy as a way of evaluating investors’ perceptions of the usefulness of IR. In particular,
41 we study whether the implementation of IR in South Africa is associated with a change in the
42 relationship between levels of environmental, social and governance (ESG) disclosures and
43 analyst forecast accuracy, consistent with IR providing useful information to financial report
44 users.

52

Three key assumptions underpin our research approach. First, we assume that a link between ESG-related *disclosures* and analyst forecast accuracy will only exist if there is a link between ESG *performance* and future financial performance for South African listed companies.² This appears to be an argument with which the promoters of IR in South Africa agree, and is crucial in attempting to make any case for IR providing useful information about the financial implications of ESG performance to capital markets users. The second assumption is that, if the claims of supporters of IR are valid, and that linking ESG performance with future financial performance through an integrated report provides stakeholders with an improved understanding of the firm and its future, we expect analyst forecast accuracy to improve after the implementation of IR.³ The third assumption is that any effects of IR will be greater the greater is the level of ESG disclosures. Therefore, an implied assumption is that ESG is a mediating variable in determining the effectiveness of IR. Put another way, the integrated reports of firms which do not disclose much on ESG performance are unlikely to enhance the understanding of the linkages between ESG performance and financial performance, or provide a holistic view of the firms activities, much differently from conventional financial statements. Under these circumstances, we would not expect to see much change in forecast accuracy for such firms.

43
44
45
46
47
48
49
50
51
52

We note, however, that there were no well accepted guidelines on what constitutes an integrated report in South Africa for the period we study, with the exception of a brief Discussion Paper entitled ‘Framework for Integrated Reporting and the Integrated Report’

² Any links are likely to be complex. For example, they might relate to factors affecting revenue streams, such as the degree of consumer activism faced by the firm, its competitive position, and the markets served. They might also relate to its cost structure, including regulatory interventions, clean-up costs associated with pollution and other environmental damage, and labour market outcomes.

³ If it is argued that the low take-up of integrated reporting on a voluntary basis around the world referred to above reflects firms rationally choosing the optimal forms of disclosure, whether mandated or not, with regards to the informational needs of stock market participants, then we would not expect to see the mandating of IR having any positive effect on analyst forecast accuracy.

1 issued in early 2011 by the Integrated Reporting Committee (IRC) of South Africa. How
2 effective the implementation of IR is in South Africa is an empirical question, therefore. This
3
4 also implies that tests on the usefulness of IR in South Africa are joint tests of the usefulness
5
6 of the underlying concept of IR and the effectiveness of the application of the concept.⁴
7
8
9

10
11 Our work can be related to two prior papers which either challenge the assumptions
12
13 underlying our work, or complement our study. The results and theorising in Dhaliwal,
14
15 Radhakrishnan, Tsang and Yang (2012) challenge the assumptions underlying our research.
16
17 As part of an international study, they provide results on whether publishing a standalone
18
19 CSR report improves analyst forecast accuracy in South Africa. They investigate an earlier
20
21 period than we do (i.e., prior to the mandating of IR in South Africa).
22
23
24
25
26
27
28

29 A crucial part of their argument is that a link between ESG performance and future financial
30
31 performance is only likely to be found for firms in stakeholder-oriented, not shareholder-
32
33 oriented, economies. Dhaliwal *et al.* (2012) identify South Africa as a shareholder-oriented
34
35 economy and, hence, do not expect the publication of a standalone CSR report to improve
36
37 analyst forecast accuracy in South Africa.
38
39
40
41
42
43
44
45
46

47 ⁴ South Africa later adopted the more detailed IIRC IR guidelines issued in 2013 (IIRC, 2013). The IIRC
48 guidelines adopt a shareholder focus, a focus that is subject to debate in academic circles (see Adams,
49 2015; Flower, 2015; Thomson, 2015). Therefore, the period we study is one where firms were not
50 expected to adopt an explicit investor focus in preparing integrated reports. If this implies that the
51 integrated reports are less useful to analysts, our tests are less likely to find any impact of IR on the
52 relationship between ESG disclosure levels and analyst forecast accuracy. If we do find results suggesting
53 that there is an impact, such results provide evidence that an investor focus in IR is not necessary for the
54 resulting integrated reports to be relevant to investors. Further, these guidelines suggest that firms should
55 concentrate on *material* links between aspects of ESG and financial performance in their integrated
56 reports. This suggestion is consistent with the idea that underlying business models differ across firms and
57 that firms have different key aspects of ESG performance that they need to manage. As a consequence, it
58 is not clear which, if any, aspects of ESG disclosures will be linked to forecast accuracy. Therefore, we
59 investigate the links between three different components of ESG disclosures (environmental, social, and
60 governance) and forecast accuracy.
61
62
63
64
65

1 Consistent with their argument, they find no association between the existence of a
2 standalone CSR report and analyst forecast accuracy in South Africa. More generally, they
3
4 find that a relationship between the publication of a standalone CSR report and improved
5 forecast accuracy is found more in stakeholder-oriented countries. As a consequence, and
6
7 notwithstanding the views of the promoters of IR in South Africa and elsewhere, it is not
8
9 clear whether the assumption of a link between ESG performance and future financial
10 performance is justified and, therefore, it is also not clear that IR will improve analyst
11 forecast accuracy in South Africa.
12
13
14
15
16
17
18
19
20
21

22 Two points can be made here. First, Dhaliwal *et al.* (2012) do not evaluate the *quality* of the
23 standalone CSR reports in South Africa, or in any of the countries they study, merely their
24 existence. Therefore, one explanation of their results that cannot be ruled out is that the
25 quality of the CSR standalone reports in South Africa in communicating relevant information
26 to capital markets was poor over the period they study and, as a consequence, it is this that
27 explains their results, not any shareholder orientation of the South African economy. Second,
28 it is possible that, although the South African economy during their study period *was*
29 primarily shareholder-oriented, the various South African King reports have produced a move
30 towards a more stakeholder-oriented economy.⁵ If such is the case, it is not clear that results
31 from periods prior to the one studied here will generalise to subsequent periods.

36
37
38
39
40
41
42
43
44
45
46
47
48

49 In complementary work, Zhou, Simnett and Green (forthcoming) study the degree of
50 integration of the financial reports of South African firms and its effect on analyst forecast
51 accuracy. Using a sample of South African firm-years from 2009 to 2012, they first develop
52 a measure which captures the extent to which the firms' reports are integrated in line with the
53
54
55
56
57
58

59 ⁵ See, for example, Angelopoulos, Parnell and Scott (2013) and Muswaka (2013) for discussions of this
60 possibility.
61
62
63
64
65

1 IIRC framework for IR (IIRC, 2013). They find evidence suggesting that the higher the
2 degree of integration of the reports, the better the accuracy of analyst forecast errors,
3
4 consistent with the idea of integrated reporting providing useful information to capital market
5
6 participants.⁶
7

8
9
10
11 Our work differs from theirs in the following key respects.⁷ Whereas they study the effects
12 of the *degree* of integration of reports across their whole study period, irrespective of whether
13
14 IR is or is not mandated, they do not explicitly study the effects of the *level* of disclosure of
15
16 any underlying ESG material. Essentially, they study whether the IIRC framework is
17
18 effective in defining the characteristics of good integrated reporting, applied to the South
19
20 African context. In contrast, we focus on the disclosure levels of the base ESG material that
21
22 arguably provides some of the input of non-financial information that needs to be integrated
23
24 *via* IR. Then, we consider how the relationship between ESG disclosure levels and analyst
25
26 forecast accuracy changes with the *mandating* of IR. This approach also allows us to look at
27
28 separate aspects of ESG disclosure and how their relationships with forecast accuracy change
29
30 with the mandating of IR. Nonetheless, we do not focus explicitly on the differing degrees of
31
32 effectiveness across firms in integrating ESG and other non-financial information.⁸
33
34
35
36
37
38
39
40
41
42

43 Our main contribution, therefore, is to investigate the impact of the mandating of IR in South
44
45 Africa on analyst forecast accuracy, using the level of ESG disclosures as a mediating
46
47 variable in identifying any impact. Secondary contributions of the study are, first, to revisit
48
49
50
51
52

53 ⁶ They also study analyst forecast dispersion and the cost of capital as capital market outcomes that could be
54 affected by IR. They find some evidence that the degree to which reports are integrated according to their
55 measure is associated with reductions in the cost of capital, at least for some firms (those with smaller
56 analyst followings).

