# Table of Contents

# What is Amazon S3?

Amazon Simple Storage Service (Amazon S3) is an object storage service that offers industry-leading scalability, data availability, security, and performance. Customers of all sizes and industries can use Amazon S3 to store and protect any amount of data for a range of use cases, such as data lakes, websites, mobile applications, backup and restore, archive, enterprise applications, IoT devices, and big data analytics. Amazon S3 provides management features so that you can optimize, organize, and configure access to your data to meet your specific business, organizational, and compliance requirements.

> **Note**
>
> For more information about using the Amazon S3 Express One Zone storage class with directory buckets, see What is S3 Express One Zone? and Directory buckets.

**Topics**

# Features of Amazon S3

## Storage classes

Amazon S3 offers a range of storage classes designed for different use cases. For example, you can store mission-critical production data in S3 Standard or S3 Express One Zone for frequent access, save costs by storing infrequently accessed data in S3 Standard-IA or S3 One Zone-IA, and archive data at the lowest costs in S3 Glacier Instant Retrieval, S3 Glacier Flexible Retrieval, and S3 Glacier Deep Archive.

Amazon S3 Express One Zone is a high-performance, single-zone Amazon S3 storage class that is purpose-built to deliver consistent, single-digit millisecond data access for your most latency-sensitive applications. S3 Express One Zone is the lowest latency cloud object storage class available today, with data access speeds up to 10x faster and with request costs 50 percent lower than S3 Standard. S3 Express One Zone is the first S3 storage class where you can select a single Availability Zone with the option to co-locate your object storage with your compute resources, which provides the highest possible access speed. Additionally, to further increase access speed and support hundreds of thousands of requests per second, data is stored in a new bucket type: an Amazon S3 directory bucket. For more information, see What is S3 Express One Zone? and Directory buckets.

You can store data with changing or unknown access patterns in S3 Intelligent-Tiering, which optimizes storage costs by automatically moving your data between four access tiers when your access patterns change. These four access tiers include two low-latency access tiers optimized for frequent and infrequent access, and two opt-in archive access tiers designed for asynchronous access for rarely accessed data.

For more information, see Using Amazon S3 storage classes.

## Storage management

Amazon S3 has storage management features that you can use to manage costs, meet regulatory requirements, reduce latency, and save multiple distinct copies of your data for compliance requirements.

- S3 Lifecycle – Configure a lifecycle configuration to manage your objects and store them cost effectively throughout their lifecycle. You can transition objects to other S3 storage classes or expire objects that reach the end of their lifetimes.
- S3 Object Lock – Prevent Amazon S3 objects from being deleted or overwritten for a fixed amount of time or indefinitely. You can use Object Lock to help meet regulatory requirements that require *write-once-read-many (WORM)* storage or to simply add another layer of protection against object changes and deletions.
- S3 Replication – Replicate objects and their respective metadata and object tags to one or more destination buckets in the same or different AWS Regions for reduced latency, compliance, security, and other use cases.
- S3 Batch Operations – Manage billions of objects at scale with a single S3 API request or a few clicks in the Amazon S3 console. You can use Batch Operations to perform operations such as **Copy**, **Invoke AWS Lambda function**, and **Restore** on millions or billions of objects.

# Access management and security

Amazon S3 provides features for auditing and managing access to your buckets and objects. By default, S3 buckets and the objects in them are private. You have access only to the S3 resources that you create. To grant granular resource permissions that support your specific use case or to audit the permissions of your Amazon S3 resources, you can use the following features.

- S3 Block Public Access – Block public access to S3 buckets and objects. By default, Block Public Access settings are turned on at the bucket level. We recommend that you keep all Block Public Access settings enabled unless you know that you need to turn off one or more of them for your specific use case. For more information, see Configuring block public access settings for your S3 buckets.
- AWS Identity and Access Management (IAM) – IAM is a web service that helps you securely control access to AWS resources, including your Amazon S3 resources. With IAM, you can centrally manage permissions that control which AWS resources users can access. You use IAM to control who is authenticated (signed in) and authorized (has permissions) to use resources.
- Bucket policies – Use IAM-based policy language to configure resource-based permissions for your S3 buckets and the objects in them.
- Amazon S3 access points – Configure named network endpoints with dedicated access policies to manage data access at scale for shared datasets in Amazon S3.
- Access control lists (ACLs) – Grant read and write permissions for individual buckets and objects to authorized users. As a general rule, we recommend using S3 resource-based policies (bucket policies and access point policies) or IAM user policies for access control instead of ACLs. Policies are a simplified and more flexible access control option. With bucket policies and access point policies, you can define rules that apply broadly across all requests to your Amazon S3 resources. For more information about the specific cases when you'd use ACLs instead of resource-based policies or IAM user policies, see Managing access with ACLs.
- S3 Object Ownership – Take ownership of every object in your bucket, simplifying access management for data stored in Amazon S3. S3 Object Ownership is an Amazon S3 bucket-level setting that you can use to disable or enable ACLs. By default, ACLs are disabled. With ACLs disabled, the bucket owner owns all the objects in the bucket and manages access to data exclusively by using access-management policies.
- IAM Access Analyzer for S3 – Evaluate and monitor your S3 bucket access policies, ensuring that the policies provide only the intended access to your S3 resources.

## Data processing

To transform data and trigger workflows to automate a variety of other processing activities at scale, you can use the following features.

- S3 Object Lambda – Add your own code to S3 GET, HEAD, and LIST requests to modify and process data as it is returned to an application. Filter rows, dynamically resize images, redact confidential data, and much more.
- Event notifications – Trigger workflows that use Amazon Simple Notification Service (Amazon SNS), Amazon Simple Queue Service (Amazon SQS), and AWS Lambda when a change is made to your S3 resources.

## Storage logging and monitoring

Amazon S3 provides logging and monitoring tools that you can use to monitor and control how your Amazon S3 resources are being used. For more information, see Monitoring tools.

### Automated monitoring tools

- Amazon CloudWatch metrics for Amazon S3 – Track the operational health of your S3 resources and configure billing alerts when estimated charges reach a user-defined threshold.
- AWS CloudTrail – Record actions taken by a user, a role, or an AWS service in Amazon S3. CloudTrail logs provide you with detailed API tracking for S3 bucket-level and object-level operations.

### Manual monitoring tools

- Server access logging – Get detailed records for the requests that are made to a bucket. You can use server access logs for many use cases, such as conducting security and access audits, learning about your customer base, and understanding your Amazon S3 bill.
- AWS Trusted Advisor – Evaluate your account by using AWS best practice checks to identify ways to optimize your AWS infrastructure, improve security and performance, reduce costs, and monitor service quotas. You can then follow the recommendations to optimize your services and resources.

## Analytics and insights

Amazon S3 offers features to help you gain visibility into your storage usage, which empowers you to better understand, analyze, and optimize your storage at scale.

- Amazon S3 Storage Lens – Understand, analyze, and optimize your storage. S3 Storage Lens provides 60+ usage and activity metrics and interactive dashboards to aggregate data for your entire organization, specific accounts, AWS Regions, buckets, or prefixes.
- Storage Class Analysis – Analyze storage access patterns to decide when it's time to move data to a more cost-effective storage class.
- S3 Inventory with Inventory reports – Audit and report on objects and their corresponding metadata and configure other Amazon S3 features to take action in Inventory reports. For example, you can report on the replication and encryption status of your objects. For a list of all the metadata available for each object in Inventory reports, see Amazon S3 Inventory list.

## Strong consistency

Amazon S3 provides strong read-after-write consistency for PUT and DELETE requests of objects in your Amazon S3 bucket in all AWS Regions. This behavior applies to both writes of new objects as well as PUT requests that overwrite existing objects and DELETE requests. In addition, read operations on Amazon S3 Select, Amazon S3 access control lists (ACLs), Amazon S3 Object Tags, and object metadata (for example, the HEAD object) are strongly consistent. For more information, see Amazon S3 data consistency model.

# How Amazon S3 works

Amazon S3 is an object storage service that stores data as objects within buckets. An *object* is a file and any metadata that describes the file. A *bucket* is a container for objects.

To store your data in Amazon S3, you first create a bucket and specify a bucket name and AWS Region. Then, you upload your data to that bucket as objects in Amazon S3. Each object has a *key* (or *key name*), which is the unique identifier for the object within the bucket.

S3 provides features that you can configure to support your specific use case. For example, you can use S3 Versioning to keep multiple versions of an object in the same bucket, which allows you to restore objects that are accidentally deleted or overwritten.

Buckets and the objects in them are private and can be accessed only if you explicitly grant access permissions. You can use bucket policies, AWS Identity and Access Management (IAM) policies, access control lists (ACLs), and S3 Access Points to manage access.

**Topics**

## Buckets

A bucket is a container for objects stored in Amazon S3. You can store any number of objects in a bucket and can have up to 100 buckets in your account. To request an increase, visit the Service Quotas console.

Every object is contained in a bucket. For example, if the object named `photos/puppy.jpg` is stored in the `amzn-s3-demo-bucket` bucket in the US West (Oregon) Region, then it is addressable by using the URL `https://amzn-s3-demo-bucket.s3.us-west-2.amazonaws.com/photos/puppy.jpg`. For more information, see Accessing a Bucket.

When you create a bucket, you enter a bucket name and choose the AWS Region where the bucket will reside. After you create a bucket, you cannot change the name of the bucket or its Region. Bucket names must follow the bucket naming rules. You can also configure a bucket to use S3 Versioning or other storage management features.

Buckets also:

- Organize the Amazon S3 namespace at the highest level.
- Identify the account responsible for storage and data transfer charges.

- Provide access control options, such as bucket policies, access control lists (ACLs), and S3 Access Points, that you can use to manage access to your Amazon S3 resources.
- Serve as the unit of aggregation for usage reporting.

For more information about buckets, see Buckets overview.

## Objects

Objects are the fundamental entities stored in Amazon S3. Objects consist of object data and metadata. The metadata is a set of name-value pairs that describe the object. These pairs include some default metadata, such as the date last modified, and standard HTTP metadata, such as `Content-Type`. You can also specify custom metadata at the time that the object is stored.

An object is uniquely identified within a bucket by a key (name) and a version ID (if S3 Versioning is enabled on the bucket). For more information about objects, see Amazon S3 objects overview.

### Keys

An *object key* (or *key name*) is the unique identifier for an object within a bucket. Every object in a bucket has exactly one key. The combination of a bucket, object key, and optionally, version ID (if S3 Versioning is enabled for the bucket) uniquely identify each object. So you can think of Amazon S3 as a basic data map between "bucket + key + version" and the object itself.

Every object in Amazon S3 can be uniquely addressed through the combination of the web service endpoint, bucket name, key, and optionally, a version. For example, in the URL `https://amzn-s3-demo-bucket.s3.us-west-2.amazonaws.com/photos/puppy.jpg`, *amzn-s3-demo-bucket* is the name of the bucket and `photos/puppy.jpg` is the key.

For more information about object keys, see Creating object key names.

### S3 Versioning

You can use S3 Versioning to keep multiple variants of an object in the same bucket. With S3 Versioning, you can preserve, retrieve, and restore every version of every object stored in your buckets. You can easily recover from both unintended user actions and application failures.

For more information, see Using versioning in S3 buckets.

## Version ID

When you enable S3 Versioning in a bucket, Amazon S3 generates a unique version ID for each object added to the bucket. Objects that already existed in the bucket at the time that you enable versioning have a version ID of `null`. If you modify these (or any other) objects with other operations, such as CopyObject and PutObject, the new objects get a unique version ID.

For more information, see Using versioning in S3 buckets.

## Bucket policy

A bucket policy is a resource-based AWS Identity and Access Management (IAM) policy that you can use to grant access permissions to your bucket and the objects in it. Only the bucket owner can associate a policy with a bucket. The permissions attached to the bucket apply to all of the objects in the bucket that are owned by the bucket owner. Bucket policies are limited to 20 KB in size.

Bucket policies use JSON-based access policy language that is standard across AWS. You can use bucket policies to add or deny permissions for the objects in a bucket. Bucket policies allow or deny requests based on the elements in the policy, including the requester, S3 actions, resources, and aspects or conditions of the request (for example, the IP address used to make the request). For example, you can create a bucket policy that grants cross-account permissions to upload objects to an S3 bucket while ensuring that the bucket owner has full control of the uploaded objects. For more information, see Examples of Amazon S3 bucket policies.

In your bucket policy, you can use wildcard characters on Amazon Resource Names (ARNs) and other values to grant permissions to a subset of objects. For example, you can control access to groups of objects that begin with a common prefix or end with a given extension, such as `.html`.

## S3 Access Points

Amazon S3 Access Points are named network endpoints with dedicated access policies that describe how data can be accessed using that endpoint. Access Points are attached to buckets that you can use to perform S3 object operations, such as GetObject and PutObject. Access Points simplify managing data access at scale for shared datasets in Amazon S3.

Each access point has its own access point policy. You can configure Block Public Access settings for each access point. To restrict Amazon S3 data access to a private network, you can also configure any access point to accept requests only from a virtual private cloud (VPC).

For more information, see Managing data access with Amazon S3 access points.

## Access control lists (ACLs)

You can use ACLs to grant read and write permissions to authorized users for individual buckets and objects. Each bucket and object has an ACL attached to it as a subresource. The ACL defines which AWS accounts or groups are granted access and the type of access. ACLs are an access control mechanism that predates IAM. For more information about ACLs, see Access control list (ACL) overview.

S3 Object Ownership is an Amazon S3 bucket-level setting that you can use to both control ownership of the objects that are uploaded to your bucket and to disable or enable ACLs. By default, Object Ownership is set to the Bucket owner enforced setting, and all ACLs are disabled. When ACLs are disabled, the bucket owner owns all the objects in the bucket and manages access to them exclusively by using access-management policies.

A majority of modern use cases in Amazon S3 no longer require the use of ACLs. We recommend that you keep ACLs disabled, except in unusual circumstances where you need to control access for each object individually. With ACLs disabled, you can use policies to control access to all objects in your bucket, regardless of who uploaded the objects to your bucket. For more information, see Controlling ownership of objects and disabling ACLs for your bucket.

## Regions

You can choose the geographical AWS Region where Amazon S3 stores the buckets that you create. You might choose a Region to optimize latency, minimize costs, or address regulatory requirements. Objects stored in an AWS Region never leave the Region unless you explicitly transfer or replicate them to another Region. For example, objects stored in the Europe (Ireland) Region never leave it.

> **Note**
>
> You can access Amazon S3 and its features only in the AWS Regions that are enabled for your account. For more information about enabling a Region to create and manage AWS resources, see Managing AWS Regions in the *AWS General Reference*.

For a list of Amazon S3 Regions and endpoints, see Regions and endpoints in the *AWS General Reference*.

# Amazon S3 data consistency model

Amazon S3 provides strong read-after-write consistency for PUT and DELETE requests of objects in your Amazon S3 bucket in all AWS Regions. This behavior applies to both writes to new objects as well as PUT requests that overwrite existing objects and DELETE requests. In addition, read operations on Amazon S3 Select, Amazon S3 access controls lists (ACLs), Amazon S3 Object Tags, and object metadata (for example, the HEAD object) are strongly consistent.

Updates to a single key are atomic. For example, if you make a PUT request to an existing key from one thread and perform a GET request on the same key from a second thread concurrently, you will get either the old data or the new data, but never partial or corrupt data.

Amazon S3 achieves high availability by replicating data across multiple servers within AWS data centers. If a PUT request is successful, your data is safely stored. Any read (GET or LIST request) that is initiated following the receipt of a successful PUT response will return the data written by the PUT request. Here are examples of this behavior:

- A process writes a new object to Amazon S3 and immediately lists keys within its bucket. The new object appears in the list.
- A process replaces an existing object and immediately tries to read it. Amazon S3 returns the new data.
- A process deletes an existing object and immediately tries to read it. Amazon S3 does not return any data because the object has been deleted.
- A process deletes an existing object and immediately lists keys within its bucket. The object does not appear in the listing.

**Note**

- Amazon S3 does not support object locking for concurrent writers. If two PUT requests are simultaneously made to the same key, the request with the latest timestamp wins. If this is an issue, you must build an object-locking mechanism into your application.
- Updates are key-based. There is no way to make atomic updates across keys. For example, you cannot make the update of one key dependent on the update of another key unless you design this functionality into your application.

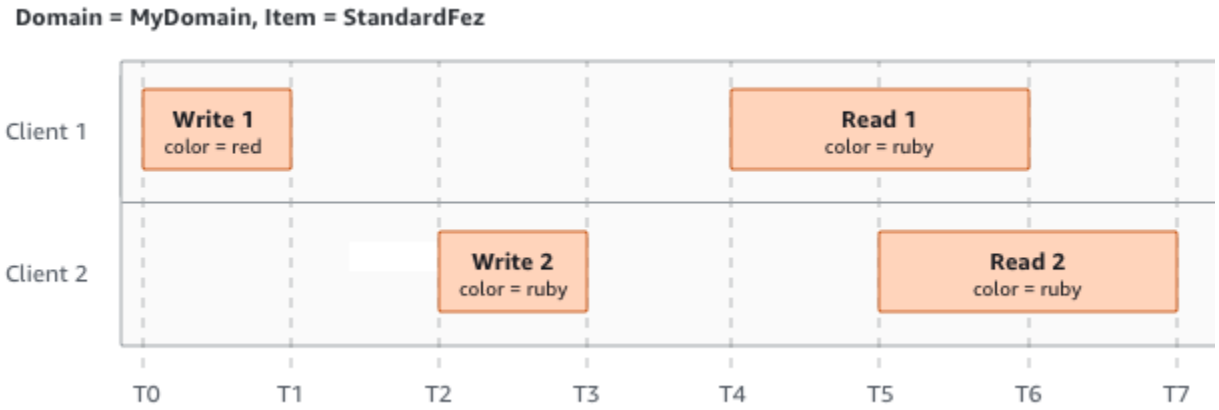
Bucket configurations have an eventual consistency model. Specifically, this means that:

- If you delete a bucket and immediately list all buckets, the deleted bucket might still appear in the list.
- If you enable versioning on a bucket for the first time, it might take a short amount of time for the change to be fully propagated. We recommend that you wait for 15 minutes after enabling versioning before issuing write operations (PUT or DELETE requests) on objects in the bucket.

## Concurrent applications

This section provides examples of behavior to be expected from Amazon S3 when multiple clients are writing to the same items.

In this example, both W1 (write 1) and W2 (write 2) finish before the start of R1 (read 1) and R2 (read 2). Because S3 is strongly consistent, R1 and R2 both return `color = ruby`.



In the next example, W2 does not finish before the start of R1. Therefore, R1 might return `color = ruby` or `color = garnet`. However, because W1 and W2 finish before the start of R2, R2 returns `color = garnet`.

In the last example, W2 begins before W1 has received an acknowledgment. Therefore, these writes are considered concurrent. Amazon S3 internally uses last-writer-wins semantics to determine which write takes precedence. However, the order in which Amazon S3 receives the requests and the order in which applications receive acknowledgments cannot be predicted because of various factors, such as network latency. For example, W2 might be initiated by an Amazon EC2 instance in the same Region, while W1 might be initiated by a host that is farther away. The best way to determine the final value is to perform a read after both writes have been acknowledged.

## Related services

After you load your data into Amazon S3, you can use it with other AWS services. The following are the services that you might use most frequently:

- **Amazon Elastic Compute Cloud (Amazon EC2)** – Provides secure and scalable computing capacity in the AWS Cloud. Using Amazon EC2 eliminates your need to invest in hardware

upfront, so you can develop and deploy applications faster. You can use Amazon EC2 to launch as many or as few virtual servers as you need, configure security and networking, and manage storage.

- **Amazon EMR** – Helps businesses, researchers, data analysts, and developers easily and cost-effectively process vast amounts of data. Amazon EMR uses a hosted Hadoop framework running on the web-scale infrastructure of Amazon EC2 and Amazon S3.
- **AWS Snow Family** – Helps customers that need to run operations in austere, non-data center environments, and in locations where there's a lack of consistent network connectivity. You can use AWS Snow Family devices to locally and cost-effectively access the storage and compute power of the AWS Cloud in places where an internet connection might not be an option.
- **AWS Transfer Family** – Provides fully managed support for file transfers directly into and out of Amazon S3 or Amazon Elastic File System (Amazon EFS) using Secure Shell (SSH) File Transfer Protocol (SFTP), File Transfer Protocol over SSL (FTPS), and File Transfer Protocol (FTP).

# Accessing Amazon S3

You can work with Amazon S3 in any of the following ways:

## AWS Management Console

The console is a web-based user interface for managing Amazon S3 and AWS resources. If you've signed up for an AWS account, you can access the Amazon S3 console by signing into the AWS Management Console and choosing **S3** from the AWS Management Console home page.

## AWS Command Line Interface

You can use the AWS command line tools to issue commands or build scripts at your system's command line to perform AWS (including S3) tasks.

The AWS Command Line Interface (AWS CLI) provides commands for a broad set of AWS services. The AWS CLI is supported on Windows, macOS, and Linux. To get started, see the *AWS Command Line Interface User Guide*. For more information about the commands for Amazon S3, see s3api and s3control in the *AWS CLI Command Reference*.

## AWS SDKs

AWS provides SDKs (software development kits) that consist of libraries and sample code for various programming languages and platforms (Java, Python, Ruby, .NET, iOS, Android, and so on).

The AWS SDKs provide a convenient way to create programmatic access to S3 and AWS. Amazon S3 is a REST service. You can send requests to Amazon S3 using the AWS SDK libraries, which wrap the underlying Amazon S3 REST API and simplify your programming tasks. For example, the SDKs take care of tasks such as calculating signatures, cryptographically signing requests, managing errors, and retrying requests automatically. For information about the AWS SDKs, including how to download and install them, see Tools for AWS.

Every interaction with Amazon S3 is either authenticated or anonymous. If you are using the AWS SDKs, the libraries compute the signature for authentication from the keys that you provide. For more information about how to make requests to Amazon S3, see Making requests.

## Amazon S3 REST API

The architecture of Amazon S3 is designed to be programming language-neutral, using AWS-supported interfaces to store and retrieve objects. You can access S3 and AWS programmatically by using the Amazon S3 REST API. The REST API is an HTTP interface to Amazon S3. With the REST API, you use standard HTTP requests to create, fetch, and delete buckets and objects.

To use the REST API, you can use any toolkit that supports HTTP. You can even use a browser to fetch objects, as long as they are anonymously readable.

The REST API uses standard HTTP headers and status codes, so that standard browsers and toolkits work as expected. In some areas, we have added functionality to HTTP (for example, we added headers to support access control). In these cases, we have done our best to add the new functionality in a way that matches the style of standard HTTP usage.

If you make direct REST API calls in your application, you must write the code to compute the signature and add it to the request. For more information about how to make requests to Amazon S3, see Making requests.

> **Note**
>
> SOAP API support over HTTP is deprecated, but it is still available over HTTPS. Newer Amazon S3 features are not supported for SOAP. We recommend that you use either the REST API or the AWS SDKs.

# Paying for Amazon S3

Pricing for Amazon S3 is designed so that you don't have to plan for the storage requirements of your application. Most storage providers require you to purchase a predetermined amount of storage and network transfer capacity. In this scenario, if you exceed that capacity, your service is shut off or you are charged high overage fees. If you do not exceed that capacity, you pay as though you used it all.

Amazon S3 charges you only for what you actually use, with no hidden fees and no overage charges. This model gives you a variable-cost service that can grow with your business while giving you the cost advantages of the AWS infrastructure. For more information, see Amazon S3 Pricing.

When you sign up for AWS, your AWS account is automatically signed up for all services in AWS, including Amazon S3. However, you are charged only for the services that you use. If you are a new Amazon S3 customer, you can get started with Amazon S3 for free. For more information, see AWS free tier.

To see your bill, go to the Billing and Cost Management Dashboard in the AWS Billing and Cost Management console. To learn more about AWS account billing, see the *AWS Billing User Guide*. If you have questions concerning AWS billing and AWS accounts, contact AWS Support.

# PCI DSS compliance

Amazon S3 supports the processing, storage, and transmission of credit card data by a merchant or service provider, and has been validated as being compliant with Payment Card Industry (PCI) Data Security Standard (DSS). For more information about PCI DSS, including how to request a copy of the AWS PCI Compliance Package, see PCI DSS Level 1.

# Getting started with Amazon S3

You can get started with Amazon S3 by working with buckets and objects. A *bucket* is a container for objects. An *object* is a file and any metadata that describes that file.

To store an object in Amazon S3, you create a bucket and then upload the object to the bucket. When the object is in the bucket, you can open it, download it, and move it. When you no longer need an object or a bucket, you can clean up your resources.

With Amazon S3, you pay only for what you use. For more information about Amazon S3 features and pricing, see Amazon S3. If you are a new Amazon S3 customer, you can get started with Amazon S3 for free. For more information, see AWS Free Tier.

> **Note**
>
> For more information about using the Amazon S3 Express One Zone storage class with directory buckets, see What is S3 Express One Zone? and Directory buckets.

**Video: Getting started with Amazon S3**

**Prerequisites**

Before you begin, confirm that you've completed the steps in Prerequisite: Setting up Amazon S3.

**Topics**

# Prerequisite: Setting up Amazon S3

When you sign up for AWS, your AWS account is automatically signed up for all services in AWS, including Amazon S3. You are charged only for the services that you use.

With Amazon S3, you pay only for what you use. For more information about Amazon S3 features and pricing, see Amazon S3. If you are a new Amazon S3 customer, you can get started with Amazon S3 for free. For more information, see AWS Free Tier.

To set up Amazon S3, use the steps in the following sections.

When you sign up for AWS and set up Amazon S3, you can optionally change the display language in the AWS Management Console. For more information, see Changing the language of the AWS Management Console in the *AWS Management Console Getting Started Guide*.

**Topics**

## Sign up for an AWS account

If you do not have an AWS account, complete the following steps to create one.

**To sign up for an AWS account**

1. Open https://portal.aws.amazon.com/billing/signup.
2. Follow the online instructions.

   Part of the sign-up procedure involves receiving a phone call and entering a verification code on the phone keypad.

   When you sign up for an AWS account, an *AWS account root user* is created. The root user has access to all AWS services and resources in the account. As a security best practice, assign administrative access to a user, and use only the root user to perform tasks that require root user access.

AWS sends you a confirmation email after the sign-up process is complete. At any time, you can view your current account activity and manage your account by going to https://aws.amazon.com/ and choosing **My Account**.

## Create a user with administrative access

After you sign up for an AWS account, secure your AWS account root user, enable AWS IAM Identity Center, and create an administrative user so that you don't use the root user for everyday tasks.

### Secure your AWS account root user

1. Sign in to the AWS Management Console as the account owner by choosing **Root user** and entering your AWS account email address. On the next page, enter your password.

   For help signing in by using root user, see Signing in as the root user in the *AWS Sign-In User Guide*.

2. Turn on multi-factor authentication (MFA) for your root user.

   For instructions, see Enable a virtual MFA device for your AWS account root user (console) in the *IAM User Guide*.

### Create a user with administrative access

1. Enable IAM Identity Center.

   For instructions, see Enabling AWS IAM Identity Center in the *AWS IAM Identity Center User Guide*.

2. In IAM Identity Center, grant administrative access to a user.

   For a tutorial about using the IAM Identity Center directory as your identity source, see Configure user access with the default IAM Identity Center directory in the *AWS IAM Identity Center User Guide*.

### Sign in as the user with administrative access

- To sign in with your IAM Identity Center user, use the sign-in URL that was sent to your email address when you created the IAM Identity Center user.

For help signing in using an IAM Identity Center user, see Signing in to the AWS access portal in the *AWS Sign-In User Guide*.

**Assign access to additional users**

1. In IAM Identity Center, create a permission set that follows the best practice of applying least-privilege permissions.

   For instructions, see Create a permission set in the *AWS IAM Identity Center User Guide*.

2. Assign users to a group, and then assign single sign-on access to the group.

   For instructions, see Add groups in the *AWS IAM Identity Center User Guide*.

# Step 1: Create your first S3 bucket

After you sign up for AWS, you're ready to create a bucket in Amazon S3 using the AWS Management Console. Every object in Amazon S3 is stored in a *bucket*. Before you can store data in Amazon S3, you must create a bucket.

> **Note**
>
> For more information about using the Amazon S3 Express One Zone storage class with directory buckets, see What is S3 Express One Zone? and Directory buckets.

> **Note**
>
> You are not charged for creating a bucket. You are charged only for storing objects in the bucket and for transferring objects in and out of the bucket. The charges that you incur through following the examples in this guide are minimal (less than $1). For more information about storage charges, see Amazon S3 pricing.

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.

2. In the navigation bar on the top of the page, choose the name of the currently displayed AWS Region. Next, choose the Region in which you want to create a bucket.

   > **Note**
   >
   > To minimize latency and costs and address regulatory requirements, choose a Region close to you. Objects stored in a Region never leave that Region unless you explicitly transfer them to another Region. For a list of Amazon S3 AWS Regions, see AWS service endpoints in the *Amazon Web Services General Reference*.

3. In the left navigation pane, choose **Buckets**.
4. Choose **Create bucket**.

   The **Create bucket** page opens.
5. Under **General configuration**, view the AWS Region where your bucket will be created.
6. Under **Bucket type**, choose **General purpose**.
7. For **Bucket name**, enter a name for your bucket.

   The bucket name must:

   - Be unique within a partition. A partition is a grouping of Regions. AWS currently has three partitions: `aws` (Standard Regions), `aws-cn` (China Regions), and `aws-us-gov` (AWS GovCloud (US) Regions).
   - Be between 3 and 63 characters long.
   - Consist only of lowercase letters, numbers, dots (.), and hyphens (-). For best compatibility, we recommend that you avoid using dots (.) in bucket names, except for buckets that are used only for static website hosting.
   - Begin and end with a letter or number.

   After you create the bucket, you cannot change its name. For more information about naming buckets, see Bucket naming rules.

   > **Important**
   >
   > Avoid including sensitive information, such as account numbers, in the bucket name. The bucket name is visible in the URLs that point to the objects in the bucket.

8. AWS Management Console allows you to copy an existing bucket's settings to your new bucket. If you do not want to copy the settings of an existing bucket, skip to the next step.

   > **Note**
   >
   > This option:
   >
   > - Is not available in the AWS CLI and is only available in console
   > - Is not available for directory buckets
   > - Does not copy the bucket policy from the existing bucket to the new bucket

   To copy an existing bucket's settings, under **Copy settings from existing bucket**, select **Choose bucket**. The **Choose bucket** window opens. Find the bucket with the settings that you would like to copy, and select **Choose bucket**. The **Choose bucket** window closes, and the **Create bucket** window re-opens.

   Under **Copy settings from existing bucket**, you will now see the name of the bucket you selected. You will also see a **Restore defaults** option that you can use to remove the copied bucket settings. Review the remaining bucket settings, on the **Create bucket** page. You will see that they now match the settings of the bucket that you selected. You can skip to the final step.

9. Under **Object Ownership**, to disable or enable ACLs and control ownership of objects uploaded in your bucket, choose one of the following settings:

   **ACLs disabled**

   - **Bucket owner enforced (default)** – ACLs are disabled, and the bucket owner automatically owns and has full control over every object in the bucket. ACLs no longer affect access permissions to data in the S3 bucket. The bucket uses policies exclusively to define access control.

     By default, ACLs are disabled. A majority of modern use cases in Amazon S3 no longer require the use of ACLs. We recommend that you keep ACLs disabled, except in unusual circumstances where you must control access for each object individually. For more information, see Controlling ownership of objects and disabling ACLs for your bucket.

**ACLs enabled**

- **Bucket owner preferred** – The bucket owner owns and has full control over new objects that other accounts write to the bucket with the `bucket-owner-full-control` canned ACL.

  If you apply the **Bucket owner preferred** setting, to require all Amazon S3 uploads to include the `bucket-owner-full-control` canned ACL, you can add a bucket policy that allows only object uploads that use this ACL.
- **Object writer** – The AWS account that uploads an object owns the object, has full control over it, and can grant other users access to it through ACLs.

> **Note**
>
> The default setting is **Bucket owner enforced**. To apply the default setting and keep ACLs disabled, only the `s3:CreateBucket` permission is needed. To enable ACLs, you must have the `s3:PutBucketOwnershipControls` permission.

10. Under **Block Public Access settings for this bucket**, choose the Block Public Access settings that you want to apply to the bucket.

    By default, all four Block Public Access settings are enabled. We recommend that you keep all settings enabled, unless you know that you need to turn off one or more of them for your specific use case. For more information about blocking public access, see Blocking public access to your Amazon S3 storage.

    > **Note**
    >
    > To enable all Block Public Access settings, only the `s3:CreateBucket` permission is required. To turn off any Block Public Access settings, you must have the `s3:PutBucketPublicAccessBlock` permission.

11. (Optional) Under **Bucket Versioning**, you can choose if you wish to keep variants of objects in your bucket. For more information about versioning, see Using versioning in S3 buckets.

    To disable or enable versioning on your bucket, choose either **Disable** or **Enable**.

12. (Optional) Under **Tags**, you can choose to add tags to your bucket. Tags are key-value pairs used to categorize storage.

    To add a bucket tag, enter a **Key** and optionally a **Value** and choose **Add Tag**.

13. Under **Default encryption**, choose **Edit**.

14. To configure default encryption, under **Encryption type**, choose one of the following:

    - **Amazon S3 managed key (SSE-S3)**
    - **AWS Key Management Service key (SSE-KMS)**

    > **Important**
    >
    > If you use the SSE-KMS option for your default encryption configuration, you are subject to the requests per second (RPS) quota of AWS KMS. For more information about AWS KMS quotas and how to request a quota increase, see Quotas in the *AWS Key Management Service Developer Guide*.

    Buckets and new objects are encrypted with server-side encryption with an **Amazon S3 managed key** as the base level of encryption configuration. For more information about default encryption, see Setting default server-side encryption behavior for Amazon S3 buckets.

    For more information about using Amazon S3 server-side encryption to encrypt your data, see Using server-side encryption with Amazon S3 managed keys (SSE-S3).

15. If you chose **AWS Key Management Service key (SSE-KMS)**, do the following:

    a. Under **AWS KMS key**, specify your KMS key in one of the following ways:

    - To choose from a list of available KMS keys, choose **Choose from your AWS KMS keys**, and choose your **KMS key** from the list of available keys.

      Both the AWS managed key (`aws/s3`) and your customer managed keys appear in this list. For more information about customer managed keys, see Customer keys and AWS keys in the *AWS Key Management Service Developer Guide*.

    - To enter the KMS key ARN, choose **Enter AWS KMS key ARN**, and enter your KMS key ARN in the field that appears.

- To create a new customer managed key in the AWS KMS console, choose **Create a KMS key**.

  For more information about creating an AWS KMS key, see Creating keys in the *AWS Key Management Service Developer Guide*.

> **Important**
>
> You can use only KMS keys that are available in the same AWS Region as the bucket. The Amazon S3 console lists only the first 100 KMS keys in the same Region as the bucket. To use a KMS key that is not listed, you must enter your KMS key ARN. If you want to use a KMS key that is owned by a different account, you must first have permission to use the key and then you must enter the KMS key ARN. For more information on cross account permissions for KMS keys, see Creating KMS keys that other accounts can use in the *AWS Key Management Service Developer Guide*. For more information on SSE-KMS, see Specifying server-side encryption with AWS KMS (SSE-KMS).
> When you use an AWS KMS key for server-side encryption in Amazon S3, you must choose a symmetric encryption KMS key. Amazon S3 supports only symmetric encryption KMS keys and not asymmetric KMS keys. For more information, see Identifying symmetric and asymmetric KMS keys in the *AWS Key Management Service Developer Guide*.

  For more information about creating an AWS KMS key, see Creating keys in the *AWS Key Management Service Developer Guide*. For more information about using AWS KMS with Amazon S3, see Using server-side encryption with AWS KMS keys (SSE-KMS).

b. When you configure your bucket to use default encryption with SSE-KMS, you can also enable S3 Bucket Keys. S3 Bucket Keys lower the cost of encryption by decreasing request traffic from Amazon S3 to AWS KMS. For more information, see Reducing the cost of SSE-KMS with Amazon S3 Bucket Keys.

   To use S3 Bucket Keys, under **Bucket Key**, choose **Enable**.

16. (Optional) If you want to enable S3 Object Lock, do the following:

    a. Choose **Advanced settings**.

> **Important**
>
> Enabling Object Lock also enables versioning for the bucket. After enabling you must configure the Object Lock default retention and legal hold settings to protect new objects from being deleted or overwritten.

b. If you want to enable Object Lock, choose **Enable**, read the warning that appears, and acknowledge it.

For more information, see Using S3 Object Lock.

> **Note**
>
> To create an Object Lock enabled bucket, you must have the following permissions: `s3:CreateBucket`, `s3:PutBucketVersioning` and `s3:PutBucketObjectLockConfiguration`.

17. Choose **Create bucket**.

You've created a bucket in Amazon S3.

**Next step**

To add an object to your bucket, see Step 2: Upload an object to your bucket.

# Step 2: Upload an object to your bucket

After creating a bucket in Amazon S3, you're ready to upload an object to the bucket. An object can be any kind of file: a text file, a photo, a video, and so on.

> **Note**
>
> For more information about using the Amazon S3 Express One Zone storage class with directory buckets, see What is S3 Express One Zone? and Directory buckets.

**To upload an object to a bucket**

1. Open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the **Buckets** list, choose the name of the bucket that you want to upload your object to.
3. On the **Objects** tab for your bucket, choose **Upload**.
4. Under **Files and folders**, choose **Add files**.
5. Choose a file to upload, and then choose **Open.**
6. Choose **Upload**.

You've successfully uploaded an object to your bucket.

**Next step**

To view your object, see Step 3: Download an object.

# Step 3: Download an object

After you upload an object to a bucket, you can view information about your object and download the object to your local computer.

> **Note**
>
> For more information about using the Amazon S3 Express One Zone storage class with directory buckets, see What is S3 Express One Zone? and Directory buckets.

## Using the S3 console

This section explains how to use the Amazon S3 console to download an object from an S3 bucket.

> **Note**
>
> - You can download only one object at a time.
> - If you use the Amazon S3 console to download an object whose key name ends with a period (`.`), the period is removed from the key name of the downloaded object. To retain

the period at the end of the name of the downloaded object, you must use the AWS Command Line Interface (AWS CLI), AWS SDKs, or Amazon S3 REST API.

**To download an object from an S3 bucket**

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the **Buckets** list, choose the name of the bucket that you want to download an object from.
3. You can download an object from an S3 bucket in any of the following ways:
   - Select the check box next to the object, and choose **Download**. If you want to download the object to a specific folder, on the **Actions** menu, choose **Download as**.
   - If you want to download a specific version of the object, turn on **Show versions** (located next to the search box). Select the check box next to the version of the object that you want, and choose **Download**. If you want to download the object to a specific folder, on the **Actions** menu, choose **Download as**.

You've successfully downloaded your object.

**Next step**

To copy and paste your object within Amazon S3, see Step 4: Copy your object to a folder.

# Step 4: Copy your object to a folder

You've already added an object to a bucket and downloaded the object. Now, you create a folder and copy the object and paste it into the folder.

**Note**

For more information about using the Amazon S3 Express One Zone storage class with directory buckets, see What is S3 Express One Zone? and Directory buckets.

**To copy an object to a folder**

1. In the **Buckets** list, choose your bucket name.

2. Choose **Create folder** and configure a new folder:

   a. Enter a folder name (for example, `favorite-pics`).

   b. For the folder encryption setting, choose **Disable**.

   c. Choose **Save**.

3. Navigate to the Amazon S3 bucket or folder that contains the objects that you want to copy.
4. Select the check box to the left of the names of the objects that you want to copy.
5. Choose **Actions** and choose **Copy** from the list of options that appears.

   Alternatively, choose **Copy** from the options in the upper right.

6. Choose the destination folder:

   a. Choose **Browse S3**.

   b. Choose the option button to the left of the folder name.

      To navigate into a folder and choose a subfolder as your destination, choose the folder name.

   c. Choose **Choose destination**.

   The path to your destination folder appears in the **Destination** box. In **Destination**, you can alternately enter your destination path, for example, s3://*bucket-name*/*folder-name*/.

7. In the bottom right, choose **Copy**.

   Amazon S3 copies your objects to the destination folder.

**Next step**

To delete an object and a bucket in Amazon S3, see Step 5: Delete your objects and bucket.

# Step 5: Delete your objects and bucket

When you no longer need an object or a bucket, we recommend that you delete them to prevent further charges. If you completed this getting started walkthrough as a learning exercise, and you don't plan to use your bucket or objects, we recommend that you delete your bucket and objects so that charges no longer accrue.

Before you delete your bucket, empty the bucket or delete the objects in the bucket. After you delete your objects and bucket, they are no longer available.

If you want to continue to use the same bucket name, we recommend that you delete the objects or empty the bucket, but don't delete the bucket. After you delete a bucket, the name becomes available to reuse. However, another AWS account might create a bucket with the same name before you have a chance to reuse it.

> **Note**
>
> For more information about using the Amazon S3 Express One Zone storage class with directory buckets, see What is S3 Express One Zone? and Directory buckets.

**Topics**

## Deleting an object

If you want to choose which objects you delete without emptying all the objects from your bucket, you can delete an object.

1. In the **Buckets** list, choose the name of the bucket that you want to delete an object from.
2. Select the object that you want to delete.
3. Choose **Delete** from the options in the upper right.
4. On the **Delete objects** page, type **`delete`** to confirm deletion of your objects.
5. Choose **Delete objects**.

## Emptying your bucket

If you plan to delete your bucket, you must first empty your bucket, which deletes all the objects in the bucket.

**To empty a bucket**

1. In the **Buckets** list, select the bucket that you want to empty, and then choose **Empty**.
2. To confirm that you want to empty the bucket and delete all the objects in it, in **Empty bucket**, type **`permanently delete`**.

   > **Important**
   >
   > Emptying the bucket cannot be undone. Objects added to the bucket while the empty bucket action is in progress will be deleted.

3. To empty the bucket and delete all the objects in it, and choose **Empty**.

   An **Empty bucket: Status** page opens that you can use to review a summary of failed and successful object deletions.
4. To return to your bucket list, choose **Exit**.

## Deleting your bucket

After you empty your bucket or delete all the objects from your bucket, you can delete your bucket.

1. To delete a bucket, in the **Buckets** list, select the bucket.
2. Choose **Delete**.
3. To confirm deletion, in **Delete bucket**, type the name of the bucket.

   > **Important**
   >
   > Deleting a bucket cannot be undone. Bucket names are unique. If you delete your bucket, another AWS user can use the name. If you want to continue to use the same bucket name, don't delete your bucket. Instead, empty and keep the bucket.

4. To delete your bucket, choose **Delete bucket**.

# Next steps

In the preceding examples, you learned how to perform some basic Amazon S3 tasks.

The following topics explain the learning paths that you can use to gain a deeper understanding of Amazon S3 so that you can implement it in your applications.

> **Note**
>
> For more information about using the Amazon S3 Express One Zone storage class with directory buckets, see What is S3 Express One Zone? and Directory buckets.

**Topics**

## Understand common use cases

You can use Amazon S3 to support your specific use case. The AWS Solutions Library and AWS Blog provide use-case specific information and tutorials. The following are some common use cases for Amazon S3:

- **Backup and storage** – Use Amazon S3 storage management features to manage costs, meet regulatory requirements, reduce latency, and save multiple distinct copies of your data for compliance requirements.
- **Application hosting** – Deploy, install, and manage web applications that are reliable, highly scalable, and low-cost. For example, you can configure your Amazon S3 bucket to host a static website. For more information, see Hosting a static website using Amazon S3.
- **Media hosting** – Build a highly available infrastructure that hosts video, photo, or music uploads and downloads.
- **Software delivery** – Host your software applications for customers to download.

## Control access to your buckets and objects

Amazon S3 provides a variety of security features and tools. For an overview, see Access Management.

By default, S3 buckets and the objects in them are private. You have access only to the S3 resources that you create. You can use the following features to grant granular resource permissions that support your specific use case or to audit the permissions of your Amazon S3 resources.

- S3 Block Public Access – Block public access to S3 buckets and objects. By default, Block Public Access settings are turned on at the bucket level.
- AWS Identity and Access Management (IAM) identities – Use IAM or AWS IAM Identity Center to create IAM identities in your AWS account to manage access to your Amazon S3 resources. For example, you can use IAM with Amazon S3 to control the type of access that a user or group of users has to an Amazon S3 bucket that your AWS account owns. For more information about IAM identities and best practices, see IAM identities (users, user groups, and roles) in the *IAM User Guide*.
- Bucket policies – Use IAM-based policy language to configure resource-based permissions for your S3 buckets and the objects in them.
- Access control lists (ACLs) – Grant read and write permissions for individual buckets and objects to authorized users. As a general rule, we recommend using S3 resource-based policies (bucket policies and access point policies) or IAM user policies for access control instead of ACLs. Policies are a simplified and more flexible access-control option. With bucket policies and access point policies, you can define rules that apply broadly across all requests to your Amazon S3 resources. For more information about the specific cases when you'd use ACLs instead of resource-based policies or IAM user policies, see Identity and Access Management for Amazon S3.
- S3 Object Ownership – Take ownership of every object in your bucket, simplifying access management for data stored in Amazon S3. S3 Object Ownership is an Amazon S3 bucket-level setting that you can use to disable or enable ACLs. By default, ACLs are disabled. With ACLs disabled, the bucket owner owns all the objects in the bucket and manages access to data exclusively by using access-management policies.
- IAM Access Analyzer for S3 – Evaluate and monitor your S3 bucket access policies, ensuring that the policies provide only the intended access to your S3 resources.

## Manage and monitor your storage

- Managing your storage – After you create buckets and upload objects in Amazon S3, you can manage your object storage. For example, you can use S3 Versioning and S3 Replication for disaster recovery, S3 Lifecycle to manage storage costs, and S3 Object Lock to meet compliance requirements.

- Monitoring your storage – Monitoring is an important part of maintaining the reliability, availability, and performance of Amazon S3 and your AWS solutions. You can monitor storage activity and costs. Also, we recommend that you collect monitoring data from all the parts of your AWS solution so that you can more easily debug a multipoint failure if one occurs.
- Analytics and insights – You can also use analytics and insights in Amazon S3 to understand, analyze, and optimize your storage usage. For example, use Amazon S3 Storage Lens to understand, analyze, and optimize your storage. S3 Storage Lens provides 29+ usage and activity metrics and interactive dashboards to aggregate data for your entire organization, specific accounts, Regions, buckets, or prefixes. Use Storage Class Analysis to analyze storage access patterns to decide when it's time to move your data to a more cost-effective storage class.

## Develop with Amazon S3

Amazon S3 is a REST service. You can send requests to Amazon S3 using the REST API or the AWS SDK libraries, which wrap the underlying Amazon S3 REST API, simplifying your programming tasks. You can also use the AWS Command Line Interface (AWS CLI) to make Amazon S3 API calls. For more information, see Making requests.

The Amazon S3 REST API is an HTTP interface to Amazon S3. With the REST API, you use standard HTTP requests to create, fetch, and delete buckets and objects. To use the REST API, you can use any toolkit that supports HTTP. You can even use a browser to fetch objects, as long as they are anonymously readable. For more information, see Developing with Amazon S3 using the REST API.

To help you build applications using the language of your choice, we provide the following resources.

**AWS CLI**

You can access the features of Amazon S3 using the AWS CLI. To download and configure the AWS CLI, see Developing with Amazon S3 using the AWS CLI.

The AWS CLI provides two tiers of commands for accessing Amazon S3: High-level (s3) commands and API-level (s3api and s3control) commands. The high-level S3 commands simplify performing common tasks, such as creating, manipulating, and deleting objects and buckets. The s3api and s3control commands expose direct access to all Amazon S3 API operations, which you can use to carry out advanced operations that might not be possible with the high-level commands alone.

For a list of Amazon S3 AWS CLI commands, see s3, s3api, and s3control.

**AWS SDKs and Explorers**

You can use the AWS SDKs when developing applications with Amazon S3. The AWS SDKs simplify your programming tasks by wrapping the underlying REST API. The AWS Mobile SDKs and the Amplify JavaScript library are also available for building connected mobile and web applications using AWS.

In addition to the AWS SDKs, AWS Explorers are available for Visual Studio and Eclipse for Java IDE. In this case, the SDKs and the explorers are bundled together as AWS Toolkits.

For more information, see Developing with Amazon S3 using the AWS SDKs.

**Sample Code and Libraries**

The AWS Developer Center and AWS Code Sample Catalog have sample code and libraries written especially for Amazon S3. You can use these code samples to understand how to implement the Amazon S3 API. You can also view the *Amazon Simple Storage Service API Reference* to understand the Amazon S3 API operations in detail.

## Learn from tutorials

You can get started with step-by-step tutorials to learn more about Amazon S3. These tutorials are intended for a lab-type environment, and they use fictitious company names, user names, and so on. Their purpose is to provide general guidance. They are not intended for direct use in a production environment without careful review and adaptation to meet the unique needs of your organization's environment.

### Getting started

- Tutorial: Storing and retrieving a file with Amazon S3
- Tutorial: Getting started using S3 Intelligent-Tiering
- Tutorial: Getting started using the Amazon S3 Glacier storage classes

### Optimizing storage costs

- Tutorial: Getting started using S3 Intelligent-Tiering
- Tutorial: Getting started using the Amazon S3 Glacier storage classes
- Tutorial: Optimizing costs and gaining visibility into usage with S3 Storage Lens

### Managing storage

- Tutorial: Getting started with Amazon S3 Multi-Region Access Points
- Tutorial: Replicating existing objects in your Amazon S3 buckets with S3 Batch Replication

### Hosting videos and websites

- Tutorial: Hosting on-demand streaming video with Amazon S3, Amazon CloudFront, and Amazon Route 53
- Tutorial: Configuring a static website on Amazon S3
- Tutorial: Configuring a static website using a custom domain registered with Route 53

### Processing data

- Tutorial: Transforming data for your application with S3 Object Lambda
- Tutorial: Detecting and redacting PII data with S3 Object Lambda and Amazon Comprehend
- Tutorial: Using S3 Object Lambda to dynamically watermark images as they are retrieved
- Tutorial: Batch-transcoding videos with S3 Batch Operations, AWS Lambda, and AWS Elemental MediaConvert

### Protecting data

- Tutorial: Checking the integrity of data in Amazon S3 with additional checksums
- Tutorial: Replicating data within and between AWS Regions using S3 Replication
- Tutorial: Protecting data on Amazon S3 against accidental deletion or application bugs using S3 Versioning, S3 Object Lock, and S3 Replication
- Tutorial: Replicating existing objects in your Amazon S3 buckets with S3 Batch Replication

## Explore training and support

You can learn from AWS experts to advance your skills and get expert assistance achieving your objectives.

- **Training** – Training resources provide a hands-on approach to learning Amazon S3. For more information, see AWS training and certification and AWS online tech talks.
- **Discussion Forums** – On the forum, you can review posts to understand what you can and can't do with Amazon S3. You can also post your questions. For more information, see Discussion Forums.
- **Technical Support** – If you have further questions, you can contact Technical Support.

# Tutorials

The following tutorials present complete end-to-end procedures for common Amazon S3 tasks. These tutorials are intended for a lab-type environment, and they use fictitious company names, user names, and so on. Their purpose is to provide general guidance. They are not intended for direct use in a production environment without careful review and adaptation to meet the unique needs of your organization's environment.

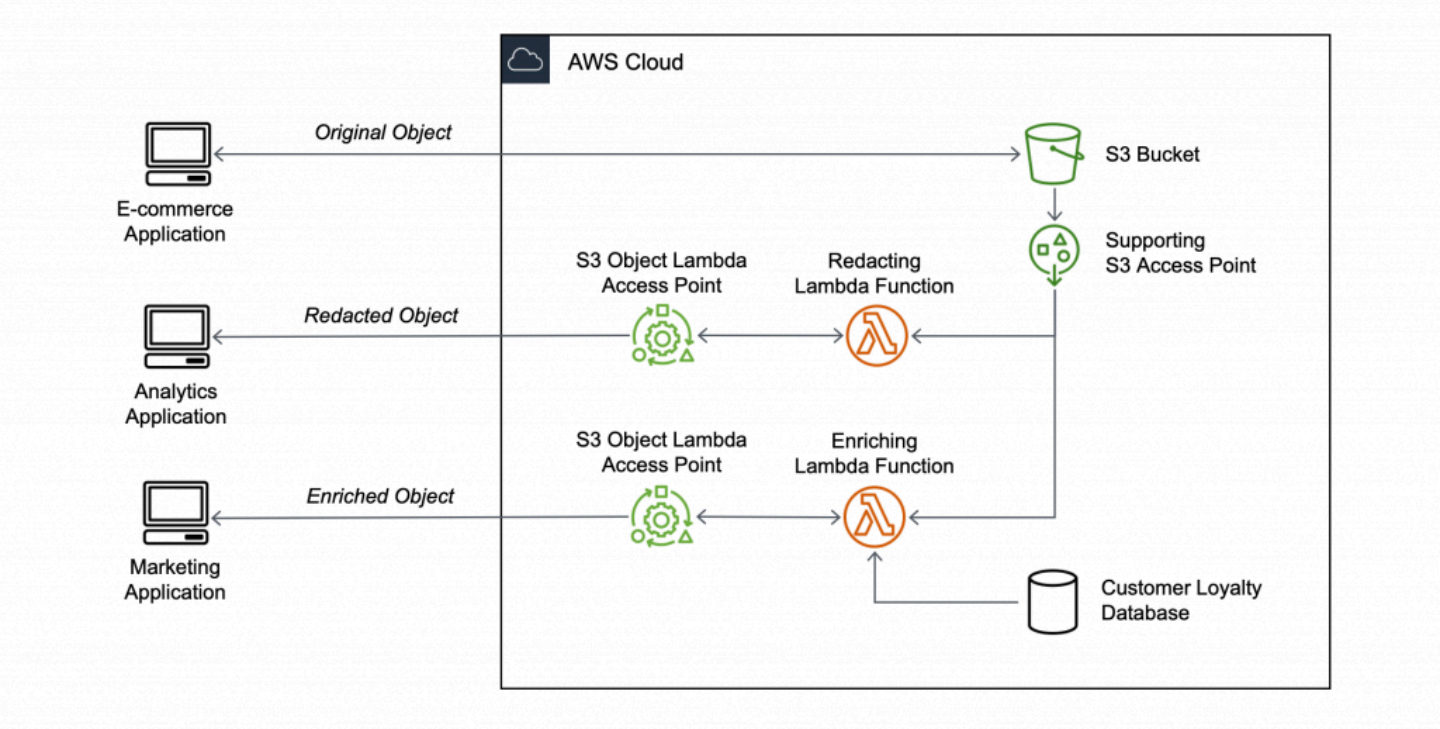
# Tutorial: Transforming data for your application with S3 Object Lambda

When you store data in Amazon S3, you can easily share it for use by multiple applications. However, each application might have unique data format requirements, and might need modification or processing of your data for a specific use case. For example, a dataset created by an ecommerce application might include personally identifiable information (PII). When the same data is processed for analytics, this PII is not needed and should be redacted. However, if the same dataset is used for a marketing campaign, you might need to enrich the data with additional details, such as information from the customer loyalty database.

With S3 Object Lambda, you can add your own code to process data retrieved from S3 before returning it to an application. Specifically, you can configure an AWS Lambda function and attach it to an S3 Object Lambda Access Point. When an application sends standard S3 GET requests through the S3 Object Lambda Access Point, the specified Lambda function is invoked to process any data retrieved from an S3 bucket through the supporting S3 access point. Then, the S3 Object Lambda Access Point returns the transformed result back to the application. You can author and execute your own custom Lambda functions, tailoring the S3 Object Lambda data transformation to your specific use case, all with no changes required to your applications.



## Objective

In this tutorial, you learn how to add custom code to standard S3 GET requests to modify the requested object retrieved from S3 so that the object suit the needs of the requesting client or application. Specifically, you learn how to transform all the text in the original object stored in S3 to uppercase through S3 Object Lambda.

> **Note**
>
> This tutorial uses Python code to transform the data, for examples using other AWS SDKs see Transform data for your application with S3 Object Lambda in the AWS SDK Code Examples Library.

**Topics**

## Prerequisites

Before you start this tutorial, you must have an AWS account that you can sign in to as an AWS Identity and Access Management (IAM) user with correct permissions. You also must install Python version 3.8 or later.

**Substeps**

- Create an IAM user with permissions in your AWS account (console)
- Install Python 3.8 or later on your local machine

### Create an IAM user with permissions in your AWS account (console)

You can create an IAM user for the tutorial. To complete this tutorial, your IAM user must attach the following IAM policies to access relevant AWS resources and perform specific actions. For more information about how to create an IAM user, see Creating IAM users (console) in the *IAM User Guide*.

Your IAM user requires the following policies:

- AmazonS3FullAccess – Grants permissions to all Amazon S3 actions, including permissions to create and use an Object Lambda Access Point.
- AWSLambda_FullAccess – Grants permissions to all Lambda actions.
- IAMFullAccess – Grants permissions to all IAM actions.

- IAMAccessAnalyzerReadOnlyAccess – Grants permissions to read all access information provided by IAM Access Analyzer.
- CloudWatchLogsFullAccess – Grants full access to CloudWatch Logs.

> **Note**
>
> For simplicity, this tutorial creates and uses an IAM user. After completing this tutorial, remember to Delete the IAM user. For production use, we recommend that you follow the Security best practices in IAM in the *IAM User Guide*. A best practice requires human users to use federation with an identity provider to access AWS with temporary credentials. Another best practice is to require workloads to use temporary credentials with IAM roles to access AWS. To learn about using AWS IAM Identity Center to create users with temporary credentials, see Getting started in the *AWS IAM Identity Center User Guide*. This tutorial also uses full-access AWS managed policies. For production use, we recommend that you instead grant only the minimum permissions necessary for your use case, in accordance with security best practices.

## Install Python 3.8 or later on your local machine

Use the following procedure to install Python 3.8 or later on your local machine. For more installation instructions, see the Downloading Python page in the *Python Beginners Guide*.

1. Open your local terminal or shell and run the following command to determine whether Python is already installed, and if so, which version is installed.

   ```
   python --version
   ```

2. If you don't have Python 3.8 or later, download the official installer of Python 3.8 or later that's suitable for your local machine.
3. Run the installer by double-clicking the downloaded file, and follow the steps to complete the installation.

   For **Windows users**, choose **Add Python 3.X to PATH** in the installation wizard before choosing **Install Now**.
4. Restart your terminal by closing and reopening it.
5. Run the following command to verify that Python 3.8 or later is installed correctly.

For **macOS users**, run this command:

```
python3 --version
```

For **Windows users**, run this command:

```
python --version
```

6. Run the following command to verify that the pip3 package manager is installed. If you see a pip version number and python 3.8 or later in the command response, that means the pip3 package manager is installed successfully.

```
pip --version
```

## Step 1: Create an S3 bucket

Create a bucket to store the original data that you plan to transform.

**To create a bucket**

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Buckets**.
3. Choose **Create bucket**.

   The **Create bucket** page opens.
4. For **Bucket name**, enter a name (for example, **`tutorial-bucket`**) for your bucket.

   For more information about naming buckets in Amazon S3, see Bucket naming rules.
5. For **Region**, choose the AWS Region where you want the bucket to reside.

   For more information about the bucket Region, see Buckets overview.
6. For **Block Public Access settings for this bucket**, keep the default settings (**Block *all* public access** is enabled).

We recommend that you keep all Block Public Access settings enabled unless you need to turn off one or more of them for your use case. For more information about blocking public access, see Blocking public access to your Amazon S3 storage.

7. For the remaining settings, keep the defaults.

   (Optional) If you want to configure additional bucket settings for your specific use case, see Creating a bucket.

8. Choose **Create bucket**.

## Step 2: Upload a file to the S3 bucket

Upload a text file to the S3 bucket. This text file contains the original data that you will transform to uppercase later in this tutorial.

For example, you can upload a `tutorial.txt` file that contains the following text:

```
Amazon S3 Object Lambda Tutorial:
You can add your own code to process data retrieved from S3 before
returning it to an application.
```

**To upload a file to a bucket**

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Buckets**.
3. In the **Buckets** list, choose the name of the bucket that you created in Step 1 (for example, **`tutorial-bucket`**) to upload your file to.
4. On the **Objects** tab for your bucket, choose **Upload**.
5. On the **Upload** page, under **Files and folders**, choose **Add files**.
6. Choose a file to upload, and then choose **Open**. For example, you can upload the `tutorial.txt` file example mentioned earlier.
7. Choose **Upload**.

# Step 3: Create an S3 access point

To use an S3 Object Lambda Access Point to access and transform the original data, you must create an S3 access point and associate it with the S3 bucket that you created in Step 1. The access point must be in the same AWS Region as the objects that you want to transform.

Later in this tutorial, you'll use this access point as a supporting access point for your Object Lambda Access Point.

**To create an access point**

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Access Points**.
3. On the **Access Points** page, choose **Create access point**.
4. In the **Access point name** field, enter the name (for example, **`tutorial-access-point`**) for the access point.

   For more information about naming access points, see Rules for naming Amazon S3 access points.
5. In the **Bucket name** field, enter the name of the bucket that you created in Step 1 (for example, **`tutorial-bucket`**). S3 attaches the access point to this bucket.

   (Optional) You can choose **Browse S3** to browse and search the buckets in your account. If you choose **Browse S3**, choose the desired bucket, and then choose **Choose path** to populate the **Bucket name** field with that bucket's name.
6. For **Network origin**, choose **Internet**.

   For more information about network origins for access points, see Creating access points restricted to a virtual private cloud.
7. By default, all Block Public Access settings are turned on for your access point. We recommend that you keep **Block *all* public access** enabled.

   For more information, see Managing public access to access points.
8. For all other access point settings, keep the default settings.

   (Optional) You can modify the access point settings to support your use case. For this tutorial, we recommend keeping the default settings.

(Optional) If you need to manage access to your access point, you can specify an access point policy. For more information, see Access point policy examples.

9. Choose **Create access point**.

## Step 4: Create a Lambda function

To transform original data, create a Lambda function for use with your S3 Object Lambda Access Point.

**Substeps**

- Write Lambda function code and create a deployment package with a virtual environment
- Create a Lambda function with an execution role (console)
- Deploy your Lambda function code with .zip file archives and configure the Lambda function (console)

### Write Lambda function code and create a deployment package with a virtual environment

1. On your local machine, create a folder with the folder name `object-lambda` for the virtual environment to use later in this tutorial.
2. In the `object-lambda` folder, create a file with a Lambda function that changes all text in the original object to uppercase. For example, you can use the following function written in Python. Save this function in a file named `transform.py`.

```
import boto3
import requests
from botocore.config import Config

# This function capitalizes all text in the original object
def lambda_handler(event, context):
    object_context = event["getObjectContext"]
    # Get the presigned URL to fetch the requested original object
    # from S3
    s3_url = object_context["inputS3Url"]
    # Extract the route and request token from the input context
    request_route = object_context["outputRoute"]
    request_token = object_context["outputToken"]
```

```
    # Get the original S3 object using the presigned URL
    response = requests.get(s3_url)
    original_object = response.content.decode("utf-8")

    # Transform all text in the original object to uppercase
    # You can replace it with your custom code based on your use case
    transformed_object = original_object.upper()

    # Write object back to S3 Object Lambda
    s3 = boto3.client('s3', config=Config(signature_version='s3v4'))
    # The WriteGetObjectResponse API sends the transformed data
    # back to S3 Object Lambda and then to the user
    s3.write_get_object_response(
        Body=transformed_object,
        RequestRoute=request_route,
        RequestToken=request_token)

    # Exit the Lambda function: return the status code
    return {'status_code': 200}
```

**Note**

The preceding example Lambda function loads the entire requested object into memory before transforming it and returning it to the client. Alternatively, you can stream the object from S3 to avoid loading the entire object into memory. This approach can be useful when working with large objects. For more information about streaming responses with Object Lambda Access Points, see the streaming examples in Working with `GetObject` requests in Lambda.

When you're writing a Lambda function for use with an S3 Object Lambda Access Point, the function is based on the input event context that S3 Object Lambda provides to the Lambda function. The event context provides information about the request being made in the event passed from S3 Object Lambda to Lambda. It contains the parameters that you use to create the Lambda function.

The fields used to create the preceding Lambda function are as follows:

The field of `getObjectContext` means the input and output details for connections to Amazon S3 and S3 Object Lambda. It has the following fields:

- `inputS3Url` – A presigned URL that the Lambda function can use to download the original object from the supporting access point. By using a presigned URL, the Lambda function doesn't need to have Amazon S3 read permissions to retrieve the original object and can only access the object processed by each invocation.
- `outputRoute` – A routing token that is added to the S3 Object Lambda URL when the Lambda function calls `WriteGetObjectResponse` to send back the transformed object.
- `outputToken` – A token used by S3 Object Lambda to match the `WriteGetObjectResponse` call with the original caller when sending back the transformed object.

For more information about all the fields in the event context, see Event context format and usage and Writing Lambda functions for S3 Object Lambda Access Points.

3. In your local terminal, enter the following command to install the `virtualenv` package:

```
python -m pip install virtualenv
```

4. In your local terminal, open the `object-lambda` folder that you created earlier, and then enter the following command to create and initialize a virtual environment called `venv`.

```
python -m virtualenv venv
```

5. To activate the virtual environment, enter the following command to execute the `activate` file from the environment's folder:

   For **macOS users**, run this command:

```
source venv/bin/activate
```

   For **Windows users**, run this command:

```
.\venv\Scripts\activate
```

Now, your command prompt changes to show **(venv)**, indicating that the virtual environment is active.

6. To install the required libraries, run the following commands line by line in the `venv` virtual environment.

   These commands install updated versions of the dependencies of your `lambda_handler` Lambda function. These dependencies are the AWS SDK for Python (Boto3) and the requests module.

   ```
   pip3 install boto3
   ```

   ```
   pip3 install requests
   ```

7. To deactivate the virtual environment, run the following command:

   ```
   deactivate
   ```

8. To create a deployment package with the installed libraries as a `.zip` file named `lambda.zip` at the root of the `object-lambda` directory, run the following commands line by line in your local terminal.

   > **Tip**
   >
   > The following commands might need to be adjusted to work in your particular environment. For example, a library might appear in `site-packages` or `dist-packages`, and the first folder might be `lib` or `lib64`. Also, the `python` folder might be named with a different Python version. To locate a specific package, use the `pip show` command.

   For **macOS users**, run these commands:

   ```
   cd venv/lib/python3.8/site-packages
   ```

   ```
   zip -r ../../../../lambda.zip .
   ```

   For **Windows users**, run these commands:

```
cd .\venv\Lib\site-packages\
```

```
powershell Compress-Archive * ../../../lambda.zip
```

The last command saves the deployment package to the root of the `object-lambda` directory.

9. Add the function code file `transform.py` to the root of your deployment package.

   For **macOS users**, run these commands:

   ```
   cd ../../../../
   ```

   ```
   zip -g lambda.zip transform.py
   ```

   For **Windows users**, run these commands:

   ```
   cd ..\..\..\
   ```

   ```
   powershell Compress-Archive -update transform.py lambda.zip
   ```

   After you complete this step, you should have the following directory structure:

   ```
   lambda.zip$
     # transform.py
     # __pycache__
     | boto3/
     # certifi/
     # pip/
     # requests/
     ...
   ```

## Create a Lambda function with an execution role (console)

1. Sign in to the AWS Management Console and open the AWS Lambda console at https://console.aws.amazon.com/lambda/.

2. In the left navigation pane, choose **Functions**.
3. Choose **Create function**.
4. Choose **Author from scratch**.
5. Under **Basic information**, do the following:

   a. For **Function name**, enter **`tutorial-object-lambda-function`**.

   b. For **Runtime**, choose **Python 3.8** or a later version.
6. Expand the **Change default execution role** section. Under **Execution role**, choose **Create a new role with basic Lambda permissions**.

   In Step 5 later in this tutorial, you attach the **AmazonS3ObjectLambdaExecutionRolePolicy** to this Lambda function's execution role.
7. Keep the remaining settings set to the defaults.
8. Choose **Create function**.

## Deploy your Lambda function code with .zip file archives and configure the Lambda function (console)

1. In the AWS Lambda console at https://console.aws.amazon.com/lambda/, choose **Functions** in the left navigation pane.
2. Choose the Lambda function that you created earlier (for example, **`tutorial-object-lambda-function`**).
3. On the Lambda function's details page, choose the **Code** tab. In the **Code Source** section, choose **Upload from** and then **.zip file**.
4. Choose **Upload** to select your local `.zip` file.
5. Choose the `lambda.zip` file that you created earlier, and then choose **Open**.
6. Choose **Save**.
7. In the **Runtime settings** section, choose **Edit**.
8. On the **Edit runtime settings** page, confirm that **Runtime** is set to **Python 3.8** or a later version.
9. To tell the Lambda runtime which handler method in your Lambda function code to invoke, enter **`transform.lambda_handler`** for **Handler**.

When you configure a function in Python, the value of the handler setting is the file name and the name of the handler module, separated by a dot. For example, `transform.lambda_handler` calls the `lambda_handler` method defined in the `transform.py` file.

10. Choose **Save**.
11. (Optional) On your Lambda function's details page, choose the **Configuration** tab. In the left navigation pane, choose **General configuration**, then choose **Edit**. In the **Timeout** field, enter **1** min **0** sec. Keep the remaining settings set to the defaults, and choose **Save**.

    **Timeout** is the amount of time that Lambda allows a function to run for an invocation before stopping it. The default is 3 seconds. The maximum duration for a Lambda function used by S3 Object Lambda is 60 seconds. Pricing is based on the amount of memory configured and the amount of time that your code runs.

## Step 5: Configure an IAM policy for your Lambda function's execution role

To enable your Lambda function to provide customized data and response headers to the `GetObject` caller, your Lambda function's execution role must have IAM permissions to call the `WriteGetObjectResponse` API.

**To attach an IAM policy to your Lambda function role**

1. In the AWS Lambda console at https://console.aws.amazon.com/lambda/, choose **Functions** in the left navigation pane.
2. Choose the function that you created in Step 4 (for example, **`tutorial-object-lambda-function`**).
3. On your Lambda function's details page, choose the **Configuration** tab, and then choose **Permissions** in the left navigation pane.
4. Under **Execution role**, choose the link of the **Role name**. The IAM console opens.
5. On the IAM console's **Summary** page for your Lambda function's execution role, choose the **Permissions** tab. Then, from the **Add Permissions** menu, choose **Attach policies**.

6. On the **Attach Permissions** page, enter **`AmazonS3ObjectLambdaExecutionRolePolicy`** in the search box to filter the list of policies. Select the check box next to the name of the **AmazonS3ObjectLambdaExecutionRolePolicy** policy.
7. Choose **Attach policies**.

## Step 6: Create an S3 Object Lambda Access Point

An S3 Object Lambda Access Point provides the flexibility to invoke a Lambda function directly from an S3 GET request so that the function can process data retrieved from an S3 access point. When creating and configuring an S3 Object Lambda Access Point, you must specify the Lambda function to invoke and provide the event context in JSON format as custom parameters for Lambda to use.

**To create an S3 Object Lambda Access Point**

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Object Lambda Access Points**.
3. On the **Object Lambda Access Points** page, choose **Create Object Lambda Access Point**.
4. For **Object Lambda Access Point name**, enter the name that you want to use for the Object Lambda Access Point (for example, **`tutorial-object-lambda-accesspoint`**).
5. For **Supporting Access Point**, enter or browse to the standard access point that you created in Step 3 (for example, **`tutorial-access-point`**), and then choose **Choose supporting Access Point**.
6. For **S3 APIs**, to retrieve objects from the S3 bucket for Lambda function to process, select **GetObject**.
7. For **Invoke Lambda function**, you can choose either of the following two options for this tutorial.
   - Choose **Choose from functions in your account**, and then choose the Lambda function that you created in Step 4 (for example, **`tutorial-object-lambda-function`**) from the **Lambda function** dropdown list.
   - Choose **Enter ARN**, and then enter the Amazon Resource Name (ARN) of the Lambda function that you created in Step 4.
8. For **Lambda function version**, choose **$LATEST** (the latest version of the Lambda function that you created in Step 4).

9. (Optional) If you need your Lambda function to recognize and process GET requests with range and part number headers, select **Lambda function supports requests using range** and **Lambda function supports requests using part numbers**. Otherwise, clear these two check boxes.

   For more information about how to use range or part numbers with S3 Object Lambda, see Working with Range and partNumber headers.

10. (Optional) Under **Payload - *optional***, add JSON text to provide your Lambda function with additional information.

    A payload is optional JSON text that you can provide to your Lambda function as input for all invocations coming from a specific S3 Object Lambda Access Point. To customize the behaviors for multiple Object Lambda Access Points that invoke the same Lambda function, you can configure payloads with different parameters, thereby extending the flexibility of your Lambda function.

    For more information about payload, see Event context format and usage.

11. (Optional) For **Request metrics - *optional***, choose **Disable** or **Enable** to add Amazon S3 monitoring to your Object Lambda Access Point. Request metrics are billed at the standard Amazon CloudWatch rate. For more information, see CloudWatch pricing.

12. Under **Object Lambda Access Point policy - *optional***, keep the default setting.

    (Optional) You can set a resource policy. This resource policy grants the `GetObject` API permission to use the specified Object Lambda Access Point.

13. Keep the remaining settings set to the defaults, and choose **Create Object Lambda Access Point**.

## Step 7: View the transformed data

Now, S3 Object Lambda is ready to transform your data for your use case. In this tutorial, S3 Object Lambda transforms all the text in your object to uppercase.

### Substeps

- View the transformed data in your S3 Object Lambda Access Point
- Run a Python script to print the original and transformed data

## View the transformed data in your S3 Object Lambda Access Point

When you request to retrieve a file through your S3 Object Lambda Access Point, you make a `GetObject` API call to S3 Object Lambda. S3 Object Lambda invokes the Lambda function to transform your data, and then returns the transformed data as the response to the standard S3 `GetObject` API call.

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Object Lambda Access Points**.
3. On the **Object Lambda Access Points** page, choose the S3 Object Lambda Access Point that you created in Step 6 (for example, **`tutorial-object-lambda-accesspoint`**).
4. On the **Objects** tab of your S3 Object Lambda Access Point, select the file that has the same name (for example, `tutorial.txt`) as the one that you uploaded to the S3 bucket in Step 2.

   This file should contain all the transformed data.
5. To view the transformed data, choose **Open** or **Download**.

## Run a Python script to print the original and transformed data

You can use S3 Object Lambda with your existing applications. To do so, update your application configuration to use the new S3 Object Lambda Access Point ARN that you created in Step 6 to retrieve data from S3.

The following example Python script prints both the original data from the S3 bucket and the transformed data from the S3 Object Lambda Access Point.

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Object Lambda Access Points**.
3. On the **Object Lambda Access Points** page, choose the radio button to the left of the S3 Object Lambda Access Point that you created in Step 6 (for example, **`tutorial-object-lambda-accesspoint`**).
4. Choose **Copy ARN**.
5. Save the ARN for use later.

6. Write a Python script on your local machine to print both the original data (for example, `tutorial.txt`) from your S3 Bucket and the transformed data (for example, `tutorial.txt`) from your S3 Object Lambda Access Point). You can use the following example script.

```
import boto3
from botocore.config import Config

s3 = boto3.client('s3', config=Config(signature_version='s3v4'))

def getObject(bucket, key):
    objectBody = s3.get_object(Bucket = bucket, Key = key)
    print(objectBody["Body"].read().decode("utf-8"))
    print("\n")

print('Original object from the S3 bucket:')
# Replace the two input parameters of getObject() below with
# the S3 bucket name that you created in Step 1 and
# the name of the file that you uploaded to the S3 bucket in Step 2
getObject("tutorial-bucket",
          "tutorial.txt")

print('Object transformed by S3 Object Lambda:')
# Replace the two input parameters of getObject() below with
# the ARN of your S3 Object Lambda Access Point that you saved earlier and
# the name of the file with the transformed data (which in this case is
# the same as the name of the file that you uploaded to the S3 bucket
# in Step 2)
getObject("arn:aws:s3-object-lambda:us-west-2:111122223333:accesspoint/tutorial-
object-lambda-accesspoint",
          "tutorial.txt")
```

7. Save your Python script with a custom name (for example, `tutorial_print.py` ) in the folder (for example, `object-lambda`) that you created in Step 4 on your local machine.

8. In your local terminal, run the following command from the root of the directory (for example, `object-lambda`) that you created in Step 4.

```
python3 tutorial_print.py
```

You should see both the original data and the transformed data (all text as uppercase) through the terminal. For example, you should see something like the following text.

```
Original object from the S3 bucket:
Amazon S3 Object Lambda Tutorial:
You can add your own code to process data retrieved from S3 before
returning it to an application.

Object transformed by S3 Object Lambda:
AMAZON S3 OBJECT LAMBDA TUTORIAL:
YOU CAN ADD YOUR OWN CODE TO PROCESS DATA RETRIEVED FROM S3 BEFORE
RETURNING IT TO AN APPLICATION.
```

## Step 8: Clean up

If you transformed your data through S3 Object Lambda only as a learning exercise, delete the AWS resources that you allocated so that you no longer accrue charges.

**Substeps**

- Delete the Object Lambda Access Point
- Delete the S3 access point
- Delete the execution role for your Lambda function
- Delete the Lambda function
- Delete the CloudWatch log group
- Delete the original file in the S3 source bucket
- Delete the S3 source bucket
- Delete the IAM user

### Delete the Object Lambda Access Point

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Object Lambda Access Points**.
3. On the **Object Lambda Access Points** page, choose the radio button to the left of the S3 Object Lambda Access Point that you created in Step 6 (for example, **`tutorial-object-lambda-accesspoint`**).
4. Choose **Delete**.

5. Confirm that you want to delete your Object Lambda Access Point by entering its name in the text field that appears, and then choose **Delete**.

## Delete the S3 access point

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Access Points**.
3. Navigate to the access point that you created in Step 3 (for example, **`tutorial-access-point`**), and choose the radio button next to the name of the access point.
4. Choose **Delete**.
5. Confirm that you want to delete your access point by entering its name in the text field that appears, and then choose **Delete**.

## Delete the execution role for your Lambda function

1. Sign in to the AWS Management Console and open the AWS Lambda console at https://console.aws.amazon.com/lambda/.
2. In the left navigation pane, choose **Functions**.
3. Choose the function that you created in Step 4 (for example, **`tutorial-object-lambda-function`**).
4. On your Lambda function's details page, choose the **Configuration** tab, and then choose **Permissions** in the left navigation pane.
5. Under **Execution role**, choose the link of the **Role name**. The IAM console opens.
6. On the IAM console's **Summary** page of your Lambda function's execution role, choose **Delete role**.
7. In the **Delete role** dialog box, choose **Yes, delete**.

## Delete the Lambda function

1. In the AWS Lambda console at https://console.aws.amazon.com/lambda/, choose **Functions** in the left navigation pane.
2. Select the check box to the left of the name of the function that you created in Step 4 (for example, **`tutorial-object-lambda-function`**).

3. Choose **Actions**, and then choose **Delete**.
4. In the **Delete function** dialog box, choose **Delete**.

## Delete the CloudWatch log group

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the left navigation pane, choose **Log groups**.
3. Find the log group whose name ends with the Lambda function that you created in Step 4 (for example, **`tutorial-object-lambda-function`**).
4. Select the check box to the left of the name of the log group.
5. Choose **Actions**, and then choose **Delete log group(s)**.
6. In the **Delete log group(s)** dialog box, choose **Delete**.

## Delete the original file in the S3 source bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Buckets**.
3. In the **Bucket name** list, choose the name of the bucket that you uploaded the original file to in Step 2 (for example, **`tutorial-bucket`**).
4. Select the check box to the left of the name of the object that you want to delete (for example, `tutorial.txt`).
5. Choose **Delete**.
6. On the **Delete objects** page, in the **Permanently delete objects?** section, confirm that you want to delete this object by entering **`permanently delete`** in the text box.
7. Choose **Delete objects**.

## Delete the S3 source bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Buckets**.

3. In the **Buckets** list, choose the radio button next to the name of the bucket that you created in Step 1 (for example, **`tutorial-bucket`**).
4. Choose **Delete**.
5. On the **Delete bucket** page, confirm that you want to delete the bucket by entering the bucket name in the text field, and then choose **Delete bucket**.

### Delete the IAM user

1. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.
2. In the left navigation pane, choose **Users**, and then select the check box next to the user name that you want to delete.
3. At the top of the page, choose **Delete**.
4. In the **Delete *`user name`*?** dialog box, enter the user name in the text input field to confirm the deletion of the user. Choose **Delete**.

## Next steps

After completing this tutorial, you can customize the Lambda function for your use case to modify the data returned by standard S3 GET requests.

The following is a list of common use cases for S3 Object Lambda:

- Masking sensitive data for security and compliance.

  For more information, see Tutorial: Detecting and redacting PII data with S3 Object Lambda and Amazon Comprehend.
- Filtering certain rows of data to deliver specific information.
- Augmenting data with information from other services or databases.
- Converting across data formats, such as converting XML to JSON for application compatibility.
- Compressing or decompressing files as they are being downloaded.
- Resizing and watermarking images.

  For more information, see Tutorial: Using S3 Object Lambda to dynamically watermark images as they are retrieved.

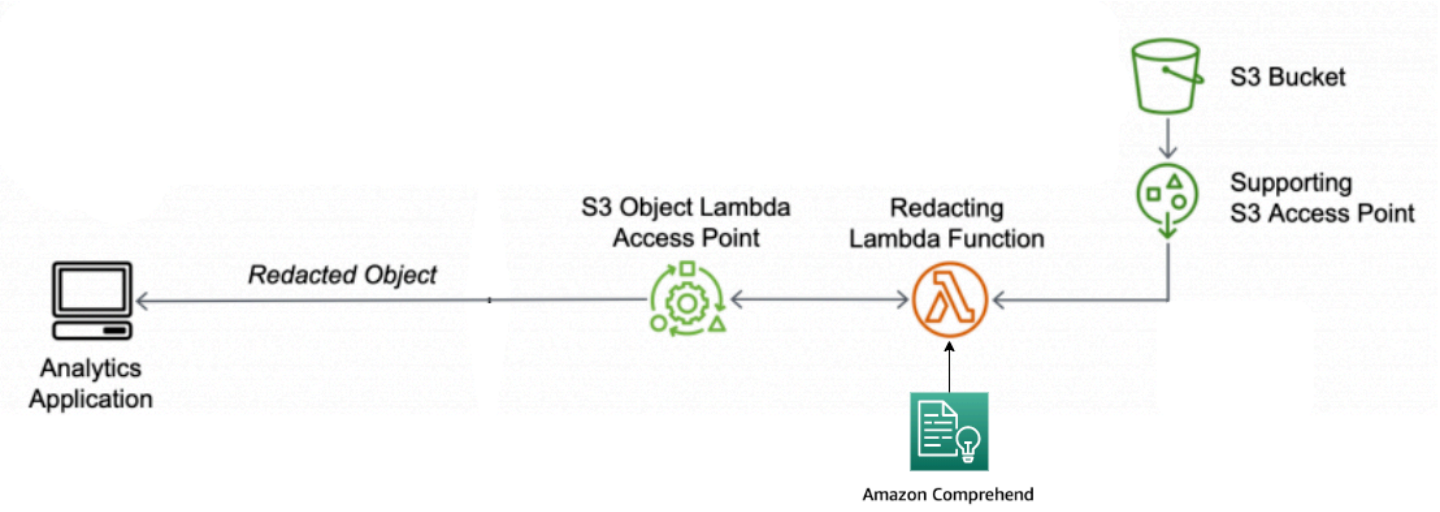
- Implementing custom authorization rules to access data.

For more information about S3 Object Lambda, see Transforming objects with S3 Object Lambda.

# Tutorial: Detecting and redacting PII data with S3 Object Lambda and Amazon Comprehend

When you're using Amazon S3 for shared datasets for multiple applications and users to access, it's important to restrict privileged information, such as personally identifiable information (PII), to only authorized entities. For example, when a marketing application uses some data containing PII, it might need to first mask PII data to meet data privacy requirements. Also, when an analytics application uses a production order inventory dataset, it might need to first redact customer credit card information to prevent unintended data leakage.

With S3 Object Lambda and a prebuilt AWS Lambda function powered by Amazon Comprehend, you can protect PII data retrieved from S3 before returning it to an application. Specifically, you can use the prebuilt Lambda function as a redacting function and attach it to an S3 Object Lambda Access Point. When an application (for example, an analytics application) sends standard S3 GET requests, these requests made through the S3 Object Lambda Access Point invoke the prebuilt redacting Lambda function to detect and redact PII data retrieved from an S3 bucket through a supporting S3 access point. Then, the S3 Object Lambda Access Point returns the redacted result back to the application.



In the process, the prebuilt Lambda function uses Amazon Comprehend, a natural language processing (NLP) service, to capture variations in how PII is represented, regardless of how PII exists

in text (such as numerically or as a combination of words and numbers). Amazon Comprehend can even use context in the text to understand if a 4-digit number is a PIN, the last four numbers of a Social Security number (SSN), or a year. Amazon Comprehend processes any text file in UTF-8 format and can protect PII at scale without affecting accuracy. For more information, see What is Amazon Comprehend? in the *Amazon Comprehend Developer Guide*.

**Objective**

In this tutorial, you learn how to use S3 Object Lambda with the prebuilt Lambda function `ComprehendPiiRedactionS3ObjectLambda`. This function uses Amazon Comprehend to detect PII entities. It then redacts these entities by replacing them with asterisks. By redacting PII, you conceal sensitive data, which can help with security and compliance.

You also learn how to use and configure a prebuilt AWS Lambda function in the AWS Serverless Application Repository to work together with S3 Object Lambda for easy deployment.

**Topics**

## Prerequisites: Create an IAM user with permissions

Before you start this tutorial, you must have an AWS account that you can sign in to as an AWS Identity and Access Management user (IAM user) with correct permissions.

You can create an IAM user for the tutorial. To complete this tutorial, your IAM user must attach the following IAM policies to access relevant AWS resources and perform specific actions.

> **Note**
>
> For simplicity, this tutorial creates and uses an IAM user. After completing this tutorial, remember to Delete the IAM user. For production use, we recommend that you follow the Security best practices in IAM in the *IAM User Guide*. A best practice requires human users to use federation with an identity provider to access AWS with temporary credentials. Another best practice is to require workloads to use temporary credentials with IAM roles to access AWS. To learn about using AWS IAM Identity Center to create users with temporary credentials, see Getting started in the *AWS IAM Identity Center User Guide*. This tutorial also uses full-access policies. For production use, we recommend that you instead grant only the minimum permissions necessary for your use case, in accordance with security best practices.

Your IAM user requires the following AWS managed policies:

- AmazonS3FullAccess – Grants permissions to all Amazon S3 actions, including permissions to create and use an Object Lambda Access Point.
- AWSLambda_FullAccess – Grants permissions to all Lambda actions.
- AWSCloudFormationFullAccess – Grants permissions to all AWS CloudFormation actions.
- IAMFullAccess – Grants permissions to all IAM actions.
- IAMAccessAnalyzerReadOnlyAccess – Grants permissions to read all access information provided by IAM Access Analyzer.

You can directly attach these existing policies when creating an IAM user. For more information about how to create an IAM user, see Creating IAM users (console) in the *IAM User Guide*.

In addition, your IAM user requires a customer managed policy. To grant the IAM user permissions to all AWS Serverless Application Repository resources and actions, you must create an IAM policy and attach the policy to the IAM user.

**To create and attach an IAM policy to your IAM user**

1. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.
2. In the left navigation pane, choose **Policies**.
3. Choose **Create policy**.

4. On the **Visual editor** tab, for **Service**, choose **Choose a service**. Then, choose **Serverless Application Repository**.
5. For **Actions**, under **Manual actions**, select **All Serverless Application Repository actions (serverlessrepo:*)** for this tutorial.

   As a security best practice, you should allow permissions to only those actions and resources that a user needs, based on your use case. For more information, see Security best practices in IAM in the *IAM User Guide*.
6. For **Resources**, choose **All resources** for this tutorial.

   As a best practice, you should define permissions for only specific resources in specific accounts. Alternatively, you can grant least privilege using condition keys. For more information, see Grant least privilege in the *IAM User Guide*.
7. Choose **Next: Tags**.
8. Choose **Next: Review**.
9. On the **Review policy** page, enter a **Name** (for example, **`tutorial-serverless-application-repository`**) and a **Description** (optional) for the policy that you are creating. Review the policy summary to make sure that you have granted the intended permissions, and then choose **Create policy** to save your new policy.
10. In the left navigation pane, choose **Users**. Then, choose the IAM user for this tutorial.
11. On the **Summary** page of the chosen user, choose the **Permissions** tab, and then choose **Add permissions**.
12. Under **Grant permissions**, choose **Attach existing policies directly**.
13. Select the check box next to the policy that you just created (for example, **`tutorial-serverless-application-repository`**) and then choose **Next: Review**.
14. Under **Permissions summary**, review the summary to make sure that you attached the intended policy. Then, choose **Add permissions**.

## Step 1: Create an S3 bucket

Create a bucket to store the original data that you plan to transform.

**To create a bucket**

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.

2. In the left navigation pane, choose **Buckets**.
3. Choose **Create bucket**.

   The **Create bucket** page opens.
4. For **Bucket name**, enter a name (for example, **`tutorial-bucket`**) for your bucket.

   For more information about naming buckets in Amazon S3, see Bucket naming rules.
5. For **Region**, choose the AWS Region where you want the bucket to reside.

   For more information about the bucket Region, see Buckets overview.
6. For **Block Public Access settings for this bucket**, keep the default settings (**Block *all* public access** is enabled).

   We recommend that you keep all Block Public Access settings enabled unless you need to turn off one or more of them for your use case. For more information about blocking public access, see Blocking public access to your Amazon S3 storage.
7. For the remaining settings, keep the defaults.

   (Optional) If you want to configure additional bucket settings for your specific use case, see Creating a bucket.
8. Choose **Create bucket**.

## Step 2: Upload a file to the S3 bucket

Upload a text file containing known PII data of various types, such as names, banking information, phone numbers, and SSNs, to the S3 bucket as the original data that you will redact PII from later in this tutorial.

For example, you can upload following the `tutorial.txt` file. This is an example input file from Amazon Comprehend.

```
Hello Zhang Wei, I am John. Your AnyCompany Financial Services,
LLC credit card account 1111-0000-1111-0008 has a minimum payment
of $24.53 that is due by July 31st. Based on your autopay settings,
we will withdraw your payment on the due date from your
bank account number XXXXXX1111 with the routing number XXXXX0000.

Your latest statement was mailed to 100 Main Street, Any City,
```

```
WA 98121.
After your payment is received, you will receive a confirmation
text message at 206-555-0100.
If you have questions about your bill, AnyCompany Customer Service
is available by phone at 206-555-0199 or
email at support@anycompany.com.
```

**To upload a file to a bucket**

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Buckets**.
3. In the **Buckets** list, choose the name of the bucket that you created in Step 1 (for example, **`tutorial-bucket`**) to upload your file to.
4. On the **Objects** tab for your bucket, choose **Upload**.
5. On the **Upload** page, under **Files and folders**, choose **Add files**.
6. Choose a file to upload, and then choose **Open**. For example, you can upload the `tutorial.txt` file example mentioned earlier.
7. Choose **Upload**.

## Step 3: Create an S3 access point

To use an S3 Object Lambda Access Point to access and transform the original data, you must create an S3 access point and associate it with the S3 bucket that you created in Step 1. The access point must be in the same AWS Region as the objects you want to transform.

Later in this tutorial, you'll use this access point as a supporting access point for your Object Lambda Access Point.

**To create an access point**

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Access Points**.
3. On the **Access Points** page, choose **Create access point**.
4. In the **Access point name** field, enter the name (for example, **`tutorial-pii-access-point`**) for the access point.

For more information about naming access points, see Rules for naming Amazon S3 access points.

5. In the **Bucket name** field, enter the name of the bucket that you created in Step 1 (for example, **`tutorial-bucket`**). S3 attaches the access point to this bucket.

   (Optional) You can choose **Browse S3** to browse and search the buckets in your account. If you choose **Browse S3**, choose the desired bucket, and then choose **Choose path** to populate the **Bucket name** field with that bucket's name.

6. For **Network origin**, choose **Internet**.

   For more information about network origins for access points, see Creating access points restricted to a virtual private cloud.

7. By default, all block public access settings are turned on for your access point. We recommend that you keep **Block *all* public access** enabled. For more information, see Managing public access to access points.

8. For all other access point settings, keep the default settings.

   (Optional) You can modify the access point settings to support your use case. For this tutorial, we recommend keeping the default settings.

   (Optional) If you need to manage access to your access point, you can specify an access point policy. For more information, see Access point policy examples.

9. Choose **Create access point**.

## Step 4: Configure and deploy a prebuilt Lambda function

To redact PII data, configure and deploy the prebuilt AWS Lambda function `ComprehendPiiRedactionS3ObjectLambda` for use with your S3 Object Lambda Access Point.

**To configure and deploy the Lambda function**

1. Sign in to the AWS Management Console and view the `ComprehendPiiRedactionS3ObjectLambda` function in the AWS Serverless Application Repository.
2. For **Application settings**, under **Application name**, keep the default value (`ComprehendPiiRedactionS3ObjectLambda`) for this tutorial.

(Optional) You can enter the name that you want to give to this application. You might want to do this if you plan to configure multiple Lambda functions for different access needs for the same shared dataset.

3. For **MaskCharacter**, keep the default value (*****). The mask character replaces each character in the redacted PII entity.
4. For **MaskMode**, keep the default value (**MASK**). The **MaskMode** value specifies whether the PII entity is redacted with the `MASK` character or the `PII_ENTITY_TYPE` value.
5. To redact the specified types of data, for **PiiEntityTypes**, keep the default value **ALL**. The **PiiEntityTypes** value specifies the PII entity types to be considered for redaction.

   For more information about the list of supported PII entity types, see Detect Personally Identifiable Information (PII) in the *Amazon Comprehend Developer Guide*.
6. Keep the remaining settings set to the defaults.

   (Optional) If you want to configure additional settings for your specific use case, see the **Readme file** section on the left side of the page.
7. Select the check box next to **I acknowledge that this app creates custom IAM roles**.
8. Choose **Deploy**.
9. On the new application's page, under **Resources**, choose the **Logical ID** of the Lambda function that you deployed to review the function on the Lambda function page.

## Step 5: Create an S3 Object Lambda Access Point

An S3 Object Lambda Access Point provides the flexibility to invoke a Lambda function directly from an S3 GET request so that the function can redact PII data retrieved from an S3 access point. When creating and configuring an S3 Object Lambda Access Point, you must specify the redacting Lambda function to invoke and provide the event context in JSON format as custom parameters for Lambda to use.

The event context provides information about the request being made in the event passed from S3 Object Lambda to Lambda. For more information about all the fields in the event context, see Event context format and usage.

**To create an S3 Object Lambda Access Point**

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Object Lambda Access Points**.
3. On the **Object Lambda Access Points** page, choose **Create Object Lambda Access Point**.
4. For **Object Lambda Access Point name**, enter the name that you want to use for the Object Lambda Access Point (for example, **`tutorial-pii-object-lambda-accesspoint`**).
5. For **Supporting Access Point**, enter or browse to the standard access point that you created in Step 3 (for example, **`tutorial-pii-access-point`**), and then choose **Choose supporting Access Point**.
6. For **S3 APIs**, to retrieve objects from the S3 bucket for Lambda function to process, select **GetObject**.
7. For **Invoke Lambda function**, you can choose either of the following two options for this tutorial.
   - Choose **Choose from functions in your account** and choose the Lambda function that you deployed in Step 4 (for example, **`serverlessrepo-ComprehendPiiRedactionS3ObjectLambda`**) from the **Lambda function** dropdown list.
   - Choose **Enter ARN**, and then enter the Amazon Resource Name (ARN) of the Lambda function that you created in Step 4.
8. For **Lambda function version**, choose **$LATEST** (the latest version of the Lambda function that you deployed in Step 4).
9. (Optional) If you need your Lambda function to recognize and process GET requests with range and part number headers, select **Lambda function supports requests using range** and **Lambda function supports requests using part numbers**. Otherwise, clear these two check boxes.

   For more information about how to use range or part numbers with S3 Object Lambda, see Working with Range and partNumber headers.
10. (Optional) Under **Payload - *optional***, add JSON text to provide your Lambda function with additional information.

    A payload is optional JSON text that you can provide to your Lambda function as input for all invocations coming from a specific S3 Object Lambda Access Point. To customize the behaviors

for multiple Object Lambda Access Points that invoke the same Lambda function, you can configure payloads with different parameters, thereby extending the flexibility of your Lambda function.

For more information about payload, see Event context format and usage.

11. (Optional) For **Request metrics - *optional***, choose **Disable** or **Enable** to add Amazon S3 monitoring to your Object Lambda Access Point. Request metrics are billed at the standard Amazon CloudWatch rate. For more information, see CloudWatch pricing.
12. Under **Object Lambda Access Point policy - *optional***, keep the default setting.

    (Optional) You can set a resource policy. This resource policy grants the `GetObject` API permission to use the specified Object Lambda Access Point.
13. Keep the remaining settings set to the defaults, and choose **Create Object Lambda Access Point**.

## Step 6: Use the S3 Object Lambda Access Point to retrieve the redacted file

Now, S3 Object Lambda is ready to redact PII data from your original file.

**To use the S3 Object Lambda Access Point to retrieve the redacted file**

When you request to retrieve a file through your S3 Object Lambda Access Point, you make a `GetObject` API call to S3 Object Lambda. S3 Object Lambda invokes the Lambda function to redact your PII data and returns the transformed data as the response to the standard S3 `GetObject` API call.

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Object Lambda Access Points**.
3. On the **Object Lambda Access Points** page, choose the S3 Object Lambda Access Point that you created in Step 5 (for example, **`tutorial-pii-object-lambda-accesspoint`**).
4. On the **Objects** tab of your S3 Object Lambda Access Point, select the file that has the same name (for example, `tutorial.txt`) as the one that you uploaded to the S3 bucket in Step 2.

   This file should contain all the transformed data.
5. To view the transformed data, choose **Open** or **Download**.

You should be able to see the redacted file, as shown in the following example.

```
Hello *********. Your AnyCompany Financial Services,
LLC credit card account ******************* has a minimum payment
of $24.53 that is due by *********. Based on your autopay settings,
we will withdraw your payment on the due date from your
bank account ********** with the routing number *********.

Your latest statement was mailed to ********************************.
After your payment is received, you will receive a confirmation
text message at ************.
If you have questions about your bill, AnyCompany Customer Service
is available by phone at ************ or
email at **********************.
```

## Step 7: Clean up

If you redacted your data through S3 Object Lambda only as a learning exercise, delete the AWS resources that you allocated so that you no longer accrue charges.

**Substeps**

- Delete the Object Lambda Access Point
- Delete the S3 access point
- Delete the Lambda function
- Delete the CloudWatch log group
- Delete the original file in the S3 source bucket
- Delete the S3 source bucket
- Delete the IAM role for your Lambda function
- Delete the customer managed policy for your IAM user
- Delete the IAM user

### Delete the Object Lambda Access Point

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.

2. In the left navigation pane, choose **Object Lambda Access Points**.
3. On the **Object Lambda Access Points** page, choose the option button to the left of the S3 Object Lambda Access Point that you created in Step 5 (for example, **`tutorial-pii-object-lambda-accesspoint`**).
4. Choose **Delete**.
5. Confirm that you want to delete your Object Lambda Access Point by entering its name in the text field that appears, and then choose **Delete**.

## Delete the S3 access point

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Access Points**.
3. Navigate to the access point that you created in Step 3 (for example, **`tutorial-pii-access-point`**), and choose the option button next to the name of the access point.
4. Choose **Delete**.
5. Confirm that you want to delete your access point by entering its name in the text field that appears, and then choose **Delete**.

## Delete the Lambda function

1. In the AWS Lambda console at https://console.aws.amazon.com/lambda/, choose **Functions** in the left navigation pane.
2. Choose the function that you created in Step 4 (for example, **`serverlessrepo-ComprehendPiiRedactionS3ObjectLambda`**).
3. Choose **Actions**, and then choose **Delete**.
4. In the **Delete function** dialog box, choose **Delete**.

## Delete the CloudWatch log group

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the left navigation pane, choose **Log groups**.

3. Find the log group whose name ends with the Lambda function that you created in Step 4 (for example, **`serverlessrepo-ComprehendPiiRedactionS3ObjectLambda`**).
4. Choose **Actions**, and then choose **Delete log group(s)**.
5. In the **Delete log group(s)** dialog box, choose **Delete**.

## Delete the original file in the S3 source bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Buckets**.
3. In the **Bucket name** list, choose the name of the bucket that you uploaded the original file to in Step 2 (for example, **`tutorial-bucket`**).
4. Select the check box to the left of the name of the object that you want to delete (for example, `tutorial.txt`).
5. Choose **Delete**.
6. On the **Delete objects** page, in the **Permanently delete objects?** section, confirm that you want to delete this object by entering **`permanently delete`** in the text box.
7. Choose **Delete objects**.

## Delete the S3 source bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Buckets**.
3. In the **Buckets** list, choose the option button next to the name of the bucket that you created in Step 1 (for example, **`tutorial-bucket`**).
4. Choose **Delete**.
5. On the **Delete bucket** page, confirm that you want to delete the bucket by entering the bucket name in the text field, and then choose **Delete bucket**.

## Delete the IAM role for your Lambda function

1. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.

2. In the left navigation pane, choose **Roles**, and then select the check box next to the role name that you want to delete. The role name starts with the name of the Lambda function that you deployed in Step 4 (for example, **`serverlessrepo-ComprehendPiiRedactionS3ObjectLambda`**).
3. Choose **Delete**.
4. In the **Delete** dialog box, enter the role name in the text input field to confirm deletion. Then, choose **Delete**.

### Delete the customer managed policy for your IAM user

1. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.
2. In the left navigation pane, choose **Policies**.
3. On the **Policies** page, enter the name of the customer managed policy that you created in the Prerequisites (for example, **`tutorial-serverless-application-repository`**) in the search box to filter the list of policies. Select the option button next to the name of the policy that you want to delete.
4. Choose **Actions**, and then choose **Delete**.
5. Confirm that you want to delete this policy by entering its name in the text field that appears, and then choose **Delete**.

### Delete the IAM user

1. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.
2. In the left navigation pane, choose **Users**, and then select the check box next to the user name that you want to delete.
3. At the top of the page, choose **Delete**.
4. In the **Delete *`user name`*?** dialog box, enter the user name in the text input field to confirm the deletion of the user. Choose **Delete**.

## Next steps

After completing this tutorial, you can further explore the following related use cases:

- You can create multiple S3 Object Lambda Access Points and enable them with prebuilt Lambda functions that are configured differently to redact specific types of PII depending on the data accessors' business needs.

  Each type of user assumes an IAM role and only has access to one S3 Object Lambda Access Point (managed through IAM policies). Then, you attach each `ComprehendPiiRedactionS3ObjectLambda` Lambda function configured for a different redaction use case to a different S3 Object Lambda Access Point. For each S3 Object Lambda Access Point, you can have a supporting S3 access point to read data from an S3 bucket that stores the shared dataset.

  For more information about how to create an S3 bucket policy that allows users to read from the bucket only through S3 access points, see Configuring IAM policies for using access points.

  For more information about how to grant a user permission to access the Lambda function, the S3 access point, and the S3 Object Lambda Access Point, see Configuring IAM policies for Object Lambda Access Points.
- You can build your own Lambda function and use S3 Object Lambda with your customized Lambda function to meet your specific data needs.

  For example, to explore various data values, you can use S3 Object Lambda and your own Lambda function that uses additional Amazon Comprehend features, such as entity recognition, key phrase recognition, sentiment analysis, and document classification, to process data. You can also use S3 Object Lambda together with Amazon Comprehend Medical, a HIPAA-eligible NLP service, to analyze and extract data in a context-aware manner.

  For more information about how to transform data with S3 Object Lambda and your own Lambda function, see Tutorial: Transforming data for your application with S3 Object Lambda.

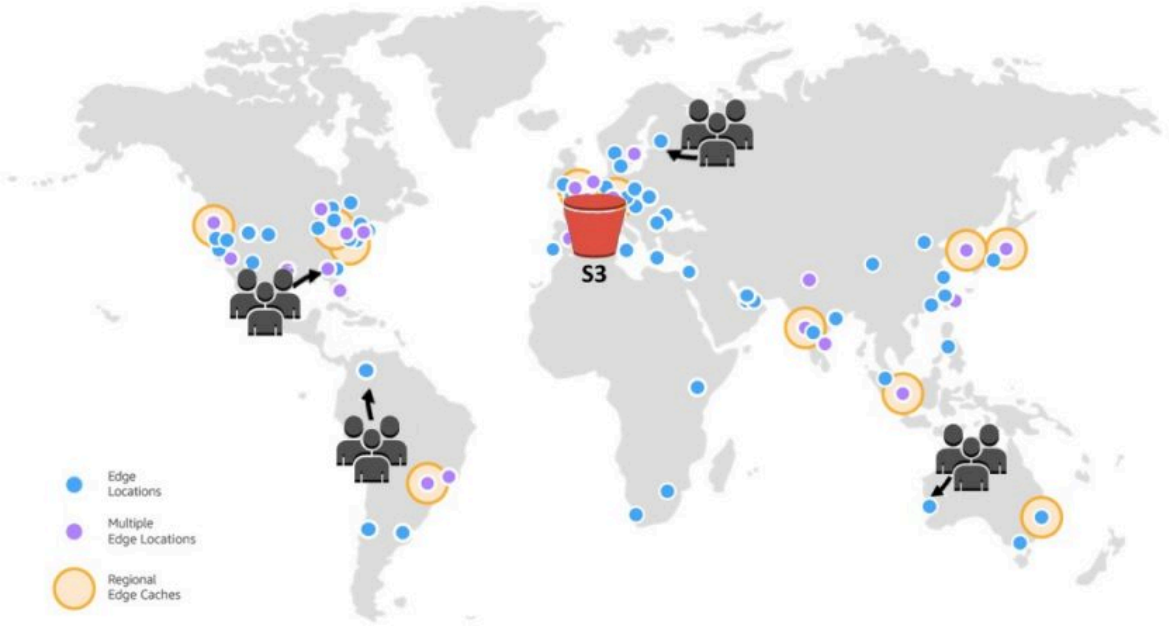
# Tutorial: Hosting on-demand streaming video with Amazon S3, Amazon CloudFront, and Amazon Route 53

You can use Amazon S3 with Amazon CloudFront to host videos for on-demand viewing in a secure and scalable way. Video on demand (VOD) streaming means that your video content is stored on a server and viewers can watch it at any time.

CloudFront is a fast, highly secure, and programmable content delivery network (CDN) service. CloudFront can deliver your content securely over HTTPS from all of the CloudFront edge locations

around the globe. For more information about CloudFront, see What is Amazon CloudFront? in the *Amazon CloudFront Developer Guide*.

CloudFront caching reduces the number of requests that your origin server must respond to directly. When a viewer (end user) requests a video that you serve with CloudFront, the request is routed to a nearby edge location closer to where the viewer is located. CloudFront serves the video from its cache, retrieving it from the S3 bucket only if it is not already cached. This caching management feature accelerates the delivery of your video to viewers globally with low latency, high throughput, and high transfer speeds. For more information about CloudFront caching management, see Optimizing caching and availability in the *Amazon CloudFront Developer Guide*.



### Objective

In this tutorial, you configure an S3 bucket to host on-demand video streaming using CloudFront for delivery and Amazon Route 53 for Domain Name System (DNS) and custom domain management.

### Topics

- Prerequisites: Register and configure a custom domain with Route 53
- Step 1: Create an S3 bucket

## Prerequisites: Register and configure a custom domain with Route 53

Before you start this tutorial, you must register and configure a custom domain (for example, **`example.com`**) with Route 53 so that you can configure your CloudFront distribution to use a custom domain name later.

Without a custom domain name, your S3 video is publicly accessible and hosted through CloudFront at a URL that looks similar to the following:

```
https://CloudFront distribution domain name/Path to an S3 video
```

For example, **`https://d111111abcdef8.cloudfront.net/sample.mp4`**.

After you configure your CloudFront distribution to use a custom domain name configured with Route 53, your S3 video is publicly accessible and hosted through CloudFront at a URL that looks similar to the following:

```
https://CloudFront distribution alternate domain name/Path to an S3 video
```

For example, **`https://www.example.com/sample.mp4`**. A custom domain name is simpler and more intuitive for your viewers to use.

To register a custom domain, see Registering a new domain using Route 53 in the *Amazon Route 53 Developer Guide*.

When you register a domain name with Route 53, Route 53 creates the hosted zone for you, which you will use later in this tutorial. This hosted zone is where you store information about how to route traffic for your domain, for example, to an Amazon EC2 instance or a CloudFront distribution.

There are fees associated with domain registration, your hosted zone, and DNS queries received by your domain. For more information, see Amazon Route 53 Pricing.

> **Note**
>
> When you register a domain, it costs money immediately and it's irreversible. You can choose not to auto-renew the domain, but you pay up front and own it for the year. For more information, see Registering a new domain in the *Amazon Route 53 Developer Guide*.

## Step 1: Create an S3 bucket

Create a bucket to store the original video that you plan to stream.

**To create a bucket**

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Buckets**.
3. Choose **Create bucket**.

   The **Create bucket** page opens.
4. For **Bucket name**, enter a name for your bucket (for example, **`tutorial-bucket`**).

   For more information about naming buckets in Amazon S3, see Bucket naming rules.
5. For **Region**, choose the AWS Region where you want the bucket to reside.

   If possible, you should pick the Region that is closest to the majority of your viewers. For more information about the bucket Region, see Buckets overview.
6. For **Block Public Access settings for this bucket**, keep the default settings (**Block *all* public access** is enabled).

   Even with **Block *all* public access** enabled, viewers can still access the uploaded video through CloudFront. This feature is a major advantage of using CloudFront to host a video stored in S3.

We recommend that you keep all settings enabled unless you need to turn off one or more of them for your use case. For more information about blocking public access, see Blocking public access to your Amazon S3 storage.

7. For the remaining settings, keep the defaults.

   (Optional) If you want to configure additional bucket settings for your specific use case, see Creating a bucket.

8. Choose **Create bucket**.

## Step 2: Upload a video to the S3 bucket

The following procedure describes how to upload a video file to an S3 bucket by using the console. If you're uploading many large video files to S3, you might want to use Amazon S3 Transfer Acceleration to configure fast and secure file transfers. Transfer Acceleration can speed up video uploading to your S3 bucket for long-distance transfer of larger videos. For more information, see Configuring fast, secure file transfers using Amazon S3 Transfer Acceleration.

**To upload a file to the bucket**

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Buckets**.
3. In the **Buckets** list, choose the name of the bucket that you created in Step 1 (for example, **`tutorial-bucket`**) to upload your file to.
4. On the **Objects** tab for your bucket, choose **Upload**.
5. On the **Upload** page, under **Files and folders**, choose **Add files**.
6. Choose a file to upload, and then choose **Open**.

   For example, you can upload a video file named `sample.mp4`.

7. Choose **Upload**.

## Step 3: Create a CloudFront origin access identity

To restrict direct access to the video from your S3 bucket, create a special CloudFront user called an origin access identity (OAI). You will associate the OAI with your distribution later in this tutorial. By

using an OAI, you make sure that viewers can't bypass CloudFront and get the video directly from the S3 bucket. Only the CloudFront OAI can access the file in the S3 bucket. For more information, see Restricting access to Amazon S3 content by using an OAI in the *Amazon CloudFront Developer Guide*.

**To create a CloudFront OAI**

1. Sign in to the AWS Management Console and open the CloudFront console at https://console.aws.amazon.com/cloudfront/v4/home.
2. In the left navigation pane, under the **Security** section, choose **Origin access**.
3. Under the **Identities** tab, choose **Create origin access identity**.
4. Enter a name (for example, **`S3-OAI`**) for the new origin access identity.
5. Choose **Create**.

## Step 4: Create a CloudFront distribution

To use CloudFront to serve and distribute the video in your S3 bucket, you must create a CloudFront distribution.

**Substeps**

- Create a CloudFront distribution
- Review the bucket policy

### Create a CloudFront distribution

1. Sign in to the AWS Management Console and open the CloudFront console at https://console.aws.amazon.com/cloudfront/v4/home.
2. In the left navigation pane, choose **Distributions**.
3. Choose **Create distribution**.
4. In the **Origin** section, for **Origin domain**, choose the domain name of your S3 origin, which starts with the name of the S3 bucket that you created in Step 1 (for example, **`tutorial-bucket`**).
5. For **Origin access**, choose **Legacy access identities**.
6. Under **Origin access identity**, choose the origin access identity that you created in Step 3 (for example, **`S3-OAI`**).

7. Under **Bucket policy**, choose **Yes, update the bucket policy**.
8. In the **Default cache behavior** section, under **Viewer protocol policy**, choose **Redirect HTTP to HTTPS**.

   When you choose this feature, HTTP requests are automatically redirected to HTTPS to secure your website and protect your viewers' data.
9. For the other settings in the **Default cache behaviors** section, keep the default values.

   (Optional) You can control how long your file stays in a CloudFront cache before CloudFront forwards another request to your origin. Reducing the duration allows you to serve dynamic content. Increasing the duration means that your viewers get better performance because your files are more likely to be served directly from the edge cache. A longer duration also reduces the load on your origin. For more information, see Managing how long content stays in the cache (expiration) in the *Amazon CloudFront Developer Guide*.
10. For the other sections, keep the remaining settings set to the defaults.

    For more information about the different settings options, see Values That You Specify When You Create or Update a Distribution in the *Amazon CloudFront Developer Guide*.
11. At the bottom of the page, choose **Create distribution**.
12. On the **General** tab for your CloudFront distribution, under **Details**, the value of the **Last modified** column for your distribution changes from **Deploying** to the timestamp when the distribution was last modified. This process typically takes a few minutes.

## Review the bucket policy

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Buckets**.
3. In the **Buckets** list, choose the name of the bucket that you used earlier as the origin of your CloudFront distribution (for example, **`tutorial-bucket`**).
4. Choose the **Permissions** tab.
5. In the **Bucket policy** section, confirm that you see a statement similar to the following in the bucket policy text:

```
{
    "Version": "2008-10-17",
```

```
    "Id": "PolicyForCloudFrontPrivateContent",
    "Statement": [
        {
            "Sid": "1",
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws:iam::cloudfront:user/CloudFront Origin Access
 Identity EH1HDMB1FH2TC"
            },
            "Action": "s3:GetObject",
            "Resource": "arn:aws:s3:::tutorial-bucket/*"
        }
    ]
}
```

This is the statement that your CloudFront distribution added to your bucket policy when you chose **Yes, update the bucket policy** earlier.

This bucket policy update indicates that you successfully configured the CloudFront distribution to restrict access to the S3 bucket. Because of this restriction, objects in the bucket can be accessed only through your CloudFront distribution.

## Step 5: Access the video through the CloudFront distribution

Now, CloudFront can serve the video stored in your S3 bucket. To access your video through CloudFront, you must combine your CloudFront distribution domain name with the path to the video in the S3 bucket.

**To create a URL to the S3 video using the CloudFront distribution domain name**

1. Sign in to the AWS Management Console and open the CloudFront console at https://console.aws.amazon.com/cloudfront/v4/home.
2. In the left navigation pane, choose **Distributions**.
3. To get the distribution domain name, do the following:

    a. In the **Origins** column, find the correct CloudFront distribution by looking for its origin name, which starts with the S3 bucket that you created in Step 1 (for example, **`tutorial-bucket`**).

   b. After finding the distribution in the list, widen the **Domain name** column to copy the domain name value for your CloudFront distribution.

4. In a new browser tab, paste the distribution domain name that you copied.
5. Return to the previous browser tab, and open the S3 console at https://console.aws.amazon.com/s3/.
6. In the left navigation pane, choose **Buckets**.
7. In the **Buckets** list, choose the name of the bucket that you created in Step 1 (for example, **`tutorial-bucket`**).
8. In the **Objects** list, choose the name of the video that you uploaded in Step 2 (for example, `sample.mp4`).
9. On the object detail page, in the **Object overview** section, copy the value of the **Key**. This value is the path to the uploaded video object in the S3 bucket.
10. Return to the browser tab where you previously pasted the distribution domain name, enter a forward slash (**/**) after the distribution domain name, and then paste the path to the video that you copied earlier (for example, `sample.mp4`).

    Now, your S3 video is publicly accessible and hosted through CloudFront at a URL that looks similar to the following:

    ```
    https://CloudFront distribution domain name/Path to the S3 video
    ```

    Replace *`CloudFront distribution domain name`* and *`Path to the S3 video`* with the appropriate values. An example URL is **`https://d111111abcdef8.cloudfront.net/sample.mp4`**.

## Step 6: Configure your CloudFront distribution to use your custom domain name

To use your own domain name instead of the CloudFront domain name in the URL to access the S3 video, add an alternate domain name to your CloudFront distribution.

### Substeps

- Request an SSL certificate
- Add the alternate domain name to your CloudFront distribution

- Create a DNS record to route traffic from your alternate domain name to your CloudFront distribution's domain name
- Check whether IPv6 is enabled for your distribution and create another DNS record if needed

### Request an SSL certificate

To allow your viewers to use HTTPS and your custom domain name in the URL for your video streaming, use AWS Certificate Manager (ACM) to request a Secure Sockets Layer (SSL) certificate. The SSL certificate establishes an encrypted network connection to the website.

1. Sign in to the AWS Management Console and open the ACM console at https://console.aws.amazon.com/acm/.
2. If the introductory page appears, under **Provision certificates**, choose **Get Started**.
3. On the **Request a certificate** page, choose **Request a public certificate**, and then choose **Request a certificate**.
4. On the **Add domain names** page, enter the fully qualified domain name (FQDN) of the site that you want to secure with an SSL/TLS certificate. You can use an asterisk (*) to request a wildcard certificate to protect several site names in the same domain. For this tutorial, enter **`*`** and the custom domain name that you configured in Prerequisites. For example, enter **`*.example.com`**, and then choose **Next**.

   For more information, see To request an ACM public certificate (console) in the *AWS Certificate Manager User Guide*.
5. On the **Select validation method** page, choose **DNS validation**. Then, choose **Next**.

   If you are able to edit your DNS configuration, we recommend that you use DNS domain validation rather than email validation. DNS validation has multiple benefits over email validation. For more information, see Option 1: DNS validation in the *AWS Certificate Manager User Guide*.
6. (Optional) On the **Add tags** page, tag your certificate with metadata.
7. Choose **Review**.
8. On the **Review** page, verify that the information under **Domain name** and **Validation method** are correct. Then, choose **Confirm and request**.

The **Validation** page shows that your request is being processed and that the certificate domain is being validated. The certificate awaiting validation is in the **Pending validation** status.

9. On the **Validation** page, choose the down arrow to the left of your custom domain name, and then choose **Create record in Route 53** to validate your domain ownership through DNS.

   Doing this adds a CNAME record provided by AWS Certificate Manager to your DNS configuration.

10. In the **Create record in Route 53** dialog box, choose **Create**.

    The **Validation** page should display a status notification of **Success** at the bottom.

11. Choose **Continue** to view the **Certificates** list page.

    The **Status** for your new certificate changes from **Pending validation** to **Issued** within 30 minutes.

## Add the alternate domain name to your CloudFront distribution

1. Sign in to the AWS Management Console and open the CloudFront console at https://console.aws.amazon.com/cloudfront/v4/home.
2. In the left navigation pane, choose **Distributions**.
3. Choose the ID for the distribution that you created in Step 4.
4. On the **General** tab, go to the **Settings** section, and choose **Edit**.
5. On the **Edit settings** page, for **Alternate domain name (CNAME) - *optional***, choose **Add item** to add the custom domain names that you want to use in the URL for the S3 video served by this CloudFront distribution.

   In this tutorial, for example, if you want to route traffic for a subdomain, such as `www.example.com`, enter the subdomain name (`www`) with the domain name (`example.com`). Specifically, enter **`www.example.com`**.

   > **Note**
   >
   > The alternate domain name (CNAME) that you add must be covered by the SSL certificate that you previously attached to your CloudFront distribution.

6. For **Custom SSL certificate - *optional***, choose the SSL certificate that you requested earlier (for example, **`*.example.com`**).

   > **Note**
   >
   > If you don't see the SSL certificate immediately after you request it, wait 30 minutes, and then refresh the list until the SSL certificate is available for you to select.

7. Keep the remaining settings set to the defaults. Choose **Save changes**.
8. On the **General** tab for the distribution, wait for the value of **Last modified** to change from **Deploying** to the timestamp when the distribution was last modified.

## Create a DNS record to route traffic from your alternate domain name to your CloudFront distribution's domain name

1. Sign in to the AWS Management Console and open the Route 53 console at https://console.aws.amazon.com/route53/.
2. In the left navigation pane, choose **Hosted zones**.
3. On the **Hosted zones** page, choose the name of the hosted zone that Route 53 created for you in Prerequisites (for example, **`example.com`**).
4. Choose **Create record**, and then use the **Quick create record** method.
5. For **Record name**, keep the value for the record name the same as the alternate domain name of the CloudFront distribution that you added earlier.

   In this tutorial, to route traffic to a subdomain, such as `www.example.com`, enter the subdomain name without the domain name. For example, enter only **`www`** in the text field before your custom domain name.
6. For **Record type**, choose **A - Routes traffic to an IPv4 address and some AWS resources**.
7. For **Value**, choose the **Alias** toggle to enable the alias resource.
8. Under **Route traffic to**, choose **Alias to CloudFront distribution** from the dropdown list.
9. In the search box that says **Choose distribution**, choose the domain name of the CloudFront distribution that you created in Step 4.

   To find the domain name of your CloudFront distribution, do the following:

a. In a new browser tab, sign in to the AWS Management Console and open the CloudFront console at https://console.aws.amazon.com/cloudfront/v3/home.

b. In the left navigation pane, choose **Distributions**.

c. In the **Origins** column, find the correct CloudFront distribution by looking for its origin name, which starts with the S3 bucket that you created in Step 1 (for example, **`tutorial-bucket`**).

d. After finding the distribution in the list, widen the **Domain name** column to see the domain name value for your CloudFront distribution.

10. On the **Create record** page in the Route 53 console, for the remaining settings, keep the defaults.

11. Choose **Create records**.

## Check whether IPv6 is enabled for your distribution and create another DNS record if needed

If IPv6 is enabled for your distribution, you must create another DNS record.

1. To check whether IPv6 is enabled for your distribution, do the following:

   a. Sign in to the AWS Management Console and open the CloudFront console at https://console.aws.amazon.com/cloudfront/v4/home.

   b. In the left navigation pane, choose **Distributions**.

   c. Choose the ID of the CloudFront distribution that you created in Step 4.

   d. On the **General** tab, under **Settings**, check whether **IPv6** is set to **Enabled**.

      If IPv6 is enabled for your distribution, you must create another DNS record.

2. If IPv6 is enabled for your distribution, do the following to create a DNS record:

   a. Sign in to the AWS Management Console and open the Route 53 console at https://console.aws.amazon.com/route53/.

   b. In the left navigation pane, choose **Hosted zones**.

   c. On the **Hosted zones** page, choose the name of the hosted zone that Route 53 created for you in Prerequisites (for example, **`example.com`**).

   d. Choose **Create record**, and then use the **Quick create record** method.

e. For **Record name**, in the text field before your custom domain name, type the same value that you typed when you created the IPv4 DNS record earlier. For example, in this tutorial, to route traffic for the subdomain `www.example.com`, enter only **`www`**.

f. For **Record type**, choose **AAAA - Routes traffic to an IPv6 address and some AWS resources**.

g. For **Value**, choose the **Alias** toggle to enable the alias resource.

h. Under **Route traffic to**, choose **Alias to CloudFront distribution** from the dropdown list.

i. In the search box that says **Choose distribution**, choose the domain name of the CloudFront distribution that you created in Step 4.

j. For the remaining settings, keep the defaults.

k. Choose **Create records**.

## Step 7: Access the S3 video through the CloudFront distribution with the custom domain name

To access the S3 video using the custom URL, you must combine your alternate domain name with the path to the video in the S3 bucket.

**To create a custom URL to access the S3 video through the CloudFront distribution**

1. Sign in to the AWS Management Console and open the CloudFront console at https://console.aws.amazon.com/cloudfront/v4/home.
2. In the left navigation pane, choose **Distributions**.
3. To get the alternate domain name of your CloudFront distribution, do the following:

   a. In the **Origins** column, find the correct CloudFront distribution by looking for its origin name, which starts with the S3 bucket name for the bucket that you created in Step 1 (for example, **`tutorial-bucket`**).

   b. After finding the distribution in the list, widen the **Alternate domain names** column to copy the value of the alternate domain name of your CloudFront distribution.
4. In a new browser tab, paste the alternate domain name of the CloudFront distribution.
5. Return to the previous browser tab, and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
6. Find the path to your S3 video, as explained in Step 5.

7. Return to the browser tab where you previously pasted the alternate domain name, enter a forward slash (**/**), and then paste the path to your S3 video (for example, `sample.mp4`).

   Now, your S3 video is publicly accessible and hosted through CloudFront at a custom URL that looks similar to the following:

   ```
   https://CloudFront distribution alternate domain name/Path to the S3 video
   ```

   Replace *CloudFront distribution alternate domain name* and *Path to the S3 video* with the appropriate values. An example URL is **https://www.example.com/sample.mp4**.

## (Optional) Step 8: View data about requests received by your CloudFront distribution

**To view data about requests received by your CloudFront distribution**

1. Sign in to the AWS Management Console and open the CloudFront console at https://console.aws.amazon.com/cloudfront/v4/home.
2. In the left navigation pane, under **Reports & analytics**, choose the reports from the console, ranging from **Cache statistics**, **Popular Objects**, **Top Referrers**, **Usage**, and **Viewers**.

   You can filter each report dashboard. For more information, see CloudFront Reports in the Console in the *Amazon CloudFront Developer Guide*.
3. To filter data, choose the ID of the CloudFront distribution that you created in Step 4.

## Step 9: Clean up

If you hosted an S3 streaming video using CloudFront and Route 53 only as a learning exercise, delete the AWS resources that you allocated so that you no longer accrue charges.

> **Note**
>
> When you register a domain, it costs money immediately and it's irreversible. You can choose not to auto-renew the domain, but you pay up front and own it for the year. For more information, see Registering a new domain in the *Amazon Route 53 Developer Guide*.

**Substeps**

- Delete the CloudFront distribution
- Delete the DNS record
- Delete the public hosted zone for your custom domain
- Delete the custom domain name from Route 53
- Delete the original video in the S3 source bucket
- Delete the S3 source bucket

## Delete the CloudFront distribution

1. Sign in to the AWS Management Console and open the CloudFront console at https://console.aws.amazon.com/cloudfront/v4/home.
2. In the left navigation pane, choose **Distributions**.
3. In the **Origins** column, find the correct CloudFront distribution by looking for its origin name, which starts with the S3 bucket name for the bucket that you created in Step 1 (for example, **`tutorial-bucket`**).
4. To delete the CloudFront distribution, you must disable it first.
   - If the value of the **Status** column is **Enabled** and the value of **Last modified** is the timestamp when the distribution was last modified, continue to disable the distribution before deleting it.
   - If the value of **Status** is **Enabled** and the value of **Last modified** is **Deploying**, wait until the value of **Status** changes to the timestamp when the distribution was last modified. Then continue to disable the distribution before deleting it.
5. To disable the CloudFront distribution, do the following:
   a. In the **Distributions** list, select the check box next to the ID for the distribution that you want to delete.
   b. To disable the distribution, choose **Disable**, and then choose **Disable** to confirm.

      If you disable a distribution that has an alternate domain name associated with it, CloudFront stops accepting traffic for that domain name (such as `www.example.com`), even if another distribution has an alternate domain name with a wildcard (`*`) that matches the same domain (such as `*.example.com`).

c. The value of **Status** immediately changes to **Disabled**. Wait until the value of **Last modified** changes from **Deploying** to the timestamp when the distribution was last modified.

   Because CloudFront must propagate this change to all edge locations, it might take a few minutes before the update is complete and the **Delete** option is available for you to delete the distribution.

6. To delete the disabled distribution, do the following:

   a. Choose the check box next to the ID for the distribution that you want to delete.

   b. Choose **Delete**, and then choose **Delete** to confirm.

## Delete the DNS record

If you want to delete the public hosted zone for the domain (including the DNS record), see Delete the public hosted zone for your custom domain in the *Amazon Route 53 Developer Guide*. If you only want to delete the DNS record created in Step 6, do the following:

1. Sign in to the AWS Management Console and open the Route 53 console at https://console.aws.amazon.com/route53/.
2. In the left navigation pane, choose **Hosted zones**.
3. On the **Hosted zones** page, choose the name of the hosted zone that Route 53 created for you in Prerequisites (for example, **`example.com`**).
4. In the list of records, select the check box next to the records that you want to delete (the records that you created in Step 6).

   > **Note**
   >
   > You can't delete records that have a **Type** value of **NS** or **SOA**.

5. Choose **Delete records**.
6. To confirm the deletion, choose **Delete**.

   Changes to records take time to propagate to the Route 53 DNS servers. Currently, the only way to verify that your changes have propagated is to use the GetChange API action. Changes usually propagate to all Route 53 name servers within 60 seconds.

## Delete the public hosted zone for your custom domain

**Warning**

If you want to keep your domain registration but stop routing internet traffic to your website or web application, we recommend that you delete records in the hosted zone (as described in the prior section) instead of deleting the hosted zone.
If you delete a hosted zone, someone else can use the domain and route traffic to their own resources using your domain name.
In addition, if you delete a hosted zone, you can't undelete it. You must create a new hosted zone and update the name servers for your domain registration, which can take up to 48 hours to take effect.
If you want to make the domain unavailable on the internet, you can first transfer your DNS service to a free DNS service and then delete the Route 53 hosted zone. This prevents future DNS queries from possibly being misrouted.

1. If the domain is registered with Route 53, see Adding or changing name servers and glue records for a domain in the *Amazon Route 53 Developer Guide* for information about how to replace Route 53 name servers with name servers for the new DNS service.
2. If the domain is registered with another registrar, use the method provided by the registrar to change name servers for the domain.

**Note**

If you're deleting a hosted zone for a subdomain (`www.example.com`), you don't need to change name servers for the domain (`example.com`).

1. Sign in to the AWS Management Console and open the Route 53 console at https://console.aws.amazon.com/route53/.
2. In the left navigation pane, choose **Hosted zones**.
3. On the **Hosted zones** page, choose the name of the hosted zone that you want to delete.
4. On the **Records** tab for your hosted zone, confirm that the hosted zone that you want to delete contains only an **NS** and an **SOA** record.

   If it contains additional records, delete them first.

If you created any NS records for subdomains in the hosted zone, delete those records too.

5. On the **DNSSEC signing** tab for your hosted zone, disable DNNSSEC signing if it was enabled. For more information, see Disabling DNSSEC signing in the *Amazon Route 53 Developer Guide*.
6. At the top of the details page of the hosted zone, choose **Delete zone**.
7. To confirm the deletion, enter **`delete`**, and then choose **Delete**.

## Delete the custom domain name from Route 53

For most top-level domains (TLDs), you can delete the registration if you no longer want it. If you delete a domain name registration from Route 53 before the registration is scheduled to expire, AWS does not refund the registration fee. For more information, see Deleting a domain name registration in the *Amazon Route 53 Developer Guide*.

> **Important**
>
> If you want to transfer the domain between AWS accounts or transfer the domain to another registrar, don't delete the domain and expect to immediately reregister it. Instead, see the applicable documentation in the *Amazon Route 53 Developer Guide*:
>
> - Transferring a domain to a different AWS account
> - Transferring a domain from Amazon Route 53 to another registrar

## Delete the original video in the S3 source bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Buckets**.
3. In the **Bucket name** list, choose the name of the bucket that you uploaded the video to in Step 2 (for example, **`tutorial-bucket`**).
4. On the **Objects** tab, select the check box next to the name of the object that you want to delete (for example, `sample.mp4`).
5. Choose **Delete**.
6. Under **Permanently delete objects?**, enter **`permanently delete`** to confirm that you want to delete this object.

7. Choose **Delete objects**.

### Delete the S3 source bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Buckets**.
3. In the **Buckets** list, select the option button next to the name of the bucket that you created in Step 1 (for example, **`tutorial-bucket`**).
4. Choose **Delete**.
5. On the **Delete bucket** page, confirm that you want to delete the bucket by entering the bucket name in the text field, and then choose **Delete bucket**.

## Next steps

After you complete this tutorial, you can further explore the following related use cases:

- Transcode S3 videos into streaming formats needed by a particular television or connected device before hosting these videos with a CloudFront distribution.

  To use Amazon S3 Batch Operations, AWS Lambda and AWS Elemental MediaConvert to batch-transcode a collection of videos to a variety of output media formats, see Tutorial: Batch-transcoding videos with S3 Batch Operations, AWS Lambda, and AWS Elemental MediaConvert.
- Host other objects stored in S3, such as images, audio, motion graphics, style sheets, HTML, JavaScript, React apps, and so on, using CloudFront and Route 53.

  For example, see Tutorial: Configuring a static website using a custom domain registered with Route 53 and Speeding up your website with Amazon CloudFront.
- Use Amazon S3 Transfer Acceleration to configure fast and secure file transfers. Transfer Acceleration can speed up video uploading to your S3 bucket for long-distance transfer of larger videos. Transfer Acceleration improves transfer performance by routing traffic through the CloudFront globally distributed edge locations and over the AWS backbone networks. It also uses network protocol optimizations. For more information, see Configuring fast, secure file transfers using Amazon S3 Transfer Acceleration.

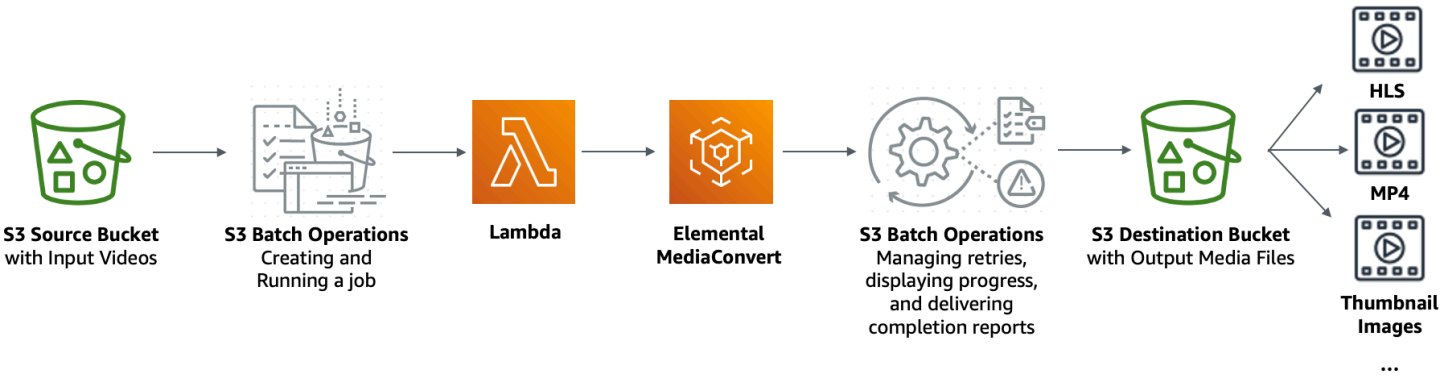
# Tutorial: Batch-transcoding videos with S3 Batch Operations, AWS Lambda, and AWS Elemental MediaConvert

Video consumers use devices of all shapes, sizes, and vintages to enjoy media content. This wide array of devices presents a challenge for content creators and distributors. Instead of being in a one-size-fits-all format, videos must be converted so that they can span a broad range of sizes, formats, and bitrates. This conversion task is even more challenging when you have a large number of videos that must be converted.

AWS offers you a method to build a scalable, distributed architecture that does the following:

- Ingests input videos
- Processes the videos for playback on a wide range of devices
- Stores the transcoded media files
- Delivers the output media files to meet demand

When you have extensive video repositories stored in Amazon S3, you can transcode these videos from their source formats into multiple file types in the size, resolution, and format needed by a particular video player or device. Specifically, S3 Batch Operations provides you with a solution to invoke AWS Lambda functions for existing input videos in an S3 source bucket. Then, the Lambda functions call AWS Elemental MediaConvert to perform large-scale video transcoding tasks. The converted output media files are stored in an S3 destination bucket.



## Objective

In this tutorial, you learn how to set up S3 Batch Operations to invoke a Lambda function for batch-transcoding of videos stored in an S3 source bucket. The Lambda function calls

MediaConvert to transcode the videos. The outputs for each video in the S3 source bucket are as follows:

- An HTTP Live Streaming (HLS) adaptive bitrate stream for playback on devices of multiple sizes and varying bandwidths
- An MP4 video file
- Thumbnail images collected at intervals

**Topics**

## Prerequisites

Before you start this tutorial, you must have an Amazon S3 source bucket (for example, **`tutorial-bucket-1`**) with videos to be transcoded already stored in it.

You can give the bucket another name if you want. For more information about bucket names in Amazon S3, see Bucket naming rules.

For the S3 source bucket, keep the settings related to **Block Public Access settings for this bucket** set to the defaults (**Block *all* public access** is enabled). For more information, see Creating a bucket.

For more information about uploading videos to the S3 source bucket, see Uploading objects. If you're uploading many large video files to S3, you might want to use Amazon S3 Transfer

Acceleration to configure fast and secure file transfers. Transfer Acceleration can speed up video uploading to your S3 bucket for long-distance transfer of larger videos. For more information, see Configuring fast, secure file transfers using Amazon S3 Transfer Acceleration.

## Step 1: Create an S3 bucket for the output media files

In this step, you create an S3 destination bucket to store the converted output media files. You also create a Cross Origin Resource Sharing (CORS) configuration to allow cross-origin access to the transcoded media files stored in your S3 destination bucket.

**Substeps**

- Create a bucket for the output media files
- Add a CORS configuration to the S3 output bucket

### Create a bucket for the output media files

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Buckets**.
3. Choose **Create bucket**.
4. For **Bucket name**, enter a name for your bucket (for example, **`tutorial-bucket-2`**).
5. For **Region**, choose the AWS Region where you want the bucket to reside.
6. To ensure public access to your output media files, in **Block Public Access settings for this bucket**, clear **Block *all* public access**.

> **Warning**
>
> Before you complete this step, review Blocking public access to your Amazon S3 storage to ensure that you understand and accept the risks involved with allowing public access. When you turn off Block Public Access settings to make your bucket public, anyone on the internet can access your bucket. We recommend that you block all public access to your buckets.
> If you don't want to clear the Block Public Access settings, you can use Amazon CloudFront to deliver the transcoded media files to viewers (end users). For more

information, see Tutorial: Hosting on-demand streaming video with Amazon S3, Amazon CloudFront, and Amazon Route 53.

7. Select the check box next to **I acknowledge that the current settings might result in this bucket and the objects within becoming public.**
8. Keep the remaining settings set to the defaults.
9. Choose **Create bucket**.

## Add a CORS configuration to the S3 output bucket

A JSON CORS configuration defines a way for client web applications (video players in this context) that are loaded in one domain to play transcoded output media files in a different domain.

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Buckets**.
3. In the **Buckets** list, choose the name of the bucket that you created earlier (for example, **`tutorial-bucket-2`**).
4. Choose the **Permissions** tab.
5. In the **Cross-origin resource sharing (CORS)** section, choose **Edit**.
6. In the CORS configuration text box, copy and paste the following CORS configuration.

   The CORS configuration must be in JSON format. In this example, the `AllowedOrigins` attribute uses the wildcard character (*) to specify all origins. If you know your specific origin, you can restrict the `AllowedOrigins` attribute to your specific player URL. For more information about configuring this and other attributes, see Elements of a CORS configuration.

```
[
    {
        "AllowedOrigins": [
            "*"
        ],
        "AllowedMethods": [
            "GET"
        ],
        "AllowedHeaders": [
            "*"
```

```
        ],
        "ExposeHeaders": []

    }
]
```

7. Choose **Save changes**.

## Step 2: Create an IAM role for MediaConvert

To use AWS Elemental MediaConvert to transcode input videos stored in your S3 bucket, you must have an AWS Identity and Access Management (IAM) service role to grant MediaConvert permissions to read and write video files from and to your S3 source and destination buckets. When you run transcoding jobs, the MediaConvert console uses this role.

**To create an IAM role for MediaConvert**

1. Create an IAM role with a role name that you choose (for example, **`tutorial-mediaconvert-role`**). To create this role, follow the steps in Create your MediaConvert role in IAM (console) in the *AWS Elemental MediaConvert User Guide*.
2. After you create the IAM role for MediaConvert, in the list of **Roles**, choose the name of the role for MediaConvert that you created (for example, **`tutorial-mediaconvert-role`**).
3. On the **Summary** page, copy the **Role ARN** (which starts with `arn:aws:iam::`), and save the ARN for use later.

   For more information about ARNs, see Amazon Resource Names (ARNs) in the *AWS General Reference*.

## Step 3: Create an IAM role for your Lambda function

To batch-transcode videos with MediaConvert and S3 Batch Operations, you use a Lambda function to connect these two services to convert videos. This Lambda function must have an IAM role that grants the Lambda function permissions to access MediaConvert and S3 Batch Operations.

**Substeps**

- Create an IAM role for your Lambda function
- Embed an inline policy for the IAM role of your Lambda function

## Create an IAM role for your Lambda function

1. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.
2. In the left navigation pane, choose **Roles**, and then choose **Create role**.
3. Choose the **AWS service** role type, and then under **Common use cases**, choose **Lambda**.
4. Choose **Next: Permissions**.
5. On the **Attach permissions policies** page, enter **`AWSLambdaBasicExecutionRole`** in the **Filter policies** box. To attach the managed policy **AWSLambdaBasicExecutionRole** to this role to grant write permissions to Amazon CloudWatch Logs, select the check box next to **AWSLambdaBasicExecutionRole**.
6. Choose **Next: Tags**.
7. (Optional) Add tags to the managed policy.
8. Choose **Next: Review**.
9. For **Role name**, enter **`tutorial-lambda-transcode-role`**.
10. Choose **Create role**.

## Embed an inline policy for the IAM role of your Lambda function

To grant permissions to the MediaConvert resource that's needed for the Lambda function to execute, you must use an inline policy.

1. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.
2. In the left navigation pane, choose **Roles**.
3. In the **Roles** list, choose the name of the IAM role that you created earlier for your Lambda function (for example, **`tutorial-lambda-transcode-role`**).
4. Choose the **Permissions** tab.
5. Choose **Add inline policy**.
6. Choose the **JSON** tab, and then copy and paste the following JSON policy.

   In the JSON policy, replace the example ARN value of `Resource` with the role ARN of the IAM role for MediaConvert that you created in Step 2 (for example, **`tutorial-mediaconvert-role`**).

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Action": [
                "logs:CreateLogGroup",
                "logs:CreateLogStream",
                "logs:PutLogEvents"
            ],
            "Resource": "*",
            "Effect": "Allow",
            "Sid": "Logging"
        },
        {
            "Action": [
                "iam:PassRole"
            ],
            "Resource": [
                "arn:aws:iam::111122223333:role/tutorial-mediaconvert-role"
            ],
            "Effect": "Allow",
            "Sid": "PassRole"
        },
        {
            "Action": [
                "mediaconvert:*"
            ],
            "Resource": [
                "*"
            ],
            "Effect": "Allow",
            "Sid": "MediaConvertService"
        },
        {
            "Action": [
                "s3:*"
            ],
            "Resource": [
                "*"
            ],
            "Effect": "Allow",
            "Sid": "S3Service"
        }
```

```
    ]
}
```

7. Choose **Review Policy**.
8. For **Name**, enter **`tutorial-lambda-policy`**.
9. Choose **Create Policy**.

   After you create an inline policy, it is automatically embedded in the IAM role of your Lambda function.

## Step 4: Create a Lambda function for video transcoding

In this section of the tutorial, you build a Lambda function using the SDK for Python to integrate with S3 Batch Operations and MediaConvert. To start transcoding the videos already stored in your S3 source bucket, you run an S3 Batch Operations job that directly invokes the Lambda function for each video in the S3 source bucket. Then, the Lambda function submits a transcoding job for each video to MediaConvert.

**Substeps**

- Write Lambda function code and create a deployment package
- Create a Lambda function with an execution role (console)
- Deploy your Lambda function with .zip file archives and configure the Lambda function (console)

### Write Lambda function code and create a deployment package

1. On your local machine, create a folder named `batch-transcode`.
2. In the `batch-transcode` folder, create a file with JSON job settings. For example, you can use the settings provided in this section, and name the file `job.json`.

   A `job.json` file specifies the following:

   - Which files to transcode
   - How you want to transcode your input videos
   - What output media files you want to create
   - What to name the transcoded files
   - Where to save the transcoded files

- Which advanced features to apply, and so on

In this tutorial, we use the following `job.json` file to create the following outputs for each video in the S3 source bucket:

- An HTTP Live Streaming (HLS) adaptive bitrate stream for playback on multiple devices of differing sizes and varying bandwidths
- An MP4 video file
- Thumbnail images collected at intervals

This example `job.json` file uses Quality-Defined Variable Bitrate (QVBR) to optimize video quality. The HLS output is Apple-compliant (audio unmixed from video, segment duration of 6 seconds, and optimized video quality through auto QVBR).

If you don't want to use the example settings provided here, you can generate a `job.json` specification based on your use case. To ensure consistency across your outputs, make sure that your input files have similar video and audio configurations. For any input files with different video and audio configurations, create separate automations (unique `job.json` settings). For more information, see Example AWS Elemental MediaConvert job settings in JSON in the *AWS Elemental MediaConvert User Guide*.

```

3. In the `batch-transcode` folder, create a file with a Lambda function. You can use the following Python example and name the file `convert.py`.

   S3 Batch Operations sends specific task data to a Lambda function and requires result data back. For request and response examples for the Lambda function, information about response and result codes, and example Lambda functions for S3 Batch Operations, see Invoke AWS Lambda function.

```
import json
import os
from urllib.parse import urlparse
import uuid
import boto3

"""
When you run an S3 Batch Operations job, your job
invokes this Lambda function. Specifically, the Lambda function is
invoked on each video object listed in the manifest that you specify
```

```
for the S3 Batch Operations job in Step 5.

Input parameter "event": The S3 Batch Operations event as a request
                         for the Lambda function.

Input parameter "context": Context about the event.

Output: A result structure that Amazon S3 uses to interpret the result
        of the operation. It is a job response returned back to S3 Batch
 Operations.
"""
def handler(event, context):

    invocation_schema_version = event['invocationSchemaVersion']
    invocation_id = event['invocationId']
    task_id = event['tasks'][0]['taskId']

    source_s3_key = event['tasks'][0]['s3Key']
    source_s3_bucket = event['tasks'][0]['s3BucketArn'].split(':::')[-1]
    source_s3 = 's3://' + source_s3_bucket + '/' + source_s3_key

    result_list = []
    result_code = 'Succeeded'
    result_string = 'The input video object was converted successfully.'

    # The type of output group determines which media players can play
    # the files transcoded by MediaConvert.
    # For more information, see Creating outputs with AWS Elemental MediaConvert.
    output_group_type_dict = {
        'HLS_GROUP_SETTINGS': 'HlsGroupSettings',
        'FILE_GROUP_SETTINGS': 'FileGroupSettings',
        'CMAF_GROUP_SETTINGS': 'CmafGroupSettings',
        'DASH_ISO_GROUP_SETTINGS': 'DashIsoGroupSettings',
        'MS_SMOOTH_GROUP_SETTINGS': 'MsSmoothGroupSettings'
    }

    try:
        job_name = 'Default'
        with open('job.json') as file:
            job_settings = json.load(file)

        job_settings['Inputs'][0]['FileInput'] = source_s3

        # The path of each output video is constructed based on the values of
```

```
        # the attributes in each object of OutputGroups in the job.json file.
        destination_s3 = 's3://{0}/{1}/{2}' \
            .format(os.environ['DestinationBucket'],
                    os.path.splitext(os.path.basename(source_s3_key))[0],
                    os.path.splitext(os.path.basename(job_name))[0])

            'settings': job_name
        }

        region = os.environ['AWS_DEFAULT_REGION']
        endpoints = boto3.client('mediaconvert', region_name=region) \
            .describe_endpoints()
        client = boto3.client('mediaconvert', region_name=region,
                              endpoint_url=endpoints['Endpoints'][0]['Url'],
                              verify=False)

        try:
            client.create_job(Role=os.environ['MediaConvertRole'],
                              UserMetadata=job_metadata_dict,
                              Settings=job_settings)
        # You can customize error handling based on different error codes that
        # MediaConvert can return.
        # For more information, see MediaConvert error codes.
        # When the result_code is TemporaryFailure, S3 Batch Operations retries
        # the task before the job is completed. If this is the final retry,
        # the error message is included in the final report.
        except Exception as error:
```

```
            result_code = 'TemporaryFailure'
            raise

    except Exception as error:
        if result_code != 'TemporaryFailure':
            result_code = 'PermanentFailure'
        result_string = str(error)

    finally:
        result_list.append({
            'taskId': task_id,
            'resultCode': result_code,
            'resultString': result_string,
        })

    return {
        'invocationSchemaVersion': invocation_schema_version,
        'treatMissingKeyAs': 'PermanentFailure',
        'invocationId': invocation_id,
        'results': result_list
    }
```

4. To create a deployment package with `convert.py` and `job.json` as a `.zip` file named `lambda.zip`, in your local terminal, open the `batch-transcode` folder that you created earlier, and run the following command.

   For **macOS users**, run the following command:

   ```
   zip -r lambda.zip convert.py job.json
   ```

   For **Windows users**, run the following commands:

   ```
   powershell Compress-Archive convert.py lambda.zip
   ```

   ```
   powershell Compress-Archive -update job.json lambda.zip
   ```

## Create a Lambda function with an execution role (console)

1. Open the AWS Lambda console at https://console.aws.amazon.com/lambda/.

2. In the left navigation pane, choose **Functions**.
3. Choose **Create function**.
4. Choose **Author from scratch**.
5. Under **Basic information**, do the following:

   a. For **Function name**, enter **`tutorial-lambda-convert`**.

   b. For **Runtime**, choose **Python 3.8** or a later version of Python.
6. Choose **Change default execution role**, and under **Execution role**, choose **Use an existing role**.
7. Under **Existing role**, choose the name of the IAM role that you created for your Lambda function in Step 3 (for example, **`tutorial-lambda-transcode-role`**).
8. For the remaining settings, keep the defaults.
9. Choose **Create function**.

## Deploy your Lambda function with .zip file archives and configure the Lambda function (console)

1. In the **Code Source** section of the page for the Lambda function that you created (for example, **`tutorial-lambda-convert`**), choose **Upload from** and then **.zip file**.
2. Choose **Upload** to select your local `.zip` file.
3. Choose the `lambda.zip` file that you created earlier, and choose **Open**.
4. Choose **Save**.
5. In the **Runtime settings** section, choose **Edit**.
6. To tell the Lambda runtime which handler method in your Lambda function code to invoke, enter **`convert.handler`** in the **Handler** field.

   When you configure a function in Python, the value of the handler setting is the file name and the name of the handler module, separated by a dot (`.`). For example, `convert.handler` calls the `handler` method defined in the `convert.py` file.
7. Choose **Save**.
8. On your Lambda function page, choose the **Configuration** tab. In the left navigation pane on the **Configuration** tab, choose **Environment variables**, and then choose **Edit**.
9. Choose **Add environment variable**. Then, enter the specified **Key** and **Value** for each of the following environment variables:

- **Key**: **`DestinationBucket`** **Value**: **`tutorial-bucket-2`**

  This value is the S3 bucket for output media files that you created in Step 1.

- **Key**: **`MediaConvertRole`** **Value**: **`arn:aws:iam::`*`111122223333`*`:role/tutorial-mediaconvert-role`**

  This value is the ARN of the IAM role for MediaConvert that you created in Step 2. Make sure to replace this ARN with the actual ARN of your IAM role.

- **Key**: **`Application`** **Value**: **`Batch-Transcoding`**

  This value is the name of the application.

10. Choose **Save**.
11. (Optional) On the **Configuration** tab, in the **General configuration** section of the left navigation pane, choose **Edit**. In the **Timeout** field, enter **2** min **0** sec. Then, choose **Save**.

    **Timeout** is the amount of time that Lambda allows a function to run for an invocation before stopping it. The default is 3 seconds. Pricing is based on the amount of memory configured and the amount of time that your code runs. For more information, see AWS Lambda pricing.

## Step 5: Configure Amazon S3 Inventory for your S3 source bucket

After setting up the transcoding Lambda function, create an S3 Batch Operations job to transcode a set of videos. First, you need a list of input video objects that you want S3 Batch Operations to run the specified transcoding action on. To get a list of input video objects, you can generate an S3 Inventory report for your S3 source bucket (for example, **`tutorial-bucket-1`**).

**Substeps**

- Create and configure a bucket for S3 Inventory reports for input videos
- Configure Amazon S3 Inventory for your S3 video source bucket
- Check the inventory report for your S3 video source bucket

### Create and configure a bucket for S3 Inventory reports for input videos

To store an S3 Inventory report that lists the objects of the S3 source bucket, create an S3 Inventory destination bucket, and then configure a bucket policy for the bucket to write inventory files to the S3 source bucket.

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Buckets**.
3. Choose **Create bucket**.
4. For **Bucket name**, enter a name for your bucket (for example, **`tutorial-bucket-3`**).
5. For **AWS Region**, choose the AWS Region where you want the bucket to reside.

   The inventory destination bucket must be in the same AWS Region as the source bucket where you are setting up S3 Inventory. The inventory destination bucket can be in a different AWS account.
6. In **Block Public Access settings for this bucket**, keep the default settings (**Block *all* public access** is enabled).
7. For the remaining settings, keep the defaults.
8. Choose **Create bucket**.
9. In the **Buckets** list, choose the name of the bucket that you just created (for example, **`tutorial-bucket-3`**).
10. To grant Amazon S3 permission to write data for the inventory reports to the S3 Inventory destination bucket, choose the **Permissions** tab.
11. Scroll down to the **Bucket policy** section, and choose **Edit**. The **Bucket policy** page opens.
12. To grant permissions for S3 Inventory, in the **Policy** field, paste the following bucket policy.

    Replace the three example values with the following values:

    - The name of the bucket that you created to store the inventory reports (for example, *`tutorial-bucket-3`*).
    - The name of the source bucket that stores the input videos (for example, *`tutorial-bucket-1`*).
    - The AWS account ID that you used to create the S3 video source bucket (for example, *`111122223333`*.

```
{
  "Version":"2012-10-17",
  "Statement":[
    {
```

```
      "Sid":"InventoryAndAnalyticsExamplePolicy",
      "Effect":"Allow",
      "Principal": {"Service": "s3.amazonaws.com"},
      "Action":"s3:PutObject",
      "Resource":["arn:aws:s3:::tutorial-bucket-3/*"],
      "Condition": {
          "ArnLike": {
              "aws:SourceArn": "arn:aws:s3:::tutorial-bucket-1"
           },
         "StringEquals": {
             "aws:SourceAccount": "111122223333",
             "s3:x-amz-acl": "bucket-owner-full-control"
          }
       }
    }
  ]
}
```

13. Choose **Save changes**.

## Configure Amazon S3 Inventory for your S3 video source bucket

To generate a flat file list of video objects and metadata, you must configure S3 Inventory for your S3 video source bucket. These scheduled inventory reports can include all the objects in the bucket or objects grouped by a shared prefix. In this tutorial, the S3 Inventory report includes all the video objects in your S3 source bucket.

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Buckets**.
3. To configure an S3 Inventory report of the input videos in your S3 source bucket, in the **Buckets** list, choose the name of the S3 source bucket (for example, **`tutorial-bucket-1`**).
4. Choose the **Management** tab.
5. Scroll down to the **Inventory configurations** section, and choose **Create inventory configuration**.
6. For **Inventory configuration name**, enter a name (for example, **`tutorial-inventory-config`**).
7. Under **Inventory scope**, choose **Current version only** for **Object versions** and keep the other **Inventory scope** settings set to the defaults for this tutorial.

8. In the **Report details** section, for **Destination bucket**, choose **This account**.
9. For **Destination**, choose **Browse S3**, and choose the destination bucket that you created earlier to save the inventory reports to (for example, **`tutorial-bucket-3`**). Then choose **Choose path**.

   The inventory destination bucket must be in the same AWS Region as the source bucket where you are setting up S3 Inventory. The inventory destination bucket can be in a different AWS account.

   Under the **Destination** bucket field, the **Destination bucket permission** is added to the inventory destination bucket policy, allowing Amazon S3 to place data in the inventory destination bucket. For more information, see Creating a destination bucket policy.
10. For **Frequency**, choose **Daily**.
11. For **Output format**, choose **CSV**.
12. For **Status**, choose **Enable**.
13. In the **Server-side encryption** section, choose **Disable** for this tutorial.

    For more information, see Configuring inventory by using the S3 console and Granting Amazon S3 permission to use your customer managed key for encryption.
14. In the **Additional fields - *optional*** section, select **Size**, **Last modified**, and **Storage class**.
15. Choose **Create**.

For more information, see Configuring inventory by using the S3 console.

## Check the inventory report for your S3 video source bucket

When an inventory report is published, the manifest files are sent to the S3 Inventory destination bucket.

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Buckets**.
3. In the **Buckets** list, choose the name of the video source bucket (for example, **`tutorial-bucket-1`**).
4. Choose **Management**.

5. To see if your S3 Inventory report is ready so that you can create an S3 Batch Operations job in Step 7, under **Inventory configurations**, check whether the **Create job from manifest** button is enabled.

   > **Note**
   >
   > It can take up to 48 hours to deliver the first inventory report. If the **Create job from manifest** button is disabled, the first inventory report has not been delivered. Wait until the first inventory report is delivered and the **Create job from manifest** button is enabled before you create an S3 Batch Operations job in Step 7.

6. To check an S3 Inventory report (`manifest.json`), in the **Destination** column, choose the name of the inventory destination bucket that you created earlier for storing inventory reports (for example, **`tutorial-bucket-3`**).
7. On the **Objects** tab, choose the existing folder with the name of your S3 source bucket (for example, **`tutorial-bucket-1`**). Then choose the name that you entered in **Inventory configuration name** when you created the inventory configuration earlier (for example, **`tutorial-inventory-config`**).

   You can see a list of folders with the generation dates of the reports as their names.
8. To check the daily S3 Inventory report for a particular date, choose the folder with the corresponding generation date name, and then choose `manifest.json`.
9. To check the details of the inventory report on a specific date, on the **manifest.json** page, choose **Download** or **Open**.

## Step 6: Create an IAM role for S3 Batch Operations

To use S3 Batch Operations to do batch-transcoding, you must first create an IAM role to give Amazon S3 permissions to perform S3 Batch Operations.

### Substeps

- Create an IAM policy for S3 Batch Operations
- Create an S3 Batch Operations IAM role and attach permissions policies

## Create an IAM policy for S3 Batch Operations

You must create an IAM policy that gives S3 Batch Operations permission to read the input manifest, invoke the Lambda function, and write the S3 Batch Operations job completion report.

1. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.
2. In the left navigation pane, choose **Policies**.
3. Choose **Create policy**.
4. Choose the **JSON** tab.
5. In the **JSON** text field, paste the following JSON policy.

   In the JSON policy, replace the four example values with the following values:

   - The name of the source bucket that stores your input videos (for example, *tutorial-bucket-1*).
   - The name of the inventory destination bucket that you created in Step 5 to store `manifest.json` files (for example, *tutorial-bucket-3*).
   - The name of the bucket that you created in Step 1 to store output media files (for example, *tutorial-bucket-2*). In this tutorial, we put job completion reports in the destination bucket for output media files.
   - The role ARN of the Lambda function that you created in Step 4. To find and copy the role ARN of the Lambda function, do the following:
     - In a new browser tab, open the **Functions** page on the Lambda console at https://console.aws.amazon.com/lambda/home#/functions.
     - In **Functions** list, choose the name of the Lambda function that you created in Step 4 (for example, **`tutorial-lambda-convert`**).
     - Choose **Copy ARN**.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "S3Get",
            "Effect": "Allow",
            "Action": [
```

```
                "s3:GetObject",
                "s3:GetObjectVersion"
            ],
            "Resource": [
                "arn:aws:s3:::tutorial-bucket-1/*",
                "arn:aws:s3:::tutorial-bucket-3/*"
            ]
        },
        {
            "Sid": "S3PutJobCompletionReport",
            "Effect": "Allow",
            "Action": "s3:PutObject",
            "Resource": "arn:aws:s3:::tutorial-bucket-2/*"
        },
        {
            "Sid": "S3BatchOperationsInvokeLambda",
            "Effect": "Allow",
            "Action": [
                "lambda:InvokeFunction"
            ],
            "Resource": [
                "arn:aws:lambda:us-west-2:111122223333:function:tutorial-lambda-
convert"
            ]
        }
    ]
}
```

6. Choose **Next: Tags**.
7. Choose **Next: Review**.
8. In the **Name** field, enter **`tutorial-s3batch-policy`**.
9. Choose **Create policy**.

## Create an S3 Batch Operations IAM role and attach permissions policies

1. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.
2. In the left navigation pane, choose **Roles**, and then choose **Create role**.
3. Choose the **AWS service** role type, and then choose the **S3** service.
4. Under **Select your use case**, choose **S3 Batch Operations**.

5. Choose **Next: Permissions**.
6. Under **Attach permissions policies**, enter the name of the IAM policy that you created earlier (for example, **`tutorial-s3batch-policy`**) in the search box to filter the list of policies. Select the check box next to the name of the policy (for example, **`tutorial-s3batch-policy`**).
7. Choose **Next: Tags**.
8. Choose **Next: Review**.
9. For **Role name**, enter **`tutorial-s3batch-role`**.
10. Choose **Create role**.

    After you create the IAM role for S3 Batch Operations, the following trust policy is automatically attached to the role. This trust policy allows the S3 Batch Operations service principal to assume the IAM role.

```
{
   "Version":"2012-10-17",
   "Statement":[
      {
         "Effect":"Allow",
         "Principal":{
            "Service":"batchoperations.s3.amazonaws.com"
         },
         "Action":"sts:AssumeRole"
      }
   ]
}
```

## Step 7: Create and run an S3 Batch Operations job

To create an S3 Batch Operations job to process the input videos in your S3 source bucket, you must specify parameters for this particular job.

> **Note**
>
> Before you start creating an S3 Batch Operations job, make sure that the **Create job from manifest** button is enabled. For more information, see Check the inventory report for your S3 video source bucket. If the **Create job from manifest** button is disabled, the first inventory report has not been delivered and you must wait until the button is enabled.

After you configure Amazon S3 Inventory for your S3 source bucket in Step 5, it can take up to 48 hours to deliver the first inventory report.

**Substeps**

- Create an S3 Batch Operations job
- Run the S3 Batch Operations job to invoke your Lambda function
- (Optional) Check your completion report
- (Optional) Monitor each Lambda invocation in the Lambda console
- (Optional) Monitor each MediaConvert video-transcoding job in the MediaConvert console

## Create an S3 Batch Operations job

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Batch Operations**.
3. Choose **Create job**.
4. For **AWS Region**, choose the Region where you want to create your job.

   In this tutorial, to use the S3 Batch Operations job to invoke a Lambda function, you must create the job in the same Region as the S3 video source bucket where the objects referenced in the manifest are located.
5. In the **Manifest** section, do the following:

   a. For **Manifest format**, choose **S3 Inventory report (manifest.json)**.

   b. For **Manifest object**, choose **Browse S3** to find the bucket that you created in Step 5 for storing inventory reports (for example, **`tutorial-bucket-3`**). On the **Manifest object** page, navigate through the object names until you find a `manifest.json` file for a specific date. This file lists the information about all the videos that you want to batch-transcode. When you've found the `manifest.json` file that you want to use, choose the option button next to it. Then choose **Choose path**.

   c. (Optional) For **Manifest object version ID - *optional***, enter the version ID for the manifest object if you want to use a version other than the most recent.
6. Choose **Next**.

7. To use the Lambda function to transcode all the objects listed in the selected `manifest.json` file, under **Operation type**, choose **Invoke AWS Lambda function**.
8. In the **Invoke Lambda function** section, do the following:
   a. Choose **Choose from functions in your account**.
   b. For **Lambda function**, choose the Lambda function that you created in Step 4 (for example, **`tutorial-lambda-convert`**).
   c. For **Lambda function version**, keep the default value **$LATEST**.
9. Choose **Next**. The **Configure additional options** page opens.
10. In the **Additional options** section, keep the default settings.

    For more information about these options, see Batch Operations job request elements.
11. In the **Completion report** section, for **Path to completion report destination**, choose **Browse S3**. Find the bucket that you created for output media files in Step 1 (for example, **`tutorial-bucket-2`**). Choose the option button next to that bucket's name. Then choose **Choose path**.

    For the remaining **Completion report** settings, keep the defaults. For more information about completion report settings, see Batch Operations job request elements. A completion report maintains a record of the job's details and the operations performed.
12. In the **Permissions** section, choose **Choose from existing IAM roles**. For **IAM role**, choose the IAM role for your S3 Batch Operations job that you created in Step 6 (for example, **`tutorial-s3batch-role`**).
13. Choose **Next**.
14. On the **Review** page, review the settings. Then choose **Create job**.

    After S3 finishes reading your S3 Batch Operations job's manifest, it sets the **Status** of the job to **Awaiting your confirmation to run**. To see updates to the job's status, refresh the page. You can't run your job until its status is **Awaiting your confirmation to run**.

## Run the S3 Batch Operations job to invoke your Lambda function

Run your Batch Operations job to invoke your Lambda function for video transcoding. If your job fails, you can check your completion report to identify the cause.

**To run the S3 Batch Operations job**

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Batch Operations**.
3. In the **Jobs** list, choose the **Job ID** of the job on the first row, which is the S3 Batch Operations job that you created earlier.
4. Choose **Run job**.
5. Review your job parameters again, and confirm that the value for **Total objects listed in manifest** is the same as the number of objects in the manifest. Then choose **Run job**.

   Your S3 Batch Operations job page opens.
6. After the job starts running, on your job page, under **Status**, check the progress of your S3 Batch Operations job, such as **Status**, **% Complete**, **Total succeeded (rate)**, **Total failed (rate)**, **Date terminated**, and **Reason for termination**.

   When the S3 Batch Operations job completes, view the data on your job page to confirm that the job finished as expected.

   If more than 50 percent of an S3 Batch Operations job's object operations fail after more than 1,000 operations have been attempted, the job automatically fails. To check your completion report to identify the cause of the failures, use the following optional procedure.

## (Optional) Check your completion report

You can use your completion report to determine which objects failed and the cause of the failures.

**To check your completion report for details about failed objects**

1. On the page of your S3 Batch Operations job, scroll down to the **Completion report** section, and choose the link under **Completion report destination**.

   The S3 output destination bucket's page opens.
2. On the **Objects** tab, choose the folder that has a name ending with the job ID of the S3 Batch Operations job that you created earlier.
3. Choose **results/**.
4. Select the check box next to the `.csv` file.

5. To view the job report, choose **Open** or **Download**.

## (Optional) Monitor each Lambda invocation in the Lambda console

After the S3 Batch Operations job starts running, the job invokes the Lambda function for each input video object. S3 writes logs of each Lambda invocation to CloudWatch Logs. You can use the Lambda console's monitoring dashboard to monitor your Lambda function.

1. Open the AWS Lambda console at https://console.aws.amazon.com/lambda/.
2. In the left navigation pane, choose **Functions**.
3. In the **Functions** list, choose the name of the Lambda function that you created in Step 4 (for example, **`tutorial-lambda-convert`**).
4. Choose the **Monitor** tab.
5. Under **Metrics**, see the runtime metrics for your Lambda function.
6. Under **Logs**, view log data for each Lambda invocation through CloudWatch Logs Insights.

> **Note**
>
> When you use S3 Batch Operations with a Lambda function, the Lambda function is invoked on each object. If your S3 Batch Operations job is large, it can invoke multiple Lambda functions at the same time, causing a spike in Lambda concurrency.
> Each AWS account has a Lambda concurrency quota per Region. For more information, see AWS Lambda Function Scaling in the *AWS Lambda Developer Guide*. A best practice for using Lambda functions with S3 Batch Operations is to set a concurrency limit on the Lambda function itself. Setting a concurrency limit keeps your job from consuming most of your Lambda concurrency and potentially throttling other functions in your account. For more information, see Managing Lambda reserved concurrency in the *AWS Lambda Developer Guide*.

## (Optional) Monitor each MediaConvert video-transcoding job in the MediaConvert console

A MediaConvert job does the work of transcoding a media file. When your S3 Batch Operations job invokes your Lambda function for each video, each Lambda function invocation creates a MediaConvert transcoding job for each input video.

1. Sign in to the AWS Management Console and open the MediaConvert console at https://console.aws.amazon.com/mediaconvert/.
2. If the MediaConvert introductory page appears, choose **Get started**.
3. From the list of **Jobs**, view each row to monitor the transcoding task for each input video.
4. Identify the row of a job that you want to check, and choose the **Job ID** link to open the job details page.
5. On the **Job summary** page, under **Outputs**, choose the link for the HLS, MP4, or Thumbnails output, depending on what is supported by your browser, to go to the S3 destination bucket for the output media files.
6. In the corresponding folder (HLS, MP4, or Thumbnails) of your S3 output destination bucket, choose the name of the output media file object.

   The object's detail page opens.
7. On the object's detail page, under **Object overview**, choose the link under **Object URL** to watch the transcoded output media file.

## Step 8: Check the output media files from your S3 destination bucket

**To check the output media files from your S3 destination bucket**

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Buckets**.
3. In the **Buckets** list, choose the name of the S3 destination bucket for output media files that you created in Step 1 (for example, **`tutorial-bucket-2`**).
4. On the **Objects** tab, each input video has a folder that has the name of the input video. Each folder contains the transcoded output media files for an input video.

   To check the output media files for an input video, do the following:

   a. Choose the folder with the name of the input video that you want to check.

   b. Choose the **Default/** folder.

   c. Choose the folder for a transcoded format (HLS, MP4, or thumbnails in this tutorial).

   d. Choose the name of the output media file.

e. To watch the transcoded file, on the object's details page, choose the link under **Object URL**.

   Output media files in the HLS format are split into short segments. To play these videos, embed the object URL of the `.m3u8` file in a compatible player.

## Step 9: Clean up

If you transcoded videos using S3 Batch Operations, Lambda, and MediaConvert only as a learning exercise, delete the AWS resources that you allocated so that you no longer accrue charges.

**Substeps**

- Delete the S3 Inventory configuration for your S3 source bucket
- Delete the Lambda function
- Delete the CloudWatch log group
- Delete the IAM roles together with the inline policies for the IAM roles
- Delete the customer-managed IAM policy
- Empty the S3 buckets
- Delete the S3 buckets

### Delete the S3 Inventory configuration for your S3 source bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Buckets**.
3. In the **Buckets** list, choose the name of your source bucket (for example, **`tutorial-bucket-1`**).
4. Choose the **Management** tab.
5. In the **Inventory configurations** section, choose the option button next to the inventory configuration that you created in Step 5 (for example, **`tutorial-inventory-config`**).
6. Choose **Delete**, and then choose **Confirm**.

## Delete the Lambda function

1. Open the AWS Lambda console at https://console.aws.amazon.com/lambda/.
2. In the left navigation pane, choose **Functions**.
3. Select the check box next to the function that you created in Step 4 (for example, **`tutorial-lambda-convert`**).
4. Choose **Actions**, and then choose **Delete**.
5. In the **Delete function** dialog box, choose **Delete**.

## Delete the CloudWatch log group

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the left navigation pane, choose **Logs**, and then choose **Log groups**.
3. Select the check box next to the log group that has a name ending with the Lambda function that you created in Step 4 (for example, **`tutorial-lambda-convert`**).
4. Choose **Actions**, and then choose **Delete log group(s)**.
5. In the **Delete log group(s)** dialog box, choose **Delete**.

## Delete the IAM roles together with the inline policies for the IAM roles

To delete the IAM roles that you created in Step 2, Step 3, and Step 6, do the following:

1. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.
2. In the left navigation pane, choose **Roles**, and then select the check boxes next to the role names that you want to delete.
3. At the top of the page, choose **Delete**.
4. In the confirmation dialog box, enter the required response in the text input field based on the prompt, and choose **Delete**.

## Delete the customer-managed IAM policy

To delete the customer-managed IAM policy that you created in Step 6, do the following:

1. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.
2. In the left navigation pane, choose **Policies**.
3. Choose the option button next to the policy that you created in Step 6 (for example, **`tutorial-s3batch-policy`**). You can use the search box to filter the list of policies.
4. Choose **Actions**, and then choose **Delete**.
5. Confirm that you want to delete this policy by entering its name in the text field, and then choose **Delete**.

## Empty the S3 buckets

To empty the S3 buckets that you created in Prerequisites, Step 1, and Step 5, do the following:

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Buckets**.
3. In the **Buckets** list, choose the option button next to the name of the bucket that you want to empty, and then choose **Empty**.
4. On the **Empty bucket** page, confirm that you want to empty the bucket by entering **`permanently delete`** in the text field, and then choose **Empty**.

## Delete the S3 buckets

To delete the S3 buckets that you created in Prerequisites, Step 1, and Step 5, do the following:

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Buckets**.
3. In the **Buckets** list, choose the option button next to the name of the bucket that you want to delete.
4. Choose **Delete**.
5. On the **Delete bucket** page, confirm that you want to delete the bucket by entering the bucket name in the text field, and then choose **Delete bucket**.

## Next steps

After completing this tutorial, you can further explore other relevant use cases:

- You can use Amazon CloudFront to stream the transcoded media files to viewers across the globe. For more information, see Tutorial: Hosting on-demand streaming video with Amazon S3, Amazon CloudFront, and Amazon Route 53.
- You can transcode videos at the moment when you upload them to the S3 source bucket. To do so, you can configure an Amazon S3 event trigger that automatically invokes the Lambda function to transcode new objects in S3 with MediaConvert. For more information, see Tutorial: Using an Amazon S3 trigger to invoke a Lambda function in the *AWS Lambda Developer Guide*.

# Tutorial: Configuring a static website on Amazon S3

**Important**

Amazon S3 now applies server-side encryption with Amazon S3 managed keys (SSE-S3) as the base level of encryption for every bucket in Amazon S3. Starting January 5, 2023, all new object uploads to Amazon S3 are automatically encrypted at no additional cost and with no impact on performance. The automatic encryption status for S3 bucket default encryption configuration and for new object uploads is available in AWS CloudTrail logs, S3 Inventory, S3 Storage Lens, the Amazon S3 console, and as an additional Amazon S3 API response header in the AWS Command Line Interface and AWS SDKs. For more information, see Default encryption FAQ.

You can configure an Amazon S3 bucket to function like a website. This example walks you through the steps of hosting a website on Amazon S3.

**Important**

The following tutorial requires disabling Block Public Access. We recommend keeping Block Public Access enabled. If you want to keep all four Block Public Access settings enabled and host a static website, you can use Amazon CloudFront origin access control (OAC). Amazon CloudFront provides the capabilities required to set up a secure static website. Amazon S3 static websites support only HTTP endpoints. Amazon CloudFront uses the durable storage of Amazon S3 while providing additional security headers, such as HTTPS.

HTTPS adds security by encrypting a normal HTTP request and protecting against common cyberattacks. For more information, see Getting started with a secure static website in the *Amazon CloudFront Developer Guide*.

**Topics**

## Step 1: Create a bucket

The following instructions provide an overview of how to create your buckets for website hosting. For detailed, step-by-step instructions on creating a bucket, see Creating a bucket.

**To create a bucket**

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. Choose **Create bucket**.
3. Enter the **Bucket name** (for example, **`example.com`**).
4. Choose the Region where you want to create the bucket.

   Choose a Region that is geographically close to you to minimize latency and costs, or to address regulatory requirements. The Region that you choose determines your Amazon S3 website endpoint. For more information, see Website endpoints.
5. To accept the default settings and create the bucket, choose **Create**.

# Step 2: Enable static website hosting

After you create a bucket, you can enable static website hosting for your bucket. You can create a new bucket or use an existing bucket.

**To enable static website hosting**

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the **Buckets** list, choose the name of the bucket that you want to enable static website hosting for.
3. Choose **Properties**.
4. Under **Static website hosting**, choose **Edit**.
5. Choose **Use this bucket to host a website**.
6. Under **Static website hosting**, choose **Enable**.
7. In **Index document**, enter the file name of the index document, typically `index.html`.

   The index document name is case sensitive and must exactly match the file name of the HTML index document that you plan to upload to your S3 bucket. When you configure a bucket for website hosting, you must specify an index document. Amazon S3 returns this index document when requests are made to the root domain or any of the subfolders. For more information, see Configuring an index document.
8. To provide your own custom error document for 4XX class errors, in **Error document**, enter the custom error document file name.

   The error document name is case sensitive and must exactly match the file name of the HTML error document that you plan to upload to your S3 bucket. If you don't specify a custom error document and an error occurs, Amazon S3 returns a default HTML error document. For more information, see Configuring a custom error document.
9. (Optional) If you want to specify advanced redirection rules, in **Redirection rules**, enter JSON to describe the rules.

   For example, you can conditionally route requests according to specific object key names or prefixes in the request. For more information, see Configure redirection rules to use advanced conditional redirects.
10. Choose **Save changes**.

Amazon S3 enables static website hosting for your bucket. At the bottom of the page, under **Static website hosting**, you see the website endpoint for your bucket.

11. Under **Static website hosting**, note the **Endpoint**.

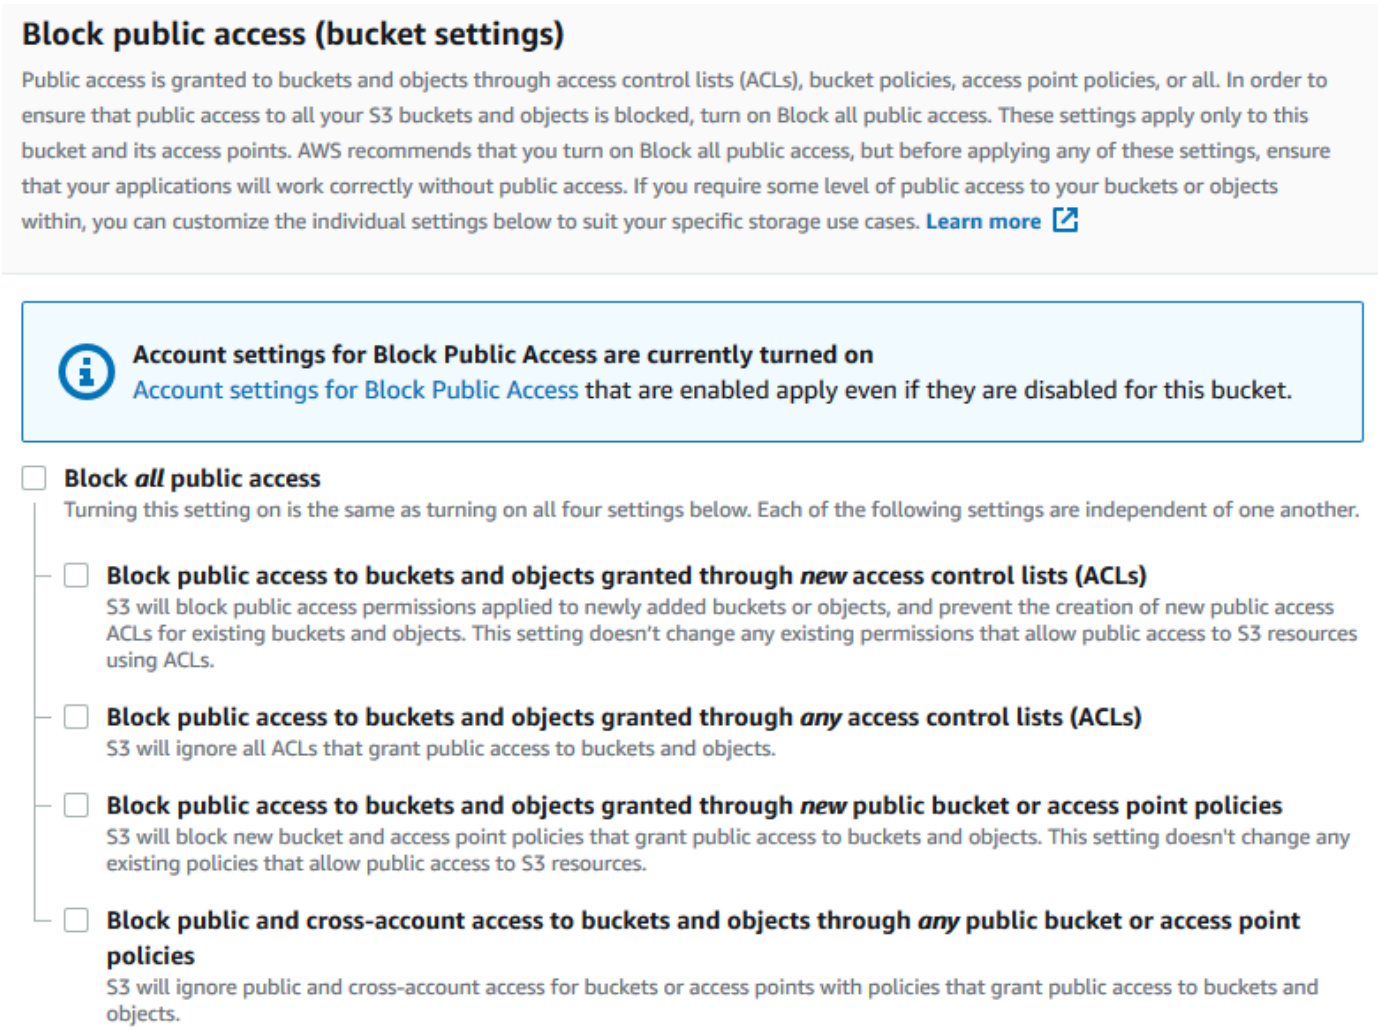
    The **Endpoint** is the Amazon S3 website endpoint for your bucket. After you finish configuring your bucket as a static website, you can use this endpoint to test your website.

## Step 3: Edit Block Public Access settings

By default, Amazon S3 blocks public access to your account and buckets. If you want to use a bucket to host a static website, you can use these steps to edit your block public access settings.

> **Warning**
>
> Before you complete these steps, review Blocking public access to your Amazon S3 storage to ensure that you understand and accept the risks involved with allowing public access. When you turn off block public access settings to make your bucket public, anyone on the internet can access your bucket. We recommend that you block all public access to your buckets.

1. Open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. Choose the name of the bucket that you have configured as a static website.
3. Choose **Permissions**.
4. Under **Block public access (bucket settings)**, choose **Edit**.
5. Clear **Block *all* public access**, and choose **Save changes**.



Amazon S3 turns off the Block Public Access settings for your bucket. To create a public static website, you might also have to edit the Block Public Access settings for your account before adding a bucket policy. If the Block Public Access settings for your account are currently turned on, you see a note under **Block public access (bucket settings)**.

## Step 4: Add a bucket policy that makes your bucket content publicly available

After you edit S3 Block Public Access settings, you can add a bucket policy to grant public read access to your bucket. When you grant public read access, anyone on the internet can access your bucket.

**Important**

The following policy is an example only and allows full access to the contents of your bucket. Before you proceed with this step, review How can I secure the files in my Amazon S3 bucket? to ensure that you understand the best practices for securing the files in your S3 bucket and risks involved in granting public access.

1. Under **Buckets**, choose the name of your bucket.
2. Choose **Permissions**.
3. Under **Bucket Policy**, choose **Edit**.
4. To grant public read access for your website, copy the following bucket policy, and paste it in the **Bucket policy editor**.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "PublicReadGetObject",
            "Effect": "Allow",
            "Principal": "*",
            "Action": [
                "s3:GetObject"
            ],
            "Resource": [
                "arn:aws:s3:::Bucket-Name/*"
            ]
        }
    ]
}
```

5. Update the `Resource` to your bucket name.

   In the preceding example bucket policy, *Bucket-Name* is a placeholder for the bucket name. To use this bucket policy with your own bucket, you must update this name to match your bucket name.

6. Choose **Save changes**.

   A message appears indicating that the bucket policy has been successfully added.

If you see an error that says `Policy has invalid resource`, confirm that the bucket name in the bucket policy matches your bucket name. For information about adding a bucket policy, see How do I add an S3 bucket policy?

If you get an error message and cannot save the bucket policy, check your account and bucket Block Public Access settings to confirm that you allow public access to the bucket.

## Step 5: Configure an index document

When you enable static website hosting for your bucket, you enter the name of the index document (for example, **`index.html`**). After you enable static website hosting for the bucket, you upload an HTML file with this index document name to your bucket.

**To configure the index document**

1. Create an `index.html` file.

   If you don't have an `index.html` file, you can use the following HTML to create one:

   ```
   <html xmlns="http://www.w3.org/1999/xhtml" >
   <head>
       <title>My Website Home Page</title>
   </head>
   <body>
     <h1>Welcome to my website</h1>
     <p>Now hosted on Amazon S3!</p>
   </body>
   </html>
   ```

2. Save the index file locally.

   The index document file name must exactly match the index document name that you enter in the **Static website hosting** dialog box. The index document name is case sensitive. For example, if you enter `index.html` for the **Index document** name in the **Static website hosting** dialog box, your index document file name must also be `index.html` and not `Index.html`.

3. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.

4. In the **Buckets** list, choose the name of the bucket that you want to use to host a static website.
5. Enable static website hosting for your bucket, and enter the exact name of your index document (for example, `index.html`). For more information, see Enabling website hosting.

   After enabling static website hosting, proceed to step 6.
6. To upload the index document to your bucket, do one of the following:

   - Drag and drop the index file into the console bucket listing.
   - Choose **Upload**, and follow the prompts to choose and upload the index file.

   For step-by-step instructions, see Uploading objects.
7. (Optional) Upload other website content to your bucket.

## Step 6: Configure an error document

When you enable static website hosting for your bucket, you enter the name of the error document (for example, **`404.html`**). After you enable static website hosting for the bucket, you upload an HTML file with this error document name to your bucket.

**To configure an error document**

1. Create an error document, for example `404.html`.
2. Save the error document file locally.

   The error document name is case sensitive and must exactly match the name that you enter when you enable static website hosting. For example, if you enter `404.html` for the **Error document** name in the **Static website hosting** dialog box, your error document file name must also be `404.html`.
3. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
4. In the **Buckets** list, choose the name of the bucket that you want to use to host a static website.
5. Enable static website hosting for your bucket, and enter the exact name of your error document (for example, `404.html`). For more information, see Enabling website hosting and Configuring a custom error document.

After enabling static website hosting, proceed to step 6.

6. To upload the error document to your bucket, do one of the following:

   - Drag and drop the error document file into the console bucket listing.
   - Choose **Upload**, and follow the prompts to choose and upload the index file.

   For step-by-step instructions, see Uploading objects.

## Step 7: Test your website endpoint

After you configure static website hosting for your bucket, you can test your website endpoint.

> **Note**
>
> Amazon S3 does not support HTTPS access to the website. If you want to use HTTPS, you can use Amazon CloudFront to serve a static website hosted on Amazon S3.
> For more information, see How do I use CloudFront to serve a static website hosted on Amazon S3? and Requiring HTTPS for communication between viewers and CloudFront.

1. Under **Buckets**, choose the name of your bucket.
2. Choose **Properties**.
3. At the bottom of the page, under **Static website hosting**, choose your **Bucket website endpoint**.

   Your index document opens in a separate browser window.

You now have a website hosted on Amazon S3. This website is available at the Amazon S3 website endpoint. However, you might have a domain, such as `example.com`, that you want to use to serve the content from the website you created. You might also want to use Amazon S3 root domain support to serve requests for both `http://www.example.com` and `http://example.com`. This requires additional steps. For an example, see Tutorial: Configuring a static website using a custom domain registered with Route 53.

## Step 8: Clean up

If you created your static website only as a learning exercise, delete the AWS resources that you allocated so that you no longer accrue charges. After you delete your AWS resources, your website is no longer available. For more information, see Deleting a bucket.

# Tutorial: Configuring a static website using a custom domain registered with Route 53

Suppose that you want to host a static website on Amazon S3. You've registered a domain with Amazon Route 53 (for example, `example.com`), and you want requests for `http://www.example.com` and `http://example.com` to be served from your Amazon S3 content. You can use this walkthrough to learn how to host a static website and create redirects on Amazon S3 for a website with a custom domain name that is registered with Route 53. You can work with an existing website that you want to host on Amazon S3, or use this walkthrough to start from scratch.

After you complete this walkthrough, you can optionally use Amazon CloudFront to improve the performance of your website. For more information, see Speeding up your website with Amazon CloudFront.

> **Note**
>
> Amazon S3 website endpoints do not support HTTPS or access points. If you want to use HTTPS, you can use Amazon CloudFront to serve a static website hosted on Amazon S3. For a tutorial about how to host your content securely with CloudFront and Amazon S3, see Tutorial: Hosting on-demand streaming video with Amazon S3, Amazon CloudFront, and Amazon Route 53. For more information, see How do I use CloudFront to serve a static website hosted on Amazon S3? and Requiring HTTPS for communication between viewers and CloudFront.

### Automating static website setup with an AWS CloudFormation template

You can use an AWS CloudFormation template to automate your static website setup. The AWS CloudFormation template sets up the components that you need to host a secure static website so that you can focus more on your website's content and less on configuring components.

The AWS CloudFormation template includes the following components:

- Amazon S3 – Creates an Amazon S3 bucket to host your static website.
- CloudFront – Creates a CloudFront distribution to speed up your static website.
- Lambda@Edge – Uses Lambda@Edge to add security headers to every server response. Security headers are a group of headers in the web server response that tell web browsers to take extra security precautions. For more information, see the blog post Adding HTTP security headers using Lambda@Edge and Amazon CloudFront.

This AWS CloudFormation template is available for you to download and use. For information and instructions, see Getting started with a secure static website in the *Amazon CloudFront Developer Guide*.

**Topics**

## Before you begin

As you follow the steps in this example, you work with the following services:

**Amazon Route 53** – You use Route 53 to register domains and to define where you want to route internet traffic for your domain. The example shows how to create Route 53 alias records that route traffic for your domain (`example.com`) and subdomain (`www.example.com`) to an Amazon S3 bucket that contains an HTML file.

**Amazon S3** – You use Amazon S3 to create buckets, upload a sample website page, configure permissions so that everyone can see the content, and then configure the buckets for website hosting.

## Step 1: Register a custom domain with Route 53

If you don't already have a registered domain name, such as `example.com`, register one with Route 53. For more information, see Registering a new domain in the *Amazon Route 53 Developer Guide*. After you register your domain name, you can create and configure your Amazon S3 buckets for website hosting.

## Step 2: Create two buckets

To support requests from both the root domain and subdomain, you create two buckets.

- **Domain bucket** – `example.com`
- **Subdomain bucket** – `www.example.com`

These bucket names must match your domain name exactly. In this example, the domain name is `example.com`. You host your content out of the root domain bucket (`example.com`). You create a redirect request for the subdomain bucket (`www.example.com`). If someone enters `www.example.com` in their browser, they are redirected to `example.com` and see the content that is hosted in the Amazon S3 bucket with that name.

**To create your buckets for website hosting**

The following instructions provide an overview of how to create your buckets for website hosting. For detailed, step-by-step instructions on creating a bucket, see Creating a bucket.

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. Create your root domain bucket:

    a. Choose **Create bucket**.

b. Enter the **Bucket name** (for example, **`example.com`**).

c. Choose the Region where you want to create the bucket.

Choose a Region that is geographically close to you to minimize latency and costs, or to address regulatory requirements. The Region that you choose determines your Amazon S3 website endpoint. For more information, see Website endpoints.

d. To accept the default settings and create the bucket, choose **Create**.

3. Create your subdomain bucket:

a. Choose **Create bucket**.

b. Enter the **Bucket name** (for example, **`www.example.com`**).

c. Choose the Region where you want to create the bucket.

Choose a Region that is geographically close to you to minimize latency and costs, or to address regulatory requirements. The Region that you choose determines your Amazon S3 website endpoint. For more information, see Website endpoints.

d. To accept the default settings and create the bucket, choose **Create**.

In the next step, you configure `example.com` for website hosting.

## Step 3: Configure your root domain bucket for website hosting

In this step, you configure your root domain bucket (`example.com`) as a website. This bucket will contain your website content. When you configure a bucket for website hosting, you can access the website using the Website endpoints.

**To enable static website hosting**

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the **Buckets** list, choose the name of the bucket that you want to enable static website hosting for.
3. Choose **Properties**.
4. Under **Static website hosting**, choose **Edit**.
5. Choose **Use this bucket to host a website**.
6. Under **Static website hosting**, choose **Enable**.

7. In **Index document**, enter the file name of the index document, typically `index.html`.

   The index document name is case sensitive and must exactly match the file name of the HTML index document that you plan to upload to your S3 bucket. When you configure a bucket for website hosting, you must specify an index document. Amazon S3 returns this index document when requests are made to the root domain or any of the subfolders. For more information, see Configuring an index document.

8. To provide your own custom error document for 4XX class errors, in **Error document**, enter the custom error document file name.

   The error document name is case sensitive and must exactly match the file name of the HTML error document that you plan to upload to your S3 bucket. If you don't specify a custom error document and an error occurs, Amazon S3 returns a default HTML error document. For more information, see Configuring a custom error document.

9. (Optional) If you want to specify advanced redirection rules, in **Redirection rules**, enter JSON to describe the rules.

   For example, you can conditionally route requests according to specific object key names or prefixes in the request. For more information, see Configure redirection rules to use advanced conditional redirects.

10. Choose **Save changes**.

    Amazon S3 enables static website hosting for your bucket. At the bottom of the page, under **Static website hosting**, you see the website endpoint for your bucket.

11. Under **Static website hosting**, note the **Endpoint**.

    The **Endpoint** is the Amazon S3 website endpoint for your bucket. After you finish configuring your bucket as a static website, you can use this endpoint to test your website.

After you edit block public access settings and add a bucket policy that allows public read access, you can use the website endpoint to access your website.

In the next step, you configure your subdomain (`www.example.com`) to redirect requests to your domain (`example.com`).

## Step 4: Configure your subdomain bucket for website redirect

After you configure your root domain bucket for website hosting, you can configure your subdomain bucket to redirect all requests to the domain. In this example, all requests for `www.example.com` are redirected to `example.com`.

**To configure a redirect request**

1. On the Amazon S3 console, in the **Buckets** list, choose your subdomain bucket name (`www.example.com` in this example).
2. Choose **Properties**.
3. Under **Static website hosting**, choose **Edit**.
4. Choose **Redirect requests for an object**.
5. In the **Target bucket** box, enter your root domain, for example, **`example.com`**.
6. For **Protocol**, choose **http**.
7. Choose **Save changes**.

## Step 5: Configure logging for website traffic

If you want to track the number of visitors accessing your website, you can optionally enable logging for your root domain bucket. For more information, see Logging requests with server access logging. If you plan to use Amazon CloudFront to speed up your website, you can also use CloudFront logging.

**To enable server access logging for your root domain bucket**

1. Open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the same Region where you created the bucket that is configured as a static website, create a bucket for logging, for example `logs.example.com`.
3. Create a folder for the server access logging log files (for example, `logs`).
4. (Optional) If you want to use CloudFront to improve your website performance, create a folder for the CloudFront log files (for example, `cdn`).

> **Important**
>
> When you create or update a distribution and enable CloudFront logging, CloudFront updates the bucket access control list (ACL) to give the `awslogsdelivery` account `FULL_CONTROL` permissions to write logs to your bucket. For more information, see Permissions required to configure standard logging and to access your log files in the *Amazon CloudFront Developer Guide*. If the bucket that stores the logs uses the Bucket owner enforced setting for S3 Object Ownership to disable ACLs, CloudFront cannot write logs to the bucket. For more information, see Controlling ownership of objects and disabling ACLs for your bucket.

5. In the **Buckets** list, choose your root domain bucket.
6. Choose **Properties**.
7. Under **Server access logging**, choose **Edit**.
8. Choose **Enable**.
9. Under the **Target bucket**, choose the bucket and folder destination for the server access logs:
   - Browse to the folder and bucket location:
     1. Choose **Browse S3**.
     2. Choose the bucket name, and then choose the logs folder.
     3. Choose **Choose path**.
   - Enter the S3 bucket path, for example, `s3://logs.example.com/logs/`.
10. Choose **Save changes**.

    In your log bucket, you can now access your logs. Amazon S3 writes website access logs to your log bucket every 2 hours.

## Step 6: Upload index and website content

In this step, you upload your index document and optional website content to your root domain bucket.

When you enable static website hosting for your bucket, you enter the name of the index document (for example, **`index.html`**). After you enable static website hosting for the bucket, you upload an HTML file with this index document name to your bucket.

**To configure the index document**

1. Create an `index.html` file.

   If you don't have an `index.html` file, you can use the following HTML to create one:

   ```
   <html xmlns="http://www.w3.org/1999/xhtml" >
   <head>
       <title>My Website Home Page</title>
   </head>
   <body>
     <h1>Welcome to my website</h1>
     <p>Now hosted on Amazon S3!</p>
   </body>
   </html>
   ```

2. Save the index file locally.

   The index document file name must exactly match the index document name that you enter in the **Static website hosting** dialog box. The index document name is case sensitive. For example, if you enter `index.html` for the **Index document** name in the **Static website hosting** dialog box, your index document file name must also be `index.html` and not `Index.html`.

3. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.

4. In the **Buckets** list, choose the name of the bucket that you want to use to host a static website.

5. Enable static website hosting for your bucket, and enter the exact name of your index document (for example, `index.html`). For more information, see Enabling website hosting.

   After enabling static website hosting, proceed to step 6.

6. To upload the index document to your bucket, do one of the following:

   - Drag and drop the index file into the console bucket listing.
   - Choose **Upload**, and follow the prompts to choose and upload the index file.

   For step-by-step instructions, see Uploading objects.

7. (Optional) Upload other website content to your bucket.

## Step 7: Upload an error document

When you enable static website hosting for your bucket, you enter the name of the error document (for example, **`404.html`**). After you enable static website hosting for the bucket, you upload an HTML file with this error document name to your bucket.

**To configure an error document**

1. Create an error document, for example `404.html`.
2. Save the error document file locally.

   The error document name is case sensitive and must exactly match the name that you enter when you enable static website hosting. For example, if you enter `404.html` for the **Error document** name in the **Static website hosting** dialog box, your error document file name must also be `404.html`.
3. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
4. In the **Buckets** list, choose the name of the bucket that you want to use to host a static website.
5. Enable static website hosting for your bucket, and enter the exact name of your error document (for example, `404.html`). For more information, see Enabling website hosting and Configuring a custom error document.

   After enabling static website hosting, proceed to step 6.
6. To upload the error document to your bucket, do one of the following:

   - Drag and drop the error document file into the console bucket listing.
   - Choose **Upload**, and follow the prompts to choose and upload the index file.

   For step-by-step instructions, see Uploading objects.

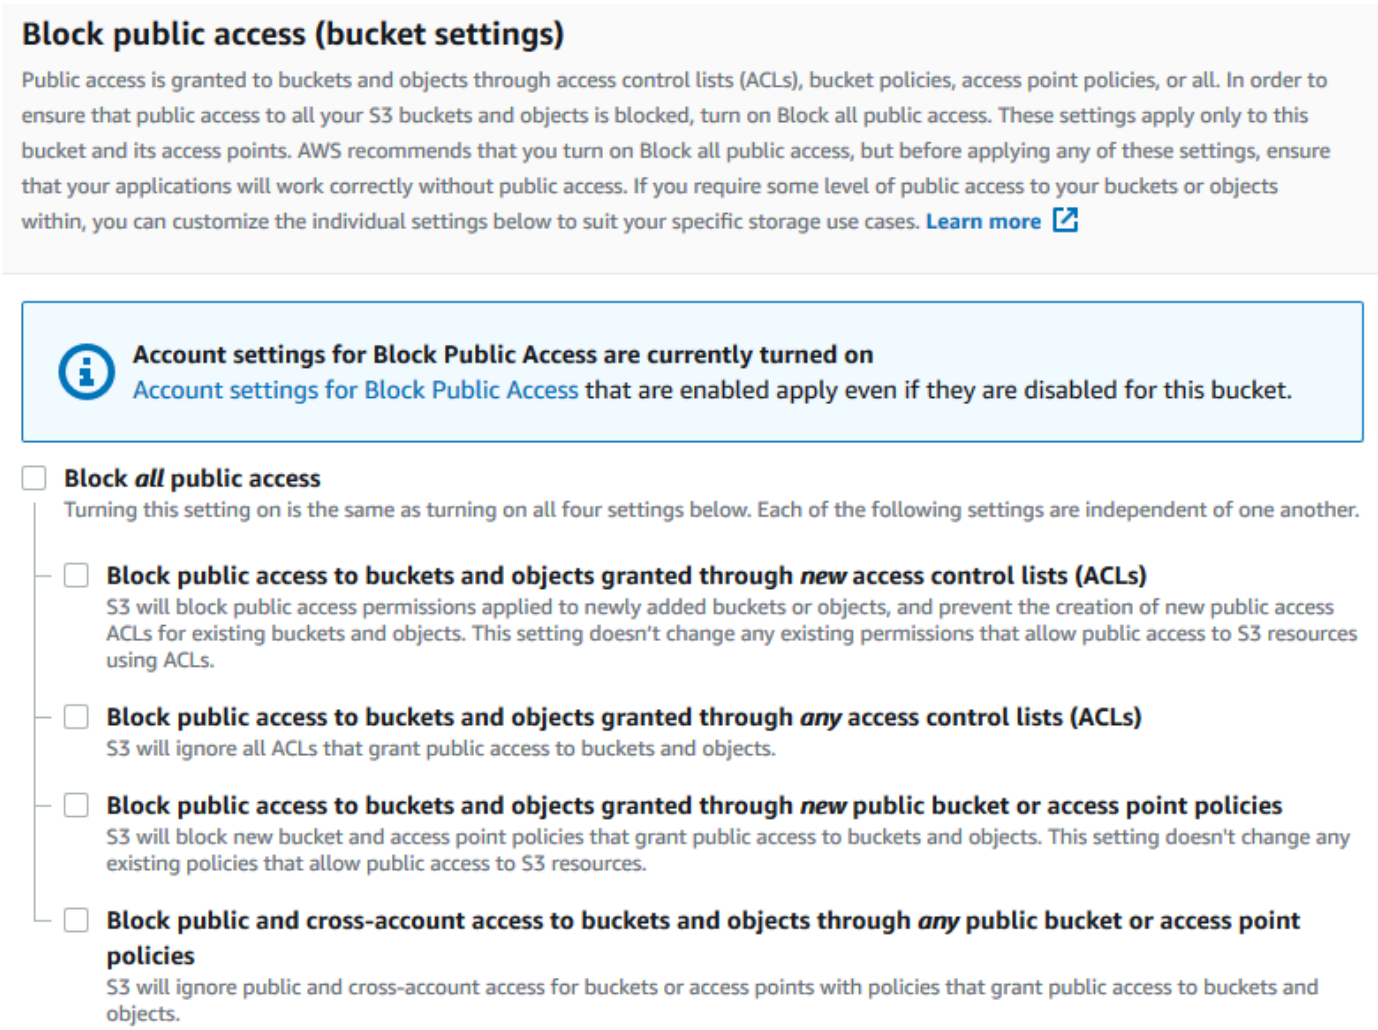
## Step 8: Edit S3 Block Public Access settings

In this example, you edit block public access settings for the domain bucket (`example.com`) to allow public access.

By default, Amazon S3 blocks public access to your account and buckets. If you want to use a bucket to host a static website, you can use these steps to edit your block public access settings.

> **Warning**
>
> Before you complete these steps, review Blocking public access to your Amazon S3 storage to ensure that you understand and accept the risks involved with allowing public access. When you turn off block public access settings to make your bucket public, anyone on the internet can access your bucket. We recommend that you block all public access to your buckets.

1. Open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. Choose the name of the bucket that you have configured as a static website.
3. Choose **Permissions**.
4. Under **Block public access (bucket settings)**, choose **Edit**.
5. Clear **Block *all* public access**, and choose **Save changes**.



Amazon S3 turns off the Block Public Access settings for your bucket. To create a public static website, you might also have to edit the Block Public Access settings for your account before adding a bucket policy. If the Block Public Access settings for your account are currently turned on, you see a note under **Block public access (bucket settings)**.

## Step 9: Attach a bucket policy

In this example, you attach a bucket policy to the domain bucket (`example.com`) to allow public read access. You replace the *`Bucket-Name`* in the example bucket policy with the name of your domain bucket, for example `example.com`.

After you edit S3 Block Public Access settings, you can add a bucket policy to grant public read access to your bucket. When you grant public read access, anyone on the internet can access your bucket.

**Important**

The following policy is an example only and allows full access to the contents of your bucket. Before you proceed with this step, review How can I secure the files in my Amazon S3 bucket? to ensure that you understand the best practices for securing the files in your S3 bucket and risks involved in granting public access.

