Amazon Relational Database Service

Amazon Relational Database Service: User Guide

Table of Contents

What is Amazon Relational Database Service (Amazon RDS)?

Amazon Relational Database Service (Amazon RDS) is a web service that makes it easier to set up, operate, and scale a relational database in the AWS Cloud. It provides cost-efficient, resizable capacity for an industry-standard relational database and manages common database administration tasks.

> **Note**
>
> This guide covers Amazon RDS database engines other than Amazon Aurora. For information about using Amazon Aurora, see the *Amazon Aurora User Guide*.

If you are new to AWS products and services, begin learning more with the following resources:

- For an overview of all AWS products, see What is cloud computing?
- Amazon Web Services provides a number of database services. To learn more about the variety of database options available on AWS, see Choosing an AWS database service and Running databases on AWS.

Advantages of Amazon RDS

Amazon RDS is a managed database service. It's responsible for most management tasks. By eliminating tedious manual processes, Amazon RDS frees you to focus on your application and your users.

Amazon RDS provides the following principal advantages over database deployments that aren't fully managed:

- You can use database engines that you are already familiar with: IBM Db2, MariaDB, Microsoft SQL Server, MySQL, Oracle Database, and PostgreSQL.
- Amazon RDS manages backups, software patching, automatic failure detection, and recovery.
- You can turn on automated backups, or manually create your own backup snapshots. You can use these backups to restore a database. The Amazon RDS restore process works reliably and efficiently.

- You can get high availability with a primary DB instance and a synchronous secondary DB instance that you can fail over to when problems occur. You can also use read replicas to increase read scaling.
- In addition to the security in your database package, you can control access by using AWS Identity and Access Management (IAM) to define users and permissions. You can also help protect your databases by putting them in a virtual private cloud (VPC).

Comparison of responsibilities with Amazon EC2 and on-premises deployments

We recommend Amazon RDS as your default choice for most relational database deployments. The following alternatives have the disadvantage of making you spend more time managing software and hardware:

On-premises deployment

When you buy an on-premises server, you get CPU, memory, storage, and IOPS, all bundled together. You assume full responsibility for the server, operating system, and database software.

Amazon EC2

Amazon Elastic Compute Cloud (Amazon EC2) provides scalable computing capacity in the AWS Cloud. Unlike in an on-premises server, CPU, memory, storage, and IOPS are separated so that you can scale them independently. AWS manages the hardware layers, which eliminates some of the burden of managing an on-premises database server.

The disadvantage to running a database on Amazon EC2 is that you're more prone to user errors. For example, when you update the operating system or database software manually, you might accidentally cause application downtime. You might spend hours checking every change to identify and fix an issue.

The following table compares the management models for on-premises databases, Amazon EC2, and Amazon RDS.