57 ⁷ Our study also differs from theirs in a number of research design choices. These differences are arguably
58 second-order compared to the differences identified in the main text.

59 ⁸ Other studies of IR and capital market outcomes in South Africa include Barth, Cahan, Chen and Venter
60 (2015) and Lee and Yeo (2015). These papers are discussed in the next section of the paper.
61
62
63
64
65

1 the link between ESG disclosure levels and analyst forecast accuracy and, within this context,
2 to introduce a more nuanced view of the quality of CSR disclosures, at least in a South
3 African setting.
4
5
6
7
8

9 We use a balanced panel research design as our primary methodology. The balanced panel
10 includes forty-one firms from eight sectors (consumer discretionary; consumer staples;
11 communications; energy; financial services; health care; industrials; materials) for the period
12 2008 to 2012.⁹ Bloomberg ESG disclosure scores are used to capture the level of disclosures.
13
14 Controlling for firm and time fixed effects and other control variables, our key result is that
15 the relationship between overall ESG disclosure scores and analyst forecast accuracy
16 significantly strengthens once the IR regime is introduced. This result is consistent with IR
17 providing useful information to analysts and investors in general (there tends to be little or no
18 relationship before IR, and a relationship after the introduction of IR). It is primarily driven
19 by the environmental disclosure component of the ESG disclosure score. There is also some
20 evidence of links between the level of governance disclosures and analyst forecast accuracy,
21 but the evidence is not as strong as for environmental disclosure levels. We delve further into
22 our results, by splitting up the sample into financial services firms and the firms from the
23 other seven sectors grouped together. For financial services firms, we find little evidence of
24 relationships between the level of any aspect of ESG disclosure and forecast accuracy, either
25

44
45
46
47
48
49

50 ⁹ We use a small sample by the standards of capital markets research in accounting. Nonetheless, precedent
51 exists for the use of small samples when the question is deemed interesting enough. For example, Leuz
52 and Verrechia (2000) study a sample of 102 German Dax firm-years in considering the impact on measures
53 of information asymmetry of German firms switching from German GAAP to some form of international
54 accounting standards (US GAAP or IAS). Also, Leuz (2003) uses two small samples, one of 69 and the
55 other of 195 German Neue Markt firm-years, to study the relative impacts of US GAAP and IAS on
56 measures of information asymmetry. The research settings used in these two analyses were unique in
57 providing a good site to study interesting research questions. We believe that South Africa provides such a
58 unique site for the initial study of the impact of mandating IR, which we regard as a similarly interesting
59 research question. We should also emphasise that our statistical tests have plenty of degrees of freedom
60 available.
61
62
63
64
65

1 existing in, or changing between, the pre- and post-IR periods. The results for the firms from
2 the other seven sectors grouped together are similar to the results for the whole sample.
3
4

5
6
7 The use of firm and time fixed effects is a crucial aspect of our research design in that our
8 results largely disappear or, at the least, substantially weaken in the absence of either, or the
9 presence of less finely granulated firm effects such as sector fixed effects. The use of an
10 unbalanced panel of 310 firm-years produces similar results to the balanced panel, other than
11 that the results also provide evidence that there is a strengthening of the relationships between
12 overall ESG, environmental and governance disclosure levels and analyst forecast accuracy
13 for financial services firms as well.
14
15
16

18
19
20
21
22
23
24
25

26 Overall, we find some results consistent with those who support IR, and our theory that the
27 level of ESG disclosures is a mediating variable in determining the effectiveness of IR in the
28 particular capital market context we study. This outcome is found despite the lack of clear
29 guidance to South African companies concerning the preparation of the early versions of
30 integrated reports. Our results also provide support for the idea that specific aspects of ESG
31 performance could be more important than others for some sets of firms in understanding
32 future performance.

our paper, the overall conclusions to be drawn from our work, a discussion of its limitations, and suggestions for further research.

2 RELEVANT PRIOR LITERATURE AND HYPOTHESIS DEVELOPMENT

2.1 *Relevant Prior Literature*

In this section, for reasons of space, we concentrate on work that is directly relevant to this study, as opposed to providing a background of the development of IR and a description of previous work on IR. Two recent papers that provide the necessary background information and that review the IR literature, although with different rules for the incorporation of studies to be included in the review, are Velte and Stawinoga (2016) and Dumay, Bernardi, Guthrie and Demartini (2016). We focus on papers that relate integrated reporting to capital market outcomes.

In this context, two recent papers can be interpreted as investigating the effectiveness of the IIRC's framework for the desirable characteristics of an integrated report in a South African context. Both studies use data from before and after the date of implementation of IR in South Africa, and develop measures of the degree of integration of financial statements. Lee *et al.* (2015) investigate the relationship between the degree of integration and market value, with the extent of organisational complexity and the need to raise external financing as mediating variables. Using estimates of Tobin's Q as a measure of market value, they find evidence of a relationship between the degree of integration and market value and that, further, the relationship is stronger for firms with higher degrees of organisational complexity and with higher external financing needs. They also find a positive association between the

1 degree of integration and future performance and that the degree of integration could be mis-
2 priced. Zhou *et al.* (forthcoming) study whether the degree to which South African financial
3 reports are integrated affects analyst forecast accuracy, forecast dispersion, and the cost of
4 capital. They find that the higher the degree of integration, the higher is the degree of
5 forecast accuracy and the lower is the cost of capital, the latter especially for firms with small
6 analyst followings. Nonetheless, the *foci* of these studies are neither the impact of the
7 mandating of IR in South Africa nor the role of ESG disclosure levels as a mediating variable
8 in investigating the impact of mandating IR.
9
10
11
12
13
14
15
16
17
18
19
20
21

22 Barth *et al.* (2015) look at the relationship between IR and stock liquidity and market value in
23 South Africa. They find that IR improves stock liquidity and is associated with higher values
24 of Tobin's Q. Unlike Lee *et al.* (2015), they do not use organisational complexity and the
25 need for external financing as mediating variables in the relationship between IR and market
26 value. Like them, however, the effect of IR on Tobin's Q is then attributed mainly to a future
27 cash flow effect, as opposed to a cost of capital effect (in apparent contrast to Zhou *et al.*,
28 forthcoming, who find cost of capital effects, especially for firms with small analyst
29 followings). They suggest that this effect is a result of market participants either having a
30 better understanding of the firm's future cash flow generating capacity or that future cash
31 flow expectations are higher as a result of expected improvements in internal decision-
32 making by managers. Again, and unlike us, Barth *et al.* (2015) do not explicitly study the
33 level of ESG disclosure (or its components) as mediating variables for the relationship
34 between IR and their capital market outcomes.