1. Under **Buckets**, choose the name of your bucket.
2. Choose **Permissions**.
3. Under **Bucket Policy**, choose **Edit**.
4. To grant public read access for your website, copy the following bucket policy, and paste it in the **Bucket policy editor**.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "PublicReadGetObject",
            "Effect": "Allow",
            "Principal": "*",
            "Action": [
                "s3:GetObject"
            ],
            "Resource": [
                "arn:aws:s3:::Bucket-Name/*"
            ]
        }
    ]
}
```

5. Update the `Resource` to your bucket name.

   In the preceding example bucket policy, *Bucket-Name* is a placeholder for the bucket name. To use this bucket policy with your own bucket, you must update this name to match your bucket name.

6. Choose **Save changes**.

   A message appears indicating that the bucket policy has been successfully added.

If you see an error that says `Policy has invalid resource`, confirm that the bucket name in the bucket policy matches your bucket name. For information about adding a bucket policy, see How do I add an S3 bucket policy?

If you get an error message and cannot save the bucket policy, check your account and bucket Block Public Access settings to confirm that you allow public access to the bucket.

In the next step, you can figure out your website endpoints and test your domain endpoint.

## Step 10: Test your domain endpoint

After you configure your domain bucket to host a public website, you can test your endpoint. For more information, see Website endpoints. You can only test the endpoint for your domain bucket because your subdomain bucket is set up for website redirect and not static website hosting.

> **Note**
>
> Amazon S3 does not support HTTPS access to the website. If you want to use HTTPS, you can use Amazon CloudFront to serve a static website hosted on Amazon S3.
> For more information, see How do I use CloudFront to serve a static website hosted on Amazon S3? and Requiring HTTPS for communication between viewers and CloudFront.

1. Under **Buckets**, choose the name of your bucket.
2. Choose **Properties**.
3. At the bottom of the page, under **Static website hosting**, choose your **Bucket website endpoint**.

   Your index document opens in a separate browser window.

In the next step, you use Amazon Route 53 to enable customers to use both of your custom URLs to navigate to your site.

## Step 11: Add alias records for your domain and subdomain

In this step, you create the alias records that you add to the hosted zone for your domain maps `example.com` and `www.example.com`. Instead of using IP addresses, the alias records use the

Amazon S3 website endpoints. Amazon Route 53 maintains a mapping between the alias records and the IP addresses where the Amazon S3 buckets reside. You create two alias records, one for your root domain and one for your subdomain.

**Add an alias record for your root domain and subdomain**

**To add an alias record for your root domain (`example.com`)**

1. Open the Route 53 console at https://console.aws.amazon.com/route53/.

   > **Note**
   >
   > If you don't already use Route 53, see Step 1: Register a domain in the *Amazon Route 53 Developer Guide*. After completing your setup, you can resume the instructions.

2. Choose **Hosted zones**.
3. In the list of hosted zones, choose the name of the hosted zone that matches your domain name.
4. Choose **Create record**.
5. Choose **Switch to wizard**.

   > **Note**
   >
   > If you want to use quick create to create your alias records, see Configuring Route 53 to route traffic to an S3 Bucket.

6. Choose **Simple routing**, and choose **Next**.
7. Choose **Define simple record**.
8. In **Record name**, accept the default value, which is the name of your hosted zone and your domain.
9. In **Value/Route traffic to**, choose **Alias to S3 website endpoint**.
10. Choose the Region.
11. Choose the S3 bucket.

    The bucket name should match the name that appears in the **Name** box. In the **Choose S3 bucket** list, the bucket name appears with the Amazon S3 website endpoint for the Region

where the bucket was created, for example, `s3-website-us-west-1.amazonaws.com (example.com)`.

**Choose S3 bucket** lists a bucket if:

- You configured the bucket as a static website.
- The bucket name is the same as the name of the record that you're creating.
- The current AWS account created the bucket.

If your bucket does not appear in the **Choose S3 bucket** list, enter the Amazon S3 website endpoint for the Region where the bucket was created, for example, **`s3-website-us-west-2.amazonaws.com`**. For a complete list of Amazon S3 website endpoints, see Amazon S3 Website endpoints. For more information about the alias target, see Value/route traffic to in the *Amazon Route 53 Developer Guide*.

12. In **Record type**, choose **A - Routes traffic to an IPv4 address and some AWS resources**.
13. For **Evaluate target health**, choose **No**.
14. Choose **Define simple record**.

**To add an alias record for your subdomain (`www.example.com`)**

1. Under **Configure records**, choose **Define simple record**.
2. In **Record name** for your subdomain, type `www`.
3. In **Value/Route traffic to**, choose **Alias to S3 website endpoint**.
4. Choose the Region.
5. Choose the S3 bucket, for example, `s3-website-us-west-2.amazonaws.com (www.example.com)`.

   If your bucket does not appear in the **Choose S3 bucket** list, enter the Amazon S3 website endpoint for the Region where the bucket was created, for example, **`s3-website-us-west-2.amazonaws.com`**. For a complete list of Amazon S3 website endpoints, see Amazon S3 Website endpoints. For more information about the alias target, see Value/route traffic to in the *Amazon Route 53 Developer Guide*.
6. In **Record type**, choose **A - Routes traffic to an IPv4 address and some AWS resources**.
7. For **Evaluate target health**, choose **No**.
8. Choose **Define simple record**.

9. On the **Configure records** page, choose **Create records**.

> **Note**
>
> Changes generally propagate to all Route 53 servers within 60 seconds. When propagation is done, you can route traffic to your Amazon S3 bucket by using the names of the alias records that you created in this procedure.

**Add an alias record for your root domain and subdomain (old Route 53 console)**

**To add an alias record for your root domain (`example.com`)**

The Route 53 console has been redesigned. In the Route 53 console you can temporarily use the old console. If you choose to work with the old Route 53 console, use the procedure below.

1. Open the Route 53 console at https://console.aws.amazon.com/route53/.

   > **Note**
   >
   > If you don't already use Route 53, see Step 1: Register a domain in the *Amazon Route 53 Developer Guide*. After completing your setup, you can resume the instructions.

2. Choose **Hosted Zones**.
3. In the list of hosted zones, choose the name of the hosted zone that matches your domain name.
4. Choose **Create Record Set**.
5. Specify the following values:

   **Name**

   Accept the default value, which is the name of your hosted zone and your domain.

   For the root domain, you don't need to enter any additional information in the **Name** field.

   **Type**

   Choose **A – IPv4 address**.

**Alias**

Choose **Yes**.

**Alias Target**

In the **S3 website endpoints** section of the list, choose your bucket name.

The bucket name should match the name that appears in the **Name** box. In the **Alias Target** listing, the bucket name is followed by the Amazon S3 website endpoint for the Region where the bucket was created, for example `example.com (s3-website-us-west-2.amazonaws.com)`. **Alias Target** lists a bucket if:

- You configured the bucket as a static website.
- The bucket name is the same as the name of the record that you're creating.
- The current AWS account created the bucket.

If your bucket does not appear in the **Alias Target** listing, enter the Amazon S3 website endpoint for the Region where the bucket was created, for example, `s3-website-us-west-2`. For a complete list of Amazon S3 website endpoints, see Amazon S3 Website endpoints. For more information about the alias target, see Value/route traffic to in the *Amazon Route 53 Developer Guide*.

**Routing Policy**

Accept the default value of **Simple**.

**Evaluate Target Health**

Accept the default value of **No**.

6. Choose **Create**.

**To add an alias record for your subdomain (`www.example.com`)**

1. In the hosted zone for your root domain (`example.com`), choose **Create Record Set**.
2. Specify the following values:

**Name**

For the subdomain, enter `www` in the box.

**Type**

Choose **A – IPv4 address**.

**Alias**

Choose **Yes**.

**Alias Target**

In the **S3 website endpoints** section of the list, choose the same bucket name that appears in the **Name** field—for example, `www.example.com (s3-website-us-west-2.amazonaws.com)`.

**Routing Policy**

Accept the default value of **Simple**.

**Evaluate Target Health**

Accept the default value of **No**.

3. Choose **Create**.

> **Note**
>
> Changes generally propagate to all Route 53 servers within 60 seconds. When propagation is done, you can route traffic to your Amazon S3 bucket by using the names of the alias records that you created in this procedure.

## Step 12: Test the website

Verify that the website and the redirect work correctly. In your browser, enter your URLs. In this example, you can try the following URLs:

- **Domain** (`http://example.com`) – Displays the index document in the `example.com` bucket.
- **Subdomain** (`http://www.example.com`) – Redirects your request to `http://example.com`. You see the index document in the `example.com` bucket.

If your website or redirect links don't work, you can try the following:

- **Clear cache** – Clear the cache of your web browser.
- **Check name servers** – If your web page and redirect links don't work after you've cleared your cache, you can compare the name servers for your domain and the name servers for your hosted zone. If the name servers don't match, you might need to update your domain name servers to match those listed under your hosted zone. For more information, see Adding or changing name servers and glue records for a domain.

After you've successfully tested your root domain and subdomain, you can set up an Amazon CloudFront distribution to improve the performance of your website and provide logs that you can use to review website traffic. For more information, see Speeding up your website with Amazon CloudFront.

## Speeding up your website with Amazon CloudFront

You can use Amazon CloudFront to improve the performance of your Amazon S3 website. CloudFront makes your website files (such as HTML, images, and video) available from data centers around the world (known as *edge locations*). When a visitor requests a file from your website, CloudFront automatically redirects the request to a copy of the file at the nearest edge location. This results in faster download times than if the visitor had requested the content from a data center that is located farther away.

CloudFront caches content at edge locations for a period of time that you specify. If a visitor requests content that has been cached for longer than the expiration date, CloudFront checks the origin server to see if a newer version of the content is available. If a newer version is available, CloudFront copies the new version to the edge location. Changes that you make to the original content are replicated to edge locations as visitors request the content.

### Using CloudFront without Route 53

The tutorial on this page uses Route 53 to point to your CloudFront distribution. However, if you want to serve content hosted in an Amazon S3 bucket using CloudFront without using Route 53, see Amazon CloudFront Tutorials: Setting up a Dynamic Content Distribution for Amazon S3. When you serve content hosted in an Amazon S3 bucket using CloudFront, you can use any bucket name, and both HTTP and HTTPS are supported.

### Automating set up with an AWS CloudFormation template

For more information about using an AWS CloudFormation template to configure a secure static website that creates a CloudFront distribution to serve your website, see Getting started with a secure static website in the *Amazon CloudFront Developer Guide*.

**Topics**

## Step 1: Create a CloudFront distribution

First, you create a CloudFront distribution. This makes your website available from data centers around the world.

**To create a distribution with an Amazon S3 origin**

1. Open the CloudFront console at https://console.aws.amazon.com/cloudfront/v4/home.
2. Choose **Create Distribution**.
3. On the **Create Distribution** page, in the **Origin Settings** section, for **Origin Domain Name**, enter the Amazon S3 website endpoint for your bucket—for example, **`example.com.s3-website.us-west-1.amazonaws.com`**.

   CloudFront fills in the **Origin ID** for you.
4. For **Default Cache Behavior Settings**, keep the values set to the defaults.

   With the default settings for **Viewer Protocol Policy**, you can use HTTPS for your static website. For more information these configuration options, see Values that You Specify When You Create or Update a Web Distribution in the *Amazon CloudFront Developer Guide*.
5. For **Distribution Settings**, do the following:

   a. Leave **Price Class** set to **Use All Edge Locations (Best Performance)**.

   b. Set **Alternate Domain Names (CNAMEs)** to the root domain and www subdomain. In this tutorial, these are `example.com` and `www.example.com`.

> **Important**
>
> Before you perform this step, note the requirements for using alternate domain names, in particular the need for a valid SSL/TLS certificate.

c. For **SSL Certificate**, choose **Custom SSL Certificate (example.com)**, and choose the custom certificate that covers the domain and subdomain names.

   For more information, see SSL Certificate in the *Amazon CloudFront Developer Guide*.

d. In **Default Root Object**, enter the name of your index document, for example, `index.html`.

   If the URL used to access the distribution doesn't contain a file name, the CloudFront distribution returns the index document. The **Default Root Object** should exactly match the name of the index document for your static website. For more information, see Configuring an index document.

e. Set **Logging** to **On**.

> **Important**
>
> When you create or update a distribution and enable CloudFront logging, CloudFront updates the bucket access control list (ACL) to give the `awslogsdelivery` account `FULL_CONTROL` permissions to write logs to your bucket. For more information, see Permissions required to configure standard logging and to access your log files in the *Amazon CloudFront Developer Guide*. If the bucket that stores the logs uses the Bucket owner enforced setting for S3 Object Ownership to disable ACLs, CloudFront cannot write logs to the bucket. For more information, see Controlling ownership of objects and disabling ACLs for your bucket.

f. For **Bucket for Logs**, choose the logging bucket that you created.

   For more information about configuring a logging bucket, see (Optional) Logging web traffic.

g. If you want to store the logs that are generated by traffic to the CloudFront distribution in a folder, in **Log Prefix**, enter the folder name.

h. Keep all other settings at their default values.

6. Choose **Create Distribution**.
7. To see the status of the distribution, find the distribution in the console and check the **Status** column.

   A status of `InProgress` indicates that the distribution is not yet fully deployed.

   After your distribution is deployed, you can reference your content with the new CloudFront domain name.
8. Record the value of **Domain Name** shown in the CloudFront console, for example, `dj4p1rv6mvubz.cloudfront.net`.
9. To verify that your CloudFront distribution is working, enter the domain name of the distribution in a web browser.

   If your website is visible, the CloudFront distribution works. If your website has a custom domain registered with Amazon Route 53, you will need the CloudFront domain name to update the record set in the next step.

## Step 2: Update the record sets for your domain and subdomain

Now that you have successfully created a CloudFront distribution, update the alias record in Route 53 to point to the new CloudFront distribution.

**To update the alias record to point to a CloudFront distribution**

1. Open the Route 53 console at https://console.aws.amazon.com/route53/.
2. In the left navigation, choose **Hosted zones**.
3. On the **Hosted Zones** page, choose the hosted zone that you created for your subdomain, for example, `www.example.com`.
4. Under **Records**, select the *A* record that you created for your subdomain.
5. Under **Record details**, choose **Edit record**.
6. Under **Route traffic to**, choose **Alias to CloudFront distribution**.
7. Under **Choose distribution**, choose the CloudFront distribution.
8. Choose **Save**.
9. To redirect the *A* record for the root domain to the CloudFront distribution, repeat this procedure for the root domain, for example, `example.com`.

The update to the record sets takes effect within 2–48 hours.

10. To see whether the new *A* records have taken effect, in a web browser, enter your subdomain URL, for example, `http://www.example.com`.

    If the browser no longer redirects you to the root domain (for example, `http://example.com`), the new A records are in place. When the new *A* record has taken effect, traffic routed by the new *A* record to the CloudFront distribution is not redirected to the root domain. Any visitors who reference the site by using `http://example.com` or `http://www.example.com` are redirected to the nearest CloudFront edge location, where they benefit from faster download times.

    > **Tip**
    >
    > Browsers can cache redirect settings. If you think the new *A* record settings should have taken effect, but your browser still redirects `http://www.example.com` to `http://example.com`, try clearing your browser history and cache, closing and reopening your browser application, or using a different web browser.

## (Optional) Step 3: Check the log files

The access logs tell you how many people are visiting the website. They also contain valuable business data that you can analyze with other services, such as Amazon EMR.

CloudFront logs are stored in the bucket and folder that you choose when you create a CloudFront distribution and enable logging. CloudFront writes logs to your log bucket within 24 hours from when the corresponding requests are made.

**To see the log files for your website**

1. Open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. Choose the name of the logging bucket for your website.
3. Choose the CloudFront logs folder.
4. Download the `.gzip` files written by CloudFront before opening them.

If you created your website only as a learning exercise, you can delete the resources that you allocated so that you no longer accrue charges. To do so, see Cleaning up your example resources. After you delete your AWS resources, your website is no longer available.

## Cleaning up your example resources

If you created your static website as a learning exercise, you should delete the AWS resources that you allocated so that you no longer accrue charges. After you delete your AWS resources, your website is no longer available.

**Tasks**

- Step 1: Delete the Amazon CloudFront distribution
- Step 2: Delete the Route 53 hosted zone
- Step 3: Disable logging and delete your S3 bucket

### Step 1: Delete the Amazon CloudFront distribution

Before you delete an Amazon CloudFront distribution, you must disable it. A disabled distribution is no longer functional and does not accrue charges. You can enable a disabled distribution at any time. After you delete a disabled distribution, it is no longer available.

**To disable and delete a CloudFront distribution**

1. Open the CloudFront console at https://console.aws.amazon.com/cloudfront/v4/home.
2. Select the distribution that you want to disable, and then choose **Disable**.
3. When prompted for confirmation, choose **Yes, Disable**.
4. Select the disabled distribution, and then choose **Delete**.
5. When prompted for confirmation, choose **Yes, Delete**.

### Step 2: Delete the Route 53 hosted zone

Before you delete the hosted zone, you must delete the record sets that you created. You don't need to delete the NS and SOA records; these are automatically deleted when you delete the hosted zone.

**To delete the record sets**

1. Open the Route 53 console at https://console.aws.amazon.com/route53/.
2. In the list of domain names, select your domain name, and then choose **Go to Record Sets**.
3. In the list of record sets, select the *A* records that you created.

   The type of each record set is listed in the **Type** column.
4. Choose **Delete Record Set**.
5. When prompted for confirmation, choose **Confirm**.

**To delete a Route 53 hosted zone**

1. Continuing from the previous procedure, choose **Back to Hosted Zones**.
2. Select your domain name, and then choose **Delete Hosted Zone**.
3. When prompted for confirmation, choose **Confirm**.

## Step 3: Disable logging and delete your S3 bucket

Before you delete your S3 bucket, make sure that logging is disabled for the bucket. Otherwise, AWS continues to write logs to your bucket as you delete it.

**To disable logging for a bucket**

1. Open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. Under **Buckets**, choose your bucket name, and then choose **Properties**.
3. From **Properties**, choose **Logging**.
4. Clear the **Enabled** check box.
5. Choose **Save**.

Now, you can delete your bucket. For more information, see Deleting a bucket.

# Creating, configuring, and working with Amazon S3 buckets

To store your data in Amazon S3, you work with resources known as buckets and objects. A *bucket* is a container for objects. An *object* is a file and any metadata that describes that file.

To store an object in Amazon S3, you create a bucket and then upload the object to a bucket. When the object is in the bucket, you can open it, download it, and move it. When you no longer need an object or a bucket, you can clean up your resources.

> **Note**
>
> For more information about using the Amazon S3 Express One Zone storage class with directory buckets, see What is S3 Express One Zone? and Directory buckets.

> **Note**
>
> With Amazon S3, you pay only for what you use. For more information about Amazon S3 features and pricing, see Amazon S3. If you are a new Amazon S3 customer, you can get started with Amazon S3 for free. For more information, see AWS Free Tier.

The topics in this section provide an overview of working with buckets in Amazon S3. They include information about naming, creating, accessing, and deleting buckets. For more information about viewing or listing objects in a bucket, see Organizing, listing, and working with your objects.

**Topics**

- Setting default server-side encryption behavior for Amazon S3 buckets
- Working with Mountpoint for Amazon S3
- Configuring fast, secure file transfers using Amazon S3 Transfer Acceleration
- Using Requester Pays buckets for storage transfers and usage
- Bucket quotas, restrictions, and limitations

## Buckets overview

To upload your data (photos, videos, documents, etc.) to Amazon S3, you must first create an S3 bucket in one of the AWS Regions.

A bucket is a container for objects stored in Amazon S3. You can store any number of objects in a bucket and can have up to 100 buckets in your account. To request an increase, visit the Service Quotas console.

Every object is contained in a bucket. For example, if the object named `photos/puppy.jpg` is stored in the `amzn-s3-demo-bucket` bucket in the US West (Oregon) Region, then it is addressable by using the URL `https://amzn-s3-demo-bucket.s3.us-west-2.amazonaws.com/photos/puppy.jpg`. For more information, see Accessing a Bucket.

In terms of implementation, buckets and objects are AWS resources, and Amazon S3 provides APIs for you to manage them. For example, you can create a bucket and upload objects using the Amazon S3 API. You can also use the Amazon S3 console to perform these operations. The console uses the Amazon S3 APIs to send requests to Amazon S3.

This section describes how to work with buckets. For information about working with objects, see Amazon S3 objects overview.

Amazon S3 supports global buckets, which means that each bucket name must be unique across all AWS accounts in all the AWS Regions within a partition. A partition is a grouping of Regions. AWS currently has three partitions: `aws` (Standard Regions), `aws-cn` (China Regions), and `aws-us-gov` (AWS GovCloud (US)).

After a bucket is created, the name of that bucket cannot be used by another AWS account in the same partition until the bucket is deleted. You should not depend on specific bucket naming conventions for availability or security verification purposes. For bucket naming guidelines, see Bucket naming rules.

Amazon S3 creates buckets in a Region that you specify. To reduce latency, minimize costs, or address regulatory requirements, choose any AWS Region that is geographically close to you. For example, if you reside in Europe, you might find it advantageous to create buckets in the Europe (Ireland) or Europe (Frankfurt) Regions. For a list of Amazon S3 Regions, see Regions and Endpoints in the *AWS General Reference*.

**Note**

For more information about using the Amazon S3 Express One Zone storage class with directory buckets, see What is S3 Express One Zone? and Directory buckets.

**Note**

Objects that belong to a bucket that you create in a specific AWS Region never leave that Region, unless you explicitly transfer them to another Region. For example, objects that are stored in the Europe (Ireland) Region never leave it.

**Topics**

## About permissions

You can use your AWS account root user credentials to create a bucket and perform any other Amazon S3 operation. However, we recommend that you do not use the root user credentials of your AWS account to make requests, such as to create a bucket. Instead, create an AWS Identity and Access Management (IAM) user, and grant that user full access (users by default have no permissions).

These users are referred to as *administrators*. You can use the administrator user credentials, instead of the root user credentials of your account, to interact with AWS and perform tasks, such as create a bucket, create users, and grant them permissions.

For more information, see AWS account root user credentials and IAM user credentials in the *AWS General Reference* and Security best practices in IAM in the *IAM User Guide*.

The AWS account that creates a resource owns that resource. For example, if you create an IAM user in your AWS account and grant the user permission to create a bucket, the user can create a bucket. But the user does not own the bucket; the AWS account that the user belongs to owns the bucket. The user needs additional permission from the resource owner to perform any other bucket operations. For more information about managing permissions for your Amazon S3 resources, see Identity and Access Management for Amazon S3.

## Managing public access to buckets

Public access is granted to buckets and objects through bucket policies, access control lists (ACLs), or both. To help you manage public access to Amazon S3 resources, Amazon S3 provides settings to block public access. Amazon S3 Block Public Access settings can override ACLs and bucket policies so that you can enforce uniform limits on public access to these resources. You can apply Block Public Access settings to individual buckets or to all buckets in your account.

To ensure that all of your Amazon S3 buckets and objects have their public access blocked, all four settings for Block Public Access are enabled by default when you create a new bucket. We recommend that you turn on all four settings for Block Public Access for your account too. These settings block all public access for all current and future buckets.

Before applying these settings, verify that your applications will work correctly without public access. If you require some level of public access to your buckets or objects—for example, to host a static website, as described at Hosting a static website using Amazon S3—you can customize the individual settings to suit your storage use cases. For more information, see Blocking public access to your Amazon S3 storage.

However, we highly recommend keeping Block Public Access enabled. If you want to keep all four Block Public Access settings enabled and host a static website, you can use Amazon CloudFront origin access control (OAC). Amazon CloudFront provides the capabilities required to set up a secure static website. Amazon S3 static websites support only HTTP endpoints. Amazon CloudFront uses the durable storage of Amazon S3 while providing additional security headers, such as HTTPS. HTTPS adds security by encrypting a normal HTTP request and protecting against common cyberattacks.

For more information, see Getting started with a secure static website in the *Amazon CloudFront Developer Guide*.

**Note**

If you see an `Error` when you list your buckets and their public access settings, you might not have the required permissions. Make sure that you have the following permissions added to your user or role policy:

```
s3:GetAccountPublicAccessBlock
s3:GetBucketPublicAccessBlock
s3:GetBucketPolicyStatus
s3:GetBucketLocation
s3:GetBucketAcl
s3:ListAccessPoints
s3:ListAllMyBuckets
```

In some rare cases, requests can also fail because of an AWS Region outage.

## Bucket configuration options

Amazon S3 supports various options for you to configure your bucket. For example, you can configure your bucket for website hosting, add a configuration to manage the lifecycle of objects in the bucket, and configure the bucket to log all access to the bucket. Amazon S3 supports subresources for you to store and manage the bucket configuration information. You can use the Amazon S3 API to create and manage these subresources. However, you can also use the console or the AWS SDKs.

**Note**

There are also object-level configurations. For example, you can configure object-level permissions by configuring an access control list (ACL) specific to that object.

These are referred to as subresources because they exist in the context of a specific bucket or object. The following table lists subresources that enable you to manage bucket-specific configurations.

| Subresource | Description |
| --- | --- |
| *cors* (cross-origin resource sharing) | You can configure your bucket to allow cross-origin requests.<br><br>For more information, see Using cross-origin resource sharing (CORS). |
| *event notification* | You can enable your bucket to send you notifications of specified bucket events.<br><br>For more information, see Amazon S3 Event Notifications. |
| *lifecycle* | You can define lifecycle rules for objects in your bucket that have a well-defined lifecycle. For example, you can define a rule to archive objects one year after creation, or delete an object 10 years after creation.<br><br>For more information, see Managing your storage lifecycle. |
| *location* | When you create a bucket, you specify the AWS Region where you want Amazon S3 to create the bucket. Amazon S3 stores this information in the location subresource and provides an API for you to retrieve this infor mation. |
| *logging* | Logging enables you to track requests for access to your bucket. Each access log record provides details about a single access request, such as the requester, bucket name, request time, request action, response status, and error code, if any. Access log information can be useful in security and access audits. It can also help you learn about your customer base and understand your Amazon S3 bill.<br><br>For more information, see Logging requests with server access logging. |
| *object locking* | To use S3 Object Lock, you must enable it for a bucket. You can also optionally configure a default retention mode and period that applies to new objects that are placed in the bucket.<br><br>For more information, see Using S3 Object Lock. |
| *policy* and *ACL* (access control list) | All your resources (such as buckets and objects) are private by default . Amazon S3 supports both bucket policy and access control list (ACL) |

| Subresource | Description |
| --- | --- |
| | options for you to grant and manage bucket-level permissions. Amazon S3 stores the permission information in the *policy* and *acl* subresources.<br><br>For more information, see Identity and Access Management for Amazon S3. |
| *replication* | Replication is the automatic, asynchronous copying of objects across buckets in different or the same AWS Regions. For more information, see Replicating objects overview. |
| *requestPayment* | By default, the AWS account that creates the bucket (the bucket owner) pays for downloads from the bucket. Using this subresource, the bucket owner can specify that the person requesting the download will be charged for the download. Amazon S3 provides an API for you to manage this subresource.<br><br>For more information, see Using Requester Pays buckets for storage transfers and usage. |
| *tagging* | You can add cost allocation tags to your bucket to categorize and track your AWS costs. Amazon S3 provides the *tagging* subresource to store and manage tags on a bucket. Using tags you apply to your bucket, AWS generates a cost allocation report with usage and costs aggregated by your tags.<br><br>For more information, see Billing and usage reporting for Amazon S3. |
| *transfer acceleration* | Transfer Acceleration enables fast, easy, and secure transfers of files over long distances between your client and an S3 bucket. Transfer Acceleration takes advantage of the globally distributed edge locations of Amazon CloudFront.<br><br>For more information, see Configuring fast, secure file transfers using Amazon S3 Transfer Acceleration. |

| Subresource | Description |
| --- | --- |
| *versioning* | Versioning helps you recover accidental overwrites and deletes.<br><br>We recommend versioning as a best practice to recover objects from being deleted or overwritten by mistake.<br><br>For more information, see Using versioning in S3 buckets. |
| *website* | You can configure your bucket for static website hosting. Amazon S3 stores this configuration by creating a *website* subresource.<br><br>For more information, see Hosting a static website using Amazon S3. |

# Bucket naming rules

The following rules apply for naming general purpose buckets and directory buckets in Amazon S3:

**Topics**

- General purpose buckets naming rules
- Directory bucket naming rules

## General purpose buckets naming rules

The following naming rules apply for general purpose buckets.

- Bucket names must be between 3 (min) and 63 (max) characters long.
- Bucket names can consist only of lowercase letters, numbers, dots (.), and hyphens (-).
- Bucket names must begin and end with a letter or number.
- Bucket names must not contain two adjacent periods.
- Bucket names must not be formatted as an IP address (for example, 192.168.5.4).
- Bucket names must not start with the prefix `xn--`.
- Bucket names must not start with the prefix `sthree-`.
- Bucket names must not start with the prefix `sthree-configurator`.
- Bucket names must not start with the prefix `amzn-s3-demo-`.

- Bucket names must not end with the suffix `-s3alias`. This suffix is reserved for access point alias names. For more information, see Using a bucket-style alias for your S3 bucket access point.
- Bucket names must not end with the suffix `--ol-s3`. This suffix is reserved for Object Lambda Access Point alias names. For more information, see How to use a bucket-style alias for your S3 bucket Object Lambda Access Point.
- Bucket names must not end with the suffix `.mrap`. This suffix is reserved for Multi-Region Access Point names. For more information, see Rules for naming Amazon S3 Multi-Region Access Points.
- Bucket names must not end with the suffix `--x-s3`. This suffix is reserved for directory buckets. For more information, see Directory bucket naming rules.
- Bucket names must be unique across all AWS accounts in all the AWS Regions within a partition. A partition is a grouping of Regions. AWS currently has three partitions: `aws` (Standard Regions), `aws-cn` (China Regions), and `aws-us-gov` (AWS GovCloud (US)).
- A bucket name cannot be used by another AWS account in the same partition until the bucket is deleted.
- Buckets used with Amazon S3 Transfer Acceleration can't have dots (.) in their names. For more information about Transfer Acceleration, see Configuring fast, secure file transfers using Amazon S3 Transfer Acceleration.

For best compatibility, we recommend that you avoid using dots (.) in bucket names, except for buckets that are used only for static website hosting. If you include dots in a bucket's name, you can't use virtual-host-style addressing over HTTPS, unless you perform your own certificate validation. This is because the security certificates used for virtual hosting of buckets don't work for buckets with dots in their names.

This limitation doesn't affect buckets used for static website hosting, because static website hosting is only available over HTTP. For more information about virtual-host-style addressing, see Virtual hosting of buckets. For more information about static website hosting, see Hosting a static website using Amazon S3.

**Note**

Before March 1, 2018, buckets created in the US East (N. Virginia) Region could have names that were up to 255 characters long and included uppercase letters and underscores. Beginning March 1, 2018, new buckets in US East (N. Virginia) must conform to the same rules applied in all other Regions.

For information on object key names, see Creating object key names.

### Example general purpose bucket names

The following example bucket names are valid and follow the recommended naming guidelines for general purpose buckets:

- `docexamplebucket1`
- `log-delivery-march-2020`
- `my-hosted-content`

The following example bucket names are valid but not recommended for uses other than static website hosting:

- `docexamplewebsite.com`
- `www.docexamplewebsite.com`
- `my.example.s3.bucket`

The following example bucket names are *not* valid:

- `doc_example_bucket` (contains underscores)
- `DocExampleBucket` (contains uppercase letters)
- `doc-example-bucket-` (ends with a hyphen)

## Directory bucket naming rules

The following naming rules apply for directory buckets.

- Be unique within the chosen AWS Region and Availability Zone.
- Name must be between 3 (min) and 63 (max) characters long, including the suffix.
- Consists only of lowercase letters, numbers and hyphens (-).
- Begin and end with a letter or number.
- Must include the following suffix: `--`*`azid`*`--x-s3`.
- Bucket names must not start with the prefix `xn--`.

- Bucket names must not start with the prefix `sthree-`.
- Bucket names must not start with the prefix `sthree-configurator`.
- Bucket names must not start with the prefix `amzn-s3-demo-`.
- Bucket names must not end with the suffix `-s3alias`. This suffix is reserved for access point alias names. For more information, see Using a bucket-style alias for your S3 bucket access point.
- Bucket names must not end with the suffix `--ol-s3`. This suffix is reserved for Object Lambda Access Point alias names. For more information, see How to use a bucket-style alias for your S3 bucket Object Lambda Access Point.
- Bucket names must not end with the suffix `.mrap`. This suffix is reserved for Multi-Region Access Point names. For more information, see Rules for naming Amazon S3 Multi-Region Access Points.

> **Note**
>
> When you create a directory bucket by using the console a suffix is automatically added to the base name that you provide. This suffix includes the Availability Zone ID of the Availability Zone that you chose.
> When you create a directory bucket by using an API you must provide the full suffix, including the Availability Zone ID, in your request. For a list of Availability Zone IDs, see S3 Express One Zone Availability Zones and Regions.

## Accessing and listing an Amazon S3 bucket

To list and access your Amazon S3 buckets, you can use various tools. Review the following tools to determine which approach fits your use case:

- **Amazon S3 console:** With the Amazon S3 console, you can easily access a bucket and modify the bucket's properties. You can also perform most bucket operations by using the console UI, without having to write any code.
- **AWS CLI**: If you need to access multiple buckets, you can save time by using the AWS Command Line Interface (AWS CLI) to automate common and repetitive tasks. Scriptability and repeatability for common actions are frequent considerations as organizations scale. For more information, see Developing with Amazon S3 using the AWS CLI.
- **Amazon S3 REST API:** You can use the Amazon S3 REST API to write your own programs and access buckets programmatically. Amazon S3 supports an API architecture in which your buckets

and objects are resources, each with a resource URI that uniquely identifies the resource. For more information, see Developing with Amazon S3 using the REST API.

Depending on the use case for your Amazon S3 bucket, there are different recommended methods to access the underlying data in your buckets. The following list includes common use cases for accessing your data.

- **Static websites** – You can use Amazon S3 to host a static website. In this use case, you can configure your S3 bucket to function like a website. For an example that walks you through the steps of hosting a website on Amazon S3, see Tutorial: Configuring a static website on Amazon S3.

  To host a static website with security settings like Block Public Access enabled, we recommend using Amazon CloudFront with Origin Access Control (OAC) and implementing additional security headers, such as HTTPS. For more information, see Getting started with a secure static website.

  > **Note**
  >
  > Amazon S3 supports both virtual-hosted–style and path-style URLs for static website access. Because buckets can be accessed using path-style and virtual-hosted–style URLs, we recommend that you create buckets with DNS-compliant bucket names. For more information, see Bucket quotas, restrictions, and limitations.

- **Shared datasets** – As you scale on Amazon S3, it's common to adopt a multi-tenant model, where you assign different end customers or business units to unique prefixes within a shared bucket. By using Amazon S3 access points, you can divide one large bucket policy into separate, discrete access point policies for each application that needs to access the shared dataset. This approach makes it simpler to focus on building the right access policy for an application without disrupting what any other application is doing within the shared dataset. For more information, see Managing data access with Amazon S3 access points.
- **High-throughput workloads** – Mountpoint for Amazon S3 is a high-throughput open source file client for mounting an Amazon S3 bucket as a local file system. With Mountpoint, your applications can access objects stored in Amazon S3 through file-system operations, such as open and read. Mountpoint automatically translates these operations into S3 object API calls, giving your applications access to the elastic storage and throughput of Amazon S3 through a file interface. For more information, see Working with Mountpoint for Amazon S3.

- **Multi-Region applications** – Amazon S3 Multi-Region Access Points provide a global endpoint that applications can use to fulfill requests from S3 buckets that are located in multiple AWS Regions. You can use Multi-Region Access Points to build multi-Region applications with the same architecture that's used in a single Region, and then run those applications anywhere in the world. Instead of sending requests over the public internet, Multi-Region Access Points provide built-in network resilience with acceleration of internet-based requests to Amazon S3. For more information, see Multi-Region Access Points in Amazon S3.
- **Building new applications** – You can use the AWS SDKs when developing applications with Amazon S3. The AWS SDKs simplify your programming tasks by wrapping the underlying Amazon S3 REST API. To build connected mobile and web applications, you can use the AWS Mobile SDKs and the AWS Amplify JavaScript library. For more information, see Developing with Amazon S3 using the AWS SDKs.
- **Secure Shell (SSH) File Transfer Protocol (SFTP)** – If you're trying to securely transfer sensitive data over the internet, you can use an SFTP-enabled server with your Amazon S3 bucket. AWS SFTP is a network protocol that supports the full security and authentication functionality of SSH. With this protocol, you have fine-grained control over user identity, permissions, and keys or you can use IAM policies to manage access. To associate an SFTP enabled server with your Amazon S3 bucket, make sure to create your SFTP-enabled server first. Then, you set up user accounts, and associate the server with an Amazon S3 bucket. For a walkthrough of this process, see AWS Transfer for SFTP – Fully Managed SFTP Service for Amazon S3 in *AWS Blogs*.

## Listing a bucket

To list all of your buckets, you must have the `s3:ListAllMyBuckets` permission. To access a bucket, make sure to also obtain the required AWS Identity and Access Management (IAM) permissions to list the contents of the specified bucket. For an example bucket policy that grants access to an S3 bucket, see Allowing an IAM user access to one of your buckets. If you're encountering an HTTP Access Denied (403 Forbidden) error, see Bucket policies and IAM policies.

You can list your bucket by using the Amazon S3 console, the AWS CLI, or the AWS SDKs.

### Using the S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Buckets**.
3. From the **General purpose buckets** list, choose the bucket that you want to view.

> **Note**
>
> The **General purpose buckets** list includes buckets that are located in all AWS Regions.

#### Using the AWS CLI

To use the AWS CLI to access an S3 bucket or generate a listing of S3 buckets, use the `ls` command. When you list all of the objects in your bucket, note that you must have the `s3:ListBucket` permission.

To use this example command, replace *DOC-EXAMPLE-BUCKET1* with the name of your bucket.

```
$ aws s3 ls s3://DOC-EXAMPLE-BUCKET1
```

The following example command lists all the Amazon S3 buckets in your account:

```
$ aws s3 ls
```

For more information and examples, see List bucket and objects.

#### Using the AWS SDKs

You can also access an Amazon S3 bucket by using the ListBuckets API operation. For examples of how to use this operation with different AWS SDKs, see Use `ListBuckets` with an AWS SDK or CLI.

## Creating a bucket

To upload your data to Amazon S3, you must first create an Amazon S3 bucket in one of the AWS Regions. When you create a bucket, you must choose a bucket name and Region. You can optionally choose other storage management options for the bucket. After you create a bucket, you cannot change the bucket name or Region. For information about naming buckets, see Bucket naming rules.

The AWS account that creates the bucket owns it. You can upload any number of objects to the bucket. By default, you can create up to 100 buckets in each of your AWS accounts. If you need more buckets, you can increase your account bucket limit to a maximum of 1,000 buckets by submitting a service limit increase. To learn how to submit a bucket limit increase, see AWS service quotas in the *AWS General Reference*. You can store any number of objects in a bucket.

S3 Object Ownership is an Amazon S3 bucket-level setting that you can use both to control ownership of objects that are uploaded to your bucket and to disable or enable access control lists (ACLs). By default, Object Ownership is set to the Bucket owner enforced setting, and all ACLs are disabled. With ACLs disabled, the bucket owner owns every object in the bucket and manages access to data exclusively by using policies.

For more information, see Controlling ownership of objects and disabling ACLs for your bucket.

Server-side encryption with Amazon S3 managed keys (SSE-S3) is the base level of encryption configuration for every bucket in Amazon S3. All new objects uploaded to an S3 bucket are automatically encrypted with SSE-S3 as the base level of encryption setting. If you want to use a different type of default encryption, you can also specify server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS) or customer-provided keys (SSE-C) to encrypt your data. For more information, see Setting default server-side encryption behavior for Amazon S3 buckets.

You can use the Amazon S3 console, Amazon S3 APIs, AWS CLI, or AWS SDKs to create a bucket. For more information about the permissions required to create a bucket, see CreateBucket in the *Amazon Simple Storage Service API Reference*.

## Using the S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the navigation bar on the top of the page, choose the name of the currently displayed AWS Region. Next, choose the Region in which you want to create a bucket.

   > **Note**
   >
   > To minimize latency and costs and address regulatory requirements, choose a Region close to you. Objects stored in a Region never leave that Region unless you explicitly transfer them to another Region. For a list of Amazon S3 AWS Regions, see AWS service endpoints in the *Amazon Web Services General Reference*.

3. In the left navigation pane, choose **Buckets**.
4. Choose **Create bucket**.

   The **Create bucket** page opens.

5. Under **General configuration**, view the AWS Region where your bucket will be created.
6. Under **Bucket type**, choose **General purpose**.
7. For **Bucket name**, enter a name for your bucket.

   The bucket name must:

   - Be unique within a partition. A partition is a grouping of Regions. AWS currently has three partitions: `aws` (Standard Regions), `aws-cn` (China Regions), and `aws-us-gov` (AWS GovCloud (US) Regions).
   - Be between 3 and 63 characters long.
   - Consist only of lowercase letters, numbers, dots (.), and hyphens (-). For best compatibility, we recommend that you avoid using dots (.) in bucket names, except for buckets that are used only for static website hosting.
   - Begin and end with a letter or number.

   After you create the bucket, you cannot change its name. For more information about naming buckets, see Bucket naming rules.

   > **Important**
   >
   > Avoid including sensitive information, such as account numbers, in the bucket name. The bucket name is visible in the URLs that point to the objects in the bucket.

8. AWS Management Console allows you to copy an existing bucket's settings to your new bucket. If you do not want to copy the settings of an existing bucket, skip to the next step.

   > **Note**
   >
   > This option:
   >
   > - Is not available in the AWS CLI and is only available in console
   > - Is not available for directory buckets
   > - Does not copy the bucket policy from the existing bucket to the new bucket

   To copy an existing bucket's settings, under **Copy settings from existing bucket**, select **Choose bucket**. The **Choose bucket** window opens. Find the bucket with the settings that you would

like to copy, and select **Choose bucket**. The **Choose bucket** window closes, and the **Create bucket** window re-opens.

Under **Copy settings from existing bucket**, you will now see the name of the bucket you selected. You will also see a **Restore defaults** option that you can use to remove the copied bucket settings. Review the remaining bucket settings, on the **Create bucket** page. You will see that they now match the settings of the bucket that you selected. You can skip to the final step.

9. Under **Object Ownership**, to disable or enable ACLs and control ownership of objects uploaded in your bucket, choose one of the following settings:

   **ACLs disabled**

   - **Bucket owner enforced (default)** – ACLs are disabled, and the bucket owner automatically owns and has full control over every object in the bucket. ACLs no longer affect access permissions to data in the S3 bucket. The bucket uses policies exclusively to define access control.

     By default, ACLs are disabled. A majority of modern use cases in Amazon S3 no longer require the use of ACLs. We recommend that you keep ACLs disabled, except in unusual circumstances where you must control access for each object individually. For more information, see Controlling ownership of objects and disabling ACLs for your bucket.

   **ACLs enabled**

   - **Bucket owner preferred** – The bucket owner owns and has full control over new objects that other accounts write to the bucket with the `bucket-owner-full-control` canned ACL.

     If you apply the **Bucket owner preferred** setting, to require all Amazon S3 uploads to include the `bucket-owner-full-control` canned ACL, you can add a bucket policy that allows only object uploads that use this ACL.
   - **Object writer** – The AWS account that uploads an object owns the object, has full control over it, and can grant other users access to it through ACLs.

> **Note**
>
> The default setting is **Bucket owner enforced**. To apply the default setting and keep ACLs disabled, only the `s3:CreateBucket` permission is needed. To enable ACLs, you must have the `s3:PutBucketOwnershipControls` permission.

10. Under **Block Public Access settings for this bucket**, choose the Block Public Access settings that you want to apply to the bucket.

    By default, all four Block Public Access settings are enabled. We recommend that you keep all settings enabled, unless you know that you need to turn off one or more of them for your specific use case. For more information about blocking public access, see Blocking public access to your Amazon S3 storage.

    > **Note**
    >
    > To enable all Block Public Access settings, only the `s3:CreateBucket` permission is required. To turn off any Block Public Access settings, you must have the `s3:PutBucketPublicAccessBlock` permission.

11. (Optional) Under **Bucket Versioning**, you can choose if you wish to keep variants of objects in your bucket. For more information about versioning, see Using versioning in S3 buckets.

    To disable or enable versioning on your bucket, choose either **Disable** or **Enable**.

12. (Optional) Under **Tags**, you can choose to add tags to your bucket. Tags are key-value pairs used to categorize storage.

    To add a bucket tag, enter a **Key** and optionally a **Value** and choose **Add Tag**.

13. Under **Default encryption**, choose **Edit**.

14. To configure default encryption, under **Encryption type**, choose one of the following:

    - **Amazon S3 managed key (SSE-S3)**
    - **AWS Key Management Service key (SSE-KMS)**

> **Important**
>
> If you use the SSE-KMS option for your default encryption configuration, you are subject to the requests per second (RPS) quota of AWS KMS. For more information about AWS KMS quotas and how to request a quota increase, see Quotas in the *AWS Key Management Service Developer Guide*.

Buckets and new objects are encrypted with server-side encryption with an **Amazon S3 managed key** as the base level of encryption configuration. For more information about default encryption, see Setting default server-side encryption behavior for Amazon S3 buckets.

For more information about using Amazon S3 server-side encryption to encrypt your data, see Using server-side encryption with Amazon S3 managed keys (SSE-S3).

15. If you chose **AWS Key Management Service key (SSE-KMS)**, do the following:

    a. Under **AWS KMS key**, specify your KMS key in one of the following ways:

    - To choose from a list of available KMS keys, choose **Choose from your AWS KMS keys**, and choose your **KMS key** from the list of available keys.

      Both the AWS managed key (`aws/s3`) and your customer managed keys appear in this list. For more information about customer managed keys, see Customer keys and AWS keys in the *AWS Key Management Service Developer Guide*.
    - To enter the KMS key ARN, choose **Enter AWS KMS key ARN**, and enter your KMS key ARN in the field that appears.
    - To create a new customer managed key in the AWS KMS console, choose **Create a KMS key**.

      For more information about creating an AWS KMS key, see Creating keys in the *AWS Key Management Service Developer Guide*.

> **Important**
>
> You can use only KMS keys that are available in the same AWS Region as the bucket. The Amazon S3 console lists only the first 100 KMS keys in the same

Region as the bucket. To use a KMS key that is not listed, you must enter your KMS key ARN. If you want to use a KMS key that is owned by a different account, you must first have permission to use the key and then you must enter the KMS key ARN. For more information on cross account permissions for KMS keys, see Creating KMS keys that other accounts can use in the *AWS Key Management Service Developer Guide*. For more information on SSE-KMS, see Specifying server-side encryption with AWS KMS (SSE-KMS).
When you use an AWS KMS key for server-side encryption in Amazon S3, you must choose a symmetric encryption KMS key. Amazon S3 supports only symmetric encryption KMS keys and not asymmetric KMS keys. For more information, see Identifying symmetric and asymmetric KMS keys in the *AWS Key Management Service Developer Guide*.

For more information about creating an AWS KMS key, see Creating keys in the *AWS Key Management Service Developer Guide*. For more information about using AWS KMS with Amazon S3, see Using server-side encryption with AWS KMS keys (SSE-KMS).

b. When you configure your bucket to use default encryption with SSE-KMS, you can also enable S3 Bucket Keys. S3 Bucket Keys lower the cost of encryption by decreasing request traffic from Amazon S3 to AWS KMS. For more information, see Reducing the cost of SSE-KMS with Amazon S3 Bucket Keys.

   To use S3 Bucket Keys, under **Bucket Key**, choose **Enable**.

16. (Optional) If you want to enable S3 Object Lock, do the following:

    a. Choose **Advanced settings**.

> **Important**
>
> Enabling Object Lock also enables versioning for the bucket. After enabling you must configure the Object Lock default retention and legal hold settings to protect new objects from being deleted or overwritten.

    b. If you want to enable Object Lock, choose **Enable**, read the warning that appears, and acknowledge it.

For more information, see Using S3 Object Lock.

> **Note**
>
> To create an Object Lock enabled bucket, you must have the following permissions: `s3:CreateBucket`, `s3:PutBucketVersioning` and `s3:PutBucketObjectLockConfiguration`.

17. Choose **Create bucket**.

## Using the AWS SDKs

When you use the AWS SDKs to create a bucket, you must create a client and then use the client to send a request to create a bucket. As a best practice, you should create your client and bucket in the same AWS Region. If you don't specify a Region when you create a client or a bucket, Amazon S3 uses the default Region, US East (N. Virginia). If you want to constrain the bucket creation to a specific AWS Region, use the `LocationConstraint` condition key.

To create a client to access a dual-stack endpoint, you must specify an AWS Region. For more information, see Dual-stack endpoints. For a list of available AWS Regions, see Regions and endpoints in the *AWS General Reference*.

When you create a client, the Region maps to the Region-specific endpoint. The client uses this endpoint to communicate with Amazon S3: `s3.region.amazonaws.com`. If your Region launched after March 20, 2019, your client and bucket must be in the same Region. However, you can use a client in the US East (N. Virginia) Region to create a bucket in any Region that launched before March 20, 2019. For more information, see Legacy endpoints.

These AWS SDK code examples perform the following tasks:

- **Create a client by explicitly specifying an AWS Region** – In the example, the client uses the `s3.us-west-2.amazonaws.com` endpoint to communicate with Amazon S3. You can specify any AWS Region. For a list of AWS Regions, see Regions and endpoints in the *AWS General Reference*.
- **Send a create bucket request by specifying only a bucket name** – The client sends a request to Amazon S3 to create the bucket in the Region where you created a client.
- **Retrieve information about the location of the bucket** – Amazon S3 stores bucket location information in the *location* subresource that is associated with the bucket.

Java

This example shows how to create an Amazon S3 bucket using the AWS SDK for Java. For instructions on creating and testing a working sample, see Getting Started in the AWS SDK for Java Developer Guide.

```
import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import com.amazonaws.auth.profile.ProfileCredentialsProvider;
import com.amazonaws.regions.Regions;
import com.amazonaws.services.s3.AmazonS3;
import com.amazonaws.services.s3.AmazonS3ClientBuilder;
import com.amazonaws.services.s3.model.CreateBucketRequest;
import com.amazonaws.services.s3.model.GetBucketLocationRequest;

import java.io.IOException;

public class CreateBucket2 {

    public static void main(String[] args) throws IOException {
        Regions clientRegion = Regions.DEFAULT_REGION;
        String bucketName = "*** Bucket name ***";

        try {
            AmazonS3 s3Client = AmazonS3ClientBuilder.standard()
                    .withCredentials(new ProfileCredentialsProvider())
                    .withRegion(clientRegion)
                    .build();

            if (!s3Client.doesBucketExistV2(bucketName)) {
                // Because the CreateBucketRequest object doesn't specify a region,
 the
                // bucket is created in the region specified in the client.
                s3Client.createBucket(new CreateBucketRequest(bucketName));

                // Verify that the bucket was created by retrieving it and checking
 its
                // location.
                String bucketLocation = s3Client.getBucketLocation(new
 GetBucketLocationRequest(bucketName));
                System.out.println("Bucket location: " + bucketLocation);
            }
```

```
        } catch (AmazonServiceException e) {
            // The call was transmitted successfully, but Amazon S3 couldn't process
            // it and returned an error response.
            e.printStackTrace();
        } catch (SdkClientException e) {
            // Amazon S3 couldn't be contacted for a response, or the client
            // couldn't parse the response from Amazon S3.
            e.printStackTrace();
        }
    }
}
```

.NET

For information about how to create and test a working sample, see AWS SDK for .NET Version 3 API Reference.

**Example**

```
using Amazon;
using Amazon.S3;
using Amazon.S3.Model;
using Amazon.S3.Util;
using System;
using System.Threading.Tasks;

namespace Amazon.DocSamples.S3
{
    class CreateBucketTest
    {
        private const string bucketName = "*** bucket name ***";
        // Specify your bucket region (an example region is shown).
        private static readonly RegionEndpoint bucketRegion =
 RegionEndpoint.USWest2;
        private static IAmazonS3 s3Client;
        public static void Main()
        {
            s3Client = new AmazonS3Client(bucketRegion);
            CreateBucketAsync().Wait();
        }

        static async Task CreateBucketAsync()
        {
```

```
            try
            {
                if (!(await AmazonS3Util.DoesS3BucketExistAsync(s3Client,
 bucketName)))
                {
                    var putBucketRequest = new PutBucketRequest
                    {
                        BucketName = bucketName,
                        UseClientRegion = true
                    };

                    PutBucketResponse putBucketResponse = await
 s3Client.PutBucketAsync(putBucketRequest);
                }
                // Retrieve the bucket location.
                string bucketLocation = await FindBucketLocationAsync(s3Client);
            }
            catch (AmazonS3Exception e)
            {
                Console.WriteLine("Error encountered on server. Message:'{0}' when
 writing an object", e.Message);
            }
            catch (Exception e)
            {
                Console.WriteLine("Unknown encountered on server. Message:'{0}' when
 writing an object", e.Message);
            }
        }
        static async Task<string> FindBucketLocationAsync(IAmazonS3 client)
        {
            string bucketLocation;
            var request = new GetBucketLocationRequest()
            {
                BucketName = bucketName
            };
            GetBucketLocationResponse response = await
 client.GetBucketLocationAsync(request);
            bucketLocation = response.Location.ToString();
            return bucketLocation;
        }
    }
}
```

Ruby

For information about how to create and test a working sample, see AWS SDK for Ruby - Version 3.

**Example**

```
require "aws-sdk-s3"

# Wraps Amazon S3 bucket actions.
class BucketCreateWrapper
  attr_reader :bucket

  # @param bucket [Aws::S3::Bucket] An Amazon S3 bucket initialized with a name.
 This is a client-side object until
  #                                  create is called.
  def initialize(bucket)
    @bucket = bucket
  end

  # Creates an Amazon S3 bucket in the specified AWS Region.
  #
  # @param region [String] The Region where the bucket is created.
  # @return [Boolean] True when the bucket is created; otherwise, false.
  def create?(region)
    @bucket.create(create_bucket_configuration: { location_constraint: region })
    true
  rescue Aws::Errors::ServiceError => e
    puts "Couldn't create bucket. Here's why: #{e.message}"
    false
  end

  # Gets the Region where the bucket is located.
  #
  # @return [String] The location of the bucket.
  def location
    if @bucket.nil?
      "None. You must create a bucket before you can get its location!"
    else
      @bucket.client.get_bucket_location(bucket: @bucket.name).location_constraint
    end
  rescue Aws::Errors::ServiceError => e
    "Couldn't get the location of #{@bucket.name}. Here's why: #{e.message}"
  end
```

```
end

# Example usage:
def run_demo
  region = "us-west-2"
  wrapper = BucketCreateWrapper.new(Aws::S3::Bucket.new("doc-example-bucket-
#{Random.uuid}"))
  return unless wrapper.create?(region)

  puts "Created bucket #{wrapper.bucket.name}."
  puts "Your bucket's region is: #{wrapper.location}"
end

run_demo if $PROGRAM_NAME == __FILE__
```

### Using the AWS CLI

You can also use the AWS Command Line Interface (AWS CLI) to create an S3 bucket. For more information, see create-bucket in the *AWS CLI Command Reference*.

For information about the AWS CLI, see What is the AWS Command Line Interface? in the *AWS Command Line Interface User Guide*.

## Viewing the properties for an S3 bucket

You can view properties for any Amazon S3 bucket you own. These settings include the following:

- **Bucket Versioning** – Keep multiple versions of an object in one bucket by using versioning. By default, versioning is disabled for a new bucket. For information about enabling versioning, see Enabling versioning on buckets.
- **Tags** – With AWS cost allocation, you can use bucket tags to annotate billing for your use of a bucket. A tag is a key-value pair that represents a label that you assign to a bucket. For more information, see Using cost allocation S3 bucket tags.
- **Default encryption** – Enabling default encryption provides you with automatic server-side encryption. Amazon S3 encrypts an object before saving it to a disk and decrypts the object when you download it. For more information, see Setting default server-side encryption behavior for Amazon S3 buckets.

- **Server access logging** – Get detailed records for the requests that are made to your bucket with server access logging. By default, Amazon S3 doesn't collect server access logs. For information about enabling server access logging, see Enabling Amazon S3 server access logging.
- **AWS CloudTrail data events** – Use CloudTrail to log data events. By default, trails don't log data events. Additional charges apply for data events. For more information, see Logging Data Events for Trails in the *AWS CloudTrail User Guide*.
- **Event notifications** – Enable certain Amazon S3 bucket events to send notification messages to a destination whenever the events occur. For more information, see Enabling and configuring event notifications using the Amazon S3 console.
- **Transfer acceleration** – Enable fast, easy, and secure transfers of files over long distances between your client and an S3 bucket. For information about enabling transfer acceleration, see Enabling and using S3 Transfer Acceleration.
- **Object Lock** – Use S3 Object Lock to prevent an object from being deleted or overwritten for a fixed amount of time or indefinitely. For more information, see Using S3 Object Lock.
- **Requester Pays** – Enable Requester Pays if you want the requester (instead of the bucket owner) to pay for requests and data transfers. For more information, see Using Requester Pays buckets for storage transfers and usage.
- **Static website hosting** – You can host a static website on Amazon S3. For more information, see Hosting a static website using Amazon S3.

You can view bucket properties using the AWS Management Console, AWS CLI, or AWS SDKs

## Using the S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the **Buckets** list, choose the name of the bucket that you want to view the properties for.
3. Choose the **Properties** tab.
4. On the **Properties** page, you can configure the above properties for the bucket.

## Using the AWS CLI

### View bucket properties with the AWS CLI

The following commands show how you can use the AWS CLI to list different bucket properties.

The following returns the tag set associated with the bucket *amzn-s3-demo-bucket1*. For more information about bucket tags see, Using cost allocation S3 bucket tags.

```
aws s3api get-bucket-tagging --bucket amzn-s3-demo-bucket1
```

For more information and examples, see get-bucket-tagging in the *AWS CLI Command Reference*.

The following returns the versioning state of the bucket *amzn-s3-demo-bucket1*. For information about the bucket versioning, see Using versioning in S3 buckets.

```
aws s3api get-bucket-versioning --bucket amzn-s3-demo-bucket1
```

For more information and examples, see get-bucket-versioning in the *AWS CLI Command Reference*.

The following returns the default encryption configuration for the bucket *amzn-s3-demo-bucket1*. By default, all buckets have a default encryption configuration that uses server-side encryption with Amazon S3 managed keys (SSE-S3). For information about the bucket default encryption, see Setting default server-side encryption behavior for Amazon S3 buckets.

```
aws s3api get-bucket-encryption --bucket amzn-s3-demo-bucket1
```

For more information and examples, see get-bucket-encryption in the *AWS CLI Command Reference*.

The following returns the notification configuration of the bucket *amzn-s3-demo-bucket1*. For information about the bucket event notifications, see Amazon S3 Event Notifications.

```
aws s3api get-bucket-notification-configuration --bucket amzn-s3-demo-bucket1
```

For more information and examples, see get-bucket-notification-configuration in the *AWS CLI Command Reference*.

The following returns the logging status for the bucket *amzn-s3-demo-bucket1*. For information about the bucket logging, see Logging requests with server access logging.

```
aws s3api get-bucket-logging --bucket amzn-s3-demo-bucket1
```

For more information and examples, see get-bucket-logging in the *AWS CLI Command Reference*.

### Using the AWS SDKs

For examples of how to return bucket properties with the AWS SDKs, such as versioning, tags, and more, see Actions for Amazon S3 using AWS SDKs.

For general information about using different AWS SDKs, see Developing with Amazon S3 using the AWS SDKs.

## Emptying a bucket

You can empty a bucket's contents using the Amazon S3 console, AWS SDKs, or AWS Command Line Interface (AWS CLI). When you empty a bucket, you delete all the objects, but you keep the bucket. After you empty a bucket, it cannot be undone. Objects added to the bucket while the empty bucket action is in progress might be deleted. All objects (including all object versions and delete markers) in the bucket must be deleted before the bucket itself can be deleted.

When you empty a bucket that has S3 Versioning enabled or suspended, all versions of all the objects in the bucket are deleted. For more information, see Working with objects in a versioning-enabled bucket.

You can also specify a lifecycle configuration on a bucket to expire objects so that Amazon S3 can delete them. For more information, see Setting a lifecycle configuration on a bucket. To empty a large bucket, we recommend that you use an S3 Lifecycle configuration rule. Lifecycle expiration is an asynchronous process, so the rule might take some days to run before the bucket is empty. After the first time that Amazon S3 runs the rule, all objects that are eligible for expiration are marked for deletion. You're no longer charged for those objects that are marked for deletion. For more information, see How do I empty an Amazon S3 bucket using a lifecycle configuration rule?.

### Using the S3 console

You can use the Amazon S3 console to empty a bucket, which deletes all of the objects in the bucket without deleting the bucket.

#### To empty an S3 bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the **Bucket name** list, select the option next to the name of the bucket that you want to empty, and then choose **Empty**.

3. On the **Empty bucket** page, confirm that you want to empty the bucket by entering the bucket name into the text field, and then choose **Empty**.
4. Monitor the progress of the bucket emptying process on the **Empty bucket: Status** page.

## Using the AWS CLI

You can empty a bucket using the AWS CLI only if the bucket does not have Bucket Versioning enabled. If versioning is not enabled, you can use the `rm` (remove) AWS CLI command with the `--recursive` parameter to empty the bucket (or remove a subset of objects with a specific key name prefix).

The following `rm` command removes objects that have the key name prefix `doc`, for example, `doc/doc1` and `doc/doc2`.

```
$ aws s3 rm s3://bucket-name/doc --recursive
```

Use the following command to remove all objects without specifying a prefix.

```
$ aws s3 rm s3://bucket-name --recursive
```

For more information, see Using high-level S3 commands with the AWS CLI in the *AWS Command Line Interface User Guide*.

> **Note**
>
> You can't remove objects from a bucket that has versioning enabled. Amazon S3 adds a delete marker when you delete an object, which is what this command does. For more information about S3 Bucket Versioning, see Using versioning in S3 buckets.

## Using the AWS SDKs

You can use the AWS SDKs to empty a bucket or remove a subset of objects that have a specific key name prefix.

For an example of how to empty a bucket using AWS SDK for Java, see Deleting a bucket. The code deletes all objects, regardless of whether the bucket has versioning enabled, and then it deletes

the bucket. To just empty the bucket, make sure that you remove the statement that deletes the bucket.

For more information about using other AWS SDKs, see Tools for Amazon Web Services.

### Using a lifecycle configuration

To empty a large bucket, we recommend that you use an S3 Lifecycle configuration rule. Lifecycle expiration is an asynchronous process, so the rule might take some days to run before the bucket is empty. After the first time that Amazon S3 runs the rule, all objects that are eligible for expiration are marked for deletion. You're no longer charged for those objects that are marked for deletion. For more information, see How do I empty an Amazon S3 bucket using a lifecycle configuration rule?.

If you use a lifecycle configuration to empty your bucket, the configuration should include current versions, non-current versions, delete markers, and incomplete multipart uploads.

You can add lifecycle configuration rules to expire all objects or a subset of objects that have a specific key name prefix. For example, to remove all objects in a bucket, you can set a lifecycle rule to expire objects one day after creation.

Amazon S3 supports a bucket lifecycle rule that you can use to stop multipart uploads that don't complete within a specified number of days after being initiated. We recommend that you configure this lifecycle rule to minimize your storage costs. For more information, see Configuring a bucket lifecycle configuration to delete incomplete multipart uploads.

For more information about using a lifecycle configuration to empty a bucket, see Setting a lifecycle configuration on a bucket and Expiring objects.

## Emptying a bucket with AWS CloudTrail configured

AWS CloudTrail tracks object-level data events in an Amazon S3 bucket, such as deleting objects. If you use a bucket as a destination to log your CloudTrail events and are deleting objects from that same bucket you may be creating new objects while emptying your bucket. To prevent this, stop your AWS CloudTrail trails. For more information about stopping your CloudTrail trails from logging events, see Turning off logging for a trail in the *AWS CloudTrail User Guide*.

Another alternative to stopping CloudTrail trails from being added to the bucket is to add a deny `s3:PutObject` statement to your bucket policy. If you want to store new objects in the bucket at a

later time you will need to remove this deny `s3:PutObject` statement. For more information, see Object operations and IAM JSON policy elements: Effect in the *IAM User Guide*.

# Deleting a bucket

You can delete an empty Amazon S3 bucket. Before deleting a bucket, consider the following:

- Bucket names are unique. If you delete a bucket, another AWS user can use the name.
- If the bucket hosts a static website, and you created and configured an Amazon Route 53 hosted zone as described in Tutorial: Configuring a static website using a custom domain registered with Route 53, you must clean up the Route 53 hosted zone settings that are related to the bucket. For more information, see Step 2: Delete the Route 53 hosted zone.
- If the bucket receives log data from Elastic Load Balancing (ELB): We recommend that you stop the delivery of ELB logs to the bucket before deleting it. After you delete the bucket, if another user creates a bucket using the same name, your log data could potentially be delivered to that bucket. For information about ELB access logs, see Access logs in the *User Guide for Classic Load Balancers* and Access logs in the *User Guide for Application Load Balancers*.

### Troubleshooting

If you are unable to delete an Amazon S3 bucket, consider the following:

- **Make sure the bucket is empty** – You can only delete buckets that don't have any objects in them. Make sure the bucket is empty.
- **Make sure there aren't any access points attached** – You can only delete buckets that don't have any access points attached to them. Delete any access points that are attached to the bucket, before deleting the bucket.
- **AWS Organizations service control policies (SCPs)** – A service control policy can deny the delete permission on a bucket. For information about SCPs, see Service control policies in the *AWS Organizations User Guide*.
- **s3:DeleteBucket permissions** – If you cannot delete a bucket, work with your IAM administrator to confirm that you have `s3:DeleteBucket` permissions. For information about how to view or update IAM permissions, see Changing permissions for an IAM user in the *IAM User Guide*.
- **s3:DeleteBucket deny statement** – If you have `s3:DeleteBucket` permissions in your IAM policy and you cannot delete a bucket, the bucket policy might include a deny statement for `s3:DeleteBucket`. Buckets created by ElasticBeanstalk have a policy containing this statement

by default. Before you can delete the bucket, you must delete this statement or the bucket policy.

> **Important**
>
> Bucket names are unique. If you delete a bucket, another AWS user can use the name. If you want to continue to use the same bucket name, don't delete the bucket. We recommend that you empty the bucket and keep it.

## Using the S3 console

### To delete an S3 bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the **Buckets** list, select the option next to the name of the bucket that you want to delete, and then choose **Delete** at the top of the page.
3. On the **Delete bucket** page, confirm that you want to delete the bucket by entering the bucket name into the text field, and then choose **Delete bucket**.

   > **Note**
   >
   > If the bucket contains any objects, empty the bucket before deleting it by selecting the *empty bucket configuration* link in the **This bucket is not empty** error alert and following the instructions on the **Empty bucket** page. Then return to the **Delete bucket** page and delete the bucket.

4. To verify that you've deleted the bucket, open the **Buckets** list and enter the name of the bucket that you deleted. If the bucket can't be found, your deletion was successful.

## Using the AWS SDK for Java

The following example shows you how to delete a bucket using the AWS SDK for Java. First, the code deletes objects in the bucket and then it deletes the bucket. For information about other AWS SDKs, see Tools for Amazon Web Services.

Java

The following Java example deletes a bucket that contains objects. The example deletes all objects, and then it deletes the bucket. The example works for buckets with or without versioning enabled.

> **Note**
>
> For buckets without versioning enabled, you can delete all objects directly and then delete the bucket. For buckets with versioning enabled, you must delete all object versions before deleting the bucket.

For instructions on creating and testing a working sample, ssee Getting Started in the AWS SDK for Java Developer Guide.

```
import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import com.amazonaws.auth.profile.ProfileCredentialsProvider;
import com.amazonaws.regions.Regions;
import com.amazonaws.services.s3.AmazonS3;
import com.amazonaws.services.s3.AmazonS3ClientBuilder;
import com.amazonaws.services.s3.model.*;

import java.util.Iterator;

public class DeleteBucket2 {

    public static void main(String[] args) {
        Regions clientRegion = Regions.DEFAULT_REGION;
        String bucketName = "*** Bucket name ***";

        try {
            AmazonS3 s3Client = AmazonS3ClientBuilder.standard()
                    .withCredentials(new ProfileCredentialsProvider())
```

```
                    .withRegion(clientRegion)
                    .build();

            // Delete all objects from the bucket. This is sufficient
            // for unversioned buckets. For versioned buckets, when you attempt to
delete
            // objects, Amazon S3 inserts
            // delete markers for all objects, but doesn't delete the object
versions.
            // To delete objects from versioned buckets, delete all of the object
versions
            // before deleting
            // the bucket (see below for an example).
            ObjectListing objectListing = s3Client.listObjects(bucketName);
            while (true) {
                Iterator<S3ObjectSummary> objIter =
objectListing.getObjectSummaries().iterator();
                while (objIter.hasNext()) {
                    s3Client.deleteObject(bucketName, objIter.next().getKey());
                }

                // If the bucket contains many objects, the listObjects() call
                // might not return all of the objects in the first listing. Check
to
                // see whether the listing was truncated. If so, retrieve the next
page of
                // objects
                // and delete them.
                if (objectListing.isTruncated()) {
                    objectListing = s3Client.listNextBatchOfObjects(objectListing);
                } else {
                    break;
                }
            }

            // Delete all object versions (required for versioned buckets).
            VersionListing versionList = s3Client.listVersions(new
ListVersionsRequest().withBucketName(bucketName));
            while (true) {
                Iterator<S3VersionSummary> versionIter =
versionList.getVersionSummaries().iterator();
                while (versionIter.hasNext()) {
                    S3VersionSummary vs = versionIter.next();
```

```
                    s3Client.deleteVersion(bucketName, vs.getKey(),
 vs.getVersionId());
                }

                if (versionList.isTruncated()) {
                    versionList = s3Client.listNextBatchOfVersions(versionList);
                } else {
                    break;
                }
            }

            // After all objects and object versions are deleted, delete the bucket.
            s3Client.deleteBucket(bucketName);
        } catch (AmazonServiceException e) {
            // The call was transmitted successfully, but Amazon S3 couldn't process
            // it, so it returned an error response.
            e.printStackTrace();
        } catch (SdkClientException e) {
            // Amazon S3 couldn't be contacted for a response, or the client
 couldn't
            // parse the response from Amazon S3.
            e.printStackTrace();
        }
    }
}
```

## Using the AWS CLI

You can delete a bucket that contains objects with the AWS CLI if it doesn't have versioning enabled. When you delete a bucket that contains objects, all the objects in the bucket are permanently deleted, including objects that are transitioned to the `S3 Glacier` storage class.

If your bucket does not have versioning enabled, you can use the `rb` (remove bucket) AWS CLI command with the `--force` parameter to delete the bucket and all the objects in it. This command deletes all objects first and then deletes the bucket.

If versioning is enabled versioned objects will not be deleted in this process which would cause the bucket deletion to fail because the bucket would not be empty. For more information about deleting versioned objects, see Deleting object versions.

```
$ aws s3 rb s3://bucket-name --force
```

For more information, see Using High-Level S3 Commands with the AWS Command Line Interface in the AWS Command Line Interface User Guide.

# Setting default server-side encryption behavior for Amazon S3 buckets

**Important**

Amazon S3 now applies server-side encryption with Amazon S3 managed keys (SSE-S3) as the base level of encryption for every bucket in Amazon S3. Starting January 5, 2023, all new object uploads to Amazon S3 are automatically encrypted at no additional cost and with no impact on performance. The automatic encryption status for S3 bucket default encryption configuration and for new object uploads is available in AWS CloudTrail logs, S3 Inventory, S3 Storage Lens, the Amazon S3 console, and as an additional Amazon S3 API response header in the AWS Command Line Interface and AWS SDKs. For more information, see Default encryption FAQ.

All Amazon S3 buckets have encryption configured by default, and objects are automatically encrypted by using server-side encryption with Amazon S3 managed keys (SSE-S3). This encryption setting applies to all objects in your Amazon S3 buckets.

If you need more control over your keys, such as managing key rotation and access policy grants, you can choose to use server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS), or dual-layer server-side encryption with AWS KMS keys (DSSE-KMS). For more information about editing KMS keys, see Editing keys in *AWS Key Management Service Developer Guide*.

**Note**

We've changed buckets to encrypt new object uploads automatically. If you previously created a bucket without default encryption, Amazon S3 will enable encryption by default for the bucket using SSE-S3. There will be no changes to the default encryption configuration for an existing bucket that already has SSE-S3 or SSE-KMS configured. If you

want to encrypt your objects with SSE-KMS, you must change the encryption type in your bucket settings. For more information, see Using server-side encryption with AWS KMS keys (SSE-KMS).

When you configure your bucket to use default encryption with SSE-KMS, you can also enable S3 Bucket Keys to decrease request traffic from Amazon S3 to AWS KMS and reduce the cost of encryption. For more information, see Reducing the cost of SSE-KMS with Amazon S3 Bucket Keys.

To identify buckets that have SSE-KMS enabled for default encryption, you can use Amazon S3 Storage Lens metrics. S3 Storage Lens is a cloud-storage analytics feature that you can use to gain organization-wide visibility into object-storage usage and activity. For more information, see Using S3 Storage Lens to protect your data.

When you use server-side encryption, Amazon S3 encrypts an object before saving it to disk and decrypts it when you download the object. For more information about protecting data using server-side encryption and encryption-key management, see Protecting data with server-side encryption.

For more information about the permissions required for default encryption, see PutBucketEncryption in the *Amazon Simple Storage Service API Reference*.

You can configure the Amazon S3 default encryption behavior for an S3 bucket by using the Amazon S3 console, the AWS SDKs, the Amazon S3 REST API, and the AWS Command Line Interface (AWS CLI).

**Encrypting existing objects**

To encrypt your existing unencrypted Amazon S3 objects, you can use Amazon S3 Batch Operations. You provide S3 Batch Operations with a list of objects to operate on, and Batch Operations calls the respective API to perform the specified operation. You can use the Batch Operations Copy operation to copy existing unencrypted objects and write them back to the same bucket as encrypted objects. A single Batch Operations job can perform the specified operation on billions of objects. For more information, see Performing large-scale batch operations on Amazon S3 objects and the *AWS Storage Blog* post Encrypting objects with Amazon S3 Batch Operations.

You can also encrypt existing objects by using the `CopyObject` API operation or the `copy-object` AWS CLI command. For more information, see the *AWS Storage Blog* post Encrypting existing Amazon S3 objects with the AWS CLI.

> **Note**
>
> Amazon S3 buckets with default bucket encryption set to SSE-KMS cannot be used as destination buckets for the section called "Logging server access". Only SSE-S3 default encryption is supported for server access log destination buckets.

## Using SSE-KMS encryption for cross-account operations

When using encryption for cross-account operations, be aware of the following:

- If an AWS KMS key Amazon Resource Name (ARN) or alias is not provided at request time or through the bucket's default encryption configuration, the AWS managed key (`aws/s3`) is used.
- If you're uploading or accessing S3 objects by using AWS Identity and Access Management (IAM) principals that are in the same AWS account as your KMS key, you can use the AWS managed key (`aws/s3`).
- If you want to grant cross-account access to your S3 objects, use a customer managed key. You can configure the policy of a customer managed key to allow access from another account.
- If you're specifying a customer managed KMS key, we recommend using a fully qualified KMS key ARN. If you use a KMS key alias instead, AWS KMS resolves the key within the requester's account. This behavior can result in data that's encrypted with a KMS key that belongs to the requester, and not the bucket owner.
- You must specify a key that you (the requester) have been granted `Encrypt` permission to. For more information, see Allow key users to use a KMS key for cryptographic operations in the *AWS Key Management Service Developer Guide*.

For more information about when to use customer managed keys and AWS managed KMS keys, see Should I use an AWS managed key or a customer managed key to encrypt my objects in Amazon S3?

## Using default encryption with replication

When you enable default encryption for a replication destination bucket, the following encryption behavior applies:

- If objects in the source bucket are not encrypted, the replica objects in the destination bucket are encrypted by using the default encryption settings of the destination bucket. As a result, the

entity tags (ETags) of the source objects differ from the ETags of the replica objects. If you have applications that use ETags, you must update those applications to account for this difference.

- If objects in the source bucket are encrypted by using server-side encryption with Amazon S3 managed keys (SSE-S3), server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS), or dual-layer server-side encryption with AWS KMS keys (DSSE-KMS), the replica objects in the destination bucket use the same type of encryption as the source objects. The default encryption settings of the destination bucket are not used.

For more information about using default encryption with SSE-KMS, see Replicating encrypted objects.

## Using Amazon S3 Bucket Keys with default encryption

When you configure your bucket to use SSE-KMS as the default encryption behavior for new objects, you can also configure S3 Bucket Keys. S3 Bucket Keys decrease the number of transactions from Amazon S3 to AWS KMS to reduce the cost of SSE-KMS.

When you configure your bucket to use S3 Bucket Keys for SSE-KMS on new objects, AWS KMS generates a bucket-level key that is used to create a unique data key for objects in the bucket. This S3 Bucket Key is used for a time-limited period within Amazon S3, reducing the need for Amazon S3 to make requests to AWS KMS to complete encryption operations.

For more information about using S3 Bucket Keys, see Using Amazon S3 Bucket Keys.

## Configuring default encryption

**Important**

Amazon S3 now applies server-side encryption with Amazon S3 managed keys (SSE-S3) as the base level of encryption for every bucket in Amazon S3. Starting January 5, 2023, all new object uploads to Amazon S3 are automatically encrypted at no additional cost and with no impact on performance. The automatic encryption status for S3 bucket default encryption configuration and for new object uploads is available in AWS CloudTrail logs, S3 Inventory, S3 Storage Lens, the Amazon S3 console, and as an additional Amazon S3 API response header in the AWS Command Line Interface and AWS SDKs. For more information, see Default encryption FAQ.

Amazon S3 buckets have bucket encryption enabled by default, and new objects are automatically encrypted by using server-side encryption with Amazon S3 managed keys (SSE-S3). This encryption applies to all new objects in your Amazon S3 buckets, and comes at no cost to you.

If you need more control over your encryption keys, such as managing key rotation and access policy grants, you can elect to use server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS), or dual-layer server-side encryption with AWS KMS keys (DSSE-KMS). For more information about SSE-KMS, see Specifying server-side encryption with AWS KMS (SSE-KMS). For more information about DSSE-KMS, see the section called "Dual-layer server-side encryption (DSSE-KMS)".

If you want to use a KMS key that is owned by a different account, you must have permission to use the key. For more information about cross-account permissions for KMS keys, see Creating KMS keys that other accounts can use in the *AWS Key Management Service Developer Guide*.

When you set default bucket encryption to SSE-KMS, you can also configure an S3 Bucket Key to reduce your AWS KMS request costs. For more information, see Reducing the cost of SSE-KMS with Amazon S3 Bucket Keys.

> **Note**
>
> If you use PutBucketEncryption to set your default bucket encryption to SSE-KMS, you should verify that your KMS key ID is correct. Amazon S3 does not validate the KMS key ID provided in PutBucketEncryption requests.

There are no additional charges for using default encryption for S3 buckets. Requests to configure the default encryption behavior incur standard Amazon S3 request charges. For information about pricing, see Amazon S3 pricing. For SSE-KMS and DSSE-KMS, AWS KMS charges apply and are listed at AWS KMS pricing.

Server-side encryption with customer-provided keys (SSE-C) is not supported for default encryption.

You can configure Amazon S3 default encryption for an S3 bucket by using the Amazon S3 console, the AWS SDKs, the Amazon S3 REST API, and the AWS Command Line Interface (AWS CLI).

**Changes to note before enabling default encryption**

After you enable default encryption for a bucket, the following encryption behavior applies:

- There is no change to the encryption of the objects that existed in the bucket before default encryption was enabled.
- When you upload objects after enabling default encryption:
  - If your PUT request headers don't include encryption information, Amazon S3 uses the bucket's default encryption settings to encrypt the objects.
  - If your PUT request headers include encryption information, Amazon S3 uses the encryption information from the PUT request to encrypt objects before storing them in Amazon S3.
- If you use the SSE-KMS or DSSE-KMS option for your default encryption configuration, you are subject to the requests per second (RPS) quotas of AWS KMS. For more information about AWS KMS quotas and how to request a quota increase, see Quotas in the *AWS Key Management Service Developer Guide*.

> **Note**
>
> Objects uploaded before default encryption was enabled will not be encrypted. For information about encrypting existing objects, see the section called "Setting default bucket encryption".

### Using the S3 console

### To configure default encryption on an Amazon S3 bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Buckets**.
3. In the **Buckets** list, choose the name of the bucket that you want.
4. Choose the **Properties** tab.
5. Under **Default encryption**, choose **Edit**.
6. To configure encryption, under **Encryption type**, choose one of the following:
   - **Server-side encryption with Amazon S3 managed keys (SSE-S3)**
   - **Server-side encryption with AWS Key Management Service keys (SSE-KMS)**
   - **Dual-layer server-side encryption with AWS Key Management Service keys (DSSE-KMS)**

> **Important**
>
> If you use the SSE-KMS or DSSE-KMS options for your default encryption configuration, you are subject to the requests per second (RPS) quotas of AWS KMS. For more information about AWS KMS quotas and how to request a quota increase, see Quotas in the *AWS Key Management Service Developer Guide*.

Buckets and new objects are encrypted by default with SSE-S3, unless you specify another type of default encryption for your buckets. For more information about default encryption, see Setting default server-side encryption behavior for Amazon S3 buckets.

For more information about using Amazon S3 server-side encryption to encrypt your data, see Using server-side encryption with Amazon S3 managed keys (SSE-S3).

7. If you chose **Server-side encryption with AWS Key Management Service keys (SSE-KMS)** or **Dual-layer server-side encryption with AWS Key Management Service keys (DSSE-KMS)**, do the following:

   a. Under **AWS KMS key**, specify your KMS key in one of the following ways:

   - To choose from a list of available KMS keys, choose **Choose from your AWS KMS keys**, and choose your **KMS key** from the list of available keys.

     Both the AWS managed key (`aws/s3`) and your customer managed keys appear in this list. For more information about customer managed keys, see Customer keys and AWS keys in the *AWS Key Management Service Developer Guide*.
   - To enter the KMS key ARN, choose **Enter AWS KMS key ARN**, and enter your KMS key ARN in the field that appears.
   - To create a new customer managed key in the AWS KMS console, choose **Create a KMS key**.

     For more information about creating an AWS KMS key, see Creating keys in the *AWS Key Management Service Developer Guide*.

> **Important**
>
> You can only use KMS keys that are enabled in the same AWS Region as the bucket. When you choose **Choose from your KMS keys**, the S3 console only lists 100 KMS keys per Region. If you have more than 100 KMS keys in the same Region, you can only see the first 100 KMS keys in the S3 console. To use a KMS key that is not listed in the console, choose **Enter AWS KMS key ARN**, and enter the KMS key ARN.
>
> When you use an AWS KMS key for server-side encryption in Amazon S3, you must choose a symmetric encryption KMS key. Amazon S3 only supports symmetric encryption KMS keys. For more information about these keys, see Symmetric encryption KMS keys in the *AWS Key Management Service Developer Guide*.

For more information about using SSE-KMS with Amazon S3, see Using server-side encryption with AWS KMS keys (SSE-KMS). For more information about using DSSE-KMS, see the section called "Dual-layer server-side encryption (DSSE-KMS)".

b. When you configure your bucket to use default encryption with SSE-KMS, you can also enable an S3 Bucket Key. S3 Bucket Keys lower the cost of encryption by decreasing request traffic from Amazon S3 to AWS KMS. For more information, see Reducing the cost of SSE-KMS with Amazon S3 Bucket Keys.

   To use S3 Bucket Keys, under **Bucket Key**, choose **Enable**.

> **Note**
>
> S3 Bucket Keys aren't supported for DSSE-KMS.

8. Choose **Save changes**.

### Using the AWS CLI

These examples show you how to configure default encryption by using SSE-S3 or by using SSE-KMS with an S3 Bucket Key.

For more information about default encryption, see Setting default server-side encryption behavior for Amazon S3 buckets. For more information about using the AWS CLI to configure default encryption, see put-bucket-encryption.

**Example – Default encryption with SSE-S3**

This example configures default bucket encryption with Amazon S3 managed keys.

```
aws s3api put-bucket-encryption --bucket amzn-s3-demo-bucket --server-side-encryption-
configuration '{
    "Rules": [
        {
            "ApplyServerSideEncryptionByDefault": {
                "SSEAlgorithm": "AES256"
            }
        }
    ]
}'
```

**Example – Default encryption with SSE-KMS using an S3 Bucket Key**

This example configures default bucket encryption with SSE-KMS using an S3 Bucket Key.

```
aws s3api put-bucket-encryption --bucket amzn-s3-demo-bucket --server-side-encryption-
configuration '{
    "Rules": [
            {
                "ApplyServerSideEncryptionByDefault": {
                    "SSEAlgorithm": "aws:kms",
                    "KMSMasterKeyID": "KMS-Key-ARN"
                },
                "BucketKeyEnabled": true
            }
        ]
    }'
```

**Using the REST API**

Use the REST API `PutBucketEncryption` operation to enable default encryption and to set the type of server-side encryption to use—SSE-S3, SSE-KMS, or DSSE-KMS.

For more information, see PutBucketEncryption in the *Amazon Simple Storage Service API Reference*.

# Monitoring default encryption with AWS CloudTrail and Amazon EventBridge

> **Important**
>
> Amazon S3 now applies server-side encryption with Amazon S3 managed keys (SSE-S3) as the base level of encryption for every bucket in Amazon S3. Starting January 5, 2023, all new object uploads to Amazon S3 are automatically encrypted at no additional cost and with no impact on performance. The automatic encryption status for S3 bucket default encryption configuration and for new object uploads is available in AWS CloudTrail logs, S3 Inventory, S3 Storage Lens, the Amazon S3 console, and as an additional Amazon S3 API response header in the AWS Command Line Interface and AWS SDKs. For more information, see Default encryption FAQ.

You can track default encryption configuration requests for Amazon S3 buckets by using AWS CloudTrail events. The following API event names are used in CloudTrail logs:

- `PutBucketEncryption`
- `GetBucketEncryption`
- `DeleteBucketEncryption`

You can also create EventBridge rules to match the CloudTrail events for these API calls. For more information about CloudTrail events, see Enable logging for objects in a bucket using the console. For more information about EventBridge events, see Events from AWS services.

You can use CloudTrail logs for object-level Amazon S3 actions to track PUT and POST requests to Amazon S3. You can use these actions to verify whether default encryption is being used to encrypt objects when incoming PUT requests don't have encryption headers.

When Amazon S3 encrypts an object by using the default encryption settings, the log includes one of the following fields as the name-value pair: `"SSEApplied":"Default_SSE_S3"`, `"SSEApplied":"Default_SSE_KMS"`, or `"SSEApplied":"Default_DSSE_KMS"`.

When Amazon S3 encrypts an object by using the PUT encryption headers, the log includes one of the following fields as the name-value pair: `"SSEApplied":"SSE_S3"`, `"SSEApplied":"SSE_KMS"`, `"SSEApplied":"DSSE_KMS"`, or `"SSEApplied":"SSE_C"`.

For multipart uploads, this information is included in your `InitiateMultipartUpload` API operation requests. For more information about using CloudTrail and CloudWatch, see Monitoring Amazon S3.

# Working with Mountpoint for Amazon S3

Mountpoint for Amazon S3 is a high-throughput open source file client for mounting an Amazon S3 bucket as a local file system. With Mountpoint, your applications can access objects stored in Amazon S3 through file system operations, such as open and read. Mountpoint automatically translates these operations into S3 object API calls, giving your applications access to the elastic storage and throughput of Amazon S3 through a file interface.

Mountpoint for Amazon S3 is generally available for production use on your large-scale read-heavy applications: data lakes, machine learning training, image rendering, autonomous vehicle simulation, extract, transform, and load (ETL), and more.

Mountpoint supports basic file system operations, and can read files up to 5 TB in size. It can list and read existing files, and it can create new ones. It cannot modify existing files or delete directories, and it does not support symbolic links or file locking. Mountpoint is ideal for applications that do not need all of the features of a shared file system and POSIX-style permissions but require Amazon S3's elastic throughput to read and write large S3 datasets. For details, see Mountpoint file system behavior on GitHub. For workloads that require full POSIX support, we recommend Amazon FSx for Lustre and its support for linking S3 buckets.

Mountpoint for Amazon S3 is available only for Linux operating systems. You can use Mountpoint to access S3 objects in all storage classes except S3 Glacier Flexible Retrieval, S3 Glacier Deep Archive, S3 Intelligent-Tiering Archive Access Tier, and S3 Intelligent-Tiering Deep Archive Access Tier.

**Topics**

## Installing Mountpoint

You can download and install prebuilt packages of Mountpoint for Amazon S3 by using the command line. The instructions for downloading and installing Mountpoint vary, depending on which Linux operating system that you're using.

**Topics**

## RPM-based distributions (Amazon Linux, Fedora, CentOS, RHEL)

1. Copy the following download URL for your architecture.

   *x86_64*:

   ```
   https://s3.amazonaws.com/mountpoint-s3-release/latest/x86_64/mount-s3.rpm
   ```

   *ARM64 (Graviton)*:

   ```
   https://s3.amazonaws.com/mountpoint-s3-release/latest/arm64/mount-s3.rpm
   ```

2. Download the Mountpoint for Amazon S3 package. Replace *download-link* with the appropriate download URL from the preceding step.

   ```
   wget download-link
   ```

3. (Optional) Verify the authenticity and integrity of the downloaded file. First, copy the appropriate signature URL for your architecture.

   *x86_64*:

   ```
   https://s3.amazonaws.com/mountpoint-s3-release/latest/x86_64/mount-s3.rpm.asc
   ```

   *ARM64 (Graviton)*:

   ```
   https://s3.amazonaws.com/mountpoint-s3-release/latest/arm64/mount-s3.rpm.asc
   ```

   Next, see Verifying the signature of the Mountpoint for Amazon S3 package.

4. Install the package by using the following command:

```
sudo yum install ./mount-s3.rpm
```

5. Verify that Mountpoint is successfully installed by entering the following command:

```
mount-s3 --version
```

You should see output similar to the following:

```
mount-s3 1.3.1
```

## DEB-based distributions (Debian, Ubuntu)

1. Copy the download URL for your architecture.

*x86_64*:

```
https://s3.amazonaws.com/mountpoint-s3-release/latest/x86_64/mount-s3.deb
```

*ARM64 (Graviton)*:

```
https://s3.amazonaws.com/mountpoint-s3-release/latest/arm64/mount-s3.deb
```

2. Download the Mountpoint for Amazon S3 package. Replace *download-link* with the appropriate download URL from the preceding step.

```
wget download-link
```

3. (Optional) Verify the authenticity and integrity of the downloaded file. First, copy the signature URL for your architecture.

*x86_64*:

```
https://s3.amazonaws.com/mountpoint-s3-release/latest/x86_64/mount-s3.deb.asc
```

*ARM64 (Graviton)*:

```
https://s3.amazonaws.com/mountpoint-s3-release/latest/arm64/mount-s3.deb.asc
```

Next, see Verifying the signature of the Mountpoint for Amazon S3 package.

4. Install the package by using the following command:

```
sudo apt-get install ./mount-s3.deb
```

5. Verify that Mountpoint for Amazon S3 is successfully installed by running the following command:

```
mount-s3 --version
```

You should see output similar to the following:

```
mount-s3 1.3.1
```

## Other Linux distributions

1. Consult your operating system documentation to install the FUSE and `libfuse2` packages, which are required.
2. Copy the download URL for your architecture.

*x86_64*:

```
https://s3.amazonaws.com/mountpoint-s3-release/latest/x86_64/mount-s3.tar.gz
```

*ARM64 (Graviton)*:

```
https://s3.amazonaws.com/mountpoint-s3-release/latest/arm64/mount-s3.tar.gz
```

3. Download the Mountpoint for Amazon S3 package. Replace *`download-link`* with the appropriate download URL from the preceding step.

```
wget download-link
```

4. (Optional) Verify the authenticity and integrity of the downloaded file. First, copy the signature URL for your architecture.

*x86_64*:

```
https://s3.amazonaws.com/mountpoint-s3-release/latest/x86_64/mount-s3.tar.gz.asc
```

*ARM64 (Graviton)*:

```
https://s3.amazonaws.com/mountpoint-s3-release/latest/arm64/mount-s3.tar.gz.asc
```

Next, see Verifying the signature of the Mountpoint for Amazon S3 package.

5. Install the package by using the following command:

```
sudo mkdir -p /opt/aws/mountpoint-s3 && sudo tar -C /opt/aws/mountpoint-s3 -xzf ./
mount-s3.tar.gz
```

6. Add the `mount-s3` binary to your `PATH` environment variable. In your `$HOME/.profile` file, append the following line:

```
export PATH=$PATH:/opt/aws/mountpoint-s3/bin
```

Save the `.profile` file, and run the following command:

```
source $HOME/.profile
```

7. Verify that Mountpoint for Amazon S3 is successfully installed by running the following command:

```
mount-s3 --version
```

You should see output similar to the following:

```
mount-s3 1.3.1
```

## Verifying the signature of the Mountpoint for Amazon S3 package

1. Install GnuPG (the gpg command). It is required to verify the authenticity and integrity of a downloaded Mountpoint for Amazon S3 package. GnuPG is installed by default on Amazon Linux Amazon Machine Images (AMIs). After you installGnuPG, proceed to step 2.
2. Download the Mountpoint public key by running the following command:

```
wget https://s3.amazonaws.com/mountpoint-s3-release/public_keys/KEYS
```

3. Import the Mountpoint public key into your keyring by running the following command:

```
gpg --import KEYS
```

4. Verify the fingerprint of the Mountpoint public key by running the following command:

```
gpg --fingerprint mountpoint-s3@amazon.com
```

Confirm that the displayed fingerprint string matches the following:

```
673F E406 1506 BB46 9A0E  F857 BE39 7A52 B086 DA5A
```

If the fingerprint string doesn't match, do not finish installing Mountpoint, and contact AWS Support.

5. Download the package signature file. Replace *signature-link* with the appropriate signature link from the preceding sections.

```
wget signature-link
```

6. Verify the signature of the downloaded package by running the following command. Replace *signature-filename* with the file name from the previous step.

```
gpg --verify signature-filename
```

For example, on RPM-based distributions, including Amazon Linux, enter the following command:

```
gpg --verify mount-s3.rpm.asc
```

7. The output should include the phrase `Good signature`. If the output includes the phrase `BAD signature`, redownload the Mountpoint package file and repeat these steps. If the issue persists, do not finish installing Mountpoint, and contact AWS Support.

The output may include a warning about a trusted signature. This does not indicate a problem. It only means that you have not independently verified the Mountpoint public key.

# Configuring and using Mountpoint

To use Mountpoint for Amazon S3, your host needs valid AWS credentials with access to the bucket or buckets that you would like to mount. For different ways to authenticate, see Mountpoint AWS Credentials on GitHub.

For example, you can create a new AWS Identity and Access Management (IAM) user and role for this purpose. Make sure that this role has access to the bucket or buckets that you would like to mount. You can pass the IAM role to your Amazon EC2 instance with an instance profile.

## Using Mountpoint for Amazon S3

Use Mountpoint for Amazon S3 to do the following:

1. Mount buckets with the `mount-s3` command.

   In the following example, replace *DOC-EXAMPLE-BUCKET* with the name of your S3 bucket, and replace *~/mnt* with the directory on your host where you want your S3 bucket to be mounted.

   ```
   mkdir ~/mnt
   mount-s3 DOC-EXAMPLE-BUCKET ~/mnt
   ```

   Because the Mountpoint client runs in the background by default, the *~/mnt* directory now gives you access to the objects in your S3 bucket.

2. Access the objects in your bucket through Mountpoint.

   After you mount your bucket locally, you can use common Linux commands, such as `cat` or `ls`, to work with your S3 objects. Mountpoint for Amazon S3 interprets keys in your S3 bucket as file system paths by splitting them on the forward slash (/) character. For example, if you have the object key `Data/2023-01-01.csv` in your bucket, you will have a directory named `Data` in your Mountpoint file system, with a file named `2023-01-01.csv` inside it.

   Mountpoint for Amazon S3 intentionally does not implement the full POSIX standard specification for file systems. Mountpoint is optimized for workloads that need high-throughput read and write access to data stored in Amazon S3 through a file system interface, but that otherwise do not rely on file system features. For more information, see Mountpoint for Amazon S3 file system behavior on GitHub. Customers that need richer file system

semantics should consider other AWS file services, such as Amazon Elastic File System (Amazon EFS) or Amazon FSx.

3. Unmount your bucket by using the `umount` command. This command unmounts your S3 bucket and exits Mountpoint.

   To use the following example command, replace *~/mnt* with the directory on your host where your S3 bucket is mounted.

   ```
   umount ~/mnt
   ```

   **Note**

   To get a list of options for this command, run `umount --help`.

For additional Mountpoint configuration details, see S3 bucket configuration, and file system configuration on GitHub.

## Configuring caching in Mountpoint

When you use Mountpoint for Amazon S3, you can configure it to cache the most recently accessed data from your S3 buckets on Amazon EC2 instance storage or an attached Amazon EBS volume. Caching this data can help to accelerate performance and reduce the cost of repeated data access. Caching in Mountpoint is ideal for use cases where you repeatedly read the same data that doesn't change during the multiple reads. For example, you can use caching with machine learning training jobs that need to read a training dataset multiple times to improve model accuracy.

When you mount an S3 bucket, you can optionally enable caching through flags. You can configure the location and size of the data cache and the amount of time metadata is retained in the cache. When you mount a bucket and caching is enabled, Mountpoint creates an empty sub-directory at the configured cache location, if that sub-directory doesn't already exist. When you first mount a bucket and when you unmount, Mountpoint deletes the contents of the cache location. For more information about configuring and using caching in Mountpoint, see Mountpoint for Amazon S3 Caching configuration on GitHub.

When you mount an S3 bucket, you can enable caching with the `--cache` *CACHE_PATH* flag. In the following example, replace *CACHE_PATH* with the filepath to the directory that you want to

cache your data in. Replace *DOC-EXAMPLE-BUCKET* with the name of your S3 bucket, and replace *~/mnt* with the directory on your host where you want your S3 bucket to be mounted.

```
mkdir ~/mnt
mount-s3 --cache CACHE_PATH DOC-EXAMPLE-BUCKET ~/mnt
```

**Important**

If you enable caching, Mountpoint will persist unencrypted object content from your S3 bucket at the caching location configured at mount. In order to protect your data, we recommend that you restrict access to the data cache location.

## Troubleshooting Mountpoint

Mountpoint for Amazon S3 is backed by AWS Support. If you need assistance, contact the AWS Support Center.

You can also review and submit Mountpoint Issues on GitHub.

If you discover a potential security issue in this project, we ask that you notify AWS Security through our vulnerability reporting page. Do not create a public GitHub issue.

If your application behaves unexpectedly with Mountpoint, you can inspect your log information to diagnose the problem.

### Logging

By default, Mountpoint emits high-severity log information to syslog.

To view logs on most modern Linux distributions, including Amazon Linux, run the following `journald` command:

```
journalctl -e SYSLOG_IDENTIFIER=mount-s3
```

On other Linux systems, `syslog` entries are likely written to a file such as `/var/log/syslog`.

You can use these logs to troubleshoot your application. For example, if your application tries to overwrite an existing file, the operation fails, and you will see a line similar to the following in the log:

```
[WARN] open{req=12 ino=2}: mountpoint_s3::fuse: open failed: inode error: inode 2 (full
 key "README.md") is not writable
```

For more information, see Mountpoint for Amazon S3 Logging on GitHub.

# Configuring fast, secure file transfers using Amazon S3 Transfer Acceleration

Amazon S3 Transfer Acceleration is a bucket-level feature that enables fast, easy, and secure transfers of files over long distances between your client and an S3 bucket. Transfer Acceleration is designed to optimize transfer speeds from across the world into S3 buckets. Transfer Acceleration takes advantage of the globally distributed edge locations in Amazon CloudFront. As the data arrives at an edge location, the data is routed to Amazon S3 over an optimized network path.

When you use Transfer Acceleration, additional data transfer charges might apply. For more information about pricing, see Amazon S3 pricing.

## Why use Transfer Acceleration?

You might want to use Transfer Acceleration on a bucket for various reasons:

- Your customers upload to a centralized bucket from all over the world.
- You transfer gigabytes to terabytes of data on a regular basis across continents.
- You can't use all of your available bandwidth over the internet when uploading to Amazon S3.

For more information about when to use Transfer Acceleration, see Amazon S3 FAQs.

## Requirements for using Transfer Acceleration

The following are required when you are using Transfer Acceleration on an S3 bucket:

- Transfer Acceleration is only supported on virtual-hosted style requests. For more information about virtual-hosted style requests, see Making requests using the REST API.
- The name of the bucket used for Transfer Acceleration must be DNS-compliant and must not contain periods (".").
- Transfer Acceleration must be enabled on the bucket. For more information, see Enabling and using S3 Transfer Acceleration.

After you enable Transfer Acceleration on a bucket, it might take up to 20 minutes before the data transfer speed to the bucket increases.

> **Note**
>
> Transfer Acceleration is currently supported for buckets located in the following Regions:
>
> - Asia Pacific (Tokyo) (ap-northeast-1)
> - Asia Pacific (Seoul) (ap-northeast-2)
> - Asia Pacific (Mumbai) (ap-south-1)
> - Asia Pacific (Singapore) (ap-southeast-1)
> - Asia Pacific (Sydney) (ap-southeast-2)
> - Canada (Central) (ca-central-1)
> - Europe (Frankfurt) (eu-central-1)
> - Europe (Ireland) (eu-west-1)
> - Europe (London) (eu-west-2)
> - Europe (Paris) (eu-west-3)
> - South America (São Paulo) (sa-east-1)
> - US East (N. Virginia) (us-east-1)
> - US East (Ohio) (us-east-2)
> - US West (N. California) (us-west-1)
> - US West (Oregon) (us-west-2)

- To access the bucket that is enabled for Transfer Acceleration, you must use the endpoint *bucketname*`.s3-accelerate.amazonaws.com`. Or, use the dual-stack endpoint *bucketname*`.s3-accelerate.dualstack.amazonaws.com` to connect to the enabled bucket over IPv6. You can continue to use the regular endpoints for standard data transfer.
- You must be the bucket owner to set the transfer acceleration state. The bucket owner can assign permissions to other users to allow them to set the acceleration state on a bucket. The `s3:PutAccelerateConfiguration` permission permits users to enable or disable Transfer Acceleration on a bucket. The `s3:GetAccelerateConfiguration` permission permits users to return the Transfer Acceleration state of a bucket, which is either `Enabled` or `Suspended`.

The following sections describe how to get started and use Amazon S3 Transfer Acceleration for transferring data.

**Topics**

## Getting started with Amazon S3 Transfer Acceleration

You can use Amazon S3 Transfer Acceleration for fast, easy, and secure transfers of files over long distances between your client and an S3 bucket. Transfer Acceleration uses the globally distributed edge locations in Amazon CloudFront. As the data arrives at an edge location, data is routed to Amazon S3 over an optimized network path.

To get started using Amazon S3 Transfer Acceleration, perform the following steps:

1. **Enable Transfer Acceleration on a bucket**

   You can enable Transfer Acceleration on a bucket any of the following ways:

   - Use the Amazon S3 console.
   - Use the REST API PUT Bucket accelerate operation.
   - Use the AWS CLI and AWS SDKs. For more information, see Developing with Amazon S3 using the AWS SDKs.

   For more information, see Enabling and using S3 Transfer Acceleration.

   > **Note**
   >
   > For your bucket to work with transfer acceleration, the bucket name must conform to DNS naming requirements and must not contain periods (".").

2. **Transfer data to and from the acceleration-enabled bucket**

   Use one of the following s3-accelerate endpoint domain names:

   - To access an acceleration-enabled bucket, use *`bucketname`*`.s3-accelerate.amazonaws.com`.

- To access an acceleration-enabled bucket over IPv6, use *bucketname*.s3-accelerate.dualstack.amazonaws.com.

  Amazon S3 dual-stack endpoints support requests to S3 buckets over IPv6 and IPv4. The Transfer Acceleration dual-stack endpoint only uses the virtual hosted-style type of endpoint name. For more information, see Getting started making requests over IPv6 and Using Amazon S3 dual-stack endpoints.

> **Note**
>
> Your data transfer application must use one of the following two types of endpoints to access the bucket for faster data transfer: .s3-accelerate.amazonaws.com or .s3-accelerate.dualstack.amazonaws.com for the dual-stack endpoint. If you want to use standard data transfer, you can continue to use the regular endpoints.

You can point your Amazon S3 PUT object and GET object requests to the s3-accelerate endpoint domain name after you enable Transfer Acceleration. For example, suppose that you currently have a REST API application using PUT Object that uses the hostname mybucket.s3.us-east-1.amazonaws.com in the PUT request. To accelerate the PUT, you change the hostname in your request to mybucket.s3-accelerate.amazonaws.com. To go back to using the standard upload speed, change the name back to mybucket.s3.us-east-1.amazonaws.com.

After Transfer Acceleration is enabled, it can take up to 20 minutes for you to realize the performance benefit. However, the accelerate endpoint is available as soon as you enable Transfer Acceleration.

You can use the accelerate endpoint in the AWS CLI, AWS SDKs, and other tools that transfer data to and from Amazon S3. If you are using the AWS SDKs, some of the supported languages use an accelerate endpoint client configuration flag so you don't need to explicitly set the endpoint for Transfer Acceleration to *bucketname*.s3-accelerate.amazonaws.com. For examples of how to use an accelerate endpoint client configuration flag, see Enabling and using S3 Transfer Acceleration.

You can use all Amazon S3 operations through the transfer acceleration endpoints *except* for the following:

- GET Service (list buckets)
- PUT Bucket (create bucket)
- DELETE Bucket

Also, Amazon S3 Transfer Acceleration does not support cross-Region copies using PUT Object - Copy.

## Enabling and using S3 Transfer Acceleration

You can use Amazon S3 Transfer Acceleration transfer files quickly and securely over long distances between your client and an S3 bucket. You can enable Transfer Acceleration using the S3 console, the AWS Command Line Interface (AWS CLI), API, or the AWS SDKs.

This section provides examples of how to enable Amazon S3 Transfer Acceleration on a bucket and use the acceleration endpoint for the enabled bucket.

For more information about Transfer Acceleration requirements, see Configuring fast, secure file transfers using Amazon S3 Transfer Acceleration.

### Using the S3 console

> **Note**
>
> If you want to compare accelerated and non-accelerated upload speeds, open the Amazon S3 Transfer Acceleration Speed Comparison tool.
> The Speed Comparison tool uses multipart upload to transfer a file from your browser to various AWS Regions with and without Amazon S3 transfer acceleration. You can compare the upload speed for direct uploads and transfer accelerated uploads by Region.

#### To enable transfer acceleration for an S3 bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the **Buckets** list, choose the name of the bucket that you want to enable transfer acceleration for.
3. Choose **Properties**.
4. Under **Transfer acceleration**, choose **Edit**.

5. Choose **Enable**, and choose **Save changes**.

### To access accelerated data transfers

1. After Amazon S3 enables transfer acceleration for your bucket, view the **Properties** tab for the bucket.
2. Under **Transfer acceleration**, **Accelerated endpoint** displays the transfer acceleration endpoint for your bucket. Use this endpoint to access accelerated data transfers to and from your bucket.

   If you suspend transfer acceleration, the accelerate endpoint no longer works.

### Using the AWS CLI

The following are examples of AWS CLI commands used for Transfer Acceleration. For instructions on setting up the AWS CLI, see Developing with Amazon S3 using the AWS CLI.

#### Enabling Transfer Acceleration on a bucket

Use the AWS CLI put-bucket-accelerate-configuration command to enable or suspend Transfer Acceleration on a bucket.

The following example sets `Status=Enabled` to enable Transfer Acceleration on a bucket. You use `Status=Suspended` to suspend Transfer Acceleration.

#### Example

```
$ aws s3api put-bucket-accelerate-configuration --bucket bucketname --accelerate-
configuration Status=Enabled
```

#### Using Transfer Acceleration

You can direct all Amazon S3 requests made by s3 and s3api AWS CLI commands to the accelerate endpoint: `s3-accelerate.amazonaws.com`. To do this, set the configuration value `use_accelerate_endpoint` to `true` in a profile in your AWS Config file. Transfer Acceleration must be enabled on your bucket to use the accelerate endpoint.

All requests are sent using the virtual style of bucket addressing: `my-bucket.s3-accelerate.amazonaws.com`. Any `ListBuckets`, `CreateBucket`, and `DeleteBucket` requests are not sent to the accelerate endpoint because the endpoint doesn't support those operations.

For more information about `use_accelerate_endpoint`, see AWS CLI S3 Configuration in the *AWS CLI Command Reference*.

The following example sets `use_accelerate_endpoint` to `true` in the default profile.

**Example**

```
$ aws configure set default.s3.use_accelerate_endpoint true
```

If you want to use the accelerate endpoint for some AWS CLI commands but not others, you can use either one of the following two methods:

- Use the accelerate endpoint for any s3 or s3api command by setting the `--endpoint-url` parameter to `https://s3-accelerate.amazonaws.com`.
- Set up separate profiles in your AWS Config file. For example, create one profile that sets `use_accelerate_endpoint` to `true` and a profile that does not set `use_accelerate_endpoint`. When you run a command, specify which profile you want to use, depending upon whether you want to use the accelerate endpoint.

### Uploading an object to a bucket enabled for Transfer Acceleration

The following example uploads a file to a bucket enabled for Transfer Acceleration by using the default profile that has been configured to use the accelerate endpoint.

**Example**

```
$ aws s3 cp file.txt s3://bucketname/keyname --region region
```

The following example uploads a file to a bucket enabled for Transfer Acceleration by using the `--endpoint-url` parameter to specify the accelerate endpoint.

**Example**

```
$ aws configure set s3.addressing_style virtual
$ aws s3 cp file.txt s3://bucketname/keyname --region region --endpoint-url https://s3-accelerate.amazonaws.com
```

### Using the AWS SDKs

The following are examples of using Transfer Acceleration to upload objects to Amazon S3 using the AWS SDK. Some of the AWS SDK supported languages (for example, Java and .NET) use an accelerate endpoint client configuration flag so you don't need to explicitly set the endpoint for Transfer Acceleration to *bucketname*.s3-accelerate.amazonaws.com.

Java

#### Example

The following example shows how to use an accelerate endpoint to upload an object to Amazon S3. The example does the following:

- Creates an `AmazonS3Client` that is configured to use accelerate endpoints. All buckets that the client accesses must have Transfer Acceleration enabled.
- Enables Transfer Acceleration on a specified bucket. This step is necessary only if the bucket you specify doesn't already have Transfer Acceleration enabled.
- Verifies that transfer acceleration is enabled for the specified bucket.
- Uploads a new object to the specified bucket using the bucket's accelerate endpoint.

For more information about using Transfer Acceleration, see Getting started with Amazon S3 Transfer Acceleration. For instructions on creating and testing a working sample, see Getting Started in the AWS SDK for Java Developer Guide.

```
import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import com.amazonaws.auth.profile.ProfileCredentialsProvider;
import com.amazonaws.regions.Regions;
import com.amazonaws.services.s3.AmazonS3;
import com.amazonaws.services.s3.AmazonS3ClientBuilder;
import com.amazonaws.services.s3.model.BucketAccelerateConfiguration;
import com.amazonaws.services.s3.model.BucketAccelerateStatus;
import com.amazonaws.services.s3.model.GetBucketAccelerateConfigurationRequest;
import com.amazonaws.services.s3.model.SetBucketAccelerateConfigurationRequest;

public class TransferAcceleration {
    public static void main(String[] args) {
        Regions clientRegion = Regions.DEFAULT_REGION;
```

```
        String bucketName = "*** Bucket name ***";
        String keyName = "*** Key name ***";

        try {
            // Create an Amazon S3 client that is configured to use the accelerate
 endpoint.
            AmazonS3 s3Client = AmazonS3ClientBuilder.standard()
                    .withRegion(clientRegion)
                    .withCredentials(new ProfileCredentialsProvider())
                    .enableAccelerateMode()
                    .build();

            // Enable Transfer Acceleration for the specified bucket.
            s3Client.setBucketAccelerateConfiguration(
                    new SetBucketAccelerateConfigurationRequest(bucketName,
                            new BucketAccelerateConfiguration(
                                    BucketAccelerateStatus.Enabled)));

            // Verify that transfer acceleration is enabled for the bucket.
            String accelerateStatus = s3Client.getBucketAccelerateConfiguration(
                    new GetBucketAccelerateConfigurationRequest(bucketName))
                    .getStatus();
            System.out.println("Bucket accelerate status: " + accelerateStatus);

            // Upload a new object using the accelerate endpoint.
            s3Client.putObject(bucketName, keyName, "Test object for transfer
 acceleration");
            System.out.println("Object \"" + keyName + "\" uploaded with transfer
 acceleration.");
        } catch (AmazonServiceException e) {
            // The call was transmitted successfully, but Amazon S3 couldn't process
            // it, so it returned an error response.
            e.printStackTrace();
        } catch (SdkClientException e) {
            // Amazon S3 couldn't be contacted for a response, or the client
            // couldn't parse the response from Amazon S3.
            e.printStackTrace();
        }
    }
}
```

.NET

The following example shows how to use the AWS SDK for .NET to enable Transfer Acceleration on a bucket. For information about setting up and running the code examples, see Getting Started with the AWS SDK for .NET in the *AWS SDK for .NET Developer Guide*.

**Example**

```
using Amazon;
using Amazon.S3;
using Amazon.S3.Model;
using System;
using System.Threading.Tasks;

namespace Amazon.DocSamples.S3
{
    class TransferAccelerationTest
    {
        private const string bucketName = "*** bucket name ***";
        // Specify your bucket region (an example region is shown).
        private static readonly RegionEndpoint bucketRegion =
 RegionEndpoint.USWest2;
        private static IAmazonS3 s3Client;
        public static void Main()
        {
            s3Client = new AmazonS3Client(bucketRegion);
            EnableAccelerationAsync().Wait();
        }

        static async Task EnableAccelerationAsync()
        {
                try
                {
                    var putRequest = new PutBucketAccelerateConfigurationRequest
                    {
                        BucketName = bucketName,
                        AccelerateConfiguration = new AccelerateConfiguration
                        {
                            Status = BucketAccelerateStatus.Enabled
                        }
                    };
                    await
 s3Client.PutBucketAccelerateConfigurationAsync(putRequest);
```

```
                    var getRequest = new GetBucketAccelerateConfigurationRequest
                    {
                        BucketName = bucketName
                    };
                    var response = await
 s3Client.GetBucketAccelerateConfigurationAsync(getRequest);

                    Console.WriteLine("Acceleration state = '{0}' ",
 response.Status);
                }
                catch (AmazonS3Exception amazonS3Exception)
                {
                    Console.WriteLine(
                        "Error occurred. Message:'{0}' when setting transfer
 acceleration",
                        amazonS3Exception.Message);
                }
        }
    }
}
```

When uploading an object to a bucket that has Transfer Acceleration enabled, you specify using the acceleration endpoint at the time of creating a client.

```
var client = new AmazonS3Client(new AmazonS3Config
            {
                RegionEndpoint = TestRegionEndpoint,
                UseAccelerateEndpoint = true
            }
```

Javascript

For an example of enabling Transfer Acceleration by using the AWS SDK for JavaScript, see Calling the putBucketAccelerateConfiguration operation in the *AWS SDK for JavaScript API Reference*.

Python (Boto)

For an example of enabling Transfer Acceleration by using the SDK for Python, see put_bucket_accelerate_configuration in the *AWS SDK for Python (Boto3) API Reference*.

Other

For information about using other AWS SDKs, see Sample Code and Libraries.

#### Using the REST API

Use the REST API `PutBucketAccelerateConfiguration` operation to enable accelerate configuration on an existing bucket.

For more information, see PutBucketAccelerateConfiguration in the *Amazon Simple Storage Service API Reference*.

## Using the Amazon S3 Transfer Acceleration Speed Comparison tool

You can use the Amazon S3 Transfer Acceleration Speed Comparison tool to compare accelerated and non-accelerated upload speeds across Amazon S3 Regions. The Speed Comparison tool uses multipart uploads to transfer a file from your browser to various Amazon S3 Regions with and without using Transfer Acceleration.

You can access the Speed Comparison tool using either of the following methods:

- Copy the following URL into your browser window, replacing *`region`* with the AWS Region that you are using (for example, `us-west-2`) and *`yourBucketName`* with the name of the bucket that you want to evaluate:

  ```
  https://s3-accelerate-speedtest.s3-accelerate.amazonaws.com/en/
  accelerate-speed-comparsion.html?
  region=region&origBucketName=yourBucketName
  ```

  For a list of the Regions supported by Amazon S3, see Amazon S3 endpoints and quotas in the *AWS General Reference*.
- Use the Amazon S3 console.

# Using Requester Pays buckets for storage transfers and usage

In general, bucket owners pay for all Amazon S3 storage and data transfer costs that are associated with their bucket. However, you can configure a bucket to be a *Requester Pays* bucket. With Requester Pays buckets, the requester instead of the bucket owner pays the cost of the request and the data download from the bucket. The bucket owner always pays the cost of storing data.

Typically, you configure buckets to be Requester Pays buckets when you want to share data but not incur charges associated with others accessing the data. For example, you might use Requester Pays buckets when making available large datasets, such as zip code directories, reference data, geospatial information, or web crawling data.

> **Important**
>
> If you enable Requester Pays on a bucket, anonymous access to that bucket is not allowed.

You must authenticate all requests involving Requester Pays buckets. The request authentication enables Amazon S3 to identify and charge the requester for their use of the Requester Pays bucket.

When the requester assumes an AWS Identity and Access Management (IAM) role before making their request, the account to which the role belongs is charged for the request. For more information about IAM roles, see IAM roles in the *IAM User Guide*.

After you configure a bucket to be a Requester Pays bucket, requesters must show they understand that they will be charged for the request and for the data download. To show they accept the charges, requesters must either include `x-amz-request-payer` as a header in their API request for DELETE, GET, HEAD, POST, and PUT requests, or add the `RequestPayer` parameter in their REST request. For CLI requests, requesters can use the `--request-payer` parameter.

**Example – Using Requester Pays when deleting an object**

To use the following DeleteObjectVersion API example, replace the *`user input placeholders`* with your own information.

```
DELETE /Key+?versionId=VersionId HTTP/1.1
Host: Bucket.s3.amazonaws.com
x-amz-mfa: MFA
x-amz-request-payer: RequestPayer
x-amz-bypass-governance-retention: BypassGovernanceRetention
x-amz-expected-bucket-owner: ExpectedBucketOwner
```

If the requester restores objects by using the RestoreObject API, Requester Pays is supported as long as the `x-amz-request-payer` header or the `RequestPayer` parameter are in the request; however, the requester only pays for the cost of the request. The bucket owner pays the retrieval charges.

Requester Pays buckets do not support the following:

- Anonymous requests
- SOAP requests
- Using a Requester Pays bucket as the target bucket for end-user logging, or vice versa. However, you can turn on end-user logging on a Requester Pays bucket where the target bucket is not a Requester Pays bucket.

## How Requester Pays charges work

The charge for successful Requester Pays requests is straightforward: The requester pays for the data transfer and the request, and the bucket owner pays for the data storage. However, the bucket owner is charged for the request under the following conditions:

- The request returns an `AccessDenied` (HTTP `403 Forbidden`) error and the request is initiated inside the bucket owner's individual AWS account or AWS organization.
- The request is a SOAP request.

For more information about Requester Pays, see the following topics.

**Topics**

- Configuring Requester Pays on a bucket
- Retrieving the requestPayment configuration using the REST API
- Downloading objects from Requester Pays buckets

## Configuring Requester Pays on a bucket

You can configure an Amazon S3 bucket to be a *Requester Pays* bucket so that the requester pays the cost of the request and data download instead of the bucket owner.

This section provides examples of how to configure Requester Pays on an Amazon S3 bucket using the console and the REST API.

### Using the S3 console

#### To enable Requester Pays for an S3 bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the **Buckets** list, choose the name of the bucket that you want to enable Requester Pays for.
3. Choose **Properties**.
4. Under **Requester pays**, choose **Edit**.
5. Choose **Enable**, and choose **Save changes**.

   Amazon S3 enables Requester Pays for your bucket and displays your **Bucket overview**. Under **Requester pays**, you see **Enabled**.

### Using the REST API

Only the bucket owner can set the `RequestPaymentConfiguration.payer` configuration value of a bucket to `BucketOwner` (the default) or `Requester`. Setting the `requestPayment` resource is optional. By default, the bucket is not a Requester Pays bucket.

To revert a Requester Pays bucket to a regular bucket, you use the value `BucketOwner`. Typically, you would use `BucketOwner` when uploading data to the Amazon S3 bucket, and then you would set the value to `Requester` before publishing the objects in the bucket.

#### To set requestPayment

- Use a PUT request to set the `Payer` value to `Requester` on a specified bucket.

```
PUT ?requestPayment HTTP/1.1
Host: [BucketName].s3.amazonaws.com
Content-Length: 173
Date: Wed, 01 Mar 2009 12:00:00 GMT
Authorization: AWS [Signature]

<RequestPaymentConfiguration xmlns="http://s3.amazonaws.com/doc/2006-03-01/">
<Payer>Requester</Payer>
</RequestPaymentConfiguration>
```

If the request succeeds, Amazon S3 returns a response similar to the following.

```
HTTP/1.1 200 OK
x-amz-id-2: [id]
x-amz-request-id: [request_id]
Date: Wed, 01 Mar 2009 12:00:00 GMT
Content-Length: 0
Connection: close
Server: AmazonS3
x-amz-request-charged:requester
```

You can set Requester Pays only at the bucket level. You can't set Requester Pays for specific objects within the bucket.

You can configure a bucket to be `BucketOwner` or `Requester` at any time. However, there might be a few minutes before the new configuration value takes effect.

> **Note**
>
> Bucket owners who give out presigned URLs should consider carefully before configuring a bucket to be Requester Pays, especially if the URL has a long lifetime. The bucket owner is charged each time the requester uses a presigned URL that uses the bucket owner's credentials.

## Retrieving the requestPayment configuration using the REST API

You can determine the `Payer` value that is set on a bucket by requesting the resource `requestPayment`.

**To return the requestPayment resource**

- Use a GET request to obtain the `requestPayment` resource, as shown in the following request.

```
GET ?requestPayment HTTP/1.1
Host: [BucketName].s3.amazonaws.com
Date: Wed, 01 Mar 2009 12:00:00 GMT
Authorization: AWS [Signature]
```

If the request succeeds, Amazon S3 returns a response similar to the following.

```
HTTP/1.1 200 OK
x-amz-id-2: [id]
x-amz-request-id: [request_id]
Date: Wed, 01 Mar 2009 12:00:00 GMT
Content-Type: [type]
Content-Length: [length]
Connection: close
Server: AmazonS3

<?xml version="1.0" encoding="UTF-8"?>
<RequestPaymentConfiguration xmlns="http://s3.amazonaws.com/doc/2006-03-01/">
<Payer>Requester</Payer>
</RequestPaymentConfiguration>
```

This response shows that the `payer` value is set to `Requester`.

## Downloading objects from Requester Pays buckets

Because requesters are charged for downloading data from Requester Pays buckets, the requests must contain a special parameter, `x-amz-request-payer`, which confirms that the requester knows that they will be charged for the download. To access objects in Requester Pays buckets, requests must include one of the following.

- For DELETE, GET, HEAD, POST, and PUT requests, include `x-amz-request-payer : requester` in the header
- For signed URLs, include `x-amz-request-payer=requester` in the request

If the request succeeds and the requester is charged, the response includes the header `x-amz-request-charged:requester`. If `x-amz-request-payer` is not in the request, Amazon S3 returns a 403 error and charges the bucket owner for the request.

> **Note**
>
> Bucket owners do not need to add `x-amz-request-payer` to their requests.
> Ensure that you have included `x-amz-request-payer` and its value in your signature calculation. For more information, see Constructing the CanonicalizedAmzHeaders Element.

### Using the REST API

#### To download objects from a Requester Pays bucket

- Use a GET request to download an object from a Requester Pays bucket, as shown in the following request.

```
GET / [destinationObject] HTTP/1.1
Host: [BucketName].s3.amazonaws.com
x-amz-request-payer : requester
Date: Wed, 01 Mar 2009 12:00:00 GMT
Authorization: AWS [Signature]
```

If the GET request succeeds and the requester is charged, the response includes `x-amz-request-charged:requester`.

Amazon S3 can return an `Access Denied` error for requests that try to get objects from a Requester Pays bucket. For more information, see Error Responses in the *Amazon Simple Storage Service API Reference*.

### Using the AWS CLI

To download objects from a Requester Pays bucket using the AWS CLI, you specify `--request-payer requester` as part of your `get-object` request. For more information, see get-object in the *AWS CLI Reference*.

## Bucket quotas, restrictions, and limitations

An Amazon S3 bucket is owned by the AWS account that created it. Bucket ownership is not transferable to another account.

### Bucket quota limits

By default, you can create up to 100 buckets in each of your AWS accounts. If you need additional buckets, you can increase your account bucket quota to a maximum of 1,000 buckets by submitting a quota increase request. There is no difference in performance whether you use many buckets or just a few.

> **Note**
>
> You do not need to submit multiple quota increase requests for each AWS Region. Your bucket quota is applied to your AWS account.

For information about how to increase your bucket quota, see Amazon S3 endpoints and quotas in the *Amazon Web Services General Reference*.

**Objects and bucket limitations**

There is no max bucket size or limit to the number of objects that you can store in a bucket. You can store all of your objects in a single bucket, or you can organize them across several buckets. However, you can't create a bucket from within another bucket.

**Bucket naming limits**

When you create a bucket, you choose its name and the AWS Region to create it in. After you create a bucket, you can't change its name or Region.

When naming a bucket, choose a name that is relevant to you or your business. Avoid using names associated with others. For example, you should avoid using `AWS` or `Amazon` in your bucket name.

**Reusing bucket names**

If a bucket is empty, you can delete it. After a bucket is deleted, the name becomes available for reuse. However, after you delete the bucket, you might not be able to reuse the name for various reasons.

For example, when you delete the bucket and the name becomes available for reuse, another AWS account might create a bucket with that name. In addition, some time might pass before you can reuse the name of a deleted bucket. If you want to use the same bucket name, we recommend that you don't delete the bucket.

For more information about bucket names, see Bucket naming rules.

**Bucket naming and automatically created buckets**

If your application automatically creates buckets, choose a bucket naming scheme that is unlikely to cause naming conflicts. Ensure that your application logic will choose a different bucket name if a bucket name is already taken.

For more information about bucket naming, see Bucket naming rules.

### Bucket operations

The high availability engineering of Amazon S3 is focused on *get*, *put*, *list*, and *delete* operations. Because bucket operations work against a centralized, global resource space, it is not recommended to create, delete, or configure buckets on the high availability code path of your application. It's better to create, delete, or configure buckets in a separate initialization or setup routine that you run less often.

# Uploading, downloading, and working with objects in Amazon S3

To store your data in Amazon S3, you work with resources known as buckets and objects. A *bucket* is a container for objects. An *object* is a file and any metadata that describes that file.

To store an object in Amazon S3, you create a bucket and then upload the object to a bucket. When the object is in the bucket, you can open it, download it, and copy it. When you no longer need an object or a bucket, you can clean up these resources.

> **Note**
>
> For more information about using the Amazon S3 Express One Zone storage class with directory buckets, see What is S3 Express One Zone? and Directory buckets.

> **Important**
>
> In the Amazon S3 console, when you choose **Open** or **Download As** for an object, these operations create presigned URLs. For the duration of five minutes, your object will be accessible to anyone who has access to these presigned URLs. For more information about presigned URLs, see Using presigned URLS.

With Amazon S3, you pay only for what you use. For more information about Amazon S3 features and pricing, see Amazon S3. If you are a new Amazon S3 customer, you can get started with Amazon S3 for free. For more information, see AWS Free Tier.

**Topics**

- Copying, moving, and renaming objects
- Downloading objects
- Checking object integrity
- Deleting Amazon S3 objects
- Organizing, listing, and working with your objects
- Working with presigned URLs
- Transforming objects with S3 Object Lambda

# Amazon S3 objects overview

Amazon S3 is an object store that uses unique key-values to store as many objects as you want. You store these objects in one or more buckets, and each object can be up to 5 TB in size. An object consists of the following:

Key

The name that you assign to an object. You use the object key to retrieve the object. For more information, see Working with object metadata.

Version ID

Within a bucket, a key and version ID uniquely identify an object. The version ID is a string that Amazon S3 generates when you add an object to a bucket. For more information, see Using versioning in S3 buckets.

Value

The content that you are storing.

An object value can be any sequence of bytes. Objects can range in size from zero to 5 TB. For more information, see Uploading objects.

Metadata

A set of name-value pairs with which you can store information regarding the object. You can assign metadata, referred to as user-defined metadata, to your objects in Amazon S3. Amazon S3 also assigns system-metadata to these objects, which it uses for managing objects. For more information, see Working with object metadata.

Subresources

Amazon S3 uses the subresource mechanism to store object-specific additional information. Because subresources are subordinates to objects, they are always associated with some other entity such as an object or a bucket. For more information, see Object subresources.

Access control information

You can control access to the objects you store in Amazon S3. Amazon S3 supports both the resource-based access control, such as an access control list (ACL) and bucket policies, and user-based access control. For more information about access control, see the following:

- Access Management
- Identity and Access Management for Amazon S3
- Configuring ACLs

Your Amazon S3 resources (for example, buckets and objects) are private by default. You must explicitly grant permission for others to access these resources. For more information about sharing objects, see Sharing objects with presigned URLs.

Tags

You can use tags to categorize your stored objects, for access control, or cost allocation. For more information, see Categorizing your storage using tags.

## Object subresources

Amazon S3 defines a set of subresources associated with buckets and objects. Subresources are subordinates to objects. This means that subresources don't exist on their own. They are always associated with some other entity, such as an object or a bucket.

The following table lists the subresources associated with Amazon S3 objects.

| Subresource | Description |
| --- | --- |
| acl | Contains a list of grants identifying the grantees and the permissions granted. When you create an object, the `acl` identifies the object owner as having full control over the object. You can retrieve an object ACL or replace it with an |

| Subresource | Description |
| --- | --- |
| | updated list of grants. Any update to an ACL requires you to replace the existing ACL. For more information about ACLs, see Access control list (ACL) overview. |

## Creating object key names

The *object key* (or key name) uniquely identifies the object in an Amazon S3 bucket. *Object metadata* is a set of name-value pairs. For more information about object metadata, see Working with object metadata.

When you create an object, you specify the key name, which uniquely identifies the object in the bucket. For example, on the Amazon S3 console, when you highlight a bucket, a list of objects in your bucket appears. These names are the *object keys*. The object key name is a sequence of Unicode characters with UTF-8 encoding of up to 1,024 bytes long. Object key names are case sensitive.

> **Note**
>
> Object key names with the value "soap" aren't supported for virtual-hosted-style requests. For object key name values where "soap" is used, a path-style URL must be used instead.

The Amazon S3 data model is a flat structure: You create a bucket, and the bucket stores objects. There is no hierarchy of subbuckets or subfolders. However, you can infer logical hierarchy using key name prefixes and delimiters as the Amazon S3 console does. The Amazon S3 console supports a concept of folders. For more information about how to edit metadata from the Amazon S3 console, see Editing object metadata in the Amazon S3 console.

Suppose that your bucket (`admin-created`) has four objects with the following object keys:

`Development/Projects.xls`

`Finance/statement1.pdf`

`Private/taxdocument.pdf`

`s3-dg.pdf`

The console uses the key name prefixes (`Development/`, `Finance/`, and `Private/`) and delimiter ('/') to present a folder structure. The `s3-dg.pdf` key does not have a prefix, so its object appears directly at the root level of the bucket. If you open the `Development/` folder, you see the `Projects.xlsx` object in it.

- Amazon S3 supports buckets and objects, and there is no hierarchy. However, by using prefixes and delimiters in an object key name, the Amazon S3 console and the AWS SDKs can infer hierarchy and introduce the concept of folders.
- The Amazon S3 console implements folder object creation by creating a zero-byte object with the folder *prefix and delimiter* value as the key. These folder objects don't appear in the console. Otherwise they behave like any other objects and can be viewed and manipulated through the REST API, AWS CLI, and AWS SDKs.

## Object key naming guidelines

You can use any UTF-8 character in an object key name. However, using certain characters in key names can cause problems with some applications and protocols. The following guidelines help you maximize compliance with DNS, web-safe characters, XML parsers, and other APIs.

### Safe characters

The following character sets are generally safe for use in key names.

| | |
|---|---|
| Alphanumeric characters | • 0-9<br>• a-z<br>• A-Z |
| Special characters | • Exclamation point (!)<br>• Hyphen (-)<br>• Underscore (_)<br>• Period (.)<br>• Asterisk (*)<br>• Single quote (')<br>• Open parenthesis (()<br>• Close parenthesis ()) |

The following are examples of valid object key names:

- `4my-organization`
- `my.great_photos-2014/jan/myvacation.jpg`
- `videos/2014/birthday/video1.wmv`

> **Note**
>
> Objects with key names ending with period(s) "." downloaded using the Amazon S3 console will have the period(s) "." removed from the key name of the downloaded object. To download an object with the key name ending in period(s) "." retained in the downloaded object, you must use the AWS Command Line Interface (AWS CLI), AWS SDKs, or REST API. In addition, be aware of the following prefix limitations:
>
> - Objects with a prefix of "./" must be uploaded or downloaded with the AWS Command Line Interface (AWS CLI), AWS SDKs, or REST API. You cannot use the Amazon S3 console.
> - Objects with a prefix of "../" cannot be uploaded using the AWS Command Line Interface (AWS CLI) or Amazon S3 console.

## Characters that might require special handling

The following characters in a key name might require additional code handling and likely need to be URL encoded or referenced as HEX. Some of these are non-printable characters that your browser might not handle, which also requires special handling:

- Ampersand ("&")
- Dollar ("$")
- ASCII character ranges 00–1F hex (0–31 decimal) and 7F (127 decimal)
- 'At' symbol ("@")
- Equals ("=")
- Semicolon (";")
- Forward slash ("/")
- Colon (":")
- Plus ("+")

- Space – Significant sequences of spaces might be lost in some uses (especially multiple spaces)
- Comma (",")
- Question mark ("?")

### Characters to avoid

We recommend that you don't use the following characters in a key name because of significant special character handling, which isn't consistent across all applications.

- Backslash ("\")
- Left curly brace ("{")
- Non-printable ASCII characters (128–255 decimal characters)
- Caret ("^")
- Right curly brace ("}")
- Percent character ("%")
- Grave accent / back tick ("`")
- Right square bracket ("]")
- Quotation marks
- 'Greater Than' symbol (">")
- Left square bracket ("[")
- Tilde ("~")
- 'Less Than' symbol ("<")
- 'Pound' character ("#")
- Vertical bar / pipe ("|")

### XML related object key constraints

As specified by the XML standard on end-of-line handling, all XML text is normalized such that single carriage returns (ASCII code 13) and carriage returns immediately followed by a line feed (ASCII code 10) are replaced by a single line feed character. To ensure the correct parsing of object keys in XML requests, carriage returns and other special characters must be replaced with their equivalent XML entity code when they are inserted within XML tags. The following is a list of such special characters and their equivalent entity codes:

- ' as '
- " as "
- & as &
- < as <
- > as >
- \r as  or 
- \n as 
 or 

**Example**

The following example illustrates the use of an XML entity code as a substitution for a carriage return. This `DeleteObjects` request deletes an object with the `key` parameter: `/some/prefix/objectwith\rcarriagereturn` (where the \r is the carriage return).

```
<Delete xmlns="http://s3.amazonaws.com/doc/2006-03-01/">
  <Object>
    <Key>/some/prefix/objectwith&#13;carriagereturn</Key>
  </Object>
</Delete>
```

# Working with object metadata

You can set object metadata in Amazon S3 at the time you upload the object. Object metadata is a set of name-value pairs. After you upload the object, you cannot modify object metadata. The only way to modify object metadata is to make a copy of the object and set the metadata.

When you create an object, you also specify the key name, which uniquely identifies the object in the bucket. The *object key* (or *key name*) uniquely identifies the object in an Amazon S3 bucket. For more information, see Creating object key names.

There are two kinds of metadata in Amazon S3: *system-defined metadata* and *user-defined metadata*. The following sections provide more information about system-defined and user-defined metadata. For more information about editing metadata using the Amazon S3 console, see Editing object metadata in the Amazon S3 console.

# System-defined object metadata

For each object stored in a bucket, Amazon S3 maintains a set of system metadata. Amazon S3 processes this system metadata as needed. For example, Amazon S3 maintains object-creation date and size metadata and uses this information as part of object management.

There are two categories of system metadata:

- **System controlled** – Metadata such as the object-creation date is system controlled, meaning that only Amazon S3 can modify the value.
- **User controlled** – Other system metadata, such as the storage class configured for the object and whether the object has server-side encryption enabled, are examples of system metadata whose values you control. If your bucket is configured as a website, sometimes you might want to redirect a page request to another page or to an external URL. In this case, a webpage is an object in your bucket. Amazon S3 stores the page redirect value as system metadata whose value you control.

  When you create objects, you can configure the values of these system metadata items or update the values when you need to. For more information about storage classes, see Using Amazon S3 storage classes.

  Amazon S3 uses AWS KMS keys to encrypt your Amazon S3 objects. AWS KMS encrypts only the object data. The checksum, along with the specified algorithm, are stored as part of the object's metadata. If server-side encryption is requested for the object, then the checksum is stored in encrypted form. For more information about server-side encryption, see Protecting data with encryption.

> **Note**
>
> The PUT request header is limited to 8 KB in size. Within the PUT request header, the system-defined metadata is limited to 2 KB in size. The size of system-defined metadata is measured by taking the sum of the number of bytes in the US-ASCII encoding of each key and value.

The following table provides a list of system-defined metadata and whether you can update it.

| Name | Description | Can user modify the value? |
| --- | --- | --- |
| `Date` | The current date and time. | No |
| `Cache-Control` | A general header field used to specify caching policies. | Yes |
| `Content-Disposition` | Object presentational information. | Yes |
| `Content-Length` | The object size in bytes. | No |
| `Content-Type` | The object type. | Yes |
| `Last-Modified` | The object creation date or the last modified date, whichever is the latest. For multipart uploads, the object creation date is the date of initiation of the multipart upload. | No |
| `ETag` | An entity tag (ETag) that represents a specific version of an object. For objects that are not uploaded as a multipart upload and are either unencrypted or encrypted by server-side encryption with Amazon S3 managed keys (SSE-S3), the ETag is an MD5 digest of the data. | No |
| `x-amz-server-side-encryption` | A header that indicates whether server-side encryption is enabled for the object, and whether that encryption is using the AWS Key Management Service (AWS KMS) keys (SSE-KMS) or using Amazon S3 managed encryption keys (SSE-S3). For more information, see Protecting data with server-side encryption. | Yes |
| `x-amz-checksum-crc32` , `x-amz-checksum-crc32c` , `x-amz-` | Headers that contain the checksum or digest of the object. At most, one of these headers will be set at a time, depending on the checksum algorithm that you instruct Amazon S3 to use. For more information about | No |

| Name | Description | Can user modify the value? |
| --- | --- | --- |
| `checksum-sha1` , `x-amz-checksum-sha256` | choosing the checksum algorithm, see Checking object integrity. | |
| `x-amz-version-id` | The object version. When you enable versioning on a bucket, Amazon S3 assigns a version ID to objects added to the bucket. For more information, see Using versioning in S3 buckets. | No |
| `x-amz-delete-marker` | A Boolean marker that indicates whether the object is a delete marker. This marker is used only in buckets that have versioning enabled, | No |
| `x-amz-storage-class` | The storage class used for storing the object. For more information, see Using Amazon S3 storage classes. | Yes |
| `x-amz-website-redirect-location` | A header that redirects requests for the associated object to another object in the same bucket or to an external URL. For more information, see (Optional) Configuring a webpage redirect. | Yes |
| `x-amz-server-side-encryption-aws-kms-key-id` | A header that indicates the ID of the AWS KMS symmetric encryption KMS key that was used to encrypt the object. This header is used only when the `x-amz-server-side-encryption` header is present and has the value of `aws:kms`. | Yes |
| `x-amz-server-side-encryption-customer-algorithm` | A header that indicates whether server-side encryption with customer-provided encryption keys (SSE-C) is enabled. For more information, see Using server-side encryption with customer-provided keys (SSE-C). | Yes |
| `x-amz-tagging` | The tag-set for the object. The tag-set must be encoded as URL Query parameters. | Yes |

# User-defined object metadata

When uploading an object, you can also assign metadata to the object. You provide this optional information as a name-value (key-value) pair when you send a PUT or POST request to create the object. When you upload objects using the REST API, the optional user-defined metadata names must begin with `x-amz-meta-` to distinguish them from other HTTP headers. When you retrieve the object using the REST API, this prefix is returned. When you upload objects using the SOAP API, the prefix is not required. When you retrieve the object using the SOAP API, the prefix is removed, regardless of which API you used to upload the object.

> **Note**
>
> SOAP support over HTTP is deprecated, but SOAP is still available over HTTPS. New Amazon S3 features are not supported for SOAP. Instead of using SOAP, we recommend that you use either the REST API or the AWS SDKs.

When metadata is retrieved through the REST API, Amazon S3 combines headers that have the same name (ignoring case) into a comma-delimited list. If some metadata contains unprintable characters, it is not returned. Instead, the `x-amz-missing-meta` header is returned with a value of the number of unprintable metadata entries. The `HeadObject` action retrieves metadata from an object without returning the object itself. This operation is useful if you're only interested in an object's metadata. To use HEAD, you must have READ access to the object. For more information, see HeadObject in the *Amazon Simple Storage Service API Reference*.

User-defined metadata is a set of key-value pairs. Amazon S3 stores user-defined metadata keys in lowercase.

Amazon S3 allows arbitrary Unicode characters in your metadata values.

To avoid issues around the presentation of these metadata values, you should conform to using US-ASCII characters when using REST and UTF-8 when using SOAP or browser-based uploads through POST.

When using non–US-ASCII characters in your metadata values, the provided Unicode string is examined for non–US-ASCII characters. Values of such headers are character decoded as per RFC 2047 before storing and encoded as per RFC 2047 to make them mail-safe before returning. If the string contains only US-ASCII characters, it is presented as is.

The following is an example.

```
PUT /Key HTTP/1.1
Host: amzn-s3-demo-bucket1.s3.amazonaws.com
x-amz-meta-nonascii: ÄMÄZÕÑ S3

HEAD /Key HTTP/1.1
Host: amzn-s3-demo-bucket1.s3.amazonaws.com
x-amz-meta-nonascii: =?UTF-8?B?w4PChE3Dg8KEWsODwpXDg8KRIFMz?=

PUT /Key HTTP/1.1
Host: amzn-s3-demo-bucket1.s3.amazonaws.com
x-amz-meta-ascii: AMAZONS3

HEAD /Key HTTP/1.1
Host: amzn-s3-demo-bucket1.s3.amazonaws.com
x-amz-meta-ascii: AMAZONS3
```

**Note**

The PUT request header is limited to 8 KB in size. Within the PUT request header, the user-defined metadata is limited to 2 KB in size. The size of user-defined metadata is measured by taking the sum of the number of bytes in the UTF-8 encoding of each key and value.

For information about changing the metadata of your object after it has been uploaded by creating a copy of the object, modifying it, and replacing the old object, or creating a new version, see Editing object metadata in the Amazon S3 console.

## Editing object metadata in the Amazon S3 console

You can use the Amazon S3 console to edit metadata of existing S3 objects. Some metadata is set by Amazon S3 when you upload the object. For example, `Content-Length` and `Last-Modified` are system-defined object metadata fields that can't be modified by a user.

You can also set some metadata when you upload the object and later edit it as your needs change. For example, you might have a set of objects that you initially store in the `STANDARD` storage class. Over time, you might no longer need this data to be highly available. So you change the storage

class to `GLACIER` by editing the value of the `x-amz-storage-class` key from `STANDARD` to `GLACIER`.

**Note**

Consider the following issues when you are editing object metadata in Amazon S3:

- This action creates a *copy* of the object with updated settings and the last-modified date. If S3 Versioning is enabled, a new version of the object is created, and the existing object becomes an older version. If S3 Versioning is not enabled, a new copy of the object replaces the original object. The AWS account associated with the IAM role that changes the property also becomes the owner of the new object or (object version).
- To use the Amazon S3 console to edit metadata for an object that has user-defined tags, you must also have the `s3:GetObjectTagging` permission. If you are using the Amazon S3 console to edit the metadata for an object that doesn't have user-defined tags but is over 16 MB in size, you must also have the `s3:GetObjectTagging` permission.

  If the destination bucket policy denies the `s3:GetObjectTagging` action, the metadata for the object will be updated, but the user-defined tags will be removed from the object, and you will receive an error.
- Editing metadata updates values for existing key names.
- Objects that are encrypted with customer-provided encryption keys (SSE-C) cannot be copied using the console. You must use the AWS CLI, AWS SDK, or the Amazon S3 REST API.

**Warning**

When editing metadata of folders, wait for the `Edit metadata` operation to finish before adding new objects to the folder. Otherwise, new objects might also be edited.

The following topics describe how to edit metadata of an object using the Amazon S3 console.

### Editing system-defined metadata

You can configure some, but not all, system metadata for an S3 object. For a list of system-defined metadata and whether you can modify their values, see System-defined object metadata.

**To edit system-defined metadata of an object**

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. Navigate to your Amazon S3 bucket or folder, and select the check box to the left of the names of the objects with metadata you want to edit.
3. On the **Actions** menu, choose **Edit actions**, and choose **Edit metadata**.
4. Review the objects listed, and choose **Add metadata**.
5. For metadata **Type**, select **System-defined**.
6. Specify a unique **Key** and the metadata **Value**.
7. To edit additional metadata, choose **Add metadata**. You can also choose **Remove** to remove a set of type-key-values.
8. When you are done, choose **Edit metadata** and Amazon S3 edits the metadata of the specified objects.

### Editing user-defined metadata

You can edit user-defined metadata of an object by combining the metadata prefix, `x-amz-meta-`, and a name you choose to create a custom key. For example, if you add the custom name `alt-name`, the metadata key would be `x-amz-meta-alt-name`.

User-defined metadata can be as large as 2 KB total. To calculate the total size of user-defined metadata, sum the number of bytes in the UTF-8 encoding for each key and value. Both keys and their values must conform to US-ASCII standards. For more information, see User-defined object metadata.

**To edit user-defined metadata of an object**

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the **Buckets** list, choose the name of the bucket that contains the objects that you want to add metadata to.

   You can also optionally navigate to a folder.
3. In the **Objects** list, select the check box next to the names of the objects that you want to add metadata to.

4. On the **Actions** menu, choose **Edit metadata**.
5. Review the objects listed, and choose **Add metadata**.
6. For metadata **Type**, choose **User-defined**.
7. Enter a unique custom **Key** following `x-amz-meta-`. Also enter a metadata **Value**.
8. To add additional metadata, choose **Add metadata**. You can also choose **Remove** to remove a set of type-key-values.
9. Choose **Edit metadata**.

   Amazon S3 edits the metadata of the specified objects.

# Uploading objects

When you upload a file to Amazon S3, it is stored as an S3 *object*. Objects consist of the file data and metadata that describes the object. You can have an unlimited number of objects in a bucket. Before you can upload files to an Amazon S3 bucket, you need write permissions for the bucket. For more information about access permissions, see Identity and Access Management for Amazon S3.

You can upload any file type—images, backups, data, movies, and so on—into an S3 bucket. The maximum size of a file that you can upload by using the Amazon S3 console is 160 GB. To upload a file larger than 160 GB, use the AWS Command Line Interface (AWS CLI), AWS SDKs, or Amazon S3 REST API.

If you upload an object with a key name that already exists in a versioning-enabled bucket, Amazon S3 creates another version of the object instead of replacing the existing object. For more information about versioning, see Using the S3 console.

Depending on the size of the data that you're uploading, Amazon S3 offers the following options:

- **Upload an object in a single operation by using the AWS SDKs, REST API, or AWS CLI** – With a single PUT operation, you can upload a single object up to 5 GB in size.
- **Upload a single object by using the Amazon S3 console –** With the Amazon S3 console, you can upload a single object up to 160 GB in size.
- **Upload an object in parts by using the AWS SDKs, REST API, or AWS CLI –** Using the multipart upload API operation, you can upload a single large object, up to 5 TB in size.

The multipart upload API operation is designed to improve the upload experience for larger objects. You can upload an object in parts. These object parts can be uploaded independently, in any order, and in parallel. You can use a multipart upload for objects from 5 MB to 5 TB in size. For more information, see Uploading and copying objects using multipart upload.

When you upload an object, the object is automatically encrypted using server-side encryption with Amazon S3 managed keys (SSE-S3) by default. When you download it, the object is decrypted. For more information, see Setting default server-side encryption behavior for Amazon S3 buckets and Protecting data with encryption.

When you're uploading an object, if you want to use a different type of default encryption, you can also specify server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS) in your S3 PUT requests or set the default encryption configuration in the destination bucket to use SSE-KMS to encrypt your data. For more information about SSE-KMS, see Specifying server-side encryption with AWS KMS (SSE-KMS). If you want to use a KMS key that is owned by a different account, you must have permission to use the key. For more information about cross-account permissions for KMS keys, see Creating KMS keys that other accounts can use in the *AWS Key Management Service Developer Guide*.

If you encounter an Access Denied (403 Forbidden) error in Amazon S3, see Troubleshoot Access Denied (403 Forbidden) errors in Amazon S3 to learn more about its common causes.

## Using the S3 console

This procedure explains how to upload objects and folders to an Amazon S3 bucket by using the console.

When you upload an object, the object key name is the file name and any optional prefixes. In the Amazon S3 console, you can create folders to organize your objects. In Amazon S3, folders are represented as prefixes that appear in the object key name. If you upload an individual object to a folder in the Amazon S3 console, the folder name is included in the object key name.

For example, if you upload an object named `sample1.jpg` to a folder named `backup`, the key name is `backup/sample1.jpg`. However, the object is displayed in the console as `sample1.jpg` in the `backup` folder. For more information about key names, see Working with object metadata.

> **Note**
>
> If you rename an object or change any of the properties in the Amazon S3 console, for example **Storage Class**, **Encryption**, or **Metadata**, a new object is created to replace the old one. If S3 Versioning is enabled, a new version of the object is created, and the existing object becomes an older version. The role that changes the property also becomes the owner of the new object (or object version).

When you upload a folder, Amazon S3 uploads all of the files and subfolders from the specified folder to your bucket. It then assigns an object key name that is a combination of the uploaded file name and the folder name. For example, if you upload a folder named `/images` that contains two files, `sample1.jpg` and `sample2.jpg`, Amazon S3 uploads the files and then assigns the corresponding key names, `images/sample1.jpg` and `images/sample2.jpg`. The key names include the folder name as a prefix. The Amazon S3 console displays only the part of the key name that follows the last `/`. For example, within an `images` folder, the `images/sample1.jpg` and `images/sample2.jpg` objects are displayed as `sample1.jpg` and a `sample2.jpg`.

**To upload folders and files to an S3 bucket**

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Buckets**.
3. In the **Buckets** list, choose the name of the bucket that you want to upload your folders or files to.
4. Choose **Upload**.
5. In the **Upload** window, do one of the following:
   - Drag and drop files and folders to the **Upload** window.
   - Choose **Add file** or **Add folder**, choose the files or folders to upload, and choose **Open**.
6. To enable versioning, under **Destination**, choose **Enable Bucket Versioning**.
7. To upload the listed files and folders without configuring additional upload options, at the bottom of the page, choose **Upload**.

   Amazon S3 uploads your objects and folders. When the upload is finished, you see a success message on the **Upload: status** page.

**To configure additional object properties**

1. To change access control list permissions, choose **Permissions**.
2. Under **Access control list (ACL)**, edit the permissions.

   For information about object access permissions, see Using the S3 console to set ACL permissions for an object. You can grant read access to your objects to the public (everyone in the world) for all of the files that you're uploading. However, we recommend not changing the default setting for public read access. Granting public read access is applicable to a small subset of use cases, such as when buckets are used for websites. You can always change the object permissions after you upload the object.
3. To configure other additional properties, choose **Properties**.
4. Under **Storage class**, choose the storage class for the files that you're uploading.

   For more information about storage classes, see Using Amazon S3 storage classes.
5. To update the encryption settings for your objects, under **Server-side encryption settings**, do the following.

   a. Choose **Specify an encryption key**.

   b. Under **Encryption settings**, choose **Use bucket settings for default encryption** or **Override bucket settings for default encryption**.

   c. If you chose **Override bucket settings for default encryption**, you must configure the following encryption settings.

   - To encrypt the uploaded files by using keys that are managed by Amazon S3, choose **Amazon S3 managed key (SSE-S3)**.

     For more information, see Using server-side encryption with Amazon S3 managed keys (SSE-S3).
   - To encrypt the uploaded files by using keys stored in AWS Key Management Service (AWS KMS), choose **AWS Key Management Service key (SSE-KMS)**. Then choose one of the following options for **AWS KMS key**:
     - To choose from a list of available KMS keys, choose **Choose from your AWS KMS keys**, and then choose your **KMS key** from the list of available keys.

Both the AWS managed key (`aws/s3`) and your customer managed keys appear in this list. For more information about customer managed keys, see Customer keys and AWS keys in the *AWS Key Management Service Developer Guide*.

- To enter the KMS key ARN, choose **Enter AWS KMS key ARN**, and then enter your KMS key ARN in the field that appears.
- To create a new customer managed key in the AWS KMS console, choose **Create a KMS key**.

  For more information about creating an AWS KMS key, see Creating keys in the *AWS Key Management Service Developer Guide*.

> **Important**
>
> You can use only KMS keys that are available in the same AWS Region as the bucket. The Amazon S3 console lists only the first 100 KMS keys in the same Region as the bucket. To use a KMS key that is not listed, you must enter your KMS key ARN. If you want to use a KMS key that is owned by a different account, you must first have permission to use the key and then you must enter the KMS key ARN.
> Amazon S3 supports only symmetric encryption KMS keys, and not asymmetric KMS keys. For more information, see Identifying symmetric and asymmetric KMS keys in the *AWS Key Management Service Developer Guide*.

6. To use additional checksums, choose **On**. Then for **Checksum function**, choose the function that you would like to use. Amazon S3 calculates and stores the checksum value after it receives the entire object. You can use the **Precalculated value** box to supply a precalculated value. If you do, Amazon S3 compares the value that you provided to the value that it calculates. If the two values do not match, Amazon S3 generates an error.

   Additional checksums enable you to specify the checksum algorithm that you would like to use to verify your data. For more information about additional checksums, see Checking object integrity.

7. To add tags to all of the objects that you are uploading, choose **Add tag**. Enter a tag name in the **Key** field. Enter a value for the tag.

   Object tagging gives you a way to categorize storage. Each tag is a key-value pair. Key and tag values are case sensitive. You can have up to 10 tags per object. A tag key can be up to 128

Unicode characters in length, and tag values can be up to 255 Unicode characters in length. For more information about object tags, see Categorizing your storage using tags.

8. To add metadata, choose **Add metadata**.

   a. Under **Type**, choose **System defined** or **User defined**.

      For system-defined metadata, you can select common HTTP headers, such as **Content-Type** and **Content-Disposition**. For a list of system-defined metadata and information about whether you can add the value, see System-defined object metadata. Any metadata starting with the prefix `x-amz-meta-` is treated as user-defined metadata. User-defined metadata is stored with the object and is returned when you download the object. Both the keys and their values must conform to US-ASCII standards. User-defined metadata can be as large as 2 KB. For more information about system-defined and user-defined metadata, see Working with object metadata.

   b. For **Key**, choose a key.

   c. Type a value for the key.

9. To upload your objects, choose **Upload**.

   Amazon S3 uploads your object. When the upload completes, you can see a success message on the **Upload: status** page.

10. Choose **Exit**.

## Using the AWS SDKs

You can use the AWS SDKs to upload objects in Amazon S3. The SDKs provide wrapper libraries for you to upload data easily. For information, see the List of supported SDKs.

Here are some examples with a few select SDKs:

.NET

The following C# code example creates two objects with two `PutObjectRequest` requests:

- The first `PutObjectRequest` request saves a text string as sample object data. It also specifies the bucket and object key names.
- The second `PutObjectRequest` request uploads a file by specifying the file name. This request also specifies the `ContentType` header and optional object metadata (a title).

For information about setting up and running the code examples, see Getting Started with the AWS SDK for .NET in the *AWS SDK for .NET Developer Guide*.

```
using Amazon;
using Amazon.S3;
using Amazon.S3.Model;
using System;
using System.Threading.Tasks;

namespace Amazon.DocSamples.S3
{
    class UploadObjectTest
    {
        private const string bucketName = "*** bucket name ***";
        // For simplicity the example creates two objects from the same file.
        // You specify key names for these objects.
        private const string keyName1 = "*** key name for first object created ***";
        private const string keyName2 = "*** key name for second object created
 ***";
        private const string filePath = @"*** file path ***";
        private static readonly RegionEndpoint bucketRegion =
 RegionEndpoint.EUWest1;

        private static IAmazonS3 client;

        public static void Main()
        {
            client = new AmazonS3Client(bucketRegion);
            WritingAnObjectAsync().Wait();
        }

        static async Task WritingAnObjectAsync()
        {
            try
            {
                // 1. Put object-specify only key name for the new object.
                var putRequest1 = new PutObjectRequest
                {
                    BucketName = bucketName,
                    Key = keyName1,
                    ContentBody = "sample text"
                };
```

```
                PutObjectResponse response1 = await
 client.PutObjectAsync(putRequest1);

                // 2. Put the object-set ContentType and add metadata.
                var putRequest2 = new PutObjectRequest
                {
                    BucketName = bucketName,
                    Key = keyName2,
                    FilePath = filePath,
                    ContentType = "text/plain"
                };

                putRequest2.Metadata.Add("x-amz-meta-title", "someTitle");
                PutObjectResponse response2 = await
 client.PutObjectAsync(putRequest2);
            }
            catch (AmazonS3Exception e)
            {
                Console.WriteLine(
                        "Error encountered ***. Message:'{0}' when writing an
 object"
                        , e.Message);
            }
            catch (Exception e)
            {
                Console.WriteLine(
                    "Unknown encountered on server. Message:'{0}' when writing an
 object"
                    , e.Message);
            }
        }
    }
}
```

Java

The following example creates two objects. The first object has a text string as data, and the second object is a file. The example creates the first object by specifying the bucket name, object key, and text data directly in a call to `AmazonS3Client.putObject()`. The example creates the second object by using a `PutObjectRequest` that specifies the bucket name, object key, and file path. The `PutObjectRequest` also specifies the `ContentType` header and title metadata.

For instructions on creating and testing a working sample, see Getting Started in the AWS SDK for Java Developer Guide.

```
import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import com.amazonaws.regions.Regions;
import com.amazonaws.services.s3.AmazonS3;
import com.amazonaws.services.s3.AmazonS3ClientBuilder;
import com.amazonaws.services.s3.model.ObjectMetadata;
import com.amazonaws.services.s3.model.PutObjectRequest;

import java.io.File;
import java.io.IOException;

public class UploadObject {

    public static void main(String[] args) throws IOException {
        Regions clientRegion = Regions.DEFAULT_REGION;
        String bucketName = "*** Bucket name ***";
        String stringObjKeyName = "*** String object key name ***";
        String fileObjKeyName = "*** File object key name ***";
        String fileName = "*** Path to file to upload ***";

        try {
            // This code expects that you have AWS credentials set up per:
            // https://docs.aws.amazon.com/sdk-for-java/v1/developer-guide/setup-
credentials.html
            AmazonS3 s3Client = AmazonS3ClientBuilder.standard()
                    .withRegion(clientRegion)
                    .build();

            // Upload a text string as a new object.
            s3Client.putObject(bucketName, stringObjKeyName, "Uploaded String
 Object");

            // Upload a file as a new object with ContentType and title specified.
            PutObjectRequest request = new PutObjectRequest(bucketName,
 fileObjKeyName, new File(fileName));
            ObjectMetadata metadata = new ObjectMetadata();
            metadata.setContentType("plain/text");
            metadata.addUserMetadata("title", "someTitle");
            request.setMetadata(metadata);
```

```
            s3Client.putObject(request);
        } catch (AmazonServiceException e) {
            // The call was transmitted successfully, but Amazon S3 couldn't process
            // it, so it returned an error response.
            e.printStackTrace();
        } catch (SdkClientException e) {
            // Amazon S3 couldn't be contacted for a response, or the client
            // couldn't parse the response from Amazon S3.
            e.printStackTrace();
        }
    }
}
```

JavaScript

The following example uploads an existing file to an Amazon S3 bucket in a specific Region.

```
import { PutObjectCommand, S3Client } from "@aws-sdk/client-s3";

const client = new S3Client({});

export const main = async () => {
  const command = new PutObjectCommand({
    Bucket: "test-bucket",
    Key: "hello-s3.txt",
    Body: "Hello S3!",
  });

  try {
    const response = await client.send(command);
    console.log(response);
  } catch (err) {
    console.error(err);
  }
};
```

PHP

This example guides you through using classes from the AWS SDK for PHP to upload an object of up to 5 GB in size. For larger files, you must use the multipart upload API operation. For more information, see Uploading and copying objects using multipart upload.

For more information about the AWS SDK for Ruby API, go to AWS SDK for Ruby - Version 2.

**Example — Creating an object in an Amazon S3 bucket by uploading data**

The following PHP example creates an object in a specified bucket by uploading data using the `putObject()` method.

```
 require 'vendor/autoload.php';

use Aws\S3\Exception\S3Exception;
use Aws\S3\S3Client;

$bucket = '*** Your Bucket Name ***';
$keyname = '*** Your Object Key ***';

$s3 = new S3Client([
    'version' => 'latest',
    'region'  => 'us-east-1'
]);

try {
    // Upload data.
    $result = $s3->putObject([
        'Bucket' => $bucket,
        'Key'    => $keyname,
        'Body'   => 'Hello, world!',
        'ACL'    => 'public-read'
    ]);

    // Print the URL to the object.
    echo $result['ObjectURL'] . PHP_EOL;
} catch (S3Exception $e) {
    echo $e->getMessage() . PHP_EOL;
}
```

Ruby

The AWS SDK for Ruby - Version 3 has two ways of uploading an object to Amazon S3. The first uses a managed file uploader, which makes it easier to upload files of any size from disk. To use the managed file uploader method:

1. Create an instance of the `Aws::S3::Resource` class.

2. Reference the target object by bucket name and key. Objects live in a bucket and have unique keys that identify each object.
3. Call#`upload_file` on the object.

**Example**

```
require "aws-sdk-s3"

# Wraps Amazon S3 object actions.
class ObjectUploadFileWrapper
  attr_reader :object

  # @param object [Aws::S3::Object] An existing Amazon S3 object.
  def initialize(object)
    @object = object
  end

  # Uploads a file to an Amazon S3 object by using a managed uploader.
  #
  # @param file_path [String] The path to the file to upload.
  # @return [Boolean] True when the file is uploaded; otherwise false.
  def upload_file(file_path)
    @object.upload_file(file_path)
    true
  rescue Aws::Errors::ServiceError => e
    puts "Couldn't upload file #{file_path} to #{@object.key}. Here's why:
 #{e.message}"
    false
  end
end

# Example usage:
def run_demo
  bucket_name = "doc-example-bucket"
  object_key = "my-uploaded-file"
  file_path = "object_upload_file.rb"

  wrapper = ObjectUploadFileWrapper.new(Aws::S3::Object.new(bucket_name,
 object_key))
  return unless wrapper.upload_file(file_path)

  puts "File #{file_path} successfully uploaded to #{bucket_name}:#{object_key}."
```

```
end

run_demo if $PROGRAM_NAME == __FILE__
```

The second way that the AWS SDK for Ruby - Version 3 can upload an object uses the `#put` method of `Aws::S3::Object`. This is useful if the object is a string or an I/O object that is not a file on disk. To use this method:

1. Create an instance of the `Aws::S3::Resource` class.
2. Reference the target object by bucket name and key.
3. Call`#put`, passing in the string or I/O object.

**Example**

```
require "aws-sdk-s3"

# Wraps Amazon S3 object actions.
class ObjectPutWrapper
  attr_reader :object

  # @param object [Aws::S3::Object] An existing Amazon S3 object.
  def initialize(object)
    @object = object
  end

  def put_object(source_file_path)
    File.open(source_file_path, "rb") do |file|
      @object.put(body: file)
    end
    true
  rescue Aws::Errors::ServiceError => e
    puts "Couldn't put #{source_file_path} to #{object.key}. Here's why:
 #{e.message}"
    false
  end
end

# Example usage:
def run_demo
  bucket_name = "doc-example-bucket"
  object_key = "my-object-key"
```

```
  file_path = "my-local-file.txt"

  wrapper = ObjectPutWrapper.new(Aws::S3::Object.new(bucket_name, object_key))
  success = wrapper.put_object(file_path)
  return unless success

  puts "Put file #{file_path} into #{object_key} in #{bucket_name}."
end

run_demo if $PROGRAM_NAME == __FILE__
```

### Using the REST API

You can send REST requests to upload an object. You can send a PUT request to upload data in a single operation. For more information, see PUT Object.

### Using the AWS CLI

You can send a PUT request to upload an object of up to 5 GB in a single operation. For more information, see the `PutObject` example in the *AWS CLI Command Reference*.

## Uploading and copying objects using multipart upload

Multipart upload allows you to upload a single object as a set of parts. Each part is a contiguous portion of the object's data. You can upload these object parts independently and in any order. If transmission of any part fails, you can retransmit that part without affecting other parts. After all parts of your object are uploaded, Amazon S3 assembles these parts and creates the object. In general, when your object size reaches 100 MB, you should consider using multipart uploads instead of uploading the object in a single operation.

Using multipart upload provides the following advantages:

- **Improved throughput** – You can upload parts in parallel to improve throughput.
- **Quick recovery from any network issues** – Smaller part size minimizes the impact of restarting a failed upload due to a network error.
- **Pause and resume object uploads** – You can upload object parts over time. After you initiate a multipart upload, there is no expiry; you must explicitly complete or stop the multipart upload.
- **Begin an upload before you know the final object size** – You can upload an object as you are creating it.

We recommend that you use multipart upload in the following ways:

- If you're uploading large objects over a stable high-bandwidth network, use multipart upload to maximize the use of your available bandwidth by uploading object parts in parallel for multi-threaded performance.
- If you're uploading over a spotty network, use multipart upload to increase resiliency to network errors by avoiding upload restarts. When using multipart upload, you need to retry uploading only the parts that are interrupted during the upload. You don't need to restart uploading your object from the beginning.

> **Note**
>
> For more information about using the Amazon S3 Express One Zone storage class with directory buckets, see What is S3 Express One Zone? and Directory buckets. For more information about using multipart upload with S3 Express One Zone and directory buckets, see Using multipart uploads with directory buckets.

## Multipart upload process

Multipart upload is a three-step process: You initiate the upload, you upload the object parts, and after you have uploaded all the parts, you complete the multipart upload. Upon receiving the complete multipart upload request, Amazon S3 constructs the object from the uploaded parts, and you can then access the object just as you would any other object in your bucket.

You can list all of your in-progress multipart uploads or get a list of the parts that you have uploaded for a specific multipart upload. Each of these operations is explained in this section.

### Multipart upload initiation

When you send a request to initiate a multipart upload, Amazon S3 returns a response with an upload ID, which is a unique identifier for your multipart upload. You must include this upload ID whenever you upload parts, list the parts, complete an upload, or stop an upload. If you want to provide any metadata describing the object being uploaded, you must provide it in the request to initiate multipart upload.

### Parts upload

When uploading a part, in addition to the upload ID, you must specify a part number. You can choose any part number between 1 and 10,000. A part number uniquely identifies a part and its position in the object you are uploading. The part number that you choose doesn't need to be in a consecutive sequence (for example, it can be 1, 5, and 14). If you upload a new part using the same part number as a previously uploaded part, the previously uploaded part is overwritten.

When you upload a part, Amazon S3 returns an *entity tag (ETag)* for the part as a header in the response. For each part upload, you must record the part number and the ETag value. You must include these values in the subsequent request to complete the multipart upload. Each part will have its own ETag at the time of upload. However, once the multipart upload is complete and all parts are consolidated, all the parts will be under one ETag as a checksum of checksums.

> **Note**
>
> After you initiate a multipart upload and upload one or more parts, you must either complete or stop the multipart upload to stop getting charged for storage of the uploaded parts. Only *after* you either complete or stop a multipart upload will Amazon S3 free up the parts storage and stop charging you for the parts storage.
> After stopping a multipart upload, you cannot upload any part using that upload ID again. If any part uploads were in-progress, they can still succeed or fail even after you stop the upload. To make sure you free all storage consumed by all parts, you must stop a multipart upload only after all part uploads have been completed.

### Multipart upload completion

When you complete a multipart upload, Amazon S3 creates an object by concatenating the parts in ascending order based on the part number. If any object metadata was provided in the *initiate multipart upload* request, Amazon S3 associates that metadata with the object. After a successful *complete* request, the parts no longer exist.

Your *complete multipart upload* request must include the upload ID and a list of both part numbers and corresponding ETag values. The Amazon S3 response includes an ETag that uniquely identifies the combined object data. This ETag is not necessarily an MD5 hash of the object data.

### Sample multipart upload calls

For this example, assume that you are generating a multipart upload for a 100 GB file. In this case, you would have the following API calls for the entire process. There would be a total of 1002 API calls.

- A `CreateMultipartUpload` call to start the process.
- 1000 individual `UploadPart` calls, each uploading a part of 100 MB, for a total size of 100 GB.
- A `CompleteMultipartUpload` call to finish the process.

#### Multipart upload listings

You can list the parts of a specific multipart upload or all in-progress multipart uploads. The list parts operation returns the parts information that you have uploaded for a specific multipart upload. For each list parts request, Amazon S3 returns the parts information for the specified multipart upload, up to a maximum of 1,000 parts. If there are more than 1,000 parts in the multipart upload, you must send a series of list part requests to retrieve all the parts. Note that the returned list of parts doesn't include parts that haven't finished uploading. Using the *list multipart uploads* operation, you can obtain a list of multipart uploads that are in progress.

An in-progress multipart upload is an upload that you have initiated, but have not yet completed or stopped. Each request returns at most 1,000 multipart uploads. If there are more than 1,000 multipart uploads in progress, you must send additional requests to retrieve the remaining multipart uploads. Use the returned listing only for verification. Do not use the result of this listing when sending a *complete multipart upload* request. Instead, maintain your own list of the part numbers that you specified when uploading parts and the corresponding ETag values that Amazon S3 returns.

## Checksums with multipart upload operations

When you upload an object to Amazon S3, you can specify a checksum algorithm for Amazon S3 to use. Amazon S3 uses MD5 by default to verify data integrity; however, you can specify an additional checksum algorithm to use. When using MD5, Amazon S3 calculates the checksum of the entire multipart object after the upload is complete. This checksum is not a checksum of the entire object, but rather a checksum of the checksums for each individual part.

When you instruct Amazon S3 to use additional checksums, Amazon S3 calculates the checksum value for each part and stores the values. You can use the API or SDK to retrieve the checksum value for individual parts by using `GetObject` or `HeadObject`. If you want to retrieve the checksum values for individual parts of multipart uploads still in process, you can use `ListParts`.

**Important**

If you are using a multipart upload with additional checksums, the multipart part numbers must use consecutive part numbers. When using additional checksums, if you try to complete a multipart upload request with nonconsecutive part numbers, Amazon S3 generates HTTP `500 Internal Server Error` error.

For more information about how checksums work with multipart objects, see Checking object integrity.

## Concurrent multipart upload operations

In a distributed development environment, it is possible for your application to initiate several updates on the same object at the same time. Your application might initiate several multipart uploads using the same object key. For each of these uploads, your application can then upload parts and send a complete upload request to Amazon S3 to create the object. When the buckets have S3 Versioning enabled, completing a multipart upload always creates a new version. When you initiate multiple multipart uploads that use the same object key in a versioning-enabled bucket, the current version of the object is determined by which upload started most recently (`createdDate`). For example, suppose that you start a CreateMultipartUpload request for an object at 10:00 AM. Then you submit a second `CreateMultipartUpload` request for the same object at 11:00 AM. Because the second request was submitted most recently, the object uploaded by the 11:00 AM request will be the current version, even if the first upload is completed after the second one. For buckets that don't have versioning enabled, it is possible that some other request received between the time when a multipart upload is initiated and when it is completed might take precedence.

**Note**

It is possible for some other request received between the time you initiated a multipart upload and completed it to take precedence. For example, if another operation deletes a key after you initiate a multipart upload with that key, but before you complete it, the complete multipart upload response might indicate a successful object creation without you ever seeing the object.

## Multipart upload and pricing

After you initiate a multipart upload, Amazon S3 retains all the parts until you either complete or stop the upload. Throughout its lifetime, you are billed for all storage, bandwidth, and requests for this multipart upload and its associated parts.

These parts are charged according to the storage class specified when the parts were uploaded. An exception to this are parts uploaded to S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive. In-progress multipart parts for a PUT to the S3 Glacier Flexible Retrieval storage class are billed as S3 Glacier Flexible Retrieval Staging Storage at S3 Standard storage rates until the upload completes. In addition, both CreateMultipartUpload and UploadPart are billed at S3 Standard rates. Only the CompleteMultipartUpload request is billed at the S3 Glacier Flexible Retrieval rate. Similarly, in-progress multipart parts for a PUT to the S3 Glacier Deep Archive storage class are billed as S3 Glacier Flexible Retrieval Staging Storage at S3 Standard storage rates until the upload completes, with only the CompleteMultipartUpload request charged at S3 Glacier Deep Archive rates.

If you stop the multipart upload, Amazon S3 deletes upload artifacts and any parts that you have uploaded, and you are no longer billed for them. There are no early delete charges for deleting incomplete multipart uploads regardless of storage class specified. For more information about pricing, see Amazon S3 pricing.

> **Note**
>
> To minimize your storage costs, we recommend that you configure a lifecycle rule to delete incomplete multipart uploads after a specified number of days by using the `AbortIncompleteMultipartUpload` action. For more information about creating a lifecycle rule to delete incomplete multipart uploads, see Configuring a bucket lifecycle configuration to delete incomplete multipart uploads.

## API support for multipart upload

These libraries provide a high-level abstraction that makes uploading multipart objects easy. However, if your application requires, you can use the REST API directly. The following sections in the *Amazon Simple Storage Service API Reference* describe the REST API for multipart upload.

For a multipart upload walkthrough that uses AWS Lambda functions, see Uploading large objects to Amazon S3 using multipart upload and transfer acceleration.

- Create Multipart Upload
- Upload Part
- Upload Part (Copy)
- Complete Multipart Upload
- Abort Multipart Upload
- List Parts
- List Multipart Uploads

## AWS Command Line Interface support for multipart upload

The following topics in the AWS Command Line Interface describe the operations for multipart upload.

- Initiate Multipart Upload
- Upload Part
- Upload Part (Copy)
- Complete Multipart Upload
- Abort Multipart Upload
- List Parts
- List Multipart Uploads

## AWS SDK support for multipart upload

You can use an AWS SDKs to upload an object in parts. For a list of AWS SDKs supported by API action see:

- Create Multipart Upload
- Upload Part
- Upload Part (Copy)
- Complete Multipart Upload
- Abort Multipart Upload

- List Parts
- List Multipart Uploads

## Multipart upload API and permissions

You must have the necessary permissions to use the multipart upload operations. You can use access control lists (ACLs), the bucket policy, or the user policy to grant individuals permissions to perform these operations. The following table lists the required permissions for various multipart upload operations when using ACLs, a bucket policy, or a user policy.

| Action | Required permissions |
| --- | --- |
| Create Multipart Upload | You must be allowed to perform the `s3:PutObject` action on an object to create multipart upload.<br><br>The bucket owner can allow other principals to perform the `s3:PutObject` action. |
| Initiate Multipart Upload | You must be allowed to perform the `s3:PutObject` action on an object to initiate multipart upload.<br><br>The bucket owner can allow other principals to perform the `s3:PutObject` action. |
| Initiator | Container element that identifies who initiated the multipart upload. If the initiator is an AWS account, this element provides the same information as the Owner element. If the initiator is an IAM user, this element provides the user ARN and display name. |
| Upload Part | You must be allowed to perform the `s3:PutObject` action on an object to upload a part.<br><br>The bucket owner must allow the initiator to perform the `s3:PutObject` action on an object in order for the initiator to upload a part for that object. |
| Upload Part (Copy) | You must be allowed to perform the `s3:PutObject` action on an object to upload a part. Because you are uploading a part from an existing object, you must be allowed `s3:GetObject` on the source object. |

| Action | Required permissions |
| --- | --- |
| | For the initiator to upload a part for an object, the owner of the bucket must allow the initiator to perform the `s3:PutObject` action on the object. |
| Complete Multipart Upload | You must be allowed to perform the `s3:PutObject` action on an object to complete a multipart upload.<br><br>The bucket owner must allow the initiator to perform the `s3:PutObject` action on an object in order for the initiator to complete a multipart upload for that object. |
| Stop Multipart Upload | You must be allowed to perform the `s3:AbortMultipartUpload` action to stop a multipart upload.<br><br>By default, the bucket owner and the initiator of the multipart upload are allowed to perform this action as a part of IAM and bucket polices. If the initiator is an IAM user, that user's AWS account is also allowed to stop that multipart upload. With VPC endpoint policies, the initiator of the multipart upload does not automatically gain the permission to perform the `s3:AbortMultipartUpload` action.<br><br>In addition to these defaults, the bucket owner can allow other principals to perform the `s3:AbortMultipartUpload` action on an object. The bucket owner can deny any principal the ability to perform the `s3:AbortMultipartUpload` action. |

| Action | Required permissions |
| --- | --- |
| List Parts | You must be allowed to perform the `s3:ListMultipartUploadParts` action to list parts in a multipart upload.<br><br>By default, the bucket owner has permission to list parts for any multipart upload to the bucket. The initiator of the multipart upload has the permission to list parts of the specific multipart upload. If the multipart upload initiator is an IAM user, the AWS account controlling that IAM user also has permission to list parts of that upload.<br><br>In addition to these defaults, the bucket owner can allow other principals to perform the `s3:ListMultipartUploadParts` action on an object. The bucket owner can also deny any principal the ability to perform the `s3:ListMultipartUploadParts` action. |
| List Multipart Uploads | You must be allowed to perform the `s3:ListBucketMultipartUploads` action on a bucket to list multipart uploads in progress to that bucket.<br><br>In addition to the default, the bucket owner can allow other principals to perform the `s3:ListBucketMultipartUploads` action on the bucket. |
| AWS KMS Encrypt and Decrypt related permissions | To perform a multipart upload with encryption using an AWS Key Management Service (AWS KMS) KMS key, the requester must have permission to the `kms:Decrypt` and `kms:GenerateDataKey` actions on the key. The requester must also have permissions for the `kms:GenerateDataKey` action for the CreateMultipartUpload API. Then, the requester needs permissions for the `kms:Decrypt` action on the UploadPart and UploadPartCopy APIs. These permissions are required because Amazon S3 must decrypt and read data from the encrypted file parts before it completes the multipart upload.<br><br>If your IAM user or role is in the same AWS account as the KMS key, then you must have these permissions on the key policy. If your IAM user or role belongs to a different account than the KMS key, then you must have the permissions on both the key policy and your IAM user or role. |

For information on the relationship between ACL permissions and permissions in access policies, see Mapping of ACL permissions and access policy permissions. For information about IAM users, roles, and best practices, see IAM identities (users, user groups, and roles) in the *IAM User Guide*.

**Topics**

## Configuring a bucket lifecycle configuration to delete incomplete multipart uploads

As a best practice, we recommend that you configure a lifecycle rule by using the `AbortIncompleteMultipartUpload` action to minimize your storage costs. For more information about aborting a multipart upload, see Aborting a multipart upload.

Amazon S3 supports a bucket lifecycle rule that you can use to direct Amazon S3 to stop multipart uploads that aren't completed within a specified number of days after being initiated. When a multipart upload isn't completed within the specified time frame, it becomes eligible for an abort operation. Amazon S3 then stops the multipart upload and deletes the parts associated with the multipart upload. This rule applies to both existing multipart uploads and those that you create later.

The following is an example lifecycle configuration that specifies a rule with the `AbortIncompleteMultipartUpload` action.

```
<LifecycleConfiguration>
    <Rule>
        <ID>sample-rule</ID>
        <Prefix></Prefix>
        <Status>Enabled</Status>
        <AbortIncompleteMultipartUpload>
```

```
            <DaysAfterInitiation>7</DaysAfterInitiation>
        </AbortIncompleteMultipartUpload>
    </Rule>
</LifecycleConfiguration>
```

In the example, the rule doesn't specify a value for the `Prefix` element (the object key name prefix). Therefore, the rule applies to all objects in the bucket for which you initiated multipart uploads. Any multipart uploads that were initiated and weren't completed within seven days become eligible for an abort operation. The abort action has no effect on completed multipart uploads.

For more information about the bucket lifecycle configuration, see Managing your storage lifecycle.

> **Note**
>
> If the multipart upload is completed within the number of days specified in the rule, the `AbortIncompleteMultipartUpload` lifecycle action does not apply (that is, Amazon S3 doesn't take any action). Also, this action doesn't apply to objects. No objects are deleted by this lifecycle action. Additionally, you will not incur early delete charges for S3 Lifecycle when you remove any incomplete multipart upload parts.

#### Using the S3 console

To automatically manage incomplete multipart uploads, you can use the S3 console to create a lifecycle rule to expire incomplete multipart upload bytes from your bucket after a specified number of days. The following procedure shows you how to add a lifecycle rule to delete incomplete multipart uploads after 7 days. For more information about adding lifecycle rules, see Setting a lifecycle configuration on a bucket.

**To add a lifecycle rule to abort incomplete multipart uploads that are more than 7 days old**

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the **Buckets** list, choose the name of the bucket that you want to create a lifecycle rule for.
3. Choose the **Management** tab, and choose **Create lifecycle rule**.
4. In **Lifecycle rule name**, enter a name for your rule.

   The name must be unique within the bucket.

5. Choose the scope of the lifecycle rule:

   - To create a lifecycle rule for all objects with a specific prefix, choose **Limit the scope of this rule using one or more filters**, and enter the prefix in the **Prefix** field.
   - To create a lifecycle rule for all objects in the bucket, choose **This rule applies to all objects in the bucket**, and choose **I acknowledge that this rule applies to all objects in the bucket**.
6. Under **Lifecycle rule actions**, select **Delete expired object delete markers or incomplete multipart uploads**.
7. Under **Delete expired object delete markers or incomplete multipart uploads**, select **Delete incomplete multipart uploads**.
8. In the **Number of days** field, enter the number of days after which to delete incomplete multipart uploads (for this example, 7 days).
9. Choose **Create rule**.

#### Using the AWS CLI

The following `put-bucket-lifecycle-configuration` AWS Command Line Interface (AWS CLI) command adds the lifecycle configuration for the specified bucket. To use this command, replace the *`user input placeholders`* with your information.

```
aws s3api put-bucket-lifecycle-configuration  \
        --bucket amzn-s3-demo-bucket1  \
        --lifecycle-configuration filename-containing-lifecycle-configuration
```

The following example shows how to add a lifecycle rule to abort incomplete multipart uploads by using the AWS CLI. It includes an example JSON lifecycle configuration to abort incomplete multipart uploads that are more than 7 days old.

To use the CLI commands in this example, replace the *`user input placeholders`* with your information.

#### To add a lifecycle rule to abort incomplete multipart uploads

1. Set up the AWS CLI. For instructions, see Developing with Amazon S3 using the AWS CLI.
2. Save the following example lifecycle configuration in a file (for example, *`lifecycle.json`*). This example configuration specifies an empty prefix, and therefore it applies to all objects in the bucket. To restrict the configuration to a subset of objects, you can specify a prefix.

```
{
    "Rules": [
        {
            "ID": "Test Rule",
            "Status": "Enabled",
            "Filter": {
                "Prefix": ""
            },
            "AbortIncompleteMultipartUpload": {
                "DaysAfterInitiation": 7
            }
        }
    ]
}
```

3. Run the following CLI command to set this lifecycle configuration on your bucket.

```
aws s3api put-bucket-lifecycle-configuration   \
--bucket amzn-s3-demo-bucket1  \
--lifecycle-configuration file://lifecycle.json
```

4. To verify that the lifecycle configuration has been set on your bucket, retrieve the lifecycle configuration by using the following `get-bucket-lifecycle` command.

```
aws s3api get-bucket-lifecycle  \
--bucket amzn-s3-demo-bucket1
```

5. To delete the lifecycle configuration, use the following `delete-bucket-lifecycle` command.

```
aws s3api delete-bucket-lifecycle \
--bucket amzn-s3-demo-bucket1
```

## Uploading an object using multipart upload

You can use the multipart upload to programmatically upload a single object to Amazon S3.

For more information, see the following sections.

### Using the AWS SDKs (high-level API)

Some AWS SDKs expose a high-level API that simplifies multipart upload by combining the different API operations required to complete a multipart upload into a single operation. For more information, see Uploading and copying objects using multipart upload.

If you need to pause and resume multipart uploads, vary part sizes during the upload, or do not know the size of the data in advance, use the low-level API methods. The low-level API methods for multipart uploads offer additional functionality, for more information, see Using the AWS SDKs (low-level API).

Java

To upload large files, use the `TransferManager` class. This high-level API operation can upload data from a file or a stream. You can also set advanced options, such as the part size you want to use for the multipart upload, or the number of concurrent threads you want to use when uploading the parts. You can also set optional object properties, the storage class, or the access control list (ACL). You use the `PutObjectRequest` and the `TransferManagerConfiguration` classes to set these advanced options.

When possible, `TransferManager` tries to use multiple threads to upload multiple parts of a single upload at once. When dealing with large content sizes and high bandwidth, this can increase throughput significantly.

In addition to file-upload functionality, the `TransferManager` class enables you to stop an in-progress multipart upload. An upload is considered to be in progress after you initiate it and until you complete or stop it. The `TransferManager` stops all in-progress multipart uploads on a specified bucket that were initiated before a specified date and time.

> **Note**
>
> When you're using a stream for the source of data, the `TransferManager` class does not do concurrent uploads.

The following example loads an object using the high-level multipart upload Java API (the `TransferManager` class). For instructions on creating and testing a working sample, see Getting Started in the AWS SDK for Java Developer Guide.

```
import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import com.amazonaws.auth.profile.ProfileCredentialsProvider;
import com.amazonaws.regions.Regions;
import com.amazonaws.services.s3.AmazonS3;
import com.amazonaws.services.s3.AmazonS3ClientBuilder;
import com.amazonaws.services.s3.transfer.TransferManager;
import com.amazonaws.services.s3.transfer.TransferManagerBuilder;
import com.amazonaws.services.s3.transfer.Upload;

import java.io.File;

public class HighLevelMultipartUpload {

    public static void main(String[] args) throws Exception {
        Regions clientRegion = Regions.DEFAULT_REGION;
        String bucketName = "*** Bucket name ***";
        String keyName = "*** Object key ***";
        String filePath = "*** Path for file to upload ***";

        try {
            AmazonS3 s3Client = AmazonS3ClientBuilder.standard()
                    .withRegion(clientRegion)
                    .withCredentials(new ProfileCredentialsProvider())
                    .build();
            TransferManager tm = TransferManagerBuilder.standard()
                    .withS3Client(s3Client)
                    .build();

            // TransferManager processes all transfers asynchronously,
            // so this call returns immediately.
            Upload upload = tm.upload(bucketName, keyName, new File(filePath));
            System.out.println("Object upload started");

            // Optionally, wait for the upload to finish before continuing.
            upload.waitForCompletion();
            System.out.println("Object upload complete");
        } catch (AmazonServiceException e) {
            // The call was transmitted successfully, but Amazon S3 couldn't process
            // it, so it returned an error response.
            e.printStackTrace();
        } catch (SdkClientException e) {
            // Amazon S3 couldn't be contacted for a response, or the client
            // couldn't parse the response from Amazon S3.
```

```
            e.printStackTrace();
        }
    }
}
```

.NET

To upload a file to an S3 bucket, use the `TransferUtility` class. When uploading data from a file, you must provide the object's key name. If you don't, the API uses the file name for the key name. When uploading data from a stream, you must provide the object's key name.

To set advanced upload options—such as the part size, the number of threads when uploading the parts concurrently, metadata, the storage class, or ACL—use the `TransferUtilityUploadRequest` class.

> **Note**
>
> When you're using a stream for the source of data, the `TransferUtility` class does not do concurrent uploads.

The following C# example uploads a file to an Amazon S3 bucket in multiple parts. It shows how to use various `TransferUtility.Upload` overloads to upload a file. Each successive call to upload replaces the previous upload. For information about setting up and running the code examples, see Getting Started with the AWS SDK for .NET in the *AWS SDK for .NET Developer Guide*.

 writing an object", e.Message);
            }

        }
    }
}
```

JavaScript

**Example**

Upload a large file.

```
import {
  CreateMultipartUploadCommand,
  UploadPartCommand,
  CompleteMultipartUploadCommand,
  AbortMultipartUploadCommand,
  S3Client,
} from "@aws-sdk/client-s3";

const twentyFiveMB = 25 * 1024 * 1024;
```

```
export const createString = (size = twentyFiveMB) => {
  return "x".repeat(size);
};

export const main = async () => {
  const s3Client = new S3Client({});
  const bucketName = "test-bucket";
  const key = "multipart.txt";
  const str = createString();
  const buffer = Buffer.from(str, "utf8");

  let uploadId;

  try {
    const multipartUpload = await s3Client.send(
      new CreateMultipartUploadCommand({
        Bucket: bucketName,
        Key: key,
      }),
    );

    uploadId = multipartUpload.UploadId;

    const uploadPromises = [];
    // Multipart uploads require a minimum size of 5 MB per part.
    const partSize = Math.ceil(buffer.length / 5);

    // Upload each part.
    for (let i = 0; i < 5; i++) {
      const start = i * partSize;
      const end = start + partSize;
      uploadPromises.push(
        s3Client
          .send(
            new UploadPartCommand({
              Bucket: bucketName,
              Key: key,
              UploadId: uploadId,
              Body: buffer.subarray(start, end),
              PartNumber: i + 1,
            }),
          )
          .then((d) => {
            console.log("Part", i + 1, "uploaded");
```

```
            return d;
          }),
      );
    }

    const uploadResults = await Promise.all(uploadPromises);

    return await s3Client.send(
      new CompleteMultipartUploadCommand({
        Bucket: bucketName,
        Key: key,
        UploadId: uploadId,
        MultipartUpload: {
          Parts: uploadResults.map(({ ETag }, i) => ({
            ETag,
            PartNumber: i + 1,
          })),
        },
      }),
    );

    // Verify the output by downloading the file from the Amazon Simple Storage
 Service (Amazon S3) console.
    // Because the output is a 25 MB string, text editors might struggle to open the
 file.
  } catch (err) {
    console.error(err);

    if (uploadId) {
      const abortCommand = new AbortMultipartUploadCommand({
        Bucket: bucketName,
        Key: key,
        UploadId: uploadId,
      });

      await s3Client.send(abortCommand);
    }
  }
};
```

### Example

Download a large file.

```
import { GetObjectCommand, S3Client } from "@aws-sdk/client-s3";
import { createWriteStream } from "fs";

const s3Client = new S3Client({});
const oneMB = 1024 * 1024;

export const getObjectRange = ({ bucket, key, start, end }) => {
  const command = new GetObjectCommand({
    Bucket: bucket,
    Key: key,
    Range: `bytes=${start}-${end}`,
  });

  return s3Client.send(command);
};

/**
 * @param {string | undefined} contentRange
 */
export const getRangeAndLength = (contentRange) => {
  const [range, length] = contentRange.split("/");
  const [start, end] = range.split("-");
  return {
    start: parseInt(start),
    end: parseInt(end),
    length: parseInt(length),
  };
};

export const isComplete = ({ end, length }) => end === length - 1;

// When downloading a large file, you might want to break it down into
// smaller pieces. Amazon S3 accepts a Range header to specify the start
// and end of the byte range to be downloaded.
const downloadInChunks = async ({ bucket, key }) => {
  const writeStream = createWriteStream(
    fileURLToPath(new URL(`./${key}`, import.meta.url)),
  ).on("error", (err) => console.error(err));

  let rangeAndLength = { start: -1, end: -1, length: -1 };

  while (!isComplete(rangeAndLength)) {
    const { end } = rangeAndLength;
```

```
    const nextRange = { start: end + 1, end: end + oneMB };

    console.log(`Downloading bytes ${nextRange.start} to ${nextRange.end}`);

    const { ContentRange, Body } = await getObjectRange({
      bucket,
      key,
      ...nextRange,
    });

    writeStream.write(await Body.transformToByteArray());
    rangeAndLength = getRangeAndLength(ContentRange);
  }
};

export const main = async () => {
  await downloadInChunks({
    bucket: "my-cool-bucket",
    key: "my-cool-object.txt",
  });
};
```

Go

**Example**

Upload a large object by using an upload manager to break the data into parts and upload them concurrently.

```
// BucketBasics encapsulates the Amazon Simple Storage Service (Amazon S3) actions
// used in the examples.
// It contains S3Client, an Amazon S3 service client that is used to perform bucket
// and object actions.
type BucketBasics struct {
 S3Client *s3.Client
}
```

```
// UploadLargeObject uses an upload manager to upload data to an object in a bucket.
// The upload manager breaks large data into parts and uploads the parts
 concurrently.
```

```
func (basics BucketBasics) UploadLargeObject(bucketName string, objectKey string,
 largeObject []byte) error {
 largeBuffer := bytes.NewReader(largeObject)
 var partMiBs int64 = 10
 uploader := manager.NewUploader(basics.S3Client, func(u *manager.Uploader) {
  u.PartSize = partMiBs * 1024 * 1024
 })
 _, err := uploader.Upload(context.TODO(), &s3.PutObjectInput{
  Bucket: aws.String(bucketName),
  Key:    aws.String(objectKey),
  Body:   largeBuffer,
 })
 if err != nil {
  log.Printf("Couldn't upload large object to %v:%v. Here's why: %v\n",
   bucketName, objectKey, err)
 }

 return err
}
```

**Example**

Download a large object by using a download manager to get the data in parts and download them concurrently.

```
// DownloadLargeObject uses a download manager to download an object from a bucket.
// The download manager gets the data in parts and writes them to a buffer until all
 of
// the data has been downloaded.
func (basics BucketBasics) DownloadLargeObject(bucketName string, objectKey string)
 ([]byte, error) {
 var partMiBs int64 = 10
 downloader := manager.NewDownloader(basics.S3Client, func(d *manager.Downloader) {
  d.PartSize = partMiBs * 1024 * 1024
 })
 buffer := manager.NewWriteAtBuffer([]byte{})
 _, err := downloader.Download(context.TODO(), buffer, &s3.GetObjectInput{
  Bucket: aws.String(bucketName),
  Key:    aws.String(objectKey),
 })
 if err != nil {
```

```
  log.Printf("Couldn't download large object from %v:%v. Here's why: %v\n",
   bucketName, objectKey, err)
 }
 return buffer.Bytes(), err
}
```

PHP

This topic explains how to use the high-level `Aws\S3\Model\MultipartUpload\UploadBuilder` class from the AWS SDK for PHP for multipart file uploads. For more information about the AWS SDK for Ruby API, go to AWS SDK for Ruby - Version 2.

The following PHP example uploads a file to an Amazon S3 bucket. The example demonstrates how to set parameters for the `MultipartUploader` object.

```
 require 'vendor/autoload.php';

use Aws\Exception\MultipartUploadException;
use Aws\S3\MultipartUploader;
use Aws\S3\S3Client;

$bucket = '*** Your Bucket Name ***';
$keyname = '*** Your Object Key ***';

$s3 = new S3Client([
    'version' => 'latest',
    'region'  => 'us-east-1'
]);

// Prepare the upload parameters.
$uploader = new MultipartUploader($s3, '/path/to/large/file.zip', [
    'bucket' => $bucket,
    'key'    => $keyname
]);

// Perform the upload.
try {
    $result = $uploader->upload();
    echo "Upload complete: {$result['ObjectURL']}" . PHP_EOL;
} catch (MultipartUploadException $e) {
    echo $e->getMessage() . PHP_EOL;
}
```

Python

The following example loads an object using the high-level multipart upload Python API (the `TransferManager` class).

```
import sys
import threading

import boto3
from boto3.s3.transfer import TransferConfig

MB = 1024 * 1024
s3 = boto3.resource("s3")

class TransferCallback:
    """
    Handle callbacks from the transfer manager.

    The transfer manager periodically calls the __call__ method throughout
    the upload and download process so that it can take action, such as
    displaying progress to the user and collecting data about the transfer.
    """

    def __init__(self, target_size):
        self._target_size = target_size
        self._total_transferred = 0
        self._lock = threading.Lock()
        self.thread_info = {}

    def __call__(self, bytes_transferred):
        """
        The callback method that is called by the transfer manager.

        Display progress during file transfer and collect per-thread transfer
        data. This method can be called by multiple threads, so shared instance
        data is protected by a thread lock.
        """
        thread = threading.current_thread()
        with self._lock:
```

```
            self._total_transferred += bytes_transferred
            if thread.ident not in self.thread_info.keys():
                self.thread_info[thread.ident] = bytes_transferred
            else:
                self.thread_info[thread.ident] += bytes_transferred

            target = self._target_size * MB
            sys.stdout.write(
                f"\r{self._total_transferred} of {target} transferred "
                f"({(self._total_transferred / target) * 100:.2f}%)."
            )
            sys.stdout.flush()

def upload_with_default_configuration(
    local_file_path, bucket_name, object_key, file_size_mb

```

### Using the AWS SDKs (low-level API)

The AWS SDK exposes a low-level API that closely resembles the Amazon S3 REST API for multipart uploads (see Uploading and copying objects using multipart upload. Use the low-level API when you need to pause and resume multipart uploads, vary part sizes during the upload, or do not

know the size of the upload data in advance. When you don't have these requirements, use the high-level API (see Using the AWS SDKs (high-level API)).

Java

The following example shows how to use the low-level Java classes to upload a file. It performs the following steps:

- Initiates a multipart upload using the `AmazonS3Client.initiateMultipartUpload()` method, and passes in an `InitiateMultipartUploadRequest` object.
- Saves the upload ID that the `AmazonS3Client.initiateMultipartUpload()` method returns. You provide this upload ID for each subsequent multipart upload operation.
- Uploads the parts of the object. For each part, you call the `AmazonS3Client.uploadPart()` method. You provide part upload information using an `UploadPartRequest` object.
- For each part, saves the ETag from the response of the `AmazonS3Client.uploadPart()` method in a list. You use the ETag values to complete the multipart upload.
- Calls the `AmazonS3Client.completeMultipartUpload()` method to complete the multipart upload.

**Example**

For instructions on creating and testing a working sample, see Getting Started in the AWS SDK for Java Developer Guide.

```
import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import com.amazonaws.auth.profile.ProfileCredentialsProvider;
import com.amazonaws.regions.Regions;
import com.amazonaws.services.s3.AmazonS3;
import com.amazonaws.services.s3.AmazonS3ClientBuilder;
import com.amazonaws.services.s3.model.*;

import java.io.File;
import java.io.IOException;
import java.util.ArrayList;
import java.util.List;
```

```
public class LowLevelMultipartUpload {

    public static void main(String[] args) throws IOException {
        Regions clientRegion = Regions.DEFAULT_REGION;
        String bucketName = "*** Bucket name ***";
        String keyName = "*** Key name ***";
        String filePath = "*** Path to file to upload ***";

        File file = new File(filePath);
        long contentLength = file.length();
        long partSize = 5 * 1024 * 1024; // Set part size to 5 MB.

        try {
            AmazonS3 s3Client = AmazonS3ClientBuilder.standard()
                    .withRegion(clientRegion)
                    .withCredentials(new ProfileCredentialsProvider())
                    .build();

            // Create a list of ETag objects. You retrieve ETags for each object
 part
            // uploaded,
            // then, after each individual part has been uploaded, pass the list of
 ETags to
            // the request to complete the upload.
            List<PartETag> partETags = new ArrayList<PartETag>();

            // Initiate the multipart upload.
            InitiateMultipartUploadRequest initRequest = new
 InitiateMultipartUploadRequest(bucketName, keyName);
            InitiateMultipartUploadResult initResponse =
 s3Client.initiateMultipartUpload(initRequest);

            // Upload the file parts.
            long filePosition = 0;
            for (int i = 1; filePosition < contentLength; i++) {
                // Because the last part could be less than 5 MB, adjust the part
 size as
                // needed.
                partSize = Math.min(partSize, (contentLength - filePosition));

                // Create the request to upload a part.
                UploadPartRequest uploadRequest = new UploadPartRequest()
                        .withBucketName(bucketName)
                        .withKey(keyName)
```

```
                        .withUploadId(initResponse.getUploadId())
                        .withPartNumber(i)
                        .withFileOffset(filePosition)
                        .withFile(file)
                        .withPartSize(partSize);

                // Upload the part and add the response's ETag to our list.
                UploadPartResult uploadResult = s3Client.uploadPart(uploadRequest);
                partETags.add(uploadResult.getPartETag());

                filePosition += partSize;
            }

            // Complete the multipart upload.
            CompleteMultipartUploadRequest compRequest = new
 CompleteMultipartUploadRequest(bucketName, keyName,
                    initResponse.getUploadId(), partETags);
            s3Client.completeMultipartUpload(compRequest);
        } catch (AmazonServiceException e) {
            // The call was transmitted successfully, but Amazon S3 couldn't process
            // it, so it returned an error response.
            e.printStackTrace();
        } catch (SdkClientException e) {
            // Amazon S3 couldn't be contacted for a response, or the client
            // couldn't parse the response from Amazon S3.
            e.printStackTrace();
        }
    }
}
```

.NET

The following C# example shows how to use the low-level AWS SDK for .NET multipart upload API to upload a file to an S3 bucket. For information about Amazon S3 multipart uploads, see Uploading and copying objects using multipart upload.

> **Note**
>
> When you use the AWS SDK for .NET API to upload large objects, a timeout might occur while data is being written to the request stream. You can set an explicit timeout using the `UploadPartRequest`.

The following C# example uploads a file to an S3 bucket using the low-level multipart upload API. For information about setting up and running the code examples, see Getting Started with the AWS SDK for .NET in the *AWS SDK for .NET Developer Guide*.

```
using Amazon;
using Amazon.Runtime;
using Amazon.S3;
using Amazon.S3.Model;
using System;
using System.Collections.Generic;
using System.IO;
using System.Threading.Tasks;

namespace Amazon.DocSamples.S3
{
    class UploadFileMPULowLevelAPITest
    {
        private const string bucketName = "*** provide bucket name ***";
        private const string keyName = "*** provide a name for the uploaded object
 ***";
        private const string filePath = "*** provide the full path name of the file
 to upload ***";
       // Specify your bucket region (an example region is shown).
        private static readonly RegionEndpoint bucketRegion =
 RegionEndpoint.USWest2;
        private static IAmazonS3 s3Client;

        public static void Main()
        {
            s3Client = new AmazonS3Client(bucketRegion);
            Console.WriteLine("Uploading an object");
            UploadObjectAsync().Wait();
        }

        private static async Task UploadObjectAsync()
        {
            // Create list to store upload part responses.
            List<UploadPartResponse> uploadResponses = new
 List<UploadPartResponse>();

            // Setup information required to initiate the multipart upload.
            InitiateMultipartUploadRequest initiateRequest = new
 InitiateMultipartUploadRequest
```

```
            {
                BucketName = bucketName,
                Key = keyName
            };

            // Initiate the upload.
            InitiateMultipartUploadResponse initResponse =
                await s3Client.InitiateMultipartUploadAsync(initiateRequest);

            // Upload parts.
            long contentLength = new FileInfo(filePath).Length;
            long partSize = 5 * (long)Math.Pow(2, 20); // 5 MB

            try
            {
                Console.WriteLine("Uploading parts");

                long filePosition = 0;
                for (int i = 1; filePosition < contentLength; i++)
                {
                    UploadPartRequest uploadRequest = new UploadPartRequest
                        {
                            BucketName = bucketName,
                            Key = keyName,
                            UploadId = initResponse.UploadId,
                            PartNumber = i,
                            PartSize = partSize,
                            FilePosition = filePosition,
                            FilePath = filePath
                        };

                    // Track upload progress.
                    uploadRequest.StreamTransferProgress +=
                        new
EventHandler<StreamTransferProgressArgs>(UploadPartProgressEventCallback);

                    // Upload a part and add the response to our list.
                    uploadResponses.Add(await
s3Client.UploadPartAsync(uploadRequest));

                    filePosition += partSize;
                }

                // Setup to complete the upload.
```

```
                CompleteMultipartUploadRequest completeRequest = new
 CompleteMultipartUploadRequest
                    {
                        BucketName = bucketName,
                        Key = keyName,
                        UploadId = initResponse.UploadId
                     };
                completeRequest.AddPartETags(uploadResponses);

                // Complete the upload.
                CompleteMultipartUploadResponse completeUploadResponse =
                    await s3Client.CompleteMultipartUploadAsync(completeRequest);
            }
            catch (Exception exception)
            {
                Console.WriteLine("An AmazonS3Exception was thrown: { 0}",
 exception.Message);

                // Abort the upload.
                AbortMultipartUploadRequest abortMPURequest = new
 AbortMultipartUploadRequest
                {
                    BucketName = bucketName,
                    Key = keyName,
                    UploadId = initResponse.UploadId
                };
               await s3Client.AbortMultipartUploadAsync(abortMPURequest);
            }
        }
        public static void UploadPartProgressEventCallback(object sender,
 StreamTransferProgressArgs e)
        {
            // Process event.
            Console.WriteLine("{0}/{1}", e.TransferredBytes, e.TotalBytes);
        }
    }
}
```

PHP

This topic shows how to use the low-level `uploadPart` method from version 3 of the AWS SDK for PHP to upload a file in multiple parts. For more information about the AWS SDK for Ruby API, go to AWS SDK for Ruby - Version 2.

The following PHP example uploads a file to an Amazon S3 bucket using the low-level PHP API multipart upload.

```
 require 'vendor/autoload.php';

use Aws\S3\Exception\S3Exception;
use Aws\S3\S3Client;

$bucket = '*** Your Bucket Name ***';
$keyname = '*** Your Object Key ***';
$filename = '*** Path to and Name of the File to Upload ***';

$s3 = new S3Client([
    'version' => 'latest',
    'region'  => 'us-east-1'
]);

$result = $s3->createMultipartUpload([
    'Bucket'       => $bucket,
    'Key'          => $keyname,
    'StorageClass' => 'REDUCED_REDUNDANCY',
    'Metadata'     => [
        'param1' => 'value 1',
        'param2' => 'value 2',
        'param3' => 'value 3'
    ]
]);
$uploadId = $result['UploadId'];

// Upload the file in parts.
try {
    $file = fopen($filename, 'r');
    $partNumber = 1;
    while (!feof($file)) {
        $result = $s3->uploadPart([
            'Bucket'     => $bucket,
            'Key'        => $keyname,
            'UploadId'   => $uploadId,
            'PartNumber' => $partNumber,
            'Body'       => fread($file, 5 * 1024 * 1024),
        ]);
        $parts['Parts'][$partNumber] = [
            'PartNumber' => $partNumber,
```

```
            'ETag' => $result['ETag'],
        ];
        $partNumber++;

        echo "Uploading part $partNumber of $filename." . PHP_EOL;
    }
    fclose($file);
} catch (S3Exception $e) {
    $result = $s3->abortMultipartUpload([
        'Bucket'   => $bucket,
        'Key'      => $keyname,
        'UploadId' => $uploadId
    ]);

    echo "Upload of $filename failed." . PHP_EOL;
}

// Complete the multipart upload.
$result = $s3->completeMultipartUpload([
    'Bucket'   => $bucket,
    'Key'      => $keyname,
    'UploadId' => $uploadId,
    'MultipartUpload'    => $parts,
]);
$url = $result['Location'];

echo "Uploaded $filename to $url." . PHP_EOL;
```

### Using the AWS SDK for Ruby

The AWS SDK for Ruby version 3 supports Amazon S3 multipart uploads in two ways. For the first option, you can use managed file uploads. For more information, see Uploading Files to Amazon S3 in the *AWS Developer Blog*. Managed file uploads are the recommended method for uploading files to a bucket. They provide the following benefits:

- Manage multipart uploads for objects larger than 15MB.
- Correctly open files in binary mode to avoid encoding issues.
- Use multiple threads for uploading parts of large objects in parallel.

Alternatively, you can use the following multipart upload client operations directly:

- create_multipart_upload – Initiates a multipart upload and returns an upload ID.
- upload_part – Uploads a part in a multipart upload.
- upload_part_copy – Uploads a part by copying data from an existing object as data source.
- complete_multipart_upload – Completes a multipart upload by assembling previously uploaded parts.
- abort_multipart_upload – Stops a multipart upload.

**Using the REST API**

The following sections in the *Amazon Simple Storage Service API Reference* describe the REST API for multipart upload.

- Initiate Multipart Upload
- Upload Part
- Complete Multipart Upload
- Stop Multipart Upload
- List Parts
- List Multipart Uploads

**Using the AWS CLI**

The following sections in the AWS Command Line Interface (AWS CLI) describe the operations for multipart upload.

- Initiate Multipart Upload
- Upload Part
- Upload Part (Copy)
- Complete Multipart Upload
- Abort Multipart Upload
- List Parts
- List Multipart Uploads

You can also use the REST API to make your own REST requests, or you can use one of the AWS SDKs. For more information about the REST API, see Using the REST API. For more information about the SDKs, see Uploading an object using multipart upload.

## Uploading a directory using the high-level .NET TransferUtility class

You can use the `TransferUtility` class to upload an entire directory. By default, the API uploads only the files at the root of the specified directory. You can, however, specify recursively uploading files in all of the subdirectories.

To select files in the specified directory based on filtering criteria, specify filtering expressions. For example, to upload only the .pdf files from a directory, specify the `"*.pdf"` filter expression.