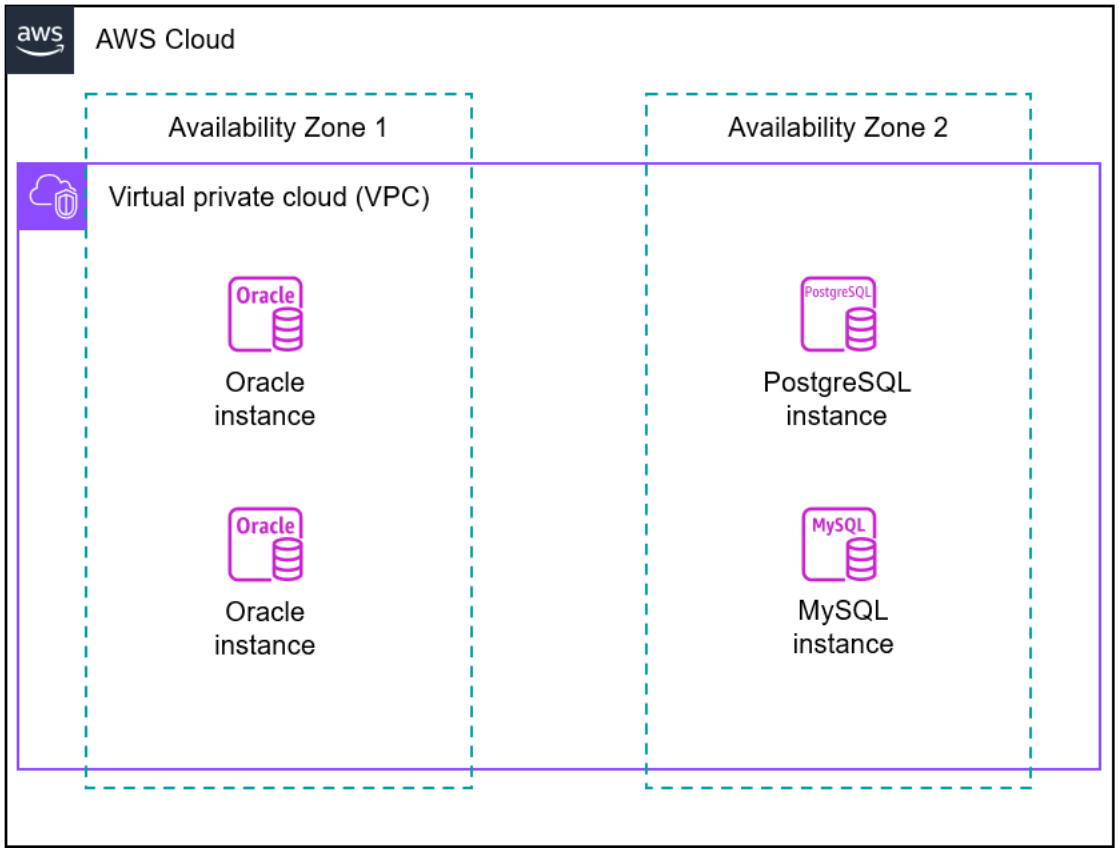
Feature	On-premises management	Amazon EC2 management	Amazon RDS management
Application optimization	Customer	Customer	Customer
Scaling	Customer	Customer	AWS
High availability	Customer	Customer	AWS
Database backups	Customer	Customer	AWS
Database software patching	Customer	Customer	AWS
Database software install	Customer	Customer	AWS
Operating system (OS) patching	Customer	Customer	AWS
OS installation	Customer	Customer	AWS
Server maintenance	Customer	AWS	AWS
Hardware lifecycle	Customer	AWS	AWS
Power, network, and cooling	Customer	AWS	AWS

Amazon RDS shared responsibility model

Amazon RDS is responsible for hosting the software components and infrastructure of DB instances and DB clusters. You are responsible for query tuning, which is the process of adjusting SQL queries to improve performance. Query performance is highly dependent on database design, data size, data distribution, application workload, and query patterns, which can vary greatly. Monitoring and tuning are highly individualized processes that you own for your RDS databases. You can use Amazon RDS Performance Insights and other tools to identify problematic queries.

Amazon RDS DB instances

A *DB instance* is an isolated database environment in the AWS Cloud. The basic building block of Amazon RDS is the DB instance. Your DB instance can contain one or more user-created databases. The following diagram shows a virtual private cloud (VPC) that contains two Availability Zones, with each AZ containing two DB instances.