2.2 Development of Hypotheses

1
2
3
4
5 Given that IR does not *directly* affect the properties of accounting numbers, but does
6
7 potentially affect the information set available *via* which the information content of
8
9 accounting numbers is interpreted, we focus on the properties of analyst forecasts. In
10
11 particular, we argue that, if IR in South Africa provides useful information to investors, by
12
13 linking ESG and future financial performance, analyst forecast accuracy should improve
14
15 subsequent to the start of the IR regime.
16
17
18
19
20

21
22 Evidence from Bloomberg ESG disclosure scores for South Africa suggests that the quality
23
24 of ESG reporting varies across firms. *A priori*, it seems unlikely that IR will provide much
25
26 benefit to users and, specifically, analysts if there is little ESG disclosure to help link ESG
27
28 performance to future financial performance. Therefore, we argue that IR will improve the
29
30 forecasting relevance of disclosures concerning ESG performance for analysts and, further,
31
32 the higher the disclosure levels of ESG performance, the larger will be the improvement.
33
34 Also, if the arguments of proponents of IR are correct – that, in the absence of IR, ESG
35
36 disclosures will have limited impact on capital markets because the links to financial
37
38 performance are not understood – we expect to observe less of a, or indeed no, relationship
39
40 between ESG disclosure levels and analyst forecast accuracy prior to the IR regime.
41
42
43
44
45
46
47

48 Therefore, our formal hypothesis for the pre-IR regime period, in null and alternative form, is
49
50 as follows:
51
52
53
54

55
56 H_{1N} Prior to the IR regime, ESG disclosure levels have no association with analyst
57
58 forecast accuracy; and
59
60
61
62
63
64
65

1 H_{1A} Prior to the IR regime, increased levels of ESG disclosure improve analyst forecast
2 accuracy.
3
4
5
6

7 For the IR regime period, our second hypothesis, in null and alternative form, is as follows:
8
9

10
11
12 H_{2N} During the IR regime, ESG disclosure levels have no association with analyst forecast
13 accuracy; and
14
15

16
17 H_{2A} During IR regime, increased levels of ESG disclosure improve analyst forecast
18 accuracy.
19
20
21
22
23

24 For differences between the pre-and post-IR regime periods, our third, and *main*, hypothesis,
25 in null and alternative form, is as follows:
26
27
28
29
30

31 H_{3N} There is no difference in the extent to which increasing ESG disclosure levels
32 improves analyst forecast accuracy before and after the IR regime; and
33
34
35

36 H_{3A} There is an increase in the extent to which increasing ESG disclosure levels improves
37 analyst forecast accuracy after the IR regime.
38
39
40
41
42
43

44 **3 METHODOLOGY**

45
46
47
48

49 We adopt a regression approach to testing our hypotheses. Within that general approach, we
50 adopt a balanced panel strategy. We do so for a number of reasons. Pope *et al.* (2011) argue
51 that the experimental design necessary to pin down the impact of an accounting regime
52 change can be difficult because, along with the regime change, firm and economic
53 characteristics that might affect some outcome variable (in our case, analyst forecast
54
55
56
57
58
59
60
61
62
63
64
65

1 accuracy) also change over time. As a consequence, the observation of a change in an
2 outcome variable (in our study, the relationship between the level of ESG disclosure and
3 analyst forecast accuracy) over time could be associated with the regime change, or changes
4 in relevant firm and economic characteristics, or both. Disentangling the impact of one
5 possible cause from the others is, therefore, problematic.
6
7
8
9
10

11
12
13
14 In this context, Pope *et al.* (2011) suggest that a balanced panel approach has some
15 advantages because each firm observation prior to the regime change acts as a control for
16 itself. If it can be assumed that relevant firm characteristics, and their impact on the outcome
17 variable, do not change over time, the inclusion of firm fixed effects in the model can control
18 for these effects (e.g., how difficult it is to forecast the firm's earnings per share). Further, if
19 there are time effects that are constant across firms in their impact on the outcome variable,
20 they can be controlled for *via* the introduction of time fixed effects.¹⁰
21
22
23
24
25
26
27
28
29
30
31

32
33
34 We adopt the approach of introducing firm and time fixed effects as a partial solution to
35 controlling for the effects of firm and economic characteristics that change over time and
36 affect analyst forecast accuracy. Given the implicit assumptions underlying the use of fixed
37 effects, we also control for seven specific variables that have been found to affect analyst
38 forecast accuracy in other studies – firm size, the size of analyst following, leverage, return
39 on assets, the sign of earnings, the book-to-market ratio, and lagged accuracy (as in, for
40 example, Glaum, Baetge, Grothe and Oberdörster, 2013; Preiato, Brown and Tarca, 2015).
41
42
43
44
45
46
47
48
49
50
51

52
53 We investigate the impact of the introduction of an IR regime in South Africa on forecast
54 accuracy by first defining the following variables:
55
56
57

58 ¹⁰ Zhou *et al.* (forthcoming) find that their measure of the degree of integration of reporting generally
59 increases over their sample period from 2009 to 2012. If their measure is an omitted variable from our
60 regressions, time dummies will at least help capture some of the average effects of this variable.
61
62
63
64
65

1 $Accuracy_{ij+1} =$ a measure of analyst forecast accuracy for firm i for year j ($j = 1$ to t , where
 2 t is the number of calendar years containing financial year-ends in the
 3 sample);
 4
 5

6
 7 $F_i =$ a firm fixed effect which takes the value of one for any firm-year for firm i
 8 ($i = 1$ to n , where n is the number of firms in the sample); zero otherwise;
 9

10
 11 $T_j =$ a time fixed effect which takes the value of one for any firm-year with a
 12 financial year-end in calendar year j ; zero otherwise;
 13
 14

15
 16 $C_{ikj} =$ control variable k ($k = 1$ to m) for firm i for year j ; and
 17

18
 19 $ESG_{ij} =$ the overall environmental, social and governance disclosure score for firm i
 20 for year j ;
 21
 22
 23
 24
 25

26 Then, we estimate the following equation on a balanced panel of South African firms:
 27

$$Accuracy_{ij+1} = \sum_{i=1}^n F_i + \sum_{j=1}^t T_j + \alpha_1 ESG_{ij} + \sum_{k=1}^m \delta_k C_{ikj} + \varepsilon_{ij} \quad (1)$$

28
 29 Subsequently, we create two variables, $PreESG$ and $PostESG$. The two variables effectively
 30 decompose ESG into two components. One takes the value of ESG during the period prior to
 31 the IR regime starting, and zero otherwise ($PreESG$). The other takes the value of ESG
 32 during the period after the IR regime starts, and zero otherwise ($PostESG$). Hence, we define
 33 $PreESG$ and $PostESG$ by the following equations:
 34
 35
 36
 37
 38
 39
 40
 41
 42
 43
 44

$$PreESG_{ij} = (1 - IRRD) \cdot ESG_{ij} \quad (2)$$

45 and

$$PostESG_{ij} = IRRD \cdot ESG_{ij} \quad (3)$$

46
 47
 48
 49
 50
 51
 52 where:

53
 54
 55
 56
 57 $IRRD =$ 1 for any firm-year t with a financial year-end subsequent to March 2011; 0
 58 otherwise.
 59
 60
 61
 62
 63
 64
 65

We then estimate the following equation:

$$Accuracy_{ij+1} = \sum_{i=1}^n F_i + \sum_{j=1}^t T_j + \alpha_{11} PreESG_{ij} + \alpha_{12} PostESG_{ij} + \sum_{k=1}^m \delta_k C_{ikj} + \varepsilon_{ij} \quad (4)$$

We estimate equation (1) to allow us to see whether there is an average effect on forecast accuracy associated with environmental, social and governance disclosure levels across the period studied. This effect is captured by the coefficient of *ESG*, α_l . Equation (4) allows us to identify the effects before and after the IR regime is introduced. More specifically, α_{11} captures the relationship between ESG disclosure levels and forecasting accuracy in the period prior to the introduction of IR and α_{12} captures the relationship between ESG disclosure levels and forecasting accuracy in the period subsequent to the introduction of IR. The coefficients α_{11} and α_{12} allow us to test hypotheses 1 and 2 respectively and the difference between them allows the testing of hypothesis 3.