When uploading files from a directory, you don't specify the key names for the resulting objects. Amazon S3 constructs the key names using the original file path. For example, assume that you have a directory called `c:\myfolder` with the following structure:

**Example**

```
C:\myfolder
      \a.txt
      \b.pdf
      \media\
             An.mp3
```

When you upload this directory, Amazon S3 uses the following key names:

**Example**

```
a.txt
b.pdf
media/An.mp3
```

**Example**

The following C# example uploads a directory to an Amazon S3 bucket. It shows how to use various `TransferUtility.UploadDirectory` overloads to upload the directory. Each successive call to upload replaces the previous upload. For information about setting up and running the code examples, see Getting Started with the AWS SDK for .NET in the *AWS SDK for .NET Developer Guide*.

```
using Amazon;
```

```
using Amazon.S3;
using Amazon.S3.Transfer;
using System;
using System.IO;
using System.Threading.Tasks;

namespace Amazon.DocSamples.S3
{
    class UploadDirMPUHighLevelAPITest
    {
        private const string existingBucketName = "*** bucket name ***";
        private const string directoryPath = @"*** directory path ***";
        // The example uploads only .txt files.
        private const string wildCard = "*.txt";
        // Specify your bucket region (an example region is shown).
        private static readonly RegionEndpoint bucketRegion = RegionEndpoint.USWest2;
        private static IAmazonS3 s3Client;
        static void Main()
        {
            s3Client = new AmazonS3Client(bucketRegion);
            UploadDirAsync().Wait();
        }

        private static async Task UploadDirAsync()
        {
            try
            {
                var directoryTransferUtility =
                    new TransferUtility(s3Client);

                // 1. Upload a directory.
                await directoryTransferUtility.UploadDirectoryAsync(directoryPath,
                    existingBucketName);
                Console.WriteLine("Upload statement 1 completed");

                // 2. Upload only the .txt files from a directory
                //    and search recursively.
                await directoryTransferUtility.UploadDirectoryAsync(
                                                directoryPath,
                                                existingBucketName,
                                                wildCard,
                                                SearchOption.AllDirectories);
                Console.WriteLine("Upload statement 2 completed");
```

```
                // 3. The same as Step 2 and some optional configuration.
                //    Search recursively for .txt files to upload.
                var request = new TransferUtilityUploadDirectoryRequest
                {
                    BucketName = existingBucketName,
                    Directory = directoryPath,
                    SearchOption = SearchOption.AllDirectories,
                    SearchPattern = wildCard
                };

                await directoryTransferUtility.UploadDirectoryAsync(request);
                Console.WriteLine("Upload statement 3 completed");
            }
            catch (AmazonS3Exception e)
            {
                Console.WriteLine(
                        "Error encountered ***. Message:'{0}' when writing an object",
 e.Message);
            }
            catch (Exception e)
            {
                Console.WriteLine(
                    "Unknown encountered on server. Message:'{0}' when writing an
 object", e.Message);
            }
        }
    }
}
```

## Listing multipart uploads

You can use the AWS SDKs (low-level API) to retrieve a list of in-progress multipart uploads in Amazon S3.

### Listing multipart uploads using the AWS SDK (low-level API)

Java

The following tasks guide you through using the low-level Java classes to list all in-progress multipart uploads on a bucket.

**Low-level API multipart uploads listing process**

| | |
|---|---|
| 1 | Create an instance of the `ListMultipartUploadsRequest` class and provide the bucket name. |
| 2 | Run the `AmazonS3Client.listMultipartUploads` method. The method returns an instance of the `MultipartUploadListing` class that gives you information about the multipart uploads in progress. |

The following Java code example demonstrates the preceding tasks.

**Example**

```
ListMultipartUploadsRequest allMultpartUploadsRequest =
     new ListMultipartUploadsRequest(existingBucketName);
MultipartUploadListing multipartUploadListing =
     s3Client.listMultipartUploads(allMultpartUploadsRequest);
```

.NET

To list all of the in-progress multipart uploads on a specific bucket, use the AWS SDK for .NET low-level multipart upload API's `ListMultipartUploadsRequest` class. The `AmazonS3Client.ListMultipartUploads` method returns an instance of the `ListMultipartUploadsResponse` class that provides information about the in-progress multipart uploads.

An in-progress multipart upload is a multipart upload that has been initiated using the initiate multipart upload request, but has not yet been completed or stopped. For more information about Amazon S3 multipart uploads, see Uploading and copying objects using multipart upload.

The following C# example shows how to use the AWS SDK for .NET to list all in-progress multipart uploads on a bucket. For information about setting up and running the code examples, see Getting Started with the AWS SDK for .NET in the *AWS SDK for .NET Developer Guide*.

```
ListMultipartUploadsRequest request = new ListMultipartUploadsRequest
{
```

```
  BucketName = bucketName // Bucket receiving the uploads.
};

ListMultipartUploadsResponse response = await
 AmazonS3Client.ListMultipartUploadsAsync(request);
```

PHP

This topic shows how to use the low-level API classes from version 3 of the AWS SDK for PHP to list all in-progress multipart uploads on a bucket. For more information about the AWS SDK for Ruby API, go to AWS SDK for Ruby - Version 2.

The following PHP example demonstrates listing all in-progress multipart uploads on a bucket.

```
 require 'vendor/autoload.php';

use Aws\S3\S3Client;

$bucket = '*** Your Bucket Name ***';

$s3 = new S3Client([
    'version' => 'latest',
    'region'  => 'us-east-1'
]);

// Retrieve a list of the current multipart uploads.
$result = $s3->listMultipartUploads([
    'Bucket' => $bucket
]);

// Write the list of uploads to the page.
print_r($result->toArray());
```

### Listing multipart uploads using the REST API

The following sections in the *Amazon Simple Storage Service API Reference* describe the REST API for listing multipart uploads:

- ListParts-list the uploaded parts for a specific multipart upload.
- ListMultipartUploads-list in-progress multipart uploads.

### Listing multipart uploads using the AWS CLI

The following sections in the AWS Command Line Interface describe the operations for listing multipart uploads.

- list-parts-list the uploaded parts for a specific multipart upload.
- list-multipart-uploads-list in-progress multipart uploads.

## Tracking a multipart upload

The high-level multipart upload API provides a listen interface, `ProgressListener`, to track the upload progress when uploading an object to Amazon S3. Progress events occur periodically and notify the listener that bytes have been transferred.

Java

**Example**

```
TransferManager tm = new TransferManager(new ProfileCredentialsProvider());

PutObjectRequest request = new PutObjectRequest(
    existingBucketName, keyName, new File(filePath));

// Subscribe to the event and provide event handler.
request.setProgressListener(new ProgressListener() {
   public void progressChanged(ProgressEvent event) {
    System.out.println("Transferred bytes: " +
      event.getBytesTransfered());
            }
});
```

**Example**

The following Java code uploads a file and uses the `ProgressListener` to track the upload progress. For instructions on how to create and test a working sample, see Getting Started in the AWS SDK for Java Developer Guide.

```
import java.io.File;

import com.amazonaws.AmazonClientException;
import com.amazonaws.auth.profile.ProfileCredentialsProvider;
```

```
import com.amazonaws.event.ProgressEvent;
import com.amazonaws.event.ProgressListener;
import com.amazonaws.services.s3.model.PutObjectRequest;
import com.amazonaws.services.s3.transfer.TransferManager;
import com.amazonaws.services.s3.transfer.Upload;

public class TrackMPUProgressUsingHighLevelAPI {

    public static void main(String[] args) throws Exception {
        String existingBucketName = "*** Provide bucket name ***";
        String keyName            = "*** Provide object key ***";
        String filePath           = "*** file to upload ***";

        TransferManager tm = new TransferManager(new ProfileCredentialsProvider());

        // For more advanced uploads, you can create a request object
        // and supply additional request parameters (ex: progress listeners,
        // canned ACLs, etc.)
        PutObjectRequest request = new PutObjectRequest(
          existingBucketName, keyName, new File(filePath));

        // You can ask the upload for its progress, or you can
        // add a ProgressListener to your request to receive notifications
        // when bytes are transferred.
        request.setGeneralProgressListener(new ProgressListener() {
   @Override
   public void progressChanged(ProgressEvent progressEvent) {
    System.out.println("Transferred bytes: " +
      progressEvent.getBytesTransferred());
   }
  });

        // TransferManager processes all transfers asynchronously,
        // so this call will return immediately.
        Upload upload = tm.upload(request);

        try {
         // You can block and wait for the upload to finish
         upload.waitForCompletion();
        } catch (AmazonClientException amazonClientException) {
         System.out.println("Unable to upload file, upload aborted.");
         amazonClientException.printStackTrace();
        }
```

```
    }
}
```

.NET

The following C# example uploads a file to an S3 bucket using the `TransferUtility` class, and tracks the progress of the upload. For information about setting up and running the code examples, see Getting Started with the AWS SDK for .NET in the *AWS SDK for .NET Developer Guide*.

```
using Amazon;
using Amazon.S3;
using Amazon.S3.Transfer;
using System;
using System.Threading.Tasks;

namespace Amazon.DocSamples.S3
{
    class TrackMPUUsingHighLevelAPITest
    {
        private const string bucketName = "*** provide the bucket name ***";
        private const string keyName = "*** provide the name for the uploaded object
 ***";
        private const string filePath = " *** provide the full path name of the file
 to upload **";
        // Specify your bucket region (an example region is shown).
        private static readonly RegionEndpoint bucketRegion =
 RegionEndpoint.USWest2;
        private static IAmazonS3 s3Client;

        public static void Main()
        {
            s3Client = new AmazonS3Client(bucketRegion);
            TrackMPUAsync().Wait();
        }

        private static async Task TrackMPUAsync()
        {
            try
            {
                var fileTransferUtility = new TransferUtility(s3Client);
```

```
                // Use TransferUtilityUploadRequest to configure options.
                // In this example we subscribe to an event.
                var uploadRequest =
                    new TransferUtilityUploadRequest
                    {
                        BucketName = bucketName,
                        FilePath = filePath,
                        Key = keyName
                    };

                uploadRequest.UploadProgressEvent +=
                    new EventHandler<UploadProgressArgs>
                        (uploadRequest_UploadPartProgressEvent);

                await fileTransferUtility.UploadAsync(uploadRequest);
                Console.WriteLine("Upload completed");
            }
            catch (AmazonS3Exception e)
            {
                Console.WriteLine("Error encountered on server. Message:'{0}' when
 writing an object", e.Message);
            }
            catch (Exception e)
            {
                Console.WriteLine("Unknown encountered on server. Message:'{0}' when
 writing an object", e.Message);
            }
        }

        static void uploadRequest_UploadPartProgressEvent(object sender,
 UploadProgressArgs e)
        {
            // Process event.
            Console.WriteLine("{0}/{1}", e.TransferredBytes, e.TotalBytes);
        }
    }
}
```

## Aborting a multipart upload

After you initiate a multipart upload, you begin uploading parts. Amazon S3 stores these parts, but it creates the object from the parts only after you upload all of them and send a `successful`

request to complete the multipart upload (you should verify that your request to complete multipart upload is successful). Upon receiving the complete multipart upload request, Amazon S3 assembles the parts and creates an object. If you don't send the complete multipart upload request successfully, Amazon S3 does not assemble the parts and does not create any object.

You are billed for all storage associated with uploaded parts. For more information, see Multipart upload and pricing. So it's important that you either complete the multipart upload to have the object created or stop the multipart upload to remove any uploaded parts.

You can stop an in-progress multipart upload in Amazon S3 using the AWS Command Line Interface (AWS CLI), REST API, or AWS SDKs. You can also stop an incomplete multipart upload using a bucket lifecycle configuration.

**Using the AWS SDKs (high-level API)**

Java

The `TransferManager` class provides the `abortMultipartUploads` method to stop multipart uploads in progress. An upload is considered to be in progress after you initiate it and until you complete it or stop it. You provide a `Date` value, and this API stops all the multipart uploads on that bucket that were initiated before the specified `Date` and are still in progress.

The following tasks guide you through using the high-level Java classes to stop multipart uploads.

High-level API multipart uploads stopping process

| | |
|---|---|
| 1 | Create an instance of the `TransferManager` class. |
| 2 | Run the `TransferManager.abortMultipartUploads` method by passing the bucket name and a `Date` value. |

The following Java code stops all multipart uploads in progress that were initiated on a specific bucket over a week ago. For instructions on how to create and test a working sample, see Getting Started in the AWS SDK for Java Developer Guide.

```
import java.util.Date;

import com.amazonaws.AmazonClientException;
import com.amazonaws.auth.profile.ProfileCredentialsProvider;
```

```
import com.amazonaws.services.s3.transfer.TransferManager;

public class AbortMPUUsingHighLevelAPI {

    public static void main(String[] args) throws Exception {
        String existingBucketName = "*** Provide existing bucket name ***";

        TransferManager tm = new TransferManager(new ProfileCredentialsProvider());

        int sevenDays = 1000 * 60 * 60 * 24 * 7;
  Date oneWeekAgo = new Date(System.currentTimeMillis() - sevenDays);

        try {
         tm.abortMultipartUploads(existingBucketName, oneWeekAgo);
        } catch (AmazonClientException amazonClientException) {
         System.out.println("Unable to upload file, upload was aborted.");
         amazonClientException.printStackTrace();
        }
    }
}
```

> **Note**
>
> You can also stop a specific multipart upload. For more information, see Using the AWS SDKs (low-level API).

.NET

The following C# example stops all in-progress multipart uploads that were initiated on a specific bucket over a week ago. For information about setting up and running the code examples, see Getting Started with the AWS SDK for .NET in the *AWS SDK for .NET Developer Guide*.

```
using Amazon;
using Amazon.S3;
using Amazon.S3.Transfer;
using System;
using System.Threading.Tasks;

namespace Amazon.DocSamples.S3
```

```
{
    class AbortMPUUsingHighLevelAPITest
    {
        private const string bucketName = "*** provide bucket name ***";
        // Specify your bucket region (an example region is shown).
        private static readonly RegionEndpoint bucketRegion =
 RegionEndpoint.USWest2;
        private static IAmazonS3 s3Client;

        public static void Main()
        {
            s3Client = new AmazonS3Client(bucketRegion);
            AbortMPUAsync().Wait();
        }

        private static async Task AbortMPUAsync()
        {
            try
            {
                var transferUtility = new TransferUtility(s3Client);

                // Abort all in-progress uploads initiated before the specified
 date.
                await transferUtility.AbortMultipartUploadsAsync(
                    bucketName, DateTime.Now.AddDays(-7));
            }
            catch (AmazonS3Exception e)
            {
                Console.WriteLine("Error encountered on server. Message:'{0}' when
 writing an object", e.Message);
            }
            catch (Exception e)
            {
                Console.WriteLine("Unknown encountered on server. Message:'{0}' when
 writing an object", e.Message);
            }
        }
    }
}
```

> **Note**
>
> You can also stop a specific multipart upload. For more information, see Using the AWS SDKs (low-level API).

### Using the AWS SDKs (low-level API)

You can stop an in-progress multipart upload by calling the `AmazonS3.abortMultipartUpload` method. This method deletes any parts that were uploaded to Amazon S3 and frees up the resources. You must provide the upload ID, bucket name, and key name. The following Java code example demonstrates how to stop an in-progress multipart upload.

To stop a multipart upload, you provide the upload ID, and the bucket and key names that are used in the upload. After you have stopped a multipart upload, you can't use the upload ID to upload additional parts. For more information about Amazon S3 multipart uploads, see Uploading and copying objects using multipart upload.

Java

The following Java code example stops an in-progress multipart upload.

**Example**

```
InitiateMultipartUploadRequest initRequest =
    new InitiateMultipartUploadRequest(existingBucketName, keyName);
InitiateMultipartUploadResult initResponse =
               s3Client.initiateMultipartUpload(initRequest);

AmazonS3 s3Client = new AmazonS3Client(new ProfileCredentialsProvider());
s3Client.abortMultipartUpload(new AbortMultipartUploadRequest(
            existingBucketName, keyName, initResponse.getUploadId()));
```

> **Note**
>
> Instead of a specific multipart upload, you can stop all your multipart uploads initiated before a specific time that are still in progress. This clean-up operation is useful to stop old multipart uploads that you initiated but did not complete or stop. For more information, see Using the AWS SDKs (high-level API).

.NET

The following C# example shows how to stop a multipart upload. For a complete C# sample that includes the following code, see Using the AWS SDKs (low-level API).

```
AbortMultipartUploadRequest abortMPURequest = new AbortMultipartUploadRequest
{
    BucketName = existingBucketName,
    Key = keyName,
    UploadId = initResponse.UploadId
};
await AmazonS3Client.AbortMultipartUploadAsync(abortMPURequest);
```

You can also abort all in-progress multipart uploads that were initiated prior to a specific time. This clean-up operation is useful for aborting multipart uploads that didn't complete or were aborted. For more information, see Using the AWS SDKs (high-level API).

PHP

This example shows how to use a class from version 3 of the AWS SDK for PHP to abort a multipart upload that is in progress. For more information about the AWS SDK for Ruby API, go to AWS SDK for Ruby - Version 2. The example the `abortMultipartUpload()` method.

For more information about the AWS SDK for Ruby API, go to AWS SDK for Ruby - Version 2.

```
 require 'vendor/autoload.php';

use Aws\S3\S3Client;

$bucket = '*** Your Bucket Name ***';
$keyname = '*** Your Object Key ***';
$uploadId = '*** Upload ID of upload to Abort ***';

$s3 = new S3Client([
    'version' => 'latest',
    'region'  => 'us-east-1'
]);

// Abort the multipart upload.
$s3->abortMultipartUpload([
    'Bucket'   => $bucket,
    'Key'      => $keyname,
```

```
    'UploadId' => $uploadId,
]);
```

### Using the REST API

For more information about using the REST API to stop a multipart upload, see AbortMultipartUpload in the *Amazon Simple Storage Service API Reference*.

### Using the AWS CLI

For more information about using the AWS CLI to stop a multipart upload, see abort-multipart-upload in the *AWS CLI Command Reference*.

## Copying an object using multipart upload

The examples in this section show you how to copy objects greater than 5 GB using the multipart upload API. You can copy objects less than 5 GB in a single operation. For more information, see Copying, moving, and renaming objects.

### Using the AWS SDKs

To copy an object using the low-level API, do the following:

- Initiate a multipart upload by calling the `AmazonS3Client.initiateMultipartUpload()` method.
- Save the upload ID from the response object that the `AmazonS3Client.initiateMultipartUpload()` method returns. You provide this upload ID for each part-upload operation.
- Copy all of the parts. For each part that you need to copy, create a new instance of the `CopyPartRequest` class. Provide the part information, including the source and destination bucket names, source and destination object keys, upload ID, locations of the first and last bytes of the part, and part number.
- Save the responses of the `AmazonS3Client.copyPart()` method calls. Each response includes the `ETag` value and part number for the uploaded part. You need this information to complete the multipart upload.
- Call the `AmazonS3Client.completeMultipartUpload()` method to complete the copy operation.

Java

### Example

The following example shows how to use the Amazon S3 low-level Java API to perform a multipart copy. For instructions on creating and testing a working sample, see Getting Started in the AWS SDK for Java Developer Guide.

```
import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import com.amazonaws.auth.profile.ProfileCredentialsProvider;
import com.amazonaws.regions.Regions;
import com.amazonaws.services.s3.AmazonS3;
import com.amazonaws.services.s3.AmazonS3ClientBuilder;
import com.amazonaws.services.s3.model.*;

import java.io.IOException;
import java.util.ArrayList;
import java.util.List;

public class LowLevelMultipartCopy {

    public static void main(String[] args) throws IOException {
        Regions clientRegion = Regions.DEFAULT_REGION;
        String sourceBucketName = "*** Source bucket name ***";
        String sourceObjectKey = "*** Source object key ***";
        String destBucketName = "*** Target bucket name ***";
        String destObjectKey = "*** Target object key ***";

        try {
            AmazonS3 s3Client = AmazonS3ClientBuilder.standard()
                    .withCredentials(new ProfileCredentialsProvider())
                    .withRegion(clientRegion)
                    .build();

            // Initiate the multipart upload.
            InitiateMultipartUploadRequest initRequest = new
 InitiateMultipartUploadRequest(destBucketName,
                    destObjectKey);
            InitiateMultipartUploadResult initResult =
 s3Client.initiateMultipartUpload(initRequest);
```

```
            // Get the object size to track the end of the copy operation.
            GetObjectMetadataRequest metadataRequest = new
GetObjectMetadataRequest(sourceBucketName, sourceObjectKey);
            ObjectMetadata metadataResult =
s3Client.getObjectMetadata(metadataRequest);
            long objectSize = metadataResult.getContentLength();

            // Copy the object using 5 MB parts.
            long partSize = 5 * 1024 * 1024;
            long bytePosition = 0;
            int partNum = 1;
            List<CopyPartResult> copyResponses = new ArrayList<CopyPartResult>();
            while (bytePosition < objectSize) {
                // The last part might be smaller than partSize, so check to make
sure
                // that lastByte isn't beyond the end of the object.
                long lastByte = Math.min(bytePosition + partSize - 1, objectSize -
1);

                // Copy this part.
                CopyPartRequest copyRequest = new CopyPartRequest()
                        .withSourceBucketName(sourceBucketName)
                        .withSourceKey(sourceObjectKey)
                        .withDestinationBucketName(destBucketName)
                        .withDestinationKey(destObjectKey)
                        .withUploadId(initResult.getUploadId())
                        .withFirstByte(bytePosition)
                        .withLastByte(lastByte)
                        .withPartNumber(partNum++);
                copyResponses.add(s3Client.copyPart(copyRequest));
                bytePosition += partSize;
            }

            // Complete the upload request to concatenate all uploaded parts and
make the
            // copied object available.
            CompleteMultipartUploadRequest completeRequest = new
CompleteMultipartUploadRequest(
                    destBucketName,
                    destObjectKey,
                    initResult.getUploadId(),
                    getETags(copyResponses));
            s3Client.completeMultipartUpload(completeRequest);
            System.out.println("Multipart copy complete.");
```

```
        } catch (AmazonServiceException e) {
            // The call was transmitted successfully, but Amazon S3 couldn't process
            // it, so it returned an error response.
            e.printStackTrace();
        } catch (SdkClientException e) {
            // Amazon S3 couldn't be contacted for a response, or the client
            // couldn't parse the response from Amazon S3.
            e.printStackTrace();
        }
    }

    // This is a helper function to construct a list of ETags.
    private static List<PartETag> getETags(List<CopyPartResult> responses) {
        List<PartETag> etags = new ArrayList<PartETag>();
        for (CopyPartResult response : responses) {
            etags.add(new PartETag(response.getPartNumber(), response.getETag()));
        }
        return etags;
    }
}
```

.NET

The following C# example shows how to use the AWS SDK for .NET to copy an Amazon S3 object that is larger than 5 GB from one source location to another, such as from one bucket to another. To copy objects that are smaller than 5 GB, use the single-operation copy procedure described in Using the AWS SDKs. For more information about Amazon S3 multipart uploads, see Uploading and copying objects using multipart upload.

This example shows how to copy an Amazon S3 object that is larger than 5 GB from one S3 bucket to another using the AWS SDK for .NET multipart upload API.

```
using Amazon;
using Amazon.S3;
using Amazon.S3.Model;
using System;
using System.Collections.Generic;
using System.Threading.Tasks;

namespace Amazon.DocSamples.S3
{
    class CopyObjectUsingMPUapiTest
```

```
   {
       private const string sourceBucket = "*** provide the name of the bucket with
source object ***";
       private const string targetBucket = "*** provide the name of the bucket to
copy the object to ***";
       private const string sourceObjectKey = "*** provide the name of object to
copy ***";
       private const string targetObjectKey = "*** provide the name of the object
copy ***";
       // Specify your bucket region (an example region is shown).
       private static readonly RegionEndpoint bucketRegion =
RegionEndpoint.USWest2;
       private static IAmazonS3 s3Client;

       public static void Main()
       {
           s3Client = new AmazonS3Client(bucketRegion);
           Console.WriteLine("Copying an object");
           MPUCopyObjectAsync().Wait();
       }
       private static async Task MPUCopyObjectAsync()
       {
           // Create a list to store the upload part responses.
           List<UploadPartResponse> uploadResponses = new
List<UploadPartResponse>();
           List<CopyPartResponse> copyResponses = new List<CopyPartResponse>();

           // Setup information required to initiate the multipart upload.
           InitiateMultipartUploadRequest initiateRequest =
               new InitiateMultipartUploadRequest
               {
                   BucketName = targetBucket,
                   Key = targetObjectKey
               };

           // Initiate the upload.
           InitiateMultipartUploadResponse initResponse =
               await s3Client.InitiateMultipartUploadAsync(initiateRequest);

           // Save the upload ID.
           String uploadId = initResponse.UploadId;

           try
           {
```

```
                // Get the size of the object.
                GetObjectMetadataRequest metadataRequest = new
GetObjectMetadataRequest
                {
                    BucketName = sourceBucket,
                    Key = sourceObjectKey
                };

                GetObjectMetadataResponse metadataResponse =
                    await s3Client.GetObjectMetadataAsync(metadataRequest);
                long objectSize = metadataResponse.ContentLength; // Length in
bytes.

                // Copy the parts.
                long partSize = 5 * (long)Math.Pow(2, 20); // Part size is 5 MB.

                long bytePosition = 0;
                for (int i = 1; bytePosition < objectSize; i++)
                {
                    CopyPartRequest copyRequest = new CopyPartRequest
                    {
                        DestinationBucket = targetBucket,
                        DestinationKey = targetObjectKey,
                        SourceBucket = sourceBucket,
                        SourceKey = sourceObjectKey,
                        UploadId = uploadId,
                        FirstByte = bytePosition,
                        LastByte = bytePosition + partSize - 1 >= objectSize ?
objectSize - 1 : bytePosition + partSize - 1,
                        PartNumber = i
                    };

                    copyResponses.Add(await s3Client.CopyPartAsync(copyRequest));

                    bytePosition += partSize;
                }

                // Set up to complete the copy.
                CompleteMultipartUploadRequest completeRequest =
                new CompleteMultipartUploadRequest
                {
                    BucketName = targetBucket,
                    Key = targetObjectKey,
                    UploadId = initResponse.UploadId
```

```
                };
                completeRequest.AddPartETags(copyResponses);

                // Complete the copy.
                CompleteMultipartUploadResponse completeUploadResponse =
                    await s3Client.CompleteMultipartUploadAsync(completeRequest);
            }
            catch (AmazonS3Exception e)
            {
                Console.WriteLine("Error encountered on server. Message:'{0}' when
 writing an object", e.Message);
            }
            catch (Exception e)
            {
                Console.WriteLine("Unknown encountered on server. Message:'{0}' when
 writing an object", e.Message);
            }
        }
    }
}
```

### Using the REST API

The following sections in the *Amazon Simple Storage Service API Reference* describe the REST API for multipart upload. For copying an existing object, use the Upload Part (Copy) API and specify the source object by adding the `x-amz-copy-source` request header in your request.

- Initiate Multipart Upload
- Upload Part
- Upload Part (Copy)
- Complete Multipart Upload
- Abort Multipart Upload
- List Parts
- List Multipart Uploads

You can use these APIs to make your own REST requests, or you can use one of the SDKs we provide. For more information about using Multipart Upload with the AWS CLI, see Using the AWS CLI. For more information about the SDKs, see AWS SDK support for multipart upload.

## Amazon S3 multipart upload limits

The following table provides multipart upload core specifications. For more information, see Uploading and copying objects using multipart upload.

| Item | Specification |
| --- | --- |
| Maximum object size | 5 TiB |
| Maximum number of parts per upload | 10,000 |
| Part numbers | 1 to 10,000 (inclusive) |
| Part size | 5 MiB to 5 GiB. There is no minimum size limit on the last part of your multipart upload. |
| Maximum number of parts returned for a list parts request | 1000 |
| Maximum number of multipart uploads returned in a list multipart uploads request | 1000 |

# Copying, moving, and renaming objects

The `CopyObject` operation creates a copy of an object that is already stored in Amazon S3.

You can create a copy of an object up to 5 GB in a single atomic operation. However, to copy an object that is larger than 5 GB, you must use a multipart upload. For more information, see the section called "Copying an object".

Using the `CopyObject` operation, you can:

- Create additional copies of objects.
- Rename objects by copying them and deleting the original ones.

- Copy or move objects from one bucket to another, including across AWS Regions (for example, from `us-west-1` to `eu-west-2`). When you move an object, Amazon S3 copies the object to the specified destination and then deletes the source object.

  > **Note**
  >
  > Copying or moving objects across AWS Regions incurs bandwidth charges. For more information, see Amazon S3 Pricing.

- Change object metadata. Each Amazon S3 object has metadata. This metadata is a set of name-value pairs. You can set object metadata at the time you upload an object. After you upload the object, you cannot modify the object metadata. The only way to modify object metadata is to make a copy of the object and set the metadata. To do so, in the copy operation, set the same object as the source and target.

  Some object metadata is system metadata and other is user-defined. You can control some of the system metadata. For example, you can control the storage class and the type of server-side encryption to use for the object. When you copy an object, user-controlled system metadata and user-defined metadata are also copied. Amazon S3 resets the system-controlled metadata. For example, when you copy an object, Amazon S3 resets the creation date of the copied object. You don't need to set any of these system-controlled metadata values in your copy request.

  When copying an object, you might decide to update some of the metadata values. For example, if your source object is configured to use S3 Standard storage, you might choose to use S3 Intelligent-Tiering for the object copy. You might also decide to alter some of the user-defined metadata values present on the source object. If you choose to update any of the object's user-configurable metadata (system or user-defined) during the copy, then you must explicitly specify all of the user-configurable metadata present on the source object in your request, even if you are changing only one of the metadata values.

  For more information about the object metadata, see Working with object metadata.

### Copying archived and restored objects

If the source object is archived in S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive, you must first restore a temporary copy before you can copy the object to another bucket. For information about archiving objects, see Transitioning to the S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive storage classes (object archival).

The **Copy** operation in the Amazon S3 console isn't supported for restored objects in the S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive storage classes. To copy these restored objects, use the AWS Command Line Interface (AWS CLI), the AWS SDKs, or the Amazon S3 REST API.

### Copying encrypted objects

Amazon S3 automatically encrypts all new objects that are copied to an S3 bucket. If you don't specify encryption information in your copy request, the encryption setting of the target object is set to the default encryption configuration of the destination bucket. By default, all buckets have a base level of encryption configuration that uses server-side encryption with Amazon S3 managed keys (SSE-S3). If the destination bucket has a default encryption configuration that uses server-side encryption with an AWS Key Management Service (AWS KMS) key (SSE-KMS), or a customer-provided encryption key (SSE-C), Amazon S3 uses the corresponding KMS key, or a customer-provided key to encrypt the target object copy.

When copying an object, if you want to use a different type of encryption setting for the target object, you can request that Amazon S3 encrypt the target object with a KMS key, an Amazon S3 managed key, or a customer-provided key. If the encryption setting in your request is different from the default encryption configuration of the destination bucket, the encryption setting in your request takes precedence. If the source object for the copy is encrypted with SSE-C, you must provide the necessary encryption information in your request so that Amazon S3 can decrypt the object for copying. For more information, see Protecting data with encryption.

### Using checksums when copying objects

When copying objects, you can choose to use a different checksum algorithm for the object. Whether you choose to use the same algorithm or a new one, Amazon S3 calculates a new checksum value after the object is copied. Amazon S3 does not directly copy the value of the checksum. The checksum value of objects that were loaded by using multipart uploads might change. For more information about how the checksum is calculated, see Using part-level checksums for multipart uploads.

### Copying multiple objects in a single request

To copy more than one Amazon S3 object with a single request, you can also use S3 Batch Operations. You provide S3 Batch Operations with a list of objects to operate on. S3 Batch Operations calls the respective API operation to perform the specified operation. A single Batch Operations job can perform the specified operation on billions of objects containing exabytes of data.

The S3 Batch Operations feature tracks progress, sends notifications, and stores a detailed completion report of all actions, providing a fully managed, auditable, serverless experience. You can use S3 Batch Operations through the Amazon S3 console, AWS CLI, AWS SDKs, or REST API. For more information, see the section called "Batch Operations basics".

### Copying objects to directory buckets

For information about copying an object to a directory bucket, see Copying an object to a directory bucket. For information about using the Amazon S3 Express One Zone storage class with directory buckets, see What is S3 Express One Zone? and Directory buckets.

## To copy an object

To copy an object, use the following methods.

### Using the S3 console

**Note**

- When copying an object by using the Amazon S3 console, you must have the `s3:ListAllMyBuckets` permission. The console needs this permission to validate the **Copy** operation. For example policies that grant this permission, see the section called "Identity-based policy examples".

  If you're copying an object that has user-defined tags, you must also have the `s3:GetObjectTagging` permission. If you're copying an object that doesn't have user-defined tags but is over 16 MB in size, you must also have the s3:`GetObjectTagging` permission.

  If the destination bucket policy denies the `s3:GetObjectTagging` action, the object will be copied without the user-defined tags, and you will receive an error.
- Objects encrypted with customer-provided encryption keys (SSE-C) cannot be copied by using the S3 console. To copy objects encrypted with SSE-C, use the AWS CLI, AWS SDK, or the Amazon S3 REST API.
- Cross-Region copying of objects encrypted with SSE-KMS is not supported by the Amazon S3 console. To copy objects encrypted with SSE-KMS across Regions, use the AWS CLI, AWS SDK, or the Amazon S3 REST API.

**To copy an object**

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Buckets**, and then choose the **General purpose buckets** tab. Navigate to the Amazon S3 bucket or folder that contains the objects that you want to copy.
3. Select the check box to the left of the names of the objects that you want to copy.
4. On the **Actions** menu, choose **Copy** from the list of options that appears.
5. Select the destination type and destination account. To specify the destination path, choose **Browse S3**, navigate to the destination, and select the check box to the left of the destination. Choose **Choose destination** in the lower-right corner.

   Alternatively, enter the destination path.
6. If you do *not* have bucket versioning enabled, you might be asked to acknowledge that existing objects with the same name are overwritten. If this is OK, select the check box and proceed. If you want to keep all versions of objects in this bucket, select **Enable Bucket Versioning**. You can also update the default encryption and S3 Object Lock properties.
7. Under **Additional checksums**, choose whether you want to copy the objects using the existing checksum function or replace the existing checksum function with a new one. When you uploaded the objects, you had the option to specify the checksum algorithm that was used to verify data integrity. When copying the object, you have the option to choose a new function. If you did not originally specify an additional checksum, you can use this section of the copy options to add one.

   > **Note**
   >
   > Even if you opt to use the same checksum function, your checksum value might change if you copy the object and it is over 16 MB in size. The checksum value might change because of how checksums are calculated for multipart uploads. For more information about how the checksum might change when copying the object, see Using part-level checksums for multipart uploads.

To change the checksum function, choose **Replace with a new checksum function**. Choose the new checksum function from the box. When the object is copied over, the new checksum is calculated and stored using the specified algorithm.

8. Choose **Copy** in the bottom-right corner. Amazon S3 copies your objects to the destination.

### Using the AWS SDKs

The examples in this section show how to copy objects up to 5 GB in a single operation. To copy objects larger than 5 GB, you must use a multipart upload. For more information, see Copying an object using multipart upload.

Java

#### Example

The following example copies an object in Amazon S3 using the AWS SDK for Java. For instructions on creating and testing a working sample, see Getting Started in the AWS SDK for Java Developer Guide.

```
import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import com.amazonaws.auth.profile.ProfileCredentialsProvider;
import com.amazonaws.regions.Regions;
import com.amazonaws.services.s3.AmazonS3;
import com.amazonaws.services.s3.AmazonS3ClientBuilder;
import com.amazonaws.services.s3.model.CopyObjectRequest;

import java.io.IOException;

public class CopyObjectSingleOperation {

    public static void main(String[] args) throws IOException {
        Regions clientRegion = Regions.DEFAULT_REGION;
        String bucketName = "*** Bucket name ***";
        String sourceKey = "*** Source object key *** ";
        String destinationKey = "*** Destination object key ***";

        try {
            AmazonS3 s3Client = AmazonS3ClientBuilder.standard()
```

```
                    .withCredentials(new ProfileCredentialsProvider())
                    .withRegion(clientRegion)
                    .build();

            // Copy the object into a new object in the same bucket.
            CopyObjectRequest copyObjRequest = new CopyObjectRequest(bucketName,
 sourceKey, bucketName, destinationKey);
            s3Client.copyObject(copyObjRequest);
        } catch (AmazonServiceException e) {
            // The call was transmitted successfully, but Amazon S3 couldn't process
            // it, so it returned an error response.
            e.printStackTrace();
        } catch (SdkClientException e) {
            // Amazon S3 couldn't be contacted for a response, or the client
            // couldn't parse the response from Amazon S3.
            e.printStackTrace();
        }
    }
}
```

.NET

The following C# example uses the high-level AWS SDK for .NET to copy objects that are as large as 5 GB in a single operation. For objects that are larger than 5 GB, use the multipart upload copy example described in Copying an object using multipart upload.

This example makes a copy of an object that is a maximum of 5 GB. For information about setting up and running the code examples, see Getting Started with the AWS SDK for .NET in the *AWS SDK for .NET Developer Guide*.

```
using Amazon;
using Amazon.S3;
using Amazon.S3.Model;
using System;
using System.Threading.Tasks;

namespace Amazon.DocSamples.S3
{
    class CopyObjectTest
    {
        private const string sourceBucket = "*** provide the name of the bucket with
 source object ***";
```

```
        private const string destinationBucket = "*** provide the name of the bucket
to copy the object to ***";
        private const string objectKey = "*** provide the name of object to copy
***";
        private const string destObjectKey = "*** provide the destination object key
name ***";
        // Specify your bucket region (an example region is shown).
        private static readonly RegionEndpoint bucketRegion =
RegionEndpoint.USWest2;
        private static IAmazonS3 s3Client;

        public static void Main()
        {
            s3Client = new AmazonS3Client(bucketRegion);
            Console.WriteLine("Copying an object");
            CopyingObjectAsync().Wait();
        }

        private static async Task CopyingObjectAsync()
        {
            try
            {
                CopyObjectRequest request = new CopyObjectRequest
                {
                    SourceBucket = sourceBucket,
                    SourceKey = objectKey,
                    DestinationBucket = destinationBucket,
                    DestinationKey = destObjectKey
                };
                CopyObjectResponse response = await
s3Client.CopyObjectAsync(request);
            }
            catch (AmazonS3Exception e)
            {
                Console.WriteLine("Error encountered on server. Message:'{0}' when
writing an object", e.Message);
            }
            catch (Exception e)
            {
                Console.WriteLine("Unknown encountered on server. Message:'{0}' when
writing an object", e.Message);
            }
        }
    }
```

```
}
```

PHP

This topic guides you through using classes from version 3 of the AWS SDK for PHP to copy a single object and multiple objects within Amazon S3, from one bucket to another or within the same bucket.

For more information about the AWS SDK for Ruby API, go to AWS SDK for Ruby - Version 2.

The following PHP example illustrates the use of the `copyObject()` method to copy a single object within Amazon S3. It also demonstrates how to make multiple copies of an object by using a batch of calls to `CopyObject` with the `getcommand()` method.

**Copying objects**

| | |
|---|---|
| 1 | Create an instance of an Amazon S3 client by using the `Aws\S3\S3Client` class constructor. |
| 2 | To make multiple copies of an object, you run a batch of calls to the Amazon S3 client getCommand() method, which is inherited from the Aws\CommandInterface class. You provide the `CopyObject` command as the first argument and an array containing the source bucket, source key name, target bucket, and target key name as the second argument. |

```
 require 'vendor/autoload.php';

use Aws\CommandPool;
use Aws\Exception\AwsException;
use Aws\ResultInterface;
use Aws\S3\S3Client;

$sourceBucket = '*** Your Source Bucket Name ***';
$sourceKeyname = '*** Your Source Object Key ***';
$targetBucket = '*** Your Target Bucket Name ***';

$s3 = new S3Client([
    'version' => 'latest',
    'region' => 'us-east-1'
]);
```

```
// Copy an object.
$s3->copyObject([
    'Bucket' => $targetBucket,
    'Key' => "$sourceKeyname-copy",
    'CopySource' => "$sourceBucket/$sourceKeyname",
]);

// Perform a batch of CopyObject operations.
$batch = array();
for ($i = 1; $i <= 3; $i++) {
    $batch[] = $s3->getCommand('CopyObject', [
        'Bucket' => $targetBucket,
        'Key' => "{targetKeyname}-$i",
        'CopySource' => "$sourceBucket/$sourceKeyname",
    ]);
}
try {
    $results = CommandPool::batch($s3, $batch);
    foreach ($results as $result) {
        if ($result instanceof ResultInterface) {
            // Result handling here
        }
        if ($result instanceof AwsException) {
            // AwsException handling here
        }
    }
} catch (Exception $e) {
    // General error handling here
}
```

Python

```
class ObjectWrapper:
    """Encapsulates S3 object actions."""

    def __init__(self, s3_object):
        """
        :param s3_object: A Boto3 Object resource. This is a high-level resource in
 Boto3
                          that wraps object actions in a class-like structure.
        """
```

```
        self.object = s3_object
        self.key = self.object.key
```

```
   def copy(self, dest_object):
        """
        Copies the object to another bucket.

        :param dest_object: The destination object initialized with a bucket and
key.
                            This is a Boto3 Object resource.
        """
        try:
            dest_object.copy_from(
                CopySource={"Bucket": self.object.bucket_name, "Key":
self.object.key}
            )
            dest_object.wait_until_exists()
            logger.info(
                "Copied object from %s:%s to %s:%s.",
                self.object.bucket_name,
                self.object.key,
                dest_object.bucket_name,
                dest_object.key,
            )
        except ClientError:
            logger.exception(
                "Couldn't copy object from %s/%s to %s/%s.",
                self.object.bucket_name,
                self.object.key,
                dest_object.bucket_name,
                dest_object.key,
            )
            raise
```

Ruby

The following tasks guide you through using the Ruby classes to copy an object in Amazon S3 from one bucket to another or within the same bucket.

### Copying objects

| | |
|---|---|
| 1 | Use the Amazon S3 modularized gem for version 3 of the AWS SDK for Ruby, require `aws-sdk-s3` , and provide your AWS credentials. For more information about how to provide your credentials, see Making requests using AWS account or IAM user credentials. |
| 2 | Provide the request information, such as the source bucket name, source key name, destination bucket name, and destination key. |

The following Ruby code example demonstrates the preceding tasks by using the `#copy_object` method to copy an object from one bucket to another.

```
require "aws-sdk-s3"

# Wraps Amazon S3 object actions.
class ObjectCopyWrapper
  attr_reader :source_object

  # @param source_object [Aws::S3::Object] An existing Amazon S3 object. This is
 used as the source object for
  #                                        copy actions.
  def initialize(source_object)
    @source_object = source_object
  end

  # Copy the source object to the specified target bucket and rename it with the
 target key.
  #
  # @param target_bucket [Aws::S3::Bucket] An existing Amazon S3 bucket where the
 object is copied.
  # @param target_object_key [String] The key to give the copy of the object.
  # @return [Aws::S3::Object, nil] The copied object when successful; otherwise,
 nil.
  def copy_object(target_bucket, target_object_key)
    @source_object.copy_to(bucket: target_bucket.name, key: target_object_key)
    target_bucket.object(target_object_key)
  rescue Aws::Errors::ServiceError => e
    puts "Couldn't copy #{@source_object.key} to #{target_object_key}. Here's why:
 #{e.message}"
  end
```

```
end

# Example usage:
def run_demo
  source_bucket_name = "doc-example-bucket1"
  source_key = "my-source-file.txt"
  target_bucket_name = "doc-example-bucket2"
  target_key = "my-target-file.txt"

  source_bucket = Aws::S3::Bucket.new(source_bucket_name)
  wrapper = ObjectCopyWrapper.new(source_bucket.object(source_key))
  target_bucket = Aws::S3::Bucket.new(target_bucket_name)
  target_object = wrapper.copy_object(target_bucket, target_key)
  return unless target_object

  puts "Copied #{source_key} from #{source_bucket_name} to
 #{target_object.bucket_name}:#{target_object.key}."
end

run_demo if $PROGRAM_NAME == __FILE__
```

### Using the REST API

This example describes how to copy an object by using the Amazon S3 REST API. For more information about the REST API, see CopyObject.

This example copies the `flotsam` object from the *amzn-s3-demo-bucket1* bucket to the `jetsam` object of the *amzn-s3-demo-bucket2* bucket, preserving its metadata.

```
PUT /jetsam HTTP/1.1
Host: amzn-s3-demo-bucket2.s3.amazonaws.com
x-amz-copy-source: /amzn-s3-demo-bucket1/flotsam
Authorization: AWS AKIAIOSFODNN7EXAMPLE:ENoSbxYByFA0UGLZUqJN5EUnLDg=
Date: Wed, 20 Feb 2008 22:12:21 +0000
```

The signature was generated from the following information.

```
PUT\r\n
\r\n
\r\n
Wed, 20 Feb 2008 22:12:21 +0000\r\n
```

```
x-amz-copy-source:/amzn-s3-demo-bucket1/flotsam\r\n
/amzn-s3-demo-bucket2/jetsam
```

Amazon S3 returns the following response that specifies the ETag of the object and when it was last modified.

```
HTTP/1.1 200 OK
x-amz-id-2: Vyaxt7qEbzv34BnSu5hctyyNSlHTYZFMWK4FtzO+iX8JQNyaLdTshL0KxatbaOZt
x-amz-request-id: 6B13C3C5B34AF333
Date: Wed, 20 Feb 2008 22:13:01 +0000

Content-Type: application/xml
Transfer-Encoding: chunked
Connection: close
Server: AmazonS3
<?xml version="1.0" encoding="UTF-8"?>

<CopyObjectResult>
   <LastModified>2008-02-20T22:13:01</LastModified>
   <ETag>"7e9c608af58950deeb370c98608ed097"</ETag>
</CopyObjectResult>
```

### Using the AWS CLI

You can also use the AWS Command Line Interface (AWS CLI) to copy an S3 object. For more information, see copy-object in the *AWS CLI Command Reference*.

For information about the AWS CLI, see What is the AWS Command Line Interface? in the *AWS Command Line Interface User Guide*.

## To move an object

To move an object, use the following methods.

### Using the S3 console

**Note**

- If you're moving an object that has user-defined tags, you must have the `s3:GetObjectTagging` permission. If you're moving an object that doesn't have user-

defined tags but is over 16 MB in size, you must also have the s3:GetObjectTagging permission.

If the destination bucket policy denies the s3:GetObjectTagging action, the object will be moved without the user-defined tags, and you will receive an error.

- Objects encrypted with customer-provided encryption keys (SSE-C) cannot be moved by using the Amazon S3 console. To move objects encrypted with SSE-C, use the AWS CLI, AWS SDKs, or the Amazon S3 REST API.
- When moving folders, wait for the **Move** operation to finish before making additional changes in the folders.
- You can't use S3 access point aliases as the source or destination for **Move** operations in the Amazon S3 console.

**To move an object**

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Buckets**, and then choose the **General purpose buckets** tab. Navigate to the Amazon S3 bucket or folder that contains the objects that you want to move.
3. Select the check box to the left of the names of the objects that you want to move.
4. On the **Actions** menu, choose **Move**.
5. To specify the destination path, choose **Browse S3**, navigate to the destination, and select the check box to the left of the destination. Choose **Choose destination** in the lower-right corner.

   Alternatively, enter the destination path.
6. If you do *not* have bucket versioning enabled, you might be asked to acknowledge that existing objects with the same name are overwritten. If this is OK, select the check box and proceed. If you want to keep all versions of objects in this bucket, select **Enable Bucket Versioning**. You can also update the default encryption and Object Lock properties.
7. Choose **Move** in the bottom-right corner. Amazon S3 moves your objects to the destination.

**Note**

- This action creates a copy of all specified objects with updated settings, updates the last-modified date in the specified location, and adds a delete marker to the original object.
- This action updates metadata for bucket versioning, encryption, Object Lock features, and archived objects.

#### Using the AWS CLI

You can also use the AWS Command Line Interface (AWS CLI) to move an S3 object. For more information, see mv in the *AWS CLI Command Reference*.

For information about the AWS CLI, see What is the AWS Command Line Interface? in the *AWS Command Line Interface User Guide*.

## To rename an object

To rename an object, use the following procedure.

**Note**

- Renaming an object creates a copy of the object with a new last-modified date, and then adds a delete marker to the original object.
- Bucket settings for default encryption are automatically applied to any specified object that is unencrypted.
- You can't use the Amazon S3 console to rename objects with customer-provided encryption keys (SSE-C) . To rename objects encrypted with SSE-C, use the AWS CLI, AWS SDKs, or the Amazon S3 REST API to copy those objects with new names.
- If this bucket uses the bucket owner enforced setting for S3 Object Ownership, object access control lists (ACLs) won't be copied.
- If you're renaming an object that has user-defined tags, you must have the `s3:GetObjectTagging` permission. If you're renaming an object that doesn't have user-defined tags but is over 16 MB in size, you must also have the s3:`GetObjectTagging` permission.

If the destination bucket policy denies the `s3:GetObjectTagging` action, the object will be renamed, but the user-defined tags will be removed from the object, and you will receive an error.

**To rename an object**

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Buckets**, and then choose the **General purpose buckets** tab. Navigate to the Amazon S3 bucket or folder that contains the object that you want to rename.
3. Select the check box to the left of the name of the object that you want to rename.
4. On the **Actions** menu, choose **Rename object**.
5. In the **New object name** box, enter the new name for the object.
6. Choose **Save changes** in the bottom-right corner. Amazon S3 renames your object.

# Downloading objects

This section explains how to download objects from an Amazon S3 bucket. With Amazon S3, you can store objects in one or more buckets, and each single object can be up to 5 TB in size. Any Amazon S3 object that is not archived is accessible in real time. Archived objects, however, must be restored before they can be downloaded. For information about downloading archived objects, see the section called "Downloading archived objects".

You can download a single object by using the Amazon S3 console, AWS Command Line Interface (AWS CLI), AWS SDKs, or Amazon S3 REST API. To download an object from S3 without writing any code or running any commands, use the S3 console. For more information, see the section called "Downloading an object".

To download multiple objects, use AWS CloudShell, the AWS CLI, or the AWS SDKs. For more information, see the section called "Downloading multiple objects".

If you need to download part of an object, you use extra parameters with the AWS CLI or REST API to specify only the bytes that you want to download. For more information, see the section called "Downloading part of an object".

If you need to download an object that you don't own, ask the object owner to generate a presigned URL that allows you to download the object. For more information, see the section called “Downloading an object from another AWS account”.

When you download objects outside of the AWS network, data-transfer fees apply. Data transfer within the AWS network is free within the same AWS Region, but you will be charged for any GET requests. For more information about data-transfer costs and data-retrieval charges, see Amazon S3 pricing.

**Topics**

## Downloading an object

You can download an object by using the Amazon S3 console, AWS CLI, AWS SDKs, or REST API.

### Using the S3 console

This section explains how to use the Amazon S3 console to download an object from an S3 bucket.

> **Note**
>
> - You can download only one object at a time.
> - If you use the Amazon S3 console to download an object whose key name ends with a period (`.`), the period is removed from the key name of the downloaded object. To retain the period at the end of the name of the downloaded object, you must use the AWS Command Line Interface (AWS CLI), AWS SDKs, or Amazon S3 REST API.

**To download an object from an S3 bucket**

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the **Buckets** list, choose the name of the bucket that you want to download an object from.
3. You can download an object from an S3 bucket in any of the following ways:
   - Select the check box next to the object, and choose **Download**. If you want to download the object to a specific folder, on the **Actions** menu, choose **Download as**.
   - If you want to download a specific version of the object, turn on **Show versions** (located next to the search box). Select the check box next to the version of the object that you want, and choose **Download**. If you want to download the object to a specific folder, on the **Actions** menu, choose **Download as**.

### Using the AWS CLI

The following `get-object` example command shows how you can use the AWS CLI to download an object from Amazon S3. This command gets the object *`folder/my_image`* from the bucket *`amzn-s3-demo-bucket1`*. The object will be downloaded to a file named *`my_downloaded_image`*.

```
aws s3api get-object --bucket amzn-s3-demo-bucket1 --key folder/
my_image my_downloaded_image
```

For more information and examples, see get-object in the *AWS CLI Command Reference*.

### Using the AWS SDKs

For examples of how to download an object with the AWS SDKs, see Use `GetObject` with an AWS SDK or CLI.

For general information about using different AWS SDKs, see Developing with Amazon S3 using the AWS SDKs.

### Using the REST API

You can use the REST API to retrieve objects from Amazon S3. For more information, see GetObject in the *Amazon Simple Storage Service API Reference*.

# Downloading multiple objects

You can download multiple objects by using AWS CloudShell, the AWS CLI, or the AWS SDKs.

### Using AWS CloudShell in the AWS Management Console

AWS CloudShell is a browser-based, pre-authenticated shell that you can launch directly from the AWS Management Console.

For more information about AWS CloudShell, see What is CloudShell? in the *AWS CloudShell User Guide*.

> **Important**
>
> With AWS CloudShell, your home directory has storage up to 1GB per AWS Region. Therefore you cannot sync buckets with objects totaling over this amount. For more limitations, see Service quotas and restrictions in the *AWS CloudShell User Guide*.

### To download objects by using AWS CloudShell

1. Sign in to the AWS Management Console and open the CloudShell console at https://console.aws.amazon.com/cloudshell/.
2. Run the following command to sync objects in your bucket to CloudShell. The following command syncs objects from the bucket named *amzn-s3-demo-bucket1* and creates a folder named *temp* in CloudShell. CloudShell syncs your objects to this folder. To use this command, replace the *user input placeholders* with your own information.

   ```
   aws s3 sync s3://amzn-s3-demo-bucket1 ./temp
   ```

   > **Note**
   >
   > To perform pattern matching to either exclude or include particular objects, you can use the `--exclude "value"` and `--include "value"` parameters with the `sync` command.

3. Run the following command to zip your objects in the folder named *temp* to a file named *temp.zip*.

```
zip temp.zip -r temp/
```

4. Choose **Actions**, and then choose **Download file**.
5. Enter the file name **`temp.zip`** and then choose **Download**.
6. (Optional) Delete the *`temp.zip`* file and the objects that are synced to the *`temp`* folder in CloudShell. With AWS CloudShell, you have persistent storage of up to 1 GB for each AWS Region.

   You can use the following example command to delete your `.zip` file and your folder. To use this example command, replace the *`user input placeholders`* with your own information.

   ```
   rm temp.zip && rm -rf temp/
   ```

### Using the AWS CLI

The following example shows how you can use the AWS CLI to download all of the files or objects under the specified directory or prefix. This command copies all objects from the bucket *`amzn-s3-demo-bucket1`* to your current directory. To use this example command, use your bucket name in place of *`amzn-s3-demo-bucket1`*.

```
aws s3 cp s3://amzn-s3-demo-bucket1 . --recursive
```

The following command downloads all of the objects under the prefix *`logs`* in the bucket *`amzn-s3-demo-bucket1`* to your current directory. It also uses the `--exclude` and `--include` parameters to copy only objects with the suffix *`.log`*. To use this example command, replace the *`user input placeholders`* with your own information.

```
aws s3 cp s3://amzn-s3-demo-bucket1/logs/ . --recursive --exclude "*" --include "*.log"
```

For more information and examples, see cp in the *AWS CLI Command Reference*.

### Using the AWS SDKs

For examples of how to download all objects in an Amazon S3 bucket with the AWS SDKs, see Download all objects in an Amazon Simple Storage Service (Amazon S3) bucket to a local directory.

For general information about using different AWS SDKs, see Developing with Amazon S3 using the AWS SDKs.

# Downloading part of an object

You can download part of an object by using the AWS CLI or REST API. To do so, you use additional parameters to specify which part of an object that you want to download.

### Using the AWS CLI

The following example command performs a `GET` request for a range of bytes in the object named *`folder/my_data`* in the bucket named *`amzn-s3-demo-bucket1`*. In the request, the byte range must be prefixed with `bytes=`. The partial object is downloaded to the output file named *`my_data_range`*. To use this example command, replace the *`user input placeholders`* with your own information.

```
aws s3api get-object --bucket amzn-s3-demo-bucket1 --key folder/my_data --range
 bytes=0-500 my_data_range
```

For more information and examples, see get-object in the *AWS CLI Command Reference*.

For more information about the HTTP `Range` header, see RFC 9110 on the RFC Editor website.

> **Note**
>
> Amazon S3 doesn't support retrieving multiple ranges of data in a single `GET` request.

### Using the REST API

You can use the `partNumber` and `Range` parameters in the REST API to retrieve object parts from Amazon S3. For more information, see GetObject in the *Amazon Simple Storage Service API Reference*.

# Downloading an object from another AWS account

You can use a presigned URL to grant others time-limited access to your objects without updating your bucket policy.

The presigned URL can be entered in a browser or used by a program to download an object. The credentials used by the URL are those of the AWS user who generated the URL. After the URL is

created, anyone with the presigned URL can download the corresponding object until the URL expires.

### Using a presigned URL in the S3 console

You can use the Amazon S3 console to generate a presigned URL for sharing an object by following these steps. When using the console, the maximum expiration time for a presigned URL is 12 hours from the time of creation.

**To generate a presigned URL by using the Amazon S3 console**

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Buckets**.
3. In the **Buckets** list, choose the name of the bucket that contains the object that you want a presigned URL for.
4. In the **Objects** list, select the object that you want to create a presigned URL for.
5. On the **Object actions** menu, choose **Share with a presigned URL**.
6. Specify how long you want the presigned URL to be valid.
7. Choose **Create presigned URL**.
8. When a confirmation message appears, the URL is automatically copied to your clipboard. You will see a button to copy the presigned URL if you need to copy it again.
9. To download the object, paste the URL into any browser, and the object will attempt to download.

For more information about presigned URLs and other methods for creating them, see Working with presigned URLs.

## Downloading archived objects

To reduce your storage costs for infrequently accessed objects, you can *archive* those objects. When you archive an object, it is moved into low-cost storage, which means that you can't access it in real time. To download an archived object, you must first restore it.

You can restore archived objects in minutes or hours, depending on the storage class. You can restore an archived object by using the Amazon S3 console, S3 Batch Operations, the Amazon S3 REST API, the AWS SDKs, and the AWS Command Line Interface (AWS CLI).

For instructions, see Restoring an archived object. After you restore the archived object, you can download it.

### Troubleshooting downloading objects

Insufficient permissions or incorrect bucket or AWS Identity and Access Management (IAM) user policies can cause errors when you're trying to download objects from Amazon S3. These problems can often cause Access Denied (403 Forbidden) errors, where Amazon S3 is unable to allow access to a resource.

For common causes of Access Denied (403 Forbidden) errors, see Troubleshoot Access Denied (403 Forbidden) errors in Amazon S3.

## Checking object integrity

Amazon S3 uses checksum values to verify the integrity of data that you upload to or download from Amazon S3. In addition, you can request that another checksum value be calculated for any object that you store in Amazon S3. You can select from one of several checksum algorithms to use when uploading or copying your data. Amazon S3 uses this algorithm to compute an additional checksum value and store it as part of the object metadata. To learn more about how to use additional checksums to verify data integrity, see Tutorial: Checking the integrity of data in Amazon S3 with additional checksums.

When you upload an object, you can optionally include a precalculated checksum as part of your request. Amazon S3 compares the provided checksum to the checksum that it calculates by using your specified algorithm. If the two values don't match, Amazon S3 reports an error.

### Using supported checksum algorithms

Amazon S3 offers you the option to choose the checksum algorithm that is used to validate your data during upload or download. You can select one of the following Secure Hash Algorithms (SHA) or Cyclic Redundancy Check (CRC) data-integrity check algorithms:

- CRC32
- CRC32C
- SHA-1
- SHA-256

When you upload an object, you can specify the algorithm that you want to use:

- **When you're using the AWS Management Console**, you select the checksum algorithm that you want to use. When you do, you can optionally specify the checksum value of the object. When Amazon S3 receives the object, it calculates the checksum by using the algorithm that you specified. If the two checksum values don't match, Amazon S3 generates an error.
- **When you're using an SDK**, you can set the value of the `x-amz-sdk-checksum-algorithm` parameter to the algorithm that you want Amazon S3 to use when calculating the checksum. Amazon S3 automatically calculates the checksum value.
- **When you're using the REST API**, you don't use the `x-amz-sdk-checksum-algorithm` parameter. Instead, you use one of the algorithm-specific headers (for example, `x-amz-checksum-crc32`).

For more information about uploading objects, see Uploading objects.

To apply any of these checksum values to objects that are already uploaded to Amazon S3, you can copy the object. When you copy an object, you can specify whether you want to use the existing checksum algorithm or use a new one. You can specify a checksum algorithm when using any supported mechanism for copying objects, including S3 Batch Operations. For more information about S3 Batch Operations, see Performing large-scale batch operations on Amazon S3 objects.

> **Important**
>
> If you're using a multipart upload with additional checksums, the multipart part numbers must use consecutive part numbers. When using additional checksums, if you try to complete a multipart upload request with nonconsecutive part numbers, Amazon S3 generates an HTTP `500 Internal Server Error` error.

After uploading objects, you can get the checksum value and compare it to a precalculated or previously stored checksum value calculated using the same algorithm.

**Using the S3 console**

To learn more about using the console and specifying checksum algorithms to use when uploading objects, see Uploading objects and Tutorial: Checking the integrity of data in Amazon S3 with additional checksums.

### Using the AWS SDKs

The following example shows how you can use the AWS SDKs to upload a large file with multipart upload, download a large file, and validate a multipart upload file, all with using SHA-256 for file validation.

Java

#### Example Example: Uploading, downloading, and verifying a large file with SHA-256

For instructions on creating and testing a working sample, see Getting Started in the AWS SDK for Java Developer Guide.

        }
    }
```

**Using the REST API**

You can send REST requests to upload an object with a checksum value to verify the integrity of the data with PutObject. You can also retrieve the checksum value for objects using GetObject or HeadObject.

**Using the AWS CLI**

You can send a PUT request to upload an object of up to 5 GB in a single operation. For more information, see the `PutObject` in the *AWS CLI Command Reference*. You can also use `get-object` and `head-object` to retrieve the checksum of an already-uploaded object to verify the integrity of the data.

For information, see Amazon S3 CLI FAQ in the *AWS Command Line Interface User Guide*.

## Using Content-MD5 when uploading objects

Another way to verify the integrity of your object after uploading is to provide an MD5 digest of the object when you upload it. If you calculate the MD5 digest for your object, you can provide the digest with the PUT command by using the `Content-MD5` header.

After uploading the object, Amazon S3 calculates the MD5 digest of the object and compares it to the value that you provided. The request succeeds only if the two digests match.

Supplying an MD5 digest isn't required, but you can use it to verify the integrity of the object as part of the upload process.

## Using Content-MD5 and the ETag to verify uploaded objects

The entity tag (ETag) for an object represents a specific version of that object. Keep in mind that the ETag reflects changes only to the content of an object, not to its metadata. If only the metadata of an object changes, the ETag remains the same.

Depending on the object, the ETag of the object might be an MD5 digest of the object data:

- If an object is created by the `PutObject`, `PostObject`, or `CopyObject` operation, or through the AWS Management Console, and that object is also plaintext or encrypted by server-side encryption with Amazon S3 managed keys (SSE-S3), that object has an ETag that is an MD5 digest of its object data.
- If an object is created by the `PutObject`, `PostObject`, or `CopyObject` operation, or through the AWS Management Console, and that object is encrypted by server-side encryption with customer-provided keys (SSE-C) or server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS), that object has an ETag that is not an MD5 digest of its object data.
- If an object is created by either the `Multipart Upload` or `Part Copy` operation, the object's ETag is not an MD5 digest, regardless of the method of encryption. If an object is larger than 16 MB, the AWS Management Console uploads or copies that object as a multipart upload, and therefore the ETag isn't an MD5 digest.

For objects where the ETag is the `Content-MD5` digest of the object, you can compare the ETag value of the object with a calculated or previously stored `Content-MD5` digest.

## Using trailing checksums

When uploading objects to Amazon S3, you can either provide a precalculated checksum for the object or use an AWS SDK to automatically create trailing checksums on your behalf. If you decide to use a trailing checksum, Amazon S3 automatically generates the checksum by using your specified algorithm and uses it to validate the integrity of the object during upload.

To create a trailing checksum when using an AWS SDK, populate the `ChecksumAlgorithm` parameter with your preferred algorithm. The SDK uses that algorithm to calculate the checksum for your object (or object parts) and automatically appends it to the end of your upload request.

This behavior saves you time because Amazon S3 performs both the verification and upload of your data in a single pass.

> **Important**
>
> If you're using S3 Object Lambda, all requests to S3 Object Lambda are signed using `s3-object-lambda` instead of `s3`. This behavior affects the signature of trailing checksum values. For more information about S3 Object Lambda, see Transforming objects with S3 Object Lambda.

## Using part-level checksums for multipart uploads

When objects are uploaded to Amazon S3, they can either be uploaded as a single object or through the multipart upload process. Objects that are larger than 16 MB and uploaded through the console are automatically uploaded using multipart uploads. For more information about multipart uploads, see Uploading and copying objects using multipart upload.

When an object is uploaded as a multipart upload, the ETag for the object is not an MD5 digest of the entire object. Amazon S3 calculates the MD5 digest of each individual part as it is uploaded. The MD5 digests are used to determine the ETag for the final object. Amazon S3 concatenates the bytes for the MD5 digests together and then calculates the MD5 digest of these concatenated values. The final step for creating the ETag is when Amazon S3 adds a dash with the total number of parts to the end.

For example, consider an object uploaded with a multipart upload that has an ETag of `C9A5A6878D97B48CC965C1E41859F034-14`. In this case, `C9A5A6878D97B48CC965C1E41859F034` is the MD5 digest of all the digests concatenated together. The `-14` indicates that there are 14 parts associated with this object's multipart upload.

If you've enabled additional checksum values for your multipart object, Amazon S3 calculates the checksum for each individual part by using the specified checksum algorithm. The checksum for the completed object is calculated in the same way that Amazon S3 calculates the MD5 digest for the multipart upload. You can use this checksum to verify the integrity of the object.

To retrieve information about the object, including how many parts make up the entire object, you can use the GetObjectAttributes operation. With additional checksums, you can also recover information for each individual part that includes each part's checksum value.

For completed uploads, you can get an individual part's checksum by using the GetObject or HeadObject operations and specifying a part number or byte range that aligns to a single part. If you want to retrieve the checksum values for individual parts of multipart uploads still in progress, you can use ListParts.

Because of how Amazon S3 calculates the checksum for multipart objects, the checksum value for the object might change if you copy it. If you're using an SDK or the REST API and you call CopyObject, Amazon S3 copies any object up to the size limitations of the `CopyObject` API operation. Amazon S3 does this copy as a single action, regardless of whether the object was uploaded in a single request or as part of a multipart upload. With a copy command, the checksum of the object is a direct checksum of the full object. If the object was originally uploaded using a multipart upload, then the checksum value changes even though the data has not.

**Note**

Objects that are larger than the size limitations of the `CopyObject` API operation must use multipart copy commands.

**Important**

When you perform some operations using the AWS Management Console, Amazon S3 uses a multipart upload if the object is greater than 16 MB in size. In this case, the checksum is not a direct checksum of the full object, but rather a calculation based on the checksum values of each individual part.

For example, consider an object 100 MB in size that you uploaded as a single-part direct upload using the REST API. The checksum in this case is a checksum of the entire object. If you later use the console to rename that object, copy it, change the storage class, or edit the metadata, Amazon S3 uses the multipart upload functionality to update the object. As a result, Amazon S3 creates a new checksum value for the object that is calculated based on the checksum values of the individual parts.

**The preceding list of console operations is not a complete list of all the possible actions that you can take in the AWS Management Console that result in Amazon S3 updating the object using the multipart upload functionality.** Keep in mind that whenever you use the console to act on objects over 16 MB in size, the checksum value might not be the checksum of the entire object.

# Deleting Amazon S3 objects

You can delete one or more objects directly from Amazon S3 using the Amazon S3 console, AWS SDKs, AWS Command Line Interface (AWS CLI), or REST API. Because all objects in your S3 bucket incur storage costs, you should delete objects that you no longer need. For example, if you're collecting log files, it's a good idea to delete them when they're no longer needed. You can set up a lifecycle rule to automatically delete objects such as log files. For more information, see the section called “Setting lifecycle configuration”.

For information about Amazon S3 features and pricing, see Amazon S3 pricing.

You have the following API options when deleting an object:

- **Delete a single object** – Amazon S3 provides the `DELETE` (`DeleteObject`) API operation that you can use to delete one object in a single HTTP request.
- **Delete multiple objects** – Amazon S3 provides the Multi-Object Delete (`DeleteObjects`) API operation that you can use to delete up to 1,000 objects in a single HTTP request.

When deleting objects from a bucket where versioning is not enabled, you provide only the object key name. However, when deleting objects from a versioning-enabled bucket, you can optionally provide the version ID of the object to delete a specific version of the object.

## Programmatically deleting objects from a versioning-enabled bucket

If your bucket has versioning enabled, multiple versions of the same object can exist in the bucket. When working with versioning-enabled buckets, the delete API operations enable the following options:

- **Specify a non-versioned delete request** – Specify only the object's key, and not the version ID. In this case, Amazon S3 creates a delete marker and returns its version ID in the response. This makes your object disappear from the bucket. For information about object versioning and the delete marker concept, see Using versioning in S3 buckets.
- **Specify a versioned delete request** – Specify both the key and also a version ID. In this case the following two outcomes are possible:
  - If the version ID maps to a specific object version, Amazon S3 deletes the specific version of the object.

- If the version ID maps to the delete marker of that object, Amazon S3 deletes the delete marker. This makes the object reappear in your bucket.

## Deleting objects from an MFA-enabled bucket

When deleting objects from a multi-factor authentication (MFA)-enabled bucket, note the following:

- If you provide an MFA token that isn't valid, the request always fails.
- If you have an MFA-enabled bucket and you make a versioned delete request (you provide an object key and version ID), the request fails if you don't provide a valid MFA token. In addition, when using the Multi-Object Delete API operation on an MFA-enabled bucket, if any of the deletes are a versioned delete request (that is, you specify an object key and version ID), the entire request fails if you don't provide an MFA token.

However, in the following cases, the request succeeds:

- If you have an MFA-enabled bucket and you make a non-versioned delete request (you are not deleting a versioned object), and you don't provide an MFA token, the delete succeeds.
- If you have a Multi-Object Delete request that specifies only non-versioned objects to delete from an MFA-enabled bucket and you don't provide an MFA token, the deletions succeed.

For information about MFA delete, see Configuring MFA delete.

**Topics**

## Deleting a single object

You can use the Amazon S3 console or the DELETE API to delete a single existing object from an S3 bucket. For more information about deleting objects in Amazon S3, see Deleting Amazon S3 objects.

Because all objects in your S3 bucket incur storage costs, you should delete objects that you no longer need. For example, if you are collecting log files, it's a good idea to delete them when

they're no longer needed. You can set up a lifecycle rule to automatically delete objects such as log files. For more information, see the section called “Setting lifecycle configuration”.

For information about Amazon S3 features and pricing, see Amazon S3 pricing.

### Using the S3 console

Follow these steps to use the Amazon S3 console to delete a single object from a bucket.

> **Warning**
>
> When you permanently delete an object or specified object version in the Amazon S3 console, the deletion can't be undone.

### To delete an object that has versioning enabled or suspended

> **Note**
>
> If the version ID for an object in a versioning-suspended bucket is marked as NULL, S3 permanently deletes the object since no previous versions exist. However, if a valid version ID is listed for the object in a versioning-suspended bucket, then S3 creates a delete marker for the deleted object, while retaining the previous versions of the object.

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the **Bucket name** list, choose the name of the bucket that you want to delete an object from.
3. Select the object and then choose **Delete**.
4. To confirm deletion of the objects list under **Specified objects** in the **Delete objects?** text box, enter **`delete`**.

**To permanently delete a specific object version in a versioning-enabled bucket**

> **Warning**
>
> When you permanently delete a specific object version in Amazon S3, the deletion can't be undone.

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the **Bucket name** list, choose the name of the bucket that you want to delete an object from.
3. Select the object that you want to delete.
4. Choose the **Show versions** toggle.
5. Select the object version and then choose **Delete**.
6. To confirm permanent deletion of the specific object versions listed under **Specified objects**, in the **Delete objects?** text box, enter **Permanently delete**. Amazon S3 permanently deletes the specific object version.

**To permanently delete an object in an Amazon S3 bucket that *doesn't* have versioning enabled**

> **Warning**
>
> When you permanently delete an object in Amazon S3, the deletion can't be undone. Also, for any buckets without versioning enabled, deletions are permanent.

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the **Bucket name** list, choose the name of the bucket that you want to delete an object from.
3. Select the object and then choose **Delete**.
4. To confirm permanent deletion of the object listed under **Specified objects**, in the **Delete objects?** text box, enter **permanently delete**.

**Note**

If you're experiencing any issues with deleting your object, see I want to permanently delete versioned objects.

### Using the AWS SDKs

The following examples show how you can use the AWS SDKs to delete an object from a bucket. For more information, see DELETE Object in the *Amazon Simple Storage Service API Reference*

If you have S3 Versioning enabled on the bucket, you have the following options:

- Delete a specific object version by specifying a version ID.
- Delete an object without specifying a version ID, in which case Amazon S3 adds a delete marker to the object.

For more information about S3 Versioning, see Using versioning in S3 buckets.

Java

**Example Example 1: Deleting an object (non-versioned bucket)**

The following example assumes that the bucket is not versioning-enabled and the object doesn't have any version IDs. In the delete request, you specify only the object key and not a version ID.

For instructions on creating and testing a working sample, see Getting Started in the AWS SDK for Java Developer Guide.

```
import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import com.amazonaws.auth.profile.ProfileCredentialsProvider;
import com.amazonaws.regions.Regions;
import com.amazonaws.services.s3.AmazonS3;
import com.amazonaws.services.s3.AmazonS3ClientBuilder;
import com.amazonaws.services.s3.model.DeleteObjectRequest;

import java.io.IOException;
```

```
public class DeleteObjectNonVersionedBucket {

    public static void main(String[] args) throws IOException {
        Regions clientRegion = Regions.DEFAULT_REGION;
        String bucketName = "*** Bucket name ***";
        String keyName = "*** Key name ****";

        try {
            AmazonS3 s3Client = AmazonS3ClientBuilder.standard()
                    .withCredentials(new ProfileCredentialsProvider())
                    .withRegion(clientRegion)
                    .build();

            s3Client.deleteObject(new DeleteObjectRequest(bucketName, keyName));
        } catch (AmazonServiceException e) {
            // The call was transmitted successfully, but Amazon S3 couldn't process
            // it, so it returned an error response.
            e.printStackTrace();
        } catch (SdkClientException e) {
            // Amazon S3 couldn't be contacted for a response, or the client
            // couldn't parse the response from Amazon S3.
            e.printStackTrace();
        }
    }
}
```

**Example Example 2: Deleting an object (versioned bucket)**

The following example deletes an object from a versioned bucket. The example deletes a specific object version by specifying the object key name and version ID.

The example does the following:

1. Adds a sample object to the bucket. Amazon S3 returns the version ID of the newly added object. The example uses this version ID in the delete request.
2. Deletes the object version by specifying both the object key name and a version ID. If there are no other versions of that object, Amazon S3 deletes the object entirely. Otherwise, Amazon S3 only deletes the specified version.

> **Note**
>
> You can get the version IDs of an object by sending a `ListVersions` request.

```

        String keyName = "*** Key name ****";

        try {
            AmazonS3 s3Client = AmazonS3ClientBuilder.standard()
                    .withCredentials(new ProfileCredentialsProvider())
                    .withRegion(clientRegion)
                    .build();

            // Check to ensure that the bucket is versioning-enabled.
            String bucketVersionStatus =
 s3Client.getBucketVersioningConfiguration(bucketName).getStatus();
            if (!bucketVersionStatus.equals(BucketVersioningConfiguration.ENABLED))
 {
                System.out.printf("Bucket %s is not versioning-enabled.",
 bucketName);
            } else {
                // Add an object.
                PutObjectResult putResult = s3Client.putObject(bucketName, keyName,
```

```
                        "Sample content for deletion example.");
                System.out.printf("Object %s added to bucket %s\n", keyName,
 bucketName);

                // Delete the version of the object that we just created.
                System.out.println("Deleting versioned object " + keyName);
                s3Client.deleteVersion(new DeleteVersionRequest(bucketName, keyName,
 putResult.getVersionId()));
                System.out.printf("Object %s, version %s deleted\n", keyName,
 putResult.getVersionId());
            }
        } catch (AmazonServiceException e) {
            // The call was transmitted successfully, but Amazon S3 couldn't process
            // it, so it returned an error response.
            e.printStackTrace();
        } catch (SdkClientException e) {
            // Amazon S3 couldn't be contacted for a response, or the client
            // couldn't parse the response from Amazon S3.
            e.printStackTrace();
        }
    }
}
```

.NET

The following examples show how to delete an object from both versioned and non-versioned buckets. For more information about S3 Versioning, see Using versioning in S3 buckets.

**Example Deleting an object from a non-versioned bucket**

The following C# example deletes an object from a non-versioned bucket. The example assumes that the objects don't have version IDs, so you don't specify version IDs. You specify only the object key.

For information about setting up and running the code examples, see Getting Started with the AWS SDK for .NET in the *AWS SDK for .NET Developer Guide*.

```
using Amazon;
using Amazon.S3;
using Amazon.S3.Model;
using System;
using System.Threading.Tasks;
```

```
namespace Amazon.DocSamples.S3
{
    class DeleteObjectNonVersionedBucketTest
    {
        private const string bucketName = "*** bucket name ***";
        private const string keyName = "*** object key ***";
        // Specify your bucket region (an example region is shown).
        private static readonly RegionEndpoint bucketRegion =
 RegionEndpoint.USWest2;
        private static IAmazonS3 client;

        public static void Main()
        {
            client = new AmazonS3Client(bucketRegion);
            DeleteObjectNonVersionedBucketAsync().Wait();
        }
        private static async Task DeleteObjectNonVersionedBucketAsync()
        {
            try
            {
                var deleteObjectRequest = new DeleteObjectRequest
                {
                    BucketName = bucketName,
                    Key = keyName
                };

                Console.WriteLine("Deleting an object");
                await client.DeleteObjectAsync(deleteObjectRequest);
            }
            catch (AmazonS3Exception e)
            {
                Console.WriteLine("Error encountered on server. Message:'{0}' when
 deleting an object", e.Message);
            }
            catch (Exception e)
            {
                Console.WriteLine("Unknown encountered on server. Message:'{0}' when
 deleting an object", e.Message);
            }
        }
    }
}
```

### Example Deleting an object from a versioned bucket

The following C# example deletes an object from a versioned bucket. It deletes a specific version of the object by specifying the object key name and version ID.

The code performs the following tasks:

1. Enables S3 Versioning on a bucket that you specify (if S3 Versioning is already enabled, this has no effect).
2. Adds a sample object to the bucket. In response, Amazon S3 returns the version ID of the newly added object. The example uses this version ID in the delete request.
3. Deletes the sample object by specifying both the object key name and a version ID.

> **Note**
>
> You can also get the version ID of an object by sending a `ListVersions` request.
>
> ```
> var listResponse = client.ListVersions(new ListVersionsRequest { BucketName
>  = bucketName, Prefix = keyName });
> ```

For information about setting up and running the code examples, see Getting Started with the AWS SDK for .NET in the *AWS SDK for .NET Developer Guide*.

```
using Amazon;
using Amazon.S3;
using Amazon.S3.Model;
using System;
using System.Threading.Tasks;

namespace Amazon.DocSamples.S3
{
    class DeleteObjectVersion
    {
        private const string bucketName = "*** versioning-enabled bucket name ***";
        private const string keyName = "*** Object Key Name ***";
        // Specify your bucket region (an example region is shown).
        private static readonly RegionEndpoint bucketRegion =
 RegionEndpoint.USWest2;
        private static IAmazonS3 client;
```

```
        public static void Main()
        {
            client = new AmazonS3Client(bucketRegion);
            CreateAndDeleteObjectVersionAsync().Wait();
        }

        private static async Task CreateAndDeleteObjectVersionAsync()
        {
            try
            {
                // Add a sample object.
                string versionID = await PutAnObject(keyName);

                // Delete the object by specifying an object key and a version ID.
                DeleteObjectRequest request = new DeleteObjectRequest
                {
                    BucketName = bucketName,
                    Key = keyName,
                    VersionId = versionID
                };
                Console.WriteLine("Deleting an object");
                await client.DeleteObjectAsync(request);
            }
            catch (AmazonS3Exception e)
            {
                Console.WriteLine("Error encountered on server. Message:'{0}' when
deleting an object", e.Message);
            }
            catch (Exception e)
            {
                Console.WriteLine("Unknown encountered on server. Message:'{0}' when
deleting an object", e.Message);
            }
        }

        static async Task<string> PutAnObject(string objectKey)
        {
            PutObjectRequest request = new PutObjectRequest
            {
                BucketName = bucketName,
                Key = objectKey,
                ContentBody = "This is the content body!"
            };
```

```
            PutObjectResponse response = await client.PutObjectAsync(request);
            return response.VersionId;
        }
    }
}
```

PHP

This example shows how to use classes from version 3 of the AWS SDK for PHP to delete an object from a non-versioned bucket. For information about deleting an object from a versioned bucket, see Using the REST API.

For more information about the AWS SDK for Ruby API, go to AWS SDK for Ruby - Version 2.

The following PHP example deletes an object from a bucket. Because this example shows how to delete objects from non-versioned buckets, it provides only the bucket name and object key (not a version ID) in the delete request.

```
<?php

require 'vendor/autoload.php';

use Aws\S3\S3Client;
use Aws\S3\Exception\S3Exception;

$bucket = '*** Your Bucket Name ***';
$keyname = '*** Your Object Key ***';

$s3 = new S3Client([
    'version' => 'latest',
    'region'  => 'us-east-1'
]);

// 1. Delete the object from the bucket.
try
{
    echo 'Attempting to delete ' . $keyname . '...' . PHP_EOL;

    $result = $s3->deleteObject([
        'Bucket' => $bucket,
        'Key'    => $keyname
    ]);
```

```
    if ($result['DeleteMarker'])
    {
        echo $keyname . ' was deleted or does not exist.' . PHP_EOL;
    } else {
        exit('Error: ' . $keyname . ' was not deleted.' . PHP_EOL);
    }
}
catch (S3Exception $e) {
    exit('Error: ' . $e->getAwsErrorMessage() . PHP_EOL);
}

// 2. Check to see if the object was deleted.
try
{
    echo 'Checking to see if ' . $keyname . ' still exists...' . PHP_EOL;

    $result = $s3->getObject([
        'Bucket' => $bucket,
        'Key'    => $keyname
    ]);

    echo 'Error: ' . $keyname . ' still exists.';
}
catch (S3Exception $e) {
    exit($e->getAwsErrorMessage());
}
```

### Javascript

```
import { DeleteObjectCommand } from "@aws-sdk/client-s3";
import { s3Client } from "./libs/s3Client.js" // Helper function that creates Amazon
 S3 service client module.

export const bucketParams = { Bucket: "BUCKET_NAME", Key: "KEY" };

export const run = async () => {
  try {
    const data = await s3Client.send(new DeleteObjectCommand(bucketParams));
    console.log("Success. Object deleted.", data);
    return data; // For unit tests.
  } catch (err) {
    console.log("Error", err);
  }
```

```
};
run();
```

### Using the AWS CLI

To delete one object per request, use the DELETE API. For more information, see DELETE Object. For more information about using the CLI to delete an object, see delete-object.

### Using the REST API

You can use the AWS SDKs to delete an object. However, if your application requires it, you can send REST requests directly. For more information, see DELETE Object in the *Amazon Simple Storage Service API Reference*.

## Deleting multiple objects

Because all objects in your S3 bucket incur storage costs, you should delete objects that you no longer need. For example, if you are collecting log files, it's a good idea to delete them when they're no longer needed. You can set up a lifecycle rule to automatically delete objects such as log files. For more information, see the section called “Setting lifecycle configuration”.

For information about Amazon S3 features and pricing, see Amazon S3 pricing.

You can use the Amazon S3 console, AWS SDKs, or the REST API to delete multiple objects simultaneously from an S3 bucket.

### Using the S3 console

Follow these steps to use the Amazon S3 console to delete multiple objects from a bucket.

**Warning**

- Deleting a specified object cannot be undone.
- This action deletes all specified objects. When deleting folders, wait for the delete action to finish before adding new objects to the folder. Otherwise, new objects might be deleted as well.
- When deleting objects in a bucket without versioning enabled, Amazon S3 will permanently delete the objects.

- When deleting objects in a bucket with bucket versioning **enabled** or **suspended**, Amazon S3 creates delete markers. For more information, see Working with delete markers.

**To delete objects that have versioning enabled or suspended**

> **Note**
>
> If the version IDs for the object in a versioning-suspended bucket are marked as NULL, S3 permanently deletes the objects since no previous versions exist. However, if a valid version ID is listed for the objects in a versioning-suspended bucket, then S3 creates delete markers for the deleted objects, while retaining the previous versions of the objects.

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the **Bucket name** list, choose the name of the bucket that you want to delete the objects from.
3. Select the objects and then choose **Delete**.
4. To confirm deletion of the objects list under **Specified objects** in the **Delete objects?** text box, enter **`delete`**.

**To permanently delete specific object versions in a versioning-enabled bucket**

> **Warning**
>
> When you permanently delete specific object versions in Amazon S3, the deletion can't be undone.

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the **Bucket name** list, choose the name of the bucket that you want to delete the objects from.
3. Select the objects that you want to delete.

4. Choose the **Show versions** toggle.
5. Select the object versions and then choose **Delete**.
6. To confirm permanent deletion of the specific object versions listed under **Specified objects**, in the **Delete objects?** text box, enter **Permanently delete**. Amazon S3 permanently deletes the specific object versions.

**To permanently delete the objects in an Amazon S3 bucket that *don't* have versioning enabled**

> **Warning**
>
> When you permanently delete an object in Amazon S3, the deletion can't be undone. Also, for any buckets without versioning enabled, deletions are permanent.

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the **Bucket name** list, choose the name of the bucket that you want to delete the objects from.
3. Select the objects and then choose **Delete**.
4. To confirm permanent deletion of the objects listed under **Specified objects**, in the **Delete objects?** text box, enter **permanently delete**.

> **Note**
>
> If you're experiencing any issues with deleting your objects, see I want to permanently delete versioned objects.

### Using the AWS SDKs

For examples of how to delete multiple objects with the AWS SDKs, see Use `DeleteObjects` with an AWS SDK or CLI.

For general information about using different AWS SDKs, see Developing with Amazon S3 using the AWS SDKs.

### Using the REST API

You can use the AWS SDKs to delete multiple objects using the Multi-Object Delete API. However, if your application requires it, you can send REST requests directly.

For more information, see Delete Multiple Objects in the *Amazon Simple Storage Service API Reference*.

# Organizing, listing, and working with your objects

In Amazon S3, you can use prefixes to organize your storage. A prefix is a logical grouping of the objects in a bucket. The prefix value is similar to a directory name that enables you to store similar data under the same directory in a bucket. When you programmatically upload objects, you can use prefixes to organize your data.

In the Amazon S3 console, prefixes are called folders. You can view all your objects and folders in the S3 console by navigating to a bucket. You can also view information about each object, including object properties.

For more information about listing and organizing your data in Amazon S3, see the following topics.

### Topics

- Organizing objects using prefixes
- Listing object keys programmatically
- Organizing objects in the Amazon S3 console by using folders
- Viewing an object overview in the Amazon S3 console
- Viewing object properties in the Amazon S3 console

## Organizing objects using prefixes

You can use prefixes to organize the data that you store in Amazon S3 buckets. A prefix is a string of characters at the beginning of the object key name. A prefix can be any length, subject to the maximum length of the object key name (1,024 bytes). You can think of prefixes as a way to organize your data in a similar way to directories. However, prefixes are not directories.

Searching by prefix limits the results to only those keys that begin with the specified prefix. The delimiter causes a list operation to roll up all the keys that share a common prefix into a single summary list result.

The purpose of the prefix and delimiter parameters is to help you organize and then browse your keys hierarchically. To do this, first pick a delimiter for your bucket, such as slash (/), that doesn't occur in any of your anticipated key names. You can use another character as a delimiter. There is nothing unique about the slash (/) character, but it is a very common prefix delimiter. Next, construct your key names by concatenating all containing levels of the hierarchy, separating each level with the delimiter.

For example, if you were storing information about cities, you might naturally organize them by continent, then by country, then by province or state. Because these names don't usually contain punctuation, you might use slash (/) as the delimiter. The following examples use a slash (/) delimiter.

- Europe/France/Nouvelle-Aquitaine/Bordeaux
- North America/Canada/Quebec/Montreal
- North America/USA/Washington/Bellevue
- North America/USA/Washington/Seattle

If you stored data for every city in the world in this manner, it would become awkward to manage a flat key namespace. By using `Prefix` and `Delimiter` with the list operation, you can use the hierarchy that you've created to list your data. For example, to list all the states in USA, set `Delimiter='/'` and `Prefix='North America/USA/'`. To list all the provinces in Canada for which you have data, set `Delimiter='/'` and `Prefix='North America/Canada/'`.

For more information about delimiters, prefixes, and nested folders, see Difference between prefixes and nested folders.

## Listing objects using prefixes and delimiters

If you issue a list request with a delimiter, you can browse your hierarchy at only one level, skipping over and summarizing the (possibly millions of) keys nested at deeper levels. For example, assume that you have a bucket (*DOC-EXAMPLE-BUCKET*) with the following keys:

```
sample.jpg
```

```
photos/2006/January/sample.jpg

photos/2006/February/sample2.jpg

photos/2006/February/sample3.jpg

photos/2006/February/sample4.jpg
```

The sample bucket has only the `sample.jpg` object at the root level. To list only the root level objects in the bucket, you send a GET request on the bucket with the slash (/) delimiter character. In response, Amazon S3 returns the `sample.jpg` object key because it does not contain the / delimiter character. All other keys contain the delimiter character. Amazon S3 groups these keys and returns a single `CommonPrefixes` element with the prefix value `photos/`, which is a substring from the beginning of these keys to the first occurrence of the specified delimiter.

**Example**

```
<ListBucketResult xmlns="http://s3.amazonaws.com/doc/2006-03-01/">
  <Name>DOC-EXAMPLE-BUCKET</Name>
  <Prefix></Prefix>
  <Marker></Marker>
  <MaxKeys>1000</MaxKeys>
  <Delimiter>/</Delimiter>
  <IsTruncated>false</IsTruncated>
  <Contents>
    <Key>sample.jpg</Key>
    <LastModified>2011-07-24T19:39:30.000Z</LastModified>
    <ETag>&quot;d1a7fb5eab1c16cb4f7cf341cf188c3d&quot;</ETag>
    <Size>6</Size>
    <Owner>
      <ID>75cc57f09aa0c8caeab4f8c24e99d10f8e7faeebf76c078efc7c6caea54ba06a</ID>
      <DisplayName>displayname</DisplayName>
    </Owner>
    <StorageClass>STANDARD</StorageClass>
  </Contents>
  <CommonPrefixes>
    <Prefix>photos/</Prefix>
  </CommonPrefixes>
</ListBucketResult>
```

For more information about listing object keys programmatically, see Listing object keys programmatically.

# Listing object keys programmatically

In Amazon S3, keys can be listed by prefix. You can choose a common prefix for the names of related keys and mark these keys with a special character that delimits hierarchy. You can then use the list operation to select and browse keys hierarchically. This is similar to how files are stored in directories within a file system.

Amazon S3 exposes a list operation that lets you enumerate the keys contained in a bucket. Keys are selected for listing by bucket and prefix. For example, consider a bucket named "`dictionary`" that contains a key for every English word. You might make a call to list all the keys in that bucket that start with the letter "q". List results are always returned in UTF-8 binary order.

Both the SOAP and REST list operations return an XML document that contains the names of matching keys and information about the object identified by each key.

> **Note**
>
> SOAP support over HTTP is deprecated, but SOAP is still available over HTTPS. New Amazon S3 features are not supported for SOAP. Instead of using SOAP, we recommend that you use either the REST API or the AWS SDKs.

Groups of keys that share a prefix terminated by a special delimiter can be rolled up by that common prefix for the purposes of listing. This enables applications to organize and browse their keys hierarchically, much like how you would organize your files into directories in a file system.

For example, to extend the dictionary bucket to contain more than just English words, you might form keys by prefixing each word with its language and a delimiter, such as "`French/logical`". Using this naming scheme and the hierarchical listing feature, you could retrieve a list of only French words. You could also browse the top-level list of available languages without having to iterate through all the lexicographically intervening keys. For more information about this aspect of listing, see Organizing objects using prefixes.

**REST API**

If your application requires it, you can send REST requests directly. You can send a GET request to return some or all of the objects in a bucket or you can use selection criteria to return a subset of the objects in a bucket. For more information, see GET Bucket (List Objects) Version 2 in the *Amazon Simple Storage Service API Reference*.

### List implementation efficiency

List performance is not substantially affected by the total number of keys in your bucket. It's also not affected by the presence or absence of the `prefix`, `marker`, `maxkeys`, or `delimiter` arguments.

### Iterating through multipage results

As buckets can contain a virtually unlimited number of keys, the complete results of a list query can be extremely large. To manage large result sets, the Amazon S3 API supports pagination to split them into multiple responses. Each list keys response returns a page of up to 1,000 keys with an indicator indicating if the response is truncated. You send a series of list keys requests until you have received all the keys. AWS SDK wrapper libraries provide the same pagination.

## Examples

The following code examples show how to use `ListObjects`.

CLI

#### AWS CLI

The following example uses the `list-objects` command to display the names of all the objects in the specified bucket:

```
aws s3api list-objects --bucket text-content --query 'Contents[].{Key: Key, Size:
 Size}'
```

The example uses the `--query` argument to filter the output of `list-objects` down to the key value and size for each object

For more information about objects, see Working with Amazon S3 Objects in the *Amazon S3 Developer Guide*.

- For API details, see ListObjects in *AWS CLI Command Reference*.

PowerShell

#### Tools for PowerShell

**Example 1: This command retrieves the information about all of the items in the bucket "test-files".**

```
Get-S3Object -BucketName test-files
```

**Example 2: This command retrieves the information about the item "sample.txt" from bucket "test-files".**

```
Get-S3Object -BucketName test-files -Key sample.txt
```

**Example 3: This command retrieves the information about all items with the prefix "sample" from bucket "test-files".**

```
Get-S3Object -BucketName test-files -KeyPrefix sample
```

- For API details, see ListObjects in *AWS Tools for PowerShell Cmdlet Reference*.

## Organizing objects in the Amazon S3 console by using folders

In Amazon S3, buckets and objects are the primary resources, and objects are stored in buckets. Amazon S3 has a flat structure instead of a hierarchy like you would see in a file system. However, for the sake of organizational simplicity, the Amazon S3 console supports the *folder* concept as a means of grouping objects. The console does this by using a shared name *prefix* for the grouped objects. In other words, the grouped objects have names that begin with a common string. This common string, or shared prefix, is the folder name. Object names are also referred to as *key names*.

For example, you can create a folder in the console named `photos` and store an object named `myphoto.jpg` in it. The object is then stored with the key name `photos/myphoto.jpg`, where `photos/` is the prefix.

Here are two more examples:

- If you have three objects in your bucket—`logs/date1.txt`, `logs/date2.txt`, and `logs/date3.txt`—the console will show a folder named `logs`. If you open the folder in the console, you will see three objects: `date1.txt`, `date2.txt`, and `date3.txt`.
- If you have an object named `photos/2017/example.jpg`, the console will show you a folder named `photos` containing the folder `2017`. The folder `2017` will contain the object `example.jpg`.

You can have folders within folders, but not buckets within buckets. You can upload and copy objects directly into a folder. Folders can be created, deleted, and made public, but they cannot be renamed. Objects can be copied from one folder to another.

> **Important**
>
> When you create a folder in Amazon S3, S3 creates a 0-byte object with a key that's set to the folder name that you provided. For example, if you create a folder named `photos` in your bucket, the Amazon S3 console creates a 0-byte object with the key `photos/`. The console creates this object to support the idea of folders.
>
> The Amazon S3 console treats all objects that have a forward slash (/) character as the last (trailing) character in the key name as a folder (for example, `examplekeyname/`). You can't upload an object that has a key name with a trailing / character by using the Amazon S3 console. However, you can upload objects that are named with a trailing / with the Amazon S3 API by using the AWS Command Line Interface (AWS CLI), AWS SDKs, or REST API.
>
> An object that is named with a trailing / appears as a folder in the Amazon S3 console. The Amazon S3 console does not display the content and metadata for such an object. When you use the console to copy an object named with a trailing /, a new folder is created in the destination location, but the object's data and metadata are not copied.

**Topics**

## Creating a folder

This section describes how to use the Amazon S3 console to create a folder.

> **Important**
>
> If your bucket policy prevents uploading objects to this bucket without tags, metadata, or access control list (ACL) grantees, you can't create a folder by using the following

procedure. Instead, upload an empty folder and specify the following settings in the upload configuration.

**To create a folder**

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Buckets**.
3. In the **Buckets** list, choose the name of the bucket that you want to create a folder in.
4. If your bucket policy prevents uploading objects to this bucket without encryption, you must choose **Enable** under **Server-side encryption**.
5. Choose **Create folder**.
6. Enter a name for the folder (for example, **`favorite-pics`**). Then choose **Create folder**.

## Making folders public

We recommend blocking all public access to your Amazon S3 folders and buckets unless you specifically require a public folder or bucket. When you make a folder public, anyone on the internet can view all the objects that are grouped in that folder.

In the Amazon S3 console, you can make a folder public. You can also make a folder public by creating a bucket policy that limits data access by prefix. For more information, see Identity and Access Management for Amazon S3.

**Warning**

After you make a folder public in the Amazon S3 console, you can't make it private again. Instead, you must set permissions on each individual object in the public folder so that the objects have no public access. For more information, see Configuring ACLs.

**Topics**

- Calculating folder size
- Deleting folders

## Calculating folder size

This section describes how to use the Amazon S3 console to calculate a folder's size.

### To calculate a folder's size

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Buckets**.
3. In the **Buckets** list, choose the name of the bucket in which your folder is stored.
4. In the **Objects** list, select the check box next to the name of the folder.
5. Choose **Actions**, and then choose **Calculate total size**.

> **Note**
>
> When you navigate away from the page, the folder information (including the total size) will no longer be available. You must calculate the total size again if you want to see it again.

> **Important**
>
> When you use the **Calculate total size** action on specified objects or folders within your bucket, Amazon S3 calculates the total number of objects and the total storage size. However, incomplete or in-progress multipart uploads and previous or noncurrent versions aren't calculated in the total number of objects or the total size. This action calculates only the total number of objects and the total size for the current or newest version of each object that is stored in the bucket.
>
> For example, if there are two versions of an object in your bucket, then the storage calculator in Amazon S3 counts them as only one object. As a result, the total number of objects that is calculated in the Amazon S3 console can differ from the **Object Count** metric shown in S3 Storage Lens and from the number reported by the Amazon CloudWatch metric, `NumberOfObjects`. Likewise, the total storage size can also differ from the **Total Storage** metric shown in S3 Storage Lens and from the `BucketSizeBytes` metric shown in CloudWatch.

## Deleting folders

This section explains how to use the Amazon S3 console to delete folders from an S3 bucket.

For information about Amazon S3 features and pricing, see Amazon S3.

### To delete folders from an S3 bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the **Buckets** list, choose the name of the bucket that you want to delete folders from.
3. In the **Objects** list, select the check box next to the folders and objects that you want to delete.
4. Choose **Delete**.
5. On the **Delete objects** page, verify that the names of the folders you selected for deletion are listed.
6. In the **Delete objects** box, enter **`delete`**, and choose **Delete objects**.

> **Warning**
>
> This action deletes all specified objects. When deleting folders, wait for the delete action to finish before adding new objects to the folder. Otherwise, new objects might be deleted as well.

# Viewing an object overview in the Amazon S3 console

You can use the Amazon S3 console to view an overview of an object. The console provides all the essential information for an object in one place.

### To open the details page for an object

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the **Buckets** list, choose the name of the bucket that contains the object.
3. In the **Objects** list, choose the name of the object for which you want an overview.

The object details page opens.

4. To download the object, choose **Object actions**, and then choose **Download**. To copy the path of the object to the clipboard, under **Object URL**, choose the URL.
5. If versioning is enabled on the bucket, choose **Versions** to list the versions of the object.

   - To download an object version, select the check box next to the version ID, choose **Actions**, and then choose **Download**.
   - To delete an object version, select the check box next to the version ID, and choose **Delete**.

> **Important**
>
> You can undelete an object only if it was deleted as the latest (current) version. You can't undelete a previous version of an object that was deleted.

## Viewing object properties in the Amazon S3 console

You can use the Amazon S3 console to view the properties of an object, including storage class, encryption settings, tags, and metadata.

**To view the properties of an object**

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the **Buckets** list, choose the name of the bucket that contains the object.
3. In the **Objects** list, choose the name of the object you want to view properties for.

   The **Object overview** for your object opens. You can scroll down to view the object properties.
4. On the **Object overview** page, you can configure the following properties for the object.

> **Note**
>
> - If you change the **Storage Class**, **Encryption**, or **Metadata** properties, a new object is created to replace the old one. If S3 Versioning is enabled, a new version of the object is created, and the existing object becomes an older version. The role that changes the property also becomes the owner of the new object or (object version).

- If you change the **Storage Class**, **Encryption**, or **Metadata** properties for an object that has user-defined tags, you must have the `s3:GetObjectTagging` permission. If you're changing these properties for an object that doesn't have user-defined tags but is over 16 MB in size, you must also have the `s3:GetObjectTagging` permission.

  If the destination bucket policy denies the `s3:GetObjectTagging` action, these properties for the object will be updated, but the user-defined tags will be removed from the object, and you will receive an error.

a. **Storage class** – Each object in Amazon S3 has a storage class associated with it. The storage class that you choose to use depends on how frequently you access the object. The default storage class for S3 objects is STANDARD. You choose which storage class to use when you upload an object. For more information about storage classes, see Using Amazon S3 storage classes.

   To change the storage class after you upload an object, choose **Storage class**. Choose the storage class that you want, and then choose **Save**.

b. **Server-side encryption settings** – You can use server-side encryption to encrypt your S3 objects. For more information, see Specifying server-side encryption with AWS KMS (SSE-KMS) or Specifying server-side encryption with Amazon S3 managed keys (SSE-S3).

c. **Metadata** – Each object in Amazon S3 has a set of name-value pairs that represents its metadata. For information about adding metadata to an S3 object, see Editing object metadata in the Amazon S3 console.

d. **Tags** – You categorize storage by adding tags to an S3 object. For more information, see Categorizing your storage using tags.

e. **Object lock legal hold and retention** – You can prevent an object from being deleted. For more information, see Using S3 Object Lock.

# Working with presigned URLs

You can use presigned URLs to grant time-limited access to objects in Amazon S3 without updating your bucket policy. A presigned URL can be entered in a browser or used by a program to download an object. The credentials used by the presigned URL are those of the AWS user who generated the URL.

You can also use presigned URLs to allow someone to upload a specific object to your Amazon S3 bucket. This allows an upload without requiring another party to have AWS security credentials or permissions. If an object with the same key already exists in the bucket as specified in the presigned URL, Amazon S3 replaces the existing object with the uploaded object.

You can use the presigned URL multiple times, up to the expiration date and time.

When you create a presigned URL, you must provide your security credentials, and then specify the following:

- An Amazon S3 bucket
- An object key (if downloading this object will be in your Amazon S3 bucket, if uploading this is the file name to be uploaded)
- An HTTP method (`GET` for downloading objects or `PUT` for uploading)
- An expiration time interval

Currently, Amazon S3 presigned URLs don't support using the following data-integrity checksum algorithms (CRC32, CRC32C, SHA-1, SHA-256) when you upload objects. To verify the integrity of your object after uploading, you can provide an MD5 digest of the object when you upload it with a presigned URL. For more information about object integrity, see Checking object integrity.

**Topics**

## Who can create a presigned URL

Anyone with valid security credentials can create a presigned URL. But for someone to successfully access an object, the presigned URL must be created by someone who has permission to perform the operation that the presigned URL is based upon.

The following are the types of credentials that you can use to create a presigned URL:

- **IAM instance profile** – Valid up to 6 hours.
- **AWS Security Token Service** – Valid up to maximum 36 hours when signed with long-term security credentials or the duration of the temporary credential, whichever ends first.
- **IAM user** – Valid up to 7 days when you're using AWS Signature Version 4.

  To create a presigned URL that's valid for up to 7 days, first delegate IAM user credentials (the access key and secret key) to the method you're using to create the presigned URL.

> **Note**
>
> If you created a presigned URL using a temporary credential, the URL expires when the credential expires. In general, a presigned URL expires when the credential you used to create it is revoked, deleted, or deactivated. This is true even if the URL was created with a later expiration time. For temporary security credentials lifetimes, see Comparing AWS STS API operations in the *IAM User Guide*.

## Expiration time for presigned URLs

A presigned URL remains valid for the period of time specified when the URL is generated. If you create a presigned URL with the Amazon S3 console, the expiration time can be set between 1 minute and 12 hours. If you use the AWS CLI or AWS SDKs, the expiration time can be set as high as 7 days.

If you created a presigned URL by using a temporary token, then the URL expires when the token expires. In general, a presigned URL expires when the credential you used to create it is revoked, deleted, or deactivated. This is true even if the URL was created with a later expiration time. For more information about how the credentials you use affect the expiration time, see Who can create a presigned URL.

Amazon S3 checks the expiration date and time of a signed URL at the time of the HTTP request. For example, if a client begins to download a large file immediately before the expiration time, the download continues even if the expiration time passes during the download. However, if the connection drops and the client tries to restart the download after the expiration time passes, the download fails.

# Limiting presigned URL capabilities

The capabilities of a presigned URL are limited by the permissions of the user who created it. In essence, presigned URLs are bearer tokens that grant access to those who possess them. As such, we recommend that you protect them appropriately. The following are some methods that you can use to restrict the use of your presigned URLs.

### AWS Signature Version 4 (SigV4)

To enforce specific behavior when presigned URL requests are authenticated by using AWS Signature Version 4 (SigV4), you can use condition keys in bucket policies and access point policies. For example, the following bucket policy uses the `s3:signatureAge` condition to deny any Amazon S3 presigned URL request on objects in the *`amzn-s3-demo-bucket1`* bucket if the signature is more than 10 minutes old. To use this example, replace the *`user input placeholders`* with your own information.

```
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Sid": "Deny a presigned URL request if the signature is more than 10 min
 old",
         "Effect": "Deny",
         "Principal": {"AWS":"*"},
         "Action": "s3:*",
         "Resource": "arn:aws:s3:::amzn-s3-demo-bucket1/*",
         "Condition": {
            "NumericGreaterThan": {
               "s3:signatureAge": 600000
            }
         }
      }
   ]
}
```

For more information about policy keys related AWS Signature Version 4, see AWS Signature Version 4 Authentication in the *Amazon Simple Storage Service API Reference*.

### Network path restriction

If you want to restrict the use of presigned URLs and all Amazon S3 access to particular network paths, you can write AWS Identity and Access Management (IAM) policies. You can set these policies on the IAM principal that makes the call, the Amazon S3 bucket, or both.

A network-path restriction on the IAM principal requires the user of those credentials to make requests from the specified network. A restriction on the bucket or access point requires that all requests to that resource originate from the specified network. These restrictions also apply outside of the presigned URL scenario.

The IAM global condition key that you use depends on the type of endpoint. If you're using the public endpoint for Amazon S3, use `aws:SourceIp`. If you're using a virtual private cloud (VPC) endpoint to Amazon S3, use `aws:SourceVpc` or `aws:SourceVpce`.

The following IAM policy statement requires the principal to access AWS only from the specified network range. With this policy statement, all access must originate from that range. This includes the case of someone who's using a presigned URL for Amazon S3. To use this example, replace the *`user input placeholders`* with your own information.

```
{
    "Sid": "NetworkRestrictionForIAMPrincipal",
    "Effect": "Deny",
    "Action": "*",
    "Resource": "*",
    "Condition": {
        "NotIpAddressIfExists": {"aws:SourceIp": "IP-address-range"},
        "BoolIfExists": {"aws:ViaAWSService": "false"}
    }
}
```

## Sharing objects with presigned URLs

By default, all Amazon S3 objects are private, only the object owner has permission to access them. However, the object owner may share objects with others by creating a presigned URL. A presigned URL uses security credentials to grant time-limited permission to download objects. The URL can be entered in a browser or used by a program to download the object. The credentials used by the presigned URL are those of the AWS user who generated the URL.

For general information about presigned URLs, see Working with presigned URLs.

You can create a presigned URL for sharing an object without writing any code by using the Amazon S3 console, AWS Explorer for Visual Studio (Windows), or AWS Toolkit for Visual Studio

Code. You can also generate a presigned URL programmatically by using the AWS Command Line Interface (AWS CLI) or the AWS SDKs.

### Using the S3 console

You can use the Amazon S3 console to generate a presigned URL for sharing an object by following these steps. When using the console the maximum expiration time for a presigned URL is 12 hours from the time of creation.

**To generate a presigned URL by using the Amazon S3 console**

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Buckets**.
3. In the **Buckets** list, choose the name of the bucket that contains the object that you want a presigned URL for.
4. In the **Objects** list, select the object that you want to create a presigned URL for.
5. On the **Object actions** menu, choose **Share with a presigned URL**.
6. Specify how long you want the presigned URL to be valid.
7. Choose **Create presigned URL**.
8. When a confirmation appears, the URL is automatically copied to your clipboard. You will see a button to copy the presigned URL if you need to copy it again.

### Using the AWS CLI

The following example AWS CLI command generates a presigned URL for sharing an object from an Amazon S3 bucket. When you use the AWS CLI, the maximum expiration time for a presigned URL is 7 days from the time of creation. To use this example, replace the *`user input placeholders`* with your own information.

```
aws s3 presign s3://amzn-s3-demo-bucket1/mydoc.txt --expires-in 604800
```

> **Note**
>
> For all AWS Regions launched after March 20, 2019 you need to specify the `endpoint-url` and `AWS Region` with the request. For a list of all the Amazon S3 Regions and endpoints, see Regions and Endpoints in the *AWS General Reference*.

```
aws s3 presign s3://amzn-s3-demo-bucket1/mydoc.txt --expires-in 604800 --region af-south-1 --endpoint-url https://s3.af-south-1.amazonaws.com
```

For more information, see presign in the *AWS CLI Command Reference*.

**Using the AWS SDKs**

For examples of using the AWS SDKs to generate a presigned URL for sharing an object, see Create a presigned URL for Amazon S3 by using an AWS SDK.

When you use the AWS SDKs to generate a presigned URL, the maximum expiration time is 7 days from the time of creation.

> **Note**
>
> For all AWS Regions launched after March 20, 2019 you need to specify the `endpoint-url` and `AWS Region` with the request. For a list of all the Amazon S3 Regions and endpoints, see Regions and Endpoints in the *AWS General Reference*.

> **Note**
>
> When using the AWS SDKs, the Tagging attribute must be a header and not a query parameter. All other attributes can be passed as a parameter for the presigned URL.

**Using the AWS Toolkit for Visual Studio (Windows)**

> **Note**
>
> At this time, the AWS Toolkit for Visual Studio does not support Visual Studio for Mac.

1. Install the AWS Toolkit for Visual Studio using the following instructions, Installing and setting up the Toolkit for Visual Studio in the *AWS Toolkit for Visual Studio User Guide*.
2. Connect to AWS using the following steps, Connecting to AWS in the *AWS Toolkit for Visual Studio User Guide*.
3. In the left side panel labeled **AWS Explorer**, double-click the bucket containing your object.
4. Right-click the object you wish to have a presigned URL generated for and select **Create Pre-Signed URL...**.
5. In the pop-up window, set the expiration date and time for your presigned URL.
6. The **Object Key**, should pre-populate based on the object you selected.
7. Choose **GET** to specify that this presigned URL will be used for downloading an object.
8. Choose the **Generate** button.
9. To copy the URL to the clipboard, choose **Copy**.
10. To use the generated presigned URL, paste the URL into any browser.

#### Using AWS Toolkit for Visual Studio Code

If you're using Visual Studio Code, you can generate a presigned URL to share an object without writing any code by using AWS Toolkit for Visual Studio Code. For general information, see AWS Toolkit for Visual Studio Code in the *AWS Toolkit for Visual Studio Code User Guide*.

For instructions on how to install the AWS Toolkit for Visual Studio Code, see Installing the AWS Toolkit for Visual Studio Code in the *AWS Toolkit for Visual Studio Code User Guide*.

1. Connect to AWS using the following steps, Connecting to AWS Toolkit for Visual Studio Code in the *AWS Toolkit for Visual Studio Code User Guide*.
2. Select the AWS logo on the left panel in Visual Studio Code.
3. Under **EXPLORER**, select **S3**.
4. Choose a bucket and file and open the context menu (right-click).
5. Choose **Generate presigned URL**, and then set the expiration time (in minutes).
6. Press Enter, and the presigned URL will be copied to your clipboard.

## Uploading objects with presigned URLs

You may use presigned URLs to allow someone to upload an object to your Amazon S3 bucket. Using a presigned URL will allow an upload without requiring another party to have AWS security credentials or permissions. A presigned URL is limited by the permissions of the user who creates it. That is, if you receive a presigned URL to upload an object, you can upload an object only if the creator of the URL has the necessary permissions to upload that object.

When someone uses the URL to upload an object, Amazon S3 creates the object in the specified bucket. If an object with the same key that is specified in the presigned URL already exists in the bucket, Amazon S3 replaces the existing object with the uploaded object. After upload, the bucket owner will own the object.

For general information about presigned URLs, see Working with presigned URLs.

You can create a presigned URL for uploading an object without writing any code by using AWS Explorer for Visual Studio. You can also generate a presigned URL programmatically by using the AWS SDKs.

**Using the AWS Toolkit for Visual Studio (Windows)**

> **Note**
>
> At this time, the AWS Toolkit for Visual Studio does not support Visual Studio for Mac.

1. Install the AWS Toolkit for Visual Studio using the following instructions, Installing and setting up the Toolkit for Visual Studio in the *AWS Toolkit for Visual Studio User Guide*.
2. Connect to AWS using the following steps, Connecting to AWS in the *AWS Toolkit for Visual Studio User Guide*.
3. In the left side panel labeled **AWS Explorer**, right-click the bucket you wish to have an object uploaded to.
4. Choose **Create Pre-Signed URL...**.
5. In the pop-up window, set the expiration date and time for your presigned URL.
6. For **Object Key**, set the name of the file to be uploaded. The file you're uploading must match this name exactly. If an object with the same object key already exists in the bucket, Amazon S3 will replace the existing object with the newly uploaded object.
7. Choose **PUT** to specify that this presigned URL will be used for uploading an object.

8. Choose the **Generate** button.
9. To copy the URL to the clipboard, choose **Copy**.
10. To use this URL you can send a PUT request with the `curl` command. Include the full path to your file and the presigned URL itself.

```
curl -X PUT -T "/path/to/file" "presigned URL"
```

#### Using the AWS SDKs

For examples of using the AWS SDKs to generate a presigned URL for uploading an object, see Create a presigned URL for Amazon S3 by using an AWS SDK.

When you use the AWS SDKs to generate a presigned URL, the maximum expiration time is 7 days from the time of creation.

> **Note**
>
> For all AWS Regions launched after March 20, 2019 you need to specify the `endpoint-url` and `AWS Region` with the request. For a list of all the Amazon S3 Regions and endpoints, see Regions and Endpoints in the *AWS General Reference*.

## Transforming objects with S3 Object Lambda

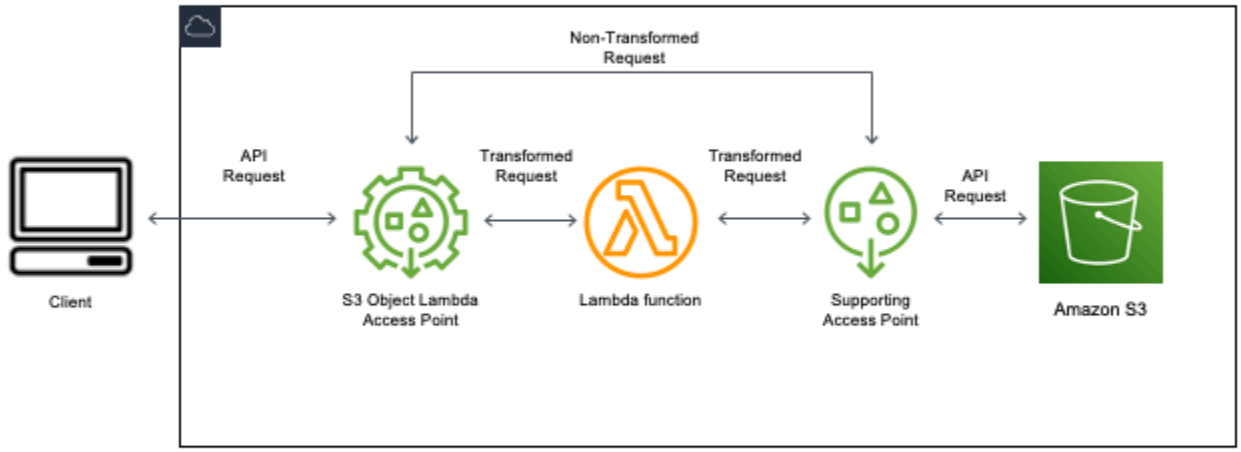
With Amazon S3 Object Lambda, you can add your own code to Amazon S3 `GET`, `LIST`, and `HEAD` requests to modify and process data as it is returned to an application. You can use custom code to modify the data returned by S3 `GET` requests to filter rows, dynamically resize and watermark images, redact confidential data, and more. You can also use S3 Object Lambda to modify the output of S3 `LIST` requests to create a custom view of all objects in a bucket and S3 `HEAD` requests to modify object metadata such as object name and size. You can use S3 Object Lambda as an origin for your Amazon CloudFront distribution to tailor data for end users, such as automatically resizing images, transcoding older formats (like from JPEG to WebP), or stripping metadata. For more information, see the AWS Blog post Use Amazon S3 Object Lambda with Amazon CloudFront. Powered by AWS Lambda functions, your code runs on infrastructure that is fully managed by AWS. Using S3 Object Lambda reduces the need to create and store derivative copies of your data or to run proxies, all with no need to change your applications.

### How S3 Object Lambda works

S3 Object Lambda uses AWS Lambda functions to automatically process the output of standard S3 `GET`, `LIST`, or `HEAD` requests. AWS Lambda is a serverless compute service that runs customer-defined code without requiring management of underlying compute resources. You can author and run your own custom Lambda functions, tailoring the data transformation to your specific use cases.

After you configure a Lambda function, you attach it to an S3 Object Lambda service endpoint, known as an *Object Lambda Access Point*. The Object Lambda Access Point uses a standard S3 access point, known as a *supporting access point*, to access Amazon S3.

When you send a request to your Object Lambda Access Point, Amazon S3 automatically calls your Lambda function. Any data retrieved by using an S3 `GET`, `LIST`, or `HEAD` request through the Object Lambda Access Point returns a transformed result back to the application. All other requests are processed as normal, as illustrated in the following diagram.



The topics in this section describe how to work with S3 Object Lambda.

### Topics

## Creating Object Lambda Access Points

An Object Lambda Access Point is associated with exactly one standard access point and thus one Amazon S3 bucket. To create an Object Lambda Access Point, you need the following resources:

- **An Amazon S3 bucket.** For information about creating buckets, see the section called "Creating a bucket".
- **A standard S3 access point.** When you're working with Object Lambda Access Points, this standard access point is known as a *supporting access point*. For information about creating standard access points, see the section called "Creating access points".
- **An AWS Lambda function.** You can either create your own Lambda function, or you can use a prebuilt function. For more information about creating Lambda functions, see the section called "Writing Lambda functions". For more information about prebuilt functions, see Using AWS built Lambda functions.
- **(Optional) An AWS Identity and Access Management (IAM) policy.** Amazon S3 access points support IAM resource policies that you can use to control the use of the access point by resource, user, or other conditions. For more information about creating these policies, see the section called "Configuring IAM policies".

The following sections describe how to create an Object Lambda Access Point by using:

- The AWS Management Console
- The AWS Command Line Interface (AWS CLI)
- An AWS CloudFormation template
- The AWS Cloud Development Kit (AWS CDK)

For information about how to create an Object Lambda Access Point by using the REST API, see `CreateAccessPointForObjectLambda` in the *Amazon Simple Storage Service API Reference*.

## Create an Object Lambda Access Point

Use one of the following procedures to create your Object Lambda Access Point.

### Using the S3 console

#### To create an Object Lambda Access Point by using the console

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the navigation bar, choose the name of the currently displayed AWS Region. Next, choose the Region that you want to switch to.
3. In the left navigation pane, choose **Object Lambda Access Points**.
4. On the **Object Lambda Access Points** page, choose **Create Object Lambda Access Point**.
5. For **Object Lambda Access Point name**, enter the name that you want to use for the access point.

   As with standard access points, there are rules for naming Object Lambda Access Points. For more information, see Rules for naming Amazon S3 access points.
6. For **Supporting Access Point**, enter or browse to the standard access point that you want to use. The access point must be in the same AWS Region as the objects that you want to transform. For information about creating standard access points, see the section called "Creating access points".
7. Under **Transformation configuration**, you can add a function that transforms your data for your Object Lambda Access Point. Do one of the following:

   - If you already have a AWS Lambda function in your account you can choose it under **Invoke Lambda function**. Here you may enter the Amazon Resource Name (ARN) of an Lambda function in your AWS account or choose a Lambda function from the drop-down menu.
   - If you wish to use a AWS built function choose the function name under **AWS built function** and select **Create Lambda function**. This will take you to the Lambda console where you can deploy a built function into your AWS account. For more information about built functions, see Using AWS built Lambda functions.

Under **S3 APIs**, choose one or more API operations to invoke. For each API selected you must specify a Lambda function to invoke.

8. (Optional) Under **Payload**, add JSON text that you want to provide to your Lambda function as input. You can configure payloads with different parameters for different Object Lambda Access Points that invoke the same Lambda function, thereby extending the flexibility of your Lambda function.

   > **Important**
   >
   > When you're using Object Lambda Access Points, make sure that the payload does not contain any confidential information.

9. (Optional) For **Range and part number**, you must enable this option if you want to process GET and HEAD requests with range and part number headers. Enabling this option confirms that your Lambda function can recognize and process these requests. For more information about range headers and part numbers, see Working with Range and partNumber headers.
10. (Optional) For **Request metrics**, choose **Enable** or **Disable** to add Amazon S3 monitoring to your Object Lambda Access Point. Request metrics are billed at the standard Amazon CloudWatch rate.
11. (Optional) Under **Object Lambda Access Point policy**, set a resource policy. Resource policies grant permissions for the specified Object Lambda Access Point and can control the use of the access point by resource, user, or other conditions. For more information about Object Lambda Access Point resource policies see, Configuring IAM policies for Object Lambda Access Points.
12. Under **Block Public Access settings for this Object Lambda Access Point**, select the block public access settings that you want to apply. All block public access settings are enabled by default for new Object Lambda Access Points, and we recommend that you leave default settings enabled. Amazon S3 currently doesn't support changing an Object Lambda Access Point's block public access settings after the Object Lambda Access Points has been created.

    For more information about using Amazon S3 Block Public Access, see Managing public access to access points.
13. Choose **Create Object Lambda Access Point**.

### Using the AWS CLI

#### To create an Object Lambda Access Point by using an AWS CloudFormation template

> **Note**
>
> To use the following commands, replace the *user input placeholders* with your own information.

1. Download the AWS Lambda function deployment package `s3objectlambda_deployment_package.zip` at S3 Object Lambda default configuration.
2. Run the following `put-object` command to upload the package to an Amazon S3 bucket.

```
aws s3api put-object --bucket Amazon S3 bucket name --key
 s3objectlambda_deployment_package.zip --body release/
s3objectlambda_deployment_package.zip
```

3. Download the AWS CloudFormation template `s3objectlambda_defaultconfig.yaml` at S3 Object Lambda default configuration.
4. Run the following `deploy` command to deploy the template to your AWS account.

```
aws cloudformation deploy --template-file s3objectlambda_defaultconfig.yaml \
 --stack-name AWS CloudFormation stack name \
 --parameter-overrides ObjectLambdaAccessPointName=Object Lambda Access Point name
 \
  SupportingAccessPointName=Amazon S3 access point S3BucketName=Amazon S3 bucket \
  LambdaFunctionS3BucketName=Amazon S3 bucket containing your Lambda package \
  LambdaFunctionS3Key=Lambda object key LambdaFunctionS3ObjectVersion=Lambda object
 version \
  LambdaFunctionRuntime=Lambda function runtime --capabilities capability_IAM
```

You can configure this AWS CloudFormation template to invoke Lambda for `GET`, `HEAD`, and `LIST` API operations. For more information about modifying the template's default configuration, see the section called “Automate S3 Object Lambda setup with AWS CloudFormation”.

### To create an Object Lambda Access Point by using the AWS CLI

> **Note**
>
> To use the following commands, replace the *`user input placeholders`* with your own information.

The following example creates an Object Lambda Access Point named *`my-object-lambda-ap`* for the bucket *`amzn-s3-demo-bucket1`* in the account *`111122223333`*. This example assumes that a standard access point named *`example-ap`* has already been created. For information about creating a standard access point, see the section called "Creating access points".

This example uses the AWS prebuilt function `decompress`. For more information about prebuilt functions, see the section called "Using AWS built functions".

1. Create a bucket. In this example, we will use *`amzn-s3-demo-bucket1`*. For information about creating buckets, see the section called "Creating a bucket".
2. Create a standard access point and attach it to your bucket. In this example, we will use *`example-ap`*. For information about creating standard access points, see the section called "Creating access points".
3. Do one of the following:

   - Create a Lambda function in your account that you would like to use to transform your Amazon S3 object. For more information about creating Lambda functions, see the section called "Writing Lambda functions". To use your custom function with the AWS CLI, see Using Lambda with the AWS CLI in the *AWS Lambda Developer Guide*.
   - Use an AWS prebuilt Lambda function. For more information about prebuilt functions, see Using AWS built Lambda functions.
4. Create a JSON configuration file named `my-olap-configuration.json`. In this configuration, provide the supporting access point and the Amazon Resource Name (ARN) for the Lambda function that you created in the previous steps or the ARN for the prebuilt function that you're using.

   **Example**

```
{
```

```
    "SupportingAccessPoint" : "arn:aws:s3:us-
east-1:111122223333:accesspoint/example-ap",
    "TransformationConfigurations": [{
        "Actions" : ["GetObject", "HeadObject", "ListObjects", "ListObjectsV2"],
        "ContentTransformation" : {
            "AwsLambda": {
                "FunctionPayload" : "{\"compressionType\":\"gzip\"}",
                "FunctionArn" : "arn:aws:lambda:us-east-1:111122223333:function/
compress"
            }
        }
    }]
}
```

5. Run the `create-access-point-for-object-lambda` command to create your Object Lambda Access Point.

```
aws s3control create-access-point-for-object-lambda --account-id 111122223333 --
name my-object-lambda-ap --configuration file://my-olap-configuration.json
```

6. (Optional) Create a JSON policy file named `my-olap-policy.json`.

   Adding an Object Lambda Access Point resource policy can control the use of the access point by resource, user, or other conditions. This resource policy grants the `GetObject` permission for account *444455556666* to the specified Object Lambda Access Point.

   **Example**

```
{
    "Version": "2008-10-17",
    "Statement": [
        {
            "Sid": "Grant account 444455556666 GetObject access",
            "Effect": "Allow",
            "Action": "s3-object-lambda:GetObject",
            "Principal": {
                "AWS": "arn:aws:iam::444455556666:root"
            },
            "Resource": "your-object-lambda-access-point-arn"
        }
    ]
```

```
}
```

7. (Optional) Run the `put-access-point-policy-for-object-lambda` command to set your resource policy.

```
aws s3control put-access-point-policy-for-object-lambda --account-id 111122223333
 --name my-object-lambda-ap --policy file://my-olap-policy.json
```

8. (Optional) Specify a payload.

   A payload is optional JSON that you can provide to your AWS Lambda function as input. You can configure payloads with different parameters for different Object Lambda Access Points that invoke the same Lambda function, thereby extending the flexibility of your Lambda function.

   The following Object Lambda Access Point configuration shows a payload with two parameters.

```
{
 "SupportingAccessPoint": "AccessPointArn",
 "CloudWatchMetricsEnabled": false,
 "TransformationConfigurations": [{
  "Actions": ["GetObject", "HeadObject", "ListObjects", "ListObjectsV2"],
  "ContentTransformation": {
   "AwsLambda": {
    "FunctionArn": "FunctionArn",
    "FunctionPayload": "{\"res-x\": \"100\",\"res-y\": \"100\"}"
   }
  }
 }]
}
```

   The following Object Lambda Access Point configuration shows a payload with one parameter, and with `GetObject-Range`, `GetObject-PartNumber`, `HeadObject-Range`, and `HeadObject-PartNumber` enabled.

```
{
    "SupportingAccessPoint":"AccessPointArn",
    "CloudWatchMetricsEnabled": false,
    "AllowedFeatures": ["GetObject-Range", "GetObject-PartNumber", "HeadObject-
Range", "HeadObject-PartNumber"],
```

```
    "TransformationConfigurations": [{
        "Action": ["GetObject", "HeadObject", "ListObjects", "ListObjectsV2"],
        "ContentTransformation": {
            "AwsLambda": {
                "FunctionArn":"FunctionArn",
                "FunctionPayload": "{\"compression-amount\": \"5\"}"
            }
        }
    }]
}
```

> **Important**
>
> When you're using Object Lambda Access Points, make sure that the payload does not contain any confidential information.

### Using the AWS CloudFormation console and template

You can create an Object Lambda Access Point by using the default configuration provided by Amazon S3. You can download an AWS CloudFormation template and Lambda function source code from the GitHub repository and deploy these resources to set up a functional Object Lambda Access Point.

For information about modifying the AWS CloudFormation template's default configuration, see the section called “Automate S3 Object Lambda setup with AWS CloudFormation”.

For information about configuring Object Lambda Access Points by using AWS CloudFormation without the template, see `AWS::S3ObjectLambda::AccessPoint` in the *AWS CloudFormation User Guide*.

### To upload the Lambda function deployment package

1. Download the AWS Lambda function deployment package `s3objectlambda_deployment_package.zip` at S3 Object Lambda default configuration.
2. Upload the package to an Amazon S3 bucket.

**To create an Object Lambda Access Point by using the AWS CloudFormation console**

1. Download the AWS CloudFormation template `s3objectlambda_defaultconfig.yaml` at S3 Object Lambda default configuration.
2. Sign in to the AWS Management Console and open the AWS CloudFormation console at https://console.aws.amazon.com/cloudformation.
3. Do one of the following:
   - If you've never used AWS CloudFormation before, on the AWS CloudFormation home page, choose **Create stack**.
   - If you have used AWS CloudFormation before, in the left navigation pane, choose **Stacks**. Choose **Create stack**, then choose **With new resources (standard)**.
4. For **Prerequisite - Prepare template**, choose **Template is ready**.
5. For **Specify template**, choose **Upload a template file** and upload `s3objectlambda_defaultconfig.yaml`.
6. Choose **Next**.
7. On the **Specify stack details** page, enter a name for the stack.
8. In the **Parameters** section, specify the following parameters that are defined in the stack template:
   a. For **CreateNewSupportingAccessPoint**, do one of the following:
      - If you already have a supporting access point for the S3 bucket where you uploaded the template, choose **false**.
      - If you want to create a new access point for this bucket, choose **true**.
   b. For **EnableCloudWatchMonitoring**, choose **true** or **false**, depending on whether you want to enable Amazon CloudWatch request metrics and alarms.
   c. (Optional) For **LambdaFunctionPayload**, add JSON text that you want to provide to your Lambda function as input. You can configure payloads with different parameters for different Object Lambda Access Points that invoke the same Lambda function, thereby extending the flexibility of your Lambda function.

> **Important**
>
> When you're using Object Lambda Access Points, make sure that the payload does not contain any confidential information.

d. For **LambdaFunctionRuntime**, enter your preferred runtime for the Lambda function. The available choices are `nodejs14.x`, `python3.9`, `java11`.

e. For **LambdaFunctionS3BucketName**, enter the Amazon S3 bucket name where you uploaded the deployment package.

f. For **LambdaFunctionS3Key**, enter the Amazon S3 object key where you uploaded the deployment package.

g. For **LambdaFunctionS3ObjectVersion**, enter the Amazon S3 object version where you uploaded the deployment package.

h. For **ObjectLambdaAccessPointName**, enter a name for your Object Lambda Access Point.

i. For **S3BucketName**, enter the Amazon S3 bucket name that will be associated with your Object Lambda Access Point.

j. For **SupportingAccessPointName**, enter the name of your supporting access point.

> **Note**
>
> This is an access point that is associated with the Amazon S3 bucket that you chose in the previous step. If you do not have any access points associated with your Amazon S3 bucket, you can configure the template to create one for you by choosing **true** for **CreateNewSupportingAccessPoint**.

9. Choose **Next**.
10. On the **Configure stack options page**, choose **Next**.

    For more information about the optional settings on this page, see Setting AWS CloudFormation stack options in the *AWS CloudFormation User Guide*.
11. On the **Review** page, choose **Create stack**.

### Using the AWS Cloud Development Kit (AWS CDK)

For more information about configuring Object Lambda Access Points by using the AWS CDK, see `AWS::S3ObjectLambda` Construct Library in the *AWS Cloud Development Kit (AWS CDK) API Reference*.

## Automate S3 Object Lambda setup with a CloudFormation template

You can use an AWS CloudFormation template to quickly create an Amazon S3 Object Lambda Access Point. The CloudFormation template automatically creates relevant resources, configures AWS Identity and Access Management (IAM) roles, and sets up an AWS Lambda function that automatically handles requests through the Object Lambda Access Point. With the CloudFormation template, you can implement best practices, improve your security posture, and reduce errors caused by manual processes.

This GitHub repository contains the CloudFormation template and Lambda function source code. For instructions on how to use the template, see the section called "Creating Object Lambda Access Points".

The Lambda function provided in the template does not run any transformation. Instead, it returns your objects as-is from your S3 bucket. You can clone the function and add your own transformation code to modify and process data as it is returned to an application. For more information about modifying your function, see the section called "Modifying the Lambda function" and the section called "Writing Lambda functions".

### Modifying the template

#### Creating a new supporting access point

S3 Object Lambda uses two access points, an Object Lambda Access Point and a standard S3 access point, which is referred to as the *supporting access point*. When you make a request to an Object Lambda Access Point, S3 either invokes Lambda on your behalf, or it delegates the request to the supporting access point, depending upon the S3 Object Lambda configuration. You can create a new supporting access point by passing the following parameter as part of the `aws cloudformation deploy` command when deploying the template.

```
CreateNewSupportingAccessPoint=true
```

#### Configuring a function payload

You can configure a payload to provide supplemental data to the Lambda function by passing the following parameter as part of the `aws cloudformation deploy` command when deploying the template.

```
LambdaFunctionPayload="format=json"
```

### Enabling Amazon CloudWatch monitoring

You can enable CloudWatch monitoring by passing the following parameter as part of the `aws cloudformation deploy` command when deploying the template.

```
EnableCloudWatchMonitoring=true
```

This parameter enables your Object Lambda Access Point for Amazon S3 request metrics and creates two CloudWatch alarms to monitor client-side and server-side errors.

> **Note**
>
> Amazon CloudWatch usage will incur additional costs. For more information about Amazon S3 request metrics, see Monitoring and logging access points.
> For pricing details, see CloudWatch pricing.

### Configuring provisioned concurrency

To reduce latency, you can configure provisioned concurrency for the Lambda function that's backing the Object Lambda Access Point by editing the template to include the following lines under `Resources`.

```
LambdaFunctionVersion:
      Type: AWS::Lambda::Version
      Properties:
        FunctionName: !Ref LambdaFunction
        ProvisionedConcurrencyConfig:
            ProvisionedConcurrentExecutions: Integer
```

> **Note**
>
> You will incur additional charges for provisioning concurrency. For more information about provisioned concurrency, see Managing Lambda provisioned concurrency in the *AWS Lambda Developer Guide*.
> For pricing details, see AWS Lambda pricing.

### Modifying the Lambda function

#### Changing header values for a `GetObject` request

By default, the Lambda function forwards all headers, except `Content-Length` and `ETag`, from the presigned URL request to the `GetObject` client. Based on your transformation code in the Lambda function, you can choose to send new header values to the `GetObject` client.

You can update your Lambda function to send new header values by passing them in the `WriteGetObjectResponse` API operation.

For example, if your Lambda function translates text in Amazon S3 objects to a different language, you can pass a new value in the `Content-Language` header. You can do this by modifying the `writeResponse` function as follows:

```
async function writeResponse (s3Client: S3, requestContext: GetObjectContext,
 transformedObject: Buffer,
  headers: Headers): Promise<PromiseResult<{}, AWSError>> {
  const { algorithm, digest } = getChecksum(transformedObject);

  return s3Client.writeGetObjectResponse({
    RequestRoute: requestContext.outputRoute,
    RequestToken: requestContext.outputToken,
    Body: transformedObject,
    Metadata: {
      'body-checksum-algorithm': algorithm,
      'body-checksum-digest': digest
    },
    ...headers,
    ContentLanguage: 'my-new-language'
  }).promise();
}
```

For a full list of supported headers, see `WriteGetObjectResponse` in the *Amazon Simple Storage Service API Reference*.

### Returning metadata headers

You can update your Lambda function to send new header values by passing them in the `WriteGetObjectResponse` API operation request.

```
async function writeResponse (s3Client: S3, requestContext: GetObjectContext,
 transformedObject: Buffer,
  headers: Headers): Promise<PromiseResult<{}, AWSError>> {
  const { algorithm, digest } = getChecksum(transformedObject);

  return s3Client.writeGetObjectResponse({
    RequestRoute: requestContext.outputRoute,
    RequestToken: requestContext.outputToken,
    Body: transformedObject,
    Metadata: {
      'body-checksum-algorithm': algorithm,
      'body-checksum-digest': digest,
      'my-new-header': 'my-new-value'
    },
    ...headers
  }).promise();
}
```

### Returning a new status code

You can return a custom status code to the `GetObject` client by passing it in the `WriteGetObjectResponse` API operation request.

```
async function writeResponse (s3Client: S3, requestContext: GetObjectContext,
 transformedObject: Buffer,
  headers: Headers): Promise<PromiseResult<{}, AWSError>> {
  const { algorithm, digest } = getChecksum(transformedObject);

  return s3Client.writeGetObjectResponse({
    RequestRoute: requestContext.outputRoute,
    RequestToken: requestContext.outputToken,
    Body: transformedObject,
    Metadata: {
      'body-checksum-algorithm': algorithm,
      'body-checksum-digest': digest
```

```
    },
    ...headers,
    StatusCode: Integer
  }).promise();
}
```

For a full list of supported status codes, see `WriteGetObjectResponse` in the *Amazon Simple Storage Service API Reference*.

**Applying Range and `partNumber` parameters to the source object**

By default, the Object Lambda Access Point created by the CloudFormation template can handle the `Range` and `partNumber` parameters. The Lambda function applies the range or part number requested to the transformed object. To do so, the function must download the whole object and run the transformation. In some cases, your transformed object ranges might map exactly to your source object ranges. This means that requesting byte range A-B on your source object and running the transformation might produce the same result as requesting the whole object, running the transformation, and returning byte range A-B on the transformed object.

In such cases, you can change the Lambda function implementation to apply the range or part number directly to the source object. This approach reduces the overall function latency and memory required. For more information, see the section called “Working with Range and partNumber headers”.

**Disabling Range and `partNumber` handling**

By default, the Object Lambda Access Point created by the CloudFormation template can handle the `Range` and `partNumber` parameters. If you don't need this behavior, you can disable it by removing the following lines from the template:

```
AllowedFeatures:
  - GetObject-Range
  - GetObject-PartNumber
  - HeadObject-Range
  - HeadObject-PartNumber
```

**Transforming large objects**

By default, the Lambda function processes the entire object in memory before it can start streaming the response to S3 Object Lambda. You can modify the function to stream the response

as it performs the transformation. Doing so helps reduce the transformation latency and the Lambda function memory size. For an example implementation, see the Stream compressed content example.

## Using Amazon S3 Object Lambda Access Points

Making requests through Amazon S3 Object Lambda Access Points works the same as making requests through other access points. For more information about how to make requests through an access point, see Using access points. You can make requests through Object Lambda Access Points by using the Amazon S3 console, AWS Command Line Interface (AWS CLI), AWS SDKs, or Amazon S3 REST API.

> **Important**
>
> The Amazon Resource Names (ARNs) for Object Lambda Access Points use a service name of `s3-object-lambda`. Thus, Object Lambda Access Point ARNs begin with `arn:aws::s3-object-lambda`, instead of `arn:aws::s3`, which is used with other access points.

### How to find the ARN for your Object Lambda Access Point

To use an Object Lambda Access Point with the AWS CLI or AWS SDKs, you need to know the Amazon Resource Name (ARN) of the Object Lambda Access Point. The following examples show how to find the ARN for an Object Lambda Access Point by using the Amazon S3 console or AWS CLI.

#### Using the S3 console

#### To find the ARN for your Object Lambda Access Point by using the console

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Object Lambda Access Points**.
3. Choose the option button next to the Object Lambda Access Point whose ARN you want to copy.
4. Choose **Copy ARN**.

### Using the AWS CLI

#### To find the ARN for your Object Lambda Access Point by using the AWS CLI

1. To retrieve a list of the Object Lambda Access Points that are associated with your AWS account, run the following command. Before running the command, replace the account ID *111122223333* with your AWS account ID.

```
aws s3control list-access-points-for-object-lambda --account-id 111122223333
```

2. Review the command output to find the Object Lambda Access Point ARN that you want to use. The output of the previous command should look similar to the following example.

```
{
    "ObjectLambdaAccessPointList": [
        {
            "Name": "my-object-lambda-ap",
            "ObjectLambdaAccessPointArn": "arn:aws:s3-object-lambda:us-
east-1:111122223333:accesspoint/my-object-lambda-ap"
        },
        ...
    ]
}
```

## How to use a bucket-style alias for your S3 bucket Object Lambda Access Point

When you create an Object Lambda Access Point, Amazon S3 automatically generates a unique alias for your Object Lambda Access Point. You can use this alias instead of an Amazon S3 bucket name or the Object Lambda Access Point Amazon Resource Name (ARN) in a request for access point data plane operations. For a list of these operations, see Access point compatibility with AWS services.

An Object Lambda Access Point alias name is created within the same namespace as an Amazon S3 bucket. This alias name is automatically generated and cannot be changed. For an existing Object Lambda Access Point, an alias is automatically assigned for use. An Object Lambda Access Point alias name meets all the requirements of a valid Amazon S3 bucket name and consists of the following parts:

*Object Lambda Access Point name prefix*-*metadata*--ol-s3

> **Note**
>
> The `--ol-s3` suffix is reserved for Object Lambda Access Point alias names and can't be used for bucket or Object Lambda Access Point names. For more information about Amazon S3 bucket-naming rules, see Bucket naming rules.

The following examples show the ARN and the Object Lambda Access Point alias for an Object Lambda Access Point named *my-object-lambda-access-point*:

- **ARN** – `arn:aws:s3-object-lambda:`*region*`:`*account-id*`:accesspoint/`*my-object-lambda-access-point*
- **Object Lambda Access Point alias** – *my-object-lambda-acc-1a4n8yjrb3kda96f67zwrwiiuse1a*`--ol-s3`

When you use an Object Lambda Access Point, you can use the Object Lambda Access Point alias name without requiring extensive code changes.

When you delete an Object Lambda Access Point, the Object Lambda Access Point alias name becomes inactive and unprovisioned.

**How to find the alias for your Object Lambda Access Point**

**Using the S3 console**

**To find the alias for your Object Lambda Access Point by using the console**

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Object Lambda Access Points**.
3. For the Object Lambda Access Point that you want to use, copy the **Object Lambda Access Point alias** value.

**Using the AWS CLI**

When you create an Object Lambda Access Point, Amazon S3 automatically generates an Object Lambda Access Point alias name, as shown in the following example command. To run this command, replace the *user input placeholders* with your own information. For information

about how to create an Object Lambda Access Point by using the AWS CLI, see To create an Object Lambda Access Point by using the AWS CLI.

```
aws s3control create-access-point-for-object-lambda --account-id 111122223333 --
name my-object-lambda-access-point --configuration file://my-olap-configuration.json
{
    "ObjectLambdaAccessPointArn": "arn:aws:s3:region:111122223333:accesspoint/my-
access-point",
    "Alias": {
        "Value": "my-object-lambda-acc-1a4n8yjrb3kda96f67zwrwiiuse1a--ol-s3",
        "Status": "READY"
    }
}
```

The generated Object Lambda Access Point alias name has two fields:

- The `Value` field is the alias value of the Object Lambda Access Point.
- The `Status` field is the status of the Object Lambda Access Point alias. If the status is `PROVISIONING`, Amazon S3 is provisioning the Object Lambda Access Point alias, and the alias is not yet ready for use. If the status is `READY`, the Object Lambda Access Point alias has been successfully provisioned and is ready for use.

For more information about the `ObjectLambdaAccessPointAlias` data type in the REST API, see CreateAccessPointForObjectLambda and ObjectLambdaAccessPointAlias in the *Amazon Simple Storage Service API Reference*.

**How to use the Object Lambda Access Point alias**

You can use an Object Lambda Access Point alias instead of an Amazon S3 bucket name for the operations listed in Access point compatibility with AWS services.

The following AWS CLI example for the `get-bucket-location` command uses the bucket's access point alias to return the AWS Region that the bucket is in. To run this command, replace the *`user input placeholders`* with your own information.

```
aws s3api get-bucket-location --bucket my-object-lambda-
acc-w7i37nq6xuzgax3jw3oqtifiusw2a--ol-s3

{
    "LocationConstraint": "us-west-2"
```

```
}
```

If the Object Lambda Access Point alias in a request isn't valid, the error code `InvalidAccessPointAliasError` is returned. For more information about `InvalidAccessPointAliasError`, see List of Error Codes in the *Amazon Simple Storage Service API Reference*.

The limitations of an Object Lambda Access Point alias are the same as those of an access point alias. For more information about the limitations of an access point alias, see Limitations.

## Security considerations for S3 Object Lambda Access Points

With Amazon S3 Object Lambda, you can perform custom transformations on data as it leaves Amazon S3 by using the scale and flexibility of AWS Lambda as a compute platform. S3 and Lambda remain secure by default, but to maintain this security, special consideration by the Lambda function author is required. S3 Object Lambda requires that all access be made by authenticated principals (no anonymous access) and over HTTPS.

To mitigate security risks, we recommend the following:

- Scope the Lambda execution role to the smallest set of permissions possible.
- Whenever possible, make sure your Lambda function accesses Amazon S3 through the provided presigned URL.

### Configuring IAM policies

S3 access points support AWS Identity and Access Management (IAM) resource policies that allow you to control the use of the access point by resource, user, or other conditions. For more information, see Configuring IAM policies for Object Lambda Access Points.

### Encryption behavior

Because Object Lambda Access Points use both Amazon S3 and AWS Lambda, there are differences in encryption behavior. For more information about default S3 encryption behavior, see Setting default server-side encryption behavior for Amazon S3 buckets.

- When you're using S3 server-side encryption with Object Lambda Access Points, the object is decrypted before being sent to Lambda. After the object is sent to Lambda, it is processed unencrypted (in the case of a GET or HEAD request).

- To prevent the encryption key from being logged, S3 rejects `GET` and `HEAD` requests for objects that are encrypted by using server-side encryption with customer-provided keys (SSE-C). However, the Lambda function might still retrieve these objects if it has access to the client-provided key.
- When using S3 client-side encryption with Object Lambda Access Points, make sure that Lambda has access to the encryption key so that it can decrypt and re-encrypt the object.

## Access points security

S3 Object Lambda uses two access points, an Object Lambda Access Point and a standard S3 access point, which is referred to as the *supporting access point*. When you make a request to an Object Lambda Access Point, S3 either invokes Lambda on your behalf, or it delegates the request to the supporting access point, depending upon the S3 Object Lambda configuration. When Lambda is invoked for a request S3 generates a presigned URL to your object on your behalf through the supporting access point. Your Lambda function receives this URL as input when the function is invoked.

You can set your Lambda function to use this presigned URL to retrieve the original object, instead of invoking S3 directly. By using this model, you can apply better security boundaries to your objects. You can limit direct object access through S3 buckets or S3 access points to a limited set of IAM roles or users. This approach also protects your Lambda functions from being subject to the confused deputy problem, where a misconfigured function with different permissions than the invoker could allow or deny access to objects when it should not.

## Object Lambda Access Point public access

S3 Object Lambda does not allow anonymous or public access because Amazon S3 must authorize your identity to complete any S3 Object Lambda request. When invoking requests through an Object Lambda Access Point, you must have the `lambda:InvokeFunction` permission for the configured Lambda function. Similarly, when invoking other API operations through an Object Lambda Access Point, you must have the required `s3:*` permissions.

Without these permissions, requests to invoke Lambda or delegate to S3 will fail with HTTP 403 (Forbidden) errors. All access must be made by authenticated principals. If you require public access, you can use Lambda@Edge as a possible alternative. For more information, see Customizing at the edge with Lambda@Edge in the *Amazon CloudFront Developer Guide*.

## Object Lambda Access Point IP addresses

The `describe-managed-prefix-lists` subnets support gateway virtual private cloud (VPC) endpoints and are related to the routing table of VPC endpoints. Since Object Lambda Access Point does not support gateway VPC its IP ranges are missing. The missing ranges belong to Amazon S3, but are not supported by gateway VPC endpoints. For more information about `describe-managed-prefix-lists`, see DescribeManagedPrefixLists in the *Amazon EC2 API Reference* and AWS IP address ranges in the *AWS General Reference*.

## Configuring IAM policies for Object Lambda Access Points

Amazon S3 access points support AWS Identity and Access Management (IAM) resource policies that you can use to control the use of the access point by resource, user, or other conditions. You can control access through an optional resource policy on your Object Lambda Access Point, or a resource policy on supporting access point. For step-by-step examples, see Tutorial: Transforming data for your application with S3 Object Lambda and Tutorial: Detecting and redacting PII data with S3 Object Lambda and Amazon Comprehend.

The following four resources must have permissions granted to work with Object Lambda Access Points:

- The IAM identity, such as user or role. For more information about IAM identities and best practices, see IAM identities (users, user groups, and roles) in the *IAM User Guide*.
- The bucket and its associated standard access point. When you're working with Object Lambda Access Points, this standard access point is known as a *supporting access point*.
- The Object Lambda Access Point.
- The AWS Lambda function.

> **Important**
>
> Before you save your policy, make sure to resolve security warnings, errors, general warnings, and suggestions from AWS Identity and Access Management Access Analyzer. IAM Access Analyzer runs policy checks to validate your policy against IAM policy grammar and best practices. These checks generate findings and provide actionable recommendations to help you author policies that are functional and conform to security best practices.

To learn more about validating policies by using IAM Access Analyzer, see IAM Access Analyzer policy validation in the *IAM User Guide*. To view a list of the warnings, errors, and suggestions that are returned by IAM Access Analyzer, see IAM Access Analyzer policy check reference.

The following policy examples assume that you have the following resources:

- An Amazon S3 bucket with the following Amazon Resource Name (ARN):

  `arn:aws:s3:::amzn-s3-demo-bucket1`
- An Amazon S3 standard access point on this bucket with the following ARN:

  `arn:aws:s3:us-east-1:111122223333:accesspoint/my-access-point`
- An Object Lambda Access Point with the following ARN:

  `arn:aws:s3-object-lambda:us-east-1:111122223333:accesspoint/my-object-lambda-ap`
- An AWS Lambda function with the following ARN:

  `arn:aws:lambda:us-east-1:111122223333:function:MyObjectLambdaFunction`

**Note**

If you're using a Lambda function from your account, you must include the specific function version in your policy statement. In the following example ARN, the version is indicated by *1*:
`arn:aws:lambda:us-east-1:111122223333:function:MyObjectLambdaFunction:1`
Lambda doesn't support adding IAM policies to the version $LATEST. For more information about Lambda function versions, see Lambda function versions in the *AWS Lambda Developer Guide*.

### Example – Bucket policy that delegates access control to standard access points

The following S3 bucket policy example delegates access control for a bucket to the bucket's standard access points. This policy allows full access to all access points that are owned by the

bucket owner's account. Thus, all access to this bucket is controlled by the policies that are attached to its access points. Users can read from the bucket only through an access point, which means that operations can be invoked only through access points. For more information, see Delegating access control to access points.

```
{
    "Version": "2012-10-17",
    "Statement" : [
    {
        "Effect": "Allow",
        "Principal" : { "AWS":"account-ARN"},
        "Action" : "*",
        "Resource" : [
            "arn:aws:s3:::amzn-s3-demo-bucket1",
            "arn:aws:s3:::amzn-s3-demo-bucket1/*"
        ],
        "Condition": {
            "StringEquals" : { "s3:DataAccessPointAccount" : "Bucket owner's account
 ID" }
        }
    }]
}
```

**Example – IAM policy that grants a user the necessary permissions to use an Object Lambda Access Point**

The following IAM policy grants a user permissions to the Lambda function, the standard access point, and the Object Lambda Access Point.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowLambdaInvocation",
      "Action": [
        "lambda:InvokeFunction"
      ],
      "Effect": "Allow",
      "Resource": "arn:aws:lambda:us-
east-1:111122223333:function:MyObjectLambdaFunction:1",
      "Condition": {
        "ForAnyValue:StringEquals": {
```

```
          "aws:CalledVia": [
            "s3-object-lambda.amazonaws.com"
          ]
        }
      }
    },
    {
      "Sid": "AllowStandardAccessPointAccess",
      "Action": [
        "s3:Get*",
        "s3:List*"
      ],
      "Effect": "Allow",
      "Resource": "arn:aws:s3:us-east-1:111122223333:accesspoint/my-access-point/*",
      "Condition": {
        "ForAnyValue:StringEquals": {
          "aws:CalledVia": [
            "s3-object-lambda.amazonaws.com"
          ]
        }
      }
    },
    {
      "Sid": "AllowObjectLambdaAccess",
      "Action": [
        "s3-object-lambda:Get*",
        "s3-object-lambda:List*"
      ],
      "Effect": "Allow",
      "Resource": "arn:aws:s3-object-lambda:us-east-1:111122223333:accesspoint/my-
object-lambda-ap"
    }
  ]
}
```

### Enable permissions for Lambda execution roles

When GET requests are made to an Object Lambda Access Point, your Lambda function needs permission to send data to S3 Object Lambda Access Point. This permission is provided by enabling the `s3-object-lambda:WriteGetObjectResponse` permission on your Lambda function's execution role. You can create a new execution role or update an existing one.

> **Note**
>
> Your function needs the `s3-object-lambda:WriteGetObjectResponse` permission only if you're making a `GET` request.

**To create an execution role in the IAM console**

1. Open the IAM console at https://console.aws.amazon.com/iam/.
2. In the left navigation pane, choose **Roles**.
3. Choose **Create role**.
4. Under **Common use cases**, choose **Lambda**.
5. Choose **Next**.
6. On the **Add permissions** page, search for the AWS managed policy `AmazonS3ObjectLambdaExecutionRolePolicy`, and then select the check box beside the policy name.

   This policy should contain the `s3-object-lambda:WriteGetObjectResponse` Action.
7. Choose **Next**.
8. On the **Name, review, and create** page, for **Role name**, enter **`s3-object-lambda-role`**.
9. (Optional) Add a description and tags for this role.
10. Choose **Create role**.
11. Apply the newly created **`s3-object-lambda-role`** as your Lambda function's execution role. This can be done during or after Lambda function creation in the Lambda console.

For more information about execution roles, see Lambda execution role in the *AWS Lambda Developer Guide*.

**Using context keys with Object Lambda Access Points**

S3 Object Lambda will evaluate context keys such as `s3-object-lambda:TlsVersion` or `s3-object-lambda:AuthType` that are related to the connection or signing of the request. All other context keys, such as `s3:prefix`, are evaluated by Amazon S3.

### Object Lambda Access Point CORS support

When S3 Object Lambda receives a request from a browser or the request includes an `Origin` header, S3 Object Lambda always adds an `“AllowedOrigins":"*"` header field.

For more information, see Using cross-origin resource sharing (CORS).

## Writing Lambda functions for S3 Object Lambda Access Points

This section details how to write AWS Lambda functions for use with Amazon S3 Object Lambda Access Points.

To learn about complete end-to-end procedures for some S3 Object Lambda tasks, see the following:

- Tutorial: Transforming data for your application with S3 Object Lambda
- Tutorial: Detecting and redacting PII data with S3 Object Lambda and Amazon Comprehend
- Tutorial: Using S3 Object Lambda to dynamically watermark images as they are retrieved

**Topics**

### Working with `GetObject` requests in Lambda

This section assumes that your Object Lambda Access Point is configured to call the Lambda function for `GetObject`. S3 Object Lambda includes the Amazon S3 API operation, `WriteGetObjectResponse`, which enables the Lambda function to provide customized data and response headers to the `GetObject` caller.

`WriteGetObjectResponse` gives you extensive control over the status code, response headers, and response body, based on your processing needs. You can use `WriteGetObjectResponse` to respond with the whole transformed object, portions of the transformed object, or other responses

based on the context of your application. The following section shows unique examples of using the `WriteGetObjectResponse` API operation.

- **Example 1:** Respond with HTTP status code 403 (Forbidden)
- **Example 2:** Respond with a transformed image
- **Example 3:** Stream compressed content

### Example 1: Respond with HTTP status code 403 (Forbidden)

You can use `WriteGetObjectResponse` to respond with the HTTP status code 403 (Forbidden) based on the content of the object.

Java

```
package com.amazon.s3.objectlambda;

import com.amazonaws.services.lambda.runtime.Context;
import com.amazonaws.services.lambda.runtime.events.S3ObjectLambdaEvent;
import com.amazonaws.services.s3.AmazonS3;
import com.amazonaws.services.s3.AmazonS3Client;
import com.amazonaws.services.s3.model.WriteGetObjectResponseRequest;

import java.io.ByteArrayInputStream;
import java.net.URI;
import java.net.http.HttpClient;
import java.net.http.HttpRequest;
import java.net.http.HttpResponse;

public class Example1 {

    public void handleRequest(S3ObjectLambdaEvent event, Context context) throws
 Exception {
        AmazonS3 s3Client = AmazonS3Client.builder().build();

        // Check to see if the request contains all of the necessary information.
        // If it does not, send a 4XX response and a custom error code and message.
        // Otherwise, retrieve the object from S3 and stream it
        // to the client unchanged.
        var tokenIsNotPresent = !
event.getUserRequest().getHeaders().containsKey("requiredToken");
        if (tokenIsNotPresent) {
```

```
            s3Client.writeGetObjectResponse(new WriteGetObjectResponseRequest()
                    .withRequestRoute(event.outputRoute())
                    .withRequestToken(event.outputToken())
                    .withStatusCode(403)
                    .withContentLength(0L).withInputStream(new
 ByteArrayInputStream(new byte[0]))
                    .withErrorCode("MissingRequiredToken")
                    .withErrorMessage("The required token was not present in the
 request."));
            return;
        }

        // Prepare the presigned URL for use and make the request to S3.
        HttpClient httpClient = HttpClient.newBuilder().build();
        var presignedResponse = httpClient.send(
                HttpRequest.newBuilder(new URI(event.inputS3Url())).GET().build(),
                HttpResponse.BodyHandlers.ofInputStream());

        // Stream the original bytes back to the caller.
        s3Client.writeGetObjectResponse(new WriteGetObjectResponseRequest()
                .withRequestRoute(event.outputRoute())
                .withRequestToken(event.outputToken())
                .withInputStream(presignedResponse.body()));
    }
}
```

Python

```
import boto3
import requests

def handler(event, context):
    s3 = boto3.client('s3')

    """
    Retrieve the operation context object from the event. This object indicates
 where the WriteGetObjectResponse request
    should be delivered and contains a presigned URL in 'inputS3Url' where we can
 download the requested object from.
    The 'userRequest' object has information related to the user who made this
 'GetObject' request to
    S3 Object Lambda.
    """
```

```
    get_context = event["getObjectContext"]
    user_request_headers = event["userRequest"]["headers"]

    route = get_context["outputRoute"]
    token = get_context["outputToken"]
    s3_url = get_context["inputS3Url"]

    # Check for the presence of a 'CustomHeader' header and deny or allow based on
 that header.
    is_token_present = "SuperSecretToken" in user_request_headers

    if is_token_present:
        # If the user presented our custom 'SuperSecretToken' header, we send the
 requested object back to the user.
        response = requests.get(s3_url)
        s3.write_get_object_response(RequestRoute=route, RequestToken=token,
 Body=response.content)
    else:
        # If the token is not present, we send an error back to the user.
        s3.write_get_object_response(RequestRoute=route, RequestToken=token,
 StatusCode=403,
        ErrorCode="NoSuperSecretTokenFound", ErrorMessage="The request was not
 secret enough.")

    # Gracefully exit the Lambda function.
    return { 'status_code': 200 }
```

Node.js

```
const { S3 } = require('aws-sdk');
const axios = require('axios').default;

exports.handler = async (event) => {
    const s3 = new S3();

    // Retrieve the operation context object from the event. This object indicates
 where the WriteGetObjectResponse request
    // should be delivered and contains a presigned URL in 'inputS3Url' where we can
 download the requested object from.
    // The 'userRequest' object has information related to the user who made this
 'GetObject' request to S3 Object Lambda.
    const { userRequest, getObjectContext } = event;
    const { outputRoute, outputToken, inputS3Url } = getObjectContext;
```

```
    // Check for the presence of a 'CustomHeader' header and deny or allow based on
 that header.
    const isTokenPresent = Object
        .keys(userRequest.headers)
        .includes("SuperSecretToken");

    if (!isTokenPresent) {
        // If the token is not present, we send an error back to the user. The
 'await' in front of the request
        // indicates that we want to wait for this request to finish sending before
 moving on.
        await s3.writeGetObjectResponse({
            RequestRoute: outputRoute,
            RequestToken: outputToken,
            StatusCode: 403,
            ErrorCode: "NoSuperSecretTokenFound",
            ErrorMessage: "The request was not secret enough.",
        }).promise();
    } else {
        // If the user presented our custom 'SuperSecretToken' header, we send the
 requested object back to the user.
        // Again, note the presence of 'await'.
        const presignedResponse = await axios.get(inputS3Url);
        await s3.writeGetObjectResponse({
            RequestRoute: outputRoute,
            RequestToken: outputToken,
            Body: presignedResponse.data,
        }).promise();
    }

    // Gracefully exit the Lambda function.
    return { statusCode: 200 };
}
```

### Example 2: Respond with a transformed image

When performing an image transformation, you might find that you need all the bytes of the source object before you can start processing them. In this case, your `WriteGetObjectResponse` request returns the whole object to the requesting application in one call.

Java

```
package com.amazon.s3.objectlambda;

import com.amazonaws.services.lambda.runtime.Context;
import com.amazonaws.services.lambda.runtime.events.S3ObjectLambdaEvent;
import com.amazonaws.services.s3.AmazonS3;
import com.amazonaws.services.s3.AmazonS3Client;
import com.amazonaws.services.s3.model.WriteGetObjectResponseRequest;

import javax.imageio.ImageIO;
import java.awt.image.BufferedImage;
import java.awt.Image;
import java.io.ByteArrayInputStream;
import java.io.ByteArrayOutputStream;
import java.net.URI;
import java.net.http.HttpClient;
import java.net.http.HttpRequest;
import java.net.http.HttpResponse;

public class Example2 {

    private static final int HEIGHT = 250;
    private static final int WIDTH = 250;

    public void handleRequest(S3ObjectLambdaEvent event, Context context) throws
 Exception {
        AmazonS3 s3Client = AmazonS3Client.builder().build();
        HttpClient httpClient = HttpClient.newBuilder().build();

        // Prepare the presigned URL for use and make the request to S3.
        var presignedResponse = httpClient.send(
                HttpRequest.newBuilder(new URI(event.inputS3Url())).GET().build(),
                HttpResponse.BodyHandlers.ofInputStream());

        // The entire image is loaded into memory here so that we can resize it.
        // Once the resizing is completed, we write the bytes into the body
        // of the WriteGetObjectResponse request.
        var originalImage = ImageIO.read(presignedResponse.body());
        var resizingImage = originalImage.getScaledInstance(WIDTH, HEIGHT,
 Image.SCALE_DEFAULT);
        var resizedImage = new BufferedImage(WIDTH, HEIGHT,
 BufferedImage.TYPE_INT_RGB);
        resizedImage.createGraphics().drawImage(resizingImage, 0, 0, WIDTH, HEIGHT,
 null);
```

```
        var baos = new ByteArrayOutputStream();
        ImageIO.write(resizedImage, "png", baos);

        // Stream the bytes back to the caller.
        s3Client.writeGetObjectResponse(new WriteGetObjectResponseRequest()
                .withRequestRoute(event.outputRoute())
                .withRequestToken(event.outputToken())
                .withInputStream(new ByteArrayInputStream(baos.toByteArray())));
    }
}
```

Python

```
import boto3
import requests
import io
from PIL import Image

def handler(event, context):
    """
    Retrieve the operation context object from the event. This object indicates
 where the WriteGetObjectResponse request
    should be delivered and has a presigned URL in 'inputS3Url' where we can
 download the requested object from.
    The 'userRequest' object has information related to the user who made this
 'GetObject' request to
    S3 Object Lambda.
    """
    get_context = event["getObjectContext"]
    route = get_context["outputRoute"]
    token = get_context["outputToken"]
    s3_url = get_context["inputS3Url"]

    """
    In this case, we're resizing .png images that are stored in S3 and are
 accessible through the presigned URL
    'inputS3Url'.
    """
    image_request = requests.get(s3_url)
    image = Image.open(io.BytesIO(image_request.content))
    image.thumbnail((256,256), Image.ANTIALIAS)
```

```
    transformed = io.BytesIO()
    image.save(transformed, "png")

    # Send the resized image back to the client.
    s3 = boto3.client('s3')
    s3.write_get_object_response(Body=transformed.getvalue(), RequestRoute=route,
 RequestToken=token)

    # Gracefully exit the Lambda function.
    return { 'status_code': 200 }
```

### Node.js

```
const { S3 } = require('aws-sdk');
const axios = require('axios').default;
const sharp = require('sharp');

exports.handler = async (event) => {
    const s3 = new S3();

    // Retrieve the operation context object from the event. This object indicates
 where the WriteGetObjectResponse request
    // should be delivered and has a presigned URL in 'inputS3Url' where we can
 download the requested object from.
    const { getObjectContext } = event;
    const { outputRoute, outputToken, inputS3Url } = getObjectContext;

    // In this case, we're resizing .png images that are stored in S3 and are
 accessible through the presigned URL
    // 'inputS3Url'.
    const { data } = await axios.get(inputS3Url, { responseType: 'arraybuffer' });

    // Resize the image.
    const resized = await sharp(data)
        .resize({ width: 256, height: 256 })
        .toBuffer();

    // Send the resized image back to the client.
    await s3.writeGetObjectResponse({
        RequestRoute: outputRoute,
        RequestToken: outputToken,
        Body: resized,
    }).promise();
```

```
    // Gracefully exit the Lambda function.
    return { statusCode: 200 };
}
```

### Example 3: Stream compressed content

When you're compressing objects, compressed data is produced incrementally. Consequently, you can use your `WriteGetObjectResponse` request to return the compressed data as soon as it's ready. As shown in this example, you don't need to know the length of the completed transformation.

Java

```
package com.amazon.s3.objectlambda;

import com.amazonaws.services.lambda.runtime.events.S3ObjectLambdaEvent;
import com.amazonaws.services.lambda.runtime.Context;
import com.amazonaws.services.s3.AmazonS3;
import com.amazonaws.services.s3.AmazonS3Client;
import com.amazonaws.services.s3.model.WriteGetObjectResponseRequest;

import java.net.URI;
import java.net.http.HttpClient;
import java.net.http.HttpRequest;
import java.net.http.HttpResponse;

public class Example3 {

    public void handleRequest(S3ObjectLambdaEvent event, Context context) throws
 Exception {
        AmazonS3 s3Client = AmazonS3Client.builder().build();
        HttpClient httpClient = HttpClient.newBuilder().build();

        // Request the original object from S3.
        var presignedResponse = httpClient.send(
                HttpRequest.newBuilder(new URI(event.inputS3Url())).GET().build(),
                HttpResponse.BodyHandlers.ofInputStream());

        // Consume the incoming response body from the presigned request,
        // apply our transformation on that data, and emit the transformed bytes
```

```
        // into the body of the WriteGetObjectResponse request as soon as they're
 ready.
        // This example compresses the data from S3, but any processing pertinent
        // to your application can be performed here.
        var bodyStream = new GZIPCompressingInputStream(presignedResponse.body());

        // Stream the bytes back to the caller.
        s3Client.writeGetObjectResponse(new WriteGetObjectResponseRequest()
                .withRequestRoute(event.outputRoute())
                .withRequestToken(event.outputToken())
                .withInputStream(bodyStream));
    }

}
```

Python

```
import boto3
import requests
import zlib
from botocore.config import Config

"""
A helper class to work with content iterators. Takes an interator and compresses the
 bytes that come from it. It
implements 'read' and '__iter__' so that the SDK can stream the response.
"""
class Compress:
    def __init__(self, content_iter):
        self.content = content_iter
        self.compressed_obj = zlib.compressobj()

    def read(self, _size):
        for data in self.__iter__()
            return data

    def __iter__(self):
        while True:
            data = next(self.content)
            chunk = self.compressed_obj.compress(data)
            if not chunk:
                break
```

```
            yield chunk

        yield self.compressed_obj.flush()

def handler(event, context):
    """
    Setting the 'payload_signing_enabled' property to False allows us to send a
 streamed response back to the client.
    in this scenario, a streamed response means that the bytes are not buffered into
 memory as we're compressing them,
    but instead are sent straight to the user.
    """
    my_config = Config(
        region_name='eu-west-1',
        signature_version='s3v4',
        s3={
            "payload_signing_enabled": False
        }
    )
    s3 = boto3.client('s3', config=my_config)

    """
    Retrieve the operation context object from the event. This object indicates
 where the WriteGetObjectResponse request
    should be delivered and has a presigned URL in 'inputS3Url' where we can
 download the requested object from.
    The 'userRequest' object has information related to the user who made this
 'GetObject' request to S3 Object Lambda.
    """
    get_context = event["getObjectContext"]
    route = get_context["outputRoute"]
    token = get_context["outputToken"]
    s3_url = get_context["inputS3Url"]

    # Compress the 'get' request stream.
    with requests.get(s3_url, stream=True) as r:
        compressed = Compress(r.iter_content())

        # Send the stream back to the client.
        s3.write_get_object_response(Body=compressed, RequestRoute=route,
 RequestToken=token, ContentType="text/plain",
                                     ContentEncoding="gzip")
```

```
    # Gracefully exit the Lambda function.
    return {'status_code': 200}
```

Node.js

```
const { S3 } = require('aws-sdk');
const axios = require('axios').default;
const zlib = require('zlib');

exports.handler = async (event) => {
    const s3 = new S3();

    // Retrieve the operation context object from the event. This object indicates
 where the WriteGetObjectResponse request
    // should be delivered and has a presigned URL in 'inputS3Url' where we can
 download the requested object from.
    const { getObjectContext } = event;
    const { outputRoute, outputToken, inputS3Url } = getObjectContext;

    // Download the object from S3 and process it as a stream, because it might be a
 huge object and we don't want to
    // buffer it in memory. Note the use of 'await' because we want to wait for
 'writeGetObjectResponse' to finish
    // before we can exit the Lambda function.
    await axios({
        method: 'GET',
        url: inputS3Url,
        responseType: 'stream',
    }).then(
        // Gzip the stream.
        response => response.data.pipe(zlib.createGzip())
    ).then(
        // Finally send the gzip-ed stream back to the client.
        stream => s3.writeGetObjectResponse({
            RequestRoute: outputRoute,
            RequestToken: outputToken,
            Body: stream,
            ContentType: "text/plain",
            ContentEncoding: "gzip",
        }).promise()
    );
```

```
    // Gracefully exit the Lambda function.
    return { statusCode: 200 };
}
```

> **Note**
>
> Although S3 Object Lambda allows up to 60 seconds to send a complete response to the caller through the `WriteGetObjectResponse` request, the actual amount of time available might be less. For example, your Lambda function timeout might be less than 60 seconds. In other cases, the caller might have more stringent timeouts.

For the original caller to receive a response other than HTTP status code 500 (Internal Server Error), the `WriteGetObjectResponse` call must be completed. If the Lambda function returns, with an exception or otherwise, before the `WriteGetObjectResponse` API operation is called, the original caller receives a 500 (Internal Server Error) response. Exceptions thrown during the time it takes to complete the response result in truncated responses to the caller. If the Lambda function receives an HTTP status code 200 (OK) response from the `WriteGetObjectResponse` API call, then the original caller has sent the complete request. The Lambda function's response, whether an exception is thrown or not, is ignored by S3 Object Lambda.

When calling the `WriteGetObjectResponse` API operation, Amazon S3 requires the route and request token from the event context. For more information, see Event context format and usage.

The route and request token parameters are required to connect the `WriteGetObjectResult` response with the original caller. Even though it is always appropriate to retry 500 (Internal Server Error) responses, because the request token is a single-use token, subsequent attempts to use it might result in HTTP status code 400 (Bad Request) responses. Although the call to `WriteGetObjectResponse` with the route and request tokens doesn't need to be made from the invoked Lambda function, it must be made by an identity in the same account. The call also must be completed before the Lambda function finishes execution.

## Working with `HeadObject` requests in Lambda

This section assumes that your Object Lambda Access Point is configured to call the Lambda function for `HeadObject`. Lambda will receive a JSON payload that contains a key called `headObjectContext`. Inside the context, there is a single property called `inputS3Url`, which is a presigned URL for the supporting access point for `HeadObject`.

The presigned URL will include the following properties if they're specified:

- `versionId` (in the query parameters)
- `requestPayer` (in the `x-amz-request-payer` header)
- `expectedBucketOwner` (in the `x-amz-expected-bucket-owner` header)

Other properties won't be presigned, and thus won't be included. Non-signed options sent as headers can be added manually to the request when calling the presigned URL that's found in the `userRequest` headers. Server-side encryption options are not supported for `HeadObject`.

For the request syntax URI parameters, see `HeadObject` in the *Amazon Simple Storage Service API Reference*.

The following example shows a Lambda JSON input payload for `HeadObject`.

```
{
  "xAmzRequestId": "requestId",
  "**headObjectContext**": {
    "**inputS3Url**": "https://my-s3-ap-111122223333.s3-accesspoint.us-
east-1.amazonaws.com/example?X-Amz-Security-Token=<snip>"
  },
  "configuration": {
        "accessPointArn": "arn:aws:s3-object-lambda:us-
east-1:111122223333:accesspoint/example-object-lambda-ap",
        "supportingAccessPointArn": "arn:aws:s3:us-
east-1:111122223333:accesspoint/example-ap",
        "payload": "{}"
  },
  "userRequest": {
        "url": "https://object-lambda-111122223333.s3-object-lambda.us-
east-1.amazonaws.com/example",
        "headers": {
            "Host": "object-lambda-111122223333.s3-object-lambda.us-
east-1.amazonaws.com",
            "Accept-Encoding": "identity",
            "X-Amz-Content-SHA256": "e3b0c44298fc1example"
        }
   },
   "userIdentity": {
        "type": "AssumedRole",
        "principalId": "principalId",
```

```
        "arn": "arn:aws:sts::111122223333:assumed-role/Admin/example",
        "accountId": "111122223333",
        "accessKeyId": "accessKeyId",
        "sessionContext": {
             "attributes": {
             "mfaAuthenticated": "false",
             "creationDate": "Wed Mar 10 23:41:52 UTC 2021"
        },
        "sessionIssuer": {
             "type": "Role",
             "principalId": "principalId",
             "arn": "arn:aws:iam::111122223333:role/Admin",
             "accountId": "111122223333",
             "userName": "Admin"
             }
        }
    },
  "protocolVersion": "1.00"
}
```

Your Lambda function should return a JSON object that contains the headers and values that will be returned for the `HeadObject` call.

The following example shows the structure of the Lambda response JSON for `HeadObject`.

```
{
    "statusCode": <number>; // Required
    "errorCode": <string>;
    "errorMessage": <string>;
    "headers": {
        "Accept-Ranges": <string>,
        "x-amz-archive-status": <string>,
        "x-amz-server-side-encryption-bucket-key-enabled": <boolean>,
        "Cache-Control": <string>,
        "Content-Disposition": <string>,
        "Content-Encoding": <string>,
        "Content-Language": <string>,
        "Content-Length": <number>, // Required
        "Content-Type": <string>,
        "x-amz-delete-marker": <boolean>,
        "ETag": <string>,
        "Expires": <string>,
        "x-amz-expiration": <string>,
```

```
        "Last-Modified": <string>,
        "x-amz-missing-meta": <number>,
        "x-amz-object-lock-mode": <string>,
        "x-amz-object-lock-legal-hold": <string>,
        "x-amz-object-lock-retain-until-date": <string>,
        "x-amz-mp-parts-count": <number>,
        "x-amz-replication-status": <string>,
        "x-amz-request-charged": <string>,
        "x-amz-restore": <string>,
        "x-amz-server-side-encryption": <string>,
        "x-amz-server-side-encryption-customer-algorithm": <string>,
        "x-amz-server-side-encryption-aws-kms-key-id": <string>,
        "x-amz-server-side-encryption-customer-key-MD5": <string>,
        "x-amz-storage-class": <string>,
        "x-amz-tagging-count": <number>,
        "x-amz-version-id": <string>,
        <x-amz-meta-headers>: <string>, // user-defined metadata
        "x-amz-meta-meta1": <string>, // example of the user-defined metadata header,
 it will need the x-amz-meta prefix
        "x-amz-meta-meta2": <string>
        ...
    };
}
```

The following example shows how to use the presigned URL to populate your response by modifying the header values as needed before returning the JSON.

Python

```
import requests

def lambda_handler(event, context):
    print(event)

    # Extract the presigned URL from the input.
    s3_url = event["headObjectContext"]["inputS3Url"]

    # Get the head of the object from S3.
    response = requests.head(s3_url)

    # Return the error to S3 Object Lambda (if applicable).
    if (response.status_code >= 400):
        return {
```

```
            "statusCode": response.status_code,
            "errorCode": "RequestFailure",
            "errorMessage": "Request to S3 failed"
    }

    # Store the headers in a dictionary.
    response_headers = dict(response.headers)

    # This obscures Content-Type in a transformation, it is optional to add
    response_headers["Content-Type"] = ""

    # Return the headers to S3 Object Lambda.
    return {
        "statusCode": response.status_code,
        "headers": response_headers
        }
```

## Working with `ListObjects` requests in Lambda

This section assumes that your Object Lambda Access Point is configured to call the Lambda function for `ListObjects`. Lambda will receive the JSON payload with a new object named `listObjectsContext`. `listObjectsContext`contains a single property, `inputS3Url`, which is a presigned URL for the supporting access point for `ListObjects`.

Unlike `GetObject` and `HeadObject`, the presigned URL will include the following properties if they're specified:

- All the query parameters
- `requestPayer` (in the `x-amz-request-payer` header)
- `expectedBucketOwner` (in the `x-amz-expected-bucket-owner` header)

For the request syntax URI parameters, see `ListObjects` in the *Amazon Simple Storage Service API Reference*.

> **Important**
>
> We recommend that you use the newer version, ListObjectsV2, when developing applications. For backward compatibility, Amazon S3 continues to support `ListObjects`.

The following example shows the Lambda JSON input payload for `ListObjects`.

```
{
    "xAmzRequestId": "requestId",
     "**listObjectsContext**": {
     "**inputS3Url**": "https://my-s3-ap-111122223333.s3-accesspoint.us-
east-1.amazonaws.com/?X-Amz-Security-Token=<snip>",
     },
    "configuration": {
        "accessPointArn": "arn:aws:s3-object-lambda:us-
east-1:111122223333:accesspoint/example-object-lambda-ap",
        "supportingAccessPointArn": "arn:aws:s3:us-
east-1:111122223333:accesspoint/example-ap",
        "payload": "{}"
    },
    "userRequest": {
        "url": "https://object-lambda-111122223333.s3-object-lambda.us-
east-1.amazonaws.com/example",
        "headers": {
            "Host": "object-lambda-111122223333.s3-object-lambda.us-
east-1.amazonaws.com",
            "Accept-Encoding": "identity",
            "X-Amz-Content-SHA256": "e3b0c44298fc1example"
        }
    },
    "userIdentity": {
        "type": "AssumedRole",
        "principalId": "principalId",
        "arn": "arn:aws:sts::111122223333:assumed-role/Admin/example",
        "accountId": "111122223333",
        "accessKeyId": "accessKeyId",
        "sessionContext": {
            "attributes": {
                "mfaAuthenticated": "false",
                "creationDate": "Wed Mar 10 23:41:52 UTC 2021"
            },
            "sessionIssuer": {
                "type": "Role",
                "principalId": "principalId",
                "arn": "arn:aws:iam::111122223333:role/Admin",
                "accountId": "111122223333",
                "userName": "Admin"
            }
        }
```

```
    },
  "protocolVersion": "1.00"
}
```

Your Lambda function should return a JSON object that contains the status code, list XML result, or error information that will be returned from S3 Object Lambda.

S3 Object Lambda does not process or validate `listResultXml`, but instead forwards it to `ListObjects` caller. For `listBucketResult`, S3 Object Lambda expects certain properties to be of a specific type and will throw exceptions if it cannot parse them. `listResultXml` and `listBucketResult` can not be provided at the same time.

The following example demonstrates how to use the presigned URL to call Amazon S3 and use the result to populate a response, including error checking.

Python

```
import requests
import xmltodict

def lambda_handler(event, context):
    # Extract the presigned URL from the input.
    s3_url = event["listObjectsContext"]["inputS3Url"]

    # Get the head of the object from Amazon S3.
    response = requests.get(s3_url)

    # Return the error to S3 Object Lambda (if applicable).
    if (response.status_code >= 400):
        error = xmltodict.parse(response.content)
        return {
            "statusCode": response.status_code,
            "errorCode": error["Error"]["Code"],
            "errorMessage": error["Error"]["Message"]
        }

    # Store the XML result in a dict.
    response_dict = xmltodict.parse(response.content)

    # This obscures StorageClass in a transformation, it is optional to add
    for item in response_dict['ListBucketResult']['Contents']:
        item['StorageClass'] = ""
```

```
    # Convert back to XML.
    listResultXml = xmltodict.unparse(response_dict)

    # Create response with listResultXml.
    response_with_list_result_xml = {
        'statusCode': 200,
        'listResultXml': listResultXml
    }

    # Create response with listBucketResult.
    response_dict['ListBucketResult'] =
 sanitize_response_dict(response_dict['ListBucketResult'])
    response_with_list_bucket_result = {
        'statusCode': 200,
        'listBucketResult': response_dict['ListBucketResult']
    }

    # Return the list to S3 Object Lambda.
    # Can return response_with_list_result_xml or response_with_list_bucket_result
    return response_with_list_result_xml

# Converting the response_dict's key to correct casing
def sanitize_response_dict(response_dict: dict):
    new_response_dict = dict()
    for key, value in response_dict.items():
        new_key = key[0].lower() + key[1:] if key != "ID" else 'id'
        if type(value) == list:
            newlist = []
            for element in value:
                if type(element) == type(dict()):
                    element = sanitize_response_dict(element)
                newlist.append(element)
            value = newlist
        elif type(value) == dict:
            value = sanitize_response_dict(value)
        new_response_dict[new_key] = value
    return new_response_dict
```

The following example shows the structure of the Lambda response JSON for `ListObjects`.

```
{
```

```
  "statusCode": <number>; // Required
  "errorCode": <string>;
  "errorMessage": <string>;
  "listResultXml": <string>; // This can also be Error XML string in case S3 returned
 error response when calling the pre-signed URL

  "listBucketResult": {  // listBucketResult can be provided instead of listResultXml,
 however they can not both be provided in the JSON response
        "name": <string>,  // Required for 'listBucketResult'
        "prefix": <string>,
        "marker": <string>,
        "nextMarker": <string>,
        "maxKeys": <int>,   // Required for 'listBucketResult'
        "delimiter": <string>,
        "encodingType": <string>
        "isTruncated": <boolean>,  // Required for 'listBucketResult'
        "contents": [  {
            "key": <string>,  // Required for 'content'
            "lastModified": <string>,
            "eTag": <string>,
            "checksumAlgorithm": <string>,   // CRC32,  CRC32C,  SHA1,  SHA256
            "size": <int>,   // Required for 'content'
            "owner": {
                "displayName": <string>,  // Required for 'owner'
                "id": <string>,  // Required for 'owner'
            },
            "storageClass": <string>
            },
        ...
        ],
        "commonPrefixes": [  {
            "prefix": <string>   // Required for 'commonPrefix'
        },
        ...
        ],
    }
}
```

## Working with `ListObjectsV2` requests in Lambda

This section assumes that your Object Lambda Access Point is configured to call the Lambda function for `ListObjectsV2`. Lambda will receive the JSON payload with a new object named

`listObjectsV2Context`. `listObjectsV2Context` contains a single property, `inputS3Url`, which is a presigned URL for the supporting access point for `ListObjectsV2`.

Unlike `GetObject` and `HeadObject`, the presigned URL will include the following properties, if they're specified:

- All the query parameters
- `requestPayer` (in the `x-amz-request-payer` header)
- `expectedBucketOwner` (in the `x-amz-expected-bucket-owner` header)

For the request syntax URI parameters, see `ListObjectsV2` in the *Amazon Simple Storage Service API Reference*.

The following example shows the Lambda JSON input payload for `ListObjectsV2`.

```
{
    "xAmzRequestId": "requestId",
     "**listObjectsV2Context**": {
     "**inputS3Url**": "https://my-s3-ap-111122223333.s3-accesspoint.us-
east-1.amazonaws.com/?list-type=2&X-Amz-Security-Token=<snip>",
     },
    "configuration": {
        "accessPointArn": "arn:aws:s3-object-lambda:us-
east-1:111122223333:accesspoint/example-object-lambda-ap",
        "supportingAccessPointArn": "arn:aws:s3:us-
east-1:111122223333:accesspoint/example-ap",
        "payload": "{}"
    },
    "userRequest": {
        "url": "https://object-lambda-111122223333.s3-object-lambda.us-
east-1.amazonaws.com/example",
        "headers": {
            "Host": "object-lambda-111122223333.s3-object-lambda.us-
east-1.amazonaws.com",
            "Accept-Encoding": "identity",
            "X-Amz-Content-SHA256": "e3b0c44298fc1example"
        }
    },
    "userIdentity": {
        "type": "AssumedRole",
        "principalId": "principalId",
        "arn": "arn:aws:sts::111122223333:assumed-role/Admin/example",
```

```
        "accountId": "111122223333",
        "accessKeyId": "accessKeyId",
        "sessionContext": {
            "attributes": {
                "mfaAuthenticated": "false",
                "creationDate": "Wed Mar 10 23:41:52 UTC 2021"
            },
            "sessionIssuer": {
                "type": "Role",
                "principalId": "principalId",
                "arn": "arn:aws:iam::111122223333:role/Admin",
                "accountId": "111122223333",
                "userName": "Admin"
            }
        }
    },
  "protocolVersion": "1.00"
}
```

Your Lambda function should return a JSON object that contains the status code, list XML result, or error information that will be returned from S3 Object Lambda.

S3 Object Lambda does not process or validate `listResultXml`, but instead forwards it to `ListObjectsV2` caller. For `listBucketResult`, S3 Object Lambda expects certain properties to be of a specific type and will throw exceptions if it cannot parse them. `listResultXml` and `listBucketResult` can not be provided at the same time.

The following example demonstrates how to use the presigned URL to call Amazon S3 and use the result to populate a response, including error checking.

Python

```
import requests
import xmltodict

def lambda_handler(event, context):
    # Extract the presigned URL from the input.
    s3_url = event["listObjectsV2Context"]["inputS3Url"]

    # Get the head of the object from Amazon S3.
    response = requests.get(s3_url)
```

```
    # Return the error to S3 Object Lambda (if applicable).
    if (response.status_code >= 400):
        error = xmltodict.parse(response.content)
        return {
            "statusCode": response.status_code,
            "errorCode": error["Error"]["Code"],
            "errorMessage": error["Error"]["Message"]
        }

    # Store the XML result in a dict.
    response_dict = xmltodict.parse(response.content)

    # This obscures StorageClass in a transformation, it is optional to add
    for item in response_dict['ListBucketResult']['Contents']:
        item['StorageClass'] = ""

    # Convert back to XML.
    listResultXml = xmltodict.unparse(response_dict)

    # Create response with listResultXml.
    response_with_list_result_xml = {
        'statusCode': 200,
        'listResultXml': listResultXml
    }

    # Create response with listBucketResult.
    response_dict['ListBucketResult'] =
 sanitize_response_dict(response_dict['ListBucketResult'])
    response_with_list_bucket_result = {
        'statusCode': 200,
        'listBucketResult': response_dict['ListBucketResult']
    }

    # Return the list to S3 Object Lambda.
    # Can return response_with_list_result_xml or response_with_list_bucket_result
    return response_with_list_result_xml

# Converting the response_dict's key to correct casing
def sanitize_response_dict(response_dict: dict):
    new_response_dict = dict()
    for key, value in response_dict.items():
        new_key = key[0].lower() + key[1:] if key != "ID" else 'id'
        if type(value) == list:
            newlist = []
```

```
            for element in value:
                if type(element) == type(dict()):
                    element = sanitize_response_dict(element)
                newlist.append(element)
            value = newlist
        elif type(value) == dict:
            value = sanitize_response_dict(value)
        new_response_dict[new_key] = value
    return new_response_dict
```

The following example shows the structure of the Lambda response JSON for `ListObjectsV2`.

```
{
    "statusCode": <number>; // Required
    "errorCode": <string>;
    "errorMessage": <string>;
    "listResultXml": <string>; // This can also be Error XML string in case S3 returned
 error response when calling the pre-signed URL

    "listBucketResult": {  // listBucketResult can be provided instead of
 listResultXml, however they can not both be provided in the JSON response
        "name": <string>, // Required for 'listBucketResult'
        "prefix": <string>,
        "startAfter": <string>,
        "continuationToken": <string>,
        "nextContinuationToken": <string>,
        "keyCount": <int>, // Required for 'listBucketResult'
        "maxKeys": <int>, // Required for 'listBucketResult'
        "delimiter": <string>,
        "encodingType": <string>
        "isTruncated": <boolean>, // Required for 'listBucketResult'
        "contents": [ {
            "key": <string>, // Required for 'content'
            "lastModified": <string>,
            "eTag": <string>,
            "checksumAlgorithm": <string>, // CRC32, CRC32C, SHA1, SHA256
            "size": <int>, // Required for 'content'
            "owner": {
                "displayName": <string>, // Required for 'owner'
                "id": <string>, // Required for 'owner'
            },
            "storageClass": <string>
```

```
            },
            ...
        ],
        "commonPrefixes": [ {
            "prefix": <string> // Required for 'commonPrefix'
            },
        ...
        ],
    }
}
```

## Event context format and usage

Amazon S3 Object Lambda provides context about the request that's being made in the event that's passed to your AWS Lambda function. The following shows an example request. Descriptions of the fields are included after the example.

```
{
    "xAmzRequestId": "requestId",
    "getObjectContext": {
        "inputS3Url": "https://my-s3-ap-111122223333.s3-accesspoint.us-
east-1.amazonaws.com/example?X-Amz-Security-Token=<snip>",
        "outputRoute": "io-use1-001",
        "outputToken": "OutputToken"
    },
    "configuration": {
        "accessPointArn": "arn:aws:s3-object-lambda:us-
east-1:111122223333:accesspoint/example-object-lambda-ap",
        "supportingAccessPointArn": "arn:aws:s3:us-
east-1:111122223333:accesspoint/example-ap",
        "payload": "{}"
    },
    "userRequest": {
        "url": "https://object-lambda-111122223333.s3-object-lambda.us-
east-1.amazonaws.com/example",
        "headers": {
            "Host": "object-lambda-111122223333.s3-object-lambda.us-
east-1.amazonaws.com",
            "Accept-Encoding": "identity",
            "X-Amz-Content-SHA256": "e3b0c44298fc1example"
        }
    },
    "userIdentity": {
```

```
        "type": "AssumedRole",
        "principalId": "principalId",
        "arn": "arn:aws:sts::111122223333:assumed-role/Admin/example",
        "accountId": "111122223333",
        "accessKeyId": "accessKeyId",
        "sessionContext": {
            "attributes": {
                "mfaAuthenticated": "false",
                "creationDate": "Wed Mar 10 23:41:52 UTC 2021"
            },
            "sessionIssuer": {
                "type": "Role",
                "principalId": "principalId",
                "arn": "arn:aws:iam::111122223333:role/Admin",
                "accountId": "111122223333",
                "userName": "Admin"
            }
        }
    },
    "protocolVersion": "1.00"
}
```

The following fields are included in the request:

- `xAmzRequestId` – The Amazon S3 request ID for this request. We recommend that you log this value to help with debugging.
- `getObjectContext` – The input and output details for connections to Amazon S3 and S3 Object Lambda.
  - `inputS3Url` – A presigned URL that can be used to fetch the original object from Amazon S3. The URL is signed by using the original caller's identity, and that user's permissions will apply when the URL is used. If there are signed headers in the URL, the Lambda function must include these headers in the call to Amazon S3, except for the `Host` header.
  - `outputRoute` – A routing token that is added to the S3 Object Lambda URL when the Lambda function calls `WriteGetObjectResponse`.
  - `outputToken` – An opaque token that's used by S3 Object Lambda to match the `WriteGetObjectResponse` call with the original caller.
- `configuration` – Configuration information about the Object Lambda Access Point.
  - `accessPointArn` – The Amazon Resource Name (ARN) of the Object Lambda Access Point that received this request.

  - `supportingAccessPointArn` – The ARN of the supporting access point that is specified in the Object Lambda Access Point configuration.
  - `payload` – Custom data that is applied to the Object Lambda Access Point configuration. S3 Object Lambda treats this data as an opaque string, so it might need to be decoded before use.
- `userRequest` – Information about the original call to S3 Object Lambda.
  - `url` – The decoded URL of the request as received by S3 Object Lambda, excluding any authorization-related query parameters.
  - `headers` – A map of string to strings containing the HTTP headers and their values from the original call, excluding any authorization-related headers. If the same header appears multiple times, the values from each instance of the same header are combined into a comma-delimited list. The case of the original headers is retained in this map.
- `userIdentity` – Details about the identity that made the call to S3 Object Lambda. For more information, see Logging data events for trails in the *AWS CloudTrail User Guide*.
  - `type` – The type of identity.
  - `accountId` – The AWS account to which the identity belongs.
  - `userName` – The friendly name of the identity that made the call.
  - `principalId` – The unique identifier for the identity that made the call.
  - `arn` – The ARN of the principal who made the call. The last section of the ARN contains the user or role that made the call.
  - `sessionContext` – If the request was made with temporary security credentials, this element provides information about the session that was created for those credentials.
  - `invokedBy` – The name of the AWS service that made the request, such as Amazon EC2 Auto Scaling or AWS Elastic Beanstalk.
  - `sessionIssuer` – If the request was made with temporary security credentials, this element provides information about how the credentials were obtained.
- `protocolVersion` – The version ID of the context provided. The format of this field is `{Major Version}.{Minor Version}`. The minor version numbers are always two-digit numbers. Any removal or change to the semantics of a field necessitates a major version bump and requires active opt-in. Amazon S3 can add new fields at any time, at which point you might experience a minor version bump. Because of the nature of software rollouts, you might see multiple minor versions in use at once.

## Working with Range and partNumber headers

When working with large objects in Amazon S3 Object Lambda, you can use the `Range` HTTP header to download a specified byte range from an object. To fetch different byte ranges from within the same object, you can use concurrent connections to Amazon S3. You can also specify the `partNumber` parameter (an integer between 1 and 10,000), which performs a ranged request for the specified part of the object.

Because there are multiple ways that you might want to handle a request that includes the `Range` or `partNumber` parameters, S3 Object Lambda doesn't apply these parameters to the transformed object. Instead, your AWS Lambda function must implement this functionality as needed for your application.

To use the `Range` and `partNumber` parameters with S3 Object Lambda, you do the following:

- Enable these parameters in your Object Lambda Access Point configuration.
- Write a Lambda function that can handle requests that include these parameters.

The following steps describe how to accomplish this.

### Step 1: Configure your Object Lambda Access Point

By default, Object Lambda Access Points respond with an HTTP status code 501 (Not Implemented) error to any `GetObject` or `HeadObject` request that contains a `Range` or `partNumber` parameter, either in the headers or query parameters.

To enable an Object Lambda Access Point to accept such requests, you must include `GetObject-Range`, `GetObject-PartNumber`, `HeadObject-Range`, or `HeadObject-PartNumber` in the `AllowedFeatures` section of your Object Lambda Access Point configuration. For more information about updating your Object Lambda Access Point configuration, see Creating Object Lambda Access Points.

### Step 2: Implement Range or `partNumber` handling in your Lambda function

When your Object Lambda Access Point invokes your Lambda function with a ranged `GetObject` or `HeadObject` request, the `Range` or `partNumber` parameter is included in the event context. The location of the parameter in the event context depends on which parameter was used and how it was included in the original request to the Object Lambda Access Point, as explained in the following table.

| Parameter | Event context location |
| --- | --- |
| Range (header) | `userRequest.headers.Range` |
| Range (query parameter) | `userRequest.url` (query parameter Range) |
| `partNumber` | `userRequest.url` (query parameter `partNumber` ) |

**Important**

The provided presigned URL for your Object Lambda Access Point doesn't contain the Range or `partNumber` parameter from the original request. See the following options on how to handle these parameters in your AWS Lambda function.

After you extract the Range or `partNumber` value, you can take one of the following approaches, based on your application's needs:

A. **Map the requested Range or `partNumber` to the transformed object (recommended).**

The most reliable way to handle Range or `partNumber` requests is to do the following:

- Retrieve the full object from Amazon S3.
- Transform the object.
- Apply the requested Range or `partNumber` parameters to the transformed object.

To do this, use the provided presigned URL to fetch the entire object from Amazon S3 and then process the object as needed. For an example Lambda function that processes a Range parameter in this way, see this sample in the AWS Samples GitHub repository.

B. **Map the requested Range to the presigned URL.**

In some cases, your Lambda function can map the requested Range directly to the presigned URL to retrieve only part of the object from Amazon S3. This approach is appropriate only if your transformation meets both of the following criteria:

1. Your transformation function can be applied to partial object ranges.

2. Applying the Range parameter before or after the transformation function results in the same transformed object.

For example, a transformation function that converts all characters in an ASCII-encoded object to uppercase meets both of the preceding criteria. The transformation can be applied to part of an object, and applying the Range parameter before the transformation achieves the same result as applying it after the transformation.

By contrast, a function that reverses the characters in an ASCII-encoded object doesn't meet these criteria. Such a function meets criterion 1, because it can be applied to partial object ranges. However, it doesn't meet criterion 2, because applying the Range parameter before the transformation achieves different results than applying the parameter after the transformation.

Consider a request to apply the function to the first three characters of an object with the contents `abcdefg`. Applying the Range parameter before the transformation retrieves only `abc` and then reverses the data, returning `cba`. But if the parameter is applied after the transformation, the function retrieves the entire object, reverses it, and then applies the Range parameter, returning `gfe`. Because these results are different, this function should not apply the Range parameter when retrieving the object from Amazon S3. Instead, it should retrieve the entire object, perform the transformation, and only then apply the Range parameter.

> **Warning**
>
> In many cases, applying the Range parameter to the presigned URL will result in unexpected behavior by the Lambda function or the requesting client. Unless you are sure that your application will work properly when retrieving only a partial object from Amazon S3, we recommend that you retrieve and transform full objects as described earlier in approach A.

If your application meets the criteria described earlier in approach B, you can simplify your AWS Lambda function by fetching only the requested object range and then running your transformation on that range.

The following Java code example demonstrates how to do the following:

- Retrieve the Range header from the `GetObject` request.

- Add the Range header to the presigned URL that Lambda can use to retrieve the requested range from Amazon S3.

```
private HttpRequest.Builder applyRangeHeader(ObjectLambdaEvent event,
 HttpRequest.Builder presignedRequest) {
    var header = event.getUserRequest().getHeaders().entrySet().stream()
            .filter(e -> e.getKey().toLowerCase(Locale.ROOT).equals("range"))
            .findFirst();

    // Add check in the query string itself.
    header.ifPresent(entry -> presignedRequest.header(entry.getKey(),
 entry.getValue()));
    return presignedRequest;
}
```

## Using AWS built Lambda functions

AWS provides some prebuilt AWS Lambda functions that you can use with Amazon S3 Object Lambda to detect and redact personally identifiable information (PII) and decompress S3 objects. These Lambda functions are available in the AWS Serverless Application Repository. You can select these functions through the AWS Management Console when you create your Object Lambda Access Point.

For more information about how to deploy serverless applications from the AWS Serverless Application Repository, see Deploying Applications in the *AWS Serverless Application Repository Developer Guide*.

> **Note**
>
> The following examples can be used only with `GetObject` requests.

### Example 1: PII access control

This Lambda function uses Amazon Comprehend, a natural language processing (NLP) service that uses machine learning to find insights and relationships in text. This function automatically detects personally identifiable information (PII), such as names, addresses, dates, credit card numbers, and social security numbers in documents in your Amazon S3 bucket. If you have documents in your

bucket that include PII, you can configure the PII Access Control function to detect these PII entity types and restrict access to unauthorized users.

To get started, deploy the following Lambda function in your account and add the Amazon Resource Name (ARN) for the function to your Object Lambda Access Point configuration.

The following is an example ARN for this function:

```
arn:aws:serverlessrepo:us-east-1:111122223333:applications/
ComprehendPiiAccessControlS3ObjectLambda
```

You can add or view this function on the AWS Management Console by using the following AWS Serverless Application Repository link: ComprehendPiiAccessControlS3ObjectLambda.

To view this function on GitHub, see Amazon Comprehend S3 Object Lambda.

### Example 2: PII redaction

This Lambda function uses Amazon Comprehend, a natural language processing (NLP) service that uses machine learning to find insights and relationships in text. This function automatically redacts personally identifiable information (PII), such as names, addresses, dates, credit card numbers, and social security numbers from documents in your Amazon S3 bucket.

If you have documents in your bucket that include information such as credit card numbers or bank account information, you can configure the PII Redaction S3 Object Lambda function to detect PII and then return a copy of these documents in which PII entity types are redacted.

To get started, deploy the following Lambda function in your account and add the ARN for the function to your Object Lambda Access Point configuration.

The following is an example ARN for this function:

```
arn:aws:serverlessrepo:us-east-1:111122223333::applications/
ComprehendPiiRedactionS3ObjectLambda
```

You can add or view this function on the AWS Management Console by using the following AWS Serverless Application Repository link: ComprehendPiiRedactionS3ObjectLambda.

To view this function on GitHub, see Amazon Comprehend S3 Object Lambda.

To learn about complete end-to-end procedures for some S3 Object Lambda tasks in PII redaction, see Tutorial: Detecting and redacting PII data with S3 Object Lambda and Amazon Comprehend.

### Example 3: Decompression

The Lambda function `S3ObjectLambdaDecompression` can decompress objects that are stored in Amazon S3 in one of six compressed file formats: `bzip2`, `gzip`, `snappy`, `zlib`, `zstandard`, and `ZIP`.

To get started, deploy the following Lambda function in your account and add the ARN for the function to your Object Lambda Access Point configuration.

The following is an example ARN for this function:

```
arn:aws:serverlessrepo:us-east-1:111122223333::applications/S3ObjectLambdaDecompression
```

You can add or view this function on the AWS Management Console by using the following AWS Serverless Application Repository link: S3ObjectLambdaDecompression.

To view this function on GitHub, see S3 Object Lambda Decompression.

## Best practices and guidelines for S3 Object Lambda

When using S3 Object Lambda, follow these best practices and guidelines to optimize operations and performance.

**Topics**

- Working with S3 Object Lambda
- AWS services used in connection with S3 Object Lambda
- Range and partNumber headers
- Transforming the expiry-date
- Working with the AWS CLI and AWS SDKs

### Working with S3 Object Lambda

S3 Object Lambda supports processing only `GET`, `LIST`, and `HEAD` requests. Any other requests don't invoke AWS Lambda and instead return standard, non-transformed API responses. You can create a maximum of 1,000 Object Lambda Access Points per AWS account per Region. The AWS

Lambda function that you use must be in the same AWS account and Region as the Object Lambda Access Point.

S3 Object Lambda allows up to 60 seconds to stream a complete response to its caller. Your function is also subject to AWS Lambda default quotas. For more information, see Lambda quotas in the *AWS Lambda Developer Guide*.

When S3 Object Lambda invokes your specified Lambda function, you are responsible for ensuring that any data that is overwritten or deleted from Amazon S3 by your specified Lambda function or application is intended and correct.

You can use S3 Object Lambda only to perform operations on objects. You cannot use S3 Object Lambda to perform other Amazon S3 operations, such as modifying or deleting buckets. For a complete list of S3 operations that support access points, see Access point compatibility with S3 operations.

In addition to this list, Object Lambda Access Points do not support the `POST Object`, `CopyObject` (as the source), and `SelectObjectContent` API operations.

### AWS services used in connection with S3 Object Lambda

S3 Object Lambda connects Amazon S3, AWS Lambda, and optionally, other AWS services of your choosing to deliver objects relevant to the requesting applications. All AWS services used with S3 Object Lambda are governed by their respective Service Level Agreements (SLAs). For example, if any AWS service does not meet its Service Commitment, you are eligible to receive a Service Credit, as documented in the service's SLA.

### Range and `partNumber` headers

When working with large objects, you can use the `Range` HTTP header to download a specified byte-range from an object. When you use the `Range` header, your request fetches only the specified portion of the object. You can also use the `partNumber` header to perform a ranged request for the specified part from the object.

For more information see, Working with Range and partNumber headers.

### Transforming the `expiry-date`

You can open or download transformed objects from your Object Lambda Access Point on the AWS Management Console. These objects must be non-expired. If your Lambda function transforms

the `expiry-date` of your objects, you might see expired objects that cannot be opened or downloaded. This behavior applies only to S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive restored objects.

### Working with the AWS CLI and AWS SDKs

AWS Command Line Interface (AWS CLI) S3 subcommands (`cp`, `mv`, and `sync`) and the use of the AWS SDK for Java `TransferManager` class are not supported for use with S3 Object Lambda.

## S3 Object Lambda tutorials

The following tutorials present complete end-to-end procedures for some S3 Object Lambda tasks.

- Tutorial: Transforming data for your application with S3 Object Lambda
- Tutorial: Detecting and redacting PII data with S3 Object Lambda and Amazon Comprehend
- Tutorial: Using S3 Object Lambda to dynamically watermark images as they are retrieved

## Debugging S3 Object Lambda

Requests to Amazon S3 Object Lambda access points might result in a new error response when something goes wrong with the Lambda function invocation or execution. These errors follow the same format as standard Amazon S3 errors. For information about S3 Object Lambda errors, see S3 Object Lambda Error Code List in the *Amazon Simple Storage Service API Reference*.

For more information about general Lambda function debugging, see Monitoring and troubleshooting Lambda applications in the *AWS Lambda Developer Guide*.

For information about standard Amazon S3 errors, see Error Responses in the *Amazon Simple Storage Service API Reference*.

You can enable request metrics in Amazon CloudWatch for your Object Lambda Access Points. These metrics help you monitor the operational performance of your access point. You can enable request metrics during or after creation of your Object Lambda Access Point. For more information, see S3 Object Lambda request metrics in CloudWatch.

To get more granular logging about requests made to your Object Lambda Access Points, you can enable AWS CloudTrail data events. For more information, see Logging data events for trails in the *AWS CloudTrail User Guide*.

For S3 Object Lambda tutorials, see the following:

- Tutorial: Transforming data for your application with S3 Object Lambda
- Tutorial: Detecting and redacting PII data with S3 Object Lambda and Amazon Comprehend
- Tutorial: Using S3 Object Lambda to dynamically watermark images as they are retrieved

For more information about standard access points, see Managing data access with Amazon S3 access points.

For information about working with buckets, see Buckets overview. For information about working with objects, see Amazon S3 objects overview.