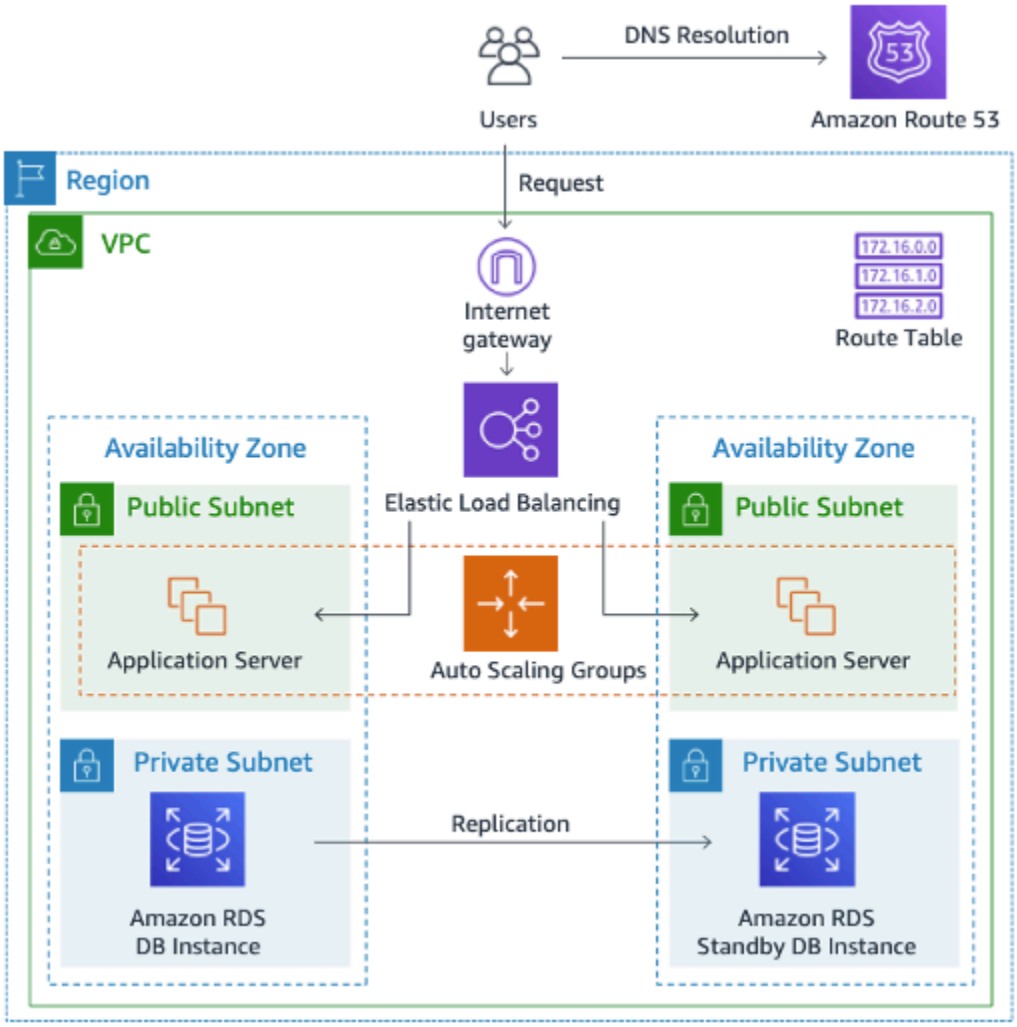
You can access your DB instances by using the same tools and applications that you use with a standalone database instance. You can create and modify a DB instance by using the AWS Command Line Interface (AWS CLI), the Amazon RDS API, or the AWS Management Console.

Topics

- Amazon RDS application architecture: example
- DB engines
- DB instance classes
- DB instance storage
- DB instances in an Amazon Virtual Private Cloud (Amazon VPC)

Amazon RDS application architecture: example

The following image shows a typical use case of a dynamic website that uses Amazon RDS DB instances for database storage:



The primary components of the preceding architecture are as follows:

Elastic Load Balancing

AWS routes user traffic through Elastic Load Balancing. A load balancer distributes workloads across multiple compute resources, such as virtual servers. In this sample use case, the Elastic Load Balancer forwards client requests to application servers.

Application servers

Application servers interact with RDS DB instances. An application server in AWS is typically hosted on EC2 instances, which provide scalable computing capacity. The application servers

reside in public subnets with different Availability Zones (AZs) within the same Virtual Private Cloud (VPC). .

RDS DB instances

The EC2 application servers interact with RDS DB instances. The DB instances reside in private subnets within different Availability Zones (AZs) within the same Virtual Private Cloud (VPC). Because the subnets are private, no requests from the internet are permitted.

The primary DB instance replicates to another DB instance, called a *read replica*. Both DB instances are in private subnets within the VPC, which means that Internet users can't access them directly.

DB engines

A *DB engine* is the specific relational database software that runs on your DB instance. Amazon RDS supports the following database engines:

- IBM Db2

  For more information, see Amazon RDS for Db2.
- MariaDB

  For more information, see Amazon RDS for MariaDB.
- Microsoft SQL Server

  For more information, see Amazon RDS for Microsoft SQL Server.
- MySQL

  For more information, see Amazon RDS for MySQL.
- Oracle Database

  For more information, see Amazon RDS for Oracle.
- PostgreSQL

  For more information, see Amazon RDS for PostgreSQL.