Having estimated equations (1) and (4) using *ESG*, the *overall* ESG disclosure score, we re-estimate the equations with the environmental disclosure score (*ED*), social disclosure score (*SD*) and governance disclosure score (*GD*) substituted for *ESG*, together with the appropriately defined *Pre* and *Post* versions of the variables, in order to see if any particular component of ESG disclosure has a different relationship with forecast accuracy than other components. In this regard, we first estimate (giving the most comprehensive models estimated):

$$Accuracy_{ij+1} = \sum_{i=1}^n F_i + \sum_{j=1}^t T_j + \sum_{l=1}^3 \alpha'_l ESG_{ij} + \sum_{k=1}^m \delta_k C_{ikj} + \varepsilon_{ij} \quad (5)$$

and then:

$$Accuracy_{ij+1} = \sum_{i=1}^n F_i + \sum_{j=1}^t T_j + \sum_{l=1}^3 \alpha'_{1l} PreESG_{ij} + \sum_{l=1}^3 \alpha'_{2l} PostESG_{ij} + \sum_{k=1}^m \delta_k C_{ikj} + \varepsilon_{ij} \quad (6)$$

1 where ESG_{ij} represents the l^{th} component (ED , SD and GD) of the overall ESG disclosure
2 score for firm i for year j .
3
4
5
6

7 We define analyst forecast accuracy in two ways and denote the measures by $Acc1$ and $Acc2$
8 respectively. In mathematical terms, the measures of forecast accuracy are defined as
9
10
11 follows:
12

$$13 \quad Acc1 = \log \left[\frac{|AEPS - MedFEPS|}{MVPS} \right] \quad (7)$$

14
15
16
17
18
19 and
20

$$21 \quad Acc2 = \log \left[\frac{|AEPS - MedFEPS|}{|AEPS|} \right] \quad (8)$$

22
23
24
25
26
27 where:
28

29
30
31
32
33 $AEPS$ = the actual earnings *per* share corresponding to the median consensus one
34 year-ahead forecast of earnings *per* share;
35
36

37
38 $MedFEPS$ = the first median consensus analyst forecast of one year-ahead earnings *per*
39 share produced after the financial year-end; and
40
41

42
43 $MVPS$ = the market price *per* share of the firm at the financial year-end prior to the
44 date of the consensus analyst forecast.
45
46
47
48
49

50 A property of both our measures of accuracy is that a *lower* value for the accuracy measures
51 denotes a *higher* degree of forecast accuracy.¹¹ Therefore, if increasing ESG disclosure
52
53
54

55
56 ¹¹ We use log measures of forecast accuracy to avoid having measures that are naturally truncated at zero,
57 leading to possible specification problems for the estimated standard errors in our regressions, and
58 attendant difficulties of economic interpretation of the estimated coefficients from our regressions.
59 Inherently, the relationship between forecasting accuracy and the various explanatory variables must be
60 non-linear. We posit no particular functional form for the relationship and, hence, taking the log of
61

1 levels increases forecast accuracy, whether in the whole period or in either of the sub-periods,
2 we will see a *negative* value for α_1 , or α_{11} , or α_{12} . When separately considering the
3 component scores of ESG disclosure, if increasing ESG component disclosure levels
4 increases forecast accuracy, whether in the whole period or in either of the sub-periods, we
5 will see a *negative* value for α'_1 , or α'_{11} , or α'_{12} . If IR has the effect of strengthening any
6 relationship between ESG disclosure levels, or its components, and analyst forecast accuracy,
7 we expect to see $\alpha_{11} > \alpha_{12}$, or $\alpha'_{11} > \alpha'_{12}$.
8
9
10
11
12
13
14
15
16
17
18
19
20

21 We estimate the coefficients in equations (1), (4), (5) and (6) using the ‘within’ estimator to
22 deal with the firm fixed effects, and estimate coefficient standard errors using firm clustering.
23 The *p*-values that we report for the coefficients of our experimental variables in these
24 equations reflect one-tailed tests, because our hypotheses specify a directional alternative
25 hypothesis – as implied above, only *negative* values of the coefficients cause us to reject the
26 null hypothesis in favour of the alternative hypothesis. The same applies to the F-tests of the
27 differences between the coefficients of the *PreESG* (*PreED*, *PreSD*, *PreGD*) and *PostESG*
28 (*PostED*, *PostSD*, *PostGD*) variables - only positive values of these differences cause us to
29 reject the null hypothesis in favour of the alternative hypothesis. The *p*-values for the
30 coefficients of all the control variables reflect two-tailed tests.
31
32
33
34
35
36
37
38
39
40
41
42
43
44
45
46
47
48
49
50
51
52
53
54
55
56

57 We should emphasise, at this stage, that any conclusions that we draw from estimating these
58 equations and, in particular, the estimates of the coefficients of the various ESG variables, are
59 conditional upon accepting that our strategy of controlling for other factors that might affect
60 forecast accuracy is just one way of implementing a non-linear relationship. As a consequence of taking
61 the log of forecast accuracy, for both measures, the numerator of the fraction of which we take the natural
62 log can be zero if the consensus forecast is correct. It is not possible to take the log of zero. In such
63 circumstances, we set the fraction equal to an arbitrary low number. In our case, the number is .00001.
64
65

1 analyst forecast accuracy by a combination of firm and time fixed effects and the seven firm-
2 specific control variables, adequately rules out alternative explanations of our results.
3
4
5

6
7 Nonetheless, we can make one point on this issue here. Our research design does not rely on
8
9 a simple assertion that the IR regime change has a blanket impact on forecast accuracy,
10
11 leading to some of the ‘identification’ problems discussed above. Instead, it suggests that the
12
13 IR regime, if successful, alters any relationship between ESG disclosure levels and forecast
14
15 accuracy. As a consequence, to argue that some omitted variable explains away our results
16
17 relies upon the existence of different correlations between that variable and ESG disclosure
18
19 scores in the pre- and post-IR periods.¹²
20
21
22
23

24
25
26 Finally, Pope *et al.* (2011, p.246) argue that the ‘... challenge to researchers is ... to find ways
27
28 of more directly associating market outcomes with ... reporting, for example, by developing
29
30 evidence showing that market outcomes are stronger for benchmark firms where the ...
31
32 reporting regime change has had most impact’. We would argue that our research design
33
34 responds to the *spirit* of their challenge in the South African context of IR. It does so by
35
36 relating the impact of the introduction of the IR regime in South Africa, a regime that intends
37
38 to enhance narrative disclosures relating ESG and financial performance, to the underlying
39
40 level of ESG disclosures.
41
42
43
44
45
46
47
48
49
50
51
52
53
54

55 ¹² There is a possibility that another regulatory change could have occurred at the same time as the
56 mandating of IR, the predicted effect of which is similar to that hypothesised for IR. We can find no
57 obvious regulatory change in South Africa that matches this description. It is the case that the
58 Companies Act of 2008, despite being passed in 2009, then entered into a prolonged period of redrafting
59 and only came into force (with some exceptions) in May, 2011. It is not clear why, however, it would act
60 to affect analyst forecast accuracy through the medium of ESG disclosures.
61

4 VARIABLE DEFINITIONS, DATA SOURCES, AND SAMPLE DESCRIPTIONS

We generate our data from three data sources – Bloomberg, IBES and Compustat Global. We use Bloomberg for ESG disclosure scores. Qui, Shaukat and Tharyan (2016) use these scores in a recent study of UK environmental and social disclosures, and Ioannou and Serafeim (2014) also use them in studying the effects of mandating ESG disclosure in China, Denmark, Malaysia, and South Africa. Descriptions of how Bloomberg create the scores can be found in both papers.

From IBES, we generate our forecast variables. In particular, we use the database to generate observations on the first median consensus one year-ahead earnings *per* share forecast subsequent to a financial year-end (*MedFEPS*), the number of analysts used by IBES in generating the consensus forecast (*NoA* – as a proxy for the number of analysts following the firm), the actual earnings *per* share figure subject to the forecast (*AEPS*), and the price *per* share at the financial year-end prior to the forecast date (*MVPS*). We also use IBES to identify the number of shares outstanding at the financial year-end, which we multiply by *MVPS* to create the market capitalisation at the financial year-end prior to the forecast date. We take the log of this product to create *Log MV*, our measure of firm size.