# What is S3 Express One Zone?

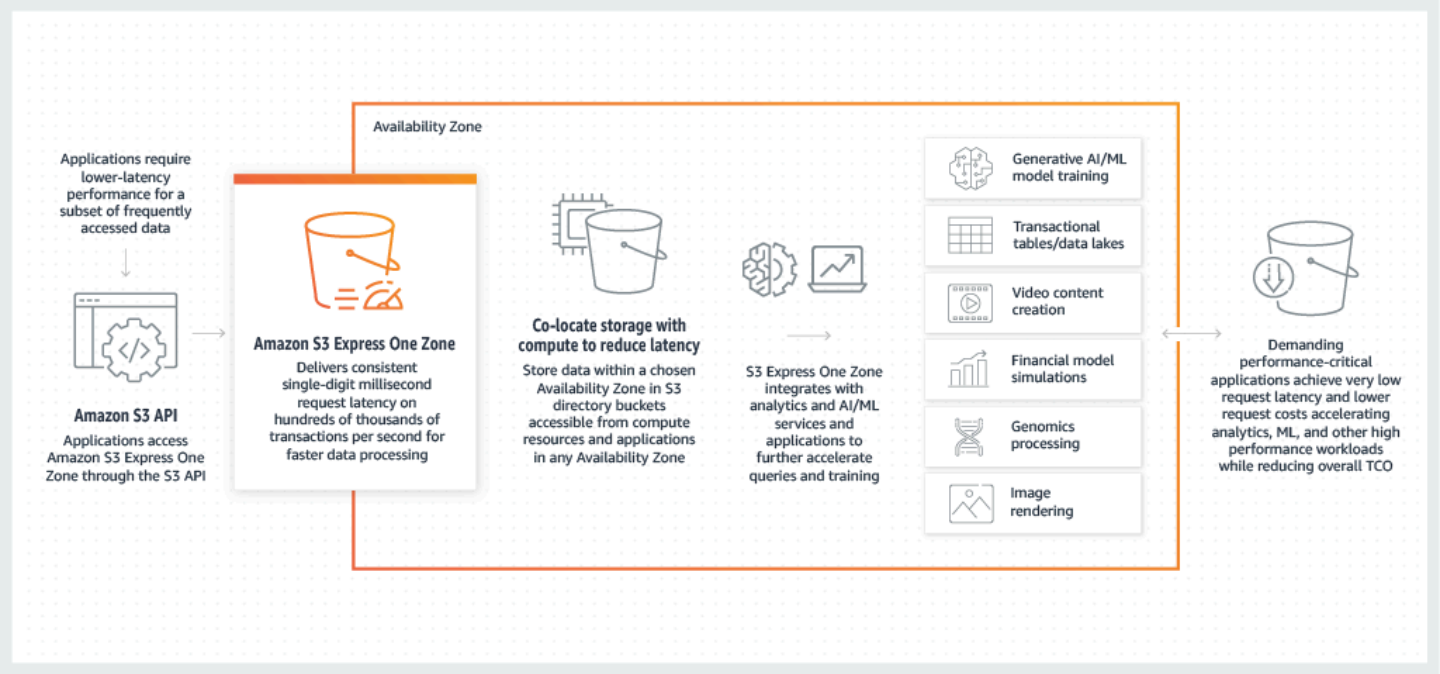
Amazon S3 Express One Zone is a high-performance, single-zone Amazon S3 storage class that is purpose-built to deliver consistent, single-digit millisecond data access for your most latency-sensitive applications. S3 Express One Zone is the lowest latency cloud-object storage class available today, with data access speeds up to 10x faster and with request costs 50 percent lower than S3 Standard. Applications can benefit immediately from requests being completed up to an order of magnitude faster. S3 Express One Zone provides similar performance elasticity as other S3 storage classes.

As with other Amazon S3 storage classes, you don't need to plan or provision capacity or throughput requirements in advance. You can scale your storage up or down, based on need, and access your data through the Amazon S3 API.

S3 Express One Zone is the first S3 storage class where you can select a single Availability Zone with the option to co-locate your object storage with your compute resources, which provides the highest possible access speed. Additionally, to further increase access speed and support hundreds of thousands of requests per second, data in S3 Express One Zone storage class is stored in a new bucket type: an Amazon S3 directory bucket. Each directory bucket can support hundreds of thousands of transactions per second (TPS), irrespective of key names or access pattern.

The Amazon S3 Express One Zone storage class is designed for 99.95 percent availability within a single Availability Zone and is backed by the Amazon S3 Service Level Agreement. With S3 Express One Zone, your data is redundantly stored on multiple devices within a single Availability Zone. S3 Express One Zone is designed to handle concurrent device failures by quickly detecting and repairing any lost redundancy. If the existing device encounters a failure, S3 Express One Zone automatically shifts requests to new devices within an Availability Zone. This redundancy helps ensure uninterrupted access to your data within an Availability Zone.

S3 Express One Zone is ideal for any application where it's important to minimize the latency required to access an object. Such applications can be human-interactive workflows, like video editing, where creative professionals need responsive access to content from their user interfaces. S3 Express One Zone also benefits analytics and machine learning workloads that have similar responsiveness requirements from their data, especially workloads with lots of smaller accesses or large numbers of random accesses. S3 Express One Zone can be used with other AWS services to support analytics and artificial intelligence and machine learning (AI/ML) workloads, such as Amazon EMR, Amazon SageMaker, and Amazon Athena.



When using S3 Express One Zone, you can interact with your directory bucket in a virtual private cloud (VPC) by using a gateway VPC endpoint. With a gateway endpoint, you can access S3 Express One Zone directory buckets from your VPC without an internet gateway or NAT device for your VPC, and at no additional cost.

You can use many of the same Amazon S3 API operations and features with directory buckets that you use with general purpose buckets and other storage classes. These include Mountpoint for Amazon S3, server-side encryption with Amazon S3 managed keys (SSE-S3), S3 Batch Operations, and S3 Block Public Access. You can access S3 Express One Zone by using the Amazon S3 console, AWS Command Line Interface (AWS CLI), AWS SDKs, and the Amazon S3 REST API.

For more information about S3 Express One Zone, see the following topics.

- Overview
- Features of S3 Express One Zone
- Related services
- Next steps

# Overview

To optimize performance and reduce latency, S3 Express One Zone introduces the following new concepts.

## Single Availability Zone

The Amazon S3 Express One Zone storage class is designed for 99.95 percent availability within a single Availability Zone and is backed by the Amazon S3 Service Level Agreement. With S3 Express One Zone, your data is redundantly stored on multiple devices within a single Availability Zone. S3 Express One Zone is designed to handle concurrent device failures by quickly detecting and repairing any lost redundancy. If the existing device encounters a failure, S3 Express One Zone automatically shifts requests to new devices within an Availability Zone. This redundancy helps ensure uninterrupted access to your data within an Availability Zone.

An Availability Zone is one or more discrete data centers with redundant power, networking, and connectivity in an AWS Region. When you create a directory bucket, you choose the Availability Zone and AWS Region where your bucket will be located.

## Directory buckets

There are two types of Amazon S3 buckets: S3 general purpose buckets and S3 directory buckets. General purpose buckets are the default Amazon S3 bucket type that is used for the vast majority of S3 use cases. Directory buckets use only the S3 Express One Zone storage class, which is designed for workloads or performance-critical applications that require consistent single-digit millisecond latency. Choose the bucket type that best fits your application and performance requirements.

Directory buckets organize data hierarchically into directories, as opposed to the flat storage structure of general purpose buckets. There aren't prefix limits for directory buckets, and individual directories can scale horizontally.

Directory buckets use the S3 Express One Zone storage class, which is built to be used by performance sensitive applications. With S3 Express One Zone, you can select a single Availability Zone with the option to co-locate your object storage with your compute resources, which provides the highest possible access speed. This is unlike general purpose buckets, which redundantly store objects across multiple Availability Zones in AWS Regions.

For more information about directory buckets, see Directory buckets. For more information about general purpose buckets, see Buckets overview.

## Endpoints and gateway VPC endpoints

Bucket-management API operations for directory buckets are available through a Regional endpoint and are referred to as Regional endpoint API operations. Examples of Regional endpoint

API operations are `CreateBucket` and `DeleteBucket`. After you create a directory bucket, you can use Zonal endpoint API operations to upload and manage the objects in your directory bucket. Zonal endpoint API operations are available through a Zonal endpoint. Examples of Zonal endpoint API operations are `PutObject` and `CopyObject`.

You can access S3 Express One Zone from your VPC by using gateway VPC endpoints. After you create a gateway endpoint, you can add it as a target in your route table for traffic destined from your VPC to S3 Express One Zone. As with Amazon S3, there is no additional charge for using gateway endpoints. For more information about how to configure gateway VPC endpoints, see Networking for S3 Express One Zone

### Session-based authorization

With S3 Express One Zone, you authenticate and authorize requests through a new session-based mechanism that is optimized to provide the lowest latency. You can use `CreateSession` to request temporary credentials that provide low-latency access to your bucket. These temporary credentials are scoped to a specific S3 directory bucket. Session tokens are used only with Zonal (object-level) operations (with the exception of CopyObject). For more information, see `CreateSession` authorization.

The supported AWS SDKs for S3 Express One Zone handle session establishment and refreshment on your behalf. To protect your sessions, temporary security credentials expire after 5 minutes. After you download and install the AWS SDKs and configure the necessary AWS Identity and Access Management (IAM) permissions, you can immediately start using API operations.

## Features of S3 Express One Zone

The following S3 features are available for S3 Express One Zone. For a complete list of supported API operationss and unsupported features, see How is S3 Express One Zone different?.

### Access management and security

With directory buckets, you can use the following features to audit and manage access. By default, directory buckets are private and can be accessed only by users who are explicitly granted access. Unlike general purpose buckets, which can set the access control boundary at the bucket, prefix, or object tag level, the access control boundary for directory buckets is set only at the bucket level. For more information, see AWS Identity and Access Management (IAM) for S3 Express One Zone.

- S3 Block Public Access – All S3 Block Public Access settings are enabled by default at the bucket level. This default setting can't be modified.
- S3 Object Ownership (bucket owner enforced by default) – Access control lists (ACLs) are not supported for directory buckets. Directory buckets automatically use the bucket owner enforced setting for S3 Object Ownership. Bucket owner enforced means that ACLs are disabled, and the bucket owner automatically owns and has full control over every object in the bucket. This default setting can't be modified.
- AWS Identity and Access Management (IAM) – IAM helps you securely control access to your directory buckets. You can use IAM to grant access to bucket management (Regional) API operations and object management (Zonal) API operations through the `s3express:CreateSession` action. For more information, see AWS Identity and Access Management (IAM) for S3 Express One Zone. Unlike object-management actions, bucket management actions cannot be cross-account. Only the bucket owner can perform those actions.
- Bucket policies – Use IAM-based policy language to configure resource-based permissions for your directory buckets. You can also use IAM to control access to the `CreateSession` API operation, which allows you to use the Zonal, or object management, API operations. You can grant same-account or cross-account access to Zonal API operations. For more information about S3 Express One Zone permissions and policies, see AWS Identity and Access Management (IAM) for S3 Express One Zone.
- IAM Access Analyzer for S3 – Evaluate and monitor your access policies to make sure that the policies provide only the intended access to your S3 resources.

## Logging and monitoring

S3 Express One Zone uses the following S3 logging and monitoring tools that you can use to monitor and control how your resources are being used:

- Amazon CloudWatch metrics – Monitor your AWS resources and applications by using CloudWatch to collect and track metrics. S3 Express One Zone uses the same CloudWatch namespace as other Amazon S3 storage classes (`AWS/S3`) and supports daily storage metrics for directory buckets: `BucketSizeBytes` and `NumberOfObjects`. For more information, see Monitoring metrics with Amazon CloudWatch.
- AWS CloudTrail logs – AWS CloudTrail is an AWS service that helps you implement operational and risk auditing, governance, and compliance of your AWS account by recording the actions taken by a user, role, or an AWS service. For S3 Express One Zone, CloudTrail captures Regional endpoint API operations (for example, `CreateBucket` and `PutBucketPolicy`) as management

events and Zonal API operations (for example, `GetObject` and `PutObject`) as data events. These events include actions taken in the AWS Management Console, AWS Command Line Interface (AWS CLI), AWS SDKs, and AWS API operations. For more information, see Logging with AWS CloudTrail for S3 Express One Zone.

> **Note**
>
> Amazon S3 server access logs aren't supported with S3 Express One Zone.

## Object management

After you create a directory bucket, you can manage your object storage by using the Amazon S3 console, AWS SDKs, and AWS CLI. The following features are available for object management with S3 Express One Zone:

- S3 Batch Operations – Use Batch Operations to perform bulk operations on objects in directory buckets, for example, **Copy** and **Invoke AWS Lambda function**. For example, you can use Batch Operations to copy objects between directory buckets and general purpose buckets. With Batch Operations, you can manage billions of objects at scale with a single S3 request by using the AWS SDKs or AWS CLI or a few clicks in the Amazon S3 console.
- Import – After you create a directory bucket, you can populate your bucket with objects by using the import feature in the Amazon S3 console. Import is a streamlined method for creating Batch Operations jobs to copy objects from general purpose buckets to directory buckets.

## AWS SDKs and client libraries

After you create a directory bucket and upload an object to your bucket, you can manage your object storage by using the following.

- Mountpoint for Amazon S3 – Mountpoint for Amazon S3 is an open-source file client that delivers high-throughput access, lowering compute costs for data lakes on Amazon S3. Mountpoint for Amazon S3 translates local file system API calls to S3 object API calls like `GET` and `LIST`. It is ideal for read-heavy data lake workloads that process petabytes of data and need the high elastic throughput provided by Amazon S3 to scale up and down across thousands of instances.

- S3A – S3A is a recommended Hadoop-compatible interface for accessing data stores in Amazon S3. S3A replaces the S3N Hadoop file system client.
- PyTorch on AWS – PyTorch on AWS is an open-source deep-learning framework that makes it easier to develop machine learning models and deploy them to production.
- AWS SDKs – You can use the AWS SDKs when developing applications with Amazon S3. The AWS SDKs simplify your programming tasks by wrapping the underlying Amazon S3 REST API. For more information about using the AWS SDKs with S3 Express One Zone, see the section called "AWS SDKs".

## Encryption and data protection

Objects stored in directory buckets are automatically encrypted by using server-side encryption with Amazon S3 managed keys (SSE-S3). Directory buckets don't support server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS), server-side encryption with customer-provided encryption keys (SSE-C), or dual-layer server-side encryption with AWS KMS keys (DSSE-KMS). For more information, see Data protection and encryption and Using server-side encryption with Amazon S3 managed keys (SSE-S3).

S3 Express One Zone offers you the option to choose the checksum algorithm that is used to validate your data during upload or download. You can select one of the following Secure Hash Algorithms (SHA) or Cyclic Redundancy Check (CRC) data-integrity check algorithms: CRC32, CRC32C, SHA-1, and SHA-256. MD5-based checksums are not supported with the S3 Express One Zone storage class.

For more information, see S3 additional checksum best practices.

## AWS Signature Version 4 (SigV4)

S3 Express One Zone uses AWS Signature Version 4 (SigV4). SigV4 is a signing protocol used to authenticate requests to Amazon S3 over HTTPS. S3 Express One Zone signs requests by using AWS Sigv4. For more information, see Authenticating Requests (AWS Signature Version 4) in the *Amazon Simple Storage Service API Reference*.

## Strong consistency

S3 Express One Zone provides strong read-after-write consistency for PUT and DELETE requests of objects in your directory buckets in all AWS Regions. For more information, see Amazon S3 data consistency model.

# Related services

You can use the following AWS services with the S3 Express One Zone storage class to support your specific low-latency use case.

- Amazon Elastic Compute Cloud (Amazon EC2) – Amazon EC2 provides secure and scalable computing capacity in the AWS Cloud. Using Amazon EC2 lessens your need to invest in hardware up front, so you can develop and deploy applications faster. You can use Amazon EC2 to launch as many or as few virtual servers as you need, configure security and networking, and manage storage.
- AWS Lambda – Lambda is a compute service that lets you run code without provisioning or managing servers. You configure notification settings on a bucket, and grant Amazon S3 permission to invoke a function on the function's resource-based permissions policy.
- Amazon Elastic Kubernetes Service (Amazon EKS) – Amazon EKS is a managed service that eliminates the need to install, operate, and maintain your own Kubernetes control plane on AWS. Kubernetes is an open-source system that automates the management, scaling, and deployment of containerized applications.
- Amazon Elastic Container Service (Amazon ECS) – Amazon ECS is a fully managed container orchestration service that helps you easily deploy, manage, and scale containerized applications.
- Amazon Athena – Athena is an interactive query service that makes it easy to analyze data directly in Amazon S3 by using standard SQL. You can also use Athena to interactively run data analytics by using Apache Spark without having to plan for, configure, or manage resources. When you run Apache Spark applications on Athena, you submit Spark code for processing and receive the results directly.
- Amazon SageMaker Runtime Model Training – Amazon SageMaker Runtime is a fully managed machine learning service. With SageMaker Runtime, data scientists and developers can quickly and easily build and train machine learning models, and then directly deploy them into a production-ready hosted environment.
- AWS Glue – AWS Glue is a serverless data-integration service that makes it easy for analytics users to discover, prepare, move, and integrate data from multiple sources. You can use AWS Glue for analytics, machine learning, and application development. AWS Glue also includes additional productivity and data-ops tooling for authoring, running jobs, and implementing business workflows.

- Amazon EMR – Amazon EMR is a managed cluster platform that simplifies running big data frameworks, such as Apache Hadoop and Apache Spark, on AWS to process and analyze vast amounts of data.

## Next steps

For more information about working with the S3 Express One Zone storage class and directory buckets, see the following topics:

- How is S3 Express One Zone different?
- Tutorial: Getting started with S3 Express One Zone
- Networking for S3 Express One Zone
- Directory buckets
- Working with objects in a directory bucket
- Security for S3 Express One Zone
- Optimizing Amazon S3 Express One Zone performance
- Developing with S3 Express One Zone

# How is S3 Express One Zone different?

Amazon S3 Express One Zone is a high-performance, single-zone Amazon S3 storage class that is purpose-built to deliver consistent, single-digit millisecond data access for your most latency-sensitive applications. S3 Express One Zone is the first S3 storage class where you can select a single Availability Zone with the option to co-locate your object storage with your compute resources, which provides the highest possible access speed. Additionally, to further increase access speed and support hundreds of thousands of requests per second, S3 Express One Zone data is stored in a new bucket type: an Amazon S3 directory bucket.

For more information, see What is S3 Express One Zone? and Directory buckets.

You can create directory buckets and access your data in S3 Express One Zone by using the Amazon S3 API. The Amazon S3 API is compatible with S3 Express One Zone and directory buckets, with the exception of a few notable differences. For more information about how S3 Express One Zone is different, see the following topics.

**Topics**

- S3 Express One Zone differences
- API operations supported by S3 Express One Zone
- Amazon S3 features not supported by S3 Express One Zone

## S3 Express One Zone differences

- **Supported bucket type** – Objects in the S3 Express One Zone storage class can only be stored in directory buckets. For more information, see Directory buckets.
- **Durability** – With S3 Express One Zone, your data is redundantly stored on multiple devices within a single Availability Zone. S3 Express One Zone is designed for 99.95% availability within a single Availability Zone and is backed by the Amazon S3 Service Level Agreement. For more information, see Single Availability Zone.
- **`ListObjectsV2` behavior**
  - For directory buckets, `ListObjectsV2` does not return objects in lexicographical (alphabetical) order. Additionally, prefixes must end in a delimiter and only "/" can be specified as the delimiter.
  - For directory buckets, `ListObjectsV2` response includes the prefixes that are related only to in-progress multipart uploads.
- **Deletion behavior** – When you delete an object in a directory bucket, Amazon S3 recursively deletes any empty directories in the object path. For example, if you delete the object key `dir1/dir2/file1.txt`, Amazon S3 deletes `file1.txt`. If the `dir1/` and `dir2/` directories are empty and contain no other objects, Amazon S3 also deletes those directories.
- **ETags and checksums** – Entity tags (ETags) for S3 Express One Zone are random alphanumeric strings and not MD5 checksums. For more information about using additional checksums with S3 Express One Zone, see S3 additional checksum best practices.
- **Object keys in `DeleteObjects` requests**
  - Object keys in `DeleteObjects` requests must contain at least one non-white space character. Strings of all white space characters aren't supported in `DeleteObjects` requests.
  - Object keys in `DeleteObjects` requests cannot contain Unicode control characters, except for the newline (`\n`), tab (`\t`), and carriage return (`\r`) characters.
- **Regional and Zonal endpoints** – When using S3 Express One Zone, you must specify the Region in all client requests. For Regional endpoints, you specify the Region, for example, `s3express-control.us-west-2.amazonaws.com`. For Zonal endpoints, you specify both the Region and

the Availability Zone, for example, `s3express-usw2-az1.us-west-2.amazonaws.com`. For more information, see Regional and Zonal endpoints.

- **Multipart uploads** – As with other objects stored in Amazon S3, you can upload and copy large objects that are stored in the S3 Express One Zone storage class by using the multipart upload process. However, the following are some differences when using the multipart upload process with objects stored in S3 Express One Zone. For more information, see the section called "Using multipart uploads with directory buckets".
  - The object creation date is the completion date of the multipart upload.
  - Multipart part numbers must use consecutive part numbers. If you try to complete a multipart upload request with nonconsecutive part numbers, Amazon S3 generates an HTTP `400 (Bad Request)` error.
  - The initiator of a multipart upload can abort the multipart upload request only if they have been granted explicit allow access to `AbortMultipartUpload` through the `s3express:CreateSession` permission. For more information, see AWS Identity and Access Management (IAM) for S3 Express One Zone.
- **Emptying a directory bucket** – The `s3 rm` command through the AWS Command Line Interface (CLI), the `delete` operation through Mountpoint, and the **Empty** bucket option button through the AWS Management Console are unable to delete in-progress multipart uploads in a directory bucket. To delete these in-progress multipart uploads, use the `ListMultipartUploads` operation to list the in-progress multipart uploads in the bucket and use the `AbortMultupartUpload` operation to abort all the in-progress multipart uploads.

## API operations supported by S3 Express One Zone

The Amazon S3 Express One Zone storage class supports both Regional (bucket level, or control plane) and Zonal (object level, or data plane) endpoint API operations. For more information, see Networking for S3 Express One Zone and Endpoints and gateway VPC endpoints.

### Regional endpoint API operations

The following Regional endpoint API operations are supported for S3 Express One Zone:

- CreateBucket
- DeleteBucket
- DeleteBucketPolicy
- GetBucketPolicy

- ListDirectoryBuckets
- PutBucketPolicy

### Zonal endpoint API operations

The following Zonal endpoint API operations are supported for S3 Express One Zone:

- CreateSession
- CopyObject
- DeleteObject
- DeleteObjects
- GetObject
- GetObjectAttributes
- HeadBucket
- HeadObject
- ListObjectsV2
- PutObject
- AbortMultipartUpload
- CompleteMultiPartUpload
- CreateMultipartUpload
- ListMultipartUploads
- ListParts
- UploadPart
- UploadPartCopy

## Amazon S3 features not supported by S3 Express One Zone

The following Amazon S3 features are not supported by S3 Express One Zone:

- AWS managed policies
- AWS PrivateLink for S3
- MD5 checksums
- Multi-factor authentication (MFA) delete

- S3 Object Lock
- Requester Pays
- S3 Access Grants
- S3 Access Points
- Bucket tags
- Amazon CloudWatch request metrics
- S3 Event Notifications
- S3 Lifecycle
- S3 Multi-Region Access Points
- S3 Object Lambda Access Points
- S3 Versioning
- S3 Inventory
- S3 Replication
- Object tags
- S3 Select
- Server access logs
- Static website hosting
- S3 Storage Lens
- S3 Storage Lens groups
- S3 Transfer Acceleration
- Dual-layer server-side encryption with AWS Key Management Service (AWS KMS) keys (DSSE-KMS)
- Server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS)
- Server-side encryption with customer-provided keys (SSE-C)
- The option to copy an existing bucket settings when creating a new bucket in AWS Management Console.

# Tutorial: Getting started with S3 Express One Zone

Amazon S3 Express One Zone is the first S3 storage class where you can select a single Availability Zone with the option to co-locate your object storage with your compute resources which provides

the highest possible access speed. Data in S3 Express One Zone is stored in S3 directory buckets. For more information on directory buckets, see Directory buckets.

S3 Express One Zone is ideal for any application where it's critical to minimize request latency. Such applications can be human-interactive workflows, like video editing, where creative professionals need responsive access to content from their user interfaces. S3 Express One Zone also benefits analytics and machine learning workloads that have similar responsiveness requirements from their data, especially workloads with a lot of smaller accesses or a large numbers of random accesses. S3 Express One Zone can be used with other AWS services such as Amazon EMR, Amazon Athena, AWS Glue Data Catalog and Amazon SageMaker Model Training to support analytics, artificial intelligence and machine learning (AI/ML) workloads,. You can work with the S3 Express One Zone storage class and directory buckets by using the Amazon S3 console, AWS SDKs, AWS Command Line Interface (AWS CLI), and Amazon S3 REST API. For more information, see What is S3 Express One Zone? and How is S3 Express One Zone different?.
This is an S3 Express One Zone workflow diagram.

**Objective**

In this tutorial, you will learn how to create a gateway endpoint, create and attach an IAM policy, create a directory bucket and then use the Import action to populate your directory bucket with objects currently stored in your general purpose bucket. Alternatively, you can manually upload objects to your directory bucket.

**Topics**

# Prerequisites

Before you start this tutorial, you must have an AWS account that you can sign in to as an AWS Identity and Access Management (IAM) user with correct permissions.

**Substeps**

- Create an AWS account
- Create an IAM user in your AWS account (console)
- Create an IAM policy and attach it to an IAM user or role (console)

## Create an AWS account

To complete this tutorial, you need an AWS account. When you sign up for AWS, your AWS account is automatically signed up for all services in AWS, including Amazon S3. You are charged only for the services that you use. For more information about pricing, see S3 pricing.

## Create an IAM user in your AWS account (console)

AWS Identity and Access Management (IAM) is an AWS service that helps administrators securely control access to AWS resources. IAM administrators control who can be authenticated (signed in) and authorized (have permissions) to access objects and use directory buckets in S3 Express One Zone. You can use IAM for no additional charge.

By default, users don't have permissions to access directory buckets and perform S3 Express One Zone operations. To grant access permissions for directory buckets and S3 Express One Zone operations, you can use IAM to create users or roles and attach permissions to those identities. For more information about how to create an IAM user, see Creating IAM users (console) in the *IAM User Guide*. For more information about how to create an IAM role, see Creating a role to delegate permissions to an IAM user in the *IAM User Guide*.

For simplicity, this tutorial creates and uses an IAM user. After completing this tutorial, remember to Delete the IAM user. For production use, we recommend that you follow the Security best practices in IAM in the *IAM User Guide*. A best practice requires human users to use federation with an identity provider to access AWS with temporary credentials. Another best practice is to require workloads to use temporary credentials with IAM roles to access AWS. To learn more about using AWS IAM Identity Center to create users with temporary credentials, see Getting started in the *AWS IAM Identity Center User Guide*.

> **Warning**
>
> IAM users have long-term credentials, which presents a security risk. To help mitigate this risk, we recommend that you provide these users with only the permissions they require to perform the task and that you remove these users when they are no longer needed.

## Create an IAM policy and attach it to an IAM user or role (console)

By default, users don't have permissions for directory buckets and S3 Express One Zone operations. To grant access permissions for directory buckets, you can use IAM to create users, groups, or roles and attach permissions to those identities. Directory buckets are the only resource that you can include in bucket policies or IAM identity policies for S3 Express One Zone access.

To use Regional endpoint API operations (bucket-level or control plane operations) with S3 Express One Zone, you use the IAM authorization model, which doesn't involve session management. Permissions are granted for actions individually. To use Zonal endpoint API operations (object-level or data plane operations), you use `CreateSession` to create and manage sessions that are optimized for low-latency authorization of data requests. To retrieve and use a session token, you must allow the `s3express:CreateSession` action for your directory bucket in an identity-based policy or a bucket policy. If you're accessing S3 Express One Zone in the Amazon S3 console, through the AWS Command Line Interface (AWS CLI), or by using the AWS SDKs, S3 Express One Zone creates a session on your behalf. For more information, see `CreateSession` authorization and AWS Identity and Access Management (IAM) for S3 Express One Zone .

**To create an IAM policy and attach the policy to an IAM user (or role)**

1. Sign in to the AWS Management Console and open the IAM Management Console.
2. In the navigation pane, choose **Policies**.
3. Choose **Create Policy**.
4. Select **JSON**.
5. Copy the policy below into the **Policy editor** window. Before you can create directory buckets or use S3 Express One Zone, you must grant the necessary permissions to your AWS Identity and Access Management (IAM) role or users. This example policy allows access to the `CreateSession` API operation (for use with other Zonal or object-level API operations) and all of the Regional endpoint (bucket-level) API operations. This policy allows the `CreateSession` API operation for use with all directory buckets, but the Regional

endpoint API operations are allowed only for use with the specified directory bucket. To use this example policy, replace the *user input placeholders* with your own information.

```
{
     "Version": "2012-10-17",
     "Statement": [
         {
             "Sid": "AllowAccessRegionalEndpointAPIs",
             "Effect": "Allow",
             "Action": [
                 "s3express:DeleteBucket",
                 "s3express:DeleteBucketPolicy",
                 "s3express:CreateBucket",
                 "s3express:PutBucketPolicy",
                 "s3express:GetBucketPolicy",
                 "s3express:ListAllMyDirectoryBuckets"
             ],

             "Resource": "arn:aws:s3express:region:account_id:bucket/bucket-base-name--azid--x-s3/*"
         },
         {
             "Sid": "AllowCreateSession",
             "Effect": "Allow",
             "Action": "s3express:CreateSession",
             "Resource": "*"
         }
     ]
 }
```

6. Choose **Next**.
7. Name the policy.

> **Note**
>
> Bucket tags are not supported for S3 Express One Zone.

8. Select **Create policy**.
9. Now that you've created an IAM policy, you can attach it to an IAM user. In the navigation pane, choose **Policies**.
10. In the **search bar**, enter the name of your policy.

11. From the **Actions** menu, select **Attach**.
12. Under **Filter by Entity Type**, select **IAM users** or **Roles**.
13. In the **search field**, type the name of the user or role you wish to use.
14. Choose **Attach Policy**.

## Step 1: Configure a gateway VPC endpoint

You can access both Zonal and Regional API operations through gateway virtual private cloud (VPC) endpoints. Gateway endpoints can allow traffic to reach S3 Express One Zone without traversing a NAT Gateway. We strongly recommend using gateway endpoints as they provide the most optimal networking path when working with S3 Express One Zone. You can access S3 Express One Zone directory buckets from your VPC without an internet gateway or NAT device for your VPC, and at no additional cost. Use the following procedure to configure a gateway endpoint that connects to S3 Express One Zone storage class objects and directory buckets.

To access S3 Express One Zone, you use Regional and Zonal endpoints that are different from standard Amazon S3 endpoints. Depending on the Amazon S3 API operation that you use, either a Zonal or Regional endpoint is required. For a complete list of supported API operations by endpoint type, see API operations supported by S3 Express One Zone . You must access both Zonal and Regional endpoints through a gateway virtual private cloud (VPC) endpoint.

Use the following procedure to create a gateway endpoint that connects to S3 Express One Zone storage class objects and directory buckets.

**To configure a gateway VPC endpoint**

1. Open the Amazon VPC Console at https://console.aws.amazon.com/vpc/.
2. In the side navigation pane under **Virtual private cloud**, choose **Endpoints**.
3. Choose **Create endpoint**.
4. Create a name for your endpoint.
5. For **Service category**, choose **AWS services**.
6. Under **Services**, search using the filter **Type=Gateway** and then choose the option button next to **com.amazonaws.*region*.s3express**.
7. For **VPC**, choose the VPC in which to create the endpoint.

8. For **Route tables**, select the route tables to be used by the endpoint. Amazon VPC automatically adds a route that points traffic destined for the service to the endpoint network interface.
9. For **Policy**, choose **Full access** to allow all operations by all principals on all resources over the VPC endpoint. Otherwise, choose **Custom** to attach a VPC endpoint policy that controls the permissions that principals have to perform actions on resources over the VPC endpoint.
10. Choose **Create endpoint**.

After creating a gateway endpoint, you can use Regional API endpoints and Zonal API endpoints to access Amazon S3 Express One Zone storage class objects and directory buckets.

## Step 2: Create a directory bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the navigation bar on the top of the page, choose the name of the currently displayed AWS Region. Next, choose the Region in which you want to create a bucket.

   > **Note**
   >
   > To minimize latency and costs and address regulatory requirements, choose a Region close to you. Objects stored in a Region never leave that Region unless you explicitly transfer them to another Region. For a list of Amazon S3 AWS Regions, see AWS service endpoints in the *Amazon Web Services General Reference*.

3. In the left navigation pane, choose **Buckets**.
4. Choose **Create bucket**.

   The **Create bucket** page opens.
5. Under **General configuration**, view the AWS Region where your bucket will be created.
6. Under **Bucket type**, choose **Directory**.

   > **Note**
   >
   > - If you've chosen a Region that doesn't support directory buckets, the **Bucket type** option disappears, and the bucket type defaults to a general purpose bucket. To

create a directory bucket, you must choose a supported Region. For a list of Regions that support directory buckets and the Amazon S3 Express One Zone storage class, see the section called "S3 Express One Zone Availability Zones and Regions".

- After you create the bucket, you can't change the bucket type.

For **Availability Zone**, choose a Availability Zone local to your compute services. For a list of Availability Zones that support directory buckets and the S3 Express One Zone storage class, see the section called "S3 Express One Zone Availability Zones and Regions".

> **Note**
>
> The Availability Zone can't be changed after the bucket is created.

7. Under **Availability Zone** , select the check box to acknowledge that in the event of an Availability Zone outage, your data might be unavailable or lost.

> **Important**
>
> Although directory buckets are stored across multiple devices within a single Availability Zone, directory buckets don't store data redundantly across Availability Zones.

8. For **Bucket name**, enter a name for your directory bucket.

   The following naming rules apply for directory buckets.

   - Be unique within the chosen AWS Region and Availability Zone.
   - Name must be between 3 (min) and 63 (max) characters long, including the suffix.
   - Consists only of lowercase letters, numbers and hyphens (-).
   - Begin and end with a letter or number.
   - Must include the following suffix: `--azid--x-s3`.
   - Bucket names must not start with the prefix `xn--`.
   - Bucket names must not start with the prefix `sthree-`.
   - Bucket names must not start with the prefix `sthree-configurator`.
   - Bucket names must not start with the prefix `amzn-s3-demo-`.

- Bucket names must not end with the suffix `-s3alias`. This suffix is reserved for access point alias names. For more information, see Using a bucket-style alias for your S3 bucket access point.
- Bucket names must not end with the suffix `--ol-s3`. This suffix is reserved for Object Lambda Access Point alias names. For more information, see How to use a bucket-style alias for your S3 bucket Object Lambda Access Point.
- Bucket names must not end with the suffix `.mrap`. This suffix is reserved for Multi-Region Access Point names. For more information, see Rules for naming Amazon S3 Multi-Region Access Points.

A suffix is automatically added to the base name that you provide when you create a directory bucket using the console. This suffix includes the Availability Zone ID of the Availability Zone that you chose.

After you create the bucket, you can't change its name. For more information about naming buckets, see Bucket naming rules.

> **Important**
>
> Do not include sensitive information, such as account numbers, in the bucket name. The bucket name is visible in the URLs that point to the objects in the bucket.

9. Under **Object Ownership**, the **Bucket owner enforced** setting is automatically enabled, and all access control lists (ACLs) are disabled. For directory buckets, ACLs can't be enabled.

   **ACLs disabled**

   - **Bucket owner enforced (default)** – ACLs are disabled, and the bucket owner automatically owns and has full control over every object in the bucket. ACLs no longer affect access permissions to data in the S3 bucket. The bucket uses policies exclusively to define access control.

     A majority of modern use cases in Amazon S3 no longer require the use of ACLs. For more information, see Controlling ownership of objects and disabling ACLs for your bucket.

10. Under **Block Public Access settings for this bucket**, all Block Public Access settings for your directory bucket are automatically enabled. These settings can't be modified for directory

buckets. For more information about blocking public access, see Blocking public access to your Amazon S3 storage.

11. Under **Server-side encryption settings**, Amazon S3 applies server-side encryption with Amazon S3 managed keys (SSE-S3) as the base level of encryption for all S3 buckets. All object uploads to directory buckets are encrypted with SSE-S3. For directory buckets, the encryption type can't be modified. For more information about SSE-S3, see the section called "Amazon S3 managed encryption keys (SSE-S3)".
12. Choose **Create bucket**.

    After creating the bucket, you can add files and folders to the bucket. For more information, see the section called "Working with objects in a directory bucket".

The following step demonstrates how to use the Import action in the Amazon S3 console to populate your directory bucket with data.

## Step 3: Importing data into a directory bucket

To complete this step, you must have a general purpose bucket that contains objects and is located in the same AWS Region as your directory bucket.

After you create a directory bucket in Amazon S3, you can populate the new bucket with data by using the Import action in the Amazon S3 console. Import simplifies copying data into directory buckets by letting you choose a prefix or a general purpose bucket to Import data from without having to specify all of the objects to copy individually. Import uses S3 Batch Operations which copies the objects in the selected prefix or general purpose bucket. You can monitor the progress of the Import copy job through the S3 Batch Operations job details page.

**To use the Import action**

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the navigation bar on the top of the page, choose the name of the currently displayed AWS Region. Next, choose the Region associated with the Availability Zone in which your directory bucket is located.
3. In the left navigation pane, choose **Buckets**, and then choose the **Directory buckets** tab. Choose the directory bucket that you want to import objects into.
4. Choose **Import**.

5. For **Source**, enter the general purpose bucket (or bucket path including prefix) that contains the objects that you want to import. To choose an existing general purpose bucket from a list, choose **Browse S3**.
6. In the **Permissions** section, you can choose to have an IAM role auto-generated. Alternatively, you can select an IAM role from a list, or directly enter an IAM role ARN.

   - To allow Amazon S3 to create a new IAM role on your behalf, choose **Create new IAM role**.

     > **Note**
     >
     > If your source objects are encrypted with server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS), don't choose the **Create new IAM role** option. Instead, specify an existing IAM role that has the `kms:Decrypt` permission.
     > Amazon S3 will use this permission to decrypt your objects. During the import process, Amazon S3 will then re-encrypt those objects by using server-side encryption with Amazon S3 managed keys (SSE-S3).

   - To choose an existing IAM role from a list, choose **Choose from existing IAM roles**.
   - To specify an existing IAM role by entering its Amazon Resource Name (ARN), choose **Enter IAM role ARN**, then enter the ARN in the corresponding field.
7. Review the information that's displayed in the **Destination** and **Copied object settings** sections. If the information in the **Destination** section is correct, choose **Import** to start the copy job.

   The Amazon S3 console displays the status of your new job on the **Batch Operations** page. For more information about the job, choose the option button next to the job name, and then on the **Actions** menu, choose **View details**. To open the directory bucket that the objects will be imported into, choose **View import destination**.

## Step 4: Manually upload objects to your directory bucket

You can also manually upload objects to your directory bucket.

**To manually upload objects**

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the navigation bar on the upper right corner of the page, choose the name of the currently displayed AWS Region. Next, choose the Region associated with the Availability Zone in which your directory bucket is located.
3. In the left navigation pane, choose **Buckets**.
4. Choose the **Directory buckets** tab.
5. Choose the name of the bucket that you want to upload your folders or files to.

   > **Note**
   >
   > If you chose the same directory bucket that you used in previous steps of this tutorial, your directory bucket will contain the objects that were uploaded from the Import tool. Notice that these objects are now stored in the S3 Express One Zone storage class.

6. In the **Objects** list, choose **Upload**.
7. On the **Upload** page, do one of the following:

   - Drag and drop files and folders to the dotted upload area.
   - Choose **Add files** or **Add folder**, choose the files or folders to upload, and then choose **Open** or **Upload**.

8. Under **Checksums**, choose the **Checksum function** that you want to use.

   > **Note**
   >
   > We recommend using CRC32 and CRC32C for the best performance with the S3 Express One Zone storage class. For more information, see S3 additional checksum best practices.

   (Optional) If you're uploading a single object that's less than 16 MB in size, you can also specify a pre-calculated checksum value. When you provide a pre-calculated value, Amazon S3 compares it with the value that it calculates by using the selected checksum function. If the values don't match, the upload won't start.

9. The options in the **Permissions** and **Properties** sections are automatically set to default settings and can't be modified. Block Public Access is automatically enabled, and S3 Versioning and S3 Object Lock can't be enabled for directory buckets.

   (Optional) If you want to add metadata in key-value pairs to your objects, expand the **Properties** section, and then in the **Metadata** section, choose **Add metadata**.

10. To upload the listed files and folders, choose **Upload**.

    Amazon S3 uploads your objects and folders. When the upload is finished, you see a success message on the **Upload: status** page.

    You have successfully created a directory bucket and uploaded objects to your bucket.

## Step 5: Empty your directory bucket

You can empty your Amazon S3 directory bucket by using the Amazon S3 console.

**To empty a directory bucket**

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the navigation bar on the upper right corner of the page, choose the name of the currently displayed AWS Region. Next, choose the Region associated with the Availability Zone in which your directory bucket is located.
3. In the left navigation pane, choose **Buckets**.
4. Choose the **Directory buckets** tab.
5. Choose the option button next to the name of the bucket that you want to empty, and then choose **Empty**.
6. On the **Empty bucket** page, confirm that you want to empty the bucket by entering **`permanently delete`** in the text field, and then choose **Empty**.
7. Monitor the progress of the bucket emptying process on the **Empty bucket: status** page.

## Step 6: Delete your directory bucket

After you empty your directory bucket and abort all in-progress multipart uploads, you can delete your bucket by using the Amazon S3 console.

**To delete a directory bucket**

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the navigation bar on the upper right corner of the page, choose the name of the currently displayed AWS Region. Next, choose the Region associated with the Availability Zone in which your directory bucket is located.
3. In the left navigation pane, choose **Buckets**.
4. Choose the **Directory buckets** tab.
5. In the **Directory buckets** list, choose the option button next to the bucket that you want to delete.
6. Choose **Delete**.
7. On the **Delete bucket** page, enter the name of the bucket in the text field to confirm the deletion of your bucket.

   > **Important**
   >
   > Deleting a directory bucket can't be undone.

8. To delete your directory bucket, choose **Delete bucket**.

## Next steps

In this tutorial, you have learned how to create a directory bucket and use the S3 Express One Zone storage class. After completing this tutorial, you can explore related AWS services to use with the S3 Express One Zone storage class.

You can use the following AWS services with the S3 Express One Zone storage class to support your specific low-latency use case.

- Amazon Elastic Compute Cloud (Amazon EC2) – Amazon EC2 provides secure and scalable computing capacity in the AWS Cloud. Using Amazon EC2 lessens your need to invest in hardware up front, so you can develop and deploy applications faster. You can use Amazon EC2 to launch as many or as few virtual servers as you need, configure security and networking, and manage storage.

- AWS Lambda – Lambda is a compute service that lets you run code without provisioning or managing servers. You configure notification settings on a bucket, and grant Amazon S3 permission to invoke a function on the function's resource-based permissions policy.
- Amazon Elastic Kubernetes Service (Amazon EKS) – Amazon EKS is a managed service that eliminates the need to install, operate, and maintain your own Kubernetes control plane on AWS. Kubernetes is an open-source system that automates the management, scaling, and deployment of containerized applications.
- Amazon Elastic Container Service (Amazon ECS) – Amazon ECS is a fully managed container orchestration service that helps you easily deploy, manage, and scale containerized applications.
- Amazon EMR – Amazon EMR is a managed cluster platform that simplifies running big data frameworks, such as Apache Hadoop and Apache Spark on AWS to process and analyze vast amounts of data.
- Amazon Athena – Athena is an interactive query service that makes it easy to analyze data directly in Amazon S3 by using standard SQL. You can also use Athena to interactively run data analytics by using Apache Spark without having to plan for, configure, or manage resources. When you run Apache Spark applications on Athena, you submit Spark code for processing and receive the results directly.
- AWS Glue Data Catalog – AWS Glue is a serverless data-integration service that makes it easy for analytics users to discover, prepare, move, and integrate data from multiple sources. You can use AWS Glue for analytics, machine learning, and application development. AWS Glue Data Catalog is a centralized repository that stores metadata about your organization's data sets. It acts as an index to the location, schema, and run-time metrics of your data sources.
- Amazon SageMaker Runtime Model Training – Amazon SageMaker Runtime is a fully managed machine learning service. With SageMaker Runtime, data scientists and developers can quickly and easily build and train machine learning models, and then directly deploy them into a production-ready hosted environment.

For more information on S3 Express One Zone, see What is S3 Express One Zone? and How is S3 Express One Zone different?.

## Networking for S3 Express One Zone

To access Amazon S3 Express One Zone storage class objects and directory buckets, you use Regional and Zonal API endpoints that are different from the standard Amazon S3 endpoints. Depending on the S3 API operation that you use, either a Zonal or Regional endpoint is required.

For a complete list of API operations by endpoint type, see API operations supported by S3 Express One Zone.

You can access both Zonal and Regional API operations through gateway virtual private cloud (VPC) endpoints. To configure gateway VPC endpoints, see the section called "Configuring VPC gateway endpoints".

The following topics describe the networking requirements for accessing S3 Express One Zone by using a gateway VPC endpoint.

**Topics**

## Endpoints

You can access Amazon S3 Express One Zone storage class objects and directory buckets from your VPC by using gateway VPC endpoints. S3 Express One Zone uses Regional and Zonal API endpoints. Depending on the Amazon S3 API operation that you use, either a Regional or Zonal endpoint is required. There is no additional charge for using gateway endpoints.

Bucket-level (or control plane) API operations are available through Regional endpoints and are referred to as Regional endpoint API operations. Examples of Regional endpoint API operations are `CreateBucket` and `DeleteBucket`. When you create a directory bucket, you choose a single Availability where your directory bucket will be created. After you create a directory bucket, you can use Zonal endpoint API operations to upload and manage the objects in your directory bucket.

Object-level (or data plane) API operations are available through Zonal endpoints and are referred to as Zonal endpoint API operations. Examples of Zonal endpoint API operations are `CreateSession` and `PutObject`.

The following table shows the Regional and Zonal API endpoints that are available for each Region and Availability Zone.

## Configuring VPC gateway endpoints

Use the following procedure to create a gateway endpoint that connects to Amazon S3 Express One Zone storage class objects and directory buckets.

**To configure a gateway VPC endpoint**

1. Open the Amazon VPC Console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose **Endpoints**.
3. Choose **Create endpoint**.
4. Create a name for your endpoint.
5. For **Service category**, choose **AWS services**.
6. For **Services**, add the filter **Type=Gateway** and then choose the option button next to **com.amazonaws.*region*.s3express**.
7. For **VPC**, choose the VPC in which to create the endpoint.
8. For **Route tables**, select the route tables to be used by the endpoint. Amazon VPC automatically adds a route that points traffic destined for the service to the endpoint network interface.
9. For **Policy**, choose **Full access** to allow all operations by all principals on all resources over the VPC endpoint. Otherwise, choose **Custom** to attach a VPC endpoint policy that controls the permissions that principals have to perform actions on resources over the VPC endpoint.
10. (Optional) To add a tag, choose **Add new tag**, and enter the tag key and the tag value.
11. Choose **Create endpoint**.

After creating a gateway endpoint, you can use Regional API endpoints and Zonal API endpoints to access Amazon S3 Express One Zone storage class objects and directory buckets.

# Directory buckets

There are two types of Amazon S3 buckets, general purpose buckets and directory buckets. Choose the bucket type that best fits your application and performance requirements:

- **General purpose buckets** are the original S3 bucket type and are recommended for most use cases and access patterns. General purpose buckets also allow objects that are stored across all storage classes, except S3 Express One Zone.
- **Directory buckets** use the S3 Express One Zone storage class, which is recommended if your application is performance sensitive and benefits from single-digit millisecond PUT and GET latencies.

Directory buckets are used for workloads or performance-critical applications that require consistent single-digit millisecond latency. Directory buckets organize data hierarchically into directories as opposed to the flat storage structure of general purpose buckets. There aren't prefix limits for directory buckets, and individual directories can scale horizontally.

Directory buckets use the S3 Express One Zone storage class, which stores data across multiple devices within a single Availability Zone but doesn't store data redundantly across Availability Zones. When you create a directory bucket, we recommend that you specify an AWS Region and an Availability Zone that's local to your Amazon EC2, Amazon Elastic Kubernetes Service, or Amazon Elastic Container Service (Amazon ECS) compute instances to optimize performance.

You can create up to 10 directory buckets in each of your AWS accounts, with no limit on the number of objects that you can store in a bucket. Your bucket quota is applied to each Region in your AWS account. If your application requires increasing this limit, contact AWS Support. For more information, visit the Service Quotas console.

**Important**

Directory buckets that have no request activity for a period of at least 90 days transition to an inactive state. While in an inactive state, a directory bucket is temporarily inaccessible for reads and writes. Inactive buckets retain all storage, object metadata, and bucket metadata. Existing storage charges apply to inactive buckets. If you make an access request to an inactive bucket, the bucket transitions to an active state, typically within a few minutes. During this transition period, reads and writes return an HTTP `503 (Service Unavailable)` error code.

The following topics provide information about directory buckets. For more information about general purpose buckets, see Buckets overview.

**Topics**

- Availability Zones
- Directory bucket names
- Directories
- Key names
- Access management
- Working with directory buckets

- Directory bucket naming rules
- Creating a directory bucket
- Viewing directory bucket properties
- Managing bucket policies for directory buckets
- Emptying a directory bucket
- Deleting a directory bucket
- Listing directory buckets
- Using HeadBucket with directory buckets

## Availability Zones

When you create a directory bucket, you choose the Availability Zone and AWS Region.

Directory buckets use the S3 Express One Zone storage class, which is built to be used by performance-sensitive applications. S3 Express One Zone is the first S3 storage class where you can select a single Availability Zone with the option to co-locate your object storage with your compute resources, which provides the highest possible access speed.

With S3 Express One Zone, your data is redundantly stored on multiple devices within a single Availability Zone. S3 Express One Zone is designed for 99.95 percent availability within a single Availability Zone and is backed by the Amazon S3 Service Level Agreement. For more information, see Single Availability Zone

## Directory bucket names

A directory bucket name consists of a base name that you provide and a suffix that contains the ID of the Availability Zone that your bucket is located in. Directory bucket names must use the following format and follow the naming rules for directory buckets:

```
bucket-base-name--azid--x-s3
```

For example, the following directory bucket name contains the Availability Zone ID `usw2-az1`:

```
bucket-base-name--usw2-az1--x-s3
```

For more information, see Directory bucket naming rules.

## Directories

Directory buckets organize data hierarchically into directories as opposed to the flat sorting structure of general purpose buckets. Each S3 directory bucket can support hundreds of thousands of transactions per second (TPS), independent of the number of directories within the bucket.

With a hierarchical namespace, the delimiter in the object key is important. The only supported delimiter is a forward slash (/). Directories are determined by delimiter boundaries. For example, the object key `dir1/dir2/file1.txt` results in the directories `dir1/` and `dir2/` being automatically created, and the object `file1.txt` being added to the `/dir2` directory in the path `dir1/dir2/file1.txt`.

The directory bucket indexing model returns unsorted results for the `ListObjectsV2` API operation. If you need to limit your results to a subsection of your bucket, you can specify a subdirectory path in the `prefix` parameter, for example, `prefix=dir1/`.

## Key names

For directory buckets, subdirectories that are common to multiple object keys are created with the first object key. Additional object keys for the same subdirectory use the previously created subdirectory. This model gives you flexibility in choosing object keys that are best suited to the application, with equal support for sparse and dense directories.

## Access management

Directory buckets have all S3 Block Public Access settings enabled by default at the bucket level. S3 Object Ownership is set to bucket owner enforced and access control lists (ACLs) are disabled. These settings can't be modified.

By default, users don't have permissions for directory buckets and S3 Express One Zone operations. To grant access permissions for directory buckets, you can use IAM to create users, groups, or roles and attach permissions to those identities. For more information, see AWS Identity and Access Management (IAM) for S3 Express One Zone.

## Working with directory buckets

For more information about working with directory buckets, see the following topics.

### Topics

- Directory bucket naming rules

- Creating a directory bucket
- Viewing directory bucket properties
- Managing bucket policies for directory buckets
- Emptying a directory bucket
- Deleting a directory bucket
- Listing directory buckets
- Using HeadBucket with directory buckets

## Directory bucket naming rules

When you create a directory bucket in Amazon S3, the following bucket naming rules apply. For general purpose bucket naming rules, see Bucket naming rules.

A directory bucket name consists of a base name that you provide, and a suffix that contains the ID of the AWS Availability Zone that your bucket is located in and `--x-s3`.

```
base-name--azid--x-s3
```

For example, the following directory bucket name contains the Availability Zone ID `usw2-az1`:

```
bucket-base-name--usw2-az1--x-s3
```

> **Note**
>
> When you create a directory bucket by using the console a suffix is automatically added to the base name that you provide. This suffix includes the Availability Zone ID of the Availability Zone that you chose.
> When you create a directory bucket by using an API you must provide the full suffix, including the Availability Zone ID, in your request. For a list of Availability Zone IDs, see S3 Express One Zone Availability Zones and Regions.

The following naming rules apply for directory buckets.

- Be unique within the chosen AWS Region and Availability Zone.
- Name must be between 3 (min) and 63 (max) characters long, including the suffix.

- Consists only of lowercase letters, numbers and hyphens (-).
- Begin and end with a letter or number.
- Must include the following suffix: `--azid--x-s3`.
- Bucket names must not start with the prefix `xn--`.
- Bucket names must not start with the prefix `sthree-`.
- Bucket names must not start with the prefix `sthree-configurator`.
- Bucket names must not start with the prefix `amzn-s3-demo-`.
- Bucket names must not end with the suffix `-s3alias`. This suffix is reserved for access point alias names. For more information, see Using a bucket-style alias for your S3 bucket access point.
- Bucket names must not end with the suffix `--ol-s3`. This suffix is reserved for Object Lambda Access Point alias names. For more information, see How to use a bucket-style alias for your S3 bucket Object Lambda Access Point.
- Bucket names must not end with the suffix `.mrap`. This suffix is reserved for Multi-Region Access Point names. For more information, see Rules for naming Amazon S3 Multi-Region Access Points.

## Creating a directory bucket

To start using the Amazon S3 Express One Zone storage class, you create a directory bucket. The S3 Express One Zone storage class can be used only with directory buckets. The S3 Express One Zone storage class supports low-latency use cases and provides faster data processing within a single Availability Zone. If your application is performance sensitive and benefits from single-digit millisecond PUT and GET latencies, we recommend creating a directory bucket so that you can use the S3 Express One Zone storage class.

There are two types of Amazon S3 buckets, general purpose buckets and directory buckets. You should choose the bucket type that best fits your application and performance requirements. General purpose buckets are the original S3 bucket type. General purpose buckets are recommended for most use cases and access patterns and allow objects stored across all storage classes, except S3 Express One Zone. For more information about general purpose buckets, see Buckets overview.

Directory buckets use the S3 Express One Zone storage class, which is designed to be used for workloads or performance-critical applications that require consistent single-digit millisecond latency. S3 Express One Zone is the first S3 storage class where you can select a single Availability Zone with the option to co-locate your object storage with your compute resources, which

provides the highest possible access speed. When you create a directory bucket, you can optionally specify an AWS Region and an Availability Zone that's local to your Amazon EC2, Amazon Elastic Kubernetes Service, or Amazon Elastic Container Service (Amazon ECS) compute instances to optimize performance.

With S3 Express One Zone, your data is redundantly stored on multiple devices within a single Availability Zone. S3 Express One Zone is designed for 99.95 percent availability within a single Availability Zone and is backed by the Amazon S3 Service Level Agreement. For more information, see Single Availability Zone

Directory buckets organize data hierarchically into directories, as opposed to the flat storage structure of general purpose buckets. There aren't prefix limits for directory buckets, and individual directories can scale horizontally.

For more information about directory buckets, see Directory buckets.

**Directory bucket names**

Directory bucket names must follow this format and comply with the rules for directory bucket naming:

```
bucket-base-name--azid--x-s3
```

For example, the following directory bucket name contains the Availability Zone ID `usw2-az1`:

```
bucket-base-name--usw2-az1--x-s3
```

For more information about directory bucket naming rules, see Directory bucket naming rules.

**Using the S3 console**

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the navigation bar on the top of the page, choose the name of the currently displayed AWS Region. Next, choose the Region in which you want to create a bucket.

> **Note**
>
> To minimize latency and costs and address regulatory requirements, choose a Region close to you. Objects stored in a Region never leave that Region unless you explicitly

transfer them to another Region. For a list of Amazon S3 AWS Regions, see AWS service endpoints in the *Amazon Web Services General Reference*.

3. In the left navigation pane, choose **Buckets**.
4. Choose **Create bucket**.

   The **Create bucket** page opens.
5. Under **General configuration**, view the AWS Region where your bucket will be created.
6. Under **Bucket type**, choose **Directory**.

> **Note**
>
> - If you've chosen a Region that doesn't support directory buckets, the **Bucket type** option disappears, and the bucket type defaults to a general purpose bucket. To create a directory bucket, you must choose a supported Region. For a list of Regions that support directory buckets and the Amazon S3 Express One Zone storage class, see the section called "S3 Express One Zone Availability Zones and Regions".
> - After you create the bucket, you can't change the bucket type.

For **Availability Zone**, choose a Availability Zone local to your compute services. For a list of Availability Zones that support directory buckets and the S3 Express One Zone storage class, see the section called "S3 Express One Zone Availability Zones and Regions".

> **Note**
>
> The Availability Zone can't be changed after the bucket is created.

7. Under **Availability Zone** , select the check box to acknowledge that in the event of an Availability Zone outage, your data might be unavailable or lost.

> **Important**
>
> Although directory buckets are stored across multiple devices within a single Availability Zone, directory buckets don't store data redundantly across Availability Zones.

8. For **Bucket name**, enter a name for your directory bucket.

   The following naming rules apply for directory buckets.

   - Be unique within the chosen AWS Region and Availability Zone.
   - Name must be between 3 (min) and 63 (max) characters long, including the suffix.
   - Consists only of lowercase letters, numbers and hyphens (-).
   - Begin and end with a letter or number.
   - Must include the following suffix: `--`*`azid`*`--x-s3`.
   - Bucket names must not start with the prefix `xn--`.
   - Bucket names must not start with the prefix `sthree-`.
   - Bucket names must not start with the prefix `sthree-configurator`.
   - Bucket names must not start with the prefix `amzn-s3-demo-`.
   - Bucket names must not end with the suffix `-s3alias`. This suffix is reserved for access point alias names. For more information, see Using a bucket-style alias for your S3 bucket access point.
   - Bucket names must not end with the suffix `--ol-s3`. This suffix is reserved for Object Lambda Access Point alias names. For more information, see How to use a bucket-style alias for your S3 bucket Object Lambda Access Point.
   - Bucket names must not end with the suffix `.mrap`. This suffix is reserved for Multi-Region Access Point names. For more information, see Rules for naming Amazon S3 Multi-Region Access Points.

   A suffix is automatically added to the base name that you provide when you create a directory bucket using the console. This suffix includes the Availability Zone ID of the Availability Zone that you chose.

   After you create the bucket, you can't change its name. For more information about naming buckets, see Bucket naming rules.

   > **Important**
   >
   > Do not include sensitive information, such as account numbers, in the bucket name. The bucket name is visible in the URLs that point to the objects in the bucket.

9. Under **Object Ownership**, the **Bucket owner enforced** setting is automatically enabled, and all access control lists (ACLs) are disabled. For directory buckets, ACLs can't be enabled.

   **ACLs disabled**

   - **Bucket owner enforced (default)** – ACLs are disabled, and the bucket owner automatically owns and has full control over every object in the bucket. ACLs no longer affect access permissions to data in the S3 bucket. The bucket uses policies exclusively to define access control.

     A majority of modern use cases in Amazon S3 no longer require the use of ACLs. For more information, see Controlling ownership of objects and disabling ACLs for your bucket.

10. Under **Block Public Access settings for this bucket**, all Block Public Access settings for your directory bucket are automatically enabled. These settings can't be modified for directory buckets. For more information about blocking public access, see Blocking public access to your Amazon S3 storage.
11. Under **Server-side encryption settings**, Amazon S3 applies server-side encryption with Amazon S3 managed keys (SSE-S3) as the base level of encryption for all S3 buckets. All object uploads to directory buckets are encrypted with SSE-S3. For directory buckets, the encryption type can't be modified. For more information about SSE-S3, see the section called “Amazon S3 managed encryption keys (SSE-S3)”.
12. Choose **Create bucket**.

    After creating the bucket, you can add files and folders to the bucket. For more information, see the section called “Working with objects in a directory bucket”.

### Using the AWS SDKs

SDK for Go

This example shows how to create a directory bucket by using the AWS SDK for Go.

**Example**

```
var bucket = "..."

func runCreateBucket(c *s3.Client) {
    resp, err := c.CreateBucket(context.Background(), &s3.CreateBucketInput{
        Bucket: &bucket,
```

```
        CreateBucketConfiguration: &types.CreateBucketConfiguration{
            Location: &types.LocationInfo{
                Name: aws.String("usw2-az1"),
                Type: types.LocationTypeAvailabilityZone,
            },
            Bucket: &types.BucketInfo{
                DataRedundancy: types.DataRedundancySingleAvailabilityZone,
                Type:           types.BucketTypeDirectory,
            },
        },
    })
    var terr *types.BucketAlreadyOwnedByYou
    if errors.As(err, &terr) {
        fmt.Printf("BucketAlreadyOwnedByYou: %s\n", aws.ToString(terr.Message))
        fmt.Printf("noop...\n")
        return
    }
    if err != nil {
        log.Fatal(err)
    }

    fmt.Printf("bucket created at %s\n", aws.ToString(resp.Location))
}
```

SDK for Java 2.x

This example shows how to create an directory bucket by using the AWS SDK for Java 2.x.

**Example**

```
public static void createBucket(S3Client s3Client, String bucketName) {

    //Bucket name format is {base-bucket-name}--{az-id}--x-s3
    //example: doc-example-bucket--usw2-az1--x-s3 is a valid name for a directory
 bucket created in
    //Region us-west-2, Availability Zone 2

    CreateBucketConfiguration bucketConfiguration =
 CreateBucketConfiguration.builder()
             .location(LocationInfo.builder()
                     .type(LocationType.AVAILABILITY_ZONE)
                     .name("usw2-az1").build()) //this must match the Region and
 Availability Zone in your bucket name
```

```
            .bucket(BucketInfo.builder()
                   .type(BucketType.DIRECTORY)
                   .dataRedundancy(DataRedundancy.SINGLE_AVAILABILITY_ZONE)
                   .build()).build();
    try {

            CreateBucketRequest bucketRequest =
 CreateBucketRequest.builder().bucket(bucketName).createBucketConfiguration(bucketConfigurat
            CreateBucketResponse response = s3Client.createBucket(bucketRequest);
            System.out.println(response);
    }

    catch (S3Exception e) {
            System.err.println(e.awsErrorDetails().errorMessage());
            System.exit(1);
         }
    }
```

AWS SDK for JavaScript

This example shows how to create a directory bucket by using the AWS SDK for JavaScript.

**Example**

```
// file.mjs, run with Node.js v16 or higher
// To use with the preview build, place this in a folder
// inside the preview build directory, such as /aws-sdk-js-v3/workspace/

import { S3 } from "@aws-sdk/client-s3";

const region = "us-east-1";
const zone = "use1-az4";
const suffix = `${zone}--x-s3`;

const s3 = new S3({ region });

const bucketName = `...--${suffix}`;

const createResponse = await s3.createBucket(
    { Bucket: bucketName,
      CreateBucketConfiguration: {Location: {Type: "AvailabilityZone", Name: zone},
```

```
      Bucket: { Type: "Directory", DataRedundancy: "SingleAvailabilityZone" }}
    }
   );
```

AWS SDK for .NET

This example shows how to create a directory bucket by using the AWS SDK for .NET.

**Example**

```
using (var amazonS3Client = new AmazonS3Client())
{
    var putBucketResponse = await amazonS3Client.PutBucketAsync(new PutBucketRequest
    {

       BucketName = "DOC-EXAMPLE-BUCKET--usw2-az1--x-s3",
       PutBucketConfiguration = new PutBucketConfiguration
       {
         BucketInfo = new BucketInfo { DataRedundancy =
 DataRedundancy.SingleAvailabilityZone, Type = BucketType.Directory },
         Location = new LocationInfo { Name = "usw2-az1", Type =
 LocationType.AvailabilityZone }
       }
     }).ConfigureAwait(false);
}
```

SDK for PHP

This example shows how to create a directory bucket by using the AWS SDK for PHP.

**Example**

```
require 'vendor/autoload.php';

$s3Client = new S3Client([

    'region'      => 'us-east-1',
]);

$result = $s3Client->createBucket([
```

```
    'Bucket' => 'doc-example-bucket--use1-az4--x-s3',
    'CreateBucketConfiguration' => [
        'Location' => ['Name'=> 'use1-az4', 'Type'=> 'AvailabilityZone'],
        'Bucket' => ["DataRedundancy" => "SingleAvailabilityZone" ,"Type" =>
 "Directory"]   ],
]);
```

SDK for Python

This example shows how to create a directory bucket by using the AWS SDK for Python (Boto3).

**Example**

```
import logging
import boto3
from botocore.exceptions import ClientError

def create_bucket(s3_client, bucket_name, availability_zone):
    '''
    Create a directory bucket in a specified Availability Zone

    :param s3_client: boto3 S3 client
    :param bucket_name: Bucket to create; for example, 'doc-example-bucket--usw2-
az1--x-s3'
    :param availability_zone: String; Availability Zone ID to create the bucket in,
 for example, 'usw2-az1'
    :return: True if bucket is created, else False
    '''

    try:
        bucket_config = {
                'Location': {
                    'Type': 'AvailabilityZone',
                    'Name': availability_zone
                },
                'Bucket': {
                    'Type': 'Directory',
                    'DataRedundancy': 'SingleAvailabilityZone'
                }
            }
        s3_client.create_bucket(
            Bucket = bucket_name,
            CreateBucketConfiguration = bucket_config
```

```
        )
    except ClientError as e:
        logging.error(e)
        return False
    return True

if __name__ == '__main__':
    bucket_name = 'BUCKET_NAME'
    region = 'us-west-2'
    availability_zone = 'usw2-az1'
    s3_client = boto3.client('s3', region_name = region)
    create_bucket(s3_client, bucket_name, availability_zone)
```

SDK for Ruby

This example shows how to create an directory bucket by using the AWS SDK for Ruby.

**Example**

```
s3 = Aws::S3::Client.new(region:'us-west-2')
s3.create_bucket(
  bucket: "bucket_base_name--az_id--x-s3",
  create_bucket_configuration: {
    location: { name: 'usw2-az1', type: 'AvailabilityZone' },
    bucket: { data_redundancy: 'SingleAvailabilityZone', type: 'Directory' }
  }
)
```

### Using the AWS CLI

This example shows how to create a directory bucket by using the AWS CLI. To use the command replace the *`user input placeholders`* with your own information.

When you create a directory bucket you must provide configuration details and use the following naming convention: *`bucket-base-name`*`--`*`azid`*`--x-s3`

```
aws s3api create-bucket
--bucket bucket-base-name--azid--x-s3
--create-bucket-configuration 'Location={Type=AvailabilityZone,Name=usw2-
az1},Bucket={DataRedundancy=SingleAvailabilityZone,Type=Directory}'
```

```
--region us-west-2
```

For more information, see create-bucket in the AWS Command Line Interface.

## Viewing directory bucket properties

You can view and configure the properties for an Amazon S3 directory bucket by using the Amazon S3 console. For more information, see Directory buckets and What is S3 Express One Zone?.

### Using the S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Buckets**.
3. Choose the **Directory buckets** tab.
4. In the **Directory buckets** list, choose the name of the bucket that you want to view the properties for.
5. Choose the **Properties** tab.
6. On the **Properties** tab, you can view the following properties for the bucket:

   - **Directory bucket overview** – You can see the AWS Region, Availability Zone, Amazon Resource Name (ARN), and creation date for the bucket.
   - **Default encryption** – Amazon S3 applies server-side encryption with Amazon S3 managed keys (SSE-S3) as the base level of encryption for all S3 buckets. For directory buckets, this setting can't be modified. Amazon S3 encrypts an object before saving it to a disk and decrypts the object when you download it. For more information, see Setting default server-side encryption behavior for Amazon S3 buckets.

     For more information about supported features for directory buckets, see Features of S3 Express One Zone.

## Managing bucket policies for directory buckets

You can add, delete, update, and view bucket policies for Amazon S3 directory buckets by using the Amazon S3 console and the AWS SDKs. For more information, see the following topics. For more information about supported AWS Identity and Access Management (IAM) actions and condition keys for S3 Express One Zone, see AWS Identity and Access Management (IAM) for S3 Express One

Zone. For example bucket policies for directory buckets, see Example directory bucket policies for S3 Express One Zone.

**Topics**

## Adding a bucket policy

To add a bucket policy to a directory bucket, you can use the Amazon S3 console, the AWS SDKs, or the AWS CLI.

### Using the S3 console

**To create or edit a bucket policy**

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Buckets**.
3. Choose the **Directory buckets** tab.
4. In the **Directory buckets** list, choose the name of the bucket that you want to upload your folders or files to.
5. Choose the **Permissions** tab.
6. Under **Bucket policy**, choose **Edit**. The **Edit bucket policy** page appears.
7. To generate a policy automatically, choose **Policy generator**.

   If you choose **Policy generator**, the AWS Policy Generator opens in a new window.

   If you don't want to use the AWS Policy Generator, you can add or edit JSON statements in the **Policy** section.

   a. On the **AWS Policy Generator** page, for **Select Type of Policy**, choose **S3 Bucket Policy**.

   b. Add a statement by entering the information in the provided fields, and then choose **Add Statement**. Repeat this step for as many statements as you want to add. For more information about these fields, see the IAM JSON policy elements reference in the *IAM User Guide*.

> **Note**
>
> For your convenience, the **Edit bucket policy** page displays the **Bucket ARN** (Amazon Resource Name) of the current bucket above the **Policy** text field. You can copy this ARN for use in the statements on the **AWS Policy Generator** page.

c. After you finish adding statements, choose **Generate Policy**.

d. Copy the generated policy text, choose **Close**, and return to the **Edit bucket policy** page in the Amazon S3 console.

8. In the **Policy** box, edit the existing policy or paste the bucket policy from the AWS Policy Generator. Make sure to resolve security warnings, errors, general warnings, and suggestions before you save your policy.

> **Note**
>
> Bucket policies are limited to 20 KB in size.

9. Choose **Save changes**, which returns you to the **Permissions** tab.

### Using the AWS SDKs

SDK for Java 2.x

#### Example

PutBucketPolicy AWS SDK for Java 2.x

```
public static void setBucketPolicy(S3Client s3Client, String bucketName, String
 policyText) {

      //sample policy text
      /**
       * policy_statement = {
       *         'Version': '2012-10-17',
       *         'Statement': [
       *             {
       *                 'Sid': 'AdminPolicy',
       *                 'Effect': 'Allow',
       *                 'Principal': {
```

```
        *                     "AWS": "111122223333"
        *                 },
        *                 'Action': 's3express:*',
        *                 'Resource':
'arn:aws:s3express:region:111122223333:bucket/bucket-base-name--azid--x-s3'
        *             }
        *         ]
        *     }
        */
        System.out.println("Setting policy:");
        System.out.println("----");
        System.out.println(policyText);
        System.out.println("----");
        System.out.format("On Amazon S3 bucket: \"%s\"\n", bucketName);

        try {
            PutBucketPolicyRequest policyReq = PutBucketPolicyRequest.builder()
                    .bucket(bucketName)
                    .policy(policyText)
                    .build();
            s3Client.putBucketPolicy(policyReq);
            System.out.println("Done!");
        }

        catch (S3Exception e) {
            System.err.println(e.awsErrorDetails().errorMessage());
            System.exit(1);
        }
    }
```

### Using the AWS CLI

This example shows how to add a bucket policy to a directory bucket by using the AWS CLI. To use the command replace the *user input placeholders* with your own information.

```
aws s3api put-bucket-policy --bucket bucket-base-name--azid--x-s3 --policy file://
bucket_policy.json
```

bucket_policy.json:

```
{
```

```
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AdminPolicy",
            "Effect": "Allow",
            "Principal": {
                "AWS": "111122223333"
            },
            "Action": "s3express*",
            "Resource": "arn:aws:s3express:us-west-2:111122223333:bucket/"
        }
    ]
}
```

For more information, see put-bucket-policy in the AWS Command Line Interface.

## Viewing a bucket policy

To view a bucket policy for a directory bucket, use the following examples.

### Using the AWS CLI

This example shows how to view the bucket policy attached to a directory bucket by using the AWS CLI. To use the command replace the *user input placeholders* with your own information.

```
aws s3api get-bucket-policy --bucket bucket-base-name--azid--x-s3
```

For more information, see get-bucket-policy in the AWS Command Line Interface.

## Deleting a bucket policy

To delete a bucket policy for a directory bucket, use the following examples.

### Using the AWS SDKs

SDK for Java 2.x

#### Example

`DeleteBucketPolicy` AWS SDK for Java 2.x

```
public static void deleteBucketPolicy(S3Client s3Client, String bucketName) {
      try {
          DeleteBucketPolicyRequest deleteBucketPolicyRequest =
 DeleteBucketPolicyRequest
                  .builder()
                  .bucket(bucketName)
                  .build()
          s3Client.deleteBucketPolicy(deleteBucketPolicyRequest);
          System.out.println("Successfully deleted bucket policy");
      }

      catch (S3Exception e) {
          System.err.println(e.awsErrorDetails().errorMessage());
          System.exit(1);
      }
```

#### Using the AWS CLI

This example shows how to delete a bucket policy for a directory bucket by using the AWS CLI. To use the command replace the *user input placeholders* with your own information.

```
aws s3api delete-bucket-policy --bucket bucket-base-name--azid--x-s3
```

For more information, see delete-bucket-policy in the AWS Command Line Interface.

## Emptying a directory bucket

You can empty an Amazon S3 directory bucket by using the Amazon S3 console. For more information about directory buckets, see Directory buckets.

Before you empty a directory bucket, note the following:

- When you empty a directory bucket, you delete all the objects, but you keep the directory bucket.
- After you empty a directory bucket, the empty action can't be undone.
- Objects that are added to the directory bucket while the empty bucket action is in progress might be deleted.

If you also want to delete the bucket, note the following:

- All objects in the directory bucket must be deleted before the bucket itself can be deleted.
- In-progress multipart uploads in the directory bucket must be aborted before the bucket itself can be deleted.

> **Note**
>
> The `s3 rm` command through the AWS Command Line Interface (CLI), the `delete` operation through Mountpoint, and the **Empty** bucket option button through the AWS Management Console are unable to delete in-progress multipart uploads in a directory bucket. To delete these in-progress multipart uploads, use the `ListMultipartUploads` operation to list the in-progress multipart uploads in the bucket and use the `AbortMultipartUpload` operation to abort all the in-progress multipart uploads.

To delete a directory bucket, see Deleting a directory bucket. To abort an in-progress multipart upload, see the section called "Aborting a multipart upload".

To empty a general purpose bucket, see Emptying a bucket.

**Using the S3 console**

**To empty a directory bucket**

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Buckets**.
3. Choose the **Directory buckets** tab.
4. Choose the option button next to the name of the bucket that you want to empty, and then choose **Empty**.
5. On the **Empty bucket** page, confirm that you want to empty the bucket by entering **`permanently delete`** in the text field, and then choose **Empty**.
6. Monitor the progress of the bucket emptying process on the **Empty bucket: status** page.

## Deleting a directory bucket

You can delete only empty Amazon S3 directory buckets. Before you delete your directory bucket, you must delete all objects in the bucket and abort all in-progress multipart uploads.

To empty a directory bucket, see Emptying a directory bucket. To abort an in-progress multipart upload, see the section called "Aborting a multipart upload".

To delete a general purpose bucket, see Deleting a bucket.

### Using the S3 console

After you empty your directory bucket and abort all in-progress multipart uploads, you can delete your bucket.

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Buckets**.
3. Choose the **Directory buckets** tab.
4. In the **Directory buckets** list, choose the option button next to the bucket that you want to delete.
5. Choose **Delete**.
6. On the **Delete bucket** page, enter the name of the bucket in the text field to confirm the deletion of your bucket.

   > **Important**
   >
   > Deleting a directory bucket can't be undone.

7. To delete your directory bucket, choose **Delete bucket**.

### Using the AWS SDKs

The following examples delete a directory bucket by using the AWS SDK for Java 2.x and AWS SDK for Python (Boto3).

SDK for Java 2.x

**Example**

```
public static void deleteBucket(S3Client s3Client, String bucketName) {

    try {
        DeleteBucketRequest del = DeleteBucketRequest.builder()
```

```
                .bucket(bucketName)
                .build();
        s3Client.deleteBucket(del);
        System.out.println("Bucket " + bucketName + " has been deleted");
    }
    catch (S3Exception e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}
```

SDK for Python

**Example**

```
import logging
import boto3
from botocore.exceptions import ClientError

def delete_bucket(s3_client, bucket_name):
    '''
    Delete a directory bucket in a specified Region

    :param s3_client: boto3 S3 client
    :param bucket_name: Bucket to delete; for example, 'doc-example-bucket--usw2-
az1--x-s3'
    :return: True if bucket is deleted, else False
    '''

    try:
        s3_client.delete_bucket(Bucket = bucket_name)
    except ClientError as e:
        logging.error(e)
        return False
    return True

if __name__ == '__main__':
    bucket_name = 'BUCKET_NAME'
    region = 'us-west-2'
    s3_client = boto3.client('s3', region_name = region)
```

### Using the AWS CLI

This example shows how to delete a directory bucket by using the AWS CLI. To use the command replace the *user input placeholders* with your own information.

```
aws s3api delete-bucket --bucket bucket-base-name--azid--x-s3 --region us-west-2
```

For more information, see delete-bucket in the AWS Command Line Interface.

## Listing directory buckets

The following examples show how to list directory buckets by using the AWS SDKs and AWS CLI.

### Using the AWS SDKs

SDK for Java 2.x

#### Example

The following example lists directory buckets by using the AWS SDK for Java 2.x.

```
public static void listBuckets(S3Client s3Client) {
       try {
           ListDirectoryBucketsRequest listDirectoryBucketsRequest =
ListDirectoryBucketsRequest.builder().build();
           ListDirectoryBucketsResponse response =
s3Client.listDirectoryBuckets(listDirectoryBucketsRequest);
           if (response.hasBuckets()) {
               for (Bucket bucket: response.buckets()) {
                   System.out.println(bucket.name());
                   System.out.println(bucket.creationDate());
               }
           }
       }

       catch (S3Exception e) {
           System.err.println(e.awsErrorDetails().errorMessage());
           System.exit(1);
       }
   }
```

SDK for Python

**Example**

The following example lists directory buckets by using the AWS SDK for Python (Boto3).

```
import logging
import boto3
from botocore.exceptions import ClientError

def list_directory_buckets(s3_client):
'''
Prints a list of all directory buckets in a Region

:param s3_client: boto3 S3 client
:return: True if there are buckets in the Region, else False
'''
try:
    response = s3_client.list_directory_buckets()
    for bucket in response['Buckets']:
        print (bucket['Name'])
except ClientError as e:
    logging.error(e)
    return False
return True

if __name__ == '__main__':
    region = 'us-east-1'
    s3_client = boto3.client('s3', region_name = region)
    list_directory_buckets(s3_client)
```

AWS SDK for .NET

**Example**

The following example lists directory buckets by using the AWS SDK for .NET.

```
var listDirectoryBuckets = await amazonS3Client.ListDirectoryBucketsAsync(new
 ListDirectoryBucketsRequest
{
```

```
  MaxDirectoryBuckets = 10
  }).ConfigureAwait(false);
```

SDK for PHP

**Example**

The following example lists directory buckets by using the AWS SDK for PHP.

```
require 'vendor/autoload.php';

$s3Client = new S3Client([
    'region'      => 'us-east-1',
]);
$result = $s3Client->listDirectoryBuckets();
```

SDK for Ruby

**Example**

The following example lists directory buckets by using the AWS SDK for Ruby.

```
s3 = Aws::S3::Client.new(region:'us-west-1')
s3.list_directory_buckets
```

### Using the AWS CLI

The following `list-directory-buckets` example command shows how you can use the AWS CLI to list your directory buckets in the *`us-east-1`* region. To run this command, replace the *`user input placeholders`* with your own information.

```
aws s3api list-directory-buckets --region us-east-1
```

For more information, see list-directory-buckets in the *AWS CLI Command Reference*.

## Using HeadBucket with directory buckets

The following AWS SDK examples show how to use the `HeadBucket` API operation to determine if an Amazon S3 directory bucket exists and if you have permission to access it.

### Using the AWS SDKs

The following AWS SDK for Java 2.x example shows how to determine if a bucket exists and if you have permission to access it.

SDK for Java 2.x

#### Example

AWS SDK for Java 2.x

```
public static void headBucket(S3Client s3Client, String bucketName) {
   try {
        HeadBucketRequest headBucketRequest = HeadBucketRequest
                .builder()
                .bucket(bucketName)
                .build();
        s3Client.headBucket(headBucketRequest);
        System.out.format("Amazon S3 bucket: \"%s\" found.", bucketName);
   }

   catch (S3Exception e) {
       System.err.println(e.awsErrorDetails().errorMessage());
       System.exit(1);
   }
}
```

### Using the AWS CLI

The following `head-bucket` example command shows how you can use the AWS CLI to determine if a directory bucket exists and if you have permission to access it. To run this command, replace the user input placeholders with your own information.

```
aws s3api head-bucket --bucket bucket-base-name--azid--x-s3
```

For more information, see head-bucket in the *AWS CLI Command Reference*.

# Working with objects in a directory bucket

After you create an Amazon S3 directory bucket, you can work with objects by using the Amazon S3 console, AWS Command Line Interface (AWS CLI), and the AWS SDKs.

For more information about bulk object operations with objects stored in the S3 Express One Zone storage class, see Object management. For more information about importing, uploading, copying, deleting, and downloading objects and reading metadata from objects in directory buckets, see the following topics.

**Topics**

## Importing objects into a directory bucket

After you create a directory bucket in Amazon S3, you can populate the new bucket with data by using the import action. Import is a streamlined method for creating S3 Batch Operations jobs to copy objects from general purpose buckets to directory buckets.

> **Note**
>
> The following limitations apply to import jobs:
>
> - The source bucket and the destination bucket must be in the same AWS Region and account.
> - The source bucket cannot be a directory bucket.
> - Objects larger than 5GB are not supported and will be omitted from the copy operation.

- Objects in the Glacier Flexible Retrieval, Glacier Deep Archive, Intelligent-Tiering Archive Access tier, and Intelligent-Tiering Deep Archive tier storage classes must be restored before they can be imported.
- Imported objects with MD5 checksum algorithms are converted to use CRC32 checksums.
- Imported objects use server-side encryption with Amazon S3 managed keys (SSE-S3).
- Imported objects use the Express One Zone storage class, which has a different pricing structure than the storage classes used by general purpose buckets. Consider this difference in cost when importing large numbers of objects.

When you configure an import job, you specify the source bucket or prefix where the existing objects will be copied from. You also provide an AWS Identity and Access Management (IAM) role that has permissions to access the source objects. Amazon S3 then starts a Batch Operations job that copies the objects and automatically applies appropriate storage class and checksum settings.

To configure import jobs, you use the Amazon S3 console.

## Using the Amazon S3 console

### To import objects into a directory bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Buckets**, and then choose the **Directory** buckets tab. Choose the option button next to the directory bucket that you want to import objects into.
3. Choose **Import**.
4. For **Source**, enter the general purpose bucket (or bucket path including prefix) that contains the objects that you want to import. To choose an existing general purpose bucket from a list, choose **Browse S3**.
5. For **Permission to access and copy source objects**, do one of the following to specify an IAM role with the permissions necessary to import your source objects:
   - To allow Amazon S3 to create a new IAM role on your behalf, choose **Create new IAM role**.

> **Note**
>
> If your source objects are encrypted with server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS), don't choose the **Create new IAM role** option. Instead, specify an existing IAM role that has the `kms:Decrypt` permission.
> Amazon S3 will use this permission to decrypt your objects. During the import process, Amazon S3 will then re-encrypt those objects by using server-side encryption with Amazon S3 managed keys (SSE-S3).

- To choose an existing IAM role from a list, choose **Choose from existing IAM roles**.
- To specify an existing IAM role by entering its Amazon Resource Name (ARN), choose **Enter IAM role ARN**, then enter the ARN in the corresponding field.

6. Review the information that's displayed in the **Destination** and **Copied object settings** sections. If the information in the **Destination** section is correct, choose **Import** to start the copy job.

   The Amazon S3 console displays the status of your new job on the **Batch Operations** page. For more information about the job, choose the option button next to the job name, and then on the **Actions** menu, choose **View details**. To open the directory bucket that the objects will be imported into, choose **View import destination**.

## Using Batch Operations with S3 Express One Zone

You can use Amazon S3 Batch Operations to perform operations on objects stored in S3 buckets. To learn more about S3 Batch Operations, see Performing large-scale batch operations on Amazon S3 objects.

The following topics discuss performing batch operations on objects stored in the S3 Express One Zone storage class in directory buckets.

**Topics**

- Using Batch Operations with directory buckets
- Key differences

## Using Batch Operations with directory buckets

You can perform the **Copy** operation and the **Invoke AWS Lambda function** operations on objects that are stored in directory buckets. With **Copy**, you can copy objects between buckets of the same type (for example, from a directory bucket to a directory bucket). You can also copy between general purpose buckets and directory buckets. With **Invoke AWS Lambda function**, you can use a Lambda function to perform actions on objects in your directory bucket with code that you define.

### Copying objects

You can copy between the same bucket type or between directory buckets and general purpose buckets. When you copy to a directory bucket, you must use the correct Amazon Resource Name (ARN) format for this bucket type. The ARN format for a directory bucket is `arn:aws:s3express:region:account-id:bucket/bucket-base-name--x-s3`.

You can also populate your directory bucket with data by using the **Import** action in the S3 console. **Import** is a streamlined method for creating Batch Operations jobs to copy objects from general purpose buckets to directory buckets. For **Import** copy jobs from general purpose buckets to directory buckets, S3 automatically generates a manifest. For more information, see Importing objects to a directory bucket and Specifying a manifest.

### Invoking Lambda functions (`LambdaInvoke`)

There are special requirements for using Batch Operations to invoke Lambda functions that act on directory buckets. For example, you must structure your Lambda request by using a v2 JSON invocation schema, and specify InvocationSchemaVersion 2.0 when you create the job. For more information, see Invoke AWS Lambda function.

## Key differences

The following is a list of key differences when you're using Batch Operations to perform bulk operations on objects that are stored in directory buckets with the S3 Express One Zone storage class:

- Amazon S3 automatically encrypts all new objects that are uploaded to an S3 bucket. The default encryption configuration of an S3 bucket is always enabled and is at a minimum set to server-side encryption with Amazon S3 managed keys (SSE-S3). For directory buckets, only sSSE-S3 is supported. If you make a `CopyObject` request that sets server-side encryption with customer-provided keys (SSE-C) or server-side encryption with AWS Key Management Service

(AWS KMS) keys (SSE-KMS) on a directory bucket (source or destination), the response returns an HTTP `400 (Bad Request)` error.

- Objects in directory buckets can't be tagged. You can only specify an empty tag set. By default, Batch Operations copies tags. If you copy an object that has tags between general purpose buckets and directory buckets, you receive a `501 (Not Implemented)` response.
- S3 Express One Zone offers you the option to choose the checksum algorithm that is used to validate your data during uploads or downloads. You can select one of the following Secure Hash Algorithms (SHA) or Cyclic Redundancy Check (CRC) data-integrity check algorithms: CRC32, CRC32, SHA-1, and SHA-256. MD5-based checksums are not supported with the S3 Express One Zone storage class.
- By default, all Amazon S3 buckets set the S3 Object Ownership setting to bucket owner enforced and access control lists (ACLs) are disabled. For directory buckets, this setting can't be modified. You can copy an object from general purpose buckets to directory buckets. However, you can't overwrite the default ACL when you copy to or from a directory bucket.
- Regardless of how you specify your manifest, the list itself must be stored in a general purpose bucket. Batch Operations can't import existing manifests from (or save generated manifests to) directory buckets. However, objects described within the manifest can be stored in directory buckets.
- Batch Operations can't specify a directory bucket as a location in an S3 Inventory report. Inventory reports don't support directory buckets. You can create a manifest file for objects within a directory bucket by using the `ListObjectsV2` API operation to list the objects. You can then insert the list in a CSV file.

**Granting access**

To perform copy jobs, you must have the following permissions:

- To copy objects from one directory bucket to another directory bucket, you must have the `s3express:CreateSession` permission.
- To copy objects from directory buckets to general purpose buckets, you must have the `s3express:CreateSession` permission and the `s3:PutObject` permission to write the object copy to the destination bucket.
- To copy objects from general purpose buckets to directory buckets, you must have the `s3express:CreateSession` permission and the `s3:GetObject` permission to read the source object that is being copied.

For more information, see CopyObject in the *Amazon Simple Storage Service API Reference*.

- To invoke a Lambda function, you must grant permissions to your resource based on your Lambda function. To determine which permissions are required, check the corresponding API operations.

## Uploading an object to a directory bucket

After you create an Amazon S3 directory bucket, you can upload objects to it. The following examples show how to upload an object to a directory bucket by using the S3 console and the AWS SDKs. For information about bulk object upload operations with S3 Express One Zone, see Object management.

### Using the S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Buckets**.
3. Choose the **Directory buckets** tab.
4. Choose the name of the bucket that you want to upload your folders or files to.
5. In the **Objects** list, choose **Upload**.
6. On the **Upload** page, do one of the following:
   - Drag and drop files and folders to the dotted upload area.
   - Choose **Add files** or **Add folder**, choose the files or folders to upload, and then choose **Open** or **Upload**.
7. Under **Checksums**, choose the **Checksum function** that you want to use.

   (Optional) If you're uploading a single object that's less than 16 MB in size, you can also specify a precalculated checksum value. When you provide a precalculated value, Amazon S3 compares it with the value that it calculates by using the selected checksum function. If the values don't match, the upload won't start.
8. The options in the **Permissions** and **Properties** sections are automatically set to default settings and can't be modified. Block Public Access is automatically enabled, and S3 Versioning and S3 Object Lock can't be enabled for directory buckets.

(Optional) If you want to add metadata in key-value pairs to your objects, expand the **Properties** section, and then in the **Metadata** section, choose **Add metadata**.

9. To upload the listed files and folders, choose **Upload**.

   Amazon S3 uploads your objects and folders. When the upload is finished, you see a success message on the **Upload: status** page.

### Using the AWS SDKs

SDK for Java 2.x

#### Example

```
public static void putObject(S3Client s3Client, String bucketName, String objectKey,
 Path filePath) {
       //Using File Path to avoid loading the whole file into memory
       try {
           PutObjectRequest putObj = PutObjectRequest.builder()
                   .bucket(bucketName)
                   .key(objectKey)
                   //.metadata(metadata)
                   .build();
           s3Client.putObject(putObj, filePath);
           System.out.println("Successfully placed " + objectKey +" into bucket
 "+bucketName);

       }

       catch (S3Exception e) {
           System.err.println(e.getMessage());
           System.exit(1);
       }
}
```

SDK for Python

#### Example

```
import boto3
import botocore
```

```
from botocore.exceptions import ClientError

def put_object(s3_client, bucket_name, key_name, object_bytes):
    """
    Upload data to a directory bucket.
    :param s3_client: The boto3 S3 client
    :param bucket_name: The bucket that will contain the object
    :param key_name: The key of the object to be uploaded
    :param object_bytes: The data to upload
    """
    try:
        response = s3_client.put_object(Bucket=bucket_name, Key=key_name,
                                Body=object_bytes)
        print(f"Upload object '{key_name}' to bucket '{bucket_name}'.")
        return response
    except ClientError:
        print(f"Couldn't upload object '{key_name}' to bucket '{bucket_name}'.")
        raise

def main():
    # Share the client session with functions and objects to benefit from S3 Express
 One Zone auth key
    s3_client = boto3.client('s3')
    # Directory bucket name must end with --azid--x-s3
    resp = put_object(s3_client, 'doc-bucket-example--use1-az5--x-s3', 'sample.txt',
 b'Hello, World!')
    print(resp)

if __name__ == "__main__":
    main()
```

### Using the AWS CLI

The following `put-object` example command shows how you can use the AWS CLI to upload an object from Amazon S3. To run this command, replace the *`user input placeholders`* with your own information.

```
aws s3api put-object --bucket bucket-base-name--azid--x-s3 --key sampleinut/file001.bin
 --body bucket-seed/file001.bin
```

For more information, see put-object in the *AWS CLI Command Reference*.

# Using multipart uploads with directory buckets

You can use the multipart upload process to upload a single object as a set of parts. Each part is a contiguous portion of the object's data. You can upload these object parts independently and in any order. If transmission of any part fails, you can retransmit that part without affecting other parts. After all parts of your object are uploaded, Amazon S3 assembles these parts and creates the object. In general, when your object size reaches 100 MB, you should consider using multipart uploads instead of uploading the object in a single operation.

Using multipart upload provides the following advantages:

- **Improved throughput** – You can upload parts in parallel to improve throughput.
- **Quick recovery from any network issues** – Smaller part sizes minimize the impact of restarting a failed upload because of a network error.
- **Pause and resume object uploads** – You can upload object parts over time. After you initiate a multipart upload, there is no expiration date. You must explicitly complete or abort the multipart upload.
- **Begin an upload before you know the final object size** – You can upload an object as you are creating it.

We recommend that you use multipart uploads in the following ways:

- If you're uploading large objects over a stable high-bandwidth network, use multipart uploads to maximize the use of your available bandwidth by uploading object parts in parallel for multi-threaded performance.
- If you're uploading over a spotty network, use multipart uploads to increase resiliency to network errors by avoiding upload restarts. When using multipart uploads, you need to retry uploading only the parts that are interrupted during the upload. You don't need to restart uploading your object from the beginning.

When you're using multipart uploads to upload objects to the Amazon S3 Express One Zone storage class in directory buckets, the multipart upload process is similar to the process of using multipart upload to upload objects to general purpose buckets. However, there are some notable differences.

For more information about using multipart uploads to upload objects to S3 Express One Zone, see the following topics.

**Topics**

## The multipart upload process

A multipart upload is a three-step process:

- You initiate the upload.
- You upload the object parts.
- After you have uploaded all of the parts, you complete the multipart upload.

Upon receiving the complete multipart upload request, Amazon S3 constructs the object from the uploaded parts, and you can then access the object as you would any other object in your bucket.

**Multipart upload initiation**

When you send a request to initiate a multipart upload, Amazon S3 returns a response with an upload ID, which is a unique identifier for your multipart upload. You must include this upload ID whenever you upload parts, list the parts, complete an upload, or abort an upload.

**Parts upload**

When uploading a part, in addition to the upload ID, you must specify a part number. When you're using a multipart upload with S3 Express One Zone, the multipart part numbers must be consecutive part numbers. If you try to complete a multipart upload request with nonconsecutive part numbers, an `HTTP 400 Bad Request` (Invalid Part Order) error is generated.

A part number uniquely identifies a part and its position in the object that you are uploading. If you upload a new part by using the same part number as a previously uploaded part, the previously uploaded part is overwritten.

Whenever you upload a part, Amazon S3 returns an entity tag (ETag) header in its response. For each part upload, you must record the part number and the ETag value. The ETag values for all object part uploads will remain the same, but each part will be assigned a different part number. You must include these values in the subsequent request to complete the multipart upload.

Amazon S3 automatically encrypts all new objects that are uploaded to an S3 bucket. When doing a multipart upload, if you don't specify encryption information in your request, the encryption setting of the uploaded parts is set to the default encryption configuration of the destination bucket. The default encryption configuration of an Amazon S3 bucket is always enabled and is at a minimum set to server-side encryption with Amazon S3 managed keys (SSE-S3). For directory buckets, only SSE-S3 is supported. For more information, see Server-side encryption with Amazon S3 managed keys (SSE-S3).

**Multipart upload completion**

When you complete a multipart upload, Amazon S3 creates the object by concatenating the parts in ascending order based on the part number. After a successful *complete* request, the parts no longer exist.

Your *complete multipart upload* request must include the upload ID and a list of both part numbers and their corresponding ETag values. The Amazon S3 response includes an ETag that uniquely identifies the combined object data. This ETag is not an MD5 hash of the object data.

**Multipart upload listings**

You can list the parts of a specific multipart upload or all in-progress multipart uploads. The list parts operation returns the parts information that you have uploaded for a specific multipart upload. For each list parts request, Amazon S3 returns the parts information for the specified multipart upload, up to a maximum of 1,000 parts. If there are more than 1,000 parts in the multipart upload, you must use pagination to retrieve all the parts.

The returned list of parts doesn't include parts that haven't finished uploading. Using the *list multipart uploads* operation, you can obtain a list of multipart uploads that are in progress.

An in-progress multipart upload is an upload that you have initiated, but have not yet completed or aborted. Each request returns at most 1,000 multipart uploads. If there are more than 1,000 multipart uploads in progress, you must send additional requests to retrieve the remaining multipart uploads. Use the returned listing only for verification. Do not use the result of this listing when sending a *complete multipart upload* request. Instead, maintain your own list of the part

numbers that you specified when uploading parts and the corresponding ETag values that Amazon S3 returns.

For more information about multipart upload listings, see ListParts in the *Amazon Simple Storage Service API Reference*.

## Checksums with multipart upload operations

When you upload an object to, you can specify a checksum algorithm to check object integrity. MD5 is not supported for directory buckets. You can specify one of the following Secure Hash Algorithms (SHA) or Cyclic Redundancy Check (CRC) data-integrity check algorithms:

- CRC32
- CRC32C
- SHA-1
- SHA-256

You can use the Amazon S3 REST API or the AWS SDKs to retrieve the checksum value for individual parts by using `GetObject` or `HeadObject`. If you want to retrieve the checksum values for individual parts of multipart uploads still in process, you can use `ListParts`.

> **Important**
>
> When using the preceding checksum algorithms, the multipart part numbers must use consecutive part numbers. If you try to complete a multipart upload request with nonconsecutive part numbers, Amazon S3 generates an `HTTP 400 Bad Request` (Invalid Part Order) error.

For more information about how checksums work with multipart objects, see Checking object integrity.

## Concurrent multipart upload operations

In a distributed development environment, your application can initiate several updates on the same object at the same time. For example, your application might initiate several multipart uploads by using the same object key. For each of these uploads, your application can then upload

parts and send a complete upload request to Amazon S3 to create the object. For S3 Express One Zone, the object creation time is the completion date of the multipart upload.

> **Important**
>
> Versioning isn't supported for objects that are stored in directory buckets.

## Multipart uploads and pricing

After you initiate a multipart upload, Amazon S3 retains all the parts until you either complete or abort the upload. Throughout its lifetime, you are billed for all storage, bandwidth, and requests for this multipart upload and its associated parts. If you abort the multipart upload, Amazon S3 deletes the upload artifacts and any parts that you have uploaded, and you are no longer billed for them. There are no early delete charges for deleting incomplete multipart uploads, regardless of the storage class specified. For more information about pricing, see Amazon S3 pricing.

> **Important**
>
> If the complete multipart upload request isn't sent successfully, the object parts aren't assembled and an object isn't created. You are billed for all storage associated with uploaded parts. It's important that you either complete the multipart upload to have the object created or abort the multipart upload to remove any uploaded parts.
> Before you can delete a directory bucket, you must complete or abort all in-progress multipart uploads. Directory buckets don't support S3 Lifecycle configurations. If needed, you can list your active multipart uploads, then abort the uploads, and then delete your bucket.

## Multipart upload API operations and permissions

To allow access to object management API operations on a directory bucket, you grant the `s3express:CreateSession` permission in a bucket policy or an AWS Identity and Access Management (IAM) identity-based policy.

You must have the necessary permissions to use the multipart upload operations. You can use bucket policies or IAM identity-based policies to grant IAM principals permissions to perform these operations. The following table lists the required permissions for various multipart upload operations.

You can identify the initiator of a multipart upload through the `Initiator` element. If the initiator is an AWS account, this element provides the same information as the `Owner` element. If the initiator is an IAM user, this element provides the user ARN and display name.

| Action | Required permissions |
| --- | --- |
| Create a multipart upload | To create the multipart upload, you must be allowed to perform the `s3express:CreateSession` action on the directory bucket. |
| Initiate a multipart upload | To initiate the multipart upload, you must be allowed to perform the `s3express:CreateSession` action on the directory bucket. |
| Upload a part | To upload a part, you must be allowed to perform the `s3express:CreateSession` action on the directory bucket.<br><br>For the initiator to upload a part, the bucket owner must allow the initiator to perform the `s3express:CreateSession` action on the directory bucket. |
| Upload a part (copy) | To upload a part, you must be allowed to perform the `s3express:CreateSession` action on the directory bucket.<br><br>For the initiator to upload a part for an object, the owner of the bucket must allow the initiator to perform the `s3express:CreateSession` action on the object. |
| Complete a multipart upload | To complete a multipart upload, you must be allowed to perform the `s3express:CreateSession` action on the directory bucket.<br><br>For the initiator to complete a multipart upload, the bucket owner must allow the initiator to perform the `s3express:CreateSession` action on the object. |
| Abort a multipart upload | To abort a multipart upload, you must be allowed to perform the `s3express:CreateSession` action.<br><br>For the initiator to abort a multipart upload, the initiator must be granted explicit allow access to perform the `s3express:CreateSession` action. |

| Action | Required permissions |
| --- | --- |
| List parts | To list the parts in a multipart upload, you must be allowed to perform the `s3express:CreateSession` action on the directory bucket. |
| List in-progress multipart uploads | To list the in-progress multipart uploads to a bucket, you must be allowed to perform the `s3:ListBucketMultipartUploads` action on that bucket. |

### API operation support for multipart uploads

The following sections in the Amazon Simple Storage Service API Reference describe the Amazon S3 REST API operations for multipart uploads.

- CreateMultipartUpload
- UploadPart
- UploadPartCopy
- CompleteMultipartUpload
- AbortMultipartUpload
- ListParts
- ListMultipartUploads

## Examples

To use a multipart upload to upload an object to S3 Express One Zone in a directory bucket, see the following examples.

### Topics

- Creating a multipart upload
- Uploading the parts of a multipart upload
- Completing a multipart upload
- Aborting a multipart upload
- Creating a multipart upload copy operation
- Listing in-progress multipart uploads
- Listing the parts of a multipart upload

### Creating a multipart upload

The following examples show how to create a multipart upload.

### Using the AWS SDKs

SDK for Java 2.x

#### Example

```
/**
 * This method creates a multipart upload request that generates a unique upload ID
 that is used to track
 * all the upload parts
 *
 * @param s3
 * @param bucketName - for example, 'doc-example-bucket--use1-az4--x-s3'
 * @param key
 * @return
 */
 private static String createMultipartUpload(S3Client s3, String bucketName, String
 key) {

     CreateMultipartUploadRequest createMultipartUploadRequest =
 CreateMultipartUploadRequest.builder()
             .bucket(bucketName)
             .key(key)
             .build();

     String uploadId = null;

     try {
         CreateMultipartUploadResponse response =
 s3.createMultipartUpload(createMultipartUploadRequest);
         uploadId = response.uploadId();
     }
     catch (S3Exception e) {
         System.err.println(e.awsErrorDetails().errorMessage());
         System.exit(1);
     }
     return uploadId;
```

SDK for Python

**Example**

```
def create_multipart_upload(s3_client, bucket_name, key_name):
    '''
   Create a multipart upload to a directory bucket

   :param s3_client: boto3 S3 client
   :param bucket_name: The destination bucket for the multipart upload
   :param key_name: The key name for the object to be uploaded
   :return: The UploadId for the multipart upload if created successfully, else None
   '''

   try:
        mpu = s3_client.create_multipart_upload(Bucket = bucket_name, Key =
 key_name)
        return mpu['UploadId']
    except ClientError as e:
        logging.error(e)
        return None
```

### Using the AWS CLI

This example shows how to create a multipart upload to a directory bucket by using the AWS CLI. This command starts a multipart upload to the directory bucket *bucket-base-name*--*azid*--x-s3 for the object *KEY_NAME*. To use the command replace the *user input placeholders* with your own information.

```
aws s3api create-multipart-upload --bucket bucket-base-name--azid--x-s3 --key KEY_NAME
```

For more information, see create-multipart-upload in the AWS Command Line Interface.

### Uploading the parts of a multipart upload

The following examples show how to upload parts of a multipart upload.

### Using the AWS SDKs

SDK for Java 2.x

The following example shows how to break a single object into parts and then upload those parts to a directory bucket by using the SDK for Java 2.x.

#### Example

```
/**
 * This method creates part requests and uploads individual parts to S3 and then
 returns all the completed parts
 *
 * @param s3
 * @param bucketName
 * @param key
 * @param uploadId
 * @throws IOException
 */
 private static ListCompletedPartmultipartUpload(S3Client s3, String bucketName,
 String key, String uploadId, String filePath) throws IOException {

        int partNumber = 1;
        ListCompletedPart completedParts = new ArrayList<>();
        ByteBuffer bb = ByteBuffer.allocate(1024 * 1024 * 5); // 5 MB byte buffer

        // read the local file, breakdown into chunks and process
        try (RandomAccessFile file = new RandomAccessFile(filePath, "r")) {
            long fileSize = file.length();
            int position = 0;
            while (position < fileSize) {
                file.seek(position);
                int read = file.getChannel().read(bb);

                bb.flip(); // Swap position and limit before reading from the
 buffer.
                UploadPartRequest uploadPartRequest = UploadPartRequest.builder()
                        .bucket(bucketName)
                        .key(key)
                        .uploadId(uploadId)
                        .partNumber(partNumber)
                        .build();

                UploadPartResponse partResponse = s3.uploadPart(
```

```
                        uploadPartRequest,
                        RequestBody.fromByteBuffer(bb));

                CompletedPart part = CompletedPart.builder()
                        .partNumber(partNumber)
                        .eTag(partResponse.eTag())
                        .build();
                completedParts.add(part);

                bb.clear();
                position += read;
                partNumber++;
            }
        }

        catch (IOException e) {
            throw e;
        }
        return completedParts;
    }
```

SDK for Python

The following example shows how to break a single object into parts and then upload those parts to a directory bucket by using the SDK for Python.

**Example**

```
def multipart_upload(s3_client, bucket_name, key_name, mpu_id, part_size):
    '''
    Break up a file into multiple parts and upload those parts to a directory bucket

    :param s3_client: boto3 S3 client
    :param bucket_name: Destination bucket for the multipart upload
    :param key_name: Key name for object to be uploaded and for the local file
 that's being uploaded
    :param mpu_id: The UploadId returned from the create_multipart_upload call
    :param part_size: The size parts that the object will be broken into, in bytes.
                      Minimum 5 MiB, Maximum 5 GiB. There is no minimum size for the
 last part of your multipart upload.
    :return: part_list for the multipart upload if all parts are uploaded
 successfully, else None
    '''
```

```
    part_list = []
    try:
        with open(key_name, 'rb') as file:
            part_counter = 1
            while True:
                file_part = file.read(part_size)
                if not len(file_part):
                    break
                upload_part = s3_client.upload_part(
                    Bucket = bucket_name,
                    Key = key_name,
                    UploadId = mpu_id,
                    Body = file_part,
                    PartNumber = part_counter
                )
                part_list.append({'PartNumber': part_counter, 'ETag':
upload_part['ETag']})
                part_counter += 1
    except ClientError as e:
        logging.error(e)
        return None
    return part_list
```

### Using the AWS CLI

This example shows how to break a single object into parts and then upload those parts to a directory bucket by using the AWS CLI. To use the command replace the *user input placeholders* with your own information.

```
aws s3api upload-part --bucket bucket-base-name--azid--x-s3 --
key KEY_NAME --part-number 1 --body LOCAL_FILE_NAME --upload-id
 "AS_mgt9RaQE9GEaifATue15dAAAAAAAAAAEMAAAAAAAAADQwNzI4MDU0MjUyMBYAAAAAAAAAAA0AAAAAAAAAAH2AfYAA
```

For more information, see upload-part in the AWS Command Line Interface.

### Completing a multipart upload

The following examples show how to complete a multipart upload.

### Using the AWS SDKs

SDK for Java 2.x

The following examples show how to complete a multipart upload by using the SDK for Java 2.x.

#### Example

```
/**
 * This method completes the multipart upload request by collating all the upload
 parts
 * @param s3
 * @param bucketName - for example, 'doc-example-bucket--usw2-az1--x-s3'
 * @param key
 * @param uploadId
 * @param uploadParts
 */
 private static void completeMultipartUpload(S3Client s3, String bucketName, String
 key, String uploadId, ListCompletedPart uploadParts) {
        CompletedMultipartUpload completedMultipartUpload =
 CompletedMultipartUpload.builder()
                .parts(uploadParts)
                .build();

        CompleteMultipartUploadRequest completeMultipartUploadRequest =
                CompleteMultipartUploadRequest.builder()
                        .bucket(bucketName)
                        .key(key)
                        .uploadId(uploadId)
                        .multipartUpload(completedMultipartUpload)
                        .build();

        s3.completeMultipartUpload(completeMultipartUploadRequest);
    }

    public static void multipartUploadTest(S3Client s3, String bucketName, String
 key, String localFilePath)  {
        System.out.println("Starting multipart upload for: " + key);
        try {
            String uploadId = createMultipartUpload(s3, bucketName, key);
            System.out.println(uploadId);
            ListCompletedPart parts = multipartUpload(s3, bucketName, key, uploadId,
 localFilePath);
```

```
            completeMultipartUpload(s3, bucketName, key, uploadId, parts);
            System.out.println("Multipart upload completed for: " + key);
        }

        catch (Exception e) {
            System.err.println(e.getMessage());
            System.exit(1);
        }
    }
```

SDK for Python

The following examples show how to complete a multipart upload by using the SDK for Python.

**Example**

```
def complete_multipart_upload(s3_client, bucket_name, key_name, mpu_id, part_list):
    '''
    Completes a multipart upload to a directory bucket

    :param s3_client: boto3 S3 client
    :param bucket_name: The destination bucket for the multipart upload
    :param key_name: The key name for the object to be uploaded
    :param mpu_id: The UploadId returned from the create_multipart_upload call
    :param part_list: The list of uploaded part numbers with their associated ETags
    :return: True if the multipart upload was completed successfully, else False
    '''

    try:
        s3_client.complete_multipart_upload(
            Bucket = bucket_name,
            Key = key_name,
            UploadId = mpu_id,
            MultipartUpload = {
                'Parts': part_list
            }
        )
    except ClientError as e:
        logging.error(e)
        return False
    return True

if __name__ == '__main__':
    MB = 1024 ** 2
```

```
    region = 'us-west-2'
    bucket_name = 'BUCKET_NAME'
    key_name = 'OBJECT_NAME'
    part_size = 10 * MB
    s3_client = boto3.client('s3', region_name = region)
    mpu_id = create_multipart_upload(s3_client, bucket_name, key_name)
    if mpu_id is not None:
        part_list = multipart_upload(s3_client, bucket_name, key_name, mpu_id,
part_size)
        if part_list is not None:
            if complete_multipart_upload(s3_client, bucket_name, key_name, mpu_id,
part_list):
                print (f'{key_name} successfully uploaded through a ultipart upload
to {bucket_name}')
            else:
                print (f'Could not upload {key_name} hrough a multipart upload to
{bucket_name}')
```

### Using the AWS CLI

This example shows how to complete a multipart upload for a directory bucket by using the AWS CLI. To use the command replace the *user input placeholders* with your own information.

```
aws s3api complete-multipart-upload --bucket bucket-base-name--azid--x-s3 --
key KEY_NAME --upload-id
 "AS_mgt9RaQE9GEaifATue15dAAAAAAAAAAEMAAAAAAAAADQwNzI4MDU0MjUyMBYAAAAAAAAAAA0AAAAAAAAAAH2AfYAA
 --multipart-upload file://parts.json
```

This example takes a JSON structure that describes the parts of the multipart upload that should be reassembled into the complete file. In this example, the `file://` prefix is used to load the JSON structure from a file in the local folder named `parts`.

parts.json:

```
parts.json
{
  "Parts": [
    {
      "ETag": "6b78c4a64dd641a58dac8d9258b88147",
      "PartNumber": 1
    }
  ]
```

```
}
```

For more information, see complete-multipart-upload in the AWS Command Line Interface.

### Aborting a multipart upload

The following examples show how to abort a multipart upload.

### Using the AWS SDKs

SDK for Java 2.x

The following example shows how to abort a multipart upload by using the SDK for Java 2.x.

#### Example

```
public static void abortMultiPartUploads( S3Client s3, String bucketName ) {

        try {
            ListMultipartUploadsRequest listMultipartUploadsRequest =
 ListMultipartUploadsRequest.builder()
                    .bucket(bucketName)
                    .build();

            ListMultipartUploadsResponse response =
 s3.listMultipartUploads(listMultipartUploadsRequest);
            ListMultipartUpload uploads = response.uploads();

            AbortMultipartUploadRequest abortMultipartUploadRequest;
            for (MultipartUpload upload: uploads) {
                abortMultipartUploadRequest = AbortMultipartUploadRequest.builder()
                        .bucket(bucketName)
                        .key(upload.key())
                        .uploadId(upload.uploadId())
                        .build();

                s3.abortMultipartUpload(abortMultipartUploadRequest);
            }

        }

        catch (S3Exception e) {
            System.err.println(e.getMessage());
            System.exit(1);
```

```
        }
    }
```

SDK for Python

The following example shows how to abort a multipart upload by using the SDK for Python.

**Example**

```
import logging
import boto3
from botocore.exceptions import ClientError

def abort_multipart_upload(s3_client, bucket_name, key_name, upload_id):
    '''
    Aborts a partial multipart upload in a directory bucket.

    :param s3_client: boto3 S3 client
    :param bucket_name: Bucket where the multipart upload was initiated - for
 example, 'doc-example-bucket--usw2-az1--x-s3'
    :param key_name: Name of the object for which the multipart upload needs to be
 aborted
    :param upload_id: Multipart upload ID for the multipart upload to be aborted
    :return: True if the multipart upload was successfully aborted, False if not
    '''
    try:
        s3_client.abort_multipart_upload(
            Bucket = bucket_name,
            Key = key_name,
            UploadId = upload_id
        )
    except ClientError as e:
        logging.error(e)
        return False
    return True

if __name__ == '__main__':
    region = 'us-west-2'
    bucket_name = 'BUCKET_NAME'
    key_name = 'KEY_NAME'
        upload_id = 'UPLOAD_ID'
    s3_client = boto3.client('s3', region_name = region)
```

```
    if abort_multipart_upload(s3_client, bucket_name, key_name, upload_id):
        print (f'Multipart upload for object {key_name} in {bucket_name} bucket has
 been aborted')
    else:
        print (f'Unable to abort multipart upload for object {key_name} in
 {bucket_name} bucket')
```

### Using the AWS CLI

The following example shows how to abort a multipart upload by using the AWS CLI. To use the command replace the *user input placeholders* with your own information.

```
aws s3api abort-multipart-upload --bucket bucket-base-name--azid--x-s3 --key KEY_NAME
 --upload-id
 "AS_mgt9RaQE9GEaifATue15dAAAAAAAAAAEMAAAAAAAAADQwNzI4MDU0MjUyMBYAAAAAAAAAAA0AAAAAAAAAAH2AfYAA
MAQAAAAB0OxUFeA7LTbWWFS8WYwhrxDxTIDN-pdEEq_agIHqsbg"
```

For more information, see abort-multipart-upload in the AWS Command Line Interface.

### Creating a multipart upload copy operation

The following examples show how to copy bjects from one bucket to another using a multipart upload.

### Using the AWS SDKs

SDK for Java 2.x

The following example shows how to use a multipart upload to programmatically copy an object from one bucket to another by using the SDK for Java 2.x.

**Example**

```
/**
 * This method creates a multipart upload request that generates a unique upload ID
 that is used to track
 * all the upload parts.
 *
 * @param s3
 * @param bucketName
 * @param key
 * @return
```

```
*/
private static String createMultipartUpload(S3Client s3, String bucketName, String
key) {
       CreateMultipartUploadRequest createMultipartUploadRequest =
CreateMultipartUploadRequest.builder()
               .bucket(bucketName)
               .key(key)
               .build();
       String uploadId = null;
       try {
           CreateMultipartUploadResponse response =
s3.createMultipartUpload(createMultipartUploadRequest);
           uploadId = response.uploadId();
       } catch (S3Exception e) {
           System.err.println(e.awsErrorDetails().errorMessage());
           System.exit(1);
       }
       return uploadId;
 }

 /**
  * Creates copy parts based on source object size and copies over individual parts
  *
  * @param s3
  * @param sourceBucket
  * @param sourceKey
  * @param destnBucket
  * @param destnKey
  * @param uploadId
  * @return
  * @throws IOException
  */
   public static ListCompletedPart multipartUploadCopy(S3Client s3, String
sourceBucket, String sourceKey, String destnBucket, String destnKey, String
uploadId) throws IOException {

       // Get the object size to track the end of the copy operation.
       HeadObjectRequest headObjectRequest = HeadObjectRequest
               .builder()
               .bucket(sourceBucket)
               .key(sourceKey)
               .build();
       HeadObjectResponse response = s3.headObject(headObjectRequest);
       Long objectSize = response.contentLength();
```

```
        System.out.println("Source Object size: " + objectSize);

```

### Using the AWS CLI

The following example shows how to use a multipart upload to programmatically copy an object from one bucket to a directory bucket using the AWS CLI. To use the command replace the *user input placeholders* with your own information.

```
aws s3api upload-part-copy --bucket bucket-base-name--azid--x-s3 --key TARGET_KEY_NAME
 --copy-source SOURCE_BUCKET_NAME/SOURCE_KEY_NAME --part-number 1 --upload-id
 "AS_mgt9RaQE9GEaifATue15dAAAAAAAAAAEMAAAAAAAAADQwNzI4MDU0MjUyMBYAAAAAAAAAAA0AAAAAAAAAAH2AfYAA
```

For more information, see upload-part-copy in the AWS Command Line Interface.

### Listing in-progress multipart uploads

To list in-progress multipart uploads to a directory bucket, you can use the AWS SDKs, or the AWS CLI.

### Using the AWS SDKs

SDK for Java 2.x

The following examples show how to list in-progress (incomplete) multipart uploads by using the SDK for Java 2.x.

**Example**

```
public static void listMultiPartUploads( S3Client s3, String bucketName) {
       try {
           ListMultipartUploadsRequest listMultipartUploadsRequest =
ListMultipartUploadsRequest.builder()
                .bucket(bucketName)
                .build();

           ListMultipartUploadsResponse response =
s3.listMultipartUploads(listMultipartUploadsRequest);
           List MultipartUpload uploads = response.uploads();
           for (MultipartUpload upload: uploads) {
               System.out.println("Upload in progress: Key = \"" + upload.key() +
"\", id = " + upload.uploadId());
           }
     }
     catch (S3Exception e) {
           System.err.println(e.getMessage());
           System.exit(1);
     }
 }
```

SDK for Python

The following examples show how to list in-progress (incomplete) multipart uploads by using the SDK for Python.

**Example**

```
import logging
import boto3
from botocore.exceptions import ClientError

def list_multipart_uploads(s3_client, bucket_name):
```

```
    '''
    List any incomplete multipart uploads in a directory bucket in e specified gion

    :param s3_client: boto3 S3 client
    :param bucket_name: Bucket to check for incomplete multipart uploads
    :return: List of incomplete multipart uploads if there are any, None if not
    '''

    try:
        response = s3_client.list_multipart_uploads(Bucket = bucket_name)
        if 'Uploads' in response.keys():
            return response['Uploads']
        else:
            return None
    except ClientError as e:
        logging.error(e)

if __name__ == '__main__':
    bucket_name = 'BUCKET_NAME'
    region = 'us-west-2'
    s3_client = boto3.client('s3', region_name = region)
    multipart_uploads = list_multipart_uploads(s3_client, bucket_name)
    if multipart_uploads is not None:
        print (f'There are {len(multipart_uploads)} ncomplete multipart uploads for
 {bucket_name}')
    else:
        print (f'There are no incomplete multipart uploads for {bucket_name}')
```

### Using the AWS CLI

The following examples show how to list in-progress (incomplete) multipart uploads by using the AWS CLI. To use the command replace the *`user input placeholders`* with your own information.

```
aws s3api list-multipart-uploads --bucket bucket-base-name--azid--x-s3
```

For more information, see list-multipart-uploads in the AWS Command Line Interface.

### Listing the parts of a multipart upload

The following examples show how to list the parts of a multipart upload to a directory bucket.

### Using the AWS SDKs

SDK for Java 2.x

The following examples show how to list the parts of a multipart upload to a directory bucket by using SDK for Java 2.x.

```
public static void listMultiPartUploadsParts( S3Client s3, String bucketName, String
 objKey, String uploadID) {

        try {
            ListPartsRequest listPartsRequest = ListPartsRequest.builder()
                .bucket(bucketName)
                .uploadId(uploadID)
                .key(objKey)
                .build();

            ListPartsResponse response = s3.listParts(listPartsRequest);
            ListPart parts = response.parts();
            for (Part part: parts) {
                System.out.println("Upload in progress: Part number = \"" +
 part.partNumber() + "\", etag = " + part.eTag());
            }

        }

        catch (S3Exception e) {
            System.err.println(e.getMessage());
            System.exit(1);
        }

    }
```

SDK for Python

The following examples show how to list the parts of a multipart upload to a directory bucket by using SDK for Python.

```
import logging
import boto3
from botocore.exceptions import ClientError
```

```
def list_parts(s3_client, bucket_name, key_name, upload_id):
    '''
    Lists the parts that have been uploaded for a specific multipart upload to a
 directory bucket.

    :param s3_client: boto3 S3 client
    :param bucket_name: Bucket that multipart uploads parts have been uploaded to
    :param key_name: Name of the object that has parts uploaded
    :param upload_id: Multipart upload ID that the parts are associated with
    :return: List of parts associated with the specified multipart upload, None if
 there are no parts
    '''
    parts_list = []
    next_part_marker = ''
    continuation_flag = True
    try:
        while continuation_flag:
            if next_part_marker == '':
                response = s3_client.list_parts(
                    Bucket = bucket_name,
                    Key = key_name,
                    UploadId = upload_id
                )
            else:
                response = s3_client.list_parts(
                    Bucket = bucket_name,
                    Key = key_name,
                    UploadId = upload_id,
                    NextPartMarker = next_part_marker
                )
            if 'Parts' in response:
                for part in response['Parts']:
                    parts_list.append(part)
                if response['IsTruncated']:
                    next_part_marker = response['NextPartNumberMarker']
                else:
                    continuation_flag = False
            else:
                continuation_flag = False
        return parts_list
    except ClientError as e:
        logging.error(e)
        return None
```

```
if __name__ == '__main__':
    region = 'us-west-2'
    bucket_name = 'BUCKET_NAME'
    key_name = 'KEY_NAME'
    upload_id = 'UPLOAD_ID'
    s3_client = boto3.client('s3', region_name = region)
    parts_list = list_parts(s3_client, bucket_name, key_name, upload_id)
    if parts_list is not None:
        print (f'{key_name} has {len(parts_list)} parts uploaded to {bucket_name}')
    else:
        print (f'There are no multipart uploads with that upload ID for
 {bucket_name} bucket')
```

#### Using the AWS CLI

The following examples show how to list the parts of a multipart upload to a directory bucket by using the AWS CLI. To use the command replace the *user input placeholders* with your own information.

```
aws s3api list-parts --bucket bucket-base-name--azid--x-s3 --key KEY_NAME --upload-id
 "AS_mgt9RaQE9GEaifATue15dAAAAAAAAAAEMAAAAAAAAADQwNzI4MDU0MjUyMBYAAAAAAAAAAA0AAAAAAAAAAH2AfYAA
```

For more information, see list-parts in the AWS Command Line Interface.

## Copying an object to a directory bucket

The copy operation creates a copy of an object that is already stored in Amazon S3. You can copy objects between directory buckets and general purpose buckets. You can also copy objects within a bucket and across buckets of the same type, for example, from directory bucket to directory bucket.

You can create a copy of object up to 5 GB in a single atomic operation. However, to copy an object that is greater than 5 GB, you must use the multipart upload API operations. For more information, see Using multipart uploads with directory buckets.

#### Permissions

To copy objects, you must have the following permissions:

- To copy objects from one directory bucket to another directory bucket, you must have the `s3express:CreateSession` permission.

- To copy objects from directory buckets to general purpose buckets, you must have the `s3express:CreateSession` permission and the `s3:PutObject` permission to write the object copy to the destination bucket.
- To copy objects from general purpose buckets to directory buckets, you must have the `s3express:CreateSession` permission and `s3:GetObject` permission to read the source object that is being copied.

  For more information, see CopyObject in the *Amazon Simple Storage Service API Reference*.

**Encryption**

Amazon S3 automatically encrypts all new objects that are uploaded to an S3 bucket. The default encryption configuration of an S3 bucket is always enabled and is at a minimum set to server-side encryption with Amazon S3 managed keys (SSE-S3).

For directory buckets, only SSE-S3 is supported. For general purpose buckets, you can use SSE-S3 (the default), server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS), dual-layer server-side encryption with AWS KMS keys (DSSE-KMS), or server-side encryption with customer-provided keys (SSE-C).

If you make a copy request that sets SSE-C, SSE-KMS, or DSSE-KMS parameters on a directory bucket as either the source or destination, the response returns an error,

**Tags**

Directory buckets don't support tags. If you copy an object that has tags from a general purpose bucket to a directory bucket, you receive an HTTP `501 (Not Implemented)` response. For more information, see CopyObject in the *Amazon Simple Storage Service API Reference*.

**ETags**

Entity tags (ETags) for S3 Express One Zone are random alphanumeric strings and are not MD5 checksums. To help ensure object integrity, use additional checksums.

**Additional checksums**

S3 Express One Zone offers you the option to choose the checksum algorithm that is used to validate your data during upload or download. You can select one of the following Secure Hash Algorithms (SHA) or Cyclic Redundancy Check (CRC) data-integrity check algorithms: CRC32,

CRC32C, SHA-1, and SHA-256. MD5-based checksums are not supported with the S3 Express One Zone storage class.

For more information, see S3 additional checksum best practices.

**Supported features**

For more information about which Amazon S3 features are supported for S3 Express One Zone, see How is S3 Express One Zone different?.

**Using the S3 console (copy to a directory bucket)**

**To copy an object from a general purpose bucket or a directory bucket to a directory bucket**

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Buckets**.
3. Choose the bucket that you want to copy objects from:
   - To copy from a general purpose bucket, choose the **General purpose buckets** tab.
   - To copy from a directory bucket, choose the **Directory buckets** tab.
4. Choose the general purpose bucket or directory bucket that contains the objects that you want to copy.
5. Choose the **Objects** tab. On the **Objects** page, select the check box to the left of the names of the objects that you want to copy.
6. On the **Actions** menu, choose **Copy**.

   The **Copy** page appears.
7. Under **Destination**, choose **Directory bucket** for your destination type. To specify the destination path, choose **Browse S3**, navigate to the destination, and then choose the option button to the left of the destination. Choose **Choose destination** in the lower-right corner.

   Alternatively, enter the destination path.
8. Under **Checksums**, choose whether you want to copy the objects with their existing checksum functions or replace the existing checksum functions with a new one. When you uploaded the objects, you had the option to specify the checksum algorithm that was used to verify data integrity. When copying the object, you have the option to choose a new function. If you dn't originally specify an additional checksum, you can use e **Checksums** section to add one.

> **Note**
>
> Even if you opt to use the same checksum function, your checksum value might change if the object is over 16 MB in size. The checksum value might change because of how checksums are calculated for multipart uploads. For more information about how the checksum might change when copying the object, see Using part-level checksums for multipart uploads.

To change the checksum function, choose **Replace with a new checksum function**. Choose the new checksum function from the dropdown list. When the object is copied over, the new checksum is calculated and stored by using the specified algorithm.

9. Choose **Copy** in the bottom-right corner. Amazon S3 copies your objects to the destination.

**Using the S3 console (copy to a general purpose bucket)**

**To copy an object from a directory bucket to a general purpose bucket**

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Buckets**.
3. Choose the **Directory buckets** tab.
4. Choose the directory bucket that contains the objects that you want to copy.
5. Choose the **Objects** tab. On the **Objects** page, select the check box to the left of the names of the objects that you want to copy.
6. On the **Actions** menu, choose **Copy**.
7. Under **Destination**, choose **General purpose bucket** for your destination type. To specify the destination path, choose **Browse S3**, navigate to the destination, and choose the option button to the left of the destination. Choose **Choose destination** in the lower-right corner.

   Alternatively, enter the destination path.
8. Under **Checksums**, choose whether you want to copy the objects with their existing checksum functions or replace the existing checksum functions with a new one. When you uploaded the objects, you had the option to specify the checksum algorithm that was used to verify data

integrity. When copying the object, you have the option to choose a new function. If you didn't originally specify an additional checksum, you can use the **Checksums** section to add one.

> **Note**
>
> Even if you opt to use the same checksum function, your checksum value might change if the object is over 16 MB in size. The checksum value might change because of how checksums are calculated for multipart uploads. For more information about how the checksum might change when copying the object, see Using part-level checksums for multipart uploads.

To change the checksum function, choose **Replace with a new checksum function**. Choose the new checksum function from the dropdown list. When the object is copied over, the new checksum is calculated and stored by using the specified algorithm.

9. Choose **Copy** in the bottom-right corner. Amazon S3 copies your objects to the destination.

### Using the AWS SDKs

SDK for Java 2.x

#### Example

```
public static void copyBucketObject (S3Client s3, String sourceBucket, String
objectKey, String targetBucket) {
     CopyObjectRequest copyReq = CopyObjectRequest.builder()
         .sourceBucket(sourceBucket)
         .sourceKey(objectKey)
         .destinationBucket(targetBucket)
         .destinationKey(objectKey)
         .build();
      String temp = "";

      try {
          CopyObjectResponse copyRes = s3.copyObject(copyReq);
          System.out.println("Successfully copied " + objectKey +" from bucket " +
sourceBucket +" into bucket "+targetBucket);
      }

      catch (S3Exception e) {
```

```
            System.err.println(e.awsErrorDetails().errorMessage());
            System.exit(1);
        }
}
```

### Using the AWS CLI

The following `copy-object` example command shows how you can use the AWS CLI to copy an object from one bucket to another bucket. You can copy objects between bucket types. To run this command, replace the user input placeholders with your own information.

```
aws s3api copy-object --copy-source bucket SOURCE_BUCKET/SOURCE_KEY_NAME --
key TARGET_KEY_NAME --bucket TARGET_BUCKET_NAME
```

For more information, see copy-object in the *AWS CLI Command Reference*.

## Deleting an object in a directory bucket

You can delete objects from an Amazon S3 directory bucket by using the Amazon S3 console, AWS Command Line Interface (AWS CLI), or AWS SDKs. For more information, see Directory buckets and What is S3 Express One Zone?.

**Warning**

- Deleting an object can't be undone.
- This action deletes all specified objects. When deleting folders, wait for the delete action to finish before adding new objects to the folder. Otherwise, new objects might be deleted as well.

**Note**

When you programmatically delete multiple objects from a directory bucket, note the following:

- Object keys in `DeleteObjects` requests must contain at least one non-white space character. Strings of all white space characters are not supported.

- Object keys in `DeleteObjects` requests cannot contain Unicode control characters, except for newline (`\n`), tab (`\t`), and carriage return (`\r`).

### Using the S3 console

#### To delete objects

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Buckets**.
3. Choose the **Directory buckets** tab.
4. Choose the directory bucket that contains the objects that you want to delete.
5. Choose the **Objects** tab. In the **Objects** list, select the check box to the left of the object or objects that you want to delete.
6. Choose **Delete**.
7. On the **Delete objects** page, enter **`permanently delete`** in the text box.
8. Choose **Delete objects**.

### Using the AWS SDKs

SDK for Java 2.x

#### Example

The following example deletes objects in a directory bucket by using the AWS SDK for Java 2.x.

```
static void deleteObject(S3Client s3Client, String bucketName, String objectKey) {

        try {

            DeleteObjectRequest del = DeleteObjectRequest.builder()
                    .bucket(bucketName)
                    .key(objectKey)
                    .build();
```

```
            s3Client.deleteObject(del);

            System.out.println("Object " + objectKey + " has been deleted");

        } catch (S3Exception e) {
            System.err.println(e.awsErrorDetails().errorMessage());
            System.exit(1);
        }

    }
```

SDK for Python

**Example**

The following example deletes objects in a directory bucket by using the AWS SDK for Python (Boto3).

```
import logging
import boto3
from botocore.exceptions import ClientError

def delete_objects(s3_client, bucket_name, objects):
    '''
    Delete a list of objects in a directory bucket

    :param s3_client: boto3 S3 client
    :param bucket_name: Bucket that contains objects to be deleted; for example,
 'doc-example-bucket--usw2-az1--x-s3'
    :param objects: List of dictionaries that specify the key names to delete
    :return: Response output, else False
    '''

    try:
        response = s3_client.delete_objects(
            Bucket = bucket_name,
            Delete = {
                'Objects': objects
            }
        )
        return response
    except ClientError as e:
```

```
        logging.error(e)
        return False

if __name__ == '__main__':
    region = 'us-west-2'
    bucket_name = 'BUCKET_NAME'
    objects = [
        {
            'Key': '0.txt'
        },
        {
            'Key': '1.txt'
        },
        {
            'Key': '2.txt'
        },
        {
            'Key': '3.txt'
        },
        {
            'Key': '4.txt'
        }
    ]

    s3_client = boto3.client('s3', region_name = region)
    results = delete_objects(s3_client, bucket_name, objects)
    if results is not None:
        if 'Deleted' in results:
            print (f'Deleted {len(results["Deleted"])} objects from {bucket_name}')
        if 'Errors' in results:
            print (f'Failed to delete {len(results["Errors"])} objects from
 {bucket_name}')
```

### Using the AWS CLI

The following `delete-object` example command shows how you can use the AWS CLI to delete an object from a directory bucket. To run this command, replace the *`user input placeholders`* with your own information.

```
aws s3api delete-object --bucket bucket-base-name--azid--x-s3 --key KEY_NAME
```

For more information, see delete-object in the *AWS CLI Command Reference*.

## Downloading an object in a directory bucket

The following code examples show how to read data from (download) an object in an Amazon S3 directory bucket by using the `GetObject` API operation.

### Using the AWS SDKs

SDK for Java 2.x

#### Example

The following code example shows how to read data from an object in a directory bucket by using the AWS SDK for Java 2.x.

```
public static void getObject(S3Client s3Client, String bucketName, String objectKey)
 {
     try {
         GetObjectRequest objectRequest = GetObjectRequest
            .builder()
            .key(objectKey)
            .bucket(bucketName)
            .build();

         ResponseBytes GetObjectResponse objectBytes =
 s3Client.getObjectAsBytes(objectRequest);
         byte[] data = objectBytes.asByteArray();

         //Print object contents to console
         String s = new String(data, StandardCharsets.UTF_8);
         System.out.println(s);
    }

    catch (S3Exception e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}
```

SDK for Python

**Example**

The following code example shows how to read data from an object in a directory bucket by using the AWS SDK for Python (Boto3).

```
import boto3
from botocore.exceptions import ClientError
from botocore.response import StreamingBody

def get_object(s3_client: boto3.client, bucket_name: str, key_name: str) ->
 StreamingBody:
    """
    Gets the object.
    :param s3_client:
    :param bucket_name: The bucket that contains the object.
    :param key_name: The key of the object to be downloaded.
    :return: The object data in bytes.
    """
    try:
        response = s3_client.get_object(Bucket=bucket_name, Key=key_name)
        body = response['Body'].read()
        print(f"Got object '{key_name}' from bucket '{bucket_name}'.")
    except ClientError:
        print(f"Couldn't get object '{key_name}' from bucket '{bucket_name}'.")
        raise
    else:
        return body

def main():
    s3_client = boto3.client('s3')
    resp = get_object(s3_client, 'doc-example-bucket--use1-az4--x-s3', 'sample.txt')
    print(resp)

if __name__ == "__main__":
     main()
```

### Using the AWS CLI

The following `get-object` example command shows how you can use the AWS CLI to download an object from Amazon S3. This command gets the object *KEY_NAME* from the directory

bucket *bucket-base-name*--*azid*--x-s3. The object will be downloaded to a file named *LOCAL_FILE_NAME*. To run this command, replace the *user input placeholders* with your own information.

```
aws s3api get-object --bucket bucket-base-name--azid--x-s3 --
key KEY_NAME LOCAL_FILE_NAME
```

For more information, see get-object in the *AWS CLI Command Reference*.

## Using `HeadObject` with directory buckets

The following AWS SDK and AWS CLI examples show how to use the `HeadObject` API operation to retrieve metadata from an object in an Amazon S3 directory bucket without returning the object itself.

### Using the AWS SDKs

SDK for Java 2.x

#### Example

```
public static void headObject(S3Client s3Client, String bucketName, String
 objectKey) {
    try {
        HeadObjectRequest headObjectRequest = HeadObjectRequest
                .builder()
                .bucket(bucketName)
                .key(objectKey)
                .build();
        HeadObjectResponse response = s3Client.headObject(headObjectRequest);
        System.out.format("Amazon S3 object: \"%s\" found in bucket: \"%s\" with
 ETag: \"%s\"", objectKey, bucketName, response.eTag());
    }
    catch (S3Exception e) {
        System.err.println(e.awsErrorDetails().errorMessage());
```

**Using the AWS CLI**

The following `head-object` example command shows how you can use the AWS CLI to retrieve metadata from an object. To run this command, replace the *`user input placeholders`* with your own information.

```
aws s3api head-object --bucket bucket-base-name--azid--x-s3 --key KEY_NAME
```

For more information, see head-object in the *AWS CLI Command Reference*.

# Security for S3 Express One Zone

Cloud security at AWS is the highest priority. As an AWS customer, you benefit from data centers and network architectures that are built to meet the requirements of the most security-sensitive organizations. Security is a shared responsibility between AWS and you. The shared responsibility model describes this as security of the cloud and security in the cloud:

- **Security of the cloud** – AWS is responsible for protecting the infrastructure that runs AWS services in the AWS Cloud. AWS also provides you with services that you can use securely. Third-party auditors regularly test and verify the effectiveness of our security as part of the AWS Compliance Programs.

  To learn about the compliance programs that apply to Amazon S3 Express One Zone, see AWS services in Scope by Compliance Program.
- **Security in the cloud** – Your responsibility is determined by the AWS service that you use. You are also responsible for other factors, including the sensitivity of your data, your company's requirements, and applicable laws and regulations.

This documentation will help you understand how to apply the shared responsibility model when using S3 Express One Zone. The following topics show you how to configure S3 Express One Zone to meet your security and compliance objectives. You will also learn how to use other AWS services that can help you monitor and secure your resources when you're working with S3 Express One Zone.

**Topics**

- Data protection and encryption
- AWS Identity and Access Management (IAM) for S3 Express One Zone

- IAM identity-based policies for S3 Express One Zone
- Example directory bucket policies for S3 Express One Zone
- CreateSession authorization
- Security best practices for S3 Express One Zone

## Data protection and encryption

For more information about how S3 Express One Zone encrypts and protects your data, see the following topics.

**Topics**

- Server-side encryption with Amazon S3 managed keys (SSE-S3)
- Encryption in transit
- Additional checksums
- Data deletion

### Server-side encryption with Amazon S3 managed keys (SSE-S3)

By default, all objects stored in directory buckets are automatically encrypted by using server-side encryption with Amazon S3 managed keys (SSE-S3). Unencrypted uploads to directory buckets aren't permitted. For more information, see Using server-side encryption with Amazon S3 managed keys (SSE-S3) and Protecting data with encryption.

Directory buckets don't support server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS), dual-layer server-side encryption with AWS Key Management Service (AWS KMS) keys (DSSE-KMS), or server-side encryption with customer-provided encryption keys (SSE-C).

### Encryption in transit

S3 Express One Zone can only be accessed through HTTPS (TLS).

S3 Express One Zone uses Regional and Zonal API endpoints. Depending on the Amazon S3 API operation that you use, either a Regional or Zonal endpoint is required. You can access Zonal and Regional endpoints through a gateway virtual private cloud (VPC) endpoint. There is no additional charge for using gateway endpoints. To learn more about Regional and Zonal API endpoints, see Networking for S3 Express One Zone.

### Additional checksums

S3 Express One Zone offers you the option to choose the checksum algorithm that is used to validate your data during upload or download. You can select one of the following Secure Hash Algorithms (SHA) or Cyclic Redundancy Check (CRC) data-integrity check algorithms: CRC32, CRC32C, SHA-1, and SHA-256. MD5-based checksums are not supported with the S3 Express One Zone storage class.

For more information, see S3 additional checksum best practices.

### Data deletion

You can delete one or more objects directly from S3 Express One Zone by using the Amazon S3 console, AWS SDKs, AWS Command Line Interface (AWS CLI), or Amazon S3 REST API. Because all objects in your directory buckets incur storage costs, we recommend deleting objects that you no longer need.

Deleting an object that's stored in a directory bucket also recursively deletes any parent directories, if those parent directories don't contain any objects other than the object that's being deleted.

> **Note**
>
> Multi-factor authentication (MFA) delete and S3 Versioning are not supported for S3 Express One Zone.

## AWS Identity and Access Management (IAM) for S3 Express One Zone

AWS Identity and Access Management (IAM) is an AWS service that helps administrators securely control access to AWS resources. IAM administrators control who can be authenticated (signed in) and authorized (have permissions) to use Amazon S3 resources in S3 Express One Zone. You can use IAM for no additional charge.

By default, users don't have permissions for directory buckets and S3 Express One Zone operations. To grant access permissions for directory buckets, you can use IAM to create users, groups, or roles and attach permissions to those identities. For more information about IAM, see Security best practices in IAM in the *IAM User Guide*.

To provide access, you can add permissions to your users, groups, or roles through the following means:

- **Users and groups in AWS IAM Identity Center** – Create a permission set. Follow the instructions in Create a permission set in the *AWS IAM Identity Center User Guide*.
- **Users managed in IAM through an identity provider** – Create a role for identity federation. Follow the instructions in Creating a role for a third-party identity provider (federation) in the *IAM User Guide*.
- **IAM roles and users** – Create a role that your user can assume. Follow the instructions in Creating a role to delegate permissions to an IAM user in the *IAM User Guide*.

By default, directory buckets are private and can be accessed only by users who are explicitly granted access. The access control boundary for directory buckets is set only at the bucket level. In contrast, the access control boundary for general purpose buckets can be set at the bucket, prefix, or object tag level. This difference means that directory buckets are the only resource that you can include in bucket policies or IAM identity policies for S3 Express One Zone access.

With S3 Express One Zone, in addition to IAM authorization, you authenticate and authorize requests through a new session-based mechanism that's handled by the `CreateSession` API operation. You can use `CreateSession` to request temporary credentials that provide low-latency access to your bucket. These temporary credentials are scoped to a specific directory bucket.

To work with `CreateSession`, we recommend using the latest version of the AWS SDKs or using the AWS Command Line Interface (AWS CLI). The supported AWS SDKs and the AWS CLI handle session establishment, refreshment, and termination on your behalf.

You use session tokens with only Zonal (object-level) operations (except for `CopyObject` and `HeadBucket`) to distribute the latency that's associated with authorization over a number of requests in a session. For Regional endpoint API operations (bucket-level operations), you use IAM authorization, which doesn't involve managing a session. For more information, see AWS Identity and Access Management (IAM) for S3 Express One Zone and `CreateSession` authorization.

For more information about IAM for S3 Express One Zone, see the following topics.

**Topics**

- Principals
- Resources
- Actions for S3 Express One Zone
- Condition keys for S3 Express One Zone
- How API operations are authorized and authenticated

### Principals

When you create a resource-based policy to grant access to your buckets, you must use the `Principal` element to specify the person or application that can make a request for an action or operation on that resource. For directory bucket policies, you can use the following principals:

- An AWS account
- An IAM user
- An IAM role
- A federated user

For more information, see Principal in the *IAM User Guide*.

### Resources

Amazon Resource Names (ARNs) for directory buckets contain the `s3express` namespace, the AWS Region, the AWS account ID, and the directory bucket name, which includes the Availability Zone ID. To access and perform actions on your directory bucket, you must use the following ARN format:

```
arn:aws:s3express:region:account-id:bucket/base-bucket-name--azid--x-s3
```

For more information about ARNs, see Amazon Resource Names (ARNs) in the *IAM User Guide*. For more information about resources, see IAM JSON Policy Elements: Resource in the *IAM User Guide*.

### Actions for S3 Express One Zone

In an IAM identity-based policy or resource-based policy, you define which S3 actions are allowed or denied. S3 Express One Zone actions correspond to specific API operations. S3 Express One Zone has a unique IAM namespace that is distinct from the standard namespace for Amazon S3. This namespace is `s3express`.

When you allow the `s3express:CreateSession` permission, this enables the `CreateSession` API operation to retrieve session tokens when accessing Zonal endpoint API (or object level) operations . These session tokens return credentials that are used to grant access to all of the other Zonal endpoint API operations. As a result, you don't have to grant access permissions to Zonal API operations by using IAM policies. Instead, the session token enables access.

For more information about Zonal and Regional endpoint API operations, see Networking for S3 Express One Zone. To learn more about the `CreateSession` API operation, see CreateSession in the *Amazon Simple Storage Service API Reference*.

You can specify the following actions in the `Action` element of an IAM policy statement. Use policies to grant permissions to perform an operation in AWS. When you use an action in a policy, you usually allow or deny access to the API operation with the same name. However, in some cases, a single action controls access to more than one API operation. Access to bucket-level actions can be granted in only IAM identity-based policies (user or role) and not bucket policies.

**Actions and condition keys for S3 Express One Zone**

| Action | API | Description | Access level | Condition keys |
|---|---|---|---|---|
| `s3express:CreateBucket` | `CreateBucket` | Grants permission to create a new bucket. | Write | `s3express:authType`<br>`s3express:LocationName`<br>`s3express:ResourceAccount`<br>`s3express:signatureversion`<br>`s3express:TlsVersion`<br>`s3express:x-amz-content-sha256` |

| Action | API | Description | Access level | Condition keys |
| --- | --- | --- | --- | --- |
| s3express:CreateSession | CreateSession | Grants permission to create a session token, which is used for granting access to all Zonal (object-level) API operations, such as PutObject , GetObject , and so on. | Write | s3express:authType<br><br>s3express:SessionMode<br><br>s3express:ResourceAccount<br><br>s3express:signaturversion<br><br>s3express:signatureAge<br><br>s3express:TlsVersion<br><br>s3express:x-amz-content-sha256 |

| Action | API | Description | Access level | Condition keys |
| --- | --- | --- | --- | --- |
| s3express:DeleteBucket | DeleteBucket | Grants permission to delete the bucket named in the URI. | Write | s3express:authType<br>s3express:ResourceAccount<br>s3express:signatureversion<br>s3express:TlsVersion<br>s3express:x-amz-content-sha256 |

| Action | API | Description | Access level | Condition keys |
| --- | --- | --- | --- | --- |
| s3express:DeleteBucketPolicy | DeleteBucketPolicy | Grants permission to delete the policy on a specified bucket. | Permissions management | s3express:authType<br>s3express:ResourceAccount<br>s3express:signatureversion<br>s3express:TlsVersion<br>s3express:x-amz-content-sha256 |

| Action | API | Description | Access level | Condition keys |
| --- | --- | --- | --- | --- |
| s3express:GetBucketPolicy | GetBucketPolicy | Grants permission to return the policy of the specified bucket. | Read | s3express:authType<br>s3express:ResourceAccount<br>s3express:signatureversion<br>s3express:TlsVersion<br>s3express:x-amz-content-sha256 |

| Action | API | Description | Access level | Condition keys |
| --- | --- | --- | --- | --- |
| s3express:ListAllMyDirectoryBuckets | ListDirectoryBuckets | Grants permission to list all directory buckets owned by the authenticated sender of the request. | List | s3express:authType<br><br>s3express:ResourceAccount<br><br>s3express:signatureversion<br><br>s3express:TlsVersion<br><br>s3express:x-amz-content-sha256 |

| Action | API | Description | Access level | Condition keys |
|---|---|---|---|---|
| s3express:PutBucketPolicy | PutBucketPolicy | Grants permission to add or replace a bucket policy on a bucket. | Permissions management | s3express:authType<br>s3express:ResourceAccount<br>s3express:signatureversion<br>s3express:TlsVersion<br>s3express:x-amz-content-sha256 |

## Condition keys for S3 Express One Zone

S3 Express One Zone defines the following condition keys that can be used in the Condition element of an IAM policy. You can use these keys to further refine the conditions under which the policy statement applies.

| Condition key | Description | Type |
|---|---|---|
| s3express:authType | Filters access by authentication method. To restrict incoming requests to use a specific authentication method, you can use this optional condition key. For example, you can use this condition key to allow only the HTTP | String |

| Condition key | Description | Type |
| --- | --- | --- |
| | `Authorization` header to be used in request authentication.<br><br>**Valid values:** `REST-HEADER` , `REST-QUERY-STRING` | |
| `s3express:LocationName` | Filters access to the `CreateBucket` API operation by a specific Availability Zone ID (AZ ID), for example, `usw2-az1`.<br><br>**Example value:** `usw2-az1` | String |
| `s3express:ResourceAccount` | Filters access by the resource owner's AWS account ID.<br><br>To restrict user, role, or application access to the directory buckets that are owned by a specific AWS account ID, you can use either the `aws:ResourceAccount` or `s3express:ResourceAccount` condition key. You can use this condition key in either AWS Identity and Access Management (IAM) identity policies or virtual private cloud (VPC) endpoint policies. For example, you can use this condition key to restrict clients within your VPC from accessing buckets that you don't own.<br><br>**Example value:** `111122223333` | String |

| Condition key | Description | Type |
| --- | --- | --- |
| `s3express:SessionMode` | Filters access by the permission requested by the `CreateSession` API operation. By default, the session is `ReadWrite`. You can use this condition key to limit access to `ReadOnly` or to explicitly deny `ReadWrite` access. For more information, see Example directory bucket policies for S3 Express One Zone and CreateSession in the *Amazon Simple Storage Service API Reference*.<br><br>**Valid values:** `ReadWrite`, `ReadOnly` | String |
| `s3express:signatureAge` | Filters access by the age in milliseconds of the request signature. This condition works only for presigned URLs.<br><br>In AWS Signature Version 4, the signing key is valid for up to seven days. Therefore, the signatures are also valid for up to seven days. For more information, see Introduction to signing requests in the *Amazon Simple Storage Service API Reference*. You can use this condition to further limit the signature age.<br><br>**Example value:** `600000` | Numeric |
| `s3express:signatureversion` | Identifies the version of AWS Signature that you want to support for authenticated requests. For authenticated requests, S3 Express One Zone supports Signature Version 4.<br><br>**Valid value:** `"AWS4-HMAC-SHA256"` (identifies Signature Version 4) | String |

| Condition key | Description | Type |
| --- | --- | --- |
| `s3express:TlsVersion` | Filters access by the TLS version that's used by the client.<br><br>You can use the `s3:TlsVersion` condition key to write IAM, virtual private cloud endpoint (VPCE), or bucket policies that restrict user or application access to directory buckets based on the TLS version that's used by the client. You can also use this condition key to write policies that require a minimum TLS version.<br><br>**Example value:** `1.3` | Numeric |

| Condition key | Description | Type |
| --- | --- | --- |
| `s3express:x-amz-content-sha256` | Filters access by unsigned content in your bucket.<br><br>You can use this condition key to disallow unsigned content in your bucket.<br><br>When you use Signature Version 4 for requests that use the `Authorization` header, you add the `x-amz-content-sha256` header in the signature calculation and then set its value to the hash payload.<br><br>You can use this condition key in your bucket policy to deny any uploads where the payloads aren't signed. For example:<br><br>• Deny uploads that use the `Authorization` header to authenticate requests but don't sign the payload. For more information, see Transferring payload in a single chunk in the *Amazon Simple Storage Service API Reference*.<br>• Deny uploads that use presigned URLs. Presigned URLs always have an `UNSIGNED_PAYLOAD`. For more information, see Authenticating requests and Authentication methods in the *Amazon Simple Storage Service API Reference*.<br><br>**Valid value:** `UNSIGNED-PAYLOAD` | String |

## How API operations are authorized and authenticated

The following table lists authorization and authentication information for S3 Express One Zone API operations. For each API operation, the table shows the API operation name, IAM action, endpoint type (Regional or Zonal), and authorization mechanism (IAM or session-based). This table also

indicates where cross-account access is supported. Access to bucket-level actions can be granted only in IAM identity-based policies (user or role), not bucket policies.

| API | Endpoint type | IAM action | Cross-account access |
|---|---|---|---|
| CreateBucket | Regional | s3express:CreateBucket | No |
| DeleteBucket | Regional | s3express:DeleteBucket | No |
| ListDirectoryBuckets | Regional | s3express:ListAllMyDirectoryBuckets | No |
| PutBucketPolicy | Regional | s3express:PutBucketPolicy | No |
| GetBucketPolicy | Regional | s3express:GetBucketPolicy | No |
| DeleteBucketPolicy | Regional | s3express:DeleteBucketPolicy | No |
| CreateSession | Zonal | s3express:CreateSession | Yes |
| CopyObject | Zonal | s3express:CreateSession | Yes |
| DeleteObject | Zonal | s3express:CreateSession | Yes |
| DeleteObjects | Zonal | s3express:CreateSession | Yes |
| HeadObject | Zonal | s3express:CreateSession | Yes |
| PutObject | Zonal | s3express:CreateSession | Yes |
| GetObjectAttributes | Zonal | s3express:CreateSession | Yes |
| ListObjectsV2 | Zonal | s3express:CreateSession | Yes |
| HeadBucket | Zonal | s3express:CreateSession | Yes |

| API | Endpoint type | IAM action | Cross-account access |
|---|---|---|---|
| CreateMultipartUpload | Zonal | s3express:CreateSession | Yes |
| UploadPart | Zonal | s3express:CreateSession | Yes |
| UploadPartCopy | Zonal | s3express:CreateSession | Yes |
| CompleteMultipartUpload | Zonal | s3express:CreateSession | Yes |
| AbortMultipartUpload | Zonal | s3express:CreateSession | Yes |
| ListParts | Zonal | s3express:CreateSession | Yes |
| ListMultipartUploads | Zonal | s3express:CreateSession | Yes |

## IAM identity-based policies for S3 Express One Zone

Before you can create directory buckets or use Amazon S3 Express One Zone storage class, you must grant the necessary permissions to your AWS Identity and Access Management (IAM) role or users. This example policy allows access to the `CreateSession` API operation (for use with Zonal endpoint [object level] API operations) and all of the Regional endpoint (bucket-level) API operations. This policy allows the `CreateSession` API operation for use with all directory buckets, but the Regional endpoint API operations are allowed only for use with the specified directory bucket. To use this example policy, replace the *`user input placeholders`* with your own information.

```
{
    "Version": "2012-10-17",
    "Statement": [
```

```
        {
            "Sid": "AllowAccessRegionalEndpointAPIs",
            "Effect": "Allow",
            "Action": [
                "s3express:DeleteBucket",
                "s3express:DeleteBucketPolicy",
                "s3express:CreateBucket",
                "s3express:PutBucketPolicy",
                "s3express:GetBucketPolicy",
                "s3express:ListAllMyDirectoryBuckets"
            ],

            "Resource": "arn:aws:s3express:region:account_id:bucket/bucket-base-
name--azid--x-s3/*"
        },
        {
            "Sid": "AllowCreateSession",
            "Effect": "Allow",
            "Action": "s3express:CreateSession",
            "Resource": "*"
        }
    ]
}
```

## Example directory bucket policies for S3 Express One Zone

This section provides example directory bucket policies for use with the Amazon S3 Express One Zone storage class. To use these policies, replace the *`user input placeholders`* with your own information.

The following example bucket policy allows AWS account ID *`111122223333`* to use the `CreateSession` API operation with the default `ReadWrite` session for the specified directory bucket. This policy grants access to the Zonal endpoint (object level) API operations.

**Example – Bucket policy to allow `CreateSession` calls with the default `ReadWrite` session**

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "ReadWriteAccess",
```

```
            "Effect": "Allow",
            "Resource": "arn:aws:s3express:us-west-2:account-id:bucket/bucket-base-
name--azid--x-s3",
            "Principal": {
                "AWS": [
                    "111122223333"
                ]
            },
            "Action": [
                "s3express:CreateSession"
            ]
        }
    ]
}
```

### Example – Bucket policy to allow `CreateSession` calls with a `ReadOnly` session

The following example bucket policy allows AWS account ID *111122223333* to use the `CreateSession` API operation. This policy uses the `s3express:SessionMode` condition key with the `ReadOnly` value to set a read-only session.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "ReadOnlyAccess",
            "Effect": "Allow",
            "Principal": {
                "AWS": "111122223333"
            },
            "Action": "s3express:CreateSession",
            "Resource": "*",
            "Condition": {
                "StringEquals": {
                    "s3express:SessionMode": "ReadOnly"
                }
            }
        }
    ]
}
```

**Example – Bucket policy to allow cross-account access for `CreateSession` calls**

The following example bucket policy allows AWS account ID *111122223333* to use the `CreateSession` API operation for the specified directory bucket that's owned by AWS account ID *444455556666*.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "CrossAccount",
            "Effect": "Allow",
            "Principal": {
                "AWS": "111122223333"
            },
            "Action": [
                "s3express:CreateSession"
            ],
            "Resource": "arn:aws:s3express:us-west-2:444455556666:bucket/bucket-base-name--azid--x-s3"

        }
    ]
}
```

## `CreateSession` authorization

Amazon S3 Express One Zone supports both AWS Identity and Access Management (AWS IAM) authorization and session-based authorization:

- To use Regional endpoint API operations (bucket-level, or control plane, operations) with S3 Express One Zone, you use the IAM authorization model, which doesn't involve session management. Permissions are granted for actions individually. For more information, see AWS Identity and Access Management (IAM) for S3 Express One Zone.
- To use Zonal endpoint API operations (object-level, or data plane, operations), you use the `CreateSession` API operation to create and manage sessions that are optimized for low-latency authorization of data requests. To retrieve and use a session token, you must allow the `s3express:CreateSession` action for your directory bucket in an identity-based policy or

a bucket policy. For more information, see AWS Identity and Access Management (IAM) for S3 Express One Zone. If you're accessing S3 Express One Zone in the Amazon S3 console, through the AWS Command Line Interface (AWS CLI), or by using the AWS SDKs, S3 Express One Zone creates a session on your behalf.

If you use the Amazon S3 REST API, you can then use the `CreateSession` API operation to obtain temporary security credentials that include an access key ID, a secret access key, a session token, and an expiration time. The temporary credentials provide the same permissions as long-term security credentials, such as IAM user credentials, but temporary security credentials must include a session token.

**Session Mode**

Session mode defines the scope of the session. In your bucket policy, you can specify the `s3express:SessionMode` condition key to control who can create a `ReadWrite` or `ReadOnly` session. For more information about `ReadWrite` or `ReadOnly` sessions, see the `x-amz-create-session-mode` parameter for CreateSession in the *Amazon S3 API Reference*. For more information about the bucket policy to create, see Example directory bucket policies for S3 Express One Zone.

**Session Token**

When you make a call by using temporary security credentials, the call must include a session token. The session token is returned along with the temporary credentials. A session token is scoped to your directory bucket and is used to verify that the security credentials are valid and haven't expired. To protect your sessions, temporary security credentials expire after 5 minutes.

**`CopyObject` and `HeadBucket`**

Temporary security credentials are scoped to a specific directory bucket and are automatically enabled for all Zonal (object-level) operation API calls to a given directory bucket. Unlike other Zonal endpoint API operations, `CopyObject` and `HeadBucket` don't use `CreateSession` authentication. All `CopyObject` and `HeadBucket` requests must be authenticated and signed by using IAM credentials. However, `CopyObject` and `HeadBucket` are still authorized by `s3express:CreateSession`, like other Zonal endpoint API operations.

For more information, see CreateSession in the *Amazon Simple Storage Service API Reference*.

# Security best practices for S3 Express One Zone

Amazon S3 Express One Zone provides a number of security features to consider as you develop and implement your own security policies. The following best practices are general guidelines and don't represent a complete security solution. Because these best practices might not be appropriate or sufficient for your environment, treat them as helpful recommendations rather than prescriptions.

## Default Block Public Access and Object Ownership settings

To use the S3 Express One Zone storage class, you must use an S3 directory bucket. Directory buckets support S3 Block Public Access and S3 Object Ownership. These S3 features are used to audit and manage access to your buckets and objects.

By default, all Block Public Access settings for directory buckets are enabled. In addition, Object Ownership is set to bucket owner enforced, which means that access control lists (ACLs) are disabled. These settings can't be modified. For more information about these features, see the section called “Blocking public access” and the section called “Controlling object ownership”.

> **Note**
>
> You can't grant access to objects stored in directory buckets. You can grant access only to your directory buckets. The authorization model for S3 Express One Zone is different than the authorization model for Amazon S3. For more information, see `CreateSession` authorization.

## Authentication and authorization

The authentication and authorization mechanisms for S3 Express One Zone differ, depending on whether you are making requests to Zonal endpoint API operations or Regional endpoint API operations. Zonal API operations are object-level (data plane) operations. Regional API operations are bucket-level (control plane) operations.

With S3 Express One Zone, you authenticate and authorize requests to Zonal endpoint API operations through a new session-based mechanism that is optimized to provide the lowest latency. With session-based authentication, the AWS SDKs use the `CreateSession` API operation to request temporary credentials that provide low-latency access to your directory bucket. These temporary credentials are scoped to a specific directory bucket and expire after 5 minutes. You can

use these temporary credentials to sign Zonal (object level) API calls. For more information, see `CreateSession` authorization.

**Signing requests with S3 Express One Zone credentials**

You use your S3 Express One Zone credentials to sign Zonal endpoint (object level) API requests with AWS Signature Version 4, with `s3express` as the service name. When you sign your requests, use the secret key that's returned from `CreateSession` and also provide the session token with the `x-amzn-s3session-token header`. For more information, see CreateSession.

The supported AWS SDKs for S3 Express One Zone class manage credentials and signing on your behalf. We recommend using the AWS SDKs for S3 Express One Zone to refresh credentials and sign requests for you.

**Signing requests with IAM credentials**

All Regional (bucket-level) API calls must be authenticated and signed by AWS Identity and Access Management (IAM) credentials instead of temporary session credentials. IAM credentials consist of the access key ID and secret access key for the IAM identities. All `CopyObject` and `HeadBucket` requests must also be authenticated and signed by using IAM credentials.

To achieve the lowest latency for your Zonal (object-level) operation calls, we recommend using S3 Express One Zone credentials obtained from calling `CreateSession` to sign your requests, except for requests to `CopyObject` and `HeadBucket`.

## Use AWS CloudTrail

AWS CloudTrail provides a record of the actions taken by a user, a role, or an AWS service in Amazon S3. You can use information collected by CloudTrail to determine the following:

- The request that was made to Amazon S3
- The IP address from which the request was made
- Who made the request
- When the request was made
- Additional details about the request

When you set up your AWS account, CloudTrail management events are enabled by default. The following Regional endpoint API operations (bucket-level, or control plane, API operations) are logged to CloudTrail.

- CreateBucket
- DeleteBucket
- DeleteBucketPolicy
- PutBucketPolicy
- GetBucketPolicy
- ListDirectoryBuckets
- ListMultipartUploads

> **Note**
>
> `ListMultipartUploads` is a Zonal endpoint API operation. However, it is logged to CloudTrail as a management event. For more information, see ListMultipartUploads in the *Amazon Simple Storage Service API Reference*.

By default, CloudTrail trails don't log data events, but you can configure trails to log data events for directory buckets that you specify, or to log data events for all the directory buckets in your AWS account. The following Zonal endpoint API operations (object-level, or data plane, API operations) are logged to CloudTrail.

- AbortMultipartUpload
- CompleteMultipartUpload
- CreateSession
- CopyObject
- CreateMultipartUpload
- DeleteObject
- DeleteObjects
- GetObject
- GetObjectAttributes
- HeadBucket
- HeadObject
- ListObjectsV2

- ListParts
- PutObject
- UploadPart
- UploadPartCopy

For more information on using AWS CloudTrail with S3 Express One Zone, see Logging with AWS CloudTrail for S3 Express One Zone.

**Implement monitoring by using AWS monitoring tools**

Monitoring is an important part of maintaining the reliability, security, availability, and performance of Amazon S3 and your AWS solutions. AWS provides several tools and services to help you monitor Amazon S3 and your other AWS services. For example, you can monitor Amazon CloudWatch metrics for Amazon S3, particularly the `BucketSizeBytes` and `NumberOfObjects` storage metrics.

Objects stored in the S3 Express One Zone storage class won't be reflected in the `BucketSizeBytes` and `NumberOfObjects` storage metrics for Amazon S3. However, the `BucketSizeBytes` and `NumberOfObjects` storage metrics are supported for S3 Express One Zone. To see the metrics of your choice, you can differentiate between the Amazon S3 storage classes and the S3 Express One Zone storage class by specifying a `StorageType` dimension. For more information, see Monitoring metrics with Amazon CloudWatch.

For more information, see Monitoring metrics with Amazon CloudWatch and Monitoring Amazon S3.

# Logging with AWS CloudTrail for S3 Express One Zone

Amazon S3 is integrated with AWS CloudTrail, a service that provides a record of actions taken by a user, role, or an AWS service. CloudTrail captures all API calls for Amazon S3 as events. Using the information collected by CloudTrail, you can determine the request that was made to Amazon S3, the IP address from which the request was made, when it was made, and additional details. When a supported event activity occurs in Amazon S3, that activity is recorded in a CloudTrail event. You can use AWS CloudTrail trail to log management events and data events for S3 Express One Zone. For more information, see Amazon S3 CloudTrail events and What is AWS CloudTrail? in the *AWS CloudTrail User Guide*.

## CloudTrail management events for S3 Express One Zone

By default, CloudTrail logs bucket-level actions for directory buckets as management events. The `eventsource` for CloudTrail management events for S3 Express One Zone is `s3express.amazonaws.com`. When you set up your AWS account, CloudTrail management events are enabled by default. The following Regional endpoint API operations (bucket-level, or control plane, API operations) are logged to CloudTrail.

- `CreateBucket`
- `DeleteBucket`
- `DeleteBucketPolicy`
- `PutBucketPolicy`
- `GetBucketPolicy`
- `ListDirectoryBuckets`
- `ListMultipartUploads`

> **Note**
>
> `ListMultipartUploads` is a Zonal endpoint API operation. However, this API operation is logged to CloudTrail as a management event. For more information, see `ListMultipartUploads` in the *Amazon Simple Storage Service API Reference*.

For more information on CloudTrail management events, see Logging management events in the *AWS CloudTrail User Guide.*

## CloudTrail data events for S3 Express One Zone

Data events provide information about the resource operations performed on or in a resource (for example, reading or writing to an Amazon S3 object). These are also known as data plane operations. Data events are often high-volume activities. By default, CloudTrail trails don't log data events, but you can configure trails to log data events for objects stored in general purpose buckets and directory buckets. For more information, see Enable logging for objects in a bucket using the console .

When you log data events for a trail in CloudTrail, you can choose to use advanced event selectors or basic event selectors. To log data events for objects stored in directory buckets, you must use advanced event selectors. When configuring advanced resource selectors, you will choose or specify the resource type for S3 Express One Zone which is `AWS::S3Express::Object`.

The following Zonal endpoint API operations (object-level , or. data plane, API operations) are logged to CloudTrail.

- `AbortMultipartUpload`
- `CompleteMultipartUpload`
- `CreateSession`
- `CopyObject`
- `CreateMultipartUpload`
- `DeleteObject`
- `DeleteObjects`
- `GetObject`
- `GetObjectAttributes`
- `HeadBucket`
- `HeadObject`
- `ListObjectsV2`
- `ListParts`
- `PutObject`
- `UploadPart`
- `UploadPartCopy`

For more information on CloudTrail data events, see Logging data events in the *AWS CloudTrail User Guide*.

For additional information about CloudTrail events for S3 Express One Zone, see the following topics:

              "type": "AWS::S3Express::DirectoryBucket",
              "ARN": "arn:aws:s3express:us-west-2:111122223333:bucket-base-name--usw2-
az1--x-s3"
             }
           ],
           "eventType": "AwsApiCall",
           "managementEvent": false,
```

```
            "recipientAccountId": "111122223333",
            "eventCategory": "Data",
            "tlsDetails": {
              "tlsVersion": "TLSv1.3",
              "cipherSuite": "TLS_AES_128_GCM_SHA256",
              "clientProvidedHostHeader": "bucket-base-name--usw2-az1--x-s3.s3express-
usw2-az1.us-west-2.amazonaws.com"
            }
          }
```

To use Zonal endpoint API operations (object-level, or data plane, operations), you can use the `CreateSession` API operation to create and manage sessions that are optimized for low-latency authorization of data requests. You can also use `CreateSession` to reduce the amount of logging. To identify which Zonal API operations were performed during a session, you can match the `accessKeyId` under the `responseElements` in your `CreateSession` log file to the `accessKeyId` in the log file of other Zonal API operations. For more information, see [`CreateSession` authorization].

The following example shows a CloudTrail log file example that demonstrates the [`GetObject`] API operation that was authenticated by `CreateSession`.

```
    {
        "eventVersion": "1.09",
        "userIdentity": {
          "type": "AssumedRole",
          "principalId": "AROAIDPPEZS35WEXAMPLE:AssumedRoleSessionName",
          "arn": "arn:aws:sts::111122223333assumed-role/RoleToBeAssumed/MySessionName",
          "accountId": "111122223333",

          "sessionContext": {
            "attributes": {
              "creationDate": "2024-07-02T00:21:49Z"
            }
          }
        },
        "eventTime": "2024-07-02T00:22:01Z",
        "eventSource": "s3express.amazonaws.com",
        "eventName": "GetObject",
        "awsRegion": "us-west-2",
        "sourceIPAddress": "72.21.198.68",
```

```
        "userAgent": "aws-sdk-java/2.25.66 Linux/5.10.216-225.855.amzn2.x86_64
 OpenJDK_64-Bit_Server_VM/17.0.11+9-LTS Java/17.0.11 vendor/Amazon.com_Inc. md/internal
 exec-env/AWS_Lambda_java17 io/sync http/Apache cfg/retry-mode/legacy",
        "requestParameters": {
          "bucketName": "bucket-base-name--usw2-az1--x-s3",
          "x-amz-checksum-mode": "ENABLED",
          "Host": "bucket-base-name--usw2-az1--x-s3.s3express-usw2-az1.us-
west-2.amazonaws.com",
          "key": "test-get-obj-with-checksum"
        },
        "responseElements": null,
        "additionalEventData": {
          "SignatureVersion": "Sigv4",
          "CipherSuite": "TLS_AES_128_GCM_SHA256",
          "bytesTransferredIn": 0,
          "AuthenticationMethod": "AuthHeader",
          "x-amz-id-2": "oOy6w8K7LFsyFN",
          "bytesTransferredOut": 9,
          "availabilityZone": "usw2-az1",
          "sessionModeApplied": "ReadWrite"
         },
          "requestID": "28d2faaf-3319-4649-998d-EXAMPLE72818",
          "eventID": "694d604a-d190-4470-8dd1-EXAMPLEe20c1",
          "readOnly": true,
          "resources": [
            {
              "type": "AWS::S3Express::Object",
              "ARNPrefix": "arn:aws:s3express:us-west-2:111122223333:bucket-base-name--
usw2-az1--x-s3"
            },
            {
              "accountId": "111122223333",
              "type": "AWS::S3Express::DirectoryBucket",
              "ARN": "arn:aws:s3express:us-west-2:111122223333:bucket-base-name--usw2-
az1--x-s3"
             }
           ],
           "eventType": "AwsApiCall",
           "managementEvent": false,
           "recipientAccountId": "111122223333",
           "eventCategory": "Data",
           "tlsDetails": {
             "tlsVersion": "TLSv1.3",
             "cipherSuite": "TLS_AES_128_GCM_SHA256",
```

```
            "clientProvidedHostHeader": "bucket-base-name--usw2-az1--x-s3.s3express-
usw2-az1.us-west-2.amazonaws.com"
          }
        }
```

In the `GetObject` log file example above, the `accessKeyId`(AKIAI44QH8DHBEXAMPLE) matches the `accessKeyId` under the `responseElements` in the CreateSession log file example. The matching `accessKeyId` indicates the session in which `GetObject` operation was performed.

# Optimizing Amazon S3 Express One Zone performance

Amazon S3 Express One Zone is a high-performance, single Availability Zone (AZ) S3 storage class that's purpose-built to deliver consistent, single-digit millisecond data access for your most latency-sensitive applications. S3 Express One Zone is the first S3 storage class that gives you the option to co-locate high-performance object storage and AWS compute resources, such as Amazon Elastic Compute Cloud, Amazon Elastic Kubernetes Service, and Amazon Elastic Container Service, within a single Availability Zone. Co-locating your storage and compute resources optimizes compute performance and costs and provides increased data-processing speed.

S3 Express One Zone provides similar performance elasticity to other S3 storage classes, but with consistent single-digit millisecond first-byte read and write request latencies—up to 10x faster than S3 Standard. S3 Express One Zone is designed from the ground up to support burst throughput up to very high aggregate levels. The S3 Express One Zone storage class uses a custom-built architecture to optimize for performance and deliver consistently low request latency by storing data on high-performance hardware. The object protocol for S3 Express One Zone has been enhanced to streamline authentication and metadata overhead.

To further increase access speed and support hundreds of thousands of requests per second, S3 Express One Zone stores data in a new bucket type—an Amazon S3 directory bucket. Each S3 directory bucket can support hundreds of thousands of transactions per second (TPS).

The combination of high-performance, purpose-built hardware and software that delivers single-digit millisecond data access speed and directory buckets that scale for large numbers of transactions per second makes S3 Express One Zone the best Amazon S3 storage class for request-intensive operations or performance-critical applications.

The following topics describe best practice guidelines and design patterns for optimizing performance with applications that use the S3 Express One Zone storage class.

**Topics**

# Performance guidelines and design patterns for S3 Express One Zone

When building applications that upload and retrieve objects from Amazon S3 Express One Zone, follow our best practice guidelines to optimize performance. To use the S3 Express One Zone storage class, you must create an S3 directory bucket. The S3 Express One Zone storage class isn't supported for use with S3 general purpose buckets.

For performance guidelines for all other Amazon S3 storage classes and S3 general purpose buckets, see Best practices design patterns: optimizing Amazon S3 performance.

To obtain the best performance for your application when using the S3 Express One Zone storage class and directory buckets, we recommend the following guidelines and design patterns.

**Topics**

## Co-locate S3 Express One Zone storage with your AWS compute resources

Each directory bucket is stored in a single Availability Zone that you select when you create the bucket. You can get started by creating a new directory bucket in an Availability Zone local to your compute workloads or resources. You can then immediately begin very low-latency reads and writes. Directory buckets are the first S3 buckets where you can choose the Availability Zone in an AWS Region to reduce latency between compute and storage.

If you access directory buckets across Availability Zones, latency will increase. To optimize performance, we recommend that you access a directory bucket from Amazon Elastic Container

Service, Amazon Elastic Kubernetes Service, and Amazon Elastic Compute Cloud instances that are located in the same Availability Zone when possible.

## Directory buckets

Each directory bucket can support hundreds of thousands of transactions per second (TPS). Unlike general purpose buckets, directory buckets organize keys hierarchically into directories instead of prefixes. A prefix is a string of characters at the beginning of the object key name. You can think of prefixes as a way to organize your data in a similar way to directories. However, prefixes are not directories.

Prefixes organize data in a flat namespace within general purpose buckets, and there are no limits to the number of prefixes within a general purpose bucket. Each prefix can achieve at least 3,500 PUT/POST/DELETE or 5,500 GET/HEAD requests per second. You can also parallelize requests across multiple prefixes to scale performance. However, this scaling, in the case of both read and write operations, happens gradually and is not instantaneous. While general purpose buckets are scaling to your new higher request rate, you might receive some HTTP status code 503 (Service Unavailable) errors.

With a hierarchical namespace, the delimiter in the object key is important. The only supported delimiter is a forward slash (/). Directories are determined by delimiter boundaries. For example, the object key `dir1/dir2/file1.txt` results in the directories `dir1/` and `dir2/` being automatically created, and the object `file1.txt` being added to the `/dir2` directory in the path `dir1/dir2/file1.txt`.

The directories that are created when objects are uploaded to directory buckets have no per-prefix TPS limits and are automatically pre-scaled to reduce the chance of HTTP 503 (Service Unavailable) errors. This automatic scaling allows your applications to parallelize read and write requests within and across directories as needed.

## Directory bucket horizontal scaling request parallelization

You can achieve the best performance by issuing multiple concurrent requests to directory buckets to spread your requests over separate connections to maximize the accessible bandwidth. S3 Express One Zone doesn't have any limits for the number of connections made to your directory bucket. Individual directories can scale performance horizontally and automatically when large numbers of concurrent writes to the same directory are happening.

When an object key is initially created and its key name includes a directory, the directory is automatically created for the object. Subsequent object uploads to that same directory do not require the directory to be created, which reduces latency on object uploads to existing directories.

Although both shallow and deep directory structures are supported for storing objects within a directory bucket, directory buckets do automatically scale horizontally, with lower latency on concurrent uploads to the same directory or to parallel directory siblings.

## Use session-based authentication

S3 Express One Zone and directory buckets support a new session-based authorization mechanism to authenticate and authorize requests to a directory bucket. With session-based authentication, the AWS SDKs automatically use the `CreateSession` API operation to create a temporary session token that can be used for low-latency authorization of data requests to a directory bucket.

The AWS SDKs use the `CreateSession` API operation to request temporary credentials, and then automatically create and refresh tokens for you on your behalf every 5 minutes. To take advantage of the performance benefits of the S3 Express One Zone storage class, we recommended that you use the AWS SDKs to initiate and manage the `CreateSession` API request. For more information about this session-based model, see `CreateSession` authorization.

## S3 additional checksum best practices

S3 Express One Zone offers you the option to choose the checksum algorithm that is used to validate your data during upload or download. You can select one of the following Secure Hash Algorithms (SHA) or Cyclic Redundancy Check (CRC) data-integrity check algorithms: CRC32, CRC32C, SHA-1, and SHA-256. MD5-based checksums are not supported with the S3 Express One Zone storage class.

CRC32 is the default checksum used by the AWS SDKs when transmitting data to or from S3 Express One Zone. We recommend using CRC32 and CRC32C for the best performance with the S3 Express One Zone storage class.

## Use the latest version of the AWS SDKs and common runtime libraries

Several of the AWS SDKs also provide the AWS Common Runtime (CRT) libraries to further accelerate performance in S3 clients. These SDKs include the AWS SDK for Java 2.x, the AWS SDK for C++, and the AWS SDK for Python (Boto3). The CRT-based S3 client transfers objects to and

from S3 Express One Zone with enhanced performance and reliability by automatically using the multipart upload API operation and byte-range fetches to automate horizontally scaling connections.

To achieve the highest performance with the S3 Express One Zone storage class, we recommend using the latest version of the AWS SDKs that include the CRT libraries or using the AWS Command Line Interface (AWS CLI).

## Performance troubleshooting

### Retry requests for latency-sensitive applications

S3 Express One Zone is purpose-built to deliver consistent levels of high-performance without additional tuning. However, setting aggressive timeout values and retries can further help drive consistent latency and performance. The AWS SDKs have configurable timeout and retry values that you can tune to the tolerances of your specific application.

### AWS Common Runtime (CRT) libraries and Amazon EC2 instance type pairing

Applications that perform a large number of read and write operations likely need more memory or computing capacity than applications that don't. When launching your Amazon Elastic Compute Cloud (Amazon EC2) instances for your performance-demanding workload, choose instance types that have the amount of these resources that your application needs. S3 Express One Zone high-performance storage is ideally paired with larger and newer instance types with larger amounts of system memory and more powerful CPUs and GPUs that can take advantage of higher-performance storage. We also recommend using the latest versions of the CRT-enabled AWS SDKs, which can better accelerate read and write requests in parallel.

### Use session-based authentication in AWS SDKs instead of the HTTP REST APIs

With Amazon S3, you can also optimize performance when you're using HTTP REST API requests by following the same best practices that are part of the AWS SDKs. However, with the session-based authorization and authentication mechanism that's used by S3 Express One Zone, we strongly recommend that you use the AWS SDKs to manage `CreateSession` and its managed session token. The AWS SDKs automatically create and refresh tokens on your behalf by using the `CreateSession` API operation. Using `CreateSession` saves on per-request round-trip latency to AWS Identity and Access Management (IAM) to authorize each request.

# Developing with S3 Express One Zone

Amazon S3 Express One Zone is the first S3 storage class where you can select a single Availability Zone with the option to co-locate your object storage with your compute resources, which provides the highest possible access speed. With S3 Express One Zone storage class, you use S3 directory buckets to store your data. Each directory bucket uses the S3 Express One Zone storage class to store objects in a single Availability Zone that you can select when you create the bucket.

After you've created your directory bucket, you can then immediately begin very low-latency reads and writes. You can communicate with your directory bucket by using an endpoint connection over a virtual private cloud (VPC), or you can use Zonal and Regional API operations to manage your objects and directory buckets. You can also use S3 Express One Zone storage class through the Amazon S3 console, AWS Command Line Interface (AWS CLI), AWS SDKs, and the Amazon S3 REST API.

The Amazon S3 Express One Zone storage class is designed for 99.95 percent availability within a single Availability Zone and is backed by the Amazon S3 Service Level Agreement. With S3 Express One Zone, your data is redundantly stored on multiple devices within a single Availability Zone. S3 Express One Zone is designed to handle concurrent device failures by quickly detecting and repairing any lost redundancy. If the existing device encounters a failure, S3 Express One Zone automatically shifts requests to new devices within an Availability Zone. This redundancy helps ensure uninterrupted access to your data within an Availability Zone.

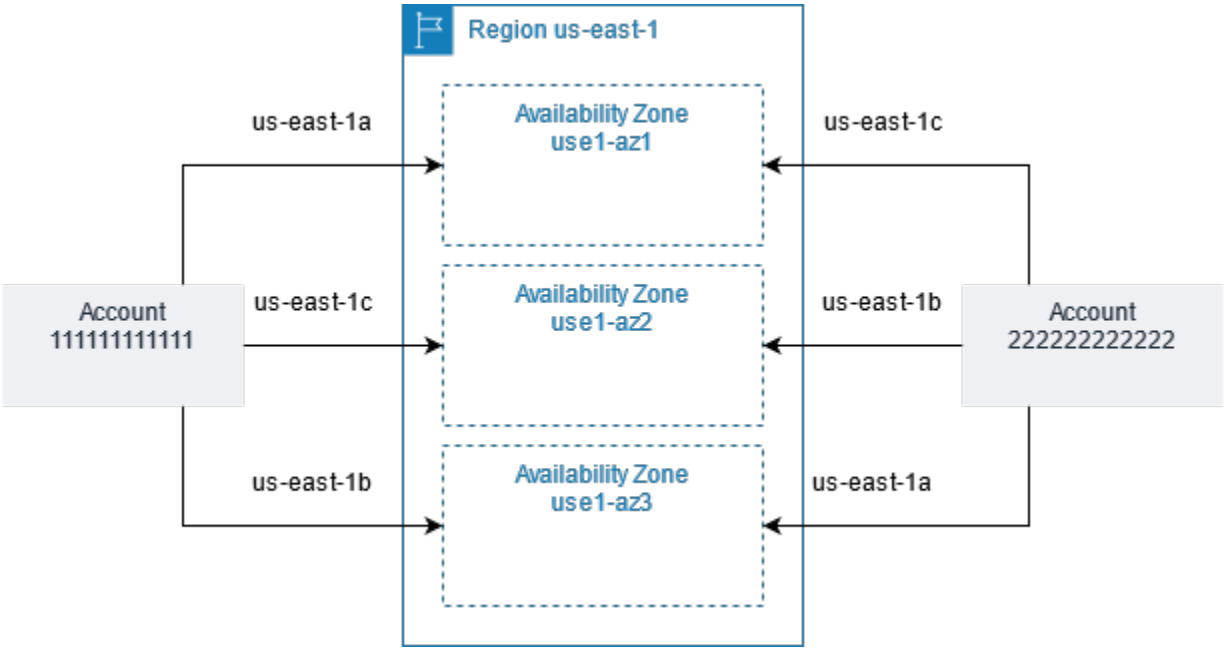
**Topics**

## S3 Express One Zone Availability Zones and Regions

An Availability Zone is one or more discrete data centers with redundant power, networking, and connectivity in an AWS Region. To optimize low-latency retrievals, objects in the Amazon S3 Express One Zone storage class are redundantly stored in S3 directory buckets in a single Availability Zone that's local to your compute workload. When you create a directory bucket, you choose the Availability Zone and AWS Region where your bucket will be located.

AWS maps the physical Availability Zones randomly to the Availability Zone names for each AWS account. This approach helps to distribute resources across the Availability Zones in an AWS Region, instead of resources likely being concentrated in the first Availability Zone for each Region. As a result, the Availability Zone `us-east-1a` for your AWS account might not represent the same physical location as `us-east-1a` for a different AWS account. For more information, see Regions and Availability Zones in the *Amazon EC2 User Guide*.

To coordinate Availability Zones across accounts, you must use the *AZ ID*, which is a unique and consistent identifier for an Availability Zone. For example, `use1-az1` is an AZ ID for the `us-east-1` Region and it has the same physical location in every AWS account. The following illustration shows how the AZ IDs are the same for every account, even though the Availability Zone names might be mapped differently for each account.



With S3 Express One Zone, your data is redundantly stored on multiple devices within a single Availability Zone. S3 Express One Zone is designed for 99.95 percent availability within a single Availability Zone and is backed by the Amazon S3 Service Level Agreement. For more information, see Single Availability Zone

S3 Express One Zone is supported in the following Regions and Availability Zones:

**S3 Express One Zone supported Regions and Availability Zones**

| Region name | Region code | Availability Zone ID |
|---|---|---|
| US East (N. Virginia) | us-east-1 | use1-az4 |
| | | use1-az5 |
| | | use1-az6 |
| US West (Oregon) | us-west-2 | usw2-az1 |
| | | usw2-az3 |
| | | usw2-az4 |
| Asia Pacific (Tokyo) | ap-northeast-1 | apne1-az1 |
| | | apne1-az4 |
| Europe (Stockholm) | eu-north-1 | eun1-az1 |
| | | eun1-az2 |
| | | eun1-az3 |

## Regional and Zonal endpoints

To access the Regional and Zonal endpoints for Amazon S3 Express One Zone from your virtual private cloud (VPC), you can use gateway VPC endpoints. After you create a gateway endpoint, you can add it as a target in your route table for traffic destined from your VPC to S3 Express One Zone. There is no additional charge for using gateway endpoints. For more information about how to configure gateway VPC endpoints, see Networking for S3 Express One Zone.

When you're working with S3 Express One Zone, bucket-level (control plane) API operations are available through a Regional endpoint and are referred to as Regional endpoint API operations. Examples of Regional endpoint API operations are `CreateBucket` and `DeleteBucket`.

After you create a directory bucket, you can use Zonal (object level, or data plane endpoint API operations) to upload and manage the objects in your directory bucket. Zonal endpoint API operations are available through a Zonal endpoint. Examples of Zonal API operations are `PutObject` and `CopyObject`.

## Working with S3 Express One Zone by using the S3 console, AWS CLI, and AWS SDKs

You can work with the S3 Express One Zone storage class and directory buckets by using the AWS SDKs, Amazon S3 console, AWS Command Line Interface (AWS CLI), and Amazon S3 REST API.

### S3 Console

To get started using the S3 console, follow these steps:

- Creating a directory bucket
- Emptying a directory bucket
- Deleting a directory bucket

For a full tutorial, see Tutorial: Getting started with S3 Express One Zone.

### AWS SDKs

S3 Express One Zone supports the following AWS SDKs:

- AWS SDK for C++
- AWS SDK for Go v2
- AWS SDK for Java 2.x
- AWS SDK for JavaScript v3
- AWS SDK for .NET
- AWS SDK for PHP
- AWS SDK for Python (Boto3)
- AWS SDK for Ruby
- AWS SDK for Kotlin

- AWS SDK for Rust

When you're working with S3 Express One Zone, we recommend using the latest version of the AWS SDKs. The supported AWS SDKs for S3 Express One Zone handle session establishment, refreshment, and termination on your behalf. This means that you can immediately start using API operations after you download and install the AWS SDKs and configure the necessary IAM permissions. For more information, see AWS Identity and Access Management (IAM) for S3 Express One Zone.

For information about the AWS SDKs, including how to download and install them, see Tools to Build on AWS.

For AWS SDK examples, see the following:

- Creating a directory bucket
- Emptying a directory bucket
- Deleting a directory bucket

### AWS Command Line Interface (AWS CLI)

You can use the AWS Command Line Interface (AWS CLI) to create directory buckets and use supported Regional and Zonal endpoint API operations for S3 Express One Zone.

To get started with the AWS CLI, see Get started with the AWS CLI in the *AWS CLI Command Reference*.

> **Note**
>
> To use directory buckets with the high-level `aws s3` commands, update your AWS CLI to the latest version. For more information about how to install and configure the AWS CLI, see Install or update the latest version of the AWS CLI in the *AWS CLI Command Reference*.

For AWS CLI examples, see the following:

- Creating a directory bucket
- Emptying a directory bucket
- Deleting a directory bucket

# S3 Express One Zone API operations

The Amazon S3 Express One Zone storage class supports both Regional (bucket level, or control plane) and Zonal (object level, or data plane) endpoint API operations. For more information, see Networking for S3 Express One Zone and Endpoints and gateway VPC endpoints.

### Regional endpoint API operations

The following Regional endpoint API operations are supported for S3 Express One Zone:

- CreateBucket
- DeleteBucket
- DeleteBucketPolicy
- GetBucketPolicy
- ListDirectoryBuckets
- PutBucketPolicy

### Zonal endpoint API operations

The following Zonal endpoint API operations are supported for S3 Express One Zone:

- CreateSession
- CopyObject
- DeleteObject
- DeleteObjects
- GetObject
- GetObjectAttributes
- HeadBucket
- HeadObject
- ListObjectsV2
- PutObject
- AbortMultipartUpload
- CompleteMultiPartUpload
- CreateMultipartUpload

- ListMultipartUploads
- ListParts
- UploadPart
- UploadPartCopy

# Managing data access with Amazon S3 access points

Amazon S3 access points simplify data access for any AWS service or customer application that stores data in S3. Access points are named network endpoints that are attached to buckets that you can use to perform S3 object operations, such as `GetObject` and `PutObject`. Each access point has distinct permissions and network controls that S3 applies for any request that is made through that access point. Each access point enforces a customized access point policy that works in conjunction with the bucket policy that is attached to the underlying bucket. You can configure any access point to accept requests only from a virtual private cloud (VPC) to restrict Amazon S3 data access to a private network. You can also configure custom block public access settings for each access point.

**Note**

- You can only use access points to perform operations on objects. You can't use access points to perform other Amazon S3 operations, such as modifying or deleting buckets. For a complete list of S3 operations that support access points, see Access point compatibility with AWS services.
- Access points work with some, but not all, AWS services and features. For example, you can't configure Cross-Region Replication to operate through an access point. For a complete list of AWS services that are compatible with S3 access points, see Access point compatibility with AWS services.

This section explains how to work with Amazon S3 access points. For information about working with buckets, see Buckets overview. For information about working with objects, see Amazon S3 objects overview.

**Topics**

# Configuring IAM policies for using access points

Amazon S3 access points support AWS Identity and Access Management (IAM) resource policies that allow you to control the use of the access point by resource, user, or other conditions. For an application or user to be able to access objects through an access point, both the access point and the underlying bucket must permit the request.

> **Important**
>
> Adding an S3 access point to a bucket doesn't change the bucket's behavior when the bucket is accessed directly through the bucket's name or Amazon Resource Name (ARN). All existing operations against the bucket will continue to work as before. Restrictions that you include in an access point policy apply only to requests made through that access point.

When you're using IAM resource policies, make sure to resolve security warnings, errors, general warnings, and suggestions from AWS Identity and Access Management Access Analyzer before you save your policy. IAM Access Analyzer runs policy checks to validate your policy against IAM policy grammar and best practices. These checks generate findings and provide recommendations to help you author policies that are functional and conform to security best practices.

To learn more about validating policies by using IAM Access Analyzer, see IAM Access Analyzer policy validation in the *IAM User Guide*. To view a list of the warnings, errors, and suggestions that are returned by IAM Access Analyzer, see IAM Access Analyzer policy check reference.

## Access point policy examples

The following examples demonstrate how to create IAM policies to control requests made through an access point.

> **Note**
>
> Permissions granted in an access point policy are effective only if the underlying bucket also allows the same access. You can accomplish this in two ways:
>
> 1. **(Recommended)** Delegate access control from the bucket to the access point, as described in Delegating access control to access points.

2. Add the same permissions contained in the access point policy to the underlying bucket's policy. The Example 1 access point policy example demonstrates how to modify the underlying bucket policy to allow the necessary access.

### Example 1 – Access point policy grant

The following access point policy grants IAM user *Jane* in account *123456789012* permissions to GET and PUT objects with the prefix *Jane/* through the access point *my-access-point* in account *123456789012*.

```
{
    "Version":"2012-10-17",
    "Statement": [
    {
        "Effect": "Allow",
        "Principal": {
            "AWS": "arn:aws:iam::123456789012:user/Jane"
        },
        "Action": ["s3:GetObject", "s3:PutObject"],
        "Resource": "arn:aws:s3:us-west-2:123456789012:accesspoint/my-access-point/
object/Jane/*"
    }]
}
```

**Note**

For the access point policy to effectively grant access to *Jane*, the underlying bucket must also allow the same access to *Jane*. You can delegate access control from the bucket to the access point as described in Delegating access control to access points. Or, you can add the following policy to the underlying bucket to grant the necessary permissions to Jane. Note that the `Resource` entry differs between the access point and bucket policies.

```
{
    "Version": "2012-10-17",
    "Statement": [
    {
        "Effect": "Allow",
        "Principal": {
            "AWS": "arn:aws:iam::123456789012:user/Jane"
```

```
        },
        "Action": ["s3:GetObject", "s3:PutObject"],
        "Resource": "arn:aws:s3:::amzn-s3-demo-bucket1/Jane/*"
    }]
}
```

### Example 2 – Access point policy with tag condition

The following access point policy grants IAM user *Mateo* in account *123456789012* permissions to GET objects through the access point *my-access-point* in the account *123456789012* that have the tag key *data* set with a value of *finance*.

```
{
    "Version":"2012-10-17",
    "Statement": [
    {
        "Effect":"Allow",
        "Principal" : {
            "AWS": "arn:aws:iam::123456789012:user/Mateo"
        },
        "Action":"s3:GetObject",
        "Resource" : "arn:aws:s3:us-west-2:123456789012:accesspoint/my-access-point/
object/*",
        "Condition" : {
            "StringEquals": {
                "s3:ExistingObjectTag/data": "finance"
            }
        }
    }]
}
```

### Example 3 – Access point policy that allows bucket listing

The following access point policy allows IAM user `Arnav` in the account *123456789012* permission to view the objects contained in the bucket underlying the access point *my-access-point* in the account *123456789012*.

```
{
    "Version":"2012-10-17",
    "Statement": [
```

```
    {
        "Effect": "Allow",
        "Principal": {
            "AWS": "arn:aws:iam::123456789012:user/Arnav"
        },
        "Action": "s3:ListBucket",
        "Resource": "arn:aws:s3:us-west-2:123456789012:accesspoint/my-access-point"
    }]
}
```

### Example 4 – Service control policy

The following service control policy requires all new access points to be created with a virtual private cloud (VPC) network origin. With this policy in place, users in your organization can't create new access points that are accessible from the internet.

```
{
    "Version": "2012-10-17",
    "Statement": [
    {
        "Effect": "Deny",
        "Action": "s3:CreateAccessPoint",
        "Resource": "*",
        "Condition": {
            "StringNotEquals": {
                "s3:AccessPointNetworkOrigin": "VPC"
            }
        }
    }]
}
```

### Example 5 – Bucket policy to limit S3 operations to VPC network origins

The following bucket policy limits access to all S3 object operations for the bucket *amzn-s3-demo-bucket* to access points with a VPC network origin.

> **Important**
>
> Before using a statement like the one shown in this example, make sure that you don't need to use features that aren't supported by access points, such as Cross-Region Replication.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Deny",
            "Principal": "*",
            "Action": [
                "s3:AbortMultipartUpload",
                "s3:BypassGovernanceRetention",
                "s3:DeleteObject",
                "s3:DeleteObjectTagging",
                "s3:DeleteObjectVersion",
                "s3:DeleteObjectVersionTagging",
                "s3:GetObject",
                "s3:GetObjectAcl",
                "s3:GetObjectLegalHold",
                "s3:GetObjectRetention",
                "s3:GetObjectTagging",
                "s3:GetObjectVersion",
                "s3:GetObjectVersionAcl",
                "s3:GetObjectVersionTagging",
                "s3:ListMultipartUploadParts",
                "s3:PutObject",
                "s3:PutObjectAcl",
                "s3:PutObjectLegalHold",
                "s3:PutObjectRetention",
                "s3:PutObjectTagging",
                "s3:PutObjectVersionAcl",
                "s3:PutObjectVersionTagging",
                "s3:RestoreObject"
            ],
            "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/*",
            "Condition": {
                "StringNotEquals": {
                    "s3:AccessPointNetworkOrigin": "VPC"
                }
            }
        }
    ]
}
```

## Condition keys

S3 access points have condition keys that you can use in IAM policies to control access to your resources. The following condition keys represent only part of an IAM policy. For full policy examples, see Access point policy examples, the section called "Delegating access control to access points", and the section called "Granting permissions for cross-account access points".

### `s3:DataAccessPointArn`

This example shows a string that you can use to match on an access point ARN. The following example matches all access points for AWS account *123456789012* in Region *us-west-2*:

```
"Condition" : {
    "StringLike": {
        "s3:DataAccessPointArn": "arn:aws:s3:us-west-2:123456789012:accesspoint/*"
    }
}
```

### `s3:DataAccessPointAccount`

This example shows a string operator that you can use to match on the account ID of the owner of an access point. The following example matches all access points that are owned by the AWS account *123456789012*.

```
"Condition" : {
    "StringEquals": {
        "s3:DataAccessPointAccount": "123456789012"
    }
}
```

### `s3:AccessPointNetworkOrigin`

This example shows a string operator that you can use to match on the network origin, either `Internet` or VPC. The following example matches only access points with a VPC origin.

```
"Condition" : {
    "StringEquals": {
        "s3:AccessPointNetworkOrigin": "VPC"
    }
}
```

For more information about using condition keys with Amazon S3, see Actions, resources, and condition keys for Amazon S3 in the *Service Authorization Reference*.

## Delegating access control to access points

You can delegate access control for a bucket to the bucket's access points. The following example bucket policy allows full access to all access points that are owned by the bucket owner's account. Thus, all access to this bucket is controlled by the policies attached to its access points. We recommend configuring your buckets this way for all use cases that don't require direct access to the bucket.

**Example 6 – Bucket policy that delegates access control to access points**

```
{
    "Version": "2012-10-17",
    "Statement" : [
    {
        "Effect": "Allow",
        "Principal" : { "AWS": "*" },
        "Action" : "*",
        "Resource" : [ "Bucket ARN", "Bucket ARN/*"],
        "Condition": {
            "StringEquals" : { "s3:DataAccessPointAccount" : "Bucket owner's account
 ID" }
        }
    }]
}
```

## Granting permissions for cross-account access points

To create an access point to a bucket that's owned by another account, you must first create the access point by specifying the bucket name and account owner ID. Then, the bucket owner must update the bucket policy to authorize requests from the access point. Creating an access point is similar to creating a DNS CNAME in that the access point doesn't provide access to the bucket contents. All bucket access is controlled by the bucket policy. The following example bucket policy allows `GET` and `LIST` requests on the bucket from an access point that's owned by a trusted AWS account.

Replace *`Bucket ARN`* with the ARN of the bucket.

**Example 7 – Bucket policy delegating permissions to another AWS account**

```
{
    "Version": "2012-10-17",
    "Statement" : [
    {
        "Effect": "Allow",
        "Principal" : { "AWS": "*" },
        "Action" : ["s3:GetObject","s3:ListBucket"],
        "Resource" : [ "Bucket ARN", "Bucket ARN/*"],
        "Condition": {
            "StringEquals" : { "s3:DataAccessPointAccount" : "Access point owner's
 account ID" }
        }
    }]
}
```

# Creating access points

Amazon S3 provides functionality for creating and managing access points. You can create S3 access points by using the AWS Management Console, AWS Command Line Interface (AWS CLI), AWS SDKs, or Amazon S3 REST API.

By default, you can create up to 10,000 access points per Region for each of your AWS accounts. If you need more than 10,000 access points for a single account in a single Region, you can request a service quota increase. For more information about service quotas and requesting an increase, see AWS Service Quotas in the *AWS General Reference*.

**Note**

Because you might want to publicize your access point name so that other users can use the access point, avoid including sensitive information in the access point name. Access point names are published in a publicly accessible database known as the Domain Name System (DNS).

## Rules for naming Amazon S3 access points

Access point names must meet the following conditions:

- Must be unique within a single AWS account and Region
- Must comply with DNS naming restrictions
- Must begin with a number or lowercase letter
- Must be between 3 and 50 characters long
- Can't begin or end with a hyphen (-)
- Can't contain underscores (_), uppercase letters, or periods (.)
- Can't end with the suffix `-s3alias`. This suffix is reserved for access point alias names. For more information, see Using a bucket-style alias for your S3 bucket access point.

To create an access point, see the following topics.

**Topics**

- Creating an access point
- Creating access points restricted to a virtual private cloud
- Managing public access to access points

## Creating an access point

An access point is associated with exactly one Amazon S3 bucket. If you want to use a bucket in your AWS account, you must first create a bucket. For more information about creating buckets, see Creating, configuring, and working with Amazon S3 buckets.

You can also create a cross-account access point that's associated with a bucket in another AWS account, as long as you know the bucket name and the bucket owner's account ID. However, creating cross-account access points doesn't grant you access to data in the bucket until you are granted permissions from the bucket owner. The bucket owner must grant the access point owner's account (your account) access to the bucket through the bucket policy. For more information, see Granting permissions for cross-account access points.

By default, you can create up to 10,000 access points per Region for each of your AWS accounts. If you need more than 10,000 access points for a single account in a single Region, you can request a service quota increase. For more information about service quotas and requesting an increase, see AWS Service Quotas in the *AWS General Reference*.

The following examples demonstrate how to create an access point with the AWS CLI and the S3 console. For more information about how to create access points by using the REST API, see CreateAccessPoint in the *Amazon Simple Storage Service API Reference*.

### Using the S3 console

#### To create an access point

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the navigation bar on the top of the page, choose the name of the currently displayed AWS Region. Next, choose the Region in which you want to create an access point.
3. In the left navigation pane, choose **Access Points**.
4. On the **Access Points** page, choose **Create access point**.
5. In the **Access point name** field, enter the name for the access point. For more information about naming access points, see Rules for naming Amazon S3 access points.
6. For **Bucket name**, specify the S3 bucket that you want to use with the access point.

   To use a bucket in your account, choose **Choose a bucket in this account**, and enter or browse for the bucket name.

   To use a bucket in a different AWS account, choose **Specify a bucket in another account**, and enter the AWS account ID and name of the bucket.

   > **Note**
   >
   > If you're using a bucket in a different AWS account, the bucket owner must update the bucket policy to authorize requests from the access point. For an example bucket policy, see Granting permissions for cross-account access points.

7. Choose a **Network origin**. If you choose **Virtual private cloud (VPC)**, enter the **VPC ID** that you want to use with the access point.

   For more information about network origins for access points, see Creating access points restricted to a virtual private cloud.

8. Under **Block Public Access settings for this Access Point**, select the block public access settings that you want to apply to the access point. All block public access settings are enabled

by default for new access points. We recommend that you keep all settings enabled unless you know that you have a specific need to disable any of them.

> **Note**
>
> After you create an access point, you can't change its block public access settings.

For more information about using Amazon S3 Block Public Access with access points, see Managing public access to access points.

9. (Optional) Under **Access Point policy - *optional***, specify the access point policy. Before you save your policy, make sure to resolve any security warnings, errors, general warnings, and suggestions. For more information about specifying an access point policy, see Access point policy examples.
10. Choose **Create access point**.

#### Using the AWS CLI

The following example command creates an access point named *example-ap* for the bucket *amzn-s3-demo-bucket* in the account *111122223333*. To create the access point, you send a request to Amazon S3 that specifies the following:

- The access point name. For information about naming rules, see the section called "Rules for naming Amazon S3 access points".
- The name of the bucket that you want to associate the access point with.
- The account ID for the AWS account that owns the bucket.

```
aws s3control create-access-point --name example-ap --account-id 111122223333 --
bucket amzn-s3-demo-bucket
```

When you're creating an access point by using a bucket in a different AWS account, include the `--bucket-account-id` parameter. The following example command creates an access point in the AWS account *111122223333*, using the bucket *amzn-s3-demo-bucket2*, which is in the AWS account *444455556666*.

```
aws s3control create-access-point --name example-ap --account-id 111122223333 --
bucket amzn-s3-demo-bucket --bucket-account-id 444455556666
```

## Creating access points restricted to a virtual private cloud

When you create an access point, you can choose to make the access point accessible from the internet, or you can specify that all requests made through that access point must originate from a specific virtual private cloud (VPC). An access point that's accessible from the internet is said to have a network origin of `Internet`. It can be used from anywhere on the internet, subject to any other access restrictions in place for the access point, underlying bucket, and related resources, such as the requested objects. An access point that's only accessible from a specified VPC has a network origin of `VPC`, and Amazon S3 rejects any request made to the access point that doesn't originate from that VPC.

> **Important**
>
> You can only specify an access point's network origin when you create the access point. After you create the access point, you can't change its network origin.

To restrict an access point to VPC-only access, you include the `VpcConfiguration` parameter with the request to create the access point. In the `VpcConfiguration` parameter, you specify the VPC ID that you want to be able to use the access point. If a request is made through the access point, the request must originate from the VPC or Amazon S3 will reject it.

You can retrieve an access point's network origin using the AWS CLI, AWS SDKs, or REST APIs. If an access point has a VPC configuration specified, its network origin is `VPC`. Otherwise, the access point's network origin is `Internet`.

**Example**

***Example: Create an access point that's restricted to VPC access***

The following example creates an access point named `example-vpc-ap` for bucket `example-bucket` in account `123456789012` that allows access only from the `vpc-1a2b3c` VPC. The example then verifies that the new access point has a network origin of `VPC`.

AWS CLI

```
aws s3control create-access-point --name example-vpc-ap --account-id 123456789012 --
bucket example-bucket --vpc-configuration VpcId=vpc-1a2b3c
```

```
aws s3control get-access-point --name example-vpc-ap --account-id 123456789012

{
    "Name": "example-vpc-ap",
    "Bucket": "example-bucket",
    "NetworkOrigin": "VPC",
    "VpcConfiguration": {
        "VpcId": "vpc-1a2b3c"
    },
    "PublicAccessBlockConfiguration": {
        "BlockPublicAcls": true,
        "IgnorePublicAcls": true,
        "BlockPublicPolicy": true,
        "RestrictPublicBuckets": true
    },
    "CreationDate": "2019-11-27T00:00:00Z"
}
```

To use an access point with a VPC, you must modify the access policy for your VPC endpoint. VPC endpoints allow traffic to flow from your VPC to Amazon S3. They have access control policies that control how resources within the VPC are allowed to interact with Amazon S3. Requests from your VPC to Amazon S3 only succeed through an access point if the VPC endpoint policy grants access to both the access point and the underlying bucket.

**Note**

To make resources accessible only within a VPC, make sure to create a private hosted zone for your VPC endpoint. To use a private hosted zone, modify your VPC settings so that the VPC network attributes `enableDnsHostnames` and `enableDnsSupport` are set to `true`.

The following example policy statement configures a VPC endpoint to allow calls to `GetObject` for a bucket named `awsexamplebucket1` and an access point named `example-vpc-ap`.

