

Changes in Land Use and Forest Biomass in Central Africa
March 20th and 21st, Libreville, Gabon

Forest degradation estimation using remote sensing

Valéry GOND, Stéphane GUITET, Guillaume CORNU
Lucas BOURBIER, Sophie PITHON

Objectives:

Development of tools to measure the degradation of harvested tropical forests:

(1) road network monitoring and (2) canopy gaps detection

Mean

Use of remote sensing in order to estimate, at large scale, forest degradation and re-vegetalization

Outcome:

These tools have to facilitate the post-harvesting control

Harvesting

Log yard

Tracks and roads

road network monitoring

© USGS-Glovis

1 - Radiometric calibration

2 - Spectral indices processing

$$\text{NDVI} = (\text{NIR} - \text{Red}) / (\text{NIR} + \text{Red})$$

$$\text{GR} = (\text{Green} - \text{Red}) / (\text{Green} + \text{Red})$$

NDVI + GR

Local contrast improved by the median spatial filter

Processing

3 – Bare soil identification
using Red, GR, NDVI+GR channels

4 - Cloud and water masking
using Blue and SWIR channels

Processing

5 - morphological filter

50 pixels size with an elongation rate of 3

Processing

6 – Yearly synthesis

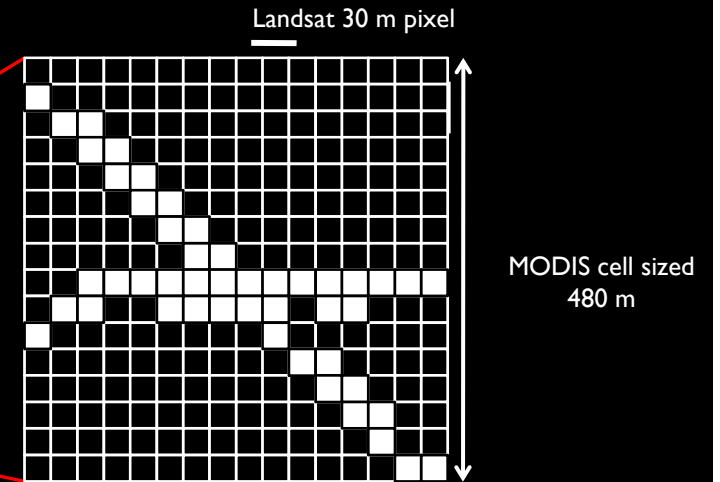

Processing

7 – Spatial synthesis

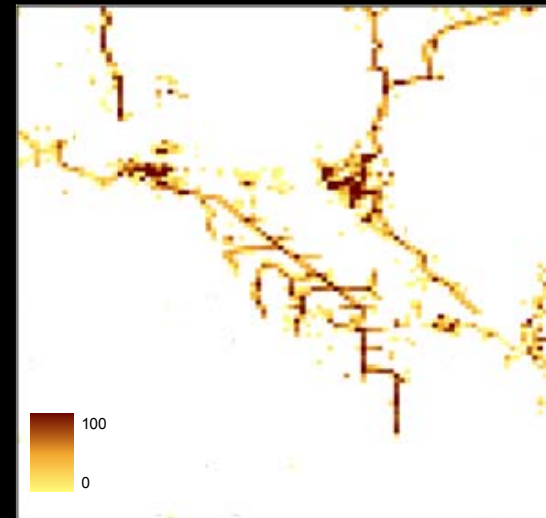

Annual bare soil mapping in 2001

47 bare soil pixels detected
on a surface of 256 pixels
= 18% of bare soil

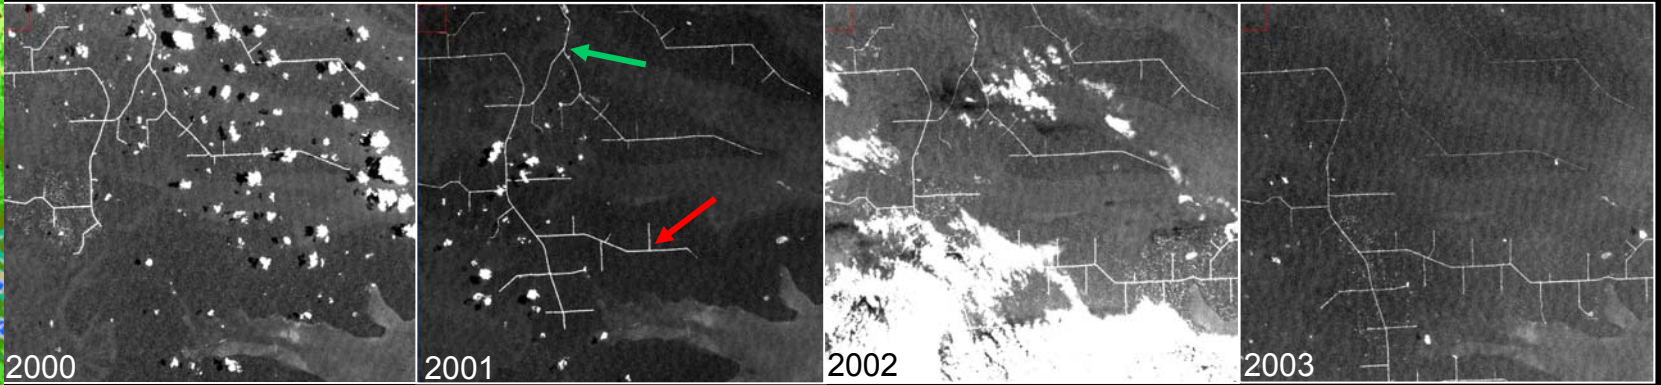

Landsat 30 m pixel

MODIS cell sized
480 m

Spatial indication of bare soil in 2001

Cell monitoring

Bare soil index

Bare soil index decreasing 2/3 in 2 years

Monitoring logging activities using Sentinel 2

30 days

10 days

50 days

Location: North Congo
Spot-4 (Take-5) experiment

Opening

Logging

canopy gaps detection

Medium spatial resolution optical satellite images produced by SPOT 5 and 4 (10 and 20 meters)

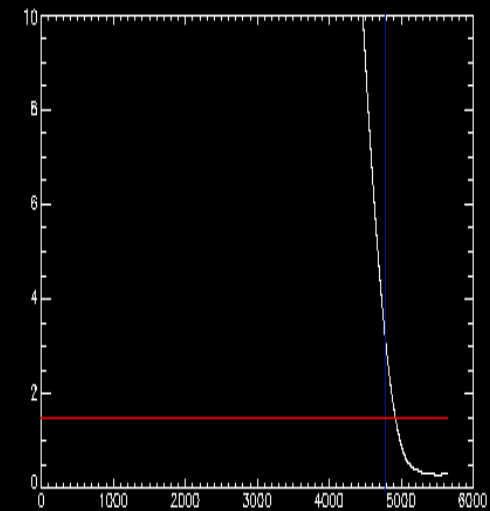

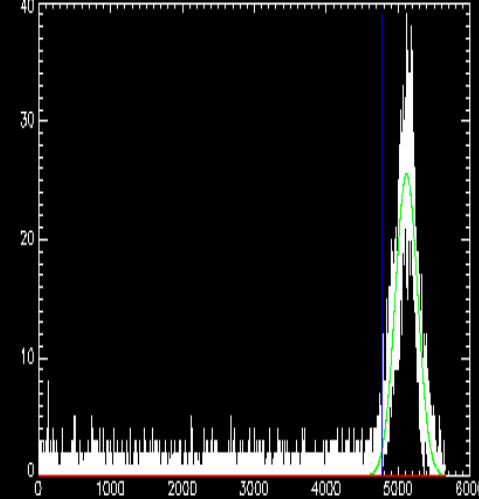