We generate accounting variables from Compustat Global. In particular, we generate data for total assets (TA), total liabilities (TL) and net income (NI). We then generate the following control variables: (i) leverage (*Lev*) as the ratio of TL to TA; (ii) return on assets (*RoA*) as the ratio of NI to TA; (iii) a loss dummy (*Loss*) equal to one if *RoA* is negative; zero otherwise; and (iv) the book-to-market ratio (*BM*) as the ratio of the difference between TA and TL to

1 the market value of the firm (estimated using IBES data on the price *per* share and the
2 number of shares outstanding).
3
4
5
6

7 From these data sources we then construct a balanced panel for the financial years 2008 to
8 2012 (with, as a consequence, consensus analyst forecasts for the years 2009 to 2013), after
9 imposing further restrictions. We start our sample period at 2008 because the number of
10 firms with ESG disclosure scores is much lower in 2007 than 2008.¹³ We require firms to: (i)
11 have the necessary accounting, ESG, IBES forecast and price data; (ii) have consistent
12 financial year-ends for 2008 to 2012;¹⁴ (iii) have their primary listing on the Johannesburg
13 Stock Exchange (JSE);¹⁵ and (iv) report in South African Rands.
14
15
16
17
18
19
20
21
22
23
24
25

26 Our final sample consists of 41 firms with 5 years of consecutive observations, giving 205
27 firm-year observations. The number of firms listed on the JSE is much larger than 41. The
28 main reason we lose firm-years is because of a lack of availability of Bloomberg ESG data –
29 only 68 firms have available ESG data for the full five years. We then lose a further nine
30 firms which do not have their primary listing on the JSE; another four because of changing
31 financial year-ends during the period; and an additional five because they do not report in
32 South African Rands. This leaves us with forty-eight remaining firms, and we lose seven
33 more because of missing accounting and/or analyst forecast data.
34
35
36
37
38
39
40
41
42
43
44
45
46
47
48
49
50
51
52
53

54 The firms in our sample cover a wide range of sectors (consumer discretionary; consumer
55 staples; communications; energy; financial services; health care; industrials; materials).
56
57
58
59
60
61
62
63
64
65

¹³ Dhaliwal *et al.* (2012) find 37 South African firms who issue standalone CSR reports at some time between 1994 and 2007, with 174 firm-years with reports. They compare these firm-years with 877 firm-years that do not feature standalone CSR reports. Perhaps coincidentally, Bloomberg have ESG scores for just 37 firms in 2007.

¹⁴ This restriction ensures that all forecasts relate to the same length of reporting period.

¹⁵ Firms whose primary listing is not on the JSE are not expected to produce integrated reports (see Solomon and Maroun, 2012, p.9, fn.2).

1 Although mining companies are an important part of the South African economy, they do not
2 dominate our sample. Of the 41 firms, six are subsidiaries of non-South African
3 multinational firms and one is a subsidiary of another listed South African firm.¹⁶ Further,
4 many of the firms have their shares traded outside of South Africa, in addition to their main
5 listing on the JSE. Ten of these firms are also traded on the Namibian Stock Exchange.
6
7 Many companies have American Depositary Receipts (ADRs) traded in the US. Nonetheless,
8 only one firm has a Level 2 ADR, implying a need to conform to elements of Securities and
9 Exchange Commission (SEC) disclosure regulations. Level 2 ADRs are traded on one of the
10 US stock exchanges, but do not allow a firm to raise capital in the US. The firms with Level
11 1 ADRs are traded over-the-counter and do not have to conform to SEC disclosure
12 regulations. Further, many of the ADRs are unsponsored, implying that the firm has not
13 deliberately sought to make their shares available for purchase in the US. One firm has a
14 listing on the London Stock Exchange.

30
31
32
33

34 Given our sample contains financial services firms, and because it is accepted that ratios
35 involving accounting variables are likely to have different characteristics for financial
36 services firms relative to those in other sectors, we split *Lev*, *RoA* and *BM* into two
37 components, one representing the value of that variable when the firm is a financial services
38 firm and zero otherwise (*Lev-FS*, *RoA-FS*, *BM-FS*), the other representing the value of that
39 variable when the firm does not belong to the financial services sector and zero otherwise
40 (*Lev-NFS*, *RoA-NFS*, *BM-NFS*). Table 1 provides descriptive statistics for our variables for
41 the two sets of firms.¹⁷

53
54
55
56

57 ¹⁶ Casual comparisons suggest that the sample contains the larger South African domiciled firms listed on the
58 JSE.

59 ¹⁷ No financial services firms have losses in the financial years ending in 2008-2012. As a consequence, we
60 provide no statistics for that variable for financial services firms.
61
62
63
64
65

Insert Table 1

Table 2 provides details of the correlations between the independent and dependent variables for both sets of firms.

Insert Table 2

The correlations in Table 2 suggest that the two measures of forecast accuracy, *Acc1* and *Acc2*, are highly correlated. The components of ESG are significantly and positively correlated, more so for financial services firms, but not to such an extent likely to cause multi-collinearity problems if they are included in the same regressions. Neither *ESG*, nor its components, are significantly correlated at the 5% level with either accuracy measure, other than for *ESG* and *Acc2* for financial services firms, where the correlation is negative. The ESG scores, and the component scores, are significantly correlated with a number of the control variables, especially for financial services firms. Again, these correlations are not of a size likely to cause multi-collinearity problems if the variables are included in the same regression.¹⁸

As a final description of our sample, we look at the way in which *ESG* scores (and, separately, its components: *ED*, *SD*, *GD*) have evolved over time, given the South African

¹⁸ We estimate variance inflation factors (VIFs) for the independent variables (not including the fixed effect dummy variables) for the various versions of equation (1) that we estimate. The VIFs are all less than 10, a conventional benchmark for judging whether there are significant multi-collinearity problems (if VIFs are over 10, a significant problem is possible). When we estimate the various versions of equation (4), fairly high correlations exist between the *Pre*- and *Post*- variables (higher for *GD* than for *SD* than for *ED*). Nonetheless, even in the presence of multi-collinearity, coefficient estimates remain unbiased. t-tests for the significance of individual coefficients might be biased towards not rejecting the null hypothesis, however. Hence, these correlations *might* cause problems with tests of the first and second hypotheses, but we do not believe they cause problems with the testing of our main hypothesis, the third hypothesis.

1 mandated requirement for sustainability reporting for financial year-ends ending in 2010
2 onwards (Ioannou *et al.*, 2014) and subsequently for integrated reporting for financial year-
3 ends ending in March 2011 onwards. We do so because the mechanism *via* which IR is
4 hypothesised to affect forecast accuracy is through *ESG* (*ED*, *SD*, *GD*). As a consequence, we
5 would like to identify, specifically, whether the introduction of IR had any incremental
6 impact on *ESG* (*ED*, *SD*, *GD*). To this end, we first estimate:

$$ESG_{ij} = \lambda_0 + \lambda_1 ESRD + \lambda_2 IRRD + \varepsilon_{ij} \quad (9)$$

17 where *ESRD* is a dummy variable equal to 1 for a firm-year observation with a financial year-
18 end of 2010 onwards, and zero otherwise. On the assumption that these changes in disclosure
19 regimes produce a once-and-for-all effect on ESG disclosure scores, we interpret λ_1 as the
20 impact of the sustainability reporting (ES) regime and λ_2 as the *incremental* impact of the IR
21 regime *relative* to the ES regime.

29 Second, we estimate:

$$ESG_{ij} = \lambda_0 + \lambda_1 ESRD + \lambda_2 IRRD + \sum_{k=1}^m \lambda_{3k} C_{ikj} + \varepsilon_{ij} \quad (10)$$

39 (and for *ED*, *SD* and *GD* separately as dependent variables) in which we also include the
40 control variables we use in our equations investigating forecast accuracy, alongside regime
41 change effects. We do so: (i) because we wish to investigate the impact of variables, some of
42 which partially capture the level of disclosure in other jurisdictions, in order to further check
43 on the regime change effects; and (ii) in order to identify the (partial) associations of our
44 control variables with the disclosure scores, given we will include them all in our regressions
45 where a measure of forecast accuracy is the dependent variable.