```
{
    "Version": "2012-10-17",
    "Statement": [
    {
        "Principal": "*",
        "Action": [
            "s3:GetObject"
        ],
        "Effect": "Allow",
        "Resource": [
            "arn:aws:s3:::awsexamplebucket1/*",
            "arn:aws:s3:us-west-2:123456789012:accesspoint/example-vpc-ap/object/*"
        ]
    }]
}
```

**Note**

The `"Resource"` declaration in this example uses an Amazon Resource Name (ARN) to specify the access point. For more information about access point ARNs, see Using access points.

For more information about VPC endpoint policies, see Using endpoint policies for Amazon S3 in the *VPC User Guide*.

## Managing public access to access points

Amazon S3 access points support independent *block public access* settings for each access point. When you create an access point, you can specify block public access settings that apply to that access point. For any request made through an access point, Amazon S3 evaluates the block public access settings for that access point, the underlying bucket, and the bucket owner's account. If any of these settings indicate that the request should be blocked, Amazon S3 rejects the request.

For more information about the S3 Block Public Access feature, see Blocking public access to your Amazon S3 storage.

**Important**

- All block public access settings are enabled by default for access points. You must explicitly disable any settings that you don't want to apply to an access point.
- Amazon S3 currently doesn't support changing an access point's block public access settings after the access point has been created.

### Example

#### *Example: Create an access point with Custom Block Public Access Settings*

This example creates an access point named `example-ap` for bucket `example-bucket` in account `123456789012` with non-default Block Public Access settings. The example then retrieves the new access point's configuration to verify its Block Public Access settings.

AWS CLI

```
aws s3control create-access-point --name example-ap --account-id
 123456789012 --bucket example-bucket --public-access-block-configuration
 BlockPublicAcls=false,IgnorePublicAcls=false,BlockPublicPolicy=true,RestrictPublicBuckets=t
```

```
aws s3control get-access-point --name example-ap --account-id 123456789012

{
    "Name": "example-ap",
    "Bucket": "example-bucket",
    "NetworkOrigin": "Internet",
    "PublicAccessBlockConfiguration": {
        "BlockPublicAcls": false,
        "IgnorePublicAcls": false,
        "BlockPublicPolicy": true,
        "RestrictPublicBuckets": true
    },
    "CreationDate": "2019-11-27T00:00:00Z"
}
```

# Using access points

You can access the objects in an Amazon S3 bucket with an *access point* using the AWS Management Console, AWS CLI, AWS SDKs, or the S3 REST APIs.

Access points have Amazon Resource Names (ARNs). Access point ARNs are similar to bucket ARNs, but they are explicitly typed and encode the access point's Region and the AWS account ID of the access point's owner. For more information about ARNs, see Amazon Resource Names (ARNs) in the *AWS General Reference*.

Access point ARNs use the format `arn:aws:s3:region:account-id:accesspoint/resource`. For example:

- **arn:aws:s3:us-west-2:123456789012:accesspoint/test** represents the access point named `test`, owned by account `123456789012` in Region `us-west-2`.
- **arn:aws:s3:us-west-2:123456789012:accesspoint/*** represents all access points under account `123456789012` in Region `us-west-2`.

ARNs for objects accessed through an access point use the format `arn:aws:s3:region:account-id:accesspoint/access-point-name/object/resource`. For example:

- **arn:aws:s3:us-west-2:123456789012:accesspoint/test/object/unit-01** represents the object `unit-01`, accessed through the access point named `test`, owned by account `123456789012` in Region `us-west-2`.
- **arn:aws:s3:us-west-2:123456789012:accesspoint/test/object/*** represents all objects for access point `test`, in account `123456789012` in Region `us-west-2`.
- **arn:aws:s3:us-west-2:123456789012:accesspoint/test/object/unit-01/finance/*** represents all objects under prefix `unit-01/finance/` for access point `test`, in account `123456789012` in Region `us-west-2`.

## Accessing a bucket through S3 access points

S3 access points only support virtual-host-style addressing. To address a bucket through an access point, use the following format.

```
https://AccessPointName-AccountId.s3-accesspoint.region.amazonaws.com
```

**Note**

- If your access point name includes dash (-) characters, include the dashes in the URL and insert another dash before the account ID. For example, to use an access point named `finance-docs` owned by account `123456789012` in Region `us-west-2`, the appropriate URL would be `https://finance-docs-123456789012.s3-accesspoint.us-west-2.amazonaws.com`.
- S3 access points don't support access by HTTP, only secure access by HTTPS.

**Topics**

If you have a Virtual Private Cloud (VPC), see Managing Amazon S3 access with VPC endpoints and S3 Access Points.

## Monitoring and logging access points

Amazon S3 logs requests made through access points and requests made to the APIs that manage access points, such as `CreateAccessPoint` and `GetAccessPointPolicy`. To monitor and manage usage patterns, you can also configure Amazon CloudWatch Logs request metrics for access points.

**Topics**

### CloudWatch request metrics

To understand and improve the performance of applications that are using access points, you can use CloudWatch for Amazon S3 request metrics. Request metrics help you monitor Amazon S3 requests to quickly identify and act on operational issues.

By default, request metrics are available at the bucket level. However, you can define a filter for request metrics using a shared prefix, object tags, or an access point. When you create an access point filter, the request metrics configuration includes requests to the access point that you specify. You can receive metrics, set alarms, and access dashboards to view real-time operations performed through this access point.

You must opt in to request metrics by configuring them in the console or by using the Amazon S3 API. Request metrics are available at 1-minute intervals after some latency for processing. Request metrics are billed at the same rate as CloudWatch custom metrics. For more information, see Amazon CloudWatch pricing.

To create a request metrics configuration that filters by access point, see Creating a metrics configuration that filters by prefix, object tag, or access point.

### Request logs

You can log requests made through access points and requests made to the APIs that manage access points, such as `CreateAccessPoint` and `GetAccessPointPolicy`, by using server access logging and AWS CloudTrail.

CloudTrail log entries for requests made through access points include the access point ARN in the `resources` section of the log.

For example, suppose you have the following configuration:

- A bucket named `amzn-s3-demo-bucket1` in Region `us-west-2` that contains an object named `my-image.jpg`
- An access point named `my-bucket-ap` that is associated with `amzn-s3-demo-bucket1`
- An AWS account ID of `123456789012`

The following example shows the `resources` section of a CloudTrail log entry for the preceding configuration:

```
"resources": [
        {"type": "AWS::S3::Object",
            "ARN": "arn:aws:s3:::amzn-s3-demo-bucket1/my-image.jpg"
        },
        {"accountId": "123456789012",
```

```
            "type": "AWS::S3::Bucket",
            "ARN": "arn:aws:s3:::amzn-s3-demo-bucket1"
        },
        {"accountId": "123456789012",
            "type": "AWS::S3::AccessPoint",
            "ARN": "arn:aws:s3:us-west-2:123456789012:accesspoint/my-bucket-ap"
        }
    ]
```

For more information about S3 Server Access Logs, see Logging requests with server access logging. For more information about AWS CloudTrail, see What is AWS CloudTrail? in the *AWS CloudTrail User Guide*.

## Using Amazon S3 access points with the Amazon S3 console

This section explains how to manage and use your Amazon S3 access points using the AWS Management Console. Before you begin, navigate to the detail page for the access point you want to manage or use, as described in the following procedure.

**Topics**

### Listing access points for your account

**To list all access points created in your AWS account**

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the navigation bar on the top of the page, choose the name of the currently displayed AWS Region. Next, choose the Region that you want to list access points for.
3. In the navigation pane on the left side of the console, choose **access points**.

4. On the **access points** page, under **access points**, view the access points in your AWS Region.
5. (Optional) Search for access points by name by entering a name into the text field next to the Region dropdown menu.
6. Choose the name of the access point you want to manage or use.

## Listing access points for a bucket

**To list all access points in you AWS account for a single bucket**

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the navigation bar on the top of the page, choose the name of the currently displayed AWS Region then choose the Region that you want to list access points for.
3. In the navigation pane on the left side of the console, choose **Buckets**.
4. On the **Buckets** page, select the name of the bucket whose access points you want to list.
5. On the bucket detail page, choose the **access points** tab.
6. Choose the name of the access point you want to manage or use.

## Viewing configuration details for an access point

1. Navigate to the access point detail page for the access point whose details you want to view, as described in Listing access points for your account.
2. Under **access point overview**, view configuration details and properties for the selected access point.

## Using an access point

1. Navigate to the access point detail page for the access point you want to use, as described in Listing access points for your account.
2. Under the **Objects** tab, choose the name of an object or objects that you want to access through the access point. On the object operation pages, the console displays a label above the name of your bucket that shows the access point that you're currently using. While you're using the access point, you can only perform the object operations that are allowed by the access point permissions.

> **Note**
>
> - The console view always shows all objects in the bucket. Using an access point as described in this procedure restricts the operations you can perform on those objects, but not whether you can see that they exist in the bucket.
> - The S3 Management Console doesn't support using virtual private cloud (VPC) access points to access bucket resources. To access bucket resources from a VPC access point, use the AWS CLI, AWS SDKs, or Amazon S3 REST APIs.

## Viewing block public access settings for an access point

1. Navigate to the access point detail page for the access point whose settings you want to view, as described in Listing access points for your account.
2. Choose **Permissions**.
3. Under **access point policy**, review the access point's Block Public Access settings.

> **Note**
>
> You can't change the Block Public Access settings for an access point after the access point is created.

## Editing an access point policy

1. Navigate to the access point detail page for the access point whose policy you want to edit, as described in Listing access points for your account.
2. Choose **Permissions**.
3. Under **access point policy**, choose **Edit**.
4. Enter the access point policy in the text field. The console automatically displays the Amazon Resource Name (ARN) for the access point, which you can use in the policy.

### Deleting an access point

1. Navigate to the list of access points for your account or for a specific bucket, as described in Listing access points for your account.
2. Select the option button next to the name of the access point that you want to delete.
3. Choose **Delete**.
4. Confirm that you want to delete your access point by entering its name in the text field that appears, and choose **Delete**.

## Using a bucket-style alias for your S3 bucket access point

When you create an access point, Amazon S3 automatically generates an alias that you can use instead of an Amazon S3 bucket name for data access. You can use this access point alias instead of an Amazon Resource Name (ARN) for access point data plane operations. For a list of these operations, see Access point compatibility with AWS services.

The following shows an example ARN and access point alias for an access point named *my-access-point*.

- **ARN** – `arn:aws:s3:`*region*`:`*account-id*`:accesspoint/`*my-access-point*
- **Access point alias** – *my-access-point*`-`*hrzrlukc5m36ft7okagglf3gmwluquse1b*`-s3alias`

For more information about ARNs, see Amazon Resource Names (ARNs) in the *AWS General Reference*.

### Access point alias names

An access point alias name is created within the same namespace as an Amazon S3 bucket. This alias name is automatically generated and cannot be changed. An access point alias name meets all the requirements of a valid Amazon S3 bucket name and consists of the following parts:

*access point prefix*`-`*metadata*`-s3alias`

**Note**

The `-s3alias` suffix is reserved for access point alias names and can't be used for bucket or access point names. For more information about Amazon S3 bucket-naming rules, see Bucket naming rules.

## Access point alias use cases and limitations

When adopting access points, you can use access point alias names without requiring extensive code changes.

When you create an access point, Amazon S3 automatically generates an access point alias name, as shown in the following example. To run this command, replace the *`user input placeholders`* with your own information.

```
aws s3control create-access-point --bucket amzn-s3-demo-bucket1 --name my-access-point
 --account-id 111122223333
{
    "AccessPointArn":
    "arn:aws:s3:region:111122223333:accesspoint/my-access-point",
    "Alias": "my-access-point-aqfqprnstn7aefdfbarligizwgyfouse1a-s3alias"
}
```

You can use this access point alias name instead of an Amazon S3 bucket name in any data plane operation. For a list of these operations, see Access point compatibility with AWS services.

The following AWS CLI example for the `get-object` command uses the bucket's access point alias to return information about the specified object. To run this command, replace the *`user input placeholders`* with your own information.

```
aws s3api get-object --bucket my-access-point-aqfqprnstn7aefdfbarligizwgyfouse1a-
s3alias --key dir/my_data.rtf my_data.rtf

{
    "AcceptRanges": "bytes",
    "LastModified": "2020-01-08T22:16:28+00:00",
    "ContentLength": 910,
    "ETag": "\"00751974dc146b76404bb7290f8f51bb\"",
    "VersionId": "null",
    "ContentType": "text/rtf",
```

```
    "Metadata": {}
}
```

### Limitations

- Aliases cannot be configured by customers.
- Aliases cannot be deleted or modified or disabled on an access point.
- You can use this access point alias name instead of an Amazon S3 bucket name in some data plane operations. For a list of these operations, see Access point compatibility with S3 operations.
- You can't use an access point alias name for Amazon S3 control plane operations. For a list of Amazon S3 control plane operations, see Amazon S3 Control in the *Amazon Simple Storage Service API Reference*.
- You can't use S3 access point aliases as the source or destination for **Move** operations in the Amazon S3 console.
- Aliases cannot be used in AWS Identity and Access Management (IAM) policies.
- Aliases cannot be used as a logging destination for S3 server access logs.
- Aliases cannot be used as a logging destination for AWS CloudTrail logs.
- Amazon SageMaker GroundTruth does not support access point aliases.

## Using access points with compatible Amazon S3 operations

The following examples demonstrate how to use access points with compatible operations in Amazon S3.

### Topics

## Access point compatibility with AWS services

Amazon S3 access point aliases allow applications that require an S3 bucket name to easily use an access point. You can use S3 access point aliases where you use S3 bucket names to access data in S3. For more information, see Access point alias use cases and limitations.

## Access point compatibility with S3 operations

You can use access points to access a bucket using the following subset of Amazon S3 APIs. All the operations listed below can accept either access point ARNs or access point aliases:

### S3 operations

- AbortMultipartUpload
- CompleteMultipartUpload
- CopyObject (same-region copies only)
- CreateMultipartUpload
- DeleteObject
- DeleteObjectTagging
- GetBucketAcl
- GetBucketCors
- GetBucketLocation
- GetBucketNotificationConfiguration
- GetBucketPolicy
- GetObject
- GetObjectAcl
- GetObjectAttributes
- GetObjectLegalHold
- GetObjectRetention
- GetObjectTagging
- HeadBucket
- HeadObject
- ListMultipartUploads
- ListObjects

- ListObjectsV2
- ListObjectVersions
- ListParts
- Presign
- PutObject
- PutObjectLegalHold
- PutObjectRetention
- PutObjectAcl
- PutObjectTagging
- RestoreObject
- UploadPart
- UploadPartCopy (same-region copies only)

### Request an object through an access point

The following example requests the object `my-image.jpg` through the access point `prod` owned by account ID `123456789012` in Region `us-west-2`, and saves the downloaded file as `download.jpg`.

AWS CLI

```
aws s3api get-object --key my-image.jpg --bucket arn:aws:s3:us-
west-2:123456789012:accesspoint/prod download.jpg
```

### Upload an object through an access point alias

The following example uploads the object `my-image.jpg` through the access point alias `my-access-point-hrzrlukc5m36ft7okagglf3gmwluquse1b-s3alias` owned by account ID `123456789012` in Region `us-west-2`.

AWS CLI

```
aws s3api put-object --bucket my-access-point-hrzrlukc5m36ft7okagglf3gmwluquse1b-
s3alias --key my-image.jpg --body my-image.jpg
```

## Delete an object through an access point

The following example deletes the object `my-image.jpg` through the access point `prod` owned by account ID `123456789012` in Region `us-west-2`.

AWS CLI

```
aws s3api delete-object --bucket arn:aws:s3:us-west-2:123456789012:accesspoint/prod
 --key my-image.jpg
```

## List objects through an access point alias

The following example lists objects through the access point alias `my-access-point-hrzrlukc5m36ft7okagglf3gmwluquse1b-s3alias` owned by account ID `123456789012` in Region `us-west-2`.

AWS CLI

```
aws s3api list-objects-v2 --bucket my-access-point-
hrzrlukc5m36ft7okagglf3gmwluquse1b-s3alias
```

## Add a tag set to an object through an access point

The following example adds a tag set to the existing object `my-image.jpg` through the access point `prod` owned by account ID `123456789012` in Region `us-west-2`.

AWS CLI

```
aws s3api put-object-tagging --bucket arn:aws:s3:us-west-2:123456789012:accesspoint/
prod --key my-image.jpg --tagging TagSet=[{Key="finance",Value="true"}]
```

## Grant access permissions through an access point using an ACL

The following example applies an ACL to an existing object `my-image.jpg` through the access point `prod` owned by account ID `123456789012` in Region `us-west-2`.

AWS CLI

```
aws s3api put-object-acl --bucket arn:aws:s3:us-west-2:123456789012:accesspoint/prod
 --key my-image.jpg --acl private
```

## Access points restrictions and limitations

Amazon S3 access points have the following restrictions and limitations:

- Each access point is associated with exactly one bucket, which you must specify when you create the access point. After you create an access point, you can't associate it with a different bucket. However, you can delete an access point, and then create another one with the same name and associate that new access point with a different bucket.
- Access point names must meet certain conditions. For more information about naming access points, see Rules for naming Amazon S3 access points.
- After you create an access point, you can't change its virtual private cloud (VPC) configuration.
- Access point policies are limited to 20 KB in size.
- You can create a maximum of 10,000 access points per AWS account per Region. If you need more than 10,000 access points for a single account in a single Region, you can request a service quota increase. For more information about service quotas and requesting an increase, see AWS service quotas in the *AWS General Reference*.
- In AWS Regions where you have more than 1,000 access points, you can't search for an access point by name in the Amazon S3 console.
- You can't use an access point as a destination for S3 Replication. For more information about replication, see Replicating objects overview.
- You can't use S3 access point aliases as the source or destination for **Move** operations in the Amazon S3 console.
- You can address access points only by using virtual-host-style URLs. For more information about virtual-host-style addressing, see Accessing and listing an Amazon S3 bucket.
- API operations that control access point functionality (for example, `PutAccessPoint` and `GetAccessPointPolicy`) don't support cross-account calls.
- You must use AWS Signature Version 4 when making requests to an access point by using the REST APIs. For more information about authenticating requests, see Authenticating Requests (AWS Signature Version 4) in the *Amazon Simple Storage Service API Reference*.

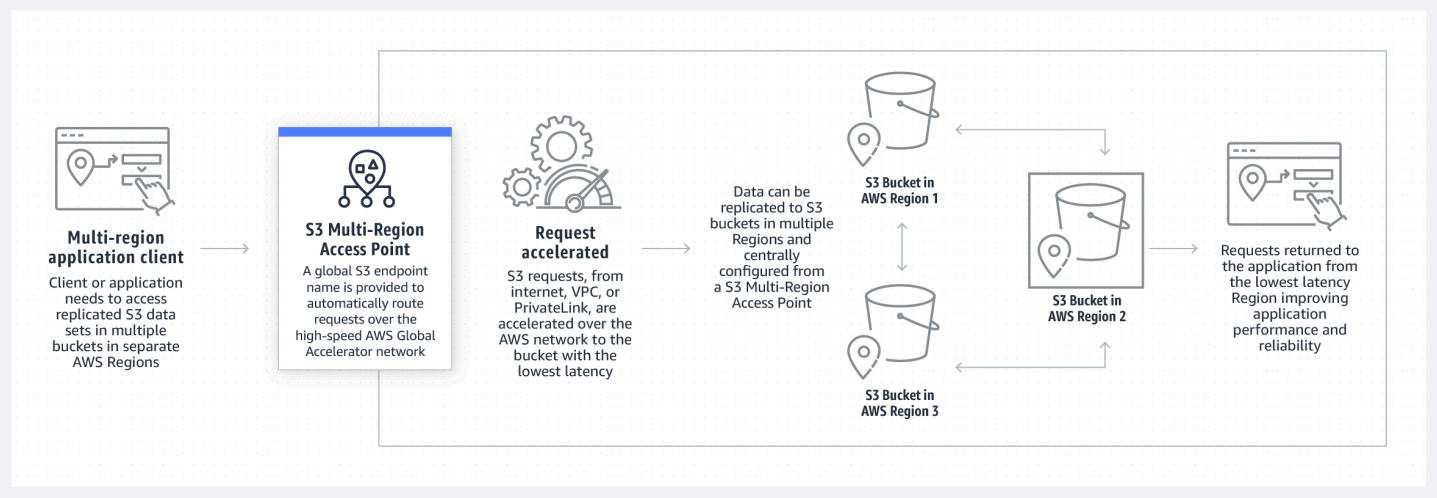
- Access points only support requests over HTTPS. Amazon S3 will automatically respond with an HTTP redirect for any requests made via HTTP, to upgrade the request to HTTPS.
- Access points don't support anonymous access.
- Cross-account access points don’t grant you access to data until you are granted permissions from the bucket owner. The bucket owner always retains ultimate control over access to the data and must update the bucket policy to authorize requests from the cross-account access point. To view a bucket policy example, see Configuring IAM policies for using access points.
- When you're viewing a cross-account access point in the Amazon S3 console, the **Access** column displays **Unknown**. The Amazon S3 console can't determine if public access is granted for the associated bucket and objects. Unless you require a public configuration for a specific use case, we recommend that you and the bucket owner block all public access to the access point and the bucket. For more information, see Blocking public access to your Amazon S3 storage.

# Multi-Region Access Points in Amazon S3

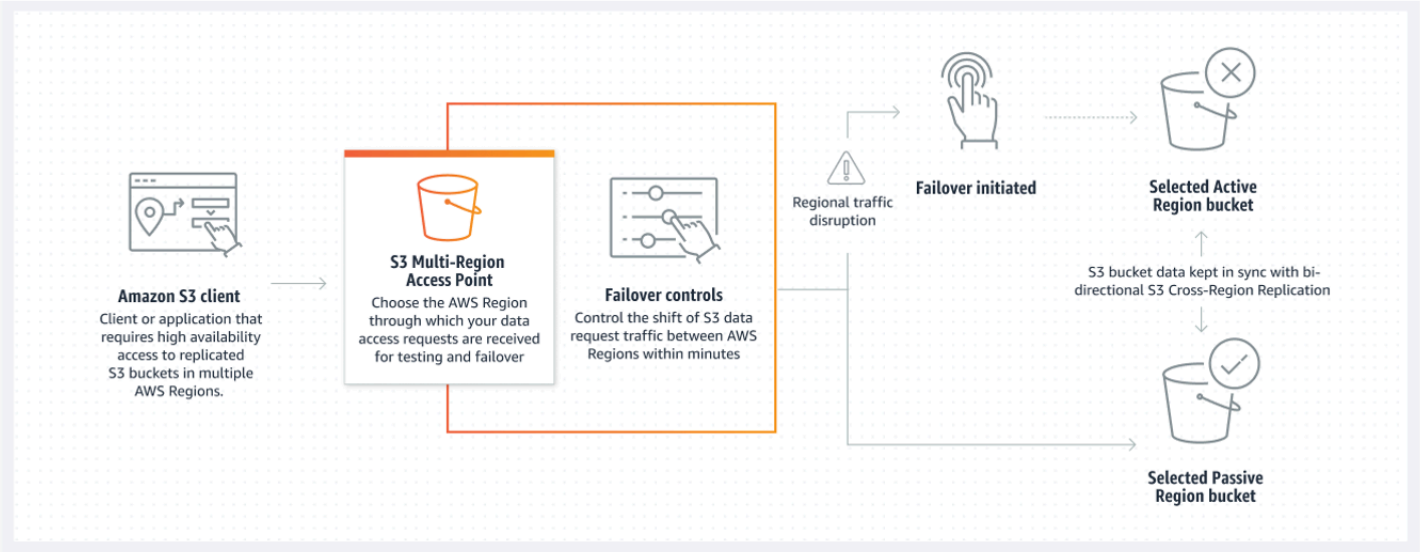
Amazon S3 Multi-Region Access Points provide a global endpoint that applications can use to fulfill requests from S3 buckets that are located in multiple AWS Regions. You can use Multi-Region Access Points to build multi-Region applications with the same architecture that's used in a single Region, and then run those applications anywhere in the world. Instead of sending requests over the congested public internet, Multi-Region Access Points provide built-in network resilience with acceleration of internet-based requests to Amazon S3. Application requests made to a Multi-Region Access Point global endpoint use AWS Global Accelerator to automatically route over the AWS global network to the closest-proximity S3 bucket with an active routing status.

When you create a Multi-Region Access Point, you specify a set of AWS Regions where you want to store data to be served through that Multi-Region Access Point. You can use S3 Cross-Region Replication (CRR) to synchronize data among buckets in those Regions. You can then request or write data through the Multi-Region Access Point global endpoint. Amazon S3 automatically serves requests to the replicated dataset from the closest available Region. Multi-Region Access Points are also compatible with applications that are running in Amazon virtual private clouds (VPCs), including those that are using AWS PrivateLink for Amazon S3.

The following image is a graphical representation of an Amazon S3 Multi-Region Access Point in an active-active configuration. The graphic shows how Amazon S3 requests are automatically routed to buckets in the closest active AWS Region.



The following image is a graphical representation of an Amazon S3 Multi-Region Access Point in an active-passive configuration. The graphic shows how you can control Amazon S3 data-access traffic to fail over between active and passive AWS Regions.



To learn more about how to use Multi-Region Access Points, see Tutorial: Getting started with Amazon S3 Multi-Region Access Points.

**Topics**

- Creating Multi-Region Access Points
- Configuring a Multi-Region Access Point for use with AWS PrivateLink
- Making requests through a Multi-Region Access Point

# Creating Multi-Region Access Points

To create a Multi-Region Access Point in Amazon S3, you do the following:

- Specify the name for the Multi-Region Access Point.
- Choose one bucket in each AWS Region that you want to serve requests for the Multi-Region Access Point.
- Configure the Amazon S3 Block Public Access settings for the Multi-Region Access Point.

You provide all of this information in a create request, which Amazon S3 processes asynchronously. Amazon S3 provides a token that you can use to monitor the status of the asynchronous creation request.

Make sure to resolve security warnings, errors, general warnings, and suggestions from AWS Identity and Access Management Access Analyzer before you save your policy. IAM Access Analyzer

runs policy checks to validate your policy against IAM policy grammar and best practices. These checks generate findings and provide actionable recommendations to help you author policies that are functional and conform to security best practices. To learn more about validating policies using IAM Access Analyzer, see IAM Access Analyzer policy validation in the *IAM User Guide*. To view a list of the warnings, errors, and suggestions that are returned by IAM Access Analyzer, see IAM Access Analyzer policy check reference.

When you use the API, the request to create a Multi-Region Access Point is asynchronous. When you submit a request to create a Multi-Region Access Point, Amazon S3 synchronously authorizes the request. It then immediately returns a token that you can use to track the progress of the creation request. For more information about tracking asynchronous requests to create and manage Multi-Region Access Points, see Using Multi-Region Access Points with supported API operations.

After you create the Multi-Region Access Point, you can create an access control policy for it. Each Multi-Region Access Point can have an associated policy. A Multi-Region Access Point policy is a resource-based policy that you can use to limit the use of the Multi-Region Access Point by resource, user, or other conditions.

**Note**

For an application or user to be able to access an object through a Multi-Region Access Point, both of the following policies must permit the request:

- The access policy for the Multi-Region Access Point
- The access policy for the underlying bucket that contains the object

When the two policies are different, the more restrictive policy takes precedence. To simplify permissions management for Multi-Region Access Points, you can delegate access control from the bucket to the Multi-Region Access Point. For more information, see the section called “Multi-Region Access Point policy examples”.

Using a bucket with a Multi-Region Access Point doesn't change the bucket's behavior when the bucket is accessed through the existing bucket name or an Amazon Resource Name (ARN). All existing operations against the bucket continue to work as before. Restrictions that you include in a Multi-Region Access Point policy apply only to requests that are made through the Multi-Region Access Point.

You can update the policy for a Multi-Region Access Point after creating it, but you can't delete the policy. However, you can update the Multi-Region Access Point policy to deny all permissions.

**Topics**

## Rules for naming Amazon S3 Multi-Region Access Points

When you create a Multi-Region Access Point, you give it a name, which is a string that you choose. You can't change the name of the Multi-Region Access Point after it is created. The name must be unique in your AWS account, and it must conform to the naming requirements listed in Multi-Region Access Point restrictions and limitations. To help you identify the Multi-Region Access Point, use a name that is meaningful to you, to your organization, or that reflects the scenario.

You use this name when invoking Multi-Region Access Point management operations, such as `GetMultiRegionAccessPoint` and `PutMultiRegionAccessPointPolicy`. The name is not used to send requests to the Multi-Region Access Point, and it doesn't need to be exposed to clients who make requests by using the Multi-Region Access Point.

When Amazon S3 creates a Multi-Region Access Point, it automatically assigns an alias to it. This alias is a unique alphanumeric string that ends in `.mrap`. The alias is used to construct the hostname and the Amazon Resource Name (ARN) for a Multi-Region Access Point. The fully qualified name is also based on the alias for the Multi-Region Access Point.

You can't determine the name of a Multi-Region Access Point from its alias, so you can disclose an alias without risk of exposing the name, purpose, or owner of the Multi-Region Access Point. Amazon S3 selects the alias for each new Multi-Region Access Point, and the alias can't be changed. For more information about addressing a Multi-Region Access Point, see Making requests through a Multi-Region Access Point.

Multi-Region Access Point aliases are unique throughout time and aren't based on the name or configuration of a Multi-Region Access Point. If you create a Multi-Region Access Point, and then

delete it and create another one with the same name and configuration, the second Multi-Region Access Point will have a different alias than the first. New Multi-Region Access Points can never have the same alias as a previous Multi-Region Access Point.

## Rules for choosing buckets for Amazon S3 Multi-Region Access Points

Each Multi-Region Access Point is associated with the Regions where you want to fulfill requests. The Multi-Region Access Point must be associated with exactly one bucket in each of those Regions. You specify the name of each bucket in the request to create the Multi-Region Access Point. Buckets that support the Multi-Region Access Point can either be in the same AWS account that owns the Multi-Region Access Point, or they can be in other AWS accounts.

A single bucket can be used by multiple Multi-Region Access Points.

**Important**

- You can specify the buckets that are associated with a Multi-Region Access Point only at the time that you create it. After it is created, you can’t add, modify, or remove buckets from the Multi-Region Access Point configuration. To change the buckets, you must delete the entire Multi-Region Access Point and create a new one.
- You can't delete a bucket that is part of a Multi-Region Access Point. If you want to delete a bucket that's attached to a Multi-Region Access Point, delete the Multi-Region Access Point first.
- If you add a bucket that's owned by another account to your Multi-Region Access Point, the bucket owner must also update their bucket policy to grant access permissions to the Multi-Region Access Point. Otherwise, the Multi-Region Access Point won't be able to retrieve data from that bucket. For example policies that show how to grant such access, see Multi-Region Access Point policy examples.
- Not all Regions support Multi-Region Access Points. To see the list of supported Regions, see Multi-Region Access Point restrictions and limitations.

You can create replication rules to synchronize data between buckets. These rules enable you to automatically copy data from source buckets to destination buckets. Having buckets connected to a Multi-Region Access Point does not affect how replication works. Configuring replication with Multi-Region Access Points is described in a later section.

**Important**

When you make a request to a Multi-Region Access Point, the Multi-Region Access Point isn't aware of the data contents of the buckets in the Multi-Region Access Point. Therefore, the bucket that gets the request might not contain the requested data. To create consistent datasets in the Amazon S3 buckets that are associated with a Multi-Region Access Point, we recommend that you configure S3 Cross-Region Replication (CRR). For more information, see Configuring replication for use with Multi-Region Access Points.

## Create an Amazon S3 Multi-Region Access Point

The following example demonstrates how to create a Multi-Region Access Point by using the Amazon S3 console.

### Using the S3 console

#### To create a Multi-Region Access Point

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Multi-Region Access Points**.
3. Choose **Create Multi-Region Access Points** to begin creating your Multi-Region Access Point.
4. On the **Multi-Region Access Point** page, supply a name for the Multi-Region Access Point in the **Multi-Region Access Point name** field.
5. Select the buckets that will be associated with this Multi-Region Access Point. You can choose buckets that are in your account, or you can choose buckets from other accounts.

**Note**

You must add at least one bucket from either your account or other accounts. Also, be aware that Multi-Region Access Points support only one bucket per AWS Region. Therefore, you can't add two buckets from the same Region. AWS Regions that are disabled by default are not supported.

- To add a bucket that is in your account, choose **Add buckets**. A list of all the buckets in your account displays. You can search for your bucket by name, or sort the bucket names in alphabetical order.
- To add a bucket from another account, choose **Add bucket from other accounts**. Make sure that you know the exact bucket name and AWS account ID because you can't search or browse for buckets in other accounts.

> **Note**
>
> You must enter a valid AWS account ID and bucket name. The bucket must also be in a supported Region, or you will encounter an error when you try to create your Multi-Region Access Point. For the list of Regions that support Multi-Region Access Points, see Multi-Region Access Points restrictions and limitations.

6. (Optional) If you need to remove a bucket that you added, choose **Remove**.

> **Note**
>
> You can’t add or remove buckets to this Multi-Region Access Point after you’ve finished creating it.

7. Under **Block Public Access settings for this Multi-Region Access Point**, select the Block Public Access settings that you want to apply to the Multi-Region Access Point. By default, all Block Public Access settings are enabled for new Multi-Region Access Points. We recommend that you leave all settings enabled unless you know that you have a specific need to disable any of them.

> **Note**
>
> You can't change the Block Public Access settings for a Multi-Region Access Point after the Multi-Region Access Point has been created. Therefore, if you're going to block public access, make sure that your applications work correctly without public access before you create a Multi-Region Access Point.

8. Choose **Create Multi-Region Access Point**.

> **Important**
>
> When you add a bucket that's owned by another account to your Multi-Region Access Point, the bucket owner must also update their bucket policy to grant access permissions to the Multi-Region Access Point. Otherwise, the Multi-Region Access Point won't be able to retrieve data from that bucket. For example policies that show how to grant such access, see Multi-Region Access Point policy examples.

### Using the AWS CLI

You can use the AWS CLI to create a Multi-Region Access Point. When you create the Multi-Region Access Point, you must provide all the buckets that it will support. You can't add buckets to the Multi-Region Access Point after it has been created.

The following example creates a Multi-Region Access Point with two buckets by using the AWS CLI. To use this example command, replace the *`user input placeholders`* with your own information.

```
aws s3control create-multi-region-access-point --account-id 111122223333 --details '{
        "Name": "simple-multiregionaccesspoint-with-two-regions",
        "PublicAccessBlock": {
            "BlockPublicAcls": true,
            "IgnorePublicAcls": true,
            "BlockPublicPolicy": true,
            "RestrictPublicBuckets": true
        },
        "Regions": [
            { "Bucket": "amzn-s3-demo-bucket1" },
            { "Bucket": "amzn-s3-demo-bucket2" }
        ]
    }' --region us-west-2
```

## Blocking public access with Amazon S3 Multi-Region Access Points

Each Multi-Region Access Point has distinct settings for Amazon S3 Block Public Access. These settings operate in conjunction with the Block Public Access settings for the AWS account that owns the Multi-Region Access Point and the underlying buckets.

When Amazon S3 authorizes a request, it applies the most restrictive combination of these settings. If the Block Public Access settings for any of these resources (the Multi-Region Access Point owner account, the underlying bucket, or the bucket owner account) block access for the requested action or resource, Amazon S3 rejects the request.

We recommend that you enable all Block Public Access settings unless you have a specific need to disable any of them. By default, all Block Public Access settings are enabled for a Multi-Region Access Point. If Block Public Access is enabled, the Multi-Region Access Point can't accept internet-based requests.

> **Important**
>
> You can't change the Block Public Access settings for a Multi-Region Access Point after it has been created.

For more information about Amazon S3 Block Public Access, see Blocking public access to your Amazon S3 storage.

## Viewing Amazon S3 Multi-Region Access Points configuration details

The following example demonstrates how to view Multi-Region Access Point configuration details by using the Amazon S3 console.

**Using the S3 console**

**To create a Multi-Region Access Point**

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Multi-Region Access Points**.
3. Choose the name of the Multi-Region Access Point for which you want to view the configuration details.

   - The **Properties** tab lists all of the buckets that are associated with your Multi-Region Access Point, the creation date, the Amazon Resource Name (ARN), and the alias. The AWS account ID column also lists any buckets owned by external accounts that are associated with your Multi-Region Access Point.

- The **Permissions** tab lists the Block Public Access settings that are applied to the buckets associated with this Multi-Region Access Point. You can also view the Multi-Region Access Point policy for your Multi-Region Access Point, if you've created one. The **Info** alert on the **Permissions** page also lists all the buckets (in your account and other accounts) for this Multi-Region Access Point that have the **Public Access is blocked** setting enabled.
- The **Replication and failover** tab provides a map view of the buckets that are associated with your Multi-Region Access Point and the Regions that the buckets reside int. If there are buckets from another account that you don't have permission to pull data from, the Region will be marked in red on the **Replication summary** map, indicating that it is an **AWS Region with errors getting replication status**.

  > **Note**
  >
  > To retrieve replication status information from a bucket in an external account, the bucket owner must grant you the `s3:GetBucketReplication` permission in their bucket policy.

  This tab also provides the replication metrics, replication rules, and failover statuses for the Regions that are used with your Multi-Region Access Point.

#### Using the AWS CLI

You can use the AWS CLI to view the configuration details for a Multi-Region Access Point.

The following AWS CLI example gets your current Multi-Region Access Point configuration. To use this example command, replace the *`user input placeholders`* with your own information.

```
aws s3control get-multi-region-access-point --account-id 111122223333 --name amzn-s3-demo-bucket1
```

## Deleting a Multi-Region Access Point

The following procedure explains how to delete a Multi-Region Access Point by using the Amazon S3 console.

Deleting a Multi-Region Access Point does not delete the buckets associated with the Multi-Region Access Point, only the Multi-Region Access Point itself.

### Using the S3 console

#### To delete a Multi-Region Access Point

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Multi-Region Access Points**.
3. Select the option button next to the name of your Multi-Region Access Point.
4. Choose **Delete**.
5. In the **Delete Multi-Region Access Point** dialog box, enter the name of the AWS bucket that you want to delete.

   > **Note**
   >
   > Make sure to enter a valid bucket name. Otherwise, the **Delete** button will be disabled.

6. Choose **Delete** to confirm deletion of your Multi-Region Access Point.

### Using the AWS CLI

You can use the AWS CLI to delete a Multi-Region Access Point. This action does not delete the buckets associated with the Multi-Region Access Point, only the Multi-Region Access Point itself. To use this example command, replace the *`user input placeholders`* with your own information.

```
aws s3control delete-multi-region-access-point --account-id 123456789012 --details
 Name=example-multi-region-access-point-name
```

## Configuring a Multi-Region Access Point for use with AWS PrivateLink

You can use Multi-Region Access Points to route Amazon S3 request traffic between AWS Regions. Each Multi-Region Access Point global endpoint routes Amazon S3 data request traffic from multiple sources without your having to build complex networking configurations with separate endpoints. These data-request traffic sources include:

- Traffic originating in a virtual private cloud (VPC)

- Traffic from on-premises data centers traveling over AWS PrivateLink
- Traffic from the public internet

If you establish an AWS PrivateLink connection to an S3 Multi-Region Access Point, you can route S3 requests into AWS, or across multiple AWS Regions, over a private connection by using a simple network architecture and configuration. When you use AWS PrivateLink, you don't need to configure a VPC peering connection.

**Topics**

## Configuring a Multi-Region Access Point for use with AWS PrivateLink

AWS PrivateLink provides you with private connectivity to Amazon S3 using private IP addresses in your virtual private cloud (VPC). You can provision one or more interface endpoints inside your VPC to connect to Amazon S3 Multi-Region Access Points.

You can create **com.amazonaws.s3-global.accesspoint** endpoints for Multi-Region Access Points through the AWS Management Console, AWS CLI, or AWS SDKs. To learn more about how to configure an interface endpoint for Multi-Region Access Point, see Interface VPC endpoints in the *VPC User Guide*.

To make requests to a Multi-Region Access Point via interface endpoints, follow these steps to configure the VPC and the Multi-Region Access Point.

**To configure a Multi-Region Access Point to use with AWS PrivateLink**

1. Create or have an appropriate VPC endpoint that can connect to Multi-Region Access Points. For more information about creating VPC endpoints, see Interface VPC endpoints in the *VPC User Guide*.

   > **Important**
   >
   > Make sure to create a **com.amazonaws.s3-global.accesspoint** endpoint. Other endpoint types cannot access Multi-Region Access Points.

After this VPC endpoint is created, all Multi-Region Access Point requests in the VPC route through this endpoint if you have private DNS enabled for the endpoint. This is enabled by default.

2. If the Multi-Region Access Point policy does not support connections from VPC endpoints, you will need to update it.
3. Verify that the individual bucket policies will allow access to the users of the Multi-Region Access Point.

Remember that Multi-Region Access Points work by routing requests to buckets, not by fulfilling requests themselves. This is important to remember because the originator of the request must have permissions to the Multi-Region Access Point and be allowed to access the individual buckets in the Multi-Region Access Point. Otherwise, the request might be routed to a bucket where the originator doesn't have permissions to fulfill the request. A Multi-Region Access Point and the buckets associated can be owned by the same or another AWS account. However, VPCs from different accounts can use a Multi-Region Access Point if the permissions are configured correctly.

Because of this, the VPC endpoint policy must allow access both to the Multi-Region Access Point and to each underlying bucket that you want to be able to fulfill requests. For example, suppose that you have a Multi-Region Access Point with the alias `mfzwi23gnjvgw.mrap`. It is backed by buckets `amzn-s3-demo-bucket1` and `amzn-s3-demo-bucket2`, all owned by AWS account `123456789012`. In this case, the following VPC endpoint policy would allow `GetObject` requests from the VPC made to `mfzwi23gnjvgw.mrap` to be fulfilled by either backing bucket.

```
{
    "Version": "2012-10-17",
    "Statement": [
    {
        "Sid": "Read-buckets-and-MRAP-VPCE-policy",
        "Principal": "*",
        "Action": [
            "s3:GetObject"
        ],
        "Effect": "Allow",
        "Resource": [
            "arn:aws:s3:::amzn-s3-demo-bucket1/*",
            "arn:aws:s3:::amzn-s3-demo-bucket2/*",
            "arn:aws:s3::123456789012:accesspoint/mfzwi23gnjvgw.mrap/object/*"
```

```
        ]
    }]
}
```

As mentioned previously, you also must make sure that the Multi-Region Access Point policy is configured to support access through a VPC endpoint. You don't need to specify the VPC endpoint that is requesting access. The following sample policy would grant access to any requester trying to use the Multi-Region Access Point for the `GetObject` requests.

```
{
    "Version": "2012-10-17",
    "Statement": [
    {
        "Sid": "Open-read-MRAP-policy",
        "Effect": "Allow",
        "Principal": "*",
        "Action": [
            "s3:GetObject"
          ],
        "Resource": "arn:aws:s3::123456789012:accesspoint/mfzwi23gnjvgw.mrap/object/*"
    }]
}
```

And of course, the individual buckets would each need a policy to support access from requests submitted through VPC endpoint. The following example policy grants read access to any anonymous users, which would include requests made through the VPC endpoint.

```
{
    "Version":"2012-10-17",
   "Statement": [
   {
       "Sid": "Public-read",
       "Effect":"Allow",
       "Principal": "*",
       "Action": "s3:GetObject",
       "Resource": [
           "arn:aws:s3:::amzn-s3-demo-bucket1",
           "arn:aws:s3:::amzn-s3-demo-bucket2/*"]
    }]
}
```

For more information about editing a VPC endpoint policy, see Control access to services with VPC endpoints in the *VPC User Guide*.

### Removing access to a Multi-Region Access Point from a VPC endpoint

If you own a Multi-Region Access Point and want to remove access to it from an interface endpoint, you must supply a new access policy for the Multi-Region Access Point that prevents access for requests coming through VPC endpoints. However, if the buckets in your Multi-Region Access Point support requests through VPC endpoints, they will continue to support these requests. If you want to prevent that support, you must also update the policies for the buckets. Supplying a new access policy to the Multi-Region Access Point prevents access only to the Multi-Region Access Point, not to the underlying buckets.

> **Note**
>
> You can't delete an access policy for a Multi-Region Access Point. To remove access to a Multi-Region Access Point, you must provide a new access policy with the modified access that you want.

Instead of updating the access policy for the Multi-Region Access Point, you can update the bucket policies to prevent requests through VPC endpoints. In this case, users can still access the Multi-Region Access Point through the VPC endpoint. However, if the Multi-Region Access Point request is routed to a bucket where the bucket policy prevents access, the request will generate an error message.

## Making requests through a Multi-Region Access Point

Like other resources, Amazon S3 Multi-Region Access Points have Amazon Resource Names (ARNs). You can use these ARNs to direct requests to Multi-Region Access Points by using the AWS Command Line Interface (AWS CLI), AWS SDKs, or the Amazon S3 API. You can also use these ARNs to identify Multi-Region Access Points in access control policies. A Multi-Region Access Point ARN doesn't include or disclose the name of the Multi-Region Access Point. For more information about ARNs, see Amazon Resource Names (ARNs) in the *AWS General Reference*.

> **Note**
>
> The Multi-Region Access Point alias and ARN cannot be used interchangeably.

Multi-Region Access Point ARNs use the following format:

`arn:aws:s3::account-id:accesspoint/MultiRegionAccessPoint_alias`

The following are a few examples of Multi-Region Access Point ARNs:

- `arn:aws:s3::123456789012:accesspoint/mfzwi23gnjvgw.mrap` represents the Multi-Region Access Point with the alias `mfzwi23gnjvgw.mrap`, which is owned by AWS account `123456789012`.
- `arn:aws:s3::123456789012:accesspoint/*` represents all Multi-Region Access Points under the account `123456789012`. This ARN matches all Multi-Region Access Points for account `123456789012`, but doesn't match any Regional Amazon S3 Access Points because the ARN doesn't include an AWS Region. In contrast, the ARN `arn:aws:s3:us-west-2:123456789012:accesspoint/*` matches all Regional Amazon S3 Access Points in the Region `us-west-2` for the account `123456789012`, but doesn't match any Multi-Region Access Points.

ARNs for objects that are accessed through a Multi-Region Access Point use the following format:

`arn:aws:s3::account_id:accesspoint/MultiRegionAccessPoint_alias//key`

As with Multi-Region Access Point ARNs, the ARNs for objects that are accessed through Multi-Region Access Points don't include an AWS Region. Here are some examples.

- `arn:aws:s3::123456789012:accesspoint/mfzwi23gnjvgw.mrap//-01` represents the `-01`, which is accessed through the Multi-Region Access Point with the alias `mfzwi23gnjvgw.mrap`, which is owned by account `123456789012`.
- `arn:aws:s3::123456789012:accesspoint/mfzwi23gnjvgw.mrap//*` represents all objects that can be accessed through the Multi-Region Access Point with the alias `mfzwi23gnjvgw.mrap`, in account `123456789012`.
- `arn:aws:s3::123456789012:accesspoint/mfzwi23gnjvgw.mrap//-01/finance/*` represents all objects that can be accessed under the `-01/finance/` for the Multi-Region Access Point with the alias `mfzwi23gnjvgw.mrap`, in account `123456789012`.

## Multi-Region Access Point hostnames

You can access data in Amazon S3 through a Multi-Region Access Point by using the hostname of the Multi-Region Access Point. Requests can be directed to this hostname from the public internet.

If you have configured one or more internet gateways for the Multi-Region Access Point, requests can also be directed to this hostname from a virtual private cloud (VPC). For more information about creating VPC interface endpoints to use with Multi-Region Access Points, see Configuring a Multi-Region Access Point for use with AWS PrivateLink.

To make requests through a Multi-Region Access Point from a VPC by using a VPC endpoint, you can use AWS PrivateLink. When you're making requests to a Multi-Region Access Point by using AWS PrivateLink, you cannot directly use an endpoint-specific Regional DOMAIN NAME SYSTEM (DNS) name that ends with *region*`.vpce.amazonaws.com`. This hostname will not have a certificate associated with it, so it cannot be used directly. You can still use the public DOMAIN NAME SYSTEM (DNS) name of the VPC endpoint as a `CNAME` or `ALIAS` target. Alternatively, you can enable private DOMAIN NAME SYSTEM (DNS) on the endpoint and use the standard Multi-Region Access Point *MultiRegionAccessPoint_alias*`.accesspoint.s3-global.amazonaws.com` DOMAIN NAME SYSTEM (DNS) name, as described in this section.

When you make requests to the API for Amazon S3 data operations (for example, `GetObject`) through a Multi-Region Access Point, the hostname for the request is as follows:

*MultiRegionAccessPoint_alias*`.accesspoint.s3-global.amazonaws.com`

For example, to make a `GetObject` request through the Multi-Region Access Point with the alias `mfzwi23gnjvgw.mrap`, make a request to the hostname `mfzwi23gnjvgw.mrap.accesspoint.s3-global.amazonaws.com`. The `s3-global` portion of the hostname indicates that this hostname is not for a specific Region.

Making requests through a Multi-Region Access Point is similar to making requests through a single-Region access point. However, it's important to be aware of the following differences:

- Multi-Region Access Point ARNs don't include an AWS Region. They follow the format `arn:aws:s3::`*account-id*`:accesspoint/`*MultiRegionAccessPoint_alias*.
- For requests made through API operations (these requests don't require the use of an ARN), Multi-Region Access Points use a different endpoint scheme. The scheme is *MultiRegionAccessPoint_alias*`.accesspoint.s3-global.amazonaws.com`—for example, `mfzwi23gnjvgw.mrap.accesspoint.s3-global.amazonaws.com`. Note the differences compared to a single-Region access point:
  - Multi-Region Access Point hostnames use their alias, not the Multi-Region Access Point name.
  - Multi-Region Access Point hostnames don't include the owner's AWS account ID.
  - Multi-Region Access Point hostnames don't include an AWS Region.

- Multi-Region Access Point hostnames include `s3-global.amazonaws.com` instead of `s3.amazonaws.com`.
- Multi-Region Access Point requests must be signed by using Signature Version 4A (SigV4A). When you use the AWS SDKs, the SDK automatically converts a SigV4 to SigV4A. Therefore, make sure that your AWS SDK supports SigV4A as the signing implementation that is used to sign the global AWS Region requests. For more information about SigV4A, see Signing AWS API requests in the *AWS General Reference*.

## Multi-Region Access Points and Amazon S3 Transfer Acceleration

Amazon S3 Transfer Acceleration is a feature that enables fast transfer of data to buckets. Transfer Acceleration is configured on the individual bucket level. For more information about Transfer Acceleration, see Configuring fast, secure file transfers using Amazon S3 Transfer Acceleration.

Multi-Region Access Points use a similar accelerated transfer mechanism as Transfer Acceleration for sending large objects over the AWS network. Because of this, you don't need to use Transfer Acceleration when sending requests through a Multi-Region Access Point. This increased transfer performance is automatically incorporated into the Multi-Region Access Point.

**Topics**

- Permissions
- Multi-Region Access Point restrictions and limitations
- Multi-Region Access Point request routing
- Amazon S3 Multi-Region Access Points failover controls
- Configuring replication for use with Multi-Region Access Points
- Using Multi-Region Access Points with supported API operations
- Monitoring and logging requests made through a Multi-Region Access Point to underlying resources

## Permissions

Amazon S3 Multi-Region Access Points can simplify data access for Amazon S3 buckets in multiple AWS Regions. Multi-Region Access Points are named global endpoints that you can use to perform Amazon S3 data-access object operations, such as `GetObject` and `PutObject`. Each Multi-Region

Access Point can have distinct permissions and network controls for any request that is made through the global endpoint.

Each Multi-Region Access Point can also enforce a customized access policy that works in conjunction with the bucket policy that is attached to the underlying bucket. For a request to succeed, all of the following must permit the operation:

- The Multi-Region Access Point policy
- The underlying AWS Identity and Access Management (IAM) policy
- The underlying bucket policy (where the request is routed to)

You can configure any Multi-Region Access Point policy to accept requests only from specific IAM users or groups. For an example of how to do this, see Example 2 in the section called "Multi-Region Access Point policy examples". To restrict Amazon S3 data access to a private network, you can configure the Multi-Region Access Point policy to accept requests only from a virtual private cloud (VPC).

For example, suppose that you make a `GetObject` request through a Multi-Region Access Point by using a user called `AppDataReader` in your AWS account. To help ensure that the request won't be denied, the `AppDataReader` user must be granted the `s3:GetObject` permission by the Multi-Region Access Point and by each bucket underlying the Multi-Region Access Point. `AppDataReader` won't be able to retrieve data from any bucket that doesn't grant this permission.

> **Important**
>
> Delegating access control for a bucket to a Multi-Region Access Point policy doesn't change the bucket's behavior when the bucket is accessed directly through its bucket name or Amazon Resource Name (ARN). All operations made directly against the bucket will continue to work as before. Restrictions that you include in a Multi-Region Access Point policy apply only to requests made through that Multi-Region Access Point.

## Managing public access to a Multi-Region Access Point

Multi-Region Access Points support independent Block Public Access settings for each Multi-Region Access Point. When you create a Multi-Region Access Point, you can specify the Block Public Access settings that apply to that Multi-Region Access Point.

> **Note**
>
> Any Block Public Access settings that are enabled under **Block Public Access settings for this account** (in your own account) or **Block Public Settings for external buckets** still apply even if the independent Block Public Access settings for your Multi-Region Access Point are disabled.

For any request that is made through a Multi-Region Access Point, Amazon S3 evaluates the Block Public Access settings for:

- The Multi-Region Access Point
- The underlying buckets (including external buckets)
- The account that owns the Multi-Region Access Point
- The account that owns the underlying buckets (including external accounts)

If any of these settings indicate that the request should be blocked, Amazon S3 rejects the request. For more information about the Amazon S3 Block Public Access feature, see Blocking public access to your Amazon S3 storage.

> **Important**
>
> By default, all Block Public Access settings are enabled for Multi-Region Access Points. You must explicitly turn off any settings that you don't want to apply to a Multi-Region Access Point.
> You can't change the Block Public Access settings for a Multi-Region Access Point after it has been created.

## Viewing Block Public Access settings for a Multi-Region Access Point

**To view the Block Public Access settings for a Multi-Region Access Point**

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Multi-Region Access Points**.

3. Choose the name of the Multi-Region Access Point that you want to review.
4. Choose the **Permissions** tab.
5. Under **Block Public Access settings for this Multi-Region Access Point**, review the Block Public Access settings for your Multi-Region Access Point.

> **Note**
>
> You can't edit the Block Public Access settings after the Multi-Region Access Point is created. Therefore, if you're going to block public access, make sure that your applications work correctly without public access before you create a Multi-Region Access Point.

## Using a Multi-Region Access Point policy

The following example Multi-Region Access Point policy grants an IAM user access to list and download files from your Multi-Region Access Point. To use this example policy, replace the *`user input placeholders`* with your own information.

```
 {
   "Version":"2012-10-17",
   "Statement":[
      {
         "Effect":"Allow",
         "Principal":{
            "AWS":"arn:aws:iam::123456789012:user/JohnDoe"
         },
         "Action":[
            "s3:ListBucket",
            "s3:GetObject"
         ],
         "Resource":[
            "arn:aws:s3::111122223333:accesspoint/MultiRegionAccessPoint_alias",
            "arn:aws:s3::111122223333:accesspoint/MultiRegionAccessPoint_alias/object/
*"
         ]
      }
   ]
}
```

To associate your Multi-Region Access Point policy with the specified Multi-Region Access Point by using the AWS Command Line Interface (AWS CLI), use the following `put-multi-region-access-point-policy` command. To use this example command, replace the *`user input placeholders`* with your own information. Each Multi-Region Access Point can have only one policy, so a request made to the `put-multi-region-access-point-policy` action replaces any existing policy that is associated with the specified Multi-Region Access Point.

AWS CLI

```
aws s3control put-multi-region-access-point-policy
--account-id 111122223333
--details { "Name": "amzn-s3-demo-bucket-MultiRegionAccessPoint",
 "Policy": "{ \"Version\": \"2012-10-17\", \"Statement\": { \"Effect\":
 \"Allow\", \"Principal\": { \"AWS\": \"arn:aws:iam::111122223333:root
\" }, \"Action\": [\"s3:ListBucket\", \"s3:GetObject\"], \"Resource\":
 [ \"arn:aws:s3::111122223333:accesspoint/MultiRegionAccessPoint_alias",
 \"arn:aws:s3::111122223333:accesspoint/MultiRegionAccessPoint_alias/object/*
\" ] } }" }
```

To query your results for the previous operation, use the following command:

AWS CLI

```
aws s3control describe-multi-region-access-point-operation
--account-id 111122223333
--request-token-arn requestArn
```

To retrieve your Multi-Region Access Point policy, use the following command:

AWS CLI

```
aws s3control get-multi-region-access-point-policy
--account-id 111122223333
--name=amzn-s3-demo-bucket-MultiRegionAccessPoint
```

## Editing the Multi-Region Access Point policy

The Multi-Region Access Point policy (written in JSON) provides storage access to the Amazon S3 buckets that are used with this Multi-Region Access Point. You can allow or deny specific principals to perform various actions on your Multi-Region Access Point. When a request is routed to a bucket through the Multi-Region Access Point, both the access policies for the Multi-Region Access Point and the bucket apply. The more restrictive access policy always takes precedence.

> **Note**
>
> If a bucket contains objects that are owned by other accounts, the Multi-Region Access Point policy doesn't apply to the objects that are owned by other AWS accounts.

After you apply a Multi-Region Access Point policy, the policy cannot be deleted. You can either edit the policy or create a new policy that overwrites the existing one.

**To edit the Multi-Region Access Point policy**

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Multi-Region Access Points**.
3. Choose the name of the Multi-Region Access Point that you want to edit the policy for.
4. Choose the **Permissions** tab.
5. Scroll down to the **Multi-Region Access Point policy** section. Choose **Edit** to update the policy (in JSON).
6. The **Edit Multi-Region Access Point policy** page appears. You can either enter the policy directly into the text field, or you can choose **Add statement** to select policy elements from a dropdown list.

   > **Note**
   >
   > The console automatically displays the Multi-Region Access Point Amazon Resource Name (ARN), which you can use in the policy. For example Multi-Region Access Point policies, see the section called “Multi-Region Access Point policy examples”.

## Multi-Region Access Point policy examples

Amazon S3 Multi-Region Access Points support AWS Identity and Access Management (IAM) resource policies. You can use these policies to control the use of the Multi-Region Access Point by resource, user, or other conditions. For an application or user to be able to access objects through a Multi-Region Access Point, both the Multi-Region Access Point and the underlying bucket must allow the same access.

To allow the same access to both the Multi-Region Access Point and the underlying bucket, do one of the following:

- **(Recommended)** To simplify access controls when using an Amazon S3 Multi-Region Access Point, delegate access control for the Amazon S3 bucket to the Multi-Region Access Point. For an example of how to do this, see Example 1 in this section.
- Add the same permissions contained in the Multi-Region Access Point policy to the underlying bucket policy.

> **Important**
>
> Delegating access control for a bucket to a Multi-Region Access Point policy doesn't change the bucket's behavior when the bucket is accessed directly through its bucket name or Amazon Resource Name (ARN). All operations made directly against the bucket will continue to work as before. Restrictions that you include in a Multi-Region Access Point policy apply only to requests made through that Multi-Region Access Point.

### Example 1 – Delegating access to specific Multi-Region Access Points in your bucket policy (for the same account or cross-account)

The following example bucket policy grants full bucket access to a specific Multi-Region Access Point. This means that all access to this bucket is controlled by the policies that are attached to the Multi-Region Access Point. We recommend configuring your buckets this way for all use cases that don't require direct access to the bucket. You can use this bucket policy structure for Multi-Region Access Points in either the same account or in another account.

```
{
    "Version": "2012-10-17",
    "Statement" : [
```

```
    {
        "Effect": "Allow",
        "Principal" : { "AWS": "*" },
        "Action" : "*",
        "Resource" : [ "Bucket ARN", "Bucket ARN/*"],
        "Condition": {
            "StringEquals" : { "s3:DataAccessPointArn" : "MultiRegionAccessPoint_ARN" }
        }
    }]
}
```

> **Note**
>
> If there are multiple Multi-Region Access Points that you're granting access to, make sure to list each Multi-Region Access Point.

### Example 2 – Granting an account access to a Multi-Region Access Point in your Multi-Region Access Point policy

The following Multi-Region Access Point policy allows account *123456789012* permission to list and read the objects contained in the Multi-Region Access Point defined by the *MultiRegionAccessPoint_ARN*.

```
{
  "Version":"2012-10-17",
  "Statement": [
    {
       "Effect": "Allow",
       "Principal": {
          "AWS":"arn:aws:iam::123456789012:user/JohnDoe"
       },
       "Action":[
          "s3:ListBucket",
          "s3:GetObject"
       ],
       "Resource":[
          "MultiRegionAccessPoint_ARN",
          "MultiRegionAccessPoint_ARN/object/*"
       ]
     }
  ]
```

```
}
```

**Example 3 – Multi-Region Access Point policy that allows bucket listing**

The following Multi-Region Access Point policy allows account *123456789012* permission to list the objects contained in the Multi-Region Access Point defined by the *MultiRegionAccessPoint_ARN*.

```
{
   "Version":"2012-10-17",
   "Statement": [
      {
       "Effect": "Allow",
       "Principal": {
        "AWS": "arn:aws:iam::123456789012:user/JohnDoe"
        },
        "Action": "s3:ListBucket",
        "Resource": "MultiRegionAccessPoint_ARN"
       }
    ]
}
```

## Multi-Region Access Point restrictions and limitations

Multi-Region Access Points in Amazon S3 have the following restrictions and limitations.

- Multi-Region Access Point names:
  - Must be unique within a single AWS account
  - Must begin with a number or lowercase letter
  - Must be between 3 and 50 characters long
  - Can't begin or end with a hyphen (-)
  - Can't contain underscores (_), uppercase letters, or periods (.)
  - Can't be edited after they are created
- Multi-Region Access Point aliases are generated by Amazon S3 and can't be edited or reused.
- You cannot access data through a Multi-Region Access Point by using gateway endpoints. However, you can access data through a Multi-Region Access Point by using interface endpoints. To use AWS PrivateLink, you must create VPC endpoints. For more information, see Configuring a Multi-Region Access Point for use with AWS PrivateLink.

- To use Multi-Region Access Points with Amazon CloudFront, you must configure the Multi-Region Access Point as a `Custom Origin` distribution type. For more information about various origin types, see Using various origins with CloudFront distributions. For more information about using Multi-Region Access Points with Amazon CloudFront, see Building an active-active, proximity-based application across multiple Regions on the *AWS Storage Blog*.
- Multi-Region Access Point minimum requirements:
  - Transport Layer Security (TLS) v1.2
  - Signature Version 4 (SigV4A)

    Multi-Region Access Points support Signature Version 4A. This version of SigV4 allows requests to be signed for multiple AWS Regions. This feature is useful in API operations that might result in data access from one of several Regions. When using an AWS SDK, you supply your credentials, and the requests to Multi-Region Access Points will use Signature Version 4A without additional configuration. Make sure to check your AWS SDK compatibility with the SigV4A algorithm. For more information about SigV4A, see Signing AWS API requests in the *AWS General Reference*.

    > **Note**
    >
    > To use SigV4A with temporary security credentials—for example, when using AWS Identity and Access Management (IAM) roles—you can request the temporary credentials from a Regional AWS Security Token Service (AWS STS) endpoint. If you request temporary credentials from the global AWS STS endpoint (`sts.amazonaws.com`), then you must first set the Region compatibility of session tokens for the global endpoint to be valid in all AWS Regions. For more information, see Managing AWS STS in an AWS Region in the *IAM User Guide*.
- Multi-Region Access Points don't support anonymous requests.
- Multi-Region Access Point limitations:
  - IPv6 is not supported.
  - Amazon S3 on Outposts buckets are not supported.
  - Multi-Region Access Points supports copy operations using Multi-Region Access Points only as a destination when using the Multi-Region Access Point ARN.
  - The S3 Batch Operations feature is not supported.

- Certain AWS SDKs are not supported. To confirm which AWS SDKs are supported for Multi-Region Access Points, see Compatibility with AWS SDKs.
- The service quotas for Multi-Region Access Points are as follows:
  - There is a maximum of 100 Multi-Region Access Points per account.
  - There is a limit of 17 Regions for a single Multi-Region Access Point.
- After you create a Multi-Region Access Point, you can't add, modify, or remove buckets from the Multi-Region Access Point configuration. To change the buckets, you must delete the entire Multi-Region Access Point and create a new one. If a cross-account bucket in your Multi-Region Access Point is deleted, the only way to reconnect this bucket is to recreate the bucket, using the same name and Region in that account.
- Underlying buckets (in the same account) that are used in a Multi-Region Access Point can be deleted only after a Multi-Region Access Point is deleted.
- All control plane requests to create or maintain Multi-Region Access Points must be routed to the `US West (Oregon)` Region. For Multi-Region Access Point data plane requests, Regions don't need to be specified.
- For the Multi-Region Access Point failover control plane, requests must be routed to one of these five supported Regions:
  - `US East (N. Virginia)`
  - `US West (Oregon)`
  - `Asia Pacific (Sydney)`
  - `Asia Pacific (Tokyo)`
  - `Europe (Ireland)`
- Your Multi-Region Access Point only supports buckets in the following AWS Regions:
  - `US East (N. Virginia)`
  - `US East (Ohio)`
  - `US West (N. California)`
  - `US West (Oregon)`
  - `Asia Pacific (Mumbai)`
  - `Asia Pacific (Osaka)`
  - `Asia Pacific (Seoul)`
  - `Asia Pacific (Singapore)`
  - `Asia Pacific (Sydney)`

- Asia Pacific (Tokyo)
- Canada (Central)
- Europe (Frankfurt)
- Europe (Ireland)
- Europe (London)
- Europe (Paris)
- Europe (Stockholm)
- South America (São Paulo)

## Multi-Region Access Point request routing

When you make a request through a Multi-Region Access Point, Amazon S3 determines which of the buckets that are associated with the Multi-Region Access Point is closest to you. Amazon S3 then directs the request to that bucket, regardless of the AWS Region it is located in.

After the Multi-Region Access Point routes the request to the closest-proximity bucket, Amazon S3 processes the request as if you made it directly to that bucket. Multi-Region Access Points aren't aware of the data contents of an Amazon S3 bucket. Therefore, the bucket that gets the request might not contain the requested data. To create consistent datasets in the Amazon S3 buckets that are associated with a Multi-Region Access Point, you can configure S3 Cross-Region Replication (CRR). Then any bucket can fulfill the request successfully.

Amazon S3 directs Multi-Region Access Point requests according to the following rules:

- Amazon S3 optimizes requests to be fulfilled according to proximity. It looks at the buckets supported by the Multi-Region Access Point and relays the request to the bucket that has the closest proximity.
- If the request specifies an existing resource (for example, `GetObject`), Amazon S3 does *not* consider the name of the object when fulfilling the request. This means that even if an object exists in one bucket in the Multi-Region Access Point, your request can be routed to a bucket that doesn't contain the object. This situation will result in a 404 error message being returned to the client.

  To avoid 404 errors, we recommend that you configure S3 Cross-Region Replication (CRR) for your buckets. Replication helps resolve the potential issue when the object that you want is in a bucket in the Multi-Region Access Point, but it's not located in the specific bucket that your

request was routed to. For more information about configuring replication, see Configuring replication for use with Multi-Region Access Points.

To ensure that your requests are fulfilled by using the specific objects that you want, we also recommend that you turn on bucket versioning and include version IDs in your requests. This approach helps ensure that you have the correct version of the object that you are looking for. Versioning-enabled buckets can also help you recover objects from accidental overwrite. For more information, see Using S3 Versioning in S3 buckets.

- If the request is to create a resource (for example, `PutObject` or `CreateMultipartUpload`), Amazon S3 fulfills the request by using the closest-proximity bucket. For example, consider a video company that wants to support video uploads from anywhere in the world. When a user makes a PUT request to the Multi-Region Access Point, the object is put into the bucket with the closest proximity. To then make that uploaded video available to others around the world for download with the lowest latency, you can use CRR with bidirectional (two-way) replication. Using CRR with two-way replication keeps the contents of all the buckets that are associated with the Multi-Region Access Point synchronized. For more information about using replication with Multi-Region Access Points, see Configuring replication for use with Multi-Region Access Points.

## Amazon S3 Multi-Region Access Points failover controls

With Amazon S3 Multi-Region Access Point failover controls, you can maintain business continuity during Regional traffic disruptions, while also giving your applications a multi-Region architecture to fulfill compliance and redundancy needs. If your Regional traffic gets disrupted, you can use Multi-Region Access Point failover controls to select which AWS Regions behind an Amazon S3 Multi-Region Access Point will process data-access and storage requests.

To support failover, you can set up your Multi-Region Access Point in an active-passive configuration, with traffic flowing to the active Region during normal conditions, and a passive Region on standby for failover.

For example, to perform failover to an AWS Region of your choice, you shift traffic from your primary (active) Region to your secondary (passive) Region. In an active-passive configuration like this, one bucket is active and accepting traffic, while the other bucket is passive and not accepting traffic. The passive bucket is used for disaster recovery. When you initiate failover, all traffic (such as GET or PUT requests) is directed to the bucket in the active state (in one Region) and away from the bucket in the passive state (in another Region).

If you have S3 Cross-Region Replication (CRR) enabled with two-way replication rules, you can keep your buckets synchronized during a failover. In addition, if you have CRR enabled in an active-active configuration, Amazon S3 Multi-Region Access Points can also fetch data from the bucket location of closest proximity, which improves application performance.

## AWS Region support

With Amazon S3 Multi-Region Access Points failover controls, your S3 buckets can be in any of the 17 Regions where Multi-Region Access Points are supported. You can initiate failover across any two Regions at one time.

> **Note**
>
> Although failover is initiated between only two Regions at one time, you can separately update the routing statuses for multiple Regions at the same time in your Multi-Region Access Point.

The following topics demonstrate how to use and manage Amazon S3 Multi-Region Access Point failover controls.

**Topics**

- Amazon S3 Multi-Region Access Points routing states
- Using Amazon S3 Multi-Region Access Point failover controls
- Amazon S3 Multi-Region Access Point failover controls errors

## Amazon S3 Multi-Region Access Points routing states

Your Amazon S3 Multi-Region Access Points failover configuration determines the routing status of the AWS Regions that are used with the Multi-Region Access Point. You can configure your Amazon S3 Multi-Region Access Point to be in an active-active state or active-passive state.

- **Active-active** – In an active-active configuration, all requests are automatically sent to the closest proximity AWS Region in your Multi-Region Access Point. After the Multi-Region Access Point has been configured to be in an active-active state, all Regions can receive traffic. If traffic disruption occurs in an active-active configuration, network traffic will automatically be redirected to one of the active Regions.

- **Active-passive** – In an active-passive configuration, the active Regions in your Multi-Region Access Point receive traffic and the passive ones do not. If you intend to use S3 failover controls to initiate failover in a disaster situation, set up your Multi-Region Access Points in an active-passive configuration while you're testing and performing disaster-recovery planning.

## Using Amazon S3 Multi-Region Access Point failover controls

This section explains how to manage and use your Amazon S3 Multi-Region Access Points failover controls by using the AWS Management Console.

There are two failover controls in the **Failover configuration** section on your Multi-Region Access Point details page in the AWS Management Console: **Edit routing status** and **Failover**. You can use these controls as follows:

- **Edit routing status** – You can manually edit the routing statuses of up to 17 AWS Regions in a single request for your Multi-Region Access Point by choosing **Edit routing status**. You can use **Edit routing status** for the following purposes:
  - To set or edit the routing statuses of one or more Regions in your Multi-Region Access Point
  - To create a failover configuration for your Multi-Region Access Point by configuring two Regions to be in an active-passive state
  - To manually fail over your Regions
  - To manually switch traffic between Regions
- **Failover** – When you initiate failover by choosing **Failover**, you are only updating the routing statuses of two Regions that are already configured to be in an active-passive state. During a failover that you initiated by choosing **Failover**, the routing statuses between the two Regions are automatically switched.

### Editing the routing status of the Regions in your Multi-Region Access Point

You can manually update the routing statuses of up to 17 AWS Regions in a single request for your Multi-Region Access Point by choosing **Edit routing status** in the **Failover configuration** section on your Multi-Region Access Point details page. However, when you initiate failover by choosing **Failover**, you are only updating the routing statuses of two Regions that are already configured to be in an active-passive state. During a failover that you initiated by choosing **Failover**, the routing statuses between the two Regions are automatically switched.

You can use **Edit routing status** (as described in the following procedure) for the following purposes:

- To set or edit the routing statuses of one or more Regions in your Multi-Region Access Point
- To create a failover configuration for your Multi-Region Access Point by configuring two Regions to be in an active-passive state
- To manually fail over your Regions
- To manually switch traffic between Regions

### Using the S3 console

#### To update the routing status of the Regions in your Multi-Region Access Point

1. Sign in to the AWS Management Console.
2. Open the Amazon S3 console at https://console.aws.amazon.com/s3/.
3. In the left navigation pane, choose **Multi-Region Access Points**.
4. Choose the Multi-Region Access Point that you want to update.
5. Choose the **Replication and failover** tab.
6. Select one or more Regions that you want to edit the routing status of.

   > **Note**
   >
   > To initiate failover, at least one AWS Region must be designated as **Active** and one Region must be designated as **Passive** in your Multi-Region Access Point.

7. Choose **Edit routing status**.
8. In the dialog box that appears, select **Active** or **Passive** for the **Routing status** for each Region.

   An active state allows traffic to be routed to the Region. A passive state stops any traffic from being directed to the Region.

   If you are creating a failover configuration for your Multi-Region Access Point or initiating failover, at least one AWS Region must be designated as **Active** and one Region must be designated as **Passive** in your Multi-Region Access Point.
9. Choose **Save routing status**. It takes about 2 minutes for traffic to be redirected.

After you submit the routing status of the AWS Regions for your Multi-Region Access Point, you can verify your routing status changes. To verify these changes, go to Amazon CloudWatch at https://console.aws.amazon.com/cloudwatch/ to monitor the shift of your Amazon S3 data-request traffic (for example, GET and PUT requests) between active and passive Regions. Any existing connections will not be terminated during failover. Existing connections will continue until they reach a success or failure status.

### Using the AWS CLI

> **Note**
>
> You can run Multi-Region Access Point AWS CLI routing commands against any of these five Regions:
>
> - ap-southeast-2
> - ap-northeast-1
> - us-east-1
> - us-west-2
> - eu-west-1

The following example command updates your current Multi-Region Access Point route configuration. To update the active or passive status of a bucket, set the TrafficDialPercentage value to 100 for active and to 0 for passive. In this example, *DOC-EXAMPLE-BUCKET-1* is set to active, and *DOC-EXAMPLE-BUCKET-2* is set to passive. To use this example command, replace the *user input placeholders* with your own information.

```
aws s3control submit-multi-region-access-point-routes
--region ap-southeast-2
--account-id 111122223333
--mrap MultiRegionAccessPoint_ARN
--route-updates Bucket=DOC-EXAMPLE-BUCKET-1,TrafficDialPercentage=100
                Bucket=DOC-EXAMPLE-BUCKET-2,TrafficDialPercentage=0
```

The following example command gets your updated Multi-Region Access Point routing configuration. To use this example command, replace the *user input placeholders* with your own information.

```
aws s3control get-multi-region-access-point-routes
--region eu-west-1
--account-id 111122223333
--mrap MultiRegionAccessPoint_ARN
```

### Initiating failover

When you initiate failover by choosing **Failover** in the **Failover configuration** section on your Multi-Region Access Point details page, Amazon S3 request traffic automatically gets shifted to an alternate AWS Region. The failover process is completed within 2 minutes.

You can initiate a failover across any two AWS Regions at one time (of the 17 Regions where Multi-Region Access Points are supported). Failover events are then logged in AWS CloudTrail. Upon failover completion, you can monitor Amazon S3 traffic and any traffic routing updates to the new active Region in Amazon CloudWatch.

> **Important**
>
> To keep all metadata and objects in sync across buckets during data replication, we recommend that you create two-way replication rules and enable replica modification sync before configuring your failover controls.
> Two-way replication rules help ensure that when data is written to the Amazon S3 bucket that traffic fails over to, that data is then replicated back to the source bucket. Replica modification sync helps ensure that object metadata is also synchronized between buckets during two-way replication.
> For more information about configuring replication to support failover, see the section called “Bucket replication”.

#### To initiate failover between replicated buckets

1. Sign in to the AWS Management Console.
2. Open the Amazon S3 console at https://console.aws.amazon.com/s3/.
3. In the left navigation pane, choose **Multi-Region Access Points**.
4. Choose the Multi-Region Access Point that you want to use to initiate failover.
5. Choose the **Replication and failover** tab.
6. Scroll down to the **Failover configuration** section and select two AWS Regions.

> **Note**
>
> To initiate failover, at least one AWS Region must be designated as **Active** and one Region must be designated as **Passive** in your Multi-Region Access Point. An active state allows traffic to be directed to a Region. A passive state stops any traffic from being directed to the Region.

7. Choose **Failover**.
8. In the dialog box, choose **Failover** again to initiate the failover process. During this process, the routing statuses of the two Regions are automatically switched. All new traffic is directed to the Region that becomes active, and traffic stops being directed to the Region that becomes passive. It takes about 2 minutes for traffic to be redirected.

   After you initiate the failover process, you can verify your traffic changes. To verify these changes, go to Amazon CloudWatch at https://console.aws.amazon.com/cloudwatch/ to monitor the shift of your Amazon S3 data-request traffic (for example, GET and PUT requests) between active and passive Regions. Any existing connections will not be terminated during failover. Existing connections will continue until they reach a success or failure status.

### Viewing your Amazon S3 Multi-Region Access Point routing controls

#### Using the S3 console

#### To view the routing controls for your Amazon S3 Multi-Region Access Point

1. Sign in to the AWS Management Console.
2. Open the Amazon S3 console at https://console.aws.amazon.com/s3/.
3. In the left navigation pane, choose **Multi-Region Access Points**.
4. Choose the Multi-Region Access Point that you want to review.
5. Choose the **Replication and failover** tab. This page displays the routing configuration details and summary for your Multi-Region Access Point, associated replication rules, and replication metrics. You can see the routing status of your Regions in the **Failover configuration** section.

### Using the AWS CLI

The following example AWS CLI command gets your current Multi-Region Access Point route configuration for the specified Region. To use this example command, replace the *user input placeholders* with your own information.

```
aws s3control get-multi-region-access-point-routes
--region eu-west-1
--account-id 111122223333
--mrap MultiRegionAccessPoint_ARN
```

> **Note**
>
> This command can only be executed against these five Regions:
>
> - ap-southeast-2
> - ap-northeast-1
> - us-east-1
> - us-west-2
> - eu-west-1

## Amazon S3 Multi-Region Access Point failover controls errors

When you update the failover configuration for your Multi-Region Access Point, you might encounter one of these errors:

- HTTP 400 Bad Request: This error can occur if you enter an invalid Multi-Region Access Point ARN while updating your failover configuration. You can confirm your Multi-Region Access Point ARN by reviewing your Multi-Region Access Point policy. To review or update your Multi-Region Access Point policy, see Editing the Multi-Region Access Point policy. This error can also occur if you use an empty string or a random string while updating your Amazon S3 Multi-Region Access Point failover controls. Make sure to use the Multi-Region Access Point ARN format:

  `arn:aws:s3::account-id:accesspoint/MultiRegionAccessPoint_alias`

- HTTP 503 Slow Down: This error occurs if you send too many requests in a short period of time. Rejected requests will result in an error.

- HTTP 409 Conflict: This error occurs when two or more concurrent route configuration update requests are targeting a single Multi-Region Access Point. The first request succeeds, but any other requests fail with an error.
- HTTP 405 Method Not Allowed: This error occurs when you've selected a Multi-Region Access Point with only one AWS Region when initiating failover. You must select two Regions before you can initiate failover. Otherwise, an error is returned.

## Configuring replication for use with Multi-Region Access Points

When you make a request to a Multi-Region Access Point endpoint, Amazon S3 automatically routes the request to the bucket that is closest to you. Amazon S3 doesn't consider the contents of the request when making this decision. If you make a request to `GET` an object, your request might be routed to a bucket that doesn't have a copy of this object. If that happens, you receive an HTTP status code 404 (Not Found) error. For more information about Multi-Region Access Point request routing, see the section called “Request routing”.

If you want the Multi-Region Access Point to be able to retrieve the object regardless of which bucket receives the request, you must configure Amazon S3 Cross-Region Replication (CRR).

For example, consider a Multi-Region Access Point with three buckets:

- A bucket named `my-bucket-usw2` in the Region `us-west-2` that contains the object `my-image.jpg`
- A bucket named `my-bucket-aps1` in the Region `ap-south-1` that contains the object `my-image.jpg`
- A bucket named `my-bucket-euc1` in the Region `eu-central-1` that doesn't contain the object `my-image.jpg`

In this situation, if you make a `GetObject` request for the object `my-image.jpg`, the success of that request depends upon which bucket receives your request. Because Amazon S3 doesn't consider the contents of the request, it might route your `GetObject` request to the `my-bucket-euc1` bucket if that bucket responds of closest proximity. Even though your object is in a bucket in the Multi-Region Access Point, you will get an HTTP 404 Not Found error because the individual bucket that received your request didn't have the object.

Enabling Cross-Region Replication (CRR) helps avoid this result. With appropriate replication rules, the `my-image.jpg` object is copied over to the `my-bucket-euc1` bucket. Therefore, if Amazon S3 routes your request to that bucket, you can now retrieve the object.

Replication works as normal with buckets that are assigned to a Multi-Region Access Point. Amazon S3 doesn't perform any special replication handling with buckets that are in Multi-Region Access Points. For more information about configuring replication in your buckets, see Setting up live replication.

**Recommendations for using replication with Multi-Region Access Points**

For the best replication performance when working with Multi-Region Access Points, we recommend the following:

- Configure S3 Replication Time Control (S3 RTC). To replicate your data across different Regions within a predictable time frame, you can use S3 RTC. S3 RTC replicates 99.99 percent of new objects stored in Amazon S3 within 15 minutes (backed by a service-level agreement). For more information, see the section called "Using S3 Replication Time Control". There are additional charges for S3 RTC. For information, see Amazon S3 pricing.
- Use two-way (bidirectional) replication to support keeping buckets synchronized when buckets are updated through the Multi-Region Access Point. For more information, see the section called "Create two-way replication rules for your Multi-Region Access Point".
- Create cross-account Multi-Region Access Points to replicate data to buckets in separate AWS accounts. This approach provides account-level separation, so that data can be accessed from and replicated across different accounts in different Regions other than the source bucket. Setting up cross-account Multi-Region Access Points comes at no additional cost. If you're a bucket owner but don't own the Multi-Region Access Point, you pay only for data transfer and request costs. Multi-Region Access Point owners pay for data routing and internet-acceleration costs. For more information, see Amazon S3 pricing.
- Enable replica modification sync for each replication rule to also keep metadata changes to your objects in sync. For more information, see Enabling replica modification sync.
- Enable Amazon CloudWatch metrics to monitor replication events. CloudWatch metrics fees apply. For more information, see Amazon CloudWatch pricing.

**Topics**

- Create one-way replication rules for your Multi-Region Access Point

- Create two-way replication rules for your Multi-Region Access Point
- View the replication rules for your Multi-Region Access Point

## Create one-way replication rules for your Multi-Region Access Point

Replication rules enable automatic and asynchronous copying of objects across buckets. A one-way replication rule helps ensure that data is fully replicated from a source bucket in one AWS Region to a destination bucket in another Region. When one-way replication is set up, a replication rule from the source bucket (DOC-EXAMPLE-BUCKET-1) to the destination bucket (DOC-EXAMPLE-BUCKET-2) is created. Like all replication rules, you can apply the one-way replication rule to the entire Amazon S3 bucket or to a subset of objects that are filtered by a prefix or object tags.

> **Important**
>
> We recommend using one-way replication if your users will only be consuming the objects in your destination buckets. If your users will be uploading or modifying the objects in your destination buckets, use two-way replication to keep all of your buckets in sync. We also recommend two-way replication if you plan to use your Multi-Region Access Point for failover. To set up two-way replication, see the section called "Create two-way replication rules for your Multi-Region Access Point".

### To create a one-way replication rule for your Multi-Region Access Point

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Multi-Region Access Points**.
3. Choose the name of your Multi-Region Access Point.
4. Choose the **Replication and failover** tab.
5. Scroll down to the **Replication rules** section, and then choose **Create replication rules**. Make sure that you have sufficient permissions to create the replication rule, or versioning will be disabled.

> **Note**
>
> You can create replication rules only for buckets in your own account. To create replication rules for external buckets, the bucket owners must create the replication rules for those buckets.

6. On the **Create replication rules** page, choose the **Replicate objects from one or more source buckets to one or more destination buckets** template.

> **Important**
>
> When you create replication rules by using this template, they replace any existing replication rules that are already assigned to the bucket.
> To add to or modify any existing replication rules instead of replacing them, go to each bucket's **Management** tab in the console, and then edit the rules in the **Replication rules** section. You can also add to or modify existing replication rules by using the AWS CLI, SDKs, or REST API. For more information, see Replication configuration.

7. In the **Source and destination** section, under **Source buckets**, select one or more buckets that you want to replicate objects from. All buckets (source and destination) that are chosen for replication must have S3 Versioning enabled, and each bucket must reside in a different AWS Region. For more information about S3 Versioning, see Using versioning in Amazon S3 buckets.

   Under **Destination buckets**, select one or more buckets that you want to replicate objects to.

> **Note**
>
> Make sure that you have the required read and replicate permissions to establish replication, or you will encounter errors. For more information, see Creating an IAM role.

8. In the **Replication rule configuration** section, choose whether the replication rule will be **Enabled** or **Disabled** when it's created.

> **Note**
>
> You can't enter a name in the **Replication rule name** box. Replication rule names are generated based on your configuration when you create the replication rule.

9. In the **Scope** section, choose the appropriate scope for your replication.

   - To replicate the whole bucket, choose **Apply to all objects in the bucket**.
   - To replicate a subset of the objects in the bucket, choose **Limit the scope of this rule using one or more filters**.

     You can filter your objects by using a prefix, object tags, or a combination of both.

     - To limit replication to all objects that have names that begin with the same string (for example `pictures`), enter a prefix in the **Prefix** box.

       If you enter a prefix that is the name of a folder, you must use a delimiter such as a `/` (forward slash) to indicate its level of hierarchy (for example, `pictures/`). For more information about prefixes, see Organizing objects using prefixes.
     - To replicate all objects that have one or more object tags, choose **Add tag** and enter the key-value pair in the boxes. To add another tag, repeat the procedure. For more information about object tags, see Categorizing your storage using tags.

10. Scroll down to the **Additional replication options** section, and select the replication options that you want to apply.

> **Note**
>
> We recommend that you apply the following options:
>
> - **Replication time control (RTC)** – To replicate your data across different Regions within a predictable time frame, you can use S3 Replication Time Control (S3 RTC). S3 RTC replicates 99.99 percent of new objects stored in Amazon S3 within 15 minutes (backed by a service-level agreement). For more information, see the section called “Using S3 Replication Time Control”.
> - **Replication metrics and notifications** – Enable Amazon CloudWatch metrics to monitor replication events.

- **Delete marker replication** – Delete markers created by S3 delete operations will be replicated. Delete markers created by lifecycle rules are not replicated. For more information, see Replicating delete markers between buckets.

There are additional charges for S3 RTC and CloudWatch replication metrics and notifications. For more information, see Amazon S3 Pricing and Amazon CloudWatch pricing.

11. If you're writing a new replication rule that replaces an existing one, select **I acknowledge that by choosing Create replication rules, these existing replication rules will be overwritten**.
12. Choose **Create replication rules** to create and save your new one-way replication rule.

## Create two-way replication rules for your Multi-Region Access Point

Replication rules enable automatic and asynchronous copying of objects across buckets. A two-way replication rule (also known as a bidirectional replication rule) ensures that data is fully synchronized between two or more buckets in different AWS Regions. When two-way replication is set up, a replication rule from the source bucket (DOC-EXAMPLE-BUCKET-1) to the bucket containing the replicas (DOC-EXAMPLE-BUCKET-2) is created. Then, a second replication rule from the bucket containing the replicas (DOC-EXAMPLE-BUCKET-2) to the source bucket (DOC-EXAMPLE-BUCKET-1) is created.

Like all replication rules, you can apply the two-way replication rule to the entire Amazon S3 bucket or to a subset of objects filtered by a prefix or object tags. You can also keep metadata changes to your objects in sync by enabling replica modification sync for each replication rule. You can enable replica modification sync through the Amazon S3 console, the AWS CLI, the AWS SDKs, the Amazon S3 REST API, or AWS CloudFormation.

To monitor the replication progress of objects and object metadata in Amazon CloudWatch, enable S3 Replication metrics and notifications. For more information, see Monitoring progress with replication metrics and Amazon S3 event notifications.

**To create a two-way replication rule for your Multi-Region Access Point**

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Multi-Region Access Points**.

3. Choose the name of the Multi-Region Access Point that you want to update.
4. Choose the **Replication and failover** tab.
5. Scroll down to the **Replication rules** section, and then choose **Create replication rules**.
6. On the **Create replication rules** page, choose the **Replicate objects among all specified buckets** template. The **Replicate objects among all specified buckets** template sets up two-way replication (with failover capabilities) for your buckets.

   > **Important**
   >
   > When you create replication rules by using this template, they replace any existing replication rules that are already assigned to the bucket.
   > To add to or modify any existing replication rules instead of replacing them, go to each bucket's **Management** tab in the console, and then edit the rules in the **Replication rules** section. You can also add to or modify existing replication rules by using the AWS CLI, AWS SDKs, or Amazon S3 REST API. For more information, see Replication configuration.

7. In the **Buckets** section, select at least two buckets that you want to replicate objects from. All buckets chosen for replication must have S3 Versioning enabled, and each bucket must reside in a different AWS Region. For more information about S3 Versioning, see Using versioning in Amazon S3 buckets.

   > **Note**
   >
   > Make sure that you have the required read and replicate permissions to establish replication, or you will encounter errors. For more information, see Creating an IAM role.

8. In the **Replication rule configuration** section, choose whether the replication rule will be **Enabled** or **Disabled** when it's created.

   > **Note**
   >
   > You can't enter a name in the **Replication rule name** box. Replication rule names are generated based on your configuration when you create the replication rule.

9. In the **Scope** section, choose the appropriate scope for your replication.

- To replicate the whole bucket, choose **Apply to all objects in the bucket**.
- To replicate a subset of the objects in the bucket, choose **Limit the scope of this rule using one or more filters**.

  You can filter your objects by using a prefix, object tags, or a combination of both.

  - To limit replication to all objects that have names that begin with the same string (for example `pictures`), enter a prefix in the **Prefix** box.

    If you enter a prefix that is the name of a folder, you must use a / (forward slash) as the last character (for example, `pictures/`).
  - To replicate all objects that have one or more object tags, choose **Add tag** and enter the key-value pair in the boxes. To add another tag, repeat the procedure. For more information about object tags, see Categorizing your storage using tags.

10. Scroll down to the **Additional replication options** section, and select the replication options that you want to apply.

> **Note**
>
> We recommend that you apply the following options, especially if you intend to configure your Multi-Region Access Point to support failover:
>
> - **Replication time control (RTC)** – To replicate your data across different Regions within a predictable time frame, you can use S3 Replication Time Control (S3 RTC). S3 RTC replicates 99.99 percent of new objects stored in Amazon S3 within 15 minutes (backed by a service-level agreement). For more information, see the section called "Using S3 Replication Time Control".
> - **Replication metrics and notifications** – Enable Amazon CloudWatch metrics to monitor replication events.
> - **Delete marker replication** – Delete markers created by S3 delete operations will be replicated. Delete markers created by lifecycle rules are not replicated. For more information, see Replicating delete markers between buckets.
> - **Replica modification sync** – Enable replica modification sync for each replication rule to also keep metadata changes to your objects in sync. For more information, see Enabling replica modification sync.

There are additional charges for S3 RTC and CloudWatch replication metrics and notifications. For more information, see Amazon S3 Pricing and Amazon CloudWatch pricing.

11. If you're writing a new replication rule that replaces an existing one, select **I acknowledge that by choosing Create replication rules, these existing replication rules will be overwritten**.
12. Choose **Create replication rules** to create and save your new two-way replication rules.

### View the replication rules for your Multi-Region Access Point

With Multi-Region Access Points, you can either set up one-way replication rules or two-way (bidirectional) replication rules. For information about how to manage your replication rules, see Managing replication rules by using the Amazon S3 console.

**To view the replication rules for your Multi-Region Access Point**

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Multi-Region Access Points**.
3. Choose the name of your Multi-Region Access Point.
4. Choose the **Replication and failover** tab.
5. Scroll down to the **Replication rules** section. This section lists all of the replication rules that have been created for your Multi-Region Access Point.

> **Note**
>
> If you've added a bucket from another account to this Multi-Region Access Point, you must have the `s3:GetBucketReplication` permission from the bucket owner to view the replication rules for that bucket.

## Using Multi-Region Access Points with supported API operations

Amazon S3 provides a set of operations to manage Multi-Region Access Points. Amazon S3 processes some of these operations synchronously and some asynchronously. When you invoke

an asynchronous operation, Amazon S3 first synchronously authorizes the requested operation. If authorization is successful, Amazon S3 returns a token that you can use to track the progress and results of the requested operation.

> **Note**
>
> Requests that are made through the Amazon S3 console are always synchronous. The console waits until the request is completed before allowing you to submit another request.

You can view the current status and results of asynchronous operations by using the console, or you can use `DescribeMultiRegionAccessPointOperation` in the AWS CLI, AWS SDKs, or REST API. Amazon S3 provides a tracking token in the response to an asynchronous operation. You include that tracking token as an argument to `DescribeMultiRegionAccessPointOperation`. When you include the tracking token, Amazon S3 then returns the current status and results of the specified operation, including any errors or relevant resource information. Amazon S3 performs `DescribeMultiRegionAccessPointOperation` operations synchronously.

All control plane requests to create or maintain Multi-Region Access Points must be routed to the `US West (Oregon)` Region. For Multi-Region Access Point data plane requests, Regions don't need to be specified. For the Multi-Region Access Point failover control plane, the request must be routed to one of the five supported Regions. For more information about Multi-Region Access Point supported Regions, see Multi-Region Access Point restrictions and limitations.

In addition, you must grant the `s3:ListAllMyBuckets` permission to the user, role, or other AWS Identity and Access Management (IAM) entity that makes a request to manage a Multi-Region Access Point.

The following examples demonstrate how to use Multi-Region Access Points with compatible operations in Amazon S3.

**Topics**

- Add an object to a bucket in your Multi-Region Access Point
- Retrieve objects from your Multi-Region Access Point
- List objects that are stored in a bucket underlying your Multi-Region Access Point
- Use a presigned URL with Multi-Region Access Points
- Use a bucket that's configured with Requester Pays with Multi-Region Access Points

## Multi-Region Access Point compatibility with AWS services and AWS SDKs

To use a Multi-Region Access Point with applications that require an Amazon S3 bucket name, use the Amazon Resource Name (ARN) of the Multi-Region Access Point when making requests by using an AWS SDK. To check which AWS SDKs are compatible with Multi-Region Access Points, see Compatibility with AWS SDKs.

## Multi-Region Access Point compatibility with S3 operations

You can use use the following Amazon S3 data plane API operations to perform actions on objects in buckets that are associated with your Multi-Region Access Point. The following S3 operations can accept Multi-Region Access Point ARNs:

- AbortMultipartUpload
- CompleteMultipartUpload
- CreateMultipartUpload
- DeleteObject
- DeleteObjectTagging
- GetObject
- GetObjectAcl
- GetObjectLegalHold
- GetObjectRetention
- GetObjectTagging
- HeadObject
- ListMultipartUploads
- ListObjectsV2
- ListParts
- PutObject

- PutObjectAcl
- PutObjectLegalHold
- PutObjectRetention
- PutObjectTagging
- RestoreObject
- UploadPart

> **Note**
>
> Multi-Region Access Points supports copy operations using Multi-Region Access Points only as a destination when using the Multi-Region Access Point ARN.

You can use the following Amazon S3 control plane operations to create and manage your Multi-Region Access Points:

- CreateMultiRegionAccessPoint
- DescribeMultiRegionAccessPointOperation
- GetMultiRegionAccessPoint
- GetMultiRegionAccessPointPolicy
- GetMultiRegionAccessPointPolicyStatus
- GetMultiRegionAccessPointRoutes
- ListMultiRegionAccessPoints
- PutMultiRegionAccessPointPolicy
- SubmitMultiRegionAccessPointRoutes

## View your Multi-Region Access Point routing configuration

AWS CLI

The following example command retrieves your Multi-Region Access Point route configuration so that you can see the current routing statuses for your buckets. To use this example command, replace the *`user input placeholders`* with your own information.

```
aws s3control get-multi-region-access-point-routes
```

```
--region eu-west-1
--account-id 111122223333
--mrap arn:aws:s3::111122223333:accesspoint/abcdef0123456.mrap
```

SDK for Java

The following SDK for Java code retrieves your Multi-Region Access Point route configuration so that you can see the current routing statuses for your buckets. To use this example syntax, replace the *user input placeholders* with your own information.

```
S3ControlClient s3ControlClient = S3ControlClient.builder()
    .region(Region.US_EAST_1)
    .credentialsProvider(credentialsProvider)
    .build();

GetMultiRegionAccessPointRoutesRequest request =
 GetMultiRegionAccessPointRoutesRequest.builder()
    .accountId("111122223333")
    .mrap("arn:aws:s3::111122223333:accesspoint/abcdef0123456.mrap")
    .build();

GetMultiRegionAccessPointRoutesResponse response =
 s3ControlClient.getMultiRegionAccessPointRoutes(request);
```

SDK for JavaScript

The following SDK for JavaScript code retrieves your Multi-Region Access Point route configuration so that you can see the current routing statuses for your buckets. To use this example syntax, replace the *user input placeholders* with your own information.

```
const REGION = 'us-east-1'

const s3ControlClient = new S3ControlClient({
  region: REGION
})

export const run = async () => {
  try {
    const data = await s3ControlClient.send(
      new GetMultiRegionAccessPointRoutesCommand({
        AccountId: '111122223333',
        Mrap: 'arn:aws:s3::111122223333:accesspoint/abcdef0123456.mrap',
      })
```

```
    )
    console.log('Success', data)
    return data
  } catch (err) {
    console.log('Error', err)
  }
}

run()
```

SDK for Python

The following SDK for Python code retrieves your Multi-Region Access Point route configuration so that you can see the current routing statuses for your buckets. To use this example syntax, replace the *user input placeholders* with your own information.

```
s3.get_multi_region_access_point_routes(
        AccountId=111122223333,
        Mrap=arn:aws:s3::111122223333:accesspoint/abcdef0123456.mrap)['Routes']
```

## Update your underlying Amazon S3 bucket policy

To grant proper access, you must also update the underlying Amazon S3 bucket policy. The following examples delegate access control to the Multi-Region Access Point policy. After you delegate access control to the Multi-Region Access Point policy, the bucket policy is no longer used for access control when requests are made through the Multi-Region Access Point.

Here's an example bucket policy that delegates access control to the Multi-Region Access Point policy. To use this example bucket policy, replace the *user input placeholders* with your own information. To apply this policy through the AWS CLI `put-bucket-policy` command, as shown in the next example, save the policy in a file, for example, `policy.json`.

```
{
  "Version": "2012-10-17",
  "Statement": {
    "Principal": { "AWS": "*" },
    "Effect": "Allow",
    "Action": ["s3:*"],
    "Resource": ["arn:aws:s3:::111122223333/*", "arn:aws:s3:::amzn-s3-demo-bucket"],
    "Condition": {
      "StringEquals": {
```

```
        "s3:DataAccessPointAccount": "444455556666"
      }
    }
  }
}
```

The following `put-bucket-policy` example command associates the updated S3 bucket policy with your S3 bucket:

```
aws s3api put-bucket-policy
  --bucket amzn-s3-demo-bucket
  --policy file:///tmp/policy.json
```

## Update a Multi-Region Access Point route configuration

The following example command updates the Multi-Region Access Point route configuration. Multi-Region Access Point route commands can be run against the following five Regions:

- `ap-southeast-2`
- `ap-northeast-1`
- `us-east-1`
- `us-west-2`
- `eu-west-1`

In a Multi-Region Access Point routing configuration, you can set buckets to an active or passive routing status. Active buckets receive traffic, whereas passive buckets do not. You can set a bucket's routing status by setting the `TrafficDialPercentage` value for the bucket to `100` for active or `0` for passive.

AWS CLI

The following example command updates your Multi-Region Access Point routing configuration. In this example, *amzn-s3-demo-bucket1* is set to active status and *amzn-s3-demo-bucket2* is set to passive. To use this example command, replace the *user input placeholders* with your own information.

```
aws s3control submit-multi-region-access-point-routes
--region ap-southeast-2
--account-id 111122223333
```

```
--mrap arn:aws:s3::111122223333:accesspoint/abcdef0123456.mrap
--route-updates Bucket=amzn-s3-demo-bucket1,TrafficDialPercentage=100
                Bucket=amzn-s3-demo-bucket2,TrafficDialPercentage=0
```

SDK for Java

The following SDK for Java code updates your Multi-Region Access Point routing configuration. To use this example syntax, replace the *user input placeholders* with your own information.

```
S3ControlClient s3ControlClient = S3ControlClient.builder()
    .region(Region.ap-southeast-2)
    .credentialsProvider(credentialsProvider)
    .build();

SubmitMultiRegionAccessPointRoutesRequest request =
 SubmitMultiRegionAccessPointRoutesRequest.builder()
    .accountId("111122223333")
    .mrap("arn:aws:s3::111122223333:accesspoint/abcdef0123456.mrap")
    .routeUpdates(
        MultiRegionAccessPointRoute.builder()
            .region("eu-west-1")
            .trafficDialPercentage(100)
            .build(),
        MultiRegionAccessPointRoute.builder()
            .region("ca-central-1")
            .bucket("111122223333")
            .trafficDialPercentage(0)
            .build()
    )
    .build();

SubmitMultiRegionAccessPointRoutesResponse response =
 s3ControlClient.submitMultiRegionAccessPointRoutes(request);
```

SDK for JavaScript

The following SDK for JavaScript code updates your Multi-Region Access Point route configuration. To use this example syntax, replace the *user input placeholders* with your own information.

```
const REGION = 'ap-southeast-2'
```

```
const s3ControlClient = new S3ControlClient({
  region: REGION
})

export const run = async () => {
  try {
    const data = await s3ControlClient.send(
      new SubmitMultiRegionAccessPointRoutesCommand({
        AccountId: '111122223333',
        Mrap: 'arn:aws:s3::111122223333:accesspoint/abcdef0123456.mrap',
        RouteUpdates: [
          {
            Region: 'eu-west-1',
            TrafficDialPercentage: 100,
          },
          {
            Region: 'ca-central-1',
            Bucket: 'amzn-s3-demo-bucket1',
            TrafficDialPercentage: 0,
          },
        ],
      })
    )
    console.log('Success', data)
    return data
  } catch (err) {
    console.log('Error', err)
  }
}

run()
```

SDK for Python

The following SDK for Python code updates your Multi-Region Access Point route configuration. To use this example syntax, replace the *user input placeholders* with your own information.

```
s3.submit_multi_region_access_point_routes(
        AccountId=111122223333,
        Mrap=arn:aws:s3::111122223333:accesspoint/abcdef0123456.mrap,
        RouteUpdates= [{
            'Bucket': DOC-EXAMPLE-BUCKET,
```

```
            'Region': ap-southeast-2,
            'TrafficDialPercentage': 10
        }])
```

## Add an object to a bucket in your Multi-Region Access Point

To add an object to the bucket that's associated with the Multi-Region Access Point, you can use the PutObject operation. To keep all buckets in the Multi-Region Access Point in sync, enable Cross-Region Replication.

> **Note**
>
> To use this operation, you must have the `s3:PutObject` permission for the Multi-Region Access Point. For more information about Multi-Region Access Point permission requirements, see Permissions.

AWS CLI

The following example data plane request uploads *example.txt* to the specified Multi-Region Access Point. To use this example, replace the *user input placeholders* with your own information.

```
aws s3api put-object --bucket
 arn:aws:s3::123456789012:accesspoint/abcdef0123456.mrap --key example.txt --
body example.txt
```

SDK for Java

```
S3Client s3Client = S3Client.builder()
        .build();

PutObjectRequest objectRequest = PutObjectRequest.builder()
        .bucket("arn:aws:s3::123456789012:accesspoint/abcdef0123456.mrap")
        .key("example.txt")
        .build();

s3Client.putObject(objectRequest, RequestBody.fromString("Hello S3!"));
```

SDK for JavaScript

```
const client = new S3Client({});

async function putObjectExample() {
    const command = new PutObjectCommand({
        Bucket: "arn:aws:s3::123456789012:accesspoint/abcdef0123456.mrap",
        Key: "example.txt",
        Body: "Hello S3!",
    });

    try {
        const response = await client.send(command);
        console.log(response);
    } catch (err) {
        console.error(err);
    }
}
```

SDK for Python

```
import boto3

client = boto3.client('s3')
client.put_object(
    Bucket='arn:aws:s3::123456789012:accesspoint/abcdef0123456.mrap',
    Key='example.txt',
    Body='Hello S3!'
)
```

## Retrieve objects from your Multi-Region Access Point

To retrieve objects from the Multi-Region Access Point, you can use the GetObject operation.

> **Note**
>
> To use this API operation, you must have the `s3:GetObject` permission for the Multi-Region Access Point. For more information about Multi-Region Access Point permissions requirements, see Permissions.

AWS CLI

The following example data plane request retrieves *example.txt* from the specified Multi-Region Access Point and downloads it as *downloaded_example.txt*. To use this example, replace the *user input placeholders* with your own information.

```
aws s3api get-object --bucket
 arn:aws:s3::123456789012:accesspoint/abcdef0123456.mrap --
key example.txt downloaded_example.txt
```

SDK for Java

```
S3Client s3 = S3Client
   .builder()
   .build();

GetObjectRequest getObjectRequest = GetObjectRequest.builder()
    .bucket("arn:aws:s3::123456789012:accesspoint/abcdef0123456.mrap")
    .key("example.txt")
    .build();

s3Client.getObject(getObjectRequest);
```

SDK for JavaScript

```
const client = new S3Client({})

async function getObjectExample() {
    const command = new GetObjectCommand({
        Bucket: "arn:aws:s3::123456789012:accesspoint/abcdef0123456.mrap",
        Key: "example.txt"
    });

    try {
        const response = await client.send(command);
        console.log(response);
    } catch (err) {
        console.error(err);
    }
}
```

SDK for Python

```
import boto3

client = boto3.client('s3')
client.get_object(
    Bucket='arn:aws:s3::123456789012:accesspoint/abcdef0123456.mrap',
    Key='example.txt'
)
```

## List objects that are stored in a bucket underlying your Multi-Region Access Point

To return a list of objects that are stored in a bucket underlying your Multi-Region Access Point, use the ListObjectsV2 operation. In the following example command, all objects for the specified Multi-Region Access Point are listed by using the ARN for the Multi-Region Access Point. In this case, the Multi-Region Access Point ARN is:

`arn:aws:s3::123456789012:accesspoint/abcdef0123456.mrap`

> **Note**
>
> To use this API operation, you must have the `s3:ListBucket` permission for the Multi-Region Access Point and the underlying bucket. For more information about Multi-Region Access Point permissions requirements, see Permissions.

AWS CLI

The following example data plane request lists the objects in the bucket that underlies the Multi-Region Access Point that's specified by the ARN. To use this example, replace the *user input placeholders* with your own information.

```
aws s3api list-objects-v2 --bucket
 arn:aws:s3::123456789012:accesspoint/abcdef0123456.mrap
```

SDK for Java

```
S3Client s3Client = S3Client.builder()
        .build();
```

```
String bucketName = "arn:aws:s3::123456789012:accesspoint/abcdef0123456.mrap";

ListObjectsV2Request listObjectsRequest = ListObjectsV2Request
    .builder()
    .bucket(bucketName)
    .build();

 s3Client.listObjectsV2(listObjectsRequest);
```

SDK for JavaScript

```
const client = new S3Client({});

async function listObjectsExample() {
    const command = new ListObjectsV2Command({
        Bucket: "arn:aws:s3::123456789012:accesspoint/abcdef0123456.mrap",
    });

    try {
        const response = await client.send(command);
        console.log(response);
    } catch (err) {
        console.error(err);
    }
}
```

SDK for Python

```
import boto3

client = boto3.client('s3')
client.list_objects_v2(
    Bucket='arn:aws:s3::123456789012:accesspoint/abcdef0123456.mrap'
)
```

## Use a presigned URL with Multi-Region Access Points

You can use a presigned URL to generate a URL that allows others to access your Amazon S3 buckets through an Amazon S3 Multi-Region Access Point. When you create a presigned URL, you associate it with a specific object action, such as an S3 upload (`PutObject`) or an S3 download

(`GetObject`). You can share the presigned URL, and anyone with access to it can perform the action embedded in the URL as if they were the original signing user.

Presigned URLs have an expiration date. When the expiration time is reached, the URL will no longer work.

Before you use S3 Multi-Region Access Points with presigned URLs, check the AWS SDK compatibility with the SigV4A algorithm. Verify that your SDK version supports SigV4A as the signing implementation that is used to sign the global AWS Region requests. For more information about using presigned URLs with Amazon S3, see Sharing objects by using presigned URLs.

The following examples show how you can use Multi-Region Access Points with presigned URLs. To use these examples, replace the *`user input placeholders`* with your own information.

AWS CLI

```
aws s3 presign
 arn:aws:s3::123456789012:accesspoint/MultiRegionAccessPoint_alias/example-file.txt
```

SDK for Python

```
import logging
import boto3
from botocore.exceptions import ClientError

s3_client = boto3.client('s3',aws_access_key_id='xxx',aws_secret_access_key='xxx')
s3_client.generate_presigned_url(HttpMethod='PUT',ClientMethod="put_object",
 Params={'Bucket':'arn:aws:s3::123456789012:accesspoint/
abcdef0123456.mrap','Key':'example-file'})
```

SDK for Java

```
S3Presigner s3Presigner = S3Presigner.builder()
    .credentialsProvider(StsAssumeRoleCredentialsProvider.builder()
        .refreshRequest(assumeRole)
        .stsClient(stsClient)
        .build())
    .build();

GetObjectRequest getObjectRequest = GetObjectRequest.builder()
    .bucket("arn:aws:s3::123456789012:accesspoint/abcdef0123456.mrap")
    .key("example-file")
```

```
    .build();

GetObjectPresignRequest preSignedReq = GetObjectPresignRequest.builder()
    .getObjectRequest(getObjectRequest)
    .signatureDuration(Duration.ofMinutes(10))
    .build();

PresignedGetObjectRequest presignedGetObjectRequest =
 s3Presigner.presignGetObject(preSignedReq);
```

**Note**

To use SigV4A with temporary security credentials—for example, when using IAM roles—make sure that you request the temporary credentials from a Regional endpoint in AWS Security Token Service (AWS STS), instead of a global endpoint. If you use the global endpoint for AWS STS (`sts.amazonaws.com`), AWS STS will generate temporary credentials from a global endpoint, which isn't supported by Sig4A. As a result, you'll get an error. To resolve this issue, use any of the listed Regional endpoints for AWS STS.

## Use a bucket that's configured with Requester Pays with Multi-Region Access Points

If an S3 bucket that is associated with your Multi-Region Access Points is configured to use Requester Pays, the requester will pay for the bucket request, the download, and any Multi-Region Access Points related costs. For more information, see Amazon S3 pricing.

Here's an example of a data plane request to a Multi-Region Access Point that is connected to a Requester Pays bucket.

AWS CLI

To download objects from a Multi-Region Access Point that is connected to a Requester Pays bucket, you must specify `--request-payer requester` as part of your get-object request. You must also specify the name of the file in the bucket and the location where the downloaded file should be stored.

```
aws s3api get-object --bucket MultiRegionAccessPoint_ARN --request-payer requester
 --key example-file-in-bucket.txt example-location-of-downloaded-file.txt
```

SDK for Java

To download objects from a Multi-Region Access Point that is connected to a Requester Pays bucket, you must specify the `RequestPayer.REQUESTER` as part of your `GetObject` request. You must also specify the name of the file in the bucket, as well as the location where it should be stored.

```
GetObjectResponse getObjectResponse = s3Client.getObject(GetObjectRequest.builder()
    .key("example-file.txt")
    .bucket("arn:aws:s3::
123456789012:accesspoint/abcdef0123456.mrap")
    .requestPayer(RequestPayer.REQUESTER)
    .build()
).response();
```

## Monitoring and logging requests made through a Multi-Region Access Point to underlying resources

Amazon S3 logs requests made through Multi-Region Access Points and requests made to the API operations that manage them, such as `CreateMultiRegionAccessPoint` and `GetMultiRegionAccessPointPolicy`. Requests made to Amazon S3 through a Multi-Region Access Point appear in your Amazon S3 server access logs and AWS CloudTrail logs with the Multi-Region Access Point hostname. An access point's hostname takes the form *`MRAP_alias`*`.accesspoint.s3-global.amazonaws.com`. For example, suppose that you have the following bucket and Multi-Region Access Point configuration:

- A bucket named `my-bucket-usw2` in the Region `us-west-2` that contains the object `my-image.jpg`.
- A bucket named `my-bucket-aps1` in the Region `ap-south-1` that contains the object `my-image.jpg`.
- A bucket named `my-bucket-euc1` in the Region `eu-central-1` that doesn't contain an object named `my-image.jpg`.
- A Multi-Region Access Point named `my-mrap` with the alias `mfzwi23gnjvgw.mrap` that is configured to fulfill requests from all three buckets.
- Your AWS account ID is `123456789012`.

A request made to retrieve `my-image.jpg` directly through any of the buckets appears in your logs with a hostname of *`bucket_name`*`.s3.`*`Region`*`.amazonaws.com`.

If you make the request through the Multi-Region Access Point instead, Amazon S3 first determines which of the buckets in the different Regions is closest. After Amazon S3 determines which bucket to use to fulfill the request, it sends the request to that bucket and logs the operation by using the Multi-Region Access Point hostname. In this example, if Amazon S3 relays the request to `my-bucket-aps1`, your logs will reflect a successful `GET` request for `my-image.jpg` from `my-bucket-aps1`, using a hostname of `mfzwi23gnjvgw.mrap.accesspoint.s3-global.amazonaws.com`.

**Important**

Multi-Region Access Points aren't aware of the data contents of the underlying buckets. Therefore, the bucket that gets the request might not contain the requested data. For example, if Amazon S3 determines that the `my-bucket-euc1` bucket is the closest, your logs will reflect a failed `GET` request for `my-image.jpg` from `my-bucket-euc1`, using a hostname of `mfzwi23gnjvgw.mrap.accesspoint.s3-global.amazonaws.com`. If the request was routed to `my-bucket-usw2` instead, your logs would indicate a successful `GET` request.

For more information about Amazon S3 server access logs, see Logging requests with server access logging. For more information about AWS CloudTrail, see What is AWS CloudTrail? in the *AWS CloudTrail User Guide*.

## Monitoring and logging requests made to Multi-Region Access Point management API operations

Amazon S3 provides several API operations to manage Multi-Region Access Points, such as `CreateMultiRegionAccessPoint` and `GetMultiRegionAccessPointPolicy`. When you make requests to these API operations by using the AWS Command Line Interface (AWS CLI), AWS SDKs, or Amazon S3 REST API, Amazon S3 processes these requests asynchronously. Provided that you have the appropriate permissions for the request, Amazon S3 returns a token for these requests. You can use this token with `DescribeAsyncOperation` to help you to view the status of ongoing asynchronous operations. Amazon S3 processes `DescribeAsyncOperation` requests synchronously. To view the status of asynchronous requests, you can use the Amazon S3 console, AWS CLI, SDKs, or REST API.

> **Note**
>
> The console displays only the status of asynchronous requests that were made within the previous 14 days. To view the status of older requests, use the AWS CLI, SDKs, or REST API.

Asynchronous management operations can be in one of several states:

NEW

Amazon S3 has received the request and is preparing to perform the operation.

IN_PROGRESS

Amazon S3 is currently performing the operation.

SUCCESS

The operation succeeded. The response includes relevant information, such as the Multi-Region Access Point alias for a `CreateMultiRegionAccessPoint` request.

FAILED

The operation failed. The response includes an error message that indicates the reason for the request failure.

## Using AWS CloudTrail with Multi-Region Access Points

You can use AWS CloudTrail to view, search, download, archive, analyze, and respond to account activity across your AWS infrastructure. With Multi-Region Access Points and CloudTrail logging, you can identify the following:

- Who or what took which action
- Which resources were acted upon
- When the event occurred
- Other details regarding the event

You can use this logging information to help you analyze and respond to activity that occurred through your Multi-Region Access Points.

### How to set up AWS CloudTrail for Multi-Region Access Points

To enable CloudTrail logging for any operations related to creating or maintaining Multi-Region Access Points, you must configure CloudTrail logging to record the events in the US West (Oregon) Region. You must set up your logging configuration this way regardless of which Region you are in when making the request, or which Regions the Multi-Region Access Point supports. All requests to create or maintain a Multi-Region Access Point are routed through the US West (Oregon) Region. We recommend that you either add this Region to an existing trail or create a new trail that contains this Region and all the Regions associated with the Multi-Region Access Point.

Amazon S3 logs all requests made through a Multi-Region Access Point and requests made to the API operations that manage access points, such as `CreateMultiRegionAccessPoint` and `GetMultiRegionAccessPointPolicy`. When you log these requests through a Multi-Region Access Point, they appear in your AWS CloudTrail logs with the hostname of the Multi-Region Access Point. For example, if you make requests to a bucket through a Multi-Region Access Point with the alias `mfzwi23gnjvgw.mrap`, the entries in the CloudTrail log will have a hostname of `mfzwi23gnjvgw.mrap.accesspoint.s3-global.amazonaws.com`.

Multi-Region Access Points route requests to the closest bucketBecause of this behavior, when you are looking at the CloudTrail logs for a Multi-Region Access Point, you will see requests being made to the underlying buckets. Some of those requests might be direct requests to the bucket that are not routed through the Multi-Region Access Point. Keep this fact in mind when reviewing traffic. When a bucket is in a Multi-Region Access Point, requests can still be made to that bucket directly without going through the Multi-Region Access Point.

There are asynchronous events involved with creating and managing Multi-Region Access Points. Asynchronous requests don't have completion events in the CloudTrail log. For more information about asynchronous requests, see Monitoring and logging requests made to Multi-Region Access Point management API operations.

For more information about AWS CloudTrail, see What is AWS CloudTrail? in the *AWS CloudTrail User Guide*.

# Amazon S3 security

Cloud security at AWS is the highest priority. As an AWS customer, you benefit from a data center and network architecture that are built to meet the requirements of the most security-sensitive organizations.

Security is a shared responsibility between AWS and you. The shared responsibility model describes this as security *of* the cloud and security *in* the cloud:

**Security of the cloud**

AWS is responsible for protecting the infrastructure that runs AWS services in the AWS Cloud. AWS also provides you with services that you can use securely. The effectiveness of our security is regularly tested and verified by third-party auditors as part of the AWS compliance programs. To learn about the compliance programs that apply to Amazon S3, see AWS Services in Scope by Compliance Program.

**Security in the cloud**

Your responsibility is determined by the AWS service that you use. You are also responsible for other factors including the sensitivity of your data, your organization's requirements, and applicable laws and regulations. For Amazon S3, your responsibility includes the following areas:

- Managing your data, including object ownership and encryption.
- Classifying your assets.
- Managing access to your data using IAM roles and other service configurations to apply the appropriate permissions.
- Enabling detective controls such as AWS CloudTrail or Amazon GuardDuty for Amazon S3.

This documentation will help you understand how to apply the shared responsibility model when using Amazon S3. The following topics show you how to configure Amazon S3 to meet your security and compliance objectives. You'll also learn how to use other AWS services that can help you monitor and secure your Amazon S3 resources.

> **Note**
>
> For more information about using the Amazon S3 Express One Zone storage class with directory buckets, see What is S3 Express One Zone? and Directory buckets.

**Topics**

# Data protection in Amazon S3

Amazon S3 provides a highly durable storage infrastructure designed for mission-critical and primary data storage. S3 Standard, S3 Intelligent-Tiering, S3 Standard-IA, S3 Glacier Instant Retrieval, S3 Glacier Flexible Retrieval, and S3 Glacier Deep Archive redundantly store objects on multiple devices across a minimum of three Availability Zones in an AWS Region. An Availability Zone is one or more discrete data centers with redundant power, networking, and connectivity in an AWS Region. Availability Zones are physically separated by a meaningful distance, many kilometers, from any other Availability Zone, although all are within 100 km (60 miles) of each other. The S3 One Zone-IA storage class stores data redundantly across multiple devices within a single Availability Zone. These services are designed to handle concurrent device failures by quickly detecting and repairing any lost redundancy, and they also regularly verify the integrity of your data using checksums.

Amazon S3 standard storage offers the following features:

- Backed with the Amazon S3 Service Level Agreement.
- Designed to provide 99.999999999% durability and 99.99% availability of objects over a given year.
- S3 Standard, S3 Intelligent-Tiering, S3 Standard-IA, S3 Glacier Instant Retrieval, S3 Glacier Flexible Retrieval, and S3 Glacier Deep Archive are all designed to sustain data in the event of the loss of an entire Amazon S3 Availability Zone.

Amazon S3 further protects your data using versioning. You can use versioning to preserve, retrieve, and restore every version of every object that is stored in your Amazon S3 bucket. With versioning, you can easily recover from both unintended user actions and application failures. By default, requests retrieve the most recently written version. You can retrieve older versions of an object by specifying a version of the object in a request.

Apart from S3 Versioning, you can also use Amazon S3 Object Lock and S3 Replication to protect your data. For more information, see Tutorial: Protecting data on Amazon S3 against accidental deletion or application bugs using S3 Versioning, S3 Object Lock, and S3 Replication.

For data protection purposes, we recommend that you protect AWS account credentials and set up individual user accounts with AWS Identity and Access Management, so that each user is given only the permissions necessary to fulfill their job duties.

If you require FIPS 140-2 validated cryptographic modules when accessing AWS through a command line interface or an API, use a FIPS endpoint. For more information about the available FIPS endpoints, see Federal Information Processing Standard (FIPS) 140-2.

The following security best practices also address data protection in Amazon S3:

- Implement server-side encryption
- Enforce encryption of data in transit
- Consider using Macie with Amazon S3
- Identify and audit all your Amazon S3 buckets
- Monitor Amazon Web Services security advisories

# Protecting data with encryption

**Important**

Amazon S3 now applies server-side encryption with Amazon S3 managed keys (SSE-S3) as the base level of encryption for every bucket in Amazon S3. Starting January 5, 2023, all new object uploads to Amazon S3 are automatically encrypted at no additional cost and with no impact on performance. The automatic encryption status for S3 bucket default encryption configuration and for new object uploads is available in AWS CloudTrail logs, S3 Inventory, S3 Storage Lens, the Amazon S3 console, and as an additional Amazon S3 API response header in the AWS Command Line Interface and AWS SDKs. For more information, see Default encryption FAQ.

Data protection refers to protecting data while it's in transit (as it travels to and from Amazon S3) and at rest (while it is stored on disks in Amazon S3 data centers). You can protect data in transit by using Secure Socket Layer/Transport Layer Security (SSL/TLS) or client-side encryption. For protecting data at rest in Amazon S3, you have the following options:

- **Server-side encryption** – Amazon S3 encrypts your objects before saving them on disks in AWS data centers and then decrypts the objects when you download them.

  All Amazon S3 buckets have encryption configured by default, and all new objects that are uploaded to an S3 bucket are automatically encrypted at rest. Server-side encryption with Amazon S3 managed keys (SSE-S3) is the default encryption configuration for every bucket in Amazon S3. To use a different type of encryption, you can either specify the type of server-side encryption to use in your S3 PUT requests, or you can set the default encryption configuration in the destination bucket.

  If you want to specify a different encryption type in your PUT requests, you can use server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS), dual-layer server-side encryption with AWS KMS keys (DSSE-KMS), or server-side encryption with customer-provided keys (SSE-C). If you want to set a different default encryption configuration in the destination bucket, you can use SSE-KMS or DSSE-KMS.

  For more information about each option for server-side encryption, see Protecting data with server-side encryption.

To configure server-side encryption, see:

- Specifying server-side encryption with Amazon S3 managed keys (SSE-S3)
- Specifying server-side encryption with AWS KMS (SSE-KMS)
- the section called "Specifying DSSE-KMS"
- Specifying server-side encryption with customer-provided keys (SSE-C)

- **Client-side encryption** – You encrypt your data client-side and upload the encrypted data to Amazon S3. In this case, you manage the encryption process, encryption keys, and related tools.

  To configure client-side encryption, see Protecting data by using client-side encryption.

To see which percentage of your storage bytes are encrypted, you can use Amazon S3 Storage Lens metrics. S3 Storage Lens is a cloud-storage analytics feature that you can use to gain organization-wide visibility into object-storage usage and activity. For more information, see Assessing your storage activity and usage with S3 Storage Lens. For a complete list of metrics, see S3 Storage Lens metrics glossary.

For more information about server-side encryption and client-side encryption, review the following topics.

**Topics**

- Protecting data with server-side encryption
- Protecting data by using client-side encryption

## Protecting data with server-side encryption

**Important**

Amazon S3 now applies server-side encryption with Amazon S3 managed keys (SSE-S3) as the base level of encryption for every bucket in Amazon S3. Starting January 5, 2023, all new object uploads to Amazon S3 are automatically encrypted at no additional cost and with no impact on performance. The automatic encryption status for S3 bucket default encryption configuration and for new object uploads is available in AWS CloudTrail logs, S3 Inventory, S3 Storage Lens, the Amazon S3 console, and as an additional Amazon S3 API

response header in the AWS Command Line Interface and AWS SDKs. For more information, see Default encryption FAQ.

Server-side encryption is the encryption of data at its destination by the application or service that receives it. Amazon S3 encrypts your data at the object level as it writes it to disks in AWS data centers and decrypts it for you when you access it. As long as you authenticate your request and you have access permissions, there is no difference in the way you access encrypted or unencrypted objects. For example, if you share your objects by using a presigned URL, that URL works the same way for both encrypted and unencrypted objects. Additionally, when you list objects in your bucket, the list API operations return a list of all objects, regardless of whether they are encrypted.

All Amazon S3 buckets have encryption configured by default, and all new objects that are uploaded to an S3 bucket are automatically encrypted at rest. Server-side encryption with Amazon S3 managed keys (SSE-S3) is the default encryption configuration for every bucket in Amazon S3. To use a different type of encryption, you can either specify the type of server-side encryption to use in your S3 PUT requests, or you can set the default encryption configuration in the destination bucket.

If you want to specify a different encryption type in your PUT requests, you can use server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS), dual-layer server-side encryption with AWS KMS keys (DSSE-KMS), or server-side encryption with customer-provided keys (SSE-C). If you want to set a different default encryption configuration in the destination bucket, you can use SSE-KMS or DSSE-KMS.

**Note**

You can't apply different types of server-side encryption to the same object simultaneously.

If you need to encrypt your existing objects, use S3 Batch Operations and S3 Inventory. For more information, see Encrypting objects with Amazon S3 Batch Operations and Performing large-scale batch operations on Amazon S3 objects.

You have four mutually exclusive options for server-side encryption, depending on how you choose to manage the encryption keys and the number of encryption layers that you want to apply.

**Server-side encryption with Amazon S3 managed keys (SSE-S3)**

All Amazon S3 buckets have encryption configured by default. The default option for server-side encryption is with Amazon S3 managed keys (SSE-S3). Each object is encrypted with a unique key. As an additional safeguard, SSE-S3 encrypts the key itself with a root key that it regularly rotates. SSE-S3 uses one of the strongest block ciphers available, 256-bit Advanced Encryption Standard (AES-256), to encrypt your data. For more information, see Using server-side encryption with Amazon S3 managed keys (SSE-S3).

**Server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS)**

Server-side encryption with AWS KMS keys (SSE-KMS) is provided through an integration of the AWS KMS service with Amazon S3. With AWS KMS, you have more control over your keys. For example, you can view separate keys, edit control policies, and follow the keys in AWS CloudTrail. Additionally, you can create and manage customer managed keys or use AWS managed keys that are unique to you, your service, and your Region. For more information, see Using server-side encryption with AWS KMS keys (SSE-KMS).

**Dual-layer server-side encryption with AWS Key Management Service (AWS KMS) keys (DSSE-KMS)**

Dual-layer server-side encryption with AWS KMS keys (DSSE-KMS) is similar to SSE-KMS, but DSSE-KMS applies two individual layers of object-level encryption instead of one layer. Because both layers of encryption are applied to an object on the server side, you can use a wide range of AWS services and tools to analyze data in S3 while using an encryption method that can satisfy your compliance requirements. For more information, see Using dual-layer server-side encryption with AWS KMS keys (DSSE-KMS).

**Server-side encryption with customer-provided keys (SSE-C)**

With server-side encryption with customer-provided keys (SSE-C), you manage the encryption keys, and Amazon S3 manages the encryption as it writes to disks and the decryption when you access your objects. For more information, see Using server-side encryption with customer-provided keys (SSE-C).

## Amazon S3 now automatically encrypts all new objects

Amazon S3 now applies server-side encryption with Amazon S3 managed keys (SSE-S3) as the base level of encryption for every bucket in Amazon S3. Starting January 5, 2023, all new object uploads to Amazon S3 are automatically encrypted at no additional cost and with no impact on performance. SSE-S3, which uses 256-bit Advanced Encryption Standard (AES-256), is automatically applied to all new buckets and to any existing S3 bucket that doesn't already have

default encryption configured. The automatic encryption status for S3 bucket default encryption configuration and for new object uploads is available in AWS CloudTrail logs, S3 Inventory, S3 Storage Lens, the Amazon S3 console, and as an additional Amazon S3 API response header in the AWS Command Line Interface (AWS CLI) and the AWS SDKs.

The following sections answer questions about this update.

**Does Amazon S3 change the default encryption settings for my existing buckets that already have default encryption configured?**

No. There are no changes to the default encryption configuration for an existing bucket that already has SSE-S3 or server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS) configured. For more information about how to set the default encryption behavior for buckets, see Setting default server-side encryption behavior for Amazon S3 buckets. For more information about SSE-S3 and SSE-KMS encryption settings, see Protecting data with server-side encryption.

**Is default encryption enabled on my existing buckets that don't have default encryption configured?**

Yes. Amazon S3 now configures default encryption on all existing unencrypted buckets to apply server-side encryption with S3 managed keys (SSE-S3) as the base level of encryption for new objects uploaded to these buckets. Objects that are already in an existing unencrypted bucket won't be automatically encrypted.

**How can I view the default encryption status of new object uploads?**

Currently, you can view the default encryption status of new object uploads in AWS CloudTrail logs, S3 Inventory, and S3 Storage Lens, the Amazon S3 console, and as an additional Amazon S3 API response header in the AWS Command Line Interface (AWS CLI) and the AWS SDKs.

- To view your CloudTrail events, see Viewing CloudTrail events in the CloudTrail console in the *AWS CloudTrail User Guide*. CloudTrail logs provide API tracking for PUT and POST requests to Amazon S3. When default encryption is being used to encrypt objects in your buckets, the CloudTrail logs for PUT and POST API requests will include the following field as the name-value pair: `"SSEApplied":"Default_SSE_S3"`.
- To view the automatic encryption status of new object uploads in S3 Inventory, configure an S3 Inventory report to include the **Encryption** metadata field, and then see the encryption status of each new object in the report. For more information, see Setting up Amazon S3 Inventory.

- To view the automatic encryption status for new object uploads in S3 Storage Lens, configure an S3 Storage Lens dashboard and see the **Encrypted bytes** and **Encrypted object count** metrics in the **Data protection** category of the dashboard. For more information, see Creating an Amazon S3 Storage Lens dashboard and Viewing S3 Storage Lens metrics on the dashboards.
- To view the automatic bucket-level encryption status in the Amazon S3 console, check the **Default encryption** of your Amazon S3 buckets in the Amazon S3 console. For more information, see Configuring default encryption.
- To view the automatic encryption status as an additional Amazon S3 API response header in the AWS Command Line Interface (AWS CLI) and the AWS SDKs, check the response header `x-amz-server-side-encryption` when you use object action APIs, such as PutObject and GetObject.

**What do I have to do to take advantage of this change?**

You are not required to make any changes to your existing applications. Because default encryption is enabled for all of your buckets, all new objects uploaded to Amazon S3 are automatically encrypted.

**Can I disable encryption for the new objects being written to my bucket?**

No. SSE-S3 is the new base level of encryption that's applied to all the new objects being uploaded to your bucket. You can no longer disable encryption for new object uploads.

**Will my charges be affected?**

No. Default encryption with SSE-S3 is available at no additional cost. You will be billed for storage, requests, and other S3 features, as usual. For pricing, see Amazon S3 pricing.

**Will Amazon S3 encrypt my existing objects that are unencrypted?**

No. Beginning on January 5, 2023, Amazon S3 only automatically encrypts new object uploads. To encrypt existing objects, you can use S3 Batch Operations to create encrypted copies of your objects. These encrypted copies will retain the existing object data and name and will be encrypted by using the encryption keys that you specify. For more details, see Encrypting objects with Amazon S3 Batch Operations in the *AWS Storage Blog*.

**I did not enable encryption for my buckets before this release. Do I need to change the way that I access objects?**

No. Default encryption with SSE-S3 automatically encrypts your data as it's written to Amazon S3 and decrypts it for you when you access it. There is no change in the way that you access objects that are automatically encrypted.

**Do I need to change the way that I access my client-side encrypted objects?**

No. All client-side encrypted objects that are encrypted before being uploaded into Amazon S3 arrive as encrypted ciphertext objects within Amazon S3. These objects will now have an additional layer of SSE-S3 encryption. Your workloads that use client-side encrypted objects will not require any changes to your client services or authorization settings.

> **Note**
>
> HashiCorp Terraform users that aren't using an updated version of the AWS Provider might see an unexpected drift after creating new S3 buckets with no customer defined encryption configuration. To avoid this drift, update your Terraform AWS Provider version to one of the following versions: any 4.x release, 3.76.1, or 2.70.4.

## Using server-side encryption with Amazon S3 managed keys (SSE-S3)

> **Important**
>
> Amazon S3 now applies server-side encryption with Amazon S3 managed keys (SSE-S3) as the base level of encryption for every bucket in Amazon S3. Starting January 5, 2023, all new object uploads to Amazon S3 are automatically encrypted at no additional cost and with no impact on performance. The automatic encryption status for S3 bucket default encryption configuration and for new object uploads is available in AWS CloudTrail logs, S3 Inventory, S3 Storage Lens, the Amazon S3 console, and as an additional Amazon S3 API response header in the AWS Command Line Interface and AWS SDKs. For more information, see Default encryption FAQ.

All new object uploads to Amazon S3 buckets are encrypted by default with server-side encryption with Amazon S3 managed keys (SSE-S3).

Server-side encryption protects data at rest. Amazon S3 encrypts each object with a unique key. As an additional safeguard, it encrypts the key itself with a key that it rotates regularly. Amazon

S3 server-side encryption uses 256-bit Advanced Encryption Standard Galois/Counter Mode (AES-GCM) to encrypt all uploaded objects.

There are no additional fees for using server-side encryption with Amazon S3 managed keys (SSE-S3). However, requests to configure the default encryption feature incur standard Amazon S3 request charges. For information about pricing, see Amazon S3 pricing.

If you require your data uploads to be encrypted using only Amazon S3 managed keys, you can use the following bucket policy. For example, the following bucket policy denies permissions to upload an object unless the request includes the `x-amz-server-side-encryption` header to request server-side encryption:

```
{
  "Version": "2012-10-17",
  "Id": "PutObjectPolicy",
  "Statement": [
    {
      "Sid": "DenyObjectsThatAreNotSSES3",
      "Effect": "Deny",
      "Principal": "*",
      "Action": "s3:PutObject",
      "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/*",
      "Condition": {
        "StringNotEquals": {
          "s3:x-amz-server-side-encryption": "AES256"
        }
      }
    }
  ]
}
```

**Note**

Server-side encryption encrypts only the object data, not the object metadata.

### API support for server-side encryption

All Amazon S3 buckets have encryption configured by default, and all new objects that are uploaded to an S3 bucket are automatically encrypted at rest. Server-side encryption with Amazon S3 managed keys (SSE-S3) is the default encryption configuration for every bucket in Amazon S3.

To use a different type of encryption, you can either specify the type of server-side encryption to use in your S3 PUT requests, or you can set the default encryption configuration in the destination bucket.

If you want to specify a different encryption type in your PUT requests, you can use server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS), dual-layer server-side encryption with AWS KMS keys (DSSE-KMS), or server-side encryption with customer-provided keys (SSE-C). If you want to set a different default encryption configuration in the destination bucket, you can use SSE-KMS or DSSE-KMS.

To configure server-side encryption by using the object creation REST APIs, you must provide the `x-amz-server-side-encryption` request header. For information about the REST APIs, see Using the REST API.

The following Amazon S3 APIs support this header:

- **PUT operations** – Specify the request header when uploading data using the PUT API. For more information, see PUT Object.
- **Initiate Multipart Upload** – Specify the header in the initiate request when uploading large objects using the multipart upload API operation. For more information, see Initiate Multipart Upload.
- **COPY operations** – When you copy an object, you have both a source object and a target object. For more information, see PUT Object - Copy.

> **Note**
>
> When using a POST operation to upload an object, instead of providing the request header, you provide the same information in the form fields. For more information, see POST Object.

The AWS SDKs also provide wrapper APIs that you can use to request server-side encryption. You can also use the AWS Management Console to upload objects and request server-side encryption.

For more general information, see AWS KMS concepts in the *AWS Key Management Service Developer Guide*.

- Specifying server-side encryption with Amazon S3 managed keys (SSE-S3)

### Specifying server-side encryption with Amazon S3 managed keys (SSE-S3)

> **Important**
>
> Amazon S3 now applies server-side encryption with Amazon S3 managed keys (SSE-S3) as the base level of encryption for every bucket in Amazon S3. Starting January 5, 2023, all new object uploads to Amazon S3 are automatically encrypted at no additional cost and with no impact on performance. The automatic encryption status for S3 bucket default encryption configuration and for new object uploads is available in AWS CloudTrail logs, S3 Inventory, S3 Storage Lens, the Amazon S3 console, and as an additional Amazon S3 API response header in the AWS Command Line Interface and AWS SDKs. For more information, see Default encryption FAQ.

All Amazon S3 buckets have encryption configured by default, and all new objects that are uploaded to an S3 bucket are automatically encrypted at rest. Server-side encryption with Amazon S3 managed keys (SSE-S3) is the default encryption configuration for every bucket in Amazon S3. To use a different type of encryption, you can either specify the type of server-side encryption to use in your S3 PUT requests, or you can set the default encryption configuration in the destination bucket.

If you want to specify a different encryption type in your PUT requests, you can use server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS), dual-layer server-side encryption with AWS KMS keys (DSSE-KMS), or server-side encryption with customer-provided keys (SSE-C). If you want to set a different default encryption configuration in the destination bucket, you can use SSE-KMS or DSSE-KMS.

You can specify SSE-S3 by using the S3 console, REST APIs, AWS SDKs, and AWS Command Line Interface (AWS CLI). For more information, see Setting default server-side encryption behavior for Amazon S3 buckets.

#### Using the S3 console

This topic describes how to set or change the type of encryption an object by using the AWS Management Console. When you copy an object by using the console, Amazon S3 copies the object as is. That means that if the source object is encrypted, the target object is also encrypted. You can use the console to add or change encryption for an object.

**Note**

- If you change an object's encryption, a new object is created to replace the old one. If S3 Versioning is enabled, a new version of the object is created, and the existing object becomes an older version. The role that changes the property also becomes the owner of the new object (or object version).
- If you change the encryption type for an object that has user-defined tags, you must have the `s3:GetObjectTagging` permission. If you're changing the encryption type for an object that doesn't have user-defined tags but is over 16 MB in size, you must also have the `s3:GetObjectTagging` permission.

  If the destination bucket policy denies the `s3:GetObjectTagging` action, the encryption type for the object will be updated, but the user-defined tags will be removed from the object, and you will receive an error.

**To change encryption for an object**

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Buckets**.
3. In the **Buckets** list, choose the name of the bucket that contains the object.
4. In the **Objects** list, choose the name of the object that you want to add or change encryption for.

   The object's details page appears, with several sections that display the properties for your object.
5. Choose the **Properties** tab.
6. Scroll down to the **Server-side encryption settings** section, and then choose **Edit**.
7. Under **Encryption settings**, choose **Use bucket default encryption settings** or **Override bucket default encryption settings**.
8. If you chose **Override bucket settings for default encryption**, configure the following encryption settings.

   - Under **Encryption type**, choose **Amazon S3 managed keys (SSE-S3)**. SSE-S3 uses one of the strongest block ciphers—256-bit Advanced Encryption Standard (AES-256) to encrypt

each object. For more information, see Using server-side encryption with Amazon S3 managed keys (SSE-S3).

9. Choose **Save changes**.

> **Note**
>
> This action applies encryption to all specified objects. When you're encrypting folders, wait for the save operation to finish before adding new objects to the folder.

### Using the REST API

At the time of object creation—that is, when you are uploading a new object or making a copy of an existing object—you can specify if you want Amazon S3 to encrypt your data with Amazon S3 managed keys (SSE-S3) by adding the `x-amz-server-side-encryption` header to the request. Set the value of the header to the encryption algorithm `AES256`, which Amazon S3 supports. Amazon S3 confirms that your object is stored with SSE-S3 by returning the response header `x-amz-server-side-encryption`.

The following REST upload API operations accept the `x-amz-server-side-encryption` request header.

- PUT Object
- PUT Object - Copy
- POST Object
- Initiate Multipart Upload

When uploading large objects by using the multipart upload API operation, you can specify server-side encryption by adding the `x-amz-server-side-encryption` header to the Initiate Multipart Upload request. When you're copying an existing object, regardless of whether the source object is encrypted or not, the destination object is not encrypted unless you explicitly request server-side encryption.

The response headers of the following REST API operations return the `x-amz-server-side-encryption` header when an object is stored using SSE-S3.

- PUT Object

- PUT Object - Copy
- POST Object
- Initiate Multipart Upload
- Upload Part
- Upload Part - Copy
- Complete Multipart Upload
- Get Object
- Head Object

> **Note**
>
> Do not send encryption request headers for GET requests and HEAD requests if your object uses SSE-S3, or you'll get an HTTP status code 400 (Bad Request) error.

### Using the AWS SDKs

When using AWS SDKs, you can request Amazon S3 to use server-side encryption with Amazon S3 managed encryption keys (SSE-S3). This section provides examples of using the AWS SDKs in multiple languages. For information about other SDKs, go to Sample Code and Libraries.

Java

When you use the AWS SDK for Java to upload an object, you can use SSE-S3 to encrypt it. To request server-side encryption, use the `ObjectMetadata` property of the `PutObjectRequest` to set the `x-amz-server-side-encryption` request header. When you call the `putObject()` method of the `AmazonS3Client`, Amazon S3 encrypts and saves the data.

You can also request SSE-S3 encryption when uploading objects with the multipart upload API operation:

- When using the high-level multipart upload API operation, you use the `TransferManager` methods to apply server-side encryption to objects as you upload them. You can use any of the upload methods that take `ObjectMetadata` as a parameter. For more information, see Uploading an object using multipart upload.
- When using the low-level multipart upload API operation, you specify server-side encryption when you initiate the multipart upload. You add the `ObjectMetadata` property by calling

the `InitiateMultipartUploadRequest.setObjectMetadata()` method. For more information, see Using the AWS SDKs (low-level API).

You can't directly change the encryption state of an object (encrypting an unencrypted object or decrypting an encrypted object). To change an object's encryption state, you make a copy of the object, specifying the desired encryption state for the copy, and then delete the original object. Amazon S3 encrypts the copied object only if you explicitly request server-side encryption. To request encryption of the copied object through the Java API, use the `ObjectMetadata` property to specify server-side encryption in the `CopyObjectRequest`.

**Example Example**

The following example shows how to set server-side encryption by using the AWS SDK for Java. It shows how to perform the following tasks:

- Upload a new object by using SSE-S3.
- Change an object's encryption state (in this example, encrypting a previously unencrypted object) by making a copy of the object.
- Check the encryption state of the object.

For more information about server-side encryption, see Using the REST API. For instructions on creating and testing a working sample, see Getting Started in the AWS SDK for Java Developer Guide.

```
import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import com.amazonaws.auth.profile.ProfileCredentialsProvider;
import com.amazonaws.regions.Regions;
import com.amazonaws.services.s3.AmazonS3;
import com.amazonaws.services.s3.AmazonS3ClientBuilder;

***";
        String keyNameToCopyAndEncrypt = "*** Key name for an unencrypted object to
be encrypted by copying ***";
        String copiedObjectKeyName = "*** Key name for the encrypted copy of the
unencrypted object ***";

        try {
            AmazonS3 s3Client = AmazonS3ClientBuilder.standard()
                    .withRegion(clientRegion)
                    .withCredentials(new ProfileCredentialsProvider())
                    .build();

            // Upload an object and encrypt it with SSE.
            uploadObjectWithSSEEncryption(s3Client, bucketName, keyNameToEncrypt);

            // Upload a new unencrypted object, then change its encryption state
            // to encrypted by making a copy.
            changeSSEEncryptionStatusByCopying(s3Client,
                    bucketName,
                    keyNameToCopyAndEncrypt,
                    copiedObjectKeyName);
        } catch (AmazonServiceException e) {
            // The call was transmitted successfully, but Amazon S3 couldn't process
            // it, so it returned an error response.
            e.printStackTrace();
        } catch (SdkClientException e) {
            // Amazon S3 couldn't be contacted for a response, or the client
            // couldn't parse the response from Amazon S3.
            e.printStackTrace();
        }
    }

    private static void uploadObjectWithSSEEncryption(AmazonS3 s3Client, String
bucketName, String keyName) {
        String objectContent = "Test object encrypted with SSE";
        byte[] objectBytes = objectContent.getBytes();

        // Specify server-side encryption.
        ObjectMetadata objectMetadata = new ObjectMetadata();
        objectMetadata.setContentLength(objectBytes.length);
```

```
objectMetadata.setSSEAlgorithm(ObjectMetadata.AES_256_SERVER_SIDE_ENCRYPTION);
       PutObjectRequest putRequest = new PutObjectRequest(bucketName,
               keyName,
               new ByteArrayInputStream(objectBytes),
               objectMetadata);

       // Upload the object and check its encryption status.
       PutObjectResult putResult = s3Client.putObject(putRequest);
       System.out.println("Object \"" + keyName + "\" uploaded with SSE.");
       printEncryptionStatus(putResult);
   }

   private static void changeSSEEncryptionStatusByCopying(AmazonS3 s3Client,
           String bucketName,
           String sourceKey,
           String destKey) {
       // Upload a new, unencrypted object.
       PutObjectResult putResult = s3Client.putObject(bucketName, sourceKey,
"Object example to encrypt by copying");
       System.out.println("Unencrypted object \"" + sourceKey + "\" uploaded.");
       printEncryptionStatus(putResult);

       // Make a copy of the object and use server-side encryption when storing the
       // copy.
       CopyObjectRequest request = new CopyObjectRequest(bucketName,
               sourceKey,
               bucketName,
               destKey);
       ObjectMetadata objectMetadata = new ObjectMetadata();

objectMetadata.setSSEAlgorithm(ObjectMetadata.AES_256_SERVER_SIDE_ENCRYPTION);
       request.setNewObjectMetadata(objectMetadata);

       // Perform the copy operation and display the copy's encryption status.
       CopyObjectResult response = s3Client.copyObject(request);
       System.out.println("Object \"" + destKey + "\" uploaded with SSE.");
       printEncryptionStatus(response);

       // Delete the original, unencrypted object, leaving only the encrypted copy
in
       // Amazon S3.
       s3Client.deleteObject(bucketName, sourceKey);
       System.out.println("Unencrypted object \"" + sourceKey + "\" deleted.");
```

```
    }

    private static void printEncryptionStatus(SSEResultBase response) {
        String encryptionStatus = response.getSSEAlgorithm();
        if (encryptionStatus == null) {
            encryptionStatus = "Not encrypted with SSE";
        }
        System.out.println("Object encryption status is: " + encryptionStatus);
    }
}
```

.NET

When you upload an object, you can direct Amazon S3 to encrypt it. To change the encryption state of an existing object, you make a copy of the object and delete the source object. By default, the copy operation encrypts the target only if you explicitly request server-side encryption of the target object. To specify SSE-S3 in the `CopyObjectRequest`, add the following:

```
ServerSideEncryptionMethod = ServerSideEncryptionMethod.AES256
```

For a working sample of how to copy an object, see Using the AWS SDKs.

The following example uploads an object. In the request, the example directs Amazon S3 to encrypt the object. The example then retrieves object metadata and verifies the encryption method that was used. For information about setting up and running the code examples, see Getting Started with the AWS SDK for .NET in the *AWS SDK for .NET Developer Guide*.

```
using Amazon;
using Amazon.S3;
using Amazon.S3.Model;
using System;
using System.Threading.Tasks;

namespace Amazon.DocSamples.S3
{
    class SpecifyServerSideEncryptionTest
    {
        private const string bucketName = "*** bucket name ***";
        private const string keyName = "*** key name for object created ***";
        // Specify your bucket region (an example region is shown).
```

```
        private static readonly RegionEndpoint bucketRegion =
RegionEndpoint.USWest2;
        private static IAmazonS3 client;

        public static void Main()
        {
            client = new AmazonS3Client(bucketRegion);
            WritingAnObjectAsync().Wait();
        }

        static async Task WritingAnObjectAsync()
        {
            try
            {
                var putRequest = new PutObjectRequest
                {
                    BucketName = bucketName,
                    Key = keyName,
                    ContentBody = "sample text",
                    ServerSideEncryptionMethod = ServerSideEncryptionMethod.AES256
                };

                var putResponse = await client.PutObjectAsync(putRequest);

                // Determine the encryption state of an object.
                GetObjectMetadataRequest metadataRequest = new
GetObjectMetadataRequest
                {
                    BucketName = bucketName,
                    Key = keyName
                };
                GetObjectMetadataResponse response = await
client.GetObjectMetadataAsync(metadataRequest);
                ServerSideEncryptionMethod objectEncryption =
response.ServerSideEncryptionMethod;

                Console.WriteLine("Encryption method used: {0}",
objectEncryption.ToString());
            }
            catch (AmazonS3Exception e)
            {
                Console.WriteLine("Error encountered ***. Message:'{0}' when writing
an object", e.Message);
            }
```

```
            catch (Exception e)
            {
                Console.WriteLine("Unknown encountered on server. Message:'{0}' when
 writing an object", e.Message);
            }
        }
    }
}
```

PHP

This topic shows how to use classes from version 3 of the AWS SDK for PHP to add SSE-S3 to objects that you upload to Amazon S3. For more information about the AWS SDK for Ruby API, go to AWS SDK for Ruby - Version 2.

To upload an object to Amazon S3, use the Aws\S3\S3Client::putObject() method. To add the `x-amz-server-side-encryption` request header to your upload request, specify the `ServerSideEncryption` parameter with the value `AES256`, as shown in the following code example. For information about server-side encryption requests, see Using the REST API.

```
 require 'vendor/autoload.php';

use Aws\S3\S3Client;

$bucket = '*** Your Bucket Name ***';
$keyname = '*** Your Object Key ***';

// $filepath should be an absolute path to a file on disk.
$filepath = '*** Your File Path ***';

$s3 = new S3Client([
    'version' => 'latest',
    'region'  => 'us-east-1'
]);

// Upload a file with server-side encryption.
$result = $s3->putObject([
    'Bucket'               => $bucket,
    'Key'                  => $keyname,
    'SourceFile'           => $filepath,
    'ServerSideEncryption' => 'AES256',
]);
```

In response, Amazon S3 returns the `x-amz-server-side-encryption` header with the value of the encryption algorithm that was used to encrypt your object's data.

When you upload large objects by using the multipart upload API operation, you can specify SSE-S3 for the objects that you are uploading, as follows:

- When you're using the low-level multipart upload API operation, specify server-side encryption when you call the Aws\S3\S3Client::createMultipartUpload() method. To add the `x-amz-server-side-encryption` request header to your request, specify the `array` parameter's `ServerSideEncryption` key with the value `AES256`. For more information about the low-level multipart upload API operation, see Using the AWS SDKs (low-level API).
- When you're using the high-level multipart upload API operation, specify server-side encryption by using the `ServerSideEncryption` parameter of the CreateMultipartUpload API operation. For an example of using the `setOption()` method with the high-level multipart upload API operation, see Uploading an object using multipart upload.

To determine the encryption state of an existing object, retrieve the object metadata by calling the Aws\S3\S3Client::headObject() method as shown in the following PHP code example.

```
 require 'vendor/autoload.php';

use Aws\S3\S3Client;

$bucket = '*** Your Bucket Name ***';
$keyname = '*** Your Object Key ***';

$s3 = new S3Client([
    'version' => 'latest',
    'region'  => 'us-east-1'
]);

// Check which server-side encryption algorithm is used.
$result = $s3->headObject([
    'Bucket' => $bucket,
    'Key'    => $keyname,
]);
echo $result['ServerSideEncryption'];
```

To change the encryption state of an existing object, make a copy of the object by using the Aws\S3\S3Client::copyObject() method and delete the source object. By default, `copyObject()` does not encrypt the target unless you explicitly request server-side encryption of the destination object by using the `ServerSideEncryption` parameter with the value `AES256`. The following PHP code example makes a copy of an object and adds server-side encryption to the copied object.

```
 require 'vendor/autoload.php';

use Aws\S3\S3Client;

$sourceBucket = '*** Your Source Bucket Name ***';
$sourceKeyname = '*** Your Source Object Key ***';

$targetBucket = '*** Your Target Bucket Name ***';
$targetKeyname = '*** Your Target Object Key ***';

$s3 = new S3Client([
    'version' => 'latest',
    'region'  => 'us-east-1'
]);

// Copy an object and add server-side encryption.
$s3->copyObject([
    'Bucket'               => $targetBucket,
    'Key'                  => $targetKeyname,
    'CopySource'           => "$sourceBucket/$sourceKeyname",
    'ServerSideEncryption' => 'AES256',
]);
```

For more information, see the following topics:

- AWS SDK for PHP for Amazon S3 Aws\S3\S3Client Class
- AWS SDK for PHP Documentation

### Ruby

When using the AWS SDK for Ruby to upload an object, you can specify that the object be stored encrypted at rest with SSE-S3. When you read the object back, it is automatically decrypted.

The following AWS SDK for Ruby Version 3 example demonstrates how to specify that a file uploaded to Amazon S3 be encrypted at rest.

```
require "aws-sdk-s3"

# Wraps Amazon S3 object actions.
class ObjectPutSseWrapper
  attr_reader :object

  # @param object [Aws::S3::Object] An existing Amazon S3 object.
  def initialize(object)
    @object = object
  end

  def put_object_encrypted(object_content, encryption)
    @object.put(body: object_content, server_side_encryption: encryption)
    true
  rescue Aws::Errors::ServiceError => e
    puts "Couldn't put your content to #{object.key}. Here's why: #{e.message}"
    false
  end
end

# Example usage:
def run_demo
  bucket_name = "doc-example-bucket"
  object_key = "my-encrypted-content"
  object_content = "This is my super-secret content."
  encryption = "AES256"

  wrapper = ObjectPutSseWrapper.new(Aws::S3::Object.new(bucket_name,
 object_content))
  return unless wrapper.put_object_encrypted(object_content, encryption)

  puts "Put your content into #{bucket_name}:#{object_key} and encrypted it with
 #{encryption}."
end

run_demo if $PROGRAM_NAME == __FILE__
```

The following code example demonstrates how to determine the encryption state of an existing object.

```
require "aws-sdk-s3"

# Wraps Amazon S3 object actions.
class ObjectGetEncryptionWrapper
  attr_reader :object

  # @param object [Aws::S3::Object] An existing Amazon S3 object.
  def initialize(object)
    @object = object
  end

  # Gets the object into memory.
  #
  # @return [Aws::S3::Types::GetObjectOutput, nil] The retrieved object data if
 successful; otherwise nil.
  def get_object
    @object.get
  rescue Aws::Errors::ServiceError => e
    puts "Couldn't get object #{@object.key}. Here's why: #{e.message}"
  end
end

# Example usage:
def run_demo
  bucket_name = "doc-example-bucket"
  object_key = "my-object.txt"

  wrapper = ObjectGetEncryptionWrapper.new(Aws::S3::Object.new(bucket_name,
 object_key))
  obj_data = wrapper.get_object
  return unless obj_data

  encryption = obj_data.server_side_encryption.nil? ? "no" :
 obj_data.server_side_encryption
  puts "Object #{object_key} uses #{encryption} encryption."
end

run_demo if $PROGRAM_NAME == __FILE__
```

If server-side encryption is not used for the object that is stored in Amazon S3, the method returns `null`.

To change the encryption state of an existing object, make a copy of the object and delete the source object. By default, the copy methods do not encrypt the target unless you explicitly request server-side encryption. You can request the encryption of the target object by specifying the `server_side_encryption` value in the option's hash argument, as shown in the following Ruby code example. The code example demonstrates how to copy an object and encrypt the copy with SSE-S3.

```
require "aws-sdk-s3"

# Wraps Amazon S3 object actions.
class ObjectCopyEncryptWrapper
  attr_reader :source_object

  # @param source_object [Aws::S3::Object] An existing Amazon S3 object. This is
 used as the source object for
  #                                        copy actions.
  def initialize(source_object)
    @source_object = source_object
  end

  # Copy the source object to the specified target bucket, rename it with the target
 key, and encrypt it.
  #
  # @param target_bucket [Aws::S3::Bucket] An existing Amazon S3 bucket where the
 object is copied.
  # @param target_object_key [String] The key to give the copy of the object.
  # @return [Aws::S3::Object, nil] The copied object when successful; otherwise,
 nil.
  def copy_object(target_bucket, target_object_key, encryption)
    @source_object.copy_to(bucket: target_bucket.name, key: target_object_key,
 server_side_encryption: encryption)
    target_bucket.object(target_object_key)
  rescue Aws::Errors::ServiceError => e
    puts "Couldn't copy #{@source_object.key} to #{target_object_key}. Here's why:
 #{e.message}"
  end
end

# Example usage:
def run_demo
  source_bucket_name = "doc-example-bucket1"
  source_key = "my-source-file.txt"
  target_bucket_name = "doc-example-bucket2"
```

```
  target_key = "my-target-file.txt"
  target_encryption = "AES256"

  source_bucket = Aws::S3::Bucket.new(source_bucket_name)
  wrapper = ObjectCopyEncryptWrapper.new(source_bucket.object(source_key))
  target_bucket = Aws::S3::Bucket.new(target_bucket_name)
  target_object = wrapper.copy_object(target_bucket, target_key, target_encryption)
  return unless target_object

  puts "Copied #{source_key} from #{source_bucket_name} to
 #{target_object.bucket_name}:#{target_object.key} and "\
       "encrypted the target with #{target_object.server_side_encryption}
 encryption."
end

run_demo if $PROGRAM_NAME == __FILE__
```

### Using the AWS CLI

To specify SSE-S3 when you upload an object by using the AWS CLI, use the following example.

```
aws s3api put-object --bucket amzn-s3-demo-bucket1 --key object-key-name --server-side-
encryption AES256  --body file path
```

For more information, see put-object in the *AWS CLI reference*. To specify SSE-S3 when you copy an object by using the AWS CLI, see copy-object.

### Using AWS CloudFormation

For examples of setting up encryption using AWS CloudFormation, see Create a bucket with default encryption and the Create a bucket by using AWS KMS server-side encryption with an S3 Bucket Key example in the `AWS::S3::Bucket ServerSideEncryptionRule` topic in the *AWS CloudFormation User Guide*.

## Using server-side encryption with AWS KMS keys (SSE-KMS)

> **Important**
>
> Amazon S3 now applies server-side encryption with Amazon S3 managed keys (SSE-S3) as the base level of encryption for every bucket in Amazon S3. Starting January 5, 2023, all

new object uploads to Amazon S3 are automatically encrypted at no additional cost and with no impact on performance. The automatic encryption status for S3 bucket default encryption configuration and for new object uploads is available in AWS CloudTrail logs, S3 Inventory, S3 Storage Lens, the Amazon S3 console, and as an additional Amazon S3 API response header in the AWS Command Line Interface and AWS SDKs. For more information, see Default encryption FAQ.

Server-side encryption is the encryption of data at its destination by the application or service that receives it.

Amazon S3 automatically enables server-side encryption with Amazon S3 managed keys (SSE-S3) for new object uploads.

Unless you specify otherwise, buckets use SSE-S3 by default to encrypt objects. However, you can choose to configure buckets to use server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS) instead. For more information, see Specifying server-side encryption with AWS KMS (SSE-KMS).

AWS KMS is a service that combines secure, highly available hardware and software to provide a key management system scaled for the cloud. Amazon S3 uses server-side encryption with AWS KMS (SSE-KMS) to encrypt your S3 object data. Also, when SSE-KMS is requested for the object, the S3 checksum (as part of the object's metadata) is stored in encrypted form. For more information about checksum, see Checking object integrity.

If you use KMS keys, you can use AWS KMS through the AWS Management Console or the AWS KMS API to do the following:

- Centrally create, view, edit, monitor, enable or disable, rotate, and schedule deletion of KMS keys.
- Define the policies that control how and by whom KMS keys can be used.
- Audit their usage to prove that they are being used correctly. Auditing is supported by the AWS KMS API, but not by the AWS KMSAWS Management Console.

The security controls in AWS KMS can help you meet encryption-related compliance requirements. You can use these KMS keys to protect your data in Amazon S3 buckets. When you use SSE-KMS encryption with an S3 bucket, the AWS KMS keys must be in the same Region as the bucket.

There are additional charges for using AWS KMS keys. For more information, see AWS KMS key concepts in the *AWS Key Management Service Developer Guide* and AWS KMS pricing.

### Permissions

To upload an object encrypted with an AWS KMS key to Amazon S3, you need `kms:GenerateDataKey` permissions on the key. To download an object encrypted with an AWS KMS key, you need `kms:Decrypt` permissions. For information about the AWS KMS permissions that are required for multipart uploads, see Multipart upload API and permissions.

> **Important**
>
> Carefully review the permissions that are granted in your KMS key policies. Always restrict customer-managed KMS key policy permissions only to the IAM principals and AWS services that must access the relevant AWS KMS key action. For more information, see Key policies in AWS KMS.

### Topics

- AWS KMS keys
- Amazon S3 Bucket Keys
- Requiring server-side encryption
- Encryption context
- Sending requests for AWS KMS encrypted objects
- Specifying server-side encryption with AWS KMS (SSE-KMS)
- Reducing the cost of SSE-KMS with Amazon S3 Bucket Keys

### AWS KMS keys

When you use server-side encryption with AWS KMS (SSE-KMS), you can use the default AWS managed key, or you can specify a customer managed key that you have already created. AWS KMS supports *envelope encryption*. S3 uses the AWS KMS features for *envelope encryption* to further protect your data. Envelope encryption is the practice of encrypting your plaintext data with a data key, and then encrypting that data key with a KMS key. For more information about envelope encryption, see Envelope encryption in the *AWS Key Management Service Developer Guide*.

If you don't specify a customer managed key, Amazon S3 automatically creates an AWS managed key in your AWS account the first time that you add an object encrypted with SSE-KMS to a bucket. By default, Amazon S3 uses this KMS key for SSE-KMS.

> **Note**
>
> Objects encrypted using SSE-KMS with AWS managed keys can't be shared cross-account. If you need to share SSE-KMS data cross-account, you must use a customer managed key from AWS KMS.

If you want to use a customer managed key for SSE-KMS, create a symmetric encryption customer managed key before you configure SSE-KMS. Then, when you configure SSE-KMS for your bucket, specify the existing customer managed key. For more information about symmetric encryption key, see Symmetric encryption KMS keys in the *AWS Key Management Service Developer Guide*.

Creating a customer managed key gives you more flexibility and control. For example, you can create, rotate, and disable customer managed keys. You can also define access controls and audit the customer managed key that you use to protect your data. For more information about customer managed and AWS managed keys, see Customer keys and AWS keys in the *AWS Key Management Service Developer Guide*.

> **Note**
>
> When you use server-side encryption with a customer managed key that's stored in an external key store, unlike standard KMS keys, you are responsible for ensuring the availability and durability of your key material. For more information about external key stores and how they shift the shared responsibility model, see External key stores in the *AWS Key Management Service Developer Guide*.

#### Using SSE-KMS encryption for cross-account operations

When using encryption for cross-account operations, be aware of the following:

- If an AWS KMS key Amazon Resource Name (ARN) or alias is not provided at request time or through the bucket's default encryption configuration, the AWS managed key (`aws/s3`) is used.

- If you're uploading or accessing S3 objects by using AWS Identity and Access Management (IAM) principals that are in the same AWS account as your KMS key, you can use the AWS managed key (`aws/s3`).
- If you want to grant cross-account access to your S3 objects, use a customer managed key. You can configure the policy of a customer managed key to allow access from another account.
- If you're specifying a customer managed KMS key, we recommend using a fully qualified KMS key ARN. If you use a KMS key alias instead, AWS KMS resolves the key within the requester's account. This behavior can result in data that's encrypted with a KMS key that belongs to the requester, and not the bucket owner.
- You must specify a key that you (the requester) have been granted `Encrypt` permission to. For more information, see Allow key users to use a KMS key for cryptographic operations in the *AWS Key Management Service Developer Guide*.

For more information about when to use customer managed keys and AWS managed KMS keys, see Should I use an AWS managed key or a customer managed key to encrypt my objects in Amazon S3?

**SSE-KMS encryption workflow**

If you choose to encrypt your data using an AWS managed key or a customer managed key, AWS KMS and Amazon S3 perform the following envelope encryption actions:

1. Amazon S3 requests a plaintext data key and a copy of the key encrypted under the specified KMS key.
2. AWS KMS generates a data key, encrypts it under the KMS key, and sends both the plaintext data key and the encrypted data key to Amazon S3.
3. Amazon S3 encrypts the data using the data key and removes the plaintext key from memory as soon as possible after use.
4. Amazon S3 stores the encrypted data key as metadata with the encrypted data.

When you request that your data be decrypted, Amazon S3 and AWS KMS perform the following actions:

1. Amazon S3 sends the encrypted data key to AWS KMS in a `Decrypt` request.
2. AWS KMS decrypts the encrypted data key by using the same KMS key and returns the plaintext data key to Amazon S3.

3. Amazon S3 decrypts the encrypted data, using the plaintext data key, and removes the plaintext data key from memory as soon as possible.

> **Important**
>
> When you use an AWS KMS key for server-side encryption in Amazon S3, you must choose a symmetric encryption KMS key. Amazon S3 supports only symmetric encryption KMS keys. For more information about these keys, see Symmetric encryption KMS keys in the *AWS Key Management Service Developer Guide*.

### Auditing SSE-KMS encryption

To identify requests that specify SSE-KMS, you can use the **All SSE-KMS requests** and **% all SSE-KMS requests** metrics in Amazon S3 Storage Lens metrics. S3 Storage Lens is a cloud-storage analytics feature that you can use to gain organization-wide visibility into object-storage usage and activity. You can also use the SSE-KMS enabled bucket count and % SSE-KMS enabled buckets to understand the count of buckets that (SSE-KMS) for default bucket encryption. For more information, see Assessing your storage activity and usage with S3 Storage Lens. For a complete list of metrics, see S3 Storage Lens metrics glossary.

To audit the usage of your AWS KMS keys for your SSE-KMS encrypted data, you can use AWS CloudTrail logs. You can get insight into your cryptographic operations, such as GenerateDataKey and Decrypt. CloudTrail supports numerous attribute values for filtering your search, including event name, user name, and event source.

### Amazon S3 Bucket Keys

When you configure server-side encryption using AWS KMS (SSE-KMS), you can configure your buckets to use S3 Bucket Keys for SSE-KMS. Using a bucket-level key for SSE-KMS can reduce your AWS KMS request costs by up to 99 percent by decreasing the request traffic from Amazon S3 to AWS KMS.

When you configure a bucket to use an S3 Bucket Key for SSE-KMS on new objects, AWS KMS generates a bucket-level key that is used to create unique data keys for objects in the bucket. This S3 Bucket Key is used for a time-limited period within Amazon S3, further reducing the need for Amazon S3 to make requests to AWS KMS to complete encryption operations. For more information about using S3 Bucket Keys, see Reducing the cost of SSE-KMS with Amazon S3 Bucket Keys.

### Requiring server-side encryption

To require server-side encryption of all objects in a particular Amazon S3 bucket, you can use a bucket policy. For example, the following bucket policy denies the upload object (`s3:PutObject`) permission to everyone if the request does not include an `x-amz-server-side-encryption-aws-kms-key-id` header that requests server-side encryption with SSE-KMS.

```
{
   "Version":"2012-10-17",
   "Id":"PutObjectPolicy",
   "Statement":[{
         "Sid":"DenyObjectsThatAreNotSSEKMS",
         "Effect":"Deny",
         "Principal":"*",
         "Action":"s3:PutObject",
         "Resource":"arn:aws:s3:::amzn-s3-demo-bucket1/*",
         "Condition":{
            "Null":{
               "s3:x-amz-server-side-encryption-aws-kms-key-id":"true"
            }
         }
      }
   ]
}
```

To require that a particular AWS KMS key be used to encrypt the objects in a bucket, you can use the `s3:x-amz-server-side-encryption-aws-kms-key-id` condition key. To specify the KMS key, you must use a key Amazon Resource Name (ARN) that is in the `arn:aws:kms:region:acct-id:key/key-id` format. AWS Identity and Access Management does not validate if the string for `s3:x-amz-server-side-encryption-aws-kms-key-id` exists.

> **Note**
>
> When you upload an object, you can specify the KMS key by using the `x-amz-server-side-encryption-aws-kms-key-id` header or rely on your default bucket encryption configuration. If your PutObject request specifies `aws:kms` in the `x-amz-server-side-encryption` header, but does not specify the `x-amz-server-side-encryption-aws-kms-key-id` header, then Amazon S3 assumes that you want to use the AWS managed

key. Regardless, the AWS KMS key ID that Amazon S3 uses for object encryption must match the AWS KMS key ID in the policy, otherwise Amazon S3 denies the request.

For a complete list of Amazon S3 specific condition keys, see Condition keys for Amazon S3 in the *Service Authorization Reference*.

**Encryption context**

An *encryption context* is a set of key-value pairs that contains additional contextual information about the data. The encryption context is not encrypted. When an encryption context is specified for an encryption operation, Amazon S3 must specify the same encryption context for the decryption operation. Otherwise, the decryption fails. AWS KMS uses the encryption context as additional authenticated data (AAD) to support authenticated encryption. For more information about the encryption context, see Encryption context in the *AWS Key Management Service Developer Guide*.

By default, Amazon S3 uses the object or bucket Amazon Resource Name (ARN) as the encryption context pair:

- **If you use SSE-KMS without enabling an S3 Bucket Key**, the object ARN is used as the encryption context.

```
arn:aws:s3:::object_ARN
```

- **If you use SSE-KMS and enable an S3 Bucket Key**, the bucket ARN is used as the encryption context. For more information about S3 Bucket Keys, see Reducing the cost of SSE-KMS with Amazon S3 Bucket Keys.

```
arn:aws:s3:::bucket_ARN
```

You can optionally provide an additional encryption context pair by using the `x-amz-server-side-encryption-context` header in an s3:PutObject request. However, because the encryption context is not encrypted, make sure it does not include sensitive information. Amazon S3 stores this additional key pair alongside the default encryption context. When it processes your PUT request, Amazon S3 appends the default encryption context of `aws:s3:arn` to the one that you provide.

You can use the encryption context to identify and categorize your cryptographic operations. You can also use the default encryption context ARN value to track relevant requests in AWS CloudTrail by viewing which Amazon S3 ARN was used with which encryption key.

In the `requestParameters` field of a CloudTrail log file, the encryption context looks similar to the following one.

```
"encryptionContext": {
    "aws:s3:arn": "arn:aws:s3:::amzn-s3-demo-bucket1/file_name"
}
```

When you use SSE-KMS with the optional S3 Bucket Keys feature, the encryption context value is the ARN of the bucket.

```
"encryptionContext": {
    "aws:s3:arn": "arn:aws:s3:::amzn-s3-demo-bucket1"
}
```

**Sending requests for AWS KMS encrypted objects**

> **Important**
>
> All GET and PUT requests for AWS KMS encrypted objects must be made using Secure Sockets Layer (SSL) or Transport Layer Security (TLS). Requests must also be signed using valid credentials, such as AWS Signature Version 4 (or AWS Signature Version 2).

AWS Signature Version 4 is the process of adding authentication information to AWS requests sent by HTTP. For security, most requests to AWS must be signed with an access key, which consists of an access key ID and secret access key. These two keys are commonly referred to as your security credentials. For more information, see Authenticating Requests (AWS Signature Version 4) and Signature Version 4 signing process.

> **Important**
>
> If your object uses SSE-KMS, don't send encryption request headers for GET requests and HEAD requests. Otherwise, you'll get an HTTP 400 Bad Request error.

**Topics**

## Specifying server-side encryption with AWS KMS (SSE-KMS)

> **Important**
>
> Amazon S3 now applies server-side encryption with Amazon S3 managed keys (SSE-S3) as the base level of encryption for every bucket in Amazon S3. Starting January 5, 2023, all new object uploads to Amazon S3 are automatically encrypted at no additional cost and with no impact on performance. The automatic encryption status for S3 bucket default encryption configuration and for new object uploads is available in AWS CloudTrail logs, S3 Inventory, S3 Storage Lens, the Amazon S3 console, and as an additional Amazon S3 API response header in the AWS Command Line Interface and AWS SDKs. For more information, see Default encryption FAQ.

All Amazon S3 buckets have encryption configured by default, and all new objects that are uploaded to an S3 bucket are automatically encrypted at rest. Server-side encryption with Amazon S3 managed keys (SSE-S3) is the default encryption configuration for every bucket in Amazon S3. To use a different type of encryption, you can either specify the type of server-side encryption to use in your S3 PUT requests, or you can set the default encryption configuration in the destination bucket.

If you want to specify a different encryption type in your PUT requests, you can use server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS), dual-layer server-side encryption with AWS KMS keys (DSSE-KMS), or server-side encryption with customer-provided keys (SSE-C). If you want to set a different default encryption configuration in the destination bucket, you can use SSE-KMS or DSSE-KMS.

You can apply encryption when you are either uploading a new object or copying an existing object.

You can specify SSE-KMS by using the Amazon S3 console, REST API operations, AWS SDKs, and the AWS Command Line Interface (AWS CLI). For more information, see the following topics.

**Note**

You can use multi-Region AWS KMS keys in Amazon S3. However, Amazon S3 currently treats multi-Region keys as though they were single-Region keys, and does not use the multi-Region features of the key. For more information, see Using multi-Region keys in *AWS Key Management Service Developer Guide*.

**Note**

If you want to use a KMS key that's owned by a different account, you must have permission to use the key. For more information about cross-account permissions for KMS keys, see Creating KMS keys that other accounts can use in the *AWS Key Management Service Developer Guide*.

### Using the S3 console

This topic describes how to set or change the type of encryption of an object to use server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS) by using the Amazon S3 console.

**Note**

- If you change an object's encryption, a new object is created to replace the old one. If S3 Versioning is enabled, a new version of the object is created, and the existing object becomes an older version. The role that changes the property also becomes the owner of the new object (or object version).
- If you change the encryption type for an object that has user-defined tags, you must have the `s3:GetObjectTagging` permission. If you're changing the encryption type for an object that doesn't have user-defined tags but is over 16 MB in size, you must also have the `s3:GetObjectTagging` permission.

  If the destination bucket policy denies the `s3:GetObjectTagging` action, the encryption type for the object will be updated, but the user-defined tags will be removed from the object, and you will receive an error.

**To add or change encryption for an object**

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Buckets**.
3. In the **Buckets** list, choose the name of the bucket that contains the object.
4. In the **Objects** list, choose the name of the object that you want to add or change encryption for.

   The object's details page appears, with several sections that display the properties for your object.
5. Choose the **Properties** tab.
6. Scroll down to the **Server-side encryption settings** section and choose **Edit**.

   The **Edit server-side encryption** page opens.
7. Under **Server-side encryption**, for **Encryption settings**, choose **Override default encryption bucket settings**.
8. Under **Encryption type**, choose **Server-side encryption with AWS Key Management Service keys (SSE-KMS)**.

   > **Important**
   >
   > If you use the SSE-KMS option for your default encryption configuration, you are subject to the requests per second (RPS) quotas of AWS KMS. For more information about AWS KMS quotas and how to request a quota increase, see Quotas in the *AWS Key Management Service Developer Guide*.
9. Under **AWS KMS key**, do one of the following to choose your KMS key:

   - To choose from a list of available KMS keys, choose **Choose from your AWS KMS keys**, and then choose your **KMS key** from the list of available keys.

     Both the AWS managed key (`aws/s3`) and your customer managed keys appear in this list. For more information about customer managed keys, see Customer keys and AWS keys in the *AWS Key Management Service Developer Guide*.
   - To enter the KMS key ARN, choose **Enter AWS KMS key ARN**, and then enter your KMS key ARN in the field that appears.

- To create a new customer managed key in the AWS KMS console, choose **Create a KMS key**.

  For more information about creating an AWS KMS key, see Creating keys in the *AWS Key Management Service Developer Guide*.

> **Important**
>
> You can use only KMS keys that are available in the same AWS Region as the bucket. The Amazon S3 console lists only the first 100 KMS keys in the same Region as the bucket. To use a KMS key that is not listed, you must enter your KMS key ARN. If you want to use a KMS key that is owned by a different account, you must first have permission to use the key and then you must enter the KMS key ARN.
> Amazon S3 supports only symmetric encryption KMS keys, and not asymmetric KMS keys. For more information, see Identifying symmetric and asymmetric KMS keys in the *AWS Key Management Service Developer Guide*.

10. Choose **Save changes**.

> **Note**
>
> This action applies encryption to all specified objects. When you're encrypting folders, wait for the save operation to finish before adding new objects to the folder.

### Using the REST API

When you create an object—that is, when you upload a new object or copy an existing object—you can specify the use of server-side encryption with AWS KMS keys (SSE-KMS) to encrypt your data. To do this, add the `x-amz-server-side-encryption` header to the request. Set the value of the header to the encryption algorithm `aws:kms`. Amazon S3 confirms that your object is stored using SSE-KMS by returning the response header `x-amz-server-side-encryption`.

If you specify the `x-amz-server-side-encryption` header with a value of `aws:kms`, you can also use the following request headers:

- `x-amz-server-side-encryption-aws-kms-key-id`
- `x-amz-server-side-encryption-context`

- `x-amz-server-side-encryption-bucket-key-enabled`

**Topics**

### Amazon S3 REST API operations that support SSE-KMS

The following REST API operations accept the `x-amz-server-side-encryption`, `x-amz-server-side-encryption-aws-kms-key-id`, and `x-amz-server-side-encryption-context` request headers.

- PutObject – When you upload data by using the PUT API operation, you can specify these request headers.
- CopyObject – When you copy an object, you have both a source object and a target object. When you pass SSE-KMS headers with the `CopyObject` operation, they're applied only to the target object. When you're copying an existing object, regardless of whether the source object is encrypted or not, the destination object isn't encrypted unless you explicitly request server-side encryption.
- POST Object – When you use a POST operation to upload an object, instead of the request headers, you provide the same information in the form fields.
- CreateMultipartUpload – When you upload large objects by using the multipart upload API operation, you can specify these headers. You specify these headers in the `CreateMultipartUpload` request.

The response headers of the following REST API operations return the `x-amz-server-side-encryption` header when an object is stored by using server-side encryption.

- PutObject
- CopyObject
- POST Object
- CreateMultipartUpload

- UploadPart
- UploadPartCopy
- CompleteMultipartUpload
- GetObject
- HeadObject

> **Important**
>
> - All GET and PUT requests for an object protected by AWS KMS fail if you don't make these requests by using Secure Sockets Layer (SSL), Transport Layer Security (TLS), or Signature Version 4.
> - If your object uses SSE-KMS, don't send encryption request headers for GET requests and HEAD requests, or you'll get an HTTP 400 BadRequest error.

#### Encryption context (`x-amz-server-side-encryption-context`)

If you specify `x-amz-server-side-encryption:aws:kms`, the Amazon S3 API supports an encryption context with the `x-amz-server-side-encryption-context` header. An encryption context is a set of key-value pairs that contain additional contextual information about the data.

Amazon S3 automatically uses the object or bucket Amazon Resource Name (ARN) as the encryption context pair. If you use SSE-KMS without enabling an S3 Bucket Key, you use the object ARN as your encryption context; for example, `arn:aws:s3:::`*`object_ARN`*. However, if you use SSE-KMS and enable an S3 Bucket Key, you use the bucket ARN for your encryption context; for example, `arn:aws:s3:::`*`bucket_ARN`*.

You can optionally provide an additional encryption context pair by using the `x-amz-server-side-encryption-context` header. However, because the encryption context isn't encrypted, make sure it doesn't include sensitive information. Amazon S3 stores this additional key pair alongside the default encryption context.

For information about the encryption context in Amazon S3, see Encryption context. For general information about the encryption context, see AWS Key Management Service Concepts - Encryption context in the *AWS Key Management Service Developer Guide*.

### AWS KMS key ID (x-amz-server-side-encryption-aws-kms-key-id)

You can use the `x-amz-server-side-encryption-aws-kms-key-id` header to specify the ID of the customer managed key that's used to protect the data. If you specify the `x-amz-server-side-encryption:aws:kms` header but don't provide the `x-amz-server-side-encryption-aws-kms-key-id` header, Amazon S3 uses the AWS managed key (`aws/s3`) to protect the data. If you want to use a customer managed key, you must provide the `x-amz-server-side-encryption-aws-kms-key-id` header of the customer managed key.

> **Important**
>
> When you use an AWS KMS key for server-side encryption in Amazon S3, you must choose a symmetric encryption KMS key. Amazon S3 supports only symmetric encryption KMS keys. For more information about these keys, see Symmetric encryption KMS keys in the *AWS Key Management Service Developer Guide*.

### S3 Bucket Keys (x-amz-server-side-encryption-aws-bucket-key-enabled)

You can use the `x-amz-server-side-encryption-aws-bucket-key-enabled` request header to enable or disable an S3 Bucket Key at the object level. S3 Bucket Keys reduce your AWS KMS request costs by decreasing the request traffic from Amazon S3 to AWS KMS. For more information, see Reducing the cost of SSE-KMS with Amazon S3 Bucket Keys.

If you specify the `x-amz-server-side-encryption:aws:kms` header but don't provide the `x-amz-server-side-encryption-aws-bucket-key-enabled` header, your object uses the S3 Bucket Key settings for the destination bucket to encrypt your object. For more information, see Configuring an S3 Bucket Key at the object level .

### Using the AWS CLI

To use the following example AWS CLI commands, replace the *`user input placeholders`* with your own information.

When you upload a new object or copy an existing object, you can specify the use of server-side encryption with AWS KMS keys to encrypt your data. To do this, add the `--server-side-encryption aws:kms` header to the request. Use the `--ssekms-key-id` *`example-key-id`* to add your customer managed AWS KMS key that you created. If you specify `--server-side-encryption aws:kms`, but don't provide an AWS KMS key ID, Amazon S3 will use an AWS managed key.

```
aws s3api put-object --bucket amzn-s3-demo-bucket --key example-object-key --
server-side-encryption aws:kms --ssekms-key-id example-key-id --ssekms-encryption-
context example-encryption-context --body filepath
```

You can enable or disable S3 Bucket Keys on your `put-object` or `copy-object` operations by adding `--bucket-key-enabled` or `--no-bucket-key-enabled`. S3 Bucket Keys can reduce your AWS KMS request costs by decreasing the request traffic from Amazon S3 to AWS KMS. For more information, see Reducing the cost of SSE-KMS with S3 Bucket Keys.

```
aws s3api put-object --bucket amzn-s3-demo-bucket --key example-object-key --server-
side-encryption aws:kms --bucket-key-enabled --body filepath
```

You can copy an object from a source bucket to a new bucket and specify SSE-KMS encryption.

```
aws s3api copy-object --copy-source amzn-s3-demo-bucket/example-object-key --
bucket amzn-s3-demo-bucket2 --key example-object-key --server-side-encryption aws:kms
 --sse-kms-key-id example-key-id --ssekms-encryption-context example-encryption-context
```

#### Using the AWS SDKs

When using AWS SDKs, you can request Amazon S3 to use AWS KMS keys for server-side encryption. The following examples show how to use SSE-KMS with the AWS SDKs for Java and .NET. For information about other SDKs, see Sample code and libraries on the AWS Developer Center.

> **Important**
>
> When you use an AWS KMS key for server-side encryption in Amazon S3, you must choose a symmetric encryption KMS key. Amazon S3 supports only symmetric encryption KMS keys. For more information about these keys, see Symmetric encryption KMS keys in the *AWS Key Management Service Developer Guide*.

#### `CopyObject` operation

When copying objects, you add the same request properties (`ServerSideEncryptionMethod` and `ServerSideEncryptionKeyManagementServiceKeyId`) to request Amazon S3 to use an AWS KMS key. For more information about copying objects, see Copying, moving, and renaming objects.

### PUT operation

Java

When uploading an object by using the AWS SDK for Java, you can request Amazon S3 to use an AWS KMS key by adding the `SSEAwsKeyManagementParams` property as shown in the following request:

```
PutObjectRequest putRequest = new PutObjectRequest(bucketName,
   keyName, file).withSSEAwsKeyManagementParams(new SSEAwsKeyManagementParams());
```

In this case, Amazon S3 uses the AWS managed key (`aws/s3`). For more information, see Using server-side encryption with AWS KMS keys (SSE-KMS). You can optionally create a symmetric encryption KMS key and specify that in the request, as shown in the following example:

```
PutObjectRequest putRequest = new PutObjectRequest(bucketName,
   keyName, file).withSSEAwsKeyManagementParams(new
 SSEAwsKeyManagementParams(keyID));
```

For more information about creating customer managed keys, see Programming the AWS KMS API in the *AWS Key Management Service Developer Guide*.

For working code examples of uploading an object, see the following topics. To use these examples, you must update the code examples and provide encryption information as shown in the preceding code fragment.

- For uploading an object in a single operation, see Uploading objects.
- For multipart uploads that use the high-level or low-level multipart upload API operations, see Uploading an object using multipart upload.

.NET

When uploading an object by using the AWS SDK for .NET, you can request Amazon S3 to use an AWS KMS key by adding the `ServerSideEncryptionMethod` property as shown in the following request:

```
PutObjectRequest putRequest = new PutObjectRequest
 {
```

```
    BucketName = amzn-s3-demo-bucket,
    Key = keyName,
    // other properties
    ServerSideEncryptionMethod = ServerSideEncryptionMethod.AWSKMS
};
```

In this case, Amazon S3 uses the AWS managed key. For more information, see Using server-side encryption with AWS KMS keys (SSE-KMS). You can optionally create your own symmetric encryption customer managed key and specify that in the request, as shown in the following example:

```
PutObjectRequest putRequest1 = new PutObjectRequest
{
  BucketName = amzn-s3-demo-bucket,
  Key = keyName,
  // other properties
  ServerSideEncryptionMethod = ServerSideEncryptionMethod.AWSKMS,
  ServerSideEncryptionKeyManagementServiceKeyId = keyId
};
```

For more information about creating customer managed keys, see Programming the AWS KMS API in the *AWS Key Management Service Developer Guide*.

For working code examples of uploading an object, see the following topics. To use these examples, you must update the code examples and provide encryption information as shown in the preceding code fragment.

- For uploading an object in a single operation, see Uploading objects.
- For multipart uploads that use the high-level or low-level multipart upload API operations, see Uploading an object using multipart upload.

### Presigned URLs

Java

When creating a presigned URL for an object that's encrypted with an AWS KMS key, you must explicitly specify Signature Version 4, as shown in the following example:

```
ClientConfiguration clientConfiguration = new ClientConfiguration();
```

```
clientConfiguration.setSignerOverride("AWSS3V4SignerType");
AmazonS3Client s3client = new AmazonS3Client(
        new ProfileCredentialsProvider(), clientConfiguration);
...
```

For a code example, see Sharing objects with presigned URLs.

.NET

When creating a presigned URL for an object that's encrypted with an AWS KMS key, you must explicitly specify Signature Version 4, as shown in the following example:

```
AWSConfigs.S3Config.UseSignatureVersion4 = true;
```

For a code example, see Sharing objects with presigned URLs.

### Reducing the cost of SSE-KMS with Amazon S3 Bucket Keys

Amazon S3 Bucket Keys reduce the cost of Amazon S3 server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS). Using a bucket-level key for SSE-KMS can reduce AWS KMS request costs by up to 99 percent by decreasing the request traffic from Amazon S3 to AWS KMS. With a few clicks in the AWS Management Console, and without any changes to your client applications, you can configure your bucket to use an S3 Bucket Key for SSE-KMS encryption on new objects.

> **Note**
>
> S3 Bucket Keys aren't supported for dual-layer server-side encryption with AWS Key Management Service (AWS KMS) keys (DSSE-KMS).

### S3 Bucket Keys for SSE-KMS

Workloads that access millions or billions of objects encrypted with SSE-KMS can generate large volumes of requests to AWS KMS. When you use SSE-KMS to protect your data without an S3 Bucket Key, Amazon S3 uses an individual AWS KMS data key for every object. In this case, Amazon S3 makes a call to AWS KMS every time a request is made against a KMS-encrypted object. For information about how SSE-KMS works, see Using server-side encryption with AWS KMS keys (SSE-KMS).

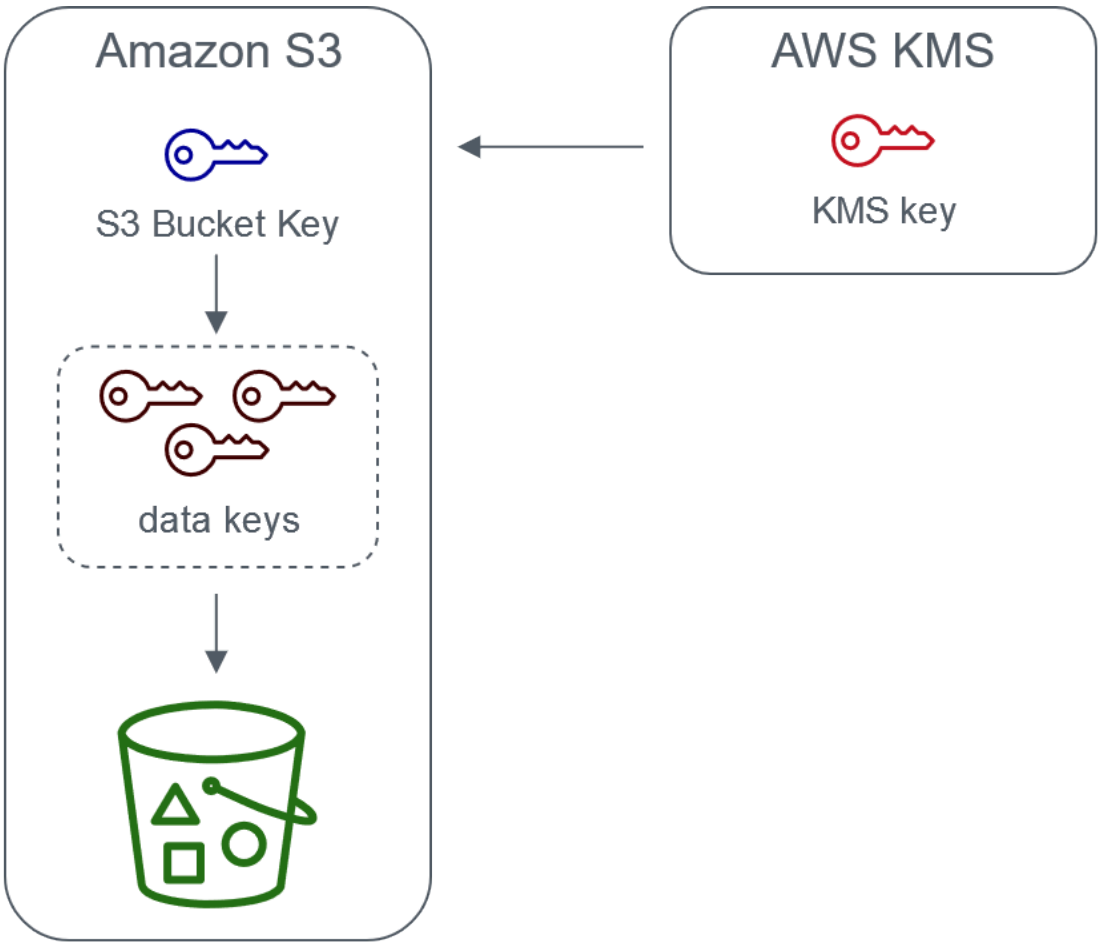
When you configure your bucket to use an S3 Bucket Key for SSE-KMS, AWS generates a short-lived bucket-level key from AWS KMS, then temporarily keeps it in S3. This bucket-level key will create data keys for new objects during its lifecycle. S3 Bucket Keys are used for a limited time period within Amazon S3, reducing the need for S3 to make requests to AWS KMS to complete encryption operations. This reduces traffic from S3 to AWS KMS, allowing you to access AWS KMS-encrypted objects in Amazon S3 at a fraction of the previous cost.

Unique bucket-level keys are fetched at least once per requester to ensure that the requester's access to the key is captured in an AWS KMS CloudTrail event. Amazon S3 treats callers as different requesters when they use different roles or accounts, or the same role with different scoping policies. AWS KMS request savings reflect the number of requesters, request patterns, and relative age of the objects requested. For example, a fewer number of requesters, requesting multiple objects in a limited time window, and encrypted with the same bucket-level key, results in greater savings.

> **Note**
>
> Using S3 Bucket Keys allows you to save on AWS KMS request costs by decreasing your requests to AWS KMS for `Encrypt`, `GenerateDataKey`, and `Decrypt` operations through the use of a bucket-level key. By design, subsequent requests that take advantage of this bucket-level key do not result in AWS KMS API requests or validate access against the AWS KMS key policy.

When you configure an S3 Bucket Key, objects that are already in the bucket do not use the S3 Bucket Key. To configure an S3 Bucket Key for existing objects, you can use a `CopyObject` operation. For more information, see Configuring an S3 Bucket Key at the object level .

Amazon S3 will only share an S3 Bucket Key for objects encrypted by the same AWS KMS key. S3 Bucket Keys are compatible with KMS keys created by AWS KMS, imported key material, and key material backed by custom key stores.



Server-side encryption with AWS Key Management service using an S3 Bucket Key

**Configuring S3 Bucket Keys**

You can configure your bucket to use an S3 Bucket Key for SSE-KMS on new objects through the Amazon S3 console, AWS SDKs, AWS CLI, or REST API. With S3 Bucket Keys enabled on your bucket, objects uploaded with a different specified SSE-KMS key will use their own S3 Bucket Keys. Regardless of your S3 Bucket Key setting, you can include the `x-amz-server-side-encryption-bucket-key-enabled` header with a `true` or `false` value in your request, to override the bucket setting.

Before you configure your bucket to use an S3 Bucket Key, review Changes to note before enabling an S3 Bucket Key.

### Configuring an S3 Bucket Key using the Amazon S3 console

When you create a new bucket, you can configure your bucket to use an S3 Bucket Key for SSE-KMS on new objects. You can also configure an existing bucket to use an S3 Bucket Key for SSE-KMS on new objects by updating your bucket properties.

For more information, see Configuring your bucket to use an S3 Bucket Key with SSE-KMS for new objects.

### REST API, AWS CLI, and AWS SDK support for S3 Bucket Keys

You can use the REST API, AWS CLI, or AWS SDK to configure your bucket to use an S3 Bucket Key for SSE-KMS on new objects. You can also enable an S3 Bucket Key at the object level.

For more information, see the following:

- Configuring an S3 Bucket Key at the object level
- Configuring your bucket to use an S3 Bucket Key with SSE-KMS for new objects

The following API operations support S3 Bucket Keys for SSE-KMS:

- PutBucketEncryption
  - `ServerSideEncryptionRule` accepts the `BucketKeyEnabled` parameter for enabling and disabling an S3 Bucket Key.
- GetBucketEncryption
  - `ServerSideEncryptionRule` returns the settings for `BucketKeyEnabled`.
- PutObject, CopyObject, CreateMultipartUpload, and POST Object
  - The `x-amz-server-side-encryption-bucket-key-enabled` request header enables or disables an S3 Bucket Key at the object level.
- HeadObject, GetObject, UploadPartCopy, UploadPart, and CompleteMultipartUpload
  - The `x-amz-server-side-encryption-bucket-key-enabled` response header indicates if an S3 Bucket Key is enabled or disabled for an object.

### Working with AWS CloudFormation

In AWS CloudFormation, the `AWS::S3::Bucket` resource includes an encryption property called `BucketKeyEnabled` that you can use to enable or disable an S3 Bucket Key.

For more information, see Using AWS CloudFormation.

**Changes to note before enabling an S3 Bucket Key**

Before you enable an S3 Bucket Key, note the following related changes:

**IAM or AWS KMS key policies**

If your existing AWS Identity and Access Management (IAM) policies or AWS KMS key policies use your object Amazon Resource Name (ARN) as the encryption context to refine or limit access to your KMS key, these policies won't work with an S3 Bucket Key. S3 Bucket Keys use the bucket ARN as encryption context. Before you enable an S3 Bucket Key, update your IAM policies or AWS KMS key policies to use your bucket ARN as the encryption context.

For more information about the encryption context and S3 Bucket Keys, see Encryption context.

**CloudTrail events for AWS KMS**

After you enable an S3 Bucket Key, your AWS KMS CloudTrail events log your bucket ARN instead of your object ARN. Additionally, you see fewer KMS CloudTrail events for SSE-KMS objects in your logs. Because key material is time-limited in Amazon S3, fewer requests are made to AWS KMS.

**Using an S3 Bucket Key with replication**

You can use S3 Bucket Keys with Same-Region Replication (SRR) and Cross-Region Replication (CRR).

When Amazon S3 replicates an encrypted object, it generally preserves the encryption settings of the replica object in the destination bucket. However, if the source object is not encrypted and your destination bucket uses default encryption or an S3 Bucket Key, Amazon S3 encrypts the object with the destination bucket's configuration.

The following examples illustrate how an S3 Bucket Key works with replication. For more information, see Replicating encrypted objects (SSE-C, SSE-S3, SSE-KMS, DSSE-KMS).

**Example Example 1 – Source object uses S3 Bucket Keys; destination bucket uses default encryption**

If your source object uses an S3 Bucket Key but your destination bucket uses default encryption with SSE-KMS, the replica object maintains its S3 Bucket Key encryption settings in the destination bucket. The destination bucket still uses default encryption with SSE-KMS.

**Example Example 2 – Source object is not encrypted; destination bucket uses an S3 Bucket Key with SSE-KMS**

If your source object is not encrypted and the destination bucket uses an S3 Bucket Key with SSE-KMS, the replica object is encrypted by using an S3 Bucket Key with SSE-KMS in the destination bucket. This results in the `ETag` of the source object being different from the `ETag` of the replica object. You must update applications that use the `ETag` to accommodate for this difference.

**Working with S3 Bucket Keys**

For more information about enabling and working with S3 Bucket Keys, see the following sections:

- Configuring your bucket to use an S3 Bucket Key with SSE-KMS for new objects
- Configuring an S3 Bucket Key at the object level
- Viewing the settings for an S3 Bucket Key

**Configuring your bucket to use an S3 Bucket Key with SSE-KMS for new objects**

When you configure server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS), you can configure your bucket to use an S3 Bucket Key for SSE-KMS on new objects. S3 Bucket Keys decrease the request traffic from Amazon S3 to AWS KMS and reduce the cost of SSE-KMS. For more information, see Reducing the cost of SSE-KMS with Amazon S3 Bucket Keys.

You can configure your bucket to use an S3 Bucket Key for SSE-KMS on new objects by using the Amazon S3 console, REST API, AWS SDKs, AWS Command Line Interface (AWS CLI), or AWS CloudFormation. If you want to enable or disable an S3 Bucket Key for existing objects, you can use a `CopyObject` operation. For more information, see Configuring an S3 Bucket Key at the object level and Using S3 Batch Operations to encrypt objects with S3 Bucket Keys.

When an S3 Bucket Key is enabled for the source or destination bucket, the encryption context will be the bucket Amazon Resource Name (ARN) and not the object ARN, for example, `arn:aws:s3:::`*`bucket_ARN`*. You need to update your IAM policies to use the bucket ARN for the encryption context. For more information, see S3 Bucket Keys and replication.

The following examples illustrate how an S3 Bucket Key works with replication. For more information, see Replicating encrypted objects (SSE-C, SSE-S3, SSE-KMS, DSSE-KMS).

**Prerequisites**

Before you configure your bucket to use an S3 Bucket Key, review Changes to note before enabling an S3 Bucket Key.

**Using the S3 console**

In the S3 console, you can enable or disable an S3 Bucket Key for a new or existing bucket. Objects in the S3 console inherit their S3 Bucket Key setting from the bucket configuration. When you enable an S3 Bucket Key for your bucket, new objects that you upload to the bucket use an S3 Bucket Key for SSE-KMS.

**Uploading, copying, or modifying objects in buckets that have an S3 Bucket Key enabled**

If you upload, modify, or copy an object in a bucket that has an S3 Bucket Key enabled, the S3 Bucket Key settings for that object might be updated to align with the bucket configuration.

If an object already has an S3 Bucket Key enabled, the S3 Bucket Key settings for that object don't change when you copy or modify the object. However, if you modify or copy an object that doesn't have an S3 Bucket Key enabled, and the destination bucket has an S3 Bucket Key configuration, the object inherits the destination bucket's S3 Bucket Key settings. For example, if your source object doesn't have an S3 Bucket Key enabled but the destination bucket has S3 Bucket Key enabled, an S3 Bucket Key is enabled for the object.

**To enable an S3 Bucket Key when you create a new bucket**

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Buckets**.
3. Choose **Create bucket**.
4. Enter your bucket name, and choose your AWS Region.
5. Under **Default encryption**, for **Encryption key type**, choose **AWS Key Management Service key (SSE-KMS)**.
6. Under **AWS KMS key**, do one of the following to choose your KMS key:

   - To choose from a list of available KMS keys, choose **Choose from your AWS KMS keys**, and then choose your **KMS key** from the list of available keys.

     Both the AWS managed key (`aws/s3`) and your customer managed keys appear in this list. For more information about customer managed keys, see Customer keys and AWS keys in the *AWS Key Management Service Developer Guide*.

- To enter the KMS key ARN, choose **Enter AWS KMS key ARN**, and enter your KMS key ARN in the field that appears.
- To create a new customer managed key in the AWS KMS console, choose **Create a KMS key**.

  For more information about creating an AWS KMS key, see Creating Keys in the *AWS Key Management Service Developer Guide*.

7. Under **Bucket Key**, choose **Enable**.
8. Choose **Create bucket**.

   Amazon S3 creates your bucket with an S3 Bucket Key enabled. New objects that you upload to the bucket will use an S3 Bucket Key.

   To disable an S3 Bucket Key, follow the previous steps, and choose **Disable**.

**To enable an S3 Bucket Key for an existing bucket**

1. Open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Buckets**.
3. In the **Buckets** list, choose the bucket that you want to enable an S3 Bucket Key for.
4. Choose the **Properties** tab.
5. Under **Default encryption**, choose **Edit**.
6. Under **Default encryption**, for **Encryption key type**, choose **AWS Key Management Service key (SSE-KMS)**.
7. Under **AWS KMS key**, do one of the following to choose your KMS key:

   - To choose from a list of available KMS keys, choose **Choose from your AWS KMS keys**, and then choose your **KMS key** from the list of available keys.

     Both the AWS managed key (`aws/s3`) and your customer managed keys appear in this list. For more information about customer managed keys, see Customer keys and AWS keys in the *AWS Key Management Service Developer Guide*.
   - To enter the KMS key ARN, choose **Enter AWS KMS key ARN**, and enter your KMS key ARN in the field that appears.
   - To create a new customer managed key in the AWS KMS console, choose **Create a KMS key**.

For more information about creating an AWS KMS key, see Creating Keys in the *AWS Key Management Service Developer Guide*.

8. Under **Bucket Key**, choose **Enable**.
9. Choose **Save changes**.

Amazon S3 enables an S3 Bucket Key for new objects added to your bucket. Existing objects don't use the S3 Bucket Key. To configure an S3 Bucket Key for existing objects, you can use a `CopyObject` operation. For more information, see Configuring an S3 Bucket Key at the object level .

To disable an S3 Bucket Key, follow the previous steps, and choose **Disable**.

#### Using the REST API

You can use PutBucketEncryption to enable or disable an S3 Bucket Key for your bucket. To configure an S3 Bucket Key with `PutBucketEncryption`, use the ServerSideEncryptionRule data type, which includes default encryption with SSE-KMS. You can also optionally use a customer managed key by specifying the KMS key ID for the customer managed key.

For more information and example syntax, see PutBucketEncryption.

#### Using the AWS SDK for Java

The following example enables default bucket encryption with SSE-KMS and an S3 Bucket Key by using the AWS SDK for Java.

Java

```
AmazonS3 s3client = AmazonS3ClientBuilder.standard()
    .withRegion(Regions.DEFAULT_REGION)
    .build();

ServerSideEncryptionByDefault serverSideEncryptionByDefault = new
 ServerSideEncryptionByDefault()
    .withSSEAlgorithm(SSEAlgorithm.KMS);
ServerSideEncryptionRule rule = new ServerSideEncryptionRule()
    .withApplyServerSideEncryptionByDefault(serverSideEncryptionByDefault)
    .withBucketKeyEnabled(true);
ServerSideEncryptionConfiguration serverSideEncryptionConfiguration =
```

```
    new ServerSideEncryptionConfiguration().withRules(Collections.singleton(rule));

SetBucketEncryptionRequest setBucketEncryptionRequest = new
 SetBucketEncryptionRequest()
    .withServerSideEncryptionConfiguration(serverSideEncryptionConfiguration)
    .withBucketName(bucketName);

s3client.setBucketEncryption(setBucketEncryptionRequest);
```

### Using the AWS CLI

The following example enables default bucket encryption with SSE-KMS and an S3 Bucket Key by using the AWS CLI. Replace the *`user input placeholders`* with your own information.

```
aws s3api put-bucket-encryption --bucket amzn-s3-demo-bucket --server-side-encryption-
configuration '{
        "Rules": [
            {
                "ApplyServerSideEncryptionByDefault": {
                    "SSEAlgorithm": "aws:kms",
                    "KMSMasterKeyID": "KMS-Key-ARN"
                },
                "BucketKeyEnabled": true
            }
        ]
    }'
```

### Using AWS CloudFormation

For more information about configuring an S3 Bucket Key with AWS CloudFormation, see AWS::S3::Bucket ServerSideEncryptionRule in the *AWS CloudFormation User Guide*.

### Configuring an S3 Bucket Key at the object level

When you perform a PUT or COPY operation using the REST API, AWS SDKs, or AWS CLI, you can enable or disable an S3 Bucket Key at the object level by adding the `x-amz-server-side-encryption-bucket-key-enabled` request header with a `true` or `false` value. S3 Bucket Keys reduce the cost of server-side encryption using AWS Key Management Service (AWS KMS) (SSE-KMS) by decreasing request traffic from Amazon S3 to AWS KMS. For more information, see Reducing the cost of SSE-KMS with Amazon S3 Bucket Keys.

When you configure an S3 Bucket Key for an object using a PUT or COPY operation, Amazon S3 only updates the settings for that object. The S3 Bucket Key settings for the destination bucket do not change. If you submit a PUT or COPY request for a KMS-encrypted object into a bucket with S3 Bucket Keys enabled, your object level operation will automatically use S3 Bucket Keys unless you disable the keys in the request header. If you don't specify an S3 Bucket Key for your object, Amazon S3 applies the S3 Bucket Key settings for the destination bucket to the object.

**Prerequisite:**

Before you configure your object to use an S3 Bucket Key, review Changes to note before enabling an S3 Bucket Key.

**Topics**

- Amazon S3 Batch Operations
- Using the REST API
- Using the AWS SDK for Java (PutObject)
- Using the AWS CLI (PutObject)

### Amazon S3 Batch Operations

To encrypt your existing Amazon S3 objects, you can use Amazon S3 Batch Operations. You provide S3 Batch Operations with a list of objects to operate on, and Batch Operations calls the respective API to perform the specified operation.

You can use the S3 Batch Operations Copy operation to copy existing unencrypted objects and write them back to the same bucket as encrypted objects. A single Batch Operations job can perform the specified operation on billions of objects. For more information, see Performing large-scale batch operations on Amazon S3 objects and Encrypting objects with Amazon S3 Batch Operations.

### Using the REST API

When you use SSE-KMS, you can enable an S3 Bucket Key for an object by using the following API operations:

- PutObject – When you upload an object, you can specify the `x-amz-server-side-encryption-bucket-key-enabled` request header to enable or disable an S3 Bucket Key at the object level.

- CopyObject – When you copy an object and configure SSE-KMS, you can specify the `x-amz-server-side-encryption-bucket-key-enabled` request header to enable or disable an S3 Bucket Key for your object.
- POST Object – When you use a POST operation to upload an object and configure SSE-KMS, you can use the `x-amz-server-side-encryption-bucket-key-enabled` form field to enable or disable an S3 Bucket Key for your object.
- CreateMultipartUpload – When you upload large objects by using the `CreateMultipartUpload` API operation and configure SSE-KMS, you can use the `x-amz-server-side-encryption-bucket-key-enabled` request header to enable or disable an S3 Bucket Key for your object.

To enable an S3 Bucket Key at the object level, include the `x-amz-server-side-encryption-bucket-key-enabled` request header. For more information about SSE-KMS and the REST API, see Using the REST API.

**Using the AWS SDK for Java (PutObject)**

You can use the following example to configure an S3 Bucket Key at the object level using the AWS SDK for Java.

Java

```
AmazonS3 s3client = AmazonS3ClientBuilder.standard()
    .withRegion(Regions.DEFAULT_REGION)
    .build();

String bucketName = "amzn-s3-demo-bucket1";
String keyName = "key name for object";
String contents = "file contents";

PutObjectRequest putObjectRequest = new PutObjectRequest(bucketName, keyName,
 contents)
    .withBucketKeyEnabled(true);

s3client.putObject(putObjectRequest);
```

### Using the AWS CLI (PutObject)

You can use the following AWS CLI example to configure an S3 Bucket Key at the object level as part of a `PutObject` request.