Each DB engine has its own supported features, and each version of a DB engine can include specific features. Support for Amazon RDS features varies across AWS Regions and specific

versions of each DB engine. To check feature support in different engine versions and Regions, see Supported features in Amazon RDS by AWS Region and DB engine.

Additionally, each DB engine has a set of parameters in a DB parameter group that control the behavior of the databases that it manages. For more information about parameter groups, see Parameter groups for Amazon RDS.

DB instance classes

A *DB instance class* determines the computation and memory capacity of a DB instance. A DB instance class consists of both the DB instance class type and the size. Amazon RDS supports the following instance class types, where the asterisk (*) represents the generation, optional attribute, and size:

- General purpose – db.m*
- Memory optimized – db.z*, db.x*, db.r*
- Compute optimized – db.c*
- Burstable performance – db.t*

Each instance class offers different compute, memory, and storage capabilities. For example, db.m7g is a 7th-generation, general-purpose DB instance class type powered by AWS Graviton3 processors. When you create a DB instance, you specify a DB instance class such as db.m7g.2xlarge, where 2xlarge is the size. For more information about the hardware specifications for the different instance classes, see Hardware specifications for DB instance classes.

You can select the DB instance class that best meets your requirements. If your requirements change over time, you can change your DB instance class. For example, you might scale up your db.m7g.2xlarge instance to db.m7g.4xlarge. For more information, see DB instance classes.

> **Note**
>
> For pricing information on DB instance classes, see the Pricing section of the Amazon RDS product page.

DB instance storage

Amazon EBS provides durable, block-level storage volumes that you can attach to a running instance. DB instance storage comes in the following types:

- General Purpose (SSD)

  This cost-effective storage type is ideal for a broad range of workloads running on medium-sized DB instances. General Purpose storage is best suited for development and testing environments.
- Provisioned IOPS (PIOPS)

  This storage type is designed to meet the needs of I/O-intensive workloads, particularly database workloads, that require low I/O latency and consistent I/O throughput. Provisioned IOPS storage is best suited for production environments.
- Magnetic

  Amazon RDS supports magnetic storage for backward compatibility. We recommend that you use General Purpose SSD or Provisioned IOPS SSD for any new storage needs.

The storage types differ in performance characteristics and price. You can tailor your storage performance and cost to the requirements of your database.

Each DB instance has minimum and maximum storage requirements depending on the storage type and the database engine it supports. It's important to have sufficient storage so that your databases have room to grow. Also, sufficient storage makes sure that features for the DB engine have room to write content or log entries. For more information, see Amazon RDS DB instance storage.

DB instances in an Amazon Virtual Private Cloud (Amazon VPC)

You can run a DB instance on a virtual private cloud (VPC) using the Amazon Virtual Private Cloud (Amazon VPC) service. When you use a VPC, you have control over your virtual networking environment. You can choose your own IP address range, create subnets, and configure routing and access control lists.