58 The results of estimating equations (9) and (10) are reported in Table 3.

Insert Table 3

When only *ESRD* and *IRRD* are considered, the results suggest that the introduction of the ES regime in 2010 has statistically significant and positive impacts on *ESG*, *ED* and *GD*. The estimates of the impacts on *SD* are positive, but only marginally statistically significant at the 10% level, under these circumstances. The introduction of the IR regime, however, has no statistically significant impacts, at the 5% level, on the levels of disclosure, other than at the 10% level for *GD*. When the control variables are added into the regression, no *IRRD* coefficient is significant at conventional levels, and the coefficients of *ESRD* reduce in terms of statistical significance when the dependent variable is either *ED* or *SD*. As a consequence, we can reasonably assume that any impact of IR that we identify in our subsequent analysis is a consequence of how IR makes ESG disclosures more relevant to analysts, rather than by increasing disclosure levels.^{19, 20}

5 RESULTS

The results of estimating equations (1), (4), (5) and (6) for *Acc1* as the dependent variable are presented in Table 4. For reasons of space, we do not separately report the results for *Acc2*, because, in most aspects, they are qualitatively similar to those for *Acc1*. Instead, we comment upon those results when they differ from those for *Acc1*.

¹⁹ We only report the results of estimating equation (10) when using *LAcc1* as the measure of lagged accuracy. The results with respect to the coefficients of *IRRD* are unchanged if we substitute *LAcc2* for *LAcc1* in the regressions. We also estimate equations (9) and (10) with firm fixed effects added. Doing so produces little qualitative change in our results other than the evidence in favour of a positive impact of the introduction of IR on *GD* is slightly strengthened.

²⁰ The result here can be contrasted with the comment in Zhou *et al.* (forthcoming) that the degree of integration, as captured by their measure, increases with the mandating of IR in South Africa. This suggests that their measure of the degree of integration is not necessarily fully capturing ESG disclosures, which appear to have been more affected by the introduction of mandatory ESG reporting in 2010.

Insert Table 4

The results can be summarised as follows. First, in the absence of any IR regime effects (equations (1) and (5)), both *ESG* and *ED* have a negative and statistically significant relationship with forecast accuracy for both measures of accuracy at least at the 5% level of significance. There is no evidence of a statistically significant relationship between *SD* and forecast accuracy at conventional levels of significance when *Acc1* is the dependent variable. *SD* has a negative and statistically significant relationship with forecast accuracy at the 10% level of significance when *Acc2* is the dependent variable. When *GD* is considered on its own, there is no evidence of a statistically significant relationship with forecast accuracy at conventional levels of significance. When *ED*, *SD* and *GD* are entered into the regression simultaneously (as in equation (5)), *ED* has a statistically significant relationship with forecast accuracy at the 10% level of significance. At conventional levels of significance, there is no evidence that any of the other *ESG* disclosure level components have a statistically significant relationship with forecast accuracy.

When an IR regime effect is considered (equations (4) and (6)), there is little evidence that any of the *ESG* disclosure scores, whether considered overall, separately as components, or simultaneously as components, have any statistically significant relationship at conventional levels of significance with forecast accuracy *prior* to the IR regime, as judged by the ‘*Pre*’ coefficients. Only the coefficients of *PreESG* and *PreED* attain a degree of statistical significance, and then only at the 10% level. As a consequence, there is little evidence to cause us to reject the null for our first hypothesis for any of our measures of the level of *ESG* disclosures.

PostESG, however, has negative and statistically significant relationships with forecast accuracy at the 1% level of significance. *PostED* also has a negative and statistically significant relationship with forecast accuracy at the 1% level of significance when included in the regression on its own, and at the 5% level of significance or better when included in the regression with the other components of ESG disclosure. *PostSD* has a negative and statistically significant relationship with forecast accuracy at the 5% (10%) level of significance when included in the regression equation individually and *Acc2* (*Acc1*) is the measure of forecast accuracy. There is no evidence of a relationship at conventional levels of statistical significance when it is included in the regression equation with the other components of ESG disclosure. There is no evidence of a relationship between *PostGD* and forecast accuracy at conventional levels of statistical significance.

Therefore, there appears to be solid evidence to reject the null for the second hypothesis for the overall ESG disclosure level and for the level of environmental disclosures. Also, there is some, model specification-dependent, evidence to reject the null hypothesis for social disclosure levels. There is no evidence to reject the null for the level of governance disclosure.

We now turn to the *differences* between the coefficients of the ‘*Pre*’ and ‘*Post*’ variables, our main concern and the subject of our third hypothesis. When disclosure levels are considered individually, there is strong evidence of a negative and statistically significant change in the relationship with forecast accuracy for *ESG*, *ED* and *GD*. The difference between the coefficients of *PreSD* and *PostSD*, when these disclosure levels are considered individually, difference is not statistically different from zero at conventional levels of significance when *Acc1* is the accuracy measure. It is significant at the 10% level when the accuracy measure is

Acc2. When the ESG disclosure level components are considered simultaneously, the difference between the coefficients of *PreED* and *PostED* retains its statistical significance at the 1% level. The differences between the coefficients of *PreSD* and *PostSD*, and between *PreGD* and *PostGD*, are not statistically significant at conventional levels, for either of the accuracy measures. Therefore, we have strong evidence to reject the null hypothesis for our third and main hypothesis for overall ESG disclosure levels and for environmental disclosure levels, some evidence for governance disclosure levels, and only weak evidence for social disclosure levels.

The results for the control variables suggest that *Log MV* is consistently statistically significant across all specifications. Other than for *Log MV*, significant coefficients are reported, if only for some model specifications, for: (i) lagged analyst forecast accuracy for both measures of accuracy; (ii) book-to-market for firms not belonging to the financial services sector when *Acc1* is the dependent variable; and (iii) leverage for those firms when *Acc2* is the dependent variable. For all the other variables, the reported coefficients are not statistically significantly different from zero.²¹

Therefore, in summary, we find little evidence that there is a relationship between ESG disclosure scores, either overall or in terms of its components, and forecast accuracy prior to the start of the IR regime. Nonetheless, there is strong evidence of a (more) negative relationship between ESG and, in particular, the environmental disclosure component of the ESG disclosure score and forecast accuracy in the IR regime, with some weaker evidence for

²¹ We do not explicitly report the coefficients for the time dummies. Nonetheless, no particular effects are revealed by the pattern of coefficients, with few significant coefficients. There is no trend in the coefficients consistent with the degree of integration in South African financial reports improving with an associated improvement in analyst forecast accuracy. This could be caused by a relative lack of improvement over time in their measure for our sample companies and/or the effects of other time-dependent, omitted variables that cancel out the effects of the degree of integration.

1 governance disclosure levels as well. Given that we have established above that the
2 mandating of IR does not increase ESG disclosure levels, the results are consistent with the
3 views of advocates of IR who suggest that IR establishes better links between ESG and
4 financial performance, with the implied consequence that forecast accuracy will be higher in
5 the IR period the higher is the level of ESG disclosure.
6
7
8
9
10

11
12
13
14 More specifically, the strongest evidence suggests that this result seems to be driven by IR
15 establishing better links between, in particular, *environmental* and financial performance. If
16 the link between environmental disclosure levels and forecast accuracy is driven by the
17 business models for the firms in our sample generating an economic link between
18 environmental and financial performance, we should stress that no attempt should be made to
19 generalise the results of our study to other samples with different distributions of business
20 models. Indeed, we develop this point immediately below. But, the results do suggest that
21 some aspects of ESG disclosure might be more informative than others for some sub-samples
22 of firms.