```
aws s3api put-object --bucket amzn-s3-demo-bucket --key object key name --server-side-
encryption aws:kms --bucket-key-enabled --body filepath
```

### Viewing the settings for an S3 Bucket Key

You can view the settings for an S3 Bucket Key at the bucket or object level by using the Amazon S3 console, REST API, AWS Command Line Interface (AWS CLI), or AWS SDKs.

S3 Bucket Keys decrease request traffic from Amazon S3 to AWS KMS and reduce the cost of server-side encryption using AWS Key Management Service (SSE-KMS). For more information, see Reducing the cost of SSE-KMS with Amazon S3 Bucket Keys.

To view the S3 Bucket Key settings for a bucket or an object that has inherited S3 Bucket Key settings from the bucket configuration, you need permission to perform the `s3:GetEncryptionConfiguration` action. For more information, see GetBucketEncryption in the *Amazon Simple Storage Service API Reference*.

### Using the S3 console

In the S3 console, you can view the S3 Bucket Key settings for your bucket or object. S3 Bucket Key settings are inherited from the bucket configuration unless the source objects already has an S3 Bucket Key configured.

Objects and folders in the same bucket can have different S3 Bucket Key settings. For example, if you upload an object using the REST API and enable an S3 Bucket Key for the object, the object retains its S3 Bucket Key setting in the destination bucket, even if S3 Bucket Key is disabled in the destination bucket. As another example, if you enable an S3 Bucket Key for an existing bucket, objects that are already in the bucket do not use an S3 Bucket Key. However, new objects have an S3 Bucket Key enabled.

#### To view the S3 Bucket Key setting for your bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Buckets**.

3. In the **Buckets** list, choose the bucket that you want to enable an S3 Bucket Key for.
4. Choose **Properties**.
5. In the **Default encryption** section, under **Bucket Key**, you see the S3 Bucket Key setting for your bucket.

   If you can't see the S3 Bucket Key setting, you might not have permission to perform the `s3:GetEncryptionConfiguration` action. For more information, see GetBucketEncryption in the *Amazon Simple Storage Service API Reference*.

**To view the S3 Bucket Key setting for your object**

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the **Buckets** list, choose the bucket that you want to enable an S3 Bucket Key for.
3. In the **Objects** list, choose your object name.
4. On the **Details** tab, under **Server-side encryption settings**, choose **Edit**.

   Under **Bucket Key**, you see the S3 Bucket Key setting for your object. You cannot edit this setting.

**Using the AWS CLI**

**To return bucket-level S3 Bucket Key settings**

To use this example, replace each *`user input placeholder`* with your own information.

```
aws s3api get-bucket-encryption --bucket amzn-s3-demo-bucket1
```

For more information, see get-bucket-encryption in the *AWS CLI Command Reference*.

**To return object-level S3 Bucket Key settings**

To use this example, replace each *`user input placeholder`* with your own information.

```
aws s3api head-object --bucket amzn-s3-demo-bucket1 --key my_images.tar.bz2
```

For more information, see head-object in the *AWS CLI Command Reference*.

#### Using the REST API

#### To return bucket-level S3 Bucket Key settings

To return encryption information for a bucket, including the settings for an S3 Bucket Key, use the `GetBucketEncryption` operation. S3 Bucket Key settings are returned in the response body in the `ServerSideEncryptionConfiguration` element with the `BucketKeyEnabled` setting. For more information, see GetBucketEncryption in the *Amazon S3 API Reference*.

#### To return object-level settings for an S3 Bucket Key

To return the S3 Bucket Key status for an object, use the `HeadObject` operation. `HeadObject` returns the `x-amz-server-side-encryption-bucket-key-enabled` response header to show whether an S3 Bucket Key is enabled or disabled for the object. For more information, see HeadObject in the *Amazon S3 API Reference*.

The following API operations also return the `x-amz-server-side-encryption-bucket-key-enabled` response header if an S3 Bucket Key is configured for an object:

- PutObject
- PostObject
- CopyObject
- CreateMultipartUpload
- UploadPartCopy
- UploadPart
- CompleteMultipartUpload
- GetObject

## Using dual-layer server-side encryption with AWS KMS keys (DSSE-KMS)

Using dual-layer server-side encryption with AWS Key Management Service (AWS KMS) keys (DSSE-KMS) applies two layers of encryption to objects when they are uploaded to Amazon S3. DSSE-KMS helps you more easily fulfill compliance standards that require you to apply multilayer encryption to your data and have full control of your encryption keys.

When you use DSSE-KMS with an Amazon S3 bucket, the AWS KMS keys must be in the same Region as the bucket. Also, when DSSE-KMS is requested for the object, the S3 checksum that's part of the object's metadata is stored in encrypted form. For more information about checksums, see Checking object integrity.

There are additional charges for using DSSE-KMS and AWS KMS keys. For more information about DSSE-KMS pricing, see AWS KMS key concepts in the *AWS Key Management Service Developer Guide* and AWS KMS pricing.

> **Note**
>
> S3 Bucket Keys aren't supported for DSSE-KMS.

### Requiring dual-layer server-side encryption with AWS KMS keys (DSSE-KMS)

To require dual-layer server-side encryption of all objects in a particular Amazon S3 bucket, you can use a bucket policy. For example, the following bucket policy denies the upload object (`s3:PutObject`) permission to everyone if the request does not include an `x-amz-server-side-encryption` header that requests server-side encryption with DSSE-KMS.

```
{
            "Version":"2012-10-17",
            "Id":"PutObjectPolicy",
            "Statement":[{
                  "Sid":"DenyUnEncryptedObjectUploads",
                  "Effect":"Deny",
                  "Principal":"*",
                  "Action":"s3:PutObject",
                  "Resource":"arn:aws:s3:::amzn-s3-demo-bucket1/*",
                  "Condition":{
                     "StringNotEquals":{
                        "s3:x-amz-server-side-encryption":"aws:kms:dsse"
                     }
                  }
               }
            ]
         }
```

### Topics

- Specifying dual-layer server-side encryption with AWS KMS keys (DSSE-KMS)

### Specifying dual-layer server-side encryption with AWS KMS keys (DSSE-KMS)

> **Important**
>
> Amazon S3 now applies server-side encryption with Amazon S3 managed keys (SSE-S3) as the base level of encryption for every bucket in Amazon S3. Starting January 5, 2023, all new object uploads to Amazon S3 are automatically encrypted at no additional cost and with no impact on performance. The automatic encryption status for S3 bucket default encryption configuration and for new object uploads is available in AWS CloudTrail logs, S3 Inventory, S3 Storage Lens, the Amazon S3 console, and as an additional Amazon S3 API response header in the AWS Command Line Interface and AWS SDKs. For more information, see Default encryption FAQ.

All Amazon S3 buckets have encryption configured by default, and all new objects that are uploaded to an S3 bucket are automatically encrypted at rest. Server-side encryption with Amazon S3 managed keys (SSE-S3) is the default encryption configuration for every bucket in Amazon S3. To use a different type of encryption, you can either specify the type of server-side encryption to use in your S3 PUT requests, or you can set the default encryption configuration in the destination bucket.

If you want to specify a different encryption type in your PUT requests, you can use server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS), dual-layer server-side encryption with AWS KMS keys (DSSE-KMS), or server-side encryption with customer-provided keys (SSE-C). If you want to set a different default encryption configuration in the destination bucket, you can use SSE-KMS or DSSE-KMS.

You can apply encryption when you are either uploading a new object or copying an existing object.

You can specify DSSE-KMS by using the Amazon S3 console, Amazon S3 REST API, and the AWS Command Line Interface (AWS CLI). For more information, see the following topics.

> **Note**
>
> You can use multi-Region AWS KMS keys in Amazon S3. However, Amazon S3 currently treats multi-Region keys as though they were single-Region keys, and does not use the

multi-Region features of the key. For more information, see Using multi-Region keys in *AWS Key Management Service Developer Guide*.

**Note**

If you want to use a KMS key that is owned by a different account, you must have permission to use the key. For more information about cross-account permissions for KMS keys, see Creating KMS keys that other accounts can use in the *AWS Key Management Service Developer Guide*.

### Using the S3 console

This section describes how to set or change the type of encryption of an object to use dual-layer server-side encryption with AWS Key Management Service (AWS KMS) keys (DSSE-KMS) by using the Amazon S3 console.

**Note**

- If you change an object's method of encryption, a new object is created to replace the old one. If S3 Versioning is enabled, a new version of the object is created, and the existing object becomes an older version. The role that changes the property also becomes the owner of the new object (or object version).
- If you change the encryption type for an object that has user-defined tags, you must have the `s3:GetObjectTagging` permission. If you're changing the encryption type for an object that doesn't have user-defined tags but is over 16 MB in size, you must also have the `s3:GetObjectTagging` permission.

  If the destination bucket policy denies the `s3:GetObjectTagging` action, the encryption type for the object will be updated, but the user-defined tags will be removed from the object, and you will receive an error.

### To add or change encryption for an object

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.

2. In the left navigation pane, choose **Buckets**.
3. In the **Buckets** list, choose the name of the bucket that contains the object that you want to encrypt.
4. In the **Objects** list, select the check box next to the object that you want to add or change encryption for.

   The object's details page appears, with several sections that display the properties for your object.
5. Choose the **Properties** tab.
6. Scroll down to the **Default encryption** section and choose **Edit**.

   The **Edit default encryption** page opens.
7. Under **Encryption type**, choose **Dual-layer server-side encryption with AWS Key Management Service keys (DSSE-KMS)**.
8. Under **AWS KMS key**, do one of the following to choose your KMS key:

   - To choose from a list of available KMS keys, choose **Choose from your AWS KMS keys**, and then choose your **KMS key** from the list of available keys.

     Both the AWS managed key (`aws/s3`) and your customer managed keys appear in this list. For more information about customer managed keys, see Customer keys and AWS keys in the *AWS Key Management Service Developer Guide*.
   - To enter the KMS key ARN, choose **Enter AWS KMS key ARN**, and then enter your KMS key ARN in the field that appears.
   - To create a new customer managed key in the AWS KMS console, choose **Create a KMS key**.

     For more information about creating an AWS KMS key, see Creating keys in the *AWS Key Management Service Developer Guide*.

> **Important**
>
> You can use only KMS keys that are available in the same AWS Region as the bucket. The Amazon S3 console lists only the first 100 KMS keys in the same Region as the bucket. To use a KMS key that is not listed, you must enter your KMS key ARN. If you want to use a KMS key that is owned by a different account, you must first have permission to use the key, and then you must enter the KMS key ARN.

Amazon S3 supports only symmetric encryption KMS keys, and not asymmetric KMS keys. For more information, see Identifying asymmetric KMS keys in the *AWS Key Management Service Developer Guide*.

9. For **Bucket Key**, choose **Disable**. S3 Bucket Keys aren't supported for DSSE-KMS.
10. Choose **Save changes**.

> **Note**
>
> This action applies encryption to all specified objects. When you're encrypting folders, wait for the save operation to finish before adding new objects to the folder.

### Using the REST API

When you create an object—that is, when you upload a new object or copy an existing object—you can specify the use of dual-layer server-side encryption with AWS KMS keys (DSSE-KMS) to encrypt your data. To do this, add the `x-amz-server-side-encryption` header to the request. Set the value of the header to the encryption algorithm `aws:kms:dsse`. Amazon S3 confirms that your object is stored with DSSE-KMS encryption by returning the response header `x-amz-server-side-encryption`.

If you specify the `x-amz-server-side-encryption` header with a value of `aws:kms:dsse`, you can also use the following request headers:

- `x-amz-server-side-encryption-aws-kms-key-id: SSEKMSKeyId`
- `x-amz-server-side-encryption-context: SSEKMSEncryptionContext`

### Topics

- Amazon S3 REST API operations that support DSSE-KMS
- Encryption context (x-amz-server-side-encryption-context)
- AWS KMS key ID (x-amz-server-side-encryption-aws-kms-key-id)

### Amazon S3 REST API operations that support DSSE-KMS

The following REST API operations accept the `x-amz-server-side-encryption`, `x-amz-server-side-encryption-aws-kms-key-id`, and `x-amz-server-side-encryption-context` request headers.

- PutObject – When you upload data by using the PUT API operation, you can specify these request headers.
- CopyObject – When you copy an object, you have both a source object and a target object. When you pass DSSE-KMS headers with the `CopyObject` operation, they are applied only to the target object. When you're copying an existing object, regardless of whether the source object is encrypted or not, the destination object is not encrypted unless you explicitly request server-side encryption.
- POST Object – When you use a `POST` operation to upload an object, instead of the request headers, you provide the same information in the form fields.
- CreateMultipartUpload – When you upload large objects by using a multipart upload, you can specify these headers in the `CreateMultipartUpload` request.

The response headers of the following REST API operations return the `x-amz-server-side-encryption` header when an object is stored with server-side encryption.

- PutObject
- CopyObject
- POST Object
- CreateMultipartUpload
- UploadPart
- UploadPartCopy
- CompleteMultipartUpload
- GetObject
- HeadObject

**Important**

- All GET and PUT requests for an object that's protected by AWS KMS fail if you don't make them by using Secure Sockets Layer (SSL), Transport Layer Security (TLS), or Signature Version 4.
- If your object uses DSSE-KMS, don't send encryption request headers for GET requests and HEAD requests, or you'll get an HTTP 400 (Bad Request) error.

#### Encryption context (`x-amz-server-side-encryption-context`)

If you specify `x-amz-server-side-encryption:aws:kms:dsse`, the Amazon S3 API supports an encryption context with the `x-amz-server-side-encryption-context` header. An encryption context is a set of key-value pairs that contain additional contextual information about the data.

Amazon S3 automatically uses the object's Amazon Resource Name (ARN) as the encryption context pair; for example, `arn:aws:s3:::`*`object_ARN`*.

You can optionally provide an additional encryption context pair by using the `x-amz-server-side-encryption-context` header. However, because the encryption context is not encrypted, make sure it does not include sensitive information. Amazon S3 stores this additional key pair alongside the default encryption context.

For information about the encryption context in Amazon S3, see Encryption context. For general information about the encryption context, see AWS Key Management Service Concepts - Encryption context in the *AWS Key Management Service Developer Guide*.

#### AWS KMS key ID (`x-amz-server-side-encryption-aws-kms-key-id`)

You can use the `x-amz-server-side-encryption-aws-kms-key-id` header to specify the ID of the customer managed key that's used to protect the data. If you specify the `x-amz-server-side-encryption:aws:kms:dsse` header but don't provide the `x-amz-server-side-encryption-aws-kms-key-id` header, Amazon S3 uses the AWS managed key (`aws/s3`) to protect the data. If you want to use a customer managed key, you must provide the `x-amz-server-side-encryption-aws-kms-key-id` header of the customer managed key.

> **Important**
>
> When you use an AWS KMS key for server-side encryption in Amazon S3, you must choose a symmetric encryption KMS key. Amazon S3 supports only symmetric encryption KMS keys. For more information about these keys, see Symmetric encryption KMS keys in the *AWS Key Management Service Developer Guide*.

#### Using the AWS CLI

When you upload a new object or copy an existing object, you can specify the use of DSSE-KMS to encrypt your data. To do this, add the `--server-side-encryption aws:kms:dsse` parameter to the request. Use the `--ssekms-key-id` *`example-key-id`* parameter to add your customer managed AWS KMS key that you created. If you specify `--server-side-encryption aws:kms:dsse`, but do not provide an AWS KMS key ID, then Amazon S3 will use the AWS managed key (`aws/s3`).

```
aws s3api put-object --bucket DOC-EXAMPLE-BUCKET --key example-object-key --server-
side-encryption aws:kms:dsse --ssekms-key-id example-key-id --body filepath
```

You can encrypt an unencrypted object to use DSSE-KMS by copying the object back in place.

```
aws s3api copy-object --bucket DOC-EXAMPLE-BUCKET --key example-object-key --
body filepath --bucket DOC-EXAMPLE-BUCKET --key example-object-key --sse aws:kms:dsse
 --sse-kms-key-id example-key-id --body filepath
```

## Using server-side encryption with customer-provided keys (SSE-C)

Server-side encryption is about protecting data at rest. Server-side encryption encrypts only the object data, not the object metadata. By using server-side encryption with customer-provided keys (SSE-C), you can store your data encrypted with your own encryption keys. With the encryption key that you provide as part of your request, Amazon S3 manages data encryption as it writes to disks and data decryption when you access your objects. Therefore, you don't need to maintain any code to perform data encryption and decryption. The only thing that you need to do is manage the encryption keys that you provide.

When you upload an object, Amazon S3 uses the encryption key that you provide to apply AES-256 encryption to your data. Amazon S3 then removes the encryption key from memory. When you retrieve an object, you must provide the same encryption key as part of your request. Amazon S3

first verifies that the encryption key that you provided matches, and then it decrypts the object before returning the object data to you.

There are no additional charges for using SSE-C. However, requests to configure and use SSE-C incur standard Amazon S3 request charges. For information about pricing, see Amazon S3 pricing.

> **Note**
>
> Amazon S3 does not store the encryption key that you provide. Instead, it stores a randomly salted Hash-based Message Authentication Code (HMAC) value of the encryption key to validate future requests. The salted HMAC value cannot be used to derive the value of the encryption key or to decrypt the contents of the encrypted object. That means if you lose the encryption key, you lose the object.

S3 Replication supports objects that are encrypted with SSE-C. For more information about replicating encrypted objects, see the section called "Replicating encrypted objects".

For more information about SSE-C, see the following topics.

**Topics**

- SSE-C overview
- Requiring and restricting SSE-C
- Presigned URLs and SSE-C
- Specifying server-side encryption with customer-provided keys (SSE-C)

### SSE-C overview

This section provides an overview of SSE-C. When using SSE-C, keep the following considerations in mind.

- You must use HTTPS.

> **Important**
>
> Amazon S3 rejects any requests made over HTTP when using SSE-C. For security considerations, we recommend that you consider any key that you erroneously send over HTTP to be compromised. Discard the key and rotate as appropriate.

- The entity tag (ETag) in the response is not the MD5 hash of the object data.
- You manage a mapping of which encryption key was used to encrypt which object. Amazon S3 does not store encryption keys. You are responsible for tracking which encryption key you provided for which object.
  - If your bucket is versioning-enabled, each object version that you upload by using this feature can have its own encryption key. You are responsible for tracking which encryption key was used for which object version.
  - Because you manage encryption keys on the client side, you manage any additional safeguards, such as key rotation, on the client side.

> **Warning**
>
> If you lose the encryption key, any GET request for an object without its encryption key fails, and you lose the object.

### Requiring and restricting SSE-C

To require SSE-C for all objects in a particular Amazon S3 bucket, you can use a bucket policy.

For example, the following bucket policy denies upload object (`s3:PutObject`) permissions for all requests that don't include the `x-amz-server-side-encryption-customer-algorithm` header requesting SSE-C.

```
{
    "Version": "2012-10-17",
    "Id": "PutObjectPolicy",
    "Statement": [
        {
            "Sid": "RequireSSECObjectUploads",
            "Effect": "Deny",
            "Principal": "*",
            "Action": "s3:PutObject",
            "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/*",
            "Condition": {
                "Null": {
                    "s3:x-amz-server-side-encryption-customer-algorithm": "true"
                }
            }
        }
```

```
    ]
}
```

You can also use a policy to restrict server-side encryption of all objects in a particular Amazon S3 bucket. For example, the following bucket policy denies the upload object (`s3:PutObject`) permission to everyone if the request includes the `x-amz-server-side-encryption-customer-algorithm` header requesting SSE-C.

```
{
    "Version": "2012-10-17",
    "Id": "PutObjectPolicy",
    "Statement": [
        {
            "Sid": "RestrictSSECObjectUploads",
            "Effect": "Deny",
            "Principal": "*",
            "Action": "s3:PutObject",
            "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/*",
            "Condition": {
                "Null": {
                    "s3:x-amz-server-side-encryption-customer-algorithm": "false"
                }
            }
        }
    ]
}
```

**Important**

If you use a bucket policy to require SSE-C on `s3:PutObject`, you must include the `x-amz-server-side-encryption-customer-algorithm` header in all multipart upload requests (CreateMultipartUpload, UploadPart, and CompleteMultipartUpload).

### Presigned URLs and SSE-C

You can generate a presigned URL that can be used for operations such as uploading a new object, retrieving an existing object, or retrieving object metadata. Presigned URLs support SSE-C as follows:

- When creating a presigned URL, you must specify the algorithm by using the `x-amz-server-side-encryption-customer-algorithm` header in the signature calculation.
- When using the presigned URL to upload a new object, retrieve an existing object, or retrieve only object metadata, you must provide all the encryption headers in your client application's request.

> **Note**
>
> For non-SSE-C objects, you can generate a presigned URL and directly paste that URL into a browser to access the data.
> However, you cannot do this for SSE-C objects, because in addition to the presigned URL, you also must include HTTP headers that are specific to SSE-C objects. Therefore, you can use presigned URLs for SSE-C objects only programmatically.

For more information about presigned URLs, see the section called “Working with presigned URLs”.

**Specifying server-side encryption with customer-provided keys (SSE-C)**

At the time of object creation with the REST API, you can specify server-side encryption with customer-provided keys (SSE-C). When you use SSE-C, you must provide encryption key information using the following request headers.

| Name | Description |
| --- | --- |
| `x-amz-server-side-encryption-customer-algorithm` | Use this header to specify the encryption algorithm. The header value must be `AES256`. |
| `x-amz-server-side-encryption-customer-key` | Use this header to provide the 256-bit, base64-encoded encryption key for Amazon S3 to use to encrypt or decrypt your data. |
| `x-amz-server-side-encryption-customer-key-MD5` | Use this header to provide the base64-encoded 128-bit MD5 digest of the encryption key according to RFC 1321. Amazon S3 uses this header for a message integrity check to ensure that the encryption key was transmitted without error. |

You can use AWS SDK wrapper libraries to add these headers to your request. If you need to, you can make the Amazon S3 REST API calls directly in your application.

> **Note**
>
> You cannot use the Amazon S3 console to upload an object and request SSE-C. You also cannot use the console to update (for example, change the storage class or add metadata) an existing object stored using SSE-C.

### Using the REST API

#### Amazon S3 rest APIs that support SSE-C

The following Amazon S3 APIs support server-side encryption with customer-provided encryption keys (SSE-C).

- **GET operation** – When retrieving objects using the GET API (see GET Object), you can specify the request headers.
- **HEAD operation** – To retrieve object metadata using the HEAD API (see HEAD Object), you can specify these request headers.
- **PUT operation** – When uploading data using the PUT Object API (see PUT Object), you can specify these request headers.
- **Multipart Upload** – When uploading large objects using the multipart upload API, you can specify these headers. You specify these headers in the initiate request (see Initiate Multipart Upload) and each subsequent part upload request (see Upload Part or Upload Part - Copy). For each part upload request, the encryption information must be the same as what you provided in the initiate multipart upload request.
- **POST operation** – When using a POST operation to upload an object (see POST Object), instead of the request headers, you provide the same information in the form fields.
- **Copy operation** – When you copy an object (see PUT Object - Copy), you have both a source object and a target object:
  - If you want the target object encrypted using server-side encryption with AWS managed keys, you must provide the `x-amz-server-side-encryption` request header.
  - If you want the target object encrypted using SSE-C, you must provide encryption information using the three headers described in the preceding table.

- If the source object is encrypted using SSE-C, you must provide encryption key information using the following headers so that Amazon S3 can decrypt the object for copying.

| Name | Description |
| --- | --- |
| `x-amz-copy-source-server-side-encryption-customer-algorithm` | Include this header to specify the algorithm Amazon S3 should use to decrypt the source object. This value must be AES256. |
| `x-amz-copy-source-server-side-encryption-customer-key` | Include this header to provide the base64-encoded encryption key for Amazon S3 to use to decrypt the source object. This encryption key must be the one that you provided Amazon S3 when you created the source object. Otherwise, Amazon S3 cannot decrypt the object. |
| `x-amz-copy-source-server-side-encryption-customer-key-MD5` | Include this header to provide the base64-encoded 128-bit MD5 digest of the encryption key according to RFC 1321. |

**Using the AWS SDKs to specify SSE-C for PUT, GET, Head, and Copy operations**

The following examples show how to request server-side encryption with customer-provided keys (SSE-C) for objects. The examples perform the following operations. Each operation shows how to specify SSE-C-related headers in the request:

- **Put object** – Uploads an object and requests server-side encryption using a customer-provided encryption key.
- **Get object** – Downloads the object uploaded in the previous step. In the request, you provide the same encryption information you provided when you uploaded the object. Amazon S3 needs this information to decrypt the object so that it can return it to you.
- **Get object metadata** – Retrieves the object's metadata. You provide the same encryption information used when the object was created.

- **Copy object** – Makes a copy of the previously-uploaded object. Because the source object is stored using SSE-C, you must provide its encryption information in your copy request. By default, Amazon S3 encrypts the copy of the object only if you explicitly request it. This example directs Amazon S3 to store an encrypted copy of the object.

Java

> **Note**
>
> This example shows how to upload an object in a single operation. When using the Multipart Upload API to upload large objects, you provide encryption information in the same way shown in this example. For examples of multipart uploads that use the AWS SDK for Java, see Uploading an object using multipart upload.

To add the required encryption information, you include an `SSECustomerKey` in your request. For more information about the `SSECustomerKey` class, see the REST API section.

For information about SSE-C, see Using server-side encryption with customer-provided keys (SSE-C). For instructions on creating and testing a working sample, see Getting Started in the AWS SDK for Java Developer Guide.

        while ((line = reader.readLine()) != null) {
            System.out.println(line);
        }
        System.out.println();
    }
}
```

.NET

> **Note**
>
> For examples of uploading large objects using the multipart upload API, see Uploading an object using multipart upload and Using the AWS SDKs (low-level API).

For information about SSE-C, see Using server-side encryption with customer-provided keys (SSE-C). For information about setting up and running the code examples, see Getting Started with the AWS SDK for .NET in the *AWS SDK for .NET Developer Guide*.

**Example**

```
using Amazon;
using Amazon.S3;
using Amazon.S3.Model;
using System;
using System.IO;
using System.Security.Cryptography;
using System.Threading.Tasks;

namespace Amazon.DocSamples.S3
{
    class SSEClientEncryptionKeyObjectOperationsTest
    {
        private const string bucketName = "*** bucket name ***";
```

```
        private const string keyName = "*** key name for new object created ***";
        private const string copyTargetKeyName = "*** key name for object copy ***";
        // Specify your bucket region (an example region is shown).
        private static readonly RegionEndpoint bucketRegion =
RegionEndpoint.USWest2;
        private static IAmazonS3 client;

        public static void Main()
        {
            client = new AmazonS3Client(bucketRegion);
            ObjectOpsUsingClientEncryptionKeyAsync().Wait();
        }

### Using the AWS SDKs to specify SSE-C for multipart uploads

The example in the preceding section shows how to request server-side encryption with customer-provided key (SSE-C) in the PUT, GET, Head, and Copy operations. This section describes other Amazon S3 APIs that support SSE-C.

Java

To upload large objects, you can use multipart upload API (see Uploading and copying objects using multipart upload). You can use either high-level or low-level APIs to upload large objects. These APIs support encryption-related headers in the request.

- When using the high-level `TransferManager` API, you provide the encryption-specific headers in the `PutObjectRequest` (see Uploading an object using multipart upload).
- When using the low-level API, you provide encryption-related information in the `InitiateMultipartUploadRequest`, followed by identical encryption information in each `UploadPartRequest`. You do not need to provide any encryption-specific headers in your `CompleteMultipartUploadRequest`. For examples, see Using the AWS SDKs (low-level API).

The following example uses `TransferManager` to create objects and shows how to provide SSE-C related information. The example does the following:

- Creates an object using the `TransferManager.upload()` method. In the `PutObjectRequest` instance, you provide encryption key information to request. Amazon S3 encrypts the object using the customer-provided key.
- Makes a copy of the object by calling the `TransferManager.copy()` method. The example directs Amazon S3 to encrypt the object copy using a new `SSECustomerKey`. Because the source object is encrypted using SSE-C, the `CopyObjectRequest` also provides the encryption key of the source object so that Amazon S3 can decrypt the object before copying it.

**Example**

```
import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import com.amazonaws.auth.profile.ProfileCredentialsProvider;
import com.amazonaws.regions.Regions;
import com.amazonaws.services.s3.AmazonS3;

import com.amazonaws.services.s3.model.CopyObjectRequest;
import com.amazonaws.services.s3.model.PutObjectRequest;
import com.amazonaws.services.s3.model.SSECustomerKey;
import com.amazonaws.services.s3.transfer.Copy;
import com.amazonaws.services.s3.transfer.TransferManager;
import com.amazonaws.services.s3.transfer.TransferManagerBuilder;
import com.amazonaws.services.s3.transfer.Upload;

import javax.crypto.KeyGenerator;
import java.io.File;
import java.security.SecureRandom;

public class ServerSideEncryptionCopyObjectUsingHLwithSSEC {

    public static void main(String[] args) throws Exception {
        Regions clientRegion = Regions.DEFAULT_REGION;
        String bucketName = "*** Bucket name ***";
        String fileToUpload = "*** File path ***";
        String keyName = "*** New object key name ***";
        String targetKeyName = "*** Key name for object copy ***";
```

```
        try {
            AmazonS3 s3Client = AmazonS3ClientBuilder.standard()
                    .withRegion(clientRegion)
                    .withCredentials(new ProfileCredentialsProvider())
                    .build();
            TransferManager tm = TransferManagerBuilder.standard()
                    .withS3Client(s3Client)
                    .build();

            // Create an object from a file.
            PutObjectRequest putObjectRequest = new PutObjectRequest(bucketName,
keyName, new File(fileToUpload));

            // Create an encryption key.
            KeyGenerator keyGenerator = KeyGenerator.getInstance("AES");
            keyGenerator.init(256, new SecureRandom());
            SSECustomerKey sseCustomerEncryptionKey = new
SSECustomerKey(keyGenerator.generateKey());

            // Upload the object. TransferManager uploads asynchronously, so this
call
            // returns immediately.
            putObjectRequest.setSSECustomerKey(sseCustomerEncryptionKey);
            Upload upload = tm.upload(putObjectRequest);

            // Optionally, wait for the upload to finish before continuing.
            upload.waitForCompletion();
            System.out.println("Object created.");

            // Copy the object and store the copy using SSE-C with a new key.
            CopyObjectRequest copyObjectRequest = new CopyObjectRequest(bucketName,
keyName, bucketName, targetKeyName);
            SSECustomerKey sseTargetObjectEncryptionKey = new
SSECustomerKey(keyGenerator.generateKey());
            copyObjectRequest.setSourceSSECustomerKey(sseCustomerEncryptionKey);

copyObjectRequest.setDestinationSSECustomerKey(sseTargetObjectEncryptionKey);

            // Copy the object. TransferManager copies asynchronously, so this call
returns
            // immediately.
            Copy copy = tm.copy(copyObjectRequest);
```

```
            // Optionally, wait for the upload to finish before continuing.
            copy.waitForCompletion();
            System.out.println("Copy complete.");
        } catch (AmazonServiceException e) {
            // The call was transmitted successfully, but Amazon S3 couldn't process
            // it, so it returned an error response.
            e.printStackTrace();
        } catch (SdkClientException e) {
            // Amazon S3 couldn't be contacted for a response, or the client
            // couldn't parse the response from Amazon S3.
            e.printStackTrace();
        }
    }
}
```

.NET

To upload large objects, you can use multipart upload API (see Uploading and copying objects using multipart upload). AWS SDK for .NET provides both high-level or low-level APIs to upload large objects. These APIs support encryption-related headers in the request.

- When using high-level `Transfer-Utility` API, you provide the encryption-specific headers in the `TransferUtilityUploadRequest` as shown. For code examples, see Uploading an object using multipart upload.

```
TransferUtilityUploadRequest request = new TransferUtilityUploadRequest()
{
    FilePath = filePath,
    BucketName = existingBucketName,
    Key = keyName,
    // Provide encryption information.
    ServerSideEncryptionCustomerMethod =
 ServerSideEncryptionCustomerMethod.AES256,
    ServerSideEncryptionCustomerProvidedKey = base64Key,
};
```

- When using the low-level API, you provide encryption-related information in the initiate multipart upload request, followed by identical encryption information in the subsequent upload part requests. You do not need to provide any encryption-specific headers in your complete multipart upload request. For examples, see Using the AWS SDKs (low-level API).

The following is a low-level multipart upload example that makes a copy of an existing large object. In the example, the object to be copied is stored in Amazon S3 using SSE-C, and you want to save the target object also using SSE-C. In the example, you do the following:

- Initiate a multipart upload request by providing an encryption key and related information.
- Provide source and target object encryption keys and related information in the `CopyPartRequest`.
- Obtain the size of the source object to be copied by retrieving the object metadata.
- Upload the objects in 5 MB parts.

**Example**

```
using Amazon;
using Amazon.S3;
using Amazon.S3.Model;
using System;
using System.Collections.Generic;
using System.IO;
using System.Security.Cryptography;
using System.Threading.Tasks;

                    {
                        BucketName = existingBucketName,
                        Key = sourceKeyName,
                        UploadId = initResponse.UploadId,
                        PartNumber = i,
                        PartSize = partSize,
                        FilePosition = filePosition,
                        FilePath = filePath,
                        ServerSideEncryptionCustomerMethod =
ServerSideEncryptionCustomerMethod.AES256,
                        ServerSideEncryptionCustomerProvidedKey = base64Key
                    };

                    // Upload part and add response to our list.
                    uploadResponses.Add(await
s3Client.UploadPartAsync(uploadRequest));

                    filePosition += partSize;
                }

                // Step 3: complete.
```

```
                CompleteMultipartUploadRequest completeRequest = new
 CompleteMultipartUploadRequest
                {
                    BucketName = existingBucketName,
                    Key = sourceKeyName,
                    UploadId = initResponse.UploadId,
                    //PartETags = new List<PartETag>(uploadResponses)

                };
                completeRequest.AddPartETags(uploadResponses);

                CompleteMultipartUploadResponse completeUploadResponse =
                    await s3Client.CompleteMultipartUploadAsync(completeRequest);

            }
            catch (Exception exception)
            {
                Console.WriteLine("Exception occurred: {0}", exception.Message);
                AbortMultipartUploadRequest abortMPURequest = new
 AbortMultipartUploadRequest
                {
                    BucketName = existingBucketName,
                    Key = sourceKeyName,
                    UploadId = initResponse.UploadId
                };
                await s3Client.AbortMultipartUploadAsync(abortMPURequest);
            }
        }
    }
}
```

## Protecting data by using client-side encryption

*Client-side encryption* is the act of encrypting your data locally to help ensure its security in transit and at rest. To encrypt your objects before you send them to Amazon S3, use the Amazon S3 Encryption Client. When your objects are encrypted in this manner, your objects aren't exposed to any third party, including AWS. Amazon S3 receives your objects already encrypted; Amazon S3 does not play a role in encrypting or decrypting your objects. You can use both the Amazon S3 Encryption Client and server-side encryption to encrypt your data. When you send encrypted objects to Amazon S3, Amazon S3 doesn't recognize the objects as being encrypted, it only detects typical objects.

The Amazon S3 Encryption Client works as an intermediary between you and Amazon S3. After you instantiate the Amazon S3 Encryption Client, your objects are automatically encrypted and decrypted as part of your Amazon S3 `PutObject` and `GetObject` requests. Your objects are all encrypted with a unique data key. The Amazon S3 Encryption Client does not use or interact with bucket keys, even if you specify a KMS key as your wrapping key.

The *Amazon S3 Encryption Client Developer Guide* focuses on versions 3.0 and later of the Amazon S3 Encryption Client. For more information, see What is the Amazon S3 Encryption Client? in the *Amazon S3 Encryption Client Developer Guide*.

For more information about previous versions of the Amazon S3 Encryption client, see the AWS SDK Developer Guide for your programming language.

# Internetwork traffic privacy

This topic describes how Amazon S3 secures connections from the service to other locations.

## Traffic between service and on-premises clients and applications

The following connections can be combined with AWS PrivateLink to provide connectivity between your private network and AWS:

- An AWS Site-to-Site VPN connection. For more information, see What is AWS Site-to-Site VPN?
- An AWS Direct Connect connection. For more information, see What is AWS Direct Connect?

Access to Amazon S3 via the network is through AWS published APIs. Clients must support Transport Layer Security (TLS) 1.2. We recommend TLS 1.3. Clients must also support cipher suites with Perfect Forward Secrecy (PFS), such as Ephemeral Diffie-Hellman (DHE) or Elliptic Curve Diffie-Hellman Ephemeral (ECDHE). Most modern systems such as Java 7 and later support these

modes. Additionally, you must sign requests using an access key ID and a secret access key that are associated with an IAM principal, or you can use the AWS Security Token Service (STS) to generate temporary security credentials to sign requests.

### Traffic between AWS resources in the same Region

A virtual private cloud (VPC) endpoint for Amazon S3 is a logical entity within a VPC that allows connectivity only to Amazon S3. The VPC routes requests to Amazon S3 and routes responses back to the VPC. For more information, see VPC Endpoints in the *VPC User Guide*. For example bucket policies that you can use to control S3 bucket access from VPC endpoints, see Controlling access from VPC endpoints with bucket policies.

## AWS PrivateLink for Amazon S3

With AWS PrivateLink for Amazon S3, you can provision *interface VPC endpoints* (interface endpoints) in your virtual private cloud (VPC). These endpoints are directly accessible from applications that are on premises over VPN and AWS Direct Connect, or in a different AWS Region over VPC peering.

Interface endpoints are represented by one or more elastic network interfaces (ENIs) that are assigned private IP addresses from subnets in your VPC. Requests to Amazon S3 over interface endpoints stay on the Amazon network. You can also access interface endpoints in your VPC from on-premises applications through AWS Direct Connect or AWS Virtual Private Network (AWS VPN). For more information about how to connect your VPC with your on-premises network, see the AWS Direct Connect User Guide and the AWS Site-to-Site VPN User Guide.

For general information about interface endpoints, see Interface VPC endpoints (AWS PrivateLink) in the *AWS PrivateLink Guide*.

**Topics**

- Types of VPC endpoints for Amazon S3
- Restrictions and limitations of AWS PrivateLink for Amazon S3
- Creating a VPC endpoint
- Accessing Amazon S3 interface endpoints
- Private DNS
- Accessing buckets, access points, and Amazon S3 Control API operations from S3 interface endpoints

- Updating an on-premises DNS configuration
- Creating a VPC endpoint policy for Amazon S3

## Types of VPC endpoints for Amazon S3

You can use two types of VPC endpoints to access Amazon S3: *gateway endpoints* and *interface endpoints* (by using AWS PrivateLink). A *gateway endpoint* is a gateway that you specify in your route table to access Amazon S3 from your VPC over the AWS network. *Interface endpoints* extend the functionality of gateway endpoints by using private IP addresses to route requests to Amazon S3 from within your VPC, on premises, or from a VPC in another AWS Region by using VPC peering or AWS Transit Gateway. For more information, see What is VPC peering? and Transit Gateway vs VPC peering.

Interface endpoints are compatible with gateway endpoints. If you have an existing gateway endpoint in the VPC, you can use both types of endpoints in the same VPC.

| Gateway endpoints for Amazon S3 | Interface endpoints for Amazon S3 |
|---|---|
| In both cases, your network traffic remains on the AWS network. | |
| Use Amazon S3 public IP addresses | Use private IP addresses from your VPC to access Amazon S3 |
| Use the same Amazon S3 DNS names | Require endpoint-specific Amazon S3 DNS names |
| Do not allow access from on premises | Allow access from on premises |
| Do not allow access from another AWS Region | Allow access from a VPC in another AWS Region by using VPC peering or AWS Transit Gateway |
| Not billed | Billed |

For more information about gateway endpoints, see Gateway VPC endpoints in the *AWS PrivateLink Guide*.

## Restrictions and limitations of AWS PrivateLink for Amazon S3

VPC limitations apply to AWS PrivateLink for Amazon S3. For more information, see Interface endpoint considerations and AWS PrivateLink quotas in the *AWS PrivateLink Guide*. In addition, the following restrictions apply.

AWS PrivateLink for Amazon S3 does not support the following:

- Federal Information Processing Standard (FIPS) endpoints
- Website endpoints
- Legacy global endpoints
- S3 dash Region endpoints
- Amazon S3 dual-stack endpoints
- Using CopyObject or UploadPartCopy between buckets in different AWS Regions
- Transport Layer Security (TLS) 1.1

## Creating a VPC endpoint

To create a VPC interface endpoint, see Create a VPC endpoint in the *AWS PrivateLink Guide*.

## Accessing Amazon S3 interface endpoints

When you create an interface endpoint, Amazon S3 generates two types of endpoint-specific, S3 DNS names: *Regional* and *zonal*.

- A *Regional* DNS name includes a unique VPC endpoint ID, a service identifier, the AWS Region, and `vpce.amazonaws.com` in its name. For example, for VPC endpoint ID *`vpce-1a2b3c4d`*, the DNS name generated might be similar to *`vpce-1a2b3c4d-5e6f`*`.s3.us-east-1.vpce.amazonaws.com`.
- A *Zonal* DNS name includes the Availability Zone—for example, *`vpce-1a2b3c4d-5e6f`***`-us-east-1a.`**`s3.us-east-1.vpce.amazonaws.com`. You might use this option if your architecture isolates Availability Zones. For example, you could use it for fault containment or to reduce Regional data transfer costs.

Endpoint-specific S3 DNS names can be resolved from the S3 public DNS domain.

# Private DNS

Private DNS options for VPC interface endpoints simplify routing S3 traffic over VPC endpoints and help you take advantage of the lowest-cost network path available to your application. You can use private DNS options to route Regional S3 traffic without updating your S3 clients to use the endpoint-specific DNS names of your interface endpoints, or managing DNS infrastructure. With private DNS names enabled, Regional S3 DNS queries resolve to the private IP addresses of AWS PrivateLink for the following endpoints:

- Regional bucket endpoints (for example, `s3.us-east-1.amazonaws.com`)
- Control endpoints (for example, `s3-control.us-east-1.amazonaws.com`)
- Access point endpoints (for example, `s3-accesspoint.us-east-1.amazonaws.com`)

If you have a gateway endpoint in your VPC, you can automatically route in-VPC requests over your existing S3 gateway endpoint and on-premises requests over your interface endpoint. This approach allows you to optimize your networking costs by using gateway endpoints, which are not billed, for your in-VPC traffic. Your on-premises applications can use AWS PrivateLink with the help of the inbound Resolver endpoint. Amazon provides a DNS server, called the Route 53 Resolver, for your VPC. An inbound Resolver endpoint forwards DNS queries from the on-premises network to Route 53 Resolver.

**Important**

To take advantage of the lowest cost network path when using **Enable private DNS only for inbound endpoints**, a gateway endpoint must be present in your VPC. The presence of a gateway endpoint helps ensure that in-VPC traffic always routes over the AWS private network when the **Enable private DNS only for inbound endpoints** option is selected. You must maintain this gateway endpoint while you have the **Enable private DNS only for inbound endpoints** option selected. If you want to delete your gateway endpoint you must first clear **Enable private DNS only for inbound endpoints**.

If you want to update an existing interface endpoint to **Enable private DNS only for inbound endpoints**, first confirm that your VPC has an S3 gateway endpoint. For more information about gateway endpoints and managing private DNS names, see Gateway VPC endpoints and Manage DNS names respectively in the *AWS PrivateLink Guide*.

The **Enable private DNS only for inbound endpoints** option is available only for services that support gateway endpoints.

For more information about creating a VPC endpoint that uses **Enable private DNS only for inbound endpoints**, see Create an interface endpoint in the *AWS PrivateLink Guide*.

**Using the VPC console**

In the console you have two options: **Enable DNS name** and **Enable private DNS only for inbound endpoints**. **Enable DNS name** is an option supported by AWS PrivateLink. By using the **Enable DNS name** option, you can use Amazon's private connectivity to Amazon S3, while making requests to the default public endpoint DNS names. When this option is enabled, customers can take advantage of the lowest cost network path available to their application.

When you enable private DNS names on an existing or new VPC interface endpoint for Amazon S3, the **Enable private DNS only for inbound endpoints** option is selected by default. If this option is selected, your applications use only interface endpoints for your on-premises traffic. This in-VPC traffic automatically uses the lower-cost gateway endpoints. Alternatively, you can clear **Enable private DNS only for inbound endpoints** to route all S3 requests over your interface endpoint.

**Using the AWS CLI**

If you don't specify a value for `PrivateDnsOnlyForInboundResolverEndpoint`, it will default to `true`. However, before your VPC applies your settings, it performs a check to make sure that you have a gateway endpoint present in the VPC. If a gateway endpoint is present in the VPC, the call succeeds. If not, you will see the following error message:

To set PrivateDnsOnlyForInboundResolverEndpoint to true, the VPC *`vpce_id`* must have a gateway endpoint for the service.

**For a new VPC Interface endpoint**

Use the `private-dns-enabled` and `dns-options` attributes to enable private DNS through the command line. The `PrivateDnsOnlyForInboundResolverEndpoint` option in the `dns-options` attribute must be set to `true`. Replace the *`user input placeholders`* with your own information.

```
aws ec2 create-vpc-endpoint \
--region us-east-1 \
--service-name s3-service-name \
```

```
--vpc-id client-vpc-id \
--subnet-ids client-subnet-id \
--vpc-endpoint-type Interface  \
--private-dns-enabled  \
--ip-address-type ip-address-type \
--dns-options PrivateDnsOnlyForInboundResolverEndpoint=true \
--security-group-ids client-sg-id
```

**For an existing VPC endpoint**

If you want to use private DNS for an existing VPC endpoint, use the following example command and replace the *user input placeholders* with your own information.

```
aws ec2 modify-vpc-endpoint \
--region us-east-1 \
--vpc-endpoint-id client-vpc-id \
--private-dns-enabled \
--dns-options PrivateDnsOnlyForInboundResolverEndpoint=false
```

If you want to update an existing VPC endpoint to enable private DNS only for the Inbound Resolver, use the following example and replace the sample values with your own.

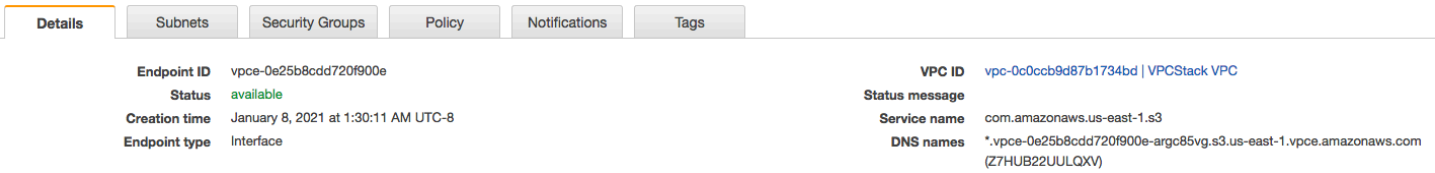
```
aws ec2 modify-vpc-endpoint \
--region us-east-1 \
--vpc-endpoint-id client-vpc-id \
--private-dns-enabled \
--dns-options PrivateDnsOnlyForInboundResolverEndpoint=true
```

## Accessing buckets, access points, and Amazon S3 Control API operations from S3 interface endpoints

You can use the AWS CLI or AWS SDKs to access buckets, S3 access points, and Amazon S3 Control API operations through S3 interface endpoints.

The following image shows the VPC console **Details** tab, where you can find the DNS name of a VPC endpoint. In this example, the *VPC endpoint ID (vpce-id)* is

vpce-0e25b8cdd720f900e and the *DNS name* is *.vpce-0e25b8cdd720f900e-argc85vg.s3.us-east-1.vpce.amazonaws.com.



When using the DNS name to access a resource, replace * with the appropriate value. The appropriate values to use in place of * are as follows:

- bucket
- accesspoint
- control

For example, to access a bucket, use a *DNS name* like this:

bucket.vpce-0e25b8cdd720f900e-argc85vg.s3.us-east-1.vpce.amazonaws.com

For examples of how to use DNS names to access buckets, access points, and Amazon S3 Control API operations, see the following sections of AWS CLI examples and AWS SDK examples.

For more information about how to view your endpoint-specific DNS names, see Viewing endpoint service private DNS name configuration in the *VPC User Guide*.

## AWS CLI examples

To access S3 buckets, S3 access points, or Amazon S3 Control API operations through S3 interface endpoints in AWS CLI commands, use the --region and --endpoint-url parameters.

**Example: Use an endpoint URL to list objects in your bucket**

In the following example, replace the bucket name *my-bucket*, Region *us-east-1*, and the DNS name of the VPC endpoint ID *vpce-1a2b3c4d-5e6f.s3.us-east-1.vpce.amazonaws.com* with your own information.

```
aws s3 ls s3://my-bucket/ --region us-east-1 --endpoint-url
 https://bucket.vpce-1a2b3c4d-5e6f.s3.us-east-1.vpce.amazonaws.com
```

**Example: Use an endpoint URL to list objects from an access point**

- **Method 1** – Using the Amazon Resource Name (ARN) of the access point with the access point endpoint

  Replace the ARN *us-east-1:123456789012:accesspoint/accesspointexamplename*, the Region *us-east-1*, and the VPC endpoint ID *vpce-1a2b3c4d-5e6f.s3.us-east-1.vpce.amazonaws.com* with your own information.

```
aws s3api list-objects-v2 --bucket arn:aws:s3:us-east-1:123456789012:accesspoint/
accesspointexamplename --region us-east-1 --endpoint-url
 https://accesspoint.vpce-1a2b3c4d-5e6f.s3.us-east-1.vpce.amazonaws.com
```

  If you can't run the command successfully, update your AWS CLI to the latest version and try again. For more information on the update instructions, see Installing or updating the latest version of the AWS CLI in the *AWS Command Line Interface User Guide*.

- **Method 2** – Using the alias of the access point with the regional bucket endpoint

  In the following example, replace the access point alias *accesspointexamplename-8tyekmigicmhun8n9kwpfur39dnw4use1a-s3alias*, the Region *us-east-1*, and the VPC endpoint ID *vpce-1a2b3c4d-5e6f.s3.us-east-1.vpce.amazonaws.com* with your own information.

```
aws s3api list-objects-v2 --
bucket accesspointexamplename-8tyekmigicmhun8n9kwpfur39dnw4use1a-s3alias
 --region us-east-1 --endpoint-url https://bucket.vpce-1a2b3c4d-5e6f.s3.us-
east-1.vpce.amazonaws.com
```

- **Method 3** – Using the alias of the access point with the access point endpoint

  First, to construct an S3 endpoint with the bucket included as part of the hostname, set the addressing style to `virtual` for `aws s3api` to use. For more information about `AWS configure`, see Configuration and credential file settings in the *AWS Command Line Interface User Guide*.

```
aws configure set default.s3.addressing_style virtual
```

  Then, in the following example, replace the access point alias *accesspointexamplename-8tyekmigicmhun8n9kwpfur39dnw4use1a-s3alias*,

the Region *us-east-1*, and the VPC endpoint ID *vpce-1a2b3c4d-5e6f.s3.us-east-1.vpce.amazonaws.com* with your own information. For more information about access point alias, see Using a bucket-style alias for your S3 bucket access point.

```
aws s3api list-objects-v2 --
bucket accesspointexamplename-8tyekmigicmhun8n9kwpfur39dnw4use1a-s3alias --
region us-east-1 --endpoint-url https://accesspoint.vpce-1a2b3c4d-5e6f.s3.us-
east-1.vpce.amazonaws.com
```

**Example: Use an endpoint URL to list jobs with an S3 control API operation**

In the following example, replace the Region *us-east-1*, the VPC endpoint ID *vpce-1a2b3c4d-5e6f.s3.us-east-1.vpce.amazonaws.com*, and the account ID *12345678* with your own information.

```
aws s3control --region us-east-1 --endpoint-url
 https://control.vpce-1a2b3c4d-5e6f.s3.us-east-1.vpce.amazonaws.com list-jobs --
account-id 12345678
```

## AWS SDK examples

To access S3 buckets, S3 access points, or Amazon S3 Control API operations through S3 interface endpoints when using the AWS SDKs, update your SDKs to the latest version. Then configure your clients to use an endpoint URL for accessing a bucket, access point, or Amazon S3 Control API operations through S3 interface endpoints.

SDK for Python (Boto3)

**Example: Use an endpoint URL to access an S3 bucket**

In the following example, replace the Region *us-east-1* and VPC endpoint ID *vpce-1a2b3c4d-5e6f.s3.us-east-1.vpce.amazonaws.com* with your own information.

```
s3_client = session.client(
service_name='s3',
region_name='us-east-1',
endpoint_url='https://bucket.vpce-1a2b3c4d-5e6f.s3.us-east-1.vpce.amazonaws.com'
)
```

**Example: Use an endpoint URL to access an S3 access point**

In the following example, replace the Region *us-east-1* and VPC endpoint ID *vpce-1a2b3c4d-5e6f.s3.us-east-1.vpce.amazonaws.com* with your own information.

```
ap_client = session.client(
service_name='s3',
region_name='us-east-1',
endpoint_url='https://accesspoint.vpce-1a2b3c4d-5e6f.s3.us-
east-1.vpce.amazonaws.com'
)
```

**Example: Use an endpoint URL to access the Amazon S3 Control API**

In the following example, replace the Region *us-east-1* and VPC endpoint ID *vpce-1a2b3c4d-5e6f.s3.us-east-1.vpce.amazonaws.com* with your own information.

```
control_client = session.client(
service_name='s3control',
region_name='us-east-1',
endpoint_url='https://control.vpce-1a2b3c4d-5e6f.s3.us-east-1.vpce.amazonaws.com'
)
```

SDK for Java 1.x

**Example: Use an endpoint URL to access an S3 bucket**

In the following example, replace the VPC endpoint ID *vpce-1a2b3c4d-5e6f.s3.us-east-1.vpce.amazonaws.com* with your own information.

```
// bucket client
final AmazonS3 s3 = AmazonS3ClientBuilder.standard().withEndpointConfiguration(
        new AwsClientBuilder.EndpointConfiguration(
                "https://bucket.vpce-1a2b3c4d-5e6f.s3.us-east-1.vpce.amazonaws.com",
                Regions.DEFAULT_REGION.getName()
        )
).build();
List<Bucket> buckets = s3.listBuckets();
```

**Example: Use an endpoint URL to access an S3 access point**

In the following example, replace the VPC endpoint ID *vpce-1a2b3c4d-5e6f.s3.us-east-1.vpce.amazonaws.com* and ARN *us-east-1:123456789012:accesspoint/prod* with your own information.

```
// accesspoint client
final AmazonS3 s3accesspoint =
 AmazonS3ClientBuilder.standard().withEndpointConfiguration(
        new AwsClientBuilder.EndpointConfiguration(
                "https://accesspoint.vpce-1a2b3c4d-5e6f.s3.us-
east-1.vpce.amazonaws.com",
                Regions.DEFAULT_REGION.getName()
        )
).build();
ObjectListing objects = s3accesspoint.listObjects("arn:aws:s3:us-
east-1:123456789012:accesspoint/prod");
```

**Example: Use an endpoint URL to access an Amazon S3 Control API operation**

In the following example, replace the VPC endpoint ID *vpce-1a2b3c4d-5e6f.s3.us-east-1.vpce.amazonaws.com* with your own information.

```
// control client
final AWSS3Control s3control =
 AWSS3ControlClient.builder().withEndpointConfiguration(
        new AwsClientBuilder.EndpointConfiguration(
                "https://control.vpce-1a2b3c4d-5e6f.s3.us-
east-1.vpce.amazonaws.com",
                Regions.DEFAULT_REGION.getName()
        )
).build();
final ListJobsResult jobs = s3control.listJobs(new ListJobsRequest());
```

SDK for Java 2.x

**Example: Use an endpoint URL to access an S3 bucket**

In the following example, replace the VPC endpoint ID *vpce-1a2b3c4d-5e6f.s3.us-east-1.vpce.amazonaws.com* and the Region *Region.US_EAST_1* with your own information.

```
// bucket client
Region region = Region.US_EAST_1;
s3Client = S3Client.builder().region(region)

 .endpointOverride(URI.create("https://bucket.vpce-1a2b3c4d-5e6f.s3.us-
east-1.vpce.amazonaws.com"))
```

```
                    .build()
```

**Example: Use an endpoint URL to access an S3 access point**

In the following example, replace the VPC endpoint ID *vpce-1a2b3c4d-5e6f.s3.us-east-1.vpce.amazonaws.com* and the Region *Region.US_EAST_1* with your own information.

```
// accesspoint client
Region region = Region.US_EAST_1;
s3Client = S3Client.builder().region(region)

 .endpointOverride(URI.create("https://accesspoint.vpce-1a2b3c4d-5e6f.s3.us-east-1.vpce.amazonaws.com"))
                    .build()
```

**Example: Use an endpoint URL to access the Amazon S3 Control API**

In the following example, replace the VPC endpoint ID *vpce-1a2b3c4d-5e6f.s3.us-east-1.vpce.amazonaws.com* and the Region *Region.US_EAST_1* with your own information.

```
// control client
Region region = Region.US_EAST_1;
s3ControlClient = S3ControlClient.builder().region(region)

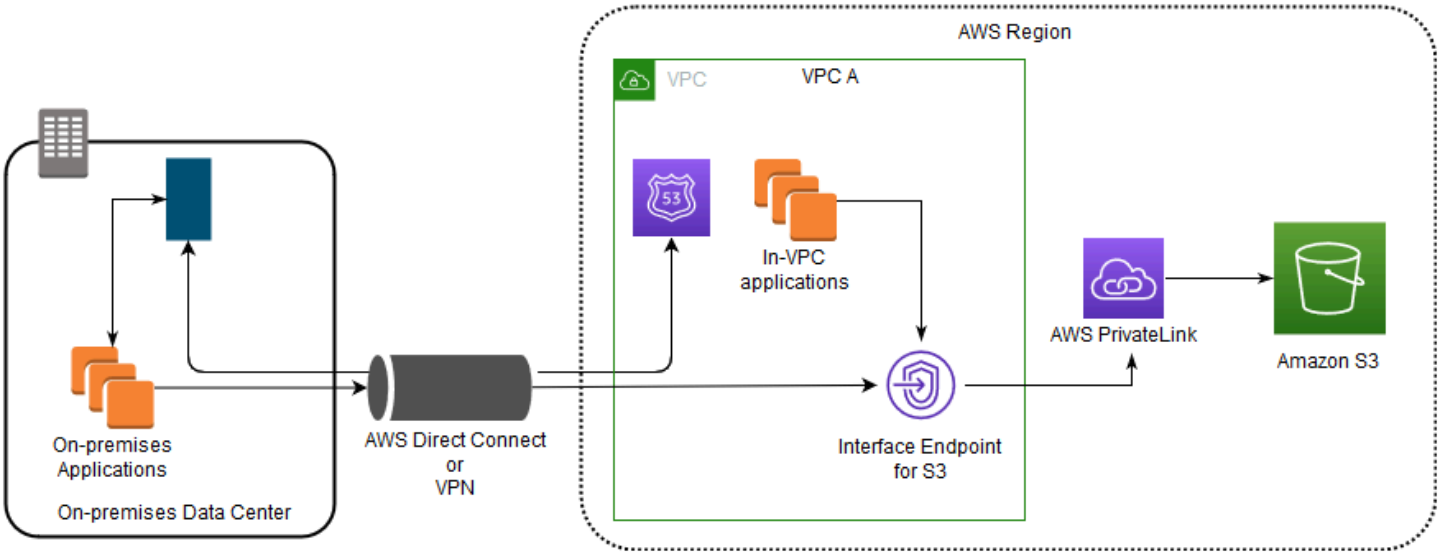
 .endpointOverride(URI.create("https://control.vpce-1a2b3c4d-5e6f.s3.us-east-1.vpce.amazonaws.com"))
                                  .build()
```

## Updating an on-premises DNS configuration

When using endpoint-specific DNS names to access the interface endpoints for Amazon S3, you don't have to update your on-premises DNS resolver. You can resolve the endpoint-specific DNS name with the private IP address of the interface endpoint from the public Amazon S3 DNS domain.

## Using interface endpoints to access Amazon S3 without a gateway endpoint or an internet gateway in the VPC

Interface endpoints in your VPC can route both in-VPC applications and on-premises applications to Amazon S3 over the Amazon network, as illustrated in the following diagram.



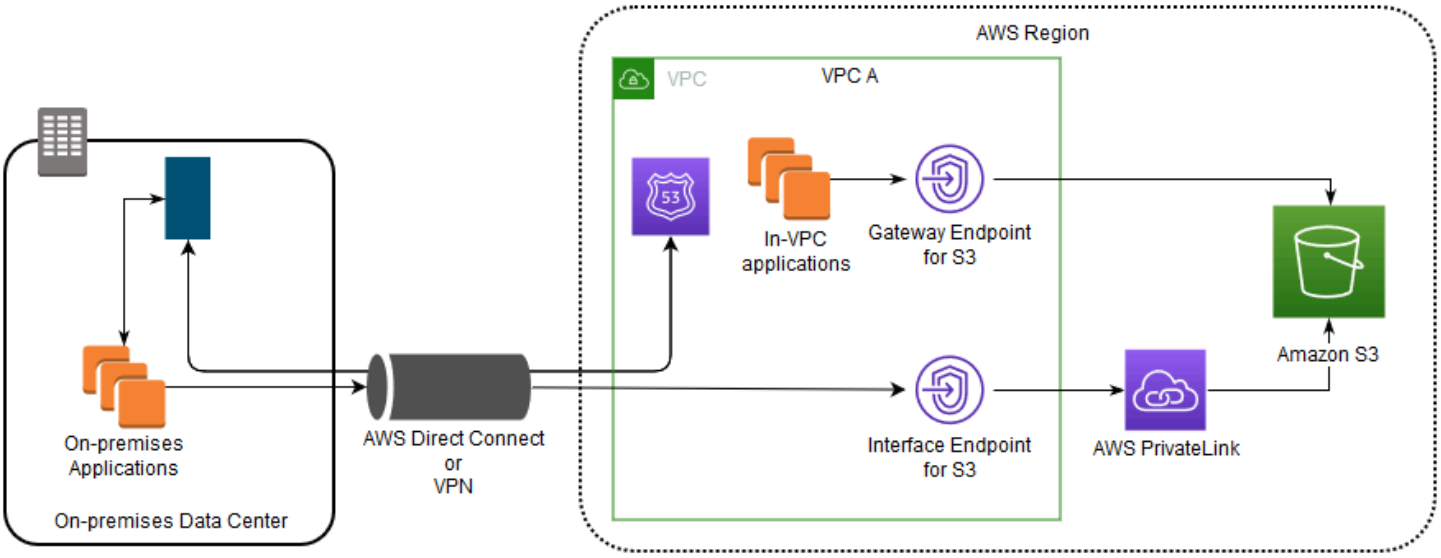
The diagram illustrates the following:

- Your on-premises network uses AWS Direct Connect or AWS VPN to connect to VPC A.
- Your applications on-premises and in VPC A use endpoint-specific DNS names to access Amazon S3 through the S3 interface endpoint.
- On-premises applications send data to the interface endpoint in the VPC through AWS Direct Connect (or AWS VPN). AWS PrivateLink moves the data from the interface endpoint to Amazon S3 over the AWS network.
- In-VPC applications also send traffic to the interface endpoint. AWS PrivateLink moves the data from the interface endpoint to Amazon S3 over the AWS network.

## Using gateway endpoints and interface endpoints together in the same VPC to access Amazon S3

You can create interface endpoints and retain the existing gateway endpoint in the same VPC, as the following diagram shows. By taking this approach, you allow in-VPC applications to continue accessing Amazon S3 through the gateway endpoint, which is not billed. Then, only your on-premises applications would use interface endpoints to access Amazon S3. To access Amazon S3

this way, you must update your on-premises applications to use endpoint-specific DNS names for Amazon S3.



The diagram illustrates the following:

- On-premises applications use endpoint-specific DNS names to send data to the interface endpoint within the VPC through AWS Direct Connect (or AWS VPN). AWS PrivateLink moves the data from the interface endpoint to Amazon S3 over the AWS network.
- Using default Regional Amazon S3 names, in-VPC applications send data to the gateway endpoint that connects to Amazon S3 over the AWS network.

For more information about gateway endpoints, see Gateway VPC endpoints in the *VPC User Guide*.

## Creating a VPC endpoint policy for Amazon S3

You can attach an endpoint policy to your VPC endpoint that controls access to Amazon S3. The policy specifies the following information:

- The AWS Identity and Access Management (IAM) principal that can perform actions
- The actions that can be performed
- The resources on which actions can be performed

You can also use Amazon S3 bucket policies to restrict access to specific buckets from a specific VPC endpoint by using the `aws:sourceVpce` condition in your bucket policy. The following examples show policies that restrict access to a bucket or to an endpoint.

**Topics**

## Example: Restricting access to a specific bucket from a VPC endpoint

You can create an endpoint policy that restricts access to only specific Amazon S3 buckets. This type of policy is useful if you have other AWS services in your VPC that use buckets. The following bucket policy restricts access to only the *amzn-s3-demo-bucket1*. To use this endpoint policy, replace *amzn-s3-demo-bucket1* with the name of your bucket.

```
{
  "Version": "2012-10-17",
  "Id": "Policy1415115909151",
  "Statement": [
    { "Sid": "Access-to-specific-bucket-only",
      "Principal": "*",
      "Action": [
        "s3:GetObject",
        "s3:PutObject"
      ],
      "Effect": "Allow",
      "Resource": ["arn:aws:s3:::amzn-s3-demo-bucket1",
                   "arn:aws:s3:::amzn-s3-demo-bucket1/*"]
    }
  ]
}
```

## Example: Restricting access to buckets in a specific account from a VPC endpoint

You can create an endpoint policy that restricts access to only the S3 buckets in a specific AWS account. To prevent clients within your VPC from accessing buckets that you don't own, use the following statement in your endpoint policy. The following example statement creates a policy that restricts access to resources owned by a single AWS account ID, *111122223333*.

```
{
  "Statement": [
    {
      "Sid": "Access-to-bucket-in-specific-account-only",
```

```
      "Principal": "*",
      "Action": [
        "s3:GetObject",
        "s3:PutObject"
      ],
      "Effect": "Deny",
      "Resource": "arn:aws:s3:::*",
      "Condition": {
        "StringNotEquals": {
          "aws:ResourceAccount": "111122223333"
        }
      }
    }
  ]
}
```

**Note**

To specify the AWS account ID of the resource being accessed, you can use either the `aws:ResourceAccount` or the `s3:ResourceAccount` key in your IAM policy. However, be aware that some AWS services rely on access to AWS managed buckets. Therefore, using the `aws:ResourceAccount` or `s3:ResourceAccount` key in your IAM policy might also affect access to these resources.

## Example: Restricting access to a specific VPC endpoint in the S3 bucket policy

### Example: Restricting access to a specific VPC endpoint in the S3 bucket policy

The following Amazon S3 bucket policy allows access to a specific bucket, *amzn-s3-demo-bucket2*, from only the VPC endpoint *vpce-1a2b3c4d*. The policy denies all access to the bucket if the specified endpoint is not being used. The `aws:sourceVpce` condition specifies the endpoint and doesn't require an Amazon Resource Name (ARN) for the VPC endpoint resource, only the endpoint ID. To use this bucket policy, replace *amzn-s3-demo-bucket2* and *vpce-1a2b3c4d* with your bucket name and endpoint.

**Important**

- When applying the following Amazon S3 bucket policy to restrict access to only certain VPC endpoints, you might block your access to the bucket without intending to do

so. Bucket policies that are intended to specifically limit bucket access to connections originating from your VPC endpoint can block all connections to the bucket. For information about how to fix this issue, see My bucket policy has the wrong VPC or VPC endpoint ID. How can I fix the policy so that I can access the bucket? in the *AWS Support Knowledge Center*.

- Before using the following example policy, replace the VPC endpoint ID with an appropriate value for your use case. Otherwise, you won't be able to access your bucket.
- This policy disables *console* access to the specified bucket, because console requests don't originate from the specified VPC endpoint.

```
{
  "Version": "2012-10-17",
  "Id": "Policy1415115909152",
  "Statement": [
    { "Sid": "Access-to-specific-VPCE-only",
      "Principal": "*",
      "Action": "s3:*",
      "Effect": "Deny",
      "Resource": ["arn:aws:s3:::amzn-s3-demo-bucket2",
                   "arn:aws:s3:::amzn-s3-demo-bucket2/*"],
      "Condition": {"StringNotEquals": {"aws:sourceVpce": "vpce-1a2b3c4d"}}
    }
  ]
}
```

For more policy examples, see Endpoints for Amazon S3 in the *VPC User Guide*.

For more information about VPC connectivity, see Network-to-VPC connectivity options in the AWS whitepaper Amazon Virtual Private Cloud Connectivity Options.

## Access Management

In AWS, a resource is an entity that you can work with. In Amazon Simple Storage Service (S3), *buckets* and *objects* are the original Amazon S3 resources. Every S3 customer likely has buckets with objects in them. As new features were added to S3, additional resources were also added, but not every customer uses these feature-specific resources. For more information about Amazon S3 resources, see S3 resources.

By default, all Amazon S3 resources are private. By default, the root user of the AWS account that created the resource (resource owner) and IAM users within that account with the necessary permissions can access a resource that they created. The resource owner decides who else can access the resource and the actions that others are allowed to perform on the resource. S3 has various access management tools that you can use to grant others access to your S3 resources.

The following sections provide you with an overview of S3 resources, the S3 access management tools available, and the best use cases for each access management tool. The lists in these sections aim to be comprehensive and include all S3 resources, access management tools, and common access management use cases. At the same time, these sections are designed to be directories that lead you to the technical details you want. If you have a good understanding of some of the following topics, you can skip to the section that applies to you.

**Topics**

## S3 resources

The original Amazon S3 resources are buckets and the objects that they contain. As new features are added to S3, new resources are also added. The following is a complete list of S3 resources and their respective features.

| Resource type | Amazon S3 feature | Description |
| --- | --- | --- |
| `bucket` | Core features | A bucket is a container for objects. To store an object in S3, create a bucket and then upload one or more objects to the bucket. For more information, see Creating, configuring, and working with Amazon S3 buckets. |

| Resource type | Amazon S3 feature | Description |
| --- | --- | --- |
| `object` | | An object can be a file and any metadata that describes that file. When an object is in the bucket, you can open it, download it, and move it. For more information, see Uploading, downloading, and working with objects in Amazon S3. |
| `accesspoint` | Access Points | Access Points are named network endpoints that are attached to buckets that you can use to perform Amazon S3 **object** operations, such as `GetObject` and `PutObject`. Each access point has distinct permissions, network controls, and a customized *access point policy* that works in conjunction with the bucket policy that is attached to the underlying bucket. You can configure any access point to accept requests only from a virtual private cloud (VPC) or configure custom block public access settings for each access point. For more information, see Managing data access with Amazon S3 access points. |
| `objectlambdaaccesspoint` | | An Object Lambda Access Point is an access point for a bucket that is also associated with a Lambda function. With Object Lambda Access Point, you can add your own code to Amazon S3 `GET`, `LIST`, and `HEAD` requests to modify and process data as it's returned to an application. For more information, see Creating Object Lambda Access Points. |

| Resource type | Amazon S3 feature | Description |
| --- | --- | --- |
| `multiregionaccesspoint` | | Multi-Region Access Points provide a global endpoint that applications can use to fulfill requests from Amazon S3 buckets that are located in multiple AWS Regions. You can use Multi-Region Access Points to build multi-Region applications with the same architecture that's used in a single Region, and then run those applications anywhere in the world. Instead of sending requests over the congested public internet, application requests made to a Multi-Region Access Point global endpoint automatically route through the AWS global network to the closest proximity Amazon S3 bucket. For more information, see Multi-Region Access Points in Amazon S3. |
| `job` | S3 Batch Operations | A job is a resource of the S3 Batch Operations feature. You can use S3 Batch Operations to perform large-scale batch operations on lists of Amazon S3 objects that you specify. Amazon S3 tracks the progress of the batch operation job, sends notifications, and stores a detailed completion report of all actions, providing you with a fully managed, auditable, and serverless experience. For more information, see Performing large-scale batch operations on Amazon S3 objects. |
| `storagelensconfiguration` | S3 Storage Lens | An S3 Storage Lens configuration collects organization-wide storage metrics and user data across accounts. S3 Storage Lens provides admins with a single view of object storage usage and activity across hundreds, or even thousands, of accounts in an organization, with details to generate insights at multiple aggregation levels. For more information, see Assessing your storage activity and usage with Amazon S3 Storage Lens. |

| Resource type | Amazon S3 feature | Description |
| --- | --- | --- |
| `storagelensgroup` | | An S3 Storage Lens group aggregates metrics by using custom filters based on object metadata. S3 Storage Lens groups help you investigate characteristics of your data, such as distribution of objects by age, your most common file types, and more. For more information, see Working with S3 Storage Lens groups. |
| `accessgrantsinstance` | S3 Access Grants | An S3 Access Grants instance is a container for the S3 grants that you create. With S3 Access Grants, you can create grants to your Amazon S3 data for IAM identities within your account, IAM identities in other accounts (cross-account), and directory identities added to AWS IAM Identity Center from your corporate directory. For more information about S3 Access Grants, see Managing access with S3 Access Grants. |
| `accessgrantslocation` | | An Access Grants Location is a bucket, prefix within a bucket, or an object that you register in your S3 Access Grants instance. You must register locations within the S3 Access Grants instance before you can create a grant to that location. Then, with S3 Access Grants, you can grant access to the bucket, prefix, or object for IAM identities within your account, IAM identities in other accounts (cross-account), and directory identities added to AWS IAM Identity Center from your corporate directory. For more information about S3 Access Grants, see Managing access with S3 Access Grants |

| Resource type | Amazon S3 feature | Description |
| --- | --- | --- |
| `accessgrant` | | An Access Grant is an individual grant to your Amazon S3 data. With S3 Access Grants, you can create grants to your Amazon S3 data for IAM identities within your account, IAM identities in other accounts (cross-account), and directory identities added to AWS IAM Identity Center from your corporate directory. For more information about S3 Access Grants, see Managing access with S3 Access Grants |

### Buckets

There are two types of Amazon S3 buckets: *general purpose buckets* and *directory buckets*.

- **General purpose buckets** are the original S3 bucket type and are recommended for most use cases and access patterns. General purpose buckets also allow objects that are stored across all storage classes, except S3 Express One Zone. For more information about S3 storage classes, see Using Amazon S3 storage classes.
- **Directory buckets** use the S3 Express One Zone storage class, which is recommended if your application is performance-sensitive and benefits from single-digit millisecond PUT and GET latencies. For more information, see Directory buckets, What is S3 Express One Zone?, and AWS Identity and Access Management (IAM) for S3 Express One Zone.

### Categorizing S3 resources

Amazon S3 provides features to categorize and organize your S3 resources. Categorizing your resources is not only useful for organizing them, but you can also set access management rules based on the resource categories. In particular, prefixes and tagging are two storage organization features that you can use when setting access management permissions.

> **Note**
>
> The following information applies to general purpose buckets. Directory buckets do not support tagging, and they have prefix limitations. For more information, see AWS Identity and Access Management (IAM) for S3 Express One Zone.

- **Prefixes** — A prefix in Amazon S3 is a string of characters at the beginning of an object key name that's used to organize the objects that are stored in your S3 buckets. You can use a delimiter character, such as a forward slash (/), to indicate the end of the prefix within the object key name. For example, you might have object key names that start with the `engineering/` prefix or object key names that start with the `marketing/campaigns/` prefix. Using a delimeter at the end of your prefix, such as as a forward slash character / emulates folder and file naming conventions. However, in S3, the prefix is part of the object key name. In general purpose S3 buckets, there is no actual folder hierarchy.

  Amazon S3 supports organizing and grouping objects by using their prefixes. You can also manage access to objects by their prefixes. For example, you can limit access to only the objects with names that start with a specific prefix.

  For more information, see Organizing objects using prefixes. S3 Console uses the concept of *folders*, which, in general purpose buckets, are essentially prefixes that are pre-pended to the object key name. For more information, see Organizing objects in the Amazon S3 console by using folders.

- **Tags** — Each tag is a key-value pair that you assign to resources. For example, you can tag some resources with the tag `topicCategory=engineering`. You can use tagging to help with cost allocation, categorizing and organizing, and access control. Bucket tagging is only used for cost allocation. You can tag objects, S3 Storage Lens, jobs, and S3 Access Grants for the purposes of organizing or for access control. In S3 Access Grants, you can also use tagging for cost-allocation. As an example of controlling access to resources by using their tags, you can share only the objects that have a specific tag or a combination of tags.

  For more information, see Controlling access to AWS resources by using resource tags in the *IAM User Guide*.

## Identities

In Amazon S3, the resource owner is the identity that created the resource, such as a bucket or an object. By default, only the root user of the account that created the resource and IAM identities within the account that have the required permission can access the S3 resource. Resource owners can give other identities access to their S3 resources.

Identities that don't own a resource can request access to that resource. Requests to a resource are either authenticated or unauthenticated. Authenticated requests must include a signature value

that authenticates the request sender, but unauthenticated requests do not require a signature. We recommend that you grant access only to authenticated users. For more information about request authentication, see Making requests.

> **Important**
>
> We recommend that you don't use the AWS account root user credentials to make authenticated requests. Instead, create an IAM role and grant that role full access. We refer to users with this role as *administrator users*. You can use credentials assigned to the administrator role, instead of AWS account root user credentials, to interact with AWS and perform tasks, such as create a bucket, create users, and grant permissions. For more information, see AWS account root user credentials and IAM user credentials in the *AWS General Reference*, and see Security best practices in IAM in the *IAM User Guide*.

Identities accessing your data in Amazon S3 can be one of the following:

**AWS account owner**

The AWS account that created the resource. For example, the account that created the bucket. This account owns the resource. For more information, see AWS account root user.

**IAM identities in the same account of the AWS account owner**

When setting up accounts for new team members who require S3 access, the AWS account owner can use AWS Identity and Access Management (IAM) to create users, groups, and roles. The AWS account owner can then share resources with these IAM identities. The account owner can also specify the permissions to give the IAM identities, which allow or deny the actions that can be performed on the shared resources.

IAM identities provide increased capabilities, including the ability to require users to enter login credentials before accessing shared resources. By using IAM identities, you can implement a form of IAM multi-factor authentication (MFA) to support a strong identity foundation. An IAM best practice is to create roles for access management instead of granting permissions to each individual user. You assign individual users to the appropriate role. For more information, see Security best practices in IAM.

**Other AWS account owners and their IAM identities (cross-account access)**

The AWS account owner can also give other AWS account owners, or IAM identities that belong to another AWS account, access to resources.

> **Note**
>
> **Permission delegation** — If an AWS account owns a resource, it can grant those permissions to another AWS account. That account can then delegate those permissions, or a subset of them, to users in the same account. This is referred to as permission delegation. But an account that receives permissions from another account cannot delegate those permissions "cross-account" to another AWS account.

#### Anonymous users (public access)

The AWS account owner can make resources public. Making a resource public technically shares the resource with *the anonymous user*. Buckets created since April 2023 block all public access by default, unless you change this setting. We recommend that you set your buckets to block public access, and that you only grant access to authenticated users. For more information about blocking public access, see Blocking public access to your Amazon S3 storage.

#### AWS services

The resource owner can grant another AWS service access to an Amazon S3 resource. For example, you can grant the AWS CloudTrail service `s3:PutObject` permission to write log files to your bucket. For more information, see Providing access to an AWS service.

#### Corporate directory identities

The resource owner can grant users or roles from your corporate directory access to an S3 resource by using S3 Access Grants. For more information about adding your corporate directory to AWS IAM Identity Center, see What is IAM Identity Center?.

### Bucket or resource owners

The AWS account that you use to create buckets and upload objects owns those resources. A bucket owner can grant cross-account permissions to another AWS account (or users in another account) to upload objects.

When a bucket owner permits another account to upload objects to a bucket, the bucket owner, by default, owns all objects uploaded to their bucket. However, if both the *Bucket owner enforced* and

*Bucket owner preferred* bucket settings are turned off, the AWS account that uploads the objects owns those objects, and the bucket owner does not have permissions on the objects owned by another account, with the following exceptions:

- The bucket owner pays the bills. The bucket owner can deny access to any objects, or delete any objects in the bucket, regardless of who owns them.
- The bucket owner can archive any objects or restore archived objects, regardless of who owns them. Archival refers to the storage class used to store the objects. For more information, see Managing your storage lifecycle.

## Access management tools

Amazon S3 provides a variety of security features and tools. The following is a comprehensive list of these features and tools. You do not need all of these access management tools, but you must use one or more to grant access to your Amazon S3 resources. Proper application of these tools can help make sure that your resources are accessible only to the intended users.

The most commonly used access management tool is an *access policy*. An access policy can be a *resource-based policy* that is attached to an AWS resource, such as a bucket policy for a bucket. An access policy can also be an *identity-based policy* that is attached to an AWS Identity and Access Management (IAM) identity, such as an IAM user, group, or role. Write an access policy to grant AWS accounts and IAM users, groups, and roles permission to perform operations on a resource. For example, you can grant `PUT Object` permission to another AWS account so that the other account can upload objects to your bucket.

An access policy describes who has access to what things. When Amazon S3 receives a request, it must evaluate all of the access policies to determine whether to authorize or deny the request. For more information about how Amazon S3 evaluates these policies, see How Amazon S3 authorizes a request.

The following are the access management tools available in Amazon S3.

**Bucket policy**

An Amazon S3 bucket policy is a JSON-formatted AWS Identity and Access Management (IAM) resource-based policy that is attached to a particular bucket. Use bucket policies to grant other AWS accounts or IAM identities permissions for the bucket and the objects in it. Many S3 access management use cases can be met by using a bucket policy. With bucket policies, you can personalize bucket access to help make sure that only the identities that you have approved can

access resources and perform actions within them. For more information, see Bucket policies for Amazon S3.

The following is an example bucket policy. You express the bucket policy by using a JSON file. This example policy grants an IAM role read permission to all objects in the bucket. It contains one statement named `BucketLevelReadPermissions`, which allows the `s3:GetObject` action (read permission) on objects in a bucket named `amzn-s3-demo-bucket1`. By specifying an IAM role as the `Principal`, this policy grants access to any IAM user with this role. To use this example policy, replace the *`user input placeholders`* with your own information.

```
{
  "Version":"2012-10-17",
  "Statement": [
    {
      "Sid":"BucketLevelReadPermissions",
      "Effect":"Allow",
      "Principal": {
     "AWS": "arn:aws:iam::123456789101:role/s3-role"
      },
      "Action":["s3:GetObject"],
      "Resource":["arn:aws:s3:::amzn-s3-demo-bucket1/*"]
    }]
  }
```

**Note**

When creating policies, avoid the use of wildcard characters (*) in the `Principal` element because using a wildcard character allows anyone to access your Amazon S3 resources. Instead, explicitly list users or groups that are allowed to access the bucket, or list conditions that must be met by using a condition clause in the policy. Also, rather than including a wildcard character for the actions of your users or groups, grant them specific permissions when applicable.

### Identity-based policy

An identity-based or IAM user policy is a type of AWS Identity and Access Management (IAM) policy. An identity-based policy is a JSON-formatted policy that is attached to IAM users, groups, or roles in your AWS account. You can use identity-based policies to grant an IAM identity access to your buckets or objects. You can create IAM users, groups, and roles in your account and

attach access policies to them. You can then grant access to AWS resources, including Amazon S3 resources. For more information, see Identity-based policies for Amazon S3.

The following is an example of an identity-based policy. The example policy allows the associated IAM role to perform six different Amazon S3 actions (permissions) on a bucket and the objects in it. If you attach this policy to an IAM role in your account and assign the role to some of your IAM users, the users with this role will be able to perform these actions on the resources (buckets) specified in your policy. To use this example policy, replace the *user input placeholders* with your own information.

```
{
  "Version": "2012-10-17",
  "Statement": [
  {
    "Sid": "AssignARoleActions",
    "Effect": "Allow",
    "Action": [
   "s3:PutObject",
   "s3:GetObject",
   "s3:ListBucket",
   "s3:DeleteObject",
   "s3:GetBucketLocation"
    ],
    "Resource": [
   "arn:aws:s3:::amzn-s3-demo-bucket1/*",
   "arn:aws:s3:::amzn-s3-demo-bucket1"
    ]
    },
  {
    "Sid": "AssignARoleActions2",
    "Effect": "Allow",
    "Action": "s3:ListAllMyBuckets",
    "Resource": "*"
  }
  ]
}
```

### S3 Access Grants

Use S3 Access Grants to create access grants to your Amazon S3 data for both identities in corporate identity directories, such as Active Directory, and to AWS Identity and Access Management (IAM) identities. S3 Access Grants helps you manage data permissions at scale.

Additionally, S3 Access Grants logs end-user identity and the application used to access the S3 data in AWS CloudTrail. This provides a detailed audit history down to the end-user identity for all access to the data in your S3 buckets. For more information, see Managing access with S3 Access Grants.

**Access Points**

Amazon S3 Access Points simplifies managing data access at scale for applications that use shared datasets on S3. Access Points are named network endpoints that are attached to a bucket. You can use access points to perform S3 object operations at scale, such as uploading and retrieving objects. A bucket can have up to 10,000 access points attached, and for each access point, you can enforce distinct permissions and network controls to give you detailed control over access to your S3 objects. S3 Access Points can be associated with buckets in the same account or in another trusted account. Access Points policies are resource-based policies that are evaluated in conjunction with the underlying bucket policy. For more information, see Managing data access with Amazon S3 access points.

**Access control list (ACL)**

An ACL is a list of grants identifying the grantee and the permission granted. ACLs grant basic read or write permissions to other AWS accounts. ACLs use an Amazon S3–specific XML schema. An ACL is a type of AWS Identity and Access Management (IAM) policy. An object ACL is used to manage access to an object, and a bucket ACL is used to manage access to a bucket. With bucket policies, there is a single policy for the entire bucket, but object ACLs are specified for each object. We recommend that you keep ACLs turned off, except in unusual circumstances where you must individually control access for each object. For more information about using ACLs, see Controlling ownership of objects and disabling ACLs for your bucket.

> **Warning**
>
> The majority of modern use cases in Amazon S3 do not require the use of ACLs.

The following is an example bucket ACL. The grant in the ACL shows a bucket owner that has full control permission.

```
<?xml version="1.0" encoding="UTF-8"?>
 <AccessControlPolicy xmlns="http://s3.amazonaws.com/doc/2006-03-01/">
  <Owner>
```

```
   <ID>Owner-Canonical-User-ID</ID>
   <DisplayName>owner-display-name</DisplayName>
  </Owner>
 <AccessControlList>
  <Grant>
   <Grantee xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" xsi:type="Canonical
 User">
    <ID>Owner-Canonical-User-ID</ID>
    <DisplayName>display-name</DisplayName>
   </Grantee>
   <Permission>FULL_CONTROL</Permission>
  </Grant>
 </AccessControlList>
</AccessControlPolicy>
```

### Object Ownership

To manage access to your objects, you must be the owner of the object. You can use the Object Ownership bucket-level setting to control ownership of objects uploaded to your bucket. Also, use Object Ownership to turn on ACLs. By default, Object Ownership is set to the *Bucket owner enforced setting* and all ACLs are turned off. When ACLs are turned off, the bucket owner owns all of the objects in the bucket and exclusively manages access to data. To manage access, the bucket owner uses policies or another access management tool, excluding ACLs. For more information, see Controlling ownership of objects and disabling ACLs for your bucket.

Object Ownership has three settings that you can use both to control ownership of objects that are uploaded to your bucket and to turn on ACLs:

#### ACLs turned off

- **Bucket owner enforced (default)** – ACLs are turned off, and the bucket owner automatically owns and has full control over every object in the bucket. ACLs do not affect permissions to data in the S3 bucket. The bucket uses policies exclusively to define access control.

#### ACLs turned on

- **Bucket owner preferred** – The bucket owner owns and has full control over new objects that other accounts write to the bucket with the `bucket-owner-full-control` canned ACL.
- **Object writer** – The AWS account that uploads an object owns the object, has full control over it, and can grant other users access to it through ACLs.

### Additional best practices

Consider using the following bucket settings and tools to help protect data in transit and at rest, both of which are crucial in maintaining the integrity and accessibility of your data:

- **Block Public Access** — Do not turn off the default bucket-level setting *Block Public Access*. This setting blocks public access to your data by default. For more information about blocking public access, see Blocking public access to your Amazon S3 storage.
- **S3 Versioning** — For data integrity, you can implement the S3 Versioning bucket setting, which versions your objects as you make updates, instead of overwriting them. You can use S3 Versioning to preserve, retrieve, and restore a previous version, if needed. For information about S3 Versioning, see Using versioning in S3 buckets.
- **S3 Object Lock** — S3 Object Lock is another setting that you can implement for achieving data integrity. This feature can implement a write-once-read-many (WORM) model to store objects immutably. For information about Object Lock, see Using S3 Object Lock.
- **Object encryption** — Amazon S3 offers several object encryption options that protect data in transit and at rest. *Server-side encryption* encrypts your object before saving it on disks in its data centers and then decrypts it when you download the objects. If you authenticate your request and you have access permissions, there is no difference in the way you access encrypted or unencrypted objects. For more information, see Protecting data with server-side encryption. S3 encrypts newly uploaded objects by default. For more information, see Setting default server-side encryption behavior for Amazon S3 buckets. *Client-side encryption* is the act of encrypting data before sending it to Amazon S3. For more information, see Protecting data by using client-side encryption.
- **Signing methods** — Signature Version 4 is the process of adding authentication information to AWS requests sent by HTTP. For security, most requests to AWS must be signed with an access key, which consists of an access key ID and secret access key. These two keys are commonly referred to as your security credentials. For more information, see Authenticating Requests (AWS Signature Version 4) and Signature Version 4 signing process.

## Actions

For a complete list of S3 permissions and condition keys, see Actions, resources, and condition keys for Amazon S3 in the *Service Authorization Reference*.

### Actions

The AWS Identity and Access Management (IAM) actions for Amazon S3 are the possible actions that can be performed on an S3 bucket or object. You grant these actions to identities so they can act on your S3 resources. Examples of S3 actions are `s3:GetObject` to read objects in a bucket, and `s3:PutObject` to write objects to a bucket.

**Condition keys**

In addition to actions, IAM condition keys are limited to granting access to only when a condition is met. Condition keys are optional.

> **Note**
>
> In a resource-based access policy, such as a bucket policy, or in an identity-based policy, you can specify the following:
>
> - An action or an array of actions in the `Action` element of the policy statement.
> - In the `Effect` element of the policy statement, you can specify `Allow` to grant the actions listed, or you can specify `Deny` to block the listed actions. To further maintain the practice of least privileges, `Deny` statements in the `Effect` element of the access policy should be as broad as possible, and `Allow` statements should be as narrow as possible. `Deny` effects paired with the `s3:*` action are another good way to implement opt-in best practices for the identities that are included in policy condition statements.
> - A condition key in the `Condition` element of a policy statement.

## Access management use cases

Amazon S3 provides resource owners with a variety of tools for granting access. The S3 access management tool that you use depends on the S3 resources that you want to share, the identities that you are granting access to, and the actions that you want to allow or deny. You might want to use one or a combination of S3 access management tools to manage access to your S3 resources.

In most cases, you can use an access policy to manage permissions. An access policy can be a resource-based policy, which is attached to a resource, such as a bucket, or another Amazon S3 resource (S3 resources). An access policy can also be an identity-based policy, which is attached to an AWS Identity and Access Management (IAM) user, group, or role in your account. You might find that a bucket policy works better for your use case. For more information, see Bucket policies for

Amazon S3. Alternatively, with AWS Identity and Access Management (IAM), you can create IAM users, groups, and roles within your AWS account and manage their access to buckets and objects through identity-based policies. For more information, see Identity-based policies for Amazon S3.

To help you navigate these access management options, the following are common Amazon S3 customer use cases and recommendations for each of the S3 access management tools.

**The AWS account owner wants to share buckets only with users within the same account**

All access management tools can fulfill this basic use case. We recommend the following access management tools for this use case:

- **Bucket policy** – If you want to grant access to one bucket or a small number of buckets, or if your bucket access permissions are similar from bucket to bucket, use a bucket policy. With bucket policies, you manage one policy for each bucket. For more information, see Bucket policies for Amazon S3.
- **Identity-based policy** – If you have a very large number of buckets with different access permissions for each bucket, and only a few user roles to manage, you can use an IAM policy for users, groups, or roles. IAM policies are also a good option if you are managing user access to other AWS resources, as well as Amazon S3 resources. For more information, see Example 1: Bucket owner granting its users bucket permissions.
- **S3 Access Grants** – You can use S3 Access Grants to grant access to your S3 buckets, prefixes, or objects. S3 Access Grants allows you to specify varying object-level permissions at scale; whereas, bucket policies are limited to 20 KB in size. For more information, see Getting started with S3 Access Grants.
- **Access Points** – You can use Access Points, which are named network endpoints that are attached to a bucket. A bucket can have up to 10,000 access points attached, and for each access point you can enforce distinct permissions and network controls to give you detailed control over access to your S3 objects. For more information, see Managing data access with Amazon S3 access points.

**The AWS account owner wants to share buckets or objects with users from another AWS account (cross-account)**

To grant permission to another AWS account, you must use a bucket policy or one of the following recommended access management tools. You cannot use an identity-based access policy for this use case. For more information about granting cross-account access, see How do I provide cross-account access to objects that are in Amazon S3 buckets?

We recommend the following access management tools for this use case:

- **Bucket policy** – With bucket policies, you manage one policy for each bucket. For more information, see Bucket policies for Amazon S3.
- **S3 Access Grants** – You can use S3 Access Grants to grant cross-account permissions to your S3 buckets, prefixes, or objects. You can use S3 Access Grants to specify varying object-level permissions at scale; whereas, bucket policies are limited to 20 KB in size. For more information, see Getting started with S3 Access Grants.
- **Access Points** – You can use Access Points, which are named network endpoints that are attached to a bucket. A bucket can have up to 10,000 access points attached, and for each access point you can enforce distinct permissions and network controls to give you detailed control over access to your S3 objects. For more information, see Managing data access with Amazon S3 access points.

**The AWS account owner or bucket owner must grant permissions at the object-level or prefix-level, and these permissions vary from object to object or prefix to prefix**

In a bucket policy, for example, you can grant access to the objects within a bucket that share a specific key name prefix or have a specific tag. You can grant read permission on objects starting with the key name prefix `logs/`. However, if your access permissions vary by object, granting permissions to individual objects by using a bucket policy might not be practical, especially since bucket policies are limited to 20 KB in size.

We recommend the following access management tools for this use case:

- **S3 Access Grants** – You can use S3 Access Grants to manage object-level or prefix-level permissions. Unlike bucket policies, you can use S3 Access Grants to specify varying object-level permissions at scale. Bucket policies are limited to 20 KB in size. For more information, see Getting started with S3 Access Grants.
- **Access Points** – You can use access points to manage object-level or prefix-level permissions. Access Points are named network endpoints that are attached to a bucket. A bucket can have up to 10,000 access points attached, and for each access point you can enforce distinct permissions and network controls to give you detailed control over access to your S3 objects. For more information, see Managing data access with Amazon S3 access points.
- **ACLs** – We do not recommend using Access Control Lists (ACLs), especially because ACLs are limited to 100 grants per object. However, if you choose to turn on ACLs, in your Bucket Settings, set *Object Ownership* to *Bucket owner preferred* and *ACLs enabled*. With this setting, new objects

that are written with the `bucket-owner-full-control` canned ACL are automatically owned by the bucket owner rather than the object writer. You can then use object ACLs, which is an XML-formatted access policy, to grant other users access to the object. For more information, see Access control list (ACL) overview.

**The AWS account owner or bucket owner wants to limit bucket access only to specific account IDs**

We recommend the following access management tools for this use case:

- **Bucket policy** – With bucket policies, you manage one policy for each bucket. For more information, see Bucket policies for Amazon S3.
- **Access Points** – Access Points are named network endpoints that are attached to a bucket. A bucket can have up to 10,000 access points attached, and for each access point you can enforce distinct permissions and network controls to give you detailed control over access to your S3 objects. For more information, see Managing data access with Amazon S3 access points.

**The AWS account owner or bucket owner wants distinct endpoints for every user or application that accesses their data**

We recommend the following access management tool for this use case:

- **Access Points** – Access Points are named network endpoints that are attached to a bucket. A bucket can have up to 10,000 access points attached, and for each access point you can enforce distinct permissions and network controls to give you detailed control over access to your S3 objects. Each access point enforces a customized access point policy that works in conjunction with the bucket policy that is attached to the underlying bucket. For more information, see Managing data access with Amazon S3 access points.

**The AWS account owner or bucket owner must manage access from Virtual Private Cloud (VPC) endpoints for S3**

Virtual Private Cloud (VPC) endpoints for Amazon S3 are logical entities within a VPC that allow connectivity only to S3. We recommend the following access management tools for this use case:

- **Buckets in a VPC setting** – You can use a bucket policy to control who is allowed to access your buckets and which VPC endpoints they can access. For more information, see Controlling access from VPC endpoints with bucket policies.

- **Access Points** – If you choose to set up access points, you can use an access point policy. You can configure any access point to accept requests only from a virtual private cloud (VPC) to restrict Amazon S3 data access to a private network. You can also configure custom block public access settings for each access point. For more information, see Managing data access with Amazon S3 access points.

**The AWS account owner or bucket owner must make a static website publicly available**

With S3, you can host a static website and allow anyone to view the content of the website, which is hosted from an S3 bucket.

We recommend the following access management tools for this use case:

- **Amazon CloudFront** – This solution allows you to host an Amazon S3 static website to the public while also continuing to block all public access to a bucket's content. If you want to keep all four S3 Block Public Access settings enabled and host an S3 static website, you can use Amazon CloudFront origin access control (OAC). Amazon CloudFront provides the capabilities required to set up a secure static website. Also, Amazon S3 static websites that do not use this solution can only support HTTP endpoints. CloudFront uses the durable storage of Amazon S3 while providing additional security headers, such as HTTPS. HTTPS adds security by encrypting a normal HTTP request and protecting against common cyberattacks.

  For more information, see Getting started with a secure static website in the *Amazon CloudFront Developer Guide*.
- **Making your Amazon S3 bucket publicly accessible** – You can configure a bucket to be used as a publicly accessed static website.

  > **Warning**
  >
  > We do not recommend this method. Instead, we recommend you use Amazon S3 static websites as a part of Amazon CloudFront. For more information, see the previous option, or see Getting started with a secure static website.

  To create an Amazon S3 static website, without Amazon CloudFront, first, you must turn off all Block Public Access settings. When writing the bucket policy for your static website, make sure that you allow only `s3:GetObject` actions, not `ListObject` or `PutObject` permissions. This

helps make sure that users cannot view all the objects in your bucket or add their own content. For more information, see Setting permissions for website access.

### The AWS account owner or bucket owner wants to make the content of a bucket publicly available

When creating a new Amazon S3 bucket, the *Block Public Access* setting is enabled by default. For more information about blocking public access, see Blocking public access to your Amazon S3 storage.

We do not recommend allowing public access to your bucket. However, if you must do so for a particular use case, we recommend the following access management tool for this use case:

- **Disable Block Public Access setting** – A bucket owner can allow unauthenticated requests to the bucket. For example, unauthenticated PUT Object requests are allowed when a bucket has a public bucket policy, or when a bucket ACL grants public access. All unauthenticated requests are made by other arbitrary AWS users, or even unauthenticated, anonymous users. This user is represented in ACLs by the specific canonical user ID `65a011a29cdf8ec533ec3d1ccaae921c`. If an object is uploaded to a `WRITE` or `FULL_CONTROL`, then this specifically grants access to the All Users group or the anonymous user. For more information about public bucket policies and public access control lists (ACLs), see The meaning of "public".

### The AWS account owner or bucket owner has exceeded access policy size limits

Both bucket policies and identity-based policies have a 20 KB size limit. If your access permission requirements are complex, you might exceed this size limit.

We recommended the following access management tools for this use case:

- **Access Points** – Use access points if this works with your use case. With access points, each bucket has multiple named network endpoints, each with its own access point policy that works with the underlying bucket policy. However, access points can only act on objects, not buckets, and does not support cross-Region replication. For more information, see Managing data access with Amazon S3 access points.
- **S3 Access Grants** – Use S3 Access Grants, which supports a very large number of grants that give access to buckets, prefixes, or objects. For more information, see Getting started with S3 Access Grants.

**The AWS account owner or admin role wants to grant bucket, prefix, or object access directly to users or groups in a corporate directory**

Instead of managing users, groups, and roles through AWS Identity and Access Management (IAM), you can add your corporate directory to AWS IAM Identity Center. For more information, see What is IAM Identity Center?.

After you add your corporate directory to AWS IAM Identity Center, we recommend that you use the following access management tool to grant corporate directory identities access to your S3 resources:

- **S3 Access Grants** – Use S3 Access Grants, which supports granting access to users or roles in your corporate directory. For more information, see Getting started with S3 Access Grants.

**The AWS account owner or bucket owner wants to give the AWS CloudFront service access to write CloudFront logs to an S3 bucket**

We recommended the following access management tool for this use case:

- **Bucket ACL** – The only recommended use case for bucket ACLs is to grant permissions to certain AWS services, such as the Amazon CloudFront `awslogsdelivery` account. When you create or update a distribution and turn on CloudFront logging, CloudFront updates the bucket ACL to give the `awslogsdelivery` account `FULL_CONTROL` permissions to write logs to your bucket. For more information, see Permissions required to configure standard logging and to access your log files in the *Amazon CloudFront Developer Guide*. If the bucket that stores the logs uses the *Bucket owner enforced* setting for S3 Object Ownership to turn off ACLs, CloudFront cannot write logs to the bucket. For more information, see Controlling ownership of objects and disabling ACLs for your bucket.

**You, as the bucket owner, want to maintain full control of objects that are added to the bucket by other users**

You can grant other accounts access to upload objects to your bucket by using a bucket policy, access point, or S3 Access Grants. If you have granted cross-account access to your bucket, you can make sure that any objects uploaded to your bucket remain under your full control.

We recommended the following access management tool for this use case:

- **Object Ownership** – Keep the bucket-level setting *Object Ownership* at the default *Bucket owner enforced* setting.

## Access management troubleshooting

The following resources can help you troubleshoot any issues with S3 access management:

**Troubleshooting Access Denied (403 Forbidden) errors**

If you encounter access denial issues, check the account-level and bucket-level settings. Also, check the access management feature that you are using to grant access to make sure that the policy, setting, or configuration is correct. For more information about common causes of Access Denied (403 Forbidden) errors in Amazon S3, see Troubleshoot Access Denied (403 Forbidden) errors in Amazon S3.

**IAM Access Analyzer for S3**

If you do not want to make any of your resources publicly available, or if you want to limit public access to your resources, you can use IAM Access Analyzer for S3. On the Amazon S3 console, use IAM Access Analyzer for S3 to review all buckets that have bucket access control lists (ACLs), bucket policies, or access point policies that grant public or shared access. IAM Access Analyzer for S3 alerts you to buckets that are configured to allow access to anyone on the internet or other AWS accounts, including AWS accounts outside of your organization. For each public or shared bucket, you receive findings that report the source and level of public or shared access.

In IAM Access Analyzer for S3, you can block all public access to a bucket with a single action. We recommend that you block all public access to your buckets, unless you require public access to support a specific use case. Before you block all public access, make sure that your applications will continue to work correctly without public access. For more information, see Blocking public access to your Amazon S3 storage.

You can also review your bucket-level permission settings to configure detailed levels of access. For specific and verified use cases that require public or shared access, you can acknowledge and record your intent for the bucket to remain public or shared by archiving the findings for the bucket. You can revisit and modify these bucket configurations at any time. You can also download your findings as a CSV report for auditing purposes.

IAM Access Analyzer for S3 is available at no extra cost on the Amazon S3 console. IAM Access Analyzer for S3 is powered by AWS Identity and Access Management (IAM) IAM Access Analyzer.

To use IAM Access Analyzer for S3 on the Amazon S3 console, you must visit the IAM Console and create an account-level analyzer in IAM Access Analyzer for each individual Region.

For more information about IAM Access Analyzer for S3, see Reviewing bucket access using IAM Access Analyzer for S3.

**Logging and monitoring**

Monitoring is an important part of maintaining the reliability, availability, and performance of your Amazon S3 solutions so that you can more easily debug an access failure. Logging can provide insight into any errors users are receiving, and when and what requests are made. AWS provides several tools for monitoring your Amazon S3 resources, such as the following:

- AWS CloudTrail
- Amazon S3 Access Logs
- AWS Trusted Advisor
- Amazon CloudWatch

For more information, see Logging and monitoring in Amazon S3.

## Identity and Access Management for Amazon S3

AWS Identity and Access Management (IAM) is an AWS service that helps an administrator securely control access to AWS resources. IAM administrators control who can be *authenticated* (signed in) and *authorized* (have permissions) to use Amazon S3 resources. IAM is an AWS service that you can use with no additional charge.

> **Note**
>
> For more information about using the Amazon S3 Express One Zone storage class with directory buckets, see What is S3 Express One Zone? and Directory buckets.

**Topics**

## Audience

How you use AWS Identity and Access Management (IAM) differs, depending on the work that you do in Amazon S3.

**Service user** – If you use the Amazon S3 service to do your job, then your administrator provides you with the credentials and permissions that you need. As you use more Amazon S3 features to do your work, you might need additional permissions. Understanding how access is managed can help you request the right permissions from your administrator. If you cannot access a feature in Amazon S3, see Troubleshooting Amazon S3 identity and access.

**Service administrator** – If you're in charge of Amazon S3 resources at your company, you probably have full access to Amazon S3. It's your job to determine which Amazon S3 features and resources your service users should access. You must then submit requests to your IAM administrator to

change the permissions of your service users. Review the information on this page to understand the basic concepts of IAM. To learn more about how your company can use IAM with Amazon S3, see How Amazon S3 works with IAM.

**IAM administrator** – If you're an IAM administrator, you might want to learn details about how you can write policies to manage access to Amazon S3. To view example Amazon S3 identity-based policies that you can use in IAM, see Identity-based policies for Amazon S3.

## Authenticating with identities

Authentication is how you sign in to AWS using your identity credentials. You must be *authenticated* (signed in to AWS) as the AWS account root user, as an IAM user, or by assuming an IAM role.

You can sign in to AWS as a federated identity by using credentials provided through an identity source. AWS IAM Identity Center (IAM Identity Center) users, your company's single sign-on authentication, and your Google or Facebook credentials are examples of federated identities. When you sign in as a federated identity, your administrator previously set up identity federation using IAM roles. When you access AWS by using federation, you are indirectly assuming a role.

Depending on the type of user you are, you can sign in to the AWS Management Console or the AWS access portal. For more information about signing in to AWS, see How to sign in to your AWS account in the *AWS Sign-In User Guide*.

If you access AWS programmatically, AWS provides a software development kit (SDK) and a command line interface (CLI) to cryptographically sign your requests by using your credentials. If you don't use AWS tools, you must sign requests yourself. For more information about using the recommended method to sign requests yourself, see Signing AWS API requests in the *IAM User Guide*.

Regardless of the authentication method that you use, you might be required to provide additional security information. For example, AWS recommends that you use multi-factor authentication (MFA) to increase the security of your account. To learn more, see Multi-factor authentication in the *AWS IAM Identity Center User Guide* and Using multi-factor authentication (MFA) in AWS in the *IAM User Guide*.

### AWS account root user

When you create an AWS account, you begin with one sign-in identity that has complete access to all AWS services and resources in the account. This identity is called the AWS account *root user* and

is accessed by signing in with the email address and password that you used to create the account. We strongly recommend that you don't use the root user for your everyday tasks. Safeguard your root user credentials and use them to perform the tasks that only the root user can perform. For the complete list of tasks that require you to sign in as the root user, see Tasks that require root user credentials in the *IAM User Guide*.

**Federated identity**

As a best practice, require human users, including users that require administrator access, to use federation with an identity provider to access AWS services by using temporary credentials.

A *federated identity* is a user from your enterprise user directory, a web identity provider, the AWS Directory Service, the Identity Center directory, or any user that accesses AWS services by using credentials provided through an identity source. When federated identities access AWS accounts, they assume roles, and the roles provide temporary credentials.

For centralized access management, we recommend that you use AWS IAM Identity Center. You can create users and groups in IAM Identity Center, or you can connect and synchronize to a set of users and groups in your own identity source for use across all your AWS accounts and applications. For information about IAM Identity Center, see What is IAM Identity Center? in the *AWS IAM Identity Center User Guide*.

**IAM users and groups**

An *IAM user* is an identity within your AWS account that has specific permissions for a single person or application. Where possible, we recommend relying on temporary credentials instead of creating IAM users who have long-term credentials such as passwords and access keys. However, if you have specific use cases that require long-term credentials with IAM users, we recommend that you rotate access keys. For more information, see Rotate access keys regularly for use cases that require long-term credentials in the *IAM User Guide*.

An *IAM group* is an identity that specifies a collection of IAM users. You can't sign in as a group. You can use groups to specify permissions for multiple users at a time. Groups make permissions easier to manage for large sets of users. For example, you could have a group named *IAMAdmins* and give that group permissions to administer IAM resources.

Users are different from roles. A user is uniquely associated with one person or application, but a role is intended to be assumable by anyone who needs it. Users have permanent long-term credentials, but roles provide temporary credentials. To learn more, see When to create an IAM user (instead of a role) in the *IAM User Guide*.

### IAM roles

An *IAM role* is an identity within your AWS account that has specific permissions. It is similar to an IAM user, but is not associated with a specific person. You can temporarily assume an IAM role in the AWS Management Console by switching roles. You can assume a role by calling an AWS CLI or AWS API operation or by using a custom URL. For more information about methods for using roles, see Using IAM roles in the *IAM User Guide*.

IAM roles with temporary credentials are useful in the following situations:

- **Federated user access** – To assign permissions to a federated identity, you create a role and define permissions for the role. When a federated identity authenticates, the identity is associated with the role and is granted the permissions that are defined by the role. For information about roles for federation, see Creating a role for a third-party Identity Provider in the *IAM User Guide*. If you use IAM Identity Center, you configure a permission set. To control what your identities can access after they authenticate, IAM Identity Center correlates the permission set to a role in IAM. For information about permissions sets, see Permission sets in the *AWS IAM Identity Center User Guide*.
- **Temporary IAM user permissions** – An IAM user or role can assume an IAM role to temporarily take on different permissions for a specific task.
- **Cross-account access** – You can use an IAM role to allow someone (a trusted principal) in a different account to access resources in your account. Roles are the primary way to grant cross-account access. However, with some AWS services, you can attach a policy directly to a resource (instead of using a role as a proxy). To learn the difference between roles and resource-based policies for cross-account access, see Cross account resource access in IAM in the *IAM User Guide*.
- **Cross-service access** – Some AWS services use features in other AWS services. For example, when you make a call in a service, it's common for that service to run applications in Amazon EC2 or store objects in Amazon S3. A service might do this using the calling principal's permissions, using a service role, or using a service-linked role.
  - **Forward access sessions (FAS)** – When you use an IAM user or role to perform actions in AWS, you are considered a principal. When you use some services, you might perform an action that then initiates another action in a different service. FAS uses the permissions of the principal calling an AWS service, combined with the requesting AWS service to make requests to downstream services. FAS requests are only made when a service receives a request that requires interactions with other AWS services or resources to complete. In this case, you must have permissions to perform both actions. For policy details when making FAS requests, see Forward access sessions.

- **Service role** – A service role is an IAM role that a service assumes to perform actions on your behalf. An IAM administrator can create, modify, and delete a service role from within IAM. For more information, see Creating a role to delegate permissions to an AWS service in the *IAM User Guide*.
- **Service-linked role** – A service-linked role is a type of service role that is linked to an AWS service. The service can assume the role to perform an action on your behalf. Service-linked roles appear in your AWS account and are owned by the service. An IAM administrator can view, but not edit the permissions for service-linked roles.

- **Applications running on Amazon EC2** – You can use an IAM role to manage temporary credentials for applications that are running on an EC2 instance and making AWS CLI or AWS API requests. This is preferable to storing access keys within the EC2 instance. To assign an AWS role to an EC2 instance and make it available to all of its applications, you create an instance profile that is attached to the instance. An instance profile contains the role and enables programs that are running on the EC2 instance to get temporary credentials. For more information, see Using an IAM role to grant permissions to applications running on Amazon EC2 instances in the *IAM User Guide*.

To learn whether to use IAM roles or IAM users, see When to create an IAM role (instead of a user) in the *IAM User Guide*.

## Managing access using policies

You control access in AWS by creating policies and attaching them to AWS identities or resources. A policy is an object in AWS that, when associated with an identity or resource, defines their permissions. AWS evaluates these policies when a principal (user, root user, or role session) makes a request. Permissions in the policies determine whether the request is allowed or denied. Most policies are stored in AWS as JSON documents. For more information about the structure and contents of JSON policy documents, see Overview of JSON policies in the *IAM User Guide*.

Administrators can use AWS JSON policies to specify who has access to what. That is, which **principal** can perform **actions** on what **resources**, and under what **conditions**.

By default, users and roles have no permissions. To grant users permission to perform actions on the resources that they need, an IAM administrator can create IAM policies. The administrator can then add the IAM policies to roles, and users can assume the roles.

IAM policies define permissions for an action regardless of the method that you use to perform the operation. For example, suppose that you have a policy that allows the `iam:GetRole` action. A

user with that policy can get role information from the AWS Management Console, the AWS CLI, or the AWS API.

**Identity-based policies**

Identity-based policies are JSON permissions policy documents that you can attach to an identity, such as an IAM user, group of users, or role. These policies control what actions users and roles can perform, on which resources, and under what conditions. To learn how to create an identity-based policy, see Creating IAM policies in the *IAM User Guide*.

Identity-based policies can be further categorized as *inline policies* or *managed policies*. Inline policies are embedded directly into a single user, group, or role. Managed policies are standalone policies that you can attach to multiple users, groups, and roles in your AWS account. Managed policies include AWS managed policies and customer managed policies. To learn how to choose between a managed policy or an inline policy, see Choosing between managed policies and inline policies in the *IAM User Guide*.

**Resource-based policies**

Resource-based policies are JSON policy documents that you attach to a resource. Examples of resource-based policies are IAM *role trust policies* and Amazon S3 *bucket policies*. In services that support resource-based policies, service administrators can use them to control access to a specific resource. For the resource where the policy is attached, the policy defines what actions a specified principal can perform on that resource and under what conditions. You must specify a principal in a resource-based policy. Principals can include accounts, users, roles, federated users, or AWS services.

Resource-based policies are inline policies that are located in that service. You can't use AWS managed policies from IAM in a resource-based policy.

**Access control lists (ACLs)**

Access control lists (ACLs) control which principals (account members, users, or roles) have permissions to access a resource. ACLs are similar to resource-based policies, although they do not use the JSON policy document format.

Amazon S3, AWS WAF, and VPC are examples of services that support ACLs. To learn more about ACLs, see Access control list (ACL) overview in the *Amazon Simple Storage Service Developer Guide*.

### Other policy types

AWS supports additional, less-common policy types. These policy types can set the maximum permissions granted to you by the more common policy types.

- **Permissions boundaries** – A permissions boundary is an advanced feature in which you set the maximum permissions that an identity-based policy can grant to an IAM entity (IAM user or role). You can set a permissions boundary for an entity. The resulting permissions are the intersection of an entity's identity-based policies and its permissions boundaries. Resource-based policies that specify the user or role in the `Principal` field are not limited by the permissions boundary. An explicit deny in any of these policies overrides the allow. For more information about permissions boundaries, see Permissions boundaries for IAM entities in the *IAM User Guide*.
- **Service control policies (SCPs)** – SCPs are JSON policies that specify the maximum permissions for an organization or organizational unit (OU) in AWS Organizations. AWS Organizations is a service for grouping and centrally managing multiple AWS accounts that your business owns. If you enable all features in an organization, then you can apply service control policies (SCPs) to any or all of your accounts. The SCP limits permissions for entities in member accounts, including each AWS account root user. For more information about Organizations and SCPs, see Service control policies in the *AWS Organizations User Guide*.
- **Session policies** – Session policies are advanced policies that you pass as a parameter when you programmatically create a temporary session for a role or federated user. The resulting session's permissions are the intersection of the user or role's identity-based policies and the session policies. Permissions can also come from a resource-based policy. An explicit deny in any of these policies overrides the allow. For more information, see Session policies in the *IAM User Guide*.

### Multiple policy types

When multiple types of policies apply to a request, the resulting permissions are more complicated to understand. To learn how AWS determines whether to allow a request when multiple policy types are involved, see Policy evaluation logic in the *IAM User Guide*.

## How Amazon S3 works with IAM

Before you use IAM to manage access to Amazon S3, learn what IAM features are available to use with Amazon S3.

**IAM features you can use with Amazon S3**

| IAM feature | Amazon S3 support |
| --- | --- |
| Identity-based policies | Yes |
| Resource-based policies | Yes |
| Policy actions | Yes |
| Policy resources | Yes |
| Policy condition keys (service-specific) | Yes |
| ACLs | Yes |
| ABAC (tags in policies) | Partial |
| Temporary credentials | Yes |
| Forward access sessions (FAS) | Yes |
| Service roles | Yes |
| Service-linked roles | Partial |

To get a high-level view of how Amazon S3 and other AWS services work with most IAM features, see AWS services that work with IAM in the *IAM User Guide*.

**Identity-based policies for Amazon S3**

**Supports identity-based policies:** Yes

Identity-based policies are JSON permissions policy documents that you can attach to an identity, such as an IAM user, group of users, or role. These policies control what actions users and roles can perform, on which resources, and under what conditions. To learn how to create an identity-based policy, see Creating IAM policies in the *IAM User Guide*.

With IAM identity-based policies, you can specify allowed or denied actions and resources as well as the conditions under which actions are allowed or denied. You can't specify the principal in an identity-based policy because it applies to the user or role to which it is attached. To learn about all

of the elements that you can use in a JSON policy, see IAM JSON policy elements reference in the *IAM User Guide*.

**Identity-based policy examples for Amazon S3**

To view examples of Amazon S3 identity-based policies, see Identity-based policies for Amazon S3.

**Resource-based policies within Amazon S3**

**Supports resource-based policies:** Yes

Resource-based policies are JSON policy documents that you attach to a resource. Examples of resource-based policies are IAM *role trust policies* and Amazon S3 *bucket policies*. In services that support resource-based policies, service administrators can use them to control access to a specific resource. For the resource where the policy is attached, the policy defines what actions a specified principal can perform on that resource and under what conditions. You must specify a principal in a resource-based policy. Principals can include accounts, users, roles, federated users, or AWS services.

To enable cross-account access, you can specify an entire account or IAM entities in another account as the principal in a resource-based policy. Adding a cross-account principal to a resource-based policy is only half of establishing the trust relationship. When the principal and the resource are in different AWS accounts, an IAM administrator in the trusted account must also grant the principal entity (user or role) permission to access the resource. They grant permission by attaching an identity-based policy to the entity. However, if a resource-based policy grants access to a principal in the same account, no additional identity-based policy is required. For more information, see Cross account resource access in IAM in the *IAM User Guide*.

The Amazon S3 service supports *bucket policies*, *access points policies*, and *access grants*:

- Bucket policies are resource-based policies that are attached to an Amazon S3 bucket. A bucket policy defines which principals can perform actions on the bucket.
- Access point policies are resource-based polices that are evaluated in conjunction with the underlying bucket policy.
- Access grants are a simplified model for defining access permissions to data in Amazon S3 by prefix, bucket, or object. For information about S3 Access Grants, see Managing access with S3 Access Grants.

### Principals for bucket policies

The `Principal` element specifies the user, account, service, or other entity that is either allowed or denied access to a resource. The following are examples of specifying `Principal`. For more information, see Principal in the *IAM User Guide*.

#### Grant permissions to an AWS account

To grant permissions to an AWS account, identify the account using the following format.

```
"AWS":"account-ARN"
```

The following are examples.

```
"Principal":{"AWS":"arn:aws:iam::AccountIDWithoutHyphens:root"}
```

```
"Principal":{"AWS":
["arn:aws:iam::AccountID1WithoutHyphens:root","arn:aws:iam::AccountID2WithoutHyphens:root"]}
```

#### Grant permissions to an IAM user

To grant permission to an IAM user within your account, you must provide an `"AWS":"user-ARN"` name-value pair.

```
"Principal":{"AWS":"arn:aws:iam::account-number-without-hyphens:user/username"}
```

For detailed examples that provide step-by-step instructions, see Example 1: Bucket owner granting its users bucket permissions and Example 3: Bucket owner granting permissions to objects it does not own.

> **Note**
>
> If an IAM identity is deleted after you update your bucket policy, the bucket policy will show a unique identifier in the principal element instead of an ARN. These unique IDs are never reused, so you can safely remove principals with unique identifiers from all of your policy statements. For more information about unique identifiers, see IAM identifiers in the *IAM User Guide*.

### Grant anonymous permissions

> **Warning**
>
> Use caution when granting anonymous access to your Amazon S3 bucket. When you grant anonymous access, anyone in the world can access your bucket. We highly recommend that you never grant any kind of anonymous write access to your S3 bucket.

To grant permission to everyone, also referred as anonymous access, you set the wildcard (`"*"`) as the `Principal` value. For example, if you configure your bucket as a website, you want all the objects in the bucket to be publicly accessible.

```
"Principal":"*"
```

```
"Principal":{"AWS":"*"}
```

Using `"Principal": "*"` with an `Allow` effect in a resource-based policy allows anyone, even if they're not signed in to AWS, to access your resource.

Using `"Principal" : { "AWS" : "*" }` with an `Allow` effect in a resource-based policy allows any root user, IAM user, assumed-role session, or federated user in any account in the same partition to access your resource.

For anonymous users, these two methods are equivalent. For more information, see All principals in the *IAM User Guide*.

You cannot use a wildcard to match part of a principal name or ARN.

> **Important**
>
> Because anyone can create an AWS account, the **security level** of these two methods is equivalent, even though they function differently.

### Restrict resource permissions

You can also use resource policy to restrict access to resources that would otherwise be available to IAM principals. Use a `Deny` statement to prevent access.

The following example blocks access if a secure transport protocol isn't used:

```
{"Effect": "Deny",
 "Principal": "*",
 "Action": "s3:*",
 "Resource": <bucket ARN>,
 "Condition": {
   "Boolean": { "aws:SecureTransport" : "false"}
 }
}
```

Using `"Principal": "*"` so that this restriction applies to everyone is a best practice for this policy, instead of attempting to deny access only to specific accounts or principals using this method.

**Require access through CloudFront URLs**

You can require that your users access your Amazon S3 content only by using CloudFront URLs instead of Amazon S3 URLs. To do this, create a CloudFront origin access control (OAC). Then, change the permissions on your S3 data. In your bucket policy, you can set CloudFront as the Principal as follows:

```
"Principal":{"Service":"cloudfront.amazonaws.com"}
```

Use a `Condition` element in the policy to allow CloudFront to access the bucket only when the request is on behalf of the CloudFront distribution that contains the S3 origin.

```
       "Condition": {
          "StringEquals": {
             "AWS:SourceArn":
 "arn:aws:cloudfront::111122223333:distribution/CloudFront-distribution-ID"
          }
       }
```

For more information about requiring S3 access through CloudFront URLs, see Restricting access to an Amazon Simple Storage Service origin in the *Amazon CloudFront Developer Guide*. For more information about the security and privacy benefits of using Amazon CloudFront, see Configuring secure access and restricting access to content.

### Resource-based policy examples for Amazon S3

- To view policy examples for Amazon S3 buckets, see Bucket policies for Amazon S3.
- To view policy examples for access points, see Configuring IAM policies for using access points.

### Policy actions for Amazon S3

**Supports policy actions:** Yes

Administrators can use AWS JSON policies to specify who has access to what. That is, which **principal** can perform **actions** on what **resources**, and under what **conditions**.

The `Action` element of a JSON policy describes the actions that you can use to allow or deny access in a policy. Policy actions usually have the same name as the associated AWS API operation. There are some exceptions, such as *permission-only actions* that don't have a matching API operation. There are also some operations that require multiple actions in a policy. These additional actions are called *dependent actions*.

Include actions in a policy to grant permissions to perform the associated operation.

The following shows different types of mapping relationship between S3 API operations and the required policy actions.

- One-to-one mapping with the same name. For example, to use the `PutBucketPolicy` API operation, the `s3:PutBucketPolicy` policy action is required.
- One-to-one mapping with different names. For example, to use the `ListObjectsV2` API operation, the `s3:ListBucket` policy action is required.
- One-to-many mapping. For example, to use the `HeadObject` API operation, the `s3:GetObject` is required. Also, when you use S3 Object Lock and want to get an object's Legal Hold status or retention settings, the corresponding `s3:GetObjectLegalHold` or `s3:GetObjectRetention` policy actions are also required before you can use the `HeadObject` API operation.
- Many-to-one mapping. For example, to use the `ListObjectsV2` or `HeadBucket` API operations, the `s3:ListBucket` policy action is required.

To see a list of Amazon S3 actions for use in policies, see Actions defined by Amazon S3 in the *Service Authorization Reference*. For a complete list of Amazon S3 API operations, see Amazon S3 API Actions in the *Amazon Simple Storage Service API Reference*.

Policy actions in Amazon S3 use the following prefix before the action:

```
s3
```

To specify multiple actions in a single statement, separate them with commas.

```
"Action": [
      "s3:action1",
      "s3:action2"
         ]
```

### Bucket operations

Bucket operations are S3 API operations that operate on the bucket resource type. For example, `CreateBucket`, `ListObjectsV2`, and `PutBucketPolicy`. S3 policy actions for bucket operations require the `Resource` element in bucket policies or IAM identity-based policies to be the S3 bucket type Amazon Resource Name (ARN) identifier in the following example format.

```
"Resource": "arn:aws:s3:::amzn-s3-demo-bucket"
```

The following bucket policy grants the user *Akua* with account *12345678901* the `s3:ListBucket` permission to perform the ListObjectsV2 API operation and list objects in an S3 bucket.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "Allow Akua to list objects in the bucket",
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws:iam::12345678901:user/Akua"
            },
            "Action": [
            "s3:ListBucket"
            ],
            "Resource": "arn:aws:s3:::amzn-s3-demo-bucket"
        }
    ]
```

```
}
```

### Bucket operations in access point policies

Permissions granted in an access point policy are effective only if the underlying bucket allows the same permissions. When you use S3 Access Points, you must delegate access control from the bucket to the access point or add the same permissions in the access point policies to the underlying bucket's policy. For more information, see Configuring IAM policies for using access points. In access point policies, S3 policy actions for bucket operations require you to use the `accesspoint` ARN for the `Resource` element in the following format.

```
"Resource": "arn:aws:s3:us-west-2:123456789012:accesspoint/DOC-EXAMPLE-ACCESS-POINT"
```

The following access point policy grants the user *Akua* with account *12345678901* the `s3:ListBucket` permission to perform the ListObjectsV2 API operation through the S3 access point *DOC-EXAMPLE-ACCESS-POINT* to list objects in the access point's associated bucket.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "Allow Akua to list objects in the bucket through access point",
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws:iam::12345678901:user/Akua"
            },
            "Action": [
            "s3:ListBucket"
            ],
            "Resource": "arn:aws:s3:us-west-2:123456789012:accesspoint/DOC-EXAMPLE-
ACCESS-POINT"
        }
    ]
}
```

> **Note**
>
> Not all bucket operations are supported by S3 Access Point. For more information, see Access point compatibility with S3 operations.

### Object operations

Object operations are S3 API operations that act upon the object resource type. For example, `GetObject`, `PutObject`, and `DeleteObject`. S3 policy actions for object operations require the `Resource` element in policies to be the S3 object ARN in the following example formats.

```
"Resource": "arn:aws:s3:::amzn-s3-demo-bucket/*"
```

```
"Resource": "arn:aws:s3:::amzn-s3-demo-bucket/prefix/*"
```

> **Note**
>
> The object ARN must contain a forward slash after the bucket name, as seen in the previous examples.

The following bucket policy grants the user *Akua* with account *12345678901* the `s3:PutObject` permission to perform the PutObject API operation to upload objects to an S3 bucket.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "Allow Akua to upload objects",
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws:iam::12345678901:user/Akua"
            },
            "Action": [
            "s3:PutObject"
            ],
            "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/*"
        }
    ]
}
```

### Object operations in access point policies

When you use S3 Access Points to control access to object operations, you can use access point policies. When you use access point policies, S3 policy actions for object operations

require you to use the `accesspoint` ARN for the `Resource` element in the following format: `arn:aws:s3:region:account-id:accesspoint/access-point-name/object/resource`. For object operations that use access point, you must include the `/object/` value after the whole access point ARN in the `Resource` element. Here are some examples.

```
"Resource": "arn:aws:s3:us-west-2:123456789012:accesspoint/DOC-EXAMPLE-ACCESS-POINT/
object/*"
```

```
"Resource": "arn:aws:s3:us-west-2:123456789012:accesspoint/DOC-EXAMPLE-ACCESS-POINT/
object/prefix/*"
```

The following access point policy grants the user *Akua* with account *12345678901* the `s3:GetObject` permission to perform the GetObject API operation through the access point *DOC-EXAMPLE-ACCESS-POINT* on all objects in the access point's associated bucket.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "Allow Akua to get objects through access point",
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws:iam::12345678901:user/Akua"
            },
            "Action": [
            "s3:GetObject"
            ],
            "Resource": "arn:aws:s3:us-west-2:123456789012:accesspoint/DOC-EXAMPLE-
ACCESS-POINT/object/*"
        }
    ]
}
```

**Note**

Not all object operations are supported by S3 Access Point. For more information, see Access point compatibility with S3 operations.

### Access point operations

Access point operations are S3 API operations that operate on the `accesspoint` resource type. For example, `CreateAccessPoint`, `DeleteAccessPoint`, and `GetAccessPointPolicy`. S3 policy actions for access point operations can only be used in IAM identity-based policies, not in bucket policies or access point policies. Access points operations require the `Resource` element to be the `accesspoint` ARN in the following example format.

```
"Resource": "arn:aws:s3:us-west-2:123456789012:accesspoint/DOC-EXAMPLE-ACCESS-POINT"
```

The following IAM identity-based policy grants the `s3:GetAccessPointPolicy` permission to perform the GetAccessPointPolicy API operation on S3 access point *DOC-EXAMPLE-ACCESS-POINT*.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "Grant permission to retrieve the access point policy of access
 point DOC-EXAMPLE-ACCESS-POINT",
            "Effect": "Allow",
            "Action": [
            "s3:GetAccessPointPolicy"
            ],
            "Resource": "arn:aws:s3:*:123456789012:access point/DOC-EXAMPLE-ACCESS-
POINT"
        }
    ]
}
```

When you use Access Points, to control access to bucket operations, see Bucket operations in access point policies; to control access to object operations, see Object operations in access point policies. For more information about how to configure access point policies, see Configuring IAM policies for using access points.

### Object Lambda Access Point operations

With Amazon S3 Object Lambda, you can add your own code to Amazon S3 `GET`, `LIST`, and `HEAD` requests to modify and process data as it is returned to an application. You can make requests through an Object Lambda Access Point, which works the same as making requests through other access points. For more information, see Transforming objects with S3 Object Lambda.

For more information about how to configure policies for Object Lambda Access Point operations, see Configuring IAM policies for Object Lambda Access Points.

**Multi-Region Access Point operations**

A Multi-Region Access Point provides a global endpoint that applications can use to fulfill requests from S3 buckets that are located in multiple AWS Region. You can use a Multi-Region Access Point to build multi-Region applications with the same architecture that's used in a single Region, and then run those applications anywhere in the world. For more information, see Multi-Region Access Points in Amazon S3.

For more information about how to configure policies for Multi-Region Access Point operations, see Multi-Region Access Point policy examples.

**Batch job operations**

(Batch Operations) job operations are S3 API operations that operate on the job resource type. For example, `DescribeJob` and `CreateJob`. S3 policy actions for job operations can only be used in IAM identity-based policies, not in bucket policies. Also, job operations require the `Resource` element in IAM identity-based policies to be the `job` ARN in the following example format.

```
"Resource": "arn:aws:s3:*:123456789012:job/*"
```

The following IAM identity-based policy grants the `s3:DescribeJob` permission to perform the DescribeJob API operation on S3 Batch Operations Job *DOC-EXAMPLE-JOB*.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "Allow describing the Batch operation job DOC-EXAMPLE-JOB",
            "Effect": "Allow",
            "Action": [
            "s3:DescribeJob"
            ],
            "Resource": "arn:aws:s3:*:123456789012:job/DOC-EXAMPLE-JOB"
        }
    ]
}
```

### S3 Storage Lens configuration operations

For more information about how to configure S3 Storage Lens configuration operations, see Amazon S3 Storage Lens permissions.

### Account operations

Account operations are S3 API operations that operate on the account level. For example, `GetPublicAccessBlock` (for account). Account isn't a resource type defined by Amazon S3. S3 policy actions for account operations can only be used in IAM identity-based policies, not in bucket policies. Also, account operations require the `Resource` element in IAM identity-based policies to be `"*"`.

The following IAM identity-based policy grants the `s3:GetAccountPublicAccessBlock` permission to perform the account-level GetPublicAccessBlock API operation and retrieve the account-level Public Access Block settings.

```
{
   "Version":"2012-10-17",
   "Statement":[
      {
         "Sid":"Allow retrieving the account-level Public Access Block settings",
         "Effect":"Allow",
         "Action":[
            "s3:GetAccountPublicAccessBlock"
         ],
         "Resource":[
            "*"
         ]
       }
    ]
}
```

### Policy examples for Amazon S3

- To view examples of Amazon S3 identity-based policies, see Identity-based policies for Amazon S3.
- To view examples of Amazon S3 resource-based policies, see Bucket policies for Amazon S3 and Configuring IAM policies for using access points.

### Policy resources for Amazon S3

**Supports policy resources:** Yes

Administrators can use AWS JSON policies to specify who has access to what. That is, which **principal** can perform **actions** on what **resources**, and under what **conditions**.

The `Resource` JSON policy element specifies the object or objects to which the action applies. Statements must include either a `Resource` or a `NotResource` element. As a best practice, specify a resource using its Amazon Resource Name (ARN). You can do this for actions that support a specific resource type, known as *resource-level permissions*.

For actions that don't support resource-level permissions, such as listing operations, use a wildcard (*) to indicate that the statement applies to all resources.

```
"Resource": "*"
```

Some Amazon S3 API actions support multiple resources. For example, `s3:GetObject` accesses EXAMPLE-RESOURCE-1 and EXAMPLE-RESOURCE-2, so a principal must have permissions to access both resources. To specify multiple resources in a single statement, separate the ARNs with commas.

```
"Resource": [
      "EXAMPLE-RESOURCE-1",
      "EXAMPLE-RESOURCE-2"
```

Resources in Amazon S3 are buckets, objects, access points, or jobs. In a policy, use the Amazon Resource Name (ARN) of the bucket, object, access point, or job to identify the resource.

To see a complete list of Amazon S3 resource types and their ARNs, see Resources defined by Amazon S3 in the *Service Authorization Reference*. To learn with which actions you can specify the ARN of each resource, see Actions defined by Amazon S3.

### Wildcards for resource ARNs

You can use wildcards as part of the resource ARN. You can use wildcard characters (* and ?) within any ARN segment (the parts separated by colons). An asterisk (*) represents any combination of zero or more characters, and a question mark (?) represents any single character. You can use multiple * or ? characters in each segment, but a wildcard cannot span segments.

- The following ARN uses the wildcard * in the relative-ID part of the ARN to identify all objects in the examplebucket bucket.

```
arn:aws:s3:::examplebucket/*
```

- The following ARN uses * to indicate all S3 buckets and objects.

```
arn:aws:s3:::*
```

- The following ARN uses both wildcards, * and ?, in the relative-ID part. It identifies all objects in buckets such as example1bucket, example2bucket, example3bucket, and so on.

```
arn:aws:s3:::example?bucket/*
```

### Policy variables for resource ARNs

You can use policy variables in Amazon S3 ARNs. At policy evaluation time, these predefined variables are replaced by their corresponding values. Suppose that you organize your bucket as a collection of folders, one folder for each of your users. The folder name is the same as the user name. To grant users permission to their folders, you can specify a policy variable in the resource ARN:

```
arn:aws:s3:::bucket_name/developers/${aws:username}/
```

At runtime, when the policy is evaluated, the variable ${aws:username} in the resource ARN is substituted with the username of the person who is making the request.

### Policy examples for Amazon S3

- To view examples of Amazon S3 identity-based policies, see Identity-based policies for Amazon S3.
- To view examples of Amazon S3 resource-based policies, see Bucket policies for Amazon S3 and Configuring IAM policies for using access points.

### Policy condition keys for Amazon S3

**Supports service-specific policy condition keys:** Yes

Administrators can use AWS JSON policies to specify who has access to what. That is, which **principal** can perform **actions** on what **resources**, and under what **conditions**.

The `Condition` element (or `Condition` *block*) lets you specify conditions in which a statement is in effect. The `Condition` element is optional. You can create conditional expressions that use condition operators, such as equals or less than, to match the condition in the policy with values in the request.

If you specify multiple `Condition` elements in a statement, or multiple keys in a single `Condition` element, AWS evaluates them using a logical `AND` operation. If you specify multiple values for a single condition key, AWS evaluates the condition using a logical `OR` operation. All of the conditions must be met before the statement's permissions are granted.

You can also use placeholder variables when you specify conditions. For example, you can grant an IAM user permission to access a resource only if it is tagged with their IAM user name. For more information, see IAM policy elements: variables and tags in the *IAM User Guide*.

AWS supports global condition keys and service-specific condition keys. To see all AWS global condition keys, see AWS global condition context keys in the *IAM User Guide*.

Each Amazon S3 condition key maps to the same name request header allowed by the API on which the condition can be set. Amazon S3-specific condition keys dictate the behavior of the same name request headers. For example, the condition key `s3:VersionId` used to grant conditional permission for the
`s3:GetObjectVersion`
permission defines behavior of the `versionId` query parameter that you set in a GET Object request.

To see a list of Amazon S3 condition keys, see Condition keys for Amazon S3 in the *Service Authorization Reference*. To learn with which actions and resources you can use a condition key, see Actions defined by Amazon S3.

**Example: Restricting object uploads to objects with a specific storage class**

Suppose that Account A, represented by account ID 123456789012, owns a bucket. The Account A administrator wants to restrict Dave, a user in Account A, so that Dave can only upload objects to the bucket that's stored with the `STANDARD_IA` storage class. To restrict object uploads to a specific storage class, the Account A administrator can use the `s3:x-amz-storage-class` condition key, as shown in the following example bucket policy.

```
{
                "Version": "2012-10-17",
                "Statement": [
                  {
                    "Sid": "statement1",
                    "Effect": "Allow",
                    "Principal": {
                      "AWS": "arn:aws:iam::123456789012:user/Dave"
                    },
                    "Action": "s3:PutObject",
                    "Resource": "arn:aws:s3:::amzn-s3-demo-bucket1/*",
                    "Condition": {
                      "StringEquals": {
                        "s3:x-amz-storage-class": [
                          "STANDARD_IA"
                        ]
                      }
                    }
                  }
                ]
            }
```

In the example, the `Condition` block specifies the `StringEquals` condition that is applied to the specified key-value pair, `"s3:x-amz-acl":["public-read"]`. There is a set of predefined keys that you can use in expressing a condition. The example uses the `s3:x-amz-acl` condition key. This condition requires the user to include the `x-amz-acl` header with value `public-read` in every PUT object request.

**Policy examples for Amazon S3**

- To view examples of Amazon S3 identity-based policies, see Identity-based policies for Amazon S3.
- To view examples of Amazon S3 resource-based policies, see Bucket policies for Amazon S3 and Configuring IAM policies for using access points.

**ACLs in Amazon S3**

**Supports ACLs:** Yes

In Amazon S3, access control lists (ACLs) control which AWS accounts have permissions to access a resource. ACLs are similar to resource-based policies, although they do not use the JSON policy document format.

> **Important**
>
> A majority of modern use cases in Amazon S3 no longer require the use of ACLs.

For information about using ACLs to control access in Amazon S3, see Managing access with ACLs.

**ABAC with Amazon S3**

**Supports ABAC (tags in policies):** Partial

Attribute-based access control (ABAC) is an authorization strategy that defines permissions based on attributes. In AWS, these attributes are called *tags*. You can attach tags to IAM entities (users or roles) and to many AWS resources. Tagging entities and resources is the first step of ABAC. Then you design ABAC policies to allow operations when the principal's tag matches the tag on the resource that they are trying to access.

ABAC is helpful in environments that are growing rapidly and helps with situations where policy management becomes cumbersome.

To control access based on tags, you provide tag information in the condition element of a policy using the `aws:ResourceTag/key-name`, `aws:RequestTag/key-name`, or `aws:TagKeys` condition keys.

If a service supports all three condition keys for every resource type, then the value is **Yes** for the service. If a service supports all three condition keys for only some resource types, then the value is **Partial**.

For more information about ABAC, see What is ABAC? in the *IAM User Guide*. To view a tutorial with steps for setting up ABAC, see Use attribute-based access control (ABAC) in the *IAM User Guide*.

To view example identity-based policies for limiting access to S3 Batch Operations jobs based on tags, see Controlling permissions for S3 Batch Operations using job tags.

**ABAC and object tags**

In ABAC policies, objects use `s3:` tags instead of `aws:` tags. To control access to objects based on object tags, you provide tag information in the condition element of a policy using the following tags:

- `s3:ExistingObjectTag/tag-key`
- `s3:s3:RequestObjectTagKeys`
- `s3:RequestObjectTag/tag-key`

For information about using object tags to control access, including example permission policies, see Tagging and access control policies.

**Using temporary credentials with Amazon S3**

**Supports temporary credentials:** Yes

Some AWS services don't work when you sign in using temporary credentials. For additional information, including which AWS services work with temporary credentials, see AWS services that work with IAM in the *IAM User Guide*.

You are using temporary credentials if you sign in to the AWS Management Console using any method except a user name and password. For example, when you access AWS using your company's single sign-on (SSO) link, that process automatically creates temporary credentials. You also automatically create temporary credentials when you sign in to the console as a user and then switch roles. For more information about switching roles, see Switching to a role (console) in the *IAM User Guide*.

You can manually create temporary credentials using the AWS CLI or AWS API. You can then use those temporary credentials to access AWS. AWS recommends that you dynamically generate temporary credentials instead of using long-term access keys. For more information, see Temporary security credentials in IAM.

**Forward access sessions for Amazon S3**

**Supports forward access sessions (FAS):** Yes

When you use an IAM user or role to perform actions in AWS, you are considered a principal. When you use some services, you might perform an action that then initiates another action in a

different service. FAS uses the permissions of the principal calling an AWS service, combined with the requesting AWS service to make requests to downstream services. FAS requests are only made when a service receives a request that requires interactions with other AWS services or resources to complete. In this case, you must have permissions to perform both actions. For policy details when making FAS requests, see Forward access sessions.

- FAS is used by Amazon S3 to make calls to AWS KMS to decrypt an object when SSE-KMS was used to encrypt it. For more information, see Using server-side encryption with AWS KMS keys (SSE-KMS).
- S3 Access Grants also uses FAS. After you create an access grant to your S3 data for a particular identity, the grantee requests a temporary credential from S3 Access Grants. S3 Access Grants obtains a temporary credential for the requester from AWS STS and vends the credential to the requester. For more information, see Request access to Amazon S3 data through S3 Access Grants.

**Service roles for Amazon S3**

**Supports service roles:** Yes

A service role is an IAM role that a service assumes to perform actions on your behalf. An IAM administrator can create, modify, and delete a service role from within IAM. For more information, see Creating a role to delegate permissions to an AWS service in the *IAM User Guide*.

> **Warning**
>
> Changing the permissions for a service role might break Amazon S3 functionality. Edit service roles only when Amazon S3 provides guidance to do so.

**Service-linked roles for Amazon S3**

**Supports service-linked roles:** Partial

A service-linked role is a type of service role that is linked to an AWS service. The service can assume the role to perform an action on your behalf. Service-linked roles appear in your AWS account and are owned by the service. An IAM administrator can view, but not edit the permissions for service-linked roles.

Amazon S3 supports service-linked roles for Amazon S3 Storage Lens. For details about creating or managing Amazon S3 service-linked roles, see Using service-linked roles for Amazon S3 Storage Lens.

**Amazon S3 Service as a Principal**

| Service name in the policy | S3 feature | More information |
|---|---|---|
| `s3.amazonaws.com` | S3 Replication | Setting up live replication |
| `s3.amazonaws.com` | S3 event notifications | Amazon S3 Event Notifications |
| `s3.amazonaws.com` | S3 Inventory | Amazon S3 Inventory |
| `access-grants.s3.amazonaws.com` | S3 Access Grants | Register a location |
| `batchoperations.s3.amazonaws.com` | S3 Batch Operations | Granting permissions for Amazon S3 Batch Operations |
| `logging.s3.amazonaws.com` | S3 Server Access Logging | Enabling Amazon S3 server access logging |
| `storage-lens.s3.amazonaws.com` | S3 Storage Lens | Viewing Amazon S3 Storage Lens metrics using a data export |

## Policies and permissions in Amazon S3

This page provides an overview of bucket and user policies in Amazon S3 and describes the basic elements of an AWS Identity and Access Management (IAM) policy. Each listed element links to more details about that element and examples of how to use it.

For a complete list of Amazon S3 actions, resources, and conditions, see Actions, resources, and condition keys for Amazon S3 in the *Service Authorization Reference*.

In its most basic sense, a policy contains the following elements:

- Resource – The Amazon S3 bucket, object, access point, or job that the policy applies to. Use the Amazon Resource Name (ARN) of the bucket, object, access point, or job to identify the resource.

  An example for bucket-level operations:

  `"Resource": "arn:aws:s3:::bucket_name"`

  Examples for object-level operations:

  - `"Resource": "arn:aws:s3:::bucket_name/*"` for all objects in the bucket.
  - `"Resource": "arn:aws:s3:::bucket_name/prefix/*"` for objects under a certain prefix in the bucket.

  For more information, see Policy resources for Amazon S3.

- Actions – For each resource, Amazon S3 supports a set of operations. You identify resource operations that you will allow (or deny) by using action keywords.

  For example, the `s3:ListBucket` permission allows the user to use the Amazon S3 ListObjectsV2 operation. (The `s3:ListBucket` permission is a case where the action name doesn't map directly to the operation name.) For more information about using Amazon S3 actions, see Policy actions for Amazon S3. For a complete list of Amazon S3 actions, see Actions in the *Amazon Simple Storage Service API Reference*.

- Effect – What the effect will be when the user requests the specific action—this can be either `Allow` or `Deny`.

  If you don't explicitly grant access to (allow) a resource, access is implicitly denied. You can also explicitly deny access to a resource. You might do this to make sure that a user can't access the resource, even if a different policy grants access. For more information, see IAM JSON Policy Elements: Effect in the *IAM User Guide*.

- Principal – The account or user who is allowed access to the actions and resources in the statement. In a bucket policy, the principal is the user, account, service, or other entity that is the recipient of this permission. For more information, see Principals for bucket policies.

- Condition – Conditions for when a policy is in effect. You can use AWS-wide keys and Amazon S3-specific keys to specify conditions in an Amazon S3 access policy. For more information, see Bucket policy examples using condition keys.

The following example bucket policy shows the `Effect`, `Principal`, `Action`, and `Resource` elements. This policy allows *Akua*, a user in account *123456789012*, `s3:GetObject`,

`s3:GetBucketLocation`, and `s3:ListBucket` Amazon S3 permissions on the *amzn-s3-demo-bucket1* bucket.

```
{
    "Version": "2012-10-17",
    "Id": "ExamplePolicy01",
    "Statement": [
        {
            "Sid": "ExampleStatement01",
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws:iam::123456789012:user/Akua"
            },
            "Action": [
                "s3:GetObject",
                "s3:GetBucketLocation",
                "s3:ListBucket"
            ],
            "Resource": [
                "arn:aws:s3:::amzn-s3-demo-bucket1/*",
                "arn:aws:s3:::amzn-s3-demo-bucket1"
            ]
        }
    ]
}
```

For complete policy language information, see Policies and permissions in IAM and IAM JSON policy reference in the *IAM User Guide*.

**Permission delegation**

If an AWS account owns a resource, it can grant those permissions to another AWS account. That account can then delegate those permissions, or a subset of them, to users in the account. This is referred to as *permission delegation*. But an account that receives permissions from another account can't delegate permission cross-account to another AWS account.

**Amazon S3 bucket and object ownership**

Buckets and objects are Amazon S3 resources. By default, only the resource owner can access these resources. The resource owner refers to the AWS account that creates the resource. For example:

- The AWS account that you use to create buckets and upload objects owns those resources.

- If you upload an object using AWS Identity and Access Management (IAM) user or role credentials, the AWS account that the user or role belongs to owns the object.
- A bucket owner can grant cross-account permissions to another AWS account (or users in another account) to upload objects. In this case, the AWS account that uploads objects owns those objects. The bucket owner doesn't have permissions on the objects that other accounts own, with the following exceptions:
  - The bucket owner pays the bills. The bucket owner can deny access to any objects, or delete any objects in the bucket, regardless of who owns them.
  - The bucket owner can archive any objects or restore archived objects regardless of who owns them. Archival refers to the storage class used to store the objects. For more information, see Managing your storage lifecycle.

**Ownership and request authentication**

All requests to a bucket are either authenticated or unauthenticated. Authenticated requests must include a signature value that authenticates the request sender, and unauthenticated requests do not. For more information about request authentication, see Making requests.

A bucket owner can allow unauthenticated requests. For example, unauthenticated PutObject requests are allowed when a bucket has a public bucket policy, or when a bucket ACL grants `WRITE` or `FULL_CONTROL` access to the `All Users` group or the anonymous user specifically. For more information about public bucket policies and public access control lists (ACLs), see The meaning of "public".

All unauthenticated requests are made by the anonymous user. This user is represented in ACLs by the specific canonical user ID `65a011a29cdf8ec533ec3d1ccaae921c`. If an object is uploaded to a bucket through an unauthenticated request, the anonymous user owns the object. The default object ACL grants `FULL_CONTROL` to the anonymous user as the object's owner. Therefore, Amazon S3 allows unauthenticated requests to retrieve the object or modify its ACL.

To prevent objects from being modified by the anonymous user, we recommend that you do not implement bucket policies that allow anonymous public writes to your bucket or use ACLs that allow the anonymous user write access to your bucket. You can enforce this recommended behavior by using Amazon S3 Block Public Access.

For more information about blocking public access, see Blocking public access to your Amazon S3 storage. For more information about ACLs, see Access control list (ACL) overview.

**Important**

We recommend that you don't use the AWS account root user credentials to make authenticated requests. Instead, create an IAM role and grant that role full access. We refer to users with this role as *administrator users*. You can use credentials assigned to the administrator role, instead of AWS account root user credentials, to interact with AWS and perform tasks, such as create a bucket, create users, and grant permissions. For more information, see AWS security credentials and Security best practices in IAM in the *IAM User Guide*.

## Bucket policies for Amazon S3

A bucket policy is a resource-based policy that you can use to grant access permissions to your Amazon S3 bucket and the objects in it. Only the bucket owner can associate a policy with a bucket. The permissions attached to the bucket apply to all of the objects in the bucket that are owned by the bucket owner. These permissions don't apply to objects that are owned by other AWS accounts.

S3 Object Ownership is an Amazon S3 bucket-level setting that you can use to control ownership of objects uploaded to your bucket and to disable or enable access control lists (ACLs). By default, Object Ownership is set to the Bucket owner enforced setting and all ACLs are disabled. The bucket owner owns all the objects in the bucket and manages access to data exclusively using policies.

Bucket policies use JSON-based AWS Identity and Access Management (IAM) policy language. You can use bucket policies to add or deny permissions for the objects in a bucket. Bucket policies can allow or deny requests based on the elements in the policy. These elements include the requester, S3 actions, resources, and aspects or conditions of the request (such as the IP address that's used to make the request).

For example, you can create a bucket policy that does the following:

- Grants other accounts cross-account permissions to upload objects to your S3 bucket
- Makes sure that you, the bucket owner, has full control of the uploaded objects

For more information, see Examples of Amazon S3 bucket policies.

**Important**

You can't use a bucket policy to prevent deletions or transitions by an S3 Lifecycle rule. For example, even if your bucket policy denies all actions for all principals, your S3 Lifecycle configuration still functions as normal.

The topics in this section provide examples and show you how to add a bucket policy in the S3 console. For information about identity-based policies, see Identity-based policies for Amazon S3. For information about bucket policy language, see Policies and permissions in Amazon S3.

**Topics**

- Adding a bucket policy by using the Amazon S3 console
- Controlling access from VPC endpoints with bucket policies
- Examples of Amazon S3 bucket policies
- Bucket policy examples using condition keys

### Adding a bucket policy by using the Amazon S3 console

You can use the AWS Policy Generator and the Amazon S3 console to add a new bucket policy or edit an existing bucket policy. A bucket policy is a resource-based AWS Identity and Access Management (IAM) policy. You add a bucket policy to a bucket to grant other AWS accounts or IAM users access permissions for the bucket and the objects in it. Object permissions apply only to the objects that the bucket owner creates. For more information about bucket policies, see Identity and Access Management for Amazon S3.

Make sure to resolve security warnings, errors, general warnings, and suggestions from AWS Identity and Access Management Access Analyzer before you save your policy. IAM Access Analyzer runs policy checks to validate your policy against IAM policy grammar and best practices. These checks generate findings and provide actionable recommendations to help you author policies that are functional and conform to security best practices. To learn more about validating policies by using IAM Access Analyzer, see IAM Access Analyzer policy validation in the *IAM User Guide*. To view a list of the warnings, errors, and suggestions that are returned by IAM Access Analyzer, see IAM Access Analyzer policy check reference.

For guidance on troubleshooting errors with a policy, see Troubleshoot Access Denied (403 Forbidden) errors in Amazon S3.

**To create or edit a bucket policy**

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Buckets**.
3. In the **Buckets** list, choose the name of the bucket that you want to create a bucket policy for or whose bucket policy you want to edit.
4. Choose the **Permissions** tab.
5. Under **Bucket policy**, choose **Edit**. The **Edit bucket policy** page appears.
6. On the **Edit bucket policy** page, do one of the following:

   - To see examples of bucket policies, choose **Policy examples**. Or see Examples of Amazon S3 bucket policies in the *Amazon S3 User Guide*.
   - To generate a policy automatically, or edit the JSON in the **Policy** section, choose **Policy generator**.

   If you choose **Policy generator**, the AWS Policy Generator opens in a new window.

   a. On the **AWS Policy Generator** page, for **Select Type of Policy**, choose **S3 Bucket Policy**.

   b. Add a statement by entering the information in the provided fields, and then choose **Add Statement**. Repeat this step for as many statements as you would like to add. For more information about these fields, see the IAM JSON policy elements reference in the *IAM User Guide*.

   > **Note**
   >
   > For your convenience, the **Edit bucket policy** page displays the **Bucket ARN** (Amazon Resource Name) of the current bucket above the **Policy** text field. You can copy this ARN for use in the statements on the **AWS Policy Generator** page.

   c. After you finish adding statements, choose **Generate Policy**.

   d. Copy the generated policy text, choose **Close**, and return to the **Edit bucket policy** page in the Amazon S3 console.
7. In the **Policy** box, edit the existing policy or paste the bucket policy from the AWS Policy Generator. Make sure to resolve security warnings, errors, general warnings, and suggestions before you save your policy.

> **Note**
>
> Bucket policies are limited to 20 KB in size.

8. (Optional) Choose **Preview external access** in the lower-right corner to preview how your new policy affects public and cross-account access to your resource. Before you save your policy, you can check whether it introduces new IAM Access Analyzer findings or resolves existing findings. If you don't see an active analyzer, choose **Go to Access Analyzer** to create an account analyzer in IAM Access Analyzer. For more information, see Preview access in the *IAM User Guide*.
9. Choose **Save changes**, which returns you to the **Permissions** tab.

### Controlling access from VPC endpoints with bucket policies

You can use Amazon S3 bucket policies to control access to buckets from specific virtual private cloud (VPC) endpoints or specific VPCs. This section contains example bucket policies that you can use to control Amazon S3 bucket access from VPC endpoints. To learn how to set up VPC endpoints, see VPC Endpoints in the *VPC User Guide*.

A VPC enables you to launch AWS resources into a virtual network that you define. A VPC endpoint enables you to create a private connection between your VPC and another AWS service. This private connection doesn't require access over the internet, through a virtual private network (VPN) connection, through a NAT instance, or through AWS Direct Connect.

A VPC endpoint for Amazon S3 is a logical entity within a VPC that allows connectivity only to Amazon S3. The VPC endpoint routes requests to Amazon S3 and routes responses back to the VPC. VPC endpoints change only how requests are routed. Amazon S3 public endpoints and DNS names will continue to work with VPC endpoints. For important information about using VPC endpoints with Amazon S3, see Gateway endpoints and Gateway endpoints for Amazon S3 in the *VPC User Guide*.

VPC endpoints for Amazon S3 provide two ways to control access to your Amazon S3 data:

- You can control the requests, users, or groups that are allowed through a specific VPC endpoint. For information about this type of access control, see Controlling access to VPC endpoints using endpoint policies in the *VPC User Guide*.

- You can control which VPCs or VPC endpoints have access to your buckets by using Amazon S3 bucket policies. For examples of this type of bucket policy access control, see the following topics on restricting access.

### Topics

- Restricting access to a specific VPC endpoint
- Restricting access to a specific VPC

> **Important**
>
> When applying the Amazon S3 bucket policies for VPC endpoints described in this section, you might block your access to the bucket unintentionally. Bucket permissions that are intended to specifically limit bucket access to connections originating from your VPC endpoint can block all connections to the bucket. For information about how to fix this issue, see How do I fix my bucket policy when it has the wrong VPC or VPC endpoint ID? in the *AWS Support Knowledge Center*.

### Restricting access to a specific VPC endpoint

The following is an example of an Amazon S3 bucket policy that restricts access to a specific bucket, `awsexamplebucket1`, only from the VPC endpoint with the ID `vpce-1a2b3c4d`. If the specified endpoint is not used, the policy denies all access to the bucket. The `aws:SourceVpce` condition specifies the endpoint. The `aws:SourceVpce` condition doesn't require an Amazon Resource Name (ARN) for the VPC endpoint resource, only the VPC endpoint ID. For more information about using conditions in a policy, see Bucket policy examples using condition keys.

> **Important**
>
> - Before using the following example policy, replace the VPC endpoint ID with an appropriate value for your use case. Otherwise, you won't be able to access your bucket.
> - This policy disables console access to the specified bucket because console requests don't originate from the specified VPC endpoint.

```
{
```

```
   "Version": "2012-10-17",
   "Id": "Policy1415115909152",
   "Statement": [
     {
       "Sid": "Access-to-specific-VPCE-only",
       "Principal": "*",
       "Action": "s3:*",
       "Effect": "Deny",
       "Resource": ["arn:aws:s3:::awsexamplebucket1",
                    "arn:aws:s3:::awsexamplebucket1/*"],
       "Condition": {
         "StringNotEquals": {
           "aws:SourceVpce": "vpce-1a2b3c4d"
         }
       }
     }
   ]
}
```

### Restricting access to a specific VPC

You can create a bucket policy that restricts access to a specific VPC by using the `aws:SourceVpc` condition. This is useful if you have multiple VPC endpoints configured in the same VPC, and you want to manage access to your Amazon S3 buckets for all of your endpoints. The following is an example of a policy that denies access to `awsexamplebucket1` and its objects from anyone outside VPC `vpc-111bbb22`. If the specified VPC isn't used, the policy denies all access to the bucket. This statement doesn't grant access to the bucket. To grant access, you must add a separate `Allow` statement. The `vpc-111bbb22` condition key doesn't require an ARN for the VPC resource, only the VPC ID.

> **Important**
>
> - Before using the following example policy, replace the VPC ID with an appropriate value for your use case. Otherwise, you won't be able to access your bucket.
> - This policy disables console access to the specified bucket because console requests don't originate from the specified VPC.

```
{
```

```
   "Version": "2012-10-17",
   "Id": "Policy1415115909153",
   "Statement": [
     {
       "Sid": "Access-to-specific-VPC-only",
       "Principal": "*",
       "Action": "s3:*",
       "Effect": "Deny",
       "Resource": ["arn:aws:s3:::awsexamplebucket1",
                    "arn:aws:s3:::awsexamplebucket1/*"],
       "Condition": {
         "StringNotEquals": {
           "aws:SourceVpc": "vpc-111bbb22"
         }
       }
     }
   ]
}
```

### Examples of Amazon S3 bucket policies

With Amazon S3 bucket policies, you can secure access to objects in your buckets, so that only users with the appropriate permissions can access them. You can even prevent authenticated users without the appropriate permissions from accessing your Amazon S3 resources.

This section presents examples of typical use cases for bucket policies. These sample policies use *amzn-s3-demo-bucket* as the resource value. To test these policies, replace the *user input placeholders* with your own information (such as your bucket name).

To grant or deny permissions to a set of objects, you can use wildcard characters (*) in Amazon Resource Names (ARNs) and other values. For example, you can control access to groups of objects that begin with a common prefix or end with a specific extension, such as `.html`.

For more information about AWS Identity and Access Management (IAM) policy language, see Policies and permissions in Amazon S3.

> **Note**
>
> When testing permissions by using the Amazon S3 console, you must grant additional permissions that the console requires—`s3:ListAllMyBuckets`, `s3:GetBucketLocation`, and `s3:ListBucket`. For an example walkthrough that grants

permissions to users and tests those permissions by using the console, see Controlling access to a bucket with user policies.

Additional resources for creating bucket policies include the following:

- For a list of the IAM policy actions, resources, and condition keys that you can use when creating a bucket policy, see Actions, resources, and condition keys for Amazon S3 in the *Service Authorization Reference*.
- For guidance on creating your S3 policy, see Adding a bucket policy by using the Amazon S3 console.
- To troubleshoot errors with a policy, see Troubleshoot Access Denied (403 Forbidden) errors in Amazon S3.

**Topics**

### Granting read-only permission to a public anonymous user

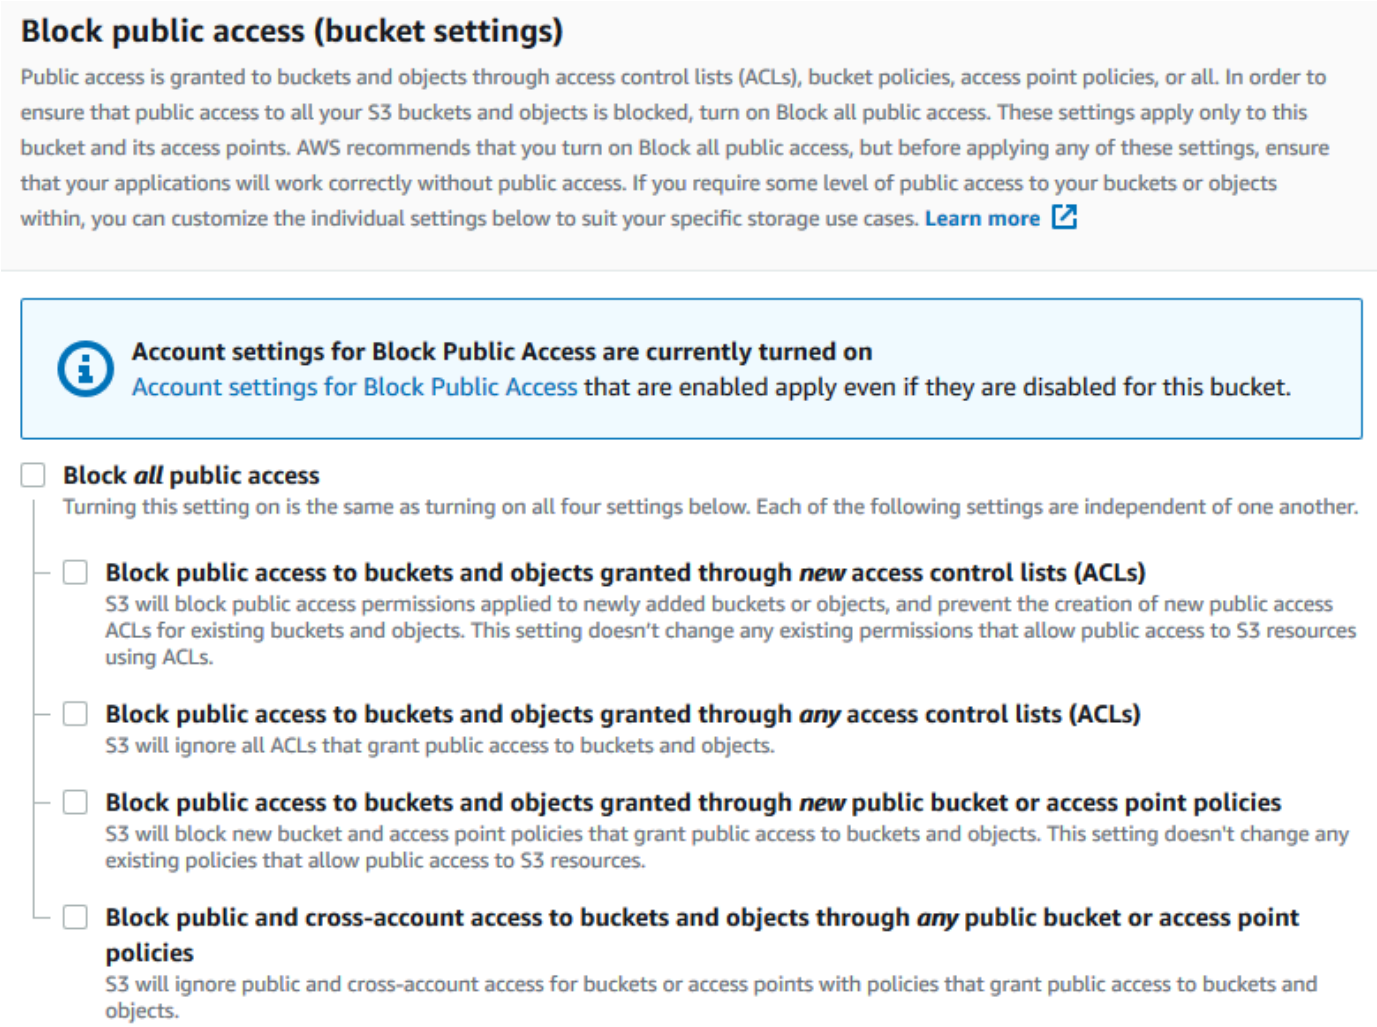
You can use your policy settings to grant access to public anonymous users, which is useful if you're configuring your bucket as a static website. Granting access to public anonymous users requires

you to disable the Block Public Access settings for your bucket. For more information about how to do this, and the policy required, see Setting permissions for website access. To learn how to set up more restrictive policies for the same purpose, see How can I grant public read access to some objects in my Amazon S3 bucket? in the AWS Knowledge Center.

By default, Amazon S3 blocks public access to your account and buckets. If you want to use a bucket to host a static website, you can use these steps to edit your block public access settings.

> **Warning**
>
> Before you complete these steps, review Blocking public access to your Amazon S3 storage to ensure that you understand and accept the risks involved with allowing public access. When you turn off block public access settings to make your bucket public, anyone on the internet can access your bucket. We recommend that you block all public access to your buckets.

1. Open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. Choose the name of the bucket that you have configured as a static website.
3. Choose **Permissions**.
4. Under **Block public access (bucket settings)**, choose **Edit**.
5. Clear **Block *all* public access**, and choose **Save changes**.



Amazon S3 turns off the Block Public Access settings for your bucket. To create a public static website, you might also have to edit the Block Public Access settings for your account before adding a bucket policy. If the Block Public Access settings for your account are currently turned on, you see a note under **Block public access (bucket settings)**.

### Requiring encryption

You can require server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS), as shown in the following examples.

### Require SSE-KMS for all objects written to a bucket

The following example policy requires every object that is written to the bucket to be encrypted with server-side encryption using AWS Key Management Service (AWS KMS) keys (SSE-KMS). If the object isn't encrypted with SSE-KMS, the request is denied.

```
{
"Version": "2012-10-17",
"Id": "PutObjPolicy",
"Statement": [{
  "Sid": "DenyObjectsThatAreNotSSEKMS",
  "Principal": "*",
  "Effect": "Deny",
  "Action": "s3:PutObject",
  "Resource": "arn:aws:s3:::DOC-EXAMPLE-BUCKET/*",
  "Condition": {
    "Null": {
      "s3:x-amz-server-side-encryption-aws-kms-key-id": "true"
    }
  }
}]
}
```

**Require SSE-KMS with a specific AWS KMS key for all objects written to a bucket**

The following example policy denies any objects from being written to the bucket if they aren't encrypted with SSE-KMS by using a specific KMS key ID. Even if the objects are encrypted with SSE-KMS by using a per-request header or bucket default encryption, the objects can't be written to the bucket if they haven't been encrypted with the specified KMS key. Make sure to replace the KMS key ARN that's used in this example with your own KMS key ARN.

```
{
"Version": "2012-10-17",
"Id": "PutObjPolicy",
"Statement": [{
  "Sid": "DenyObjectsThatAreNotSSEKMSWithSpecificKey",
  "Principal": "*",
  "Effect": "Deny",
  "Action": "s3:PutObject",
  "Resource": "arn:aws:s3:::DOC-EXAMPLE-BUCKET/*",
  "Condition": {
    "ArnNotEqualsIfExists": {
      "s3:x-amz-server-side-encryption-aws-kms-key-id": "arn:aws:kms:us-
east-2:111122223333:key/01234567-89ab-cdef-0123-456789abcdef"
    }
  }
}]
}
```

### Managing buckets using canned ACLs

#### Granting permissions to multiple accounts to upload objects or set object ACLs for public access

The following example policy grants the `s3:PutObject` and `s3:PutObjectAcl` permissions to multiple AWS accounts. Also, the example policy requires that any requests for these operations must include the `public-read` canned access control list (ACL). For more information, see Policy actions for Amazon S3 and Policy condition keys for Amazon S3.

> **Warning**
>
> The `public-read` canned ACL allows anyone in the world to view the objects in your bucket. Use caution when granting anonymous access to your Amazon S3 bucket or disabling block public access settings. When you grant anonymous access, anyone in the world can access your bucket. We recommend that you never grant anonymous access to your Amazon S3 bucket unless you specifically need to, such as with static website hosting. If you want to enable block public access settings for static website hosting, see Tutorial: Configuring a static website on Amazon S3.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AddPublicReadCannedAcl",
            "Effect": "Allow",
            "Principal": {
                "AWS": [
                    "arn:aws:iam::111122223333:root",
                    "arn:aws:iam::444455556666:root"
                ]
            },
            "Action": [
                "s3:PutObject",
                "s3:PutObjectAcl"
            ],
            "Resource": "arn:aws:s3:::DOC-EXAMPLE-BUCKET/*",
            "Condition": {
                "StringEquals": {
                    "s3:x-amz-acl": [
                        "public-read"
```

```
                    ]
                }
            }
        }
    ]
}
```

### Grant cross-account permissions to upload objects while ensuring that the bucket owner has full control

The following example shows how to allow another AWS account to upload objects to your bucket while ensuring that you have full control of the uploaded objects. This policy grants a specific AWS account (*111122223333*) the ability to upload objects only if that account includes the `bucket-owner-full-control` canned ACL on upload. The `StringEquals` condition in the policy specifies the `s3:x-amz-acl` condition key to express the canned ACL requirement. For more information, see Policy condition keys for Amazon S3.

```
{
   "Version":"2012-10-17",
   "Statement":[
     {
       "Sid":"PolicyForAllowUploadWithACL",
       "Effect":"Allow",
       "Principal":{"AWS":"111122223333"},
       "Action":"s3:PutObject",
       "Resource":"arn:aws:s3:::DOC-EXAMPLE-BUCKET/*",
       "Condition": {
         "StringEquals": {"s3:x-amz-acl":"bucket-owner-full-control"}
       }
     }
   ]
}
```

### Managing object access with object tagging

### Allow a user to read only objects that have a specific tag key and value

The following permissions policy limits a user to only reading objects that have the `environment: production` tag key and value. This policy uses the `s3:ExistingObjectTag` condition key to specify the tag key and value.

```
{
```

```
   "Version":"2012-10-17",
   "Statement":[
      {
         "Principal":{
            "AWS":"arn:aws:iam::111122223333:role/JohnDoe"
         },
         "Effect":"Allow",
         "Action":[
            "s3:GetObject",
            "s3:GetObjectVersion"
         ],
         "Resource":"arn:aws:s3:::amzn-s3-demo-bucket/*",
         "Condition":{
            "StringEquals":{
               "s3:ExistingObjectTag/environment":"production"
            }
         }
      }
   ]
}
```

**Restrict which object tag keys that users can add**

The following example policy grants a user permission to perform the `s3:PutObjectTagging` action, which allows a user to add tags to an existing object. The condition uses the `s3:RequestObjectTagKeys` condition key to specify the allowed tag keys, such as `Owner` or `CreationDate`. For more information, see Creating a condition that tests multiple key values in the *IAM User Guide*.

The policy ensures that every tag key specified in the request is an authorized tag key. The `ForAnyValue` qualifier in the condition ensures that at least one of the specified keys must be present in the request.

```
{
   "Version": "2012-10-17",
  "Statement": [
    {"Principal":{"AWS":[
            "arn:aws:iam::111122223333:role/JohnDoe"
         ]
       },
 "Effect": "Allow",
      "Action": [
```

```
        "s3:PutObjectTagging"
      ],
      "Resource": [
        "arn:aws:s3:::DOC-EXAMPLE-BUCKET/*"
      ],
      "Condition": {"ForAnyValue:StringEquals": {"s3:RequestObjectTagKeys": [
            "Owner",
            "CreationDate"
          ]
        }
      }
    }
  ]
}
```

### Require a specific tag key and value when allowing users to add object tags

The following example policy grants a user permission to perform the `s3:PutObjectTagging` action, which allows a user to add tags to an existing object. The condition requires the user to include a specific tag key (such as *`Project`*) with the value set to *`X`*.

```
{
   "Version": "2012-10-17",
  "Statement": [
    {"Principal":{"AWS":[
       "arn:aws:iam::111122223333:user/JohnDoe"
        ]
       },
      "Effect": "Allow",
      "Action": [
        "s3:PutObjectTagging"
      ],
      "Resource": [
        "arn:aws:s3:::DOC-EXAMPLE-BUCKET/*"
      ],
      "Condition": {"StringEquals": {"s3:RequestObjectTag/Project": "X"
        }
      }
    }
  ]
}
```

### Allow a user to only add objects with a specific object tag key and value

The following example policy grants a user permission to perform the `s3:PutObject` action so that they can add objects to a bucket. However, the `Condition` statement restricts the tag keys and values that are allowed on the uploaded objects. In this example, the user can only add objects that have the specific tag key (*`Department`*) with the value set to *`Finance`* to the bucket.

```
{
    "Version": "2012-10-17",
    "Statement": [{
        "Principal":{
            "AWS":[
                 "arn:aws:iam::111122223333:user/JohnDoe"
         ]
        },
        "Effect": "Allow",
        "Action": [
            "s3:PutObject"
        ],
        "Resource": [
            "arn:aws:s3:::DOC-EXAMPLE-BUCKET/*"
        ],
        "Condition": {
            "StringEquals": {
                "s3:RequestObjectTag/Department": "Finance"
            }
        }
    }]
}
```

### Managing object access by using global condition keys

Global condition keys are condition context keys with an `aws` prefix. AWS services can support global condition keys or service-specific keys that include the service prefix. You can use the `Condition` element of a JSON policy to compare the keys in a request with the key values that you specify in your policy.

### Restrict access to only Amazon S3 server access log deliveries

In the following example bucket policy, the aws:SourceArn global condition key is used to compare the Amazon Resource Name (ARN) of the resource, making a service-to-service request with the ARN that is specified in the policy. The `aws:SourceArn` global condition key is used to prevent the

Amazon S3 service from being used as a confused deputy during transactions between services. Only the Amazon S3 service is allowed to add objects to the Amazon S3 bucket.

This example bucket policy grants `s3:PutObject` permissions to only the logging service principal (`logging.s3.amazonaws.com`).

> **Note**
>
> The NotPrincipal element can't be used with AWS service principals in Amazon S3 resource-based policies, such as bucket policies. Instead, we recommend using the `aws:PrincipalServiceName` condition key, as shown in the following policy.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AllowPutObjectS3ServerAccessLogsPolicy",
            "Principal": {
                "Service": "logging.s3.amazonaws.com"
            },
            "Effect": "Allow",
            "Action": "s3:PutObject",
            "Resource": "arn:aws:s3:::DOC-EXAMPLE-BUCKET-logs/*",
            "Condition": {
                "StringEquals": {
                    "aws:SourceAccount": "111111111111"
                },
                "ArnLike": {
                    "aws:SourceArn": "arn:aws:s3:::EXAMPLE-SOURCE-BUCKET"
                }
            }
        },
        {
            "Sid": "RestrictToS3ServerAccessLogs",
            "Effect": "Deny",
            "Principal": "*",
            "Action": "s3:PutObject",
            "Resource": "arn:aws:s3:::DOC-EXAMPLE-BUCKET-logs/*",
            "Condition": {
                "StringNotEqualsIfExists": {
                    "aws:PrincipalServiceName": "logging.s3.amazonaws.com"
```

```
                }
            }
        }
    ]
}
```

### Allow access to only your organization

If you want to require all IAM principals accessing a resource to be from an AWS account in your organization (including the AWS Organizations management account), you can use the `aws:PrincipalOrgID` global condition key.

To grant or restrict this type of access, define the `aws:PrincipalOrgID` condition and set the value to your organization ID in the bucket policy. The organization ID is used to control access to the bucket. When you use the `aws:PrincipalOrgID` condition, the permissions from the bucket policy are also applied to all new accounts that are added to the organization.

Here's an example of a resource-based bucket policy that you can use to grant specific IAM principals in your organization direct access to your bucket. By adding the `aws:PrincipalOrgID` global condition key to your bucket policy, the principal account is now required to be in your organization to obtain access to the resource. Even if you accidentally specify an incorrect account when granting access, the aws:PrincipalOrgID global condition key acts as an additional safeguard. When this global key is used in a policy, it prevents all principals from outside of the specified organization from accessing the S3 bucket. Only principals from accounts in the listed organization are able to obtain access to the resource.

```
{
    "Version": "2012-10-17",
    "Statement": [{
        "Sid": "AllowGetObject",
        "Principal": {
            "AWS": "*"
        },
        "Effect": "Allow",
        "Action": "s3:GetObject",
        "Resource": "arn:aws:s3:::DOC-EXAMPLE-BUCKET/*",
        "Condition": {
            "StringEquals": {
                "aws:PrincipalOrgID": ["o-aa111bb222"]
            }
        }
```

```
    }]
}
```

### Managing access based on HTTP or HTTPS requests

#### Restrict access to only HTTPS requests

If you want to prevent potential attackers from manipulating network traffic, you can use HTTPS (TLS) to only allow encrypted connections while restricting HTTP requests from accessing your bucket. To determine whether the request is HTTP or HTTPS, use the aws:SecureTransport global condition key in your S3 bucket policy. The `aws:SecureTransport` condition key checks whether a request was sent by using HTTP.

If a request returns `true`, then the request was sent through HTTPS. If the request returns `false`, then the request was sent through HTTP. You can then allow or deny access to your bucket based on the desired request scheme.

In the following example, the bucket policy explicitly denies HTTP requests.

```
{
    "Version": "2012-10-17",
    "Statement": [{
        "Sid": "RestrictToTLSRequestsOnly",
        "Action": "s3:*",
        "Effect": "Deny",
        "Resource": [
            "arn:aws:s3:::DOC-EXAMPLE-BUCKET",
            "arn:aws:s3:::amzn-s3-demo-bucket/*"
        ],
        "Condition": {
            "Bool": {
                "aws:SecureTransport": "false"
            }
        },
        "Principal": "*"
    }]
}
```

#### Restrict access to a specific HTTP referer

Suppose that you have a website with the domain name *www.example.com* or *example.com* with links to photos and videos stored in your bucket named *amzn-s3-demo-bucket*. By default, all

Amazon S3 resources are private, so only the AWS account that created the resources can access them.

To allow read access to these objects from your website, you can add a bucket policy that allows the `s3:GetObject` permission with a condition that the `GET` request must originate from specific webpages. The following policy restricts requests by using the `StringLike` condition with the `aws:Referer` condition key.

```
{
  "Version":"2012-10-17",
  "Id":"HTTP referer policy example",
  "Statement":[
    {
      "Sid":"Allow only GET requests originating from www.example.com and
 example.com.",
      "Effect":"Allow",
      "Principal":"*",
      "Action":["s3:GetObject","s3:GetObjectVersion"],
      "Resource":"arn:aws:s3:::amzn-s3-demo-bucket/*",
      "Condition":{
        "StringLike":{"aws:Referer":["http://www.example.com/*","http://example.com/
*"]}
      }
    }
  ]
}
```

Make sure that the browsers that you use include the HTTP `referer` header in the request.

> **Warning**
>
> We recommend that you use caution when using the `aws:Referer` condition key. It is dangerous to include a publicly known HTTP referer header value. Unauthorized parties can use modified or custom browsers to provide any `aws:Referer` value that they choose. Therefore, do not use `aws:Referer` to prevent unauthorized parties from making direct AWS requests.
>
> The `aws:Referer` condition key is offered only to allow customers to protect their digital content, such as content stored in Amazon S3, from being referenced on unauthorized third-party sites. For more information, see aws:Referer in the *IAM User Guide*.

### Managing user access to specific folders

#### Grant users access to specific folders

Suppose that you're trying to grant users access to a specific folder. If the IAM user and the S3 bucket belong to the same AWS account, then you can use an IAM policy to grant the user access to a specific bucket folder. With this approach, you don't need to update your bucket policy to grant access. You can add the IAM policy to an IAM role that multiple users can switch to.

If the IAM identity and the S3 bucket belong to different AWS accounts, then you must grant cross-account access in both the IAM policy and the bucket policy. For more information about granting cross-account access, see Bucket owner granting cross-account bucket permissions.

The following example bucket policy grants *JohnDoe* full console access to only his folder (home/*JohnDoe*/). By creating a home folder and granting the appropriate permissions to your users, you can have multiple users share a single bucket. This policy consists of three `Allow` statements:

- *AllowRootAndHomeListingOfCompanyBucket*: Allows the user (*JohnDoe*) to list objects at the root level of the *DOC-EXAMPLE-BUCKET* bucket and in the home folder. This statement also allows the user to search on the prefix home/ by using the console.
- *AllowListingOfUserFolder*: Allows the user (*JohnDoe*) to list all objects in the home/*JohnDoe*/ folder and any subfolders.
- *AllowAllS3ActionsInUserFolder*: Allows the user to perform all Amazon S3 actions by granting `Read`, `Write`, and `Delete` permissions. Permissions are limited to the bucket owner's home folder.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AllowRootAndHomeListingOfCompanyBucket",
            "Principal": {
                "AWS": [
                    "arn:aws:iam::111122223333:user/JohnDoe"
                ]
            },
            "Effect": "Allow",
            "Action": ["s3:ListBucket"],
            "Resource": ["arn:aws:s3:::DOC-EXAMPLE-BUCKET"],
```

```
            "Condition": {
                "StringEquals": {
                    "s3:prefix": ["", "home/", "home/JohnDoe"],
                    "s3:delimiter": ["/"]
                }
            }
        },
        {
            "Sid": "AllowListingOfUserFolder",
            "Principal": {
                "AWS": [
                    "arn:aws:iam::111122223333:user/JohnDoe"
                ]
            },
            "Action": ["s3:ListBucket"],
            "Effect": "Allow",
            "Resource": ["arn:aws:s3:::DOC-EXAMPLE-BUCKET"],
            "Condition": {
                "StringLike": {
                    "s3:prefix": ["home/JohnDoe/*"]
                }
            }
        },
        {
            "Sid": "AllowAllS3ActionsInUserFolder",
            "Effect": "Allow",
            "Principal": {
                "AWS": [
                    "arn:aws:iam::111122223333:user/JohnDoe"
                ]
            },
            "Action": ["s3:*"],
            "Resource": ["arn:aws:s3:::DOC-EXAMPLE-BUCKET/home/JohnDoe/*"]
        }
    ]
}
```

### Managing access for access logs

#### Grant access to Application Load Balancer for enabling access logs

When you enable access logs for Application Load Balancer, you must specify the name of the S3 bucket where the load balancer will store the logs. The bucket must have an attached policy that grants Elastic Load Balancing permission to write to the bucket.

In the following example, the bucket policy grants Elastic Load Balancing (ELB) permission to write the access logs to the bucket:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Principal": {
        "AWS": "arn:aws:iam::elb-account-id:root"
      },
      "Effect": "Allow",
      "Action": "s3:PutObject",
      "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/prefix/AWSLogs/111122223333/*"
    }
  ]
}
```

> **Note**
>
> Make sure to replace *elb-account-id* with the AWS account ID for Elastic Load Balancing for your AWS Region. For the list of Elastic Load Balancing Regions, see Attach a policy to your Amazon S3 bucket in the *Elastic Load Balancing User Guide*.

If your AWS Region does not appear in the supported Elastic Load Balancing Regions list, use the following policy, which grants permissions to the specified log delivery service.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
       "Principal": {
```

```
          "Service": "logdelivery.elasticloadbalancing.amazonaws.com"
           },
      "Effect": "Allow",
      "Action": "s3:PutObject",
      "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/prefix/AWSLogs/111122223333/*"
    }
  ]
}
```

Then, make sure to configure your Elastic Load Balancing access logs by enabling them. You can verify your bucket permissions by creating a test file.

**Managing access to an Amazon CloudFront OAI**

**Grant permission to an Amazon CloudFront OAI**

The following example bucket policy grants a CloudFront origin access identity (OAI) permission to get (read) all objects in your S3 bucket. You can use a CloudFront OAI to allow users to access objects in your bucket through CloudFront but not directly through Amazon S3. For more information, see Restricting access to Amazon S3 content by using an Origin Access Identity in the *Amazon CloudFront Developer Guide*.

The following policy uses the OAI's ID as the policy's `Principal`. For more information about using S3 bucket policies to grant access to a CloudFront OAI, see Migrating from origin access identity (OAI) to origin access control (OAC) in the *Amazon CloudFront Developer Guide*.

To use this example:

- Replace *EH1HDMB1FH2TC* with the OAI's ID. To find the OAI's ID, see the Origin Access Identity page on the CloudFront console, or use ListCloudFrontOriginAccessIdentities in the CloudFront API.
- Replace *amzn-s3-demo-bucket* with the name of your bucket.

```
{
    "Version": "2012-10-17",
    "Id": "PolicyForCloudFrontPrivateContent",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
```

```
                "AWS": "arn:aws:iam::cloudfront:user/CloudFront Origin Access
 Identity EH1HDMB1FH2TC"
            },
            "Action": "s3:GetObject",
            "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/*"
        }
    ]
}
```

### Managing access for Amazon S3 Storage Lens

### Grant permissions for Amazon S3 Storage Lens

S3 Storage Lens aggregates your metrics and displays the information in the **Account snapshot** section on the Amazon S3 console **Buckets** page. S3 Storage Lens also provides an interactive dashboard that you can use to visualize insights and trends, flag outliers, and receive recommendations for optimizing storage costs and applying data-protection best practices. Your dashboard has drill-down options to generate and visualize insights at the organization, account, AWS Region, storage class, bucket, prefix, or Storage Lens group level. You can also send a daily metrics export in CSV or Parquet format to an S3 bucket.

S3 Storage Lens can export your aggregated storage usage metrics to an Amazon S3 bucket for further analysis. The bucket where S3 Storage Lens places its metrics exports is known as the *destination bucket*. When setting up your S3 Storage Lens metrics export, you must have a bucket policy for the destination bucket. For more information, see Assessing your storage activity and usage with Amazon S3 Storage Lens.

The following example bucket policy grants Amazon S3 permission to write objects (PUT requests) to a destination bucket. You use a bucket policy like this on the destination bucket when setting up an S3 Storage Lens metrics export.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "S3StorageLensExamplePolicy",
            "Effect": "Allow",
            "Principal": {
                "Service": "storage-lens.s3.amazonaws.com"
            },
            "Action": "s3:PutObject",
```

```
            "Resource": [
                "arn:aws:s3:::amzn-s3-demo-destination-bucket/destination-prefix/
StorageLens/111122223333/*"
            ],
            "Condition": {
                "StringEquals": {
                    "s3:x-amz-acl": "bucket-owner-full-control",
                    "aws:SourceAccount": "111122223333",
                    "aws:SourceArn": "arn:aws:s3:region-code:111122223333:storage-
lens/storage-lens-dashboard-configuration-id"
                }
            }
        }
    ]
}
```

When you're setting up an S3 Storage Lens organization-level metrics export, use the following modification to the previous bucket policy's `Resource` statement.

```
"Resource": "arn:aws:s3:::amzn-s3-demo-destination-bucket/destination-prefix/
StorageLens/your-organization-id/*",
```

### Managing permissions for S3 Inventory, S3 analytics, and S3 Inventory reports

#### Grant permissions for S3 Inventory and S3 analytics

S3 Inventory creates lists of the objects in a bucket, and S3 analytics Storage Class Analysis export creates output files of the data used in the analysis. The bucket that the inventory lists the objects for is called the *source bucket*. The bucket where the inventory file or the analytics export file is written to is called a *destination bucket*. When setting up an inventory or an analytics export, you must create a bucket policy for the destination bucket. For more information, see Amazon S3 Inventory and Amazon S3 analytics – Storage Class Analysis.

The following example bucket policy grants Amazon S3 permission to write objects (PUT requests) from the account for the source bucket to the destination bucket. You use a bucket policy like this on the destination bucket when setting up S3 Inventory and S3 analytics export.

```
{
      "Version": "2012-10-17",
```

```
      "Statement": [
        {
            "Sid": "InventoryAndAnalyticsExamplePolicy",
            "Effect": "Allow",
            "Principal": {
                "Service": "s3.amazonaws.com"
            },
            "Action": "s3:PutObject",
            "Resource": [
                "arn:aws:s3:::DOC-EXAMPLE-DESTINATION-BUCKET/*"
            ],
            "Condition": {
                "ArnLike": {
                    "aws:SourceArn": "arn:aws:s3:::DOC-EXAMPLE-SOURCE-BUCKET"
                },
                "StringEquals": {
                    "aws:SourceAccount": "111122223333",
                    "s3:x-amz-acl": "bucket-owner-full-control"
                }
            }
        }
    ]
}
```

**Control S3 Inventory report configuration creation**

Amazon S3 Inventory creates lists of the objects in an S3 bucket and the metadata for each object. The `s3:PutInventoryConfiguration` permission allows a user to create an inventory configuration that includes all object metadata fields that are available by default and to specify the destination bucket to store the inventory. A user with read access to objects in the destination bucket can access all object metadata fields that are available in the inventory report. For more information about the metadata fields that are available in S3 Inventory, see Amazon S3 Inventory list.

To restrict a user from configuring an S3 Inventory report, remove the `s3:PutInventoryConfiguration` permission from the user.

Some object metadata fields in S3 Inventory report configurations are optional, meaning that they're available by default but they can be restricted when you grant a user the `s3:PutInventoryConfiguration` permission. You can control whether users can include these optional metadata fields in their reports by using the `s3:InventoryAccessibleOptionalFields` condition key. For a list of the optional metadata

fields available in S3 Inventory, see OptionalFields in the *Amazon Simple Storage Service API Reference*.

To grant a user permission to create an inventory configuration with specific optional metadata fields, use the `s3:InventoryAccessibleOptionalFields` condition key to refine the conditions in your bucket policy.

The following example policy grants a user (*Ana*) permission to create an inventory configuration conditionally. The `ForAllValues:StringEquals` condition in the policy uses the `s3:InventoryAccessibleOptionalFields` condition key to specify the two allowed optional metadata fields, namely `Size` and `StorageClass`. So, when *Ana* is creating an inventory configuration, the only optional metadata fields that she can include are `Size` and `StorageClass`.

```
{
 "Id": "InventoryConfigPolicy",
 "Version": "2012-10-17",
 "Statement": [{
   "Sid": "AllowInventoryCreationConditionally",
   "Effect": "Allow",
   "Principal": {
    "AWS": "arn:aws:iam::111122223333:user/Ana"
   },
   "Action":
    "s3:PutInventoryConfiguration",
   "Resource":
    "arn:aws:s3:::DOC-EXAMPLE-SOURCE-BUCKET",
   "Condition": {
    "ForAllValues:StringEquals": {
     "s3:InventoryAccessibleOptionalFields": [
        "Size",
        "StorageClass"
        ]
      }
    }
   }
 ]
}
```

To restrict a user from configuring an S3 Inventory report that includes specific optional metadata fields, add an explicit Deny statement to the bucket policy for the source bucket. The following

example bucket policy denies the user *Ana* from creating an inventory configuration in the source bucket *DOC-EXAMPLE-SOURCE-BUCKET* that includes the optional `ObjectAccessControlList` or `ObjectOwner` metadata fields. The user *Ana* can still create an inventory configuration with other optional metadata fields.

```
{
 "Id": "InventoryConfigSomeFields",
 "Version": "2012-10-17",
 "Statement": [{
   "Sid": "AllowInventoryCreation",
   "Effect": "Allow",
   "Principal": {
    "AWS": "arn:aws:iam::111122223333:user/Ana"
   },
   "Action": "s3:PutInventoryConfiguration",
   "Resource":
    "arn:aws:s3:::DOC-EXAMPLE-SOURCE-BUCKET",

  },
  {
   "Sid": "DenyCertainInventoryFieldCreation",
   "Effect": "Deny",
   "Principal": {
    "AWS": "arn:aws:iam::111122223333:user/Ana"
   },
   "Action": "s3:PutInventoryConfiguration",
   "Resource":
     "arn:aws:s3:::DOC-EXAMPLE-SOURCE-BUCKET",
   "Condition": {
    "ForAnyValue:StringEquals": {
     "s3:InventoryAccessibleOptionalFields": [
        "ObjectOwner",
        "ObjectAccessControlList"
        ]
      }
    }
   }
 ]
}
```

**Note**

The use of the `s3:InventoryAccessibleOptionalFields` condition key in bucket policies doesn't affect the delivery of inventory reports based on the existing inventory configurations.

**Important**

We recommend that you use `ForAllValues` with an `Allow` effect or `ForAnyValue` with a `Deny` effect, as shown in the prior examples.
Don't use `ForAllValues` with a `Deny` effect nor `ForAnyValue` with an `Allow` effect, because these combinations can be overly restrictive and block inventory configuration deletion.
To learn more about the `ForAllValues` and `ForAnyValue` condition set operators, see Multivalued context keys in the *IAM User Guide*.

### Requiring MFA

Amazon S3 supports MFA-protected API access, a feature that can enforce multi-factor authentication (MFA) for access to your Amazon S3 resources. Multi-factor authentication provides an extra level of security that you can apply to your AWS environment. MFA is a security feature that requires users to prove physical possession of an MFA device by providing a valid MFA code. For more information, see AWS Multi-Factor Authentication. You can require MFA for any requests to access your Amazon S3 resources.

To enforce the MFA requirement, use the `aws:MultiFactorAuthAge` condition key in a bucket policy. IAM users can access Amazon S3 resources by using temporary credentials issued by the AWS Security Token Service (AWS STS). You provide the MFA code at the time of the AWS STS request.

When Amazon S3 receives a request with multi-factor authentication, the `aws:MultiFactorAuthAge` condition key provides a numeric value that indicates how long ago (in seconds) the temporary credential was created. If the temporary credential provided in the request was not created by using an MFA device, this key value is null (absent). In a bucket policy, you can add a condition to check this value, as shown in the following example.

This example policy denies any Amazon S3 operation on the */taxdocuments* folder in the *amzn-s3-demo-bucket* bucket if the request is not authenticated by using MFA. To learn more about MFA, see Using Multi-Factor Authentication (MFA) in AWS in the *IAM User Guide*.

```
{
    "Version": "2012-10-17",
    "Id": "123",
    "Statement": [
      {
        "Sid": "",
        "Effect": "Deny",
        "Principal": "*",
        "Action": "s3:*",
        "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/taxdocuments/*",
        "Condition": { "Null": { "aws:MultiFactorAuthAge": true }}
      }
    ]
 }
```

The `Null` condition in the `Condition` block evaluates to `true` if the `aws:MultiFactorAuthAge` condition key value is null, indicating that the temporary security credentials in the request were created without an MFA device.

The following bucket policy is an extension of the preceding bucket policy. The following policy includes two policy statements. One statement allows the `s3:GetObject` permission on a bucket (*amzn-s3-demo-bucket*) to everyone. Another statement further restricts access to the *amzn-s3-demo-bucket/taxdocuments* folder in the bucket by requiring MFA.

```
{
    "Version": "2012-10-17",
    "Id": "123",
    "Statement": [
      {
        "Sid": "",
        "Effect": "Deny",
        "Principal": "*",
        "Action": "s3:*",
        "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/taxdocuments/*",
        "Condition": { "Null": { "aws:MultiFactorAuthAge": true } }
      },
      {
        "Sid": "",
```

```
        "Effect": "Allow",
        "Principal": "*",
        "Action": ["s3:GetObject"],
        "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/*"
      }
    ]
 }
```

You can optionally use a numeric condition to limit the duration for which the `aws:MultiFactorAuthAge` key is valid. The duration that you specify with the `aws:MultiFactorAuthAge` key is independent of the lifetime of the temporary security credential that's used in authenticating the request.

For example, the following bucket policy, in addition to requiring MFA authentication, also checks how long ago the temporary session was created. The policy denies any operation if the `aws:MultiFactorAuthAge` key value indicates that the temporary session was created more than an hour ago (3,600 seconds).

```
{
    "Version": "2012-10-17",
    "Id": "123",
    "Statement": [
      {
        "Sid": "",
        "Effect": "Deny",
        "Principal": "*",
        "Action": "s3:*",
        "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/taxdocuments/*",
        "Condition": {"Null": {"aws:MultiFactorAuthAge": true }}
      },
      {
        "Sid": "",
        "Effect": "Deny",
        "Principal": "*",
        "Action": "s3:*",
        "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/taxdocuments/*",
        "Condition": {"NumericGreaterThan": {"aws:MultiFactorAuthAge": 3600 }}
       },
       {
         "Sid": "",
         "Effect": "Allow",
         "Principal": "*",
```

```
        "Action": ["s3:GetObject"],
        "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/*"
      }
   ]
}
```

### Preventing users from deleting objects

By default, users have no permissions. But as you create policies, you might grant users permissions that you didn't intend to grant. To avoid such permission loopholes, you can write a stricter access policy by adding an explicit deny.

To explicitly block users or accounts from deleting objects, you must add the following actions to a bucket policy: `s3:DeleteObject`, `s3:DeleteObjectVersion`, and `s3:PutLifecycleConfiguration` permissions. All three actions are required because you can delete objects either by explicitly calling the `DELETE Object` API operations or by configuring their lifecycle (see Managing your storage lifecycle) so that Amazon S3 can remove the objects when their lifetime expires.

In the following policy example, you explicitly deny `DELETE Object` permissions to the user *`MaryMajor`*. An explicit `Deny` statement always supersedes any other permission granted.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "statement1",
      "Effect": "Allow",
      "Principal": {
        "AWS": "arn:aws:iam::123456789012:user/MaryMajor"
      },
      "Action": [
        "s3:GetObjectVersion",
        "s3:GetBucketAcl"
      ],
      "Resource": [
        "arn:aws:s3:::amzn-s3-demo-bucket1",
   "arn:aws:s3:::amzn-s3-demo-bucket1/*"
      ]
    },
    {
      "Sid": "statement2",
```

```
      "Effect": "Deny",
      "Principal": {
        "AWS": "arn:aws:iam::123456789012:user/MaryMajor"
      },
      "Action": [
        "s3:DeleteObject",
        "s3:DeleteObjectVersion",
        "s3:PutLifecycleConfiguration"
      ],
      "Resource": [
        "arn:aws:s3:::amzn-s3-demo-bucket1",
     "arn:aws:s3:::amzn-s3-demo-bucket1/*"
      ]
    }
  ]
}
```

### Bucket policy examples using condition keys

You can use access policy language to specify conditions when you grant permissions. You can use the optional `Condition` element, or `Condition` block to specify conditions for when a policy is in effect.

For policies that use Amazon S3 condition keys for object and bucket operations, see the following examples. For more information about condition keys, see Policy condition keys for Amazon S3. For a complete list of Amazon S3 actions, condition keys, and resources that you can specify in policies, see Actions, resources, and condition keys for Amazon S3 in the *Service Authorization Reference*.

### Examples — Amazon S3 condition keys for object operations

This section provides examples that show you how you can use Amazon S3-specific condition keys for object operations. For a complete list of Amazon S3 actions, condition keys, and resources that you can specify in policies, see Actions, resources, and condition keys for Amazon S3 in the *Service Authorization Reference*.

Several of the example policies show how you can use conditions keys with PUT Object operations. PUT Object operations allow access control list (ACL)–specific headers that you can use to grant ACL-based permissions. Using these keys, the bucket owner can set a condition to require specific access permissions when the user uploads an object. You can also grant ACL–based permissions with the PutObjectAcl operation. For more information, see PutObjectAcl in the *Amazon S3*

*Amazon Simple Storage Service API Reference*. For more information about ACLs, see Access control list (ACL) overview.

**Topics**

### Example 1: Granting s3:PutObject permission requiring objects stored using server-side encryption

Suppose that Account A owns a bucket. The account administrator wants to grant Jane, a user in Account A, permission to upload objects with a condition that Jane always request server-side encryption so that Amazon S3 saves objects encrypted. The Account A administrator can accomplish using the `s3:x-amz-server-side-encryption` condition key as shown. The key-value pair in the `Condition` block specifies the `s3:x-amz-server-side-encryption` key.

```
"Condition": {
     "StringNotEquals": {
         "s3:x-amz-server-side-encryption": "AES256"
     }}
```

When testing the permission using the AWS CLI, you must add the required parameter using the `--server-side-encryption` parameter.

```
aws s3api put-object --bucket example1bucket --key HappyFace.jpg --body c:
\HappyFace.jpg --server-side-encryption "AES256" --profile AccountBadmin
```

### Example 2: Granting s3:PutObject permission to copy objects with a restriction on the copy source

In the PUT Object request, when you specify a source object, it is a copy operation (see PUT Object - Copy). Accordingly, the bucket owner can grant a user permission to copy objects with restrictions on the source, for example:

- Allow copying objects only from the `sourcebucket` bucket.
- Allow copying objects from the source bucket and only the objects whose key name prefix starts with public/ f (for example, sourcebucket/public/*).
- Allow copying only a specific object from the sourcebucket (for example, sourcebucket/example.jpg).

The following bucket policy grants user (Dave) `s3:PutObject` permission. It allows him to copy objects only with a condition that the request include the `s3:x-amz-copy-source` header and the header value specify the `/awsexamplebucket1/public/*` key name prefix.

```
{
    "Version": "2012-10-17",
    "Statement": [
       {
            "Sid": "cross-account permission to user in your own account",
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws:iam::123456789012:user/Dave"
            },
            "Action": "s3:PutObject",
            "Resource": "arn:aws:s3:::awsexamplebucket1/*"
        },
        {
            "Sid": "Deny your user permission to upload object if copy source is not /
bucket/folder",
            "Effect": "Deny",
            "Principal": {
                "AWS": "arn:aws:iam::123456789012:user/Dave"
            },
            "Action": "s3:PutObject",
            "Resource": "arn:aws:s3:::awsexamplebucket1/*",
            "Condition": {
                "StringNotLike": {
                    "s3:x-amz-copy-source": "awsexamplebucket1/public/*"
```

```
                }
            }
        }
    ]
}
```

### Test the policy with the AWS CLI

You can test the permission using the AWS CLI `copy-object` command. You specify the source by adding the `--copy-source` parameter; the key name prefix must match the prefix allowed in the policy. You need to provide the user Dave credentials using the `--profile` parameter. For more information about setting up the AWS CLI, see Developing with Amazon S3 using the AWS CLI.

```
aws s3api copy-object --bucket awsexamplebucket1 --key HappyFace.jpg
--copy-source examplebucket/public/PublicHappyFace1.jpg --profile AccountADave
```

### Give permission to copy only a specific object

The preceding policy uses the `StringNotLike` condition. To grant permission to copy only a specific object, you must change the condition from `StringNotLike` to `StringNotEquals` and then specify the exact object key as shown.

```
"Condition": {
       "StringNotEquals": {
           "s3:x-amz-copy-source": "awsexamplebucket1/public/PublicHappyFace1.jpg"
       }
}
```

### Example 3: Granting access to a specific version of an object

Suppose that Account A owns a versioning-enabled bucket. The bucket has several versions of the `HappyFace.jpg` object. The account administrator now wants to grant its user Dave permission to get only a specific version of the object. The account administrator can accomplish this by granting Dave `s3:GetObjectVersion` permission conditionally as shown below. The key-value pair in the `Condition` block specifies the `s3:VersionId` condition key. In this case, Dave needs to know the exact object version ID to retrieve the object.

For more information, see GetObject in the *Amazon Simple Storage Service API Reference*.

```
{
```

```
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "statement1",
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws:iam::123456789012:user/Dave"
            },
            "Action": "s3:GetObjectVersion",
            "Resource": "arn:aws:s3:::examplebucketversionenabled/HappyFace.jpg"
        },
        {
            "Sid": "statement2",
            "Effect": "Deny",
            "Principal": {
                "AWS": "arn:aws:iam::123456789012:user/Dave"
            },
            "Action": "s3:GetObjectVersion",
            "Resource": "arn:aws:s3:::examplebucketversionenabled/HappyFace.jpg",
            "Condition": {
                "StringNotEquals": {
                    "s3:VersionId": "AaaHbAQitwiL_h47_44lRO2DDfLlBO5e"
                }
            }
        }
    ]
}
```

### Test the policy with the AWS CLI

You can test the permissions using the AWS CLI `get-object` command with the `--version-id` parameter identifying the specific object version. The command retrieves the object and saves it to the `OutputFile.jpg` file.

```
aws s3api get-object --bucket examplebucketversionenabled --key HappyFace.jpg
 OutputFile.jpg --version-id AaaHbAQitwiL_h47_44lRO2DDfLlBO5e --profile AccountADave
```

### Example 4: Granting permissions based on object tags

For examples on how to use object tagging condition keys with Amazon S3 operations, see Tagging and access control policies.

### Example 5: Restricting access by the AWS account ID of the bucket owner

You can use either the `aws:ResourceAccount` or `s3:ResourceAccount` key to write IAM or virtual private cloud (VPC) endpoint policies that restrict user, role, or application access to the Amazon S3 buckets that are owned by a specific AWS account ID. You can use this condition key to restrict clients within your VPC from accessing buckets that you do not own.