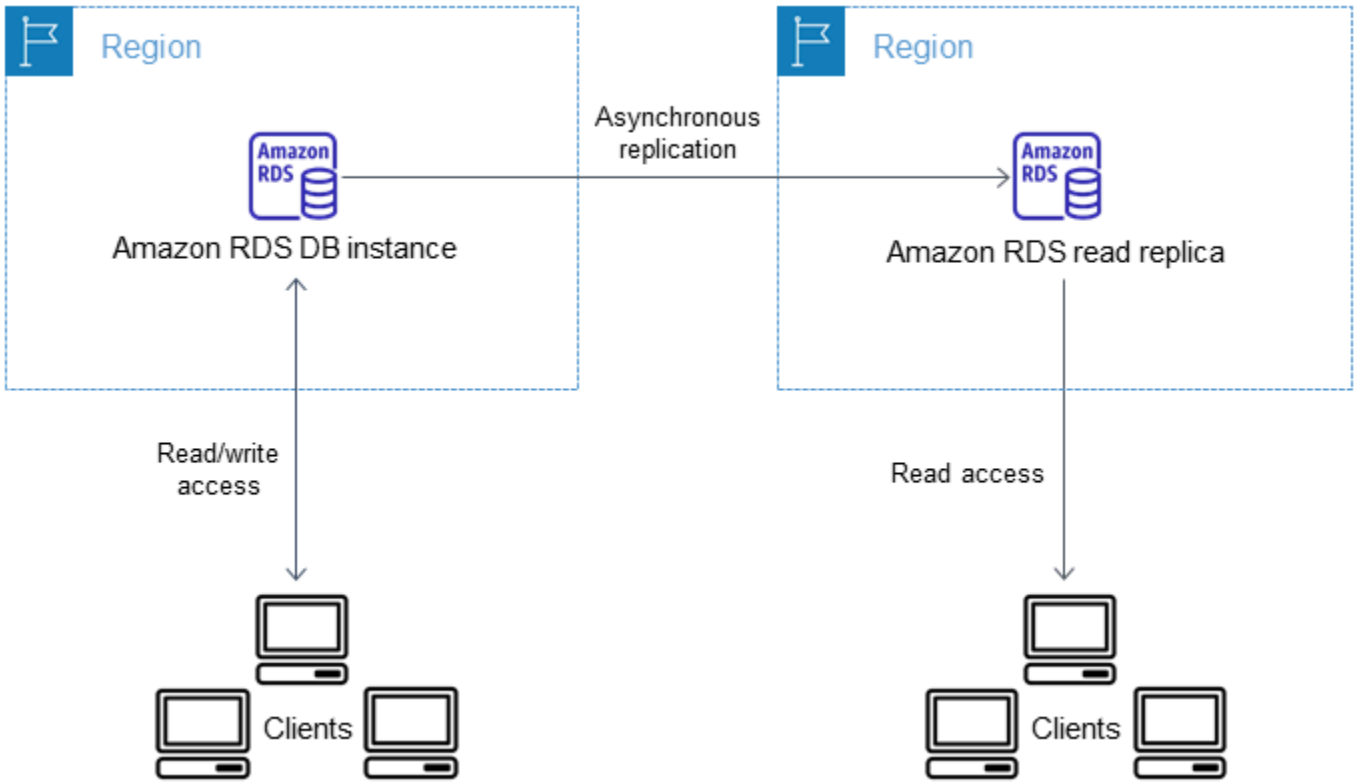
The basic functionality of Amazon RDS is the same whether it's running in a VPC or not. Amazon RDS manages backups, software patching, automatic failure detection, and recovery. There's no additional cost to run your DB instance in a VPC. For more information on using Amazon VPC with RDS, see Amazon VPC and Amazon RDS.

Amazon RDS uses Network Time Protocol (NTP) to synchronize the time on DB instances.

AWS Regions and Availability Zones

Amazon cloud computing resources are housed in highly available data center facilities in different areas of the world (for example, North America, Europe, or Asia). Each data center location is called an AWS Region. With Amazon RDS, you can create your DB instances in multiple Regions.

The following scenario shows an RDS DB instance in one Region that replicates asynchronously to a standby DB instance in a different Region. If one Region becomes unavailable, the instance in the other Region is still available.



Availability Zones

Each AWS Region contains multiple distinct locations called Availability Zones, or AZs. Each Availability Zone is engineered to be isolated from failures in other Availability Zones. Each is engineered to provide inexpensive, low-latency network connectivity to other Availability Zones in the same AWS Region. By launching DB instances in separate Availability Zones, you can protect your applications from the failure of a single location. For more information, see Regions, Availability Zones, and Local Zones.