37
38

39 It might be a little difficult to understand, however, why environmental disclosure scores
40 should drive the link between ESG disclosure levels and forecast accuracy for all firms in our
41 sample if it fundamentally reflects a strong economic link between environmental and
42 financial performance. After all, it would not be clear why such a link should exist for
43 financial services firms. As a consequence, we split our sample between the financial
44 services sector and the other sectors combined and re-run our regressions. We only report the
45 results for equations (4) and (6) when using *Acc1* as the measure of forecast accuracy (the
46 results for *Acc2* are qualitatively similar). The results are reported in Table 5.

Insert Table 5

Focussing on our third, and main, hypothesis, the results are fairly clear-cut. For financial services firms, there is little robust evidence of any change in the relationship between ESG disclosure levels and forecast accuracy. Nor do the control variables affect forecast accuracy. For firms in the other sectors combined, the results are similar to the results for the whole sample. This suggests that the firms outside of the financial services sector are driving the results for the whole sample. Specifically, for this sub-sample, the differences between the coefficients of *PreESG* and *PostESG*, and between *PreED* and *PostED*, are negative and statistically significant at least at the 5% level of significance, whatever the regression specification. A negative and statistically significant difference (at the 5% level) exists between the coefficients of *PreGD* and *PostGD*, when this aspect of ESG disclosure is considered individually. Overall, however, the sub-sample results suggest that IR is not necessarily an important disclosure mechanism for all firms in all sectors, at least for the context of this study.^{22, 23}

6 ADDITIONAL TESTS

We perform additional tests to identify the robustness of our results to alternative specifications and explanations. First, because of the relatively small number of observations in our balanced panel, and despite our preference for the balanced panel research design, we

²² An anonymous reviewer makes the suggestion to us that the additional regulations surrounding the financial services sector reinforce a shareholder focus, which could, at least in part, explain the results we get for the financial services sector.

²³ At the suggestion of an anonymous reviewer, we also re-estimate the standard errors for all our tests using the bootstrap methods (we use the standard bootstrap methodology built into STATA). This methodology still uses OLS to estimate the coefficients. The results are very similar other than there is no reason to reject our main hypothesis, the third hypothesis, for governance disclosures. All the results with respect to the overall ESG disclosure level and the environmental disclosure level are qualitatively unchanged.

1 also run our tests on an unbalanced panel of 310 firm-year observations.²⁴ This does nothing
2 to alter our main conclusion about the introduction of IR in South Africa - the relationship
3 between ESG and, more specifically, environmental disclosure levels and analyst forecast
4 accuracy strengthens after the introduction of IR. We find, however, some evidence of a
5 relationship between ESG and environmental disclosure levels and analyst forecast accuracy
6 before the IR period. We also find evidence of a strengthened relationship between ESG,
7 environmental and governance disclosure levels and analyst forecast accuracy following the
8 introduction of IR for financial services firms.^{25,26}

16
17
18
19
20
21 We also expand our model specifications to allow for the coefficients of the control variables
22 to change between the pre- and post-IR periods. Such an expansion has little qualitative
23 impact on our main results with respect to the impact of IR on the relationship between the
24 levels of ESG and environmental disclosure and analyst forecast accuracy. We then restrict
25 our sample to those firms that have at least two, or three, analysts making earnings forecasts,
26 in order to guard against the possibility that our results are caused by the idiosyncrasies of
27
28
29
30
31
32
33
34
35
36

37 ²⁴ We start from 481 firm-years with Bloomberg ESG data for South African firms.

38 ²⁵ In an attempt to rule out the possibility that some unspecified global effect associated with the passage of
39 time and coincidental with the pre- and post-IR periods in South Africa has intervened to increase the
40 strength of the relationship between ESG disclosure scores and forecast accuracy, we also replicate our
41 study using a balanced panel of 211 UK companies on data from the same period and using the same
42 sample inclusion criteria, as applicable to a UK sample. We find no evidence of a significant and *negative*
43 change in the coefficient for any of our measures of disclosure in any of our model specifications between
44 the two periods. Indeed, we find no relationships between ESG disclosure levels and analyst forecast
45 errors at all. We regard these findings as supportive of our interpretation that the South African outcomes
46 can be attributed to the mandating of IR. The generic possibility identified above is a particular example of
47 an omitted variable problem and one solution to the problem is to adopt what is typically referred to as a
48 ‘difference-in-differences’ research design. This is what we have done. Such a design finds a benchmark
49 sample without the effect under investigation (in our case, the mandating of IR) and replicates the study
50 research design on the benchmark sample. If, as in our case, no effect is found for the benchmark sample,
51 that strengthens the case that the outcome in the sample of interest can be attributed to a particular cause
52 (in our case, the mandating of IR). Nonetheless, as Pope *et al.* (2011) argue, such a research design does
53 not completely solve the omitted variable problem, essentially because the identification of an effective
54 benchmark sample is a non-trivial task.

55 ²⁶ Just in case there is anything special about the firms in the balanced panel relative to those that do not have
56 full data for each year from 2008 to 2012, we define a dummy variable equal to one if a firm-year in the
57 unbalanced panel also belongs to the balanced panel; zero otherwise. We then substitute the ‘balanced
58 panel’ dummy for the firm fixed effects. This substitution substantially weakens the results, relative to
59 using firm fixed effects. It is not possible to include both firm fixed effects and the ‘balanced panel’
60 dummy in the same regression because of multi-collinearity issues.

1 specific analysts associated with firms with limited analyst followings. Such restrictions
2 again have little impact on our main conclusions.
3
4
5
6

7 We add into our regressions proxies for the quality of the integrated report, as in Zhou *et al.*
8 (forthcoming). We note that they point out that their measure of IR quality is similar to those
9 produced by professional accountancy firms in South Africa. Hence, we use rankings
10 produced by Ernst and Young (EY) and available from their website for those firms common
11 to our sample and those covered by EY. We create three dummy variables for firms in the
12 post-IR period corresponding to whether a firm's integrated report is classified as either (i)
13 top ten; (ii) excellent; or (iii) good. Firms not featured in the EY reports, or with a
14 classification worse than the three mentioned, together with firm-years in the pre-IR period
15 become the base case. Including these dummy ranking variables does not alter our results.

26
27
28
29
30

31 Finally, we focus on the role of fixed firm and time effects. First, we investigate different
32 forms of fixed effects. Initially, we use sector fixed effects rather than firm fixed effects.²⁷
33 We retain time fixed effects. With this specification, the evidence in favour of the main
34 conclusions of our previous analyses is much weaker – specifically, there are no statistically
35 relationships between ESG disclosure levels and analyst forecast errors at the 10% level or
36 better, either before or after the mandating of IR in South Africa. When *Acc1* is the
37 dependent variable, there are, however, statistically significant differences, of the predicted
38 sign if only at the 10% level of significance, in the strengths of relationships, before and after
39 the mandating of IR, between environmental disclosure levels and analyst forecast errors.

64
65

The significance level is 5% when *Acc2* is the dependent variable.²⁸ If we substitute *IRRD*

²⁷ It is not possible to use both firm and sector fixed effects because of multi-collinearity issues.