However, be aware that some AWS services rely on access to AWS managed buckets. Therefore, using the `aws:ResourceAccount` or `s3:ResourceAccount` key in your IAM policy might also affect access to these resources.

For more information and examples, see the following resources:

- Restrict access to buckets in a specified AWS account in the *AWS PrivateLink Guide*
- Restrict access to buckets that Amazon ECR uses in the *Amazon ECR Guide*
- Provide required access to Systems Manager for AWS managed Amazon S3 buckets in the *AWS Systems Manager Guide*
- Limit access to Amazon S3 buckets owned by specific AWS accounts in the *AWS Storage Blog*

### Example 6: Requiring a minimum TLS version

You can use the s3:TlsVersion condition key to write IAM, Virtual Private Cloud Endpoint (VPCE), or bucket policies that restrict user or application access to Amazon S3 buckets based on the TLS version used by the client. You can use this condition key to write policies that require a minimum TLS version.

#### Example

This example bucket policy *denies* PutObject requests by clients that have a TLS version lower than 1.2, for example, 1.1 or 1.0.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Deny",
            "Principal": "*",
            "Action": "s3:PutObject",
```

```
            "Resource": [
                "arn:aws:s3:::amzn-s3-demo-bucket1",
                "arn:aws:s3:::amzn-s3-demo-bucket1/*"
            ],
            "Condition": {
                "NumericLessThan": {
                    "s3:TlsVersion": 1.2
                }
            }
        }
    ]
}
```

### Example

This example bucket policy *allows* PutObject requests by clients that have a TLS version higher than 1.1, for example, 1.2, 1.3 or higher.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": "*",
            "Action": "s3:PutObject",
            "Resource": [
                "arn:aws:s3:::amzn-s3-demo-bucket1",
                "arn:aws:s3:::amzn-s3-demo-bucket1/*"
            ],
            "Condition": {
                "NumericGreaterThan": {
                    "s3:TlsVersion": 1.1
                }
            }
        }
    ]
}
```

### Examples — Amazon S3 condition keys for bucket operations

This section provides example policies that show you how you can use Amazon S3-specific condition keys for bucket operations.

#### Topics

#### Example 1: Granting s3:GetObject permission with a condition on an IP address

You can give authenticated users permission to use the `s3:GetObject` action if the request originates from a specific range of IP addresses (192.0.2.*), unless the IP address is 192.0.2.188. In the condition block, the `IpAddress` and the `NotIpAddress` are conditions, and each condition is provided a key-value pair for evaluation. Both the key-value pairs in this example use the `aws:SourceIp` AWS-wide key.

> **Note**
>
> The `IPAddress` and `NotIpAddress` key values specified in the condition uses CIDR notation as described in RFC 4632. For more information, see http://www.rfc-editor.org/rfc/rfc4632.txt.

```
{
    "Version": "2012-10-17",
    "Id": "S3PolicyId1",
    "Statement": [
        {
            "Sid": "statement1",
            "Effect": "Allow",
            "Principal": "*",
            "Action":"s3:GetObject",
            "Resource": "arn:aws:s3:::awsexamplebucket1/*",
            "Condition" : {
                "IpAddress" : {
                    "aws:SourceIp": "192.0.2.0/24"
                },
```

```
                "NotIpAddress" : {
                    "aws:SourceIp": "192.0.2.188/32"
                }
            }
        }
    ]
}
```

You can also use other AWS-wide condition keys in Amazon S3 policies. For example, you can specify the `aws:SourceVpce` and `aws:SourceVpc` condition keys in bucket policies for VPC endpoints. For specific examples, see Controlling access from VPC endpoints with bucket policies.

> **Note**
>
> For some AWS global condition keys, only certain resource types are supported. Therefore, check whether Amazon S3 supports the global condition key and resource type that you want to use, or if you'll need to use an Amazon S3-specific condition key instead. For a complete list of supported resource types and condition keys for Amazon S3, see Actions, resources, and condition keys for Amazon S3 in the *Service Authorization Reference*.

**Example 2: Getting a list of objects in a bucket with a specific prefix**

You can use the `s3:prefix` condition key to limit the response of the GET Bucket (ListObjects) API to key names with a specific prefix. If you are the bucket owner, you can restrict a user to list the contents of a specific prefix in the bucket. This condition key is useful if objects in the bucket are organized by key name prefixes. The Amazon S3 console uses key name prefixes to show a folder concept. Only the console supports the concept of folders; the Amazon S3 API supports only buckets and objects. For more information about using prefixes and delimiters to filter access permissions, see Controlling access to a bucket with user policies.

For example, if you have two objects with key names `public/object1.jpg` and `public/object2.jpg`, the console shows the objects under the `public` folder. In the Amazon S3 API, these are objects with prefixes, not objects in folders. However, in the Amazon S3 API, if you organize your object keys using such prefixes, you can grant `s3:ListBucket` permission with the `s3:prefix` condition that will allow the user to get a list of key names with those specific prefixes.

In this example, the bucket owner and the parent account to which the user belongs are the same. So the bucket owner can use either a bucket policy or a user policy. For more information about other condition keys that you can use with the GET Bucket (ListObjects) API, see ListObjects.

### User policy

The following user policy grants the `s3:ListBucket` permission (see GET Bucket (List Objects)) with a condition that requires the user to specify the `prefix` in the request with the value `projects`.

```
{
   "Version":"2012-10-17",
   "Statement":[
      {
         "Sid":"statement1",
         "Effect":"Allow",
         "Action": "s3:ListBucket",
         "Resource":"arn:aws:s3:::awsexamplebucket1",
         "Condition" : {
             "StringEquals" : {
                 "s3:prefix": "projects"
             }
          }
       },
      {
         "Sid":"statement2",
         "Effect":"Deny",
         "Action": "s3:ListBucket",
         "Resource": "arn:aws:s3:::awsexamplebucket1",
         "Condition" : {
             "StringNotEquals" : {
                 "s3:prefix": "projects"
             }
          }
       }
    ]
}
```

The condition restricts the user to listing object keys with the `projects` prefix. The added explicit deny denies the user request for listing keys with any other prefix no matter what other permissions the user might have. For example, it is possible that the user gets permission to list object keys without any restriction, either by updates to the preceding user policy or via a bucket policy. Because explicit deny always supersedes, the user request to list keys other than the `projects` prefix is denied.

### Bucket policy

If you add the `Principal` element to the above user policy, identifying the user, you now have a bucket policy as shown.

```
{
   "Version":"2012-10-17",
   "Statement":[
      {
         "Sid":"statement1",
         "Effect":"Allow",
         "Principal": {
            "AWS": "arn:aws:iam::123456789012:user/bucket-owner"
         },
         "Action":  "s3:ListBucket",
         "Resource": "arn:aws:s3:::awsexamplebucket1",
         "Condition" : {
             "StringEquals" : {
                 "s3:prefix": "projects"
             }
          }
       },
      {
         "Sid":"statement2",
         "Effect":"Deny",
         "Principal": {
            "AWS": "arn:aws:iam::123456789012:user/bucket-owner"
         },
         "Action": "s3:ListBucket",
         "Resource": "arn:aws:s3:::awsexamplebucket1",
         "Condition" : {
             "StringNotEquals" : {
                 "s3:prefix": "projects"
             }
          }
       }
    ]
}
```

### Test the policy with the AWS CLI

You can test the policy using the following `list-object` AWS CLI command. In the command, you provide user credentials using the `--profile` parameter. For more information about setting up and using the AWS CLI, see Developing with Amazon S3 using the AWS CLI.

```
aws s3api list-objects --bucket awsexamplebucket1 --prefix examplefolder --profile
 AccountADave
```

If the bucket is versioning-enabled, to list the objects in the bucket, you must grant the `s3:ListBucketVersions` permission in the preceding policy, instead of `s3:ListBucket` permission. This permission also supports the `s3:prefix` condition key.

**Example 3: Setting the maximum number of keys**

You can use the `s3:max-keys` condition key to set the maximum number of keys that requester can return in a GET Bucket (ListObjects) or ListObjectVersions request. By default, the API returns up to 1,000 keys. For a list of numeric condition operators that you can use with `s3:max-keys` and accompanying examples, see Numeric Condition Operators in the *IAM User Guide*.

## Identity-based policies for Amazon S3

By default, users and roles don't have permission to create or modify Amazon S3 resources. They also can't perform tasks by using the AWS Management Console, AWS Command Line Interface (AWS CLI), or AWS API. To grant users permission to perform actions on the resources that they need, an IAM administrator can create IAM policies. The administrator can then add the IAM policies to roles, and users can assume the roles.

To learn how to create an IAM identity-based policy by using these example JSON policy documents, see Creating IAM policies in the *IAM User Guide*.

For details about actions and resource types defined by Amazon S3, including the format of the ARNs for each of the resource types, see Actions, resources, and condition keys for Amazon S3 in the *Service Authorization Reference*.

- Controlling access to a bucket with user policies

### Policy best practices

Identity-based policies determine whether someone can create, access, or delete Amazon S3 resources in your account. These actions can incur costs for your AWS account. When you create or edit identity-based policies, follow these guidelines and recommendations:

- **Get started with AWS managed policies and move toward least-privilege permissions** – To get started granting permissions to your users and workloads, use the *AWS managed policies* that grant permissions for many common use cases. They are available in your AWS account. We recommend that you reduce permissions further by defining AWS customer managed policies that are specific to your use cases. For more information, see AWS managed policies or AWS managed policies for job functions in the *IAM User Guide*.
- **Apply least-privilege permissions** – When you set permissions with IAM policies, grant only the permissions required to perform a task. You do this by defining the actions that can be taken on specific resources under specific conditions, also known as *least-privilege permissions*. For more information about using IAM to apply permissions, see Policies and permissions in IAM in the *IAM User Guide*.
- **Use conditions in IAM policies to further restrict access** – You can add a condition to your policies to limit access to actions and resources. For example, you can write a policy condition to specify that all requests must be sent using SSL. You can also use conditions to grant access to service actions if they are used through a specific AWS service, such as AWS CloudFormation. For more information, see IAM JSON policy elements: Condition in the *IAM User Guide*.
- **Use IAM Access Analyzer to validate your IAM policies to ensure secure and functional permissions** – IAM Access Analyzer validates new and existing policies so that the policies adhere to the IAM policy language (JSON) and IAM best practices. IAM Access Analyzer provides more than 100 policy checks and actionable recommendations to help you author secure and functional policies. For more information, see IAM Access Analyzer policy validation in the *IAM User Guide*.
- **Require multi-factor authentication (MFA)** – If you have a scenario that requires IAM users or a root user in your AWS account, turn on MFA for additional security. To require MFA when API operations are called, add MFA conditions to your policies. For more information, see Configuring MFA-protected API access in the *IAM User Guide*.

For more information about best practices in IAM, see Security best practices in IAM in the *IAM User Guide*.

### Identity-based policy examples for Amazon S3

This section shows several example AWS Identity and Access Management (IAM) identity-based policies for controlling access to Amazon S3. For example *bucket policies* (resource-based policies), see Bucket policies for Amazon S3. For information about IAM policy language, see Policies and permissions in Amazon S3.

The following example policies will work if you use them programmatically. However, to use them with the Amazon S3 console, you must grant additional permissions that are required by the console. For information about using policies such as these with the Amazon S3 console, see Controlling access to a bucket with user policies.

**Topics**

### Allowing an IAM user access to one of your buckets

In this example, you want to grant an IAM user in your AWS account access to one of your buckets, *amzn-s3-demo-bucket1*, and allow the user to add, update, and delete objects.

In addition to granting the `s3:PutObject`, `s3:GetObject`, and `s3:DeleteObject` permissions to the user, the policy also grants the `s3:ListAllMyBuckets`, `s3:GetBucketLocation`, and `s3:ListBucket` permissions. These are the additional permissions required by the console. Also, the `s3:PutObjectAcl` and the `s3:GetObjectAcl` actions are required to be able to copy, cut, and paste objects in the console. For an example walkthrough that grants permissions to users and tests them using the console, see Controlling access to a bucket with user policies.

```
{
   "Version":"2012-10-17",
   "Statement":[
      {
         "Effect":"Allow",
         "Action": "s3:ListAllMyBuckets",
```

```
            "Resource":"*"
        },
        {
            "Effect":"Allow",
            "Action":["s3:ListBucket","s3:GetBucketLocation"],
            "Resource":"arn:aws:s3:::amzn-s3-demo-bucket1"
        },
        {
            "Effect":"Allow",
            "Action":[
                "s3:PutObject",
                "s3:PutObjectAcl",
                "s3:GetObject",
                "s3:GetObjectAcl",
                "s3:DeleteObject"
            ],
            "Resource":"arn:aws:s3:::amzn-s3-demo-bucket1/*"
        }
    ]
}
```

### Allowing each IAM user access to a folder in a bucket

In this example, you want two IAM users, Mary and Carlos, to have access to your bucket, *amzn-s3-demo-bucket1*, so that they can add, update, and delete objects. However, you want to restrict each user's access to a single prefix (folder) in the bucket. You might create folders with names that match their usernames.

```
amzn-s3-demo-bucket1
   Mary/
   Carlos/
```

To grant each user access only to their folder, you can write a policy for each user and attach it individually. For example, you can attach the following policy to the user Mary to allow her specific Amazon S3 permissions on the *amzn-s3-demo-bucket1*/*Mary* folder.

```
{
   "Version":"2012-10-17",
   "Statement":[
      {
         "Effect":"Allow",
         "Action":[
```

```
            "s3:PutObject",
            "s3:GetObject",
            "s3:GetObjectVersion",
            "s3:DeleteObject",
            "s3:DeleteObjectVersion"
         ],
         "Resource":"arn:aws:s3:::amzn-s3-demo-bucket1/Mary/*"
      }
   ]
}
```

You can then attach a similar policy to the user Carlos, specifying the folder *Carlos* in the `Resource` value.

Instead of attaching policies to individual users, you can write a single policy that uses a policy variable and then attach the policy to a group. First, you must create a group and add both Mary and Carlos to the group. The following example policy allows a set of Amazon S3 permissions in the *amzn-s3-demo-bucket1*`/${aws:username}` folder. When the policy is evaluated, the policy variable `${aws:username}` is replaced by the requester's username. For example, if Mary sends a request to put an object, the operation is allowed only if Mary is uploading the object to the *amzn-s3-demo-bucket1*`/Mary` folder.

```
{
   "Version":"2012-10-17",
   "Statement":[
      {
         "Effect":"Allow",
         "Action":[
            "s3:PutObject",
            "s3:GetObject",
            "s3:GetObjectVersion",
            "s3:DeleteObject",
            "s3:DeleteObjectVersion"
         ],
         "Resource":"arn:aws:s3:::amzn-s3-demo-bucket1/${aws:username}/*"
      }
   ]
}
```

> **Note**
>
> When using policy variables, you must explicitly specify version 2012-10-17 in the policy. The default version of the IAM policy language, 2008-10-17, does not support policy variables.

If you want to test the preceding policy on the Amazon S3 console, the console requires additional permissions, as shown in the following policy. For information about how the console uses these permissions, see Controlling access to a bucket with user policies.

```
{
 "Version":"2012-10-17",
  "Statement": [
    {
      "Sid": "AllowGroupToSeeBucketListInTheConsole",
      "Action": [
       "s3:ListAllMyBuckets",
       "s3:GetBucketLocation"
      ],
      "Effect": "Allow",
      "Resource": "arn:aws:s3:::*"
    },
    {
      "Sid": "AllowRootLevelListingOfTheBucket",
      "Action": "s3:ListBucket",
      "Effect": "Allow",
      "Resource": "arn:aws:s3:::amzn-s3-demo-bucket1",
      "Condition":{
            "StringEquals":{
                   "s3:prefix":[""], "s3:delimiter":["/"]
                         }
               }
    },
    {
      "Sid": "AllowListBucketOfASpecificUserPrefix",
      "Action": "s3:ListBucket",
      "Effect": "Allow",
      "Resource": "arn:aws:s3:::amzn-s3-demo-bucket1",
      "Condition":{  "StringLike":{"s3:prefix":["${aws:username}/*"] }
       }
    },
```

```
      {
     "Sid": "AllowUserSpecificActionsOnlyInTheSpecificUserPrefix",
         "Effect":"Allow",
         "Action":[
            "s3:PutObject",
            "s3:GetObject",
            "s3:GetObjectVersion",
            "s3:DeleteObject",
            "s3:DeleteObjectVersion"
         ],
         "Resource":"arn:aws:s3:::amzn-s3-demo-bucket1/${aws:username}/*"
      }
  ]
}
```

**Note**

In the 2012-10-17 version of the policy, policy variables start with $. This change in syntax can potentially create a conflict if your object key (object name) includes a $.
To avoid this conflict, specify the $ character by using ${$}. For example, to include the object key my$file in a policy, specify it as my${$}file.

Although IAM user names are friendly, human-readable identifiers, they aren't required to be globally unique. For example, if the user Carlos leaves the organization and another Carlos joins, then the new Carlos could access the old Carlos's information.

Instead of using usernames, you could create folders based on IAM user IDs. Each IAM user ID is unique. In this case, you must modify the preceding policy to use the ${aws:userid} policy variable. For more information about user identifiers, see IAM Identifiers in the *IAM User Guide*.

```
{
   "Version":"2012-10-17",
   "Statement":[
      {
         "Effect":"Allow",
         "Action":[
            "s3:PutObject",
            "s3:GetObject",
            "s3:GetObjectVersion",
            "s3:DeleteObject",
```

```
            "s3:DeleteObjectVersion"
         ],
         "Resource":"arn:aws:s3:::amzn-s3-demo-bucket1/home/${aws:userid}/*"
      }
   ]
}
```

**Allowing non-IAM users (mobile app users) access to folders in a bucket**

Suppose that you want to develop a mobile app, a game that stores users' data in an S3 bucket. For each app user, you want to create a folder in your bucket. You also want to limit each user's access to their own folder. But you can't create folders before someone downloads your app and starts playing the game, because you don't have their user ID.

In this case, you can require users to sign in to your app by using public identity providers such as Login with Amazon, Facebook, or Google. After users have signed in to your app through one of these providers, they have a user ID that you can use to create user-specific folders at runtime.

You can then use web identity federation in AWS Security Token Service to integrate information from the identity provider with your app and to get temporary security credentials for each user. You can then create IAM policies that allow the app to access your bucket and perform such operations as creating user-specific folders and uploading data. For more information about web identity federation, see About web identity Federation in the *IAM User Guide*.

**Allowing a group to have a shared folder in Amazon S3**

Attaching the following policy to the group grants everybody in the group access to the following folder in Amazon S3: *amzn-s3-demo-bucket1*/share/marketing. Group members are allowed to access only the specific Amazon S3 permissions shown in the policy and only for objects in the specified folder.

```
{
   "Version":"2012-10-17",
   "Statement":[
      {
         "Effect":"Allow",
         "Action":[
            "s3:PutObject",
            "s3:GetObject",
            "s3:GetObjectVersion",
            "s3:DeleteObject",
```

```
            "s3:DeleteObjectVersion"
         ],
         "Resource":"arn:aws:s3:::amzn-s3-demo-bucket1/share/marketing/*"
      }
   ]
}
```

### Allowing all your users to read objects in a portion of a bucket

In this example, you create a group named *AllUsers*, which contains all the IAM users that are owned by the AWS account. You then attach a policy that gives the group access to `GetObject` and `GetObjectVersion`, but only for objects in the *amzn-s3-demo-bucket1*`/readonly` folder.

```
{
   "Version":"2012-10-17",
   "Statement":[
      {
         "Effect":"Allow",
         "Action":[
            "s3:GetObject",
            "s3:GetObjectVersion"
         ],
         "Resource":"arn:aws:s3:::amzn-s3-demo-bucket1/readonly/*"
      }
   ]
}
```

### Allowing a partner to drop files into a specific portion of a bucket

In this example, you create a group called *AnyCompany* that represents a partner company. You create an IAM user for the specific person or application at the partner company that needs access, and then you put the user in the group.

You then attach a policy that gives the group `PutObject` access to the following folder in a bucket:

*amzn-s3-demo-bucket1*`/uploads/anycompany`

You want to prevent the *AnyCompany* group from doing anything else with the bucket, so you add a statement that explicitly denies permission to any Amazon S3 actions except `PutObject` on any Amazon S3 resource in the AWS account.

```
{
   "Version":"2012-10-17",
   "Statement":[
      {
         "Effect":"Allow",
         "Action":"s3:PutObject",
         "Resource":"arn:aws:s3:::amzn-s3-demo-bucket1/uploads/anycompany/*"
      },
      {
         "Effect":"Deny",
         "Action":"s3:*",
         "NotResource":"arn:aws:s3:::amzn-s3-demo-bucket1/uploads/anycompany/*"
      }
   ]
}
```

### Restricting access to Amazon S3 buckets within a specific AWS account

If you want to ensure that your Amazon S3 principals are accessing only the resources that are inside of a trusted AWS account, you can restrict access. For example, this identity-based IAM policy uses a Deny effect to block access to Amazon S3 actions, unless the Amazon S3 resource that's being accessed is in account *222222222222*. To prevent an IAM principal in an AWS account from accessing Amazon S3 objects outside of the account, attach the following IAM policy:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "DenyS3AccessOutsideMyBoundary",
      "Effect": "Deny",
      "Action": [
        "s3:*"
      ],
      "Resource": "*",
      "Condition": {
        "StringNotEquals": {
          "aws:ResourceAccount": [
            "222222222222"
          ]
        }
      }
    }
```

```
  ]
}
```

> **Note**
>
> This policy doesn't replace your existing IAM access controls, because it doesn't grant any access. Instead, this policy acts as an additional guardrail for your other IAM permissions, regardless of the permissions granted through other IAM policies.

Make sure to replace account ID *222222222222* in the policy with your own AWS account. To apply a policy to multiple accounts while still maintaining this restriction, replace the account ID with the `aws:PrincipalAccount` condition key. This condition requires that the principal and the resource must be in the same account.

**Restricting access to Amazon S3 buckets within your organizational unit**

If you have an organizational unit (OU) set up in AWS Organizations, you might want to restrict Amazon S3 bucket access to a specific part of your organization. In this example, we'll use the `aws:ResourceOrgPaths` key to restrict Amazon S3 bucket access to an OU in your organization. For this example, the OU ID is *ou-acroot-exampleou*. Make sure to replace this value in your own policy with your own OU IDs.

```
{
   "Version": "2012-10-17",
   "Statement": [
     {
       "Sid": "AllowS3AccessOutsideMyBoundary",
       "Effect": "Allow",
       "Action": [
         "s3:*"
       ],
       "Resource": "*",
       "Condition": {
         "ForAllValues:StringNotLike": {
           "aws:ResourceOrgPaths": [
             "o-acorg/r-acroot/ou-acroot-exampleou/"
           ]
         }
       }
```

```
    }
  ]
}
```

> **Note**
>
> This policy doesn't grant any access. Instead, this policy acts as a backstop for your other IAM permissions, preventing your principals from accessing Amazon S3 objects outside of an OU-defined boundary.

The policy denies access to Amazon S3 actions unless the Amazon S3 object that's being accessed is in the *ou-acroot-exampleou* OU in your organization. The IAM policy condition requires `aws:ResourceOrgPaths`, a multivalued condition key, to contain any of the listed OU paths. The policy uses the `ForAllValues:StringNotLike` operator to compare the values of `aws:ResourceOrgPaths` to the listed OUs without case-sensitive matching.

**Restricting access to Amazon S3 buckets within your organization**

To restrict access to Amazon S3 objects within your organization, attach an IAM policy to the root of the organization, applying it to all accounts in your organization. To require your IAM principals to follow this rule, use a service-control policy (SCP). If you choose to use an SCP, make sure to thoroughly test the SCP before attaching the policy to the root of the organization.

In the following example policy, access is denied to Amazon S3 actions unless the Amazon S3 object that's being accessed is in the same organization as the IAM principal that is accessing it:

```
{
   "Version": "2012-10-17",
   "Statement": [
     {
       "Sid": "DenyS3AccessOutsideMyBoundary",
       "Effect": "Deny",
       "Action": [
         "s3:*"
       ],
       "Resource": "arn:aws:s3:::*/*",
       "Condition": {
         "StringNotEquals": {
           "aws:ResourceOrgID": "${aws:PrincipalOrgID}"
```

```
        }
      }
    }
  ]
}
```

> **Note**
>
> This policy doesn't grant any access. Instead, this policy acts as a backstop for your other IAM permissions, preventing your principals from accessing any Amazon S3 objects outside of your organization. This policy also applies to Amazon S3 resources that are created after the policy is put into effect.

The IAM policy condition in this example requires `aws:ResourceOrgID` and `aws:PrincipalOrgID` to be equal to each other. With this requirement, the principal making the request and the resource being accessed must be in the same organization.

**Granting permission to retrieve the PublicAccessBlock configuration for an AWS account**

The following example identity-based policy grants the `s3:GetAccountPublicAccessBlock` permission to a user. For these permissions, you set the `Resource` value to `"*"`. For information about resource ARNs, see Policy resources for Amazon S3.

```
{
   "Version":"2012-10-17",
   "Statement":[
      {
         "Sid":"statement1",
         "Effect":"Allow",
         "Action":[
            "s3:GetAccountPublicAccessBlock"
         ],
         "Resource":[
            "*"
         ]
      }
   ]
}
```

### Restricting bucket creation to one Region

Suppose that an AWS account administrator wants to grant its user (Dave) permission to create a bucket in the South America (São Paulo) Region only. The account administrator can attach the following user policy granting the `s3:CreateBucket` permission with a condition as shown. The key-value pair in the `Condition` block specifies the `s3:LocationConstraint` key and the `sa-east-1` Region as its value.

> **Note**
>
> In this example, the bucket owner is granting permission to one of its users, so either a bucket policy or a user policy can be used. This example shows a user policy.

For a list of Amazon S3 Regions, see Regions and Endpoints in the *AWS General Reference*.

```
{
   "Version":"2012-10-17",
   "Statement":[
      {
         "Sid":"statement1",
         "Effect":"Allow",
         "Action": "s3:CreateBucket",
         "Resource": "arn:aws:s3:::*",
         "Condition": {
             "StringLike": {
                 "s3:LocationConstraint": "sa-east-1"
             }
         }
       }
    ]
}
```

### Add explicit deny

The preceding policy restricts the user from creating a bucket in any other Region except `sa-east-1`. However, some other policy might grant this user permission to create buckets in another Region. For example, if the user belongs to a group, the group might have a policy attached to it that allows all users in the group permission to create buckets in another Region. To ensure that the user doesn't get permission to create buckets in any other Region, you can add an explicit deny statement in the above policy.

The Deny statement uses the StringNotLike condition. That is, a create bucket request is denied if the location constraint is not sa-east-1. The explicit deny doesn't allow the user to create a bucket in any other Region, no matter what other permission the user gets. The following policy includes an explicit deny statement.

```
{
   "Version":"2012-10-17",
   "Statement":[
      {
         "Sid":"statement1",
         "Effect":"Allow",
         "Action": "s3:CreateBucket",
         "Resource": "arn:aws:s3:::*",
         "Condition": {
             "StringLike": {
                 "s3:LocationConstraint": "sa-east-1"
             }
         }
       },
      {
         "Sid":"statement2",
         "Effect":"Deny",
         "Action": "s3:CreateBucket",
         "Resource": "arn:aws:s3:::*",
         "Condition": {
             "StringNotLike": {
                 "s3:LocationConstraint": "sa-east-1"
             }
         }
       }
    ]
}
```

### Test the policy with the AWS CLI

You can test the policy using the following create-bucket AWS CLI command. This example uses the bucketconfig.txt file to specify the location constraint. Note the Windows file path. You need to update the bucket name and path as appropriate. You must provide user credentials using the --profile parameter. For more information about setting up and using the AWS CLI, see Developing with Amazon S3 using the AWS CLI.

```
aws s3api create-bucket --bucket examplebucket --profile AccountADave --create-bucket-
configuration file://c:/Users/someUser/bucketconfig.txt
```

The `bucketconfig.txt` file specifies the configuration as follows.

```
{"LocationConstraint": "sa-east-1"}
```

### Controlling access to a bucket with user policies

This walkthrough explains how user permissions work with Amazon S3. In this example, you create a bucket with folders. You then create AWS Identity and Access Management IAM users in your AWS account and grant those users incremental permissions on your Amazon S3 bucket and the folders in it.

#### Topics

### Basics of buckets and folders

The Amazon S3 data model is a flat structure: You create a bucket, and the bucket stores objects. There is no hierarchy of subbuckets or subfolders, but you can emulate a folder hierarchy. Tools like the Amazon S3 console can present a view of these logical folders and subfolders in your bucket.

The console shows that a bucket named companybucket has three folders, Private, Development, and Finance, and an object, s3-dg.pdf. The console uses the object names (keys) to create a logical hierarchy with folders and subfolders. Consider the following examples:

- When you create the Development folder, the console creates an object with the key Development/. Note the trailing slash (/) delimiter.
- When you upload an object named Projects1.xls in the Development folder, the console uploads the object and gives it the key Development/Projects1.xls.

  In the key, Development is the prefix and / is the delimiter. The Amazon S3 API supports prefixes and delimiters in its operations. For example, you can get a list of all objects from a bucket with a specific prefix and delimiter. On the console, when you open the Development folder, the console lists the objects in that folder. In the following example, the Development folder contains one object.

  When the console lists the Development folder in the companybucket bucket, it sends a request to Amazon S3 in which it specifies a prefix of Development and a delimiter of / in the request. The console's response looks just like a folder list in your computer's file system. The preceding example shows that the bucket companybucket has an object with the key Development/Projects1.xls.

The console is using object keys to infer a logical hierarchy. Amazon S3 has no physical hierarchy. Amazon S3 only has buckets that contain objects in a flat file structure. When you create objects using the Amazon S3 API, you can use object keys that imply a logical hierarchy. When you create a logical hierarchy of objects, you can manage access to individual folders, as this walkthrough demonstrates.

Before you start, be sure that you are familiar with the concept of the *root-level* bucket content. Suppose that your companybucket bucket has the following objects:

- Private/privDoc1.txt
- Private/privDoc2.zip
- Development/project1.xls
- Development/project2.xls
- Finance/Tax2011/document1.pdf
- Finance/Tax2011/document2.pdf

- `s3-dg.pdf`

These object keys create a logical hierarchy with `Private`, `Development`, and the `Finance` as root-level folders and `s3-dg.pdf` as a root-level object. When you choose the bucket name on the Amazon S3 console, the root-level items appear. The console shows the top-level prefixes (`Private/`, `Development/`, and `Finance/`) as root-level folders. The object key `s3-dg.pdf` has no prefix, and so it appears as a root-level item.

### Walkthrough summary

In this walkthrough, you create a bucket with three folders (`Private`, `Development`, and `Finance`) in it.

You have two users, Alice and Bob. You want Alice to access only the `Development` folder, and you want Bob to access only the `Finance` folder. You want to keep the `Private` folder content private. In the walkthrough, you manage access by creating IAM users (the example uses the usernames Alice and Bob) and granting them the necessary permissions.

IAM also supports creating user groups and granting group-level permissions that apply to all users in the group. This helps you better manage permissions. For this exercise, both Alice and Bob need some common permissions. So you also create a group named `Consultants` and then add both Alice and Bob to the group. You first grant permissions by attaching a group policy to the group. Then you add user-specific permissions by attaching policies to specific users.

> **Note**
>
> The walkthrough uses `companybucket` as the bucket name, Alice and Bob as the IAM users, and `Consultants` as the group name. Because Amazon S3 requires that bucket names be globally unique, you must replace the bucket name with a name that you create.

### Preparing for the walkthrough

In this example, you use your AWS account credentials to create IAM users. Initially, these users have no permissions. You incrementally grant these users permissions to perform specific Amazon S3 actions. To test these permissions, you sign in to the console with each user's credentials. As you incrementally grant permissions as an AWS account owner and test permissions as an IAM user, you need to sign in and out, each time using different credentials. You can do this testing with one

browser, but the process will go faster if you can use two different browsers. Use one browser to connect to the AWS Management Console with your AWS account credentials and another browser to connect with the IAM user credentials.

To sign in to the AWS Management Console with your AWS account credentials, go to https://console.aws.amazon.com/. An IAM user can't sign in using the same link. An IAM user must use an IAM-enabled sign-in page. As the account owner, you can provide this link to your users.

For more information about IAM, see The AWS Management Console Sign-in Page in the *IAM User Guide*.

**To provide a sign-in link for IAM users**

1. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.
2. In the **Navigation** pane, choose **IAM Dashboard** .
3. Note the URL under **IAM users sign in link:**. You will give this link to IAM users to sign in to the console with their IAM user name and password.

### Step 1: Create a bucket

In this step, you sign in to the Amazon S3 console with your AWS account credentials, create a bucket, add folders to the bucket, and upload one or two sample documents in each folder.

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. Create a bucket.

   For step-by-step instructions, see Creating a bucket.
3. Upload one document to the bucket.

   This exercise assumes that you have the `s3-dg.pdf` document at the root level of this bucket. If you upload a different document, substitute its file name for `s3-dg.pdf`.
4. Add three folders named `Private`, `Finance`, and `Development` to the bucket.

   For step-by-step instructions to create a folder, see Organizing objects in the Amazon S3 console by using folders> in the *Amazon Simple Storage Service User Guide*.
5. Upload one or two documents to each folder.

For this exercise, assume that you have uploaded a couple of documents in each folder, resulting in the bucket having objects with the following keys:

- `Private/privDoc1.txt`
- `Private/privDoc2.zip`
- `Development/project1.xls`
- `Development/project2.xls`
- `Finance/Tax2011/document1.pdf`
- `Finance/Tax2011/document2.pdf`
- `s3-dg.pdf`

For step-by-step instructions, see Uploading objects.

### Step 2: Create IAM users and a group

Now use the IAM Console to add two IAM users, Alice and Bob, to your AWS account. For step-by-step instructions, see Creating an IAM user in your AWS account in the *IAM User Guide*.

Also create an administrative group named `Consultants`. Then add both users to the group. For step-by-step instructions, see Creating IAM user groups.

> **Warning**
>
> When you add users and a group, do not attach any policies that grant permissions to these users. At first, these users don't have any permissions. In the following sections, you grant permissions incrementally. First you must ensure that you have assigned passwords to these IAM users. You use these user credentials to test Amazon S3 actions and verify that the permissions work as expected.

For step-by-step instructions for creating a new IAM user, see Creating an IAM user in your AWS account in the *IAM User Guide*. When you create the users for this walkthrough, select **AWS Management Console access** and clear programmatic access.

For step-by-step instructions for creating an administrative group, see Creating Your First IAM Admin User and Group in the *IAM User Guide*.

### Step 3: Verify that IAM users have no permissions

If you are using two browsers, you can now use the second browser to sign in to the console using one of the IAM user credentials.

1. Using the IAM user sign-in link (see To provide a sign-in link for IAM users), sign in to the AWS Management Console using either of the IAM user credentials.
2. Open the Amazon S3 console at https://console.aws.amazon.com/s3/.

   Verify the console message telling you that access is denied.

Now, you can begin granting incremental permissions to the users. First, you attach a group policy that grants permissions that both users must have.

### Step 4: Grant group-level permissions

You want the users to be able to do the following:

- List all buckets owned by the parent account. To do so, Bob and Alice must have permission for the `s3:ListAllMyBuckets` action.
- List root-level items, folders, and objects in the `companybucket` bucket. To do so, Bob and Alice must have permission for the `s3:ListBucket` action on the `companybucket` bucket.

First, you create a policy that grants these permissions, and then you attach it to the `Consultants` group.

### Step 4.1: Grant permission to list all buckets

In this step, you create a managed policy that grants the users minimum permissions to enable them to list all buckets owned by the parent account. Then you attach the policy to the `Consultants` group. When you attach the managed policy to a user or a group, you grant the user or group permission to obtain a list of buckets owned by the parent AWS account.

1. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.

> **Note**
>
> Because you are granting user permissions, sign in using your AWS account credentials, not as an IAM user.

2. Create the managed policy.

   a. In the navigation pane on the left, choose **Policies**, and then choose **Create Policy**.

   b. Choose the **JSON** tab.

   c. Copy the following access policy and paste it into the policy text field.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowGroupToSeeBucketListInTheConsole",
      "Action": ["s3:ListAllMyBuckets"],
      "Effect": "Allow",
      "Resource": ["arn:aws:s3:::*"]
    }
  ]
}
```

   A policy is a JSON document. In the document, a `Statement` is an array of objects, each describing a permission using a collection of name-value pairs. The preceding policy describes one specific permission. The `Action` specifies the type of access. In the policy, the `s3:ListAllMyBuckets` is a predefined Amazon S3 action. This action covers the Amazon S3 GET Service operation, which returns a list of all buckets owned by the authenticated sender. The `Effect` element value determines whether specific permission is allowed or denied.

   d. Choose **Review Policy**. On the next page, enter `AllowGroupToSeeBucketListInTheConsole` in the **Name** field, and then choose **Create policy**.

> **Note**
>
> The **Summary** entry displays a message stating that the policy does not grant any permissions. For this walkthrough, you can safely ignore this message.

3. Attach the `AllowGroupToSeeBucketListInTheConsole` managed policy that you created to the `Consultants` group.

   For step-by-step instructions for attaching a managed policy, see Adding and removing IAM identity permissions in the *IAM User Guide*.

   You attach policy documents to IAM users and groups in the IAM console. Because you want both users to be able to list the buckets, you attach the policy to the group.

4. Test the permission.

   a. Using the IAM user sign-in link (see To provide a sign-in link for IAM users), sign in to the console using any one of IAM user credentials.

   b. Open the Amazon S3 console at https://console.aws.amazon.com/s3/.

      The console should now list all the buckets but not the objects in any of the buckets.

### Step 4.2: Enable users to list root-level content of a bucket

Next, you allow all users in the `Consultants` group to list the root-level `companybucket` bucket items. When a user chooses the company bucket on the Amazon S3 console, the user can see the root-level items in the bucket.

> **Note**
>
> This example uses `companybucket` for illustration. You must use the name of the bucket that you created.

To understand the request that the console sends to Amazon S3 when you choose a bucket name, the response that Amazon S3 returns, and how the console interprets the response, examine the flow a little more closely.

When you choose a bucket name, the console sends the GET Bucket (List Objects) request to Amazon S3. This request includes the following parameters:

- The `prefix` parameter with an empty string as its value.
- The `delimiter` parameter with `/` as its value.

The following is an example request.

```
GET ?prefix=&delimiter=/ HTTP/1.1
Host: companybucket.s3.amazonaws.com
Date: Wed, 01 Aug  2012 12:00:00 GMT
Authorization: AWS AKIAIOSFODNN7EXAMPLE:xQE0diMbLRepdf3YB+FIEXAMPLE=
```

Amazon S3 returns a response that includes the following `<ListBucketResult/>` element.

```
<ListBucketResult xmlns="http://s3.amazonaws.com/doc/2006-03-01/">
  <Name>companybucket</Name>
  <Prefix></Prefix>
  <Delimiter>/</Delimiter>
   ...
  <Contents>
    <Key>s3-dg.pdf</Key>
    ...
  </Contents>
  <CommonPrefixes>
    <Prefix>Development/</Prefix>
  </CommonPrefixes>
  <CommonPrefixes>
    <Prefix>Finance/</Prefix>
  </CommonPrefixes>
  <CommonPrefixes>
    <Prefix>Private/</Prefix>
  </CommonPrefixes>
</ListBucketResult>
```

The key `s3-dg.pdf` object does not contain the slash (/) delimiter, and Amazon S3 returns the key in the `<Contents>` element. However, all other keys in the example bucket contain the `/` delimiter. Amazon S3 groups these keys and returns a `<CommonPrefixes>` element for each of the distinct prefix values `Development/`, `Finance/`, and `Private/` that is a substring from the beginning of these keys to the first occurrence of the specified `/` delimiter.

The console interprets this result and displays the root-level items as three folders and one object key.

If Bob or Alice opens the **Development** folder, the console sends the GET Bucket (List Objects) request to Amazon S3 with the `prefix` and the `delimiter` parameters set to the following values:

- The `prefix` parameter with the value `Development/`.
- The `delimiter` parameter with the "`/`" value.

In response, Amazon S3 returns the object keys that start with the specified prefix.

```
<ListBucketResult xmlns="http://s3.amazonaws.com/doc/2006-03-01/">
  <Name>companybucket</Name>
  <Prefix>Development</Prefix>
  <Delimiter>/</Delimiter>
   ...
  <Contents>
    <Key>Project1.xls</Key>
    ...
  </Contents>
  <Contents>
    <Key>Project2.xls</Key>
    ...
  </Contents>
</ListBucketResult>
```

The console shows the object keys.

Now, return to granting users permission to list the root-level bucket items. To list bucket content, users need permission to call the `s3:ListBucket` action, as shown in the following policy statement. To ensure that they see only the root-level content, you add a condition that users must specify an empty `prefix` in the request—that is, they are not allowed to double-click any of the root-level folders. Finally, you add a condition to require folder-style access by requiring user requests to include the `delimiter` parameter with the value "`/`".

```
{
  "Sid": "AllowRootLevelListingOfCompanyBucket",
  "Action": ["s3:ListBucket"],
  "Effect": "Allow",
```

```
  "Resource": ["arn:aws:s3:::companybucket"],
  "Condition":{
         "StringEquals":{
             "s3:prefix":[""], "s3:delimiter":["/"]
                       }
              }
}
```

When you choose a bucket on the Amazon S3 console, the console first sends the GET Bucket location request to find the AWS Region where the bucket is deployed. Then the console uses the Region-specific endpoint for the bucket to send the GET Bucket (List Objects) request. As a result, if users are going to use the console, you must grant permission for the `s3:GetBucketLocation` action as shown in the following policy statement.

```
{
   "Sid": "RequiredByS3Console",
   "Action": ["s3:GetBucketLocation"],
   "Effect": "Allow",
   "Resource": ["arn:aws:s3:::*"]
}
```

**To enable users to list root-level bucket content**

1. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.

   Use your AWS account credentials, not the credentials of an IAM user, to sign in to the console.

2. Replace the existing `AllowGroupToSeeBucketListInTheConsole` managed policy that is attached to the `Consultants` group with the following policy, which also allows the `s3:ListBucket` action. Remember to replace *`companybucket`* in the policy `Resource` with the name of your bucket.

   For step-by-step instructions, see Editing IAM policies in the *IAM User Guide*. When following the step-by-step instructions, be sure to follow the steps for applying your changes to all principal entities that the policy is attached to.

   ```
   {
     "Version": "2012-10-17",
     "Statement": [
        {
   ```

```
      "Sid":
 "AllowGroupToSeeBucketListAndAlsoAllowGetBucketLocationRequiredForListBucket",
      "Action": [ "s3:ListAllMyBuckets", "s3:GetBucketLocation" ],
      "Effect": "Allow",
      "Resource": [ "arn:aws:s3:::*"  ]
    },
    {
      "Sid": "AllowRootLevelListingOfCompanyBucket",
      "Action": ["s3:ListBucket"],
      "Effect": "Allow",
      "Resource": ["arn:aws:s3:::companybucket"],
      "Condition":{
            "StringEquals":{
                  "s3:prefix":[""], "s3:delimiter":["/"]
                        }
                  }
    }
  ]
}
```

3. Test the updated permissions.

   a. Using the IAM user sign-in link (see To provide a sign-in link for IAM users), sign in to the AWS Management Console.

      Open the Amazon S3 console at https://console.aws.amazon.com/s3/.

   b. Choose the bucket that you created, and the console shows the root-level bucket items. If you choose any folders in the bucket, you won't be able to see the folder content because you haven't yet granted those permissions.

This test succeeds when users use the Amazon S3 console. When you choose a bucket on the console, the console implementation sends a request that includes the `prefix` parameter with an empty string as its value and the `delimiter` parameter with "/" as its value.

**Step 4.3: Summary of the group policy**

The net effect of the group policy that you added is to grant the IAM users Alice and Bob the following minimum permissions:

- List all buckets owned by the parent account.
- See root-level items in the `companybucket` bucket.

However, the users still can't do much. Next, you grant user-specific permissions, as follows:

- Allow Alice to get and put objects in the `Development` folder.
- Allow Bob to get and put objects in the `Finance` folder.

For user-specific permissions, you attach a policy to the specific user, not to the group. In the following section, you grant Alice permission to work in the `Development` folder. You can repeat the steps to grant similar permission to Bob to work in the `Finance` folder.

**Step 5: Grant IAM user Alice specific permissions**

Now you grant additional permissions to Alice so that she can see the content of the `Development` folder and get and put objects in that folder.

**Step 5.1: Grant IAM user Alice permission to list the development folder content**

For Alice to list the `Development` folder content, you must apply a policy to the user Alice that grants permission for the `s3:ListBucket` action on the `companybucket` bucket, provided the request includes the prefix `Development/`. You want this policy to be applied only to the user Alice, so you use an inline policy. For more information about inline policies, see Managed policies and inline policies in the *IAM User Guide*.

1. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.

   Use your AWS account credentials, not the credentials of an IAM user, to sign in to the console.
2. Create an inline policy to grant the user Alice permission to list the `Development` folder content.

   a. In the navigation pane on the left, choose **Users**.
   b. Choose the username **Alice**.
   c. On the user details page, choose the **Permissions** tab and then choose **Add inline policy**.
   d. Choose the **JSON** tab.
   e. Copy the following policy, and paste it into the policy text field.

```
{
    "Version": "2012-10-17",
    "Statement": [
    {
```

```
      "Sid": "AllowListBucketIfSpecificPrefixIsIncludedInRequest",
      "Action": ["s3:ListBucket"],
      "Effect": "Allow",
      "Resource": ["arn:aws:s3:::companybucket"],
      "Condition":{  "StringLike":{"s3:prefix":["Development/*"] }
       }
    }
  ]
}
```

f. Choose **Review Policy**. On the next page, enter a name in the **Name** field, and then choose **Create policy**.

3. Test the change to Alice's permissions:

   a. Using the IAM user sign-in link (see To provide a sign-in link for IAM users), sign in to the AWS Management Console.

   b. Open the Amazon S3 console at https://console.aws.amazon.com/s3/.

   c. On the Amazon S3 console, verify that Alice can see the list of objects in the `Development/` folder in the bucket.

      When the user chooses the `/Development` folder to see the list of objects in it, the Amazon S3 console sends the `ListObjects` request to Amazon S3 with the prefix `/Development`. Because the user is granted permission to see the object list with the prefix `Development` and delimiter `/`, Amazon S3 returns the list of objects with the key prefix `Development/`, and the console displays the list.

### Step 5.2: Grant IAM user Alice permissions to get and put objects in the development folder

For Alice to get and put objects in the `Development` folder, she needs permission to call the `s3:GetObject` and `s3:PutObject` actions. The following policy statements grant these permissions, provided that the request includes the `prefix` parameter with a value of `Development/`.

```
{
    "Sid":"AllowUserToReadWriteObjectData",
    "Action":["s3:GetObject", "s3:PutObject"],
    "Effect":"Allow",
    "Resource":["arn:aws:s3:::companybucket/Development/*"]
 }
```

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.

   Use your AWS account credentials, not the credentials of an IAM user, to sign in to the console.

2. Edit the inline policy that you created in the previous step.

   a. In the navigation pane on the left, choose **Users**.

   b. Choose the user name Alice.

   c. On the user details page, choose the **Permissions** tab and expand the **Inline Policies** section.

   d. Next to the name of the policy that you created in the previous step, choose **Edit Policy**.

   e. Copy the following policy and paste it into the policy text field, replacing the existing policy.

```
{
     "Version": "2012-10-17",
     "Statement":[
      {
         "Sid":"AllowListBucketIfSpecificPrefixIsIncludedInRequest",
         "Action":["s3:ListBucket"],
         "Effect":"Allow",
         "Resource":["arn:aws:s3:::companybucket"],
         "Condition":{
            "StringLike":{"s3:prefix":["Development/*"]
            }
         }
      },
      {
        "Sid":"AllowUserToReadWriteObjectDataInDevelopmentFolder",
        "Action":["s3:GetObject", "s3:PutObject"],
        "Effect":"Allow",
        "Resource":["arn:aws:s3:::companybucket/Development/*"]
      }
   ]
}
```

3. Test the updated policy:

   a. Using the IAM user sign-in link (see To provide a sign-in link for IAM users), sign into the AWS Management Console.

b. Open the Amazon S3 console at https://console.aws.amazon.com/s3/.

c. On the Amazon S3 console, verify that Alice can now add an object and download an object in the `Development` folder.

**Step 5.3: Explicitly deny IAM user Alice permissions to any other folders in the bucket**

User Alice can now list the root-level content in the `companybucket` bucket. She can also get and put objects in the `Development` folder. If you really want to tighten the access permissions, you could explicitly deny Alice access to any other folders in the bucket. If there is any other policy (bucket policy or ACL) that grants Alice access to any other folders in the bucket, this explicit deny overrides those permissions.

You can add the following statement to the user Alice policy that requires all requests that Alice sends to Amazon S3 to include the `prefix` parameter, whose value can be either `Development/*` or an empty string.

```
{
   "Sid": "ExplicitlyDenyAnyRequestsForAllOtherFoldersExceptDevelopment",
   "Action": ["s3:ListBucket"],
   "Effect": "Deny",
   "Resource": ["arn:aws:s3:::companybucket"],
   "Condition":{  "StringNotLike": {"s3:prefix":["Development/*",""] },
                  "Null"         : {"s3:prefix":false }
    }
}
```

There are two conditional expressions in the `Condition` block. The result of these conditional expressions is combined by using the logical `AND`. If both conditions are true, the result of the combined condition is true. Because the `Effect` in this policy is `Deny`, when the `Condition` evaluates to true, users can't perform the specified `Action`.

- The `Null` conditional expression ensures that requests from Alice include the `prefix` parameter.

  The `prefix` parameter requires folder-like access. If you send a request without the `prefix` parameter, Amazon S3 returns all the object keys.

  If the request includes the `prefix` parameter with a null value, the expression evaluates to true, and so the entire `Condition` evaluates to true. You must allow an empty string as value of the

`prefix` parameter. From the preceding discussion, recall that allowing the null string allows Alice to retrieve root-level bucket items as the console does in the preceding discussion. For more information, see Step 4.2: Enable users to list root-level content of a bucket.

- The `StringNotLike` conditional expression ensures that if the value of the `prefix` parameter is specified and is not `Development/*`, the request fails.

Follow the steps in the preceding section and again update the inline policy that you created for user Alice.

Copy the following policy and paste it into the policy text field, replacing the existing policy.

```
{
   "Version": "2012-10-17",
   "Statement":[
      {
         "Sid":"AllowListBucketIfSpecificPrefixIsIncludedInRequest",
         "Action":["s3:ListBucket"],
         "Effect":"Allow",
         "Resource":["arn:aws:s3:::companybucket"],
         "Condition":{
            "StringLike":{"s3:prefix":["Development/*"]
            }
         }
      },
      {
        "Sid":"AllowUserToReadWriteObjectDataInDevelopmentFolder",
        "Action":["s3:GetObject", "s3:PutObject"],
        "Effect":"Allow",
        "Resource":["arn:aws:s3:::companybucket/Development/*"]
      },
      {
         "Sid": "ExplicitlyDenyAnyRequestsForAllOtherFoldersExceptDevelopment",
         "Action": ["s3:ListBucket"],
         "Effect": "Deny",
         "Resource": ["arn:aws:s3:::companybucket"],
         "Condition":{  "StringNotLike": {"s3:prefix":["Development/*",""] },
                        "Null"         : {"s3:prefix":false }
          }
      }
   ]
}
```

### Step 6: Grant IAM user Bob specific permissions

Now you want to grant Bob permission to the `Finance` folder. Follow the steps that you used earlier to grant permissions to Alice, but replace the `Development` folder with the `Finance` folder. For step-by-step instructions, see Step 5: Grant IAM user Alice specific permissions.

### Step 7: Secure the private folder

In this example, you have only two users. You granted all the minimum required permissions at the group level and granted user-level permissions only when you really need to permissions at the individual user level. This approach helps minimize the effort of managing permissions. As the number of users increases, managing permissions can become cumbersome. For example, you don't want any of the users in this example to access the content of the `Private` folder. How do you ensure that you don't accidentally grant a user permission to the `Private` folder? You add a policy that explicitly denies access to the folder. An explicit deny overrides any other permissions.

To ensure that the `Private` folder remains private, you can add the following two deny statements to the group policy:

- Add the following statement to explicitly deny any action on resources in the `Private` folder (`companybucket/Private/*`).

```
{
  "Sid": "ExplictDenyAccessToPrivateFolderToEveryoneInTheGroup",
  "Action": ["s3:*"],
  "Effect": "Deny",
  "Resource":["arn:aws:s3:::companybucket/Private/*"]
}
```

- You also deny permission for the list objects action when the request specifies the `Private/` prefix. On the console, if Bob or Alice opens the `Private` folder, this policy causes Amazon S3 to return an error response.

```
{
  "Sid": "DenyListBucketOnPrivateFolder",
  "Action": ["s3:ListBucket"],
  "Effect": "Deny",
  "Resource": ["arn:aws:s3:::*"],
  "Condition":{
      "StringLike":{"s3:prefix":["Private/"]}
   }
```

```
}
```

Replace the `Consultants` group policy with an updated policy that includes the preceding deny statements. After the updated policy is applied, none of the users in the group can access the `Private` folder in your bucket.

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.

   Use your AWS account credentials, not the credentials of an IAM user, to sign in to the console.

2. Replace the existing `AllowGroupToSeeBucketListInTheConsole` managed policy that is attached to the `Consultants` group with the following policy. Remember to replace *`companybucket`* in the policy with the name of your bucket.

   For instructions, see Editing customer managed policies in the *IAM User Guide*. When following the instructions, make sure to follow the directions for applying your changes to all principal entities that the policy is attached to.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid":
 "AllowGroupToSeeBucketListAndAlsoAllowGetBucketLocationRequiredForListBucket",
      "Action": ["s3:ListAllMyBuckets", "s3:GetBucketLocation"],
      "Effect": "Allow",
      "Resource": ["arn:aws:s3:::*"]
    },
    {
      "Sid": "AllowRootLevelListingOfCompanyBucket",
      "Action": ["s3:ListBucket"],
      "Effect": "Allow",
      "Resource": ["arn:aws:s3:::companybucket"],
      "Condition":{
          "StringEquals":{"s3:prefix":[""]}
       }
    },
    {
      "Sid": "RequireFolderStyleList",
      "Action": ["s3:ListBucket"],
```

```
      "Effect": "Deny",
      "Resource": ["arn:aws:s3:::*"],
      "Condition":{
          "StringNotEquals":{"s3:delimiter":"/"}
       }
     },
    {
      "Sid": "ExplictDenyAccessToPrivateFolderToEveryoneInTheGroup",
      "Action": ["s3:*"],
      "Effect": "Deny",
      "Resource":["arn:aws:s3:::companybucket/Private/*"]
    },
    {
      "Sid": "DenyListBucketOnPrivateFolder",
      "Action": ["s3:ListBucket"],
      "Effect": "Deny",
      "Resource": ["arn:aws:s3:::*"],
      "Condition":{
          "StringLike":{"s3:prefix":["Private/"]}
       }
    }
  ]
}
```

### Step 8: Clean up

To clean up, open the IAM Console and remove the users Alice and Bob. For step-by-step instructions, see Deleting an IAM user in the *IAM User Guide*.

To ensure that you aren't charged further for storage, you should also delete the objects and the bucket that you created for this exercise.

### Related resources

- Managing IAM policies in the *IAM User Guide*

## Walkthroughs that use policies to manage access to your Amazon S3 resources

This topic provides the following introductory walkthrough examples for granting access to Amazon S3 resources. These examples use the AWS Management Console to create resources (buckets, objects, users) and grant them permissions. The examples then show you how to verify permissions using the command line tools, so you don't have to write any code. We provide commands using both the AWS Command Line Interface (AWS CLI) and the AWS Tools for Windows PowerShell.

- Example 1: Bucket owner granting its users bucket permissions

  The IAM users you create in your account have no permissions by default. In this exercise, you grant a user permission to perform bucket and object operations.

- Example 2: Bucket owner granting cross-account bucket permissions

  In this exercise, a bucket owner, Account A, grants cross-account permissions to another AWS account, Account B. Account B then delegates those permissions to users in its account.

- **Managing object permissions when the object and bucket owners are not the same**

  The example scenarios in this case are about a bucket owner granting object permissions to others, but not all objects in the bucket are owned by the bucket owner. What permissions does the bucket owner need, and how can it delegate those permissions?

  The AWS account that creates a bucket is called the *bucket owner*. The owner can grant other AWS accounts permission to upload objects, and the AWS accounts that create objects own them. The bucket owner has no permissions on those objects created by other AWS accounts. If the bucket owner writes a bucket policy granting access to objects, the policy doesn't apply to objects that are owned by other accounts.

  In this case, the object owner must first grant permissions to the bucket owner using an object ACL. The bucket owner can then delegate those object permissions to others, to users in its own account, or to another AWS account, as illustrated by the following examples.

  - Example 3: Bucket owner granting permissions to objects it does not own

    In this exercise, the bucket owner first gets permissions from the object owner. The bucket owner then delegates those permissions to users in its own account.

  - Example 4 - Bucket owner granting cross-account permission to objects it does not own

After receiving permissions from the object owner, the bucket owner can't delegate permission to other AWS accounts because cross-account delegation isn't supported (see Permission delegation). Instead, the bucket owner can create an IAM role with permissions to perform specific operations (such as get object) and allow another AWS account to assume that role. Anyone who assumes the role can then access objects. This example shows how a bucket owner can use an IAM role to enable this cross-account delegation.

### Before you try the example walkthroughs

These examples use the AWS Management Console to create resources and grant permissions. To test permissions, the examples use the command line tools, AWS CLI, and AWS Tools for Windows PowerShell, so you don't need to write any code. To test permissions, you must set up one of these tools. For more information, see Setting up the tools for the walkthroughs.

In addition, when creating resources, these examples don't use root user credentials of an AWS account. Instead, you create an administrator user in these accounts to perform these tasks.

### About using an administrator user to create resources and grant permissions

AWS Identity and Access Management (IAM) recommends not using the root user credentials of your AWS account to make requests. Instead, create an IAM user or role, grant them full access, and then use their credentials to make requests. We refer to this as an administrative user or role. For more information, go to AWS account root user credentials and IAM identities in the *AWS General Reference* and IAM Best Practices in the *IAM User Guide*.

All example walkthroughs in this section use the administrator user credentials. If you have not created an administrator user for your AWS account, the topics show you how.

To sign in to the AWS Management Console using the user credentials, you must use the IAM user sign-In URL. The IAM Console provides this URL for your AWS account. The topics show you how to get the URL.

### Setting up the tools for the walkthroughs

The introductory examples (see Walkthroughs that use policies to manage access to your Amazon S3 resources) use the AWS Management Console to create resources and grant permissions. To test permissions, the examples use the command line tools, AWS Command Line Interface (AWS CLI) and AWS Tools for Windows PowerShell, so you don't need to write any code. To test permissions, you must set up one of these tools.

**To set up the AWS CLI**

1. Download and configure the AWS CLI. For instructions, see the following topics in the *AWS Command Line Interface User Guide*:

   Install or update to the latest version of the AWS Command Line Interface

   Get started with the AWS Command Line Interface

2. Set the default profile.

   You store user credentials in the AWS CLI config file. Create a default profile in the config file using your AWS account credentials. For instructions on finding and editing your AWS CLI config file, see Configuration and credential file settings.

   ```
   [default]
   aws_access_key_id = access key ID
   aws_secret_access_key = secret access key
   region = us-west-2
   ```

3. Verify the setup by entering the following command at the command prompt. Both these commands don't provide credentials explicitly, so the credentials of the default profile are used.

   - Try the `help` command.

     ```
     aws help
     ```

   - To get a list of buckets on the configured account, use the `aws s3 ls` command.

     ```
     aws s3 ls
     ```

As you go through the walkthroughs, you will create users, and you will save user credentials in the config files by creating profiles, as the following example shows. These profiles have the names of `AccountAadmin` and `AccountBadmin`.

```
[profile AccountAadmin]
aws_access_key_id = User AccountAadmin access key ID
aws_secret_access_key = User AccountAadmin secret access key
region = us-west-2
```

```
[profile AccountBadmin]
aws_access_key_id = Account B access key ID
aws_secret_access_key = Account B secret access key
region = us-east-1
```

To run a command using these user credentials, you add the `--profile` parameter specifying the profile name. The following AWS CLI command retrieves a listing of objects in *examplebucket* and specifies the `AccountBadmin` profile.

```
aws s3 ls s3://examplebucket --profile AccountBadmin
```

Alternatively, you can configure one set of user credentials as the default profile by changing the `AWS_DEFAULT_PROFILE` environment variable from the command prompt. After you've done this, whenever you perform AWS CLI commands without the `--profile` parameter, the AWS CLI uses the profile you set in the environment variable as the default profile.

```
$ export AWS_DEFAULT_PROFILE=AccountAadmin
```

**To set up AWS Tools for Windows PowerShell**

1. Download and configure the AWS Tools for Windows PowerShell. For instructions, go to Installing the AWS Tools for Windows PowerShell in the *AWS Tools for Windows PowerShell User Guide*.

   > **Note**
   >
   > To load the AWS Tools for Windows PowerShell module, you must enable PowerShell script execution. For more information, see Enable Script Execution in the *AWS Tools for Windows PowerShell User Guide*.

2. For these walkthroughs, you specify AWS credentials per session using the `Set-AWSCredentials` command. The command saves the credentials to a persistent store (`-StoreAs` parameter).

   ```
   Set-AWSCredentials -AccessKey AccessKeyID -SecretKey SecretAccessKey -
   storeas string
   ```

3. Verify the setup.

- To retrieve a list of available commands that you can use for Amazon S3 operations, run the `Get-Command` command.

```
Get-Command -module awspowershell -noun s3* -StoredCredentials string
```

- To retrieve a list of objects in a bucket, run the `Get-S3Object` command.

```
Get-S3Object -BucketName bucketname -StoredCredentials string
```

For a list of commands, see AWS Tools for PowerShell Cmdlet Reference.

Now you're ready to try the walkthroughs. Follow the links provided at the beginning of each section.

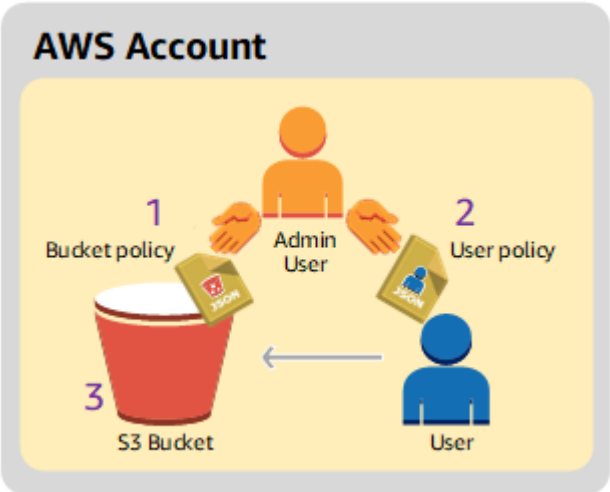
### Example 1: Bucket owner granting its users bucket permissions

> **Important**
>
> Granting permissions to IAM roles is a better practice than granting permissions to individual users.For more information about how to grant permissions to IAM roles, see Understanding cross-account permissions and using IAM roles.

**Topics**

In this walkthrough, an AWS account owns a bucket, and the account includes an IAM user By default, the user has no permissions. For the user to perform any tasks, the parent account must grant them permissions. The bucket owner and parent account are the same. Therefore, to grant the user permissions on the bucket, the AWS account can use a bucket policy, a user policy, or both. The account owner will grant some permissions using a bucket policy and other permissions using a user policy.

The following steps summarize the walkthrough:



1. Account administrator creates a bucket policy granting a set of permissions to the user.
2. Account administrator attaches a user policy to the user granting additional permissions.
3. User then tries permissions granted via both the bucket policy and the user policy.

For this example, you will need an AWS account. Instead of using the root user credentials of the account, you will create an administrator user (see About using an administrator user to create resources and grant permissions). We refer to the AWS account and the administrator user as shown in the following table.

| Account ID | Account referred to as | Administrator user in the account |
|---|---|---|
| *1111-1111-1111* | Account A | AccountAadmin |

> **Note**
>
> The administrator user in this example is **AccountAadmin**, which refers to Account A, and not **AccountAdmin**.

All the tasks of creating users and granting permissions are done in the AWS Management Console. To verify permissions, the walkthrough uses the command line tools, AWS Command Line Interface (AWS CLI) and AWS Tools for Windows PowerShell, so you don't need to write any code.

**Preparing for the walkthrough**

1. Make sure you have an AWS account and that it has a user with administrator privileges.

   a. Sign up for an AWS account, if needed. We refer to this account as Account A.

      i. Go to https://aws.amazon.com/s3 and choose **Create an AWS account**.

      ii. Follow the on-screen instructions.

      AWS will notify you by email when your account is active and available for you to use.

   b. In Account A, create an administrator user **`AccountAadmin`**. Using Account A credentials, sign in to the IAM console and do the following:

      i. Create user **`AccountAadmin`** and note the user security credentials.

      For instructions, see Creating an IAM user in your AWS account in the *IAM User Guide*.

      ii. Grant administrator privileges to **AccountAadmin** by attaching a user policy giving full access.

For instructions, see Managing IAM policies in the *IAM User Guide*.

iii. Note the **IAM user Sign-In URL** for **AccountAadmin**. You will need to use this URL when signing in to the AWS Management Console. For more information about where to find the sign-in URL, see Sign in to the AWS Management Console as an IAM user in *IAM User Guide*. Note the URL for each of the accounts.

2. Set up either the AWS CLI or the AWS Tools for Windows PowerShell. Make sure that you save administrator user credentials as follows:

   - If using the AWS CLI, create a profile, `AccountAadmin`, in the config file.
   - If using the AWS Tools for Windows PowerShell, make sure you store credentials for the session as `AccountAadmin`.

   For instructions, see Setting up the tools for the walkthroughs.

**Step 1: Create resources in Account A and grant permissions**

Using the credentials of user `AccountAadmin` in Account A, and the special IAM user sign-in URL, sign in to the AWS Management Console and do the following:

1. Create resources of a bucket and an IAM user

   a. In the Amazon S3 console, create a bucket. Note the AWS Region in which you created the bucket. For instructions, see Creating a bucket.

   b. In the IAM Console, do the following:

      i. Create a user named Dave.

      For step-by-step instructions, see Creating IAM users (console) in the *IAM User Guide*.

      ii. Note the `UserDave` credentials.

      iii. Note the Amazon Resource Name (ARN) for user Dave. In the IAM Console, select the user, and the **Summary** tab provides the user ARN.

2. Grant permissions.

   Because the bucket owner and the parent account to which the user belongs are the same, the AWS account can grant user permissions using a bucket policy, a user policy, or both. In this

example, you do both. If the object is also owned by the same account, the bucket owner can grant object permissions in the bucket policy (or an IAM policy).

a. In the Amazon S3 console, attach the following bucket policy to *awsexamplebucket1*.

The policy has two statements.

- The first statement grants Dave the bucket operation permissions `s3:GetBucketLocation` and `s3:ListBucket`.
- The second statement grants the `s3:GetObject` permission. Because Account A also owns the object, the account administrator is able to grant the `s3:GetObject` permission.

In the `Principal` statement, Dave is identified by his user ARN. For more information about policy elements, see Policies and permissions in Amazon S3.

```
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Sid": "statement1",
         "Effect": "Allow",
         "Principal": {
            "AWS": "arn:aws:iam::AccountA-ID:user/Dave"
         },
         "Action": [
            "s3:GetBucketLocation",
            "s3:ListBucket"
         ],
         "Resource": [
            "arn:aws:s3:::awsexamplebucket1"
         ]
      },
      {
         "Sid": "statement2",
         "Effect": "Allow",
         "Principal": {
            "AWS": "arn:aws:iam::AccountA-ID:user/Dave"
         },
         "Action": [
             "s3:GetObject"
```

```
         ],
         "Resource": [
            "arn:aws:s3:::awsexamplebucket1/*"
         ]
      }
   ]
}
```

b. Create an inline policy for the user Dave by using the following policy. The policy grants Dave the `s3:PutObject` permission. You need to update the policy by providing your bucket name.

```
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Sid": "PermissionForObjectOperations",
         "Effect": "Allow",
         "Action": [
            "s3:PutObject"
         ],
         "Resource": [
            "arn:aws:s3:::awsexamplebucket1/*"
         ]
      }
   ]
}
```

For instructions, see Managing IAMpolicies in the *IAM User Guide*. Note you need to sign in to the console using Account A credentials.

### Step 2: Test permissions

Using Dave's credentials, verify that the permissions work. You can use either of the following two procedures.

#### Test permissions using the AWS CLI

1. Update the AWS CLI config file by adding the following `UserDaveAccountA` profile. For more information, see Setting up the tools for the walkthroughs.

```
[profile UserDaveAccountA]
aws_access_key_id = access-key
aws_secret_access_key = secret-access-key
region = us-east-1
```

2. Verify that Dave can perform the operations as granted in the user policy. Upload a sample object using the following AWS CLI `put-object` command.

   The `--body` parameter in the command identifies the source file to upload. For example, if the file is in the root of the C: drive on a Windows machine, you specify `c:\HappyFace.jpg`. The `--key` parameter provides the key name for the object.

   ```
   aws s3api put-object --bucket awsexamplebucket1 --key HappyFace.jpg --
   body HappyFace.jpg --profile UserDaveAccountA
   ```

   Run the following AWS CLI command to get the object.

   ```
   aws s3api get-object --bucket awsexamplebucket1 --key HappyFace.jpg OutputFile.jpg
    --profile UserDaveAccountA
   ```

**Test permissions using the AWS Tools for Windows PowerShell**

1. Store Dave's credentials as `AccountADave`. You then use these credentials to PUT and GET an object.

   ```
   set-awscredentials -AccessKey AccessKeyID -SecretKey SecretAccessKey -storeas
    AccountADave
   ```

2. Upload a sample object using the AWS Tools for Windows PowerShell `Write-S3Object` command using user Dave's stored credentials.

   ```
   Write-S3Object -bucketname awsexamplebucket1 -key HappyFace.jpg -file HappyFace.jpg
    -StoredCredentials AccountADave
   ```

   Download the previously uploaded object.

```
Read-S3Object -bucketname awsexamplebucket1 -key HappyFace.jpg -file Output.jpg -
StoredCredentials AccountADave
```

### Example 2: Bucket owner granting cross-account bucket permissions

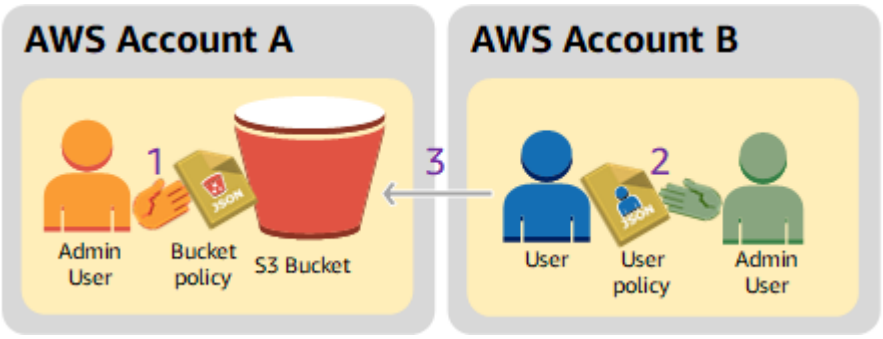
> **Important**
>
> Granting permissions to IAM roles is a better practice than granting permissions to individual users. To learn how to do this, see Understanding cross-account permissions and using IAM roles.

**Topics**

An AWS account—for example, Account A—can grant another AWS account, Account B, permission to access its resources such as buckets and objects. Account B can then delegate those permissions to users in its account. In this example scenario, a bucket owner grants cross-account permission to another account to perform specific bucket operations.

> **Note**
>
> Account A can also directly grant a user in Account B permissions using a bucket policy. However, the user will still need permission from the parent account, Account B, to which the user belongs, even if Account B doesn't have permissions from Account A. As long as the user has permission from both the resource owner and the parent account, the user will be able to access the resource.

The following is a summary of the walkthrough steps:



1. Account A administrator user attaches a bucket policy granting cross-account permissions to Account B to perform specific bucket operations.

   Note that administrator user in Account B will automatically inherit the permissions.
2. Account B administrator user attaches user policy to the user delegating the permissions it received from Account A.
3. User in Account B then verifies permissions by accessing an object in the bucket owned by Account A.

For this example, you need two accounts. The following table shows how we refer to these accounts and the administrator users in them. In accordance with the IAM guidelines (see About using an administrator user to create resources and grant permissions), we don't use the root user credentials in this walkthrough. Instead, you create an administrator user in each account and use those credentials when creating resources and granting them permissions.

| AWS account ID | Account referred to as | Administrator user in the account |
|---|---|---|
| *1111-1111-1111* | Account A | AccountAadmin |
| *2222-2222-2222* | Account B | AccountBadmin |

All the tasks of creating users and granting permissions are done in the AWS Management Console. To verify permissions, the walkthrough uses the command line tools, AWS Command Line Interface (CLI) and AWS Tools for Windows PowerShell, so you don't need to write any code.

### Preparing for the walkthrough

1. Make sure you have two AWS accounts and that each account has one administrator user as shown in the table in the preceding section.

   a. Sign up for an AWS account, if needed.

   b. Using Account A credentials, sign in to the IAM console to create the administrator user:

      i. Create user **`AccountAadmin`** and note the security credentials. For instructions, see Creating an IAM user in Your AWS account in the *IAM User Guide*.

      ii. Grant administrator privileges to **AccountAadmin** by attaching a user policy giving full access. For instructions, see Working with Policies in the *IAM User Guide*.

   c. While you are in the IAM console, note the **IAM user Sign-In URL** on the **Dashboard**. All users in the account must use this URL when signing in to the AWS Management Console.

      For more information, see How Users Sign in to Your Account in *IAM User Guide*.

   d. Repeat the preceding step using Account B credentials and create administrator user **`AccountBadmin`**.

2. Set up either the AWS Command Line Interface (AWS CLI) or the AWS Tools for Windows PowerShell. Make sure that you save administrator user credentials as follows:

   - If using the AWS CLI, create two profiles, `AccountAadmin` and `AccountBadmin`, in the config file.
   - If using the AWS Tools for Windows PowerShell, make sure that you store credentials for the session as `AccountAadmin` and `AccountBadmin`.

   For instructions, see Setting up the tools for the walkthroughs.

3. Save the administrator user credentials, also referred to as profiles. You can use the profile name instead of specifying credentials for each command you enter. For more information, see Setting up the tools for the walkthroughs.

   a. Add profiles in the AWS CLI credentials file for each of the administrator users, `AccountAadmin` and `AccountBadmin`, in the two accounts.

```
[AccountAadmin]
aws_access_key_id = access-key-ID
aws_secret_access_key = secret-access-key
```

```
region = us-east-1

[AccountBadmin]
aws_access_key_id = access-key-ID
aws_secret_access_key = secret-access-key
region = us-east-1
```

b. If you're using the AWS Tools for Windows PowerShell, run the following command.

```
set-awscredentials -AccessKey AcctA-access-key-ID -SecretKey AcctA-secret-
access-key -storeas AccountAadmin
set-awscredentials -AccessKey AcctB-access-key-ID -SecretKey AcctB-secret-
access-key -storeas AccountBadmin
```

**Step 1: Do the Account A tasks**

**Step 1.1: Sign in to the AWS Management Console**

Using the IAM user sign-in URL for Account A, first sign in to the AWS Management Console as **AccountAadmin** user. This user will create a bucket and attach a policy to it.

**Step 1.2: Create a bucket**

1. In the Amazon S3 console, create a bucket. This exercise assumes the bucket is created in the US East (N. Virginia) AWS Region and is named *amzn-s3-demo-bucket*.

   For instructions, see Creating a bucket.
2. Upload a sample object to the bucket.

   For instructions, go to Step 2: Upload an object to your bucket.

**Step 1.3: Attach a bucket policy to grant cross-account permissions to Account B**

The bucket policy grants the `s3:GetLifecycleConfiguration` and `s3:ListBucket` permissions to Account B. It's assumed that you're still signed in to the console using **AccountAadmin** user credentials.

1. Attach the following bucket policy to *amzn-s3-demo-bucket*. The policy grants Account B permission for the `s3:GetLifecycleConfiguration` and `s3:ListBucket` actions.

   For instructions, see Adding a bucket policy by using the Amazon S3 console.

```
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Sid": "Example permissions",
         "Effect": "Allow",
         "Principal": {
            "AWS": "arn:aws:iam::AccountB-ID:root"
         },
         "Action": [
            "s3:GetLifecycleConfiguration",
            "s3:ListBucket"
         ],
         "Resource": [
            "arn:aws:s3:::amzn-s3-demo-bucket"
         ]
      }
   ]
}
```

2. Verify that Account B (and thus its administrator user) can perform the operations.

   - Verify using the AWS CLI

     ```
     aws s3 ls s3://amzn-s3-demo-bucket --profile AccountBadmin
     aws s3api get-bucket-lifecycle-configuration --bucket amzn-s3-demo-bucket --
     profile AccountBadmin
     ```

   - Verify using the AWS Tools for Windows PowerShell

     ```
     get-s3object -BucketName amzn-s3-demo-bucket -StoredCredentials AccountBadmin
     get-s3bucketlifecycleconfiguration -BucketName amzn-s3-demo-bucket -
     StoredCredentials AccountBadmin
     ```

### Step 2: Do the Account B tasks

Now the Account B administrator creates a user, Dave, and delegates the permissions received from Account A.

### Step 2.1: Sign in to the AWS Management Console

Using the IAM user sign-in URL for Account B, first sign in to the AWS Management Console as **AccountBadmin** user.

### Step 2.2: Create user Dave in Account B

In the IAM Console, create a user, **Dave**.

For instructions, see Creating IAM users (console) in the *IAM User Guide*.

### Step 2.3: Delegate permissions to user Dave

Create an inline policy for the user Dave by using the following policy. You will need to update the policy by providing your bucket name.

It's assumed that you're signed in to the console using **AccountBadmin** user credentials.

```
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Sid": "Example",
         "Effect": "Allow",
         "Action": [
            "s3:ListBucket"
         ],
         "Resource": [
            "arn:aws:s3:::amzn-s3-demo-bucket"
         ]
      }
   ]
}
```

For instructions, see Managing IAM policies in the *IAM User Guide*.

### Step 2.4: Test permissions

Now Dave in Account B can list the contents of *amzn-s3-demo-bucket* owned by Account A. You can verify the permissions using either of the following procedures.

### Test permissions using the AWS CLI

1. Add the `UserDave` profile to the AWS CLI config file. For more information about the config file, see Setting up the tools for the walkthroughs.

```
[profile UserDave]
aws_access_key_id = access-key
aws_secret_access_key = secret-access-key
region = us-east-1
```

2. At the command prompt, enter the following AWS CLI command to verify Dave can now get an object list from the *amzn-s3-demo-bucket* owned by Account A. Note the command specifies the `UserDave` profile.

```
aws s3 ls s3://amzn-s3-demo-bucket --profile UserDave
```

Dave doesn't have any other permissions. So, if he tries any other operation—for example, the following `get-bucket-lifecycle` configuration—Amazon S3 returns permission denied.

```
aws s3api get-bucket-lifecycle-configuration --bucket amzn-s3-demo-bucket --profile
 UserDave
```

### Test permissions using AWS Tools for Windows PowerShell

1. Store Dave's credentials as `AccountBDave`.

```
set-awscredentials -AccessKey AccessKeyID -SecretKey SecretAccessKey -storeas
 AccountBDave
```

2. Try the List Bucket command.

```
get-s3object -BucketName amzn-s3-demo-bucket -StoredCredentials AccountBDave
```

Dave doesn't have any other permissions. So, if he tries any other operation—for example, the following `get-s3bucketlifecycleconfiguration`—Amazon S3 returns permission denied.

```
get-s3bucketlifecycleconfiguration -BucketName amzn-s3-demo-bucket -
StoredCredentials AccountBDave
```

### Step 3: (Optional) Try explicit deny

You can have permissions granted by using an access control list (ACL), a bucket policy, or a user policy. But if there is an explicit deny set by either a bucket policy or a user policy, the explicit deny takes precedence over any other permissions. For testing, update the bucket policy and explicitly deny Account B the `s3:ListBucket` permission. The policy also grants `s3:ListBucket` permission. However, explicit deny takes precedence, and Account B or users in Account B will not be able to list objects in *amzn-s3-demo-bucket*.

1. Using credentials of user `AccountAadmin` in Account A, replace the bucket policy by the following.

```
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Sid": "Example permissions",
         "Effect": "Allow",
         "Principal": {
            "AWS": "arn:aws:iam::AccountB-ID:root"
         },
         "Action": [
            "s3:GetLifecycleConfiguration",
            "s3:ListBucket"
         ],
         "Resource": [
            "arn:aws:s3:::amzn-s3-demo-bucket"
         ]
      },
      {
         "Sid": "Deny permission",
         "Effect": "Deny",
         "Principal": {
            "AWS": "arn:aws:iam::AccountB-ID:root"
         },
         "Action": [
            "s3:ListBucket"
```

```
            ],
            "Resource": [
               "arn:aws:s3:::amzn-s3-demo-bucket"
            ]
         }
      ]
}
```

2. Now if you try to get a bucket list using `AccountBadmin` credentials, access is denied.

   - Using the AWS CLI, run the following command:

     ```
     aws s3 ls s3://amzn-s3-demo-bucket --profile AccountBadmin
     ```

   - Using the AWS Tools for Windows PowerShell, run the following command:

     ```
     get-s3object -BucketName amzn-s3-demo-bucket -StoredCredentials AccountBDave
     ```

**Step 4: Clean up**

1. After you're done testing, you can do the following to clean up:

   - Sign in to the AWS Management Console (AWS Management Console) using Account A credentials, and do the following:

     - In the Amazon S3 console, remove the bucket policy attached to *amzn-s3-demo-bucket*. In the bucket **Properties**, delete the policy in the **Permissions** section.
     - If the bucket is created for this exercise, in the Amazon S3 console, delete the objects and then delete the bucket.
     - In the IAM Console, remove the `AccountAadmin` user.

2. Sign in to the IAM Console using Account B credentials. Delete user `AccountBadmin`. For step-by-step instructions, see Deleting an IAM user in the *IAM User Guide*.

### Example 3: Bucket owner granting permissions to objects it does not own

> **Important**
>
> Granting permissions to IAM roles is a better practice than granting permissions to individual users. To learn how to do this, see Understanding cross-account permissions and using IAM roles.

**Topics**

The scenario for this example is that a bucket owner wants to grant permission to access objects, but the bucket owner doesn't own all objects in the bucket. For this example, the bucket owner is trying to grant permission to users in its own account.

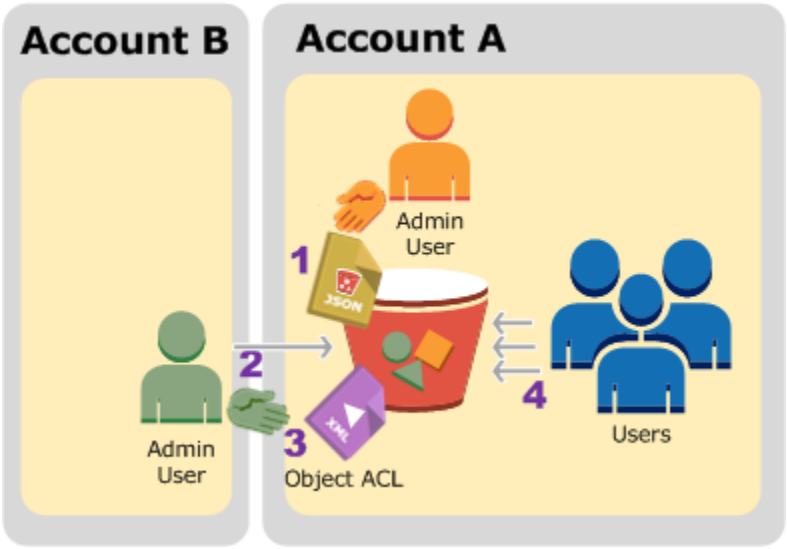
A bucket owner can enable other AWS accounts to upload objects. By default, the bucket owner doesn't own objects written to a bucket by another AWS account. Objects are owned by the accounts that write them to an S3 bucket. If the bucket owner doesn't own objects in the bucket, the object owner must first grant permission to the bucket owner using an object access control list (ACL). Then, the bucket owner can grant permissions to an object that they don't own. For more information, see Amazon S3 bucket and object ownership.

If the bucket owner applies the bucket owner enforced setting for S3 Object Ownership for the bucket, the bucket owner will own all objects in the bucket, including objects written by another AWS account. This approach resolves the issue that objects are not owned by the bucket owner. Then, you can delegate permission to users in your own account or to other AWS accounts.

> **Note**
>
> S3 Object Ownership is an Amazon S3 bucket-level setting that you can use to both control ownership of the objects that are uploaded to your bucket and to disable or enable ACLs. By default, Object Ownership is set to the Bucket owner enforced setting, and all ACLs are

disabled. When ACLs are disabled, the bucket owner owns all the objects in the bucket and manages access to them exclusively by using access-management policies.
A majority of modern use cases in Amazon S3 no longer require the use of ACLs. We recommend that you keep ACLs disabled, except in unusual circumstances where you need to control access for each object individually. With ACLs disabled, you can use policies to control access to all objects in your bucket, regardless of who uploaded the objects to your bucket. For more information, see Controlling ownership of objects and disabling ACLs for your bucket.

In this example, we assume the bucket owner has not applied the bucket owner enforced setting for Object Ownership. The bucket owner delegates permission to users in its own account. The following is a summary of the walkthrough steps:



1. Account A administrator user attaches a bucket policy with two statements.
   - Allow cross-account permission to Account B to upload objects.
   - Allow a user in its own account to access objects in the bucket.
2. Account B administrator user uploads objects to the bucket owned by Account A.
3. Account B administrator updates the object ACL adding grant that gives the bucket owner full-control permission on the object.
4. User in Account A verifies by accessing objects in the bucket, regardless of who owns them.

For this example, you need two accounts. The following table shows how we refer to these accounts and the administrator users in these accounts. In this walkthrough, you don't use

the account root user credentials, according to the recommended IAM guidelines. For more information, see About using an administrator user to create resources and grant permissions. Instead, you create an administrator in each account and use those credentials in creating resources and granting them permissions.

| AWS account ID | Account referred to as | Administrator in the account |
|---|---|---|
| *1111-1111-1111* | Account A | AccountAadmin |
| *2222-2222-2222* | Account B | AccountBadmin |

All the tasks of creating users and granting permissions are done in the AWS Management Console. To verify permissions, the walkthrough uses the command line tools, AWS Command Line Interface (AWS CLI) and AWS Tools for Windows PowerShell, so you don't need to write any code.

**Step 0: Preparing for the walkthrough**

1. Make sure that you have two AWS accounts and each account has one administrator as shown in the table in the preceding section.

   a. Sign up for an AWS account, if needed.

   b. Using Account A credentials, sign in to the IAM Console and do the following to create an administrator user:

      - Create user **`AccountAadmin`** and note the user's security credentials. For more information about adding users, see Creating an IAM user in your AWS account in the *IAM User Guide*.
      - Grant administrator permissions to **AccountAadmin** by attaching a user policy that gives full access. For instructions, see Managing IAM policies in the *IAM User Guide*.
      - In the IAM Console **Dashboard**, note the **IAM User Sign-In URL**. Users in this account must use this URL when signing in to the AWS Management Console. For more information, see How users sign in to your account in *IAM User Guide*.

   c. Repeat the preceding step using Account B credentials and create administrator user **`AccountBadmin`**.

2. Set up either the AWS CLI or the Tools for Windows PowerShell. Make sure that you save the administrator credentials as follows:

- If using the AWS CLI, create two profiles, `AccountAadmin` and `AccountBadmin`, in the config file.
- If using the Tools for Windows PowerShell, make sure that you store credentials for the session as `AccountAadmin` and `AccountBadmin`.

For instructions, see Setting up the tools for the walkthroughs.

### Step 1: Do the Account A tasks

Perform the following steps for Account A:

#### Step 1.1: Sign in to the console

Using the IAM user sign-in URL for Account A, sign in to the AWS Management Console as **`AccountAadmin`** user. This user will create a bucket and attach a policy to it.

#### Step 1.2: Create a bucket and user, and add a bucket policy to grant user permissions

1. In the Amazon S3 console, create a bucket. This exercise assumes that the bucket is created in the US East (N. Virginia) AWS Region, and the name is *`amzn-s3-demo-bucket1`*.

   For instructions, see Creating a bucket.
2. In the IAM Console, create a user **`Dave`**.

   For step-by-step instructions, see Creating IAM users (console) in the *IAM User Guide*.
3. Note the user Dave credentials.
4. In the Amazon S3 console, attach the following bucket policy to *`amzn-s3-demo-bucket1`* bucket. For instructions, see Adding a bucket policy by using the Amazon S3 console. Follow the steps to add a bucket policy. For information about how to find account IDs, see Finding your AWS account ID.

   The policy grants Account B the `s3:PutObject` and `s3:ListBucket` permissions. The policy also grants user `Dave` the `s3:GetObject` permission.

```
{
   "Version": "2012-10-17",
   "Statement": [
      {
```

```
            "Sid": "Statement1",
            "Effect": "Allow",
            "Principal": {
               "AWS": "arn:aws:iam::AccountB-ID:root"
            },
            "Action": [
               "s3:PutObject",
               "s3:ListBucket"
            ],
            "Resource": [
               "arn:aws:s3:::amzn-s3-demo-bucket1/*",
               "arn:aws:s3:::amzn-s3-demo-bucket1"
            ]
         },
         {
            "Sid": "Statement3",
            "Effect": "Allow",
            "Principal": {
               "AWS": "arn:aws:iam::AccountA-ID:user/Dave"
            },
            "Action": [
               "s3:GetObject"
            ],
            "Resource": [
               "arn:aws:s3:::amzn-s3-demo-bucket1/*"
            ]
         }
      ]
}
```

### Step 2: Do the Account B tasks

Now that Account B has permissions to perform operations on Account A's bucket, the Account B administrator does the following:

- Uploads an object to Account A's bucket
- Adds a grant in the object ACL to allow Account A, the bucket owner, full control

### Using the AWS CLI

1. Using the `put-object` AWS CLI command, upload an object. The `--body` parameter in the command identifies the source file to upload. For example, if the file is on the `C:` drive of a Windows machine, specify `c:\HappyFace.jpg`. The `--key` parameter provides the key name for the object.

```
aws s3api put-object --bucket amzn-s3-demo-bucket1 --key HappyFace.jpg --body
 HappyFace.jpg --profile AccountBadmin
```

2. Add a grant to the object ACL to allow the bucket owner full control of the object. For information about how to find a canonical user ID, see Find the canonical user ID for your AWS account in the *AWS Account Management Reference Guide*.

```
aws s3api put-object-acl --bucket amzn-s3-demo-bucket1 --key HappyFace.jpg --grant-
full-control id="AccountA-CanonicalUserID" --profile AccountBadmin
```

### Using the Tools for Windows PowerShell

1. Using the `Write-S3Object` command, upload an object.

```
Write-S3Object -BucketName amzn-s3-demo-bucket1 -key HappyFace.jpg -file
 HappyFace.jpg -StoredCredentials AccountBadmin
```

2. Add a grant to the object ACL to allow the bucket owner full control of the object.

```
Set-S3ACL -BucketName amzn-s3-demo-bucket1 -Key HappyFace.jpg -CannedACLName
 "bucket-owner-full-control" -StoredCreden
```

### Step 3: Test permissions

Now verify that user Dave in Account A can access the object owned by Account B.

### Using the AWS CLI

1. Add user Dave credentials to the AWS CLI config file and create a new profile, `UserDaveAccountA`. For more information, see Setting up the tools for the walkthroughs.

```
[profile UserDaveAccountA]
```

```
aws_access_key_id = access-key
aws_secret_access_key = secret-access-key
region = us-east-1
```

2. Run the `get-object` CLI command to download `HappyFace.jpg` and save it locally. You provide user Dave credentials by adding the `--profile` parameter.

```
aws s3api get-object --bucket amzn-s3-demo-bucket1 --key
 HappyFace.jpg Outputfile.jpg --profile UserDaveAccountA
```

**Using the Tools for Windows PowerShell**

1. Store user Dave AWS credentials, as `UserDaveAccountA`, to persistent store.

```
Set-AWSCredentials -AccessKey UserDave-AccessKey -SecretKey UserDave-
SecretAccessKey -storeas UserDaveAccountA
```

2. Run the `Read-S3Object` command to download the `HappyFace.jpg` object and save it locally. You provide user Dave credentials by adding the `-StoredCredentials` parameter.

```
Read-S3Object -BucketName amzn-s3-demo-bucket1 -Key HappyFace.jpg -file
 HappyFace.jpg  -StoredCredentials UserDaveAccountA
```

**Step 4: Clean up**

1. After you're done testing, you can do the following to clean up:

   - Sign in to the AWS Management Console using Account A credentials, and do the following:

     - In the Amazon S3 console, remove the bucket policy attached to *amzn-s3-demo-bucket1*. In the bucket **Properties**, delete the policy in the **Permissions** section.
     - If the bucket is created for this exercise, in the Amazon S3 console, delete the objects and then delete the bucket.
     - In the IAM Console, remove the **AccountAadmin** user. For step-by-step instructions, see Deleting an IAM user in the *IAM User Guide*.

2. Sign in to the AWS Management Console using Account B credentials. In the IAM Console, delete the user **AccountBadmin**.

### Example 4 - Bucket owner granting cross-account permission to objects it does not own

**Topics**

In this example scenario, you own a bucket and you have enabled other AWS accounts to upload objects. If you have applied the bucket owner enforced setting for S3 Object Ownership for the bucket, you will own all objects in the bucket, including objects written by another AWS account. This approach resolves the issue that objects are not owned by you, the bucket owner. Then, you can delegate permission to users in your own account or to other AWS accounts. Suppose the bucket owner enforced setting for S3 Object Ownership is not enabled. That is, your bucket can have objects that other AWS accounts own.

Now, suppose as a bucket owner, you need to grant cross-account permission on objects, regardless of who the owner is, to a user in another account. For example, that user could be a billing application that needs to access object metadata. There are two core issues:

- The bucket owner has no permissions on those objects created by other AWS accounts. For the bucket owner to grant permissions on objects it doesn't own, the object owner must first grant permission to the bucket owner. The object owner is the AWS account that created the objects. The bucket owner can then delegate those permissions.
- The bucket owner account can delegate permissions to users in its own account (see Example 3: Bucket owner granting permissions to objects it does not own). However, the bucket owner account can't delegate permissions to other AWS accounts because cross-account delegation isn't supported.

In this scenario, the bucket owner can create an AWS Identity and Access Management (IAM) role with permission to access objects Then, the bucket owner can grant another AWS account permission to assume the role, temporarily enabling it to access objects in the bucket.

> **Note**
>
> S3 Object Ownership is an Amazon S3 bucket-level setting that you can use to both control ownership of the objects that are uploaded to your bucket and to disable or enable ACLs. By default, Object Ownership is set to the Bucket owner enforced setting, and all ACLs are disabled. When ACLs are disabled, the bucket owner owns all the objects in the bucket and manages access to them exclusively by using access-management policies.
> A majority of modern use cases in Amazon S3 no longer require the use of ACLs. We recommend that you keep ACLs disabled, except in unusual circumstances where you need to control access for each object individually. With ACLs disabled, you can use policies to control access to all objects in your bucket, regardless of who uploaded the objects to your bucket. For more information, see Controlling ownership of objects and disabling ACLs for your bucket.

**Understanding cross-account permissions and using IAM roles**

IAM roles enable several scenarios to delegate access to your resources, and cross-account access is one of the key scenarios. In this example, the bucket owner, Account A, uses an IAM role to temporarily delegate object access cross-account to users in another AWS account, Account C. Each IAM role that you create has the following two policies attached to it:

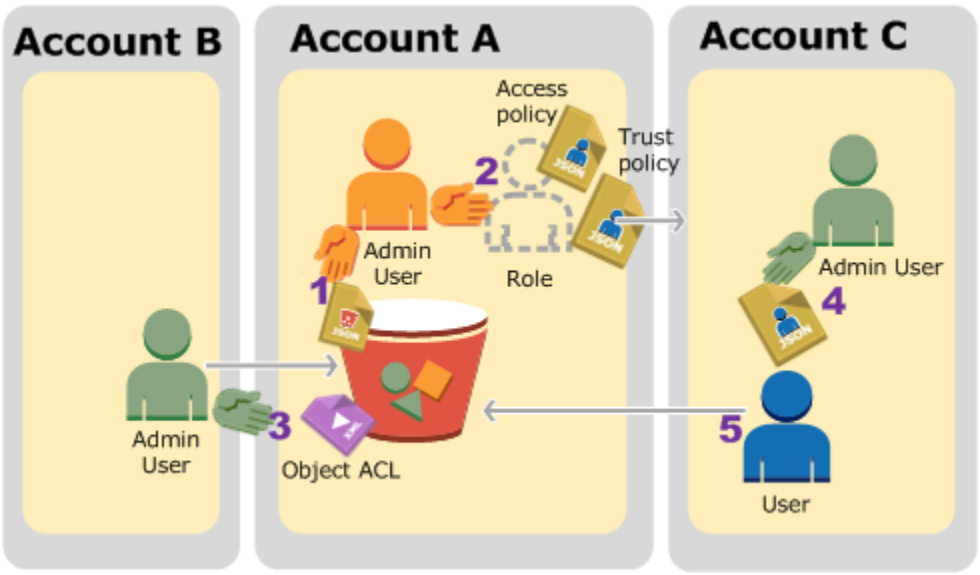
- A trust policy identifying another AWS account that can assume the role.
- An access policy defining what permissions—for example, `s3:GetObject`—are allowed when someone assumes the role. For a list of permissions you can specify in a policy, see Policy actions for Amazon S3.

The AWS account identified in the trust policy then grants its user permission to assume the role. The user can then do the following to access objects:

- Assume the role and, in response, get temporary security credentials.
- Using the temporary security credentials, access the objects in the bucket.

For more information about IAM roles, see IAM Roles in the *IAM User Guide*.

The following is a summary of the walkthrough steps:



1. Account A administrator user attaches a bucket policy granting Account B conditional permission to upload objects.
2. Account A administrator creates an IAM role, establishing trust with Account C, so users in that account can access Account A. The access policy attached to the role limits what user in Account C can do when the user accesses Account A.
3. Account B administrator uploads an object to the bucket owned by Account A, granting full-control permission to the bucket owner.
4. Account C administrator creates a user and attaches a user policy that allows the user to assume the role.
5. User in Account C first assumes the role, which returns the user temporary security credentials. Using those temporary credentials, the user then accesses objects in the bucket.

For this example, you need three accounts. The following table shows how we refer to these accounts and the administrator users in these accounts. In accordance with the IAM guidelines (see About using an administrator user to create resources and grant permissions), we don't use the AWS account root user credentials in this walkthrough. Instead, you create an administrator user in each account and use those credentials when creating resources and granting them permissions.

| AWS account ID | Account referred to as | Administrator user in the account |
|---|---|---|
| *1111-1111-1111* | Account A | AccountAadmin |

| AWS account ID | Account referred to as | Administrator user in the account |
|---|---|---|
| *2222-2222-2222* | Account B | AccountBadmin |
| *3333-3333-3333* | Account C | AccountCadmin |

### Step 0: Preparing for the walkthrough

> **Note**
>
> You might want to open a text editor, and write down some of the information as you go through the steps. In particular, you will need account IDs, canonical user IDs, IAM user Sign-in URLs for each account to connect to the console, and Amazon Resource Names (ARNs) of the IAM users, and roles.

1. Make sure that you have three AWS accounts and each account has one administrator user as shown in the table in the preceding section.

   a. Sign up for AWS accounts, as needed. We refer to these accounts as Account A, Account B, and Account C.

   b. Using Account A credentials, sign in to the IAM console and do the following to create an administrator user:

      - Create user **`AccountAadmin`** and note its security credentials. For more information about adding users, see Creating an IAM user in your AWS account in the *IAM User Guide*.
      - Grant administrator privileges to **AccountAadmin** by attaching a user policy giving full access. For instructions, see Managing IAM policies in the *IAM User Guide*.
      - In the IAM Console **Dashboard**, note the **IAM User Sign-In URL**. Users in this account must use this URL when signing in to the AWS Management Console. For more information, see Sign in to the AWS Management Console as an IAM user in the *IAM User Guide*.

   c. Repeat the preceding step to create administrator users in Account B and Account C.

2. For Account C, note the canonical user ID.

When you create an IAM role in Account A, the trust policy grants Account C permission to assume the role by specifying the account ID. You can find account information as follows:

a. Use your AWS account ID or account alias, your IAM user name, and your password to sign in to the Amazon S3 console.

b. Choose the name of an Amazon S3 bucket to view the details about that bucket.

c. Choose the **Permissions** tab and then choose **Access Control List**.

d. In the **Access for your AWS account** section, in the **Account** column is a long identifier, such as `c1daexampleaaf850ea79cf0430f33d72579fd1611c97f7ded193374c0b163b6`. This is your canonical user ID.

3. When creating a bucket policy, you will need the following information. Note these values:

- **Canonical user ID of Account A** – When the Account A administrator grants conditional upload object permission to the Account B administrator, the condition specifies the canonical user ID of the Account A user that must get full-control of the objects.

> **Note**
>
> The canonical user ID is the Amazon S3–only concept. It is a 64-character obfuscated version of the account ID.

- **User ARN for Account B administrator** – You can find the user ARN in the IAM Console.You must select the user and find the user's ARN in the **Summary** tab.

  In the bucket policy, you grant `AccountBadmin` permission to upload objects and you specify the user using the ARN. Here's an example ARN value:

```
arn:aws:iam::AccountB-ID:user/AccountBadmin
```

4. Set up either the AWS Command Line Interface (CLI) or the AWS Tools for Windows PowerShell. Make sure that you save administrator user credentials as follows:

- If using the AWS CLI, create profiles, `AccountAadmin` and `AccountBadmin`, in the config file.
- If using the AWS Tools for Windows PowerShell, make sure that you store credentials for the session as `AccountAadmin` and `AccountBadmin`.

For instructions, see Setting up the tools for the walkthroughs.

### Step 1: Do the account A tasks

In this example, Account A is the bucket owner. So user AccountAadmin in Account A will do the following:

- Create a bucket.
- Attach a bucket policy that grants the Account B administrator permission to upload objects.
- Create an IAM role that grants Account C permission to assume the role so it can access objects in the bucket.

### Step 1.1: Sign in to the AWS Management Console

Using the IAM user Sign-in URL for Account A, first sign in to the AWS Management Console as **`AccountAadmin`** user. This user will create a bucket and attach a policy to it.

### Step 1.2: Create a bucket and attach a bucket policy

In the Amazon S3 console, do the following:

1. Create a bucket. This exercise assumes the bucket name is *`amzn-s3-demo-bucket1`*.

   For instructions, see Creating a bucket.
2. Attach the following bucket policy. The policy grants conditional permission to the Account B administrator permission to upload objects.

   Update the policy by providing your own values for *`amzn-s3-demo-bucket1`*, *`AccountB-ID`*, and the *`CanonicalUserId-of-AWSaccountA-BucketOwner`*.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "111",
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws:iam::AccountB-ID:user/AccountBadmin"
```

```
            },
            "Action": "s3:PutObject",
            "Resource": "arn:aws:s3:::amzn-s3-demo-bucket1/*"
        },
        {
            "Sid": "112",
            "Effect": "Deny",
            "Principal": {
                "AWS": "arn:aws:iam::AccountB-ID:user/AccountBadmin"
            },
            "Action": "s3:PutObject",
            "Resource": "arn:aws:s3:::amzn-s3-demo-bucket1/*",
            "Condition": {
                "StringNotEquals": {
                    "s3:x-amz-grant-full-control": "id=CanonicalUserId-of-
AWSaccountA-BucketOwner"
                }
            }
        }
    ]
}
```

### Step 1.3: Create an IAM role to allow Account C cross-account access in Account A

In the IAM Console, create an IAM role (**`examplerole`**) that grants Account C permission to assume the role. Make sure that you are still signed in as the Account A administrator because the role must be created in Account A.

1. Before creating the role, prepare the managed policy that defines the permissions that the role requires. You attach this policy to the role in a later step.

   a. In the navigation pane on the left, choose **Policies** and then choose **Create Policy**.

   b. Next to **Create Your Own Policy**, choose **Select**.

   c. Enter **`access-accountA-bucket`** in the **Policy Name** field.

   d. Copy the following access policy and paste it into the **Policy Document** field. The access policy grants the role `s3:GetObject` permission so, when the Account C user assumes the role, it can only perform the `s3:GetObject` operation.

```
{
  "Version": "2012-10-17",
```

```
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "s3:GetObject",
      "Resource": "arn:aws:s3:::amzn-s3-demo-bucket1/*"
    }
  ]
}
```

e. Choose **Create Policy**.

The new policy appears in the list of managed policies.

2. In the navigation pane on the left, choose **Roles** and then choose **Create New Role**.
3. Under **Select Role Type**, select **Role for Cross-Account Access**, and then choose the **Select** button next to **Provide access between AWS accounts you own**.
4. Enter the Account C account ID.

   For this walkthrough, you don't need to require users to have multi-factor authentication (MFA) to assume the role, so leave that option unselected.
5. Choose **Next Step** to set the permissions that will be associated with the role.
6. Select the checkbox next to the **access-accountA-bucket** policy that you created, and then choose **Next Step**.

   The Review page appears so you can confirm the settings for the role before it's created. One very important item to note on this page is the link that you can send to your users who need to use this role. Users who use the link go straight to the **Switch Role** page with the Account ID and Role Name fields already filled in. You can also see this link later on the **Role Summary** page for any cross-account role.
7. Enter `examplerole` for the role name, and then choose **Next Step**.
8. After reviewing the role, choose **Create Role**.

   The `examplerole` role is displayed in the list of roles.
9. Choose the role name `examplerole`.
10. Select the **Trust Relationships** tab.
11. Choose **Show policy document** and verify the trust policy shown matches the following policy.

The following trust policy establishes trust with Account C, by allowing it the `sts:AssumeRole` action. For more information, see AssumeRole in the *AWS Security Token Service API Reference*.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "",
      "Effect": "Allow",
      "Principal": {
        "AWS": "arn:aws:iam::AccountC-ID:root"
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
```

12. Note the Amazon Resource Name (ARN) of the `examplerole` role that you created.

    Later in the following steps, you attach a user policy to allow an IAM user to assume this role, and you identify the role by the ARN value.

### Step 2: Do the Account B tasks

The example bucket owned by Account A needs objects owned by other accounts. In this step, the Account B administrator uploads an object using the command line tools.

- Using the `put-object` AWS CLI command, upload an object to *amzn-s3-demo-bucket1*.

  ```
  aws s3api put-object --bucket amzn-s3-demo-bucket1 --key HappyFace.jpg --
  body HappyFace.jpg --grant-full-control id="canonicalUserId-ofTheBucketOwner" --
  profile AccountBadmin
  ```

  Note the following:

  - The `--Profile` parameter specifies the `AccountBadmin` profile, so the object is owned by Account B.
  - The parameter `grant-full-control` grants the bucket owner full-control permission on the object as required by the bucket policy.

- The `--body` parameter identifies the source file to upload. For example, if the file is on the C: drive of a Windows computer, you specify `c:\HappyFace.jpg`.

### Step 3: Do the Account C tasks

In the preceding steps, Account A has already created a role, `examplerole`, establishing trust with Account C. This role allows users in Account C to access Account A. In this step, the Account C administrator creates a user (Dave) and delegates him the `sts:AssumeRole` permission it received from Account A. This approach allows Dave to assume the `examplerole` and temporarily gain access to Account A. The access policy that Account A attached to the role limits what Dave can do when he accesses Account A—specifically, get objects in *`amzn-s3-demo-bucket1`*.

#### Step 3.1: Create a user in Account C and delegate permission to assume examplerole

1. Using the IAM user sign-in URL for Account C, first sign in to the AWS Management Console as **`AccountCadmin`** user.

2. In the IAM Console, create a user, Dave.

   For step-by-step instructions, see Creating IAM users (AWS Management Console) in the *IAM User Guide*.
3. Note the Dave credentials. Dave will need these credentials to assume the `examplerole` role.
4. Create an inline policy for the Dave IAM user to delegate the `sts:AssumeRole` permission to Dave on the `examplerole` role in Account A.

   a. In the navigation pane on the left, choose **Users**.
   b. Choose the user name **Dave**.
   c. On the user details page, select the **Permissions** tab and then expand the **Inline Policies** section.
   d. Choose **click here** (or **Create User Policy**).
   e. Choose **Custom Policy**, and then choose **Select**.
   f. Enter a name for the policy in the **Policy Name** field.
   g. Copy the following policy into the **Policy Document** field.

      You must update the policy by providing the *`AccountA-ID`*.

```
{
```

```
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": ["sts:AssumeRole"],
      "Resource": "arn:aws:iam::AccountA-ID:role/examplerole"
    }
  ]
}
```

h. Choose **Apply Policy**.

5. Save Dave's credentials to the config file of the AWS CLI by adding another profile, `AccountCDave`.

```
[profile AccountCDave]
aws_access_key_id = UserDaveAccessKeyID
aws_secret_access_key = UserDaveSecretAccessKey
region = us-west-2
```

### Step 3.2: Assume role (examplerole) and access objects

Now Dave can access objects in the bucket owned by Account A as follows:

- Dave first assumes the `examplerole` using his own credentials. This will return temporary credentials.
- Using the temporary credentials, Dave will then access objects in Account A's bucket.

1. At the command prompt, run the following AWS CLI `assume-role` command using the `AccountCDave` profile.

   You must update the ARN value in the command by providing the *AccountA-ID* where `examplerole` is defined.

```
aws sts assume-role --role-arn arn:aws:iam::AccountA-ID:role/examplerole --profile
 AccountCDave --role-session-name test
```

   In response, AWS Security Token Service (AWS STS) returns temporary security credentials (access key ID, secret access key, and a session token).

2. Save the temporary security credentials in the AWS CLI config file under the `TempCred` profile.

```
[profile TempCred]
aws_access_key_id = temp-access-key-ID
aws_secret_access_key = temp-secret-access-key
aws_session_token = session-token
region = us-west-2
```

3. At the command prompt, run the following AWS CLI command to access objects using the temporary credentials. For example, the command specifies the head-object API to retrieve object metadata for the `HappyFace.jpg` object.

```
aws s3api get-object --bucket amzn-s3-demo-bucket1 --
key HappyFace.jpg SaveFileAs.jpg --profile TempCred
```

Because the access policy attached to `examplerole` allows the actions, Amazon S3 processes the request. You can try any other action on any other object in the bucket.

If you try any other action—for example, `get-object-acl`—you will get permission denied because the role isn't allowed that action.

```
aws s3api get-object-acl --bucket amzn-s3-demo-bucket1 --key HappyFace.jpg --
profile TempCred
```

We used user Dave to assume the role and access the object using temporary credentials. It could also be an application in Account C that accesses objects in *amzn-s3-demo-bucket1*. The application can obtain temporary security credentials, and Account C can delegate the application permission to assume `examplerole`.

### Step 4: Clean up

1. After you're done testing, you can do the following to clean up:

   - Sign in to the AWS Management Console using Account A credentials, and do the following:

     - In the Amazon S3 console, remove the bucket policy attached to *amzn-s3-demo-bucket1*. In the bucket **Properties**, delete the policy in the **Permissions** section.

- If the bucket is created for this exercise, in the Amazon S3 console, delete the objects and then delete the bucket.
- In the IAM Console, remove the `examplerole` you created in Account A. For step-by-step instructions, see Deleting an IAM user in the *IAM User Guide*.
- In the IAM Console, remove the **AccountAadmin** user.

2. Sign in to the IAM Console by using Account B credentials. Delete the user **AccountBadmin**.
3. Sign in to the IAM Console by using Account C credentials. Delete **AccountCadmin** and the user Dave.

## How Amazon S3 authorizes a request

When Amazon S3 receives a request—for example, a bucket or an object operation—it first verifies that the requester has the necessary permissions. Amazon S3 evaluates all the relevant access policies, user policies, and resource-based policies (bucket policy, bucket access control list (ACL), and object ACL) in deciding whether to authorize the request.

> **Note**
>
> If the Amazon S3 permission check fails to find valid permissions, an Access Denied (403 Forbidden)permission denied error is returned. For more information, see Troubleshoot Access Denied (403 Forbidden) errors in Amazon S3.

To determine whether the requester has permission to perform the specific operation, Amazon S3 does the following, in order, when it receives a request:

1. Converts all the relevant access policies (user policy, bucket policy, and ACLs) at run time into a set of policies for evaluation.
2. Evaluates the resulting set of policies in the following steps. In each step, Amazon S3 evaluates a subset of policies in a specific context, based on the context authority.
   a. **User context** – In the user context, the parent account to which the user belongs is the context authority.

      Amazon S3 evaluates a subset of policies owned by the parent account. This subset includes the user policy that the parent attaches to the user. If the parent also owns the resource in the request (bucket or object), Amazon S3 also evaluates the corresponding resource policies (bucket policy, bucket ACL, and object ACL) at the same time.

      A user must have permission from the parent account to perform the operation.

      This step applies only if the request is made by a user in an AWS account. If the request is made by using the root user credentials of an AWS account, Amazon S3 skips this step.

   b. **Bucket context** – In the bucket context, Amazon S3 evaluates policies owned by the AWS account that owns the bucket.

      If the request is for a bucket operation, the requester must have permission from the bucket owner. If the request is for an object, Amazon S3 evaluates all the policies owned by the

bucket owner to check if the bucket owner has not explicitly denied access to the object. If there is an explicit deny set, Amazon S3 does not authorize the request.

c. **Object context** – If the request is for an object, Amazon S3 evaluates the subset of policies owned by the object owner.

Following are some example scenarios that illustrate how Amazon S3 authorizes a request.

**Example – Requester is an IAM principal**

If the requester is an IAM principal, Amazon S3 must determine if the parent AWS account to which the principal belongs has granted the principal necessary permission to perform the operation. In addition, if the request is for a bucket operation, such as a request to list the bucket content, Amazon S3 must verify that the bucket owner has granted permission for the requester to perform the operation. To perform a specific operation on a resource, an IAM principal needs permission from both the parent AWS account to which it belongs and the AWS account that owns the resource.

**Example – Requester is an IAM principal – If the request is for an operation on an object that the bucket owner doesn't own**

If the request is for an operation on an object that the bucket owner doesn't own, in addition to making sure the requester has permissions from the object owner, Amazon S3 must also check the bucket policy to ensure the bucket owner has not set explicit deny on the object. A bucket owner (who pays the bill) can explicitly deny access to objects in the bucket regardless of who owns it. The bucket owner can also delete any object in the bucket.

By default, when another AWS account uploads an object to your S3 bucket, that account (the object writer) owns the object, has access to it, and can grant other users access to it through access control lists (ACLs). You can use Object Ownership to change this default behavior so that ACLs are disabled and you, as the bucket owner, automatically own every object in your bucket. As a result, access control for your data is based on policies, such as IAM user policies, S3 bucket policies, virtual private cloud (VPC) endpoint policies, and AWS Organizations service control policies (SCPs). For more information, see Controlling ownership of objects and disabling ACLs for your bucket.

For more information about how Amazon S3 evaluates access policies to authorize or deny requests for bucket operations and object operations, see the following topics:

**Topics**

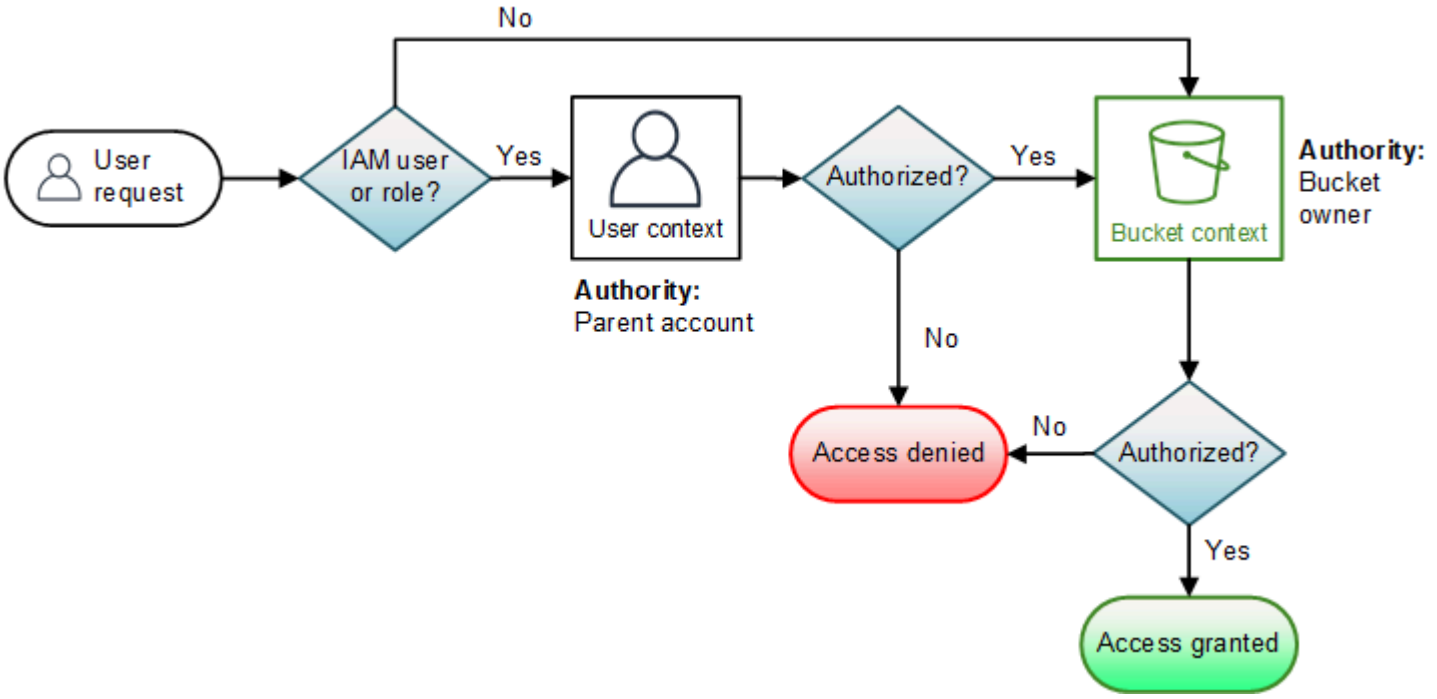
### How Amazon S3 authorizes a request for a bucket operation

When Amazon S3 receives a request for a bucket operation, Amazon S3 converts all the relevant permissions into a set of policies to evaluate at run time. Relevant permissions include resource-based permissions (for example, bucket policies and bucket access control lists) and user policies if the request is from an IAM principal. Amazon S3 then evaluates the resulting set of policies in a series of steps according to a specific context—user context or bucket context:

1. **User context** – If the requester is an IAM principal, the principal must have permission from the parent AWS account to which it belongs. In this step, Amazon S3 evaluates a subset of policies owned by the parent account (also referred to as the context authority). This subset of policies includes the user policy that the parent account attaches to the principal. If the parent also owns the resource in the request (in this case, the bucket), Amazon S3 also evaluates the corresponding resource policies (bucket policy and bucket ACL) at the same time. Whenever a request for a bucket operation is made, the server access logs record the canonical ID of the requester. For more information, see Logging requests with server access logging.
2. **Bucket context** – The requester must have permissions from the bucket owner to perform a specific bucket operation. In this step, Amazon S3 evaluates a subset of policies owned by the AWS account that owns the bucket.

   The bucket owner can grant permission by using a bucket policy or bucket ACL. If the AWS account that owns the bucket is also the parent account of an IAM principal, then it can configure bucket permissions in a user policy.

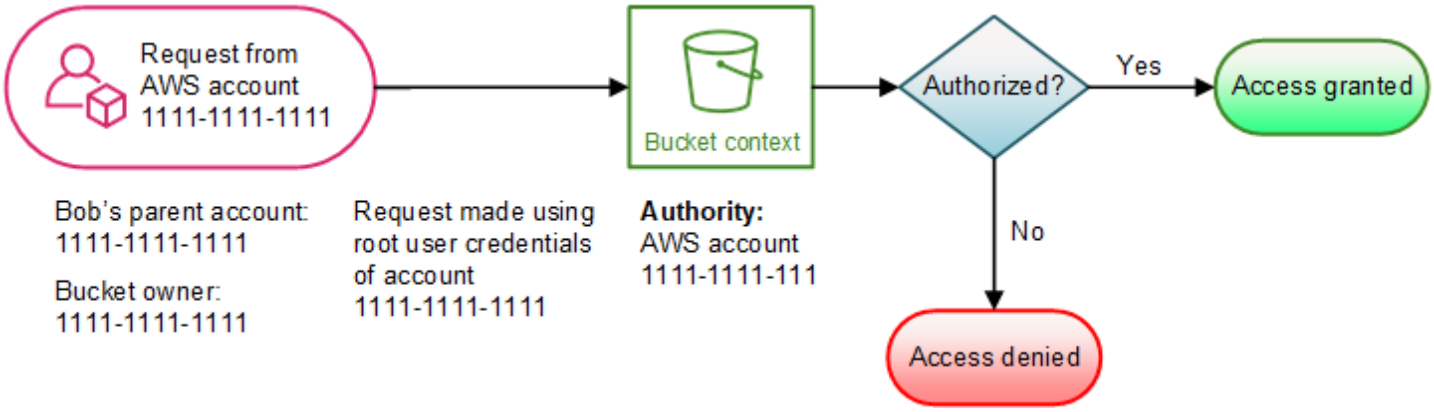
The following is a graphical illustration of the context-based evaluation for bucket operation.



The following examples illustrate the evaluation logic.

**Example 1: Bucket operation requested by bucket owner**

In this example, the bucket owner sends a request for a bucket operation by using the root credentials of the AWS account.

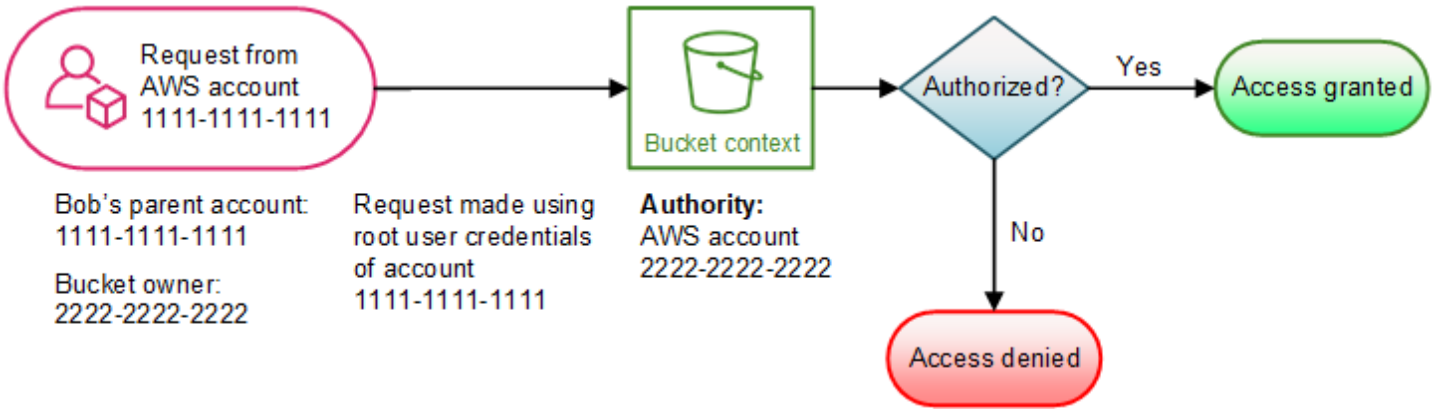


Amazon S3 performs the context evaluation as follows:

1. Because the request is made by using the root user credentials of an AWS account, the user context is not evaluated.
2. In the bucket context, Amazon S3 reviews the bucket policy to determine if the requester has permission to perform the operation. Amazon S3 authorizes the request.

### Example 2: Bucket operation requested by an AWS account that is not the bucket owner

In this example, a request is made by using the root user credentials of AWS account 1111-1111-1111 for a bucket operation owned by AWS account 2222-2222-2222. No IAM users are involved in this request.

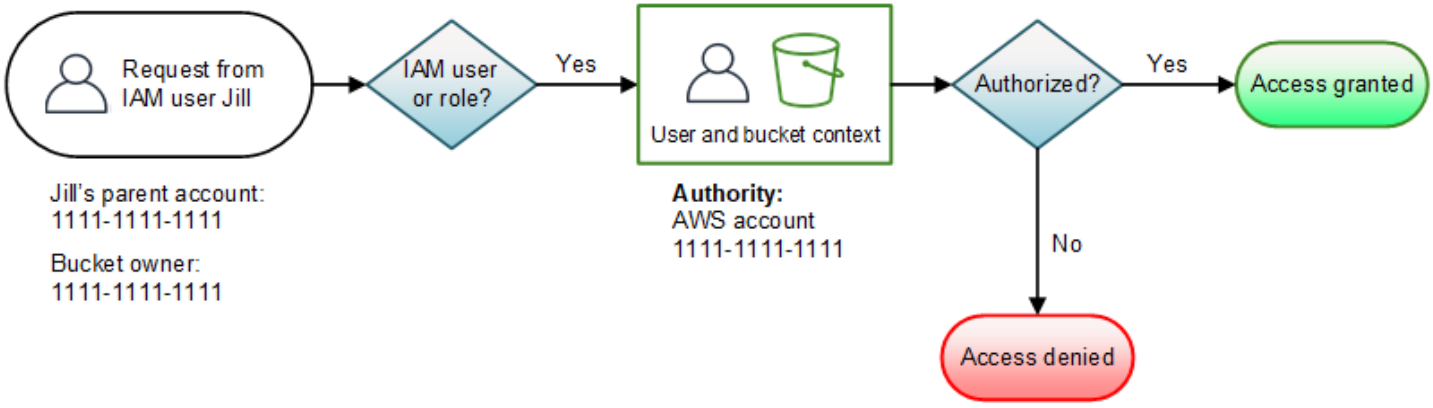


In this example, Amazon S3 evaluates the context as follows:

1. Because the request is made by using the root user credentials of an AWS account, the user context is not evaluated.
2. In the bucket context, Amazon S3 examines the bucket policy. If the bucket owner (AWS account 2222-2222-2222) has not authorized AWS account 1111-1111-1111 to perform the requested operation, Amazon S3 denies the request. Otherwise, Amazon S3 grants the request and performs the operation.

### Example 3: Bucket operation requested by an IAM principal whose parent AWS account is also the bucket owner

In the example, the request is sent by Jill, an IAM user in AWS account 1111-1111-1111, which also owns the bucket.



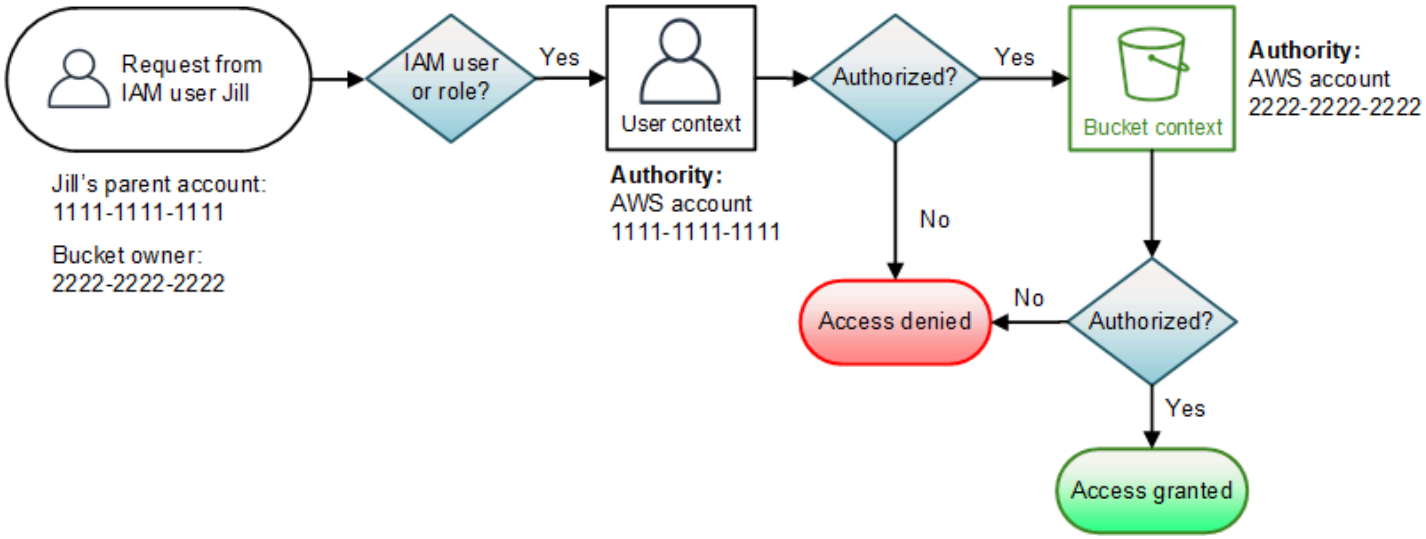
Amazon S3 performs the following context evaluation:

1. Because the request is from an IAM principal, in the user context, Amazon S3 evaluates all policies that belong to the parent AWS account to determine if Jill has permission to perform the operation.

   In this example, parent AWS account 1111-1111-1111, to which the principal belongs, is also the bucket owner. As a result, in addition to the user policy, Amazon S3 also evaluates the bucket policy and bucket ACL in the same context because they belong to the same account.
2. Because Amazon S3 evaluated the bucket policy and bucket ACL as part of the user context, it does not evaluate the bucket context.

**Example 4: Bucket operation requested by an IAM principal whose parent AWS account is not the bucket owner**

In this example, the request is sent by Jill, an IAM user whose parent AWS account is 1111-1111-1111, but the bucket is owned by another AWS account, 2222-2222-2222.



Jill will need permissions from both the parent AWS account and the bucket owner. Amazon S3 evaluates the context as follows:

1. Because the request is from an IAM principal, Amazon S3 evaluates the user context by reviewing the policies authored by the account to verify that Jill has the necessary permissions. If Jill has permission, then Amazon S3 moves on to evaluate the bucket context. If Jill doesn't have permission, it denies the request.

2. In the bucket context, Amazon S3 verifies that bucket owner 2222-2222-2222 has granted Jill (or her parent AWS account) permission to perform the requested operation. If she has that permission, Amazon S3 grants the request and performs the operation. Otherwise, Amazon S3 denies the request.

### How Amazon S3 authorizes a request for an object operation

When Amazon S3 receives a request for an object operation, it converts all the relevant permissions — resource-based permissions (object access control list (ACL), bucket policy, bucket ACL) and IAM user policies—into a set of policies to be evaluated at run time. It then evaluates the resulting set of policies in a series of steps. In each step, it evaluates a subset of policies in three specific contexts—user context, bucket context, and object context:

1. **User context** – If the requester is an IAM principal, the principal must have permission from the parent AWS account to which it belongs. In this step, Amazon S3 evaluates a subset of policies owned by the parent account (also referred as the context authority). This subset of policies includes the user policy that the parent attaches to the principal. If the parent also owns the resource in the request (bucket or object), Amazon S3 evaluates the corresponding resource policies (bucket policy, bucket ACL, and object ACL) at the same time.

   > **Note**
   >
   > If the parent AWS account owns the resource (bucket or object), it can grant resource permissions to its IAM principal by using either the user policy or the resource policy.

2. **Bucket context** – In this context, Amazon S3 evaluates policies owned by the AWS account that owns the bucket.

   If the AWS account that owns the object in the request is not same as the bucket owner, Amazon S3 checks the policies if the bucket owner has explicitly denied access to the object. If there is an explicit deny set on the object, Amazon S3 does not authorize the request.

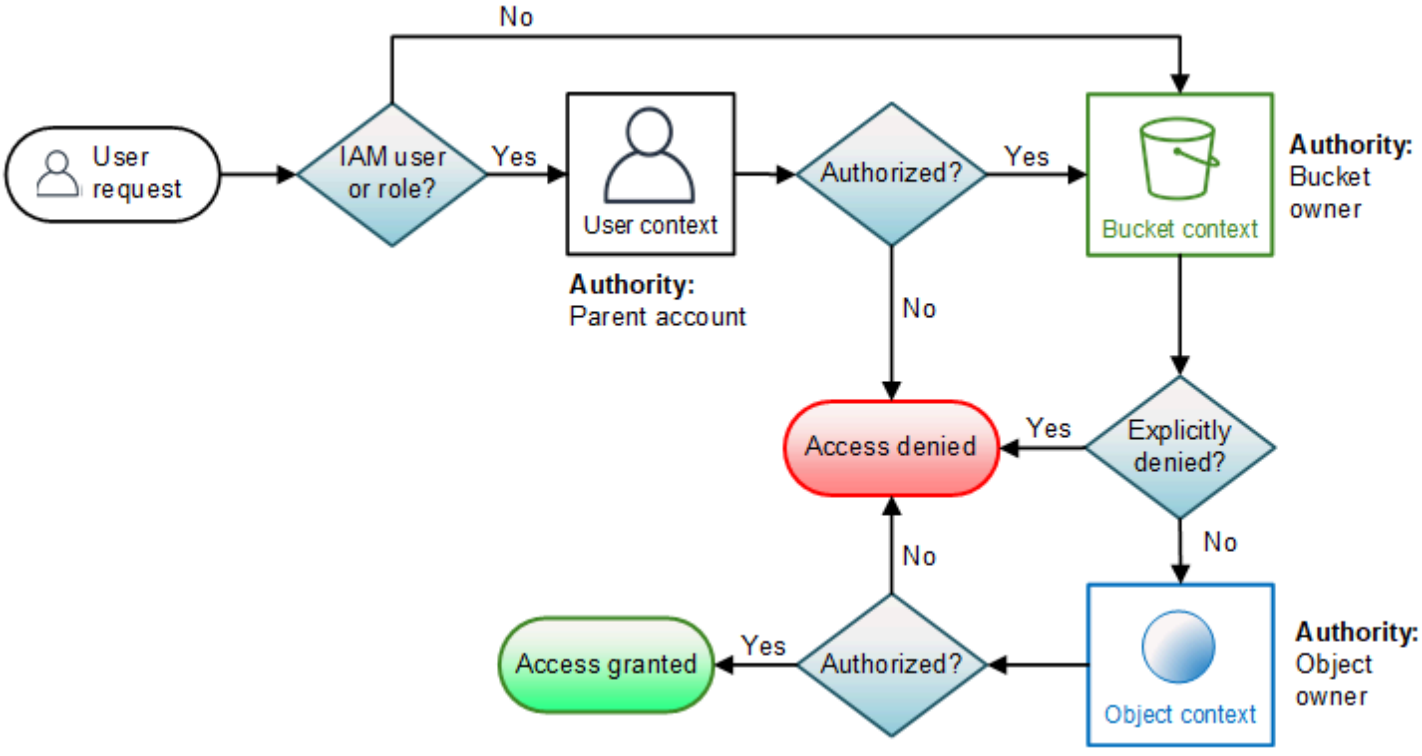
3. **Object context** – The requester must have permissions from the object owner to perform a specific object operation. In this step, Amazon S3 evaluates the object ACL.

   > **Note**
   >
   > If bucket and object owners are the same, access to the object can be granted in the bucket policy, which is evaluated at the bucket context. If the owners are different, the

object owners must use an object ACL to grant permissions. If the AWS account that owns the object is also the parent account to which the IAM principal belongs, it can configure object permissions in a user policy, which is evaluated at the user context. For more information about using these access policy alternatives, see Walkthroughs that use policies to manage access to your Amazon S3 resources.

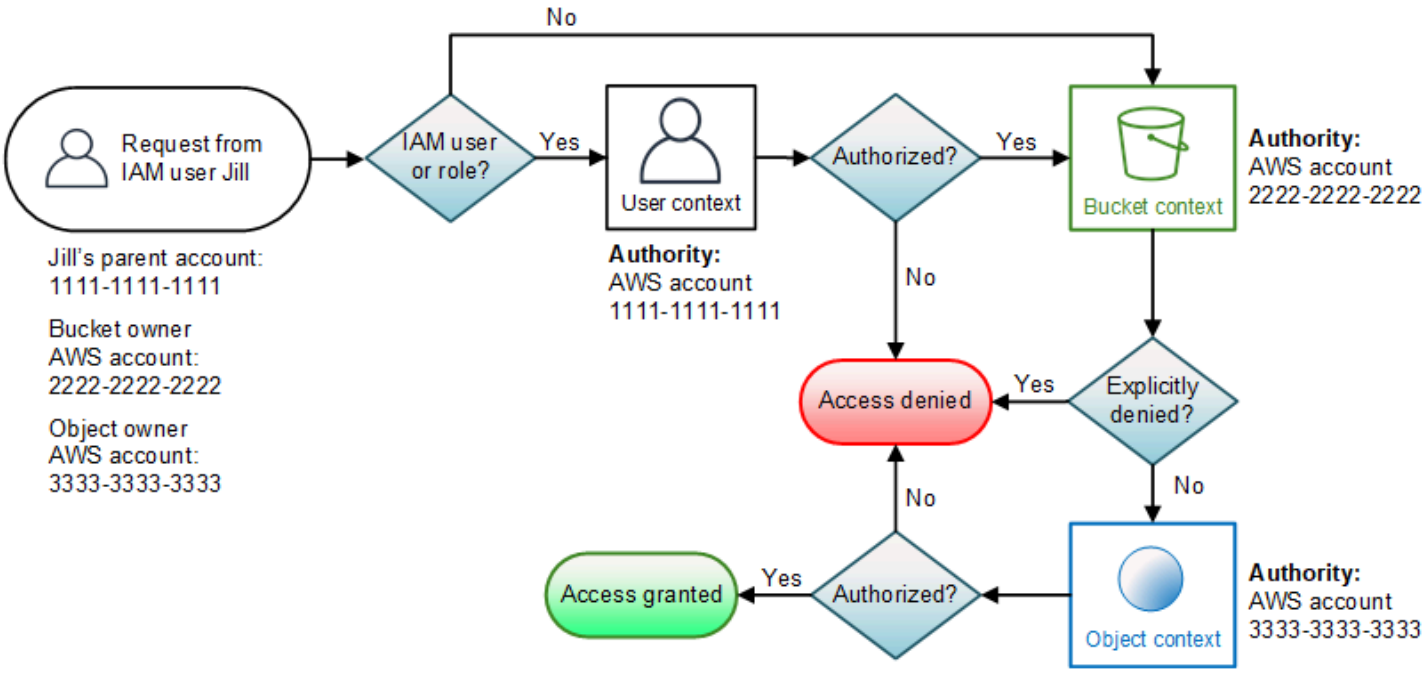
If you as the bucket owner want to own all the objects in your bucket and use bucket policies or policies based on IAMto manage access to these objects, you can apply the bucket owner enforced setting for Object Ownership. With this setting, you as the bucket owner automatically own and have full control over every object in your bucket. Bucket and object ACLs can't be edited and are no longer considered for access. For more information, see Controlling ownership of objects and disabling ACLs for your bucket.

The following is an illustration of the context-based evaluation for an object operation.



**Example of an object operation request**

In this example, IAM user Jill, whose parent AWS account is 1111-1111-1111, sends an object operation request (for example, `GetObject`) for an object owned by AWS account 3333-3333-3333 in a bucket owned by AWS account 2222-2222-2222.



Jill will need permission from the parent AWS account, the bucket owner, and the object owner. Amazon S3 evaluates the context as follows:

1. Because the request is from an IAM principal, Amazon S3 evaluates the user context to verify that the parent AWS account 1111-1111-1111 has given Jill permission to perform the requested operation. If she has that permission, Amazon S3 evaluates the bucket context. Otherwise, Amazon S3 denies the request.
2. In the bucket context, the bucket owner, AWS account 2222-2222-2222, is the context authority. Amazon S3 evaluates the bucket policy to determine if the bucket owner has explicitly denied Jill access to the object.
3. In the object context, the context authority is AWS account 3333-3333-3333, the object owner. Amazon S3 evaluates the object ACL to determine if Jill has permission to access the object. If she does, Amazon S3 authorizes the request.

## AWS managed policies for Amazon S3

An AWS managed policy is a standalone policy that is created and administered by AWS. AWS managed policies are designed to provide permissions for many common use cases so that you can start assigning permissions to users, groups, and roles.

Keep in mind that AWS managed policies might not grant least-privilege permissions for your specific use cases because they're available for all AWS customers to use. We recommend that you

reduce permissions further by defining customer managed policies that are specific to your use cases.

You cannot change the permissions defined in AWS managed policies. If AWS updates the permissions defined in an AWS managed policy, the update affects all principal identities (users, groups, and roles) that the policy is attached to. AWS is most likely to update an AWS managed policy when a new AWS service is launched or new API operations become available for existing services.

For more information, see AWS managed policies in the *IAM User Guide*.

**AWS managed policy: AmazonS3FullAccess**

You can attach the `AmazonS3FullAccess` policy to your IAM identities. This policy grants permissions that allow full access to Amazon S3.

To view the permissions for this policy, see AmazonS3FullAccess in the AWS Management Console.

**AWS managed policy: AmazonS3ReadOnlyAccess**

You can attach the `AmazonS3ReadOnlyAccess` policy to your IAM identities. This policy grants permissions that allow read-only access to Amazon S3.

To view the permissions for this policy, see AmazonS3ReadOnlyAccess in the AWS Management Console.

**AWS managed policy: AmazonS3ObjectLambdaExecutionRolePolicy**

Provides AWS Lambda functions the required permissions to send data to S3 Object Lambda when requests are made to an S3 Object Lambda access point. Also grants Lambda permissions to write to Amazon CloudWatch logs.

To view the permissions for this policy, see AmazonS3ObjectLambdaExecutionRolePolicy in the AWS Management Console.

**Amazon S3 updates to AWS managed policies**

View details about updates to AWS managed policies for Amazon S3 since this service began tracking these changes.

| Change | Description | Date |
| --- | --- | --- |
| Amazon S3 added Describe permissions to AmazonS3ReadOnlyAccess | Amazon S3 added s3:Describe* permissions to AmazonS3ReadOnlyAccess . | August 11, 2023 |
| Amazon S3 added S3 Object Lambda permissions to AmazonS3FullAccess and AmazonS3ReadOnlyAccess | Amazon S3 updated the AmazonS3FullAccess and AmazonS3ReadOnlyAccess policies to include permissions for S3 Object Lambda. | September 27, 2021 |
| Amazon S3 added AmazonS3ObjectLambdaExecutionRolePolicy | Amazon S3 added a new AWS-managed policy called AmazonS3ObjectLambdaExecutionRolePolicy that provides Lambda functions permissions to interact with S3 Object Lambda and write to CloudWatch logs. | August 18, 2021 |
| Amazon S3 started tracking changes | Amazon S3 started tracking changes for its AWS managed policies. | August 18, 2021 |

## Using service-linked roles for Amazon S3 Storage Lens

To use Amazon S3 Storage Lens to collect and aggregate metrics across all your accounts in AWS Organizations, you must first ensure that S3 Storage Lens has trusted access enabled by the management account in your organization. S3 Storage Lens creates a service-linked role (SLR) to allow it to get the list of AWS accounts belonging to your organization. This list of accounts is used by S3 Storage Lens to collect metrics for S3 resources in all the member accounts when the S3 Storage Lens dashboard or configurations are created or updated.

Amazon S3 Storage Lens uses AWS Identity and Access Management (IAM) service-linked roles. A service-linked role is a unique type of IAM role that is linked directly to S3 Storage Lens. Service-linked roles are predefined by S3 Storage Lens and include all the permissions that the service requires to call other AWS services on your behalf.

A service-linked role makes setting up S3 Storage Lens easier because you don't have to add the necessary permissions manually. S3 Storage Lens defines the permissions of its service-linked roles, and unless defined otherwise, only S3 Storage Lens can assume its roles. The defined permissions include the trust policy and the permissions policy, and that permissions policy can't be attached to any other IAM entity.

You can delete this service-linked role only after first deleting the related resources. This protects your S3 Storage Lens resources because you can't inadvertently remove permission to access the resources.

For information about other services that support service-linked roles, see AWS services that work with IAM and look for the services that have **Yes** in the **Service-Linked Role** column. Choose a **Yes** with a link to view the service-linked role documentation for that service.

**Service-linked role permissions for Amazon S3 Storage Lens**

S3 Storage Lens uses the service-linked role named **AWSServiceRoleForS3StorageLens** – This enables access to AWS services and resources used or managed by S3 Storage Lens. This allows S3 Storage Lens to access AWS Organizations resources on your behalf.

The S3 Storage Lens service-linked role trusts the following service on your organization's storage:

- `storage-lens.s3.amazonaws.com`

The role permissions policy allows S3 Storage Lens to complete the following actions:

- `organizations:DescribeOrganization`

  `organizations:ListAccounts`

  `organizations:ListAWSServiceAccessForOrganization`

  `organizations:ListDelegatedAdministrators`

You must configure permissions to allow an IAM entity (such as a user, group, or role) to create, edit, or delete a service-linked role. For more information, see Service-linked role permissions in the *IAM User Guide*.

### Creating a service-linked role for S3 Storage Lens

You don't need to manually create a service-linked role. When you complete one of the following tasks while signed into the AWS Organizations management or the delegate administrator accounts, S3 Storage Lens creates the service-linked role for you:

- Create an S3 Storage Lens dashboard configuration for your organization in the Amazon S3 console.
- PUT an S3 Storage Lens configuration for your organization using the REST API, AWS CLI and SDKs.

> **Note**
>
> S3 Storage Lens will support a maximum of five delegated administrators per organization.

If you delete this service-linked role, the preceding actions will re-create it as needed.

### Example policy for S3 Storage Lens service-linked role

### Example Permissions policy for the S3 Storage Lens service-linked role

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AwsOrgsAccess",
            "Effect": "Allow",
            "Action": [
                "organizations:DescribeOrganization",
                "organizations:ListAccounts",
                "organizations:ListAWSServiceAccessForOrganization",
                "organizations:ListDelegatedAdministrators"
            ],
            "Resource": [
                "*"
            ]
```

```
        }
    ]
}
```

### Editing a service-linked role for Amazon S3 Storage Lens

S3 Storage Lens doesn't allow you to edit the AWSServiceRoleForS3StorageLens service-linked role. After you create a service-linked role, you can't change the name of the role because various entities might reference the role. However, you can edit the description of the role using IAM. For more information, see Editing a service-linked role in the *IAM User Guide*.

### Deleting a service-linked role for Amazon S3 Storage Lens

If you no longer need to use the service-linked role, we recommend that you delete that role. That way you don't have an unused entity that is not actively monitored or maintained. However, you must clean up the resources for your service-linked role before you can manually delete it.

> **Note**
>
> If the Amazon S3 Storage Lens service is using the role when you try to delete the resources, then the deletion might fail. If that happens, wait for a few minutes and try the operation again.

To delete the AWSServiceRoleForS3StorageLens you must delete all the organization level S3 Storage Lens configurations present in all AWS Regions using the AWS Organizations management or the delegate administrator accounts.

The resources are organization-level S3 Storage Lens configurations. Use S3 Storage Lens to clean up the resources and then use the IAM Console, CLI, REST API, or AWS SDK to delete the role.

In the REST API, AWS CLI, and SDKs, S3 Storage Lens configurations can be discovered using `ListStorageLensConfigurations` in all the Regions where your organization has created S3 Storage Lens configurations. Use the action `DeleteStorageLensConfiguration` to delete these configurations so that you can then delete the role.

> **Note**
>
> To delete the service-linked role, you must delete all the organization-level S3 Storage Lens configurations in all the Regions where they exist.

**To delete Amazon S3 Storage Lens resources used by the AWSServiceRoleForS3StorageLens SLR**

1. To get a list of your organization level configurations, you must use the `ListStorageLensConfigurations` in every Region that you have S3 Storage Lens configurations. This list can also be obtained from the Amazon S3 console.
2. Delete these configurations from the appropriate Regional endpoints by invoking the `DeleteStorageLensConfiguration` API call or by using the Amazon S3 console.

**To manually delete the service-linked role using IAM**

After you have deleted the configurations, delete the AWSServiceRoleForS3StorageLens SLR from the IAM Console or by invoking the IAM API `DeleteServiceLinkedRole`, or using the AWS CLI or AWS SDK. For more information, see Deleting a service-linked role in the *IAM User Guide*.

**Supported Regions for S3 Storage Lens service-linked roles**

S3 Storage Lens supports using service-linked roles in all of the AWS Regions where the service is available. For more information, see Amazon S3 Regions and Endpoints.

## Troubleshooting Amazon S3 identity and access

Use the following information to help you diagnose and fix common issues that you might encounter when working with Amazon S3 and IAM.

**Topics**

- I received an access denied error
- I am not authorized to perform an action in Amazon S3
- I am not authorized to perform iam:PassRole
- I want to allow people outside of my AWS account to access my Amazon S3 resources

**I received an access denied error**

Verify that there is not an explicit Deny statement against the requester you are trying to grant permissions to in either the bucket policy or the identity-based policy.

For detailed information about troubleshooting access denied errors, see Troubleshoot Access Denied (403 Forbidden) errors in Amazon S3.

### I am not authorized to perform an action in Amazon S3

If you receive an error that you're not authorized to perform an action, your policies must be updated to allow you to perform the action.

The following example error occurs when the `mateojackson` IAM user tries to use the console to view details about a fictional *`my-example-widget`* resource but doesn't have the fictional `s3:`*`GetWidget`* permissions.

```
User: arn:aws:iam::123456789012:user/mateojackson is not authorized to perform:
 s3:GetWidget on resource: my-example-widget
```

In this case, the policy for the `mateojackson` user must be updated to allow access to the *`my-example-widget`* resource by using the `s3:`*`GetWidget`* action.

If you need help, contact your AWS administrator. Your administrator is the person who provided you with your sign-in credentials.

### I am not authorized to perform iam:PassRole

If you receive an error that you're not authorized to perform the `iam:PassRole` action, your policies must be updated to allow you to pass a role to Amazon S3.

Some AWS services allow you to pass an existing role to that service instead of creating a new service role or service-linked role. To do this, you must have permissions to pass the role to the service.

The following example error occurs when an IAM user named `marymajor` tries to use the console to perform an action in Amazon S3. However, the action requires the service to have permissions that are granted by a service role. Mary does not have permissions to pass the role to the service.

```
User: arn:aws:iam::123456789012:user/marymajor is not authorized to perform:
 iam:PassRole
```

In this case, Mary's policies must be updated to allow her to perform the `iam:PassRole` action.

If you need help, contact your AWS administrator. Your administrator is the person who provided you with your sign-in credentials.

**I want to allow people outside of my AWS account to access my Amazon S3 resources**

You can create a role that users in other accounts or people outside of your organization can use to access your resources. You can specify who is trusted to assume the role. For services that support resource-based policies or access control lists (ACLs), you can use those policies to grant people access to your resources.

To learn more, consult the following:

- To learn whether Amazon S3 supports these features, see How Amazon S3 works with IAM.
- To learn how to provide access to your resources across AWS accounts that you own, see Providing access to an IAM user in another AWS account that you own in the *IAM User Guide*.
- To learn how to provide access to your resources to third-party AWS accounts, see Providing access to AWS accounts owned by third parties in the *IAM User Guide*.
- To learn how to provide access through identity federation, see Providing access to externally authenticated users (identity federation) in the *IAM User Guide*.
- To learn the difference between using roles and resource-based policies for cross-account access, see Cross account resource access in IAM in the *IAM User Guide*.

## Managing access with S3 Access Grants

To adhere to the principle of least privilege, you define granular access to your Amazon S3 data based on applications, personas, groups, or organizational units. You can use various approaches to achieve granular access to your data in Amazon S3, depending on the scale and complexity of the access patterns.

The simplest approach for managing access to small-to-medium numbers of datasets in Amazon S3 by AWS Identity and Access Management (IAM) principals is to define IAM permission policies and S3 bucket policies. This strategy works, so long as the necessary policies fit within the policy size limits of S3 bucket policies (20 KB) and IAM policies (5 KB), and within the number of IAM principals allowed per account.

As your number of datasets and use cases scales, you might require more policy space. An approach that offers significantly more space for policy statements is to use S3 Access Points as additional endpoints for S3 buckets, because each access point can have its own policy. You can define quite granular access control patterns, because you can have thousands of access points per AWS Region per account, with a policy up to 20 KB in size for each access point. Although S3 Access Points

increases the amount of policy space available, it requires a mechanism for clients to discover the right access point for the right dataset.

A third approach is to implement an IAM session broker pattern, in which you implement access-decision logic and dynamically generate short-term IAM session credentials for each access session. While the IAM session broker approach supports arbitrarily dynamic permissions patterns and scales effectively, you must build the access-pattern logic.

Instead of using these approaches, you can use S3 Access Grants to manage access to your Amazon S3 data. S3 Access Grants provides a simplified model for defining access permissions to data in Amazon S3 by prefix, bucket, or object. In addition, you can use S3 Access Grants to grant access to both IAM principals and directly to users or groups from your corporate directory.

You commonly define permissions to data in Amazon S3 by mapping users and groups to datasets. You can use S3 Access Grants to define direct access mappings of S3 prefixes to users and roles within Amazon S3 buckets and objects. With the simplified access scheme in S3 Access Grants, you can grant read-only, write-only, or read-write access on a per-S3-prefix basis to both IAM principals and directly to users or groups from a corporate directory. With these S3 Access Grants capabilities, applications can request data from Amazon S3 on behalf of the application's current authenticated user.

When you integrate S3 Access Grants with the trusted identity propagation feature of AWS IAM Identity Center, your applications can make requests to AWS services (including S3 Access Grants) directly on behalf of an authenticated corporate directory user. Your applications no longer need to first map the user to an IAM principal. Furthermore, because end-user identities are propagated all the way to Amazon S3, auditing which user accessed which S3 object is simplified. You no longer need to reconstruct the relationship between different users and IAM sessions. When you're using S3 Access Grants with IAM Identity Center trusted identity propagation, each AWS CloudTrail data event for Amazon S3 contains a direct reference to the end user on whose behalf the data was accessed.

For more information about S3 Access Grants, see the following topics.

## S3 Access Grants concepts

### S3 Access Grants workflow

The S3 Access Grants workflow is:

1. Create an S3 Access Grants instance. See Create an S3 Access Grants instance.
2. Within your S3 Access Grants instance, register locations in your Amazon S3 data, and map these locations to AWS Identity and Access Management (IAM) roles. See Register a location.
3. Create grants for grantees, which give grantees access to your S3 resources. See Create grants.
4. The grantee requests temporary credentials from S3 Access Grants. See Request access to Amazon S3 data through S3 Access Grants.
5. The grantee accesses the S3 data using those temporary credentials. See Access S3 data through an access grant.

For more information, see Getting started with S3 Access Grants.

### S3 Access Grants instances

An *S3 Access Grants instance* is a logical container for individual *grants*. When you create an S3 Access Grants instance, you must specify an AWS Region. Each AWS Region in your AWS account can have one S3 Access Grants instance. For more information, see Create an S3 Access Grants instance.

If you want to use S3 Access Grants to grant access to user and group identities from your corporate directory, you must also associate your S3 Access Grants instance with an AWS IAM

Identity Center instance. For more information, see S3 Access Grants and corporate directory identities.

A newly created S3 Access Grants instance is empty. You must register a location in the instance, which can be the S3 default path (`s3://`), a bucket, or a prefix within a bucket. After you register at least one location, you can create access grants that give access to data in this registered location.

**Locations**

An S3 Access Grants *location* maps buckets or prefixes to an AWS Identity and Access Management (IAM) role. S3 Access Grants assumes this IAM role to vend temporary credentials to the grantee that's accessing that particular location. You must first register at least one location in your S3 Access Grants instance before you can create an access grant.

We recommend that you register the default location (`s3://`) and map it to an IAM role. The location at the default S3 path (`s3://`) covers access to all of your S3 buckets in the AWS Region of your account. When you create an access grant, you can narrow the grant scope to a bucket, a prefix, or an object within the default location.

More complex access-management use cases might require you to register more than the default location. Some examples of such use cases are:

- Suppose that the *`amzn-s3-demo-bucket`* is a registered location in your S3 Access Grants instance with an IAM role mapped to it, but this IAM role is denied access to a particular prefix within the bucket. In this case, you can register the prefix that the IAM role does not have access to as a separate location and map that location to a different IAM role with the necessary access.
- Suppose that you want to create grants that restrict access to only the users within a virtual private cloud (VPC) endpoint. In this case, you can register a location for a bucket in which the IAM role restricts access to the VPC endpoint. Later, when a grantee asks S3 Access Grants for credentials, S3 Access Grants assumes the location's IAM role to vend the temporary credentials. This credential will deny access to the specific bucket unless the caller is within the VPC endpoint. This deny permission is applied in addition to the regular READ, WRITE, or READWRITE permission specified in the grant.

If your use case requires you to register multiple locations in your S3 Access Grants instance, you can register any of the following:

- The default S3 location (`s3://`)

- A bucket (for example, *amzn-s3-demo-bucket*) or multiple buckets
- A bucket and a prefix (for example, *amzn-s3-demo-bucket*/prefix*) or multiple prefixes

For the maximum number of locations that you can register in your S3 Access Grants instance, see S3 Access Grants limitations. For more information about registering an S3 Access Grants location, see Register a location.

After you register the first location in your S3 Access Grants instance, your instance still does not have any individual access grants in it. So, no access has been granted yet to any of your S3 data. You can now create access grants to give access. For more information about creating grants, see Create grants.

**Grants**

An individual *grant* in an S3 Access Grants instance allows a specific identity—an IAM principal, or a user or group in a corporate directory—to get access within a location that is registered in your S3 Access Grants instance.

When you create a grant, you don't have to grant access to the entire registered location. You can narrow the grant's scope of access within a location. If the registered location is the default S3 path (s3://), you are required to narrow the scope of the grant to a bucket, a prefix within a bucket, or a specific object. If the registered location of the grant is a bucket or a prefix, then you can give access to the entire bucket or prefix, or you can optionally narrow the scope of the grant to a prefix, subprefix, or an object.

In the grant, you also set the access level of the grant to READ, WRITE, or READWRITE. Suppose you have a grant that gives the corporate directory group 01234567-89ab-cdef-0123-456789abcdef READ access to the bucket s3://*amzn-s3-demo-bucket*/projects/items/*. Users in this group can have READ access to every object that has an object key name which starts with the prefix projects/items/ in the bucket named *amzn-s3-demo-bucket*.

For the maximum number of grants that you can create in your S3 Access Grants instance, see S3 Access Grants limitations. For more information about creating grants, see Create grants.

**S3 Access Grants temporary credentials**

After you create a grant, an authorized application that utilizes the identity specified in the grant can request *just-in-time access credentials*. To do this, the application calls the GetDataAccess S3 API operation. Grantees can use this API operation to request access to the S3 data you have shared with them.

The S3 Access Grants instance evaluates the `GetDataAccess` request against the grants that it has. If there is a matching grant for the requestor, S3 Access Grants assumes the IAM role that's associated with the registered location of the matching grant. S3 Access Grants scopes the permissions of the temporary credentials to access only the S3 bucket, prefix, or object that's specified by the grant's scope.

The expiration time of the temporary access credentials defaults to 1 hour, but you can set it to any value from 15 minutes to 12 hours. See the maximum duration session in the AssumeRole API reference.

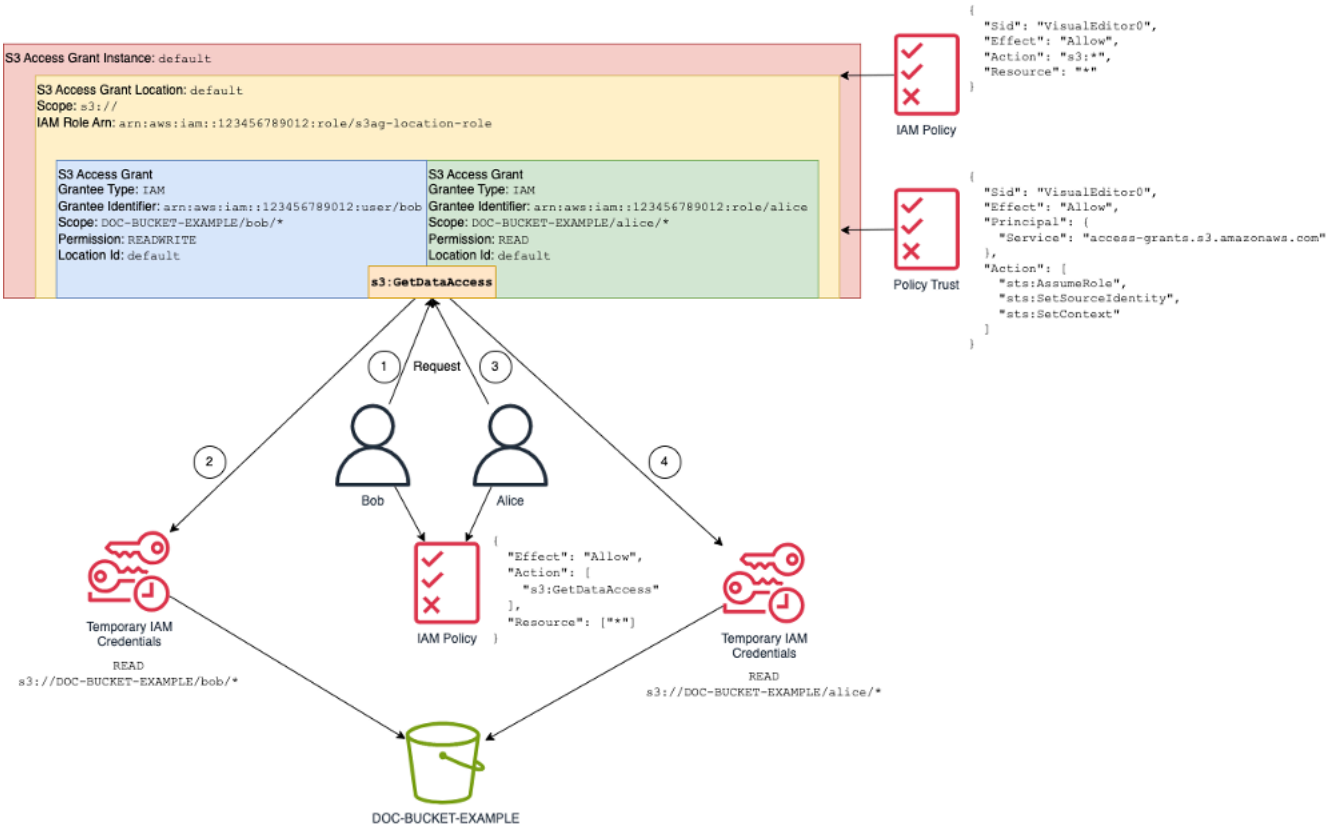
**How it works**

In the following diagram, a default Amazon S3 location with the scope `s3://` is registered with the IAM role `s3ag-location-role`. This IAM role has permissions to perform Amazon S3 actions within the account when its credentials are obtained through S3 Access Grants.

Within this location, two individual access grants are created for two IAM users. The IAM user Bob is granted both `READ` and `WRITE` access on the `bob/` prefix in the `DOC-BUCKET-EXAMPLE` bucket. Another IAM role, Alice, is granted only `READ` access on the `alice/` prefix in the `DOC-BUCKET-EXAMPLE` bucket. A grant, colored in blue, is defined for Bob to access the prefix `bob/` in the `DOC-BUCKET-EXAMPLE` bucket. A grant, colored in green, is defined for Alice to access the prefix `alice/` in the `DOC-BUCKET-EXAMPLE` bucket.

When it's time for Bob to `READ` data, the IAM role that's associated with the location that his grant is in calls the S3 Access Grants GetDataAccess API operation. If Bob tries to `READ` any S3 prefix or object that starts with `s3://DOC-BUCKET-EXAMPLE/bob/*`, the `GetDataAccess` request returns a set of temporary IAM session credentials with permission to `s3://DOC-BUCKET-EXAMPLE/bob/*`. Similarly, Bob can `WRITE` to any S3 prefix or object that starts with `s3://DOC-BUCKET-EXAMPLE/bob/*`, because the grant also allows that.

Similarly, Alice can `READ` anything that starts with `s3://DOC-BUCKET-EXAMPLE/alice/`. However, if she tries to `WRITE` anything to any bucket, prefix, or object in `s3://`, she will get an Access Denied (403 Forbidden) error, because there is no grant that gives her `WRITE` access to any data. In addition, if Alice requests any level of access (`READ` or `WRITE`) to data outside of `s3://DOC-BUCKET-EXAMPLE/alice/`, she will again receive an Access Denied error.



This pattern scales to a high number of users and buckets and simplifies management of those permissions. Rather than editing potentially large S3 bucket policies every time you want to add or remove an individual user-prefix access relationship, you can add and remove individual, discrete grants.

## S3 Access Grants and corporate directory identities

You can use Amazon S3 Access Grants to grant access to AWS Identity and Access Management (IAM) principals (users or roles), both in the same AWS account and in others. However, in many cases, the entity accessing the data is an end user from your corporate directory. Instead of granting access to IAM principals, you can use S3 Access Grants to grant access directly to your corporate users and groups. With S3 Access Grants, you no longer need to map your corporate identities to intermediate IAM principals in order to access your S3 data through your corporate applications.

This new functionality—support for using end-user identities access to data—is provided by associating your S3 Access Grants instance with an AWS IAM Identity Center instance. IAM Identity Center supports standards-based identity providers and is the hub in AWS for any services or features, including S3 Access Grants, that support end-user identities. IAM Identity Center provides

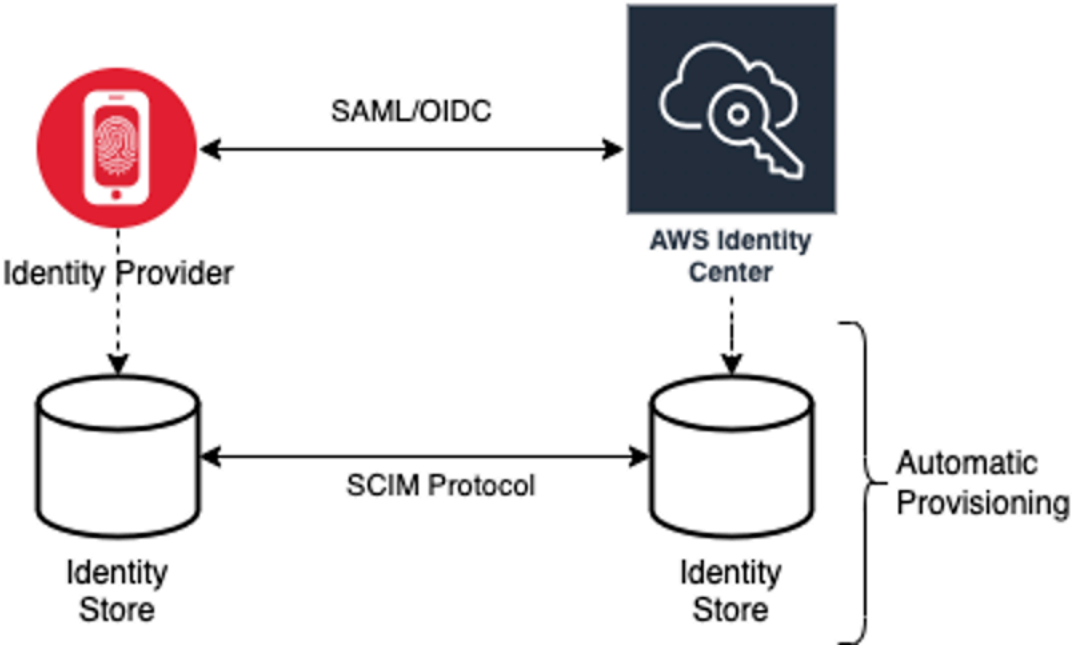
authentication support for corporate identities through its trusted identity propagation feature. For more information, see Trusted identity propagation across applications.

To get started with workforce identity support in S3 Access Grants, as a prerequisite, you start in IAM Identity Center by configuring identity provisioning between your corporate identity provider and IAM Identity Center. IAM Identity Center supports corporate identity providers such as Okta, Microsoft Entra ID (formerly Azure Active Directory), or any other external identity provider (IdP) that supports the System for Cross-domain Identity Management (SCIM) protocol. When you connect IAM Identity Center to your IdP and enable automatic provisioning, the users and groups from your IdP are synchronized into the identity store in IAM Identity Center. After this step, IAM Identity Center has its own view of your users and groups, so that you can refer to them by using other AWS services and features, such as S3 Access Grants. For more information about configuring IAM Identity Center automatic provisioning, see Automatic provisioning in the *AWS IAM Identity Center User Guide*.

IAM Identity Center is integrated with AWS Organizations so that you can centrally manage permissions across multiple AWS accounts without configuring each of your accounts manually. In a typical organization, your identity administrator configures one IAM Identity Center instance for the entire organization, as a single point of identity synchronization. This IAM Identity Center instance typically runs in a dedicated AWS account in your organization. In this common configuration, you can refer to user and group identities in S3 Access Grants from any AWS account in the organization.

However, if your AWS Organizations administrator hasn't yet configured a central IAM Identity Center instance, you can create a local one in the same account as your S3 Access Grants instance. Such a configuration is more common for proof-of-concept or local development use cases. In all cases, the IAM Identity Center instance must be in the same AWS Region as the S3 Access Grants instance to which it will be associated.

In the following diagram of an IAM Identity Center configuration with an external IdP, the IdP is configured with SCIM to synchronize the identity store from the IdP to the identity store in IAM Identity Center.



To use your corporate directory identities with S3 Access Grants, do the following:

- Set up Automatic provisioning in IAM Identity Center to synchronize user and group information from your IdP into IAM Identity Center.
- Configure your external identity source within IAM Identity Center as a trusted token issuer. For more information, see Trusted identity propagation across applications in the *AWS IAM Identity Center User Guide*.
- Associate your S3 Access Grants instance with your IAM Identity Center instance. You can do this when you create your S3 Access Grants instance. If you've already created your S3 Access Grants instance, see Associate or disassociate your IAM Identity Center instance.

**How directory identities can access S3 data**

Suppose that you have corporate directory users who need to access your S3 data through a corporate application, for example, a document-viewer application, that is integrated with your external IdP (for example, Okta) to authenticate users. Authentication of the user in these applications is typically done through redirects in the user's web browser. Because users in the directory are not IAM principals, your application needs IAM credentials with which it can call the S3 Access Grants `GetDataAccess` API operation to get access credentials to S3 data on the users' behalf. Unlike IAM users and roles who get credentials themselves, your application needs a way to represent a directory user, who isn't mapped to an IAM role, so that the user can get data access through S3 Access Grants.

This transition, from authenticated directory user to an IAM caller that can make requests to S3 Access Grants on behalf of the directory user, is done by the application through the trusted token issuer feature of IAM Identity Center. The application, after authenticating the directory user, has an identity token from the IdP (for example, Okta) that represents the directory user according to Okta. The trusted token issuer configuration in IAM Identity Center enables the application to exchange this Okta token (the Okta tenant is configured as the "trusted issuer") for a different identity token from IAM Identity Center that will securely represent the directory user within AWS services. The data application will then assume an IAM role, providing the directory user's token from IAM Identity Center as additional context. The application can use the resulting IAM session to call S3 Access Grants. The token represents both the identity of the application (the IAM principal itself) as well as the directory user's identity.

The main step of this transition is the token exchange. The application performs this token exchange by calling the `CreateTokenWithIAM` API operation in IAM Identity Center. Of course, that too is an AWS API call and requires an IAM principal to sign it. The IAM principal that makes this request is typically an IAM role that's associated with the application. For example, if the application runs on Amazon EC2, the `CreateTokenWithIAM` request is typically performed by the IAM role that's associated with the EC2 instance on which the application runs. The result of a successful `CreateTokenWithIAM` call is a new identity token, which will be recognized within AWS services.

The next step, before the application can call `GetDataAccess` on the directory user's behalf, is for the application to obtain an IAM session that includes the directory user's identity. The application does this with an AWS Security Token Service (AWS STS) `AssumeRole` request that also includes the IAM Identity Center token for the directory user as additional identity context. This additional context is what enables IAM Identity Center to propagate the directory user's identity to the next step. The IAM role that the application assumes is the role that will need IAM permissions to call the `GetDataAccess` operation.

Having assumed the identity bearer IAM role with the IAM Identity Center token for the directory user as additional context, the application now has everything it needs to make a signed request to `GetDataAccess` on behalf of the authenticated directory user.

Token propagation is based on the following steps:

**Create an IAM Identity Center application**

First, create a new application in IAM Identity Center. This application will use a template that allows IAM Identity Center to identify which type of application settings that you can use. The

command to create the application requires you to provide the IAM Identity Center instance Amazon Resource Name (ARN), an application name, and the application provider ARN. The application provider is the SAML or OAuth application provider that the application will use to make calls to IAM Identity Center.

To use the following example command, replace the *user input placeholders* with your own information:

```
aws sso-admin create-application \
 --instance-arn "arn:aws:sso:::instance/ssoins-ssoins-1234567890abcdef" \
 --application-provider-arn "arn:aws:sso::aws:applicationProvider/custom" \
 --name MyDataApplication
```

Response:

```
{
   "ApplicationArn": "arn:aws:sso::123456789012:application/ssoins-
ssoins-1234567890abcdef/apl-abcd1234a1b2c3d"
}
```

**Create a trusted token issuer**

Now that you have your IAM Identity Center application, the next step is to configure a trusted token issuer that will be used to exchange your `IdToken` values from your IdP with IAM Identity Center tokens. In this step you need to provide the following items:

- The identity provider issuer URL
- The trusted token issuer name
- The claim attribute path
- The identity store attribute path
- The JSON Web Key Set (JWKS) retrieval option

The claim attribute path is the identity provider attribute that will be used to map to the identity store attribute. Normally, the claim attribute path is the email address of the user, but you can use other attributes to perform the mapping.

Create a file called `oidc-configuration.json` with the following information. To use this file, replace the *user input placeholders* with your own information.

```
{
  "OidcJwtConfiguration":
     {
      "IssuerUrl": "https://login.microsoftonline.com/a1b2c3d4-abcd-1234-b7d5-
b154440ac123/v2.0",
      "ClaimAttributePath": "preferred_username",
      "IdentityStoreAttributePath": "userName",
      "JwksRetrievalOption": "OPEN_ID_DISCOVERY"
     }
}
```

To create the trusted token issuer, run the following command. To use this example command, replace the *user input placeholders* with your own information.

```
aws sso-admin create-trusted-token-issuer \
  --instance-arn "arn:aws:sso:::instance/ssoins-1234567890abcdef" \
  --name MyEntraIDTrustedIssuer \
  --trusted-token-issuer-type OIDC_JWT \
  --trusted-token-issuer-configuration file://./oidc-configuration.json
```

Response

```
{
  "TrustedTokenIssuerArn": "arn:aws:sso::123456789012:trustedTokenIssuer/
ssoins-1234567890abcdef/tti-43b4a822-1234-1234-1234-a1b2c3d41234"
}
```

**Connect the IAM Identity Center application with the trusted token issuer**

The trusted token issuer requires a few more configuration settings to work. Set the audience that the trusted token issuer will trust. The audience is the value inside the `IdToken` that's identified by the key and can be found in the identity provider settings. For example:

```
1234973b-abcd-1234-abcd-345c5a9c1234
```

Create a file named `grant.json` that contains the following content. To use this file, change the audience to match your identity provider settings and provide the trusted token issuer ARN that was returned by the previous command.

```
{
```

```
   "JwtBearer":
     {
       "AuthorizedTokenIssuers":
         [
           {
             "TrustedTokenIssuerArn": "arn:aws:sso::123456789012:trustedTokenIssuer/
ssoins-1234567890abcdef/tti-43b4a822-1234-1234-1234-a1b2c3d41234",
               "AuthorizedAudiences":
                 [
                   "1234973b-abcd-1234-abcd-345c5a9c1234"
                 ]
            }
         ]
     }
 }
```

Run the following example command. To use this command, replace the *`user input placeholders`* with your own information.

```
aws sso-admin put-application-grant \
  --application-arn "arn:aws:sso::123456789012:application/ssoins-
ssoins-1234567890abcdef/apl-abcd1234a1b2c3d" \
  --grant-type "urn:ietf:params:oauth:grant-type:jwt-bearer" \
  --grant file://./grant.json \
```

This command sets the trusted token issuer with configuration settings to trust the audience in the `grant.json` file and link this audience with the application created in the first step for exchanging tokens of the type `jwt-bearer`. The string `urn:ietf:params:oauth:grant-type:jwt-bearer` is not an arbitrary string. It is a registered namespace in OAuth JSON Web Token (JWT) assertion profiles. You can find more information about this namespace in RFC 7523.

Next, use the following command to set up which scopes the trusted token issuer will include when exchanging `IdToken` values from your identity provider. For S3 Access Grants, the value for the `--scope` parameter is `s3:access_grants:read_write`.

```
aws sso-admin put-application-access-scope \
  --application-arn "arn:aws:sso::111122223333:application/ssoins-
ssoins-111122223333abcdef/apl-abcd1234a1b2c3d" \
  --scope "s3:access_grants:read_write"
```

The last step is to attach a resource policy to the IAM Identity Center application. This policy will allow your application IAM role to make requests to the API operation `sso-oauth:CreateTokenWithIAM` and receive the `IdToken` values from IAM Identity Center.

Create a file named `authentication-method.json` that contains the following content. Replace *123456789012* with your account ID.

```
{
   "Iam":
       {
         "ActorPolicy":
             {
                "Version": "2012-10-17",
                    "Statement":
                    [
                        {
                           "Effect": "Allow",
                            "Principal":
                            {
                              "AWS": "arn:aws:iam::123456789012:role/webapp"
                            },
                           "Action": "sso-oauth:CreateTokenWithIAM",
                            "Resource": "*"
                        }
                    ]
                }
            }
        }
```

To attach the policy to the IAM Identity Center application, run the following command:

```
aws sso-admin put-application-authentication-method \
   --application-arn "arn:aws:sso::123456789012:application/ssoins-
ssoins-1234567890abcdef/apl-abcd1234a1b2c3d" \
   --authentication-method-type IAM \
   --authentication-method file://./authentication-method.json
```

This completes the configuration settings for using S3 Access Grants with directory users through a web application. You can test this setup directly in the application or you can call the `CreateTokenWithIAM` API operation by using the following command from an allowed IAM role in the IAM Identity Center application policy:

```
aws sso-oidc create-token-with-iam \
   --client-id "arn:aws:sso::123456789012:application/ssoins-ssoins-1234567890abcdef/
apl-abcd1234a1b2c3d"  \
   --grant-type urn:ietf:params:oauth:grant-type:jwt-bearer \
   --assertion IdToken
```

The response will be similar to this:

```
{
    "accessToken": "<suppressed long string to reduce space>",
    "tokenType": "Bearer",
    "expiresIn": 3600,
    "refreshToken": "<suppressed long string to reduce space>",
    "idToken": "<suppressed long string to reduce space>",
    "issuedTokenType": "urn:ietf:params:oauth:token-type:refresh_token",
    "scope": [
      "sts:identity_context",
      "s3:access_grants:read_write",
      "openid",
      "aws"
    ]
}
```

If you decode the `IdToken` value that is encoded with base64, you can see the key-value pairs in JSON format. The key `sts:identity_context` contains the value that your application needs to send in the `sts:AssumeRole` request to include the identity information of the directory user. Here is an example of the `IdToken` decoded:

```
{
    "aws:identity_store_id": "d-996773e796",
    "sts:identity_context": "AQoJb3JpZ2luX2VjEOTtl;<SUPRESSED>",
    "sub": "83d43802-00b1-7054-db02-f1d683aacba5",
    "aws:instance_account": "123456789012",
    "iss": "https://identitycenter.amazonaws.com/ssoins-1234567890abcdef",
    "sts:audit_context": "AQoJb3JpZ2luX2VjEOT<SUPRESSED>==",
    "aws:identity_store_arn": "arn:aws:identitystore::232642235904:identitystore/
d-996773e796",
    "aud": "abcd12344U0gi7n4Yyp0-WV1LWNlbnRyYWwtMQ",
    "aws:instance_arn": "arn:aws:sso:::instance/ssoins-6987d7fb04cf7a51",
    "aws:credential_id": "EXAMPLEHI5glPh40y9TpApJn8...",
    "act": {
```

```
       "sub": "arn:aws:sso::232642235904:trustedTokenIssuer/
ssoins-6987d7fb04cf7a51/43b4a822-1020-7053-3631-cb2d3e28d10e"
    },
    "auth_time": "2023-11-01T20:24:28Z",
    "exp": 1698873868,
    "iat": 1698870268
}
```

You can get the value from `sts:identity_context` and pass this information in an `sts:AssumeRole` call. The following is a CLI example of the syntax. The role to be assumed is a temporary role with permissions to invoke `s3:GetDataAccess`.

```
aws sts assume-role \
   --role-arn "arn:aws:iam::123456789012:role/temp-role" \
   --role-session-name "TempDirectoryUserRole" \
   --provided-contexts ProviderArn="arn:aws:iam::aws:contextProvider/
IdentityCenter",ContextAssertion="value from sts:identity_context"
```

You can now use the credentials received from this call to invoke the `s3:GetDataAccess` API operation and receive the final credentials with access to your S3 resources.

## Getting started with S3 Access Grants

Amazon S3 Access Grants is an Amazon S3 feature that provides a scalable access control solution for your S3 data. S3 Access Grants is an S3 credential vendor, meaning that you register with S3 Access Grants your list of grants and at what level. Thereafter, when users or clients need access to your S3 data, they first ask S3 Access Grants for credentials. If there is a corresponding grant that authorizes access, S3 Access Grants vends temporary, least-privilege access credentials. The users or clients can then use S3 Access Grants vended credentials to access your S3 data. With that in mind, if your S3 data requirements mandate a complex or large permission configuration, you can use S3 Access Grants to scale S3 data permissions for users, groups, roles, and applications.

For most use cases, you can manage access control for your S3 data by using AWS Identity and Access Management (IAM) with bucket policies or IAM identity-based policies.

However, if you have complex S3 access control requirements, such as the following, you could benefit greatly from using S3 Access Grants:

- You are running into the bucket policy size limit of 20 KB.

- You grant human identities, for example, Microsoft Entra ID (formerly Azure Active Directory), Okta, or Ping users and groups, access to S3 data for analytics and big data.
- You must provide cross-account access without making frequent updates to IAM policies.
- Your data is unstructured and object-level rather than structured, in row and column format.

The S3 Access Grants workflow is as follows:

| Steps | Description |
| --- | --- |
| 1 | Create an S3 Access Grants instance<br><br>To get started, initiate an S3 Access Grants instance that will contain your individual access grants. |
| 2 | Register a location<br><br>Second, register an S3 data location (such as the default, `s3://`) and then specify a default IAM role that S3 Access Grants assumes when providing access to the S3 data location. You can also add custom locations to specific buckets or prefixes and map those to custom IAM roles. |
| 3 | Create grants<br><br>Create individual permission grants. Specify in these permissio n grants the registered S3 location, the scope of data access within the location, the identity of the grantee, and their access level (`READ`, `WRITE`, or `READWRITE` ). |
| 4 | Request access to S3 data<br><br>When users, applications, and AWS services want to access S3 data, they first make an access request. S3 Access Grants determines if the request should be authorized. If there is a corresponding grant that authorizes access, S3 Access Grants uses the registered location's IAM role that's associated with that grant to vend temporary credentials back to the request er. |

| Steps | Description |
| --- | --- |
| 5 | Access S3 data<br><br>Applications use the temporary credentials vended by S3 Access Grants to access S3 data. |

## Create an S3 Access Grants instance

To get started with using AmazonS3 Access Grants, you first create an S3 Access Grants instance. You can create only one S3 Access Grants instance per AWS Region per account. The S3 Access Grants instance serves as the container for your S3 Access Grants resources, which include registered locations and grants.

With S3 Access Grants, you can create permission grants to your S3 data for AWS Identity and Access Management (IAM) users and roles. If you've added your corporate identity directory to AWS IAM Identity Center, you can associate this IAM Identity Center instance of your corporate directory with your S3 Access Grants instance. After you've done so, you can create access grants for your corporate users and groups. If you haven't yet added your corporate directory to IAM Identity Center, you can associate your S3 Access Grants instance with an IAM Identity Center instance later.

You can create an S3 Access Grants instance by using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), the Amazon S3 REST API, and AWS SDKs.

### Using the S3 console

Before you can grant access to your S3 data with S3 Access Grants, you must first create an S3 Access Grants instance in the same AWS Region as your S3 data.

#### Prerequisites

If you want to grant access to your S3 data by using identities from your corporate directory, add your corporate identity directory to AWS IAM Identity Center. If you're not yet ready to do so, you can associate your S3 Access Grants instance with an IAM Identity Center instance later.

#### To create an S3 Access Grants instance

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.

2. In the navigation bar, choose the name of the currently displayed AWS Region. Next, choose the Region that you want to switch to.
3. In the left navigation pane, choose **Access Grants**.
4. On the **S3 Access Grants** page, choose **Create S3 Access Grants instance**.

   a. In **Step 1** of the **Set up Access Grants instance** wizard, verify that you want to create the instance in the current AWS Region. Make sure that this is the same AWS Region where your S3 data is located. You can create one S3 Access Grants instance per AWS Region per account.

   b. (Optional) If you've added your corporate identity directory to AWS IAM Identity Center, you can associate this IAM Identity Center instance of your corporate directory with your S3 Access Grants instance.

      To do so, select **Add IAM Identity Center instance in *region***. Then enter the IAM Identity Center instance Amazon Resource Name (ARN).

      If you haven't yet added your corporate directory to IAM Identity Center, you can associate your S3 Access Grants instance with an IAM Identity Center instance later.

   c. To create the S3 Access Grants instance, choose **Next**. To register a location, see Step 2 - register a location.
5. If **Next** or **Create S3 Access Grants instance** is disabled:

   **Cannot create instance**

   - You might already have an S3 Access Grants instance in the same AWS Region. In the left navigation pane, choose **Access Grants**. On the **S3 Access Grants** page, scroll down to the **S3 Access Grants instance in your account** section o determine if an instance already exists.
   - You might not have the `s3:CreateAccessGrantsInstance` permission which is required to create an S3 Access Grants instance. Contact your account administrator. For additional permissions that are required if you are associating an IAM Identity Center instance, with your S3 Access Grants instance, see CreateAccessGrantsInstance .

### Using the AWS CLI

To install the AWS CLI, see Installing the AWS CLI in the *AWS Command Line Interface User Guide*.

To use the following example command, replace the *user input placeholders* with your own information.

**Example Create an S3 Access Grants instance**

```
aws s3control create-access-grants-instance \
--account-id 111122223333 \
--region us-east-2
```

Response:

```
{
    "CreatedAt": "2023-05-31T17:54:07.893000+00:00",
    "AccessGrantsInstanceId": "default",
    "AccessGrantsInstanceArn": "arn:aws:s3:us-east-2:111122223333:access-grants/
default"
}
```

### Using the REST API

You can use the Amazon S3 REST API to create an S3 Access Grants instance. For information on the REST API support for managing an S3 Access Grants instance, see the following sections in the *Amazon Simple Storage Service API Reference*:

- AssociateAccessGrantsIdentityCenter
- CreateAccessGrantsInstance
- DeleteAccessGrantsInstance
- DissociateAccessGrantsIdentityCenter
- GetAccessGrantsInstance
- GetAccessGrantsInstanceForPrefix
- GetAccessGrantsInstanceResourcePolicy
- ListAccessGrantsInstances
- PutAccessGrantsInstanceResourcePolicy

### Using the AWS SDKs

This section provides an example of how to create an S3 Access Grants instance by using the AWS SDKs.

Java

This example creates the S3 Access Grants instance, which serves as a container for your individual access grants. You can have one S3 Access Grants instance per AWS Region in your account. The response includes the instance ID `default` and an Amazon Resource Name (ARN) that's generated for your S3 Access Grants instance.

**Example Create an S3 Access Grants instance request**

```
public void createAccessGrantsInstance() {
CreateAccessGrantsInstanceRequest createRequest =
 CreateAccessGrantsInstanceRequest.builder().accountId("111122223333").build();
CreateAccessGrantsInstanceResponse createResponse =
 s3Control.createAccessGrantsInstance(createRequest);LOGGER.info("CreateAccessGrantsInstance
 " + createResponse);
}
```

Response:

```
CreateAccessGrantsInstanceResponse(
CreatedAt=2023-06-07T01:46:20.507Z,
AccessGrantsInstanceId=default,
AccessGrantsInstanceArn=arn:aws:s3:us-east-2:111122223333:access-grants/default)
```

**Topics**

- View the details of an S3 Access Grants instance
- Associate or disassociate your IAM Identity Center instance
- Delete an S3 Access Grants instance

### View the details of an S3 Access Grants instance

You can view the details of your Amazon S3 Access Grants instance in a particular AWS Region. You can also list your S3 Access Grants instances, including the instances that have been shared with you through AWS Resource Access Manager (AWS RAM).

You can view the details of your S3 Access Grants instance or list your S3 Access Grants instances by using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), the Amazon S3 REST API, and the AWS SDKs.

### Using the S3 console

#### To view an S3 Access Grants instance

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Access Grants**.
3. On the **S3 Access Grants** page, choose the Region that contains the S3 Access Grants instance that you want to work with.
4. The **S3 Access Grants** page lists your S3 Access Grants instances and any cross-account instances that have been shared with your account. To view the details of an instance, choose **View details**.

### Using the AWS CLI

To install the AWS CLI, see Installing the AWS CLI in the *AWS Command Line Interface User Guide*.

To use the following example command, replace the *`user input placeholders`* with your own information.

#### Example – Get the details of an S3 Access Grants instance

```
aws s3control get-access-grants-instance \
 --account-id 111122223333 \
 --region us-east-2
```

Response:

```
{
    "AccessGrantsInstanceArn": "arn:aws:s3:us-east-2: 111122223333:access-grants/
default",
    "AccessGrantsInstanceId": "default",
    "CreatedAt": "2023-05-31T17:54:07.893000+00:00"
}
```

#### Example – List all S3 Access Grants instances for an account

This action lists the S3 Access Grants instances for an account. You can only have one S3 Access Grants instance per AWS Region. This action also lists other cross-account S3 Access Grants instances that your account has access to.

```
aws s3control list-access-grants-instances \
 --account-id 111122223333 \
 --region us-east-2
```

Response:

```
{
    "AccessGrantsInstanceArn": "arn:aws:s3:us-east-2: 111122223333:access-grants/
default",
    "AccessGrantsInstanceId": "default",
    "CreatedAt": "2023-05-31T17:54:07.893000+00:00"
}
```

### Using the REST API

For information about the Amazon S3 REST API support for managing an S3 Access Grants instance, see the following sections in the *Amazon Simple Storage Service API Reference*:

- GetAccessGrantsInstance
- GetAccessGrantsInstanceForPrefix
- ListAccessGrantsInstances

### Using the AWS SDKs

This section provides examples of how to get the details of an S3 Access Grants instance by using the AWS SDKs.

To use the following examples, replace the *user input placeholders* with your own information.

Java

#### Example – Get an S3 Access Grants instance

```
public void getAccessGrantsInstance() {
GetAccessGrantsInstanceRequest getRequest = GetAccessGrantsInstanceRequest.builder()
.accountId("111122223333")
.build();
GetAccessGrantsInstanceResponse getResponse =
 s3Control.getAccessGrantsInstance(getRequest);
```

```
LOGGER.info("GetAccessGrantsInstanceResponse: " + getResponse);
}
```

Response:

```
GetAccessGrantsInstanceResponse(
AccessGrantsInstanceArn=arn:aws:s3:us-east-2: 111122223333:access-grants/default,
CreatedAt=2023-06-07T01:46:20.507Z)
```

**Example – List all S3 Access Grants instances for an account**

This action lists the S3 Access Grants instances for an account. You can only have one S3 Access Grants instance per Region. This action can also list other cross-account S3 Access Grants instances that your account has access to.

```
public void listAccessGrantsInstances() {
ListAccessGrantsInstancesRequest listRequest =
 ListAccessGrantsInstancesRequest.builder()
.accountId("111122223333")
.build();
ListAccessGrantsInstancesResponse listResponse =
 s3Control.listAccessGrantsInstances(listRequest);
LOGGER.info("ListAccessGrantsInstancesResponse: " + listResponse);
}
```

Response:

```
ListAccessGrantsInstancesResponse(
AccessGrantsInstancesList=[
ListAccessGrantsInstanceEntry(
AccessGrantsInstanceId=default,
AccessGrantsInstanceArn=arn:aws:s3:us-east-2:111122223333:access-grants/default,
CreatedAt=2023-06-07T04:28:11.728Z
)
]
)
```

### Associate or disassociate your IAM Identity Center instance

In Amazon S3 Access Grants, you can associate the AWS IAM Identity Center instance of your corporate identity directory with an S3 Access Grants instance. After you do so, you can create

access grants for your corporate directory users and groups, in addition to AWS Identity and Access Management (IAM) users and roles.

If you no longer want to create access grants for your corporate directory users and groups, you can disassociate your IAM Identity Center instance from your S3 Access Grants instance.

You can associate or disassociate an IAM Identity Center instance by using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), the Amazon S3 REST API, and the AWS SDKs.

**Using the S3 console**

Before you associate your IAM Identity Center instance with your S3 Access Grants instance, you must add your corporate identity directory to IAM Identity Center. For more information, see the section called "S3 Access Grants and corporate directory identities".

**To associate an IAM Identity Center instance with an S3 Access Grants instance**

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Access Grants**.
3. On the **S3 Access Grants** page, choose the Region that contains the S3 Access Grants instance that you want to work with.
4. Choose **View details** for the instance.
5. On the details page, in the **IAM Identity Center** section, choose to either **Add** an IAM Identity Center instance or **Deregister** an already associated IAM Identity Center instance.

**Using the AWS CLI**

To install the AWS CLI, see Installing the AWS CLI in the *AWS Command Line Interface User Guide*.

To use the following example command, replace the *`user input placeholders`* with your own information.

**Example – Associate an IAM Identity Center instance with an S3 Access Grants instance**

```
aws s3control associate-access-grants-identity-center \
 --account-id 111122223333 \
 --identity-center-arn arn:aws:sso:::instance/ssoins-1234a567bb89012c \
 --profile access-grants-profile \
```

```
 --region eu-central-1

// No response body
```

**Example – Disassociate an IAM Identity Center instance from an S3 Access Grants instance**

```
aws s3control dissociate-access-grants-identity-center \
 --account-id 111122223333 \
 --profile access-grants-profile \
 --region eu-central-1

// No response body
```

**Using the REST API**

For information about the Amazon S3 REST API support for managing the association between an IAM Identity Center instance and an S3 Access Grants instance, see the following sections in the *Amazon Simple Storage Service API Reference*:

- AssociateAccessGrantsIdentityCenter
- DissociateAccessGrantsIdentityCenter

### Delete an S3 Access Grants instance

You can delete an Amazon S3 Access Grants instance from an AWS Region in your account. However, before you can delete an S3 Access Grants instance, you must first do the following:

- Delete all resources within the S3 Access Grants instance, including all grants and locations. For more information, see Delete a grant and Delete a location.
- If you've associated an AWS IAM Identity Center instance with your S3 Access Grants instance, you must disassociate the IAM Identity Center instance. For more information, see Associate or disassociate your IAM Identity Center instance.

> **Important**
>
> If you delete an S3 Access Grants instance, the deletion is permanent and can't be undone. All grantees that were given access through the grants in this S3 Access Grants instance will lose access to your S3 data.

You can delete an S3 Access Grants instance by using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), the Amazon S3 REST API, and the AWS SDKs.

### Using the S3 console

#### To delete an S3 Access Grants instance

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Access Grants**.
3. On the **S3 Access Grants** page, choose the Region that contains the S3 Access Grants instance that you want to work with.
4. Choose **View details** for the instance.
5. On the instance details page, choose **Delete instance** in the upper-right corner.
6. In the dialog box that appears, choose **Delete**. This action can't be undone.

### Using the AWS CLI

To install the AWS CLI, see Installing the AWS CLI in the *AWS Command Line Interface User Guide*.

To use the following example command, replace the *`user input placeholders`* with your own information.

> **Note**
>
> Before you can delete an S3 Access Grants instance, you must first delete all grants and locations created within the S3 Access Grants instance. If you have associated an IAM Identity Center center instance with your S3 Access Grants instance, you must disassociate it first.

#### Example – Delete an S3 Access Grants instance

```
aws s3control delete-access-grants-instance \
--account-id 111122223333 \
--profile access-grants-profile \
--region us-east-2 \
--endpoint-url https://s3-control.us-east-2.amazonaws.com \
```

```
// No response body
```

### Using the REST API

For information about the Amazon S3 REST API support for deleting an S3 Access Grants instance, see DeleteAccessGrantsInstance in the *Amazon Simple Storage Service API Reference*.

### Using the AWS SDKs

This section provides examples of how to delete an S3 Access Grants instance by using the AWS SDKs.

To use the following example, replace the *`user input placeholders`* with your own information.

Java

> **Note**
>
> Before you can delete an S3 Access Grants instance, you must first delete all grants and locations created within the S3 Access Grants instance. If you have associated an IAM Identity Center center instance with your S3 Access Grants instance, you must disassociate it first.

#### Example – Delete an S3 Access Grants instance

```
public void deleteAccessGrantsInstance() {
DeleteAccessGrantsInstanceRequest deleteRequest =
 DeleteAccessGrantsInstanceRequest.builder()
.accountId("111122223333")
.build();
DeleteAccessGrantsInstanceResponse deleteResponse =
 s3Control.deleteAccessGrantsInstance(deleteRequest);
LOGGER.info("DeleteAccessGrantsInstanceResponse: " + deleteResponse);
}
```

## Register a location

After you create an Amazon S3 Access Grants instance in an AWS Region in your account, you register an S3 location in that instance. An S3 Access Grants location maps the default S3 location

(`s3://`), a bucket, or a prefix to an AWS Identity and Access Management (IAM) role. S3 Access Grants assumes this IAM role to vend temporary credentials to the grantee that is accessing that particular location. You must first register at least one location in your S3 Access Grants instance before you can create an access grant.

**Recommended use case**

We recommend that you register the default location (`s3://`) and map it to an IAM role. The location at the default S3 path (`s3://`) covers access to all of your S3 buckets in that AWS Region of your account. When you create an access grant, you can narrow the grant scope to a bucket, a prefix, or an object within the default location.

**Complex access-management use cases**

More complex access-management use cases might require you to register more than the default location. Some examples of such use cases are:

- Suppose that the *amzn-s3-demo-bucket* is a registered location in your S3 Access Grants instance with an IAM role mapped to it, but this IAM role is denied access to a particular prefix within the bucket. In this case, you can register the prefix that the IAM role does not have access to as a separate location and map that location to a different IAM role with the necessary access.
- Suppose that you want to create grants that restrict access to only the users within a virtual private cloud (VPC) endpoint. In this case, you can register a location for a bucket in which the IAM role restricts access to the VPC endpoint. Later, when a grantee asks S3 Access Grants for credentials, S3 Access Grants assumes the location's IAM role to vend the temporary credentials. This credential will deny access to the specific bucket unless the caller is within the VPC endpoint. This deny permission is applied in addition to the regular READ, WRITE, or READWRITE permission specified in the grant.

When you register a location, you must also specify the IAM role that S3 Access Grants assumes to vend temporary credentials and to scope the permissions for a specific grant.

If your use case requires you to register multiple locations in your S3 Access Grants instance, you can register any of the following:

| S3 URI | IAM role | Description |
| --- | --- | --- |
| s3:// | *Default-IAM-role* | The default location, s3://, includes all buckets in the AWS Region. |
| s3://*amzn-s3-demo-bucket1* / | *IAM-role-For-bucket* | This location includes all objects in the specified bucket. |
| s3://*amzn-s3-demo-bucket1* /*prefix-name* | *IAM-role-For-prefix* | This location includes all objects in the bucket with an object key name that starts with this prefix. |

Before you can register a specific bucket or prefix, make sure that you do the following:

- Create one or more buckets that contain the data that you want to grant access to. These buckets must be located in the same AWS Region as your S3 Access Grants instance. For more information, see Creating a bucket.

  Adding a prefix is an optional step. Prefixes are strings at the beginning of an object key name. You can use them to organize objects in your bucket as well as for access management. To add a prefix to a bucket, see Creating object key names.
- Create an IAM role that has permission to access your S3 data in the AWS Region. For more information, see Creating IAM roles in the *AWS IAM Identity Center user guide*.
- In the IAM role trust policy, give the S3 Access Grants service (access-grants.s3.amazonaws.com) principal access to the IAM role that you created. To do so, you can create a JSON file that contains the following statements. To add the trust policy to your account, see Create a role using custom trust policies.

  *TestRolePolicy.json*

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "Stmt1234567891011",
      "Action": ["sts:AssumeRole", "sts:SetSourceIdentity", "sts:SetContext"],
      "Effect": "Allow",
```

```
      "Principal": {"Service":"access-grants.s3.amazonaws.com"},
   "Condition":{
  "StringEquals":{
   "aws:SourceAccount":"accountId",
   "aws:SourceArn":"arn:aws:s3:region:accountId:access-grants/default"
  }
  //Optionally, for an IAM Identity Center use case, add:
  "ForAnyValue:StringEquals": {
   "aws:RequestContextProvider":"arn:aws:iam::aws:contextProvider/IdentityCenter"
  }
 }
    }
  ]
}
```

- Create an IAM policy to attach Amazon S3 permissions to the IAM role that you created. See the following example `iam-policy.json` file and replace the *`user input placeholders`* with your own information.

  **Note**

  - If you use server-side encryption with AWS Key Management Service (AWS KMS) keys to encrypt your data, the following example includes the necessary AWS KMS permissions for the IAM role in the policy. If you do not use this feature, you can remove these permissions from your IAM policy.
  - You can restrict the IAM role to access S3 data only if the credentials are vended by S3 Access Grants. This example shows you how to add a `Condition` statement for a specific S3 Access Grants instance. To use this `Condition`, replace the S3 Access Grants instance ARN in the `Condition` statement with your S3 Access Grants instance ARN, which has the format: `arn:aws:s3:`*`region`*`:`*`accountId`*`:access-grants/default`

  *iam-policy.json*

```
{
   "Version":"2012-10-17",
   "Statement": [
       {
```

```
         "Sid": "ObjectLevelReadPermissions",
         "Effect":"Allow",
         "Action":[
            "s3:GetObject",
            "s3:GetObjectVersion",
            "s3:GetObjectAcl",
            "s3:GetObjectVersionAcl",
            "s3:ListMultipartUploadParts"
         ],
         "Resource":[
            "arn:aws:s3:::*"
         ],
         "Condition":{
            "StringEquals": { "aws:ResourceAccount": "accountId" },
            "ArnEquals": {
                "s3:AccessGrantsInstanceArn": ["arn:aws:s3:region:accountId:access-
grants/default"]
            }
        }
      },
      {
         "Sid": "ObjectLevelWritePermissions",
         "Effect":"Allow",
         "Action":[
            "s3:PutObject",
            "s3:PutObjectAcl",
            "s3:PutObjectVersionAcl",
            "s3:DeleteObject",
            "s3:DeleteObjectVersion",
            "s3:AbortMultipartUpload"
         ],
         "Resource":[
            "arn:aws:s3:::*"
         ],
         "Condition":{
            "StringEquals": { "aws:ResourceAccount": "accountId" },
            "ArnEquals": {
                "s3:AccessGrantsInstanceArn": ["arn:aws:s3:AWS
 Region:accountId:access-grants/default"]
            }
         }
      },
      {
         "Sid": "BucketLevelReadPermissions",
```

```
            "Effect":"Allow",
            "Action":[
               "s3:ListBucket"
            ],
            "Resource":[
               "arn:aws:s3:::*"
            ],
            "Condition":{
               "StringEquals": { "aws:ResourceAccount": "accountId" },
               "ArnEquals": {
                   "s3:AccessGrantsInstanceArn": ["arn:aws:s3:AWS
 Region:accountId:access-grants/default"]
               }
            }
         },
     //Optionally add the following section if you use SSE-KMS encryption
         {
            "Sid": "KMSPermissions",
            "Effect":"Allow",
            "Action":[
               "kms:Decrypt",
               "kms:GenerateDataKey"
            ],
            "Resource":[
               "*"
            ]
         }
      ]
}
```

You can register a location in your S3 Access Grants instance by using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), the Amazon S3 REST API, or the AWS SDKs.

> **Note**
>
> After you register the first location in your S3 Access Grants instance, your instance still does not have any individual access grants in it. To create an access grant, see Create grants.

### Using the S3 console

Before you can grant access to your S3 data with S3 Access Grants, you must have at least one registered location.

**To register a location in your S3 Access Grants instance**

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Access Grants**.
3. On the **S3 Access Grants** page, choose the Region that contains the S3 Access Grants instance that you want to work with.

   If you're using S3 Access Grants instance for the first time, make sure that you have completed Step 1 - create an S3 Access Grants instance and navigated to **Step 2** of the **Set up Access Grants instance** wizard. If you already have an S3 Access Grants instance, choose **View details**, and then from the **Locations** tab, choose **Register location**.

   a. For the **Location scope**, choose **Browse S3** or enter the S3 URI path to the location that you want to register. For S3 URI formats, see the location formats table. After you enter a URI, you can choose **View** to browse the location.

   b. For the **IAM role**, choose one of the following:

      - **Choose from existing IAM roles**

        Choose an IAM role from the dropdown list. After you choose a role, choose **View** to make sure that this role has the necessary permissions to manage the location that you're registering. Specifically, make sure that this role grants S3 Access Grants the permissions `sts:AssumeRole` and `sts:SetSourceIdentity`.

      - **Enter IAM role ARN**

        Navigate to the IAM Console. Copy the Amazon Resource Name (ARN) of the IAM role and paste it in this box.

   c. To finish, choose **Next** or **Register location**.

4. Troubleshooting:

   **Cannot register location**

   - The location might already be registered.

You might not have the `s3:CreateAccessGrantsLocation` permission to register locations. Contact your account administrator.

### Using the AWS CLI

To install the AWS CLI, see Installing the AWS CLI in the *AWS Command Line Interface User Guide*.

You can register the default location, `s3://`, or a custom location in your S3 Access Grants instance. Make sure that you first create an IAM role with principal access to the location, and then make sure that you grant S3 Access Grants permission to assume this role.

To use the following example commands, replace the *`user input placeholders`* with your own information.

#### Example Create a resource policy

Create a policy that allows S3 Access Grants to assume the IAM role. To do so, you can create a JSON file that contains the following statements. To add the resource policy to your account, see Create and attach your first customer managed policy.

*TestRolePolicy.json*

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "Stmt1234567891011",
      "Action": ["sts:AssumeRole", "sts:SetSourceIdentity"],
      "Effect": "Allow",
      "Principal": {"Service":"access-grants.s3.amazonaws.com"}
    }
  ]
}
```

#### Example Create the role

Run the following IAM command to create the role.

```
aws iam create-role --role-name accessGrantsTestRole \
 --region us-east-2 \
```

```
 --assume-role-policy-document file://TestRolePolicy.json
```

Running the `create-role` command returns the policy:

```
{
    "Role": {
        "Path": "/",
        "RoleName": "accessGrantsTestRole",
        "RoleId": "AROASRDGX4WM4GH55GIDA",
        "Arn": "arn:aws:iam::111122223333:role/accessGrantsTestRole",
        "CreateDate": "2023-05-31T18:11:06+00:00",
        "AssumeRolePolicyDocument": {
            "Version": "2012-10-17",
            "Statement": [
                {
                    "Sid": "Stmt1685556427189",
                    "Action": [
                        "sts:AssumeRole",
                        "sts:SetSourceIdentity"
                    ],
                    "Effect": "Allow",
                    "Principal": {
                        "Service":"access-grants.s3.amazonaws.com"
                    }
                }
            ]
        }
    }
}
```

**Example**

Create an IAM policy to attach Amazon S3 permissions to the IAM role. See the following example `iam-policy.json` file and replace the *`user input placeholders`* with your own information.