Remote sensing process

- Filter : Canopy (majority) vs. gap (minority) – all others objects are manually eliminated (clouds, shadows, water, etc...)
- Using 2 index NDVI (photosynthetic activity) and NDWI (moist content)
- Modeling a Gaussian distribution (least squares method) = detect a divergence threshold – significant difference between G function and effective histogram

Histogramme: ROI Mask (Layer (Band 1:NDVI.tif):compa_20091012)

Gaussienne estimee

Pixels values histogram → Gaussian function estimation → K divergence threshold

Results : impacts map

red : harvested area – black : skid trails tracks green/blue : openings

- Visible during 6 months to one year
- For a two years long logging operation – complete impacts can be mapped from the cumulative information collected on at least 6 images

Monitoring logging activities : logging impacts

SPOT-5, RFE-65 plot
November 7th, 2010

Multi-index color composite
(NDVI, NDWI and MIR)

In French Guiana, 10.000 ha are exploited per year

Thanks to the SEAS reception station these areas are regularly monitored using SPOT-5 (10m)

Development of a Timber Quality Index within the certification framework (PEFC and FSC)

Production Unit (78ha)

Impacted areas digitalization

From Spot / Sentinel-2

20,8ha impacted (26,6%)

From logger

308 trees for 1550 m³

Timber statistics

3,9 trees/ha and 19,8 m³/ha (5m³/tree)

Timber Quality index

675m² impacted per tree
134m² impacted per m³

Conclusions and perspectives

- Possibility to extract precise information on road network and gap-logging using medium resolution data
- Possibility to use Sentinel-2 (2014) for a regular and systematic monitoring
- Need to scale-up to regional, continental monitoring using MODIS (250m), Proba-V (100m) or Sentinel-2 (10, 20 and 60m)
- Need to develop Radar as a complement to monitor degradation activities all year long in tropical forests

Thanks for your attention