²⁸ An anonymous reviewer points out that some of the firms are subsidiaries of larger, multinational, firms which have more resources to implement IR. We model this suggestion in two ways. First, when we substitute a 'subsidiary' dummy for firm fixed effects, our key results with respect to the third hypothesis

1 for the time fixed effects, retaining firm fixed effects and using the ‘within’ fixed effect
2 estimator, we largely return to the results reported in the previous section, but with stronger
3 evidence of IR producing a governance disclosure level effect on analyst forecast accuracy.
4
5
6
7
8

9 Second, we investigate the impact of removing the various sets of fixed effects. We remove
10 time fixed effects, whilst maintaining firm fixed effects and using the ‘within’ fixed effect
11 estimator. With this specification, we find that both the level of overall ESG disclosures and
12 the level of environmental disclosures, but only when the latter is considered on its own, are
13 significantly associated with analyst forecast accuracy both before and after the mandating of
14 IR. Additionally, the strength of the relationship does not change between the two periods.
15
16 When *ED*, *SD* and *GD* are considered jointly, the results are similar to our main results.
17
18 When we remove firm fixed effects and retain time effects, or remove both firm and time
19 fixed effects, we get little evidence to reject any of our null hypotheses for any of the
20 disclosure levels.
21
22
23

25
26
27
28
29
30
31
32
33
34
35

36 Overall, our results are fairly robust to the additional tests we run, other than in one respect.
37
38 First, the presence of firm fixed effects in the modelling substantially strengthens the
39 statistical significance of relationships to be observed between ESG disclosure levels, or any
40 of its components, and analyst forecast accuracy. Second, some form of time fixed effects is
41 generally needed in the modelling if any *change* in the relationship between ESG disclosure
42 levels and analyst forecast accuracy in the direction predicted is to be observed between pre-
43
44
45
46
47
48
49
50
51

52 are unchanged although the results for the first and second hypotheses are much weakened. The
53 coefficient of the ‘subsidiary’ dummy is positive, suggesting these firms have lower forecast accuracy,
54 *ceteris paribus*. This suggests the importance of firm fixed effects, as opposed to more tightly specified
55 effects. We also interact the ‘subsidiary’ dummy with the *Post*- disclosure measures and add it into our
56 regressions. We find that its coefficients are generally not significant, and do not alter our results, other
57 than in one case – when all the different disclosure levels are included in the equation at the same time.
58 In these cases, we find that the third hypothesis cannot be rejected for *GD* for non-subsidiary firms, but
59 can be for subsidiary firms. This applies for both measures of accuracy. For *SD*, we get a similar result,
60 but only for our first measure of accuracy.
61
62
63
64
65

1 and post-IR periods, other than when all the components of ESG disclosure levels are
2 considered simultaneously. Third, relaxing the balanced panel aspect of our research design
3 produces evidence of a strengthened relationship between ESG, environmental and
4 governance disclosure levels and analyst forecast accuracy following the introduction of IR
5 for both financial services firms and firms from the other sectors represented in our sample.
6
7
8
9

10
11
12
13
14 Given the difficulties in fully specifying a model of analyst forecast accuracy from a
15 theoretical perspective, we believe that our use of firm and time fixed effects in the modelling
16 is justifiable. Nonetheless, it is important to stress the crucial role played by including these
17 effects in coming to the conclusions that we do about the impact of the mandating of IR in
18 South Africa.

24
25
26
27

28 **7 SUMMARY AND CONCLUSIONS**

29
30
31
32
33
34 We investigate the impact of mandating IR in South Africa on the accuracy of analyst one
35 year-ahead forecasts of earnings. Given that IR is intended to link ESG and financial
36 performance, we theorise that, if there is any impact, it will be higher for firms with higher
37 ESG disclosure. Further, if there is a need for the link provided by IR, ESG disclosure levels
38 will not be strongly associated with analyst forecast accuracy before IR is implemented,
39 whereas they will be once integrated reports are provided.
40
41
42
43
44
45
46
47
48
49
50

51 The results using our main, balanced panel, methodology, with firm and time fixed effects,
52 suggest that ESG disclosure levels are not robustly associated with analyst forecast accuracy
53 before the IR regime was introduced. There is evidence, however, that ESG disclosure
54 levels, and, in particular, environmental disclosure levels, are associated with forecast
55
56
57
58
59
60
61
62
63
64
65

1 accuracy after the introduction of the IR regime. There is also evidence that the level of
2 governance disclosures has a *strengthened* association with forecast accuracy after the
3 introduction of the IR regime, but this association tends to be dominated by the
4 environmental disclosure effect. Nonetheless, we also find that the results described above
5 are driven by the firms outside the financial services sector in the sample we study, with no
6 robust relationships being found between any of our measures of the level of ESG disclosure
7 and forecast accuracy for financial services firms. The use of firm and time fixed effects as
8 an element of our modelling is crucial for generating these results. Also, if we relax the
9 balanced panel aspect of our research design, we find evidence of a strengthened relationship
10 between ESG, environmental and governance disclosure levels and analyst forecast accuracy
11 following the introduction of IR for both financial services firms and those from the other
12 sectors.

28
29
30

31 If accepted as valid, these results are consistent with IR having the potential to provide useful
32 information on the links between ESG and financial performance (although the potential
33 might not be inevitably realised for all sets of firms). These results complement other recent
34 papers, such as Lee *et al.* (2015), Zhou *et al.* (forthcoming) and Barth *et al.* (2015), which
35 also suggest that IR can provide useful information to capital markets. Importantly, the
36 results are also consistent with our theory that the usefulness of these links will improve the
37 higher is the level of ESG disclosure. Further, IR in South Africa over the period did not, of
38 necessity, have an investor focus because relatively little guidance was on offer as to how
39 integrated reports should be prepared. More recently, however, the IIRC has produced
40 guidelines concerning IR recommending an investor focus. Our results, again if accepted as
41 valid, also suggest that an *explicit* investor focus is not *required* for IR to be useful to
42 investors. It would appear that any balancing of the interests of different stakeholders by

61
62
63
64
65

1 South African firms in producing an integrated report did not produce any undue move away
2 from providing information useful to investors. This evidence can be contrasted with the
3
4 IIRC's version of IR which *specifies* an investor focus, a policy that has created academic
5
6 debate (e.g., Adams, 2015; Flower, 2015; Thomson, 2015).
7
8
9

10
11 There are limitations to our work. For example, our control variable strategy could be
12
13 inadequate, leading to an omitted variable problem, leading in turn to biased coefficient
14
15 estimates on our experimental variables and biased conclusions. This is the 'identification'
16
17 problem associated with identifying the effects of accounting and regime changes. In our
18
19 case, however, to argue that some omitted variable explains away our results relies upon both
20
21 an association of the variable with forecast accuracy and the existence of different
22
23 correlations between that variable and ESG disclosure scores in the pre- and post-IR periods,
24
25 not merely a variable associated with forecast accuracy that changes over the time period of
26
27 the regime change.
28
29
30
31
32
33
34
35

36 Our work suggests future research possibilities. For example, longer-term analyst forecasts
37
38 could be studied (e.g., two year-ahead earnings *per share* forecasts) within our framework.
39
40 Given that one of the benefits of IR is argued to be a focus on the future implications of
41
42 various actions and decisions concerning ESG activities for financial performance, studying
43
44 longer-term forecasts makes sense.²⁹ Also, following the idea in Zhou *et al.* (forthcoming),
45
46 as more data is gathered through the passage of time, the impact of firms having differing
47
48 degrees of effectiveness in integrating ESG information into their reports could be studied
49
50 within our research framework, given we only capture average effects associated with the
51
52 mandating of IR.
53
54
55
56
57
58

59 ²⁹ At the time of collecting the data, only one set of two-year forecasts, along with the associated outcomes,
60 is available.

<i>Adjusted R²</i>	0.20	0.22	0.20	0.23	0.19	0.19	0.18	0.19	0.19	0.22

Notes: The regressions include firm and time fixed effects and are estimated using OLS for the coefficient estimates. The significance levels reported are based upon heteroscedasticity-adjusted standard errors. *PreESG (PostESG)* equals *ESG* for the period prior to (after the) introduction of the IR regime; 0 otherwise. *PreED (PostED)* equals *ED* for the period prior to (after the) introduction of the IR regime; 0 otherwise. *PreSD (PostSD)* equals *SD* for the period prior to (after the) introduction of the IR regime; 0 otherwise. *PreGD (PostGD)* equals *GD* for the period prior to (after the) introduction of the IR regime; 0 otherwise. See the notes to Table 1 for other variable definitions. ***, **, * denotes significance using a one-tailed test at the 1%, 5% and 10% level respectively for the experimental variables and F-statistics, two-tailed test otherwise.