> **Note**
>
> If you use server-side encryption with AWS Key Management Service (AWS KMS) keys to encrypt your data, the following example adds the necessary AWS KMS permissions for the IAM role in the policy. If you do not use this feature, you can remove these permissions from your IAM policy.

To make sure that the IAM role can only be used to access data in S3 if the credentials are vended out by S3 Access Grants, this example shows you how to add a `Condition` statement that specifies the S3 Access Grants instance (`s3:AccessGrantsInstance:` *`InstanceArn`*) in your IAM policy. When using following example policy, replace the *`user input placeholders`* with your own information.

*iam-policy.json*

```
{
   "Version":"2012-10-17",
   "Statement": [
       {
         "Sid": "ObjectLevelReadPermissions",
         "Effect":"Allow",
         "Action":[
            "s3:GetObject",
            "s3:GetObjectVersion",
            "s3:GetObjectAcl",
            "s3:GetObjectVersionAcl",
            "s3:ListMultipartUploadParts"
         ],
         "Resource":[
            "arn:aws:s3:::*"
         ],
         "Condition":{
            "StringEquals": { "aws:ResourceAccount": "accountId" },
            "ArnEquals": {
                "s3:AccessGrantsInstanceArn": ["arn:aws:s3:region:accountId:access-
grants/default"]
            }
        }
      },
      {
         "Sid": "ObjectLevelWritePermissions",
         "Effect":"Allow",
         "Action":[
            "s3:PutObject",
            "s3:PutObjectAcl",
            "s3:PutObjectVersionAcl",
            "s3:DeleteObject",
```

```
            "s3:DeleteObjectVersion",
            "s3:AbortMultipartUpload"
         ],
         "Resource":[
            "arn:aws:s3:::*"
         ],
         "Condition":{
            "StringEquals": { "aws:ResourceAccount": "accountId" },
            "ArnEquals": {
                "s3:AccessGrantsInstanceArn": ["arn:aws:s3:AWS Region:accountId:access-
grants/default"]
            }
         }
      },
      {
         "Sid": "BucketLevelReadPermissions",
         "Effect":"Allow",
         "Action":[
            "s3:ListBucket"
         ],
         "Resource":[
            "arn:aws:s3:::*"
         ],
         "Condition":{
            "StringEquals": { "aws:ResourceAccount": "accountId" },
            "ArnEquals": {
                "s3:AccessGrantsInstanceArn": ["arn:aws:s3:AWS Region:accountId:access-
grants/default"]
            }
         }
      },
      {
         "Sid": "KMSPermissions",
         "Effect":"Allow",
         "Action":[
            "kms:Decrypt",
            "kms:GenerateDataKey"
         ],
         "Resource":[
            "*"
         ]
      }
   ]
```

```
}
```

### Example

Run the following command:

```
aws iam put-role-policy \
--role-name accessGrantsTestRole \
--policy-name accessGrantsTestRole \
--policy-document file://iam-policy.json
```

### Example Register the default location

```
aws s3control create-access-grants-location \
 --account-id 111122223333 \
 --location-scope s3:// \
 --iam-role-arn arn:aws:iam::111122223333:role/accessGrantsTestRole
```

Response:

```
{"CreatedAt": "2023-05-31T18:23:48.107000+00:00",
    "AccessGrantsLocationId": "default",
    "AccessGrantsLocationArn": "arn:aws:s3:us-east-2:111122223333:access-grants/
default/location/default",
    "LocationScope": "s3://”
    "IAMRoleArn": "arn:aws:iam::111122223333:role/accessGrantsTestRole"
}
```

### Example Register a custom location

```
aws s3control create-access-grants-location \
 --account-id 111122223333 \
 --location-scope s3://DOC-BUCKET-EXAMPLE/ \
 --iam-role-arn arn:aws:iam::123456789012:role/accessGrantsTestRole
```

Response:

```
{"CreatedAt": "2023-05-31T18:23:48.107000+00:00",
    "AccessGrantsLocationId": "635f1139-1af2-4e43-8131-a4de006eb456",
    "AccessGrantsLocationArn": "arn:aws:s3:us-east-2: 111122223333:access-grants/
default/location/635f1139-1af2-4e43-8131-a4de006eb888",
    "LocationScope": "s3://DOC-BUCKET-EXAMPLE/",
```

```
    "IAMRoleArn": "arn:aws:iam::111122223333:role/accessGrantsTestRole"
}
```

### Using the REST API

For information about Amazon S3 REST API support for managing an S3 Access Grants instance, see the following sections in the *Amazon Simple Storage Service API Reference*:

- CreateAccessGrantsLocation
- DeleteAccessGrantsLocation
- GetAccessGrantsLocation
- ListAccessGrantsLocations
- UpdateAccessGrantsLocation

### Using the AWS SDKs

This section provides examples of how to register locations by using the AWS SDKs.

To use the following examples, replace the *`user input placeholders`* with your own information.

Java

You can register the default location, `s3://`, or a custom location in your S3 Access Grants instance. Make sure that you first create an IAM role with principal access to the location, and then make sure that you grant S3 Access Grants permission to assume this role.

To use the following example commands, replace the *`user input placeholders`* with your own information.

**Example Register a default location**

Request:

```
public void createAccessGrantsLocation() {
CreateAccessGrantsLocationRequest createRequest =
 CreateAccessGrantsLocationRequest.builder()
.accountId("111122223333")
.locationScope("s3://")
.iamRoleArn("arn:aws:iam::123456789012:role/accessGrantsTestRole")
.build();
```

```
CreateAccessGrantsLocationResponse createResponse =
 s3Control.createAccessGrantsLocation(createRequest);
LOGGER.info("CreateAccessGrantsLocationResponse: " + createResponse);
}
```

Response:

```
CreateAccessGrantsLocationResponse(
CreatedAt=2023-06-07T04:35:11.027Z,
AccessGrantsLocationId=default,
AccessGrantsLocationArn=arn:aws:s3:us-east-2:111122223333:access-grants/default/
location/default,
LocationScope=s3://,
IAMRoleArn=arn:aws:iam::111122223333:role/accessGrantsTestRole
)
```

**Example Register a custom location**

Request:

```
public void createAccessGrantsLocation() {
CreateAccessGrantsLocationRequest createRequest =
 CreateAccessGrantsLocationRequest.builder()
.accountId("111122223333")
.locationScope("s3://DOC-BUCKET-EXAMPLE/")
.iamRoleArn("arn:aws:iam::111122223333:role/accessGrantsTestRole")
.build();
CreateAccessGrantsLocationResponse createResponse =
 s3Control.createAccessGrantsLocation(createRequest);
LOGGER.info("CreateAccessGrantsLocationResponse: " + createResponse);
}
```

Response:

```
CreateAccessGrantsLocationResponse(
CreatedAt=2023-06-07T04:35:10.027Z,
AccessGrantsLocationId=18cfe6fb-eb5a-4ac5-aba9-8d79f04c2012,
AccessGrantsLocationArn=arn:aws:s3:us-east-2:111122223333:access-grants/default/
location/18cfe6fb-eb5a-4ac5-aba9-8d79f04c2666,
LocationScope= s3://test-bucket-access-grants-user123/,
IAMRoleArn=arn:aws:iam::111122223333:role/accessGrantsTestRole
)
```

**Topics**

### View the details of a registered location

You can get the details of a location that's registered in your S3 Access Grants instance by using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), the Amazon S3 REST API, and the AWS SDKs.

#### Using the S3 console

**To view the locations registered in your S3 Access Grants instance**

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Access Grants**.
3. On the **S3 Access Grants** page, choose the Region that contains the S3 Access Grants instance that you want to work with.
4. Choose **View details** for the instance.
5. On the details page for the instance, choose the **Locations** tab.
6. Find the registered location that you want to view. To filter the list of registered locations, use the search box.

#### Using the AWS CLI

To install the AWS CLI, see Installing the AWS CLI in the *AWS Command Line Interface User Guide*.

To use the following example command, replace the *`user input placeholders`* with your own information.

**Example – Get the details of a registered location**

```
aws s3control get-access-grants-location \
--account-id 111122223333 \
```

```
--access-grants-location-id default
```

Response:

```
{
    "CreatedAt": "2023-05-31T18:23:48.107000+00:00",
    "AccessGrantsLocationId": "default",
    "AccessGrantsLocationArn": "arn:aws:s3:us-east-2:111122223333:access-grants/
default/location/default",
    "IAMRoleArn": "arn:aws:iam::111122223333:role/accessGrantsTestRole"
}
```

**Example – List all of the locations that are registered in an S3 Access Grants instance**

To restrict the results to an S3 prefix or bucket, you can optionally use the `--location-scope s3://bucket-and-or-prefix` parameter.

```
aws s3control list-access-grants-locations \
--account-id 111122223333 \
--region us-east-2
```

Response:

```
{"AccessGrantsLocationsList": [
  {
    "CreatedAt": "2023-05-31T18:23:48.107000+00:00",
    "AccessGrantsLocationId": "default",
    "AccessGrantsLocationArn": "arn:aws:s3:us-east-2:111122223333:access-grants/
default/location/default",
    "LocationScope": "s3://"
    "IAMRoleArn": "arn:aws:iam::111122223333:role/accessGrantsTestRole"
     },
  {
    "CreatedAt": "2023-05-31T18:23:48.107000+00:00",
    "AccessGrantsLocationId": "635f1139-1af2-4e43-8131-a4de006eb456",

default/location/635f1139-1af2-4e43-8131-a4de006eb888",
    "LocationScope": "s3://amzn-s3-demo-bucket/prefixA*",
    "IAMRoleArn": "arn:aws:iam::111122223333:role/accessGrantsTestRole"
     }
   ]
  }
```

### Using the REST API

For information about the Amazon S3 REST API support for getting the details of a registered location or listing all of the locations that are registered with an S3 Access Grants instance, see the following sections in the *Amazon Simple Storage Service API Reference*:

- GetAccessGrantsLocation
- ListAccessGrantsLocations

### Using the AWS SDKs

This section provides examples of how to get the details of a registered location or list all of the registered locations in an S3 Access Grants instance by using the AWS SDKs.

To use the following examples, replace the *`user input placeholders`* with your own information.

Java

#### Example – Get the details of a registered location

```
public void getAccessGrantsLocation() {
GetAccessGrantsLocationRequest getAccessGrantsLocationRequest =
 GetAccessGrantsLocationRequest.builder()
.accountId("111122223333")
.accessGrantsLocationId("default")
.build();
GetAccessGrantsLocationResponse getAccessGrantsLocationResponse =
 s3Control.getAccessGrantsLocation(getAccessGrantsLocationRequest);
LOGGER.info("GetAccessGrantsLocationResponse: " + getAccessGrantsLocationResponse);
}
```

Response:

```
GetAccessGrantsLocationResponse(
CreatedAt=2023-06-07T04:35:10.027Z,
AccessGrantsLocationId=default,
AccessGrantsLocationArn=arn:aws:s3:us-east-2:111122223333:access-grants/default/
location/default,
LocationScope= s3://,
```

```
IAMRoleArn=arn:aws:iam::111122223333:role/accessGrantsTestRole
)
```

### Example – List all registered locations in an S3 Access Grants instance

To restrict the results to an S3 prefix or bucket, you can optionally pass an S3 URI, such as `s3://bucket-and-or-prefix`, in the `LocationScope` parameter.

```
public void listAccessGrantsLocations() {

ListAccessGrantsLocationsRequest listRequest =
 ListAccessGrantsLocationsRequest.builder()
.accountId("111122223333")
.build();

ListAccessGrantsLocationsResponse listResponse =
 s3Control.listAccessGrantsLocations(listRequest);
LOGGER.info("ListAccessGrantsLocationsResponse: " + listResponse);
}
```

Response:

```
ListAccessGrantsLocationsResponse(
AccessGrantsLocationsList=[
ListAccessGrantsLocationsEntry(
CreatedAt=2023-06-07T04:35:11.027Z,
AccessGrantsLocationId=default,
AccessGrantsLocationArn=arn:aws:s3:us-east-2:111122223333:access-grants/default/
location/default,
LocationScope=s3://,
IAMRoleArn=arn:aws:iam::111122223333:role/accessGrantsTestRole
),
ListAccessGrantsLocationsEntry(
CreatedAt=2023-06-07T04:35:10.027Z,
AccessGrantsLocationId=635f1139-1af2-4e43-8131-a4de006eb456,
AccessGrantsLocationArn=arn:aws:s3:us-east-2:111122223333:access-grants/default/
location/635f1139-1af2-4e43-8131-a4de006eb888,
LocationScope=s3://amzn-s3-demo-bucket/prefixA*,
IAMRoleArn=arn:aws:iam::111122223333:role/accessGrantsTestRole
)
]
)
```

### Update a registered location

You can update the AWS Identity and Access Management (IAM) role of a location that's registered in your Amazon S3 Access Grants instance. For each new IAM role that you use to register a location in S3 Access Grants, be sure to give the S3 Access Grants service principal (`access-grants.s3.amazonaws.com`) access to this role. To do this, add an entry for the new IAM role in the same trust policy JSON file that you used when you first registered the location.

You can update a location in your S3 Access Grants instance by using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), the Amazon S3 REST API, and the AWS SDKs.

#### Using the S3 console

#### To update the IAM role of a location registered with your S3 Access Grants instance

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Access Grants**.
3. On the **S3 Access Grants** page, choose the Region that contains the S3 Access Grants instance that you want to work with.
4. Choose **View details** for the instance.
5. On the details page for the instance, choose the **Locations** tab.
6. Find the location that you want to update. To filter the list of locations, use the search box.
7. Choose the options button next to the registered location that you want to update.
8. Update the IAM role, and then choose **Save changes**.

#### Using the AWS CLI

To install the AWS CLI, see Installing the AWS CLI in the *AWS Command Line Interface User Guide*.

To use the following example command, replace the *`user input placeholders`* with your own information.

#### Example – Update the IAM role of a registered location

```
aws s3control update-access-grants-location \
--account-id 111122223333 \
--access-grants-location-id 635f1139-1af2-4e43-8131-a4de006eb999 \
```

```
--iam-role-arn arn:aws:iam::777788889999:role/accessGrantsTestRole
```

Response:

```
{
    "CreatedAt": "2023-05-31T18:23:48.107000+00:00",
    "AccessGrantsLocationId": "635f1139-1af2-4e43-8131-a4de006eb999",
    "AccessGrantsLocationArn": "arn:aws:s3:us-east-2:777788889999:access-grants/
default/location/635f1139-1af2-4e43-8131-a4de006eb888",
    "LocationScope": "s3://amzn-s3-demo-bucket/prefixB*",
    "IAMRoleArn": "arn:aws:iam::777788889999:role/accessGrantsTestRole"
}
```

### Using the REST API

For information on the Amazon S3 REST API support for updating a location in an S3 Access Grants instance, see UpdateAccessGrantsLocation in the *Amazon Simple Storage Service API Reference*.

### Using the AWS SDKs

This section provides examples of how to update the IAM role of a registered location by using the AWS SDKs.

To use the following example, replace the *`user input placeholders`* with your own information.

Java

#### Example – Update the IAM role of a registered location

```
public void updateAccessGrantsLocation() {
UpdateAccessGrantsLocationRequest updateRequest =
 UpdateAccessGrantsLocationRequest.builder()
.accountId("111122223333")
.accessGrantsLocationId("635f1139-1af2-4e43-8131-a4de006eb999")
.iamRoleArn("arn:aws:iam::777788889999:role/accessGrantsTestRole")
.build();
UpdateAccessGrantsLocationResponse updateResponse =
 s3Control.updateAccessGrantsLocation(updateRequest);
LOGGER.info("UpdateAccessGrantsLocationResponse: " + updateResponse);
}
```

Response:

```
UpdateAccessGrantsLocationResponse(
CreatedAt=2023-06-07T04:35:10.027Z,
AccessGrantsLocationId=635f1139-1af2-4e43-8131-a4de006eb999,
AccessGrantsLocationArn=arn:aws:s3:us-east-2:777788889999:access-grants/default/
location/635f1139-1af2-4e43-8131-a4de006eb888,
LocationScope=s3://amzn-s3-demo-bucket/prefixB*,
IAMRoleArn=arn:aws:iam::777788889999:role/accessGrantsTestRole
)
```

### Delete a registered location

You can delete a location registration from an Amazon S3 Access Grants instance. Deleting the location deregisters it from the S3 Access Grants instance.

Before you can remove a location registration from an S3 Access Grants instance, you must delete all of the grants that are associated with this location. For information about how to delete grants, see Delete a grant.

You can delete a location in your S3 Access Grants instance by using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), the Amazon S3 REST API, and the AWS SDKs.

#### Using the S3 console

#### To delete a location registration from your S3 Access Grants instance

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Access Grants**.
3. On the **S3 Access Grants** page, choose the Region that contains the S3 Access Grants instance that you want to work with.
4. Choose **View details** for the instance.
5. On the details page for the instance, choose the **Locations** tab.
6. Find the location that you want to update. To filter the list of locations, use the search box.
7. Choose the option button next to the registered location that you want to delete.
8. Choose **Deregister**.
9. A dialog box appears that warns you that this action can't be undone. To delete the location, choose **Deregister**.

### Using the AWS CLI

To install the AWS CLI, see Installing the AWS CLI in the *AWS Command Line Interface User Guide*.

To use the following example command, replace the *user input placeholders* with your own information.

#### Example – Delete a location registration

```
aws s3control delete-access-grants-location \
--account-id 111122223333 \
--access-grants-location-id  a1b2c3d4-5678-90ab-cdef-EXAMPLE11111
 // No response body
```

### Using the REST API

For information about the Amazon S3 REST API support for deleting a location from an S3 Access Grants instance, see DeleteAccessGrantsLocation in the *Amazon Simple Storage Service API Reference*.

### Using the AWS SDKs

This section provides an example of how to delete a location by using the AWS SDKs.

To use the following example, replace the *user input placeholders* with your own information.

Java

#### Example – Delete a location registration

```
public void deleteAccessGrantsLocation() {
DeleteAccessGrantsLocationRequest deleteRequest =
 DeleteAccessGrantsLocationRequest.builder()
.accountId("111122223333")
.accessGrantsLocationId("a1b2c3d4-5678-90ab-cdef-EXAMPLE11111")
.build();
DeleteAccessGrantsLocationResponse deleteResponse =
 s3Control.deleteAccessGrantsLocation(deleteRequest);
LOGGER.info("DeleteAccessGrantsLocationResponse: " + deleteResponse);
}
```

Response:

```
DeleteAccessGrantsLocationResponse()
```

## Create grants

An individual access *grant* in an S3 Access Grants instance allows a specific identity—an AWS Identity and Access Management (IAM) principal, or a user or group in a corporate directory—to get access within a location that is registered in your S3 Access Grants instance. A location maps buckets or prefixes to an IAM role. S3 Access Grants assumes this IAM role to vend temporary credentials to grantees.

After you register at least one location in your S3 Access Grants instance, you can create an access grant.

The grantee can be an IAM user or role or a directory user or group. A directory user is a user from your corporate directory or external identity source that you associated with your S3 Access Grants instance. For more information, see S3 Access Grants and corporate directory identities. To create a grant for a specific directory user or group from IAM Identity Center, find the GUID that IAM Identity Center uses to identify that user in IAM Identity Center, for example, `a1b2c3d4-5678-90ab-cdef-EXAMPLE11111`. For more information about how to use IAM Identity Center to view user information, see View user and group assignments in the *AWS IAM Identity Center user guide*.

You can grant access to a bucket, a prefix, or an object. A prefix in Amazon S3 is a string of characters in the beginning of an object key name that is used to organize objects within a bucket. This can be any string of allowed characters, for example, object key names in your bucket that start with the `engineering/` prefix.

### Subprefix

When granting access to a registered location, you can use the `Subprefix` field to narrow the scope of access to a subset of the location scope. If the registered location that you choose for the grant is the default S3 path (`s3://`), you must narrow the grant scope. You cannot create an access grant for the default location (`s3://`), which would give the grantee access to every bucket in an AWS Region. Instead, you must narrow the grant scope to one of the following:

- A bucket: `s3://`*`bucket`*`/*`
- A prefix within a bucket: `s3://`*`bucket`*`/`*`prefix`*`*`
- A prefix within a prefix: `s3://`*`bucket`*`/`*`prefixA`*`/`*`prefixB`*`*`

- An object: `s3://bucket/object-key-name`

If you are creating an access grant where the registered location is a bucket, you can pass one of the following in the `Subprefix` field to narrow the grant scope:

- A prefix within the bucket: *prefix**
- A prefix within a prefix: *prefixA/prefixB**
- An object: */object-key-name*

After you create the grant, the grant scope that's displayed in the Amazon S3 console or the `GrantScope` that is returned in the API or AWS Command Line Interface (AWS CLI) response is the result of concatenating the location path with the `Subprefix`. Make sure that this concatenated path maps correctly to the S3 bucket, prefix, or object to which you want to grant access.

> **Note**
>
> - If you need to create an access grant that grants access to only one object, you must specify that the grant type is for an object. To do this in an API call or a CLI command, pass the `s3PrefixType` parameter with the value `Object`. In the Amazon S3 console, when you create the grant, after you select a location, under **Grant Scope**, select the **Grant scope is an object** checkbox.
> - You cannot create a grant to a bucket if the bucket does not yet exist. However, you can create a grant to a prefix that does not yet exisit.
> - For the maximum number of grants that you can create in your S3 Access Grants instance, see S3 Access Grants limitations.

You can create an access grant by using the Amazon S3 console, AWS CLI, the Amazon S3 REST API, and AWS SDKs.

**Using the S3 console**

**To create an access grant**

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.

2. In the left navigation pane, choose **Access Grants**.
3. On the **S3 Access Grants** page, choose the Region that contains the S3 Access Grants instance that you want to work with.

   If you're using the S3 Access Grants instance for the first time, make sure that you have completed Step 2 - register a location and navigated to **Step 3** of the **Set up Access Grants instance** wizard. If you already have an S3 Access Grants instance, choose **View details**, and then from the **Grants** tab, choose **Create grant**.

   a. In the **Grant scope** section, select or enter a registered location.

      If you selected the default `s3://` location, use the **Subprefix** box to can narrow the scope of the access grant. For more information, see Subprefix. If you're granting access only to an object, select **Grant scope is an object**.

   b. Under **Permissions and access**, select the **Permission** level, either **Read**, **Write**, or both.

      Then choose the **Grantee type**. If you have added your corporate directory to IAM Identity Center and associated this IAM Identity Center instance with your S3 Access Grants instance, you can choose **Directory identity from IAM Identity Center**. If you choose this option, get the ID of the user or group from IAM Identity Center and enter it in this section.

      If the **Grantee type** is an IAM user or role, choose **IAM principal**. Under **IAM principal type**, choose **User** or **Role**. Then, under **IAM principal user**, either choose from the list or enter the identity's ID.

   c. To create the S3 Access Grants grant, choose **Next** or **Create grant**.
4. If **Next** or **Create grant** is disabled:

   **Cannot create grant**

   - You might need to register a location first in your S3 Access Grants instance.
   - You might not have the `s3:CreateAccessGrant` permission to create an access grant. Contact your account administrator.

### Using the AWS CLI

To install the AWS CLI, see Installing the AWS CLI in the *AWS Command Line Interface User Guide*.

The following examples show how to create an access grant request for an IAM principal and how to create an access grant request for a corporate directory user or group.

To use the following example commands, replace the *user input placeholders* with your own information.

> **Note**
>
> If you're creating an access grant that grants access to only one object, include the required parameter `--s3-prefix-type Object`.

### Example Create an access grant request for an IAM principal

```
aws s3control create-access-grant \
--account-id 111122223333 \
--access-grants-location-id a1b2c3d4-5678-90ab-cdef-EXAMPLE22222 \
--access-grants-location-configuration S3SubPrefix=prefixB* \
--permission READ \
--grantee GranteeType=IAM,GranteeIdentifier=arn:aws:iam::123456789012:user/data-consumer-3
```

### Example Create an access grant response

```
{"CreatedAt": "2023-05-31T18:41:34.663000+00:00",
    "AccessGrantId": "a1b2c3d4-5678-90ab-cdef-EXAMPLE11111",
    "AccessGrantArn": "arn:aws:s3:us-east-2:111122223333:access-grants/default/
grant/a1b2c3d4-5678-90ab-cdef-EXAMPLE11111",
    "Grantee": {
        "GranteeType": "IAM",
        "GranteeIdentifier": "arn:aws:iam::111122223333:user/data-consumer-3"
    },
    "AccessGrantsLocationId": "a1b2c3d4-5678-90ab-cdef-EXAMPLE22222",
    "AccessGrantsLocationConfiguration": {
        "S3SubPrefix": "prefixB*"
    },
    "GrantScope": "s3://DOC-BUCKET-EXAMPLE/prefix*",
    "Permission": "READ"
}
```

### Create an access grant request for a directory user or group

To create an access grant request for a directory user or group, you must first get the GUID for the directory user or group by running one of the following commands.

**Example Get a GUID for a directory user or group**

You can find the GUID of an IAM Identity Center user through the IAM Identity Center console or by using the AWS CLI or AWS SDKs. The following command lists the users in he specified IAM Identity Center instance, with their names and identifiers.

```
aws identitystore list-users --identity-store-id d-1a2b3c4d1234
```

This command lists the groups in the specified IAM Identity Center instance.

```
aws identitystore list-groups --identity-store-id d-1a2b3c4d1234
```

**Example Create an access grant for a directory user or group**

This command is similar to creating a grant for IAM users or roles, except the grantee type is `DIRECTORY_USER` or `DIRECTORY_GROUP`, and the grantee identifier is the GUID for the directory user or group.

```
aws s3control create-access-grant \
--account-id 123456789012 \
--access-grants-location-id default \
--access-grants-location-configuration S3SubPrefix="DOC-EXAMPLE-BUCKET/rafael/*" \
--permission READWRITE \
--grantee GranteeType=DIRECTORY_USER,GranteeIdentifier=83d43802-00b1-7054-db02-
f1d683aacba5 \
```

**Using the REST API**

For information about the Amazon S3 REST API support for managing access grants, see the following sections in the *Amazon Simple Storage Service API Reference*:

- CreateAccessGrant
- DeleteAccessGrant
- GetAccessGrant
- ListAccessGrants

### Using the AWS SDKs

This section provides examples of how to create an access grant by using the AWS SDKs.

Java

To use the following example, replace the *user input placeholders* with your own information:

> **Note**
>
> If you are creating an access grant that grants access to only one object, include the required parameter `.s3PrefixType(S3PrefixType.Object)`.

#### Example Create an access grant request

```
public void createAccessGrant() {
CreateAccessGrantRequest createRequest = CreateAccessGrantRequest.builder()
.accountId("111122223333")
.accessGrantsLocationId("a1b2c3d4-5678-90ab-cdef-EXAMPLEaaaaa")
.permission("READ")
.accessGrantsLocationConfiguration(AccessGrantsLocationConfiguration.builder().s3SubPrefix("
.grantee(Grantee.builder().granteeType("IAM").granteeIdentifier("arn:aws:iam::111122223333:u
data-consumer-3").build())
.build();
CreateAccessGrantResponse createResponse =
 s3Control.createAccessGrant(createRequest);
LOGGER.info("CreateAccessGrantResponse: " + createResponse);
}
```

#### Example Create an access grant response

```
CreateAccessGrantResponse(
CreatedAt=2023-06-07T05:20:26.330Z,
AccessGrantId=a1b2c3d4-5678-90ab-cdef-EXAMPLE33333,
AccessGrantArn=arn:aws:s3:us-east-2:444455556666:access-grants/default/grant/
a1b2c3d4-5678-90ab-cdef-EXAMPLE33333,
Grantee=Grantee(
GranteeType=IAM,
GranteeIdentifier=arn:aws:iam::111122223333:user/data-consumer-3
```

```
),
AccessGrantsLocationId=a1b2c3d4-5678-90ab-cdef-EXAMPLEaaaaa,
AccessGrantsLocationConfiguration=AccessGrantsLocationConfiguration(
S3SubPrefix=prefixB*
),
GrantScope=s3://DOC-BUCKET-EXAMPLE/prefixB,
Permission=READ
)
```

**Topics**

- View a grant
- Delete a grant

### View a grant

You can view the details of an access grant in your Amazon S3 Access Grants instance by using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), the Amazon S3 REST API, and the AWS SDKs.

#### Using the S3 console

**To view the details of an access grant**

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Access Grants**.
3. On the **S3 Access Grants** page, choose the Region that contains the S3 Access Grants instance that you want to work with.
4. Choose **View details** for the instance.
5. On the details page, choose the **Grants** tab.
6. In the **Grants** section, find the access grant that you want to view. To filter the list of grants, use the search box.

#### Using the AWS CLI

To install the AWS CLI, see Installing the AWS CLI in the *AWS Command Line Interface User Guide*.

To use the following example commands, replace the *user input placeholders* with your own information.

**Example – Get the details of an access grant**

```
aws s3control get-access-grant \
--account-id 111122223333 \
--access-grant-id a1b2c3d4-5678-90ab-cdef-EXAMPLE22222
```

Response:

```
{
    "CreatedAt": "2023-05-31T18:41:34.663000+00:00",
    "AccessGrantId": "a1b2c3d4-5678-90ab-cdef-EXAMPLE22222",
    "AccessGrantArn": "arn:aws:s3:us-east-2:111122223333:access-grants/default/
grant-a1b2c3d4-5678-90ab-cdef-EXAMPLE22222",
    "Grantee": {
        "GranteeType": "IAM",
        "GranteeIdentifier": "arn:aws:iam::111122223333:user/data-consumer-3"
    },
    "Permission": "READ",
    "AccessGrantsLocationId": "12a6710f-5af8-41f5-b035-0bc795bf1a2b",
    "AccessGrantsLocationConfiguration": {
        "S3SubPrefix": "prefixB*"
    },
    "GrantScope": "s3://amzn-s3-demo-bucket/"
}
```

**Example – List all of the access grants in an S3 Access Grants instance**

You can optionally use the following parameters to restrict the results to an S3 prefix or AWS Identity and Access Management (IAM) identity:

- **Subprefix** – `--grant-scope s3://bucket-name/prefix*`
- **IAM identity** – `--grantee-type IAM` and `--grantee-identifier arn:aws:iam::123456789000:role/accessGrantsConsumerRole`

```
aws s3control list-access-grants \
--account-id 111122223333
```

Response:

```
{
    "AccessGrantsList": [{"CreatedAt": "2023-06-14T17:54:46.542000+00:00",
            "AccessGrantId": "dd8dd089-b224-4d82-95f6-975b4185bbaa",
            "AccessGrantArn": "arn:aws:s3:us-east-2:111122223333:access-grants/default/
grant/dd8dd089-b224-4d82-95f6-975b4185bbaa",
            "Grantee": {
                "GranteeType": "IAM",
                "GranteeIdentifier": "arn:aws:iam::111122223333:user/data-consumer-3"
            },
            "Permission": "READ",
            "AccessGrantsLocationId": "23514a34-ea2e-4ddf-b425-d0d4bfcarda1",
            "GrantScope": "s3://amzn-s3-demo-bucket/prefixA*"
        },
        {"CreatedAt": "2023-06-24T17:54:46.542000+00:00",
            "AccessGrantId": "ee8ee089-b224-4d72-85f6-975b4185a1b2",
            "AccessGrantArn": "arn:aws:s3:us-east-2:111122223333:access-grants/default/
grant/ee8ee089-b224-4d72-85f6-975b4185a1b2",
            "Grantee": {
                "GranteeType": "IAM",
                "GranteeIdentifier": "arn:aws:iam::111122223333:user/data-consumer-9"
            },
            "Permission": "READ",
            "AccessGrantsLocationId": "12414a34-ea2e-4ddf-b425-d0d4bfcacao0",
            "GrantScope": "s3://amzn-s3-demo-bucket/prefixB*"
        },

    ]
}
```

### Using the REST API

You can use Amazon S3 API operations to view the details of an access grant and list all access grants in an S3 Access Grants instance. For information about the REST API support for managing access grants, see the following sections in the *Amazon Simple Storage Service API Reference*:

- GetAccessGrant
- ListAccessGrants

### Using the AWS SDKs

This section provides examples of how to get the details of an access grant by using the AWS SDKs.

To use the following examples, replace the *`user input placeholders`* with your own information.

Java

#### Example – Get the details of an access grant

```
public void getAccessGrant() {
GetAccessGrantRequest getRequest = GetAccessGrantRequest.builder()
.accountId("111122223333")
.accessGrantId("a1b2c3d4-5678-90ab-cdef-EXAMPLE22222")
.build();
GetAccessGrantResponse getResponse = s3Control.getAccessGrant(getRequest);
LOGGER.info("GetAccessGrantResponse: " + getResponse);
}
```

Response:

```
GetAccessGrantResponse(
CreatedAt=2023-06-07T05:20:26.330Z,
AccessGrantId=a1b2c3d4-5678-90ab-cdef-EXAMPLE22222,
AccessGrantArn=arn:aws:s3:us-east-2:111122223333:access-grants/default/
grant-fd3a5086-42f7-4b34-9fad-472e2942c70e,
Grantee=Grantee(
GranteeType=IAM,
GranteeIdentifier=arn:aws:iam::111122223333:user/data-consumer-3
),
Permission=READ,
AccessGrantsLocationId=12a6710f-5af8-41f5-b035-0bc795bf1a2b,
AccessGrantsLocationConfiguration=AccessGrantsLocationConfiguration(
S3SubPrefix=prefixB*
),
GrantScope=s3://amzn-s3-demo-bucket/
)
```

**Example – List all of the access grants in an S3 Access Grants instance**

You can optionally use these parameters to restrict the results to an S3 prefix or IAM identity:

- **Scope** – `GrantScope=s3://bucket-name/prefix*`
- **Grantee** – `GranteeType=IAM` and `GranteeIdentifier= arn:aws:iam::111122223333:role/accessGrantsConsumerRole`

```
public void listAccessGrants() {
ListAccessGrantsRequest listRequest = ListAccessGrantsRequest.builder()
.accountId("111122223333")
.build();
ListAccessGrantsResponse listResponse = s3Control.listAccessGrants(listRequest);
LOGGER.info("ListAccessGrantsResponse: " + listResponse);
}
```

Response:

```
ListAccessGrantsResponse(
AccessGrantsList=[
ListAccessGrantEntry(
CreatedAt=2023-06-14T17:54:46.540z,
AccessGrantId=dd8dd089-b224-4d82-95f6-975b4185bbaa,
AccessGrantArn=arn:aws:s3:us-east-2:111122223333:access-grants/default/
grant/dd8dd089-b224-4d82-95f6-975b4185bbaa,
Grantee=Grantee(
GranteeType=IAM, GranteeIdentifier= arn:aws:iam::111122223333:user/data-consumer-3
),
Permission=READ,
AccessGrantsLocationId=23514a34-ea2e-4ddf-b425-d0d4bfcarda1,
GrantScope=s3://amzn-s3-demo-bucket/prefixA
),
ListAccessGrantEntry(
CreatedAt=2023-06-24T17:54:46.540Z,
AccessGrantId=ee8ee089-b224-4d72-85f6-975b4185a1b2,
AccessGrantArn=arn:aws:s3:us-east-2:111122223333:access-grants/default/
grant/ee8ee089-b224-4d72-85f6-975b4185a1b2,
Grantee=Grantee(
GranteeType=IAM, GranteeIdentifier= arn:aws:iam::111122223333:user/data-consumer-9
),
Permission=READ,
```

```
AccessGrantsLocationId=12414a34-ea2e-4ddf-b425-d0d4bfcacao0,
GrantScope=s3://amzn-s3-demo-bucket/prefixB*
)
]
)
```

### Delete a grant

You can delete access grants from your Amazon S3 Access Grants instance. You can't undo an access grant deletion. After you delete an access grant, the grantee will no longer have access to your Amazon S3 data.

You can delete an access grant by using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), the Amazon S3 REST API, and the AWS SDKs.

#### Using the S3 console

**To delete an access grant**

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Access Grants**.
3. On the **S3 Access Grants** page, choose the Region that contains the S3 Access Grants instance that you want to work with.
4. Choose **View details** for the instance.
5. On the details page, choose the **Grants** tab.
6. Search for the grant that you want to delete. When you locate the grant, choose the radio button next to it.
7. Choose **Delete**. A dialog box appears with a warning that your action can't be undone. Choose **Delete** again to delete the grant.

#### Using the AWS CLI

To install the AWS CLI, see Installing the AWS CLI in the *AWS Command Line Interface User Guide*.

To use the following example command, replace the *`user input placeholders`* with your own information.

#### Example – Delete an access grant

```
aws s3control delete-access-grant \
--account-id 111122223333 \
--access-grant-id a1b2c3d4-5678-90ab-cdef-EXAMPLE11111

// No response body
```

### Using the REST API

For information about the Amazon S3 REST API support for managing access grants, see DeleteAccessGrant in the *Amazon Simple Storage Service API Reference*.

### Using the AWS SDKs

This section provides examples of how to delete an access grant by using the AWS SDKs. To use the following example, replace the *user input placeholders* with your own information.

Java

#### Example – Delete an access grant

```
public void deleteAccessGrant() {
DeleteAccessGrantRequest deleteRequest = DeleteAccessGrantRequest.builder()
.accountId("111122223333")
.accessGrantId("a1b2c3d4-5678-90ab-cdef-EXAMPLE11111")
.build();
DeleteAccessGrantResponse deleteResponse =
 s3Control.deleteAccessGrant(deleteRequest);
LOGGER.info("DeleteAccessGrantResponse: " + deleteResponse);
}
```

Response:

```
DeleteAccessGrantResponse()
```

## Request access to Amazon S3 data through S3 Access Grants

After you use Amazon S3 Access Grants to create an access grant that gives AWS Identity and Access Management (IAM) principals, your corporate directory identities, or authorized applications access to your S3 data, your grantees can request credentials to access this data.

When an application or AWS service uses the `GetDataAccess` API operation to ask S3 Access Grants for access to your S3 data on behalf of a grantee, S3 Access Grants first verifies that you have granted this identity access to the data. Then, S3 Access Grants uses the AssumeRole API operation to obtain a temporary credential token and vends it to the requester. This temporary credential token is an AWS Security Token Service (AWS STS) token.

The `GetDataAccess` request must include the `target` parameter, which specifies the scope of the S3 data that the temporary credentials apply to. This `target` scope can be the same as the scope of the grant or a subset of that scope, but the `target` scope must be within the scope of the grant that was given to the requester. The request must also specify the `permission` parameter to indicate the permission level for the temporary credentials, whether `READ`, `WRITE`, or `READWRITE`.

The requester can specify the privilege level of the temporary token in their credential request. Using the `privilege` parameter, the requester can reduce or increase the temporary credentials' scope of access, within the boundaries of the grant scope. The default value of the `privilege` parameter is `Default`, which means that the target scope of the credential returned is the original grant scope. The other possible value for `privilege` is `Minimal`. If the `target` scope is reduced from the original grant scope, then the temporary credential is de-scoped to match the `target` scope, as long as the `target` scope is within the grant scope.

The following table details the effect of the `privilege` parameter on two grants. One grant has the scope `S3://amzn-s3-demo-bucket1/bob/*`, which includes the entire bob/ prefix in the *amzn-s3-demo-bucket1* bucket. The other grant has the scope `S3://amzn-s3-demo-bucket1/bob/reports/*`, which includes only the bob/reports/ prefix in the *amzn-s3-demo-bucket1* bucket.

| Grant scope | Requested scope | Privilege | Returned scope | Effect |
|---|---|---|---|---|
| S3://*amzn-s3-demo-bucket1* /bob/* | *amzn-s3-demo-bucket1* /bob/* | Default | *amzn-s3-demo-bucket1* /bob/* | The requester has access to all objects that have key names that start with the prefix *bob/* in the *amzn-s3-demo-bucket1* bucket. |
| S3://*amzn-s3-d* | *amzn-s3-demo-* | Minimal | *amzn-s3-demo-bucket1* /bob/ | Without a wild card * character after the |

| Grant scope | Requested scope | Privilege | Returned scope | Effect |
| --- | --- | --- | --- | --- |
| *emo-bucket1* /bob/* | *bucket1* /bob/ | | | prefix name bob/, the requester has access to only the object named bob/ in the *amzn-s3-demo-bucket1* bucket. It's not common to have such an object. The requester doesn't have access to any other objects, including those that have key names that start with the bob/ prefix. |
| S3://*amzn-s3-demo-bucket1* /bob/* | *amzn-s3-demo-bucket1* /bob/images/* | Minimal | *amzn-s3-demo-bucket1* /bob/images/* | The requester has access to all objects that have key names that start with the prefix *bob/images/** in the *amzn-s3-demo-bucket1* bucket. |
| S3://*amzn-s3-demo-bucket1* /bob/reports/* | *amzn-s3-demo-bucket1* /bob/reports/file.txt | Default | *amzn-s3-demo-bucket1* /bob/reports/* | The requester has access to all objects that have key names that start with the bob/reports prefix in the *amzn-s3-demo-bucket1* bucket, which is the scope of the matching grant. |

| Grant scope | Requested scope | Privilege | Returned scope | Effect |
| --- | --- | --- | --- | --- |
| S3://*amzn-s3-demo-bucket1* /bob/reports/* | *amzn-s3-demo-bucket1* /bob/reports/file.txt | Minimal | *amzn-s3-demo-bucket1* /bob/reports/file.txt | The requester has access only to the object with the key name bob/reports/file.txt in the *amzn-s3-demo-bucket1* bucket. The requester has no access to any other object. |

The `durationSeconds` parameter sets the temporary credential's duration, in seconds. The default value is `3600` seconds (1 hour), but the requester (the grantee) can specify a range from `900` seconds (15 minutes) up to `43200` seconds (12 hours). If the grantee requests a value higher than this maximum, the request fails.

> **Note**
>
> In your request for a temporary token, if the location is an object, set the value of the `targetType` parameter in your request to `Object`. This parameter is required only if the location is an object and the privilege level is `Minimal`. If the location is a bucket or a prefix, you don't need to specify this parameter.

For more information, see GetDataAccess in the *Amazon Simple Storage Service API Reference*.

You can request temporary credentials by using AWS Command Line Interface (AWS CLI), the Amazon S3 REST API, and the AWS SDKs.

**Using the AWS CLI**

To install the AWS CLI, see Installing the AWS CLI in the *AWS Command Line Interface User Guide*.

To use the following example command, replace the *`user input placeholders`* with your own information.

**Example Request temporary credentials**

Request:

```
aws s3control get-data-access \
--account-id 111122223333 \
--target s3://amzn-s3-demo-bucket/prefixA* \
--permission READ \
--privilege Default \
--region us-east-2
```

Response:

```
{
"Credentials": {
 "AccessKeyId": "Example-key-id",
 "SecretAccessKey": "Example-access-key",
 "SessionToken": "Example-session-token",
"Expiration": "2023-06-14T18:56:45+00:00"},
    "MatchedGrantTarget": "s3://amzn-s3-demo-bucket/prefixA**"
}
```

**Using the REST API**

For information about the Amazon S3 REST API support for requesting temporary credentials from S3 Access Grants, see GetDataAccess in the *Amazon Simple Storage Service API Reference*.

**Using the AWS SDKs**

This section provides an example of how grantees request temporary credentials from S3 Access Grants by using the AWS SDKs.

Java

The following code example returns the temporary credentials that the grantee uses to access your S3 data. To use this code example, replace the *`user input placeholders`* with your own information.

**Example Get temporary credentials**

Request:

```
public void getDataAccess() {
GetDataAccessRequest getDataAccessRequest = GetDataAccessRequest.builder()
.accountId("111122223333")
.permission(Permission.READ)
.privilege(Privilege.MINIMAL)
.target("s3://amzn-s3-demo-bucket/prefixA*")
.build();
GetDataAccessResponse getDataAccessResponse =
 s3Control.getDataAccess(getDataAccessRequest);
LOGGER.info("GetDataAccessResponse: " + getDataAccessResponse);
}
```

Response:

```
GetDataAccessResponse(
Credentials=Credentials(
AccessKeyId="Example-access-key-id",
SecretAccessKey="Example-secret-access-key",
SessionToken="Example-session-token",
Expiration=2023-06-07T06:55:24Z
))
```

## Access S3 data through an access grant

After a grantee obtains temporary credentials through their access grant, they can use these temporary credentials to call Amazon S3 API operations to access your data.

Grantees can access S3 data by using the AWS Command Line Interface (AWS CLI), the AWS SDKs, and the Amazon S3 REST API.

### Using the AWS CLI

After the grantee obtains their temporary credentials from S3 Access Grants, they can set up a profile with these credentials to retrieve the data.

To install the AWS CLI, see Installing the AWS CLI in the *AWS Command Line Interface User Guide*.

To use the following example commands, replace the *`user input placeholders`* with your own information.

**Example – Set up a profile**

```
aws configure set aws_access_key_id "$accessKey" --profile access-grants-consumer-access-profile
aws configure set aws_secret_access_key "$secretKey" --profile access-grants-consumer-access-profile
aws configure set aws_session_token "$sessionToken" --profile access-grants-consumer-access-profile
```

To use the following example command, replace the *user input placeholders* with your own information.

**Example – Get the S3 data**

The grantee can use the get-object AWS CLI command to access the data. The grantee can also use put-object, ls, and other S3 AWS CLI commands.

```
aws s3api get-object \
--bucket amzn-s3-demo-bucket1 \
--key myprefix \
--region us-east-2 \
--profile access-grants-consumer-access-profile
```

**Using the AWS SDKs**

This section provides examples of how grantees can access your S3 data by using the AWS SDKs.

Java

> For examples of how to get S3 data by using temporary credentials, see how to get an object by using the AWS SDKs and Amazon S3 code examples for the AWS SDK for Java 2.x.

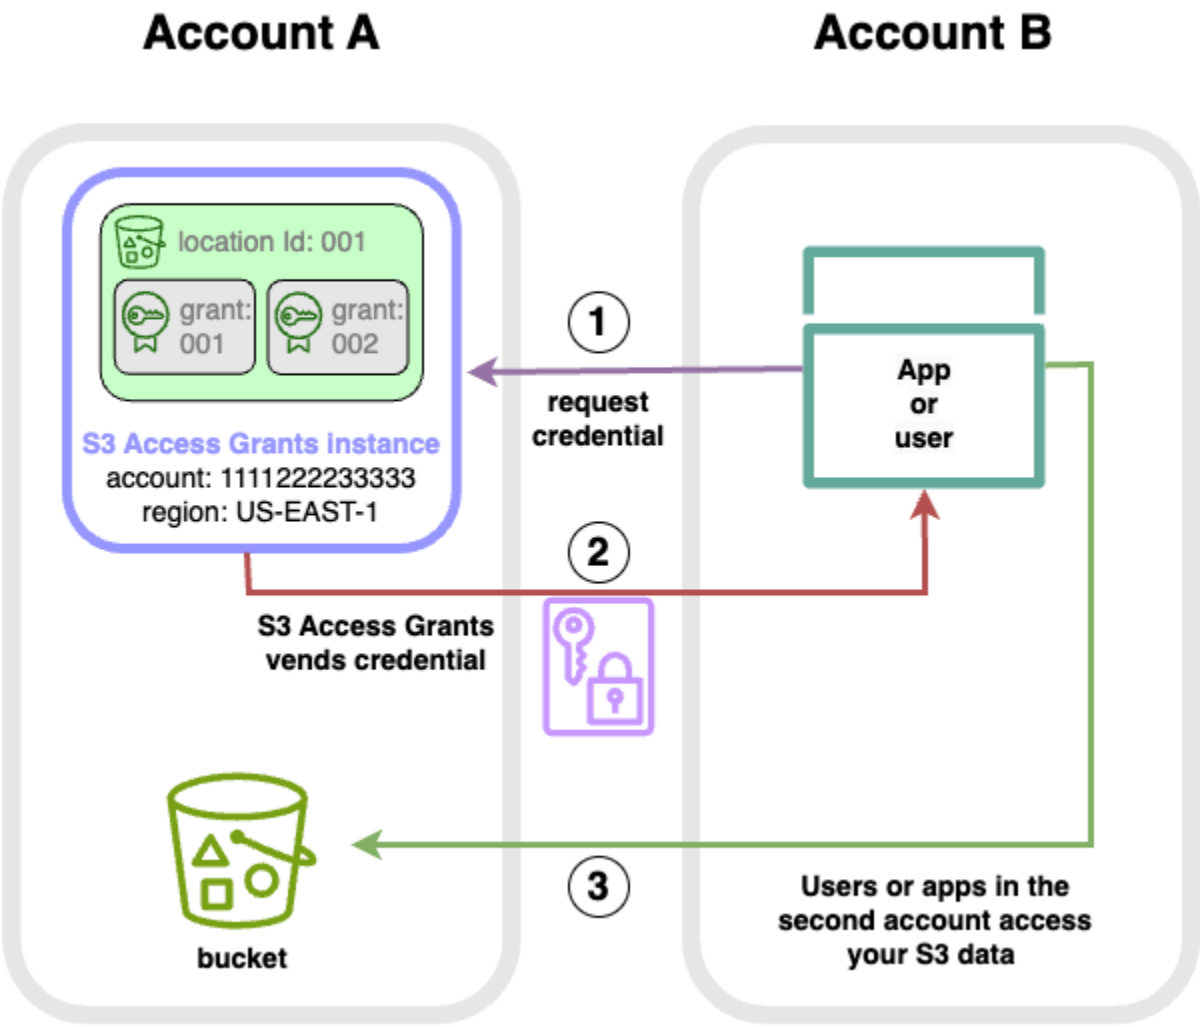
## S3 Access Grants cross-account access

With S3 Access Grants, you can grant Amazon S3 data access to the following:

- AWS Identity and Access Management (IAM) identities within your account
- IAM identities in other AWS accounts
- Directory users or groups in your AWS IAM Identity Center instance

First, configure cross-account access for the other account. This includes granting access to your S3 Access Grants instance by using a resource policy. Then, grant access to your S3 data (buckets, prefixes, or objects) by using grants.

After you configure cross-account access, the other account can request temporary access credentials to your Amazon S3 data from S3 Access Grants. The following image shows the user flow for cross-account S3 access through S3 Access Grants:



1. Users or applications in a second account (B) request credentials from the S3 Access Grants instance in your account (A), where the Amazon S3 data is stored. For more information, see Request access to Amazon S3 data through S3 Access Grants.
2. The S3 Access Grants instance in your account (A) returns temporary credentials if there is a grant that gives the second account access to your Amazon S3 data. For more information, see the section called “Create grants”.

3. Users or applications in the second account (B) use the S3 Access Grants-vended credentials to access the S3 data in your account (A).

### Configuring S3 Access Grants cross-account access

To grant cross-account S3 access through S3 Access Grants, follow these steps:

- **Step 1:** Configure an S3 Access Grants instance in your account, for example, account ID 111122223333, where the S3 data is stored.
- **Step 2:** Configure the resource policy for the S3 Access Grants instance in your account 111122223333 to give access to the second account, for example, account ID 444455556666.
- **Step 3:** Configure the IAM permissions for the IAM Principal in the second account 444455556666 to request credentials from the S3 Access Grants instance in your account 111122223333.
- **Step 4:** Create a grant in your account 111122223333 that gives the IAM Principal in the second account 444455556666 access to some of the S3 data in your account 111122223333.

### Step 1: Configure an S3 Access Grants instance in your account

First, you must have an S3 Access Grants instance in your account 111122223333 to manage access to your Amazon S3 data. You must create an S3 Access Grants instance in each AWS Region where the S3 data that you want to share is stored. If you are sharing data in more than one AWS Region, then repeat each of these configuration steps for each AWS Region. If you already have an S3 Access Grants instance in the AWS Region where your S3 data is stored, proceed to the next step. If you haven't configured an S3 Access Grants instance, see Create an S3 Access Grants instance to complete this step.

### Step 2: Configure the resource policy for your S3 Access Grants instance to grant cross-account access

After you create an S3 Access Grants instance in your account 111122223333 for cross-account access, configure the resource-based policy for the S3 Access Grants instance in your account 111122223333 to grant cross-account access. The S3 Access Grants instance itself supports resource-based policies. With the correct resource-based policy in place, you can grant access for AWS Identity and Access Management (IAM) users or roles from other AWS accounts to your S3 Access Grants instance. Cross-account access only grants these permissions (actions):

- `s3:GetAccessGrantsInstanceForPrefix` — the user, role, or app can retrieve the S3 Access Grants instance that contains a particular prefix.
- `s3:ListAccessGrants`
- `s3:ListAccessLocations`
- `s3:GetDataAccess` — the user, role, or app can request temporary credentials based on the access you were granted through S3 Access Grants. Use these credentials to access the S3 data to which you have been granted access.

You can choose which of these permissions to include in the resource policy. This resource policy on the S3 Access Grants instance is a normal resource-based policy and supports everything that the IAM policy language supports. In the same policy, you can grant access to specific IAM identities in your account `111122223333`, for example, by using the `aws:PrincipalArn` condition, but you don't have to do that with S3 Access Grants. Instead, within your S3 Access Grants instance, you can create grants for individual IAM identities from your account, as well as for the other account. By managing each access grant through S3 Access Grants, you can scale your permissions.

If you already use AWS Resource Access Manager (AWS RAM), you can use it to share your `s3:AccessGrants` resources with other accounts or within your organization. See Working with shared AWS resources for more information. If you don't use AWS RAM, you can also add the resource policy by using the S3 Access Grants API operations or the AWS Command Line Interface (AWS CLI).

**Using the S3 console**

We recommend that you use the AWS Resource Access Manager (AWS RAM) Console to share your `s3:AccessGrants` resources with other accounts or within your organization. To share S3 Access Grants cross-account, do the following:

**To configure the S3 Access Grants instance resource policy:**

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. Select the AWS Region from the AWS Region selector.
3. From the left navigation pane, select **Access Grants**.
4. On the Access Grants instance page, in the **Instance in this account** section, select **Share instance**. This will redirect you to the AWS RAM Console.
5. Select **Create resource share**.

6. Follow the AWS RAM steps to create the resource share. For more information, see Creating a resource share in AWS RAM.

### Using the AWS CLI

To install the AWS CLI, see Installing the AWS CLI in the *AWS Command Line Interface User Guide*.

You can add the resource policy by using the `put-access-grants-instance-resource-policy` CLI command.

If you want to grant cross-account access for the S3 Access Grants instance is in your account `111122223333` to the second account `444455556666`, the resource policy for the S3 Access Grants instance in your account `111122223333` should give the second account `444455556666` permission to perform the following actions:

- `s3:ListAccessGrants`
- `s3:ListAccessGrantsLocations`
- `s3:GetDataAccess`
- `s3:GetAccessGrantsInstanceForPrefix`

In the S3 Access Grants instance resource policy, specify the ARN of your S3 Access Grants instance as the `Resource`, and the second account `444455556666` as the `Principal`. To use the following example, replace the *`user input placeholders`* with your own information.

```
{
"Version": "2012-10-17",
"Statement": [
{
 "Effect": "Allow",
 "Principal": {
 "AWS": "444455556666"
},
 "Action": [
  "s3:ListAccessGrants",
  "s3:ListAccessGrantsLocations",
  "s3:GetDataAccess",
  "s3:GetAccessGrantsInstanceForPrefix"
 ],
 "Resource": "arn:aws:s3:us-east-2:111122223333:access-grants/default"
} ]
```

```
}
```

To add or update the S3 Access Grants instance resource policy, use the following command. When you use the following example command, replace the *user input placeholders* with your own information.

**Example Add or update the S3 Access Grants instance resource policy**

```
aws s3control put-access-grants-instance-resource-policy \
--account-id 111122223333 \
--policy file://resourcePolicy.json \
--region us-east-2
{
 "Policy": "{\n
   \"Version\": \"2012-10-17\",\n
   \"Statement\": [{\n
  \"Effect\": \"Allow\",\n
  \"Principal\": {\n
    \"AWS\": \"444455556666\"\n
  },\n
  \"Action\": [\n
    \"s3:ListAccessGrants\",\n
    \"s3:ListAccessGrantsLocations\",\n
    \"s3:GetDataAccess\",\n
    \"s3:GetAccessGrantsInstanceForPrefix\"\n
  ],\n
  \"Resource\": \"arn:aws:s3:us-east-2:111122223333:access-grants/default\"\n
    }\n
   ]\n
   }\n",
 "CreatedAt": "2023-06-16T00:07:47.473000+00:00"
}
```

**Example Get an S3 Access Grants resource policy**

You can also use the CLI to get or delete a resource policy for an S3 Access Grants instance.

To get an S3 Access Grants resource policy, use the following example command. To use this example command, replace the *user input placeholders* with your own information.

```
aws s3control get-access-grants-instance-resource-policy \
--account-id 111122223333 \
```

```
--region us-east-2

{
"Policy": "{\"Version\":\"2012-10-17\",\"Statement\":[{\"Effect\":\"Allow\",\"Principal
\":{\"AWS\":\"arn:aws:iam::111122223333:root\"},\"Action\":[\"s3:ListAccessGrants\",
\"s3:ListAccessGrantsLocations\",\"s3:GetDataAccess\"],\"Resource\":\"arn:aws:s3:us-
east-2:111122223333:access-grants/default\"}]}",
"CreatedAt": "2023-06-16T00:07:47.473000+00:00"
}
```

**Example Delete an S3 Access Grants resource policy**

To delete an S3 Access Grants resource policy, use the following example command. To use this example command, replace the *user input placeholders* with your own information.

```
aws s3control delete-access-grants-instance-resource-policy \
--account-id 111122223333 \
--region us-east-2

// No response body
```

**Using the REST API**

You can add the resource policy by using the PutAccessGrantsInstanceResourcePolicy API.

If you want to grant cross-account access for the S3 Access Grants instance is in your account 111122223333 to the second account 444455556666, the resource policy for the S3 Access Grants instance in your account 111122223333 should give the second account 444455556666 permission to perform the following actions:

- `s3:ListAccessGrants`
- `s3:ListAccessGrantsLocations`
- `s3:GetDataAccess`
- `s3:GetAccessGrantsInstanceForPrefix`

In the S3 Access Grants instance resource policy, specify the ARN of your S3 Access Grants instance as the `Resource`, and the second account 444455556666 as the `Principal`. To use the following example, replace the *user input placeholders* with your own information.

```
{
```

```
"Version": "2012-10-17",
"Statement": [
{
 "Effect": "Allow",
 "Principal": {
 "AWS": "444455556666"
},
 "Action": [
  "s3:ListAccessGrants",
  "s3:ListAccessGrantsLocations",
  "s3:GetDataAccess",
  "s3:GetAccessGrantsInstanceForPrefix"
 ],
 "Resource": "arn:aws:s3:us-east-2:111122223333:access-grants/default"
} ]
}
```

You can then use the PutAccessGrantsInstanceResourcePolicy API to configure the policy.

For information on the REST API support to update, get, or delete a resource policy for an S3 Access Grants instance, see the following sections in the *Amazon Simple Storage Service API Reference*:

- PutAccessGrantsInstanceResourcePolicy
- GetAccessGrantsInstanceResourcePolicy
- DeleteAccessGrantsInstanceResourcePolicy

### Using the AWS SDKs

This section provides you with the AWS SDK examples of how to configure your S3 Access Grants resource policy to grant a second AWS account access to some of your S3 data.

Java

Add, update, get, or delete a resource policy to manage cross-account access to your S3 Access Grants instance.

**Example Add or update an S3 Access Grants instance resource policy**

If you want to grant cross-account access for the S3 Access Grants instance is in your account 111122223333 to the second account 444455556666, the resource policy for the S3

Access Grants instance in your account 111122223333 should give the second account 444455556666 permission to perform the following actions:

- `s3:ListAccessGrants`
- `s3:ListAccessGrantsLocations`
- `s3:GetDataAccess`
- `s3:GetAccessGrantsInstanceForPrefix`

In the S3 Access Grants instance resource policy, specify the ARN of your S3 Access Grants instance as the `Resource`, and the second account 444455556666 as the `Principal`. To use the following example, replace the *`user input placeholders`* with your own information.

```
{
"Version": "2012-10-17",
"Statement": [
{
 "Effect": "Allow",
 "Principal": {
 "AWS": "444455556666"
},
 "Action": [
  "s3:ListAccessGrants",
  "s3:ListAccessGrantsLocations",
  "s3:GetDataAccess",
  "s3:GetAccessGrantsInstanceForPrefix"
 ],
 "Resource": "arn:aws:s3:us-east-2:111122223333:access-grants/default"
} ]
}
```

To add or update an S3 Access Grants instance resource policy, use the following code example:

```
public void putAccessGrantsInstanceResourcePolicy() {
 PutAccessGrantsInstanceResourcePolicyRequest putRequest =
 PutAccessGrantsInstanceResourcePolicyRequest.builder()
 .accountId(111122223333)
 .policy(RESOURCE_POLICY)
 .build();
 PutAccessGrantsInstanceResourcePolicyResponse putResponse =
 s3Control.putAccessGrantsInstanceResourcePolicy(putRequest);
```

```
 LOGGER.info("PutAccessGrantsInstanceResourcePolicyResponse: " + putResponse);
 }
```

Response:

```
PutAccessGrantsInstanceResourcePolicyResponse(
 Policy={
 "Version": "2012-10-17",
 "Statement": [{
 "Effect": "Allow",
 "Principal": {
 "AWS": "444455556666"
 },
 "Action": [
 "s3:ListAccessGrants",
 "s3:ListAccessGrantsLocations",
 "s3:GetDataAccess",
 "s3:GetAccessGrantsInstanceForPrefix"
 ],
 "Resource": "arn:aws:s3:us-east-2:111122223333:access-grants/default"
 }]
 }
 )
```

**Example Get an S3 Access Grants resource policy**

To get an S3 Access Grants resource policy, use the following code example. To use the following example command, replace the *user input placeholders* with your own information.

```
public void getAccessGrantsInstanceResourcePolicy() {
 GetAccessGrantsInstanceResourcePolicyRequest getRequest =
 GetAccessGrantsInstanceResourcePolicyRequest.builder()
 .accountId(111122223333)
 .build();
 GetAccessGrantsInstanceResourcePolicyResponse getResponse =
 s3Control.getAccessGrantsInstanceResourcePolicy(getRequest);
 LOGGER.info("GetAccessGrantsInstanceResourcePolicyResponse: " + getResponse);
 }
```

Response:

```
GetAccessGrantsInstanceResourcePolicyResponse(
 Policy={"Version":"2012-10-17","Statement":[{"Effect":"Allow","Principal":
{"AWS":"arn:aws:iam::444455556666:root"},"Action":
["s3:ListAccessGrants","s3:ListAccessGrantsLocations","s3:GetDataAccess"],"Resource":"arn:aw
east-2:111122223333:access-grants/default"}]},
 CreatedAt=2023-06-15T22:54:44.319Z
 )
```

**Example Delete an S3 Access Grants resource policy**

To delete an S3 Access Grants resource policy, use the following code example. To use the following example command, replace the *user input placeholders* with your own information.

```
public void deleteAccessGrantsInstanceResourcePolicy() {
 DeleteAccessGrantsInstanceResourcePolicyRequest deleteRequest =
 DeleteAccessGrantsInstanceResourcePolicyRequest.builder()
 .accountId(111122223333)
 .build();
 DeleteAccessGrantsInstanceResourcePolicyResponse deleteResponse =
 s3Control.putAccessGrantsInstanceResourcePolicy(deleteRequest);
 LOGGER.info("DeleteAccessGrantsInstanceResourcePolicyResponse: " + deleteResponse);
 }
```

Response:

```
DeleteAccessGrantsInstanceResourcePolicyResponse()
```

### Step 3: Grant IAM identities in a second account permission to call the S3 Access Grants instance in your account

After the owner of the Amazon S3 data has configured the cross-account policy for the S3 Access Grants instance in account 111122223333, the owner of the second account 444455556666 must create an identity-based policy for its IAM users or roles, and the owner must give them access to the S3 Access Grants instance. In the identity-based policy, include one or more of the following actions, depending on what's granted in the S3 Access Grants instance resource policy and the permissions you want to grant:

- `s3:ListAccessGrants`

- `s3:ListAccessGrantsLocations`
- `s3:GetDataAccess`
- `s3:GetAccessGrantsInstanceForPrefix`

Following the AWS cross-account access pattern, the IAM users or roles in the second account `444455556666` must explicitly have one or more of these permissions. For example, grant the `s3:GetDataAccess` permission so that the IAM user or role can call the S3 Access Grants instance in account `111122223333` to request credentials.

To use this example command, replace the *`user input placeholders`* with your own information.

```
{
 "Version": "2012-10-17",
 "Statement": [
 {
  "Effect": "Allow",
  "Action": [
   "s3:GetDataAccess",
  ],
   "Resource": "arn:aws:s3:us-east-2:111122223333:access-grants/default"
 }
 ]
}
```

For information on editing IAM identity-based policy, see Editing IAM policies in the *AWS Identity and Access Management guide*.

**Step 4: Create a grant in the S3 Access Grants instance of your account that gives the IAM identity in the second account access to some of your S3 data**

For the final configuration step, you can create a grant in the S3 Access Grants instance in your account 111122223333 that gives access to the IAM identity in the second account 444455556666 to some of the S3 data in your account. You can do this by using the Amazon S3 Console, CLI, API, and SDKs. For more information, see Create grants.

In the grant, specify the AWS ARN of the IAM identity from the second account, and specify which location in your S3 data (a bucket, prefix, or object) that you are granting access to. This location must already be registered with your S3 Access Grants instance. For more information, see Register a location. You can optionally specify a subprefix. For example, if the location you are granting

access to is a bucket, and you want to limit the access further to a specific object in that bucket, then pass the object key name in the `S3SubPrefix` field. Or if you want to limit access to the objects in the bucket with key names that start with a specific prefix, such as `2024-03-research-results/`, then pass `S3SubPrefix=2024-03-research-results/`.

The following is an example CLI command for creating an access grant for an identity in the second account. See Create grants for more information. To use this example command, replace the *`user input placeholders`* with your own information.

```
aws s3control create-access-grant \
--account-id 111122223333 \
--access-grants-location-id default \
--access-grants-location-configuration S3SubPrefix=prefixA* \
--permission READ \
--grantee GranteeType=IAM,GranteeIdentifier=arn:aws:iam::444455556666:role/data-consumer-1
```

After configuring cross-account access, the user or role in the second account can do the following:

- Calls `ListAccessGrantsInstances` to list the S3 Access Grants instances shared with it through AWS RAM. For more information, see View the details of an S3 Access Grants instance.
- Requests temporary credentials from S3 Access Grants. For more information on how to make these requests, see Request access to Amazon S3 data through S3 Access Grants.

## Using AWS tags with S3 Access Grants

Tags in Amazon S3 Access Grants have similar characteristics to object tags in Amazon S3. Each tag is a key-value pair. The resources in S3 Access Grants that you can tag are S3 Access Grants instances, locations, and grants.

> **Note**
>
> Tagging in S3 Access Grants uses different API operations than object tagging. S3 Access Grants uses the TagResource, UntagResource, and ListTagsForResource API operations, where a resource can be either an S3 Access Grants instance, a registered location, or an access grant.

Similar to object tags, the following limitations apply:

- You can add tags to new S3 Access Grants resources when you create them, or you can add tags to existing resources.
- You can associate up to 10 tags with a resource. If multiple tags are associated with the same resource, they must have unique tag keys.
- A tag key can be up to 128 Unicode characters in length, and tag values can be up to 256 Unicode characters in length. Tags are internally represented in UTF-16. In UTF-16, characters consume either 1 or 2 character positions.
- The keys and values are case sensitive.

For more information about tag restrictions, see User-defined tag restrictions in the *AWS Billing User Guide*.

You can tag resources in S3 Access Grants by using the AWS Command Line Interface (AWS CLI), the Amazon S3 REST API, or the AWS SDKs.

**Using the AWS CLI**

To install the AWS CLI, see Installing the AWS CLI in the *AWS Command Line Interface User Guide*.

You can tag an S3 Access Grants resource when you create it or after you have created it. The following examples show how you tag or untag an S3 Access Grants instance. You can perform similar operations for registered locations and access grants.

To use the following example commands, replace the *`user input placeholders`* with your own information.

**Example – Create an S3 Access Grants instance with tags**

```
aws s3control create-access-grants-instance \
 --account-id 111122223333 \
 --profile access-grants-profile \
 --region us-east-2 \
 --tags Key=tagKey1,Value=tagValue1
```

Response:

```
 {
    "CreatedAt": "2023-10-25T01:09:46.719000+00:00",
    "AccessGrantsInstanceId": "default",
```

```
    "AccessGrantsInstanceArn": "arn:aws:s3:us-east-2:111122223333:access-grants/
default"
}
```

### Example – Tag an already created S3 Access Grants instance

```
aws s3control tag-resource \
--account-id 111122223333 \
--resource-arn "arn:aws:s3:us-east-2:111122223333:access-grants/default" \
--profile access-grants-profile \
--region us-east-2 \
--tags Key=tagKey2,Value=tagValue2
```

### Example – List tags for the S3 Access Grants instance

```
aws s3control list-tags-for-resource \
--account-id 111122223333 \
--resource-arn "arn:aws:s3:us-east-2:111122223333:access-grants/default" \
--profile access-grants-profile \
--region us-east-2
```

Response:

```
{
    "Tags": [
        {
            "Key": "tagKey1",
            "Value": "tagValue1"
        },
        {
            "Key": "tagKey2",
            "Value": "tagValue2"
        }
    ]
}
```

### Example – Untag the S3 Access Grants instance

```
aws s3control untag-resource \
 --account-id 111122223333 \
 --resource-arn "arn:aws:s3:us-east-2:111122223333:access-grants/default" \
 --profile access-grants-profile \
```

```
--region us-east-2 \
--tag-keys "tagKey2"
```

#### Using the REST API

You can use the Amazon S3 API to tag, untag, or list tags for an S3 Access Grants instance, registered location, or access grant. For information about the REST API support for managing S3 Access Grants tags, see the following sections in the *Amazon Simple Storage Service API Reference*:

- TagResource
- UntagResource
- ListTagsForResource

## S3 Access Grants limitations

S3 Access Grants has the following limitations:

> **Note**
>
> If your use case exceeds these limitations, contact AWS support to request higher limits.

**S3 Access Grants instance**

You can create **1 S3 Access Grants instance** per AWS Region per account. See Create an S3 Access Grants instance.

**S3 Access Grants location**

You can register **1,000 S3 Access Grants locations** per S3 Access Grants instance. See Register an S3 Access Grants location.

**Grant**

You can create **100,000 grants** per S3 Access Grants instance. See Create a grant.

## S3 Access Grants integrations

S3 Access Grants can be used with the following AWS services and features. This page will be updated as new integrations become available.

**Amazon Athena**

Using IAM Identity Center enabled Athena workgroups

**Amazon EMR**

Launch an Amazon EMR cluster with S3 Access Grants

**Amazon EMR on EKS**

Launch an Amazon EMR on EKS cluster with S3 Access Grants

**Amazon EMR Serverless application**

Launch an Amazon EMR Serverless application with S3 Access Grants

**AWS IAM Identity Center**

Trusted identity propagation across applications

**Amazon SageMaker Studio**

Amazon S3 Access Grants now integrates with Amazon SageMaker Studio

**Open source Python frameworks**

Amazon S3 Access Grants now integrates with open source Python frameworks

## Managing access with ACLs

Access control lists (ACLs) are one of the resource-based options that you can use to manage access to your buckets and objects. You can use ACLs to grant basic read/write permissions to other AWS accounts. There are limits to managing permissions using ACLs.

For example, you can grant permissions only to other AWS accounts; you cannot grant permissions to users in your account. You cannot grant conditional permissions, nor can you explicitly deny permissions. ACLs are suitable for specific scenarios. For example, if a bucket owner allows other AWS accounts to upload objects, permissions to these objects can only be managed using object ACL by the AWS account that owns the object.

S3 Object Ownership is an Amazon S3 bucket-level setting that you can use to both control ownership of the objects that are uploaded to your bucket and to disable or enable ACLs. By default, Object Ownership is set to the Bucket owner enforced setting, and all ACLs are disabled. When ACLs are disabled, the bucket owner owns all the objects in the bucket and manages access to them exclusively by using access-management policies.

A majority of modern use cases in Amazon S3 no longer require the use of ACLs. We recommend that you keep ACLs disabled, except in unusual circumstances where you need to control access for each object individually. With ACLs disabled, you can use policies to control access to all objects in your bucket, regardless of who uploaded the objects to your bucket. For more information, see Controlling ownership of objects and disabling ACLs for your bucket.

> **Important**
>
> If your bucket uses the Bucket owner enforced setting for S3 Object Ownership, you must use policies to grant access to your bucket and the objects in it. With the Bucket owner enforced setting enabled, requests to set access control lists (ACLs) or update ACLs fail and return the `AccessControlListNotSupported` error code. Requests to read ACLs are still supported.

For more information about ACLs, see the following topics.

**Topics**

- Access control list (ACL) overview
- Configuring ACLs
- Policy examples for ACLs

## Access control list (ACL) overview

Amazon S3 access control lists (ACLs) enable you to manage access to buckets and objects. Each bucket and object has an ACL attached to it as a subresource. It defines which AWS accounts or groups are granted access and the type of access. When a request is received against a resource, Amazon S3 checks the corresponding ACL to verify that the requester has the necessary access permissions.

S3 Object Ownership is an Amazon S3 bucket-level setting that you can use to both control ownership of the objects that are uploaded to your bucket and to disable or enable ACLs. By default, Object Ownership is set to the Bucket owner enforced setting, and all ACLs are disabled. When ACLs are disabled, the bucket owner owns all the objects in the bucket and manages access to them exclusively by using access-management policies.

A majority of modern use cases in Amazon S3 no longer require the use of ACLs. We recommend that you keep ACLs disabled, except in unusual circumstances where you need to control access for

each object individually. With ACLs disabled, you can use policies to control access to all objects in your bucket, regardless of who uploaded the objects to your bucket. For more information, see Controlling ownership of objects and disabling ACLs for your bucket.

> **Important**
>
> If your bucket uses the Bucket owner enforced setting for S3 Object Ownership, you must use policies to grant access to your bucket and the objects in it. With the Bucket owner enforced setting enabled, requests to set access control lists (ACLs) or update ACLs fail and return the `AccessControlListNotSupported` error code. Requests to read ACLs are still supported.

When you create a bucket or an object, Amazon S3 creates a default ACL that grants the resource owner full control over the resource. This is shown in the following sample bucket ACL (the default object ACL has the same structure):

**Example**

```
<?xml version="1.0" encoding="UTF-8"?>
<AccessControlPolicy xmlns="http://s3.amazonaws.com/doc/2006-03-01/">
  <Owner>
    <ID>*** Owner-Canonical-User-ID ***</ID>
    <DisplayName>owner-display-name</DisplayName>
  </Owner>
  <AccessControlList>
    <Grant>
      <Grantee xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
               xsi:type="Canonical User">
        <ID>*** Owner-Canonical-User-ID ***</ID>
        <DisplayName>display-name</DisplayName>
      </Grantee>
      <Permission>FULL_CONTROL</Permission>
    </Grant>
  </AccessControlList>
</AccessControlPolicy>
```

The sample ACL includes an `Owner` element that identifies the owner by the AWS account's canonical user ID. For instructions on finding your canonical user ID, see Finding an AWS account canonical user ID. The `Grant` element identifies the grantee (either an AWS account or a

predefined group) and the permission granted. This default ACL has one `Grant` element for the owner. You grant permissions by adding `Grant` elements, with each grant identifying the grantee and the permission.

> **Note**
>
> An ACL can have up to 100 grants.

**Topics**

### Who is a grantee?

A grantee can be an AWS account or one of the predefined Amazon S3 groups. You grant permission to an AWS account using the email address or the canonical user ID. However, if you provide an email address in your grant request, Amazon S3 finds the canonical user ID for that account and adds it to the ACL. The resulting ACLs always contain the canonical user ID for the AWS account, not the email address of the AWS account.

When you grant access rights, you specify each grantee as a *`type`*="*`value`*" pair, where *`type`* is one of the following:

- `id` – If the value specified is the canonical user ID of an AWS account
- `uri` – If you are granting permissions to a predefined group
- `emailAddress` – If the value specified is the email address of an AWS account

> **Important**
>
> Using email addresses to specify a grantee is only supported in the following AWS Regions:
>
> - US East (N. Virginia)

- US West (N. California)
- US West (Oregon)
- Asia Pacific (Singapore)
- Asia Pacific (Sydney)
- Asia Pacific (Tokyo)
- Europe (Ireland)
- South America (São Paulo)

For a list of all the Amazon S3 supported regions and endpoints, see Regions and Endpoints in the *Amazon Web Services General Reference*.

**Example Example: Email address**

For example, the following `x-amz-grant-read` header grants the AWS accounts identified by email addresses permissions to read object data and its metadata:

```
x-amz-grant-read: emailAddress="xyz@example.com", emailAddress="abc@example.com"
```

**Warning**

When you grant other AWS accounts access to your resources, be aware that the AWS accounts can delegate their permissions to users under their accounts. This is known as *cross-account access*. For information about using cross-account access, see Creating a Role to Delegate Permissions to an IAM User in the *IAM User Guide*.

**Finding an AWS account canonical user ID**

The canonical user ID is associated with your AWS account. This ID is a long string of characters, such as:

`79a59df900b949e55d96a1e698fbacedfd6e09d98eacf8f8d5218e7cd47ef2be`

For information about how to find the canonical user ID for your account, see Find the canonical user ID for your AWS account in the *AWS Account Management Reference Guide*.

You can also look up the canonical user ID of an AWS account by reading the ACL of a bucket or an object to which the AWS account has access permissions. When an individual AWS account is granted permissions by a grant request, a grant entry is added to the ACL with the account's canonical user ID.

> **Note**
>
> If you make your bucket public (not recommended), any unauthenticated user can upload objects to the bucket. These anonymous users don't have an AWS account. When an anonymous user uploads an object to your bucket, Amazon S3 adds a special canonical user ID (`65a011a29cdf8ec533ec3d1ccaae921c`) as the object owner in the ACL. For more information, see Amazon S3 bucket and object ownership.

### Amazon S3 predefined groups

Amazon S3 has a set of predefined groups. When granting account access to a group, you specify one of the Amazon S3 URIs instead of a canonical user ID. Amazon S3 provides the following predefined groups:

- **Authenticated Users group** – Represented by `http://acs.amazonaws.com/groups/global/AuthenticatedUsers`.

  This group represents all AWS accounts. **Access permission to this group allows any AWS account to access the resource.** However, all requests must be signed (authenticated).

  > **Warning**
  >
  > When you grant access to the **Authenticated Users group**, any AWS authenticated user in the world can access your resource.

- **All Users group** – Represented by `http://acs.amazonaws.com/groups/global/AllUsers`.

  **Access permission to this group allows anyone in the world access to the resource.** The requests can be signed (authenticated) or unsigned (anonymous). Unsigned requests omit the Authentication header in the request.

> **Warning**
>
> We highly recommend that you never grant the **All Users group** `WRITE`, `WRITE_ACP`, or `FULL_CONTROL` permissions. For example, while `WRITE` permissions do not allow non-owners to overwrite or delete existing objects, `WRITE` permissions still allow anyone to store objects in your bucket, for which you are billed. For more details about these permissions, see the following section What permissions can I grant?.

- **Log Delivery group** – Represented by `http://acs.amazonaws.com/groups/s3/LogDelivery`.

  `WRITE` permission on a bucket enables this group to write server access logs (see Logging requests with server access logging) to the bucket.

> **Note**
>
> When using ACLs, a grantee can be an AWS account or one of the predefined Amazon S3 groups. However, the grantee cannot be an IAM user. For more information about AWS users and permissions within IAM, see Using AWS Identity and Access Management.

### What permissions can I grant?

The following table lists the set of permissions that Amazon S3 supports in an ACL. The set of ACL permissions is the same for an object ACL and a bucket ACL. However, depending on the context (bucket ACL or object ACL), these ACL permissions grant permissions for specific buckets or object operations. The table lists the permissions and describes what they mean in the context of objects and buckets.

For more information about ACL permissions in the Amazon S3 console, see Configuring ACLs.

### ACL permissions

| Permission | When granted on a bucket | When granted on an object |
|---|---|---|
| `READ` | Allows grantee to list the objects in the bucket | Allows grantee to read the object data and its metadata |

| Permission | When granted on a bucket | When granted on an object |
|---|---|---|
| WRITE | Allows grantee to create new objects in the bucket. For the bucket and object owners of existing objects, also allows deletions and overwrites of those objects | Not applicable |
| READ_ACP | Allows grantee to read the bucket ACL | Allows grantee to read the object ACL |
| WRITE_ACP | Allows grantee to write the ACL for the applicable bucket | Allows grantee to write the ACL for the applicable object |
| FULL_CONTROL | Allows grantee the READ, WRITE, READ_ACP, and WRITE_ACP permissions on the bucket | Allows grantee the READ, READ_ACP, and WRITE_ACP permissions on the object |

**Warning**

Use caution when granting access permissions to your S3 buckets and objects. For example, granting WRITE access to a bucket allows the grantee to create objects in the bucket. We highly recommend that you read through the entire Access control list (ACL) overview section before granting permissions.

### Mapping of ACL permissions and access policy permissions

As shown in the preceding table, an ACL allows only a finite set of permissions, compared to the number of permissions that you can set in an access policy (see Policy actions for Amazon S3). Each of these permissions allows one or more Amazon S3 operations.

The following table shows how each ACL permission maps to the corresponding access policy permissions. As you can see, access policy allows more permissions than an ACL does. You use ACLs primarily to grant basic read/write permissions, similar to file system permissions. For more information about when to use an ACL, see Identity and Access Management for Amazon S3.

For more information about ACL permissions in the Amazon S3 console, see Configuring ACLs.

| ACL permission | Corresponding access policy permissions when the ACL permission is granted on a bucket | Corresponding access policy permissions when the ACL permission is granted on an object |
|---|---|---|
| READ | s3:ListBucket , s3:ListBucketVersions , and s3:ListBucketMultipartUploads | s3:GetObject and s3:GetObjectVersion |
| WRITE | s3:PutObject<br><br>Bucket owner can create, overwrite, and delete any object in the bucket, and object owner has FULL_CONTROL over their object.<br><br>In addition, when the grantee is the bucket owner, granting WRITE permission in a bucket ACL allows the s3:DeleteObjectVersion action to be performed on any version in that bucket. | Not applicable |
| READ_ACP | s3:GetBucketAcl | s3:GetObjectAcl and s3:GetObjectVersionAcl |
| WRITE_ACP | s3:PutBucketAcl | s3:PutObjectAcl and s3:PutObjectVersionAcl |
| FULL_CONTROL | Equivalent to granting READ, WRITE, READ_ACP, and WRITE_ACP ACL permissions. Accordingly, this ACL permission maps to a combination of corresponding access policy permissions. | Equivalent to granting READ, READ_ACP, and WRITE_ACP ACL permissions. Accordingly, this ACL permission maps to a combination of corresponding access policy permissions. |

### Condition keys

When you grant access policy permissions, you can use condition keys to constrain the value for the ACL on an object using a bucket policy. The following context keys correspond to ACLs. You can use these context keys to mandate the use of a specific ACL in a request:

- `s3:x-amz-grant-read` - Require read access.
- `s3:x-amz-grant-write` - Require write access.
- `s3:x-amz-grant-read-acp` - Require read access to the bucket ACL.
- `s3:x-amz-grant-write-acp` - Require write access to the bucket ACL.
- `s3:x-amz-grant-full-control` - Require full control.
- `s3:x-amz-acl` - Require a Canned ACL.

For example policies that involve ACL-specific headers, see Granting s3:PutObject permission with a condition requiring the bucket owner to get full control. For a complete list of Amazon S3 specific condition keys, see Actions, resources, and condition keys for Amazon S3 in the *Service Authorization Reference*.

### `aclRequired` values for common Amazon S3 requests

To identify Amazon S3 requests that required ACLs for authorization, you can use the `aclRequired` value in Amazon S3 server access logs or AWS CloudTrail. The `aclRequired` value that appears in CloudTrail or Amazon S3 server access logs depends on which operations were called and certain information about the requester, object owner, and bucket owner. If no ACLs were required, or if you are setting the `bucket-owner-full-control` canned ACL, or if the requests are allowed by your bucket policy, the `aclRequired` value string is `"-"` in Amazon S3 server access logs and is absent in CloudTrail.

The following tables list the expected `aclRequired` values in CloudTrail or Amazon S3 server access logs for the various Amazon S3 API operations. You can use this information to understand which Amazon S3 operations depend on ACLs for authorization. In the following tables, A, B, and C represent the different accounts associated with the requester, object owner, and bucket owner. Entries with an asterisk (*) indicate any of accounts A, B, or C.

**Note**

`PutObject` operations in the following table, unless specified otherwise, indicate requests that do not set an ACL, unless the ACL is a `bucket-owner-full-control` ACL. A null value for `aclRequired` indicates that `aclRequired` is absent in AWS CloudTrail logs.

### `aclRequired` values for CloudTrail

| Operation name | Requester | Object owner | Bucket owner | Bucket policy grants access | `aclRequired` value | Reason |
|---|---|---|---|---|---|---|
| `GetObject` | A | A | A | Yes or No | null | Same-account access |
| | A | B | A | Yes or No | null | Same-account access with bucket owner enforced |
| | A | A | B | Yes | null | Cross-account access granted by bucket policy |
| | A | A | B | No | Yes | Cross-account access relies on ACL |

| Operation name | Requester | Object owner | Bucket owner | Bucket policy grants access | `aclRequired` value | Reason |
|---|---|---|---|---|---|---|
| | A | A | B | Yes | null | Cross-account access granted by bucket policy |
| | A | B | B | No | Yes | Cross-account access relies on ACL |
| | A | B | C | Yes | null | Cross-account access granted by bucket policy |
| | A | B | C | No | Yes | Cross-account access relies on ACL |
| `PutObject` | A | Not applicable | A | Yes or No | null | Same-account access |

| Operation name | Requester | Object owner | Bucket owner | Bucket policy grants access | aclRequired value | Reason |
|---|---|---|---|---|---|---|
| | A | Not applicable | B | Yes | null | Cross-account access granted by bucket policy |
| | A | Not applicable | B | No | Yes | Cross-account access relies on ACL |
| PutObject with an ACL (except for bucket-owner-full-control ) | * | Not applicable | * | Yes or No | Yes | Request grants ACL |
| ListObjects | A | Not applicable | A | Yes or No | null | Same-account access |
| | A | Not applicable | B | Yes | null | Cross-account access granted by bucket policy |

| Operation name | Requester | Object owner | Bucket owner | Bucket policy grants access | aclRequired value | Reason |
|---|---|---|---|---|---|---|
| | A | Not applicable | B | No | Yes | Cross-account access relies on ACL |
| DeleteObject | A | Not applicable | A | Yes or No | null | Same-account access |
| | A | Not applicable | B | Yes | null | Cross-account access granted by bucket policy |
| | A | Not applicable | B | No | Yes | Cross-account access relies on ACL |
| PutObjectAcl | * | * | * | Yes or No | Yes | Request grants ACL |
| PutBucketAcl | * | Not applicable | * | Yes or No | Yes | Request grants ACL |

**Note**

`REST.PUT.OBJECT` operations in the following table, unless specified otherwise, indicate requests that do not set an ACL, unless the ACL is a `bucket-owner-full-control` ACL. An `aclRequired` value string of "`-`" indicates a null value in Amazon S3 server access logs.

### `aclRequired` values for Amazon S3 server access logs

| Operation name | Requester | Object owner | Bucket owner | Bucket policy grants access | `aclRequired` value | Reason |
|---|---|---|---|---|---|---|
| `REST.GET.OBJECT` | A | A | A | Yes or No | - | Same-account access |
| | A | B | A | Yes or No | - | Same-account access with bucket owner enforced |
| | A | A | B | Yes | - | Cross-account access granted by bucket policy |
| | A | A | B | No | Yes | Cross-account access relies on ACL |

| Operation name | Requester | Object owner | Bucket owner | Bucket policy grants access | aclRequired value | Reason |
|---|---|---|---|---|---|---|
| | A | B | B | Yes | - | Cross-account access granted by bucket policy |
| | A | B | B | No | Yes | Cross-account access relies on ACL |
| | A | B | C | Yes | - | Cross-account access granted by bucket policy |
| | A | B | C | No | Yes | Cross-account access relies on ACL |
| REST.PUT.OBJECT | A | Not applicable | A | Yes or No | - | Same-account access |

| Operation name | Requester | Object owner | Bucket owner | Bucket policy grants access | aclRequired value | Reason |
|---|---|---|---|---|---|---|
| | A | Not applicable | B | Yes | - | Cross-account access granted by bucket policy |
| | A | Not applicable | B | No | Yes | Cross-account access relies on ACL |
| REST.PUT.OBJECT with an ACL (except for bucket-owner-full-control ) | * | Not applicable | * | Yes or No | Yes | Request grants ACL |
| REST.GET.BUCKET | A | Not applicable | A | Yes or No | - | Same-account access |
| | A | Not applicable | B | Yes | - | Cross-account access granted by bucket policy |

| Operation name | Requester | Object owner | Bucket owner | Bucket policy grants access | aclRequired value | Reason |
|---|---|---|---|---|---|---|
| | A | Not applicable | B | No | Yes | Cross-account access relies on ACL |
| REST.DELETE.OBJECT | A | Not applicable | A | Yes or No | - | Same-account access |
| | A | Not applicable | B | Yes | - | Cross-account access granted by bucket policy |
| | A | Not applicable | B | No | Yes | Cross-account access relies on ACL |
| REST.PUT.ACL | * | * | * | Yes or No | Yes | Request grants ACL |

### Sample ACL

The following sample ACL on a bucket identifies the resource owner and a set of grants. The format is the XML representation of an ACL in the Amazon S3 REST API. The bucket owner has FULL_CONTROL of the resource. In addition, the ACL shows how permissions are granted on a resource to two AWS accounts, identified by canonical user ID, and two of the predefined Amazon S3 groups discussed in the preceding section.

## Example

```
<?xml version="1.0" encoding="UTF-8"?>
<AccessControlPolicy xmlns="http://s3.amazonaws.com/doc/2006-03-01/">
  <Owner>
    <ID>Owner-canonical-user-ID</ID>
    <DisplayName>display-name</DisplayName>
  </Owner>
  <AccessControlList>
    <Grant>
      <Grantee xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
 xsi:type="CanonicalUser">
        <ID>Owner-canonical-user-ID</ID>
        <DisplayName>display-name</DisplayName>
      </Grantee>
      <Permission>FULL_CONTROL</Permission>
    </Grant>

    <Grant>
      <Grantee xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
 xsi:type="CanonicalUser">
        <ID>user1-canonical-user-ID</ID>
        <DisplayName>display-name</DisplayName>
      </Grantee>
      <Permission>WRITE</Permission>
    </Grant>

    <Grant>
      <Grantee xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
 xsi:type="CanonicalUser">
        <ID>user2-canonical-user-ID</ID>
        <DisplayName>display-name</DisplayName>
      </Grantee>
      <Permission>READ</Permission>
    </Grant>

    <Grant>
      <Grantee xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" xsi:type="Group">
        <URI>http://acs.amazonaws.com/groups/global/AllUsers</URI>
      </Grantee>
      <Permission>READ</Permission>
    </Grant>
    <Grant>
      <Grantee xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" xsi:type="Group">
```

```
        <URI>http://acs.amazonaws.com/groups/s3/LogDelivery</URI>
      </Grantee>
      <Permission>WRITE</Permission>
    </Grant>

  </AccessControlList>
</AccessControlPolicy>
```

### Canned ACL

Amazon S3 supports a set of predefined grants, known as *canned ACLs*. Each canned ACL has a predefined set of grantees and permissions. The following table lists the set of canned ACLs and the associated predefined grants.

| Canned ACL | Applies to | Permissions added to ACL |
| --- | --- | --- |
| `private` | Bucket and object | Owner gets `FULL_CONTROL` . No one else has access rights (default). |
| `public-read` | Bucket and object | Owner gets `FULL_CONTROL` . The `AllUsers` group (see Who is a grantee?) gets `READ` access. |
| `public-read-write` | Bucket and object | Owner gets `FULL_CONTROL` . The `AllUsers` group gets `READ` and `WRITE` access. Granting this on a bucket is generally not recommended. |
| `aws-exec-read` | Bucket and object | Owner gets `FULL_CONTROL` . Amazon EC2 gets `READ` access to `GET` an Amazon Machine Image (AMI) bundle from Amazon S3. |
| `authenticated-read` | Bucket and object | Owner gets `FULL_CONTROL` . The `AuthenticatedUsers` group gets `READ` access. |

| Canned ACL | Applies to | Permissions added to ACL |
| --- | --- | --- |
| `bucket-owner-read` | Object | Object owner gets `FULL_CONTROL` . Bucket owner gets `READ` access. If you specify this canned ACL when creating a bucket, Amazon S3 ignores it. |
| `bucket-owner-full-control` | Object | Both the object owner and the bucket owner get `FULL_CONTROL` over the object. If you specify this canned ACL when creating a bucket, Amazon S3 ignores it. |
| `log-delivery-write` | Bucket | The `LogDelivery` group gets `WRITE` and `READ_ACP` permissions on the bucket. For more information about logs, see (Logging requests with server access logging). |

**Note**

You can specify only one of these canned ACLs in your request.

You specify a canned ACL in your request by using the `x-amz-acl` request header. When Amazon S3 receives a request with a canned ACL in the request, it adds the predefined grants to the ACL of the resource.

## Configuring ACLs

This section explains how to manage access permissions for S3 buckets and objects using access control lists (ACLs). You can add grants to your resource ACL using the AWS Management Console, AWS Command Line Interface (CLI), REST API, or AWS SDKs.

Bucket and object permissions are independent of each other. An object does not inherit the permissions from its bucket. For example, if you create a bucket and grant write access to a user, you can't access that user's objects unless the user explicitly grants you access.

You can grant permissions to other AWS account users or to predefined groups. The user or group that you are granting permissions to is called the *grantee*. By default, the owner, which is the AWS account that created the bucket, has full permissions.

Each permission you grant for a user or group adds an entry in the ACL that is associated with the bucket. The ACL lists grants, which identify the grantee and the permission granted.

S3 Object Ownership is an Amazon S3 bucket-level setting that you can use to both control ownership of the objects that are uploaded to your bucket and to disable or enable ACLs. By default, Object Ownership is set to the Bucket owner enforced setting, and all ACLs are disabled. When ACLs are disabled, the bucket owner owns all the objects in the bucket and manages access to them exclusively by using access-management policies.

A majority of modern use cases in Amazon S3 no longer require the use of ACLs. We recommend that you keep ACLs disabled, except in unusual circumstances where you need to control access for each object individually. With ACLs disabled, you can use policies to control access to all objects in your bucket, regardless of who uploaded the objects to your bucket. For more information, see Controlling ownership of objects and disabling ACLs for your bucket.

**Important**

If your bucket uses the Bucket owner enforced setting for S3 Object Ownership, you must use policies to grant access to your bucket and the objects in it. With the Bucket owner enforced setting enabled, requests to set access control lists (ACLs) or update ACLs fail and return the `AccessControlListNotSupported` error code. Requests to read ACLs are still supported.

**Warning**

We highly recommend that you avoid granting write access to the **Everyone (public access)** or **Authenticated Users group (all AWS authenticated users)** groups. For more information about the effects of granting write access to these groups, see Amazon S3 predefined groups.

### Using the S3 console to set ACL permissions for a bucket

The console displays combined access grants for duplicate grantees. To see the full list of ACLs, use the Amazon S3 REST API, AWS CLI, or AWS SDKs.

The following table shows the ACL permissions that you can configure for buckets in the Amazon S3 console.

**Amazon S3 console ACL permissions for buckets**

| Console permission | ACL permission | Access |
|---|---|---|
| Objects - List | `READ` | Allows grantee to list the objects in the bucket. |
| Objects - Write | `WRITE` | Allows grantee to create new objects in the bucket. For the bucket and object owners of existing objects, also allows deletions and overwrites of those objects. |
| Bucket ACL - Read | `READ_ACP` | Allows grantee to read the bucket ACL. |
| Bucket ACL - Write | `WRITE_ACP` | Allows grantee to write the ACL for the applicable bucket. |
| Everyone (public access): Objects - List | `READ` | Grants public read access for the objects in the bucket. When you grant list access to **Everyone (public access)**, anyone in the world can access the objects in the bucket. |
| Everyone (public access): Bucket ACL - Read | `READ_ACP` | Grants public read access for the bucket ACL. When you grant read access to **Everyone (public access)**, anyone in the world can access the bucket ACL. |

For more information about ACL permissions, see Access control list (ACL) overview.

**Important**

If your bucket uses the Bucket owner enforced setting for S3 Object Ownership, you must use policies to grant access to your bucket and the objects in it. With the Bucket owner enforced setting enabled, requests to set access control lists (ACLs) or update ACLs fail and return the `AccessControlListNotSupported` error code. Requests to read ACLs are still supported.

**To set ACL permissions for a bucket**

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the **Buckets** list, choose the name of the bucket that you want to set permissions for.
3. Choose **Permissions**.
4. Under **Access control list**, choose **Edit**.

   You can edit the following ACL permissions for the bucket:

   **Objects**

   - **List** – Allows a grantee to list the objects in the bucket.
   - **Write** – Allows grantee to create new objects in the bucket. For the bucket and object owners of existing objects, also allows deletions and overwrites of those objects.

     In the S3 console, you can only grant write access to the S3 log delivery group and the bucket owner (your AWS account). We highly recommend that you do not grant write access for other grantees. However, if you need to grant write access, you can use the AWS CLI, AWS SDKs, or the REST API.

   **Bucket ACL**

   - **Read** – Allows grantee to read the bucket ACL.
   - **Write** – Allows grantee to write the ACL for the applicable bucket.
5. To change the bucket owner's permissions, beside **Bucket owner (your AWS account)**, clear or select from the following ACL permissions:

- **Objects** – **List** or **Write**
- **Bucket ACL** – **Read** or **Write**

The *owner* refers to the AWS account root user, not an AWS Identity and Access Management IAM user. For more information about the root user, see The AWS account root user in the *IAM User Guide*.

6. To grant or undo permissions for the general public (everyone on the internet), beside **Everyone (public access)**, clear or select from the following ACL permissions:

   - **Objects** – **List**
   - **Bucket ACL** – **Read**

   > **Warning**
   >
   > Use caution when granting the **Everyone** group public access to your S3 bucket. When you grant access to this group, anyone in the world can access your bucket. We highly recommend that you never grant any kind of public write access to your S3 bucket.

7. To grant or undo permissions for anyone with an AWS account, beside **Authenticated Users group (anyone with an AWS account)**, clear or select from the following ACL permissions:

   - **Objects** – **List**
   - **Bucket ACL** – **Read**

8. To grant or undo permissions for Amazon S3 to write server access logs to the bucket, under **S3 log delivery group**, clear or select from the following ACL permissions:

   - **Objects** – **List** or **Write**
   - **Bucket ACL** – **Read** or **Write**

   If a bucket is set up as the target bucket to receive access logs, the bucket permissions must allow the **Log Delivery** group write access to the bucket. When you enable server access logging on a bucket, the Amazon S3 console grants write access to the **Log Delivery** group for the target bucket that you choose to receive the logs. For more information about server access logging, see Enabling Amazon S3 server access logging.

9. To grant access to another AWS account, do the following:

a. Choose **Add grantee**.

b. In the **Grantee** box, enter the canonical ID of the other AWS account.

c. Select from the following ACL permissions:

- **Objects** – **List** or **Write**
- **Bucket ACL** – **Read** or **Write**

> **Warning**
>
> When you grant other AWS accounts access to your resources, be aware that the AWS accounts can delegate their permissions to users under their accounts. This is known as *cross-account access*. For information about using cross-account access, see Creating a Role to Delegate Permissions to an IAM User in the *IAM User Guide*.

10. To remove access to another AWS account, under **Access for other AWS accounts**, choose **Remove**.
11. To save your changes, choose **Save changes**.

### Using the S3 console to set ACL permissions for an object

The console displays combined access grants for duplicate grantees. To see the full list of ACLs, use the Amazon S3 REST API, AWS CLI, or AWS SDKs. The following table shows the ACL permissions that you can configure for objects in the Amazon S3 console.

### Amazon S3 console ACL permissions for objects

| Console permission | ACL permission | Access |
|---|---|---|
| Object - Read | `READ` | Allows grantee to read the object data and its metadata. |
| Object ACL - Read | `READ_ACP` | Allows grantee to read the object ACL. |
| Object ACL - Write | `WRITE_ACP` | Allows grantee to write the ACL for the applicable object |

For more information about ACL permissions, see Access control list (ACL) overview.

> **Important**
>
> If your bucket uses the Bucket owner enforced setting for S3 Object Ownership, you must use policies to grant access to your bucket and the objects in it. With the Bucket owner enforced setting enabled, requests to set access control lists (ACLs) or update ACLs fail and return the `AccessControlListNotSupported` error code. Requests to read ACLs are still supported.

**To set ACL permissions for an object**

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the **Buckets** list, choose the name of the bucket that contains the object.
3. In the **objects** list, choose the name of the object for which you want to set permissions.
4. Choose **Permissions**.
5. Under Access control list (ACL), choose **Edit**.

   You can edit the following ACL permissions for the object:

   **Object**

   - **Read** – Allows grantee to read the object data and its metadata.

   **Object ACL**

   - **Read** – Allows grantee to read the object ACL.
   - **Write** – Allows grantee to write the ACL for the applicable object. In the S3 console, you can only grant write access to the bucket owner (your AWS account). We highly recommend that you do not grant write access for other grantees. However, if you need to grant write access, you can use the AWS CLI, AWS SDKs, or the REST API.
6. You can manage object access permissions for the following:

a. **Access for object owner**

The *owner* refers to the AWS account root user, and not an AWS Identity and Access Management IAM user. For more information about the root user, see The AWS account root user in the *IAM User Guide*.

To change the owner's object access permissions, under **Access for object owner**, choose **Your AWS Account (owner)**.

Select the check boxes for the permissions that you want to change, and then choose **Save**.

b. **Access for other AWS accounts**

To grant permissions to an AWS user from a different AWS account, under **Access for other AWS accounts**, choose **Add account**. In the **Enter an ID** field, enter the canonical ID of the AWS user that you want to grant object permissions to. For information about finding a canonical ID, see Your AWS account identifiers in the *Amazon Web Services General Reference*. You can add as many as 99 users.

Select the check boxes for the permissions that you want to grant to the user, and then choose **Save**. To display information about the permissions, choose the Help icons.

c. **Public access**

To grant access to your object to the general public (everyone in the world), under **Public access**, choose **Everyone**. Granting public access permissions means that anyone in the world can access the object.

Select the check boxes for the permissions that you want to grant, and then choose **Save**.

> **Warning**
>
> - Use caution when granting the **Everyone** group anonymous access to your Amazon S3 objects. When you grant access to this group, anyone in the world can access your object. If you need to grant access to everyone, we highly recommend that you only grant permissions to **Read objects**.

- We highly recommend that you *do not* grant the **Everyone** group write object permissions. Doing so allows anyone to overwrite the ACL permissions for the object.

### Using the AWS SDKs

This section provides examples of how to configure access control list (ACL) grants on buckets and objects.

> **Important**
>
> If your bucket uses the Bucket owner enforced setting for S3 Object Ownership, you must use policies to grant access to your bucket and the objects in it. With the Bucket owner enforced setting enabled, requests to set access control lists (ACLs) or update ACLs fail and return the `AccessControlListNotSupported` error code. Requests to read ACLs are still supported.

Java

This section provides examples of how to configure access control list (ACL) grants on buckets and objects. The first example creates a bucket with a canned ACL (see Canned ACL), creates a list of custom permission grants, and then replaces the canned ACL with an ACL containing the custom grants. The second example shows how to modify an ACL using the `AccessControlList.grantPermission()` method.

**Example Create a bucket and specify a canned ACL that grants permission to the S3 log delivery group**

This example creates a bucket. In the request, the example specifies a canned ACL that grants the Log Delivery group permission to write logs to the bucket.

```
import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import com.amazonaws.regions.Regions;
import com.amazonaws.services.s3.AmazonS3;
import com.amazonaws.services.s3.AmazonS3ClientBuilder;
import com.amazonaws.services.s3.model.*;
```

```
import java.io.IOException;
import java.util.ArrayList;

public class CreateBucketWithACL {

    public static void main(String[] args) throws IOException {
        Regions clientRegion = Regions.DEFAULT_REGION;
        String bucketName = "*** Bucket name ***";
        String userEmailForReadPermission = "*** user@example.com ***";

        try {
            AmazonS3 s3Client = AmazonS3ClientBuilder.standard()
                    .withRegion(clientRegion)
                    .build();

            // Create a bucket with a canned ACL. This ACL will be replaced by the
            // setBucketAcl()
            // calls below. It is included here for demonstration purposes.
            CreateBucketRequest createBucketRequest = new
 CreateBucketRequest(bucketName, clientRegion.getName())
                    .withCannedAcl(CannedAccessControlList.LogDeliveryWrite);
            s3Client.createBucket(createBucketRequest);

            // Create a collection of grants to add to the bucket.
            ArrayList<Grant> grantCollection = new ArrayList<Grant>();

            // Grant the account owner full control.
            Grant grant1 = new Grant(new
 CanonicalGrantee(s3Client.getS3AccountOwner().getId()),
                    Permission.FullControl);
            grantCollection.add(grant1);

            // Grant the LogDelivery group permission to write to the bucket.
            Grant grant2 = new Grant(GroupGrantee.LogDelivery, Permission.Write);
            grantCollection.add(grant2);

            // Save grants by replacing all current ACL grants with the two we just
 created.
            AccessControlList bucketAcl = new AccessControlList();
            bucketAcl.grantAllPermissions(grantCollection.toArray(new Grant[0]));
            s3Client.setBucketAcl(bucketName, bucketAcl);
```

```
            // Retrieve the bucket's ACL, add another grant, and then save the new
 ACL.
            AccessControlList newBucketAcl = s3Client.getBucketAcl(bucketName);
            Grant grant3 = new Grant(new
 EmailAddressGrantee(userEmailForReadPermission), Permission.Read);
            newBucketAcl.grantAllPermissions(grant3);
            s3Client.setBucketAcl(bucketName, newBucketAcl);
        } catch (AmazonServiceException e) {
            // The call was transmitted successfully, but Amazon S3 couldn't process
            // it and returned an error response.
            e.printStackTrace();
        } catch (SdkClientException e) {
            // Amazon S3 couldn't be contacted for a response, or the client
            // couldn't parse the response from Amazon S3.
            e.printStackTrace();
        }
    }
}
```

### Example Update ACL on an existing object

This example updates the ACL on an object. The example performs the following tasks:

- Retrieves an object's ACL
- Clears the ACL by removing all existing permissions
- Adds two permissions: full access to the owner, and WRITE_ACP (see What permissions can I grant?) to a user identified by an email address
- Saves the ACL to the object

```
import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import com.amazonaws.auth.profile.ProfileCredentialsProvider;
import com.amazonaws.regions.Regions;
import com.amazonaws.services.s3.AmazonS3;
import com.amazonaws.services.s3.AmazonS3ClientBuilder;
import com.amazonaws.services.s3.model.AccessControlList;
import com.amazonaws.services.s3.model.CanonicalGrantee;
import com.amazonaws.services.s3.model.EmailAddressGrantee;
import com.amazonaws.services.s3.model.Permission;
```

```
import java.io.IOException;

public class ModifyACLExistingObject {

    public static void main(String[] args) throws IOException {
        Regions clientRegion = Regions.DEFAULT_REGION;
        String bucketName = "*** Bucket name ***";
        String keyName = "*** Key name ***";
        String emailGrantee = "*** user@example.com ***";

        try {
            AmazonS3 s3Client = AmazonS3ClientBuilder.standard()
                    .withCredentials(new ProfileCredentialsProvider())
                    .withRegion(clientRegion)
                    .build();

            // Get the existing object ACL that we want to modify.
            AccessControlList acl = s3Client.getObjectAcl(bucketName, keyName);

            // Clear the existing list of grants.
            acl.getGrantsAsList().clear();

            // Grant a sample set of permissions, using the existing ACL owner for
 Full
            // Control permissions.
            acl.grantPermission(new CanonicalGrantee(acl.getOwner().getId()),
 Permission.FullControl);
            acl.grantPermission(new EmailAddressGrantee(emailGrantee),
 Permission.WriteAcp);

            // Save the modified ACL back to the object.
            s3Client.setObjectAcl(bucketName, keyName, acl);
        } catch (AmazonServiceException e) {
            // The call was transmitted successfully, but Amazon S3 couldn't process
            // it, so it returned an error response.
            e.printStackTrace();
        } catch (SdkClientException e) {
            // Amazon S3 couldn't be contacted for a response, or the client
            // couldn't parse the response from Amazon S3.
            e.printStackTrace();
        }
    }
}
```

.NET

**Example Create a bucket and specify a canned ACL that grants permission to the S3 log delivery group**

This C# example creates a bucket. In the request, the code also specifies a canned ACL that grants the Log Delivery group permissions to write the logs to the bucket.

For information about setting up and running the code examples, see Getting Started with the AWS SDK for .NET in the *AWS SDK for .NET Developer Guide*.

```
using Amazon;
using Amazon.S3;
using Amazon.S3.Model;
using System;
using System.Threading.Tasks;

namespace Amazon.DocSamples.S3
{
    class ManagingBucketACLTest
    {
        private const string newBucketName = "*** bucket name ***";
        // Specify your bucket region (an example region is shown).
        private static readonly RegionEndpoint bucketRegion =
 RegionEndpoint.USWest2;
        private static IAmazonS3 client;

        public static void Main()
        {
            client = new AmazonS3Client(bucketRegion);
            CreateBucketUseCannedACLAsync().Wait();
        }

        private static async Task CreateBucketUseCannedACLAsync()
        {
            try
            {
                // Add bucket (specify canned ACL).
                PutBucketRequest putBucketRequest = new PutBucketRequest()
                {
                    BucketName = newBucketName,
                    BucketRegion = S3Region.EUW1, // S3Region.US,
```

```
                                                    // Add canned ACL.
                    CannedACL = S3CannedACL.LogDeliveryWrite
                };
                PutBucketResponse putBucketResponse = await
 client.PutBucketAsync(putBucketRequest);

                // Retrieve bucket ACL.
                GetACLResponse getACLResponse = await client.GetACLAsync(new
 GetACLRequest
                {
                    BucketName = newBucketName
                });
            }
            catch (AmazonS3Exception amazonS3Exception)
            {
                Console.WriteLine("S3 error occurred. Exception: " +
 amazonS3Exception.ToString());
            }
            catch (Exception e)
            {
                Console.WriteLine("Exception: " + e.ToString());
            }
        }
    }
}
```

**Example Update ACL on an existing object**

This C# example updates the ACL on an existing object. The example performs the following tasks:

- Retrieves an object's ACL.
- Clears the ACL by removing all existing permissions.
- Adds two permissions: full access to the owner, and WRITE_ACP to a user identified by email address.
- Saves the ACL by sending a `PutAcl` request.

For information about setting up and running the code examples, see Getting Started with the AWS SDK for .NET in the *AWS SDK for .NET Developer Guide*.

```
using Amazon;
```

```
using Amazon.S3;
using Amazon.S3.Model;
using System;
using System.Collections.Generic;
using System.Threading.Tasks;

namespace Amazon.DocSamples.S3
{
    class ManagingObjectACLTest
    {
        private const string bucketName = "*** bucket name ***";
        private const string keyName = "*** object key name ***";
        private const string emailAddress = "*** email address ***";
        // Specify your bucket region (an example region is shown).
        private static readonly RegionEndpoint bucketRegion =
 RegionEndpoint.USWest2;
        private static IAmazonS3 client;
        public static void Main()
        {
            client = new AmazonS3Client(bucketRegion);

                    GetACLResponse aclResponse = await client.GetACLAsync(new
 GetACLRequest
                    {
                        BucketName = bucketName,
                        Key = keyName
                    });

                    S3AccessControlList acl = aclResponse.AccessControlList;

                    // Retrieve the owner (we use this to re-add permissions after
 we clear the ACL).
                    Owner owner = acl.Owner;

                    // Clear existing grants.
                    acl.Grants.Clear();
```

```
                    // Add a grant to reset the owner's full permission (the
 previous clear statement removed all permissions).
                    S3Grant fullControlGrant = new S3Grant
                    {
                        Grantee = new S3Grantee { CanonicalUser = owner.Id },
                        Permission = S3Permission.FULL_CONTROL

                    };

                    // Describe the grant for the permission using an email address.
                    S3Grant grantUsingEmail = new S3Grant
                    {
                        Grantee = new S3Grantee { EmailAddress = emailAddress },
                        Permission = S3Permission.WRITE_ACP
                    };
                    acl.Grants.AddRange(new List<S3Grant> { fullControlGrant,
 grantUsingEmail });

                    // Set a new ACL.
                    PutACLResponse response = await client.PutACLAsync(new
 PutACLRequest
                    {
                        BucketName = bucketName,
                        Key = keyName,
                        AccessControlList = acl
                    });
            }
            catch (AmazonS3Exception amazonS3Exception)
            {
                Console.WriteLine("An AmazonS3Exception was thrown. Exception: " +
 amazonS3Exception.ToString());
            }
            catch (Exception e)
            {
                Console.WriteLine("Exception: " + e.ToString());
            }
        }
    }
}
```

### Using the REST API

Amazon S3 APIs enable you to set an ACL when you create a bucket or an object. Amazon S3 also provides API to set an ACL on an existing bucket or an object. These APIs provide the following methods to set an ACL:

- **Set ACL using request headers—** When you send a request to create a resource (bucket or object), you set an ACL using the request headers. Using these headers, you can either specify a canned ACL or specify grants explicitly (identifying grantee and permissions explicitly).
- **Set ACL using request body—** When you send a request to set an ACL on an existing resource, you can set the ACL either in the request header or in the body.

For information on the REST API support for managing ACLs, see the following sections in the *Amazon Simple Storage Service API Reference*:

- GET Bucket acl
- PUT Bucket acl
- GET Object acl
- PUT Object acl
- PUT Object
- PUT Bucket
- PUT Object - Copy
- Initiate Multipart Upload

> **Important**
>
> If your bucket uses the Bucket owner enforced setting for S3 Object Ownership, you must use policies to grant access to your bucket and the objects in it. With the Bucket owner enforced setting enabled, requests to set access control lists (ACLs) or update ACLs fail and return the `AccessControlListNotSupported` error code. Requests to read ACLs are still supported.

### Access Control List (ACL)-Specific Request Headers

You can use headers to grant access control list (ACL)-based permissions. By default, all objects are private. Only the owner has full access control. When adding a new object, you can grant permissions to individual AWS accounts or to predefined groups defined by Amazon S3. These permissions are then added to the Access Control List (ACL) on the object. For more information, see Access control list (ACL) overview.

With this operation, you can grant access permissions using one these two methods:

- **Canned ACL (`x-amz-acl`)** — Amazon S3 supports a set of predefined ACLs, known as canned ACLs. Each canned ACL has a predefined set of grantees and permissions. For more information, see Canned ACL.
- **Access Permissions** — To explicitly grant access permissions to specific AWS accounts or groups, use the following headers. Each header maps to specific permissions that Amazon S3 supports in an ACL. For more information, see Access control list (ACL) overview. In the header, you specify a list of grantees who get the specific permission.
  - x-amz-grant-read
  - x-amz-grant-write
  - x-amz-grant-read-acp
  - x-amz-grant-write-acp
  - x-amz-grant-full-control

### Using the AWS CLI

For more information about managing ACLs using the AWS CLI, see put-bucket-acl in the *AWS CLI Command Reference*.

> **Important**
>
> If your bucket uses the Bucket owner enforced setting for S3 Object Ownership, you must use policies to grant access to your bucket and the objects in it. With the Bucket owner enforced setting enabled, requests to set access control lists (ACLs) or update ACLs fail and return the `AccessControlListNotSupported` error code. Requests to read ACLs are still supported.

## Policy examples for ACLs

You can use condition keys in bucket policies to control access to Amazon S3.

### Topics

### Granting s3:PutObject permission with a condition requiring the bucket owner to get full control

The PUT Object operation allows access control list (ACL)–specific headers that you can use to grant ACL-based permissions. Using these keys, the bucket owner can set a condition to require specific access permissions when the user uploads an object.

Suppose that Account A owns a bucket, and the account administrator wants to grant Dave, a user in Account B, permissions to upload objects. By default, objects that Dave uploads are owned by Account B, and Account A has no permissions on these objects. Because the bucket owner is paying the bills, it wants full permissions on the objects that Dave uploads. The Account A administrator can do this by granting the `s3:PutObject` permission to Dave, with a condition that the request include ACL-specific headers that either grant full permission explicitly or use a canned ACL. For more information, see PUT Object.

#### Require the x-amz-full-control header

You can require the `x-amz-full-control` header in the request with full control permission to the bucket owner. The following bucket policy grants the `s3:PutObject` permission to user Dave with a condition using the `s3:x-amz-grant-full-control` condition key, which requires the request to include the `x-amz-full-control` header.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "statement1",
      "Effect": "Allow",
      "Principal": {
        "AWS": "arn:aws:iam::AccountB-ID:user/Dave"
      },
      "Action": "s3:PutObject",
```

```
      "Resource": "arn:aws:s3:::awsexamplebucket1/*",
      "Condition": {
        "StringEquals": {
          "s3:x-amz-grant-full-control": "id=AccountA-CanonicalUserID"
        }
      }
    }
  ]
}
```

> **Note**
>
> This example is about cross-account permission. However, if Dave (who is getting the permission) belongs to the AWS account that owns the bucket, this conditional permission is not necessary. This is because the parent account to which Dave belongs owns objects that the user uploads.

### Add explicit deny

The preceding bucket policy grants conditional permission to user Dave in Account B. While this policy is in effect, it is possible for Dave to get the same permission without any condition via some other policy. For example, Dave can belong to a group, and you grant the group `s3:PutObject` permission without any condition. To avoid such permission loopholes, you can write a stricter access policy by adding explicit deny. In this example, you explicitly deny the user Dave upload permission if he does not include the necessary headers in the request granting full permissions to the bucket owner. Explicit deny always supersedes any other permission granted. The following is the revised access policy example with explicit deny added.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "statement1",
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws:iam::AccountB-ID:user/AccountBadmin"
            },
            "Action": "s3:PutObject",
            "Resource": "arn:aws:s3:::awsexamplebucket1/*",
            "Condition": {
```

```
                "StringEquals": {
                    "s3:x-amz-grant-full-control": "id=AccountA-CanonicalUserID"
                }
            }
        },
        {
            "Sid": "statement2",
            "Effect": "Deny",
            "Principal": {
                "AWS": "arn:aws:iam::AccountB-ID:user/AccountBadmin"
            },
            "Action": "s3:PutObject",
            "Resource": "arn:aws:s3:::awsexamplebucket1/*",
            "Condition": {
                "StringNotEquals": {
                    "s3:x-amz-grant-full-control": "id=AccountA-CanonicalUserID"
                }
            }
        }
    ]
}
```

### Test the policy with the AWS CLI

If you have two AWS accounts, you can test the policy using the AWS Command Line Interface (AWS CLI). You attach the policy and use Dave's credentials to test the permission using the following AWS CLI `put-object` command. You provide Dave's credentials by adding the `--profile` parameter. You grant full control permission to the bucket owner by adding the `--grant-full-control` parameter. For more information about setting up and using the AWS CLI, see Developing with Amazon S3 using the AWS CLI.

```
aws s3api put-object --bucket examplebucket --key HappyFace.jpg --body c:\HappyFace.jpg
 --grant-full-control id="AccountA-CanonicalUserID" --profile AccountBUserProfile
```

### Require the x-amz-acl header

You can require the `x-amz-acl` header with a canned ACL granting full control permission to the bucket owner. To require the `x-amz-acl` header in the request, you can replace the key-value pair in the `Condition` block and specify the `s3:x-amz-acl` condition key, as shown in the following example.

```
"Condition": {
```

```
    "StringEquals": {
        "s3:x-amz-acl": "bucket-owner-full-control"
    }
}
```

To test the permission using the AWS CLI, you specify the `--acl` parameter. The AWS CLI then adds the `x-amz-acl` header when it sends the request.

```
aws s3api put-object --bucket examplebucket --key HappyFace.jpg --body c:\HappyFace.jpg
 --acl "bucket-owner-full-control" --profile AccountBadmin
```

**Granting s3:PutObject permission with a condition on the x-amz-acl header**

The following bucket policy grants the `s3:PutObject` permission for two AWS accounts if the request includes the `x-amz-acl` header making the object publicly readable. The `Condition` block uses the `StringEquals` condition, and it is provided a key-value pair, `"s3:x-amz-acl": ["public-read"]`, for evaluation. In the key-value pair, the `s3:x-amz-acl` is an Amazon S3–specific key, as indicated by the prefix `s3:`.

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
         "Sid":"AddCannedAcl",
            "Effect":"Allow",
         "Principal": {
                "AWS": [
                "arn:aws:iam::Account1-ID:root",
    "arn:aws:iam::Account2-ID:root"
    ]
            },
         "Action":"s3:PutObject",
            "Resource": ["arn:aws:s3:::awsexamplebucket1/*"],
            "Condition": {
                "StringEquals": {
                    "s3:x-amz-acl":["public-read"]
                }
            }
        }
    ]
}
```

**Important**

Not all conditions make sense for all actions. For example, it makes sense to include an `s3:LocationConstraint` condition on a policy that grants the `s3:CreateBucket` Amazon S3 permission. However, it does not make sense to include this condition on a policy that grants the `s3:GetObject` permission. Amazon S3 can test for semantic errors of this type that involve Amazon S3–specific conditions. However, if you are creating a policy for an IAM user or role and you include a semantically invalid Amazon S3 condition, no error is reported because IAM cannot validate Amazon S3 conditions.

## Blocking public access to your Amazon S3 storage

The Amazon S3 Block Public Access feature provides settings for access points, buckets, and accounts to help you manage public access to Amazon S3 resources. By default, new buckets, access points, and objects don't allow public access. However, users can modify bucket policies, access point policies, or object permissions to allow public access. S3 Block Public Access settings override these policies and permissions so that you can limit public access to these resources.

With S3 Block Public Access, account administrators and bucket owners can easily set up centralized controls to limit public access to their Amazon S3 resources that are enforced regardless of how the resources are created.

For instructions on configuring public block access, see Configuring block public access.

When Amazon S3 receives a request to access a bucket or an object, it determines whether the bucket or the bucket owner's account has a block public access setting applied. If the request was made through an access point, Amazon S3 also checks for block public access settings for the access point. If there is an existing block public access setting that prohibits the requested access, Amazon S3 rejects the request.

Amazon S3 Block Public Access provides four settings. These settings are independent and can be used in any combination. Each setting can be applied to an access point, a bucket, or an entire AWS account. If the block public access settings for the access point, bucket, or account differ, then Amazon S3 applies the most restrictive combination of the access point, bucket, and account settings.

When Amazon S3 evaluates whether an operation is prohibited by a block public access setting, it rejects any request that violates an access point, bucket, or account setting.

**Important**

Public access is granted to buckets and objects through access control lists (ACLs), access point policies, bucket policies, or all. To help ensure that all of your Amazon S3 access points, buckets, and objects have their public access blocked, we recommend that you turn on all four settings for block public access for your account. These settings block public access for all current and future buckets and access points.
Before applying these settings, verify that your applications will work correctly without public access. If you require some level of public access to your buckets or objects, for example to host a static website as described at Hosting a static website using Amazon S3, you can customize the individual settings to suit your storage use cases.
Enabling Block Public Access helps protect your resources by preventing public access from being granted through the resource policies or access control lists (ACLs) that are directly attached to S3 resources. In addition to enabling Block Public Access, carefully inspect the following policies to confirm that they do not grant public access:

- Identity-based policies attached to associated AWS principals (for example, IAM roles)
- Resource-based policies attached to associated AWS resources (for example, AWS Key Management Service (KMS) keys)

**Note**

- You can enable block public access settings only for access points, buckets, and AWS accounts. Amazon S3 doesn't support block public access settings on a per-object basis.
- When you apply block public access settings to an account, the settings apply to all AWS Regions globally. The settings might not take effect in all Regions immediately or simultaneously, but they eventually propagate to all Regions.

- Configuring block public access settings for your S3 buckets

## Block public access settings

S3 Block Public Access provides four settings. You can apply these settings in any combination to individual access points, buckets, or entire AWS accounts. If you apply a setting to an account, it applies to all buckets and access points that are owned by that account. Similarly, if you apply a setting to a bucket, it applies to all access points associated with that bucket.

The following table contains the available settings.

| Name | Description |
| --- | --- |
| `BlockPublicAcls` | Setting this option to TRUE causes the following behavior:<br>• PUT Bucket acl and PUT Object acl calls fail if the specified access control list (ACL) is public.<br>• PUT Object calls fail if the request includes a public ACL.<br>• If this setting is applied to an account, then PUT Bucket calls fail if the request includes a public ACL.<br><br>When this setting is set to TRUE, the specified operations fail (whether made through the REST API, AWS CLI, or AWS SDKs). However, existing policies and ACLs for buckets and objects are not modified. This setting enables you to protect against public access while allowing you to audit, refine, or otherwise alter the existing policies and ACLs for your buckets and objects. |

| Name | Description |
| --- | --- |
| | **Note**<br>Access points don't have ACLs associated with them. If you apply this setting to an access point, it acts as a passthrough to the underlying bucket. If an access point has this setting enabled, requests made through the access point behave as though the underlying bucket has this setting enabled, regardless of whether the bucket actually has this setting enabled. |
| `IgnorePublicAcls` | Setting this option to `TRUE` causes Amazon S3 to ignore all public ACLs on a bucket and any objects that it contains. This setting enables you to safely block public access granted by ACLs while still allowing PUT Object calls that include a public ACL (as opposed to `BlockPublicAcls`, which rejects PUT Object calls that include a public ACL). Enabling this setting doesn't affect the persistence of any existing ACLs and doesn't prevent new public ACLs from being set.<br>**Note**<br>Access points don't have ACLs associated with them. If you apply this setting to an access point, it acts as a passthrough to the underlying bucket. If an access point has this setting enabled, requests made through the access point behave as though the underlying bucket has this setting enabled, regardless of whether the bucket actually has this setting enabled. |

| Name | Description |
| --- | --- |
| `BlockPublicPolicy` | Setting this option to TRUE for a bucket causes Amazon S3 to reject calls to PUT Bucket policy if the specified bucket policy allows public access. Setting this option to TRUE for a bucket also causes Amazon S3 to reject calls to PUT access point policy for all of the bucket's same-account access points if the specified policy allows public access.<br><br>Setting this option to TRUE for an access point causes Amazon S3 to reject calls to PUT access point policy and PUT Bucket policy that are made through the access point if the specified policy (for either the access point or the underlying bucket) allows public access.<br><br>You can use this setting to allow users to manage access point and bucket policies without allowing them to publicly share the bucket or the object s it contains. Enabling this setting doesn't affect existing access point or bucket policies.<br><br>**Important**<br><br>To use this setting effectively, we recommend that you apply it at the *account* level. A bucket policy can allow users to alter a bucket's block public access settings. Therefore, users who have permission to change a bucket policy could insert a policy that allows them to disable the block public access settings for the bucket. If this setting is enabled for the entire account, rather than for a specific bucket, Amazon S3 blocks public policies even if a user alters the bucket policy to disable this setting. |

| Name | Description |
| --- | --- |
| `RestrictPublicBuckets` | Setting this option to TRUE restricts access to an access point or bucket with a public policy to only AWS service principals and authorized users within the bucket owner's account and access point owner's account. This setting blocks all cross-account access to the access point or bucket (except by AWS service principals), while still allowing users within the account to manage the access point or bucket.<br><br>Enabling this setting doesn't affect existing access point or bucket policies, except that Amazon S3 blocks public and cross-account access derived from any public access point or bucket policy, including non-public delegation to specific accounts. |

**Important**

- Calls to GET Bucket acl and GET Object acl always return the effective permissions in place for the specified bucket or object. For example, suppose that a bucket has an ACL that grants public access, but the bucket also has the `IgnorePublicAcls` setting enabled. In this case, GET Bucket acl returns an ACL that reflects the access permissions that Amazon S3 is enforcing, rather than the actual ACL that is associated with the bucket.
- Block public access settings don't alter existing policies or ACLs. Therefore, removing a block public access setting causes a bucket or object with a public policy or ACL to again be publicly accessible.

## Performing block public access operations on an access point

To perform block public access operations on an access point, use the AWS CLI service `s3control`.

**Important**

Note that it isn't currently possible to change an access point's block public access settings after creating the access point. Thus, the only way to specify block public access settings for an access point is by including them when creating the access point.

## The meaning of "public"

### ACLs

Amazon S3 considers a bucket or object ACL public if it grants any permissions to members of the predefined `AllUsers` or `AuthenticatedUsers` groups. For more information about predefined groups, see Amazon S3 predefined groups.

### Bucket policies

When evaluating a bucket policy, Amazon S3 begins by assuming that the policy is public. It then evaluates the policy to determine whether it qualifies as non-public. To be considered non-public, a bucket policy must grant access only to fixed values (values that don't contain a wildcard or an AWS Identity and Access Management Policy Variable) for one or more of the following:

- An AWS principal, user, role, or service principal (e.g. `aws:PrincipalOrgID`)
- A set of Classless Inter-Domain Routings (CIDRs), using `aws:SourceIp`. For more information about CIDR, see RFC 4632 on the RFC Editor website.

> **Note**
>
> Bucket policies that grant access conditioned on the `aws:SourceIp` condition key with very broad IP ranges (for example, 0.0.0.0/1) are evaluated as "public." This includes values broader than /8 for IPv4 and /32 for IPv6 (excluding RFC1918 private ranges). Block public access will reject these "public" policies and prevent cross-account access to buckets already using these "public" policies.

- `aws:SourceArn`
- `aws:SourceVpc`
- `aws:SourceVpce`
- `aws:SourceOwner`
- `aws:SourceAccount`
- `s3:x-amz-server-side-encryption-aws-kms-key-id`
- `aws:userid`, outside the pattern "`AROLEID:*`"
- `s3:DataAccessPointArn`

> **Note**
>
> When used in a bucket policy, this value can contain a wildcard for the access point name without rendering the policy public, as long as the account id is fixed. For example, allowing access to `arn:aws:s3:us-west-2:123456789012:accesspoint/*` would permit access to any access point associated with account `123456789012` in Region `us-west-2`, without rendering the bucket policy public. Note that this behavior is different for access point policies. For more information, see Access points.

- `s3:DataAccessPointAccount`

For more information about bucket policies, see Bucket policies for Amazon S3.

**Example : Public bucket policies**

Under these rules, the following example policies are considered public.

```
{
  "Principal": "*",
  "Resource": "*",
  "Action": "s3:PutObject",
  "Effect": "Allow"
 }
```

```
{
  "Principal": "*",
  "Resource": "*",
  "Action": "s3:PutObject",
  "Effect": "Allow",
  "Condition": { "StringLike": {"aws:SourceVpc": "vpc-*"}}
 }
```

You can make these policies non-public by including any of the condition keys listed previously, using a fixed value. For example, you can make the last policy preceding non-public by setting `aws:SourceVpc` to a fixed value, like the following.

```
{
  "Principal": "*",
```

```
  "Resource": "*",
  "Action": "s3:PutObject",
  "Effect": "Allow",
  "Condition": {"StringEquals": {"aws:SourceVpc": "vpc-91237329"}}
 }
```

### How Amazon S3 evaluates a bucket policy that contains both public and non-public access grants

This example shows how Amazon S3 evaluates a bucket policy that contains both public and non-public access grants.

Suppose that a bucket has a policy that grants access to a set of fixed principals.
Under the previously described rules, this policy isn't public. Thus, if you enable the `RestrictPublicBuckets` setting, the policy remains in effect as written, because `RestrictPublicBuckets` only applies to buckets that have public policies. However, if you add a public statement to the policy, `RestrictPublicBuckets` takes effect on the bucket. It allows only AWS service principals and authorized users of the bucket owner's account to access the bucket.

As an example, suppose that a bucket owned by "Account-1" has a policy that contains the following:

1. A statement that grants access to AWS CloudTrail (which is an AWS service principal)
2. A statement that grants access to account "Account-2"
3. A statement that grants access to the public, for example by specifying `"Principal": "*"` with no limiting `Condition`

This policy qualifies as public because of the third statement. With this policy in place and `RestrictPublicBuckets` enabled, Amazon S3 allows access only by CloudTrail. Even though statement 2 isn't public, Amazon S3 disables access by "Account-2." This is because statement 3 renders the entire policy public, so `RestrictPublicBuckets` applies. As a result, Amazon S3 disables cross-account access, even though the policy delegates access to a specific account, "Account-2." But if you remove statement 3 from the policy, then the policy doesn't qualify as public, and `RestrictPublicBuckets` no longer applies. Thus, "Account-2" regains access to the bucket, even if you leave `RestrictPublicBuckets` enabled.

### Access points

Amazon S3 evaluates block public access settings slightly differently for access points compared to buckets. The rules that Amazon S3 applies to determine when an access point policy is public are generally the same for access points as for buckets, except in the following situations:

- An access point that has a VPC network origin is always considered non-public, regardless of the contents of its access point policy.
- An access point policy that grants access to a set of access points using `s3:DataAccessPointArn` is considered public. Note that this behavior is different than for bucket policies. For example, a bucket policy that grants access to values of `s3:DataAccessPointArn` that match `arn:aws:s3:us-west-2:123456789012:accesspoint/*` is not considered public. However, the same statement in an access point policy would render the access point public.

## Using IAM Access Analyzer for S3 to review public buckets

You can use IAM Access Analyzer for S3 to review buckets with bucket ACLs, bucket policies, or access point policies that grant public access. IAM Access Analyzer for S3 alerts you to buckets that are configured to allow access to anyone on the internet or other AWS accounts, including AWS accounts outside of your organization. For each public or shared bucket, you receive findings that report the source and level of public or shared access.

In IAM Access Analyzer for S3, you can block all public access to a bucket with a single click. You can also drill down into bucket-level permission settings to configure granular levels of access. For specific and verified use cases that require public or shared access, you can acknowledge and record your intent for the bucket to remain public or shared by archiving the findings for the bucket.

In rare events, IAM Access Analyzer for S3 might report no findings for a bucket that an Amazon S3 block public access evaluation reports as public. This happens because Amazon S3 block public access reviews policies for current actions and any potential actions that might be added in the future, leading to a bucket becoming public. On the other hand, IAM Access Analyzer for S3 only analyzes the current actions specified for the Amazon S3 service in the evaluation of access status.

For more information about IAM Access Analyzer for S3, see Reviewing bucket access using IAM Access Analyzer for S3.

## Permissions

To use Amazon S3 Block Public Access features, you must have the following permissions.

| Operation | Required permissions |
| --- | --- |
| GET bucket policy status | `s3:GetBucketPolicyStatus` |
| GET bucket Block Public Access settings | `s3:GetBucketPublicAccessBlock` |
| PUT bucket Block Public Access settings | `s3:PutBucketPublicAccessBlock` |
| DELETE bucket Block Public Access settings | `s3:PutBucketPublicAccessBlock` |
| GET account Block Public Access settings | `s3:GetAccountPublicAccessBlock` |
| PUT account Block Public Access settings | `s3:PutAccountPublicAccessBlock` |
| DELETE account Block Public Access settings | `s3:PutAccountPublicAccessBlock` |
| PUT access point Block Public Access settings | `s3:CreateAccessPoint` |

**Note**

The DELETE operations require the same permissions as the PUT operations. There are no separate permissions for the DELETE operations.

## Configuring block public access

For more information about configuring block public access for your AWS account and your Amazon S3 buckets, see the following topics.

- Configuring block public access settings for your account
- Configuring block public access settings for your S3 buckets

## Configuring block public access settings for your account

Amazon S3 Block Public Access provides settings for access points, buckets, and accounts to help you manage public access to Amazon S3 resources. By default, new buckets, access points, and objects do not allow public access.

For more information, see Blocking public access to your Amazon S3 storage.

> **Note**
>
> Account level settings override settings on individual objects. Configuring your account to block public access will override any public access settings made to individual objects within your account.

You can use the S3 console, AWS CLI, AWS SDKs, and REST API to configure block public access settings for all the buckets in your account. For more information, see the sections below.

To configure block public access settings for your buckets, see Configuring block public access settings for your S3 buckets. For information about access points, see Performing block public access operations on an access point.

### Using the S3 console

Amazon S3 block public access prevents the application of any settings that allow public access to data within S3 buckets. This section describes how to edit block public access settings for all the S3 buckets in your AWS account. For more information about blocking public access, see Blocking public access to your Amazon S3 storage.

**To edit block public access settings for all the S3 buckets in an AWS account**

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. Choose **Block Public Access settings for this account**.
3. Choose **Edit** to change the block public access settings for all the buckets in your AWS account.
4. Choose the settings that you want to change, and then choose **Save changes**.
5. When you're asked for confirmation, enter **`confirm`**. Then choose **Confirm** to save your changes.

### Using the AWS CLI

You can use Amazon S3 Block Public Access through the AWS CLI. For more information about setting up and using the AWS CLI, see What is the AWS Command Line Interface?

#### Account

To perform block public access operations on an account, use the AWS CLI service `s3control`. The account-level operations that use this service are as follows:

- PUT PublicAccessBlock (for an account)
- GET PublicAccessBlock (for an account)
- DELETE PublicAccessBlock (for an account)

For additional information and examples, see put-public-access-block in the *AWS CLI Reference*.

### Using the AWS SDKs

Java

The following examples show you how to use Amazon S3 Block Public Access with the AWS SDK for Java to put a public access block configuration on an Amazon S3 account.

```
AWSS3ControlClientBuilder controlClientBuilder =
 AWSS3ControlClientBuilder.standard();
controlClientBuilder.setRegion(<region>);
controlClientBuilder.setCredentials(<credentials>);

AWSS3Control client = controlClientBuilder.build();
client.putPublicAccessBlock(new PutPublicAccessBlockRequest()
  .withAccountId(<account-id>)
  .withPublicAccessBlockConfiguration(new PublicAccessBlockConfiguration()
    .withIgnorePublicAcls(<value>)
    .withBlockPublicAcls(<value>)
    .withBlockPublicPolicy(<value>)
    .withRestrictPublicBuckets(<value>)));
```

> **Important**
>
> This example pertains only to account-level operations, which use the `AWSS3Control` client class. For bucket-level operations, see the preceding example.

Other SDKs

For information about using the other AWS SDKs, see Developing with Amazon S3 using the AWS SDKs.

#### Using the REST API

For information about using Amazon S3 Block Public Access through the REST APIs, see the following topics in the *Amazon Simple Storage Service API Reference*.

- Account-level operations
  - PUT PublicAccessBlock
  - GET PublicAccessBlock
  - DELETE PublicAccessBlock

## Configuring block public access settings for your S3 buckets

Amazon S3 Block Public Access provides settings for access points, buckets, and accounts to help you manage public access to Amazon S3 resources. By default, new buckets, access points, and objects do not allow public access.

For more information, see Blocking public access to your Amazon S3 storage.

You can use the S3 console, AWS CLI, AWS SDKs, and REST API to grant public access to one or more buckets. You can also block public access to buckets that are already public. For more information, see the sections below.

To configure block public access settings for every bucket in your account, see Configuring block public access settings for your account. For information about configuring block public access for access points, see Performing block public access operations on an access point.

### Using the S3 console

Amazon S3 Block Public Access prevents the application of any settings that allow public access to data within S3 buckets. This section describes how to edit Block Public Access settings for one or more S3 buckets. For information about blocking public access using the AWS CLI, AWS SDKs, and the Amazon S3 REST APIs, see Blocking public access to your Amazon S3 storage.

You can see if your bucket is publicly accessible in the **Buckets** list. In the **Access** column, Amazon S3 labels the permissions for a bucket as follows:

- **Public** – Everyone has access to one or more of the following: List objects, Write objects, Read and write permissions.
- **Objects can be public** – The bucket is not public, but anyone with the appropriate permissions can grant public access to objects.
- **Buckets and objects not public** – The bucket and objects do not have any public access.
- **Only authorized users of this account** – Access is isolated to IAM users and roles in this account and AWS service principals because there is a policy that grants public access.

You can also filter bucket searches by access type. Choose an access type from the drop-down list that is next to the **Search for buckets** bar.

If you see an `Error` when you list your buckets and their public access settings, you might not have the required permissions. Check to make sure you have the following permissions added to your user or role policy:

```
s3:GetAccountPublicAccessBlock
s3:GetBucketPublicAccessBlock
s3:GetBucketPolicyStatus
s3:GetBucketLocation
s3:GetBucketAcl
s3:ListAccessPoints
s3:ListAllMyBuckets
```

In some rare cases, requests can also fail because of an AWS Region outage.

#### To edit the Amazon S3 block public access settings for a single S3 bucket

Follow these steps if you need to change the public access settings for a single S3 bucket.

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the **Bucket name** list, choose the name of the bucket that you want.
3. Choose **Permissions**.
4. Choose **Edit** to change the public access settings for the bucket. For more information about the four Amazon S3 Block Public Access Settings, see Block public access settings.
5. Choose the setting that you want to change, and then choose **Save**.
6. When you're asked for confirmation, enter **`confirm`**. Then choose **Confirm** to save your changes.

You can change Amazon S3 Block Public Access settings when you create a bucket. For more information, see Creating a bucket.

**Using the AWS CLI**

To block public access on a bucket or to delete the public access block, use the AWS CLI service `s3api`. The bucket-level operations that use this service are as follows:

- PUT PublicAccessBlock (for a bucket)
- GET PublicAccessBlock (for a bucket)
- DELETE PublicAccessBlock (for a bucket)
- GET BucketPolicyStatus

For more information and examples, see put-public-access-block in the *AWS CLI Reference*.

**Using the AWS SDKs**

Java

```
AmazonS3 client = AmazonS3ClientBuilder.standard()
   .withCredentials(<credentials>)
   .build();

client.setPublicAccessBlock(new SetPublicAccessBlockRequest()
  .withBucketName(<bucket-name>)
  .withPublicAccessBlockConfiguration(new PublicAccessBlockConfiguration()
```

```
    .withBlockPublicAcls(<value>)
    .withIgnorePublicAcls(<value>)
    .withBlockPublicPolicy(<value>)
    .withRestrictPublicBuckets(<value>)));
```

> **Important**
>
> This example pertains only to bucket-level operations, which use the `AmazonS3` client class. For account-level operations, see the following example.

Other SDKs

For information about using the other AWS SDKs, see Developing with Amazon S3 using the AWS SDKs.

#### Using the REST API

For information about using Amazon S3 Block Public Access through the REST APIs, see the following topics in the *Amazon Simple Storage Service API Reference*.

- Bucket-level operations
  - PUT PublicAccessBlock
  - GET PublicAccessBlock
  - DELETE PublicAccessBlock
  - GET BucketPolicyStatus

## Reviewing bucket access using IAM Access Analyzer for S3

IAM Access Analyzer for S3 alerts you to S3 buckets that are configured to allow access to anyone on the internet or other AWS accounts, including AWS accounts outside of your organization. For each public or shared bucket, you receive findings into the source and level of public or shared access. For example, IAM Access Analyzer for S3 might show that a bucket has read or write access provided through a bucket access control list (ACL), a bucket policy, a Multi-Region Access Point policy, or an access point policy. With these findings, you can take immediate and precise corrective action to restore your bucket access to what you intended.

When reviewing an at-risk bucket in IAM Access Analyzer for S3, you can block all public access to the bucket with a single click. We recommend that you block all access to your buckets unless you require public access to support a specific use case. Before you block all public access, ensure that your applications will continue to work correctly without public access. For more information, see Blocking public access to your Amazon S3 storage.

You can also drill down into bucket-level permission settings to configure granular levels of access. For specific and verified use cases that require public access, such as static website hosting, public downloads, or cross-account sharing, you can acknowledge and record your intent for the bucket to remain public or shared by archiving the findings for the bucket. You can revisit and modify these bucket configurations at any time. You can also download your findings as a CSV report for auditing purposes.

IAM Access Analyzer for S3 is available at no extra cost on the Amazon S3 console. IAM Access Analyzer for S3 is powered by AWS Identity and Access Management (IAM) IAM Access Analyzer. To use IAM Access Analyzer for S3 in the Amazon S3 console, you must visit the IAM console and enable IAM Access Analyzer on a per-Region basis.

For more information about IAM Access Analyzer, see What is IAM Access Analyzer? in the *IAM User Guide*. For more information about IAM Access Analyzer for S3, review the following sections.

**⚠ Important**

- IAM Access Analyzer for S3 requires an account-level analyzer. To use IAM Access Analyzer for S3, you must visit IAM Access Analyzer and create an analyzer that has an account as the zone of trust. For more information, see Enabling IAM Access Analyzer in *IAM User Guide*.
- IAM Access Analyzer for S3 doesn't analyze the access point policy that's attached to cross-account access points. This behavior occurs because the access point and its policy are outside the zone of trust, that is, the account. Buckets that delegate access to a cross-account access point are listed under **Buckets with public access** if you haven't applied the `RestrictPublicBuckets` block public access setting to the bucket or account. When you apply the `RestrictPublicBuckets` block public access setting, the bucket is reported under **Buckets with access from other AWS accounts — including third-party AWS accounts**.
- When a bucket policy or bucket ACL is added or modified, IAM Access Analyzer generates and updates findings based on the change within 30 minutes. Findings related to account

level block public access settings might not be generated or updated for up to 6 hours after you change the settings. Findings related to Multi-Region Access Points might not be generated or updated for up to six hours after the Multi-Region Access Point is created, deleted, or you change its policy.

**Topics**

## What information does IAM Access Analyzer for S3 provide?

IAM Access Analyzer for S3 provides findings for buckets that can be accessed outside your AWS account. Buckets that are listed under **Buckets with public access** can be accessed by anyone on the internet. If IAM Access Analyzer for S3 identifies public buckets, you also see a warning at the top of the page that shows you the number of public buckets in your Region. Buckets listed under **Buckets with access from other AWS accounts — including third-party AWS accounts** are shared conditionally with other AWS accounts, including accounts outside of your organization.

For each bucket, IAM Access Analyzer for S3 provides the following information:

- **Bucket name**
- **Discovered by Access analyzer** - When IAM Access Analyzer for S3 discovered the public or shared bucket access.
- **Shared through** - How the bucket is shared—through a bucket policy, a bucket ACL, a Multi-Region Access Point policy, or an access point policy. Multi-Region Access Points and cross-account access points are reflected under access points. A bucket can be shared through both policies and ACLs. If you want to find and review the source for your bucket access, you can use

the information in this column as a starting point for taking immediate and precise corrective action.

- **Status** - The status of the bucket finding. IAM Access Analyzer for S3 displays findings for all public and shared buckets.
  - **Active** - Finding has not been reviewed.
  - **Archived** - Finding has been reviewed and confirmed as intended.
  - **All** - All findings for buckets that are public or shared with other AWS accounts, including AWS accounts outside of your organization.
- **Access level** - Access permissions granted for the bucket:
  - **List** - List resources.
  - **Read** - Read but not edit resource contents and attributes.
  - **Write** - Create, delete, or modify resources.
  - **Permissions** - Grant or modify resource permissions.
  - **Tagging** - Update tags associated with the resource.

## Enabling IAM Access Analyzer for S3

To use IAM Access Analyzer for S3, you must complete the following prerequisite steps.

1. Grant the required permissions.

   For more information, see Permissions Required to use IAM Access Analyzer in the *IAM User Guide*.
2. Visit IAM to create an account-level analyzer for each Region where you want to use IAM Access Analyzer.

   IAM Access Analyzer for S3 requires an account-level analyzer. To use IAM Access Analyzer for S3, you must create an analyzer that has an account as the zone of trust. For more information, see Enabling IAM Access Analyzer in *IAM User Guide*.

## Blocking all public access

If you want to block all access to a bucket in a single click, you can use the **Block all public access** button in IAM Access Analyzer for S3. When you block all public access to a bucket, no public access is granted. We recommend that you block all public access to your buckets unless you require

public access to support a specific and verified use case. Before you block all public access, ensure that your applications will continue to work correctly without public access.

If you don't want to block all public access to your bucket, you can edit your block public access settings on the Amazon S3 console to configure granular levels of access to your buckets. For more information, see Blocking public access to your Amazon S3 storage.

In rare events, IAM Access Analyzer for S3 might report no findings for a bucket that an Amazon S3 block public access evaluation reports as public. This happens because Amazon S3 block public access reviews policies for current actions and any potential actions that might be added in the future, leading to a bucket becoming public. On the other hand, IAM Access Analyzer for S3 only analyzes the current actions specified for the Amazon S3 service in the evaluation of access status.

**To block all public access to a bucket using IAM Access Analyzer for S3**

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the navigation pane on the left, under **Dashboards**, choose **Access analyzer for S3**.
3. In IAM Access Analyzer for S3, choose a bucket.
4. Choose **Block all public access**.
5. To confirm your intent to block all public access to the bucket, in **Block all public access (bucket settings)**, enter **`confirm`**.

   Amazon S3 blocks all public access to your bucket. The status of the bucket finding updates to **resolved**, and the bucket disappears from the IAM Access Analyzer for S3 listing. If you want to review resolved buckets, open IAM Access Analyzer on the IAM Console.

## Reviewing and changing bucket access

If you did not intend to grant access to the public or other AWS accounts, including accounts outside of your organization, you can modify the bucket ACL, bucket policy, the Multi-Region Access Point policy, or the access point policy to remove the access to the bucket. The **Shared through** column shows all sources of bucket access: bucket policy, bucket ACL, and/or access point policy. Multi-Region Access Points and cross-account access points are reflected under access points.

**To review and change a bucket policy, a bucket ACL, a Multi-Region Access Point, or an access point policy**

1. Open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the navigation pane, choose **Access analyzer for S3**.
3. To see whether public access or shared access is granted through a bucket policy, a bucket ACL, a Multi-Region Access Point policy, or an access point policy, look in the **Shared through** column.
4. Under **Buckets**, choose the name of the bucket with the bucket policy, bucket ACL, Multi-Region Access Point policy, or access point policy that you want to change or review.
5. If you want to change or view a bucket ACL:

   a. Choose **Permissions**.

   b. Choose **Access Control List**.

   c. Review your bucket ACL, and make changes as required.

   For more information, see Configuring ACLs.
6. If you want to change or review a bucket policy:

   a. Choose **Permissions**.

   b. Choose **Bucket Policy**.

   c. Review or change your bucket policy as required.

   For more information, see Adding a bucket policy by using the Amazon S3 console.
7. If you want to change or view a Multi-Region Access Point policy:

   a. Choose **Multi-Region Access Point**.

   b. Choose the Multi-Region Access Point name.

   c. Review or change your Multi-Region Access Point policy as required.

   For more information, see Permissions.
8. If you want to review or change an access point policy:

   a. Choose **access points**.

   b. Choose the access point name.

   c. Review or change access as required.

For more information, see Using Amazon S3 access points with the Amazon S3 console.

If you edit or remove a bucket ACL, a bucket policy, or an access point policy to remove public or shared access, the status for the bucket findings updates to resolved. The resolved bucket findings disappear from the IAM Access Analyzer for S3 listing, but you can view them in IAM Access Analyzer.

## Archiving bucket findings

If a bucket grants access to the public or other AWS accounts, including accounts outside of your organization, to support a specific use case (for example, a static website, public downloads, or cross-account sharing), you can archive the finding for the bucket. When you archive bucket findings, you acknowledge and record your intent for the bucket to remain public or shared. Archived bucket findings remain in your IAM Access Analyzer for S3 listing so that you always know which buckets are public or shared.

**To archive bucket findings in IAM Access Analyzer for S3**

1. Open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the navigation pane, choose **Access analyzer for S3**.
3. In IAM Access Analyzer for S3, choose an active bucket.
4. To acknowledge your intent for this bucket to be accessed by the public or other AWS accounts, including accounts outside of your organization, choose **Archive**.
5. Enter **`confirm`**, and choose **Archive**.

## Activating an archived bucket finding

After you archive findings, you can always revisit them and change their status back to active, indicating that the bucket requires another review.

**To activate an archived bucket finding in IAM Access Analyzer for S3**

1. Open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the navigation pane, choose **Access analyzer for S3**.
3. Choose the archived bucket findings.

4. Choose **Mark as active**.

### Viewing finding details

If you need to see more information about a bucket, you can open the bucket finding details in IAM Access Analyzer on the IAM Console.

**To view finding details in IAM Access Analyzer for S3**

1. Open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the navigation pane, choose **Access analyzer for S3**.
3. In IAM Access Analyzer for S3, choose a bucket.
4. Choose **View details**.

   The finding details open in IAM Access Analyzer on the IAM Console.

### Downloading an IAM Access Analyzer for S3 report

You can download your bucket findings as a CSV report that you can use for auditing purposes. The report includes the same information that you see in IAM Access Analyzer for S3 on the Amazon S3 console.

**To download a report**

1. Open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the navigation pane on the left, choose **Access analyzer for S3**.
3. In the Region filter, choose the Region.

   IAM Access Analyzer for S3 updates to shows buckets for the chosen Region.
4. Choose **Download report**.

   A CSV report is generated and saved to your computer.

## Verifying bucket ownership with bucket owner condition

Amazon S3 bucket owner condition ensures that the buckets you use in your S3 operations belong to the AWS accounts that you expect.

Most S3 operations read from or write to specific S3 buckets. These operations include uploading, copying, and downloading objects, retrieving or modifying bucket configurations, and retrieving or modifying object configurations. When you perform these operations, you specify the bucket that you want to use by including its name with the request. For example, to retrieve an object from S3, you make a request that specifies the name of a bucket and the object key to retrieve from that bucket.

Because Amazon S3 identifies buckets based on their names, an application that uses an incorrect bucket name in a request could inadvertently perform operations against a different bucket than expected. To help avoid unintentional bucket interactions in situations like this, you can use *bucket owner condition*. Bucket owner condition enables you to verify that the target bucket is owned by the expected AWS account, providing an additional layer of assurance that your S3 operations are having the effects you intend.

**Topics**

## When to use bucket owner condition

We recommend using bucket owner condition whenever you perform a supported S3 operation and know the account ID of the expected bucket owner. Bucket owner condition is available for all S3 object operations and most S3 bucket operations. For a list of S3 operations that don't support bucket owner condition, see Restrictions and limitations.

To see the benefit of using bucket owner condition, consider the following scenario involving AWS customer Bea:

1. Bea develops an application that uses Amazon S3. During development, Bea uses her testing-only AWS account to create a bucket named `bea-data-test`, and configures her application to make requests to `bea-data-test`.
2. Bea deploys her application, but forgets to reconfigure the application to use a bucket in her production AWS account.
3. In production, Bea's application makes requests to `bea-data-test`, which succeed. This results in production data being written to the bucket in Bea's test account.

Bea can help protect against situations like this by using bucket owner condition. With bucket owner condition, Bea can include the AWS account ID of the expected bucket owner in her requests. Amazon S3 then checks the account ID of the bucket owner before processing each request. If the actual bucket owner doesn't match the expected bucket owner, the request fails.

If Bea uses bucket owner condition, the scenario described earlier won't result in Bea's application inadvertently writing to a test bucket. Instead, the requests that her application makes at step 3 will fail with an `Access Denied` error message. By using bucket owner condition, Bea helps eliminate the risk of accidentally interacting with buckets in the wrong AWS account.

## Verifying a bucket owner

To use bucket owner condition, you include a parameter with your request that specifies the expected bucket owner. Most S3 operations involve only a single bucket, and require only this single parameter to use bucket owner condition. For `CopyObject` operations, this first parameter specifies the expected owner of the destination bucket, and you include a second parameter to specify the expected owner of the source bucket.

When you make a request that includes a bucket owner condition parameter, S3 checks the account ID of the bucket owner against the specified parameter before processing the request. If the parameter matches the bucket owner's account ID, S3 processes the request. If the parameter doesn't match the bucket owner's account ID, the request fails with an `Access Denied` error message.

You can use bucket owner condition with the AWS Command Line Interface (AWS CLI), AWS SDKs, and Amazon S3 REST APIs. When using bucket owner condition with the AWS CLI and Amazon S3 REST APIs, use the following parameter names.

| Access method | Parameter for non-copy operations | Copy operation source parameter | Copy operation destination parameter |
|---|---|---|---|
| AWS CLI | `--expected-bucket-owner` | `--expected-source-bucket-owner` | `--expected-bucket-owner` |
| Amazon S3 REST APIs | `x-amz-expected-bucket-owner` header | `x-amz-source-expected-bucket-owner` header | `x-amz-expected-bucket-owner` header |

The parameter names that are required to use bucket owner condition with the AWS SDKs vary depending on the language. To determine the required parameters, see the SDK documentation for your desired language. You can find the SDK documentation at Tools to Build on AWS.

## Examples

The following examples show how you can implement bucket owner condition in Amazon S3 using the AWS CLI or the AWS SDK for Java 2.x.

### Example

#### *Example: Upload an object*

The following example uploads an object to S3 bucket *amzn-s3-demo-bucket1*, using bucket owner condition to ensure that *amzn-s3-demo-bucket1* is owned by AWS account 111122223333.

AWS CLI

```
aws s3api put-object \
                --bucket amzn-s3-demo-bucket1 --key exampleobject --
body example_file.txt \
                --expected-bucket-owner 111122223333
```

AWS SDK for Java 2.x

```
public void putObjectExample() {
    S3Client s3Client = S3Client.create();;
    PutObjectRequest request = PutObjectRequest.builder()
            .bucket("amzn-s3-demo-bucket1")
            .key("exampleobject")
            .expectedBucketOwner("111122223333")
            .build();
    Path path = Paths.get("example_file.txt");
    s3Client.putObject(request, path);
}
```

### Example

#### *Example: Copy an object*

The following example copies the object `object1` from S3 bucket *amzn-s3-demo-bucket1* to S3 bucket *amzn-s3-demo-bucket2*. It uses bucket owner condition to ensure that the buckets are owned by the expected accounts according to the following table.

| Bucket | Expected owner |
| --- | --- |
| *amzn-s3-demo-bucket1* | 111122223333 |
| *amzn-s3-demo-bucket2* | 444455556666 |

AWS CLI

```
aws s3api copy-object --copy-source amzn-s3-demo-bucket1/object1 \
                            --bucket amzn-s3-demo-bucket2 --key object1copy \
                            --expected-source-bucket-owner 111122223333 --expected-
bucket-owner 444455556666
```

AWS SDK for Java 2.x

```
public void copyObjectExample() {
        S3Client s3Client = S3Client.create();
        CopyObjectRequest request = CopyObjectRequest.builder()
                .copySource("amzn-s3-demo-bucket1/object1")
                .destinationBucket("amzn-s3-demo-bucket2")
                .destinationKey("object1copy")
                .expectedSourceBucketOwner("111122223333")
                .expectedBucketOwner("444455556666")
                .build();
        s3Client.copyObject(request);
    }
```

**Example**

***Example: Retrieve a bucket policy***

The following example retrieves the access policy for S3 bucket *amzn-s3-demo-bucket1*, using bucket owner condition to ensure that *amzn-s3-demo-bucket1* is owned by AWS account 111122223333.

AWS CLI

```
aws s3api get-bucket-policy --bucket amzn-s3-demo-bucket1 --expected-bucket-
owner 111122223333
```

AWS SDK for Java 2.x

```
public void getBucketPolicyExample() {
    S3Client s3Client = S3Client.create();
    GetBucketPolicyRequest request = GetBucketPolicyRequest.builder()
            .bucket("amzn-s3-demo-bucket1")
            .expectedBucketOwner("111122223333")
            .build();
    try {
        GetBucketPolicyResponse response = s3Client.getBucketPolicy(request);
    }
    catch (S3Exception e) {
        // The call was transmitted successfully, but Amazon S3 couldn't process
        // it, so it returned an error response.
        e.printStackTrace();
    }
}
```

## Restrictions and limitations

Amazon S3 bucket owner condition has the following restrictions and limitations:

- The value of the bucket owner condition parameter must be an AWS account ID (12-digit numeric value). Service principals aren't supported.
- Bucket owner condition isn't available for CreateBucket, ListBuckets, or any of the operations included in AWS S3 Control. Amazon S3 ignores any bucket owner condition parameters included with requests to these operations.
- Bucket owner condition only verifies that the account specified in the verification parameter owns the bucket. Bucket owner condition doesn't check the configuration of the bucket. It also doesn't guarantee that the bucket's configuration meets any specific conditions or matches any past state.

# Controlling ownership of objects and disabling ACLs for your bucket

S3 Object Ownership is an Amazon S3 bucket-level setting that you can use to control ownership of objects uploaded to your bucket and to disable or enable access control lists (ACLs). By default, Object Ownership is set to the Bucket owner enforced setting and all ACLs are disabled. When ACLs are disabled, the bucket owner owns all the objects in the bucket and manages access to data exclusively using access management policies.

A majority of modern use cases in Amazon S3 no longer require the use of ACLs, and we recommend that you keep ACLs disabled except in unusual circumstances where you must control access for each object individually. With ACLs disabled, you can use policies to more easily control access to every object in your bucket, regardless of who uploaded the objects in your bucket.

Object Ownership has three settings that you can use to control ownership of objects uploaded to your bucket and to disable or enable ACLs:

**ACLs disabled**

- **Bucket owner enforced (default)** – ACLs are disabled, and the bucket owner automatically owns and has full control over every object in the bucket. ACLs no longer affect permissions to data in the S3 bucket. The bucket uses policies to define access control.

**ACLs enabled**

- **Bucket owner preferred** – The bucket owner owns and has full control over new objects that other accounts write to the bucket with the `bucket-owner-full-control` canned ACL.
- **Object writer** – The AWS account that uploads an object owns the object, has full control over it, and can grant other users access to it through ACLs.

For the majority of modern use cases in S3, we recommend that you keep ACLs disabled by applying the Bucket owner enforced setting and using your bucket policy to share data with users outside of your account as needed. This approach simplifies permissions management. You can disable ACLs on both newly created and already existing buckets. For newly created buckets, ACLs are disabled by default. In the case of an existing bucket that already has objects in it, after you disable ACLs, the object and bucket ACLs are no longer part of an access evaluation, and access is granted or denied on the basis of policies. For existing buckets, you can re-enable ACLs at any time after you disable them, and your preexisting bucket and object ACLs are restored.

Before you disable ACLs, we recommend that you review your bucket policy to ensure that it covers all the ways that you intend to grant access to your bucket outside of your account. After you disable ACLs, your bucket accepts only PUT requests that do not specify an ACL or PUT requests with bucket owner full control ACLs, such as the `bucket-owner-full-control` canned ACL or equivalent forms of this ACL expressed in XML. Existing applications that support bucket owner full control ACLs see no impact. PUT requests that contain other ACLs (for example, custom grants to certain AWS accounts) fail and return a `400` error with the error code `AccessControlListNotSupported`.

In contrast, a bucket with the Bucket owner preferred setting continues to accept and honor bucket and object ACLs. With this setting, new objects that are written with the `bucket-owner-full-control` canned ACL are automatically owned by the bucket owner rather than the object writer. All other ACL behaviors remain in place. To require all Amazon S3 PUT operations to include the `bucket-owner-full-control` canned ACL, you can add a bucket policy that allows only object uploads using this ACL.

To see which Object Ownership settings are applied to your buckets, you can use Amazon S3 Storage Lens metrics. S3 Storage Lens is a cloud-storage analytics feature that you can use to gain organization-wide visibility into object-storage usage and activity. For more information, see Using S3 Storage Lens to find Object Ownership settings.

> **Note**
>
> For more information about using the Amazon S3 Express One Zone storage class with directory buckets, see What is S3 Express One Zone? and Directory buckets.

## Object Ownership settings

This table shows the impact that each Object Ownership setting has on ACLs, objects, object ownership, and object uploads.

| Setting | Applies to | Effect on object ownership | Effect on ACLs | Uploads accepted |
|---|---|---|---|---|
| Bucket owner enforced (default) | All new and existing objects | Bucket owner owns every object. | ACLs are disabled and no longer | Uploads with bucket owner full control ACLs |

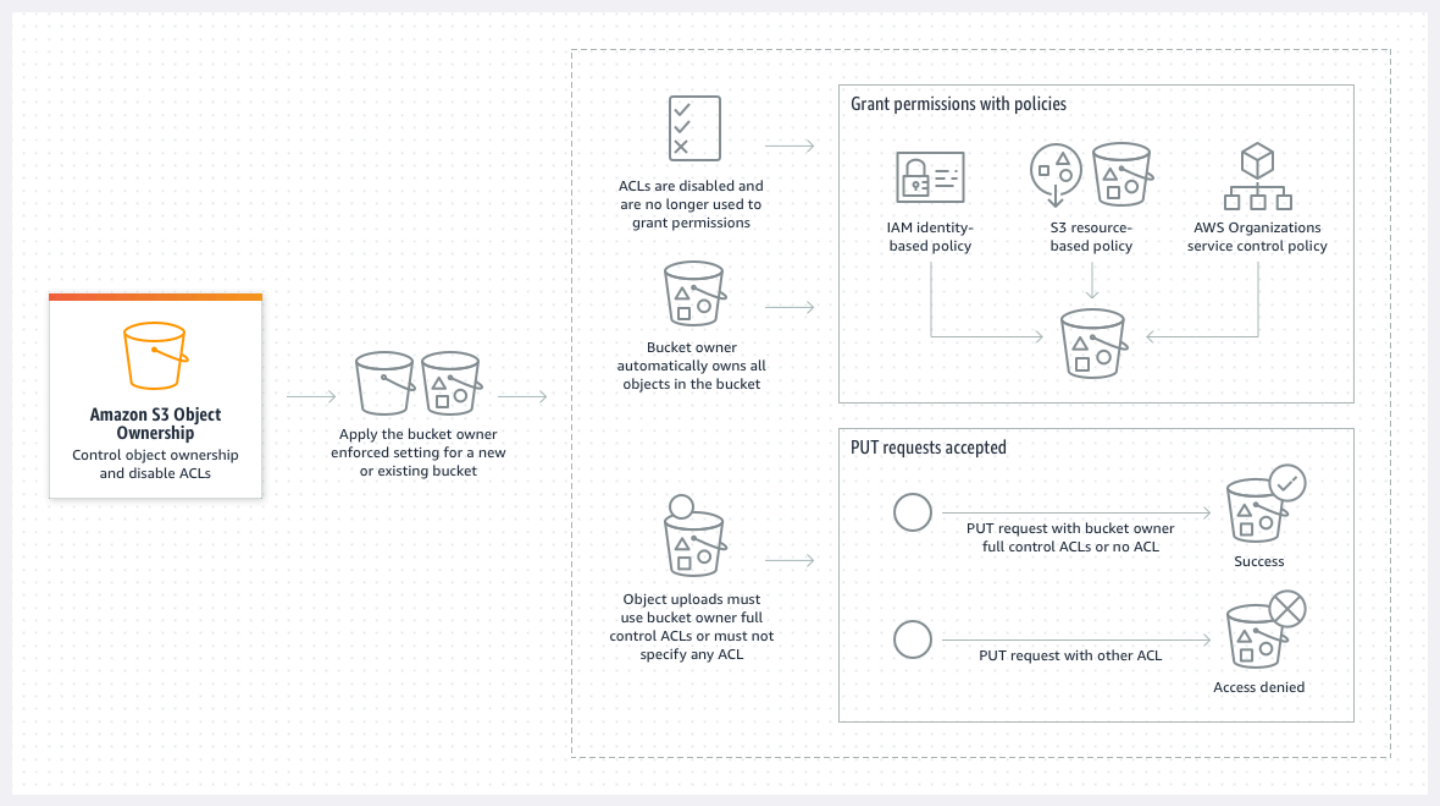
| Setting | Applies to | Effect on object ownership | Effect on ACLs | Uploads accepted |
|---|---|---|---|---|
| | | | affect access permissions to your bucket. Requests to set or update ACLs fail. However, requests to read ACLs are supported.<br><br>Bucket owner has full ownership and control.<br><br>Object writer no longer has full ownership and control. | or uploads that don't specify an ACL |

| Setting | Applies to | Effect on object ownership | Effect on ACLs | Uploads accepted |
|---|---|---|---|---|
| Bucket owner preferred | New objects | If an object upload includes the `bucket-owner-full-control` canned ACL, the bucket owner owns the object.<br><br>Objects uploaded with other ACLs are owned by the writing account. | ACLs can be updated and can grant permissions.<br><br>If an object upload includes the `bucket-owner-full-control` canned ACL, the bucket owner has full control access, and the object writer no longer has full control access. | All uploads |
| Object writer | New objects | Object writer owns the object. | ACLs can be updated and can grant permissions.<br><br>Object writer has full control access. | All uploads |

## Changes introduced by disabling ACLs

When the Bucket owner enforced setting for Object Ownership is applied, ACLs are disabled and you automatically own and take full control over every object in the bucket without taking any additional actions. Bucket owner enforced is the default setting for all newly created buckets. After the Bucket owner enforced setting is applied, you will see three changes:

- All bucket ACLs and object ACLs are disabled, which gives full access to you, as the bucket owner. When you perform a read ACL request on your bucket or object, you will see that full access is given only to the bucket owner.
- You, as the bucket owner, automatically own and have full control over every object in your bucket.
- ACLs no longer affect access permissions to your bucket. As a result, access control for your data is based on policies, such as IAM policies, S3 bucket policies, VPC endpoint policies, and Organizations SCPs.



If you use S3 Versioning, the bucket owner owns and has full control over all object versions in your bucket. Applying the Bucket owner enforced setting does not add a new version of an object.

New objects can be uploaded to your bucket only if they use bucket owner full control ACLs or don't specify an ACL. Object uploads fail if they specify any other ACL. For more information, see Troubleshooting.

Because the following example `PutObject` operation using the AWS Command Line Interface (AWS CLI) includes the `bucket-owner-full-control` canned ACL, the object can be uploaded to a bucket with disabled ACLs.

```
aws s3api put-object --bucket amzn-s3-demo-bucket --key key-name --body path-to-file --
acl bucket-owner-full-control
```

Because the following `PutObject` operation doesn't specify an ACL, it also succeeds for a bucket with disabled ACLs.

```
aws s3api put-object --bucket amzn-s3-demo-bucket --key key-name --body path-to-file
```

> **Note**
>
> If other AWS accounts need access to objects after uploading, you must grant additional permissions to those accounts through bucket policies. For more information, see Walkthroughs that use policies to manage access to your Amazon S3 resources.

#### Re-enabling ACLs

You can re-enable ACLs by changing from the Bucket owner enforced setting to another Object Ownership setting at any time. If you used object ACLs for permissions management before you applied the Bucket owner enforced setting and you didn't migrate these object ACL permissions to your bucket policy, after you re-enable ACLs, these permissions are restored. Additionally, objects written to the bucket while the Bucket owner enforced setting was applied are still owned by the bucket owner.

For example, if you change from the Bucket owner enforced setting back to the Object writer setting, you, as the bucket owner, no longer own and have full control over objects that were previously owned by other AWS accounts. Instead, the uploading accounts again own these objects. Objects owned by other accounts use ACLs for permissions, so you can't use policies to grant permissions to these objects. However, you, as the bucket owner, still own any objects that were written to the bucket while the Bucket owner enforced setting was applied. These objects are not owned by the object writer, even if you re-enable ACLs.

For instructions on enabling and managing ACLs using the AWS Management Console, AWS Command Line Interface (CLI), REST API, or AWS SDKs, see Configuring ACLs.

### Prerequisites for disabling ACLs

Before you disable ACLs for an existing bucket, complete the following prerequisites.

**Review bucket and object ACLs and migrate ACL permissions**

When you disable ACLs, permissions granted by bucket and object ACLs no longer affect access. Before you disable ACLs, review your bucket and object ACLs.

If your bucket ACLs grant read or write permissions to others outside of your account, you must migrate these permissions to your bucket policy before you can apply the Bucket owner enforced setting. If you don't migrate bucket ACLs that grant read or write access outside of your account, your request to apply the Bucket owner enforced setting fails and returns the InvalidBucketAclWithObjectOwnership error code.

For example, if you want to disable ACLs for a bucket that receives server access logs, you must migrate the bucket ACL permissions for the S3 log delivery group to the logging service principal in a bucket policy. For more information, see Grant access to the S3 log delivery group for server access logging.

If you want the object writer to maintain full control of the object that they upload, object writer is the best Object Ownership setting for your use case. If you want to control access at the individual object level, bucket owner preferred is the best choice. These use cases are uncommon.

To review ACLs and migrate ACL permissions to bucket policies, see Prerequisites for disabling ACLs.

**Identify requests that required an ACL for authorization**

To identify Amazon S3 requests that required ACLs for authorization, you can use the `aclRequired` value in Amazon S3 server access logs or AWS CloudTrail. If the request required an ACL for authorization or if you have PUT requests that specify an ACL, the string is `Yes`. If no ACLs were required, or if you are setting a `bucket-owner-full-control` canned ACL, or if the requests are allowed by your bucket policy, the `aclRequired` value string is "`-`" in Amazon S3 server access logs and is absent in CloudTrail. For more information about the expected `aclRequired` values, see `aclRequired` values for common Amazon S3 requests.

If you have `PutBucketAcl` or `PutObjectAcl` requests with headers that grant ACL-based permissions, with the exception of the `bucket-owner-full-control` canned ACL, you must remove those headers before you can disable ACLs. Otherwise, your requests will fail.

For all other requests that required an ACL for authorization, migrate those ACL permissions to bucket policies. Then, remove any bucket ACLs before you enable the bucket owner enforced setting.

> **Note**
>
> Do not remove object ACLs. Otherwise, applications that rely on object ACLs for permissions will lose access.

If you see that no requests required an ACL for authorization, you can proceed to disable ACLs. For more information about identifying requests, see Using Amazon S3 server access logs to identify requests and Identifying Amazon S3 requests using CloudTrail.

**Review and update bucket policies that use ACL-related condition keys**

After you apply the Bucket owner enforced setting to disable ACLs, new objects can be uploaded to your bucket only if the request uses bucket owner full control ACLs or doesn't specify an ACL. Before disabling ACLs, review your bucket policy for ACL-related condition keys.

If your bucket policy uses an ACL-related condition key to require the `bucket-owner-full-control` canned ACL (for example, `s3:x-amz-acl`), you don't need to update your bucket policy. The following bucket policy uses the `s3:x-amz-acl` to require the `bucket-owner-full-control` canned ACL for S3 `PutObject` requests. This policy *still* requires the object writer to specify the `bucket-owner-full-control` canned ACL. However, buckets with ACLs disabled still accept this ACL, so requests continue to succeed with no client-side changes required.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "Only allow writes to my bucket with bucket owner full control",
            "Effect": "Allow",
            "Principal": {
                "AWS": [
                    "arn:aws:iam::111122223333:user/ExampleUser"
                ]
            },
            "Action": [
                "s3:PutObject"
            ],
            "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/*",
            "Condition": {
                "StringEquals": {
                    "s3:x-amz-acl": "bucket-owner-full-control"
```

```
                }
            }
        }
    ]
}
```

However, if your bucket policy uses an ACL-related condition key that requires a different ACL, you must remove this condition key. This example bucket policy requires the `public-read` ACL for S3 `PutObject` requests and therefore must be updated before disabling ACLs.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "Only allow writes to my bucket with public read access",
            "Effect": "Allow",
            "Principal": {
                "AWS": [
                    "arn:aws:iam::111122223333:user/ExampleUser"                ]
            },
            "Action": [
                "s3:PutObject"
            ],
            "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/*",
            "Condition": {
                "StringEquals": {
                    "s3:x-amz-acl": "public-read"
                }
            }
        }
    ]
}
```

## Object Ownership permissions

To apply, update, or delete an Object Ownership setting for a bucket, you need the `s3:PutBucketOwnershipControls` permission. To return the Object Ownership setting for a bucket, you need the `s3:GetBucketOwnershipControls` permission. For more information, see Setting Object Ownership when you create a bucket and Viewing the Object Ownership setting for an S3 bucket.

## Disabling ACLs for all new buckets

By default, all new buckets are created with the Bucket owner enforced setting applied and ACLs are disabled. We recommend keeping ACLs disabled. As a general rule, we recommend using S3 resource-based policies (bucket policies and access point policies) or IAM policies for access control instead of ACLs. Policies are a simplified and more flexible access control option. With bucket policies and access point policies, you can define rules that apply broadly across all requests to your Amazon S3 resources.

## Replication and Object Ownership

When you use S3 replication and the source and destination buckets are owned by different AWS accounts, you can disable ACLs (with the Bucket owner enforced setting for Object Ownership) to change replica ownership to the AWS account that owns the destination bucket. This setting mimics the existing owner override behavior without the need of the `s3:ObjectOwnerOverrideToBucketOwner` permission. All objects that are replicated to the destination bucket with the Bucket owner enforced setting are owned by the destination bucket owner. For more information about the owner override option for replication configurations, see Changing the replica owner.

## Setting Object Ownership

You can apply an Object Ownership setting by using the Amazon S3 console, AWS CLI, AWS SDKs, Amazon S3 REST API, or AWS CloudFormation. The following REST API and AWS CLI commands support Object Ownership:

| REST API | AWS CLI | Description |
|---|---|---|
| PutBucketOwnershipControls | put-bucket-ownership-controls | Creates or modifies the Object Ownership setting for an existing S3 bucket. |
| CreateBucket | create-bucket | Creates a bucket using the `x-amz-object-ownership` request header to specify the Object Ownership setting. |

| REST API | AWS CLI | Description |
| --- | --- | --- |
| GetBucketOwnershipControls | get-bucket-ownership-controls | Retrieves the Object Ownership setting for an Amazon S3 bucket. |
| DeleteBucketOwnershipControls | delete-bucket-ownership-controls | Deletes the Object Ownership setting for an Amazon S3 bucket. |

For more information about applying and working with Object Ownership settings, see the following topics.

**Topics**

- Setting Object Ownership when you create a bucket
- Setting Object Ownership on an existing bucket
- Viewing the Object Ownership setting for an S3 bucket
- Disabling ACLs for all new buckets and enforcing Object Ownership
- Troubleshooting

## Prerequisites for disabling ACLs

If your bucket ACL grants access outside of your AWS account, before you disable ACLs, you must migrate your bucket ACL permissions to your bucket policy and reset your bucket ACL to the default private ACL. If you don't migrate these bucket ACLs, your request to apply the Bucket owner enforced setting to disable ACLs fails and returns the InvalidBucketAclWithObjectOwnership error code. We also recommend that you review your object ACL permissions and migrate them to your bucket policy. For more information about other suggested prerequisites, see Prerequisites for disabling ACLs.

Each of your existing bucket and object ACLs has an equivalent in an IAM policy. The following bucket policy examples show you how `READ` and `WRITE` permissions for bucket and object ACLs map to IAM permissions. For more information about how each ACL translates to IAM permissions, see Mapping of ACL permissions and access policy permissions.

To review and migrate ACL permissions to bucket policies, see the following topics.

**Topics**

### Bucket policies examples

These example bucket policies show you how to migrate `READ` and `WRITE` bucket and object ACL permissions for a third-party AWS account to a bucket policy. `READ_ACP` and `WRITE_ACP` ACLs are less relevant for policies because they grant ACL-related permissions (`s3:GetBucketAcl`, `s3:GetObjectAcl`, `s3:PutBucketAcl`, and `s3:PutObjectAcl`).

#### Example – READ ACL for a bucket

If your bucket had a `READ` ACL that grants AWS account *111122223333* permission to list the contents of your bucket, you can write a bucket policy that grants `s3:ListBucket`, `s3:ListBucketVersions`, `s3:ListBucketMultipartUploads` permissions for your bucket.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "Permission to list the objects in a bucket",
            "Effect": "Allow",
            "Principal": {
                "AWS": [

                    "arn:aws:iam::111122223333:root"
                ]
            },
            "Action": [
                "s3:ListBucket",
                "s3:ListBucketVersions",
                "s3:ListBucketMultipartUploads"
            ],
            "Resource": "arn:aws:s3:::DOC-EXAMPLE-BUCKET"
        }
```

```
    ]
}
```

### Example – READ ACLs for every object in a bucket

If every object in your bucket has a READ ACL that grants access to AWS account *111122223333*, you can write a bucket policy that grants `s3:GetObject` and `s3:GetObjectVersion` permissions to this account for every object in your bucket.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "Read permission for every object in a bucket",
            "Effect": "Allow",
            "Principal": {
                "AWS": [
                    "arn:aws:iam::111122223333:root"
                ]
            },
            "Action": [
                "s3:GetObject",
                "s3:GetObjectVersion"
            ],
            "Resource": "arn:aws:s3:::DOC-EXAMPLE-BUCKET/*"
        }
    ]
}
```

This example resource element grants access to a specific object.

```
"Resource": "arn:aws:s3:::DOC-EXAMPLE-BUCKET/OBJECT-KEY"
```

### Example – WRITE ACL that grants permissions to write objects to a bucket

If your bucket has a WRITE ACL that grants AWS account *111122223333* permission to write objects to your bucket, you can write a bucket policy that grants `s3:PutObject` permission for your bucket.

```
{
```

```
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "Permission to write objects to a bucket",
            "Effect": "Allow",
            "Principal": {
                "AWS": [
                    "arn:aws:iam::111122223333:root"
                ]
            },
            "Action": [
                "s3:PutObject"
            ],
            "Resource": "arn:aws:s3:::DOC-EXAMPLE-BUCKET/*"
        }
    ]
}
```

### Using the S3 console to review and migrate ACL permissions

#### To review a bucket's ACL permissions

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the **Buckets** list, choose the bucket name.
3. Choose the **Permissions** tab.
4. Under **Access control list (ACL)**, review your bucket ACL permissions.

#### To review an object's ACL permissions

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the **Buckets** list, choose the bucket name containing your object.
3. In the **Objects** list, choose your object name.
4. Choose the **Permissions** tab.
5. Under **Access control list (ACL)**, review your object ACL permissions.

**To migrate ACL permissions and update your bucket ACL**

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the **Buckets** list, choose the bucket name.
3. On the **Permissions** tab, under **Bucket policy**, choose **Edit**.
4. In the **Policy** box, add or update your bucket policy.

   For example bucket policies, see Bucket policies examples and Example walkthroughs.
5. Choose **Save changes**.
6. Update your bucket ACL to remove ACL grants to other groups or AWS accounts.
7. Apply the **Bucket owner enforced** setting for Object Ownership.

**Using the AWS CLI to review and migrate ACL permissions**

1. To return the bucket ACL for your bucket, use the get-bucket-acl AWS CLI command:

   ```
   aws s3api get-bucket-acl --bucket amzn-s3-demo-bucket
   ```

   For example, this bucket ACL grants `WRITE` and `READ` access to a third-party account. In this ACL, the third-party account is identified by the canonical user ID. To apply the Bucket owner enforced setting and disable ACLs, you must migrate these permissions for the third-party account to a bucket policy.

   ```
   {
       "Owner": {
           "DisplayName": "DOC-EXAMPLE-ACCOUNT-OWNER",
           "ID": "852b113e7a2f25102679df27bb0ae12b3f85be6BucketOwnerCanonicalUserID"
       },
       "Grants": [
           {
               "Grantee": {
                   "DisplayName": "DOC-EXAMPLE-ACCOUNT-OWNER",
                   "ID":
    "852b113e7a2f25102679df27bb0ae12b3f85be6BucketOwnerCanonicalUserID",
                   "Type": "CanonicalUser"
               },
               "Permission": "FULL_CONTROL"
   ```

```
        },
        {
            "Grantee": {
                "DisplayName": "THIRD-PARTY-EXAMPLE-ACCOUNT",
                "ID":
 "72806de9d1ae8b171cca9e2494a8d1335dfced4ThirdPartyAccountCanonicalUserID",
                "Type": "CanonicalUser"
            },
            "Permission": "READ"
        },
        {
            "Grantee": {
                "DisplayName": "THIRD-PARTY-EXAMPLE-ACCOUNT",
                "ID":
 "72806de9d1ae8b171cca9e2494a8d1335dfced4ThirdPartyAccountCanonicalUserID",
                "Type": "CanonicalUser"
            },
            "Permission": "WRITE"
        }
    ]
}
```

For other example ACLs, see Example walkthroughs.

2. Migrate your bucket ACL permissions to a bucket policy:

   This example bucket policy grants `s3:PutObject` and `s3:ListBucket` permissions for a third-party account. In the bucket policy, the third-party account is identified by the AWS account ID (*111122223333*).

```
aws s3api put-bucket-policy --bucket DOC-EXAMPLE-BUCKET --policy file://policy.json

policy.json:
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "PolicyForCrossAccountAllowUpload",
            "Effect": "Allow",
            "Principal": {
                "AWS": [
                    "arn:aws:iam::111122223333:root"
                ]
```

```
            },
            "Action": [
                "s3:PutObject",
                "s3:ListBucket"
            ],
            "Resource": [
             "arn:aws:s3:::DOC-EXAMPLE-BUCKET",
             "arn:aws:s3:::DOC-EXAMPLE-BUCKET/*"
        }
    ]
}
```

For more example bucket policies, see Bucket policies examples and Example walkthroughs.

3. To return the ACL for a specific object, use the get-object-acl AWS CLI command.

```
aws s3api get-object-acl --bucket amzn-s3-demo-bucket --key EXAMPLE-OBJECT-KEY
```

4. If required, migrate object ACL permissions to your bucket policy.

   This example resource element grants access to a specific object in a bucket policy.

```
"Resource": "arn:aws:s3:::amzn-s3-demo-bucket/EXAMPLE-OBJECT-KEY"
```

5. Reset the ACL for your bucket to the default ACL.

```
aws s3api put-bucket-acl --bucket amzn-s3-demo-bucket --acl private
```

6. Apply the Bucket owner enforced setting for Object Ownership.

### Example walkthroughs

The following examples show you how to migrate ACL permissions to bucket policies for specific use cases.

### Topics

- Grant access to the S3 log delivery group for server access logging
- Grant public read access to the objects in a bucket
- Grant Amazon ElastiCache (Redis OSS) access to your S3 bucket

### Grant access to the S3 log delivery group for server access logging

If you want to apply the Bucket owner enforced setting to disable ACLs for a server access logging destination bucket (also known as a *target bucket*), you must migrate bucket ACL permissions for the S3 log delivery group to the logging service principal (`logging.s3.amazonaws.com`) in a bucket policy. For more information about log delivery permissions, see Permissions for log delivery.

This bucket ACL grants `WRITE` and `READ_ACP` access to the S3 log delivery group:

```
{
    "Owner": {
        "DisplayName": "DOC-EXAMPLE-ACCOUNT-OWNER",
        "ID": "852b113e7a2f25102679df27bb0ae12b3f85be6BucketOwnerCanonicalUserID"
    },
    "Grants": [
        {
            "Grantee": {
                "Type": "CanonicalUser",
                "DisplayName": "DOC-EXAMPLE-ACCOUNT-OWNER",
                "ID":
 "852b113e7a2f25102679df27bb0ae12b3f85be6BucketOwnerCanonicalUserID"
            },
            "Permission": "FULL_CONTROL"
        },
        {
            "Grantee": {
                "Type": "Group",
                "URI": "http://acs.amazonaws.com/groups/s3/LogDelivery"
            },
            "Permission": "WRITE"
        },
        {
            "Grantee": {
                "Type": "Group",
                "URI": "http://acs.amazonaws.com/groups/s3/LogDelivery"
            },
            "Permission": "READ_ACP"
        }
    ]
}
```

**To migrate bucket ACL permissions for the S3 log delivery group to the logging service principal in a bucket policy**

1. Add the following bucket policy to your destination bucket, replacing the example values.

```
aws s3api put-bucket-policy --bucket amzn-s3-demo-bucket --policy file://
policy.json

policy.json:      {
    {
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "S3ServerAccessLogsPolicy",
            "Effect": "Allow",
            "Principal": {
                "Service": "logging.s3.amazonaws.com"
            },
            "Action": [
                "s3:PutObject"
            ],
            "Resource": "arn:aws:s3:::DOC-EXAMPLE-BUCKET/EXAMPLE-LOGGING-PREFIX*",
            "Condition": {
                "ArnLike": {
                    "aws:SourceArn": "arn:aws:s3:::SOURCE-BUCKET-NAME"
                },
                "StringEquals": {
                    "aws:SourceAccount": "SOURCE-AWS-ACCOUNT-ID"
                }
            }
        }
    ]
}
```

2. Reset the ACL for your destination bucket to the default ACL.

```
aws s3api put-bucket-acl --bucket amzn-s3-demo-bucket --acl private
```

3. Apply the Bucket owner enforced setting for Object Ownership to your destination bucket.

### Grant public read access to the objects in a bucket

If your object ACLs grant public read access to all of the objects in your bucket, you can migrate these ACL permissions to a bucket policy.

This object ACL grants public read access to an object in a bucket:

```
{
    "Owner": {
        "DisplayName": "DOC-EXAMPLE-ACCOUNT-OWNER",
        "ID": "852b113e7a2f25102679df27bb0ae12b3f85be6BucketOwnerCanonicalUserID"
    },
    "Grants": [
        {
            "Grantee": {
                "DisplayName": "DOC-EXAMPLE-ACCOUNT-OWNER",
                "ID":
 "852b113e7a2f25102679df27bb0ae12b3f85be6BucketOwnerCanonicalUserID",
                "Type": "CanonicalUser"
            },
            "Permission": "FULL_CONTROL"
        },
        {
            "Grantee": {
                "Type": "Group",
                "URI": "http://acs.amazonaws.com/groups/global/AllUsers"
            },
            "Permission": "READ"
        }
    ]
}
```

### To migrate public read ACL permissions to a bucket policy

1. To grant public read access to all of the objects in your bucket, add the following bucket policy, replacing the example values.

   ```
   aws s3api put-bucket-policy --bucket amzn-s3-demo-bucket --policy
    file://policy.json

   policy.json:
   {
       "Version": "2012-10-17",
   ```

```
    "Statement": [
        {
            "Sid": "PublicReadGetObject",
            "Effect": "Allow",
            "Principal": "*",
            "Action": [
                "s3:GetObject"
            ],
            "Resource": [
                "arn:aws:s3:::amzn-s3-demo-bucket/*"
            ]
        }
    ]
}
```

To grant public access to a specific object in a bucket policy, use the following format for the `Resource` element.

```
"Resource": "arn:aws:s3:::amzn-s3-demo-bucket/OBJECT-KEY"
```

To grant public access to all of the objects with a specific prefix, use the following format for the `Resource` element.

```
"Resource": "arn:aws:s3:::amzn-s3-demo-bucket/PREFIX/*"
```

2. Apply the Bucket owner enforced setting for Object Ownership.

#### Grant Amazon ElastiCache (Redis OSS) access to your S3 bucket

You can export your ElastiCache (Redis OSS) backup to an S3 bucket, which gives you access to the backup from outside ElastiCache. To export your backup to an S3 bucket, you must grant ElastiCache permissions to copy a snapshot to the bucket. If you've granted permissions to ElastiCache in a bucket ACL, you must migrate these permissions to a bucket policy before you apply the Bucket owner enforced setting to disable ACLs. For more information, see Grant ElastiCache access to your Amazon S3 bucket in the *Amazon ElastiCache User Guide*.

The following example shows the bucket ACL permissions that grant permissions to ElastiCache.

```
{
    "Owner": {
```

```
        "DisplayName": "DOC-EXAMPLE-ACCOUNT-OWNER",
        "ID": "852b113e7a2f25102679df27bb0ae12b3f85be6BucketOwnerCanonicalUserID"
    },
    "Grants": [
        {
            "Grantee": {
                "DisplayName": "DOC-EXAMPLE-ACCOUNT-OWNER",
                "ID":
 "852b113e7a2f25102679df27bb0ae12b3f85be6BucketOwnerCanonicalUserID",
                "Type": "CanonicalUser"
            },
            "Permission": "FULL_CONTROL"
        },
        {
            "Grantee": {
                "DisplayName": "aws-scs-s3-readonly",
                "ID":
 "540804c33a284a299d2547575ce1010f2312ef3da9b3a053c8bc45bf233e4353",
                "Type": "CanonicalUser"
            },
            "Permission": "READ"
        },
        {
            "Grantee": {
                "DisplayName": "aws-scs-s3-readonly",
                "ID":
 "540804c33a284a299d2547575ce1010f2312ef3da9b3a053c8bc45bf233e4353",
                "Type": "CanonicalUser"
            },
            "Permission": "WRITE"
        },
        {
            "Grantee": {
                "DisplayName": "aws-scs-s3-readonly",
                "ID":
 "540804c33a284a299d2547575ce1010f2312ef3da9b3a053c8bc45bf233e4353",
                "Type": "CanonicalUser"
            },
            "Permission": "READ_ACP"
        }
    ]
}
```

**To migrate bucket ACL permissions for ElastiCache (Redis OSS) to a bucket policy**

1. Add the following bucket policy to your bucket, replacing the example values.

```
aws s3api put-bucket-policy --bucket amzn-s3-demo-bucket --policy
 file://policy.json

policy.json:
"Id": "Policy15397346",
    "Statement": [
        {
            "Sid": "Stmt15399483",
            "Effect": "Allow",
            "Principal": {
                "Service": "Region.elasticache-snapshot.amazonaws.com"
            },
            "Action": [
                "s3:PutObject",
                "s3:GetObject",
                "s3:ListBucket",
                "s3:GetBucketAcl",
                "s3:ListMultipartUploadParts",
                "s3:ListBucketMultipartUploads"
            ],
            "Resource": [
                "arn:aws:s3:::amzn-s3-demo-bucket",
                "arn:aws:s3:::amzn-s3-demo-bucket/*"
            ]
        }
    ]
}
```

2. Reset the ACL for your bucket to the default ACL:

```
aws s3api put-bucket-acl --bucket amzn-s3-demo-bucket --acl private
```

3. Apply the Bucket owner enforced setting for Object Ownership.

## Setting Object Ownership when you create a bucket

When you create a bucket, you can configure S3 Object Ownership. To set Object Ownership for an existing bucket, see Setting Object Ownership on an existing bucket.

S3 Object Ownership is an Amazon S3 bucket-level setting that you can use to disable access control lists (ACLs) and take ownership of every object in your bucket, simplifying access management for data stored in Amazon S3. By default, S3 Object Ownership is set to the Bucket owner enforced setting, and ACLs are disabled for new buckets. With ACLs disabled, the bucket owner owns every object in the bucket and manages access to data exclusively by using access-management policies. We recommend that you keep ACLs disabled, except in unusual circumstances where you must control access for each object individually.

Object Ownership has three settings that you can use to control ownership of objects uploaded to your bucket and to disable or enable ACLs:

**ACLs disabled**

- **Bucket owner enforced (default)** – ACLs are disabled, and the bucket owner automatically owns and has full control over every object in the bucket. ACLs no longer affect permissions to data in the S3 bucket. The bucket uses policies to define access control.

**ACLs enabled**

- **Bucket owner preferred** – The bucket owner owns and has full control over new objects that other accounts write to the bucket with the `bucket-owner-full-control` canned ACL.
- **Object writer** – The AWS account that uploads an object owns the object, has full control over it, and can grant other users access to it through ACLs.

**Permissions**: To apply the **Bucket owner enforced** setting or the **Bucket owner preferred** setting, you must have the following permissions: `s3:CreateBucket` and `s3:PutBucketOwnershipControls`. No additional permissions are needed when creating a bucket with the **Object writer** setting applied. For more information about Amazon S3 permissions, see Actions, resources, and condition keys for Amazon S3 in the *Service Authorization Reference*.

> **Important**
>
> A majority of modern use cases in Amazon S3 no longer require the use of ACLs, and we recommend that you disable ACLs except in unusual circumstances where you need to control access for each object individually. With Object Ownership, you can disable ACLs and rely on policies for access control. When you disable ACLs, you can easily maintain a

bucket with objects uploaded by different AWS accounts. You, as the bucket owner, own all the objects in the bucket and can manage access to them using policies.

### Using the S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the navigation bar on the top of the page, choose the name of the currently displayed AWS Region. Next, choose the Region in which you want to create a bucket.

   **Note**

   To minimize latency and costs and address regulatory requirements, choose a Region close to you. Objects stored in a Region never leave that Region unless you explicitly transfer them to another Region. For a list of Amazon S3 AWS Regions, see AWS service endpoints in the *Amazon Web Services General Reference*.
3. In the left navigation pane, choose **Buckets**.
4. Choose **Create bucket**.

   The **Create bucket** page opens.
5. Under **General configuration**, view the AWS Region where your bucket will be created.
6. Under **Bucket type**, choose **General purpose**.
7. For **Bucket name**, enter a name for your bucket.

   The bucket name must:

   - Be unique within a partition. A partition is a grouping of Regions. AWS currently has three partitions: `aws` (Standard Regions), `aws-cn` (China Regions), and `aws-us-gov` (AWS GovCloud (US) Regions).
   - Be between 3 and 63 characters long.
   - Consist only of lowercase letters, numbers, dots (.), and hyphens (-). For best compatibility, we recommend that you avoid using dots (.) in bucket names, except for buckets that are used only for static website hosting.
   - Begin and end with a letter or number.

After you create the bucket, you cannot change its name. For more information about naming buckets, see Bucket naming rules.

> **Important**
>
> Avoid including sensitive information, such as account numbers, in the bucket name. The bucket name is visible in the URLs that point to the objects in the bucket.

8. AWS Management Console allows you to copy an existing bucket's settings to your new bucket. If you do not want to copy the settings of an existing bucket, skip to the next step.

> **Note**
>
> This option:
>
> - Is not available in the AWS CLI and is only available in console
> - Is not available for directory buckets
> - Does not copy the bucket policy from the existing bucket to the new bucket

To copy an existing bucket's settings, under **Copy settings from existing bucket**, select **Choose bucket**. The **Choose bucket** window opens. Find the bucket with the settings that you would like to copy, and select **Choose bucket**. The **Choose bucket** window closes, and the **Create bucket** window re-opens.

Under **Copy settings from existing bucket**, you will now see the name of the bucket you selected. You will also see a **Restore defaults** option that you can use to remove the copied bucket settings. Review the remaining bucket settings, on the **Create bucket** page. You will see that they now match the settings of the bucket that you selected. You can skip to the final step.

9. Under **Object Ownership**, to disable or enable ACLs and control ownership of objects uploaded in your bucket, choose one of the following settings:

**ACLs disabled**

- **Bucket owner enforced (default)** – ACLs are disabled, and the bucket owner automatically owns and has full control over every object in the bucket. ACLs no longer affect access

permissions to data in the S3 bucket. The bucket uses policies exclusively to define access control.

By default, ACLs are disabled. A majority of modern use cases in Amazon S3 no longer require the use of ACLs. We recommend that you keep ACLs disabled, except in unusual circumstances where you must control access for each object individually. For more information, see Controlling ownership of objects and disabling ACLs for your bucket.

**ACLs enabled**

- **Bucket owner preferred** – The bucket owner owns and has full control over new objects that other accounts write to the bucket with the `bucket-owner-full-control` canned ACL.

  If you apply the **Bucket owner preferred** setting, to require all Amazon S3 uploads to include the `bucket-owner-full-control` canned ACL, you can add a bucket policy that allows only object uploads that use this ACL.
- **Object writer** – The AWS account that uploads an object owns the object, has full control over it, and can grant other users access to it through ACLs.

> **Note**
>
> The default setting is **Bucket owner enforced**. To apply the default setting and keep ACLs disabled, only the `s3:CreateBucket` permission is needed. To enable ACLs, you must have the `s3:PutBucketOwnershipControls` permission.

10. Under **Block Public Access settings for this bucket**, choose the Block Public Access settings that you want to apply to the bucket.

    By default, all four Block Public Access settings are enabled. We recommend that you keep all settings enabled, unless you know that you need to turn off one or more of them for your specific use case. For more information about blocking public access, see Blocking public access to your Amazon S3 storage.

> **Note**
>
> To enable all Block Public Access settings, only the `s3:CreateBucket` permission is required. To turn off any Block Public Access settings, you must have the `s3:PutBucketPublicAccessBlock` permission.

11. (Optional) Under **Bucket Versioning**, you can choose if you wish to keep variants of objects in your bucket. For more information about versioning, see Using versioning in S3 buckets.

    To disable or enable versioning on your bucket, choose either **Disable** or **Enable**.

12. (Optional) Under **Tags**, you can choose to add tags to your bucket. Tags are key-value pairs used to categorize storage.

    To add a bucket tag, enter a **Key** and optionally a **Value** and choose **Add Tag**.

13. Under **Default encryption**, choose **Edit**.

14. To configure default encryption, under **Encryption type**, choose one of the following:

    - **Amazon S3 managed key (SSE-S3)**
    - **AWS Key Management Service key (SSE-KMS)**

    > **Important**
    >
    > If you use the SSE-KMS option for your default encryption configuration, you are subject to the requests per second (RPS) quota of AWS KMS. For more information about AWS KMS quotas and how to request a quota increase, see Quotas in the *AWS Key Management Service Developer Guide*.

    Buckets and new objects are encrypted with server-side encryption with an **Amazon S3 managed key** as the base level of encryption configuration. For more information about default encryption, see Setting default server-side encryption behavior for Amazon S3 buckets.

    For more information about using Amazon S3 server-side encryption to encrypt your data, see Using server-side encryption with Amazon S3 managed keys (SSE-S3).

15. If you chose **AWS Key Management Service key (SSE-KMS)**, do the following:

a. Under **AWS KMS key**, specify your KMS key in one of the following ways:

- To choose from a list of available KMS keys, choose **Choose from your AWS KMS keys**, and choose your **KMS key** from the list of available keys.

  Both the AWS managed key (`aws/s3`) and your customer managed keys appear in this list. For more information about customer managed keys, see Customer keys and AWS keys in the *AWS Key Management Service Developer Guide*.
- To enter the KMS key ARN, choose **Enter AWS KMS key ARN**, and enter your KMS key ARN in the field that appears.
- To create a new customer managed key in the AWS KMS console, choose **Create a KMS key**.

  For more information about creating an AWS KMS key, see Creating keys in the *AWS Key Management Service Developer Guide*.

> **Important**
>
> You can use only KMS keys that are available in the same AWS Region as the bucket. The Amazon S3 console lists only the first 100 KMS keys in the same Region as the bucket. To use a KMS key that is not listed, you must enter your KMS key ARN. If you want to use a KMS key that is owned by a different account, you must first have permission to use the key and then you must enter the KMS key ARN. For more information on cross account permissions for KMS keys, see Creating KMS keys that other accounts can use in the *AWS Key Management Service Developer Guide*. For more information on SSE-KMS, see Specifying server-side encryption with AWS KMS (SSE-KMS).
> When you use an AWS KMS key for server-side encryption in Amazon S3, you must choose a symmetric encryption KMS key. Amazon S3 supports only symmetric encryption KMS keys and not asymmetric KMS keys. For more information, see Identifying symmetric and asymmetric KMS keys in the *AWS Key Management Service Developer Guide*.

For more information about creating an AWS KMS key, see Creating keys in the *AWS Key Management Service Developer Guide*. For more information about using AWS KMS with Amazon S3, see Using server-side encryption with AWS KMS keys (SSE-KMS).

b. When you configure your bucket to use default encryption with SSE-KMS, you can also enable S3 Bucket Keys. S3 Bucket Keys lower the cost of encryption by decreasing request traffic from Amazon S3 to AWS KMS. For more information, see Reducing the cost of SSE-KMS with Amazon S3 Bucket Keys.

To use S3 Bucket Keys, under **Bucket Key**, choose **Enable**.

16. (Optional) If you want to enable S3 Object Lock, do the following:

a. Choose **Advanced settings**.

> **Important**
>
> Enabling Object Lock also enables versioning for the bucket. After enabling you must configure the Object Lock default retention and legal hold settings to protect new objects from being deleted or overwritten.

b. If you want to enable Object Lock, choose **Enable**, read the warning that appears, and acknowledge it.

For more information, see Using S3 Object Lock.

> **Note**
>
> To create an Object Lock enabled bucket, you must have the following permissions: `s3:CreateBucket`, `s3:PutBucketVersioning` and `s3:PutBucketObjectLockConfiguration`.

17. Choose **Create bucket**.

### Using the AWS CLI

To set Object Ownership when you create a new bucket, use the `create-bucket` AWS CLI command with the `--object-ownership` parameter.

This example applies the Bucket owner enforced setting for a new bucket using the AWS CLI:

```
aws s3api create-bucket --bucket  amzn-s3-demo-bucket --region us-east-1 --object-
ownership BucketOwnerEnforced
```

> **Important**
>
> If you don't set Object Ownership when you create a bucket by using the AWS CLI, the default setting will be `ObjectWriter` (ACLs enabled).

### Using the AWS SDK for Java

This example sets the Bucket owner enforced setting for a new bucket using the AWS SDK for Java:

```
    // Build the ObjectOwnership for CreateBucket
    CreateBucketRequest createBucketRequest = CreateBucketRequest.builder()
            .bucket(bucketName)
            .objectOwnership(ObjectOwnership.BucketOwnerEnforced)
            .build()

     // Send the request to Amazon S3
     s3client.createBucket(createBucketRequest);
```

### Using AWS CloudFormation

To use the `AWS::S3::Bucket` AWS CloudFormation resource to set Object Ownership when you create a new bucket, see OwnershipControls within AWS::S3::Bucket in the *AWS CloudFormation User Guide*.

### Using the REST API

To apply the Bucket owner enforced setting for S3 Object Ownership, use the `CreateBucket` API operation with the `x-amz-object-ownership` request header set to `BucketOwnerEnforced`. For information and examples, see CreateBucket in the *Amazon Simple Storage Service API Reference*.

**Next steps**: After you apply the Bucket owner enforced or bucket owner preferred settings for Object Ownership, you can further take the following steps:

- Bucket owner enforced – Require that all new buckets are created with ACLs disabled by using an IAM or Organizations policy.
- Bucket owner preferred – Add an S3 bucket policy to require the `bucket-owner-full-control` canned ACL for all object uploads to your bucket.

## Setting Object Ownership on an existing bucket

You can configure S3 Object Ownership on an existing S3 bucket. To apply Object Ownership when you create a bucket, see Setting Object Ownership when you create a bucket.

S3 Object Ownership is an Amazon S3 bucket-level setting that you can use to disable access control lists (ACLs) and take ownership of every object in your bucket, simplifying access management for data stored in Amazon S3. By default, S3 Object Ownership is set to the Bucket owner enforced setting, and ACLs are disabled for new buckets. With ACLs disabled, the bucket owner owns every object in the bucket and manages access to data exclusively by using access-management policies. We recommend that you keep ACLs disabled, except in unusual circumstances where you must control access for each object individually.

Object Ownership has three settings that you can use to control ownership of objects uploaded to your bucket and to disable or enable ACLs:

**ACLs disabled**

- **Bucket owner enforced (default)** – ACLs are disabled, and the bucket owner automatically owns and has full control over every object in the bucket. ACLs no longer affect permissions to data in the S3 bucket. The bucket uses policies to define access control.

**ACLs enabled**

- **Bucket owner preferred** – The bucket owner owns and has full control over new objects that other accounts write to the bucket with the `bucket-owner-full-control` canned ACL.
- **Object writer** – The AWS account that uploads an object owns the object, has full control over it, and can grant other users access to it through ACLs.

**Prerequisites**: Before you apply the Bucket owner enforced setting to disable ACLs, you must migrate bucket ACL permissions to bucket policies and reset your bucket ACLs to the default private ACL. We also recommend that you migrate object ACL permissions to bucket policies

and edit bucket policies that require ACLs other than bucket owner full control ACLs. For more information, see Prerequisites for disabling ACLs.

**Permissions**: To use this operation, you must have the `s3:PutBucketOwnershipControls` permission. For more information about Amazon S3 permissions, see Actions, resources, and condition keys for Amazon S3 in the *Service Authorization Reference*.

**Using the S3 console**

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the **Buckets** list, choose the name of the bucket that you want to apply an S3 Object Ownership setting to.
3. Choose the **Permissions** tab.
4. Under **Object Ownership**, choose **Edit**.
5. Under **Object Ownership**, to disable or enable ACLs and control ownership of objects uploaded in your bucket, choose one of the following settings:

   **ACLs disabled**

   - **Bucket owner enforced** – ACLs are disabled, and the bucket owner automatically owns and has full control over every object in the bucket. ACLs no longer affect permissions to data in the S3 bucket. The bucket uses policies to define access control.

     To require that all new buckets are created with ACLs disabled by using IAM or AWS Organizations policies, see Disabling ACLs for all new buckets (bucket owner enforced).

   **ACLs enabled**

   - **Bucket owner preferred** – The bucket owner owns and has full control over new objects that other accounts write to the bucket with the `bucket-owner-full-control` canned ACL.

     If you apply the bucket owner preferred setting, to require all Amazon S3 uploads to include the `bucket-owner-full-control` canned ACL, you can add a bucket policy that only allows object uploads that use this ACL.