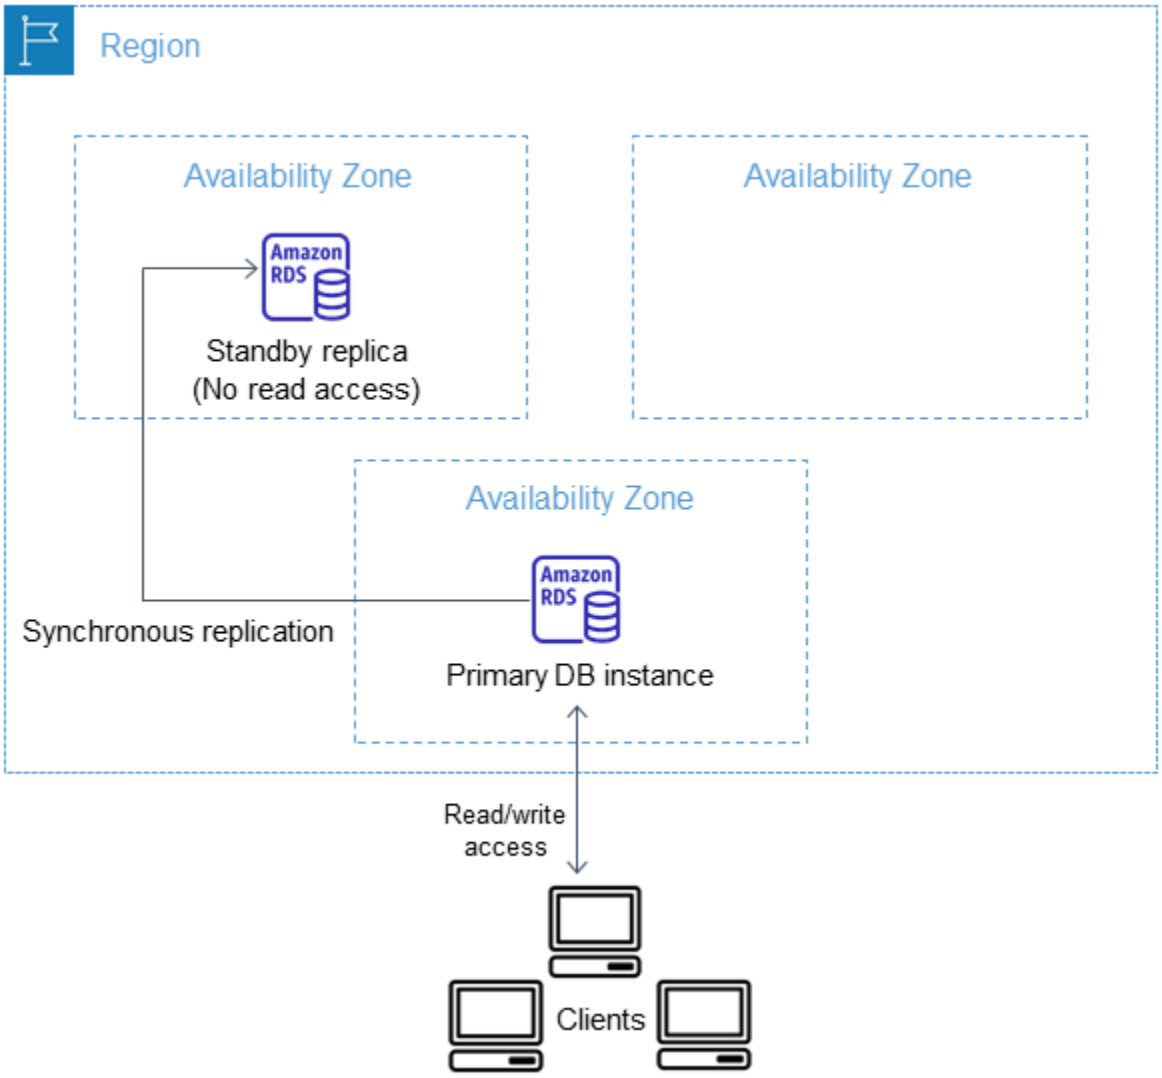
Multi-AZ deployments

You can run your DB instance in several Availability Zones, an option called a Multi-AZ deployment. When you choose this option, Amazon automatically provisions and maintains one or more secondary standby DB instances in a different AZ. Your primary DB instance is replicated across Availability Zones to each secondary DB instance.

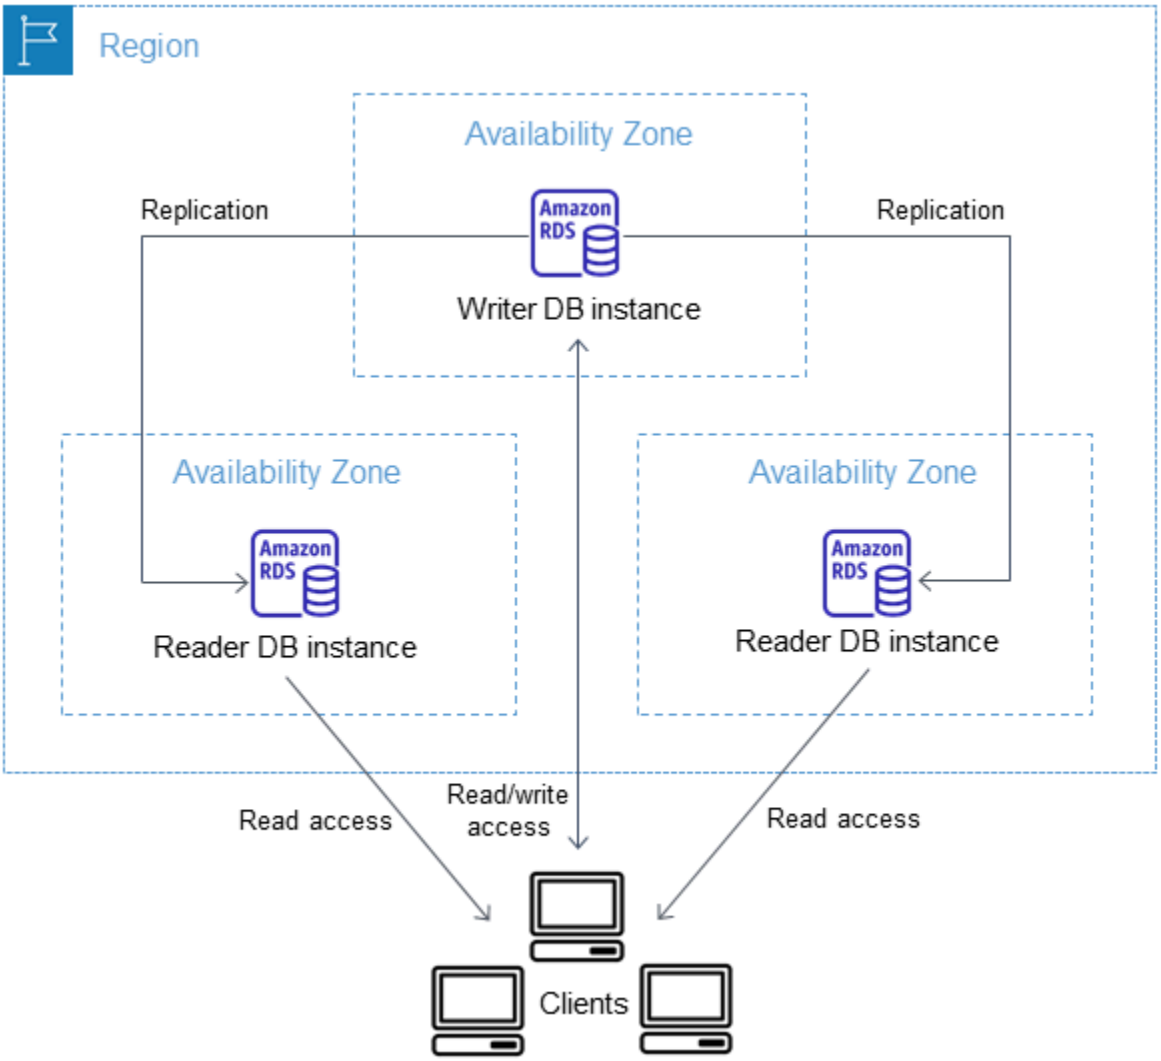
A Multi-AZ deployment provides the following advantages:

- Providing data redundancy and failover support
- Eliminating I/O freezes
- Minimizing latency spikes during system backups
- Serving read traffic on secondary DB instances (Multi-AZ DB clusters deployment only)

The following diagram depicts a Multi-AZ DB instance deployment, where Amazon RDS automatically provisions and maintains a synchronous standby replica in a different Availability Zone. The replica database doesn't serve read traffic.



The following diagram depicts a Multi-AZ DB cluster deployment, which has a writer DB instance and two reader DB instances in three separate Availability Zones in the same AWS Region. All three DB instances can serve read traffic.

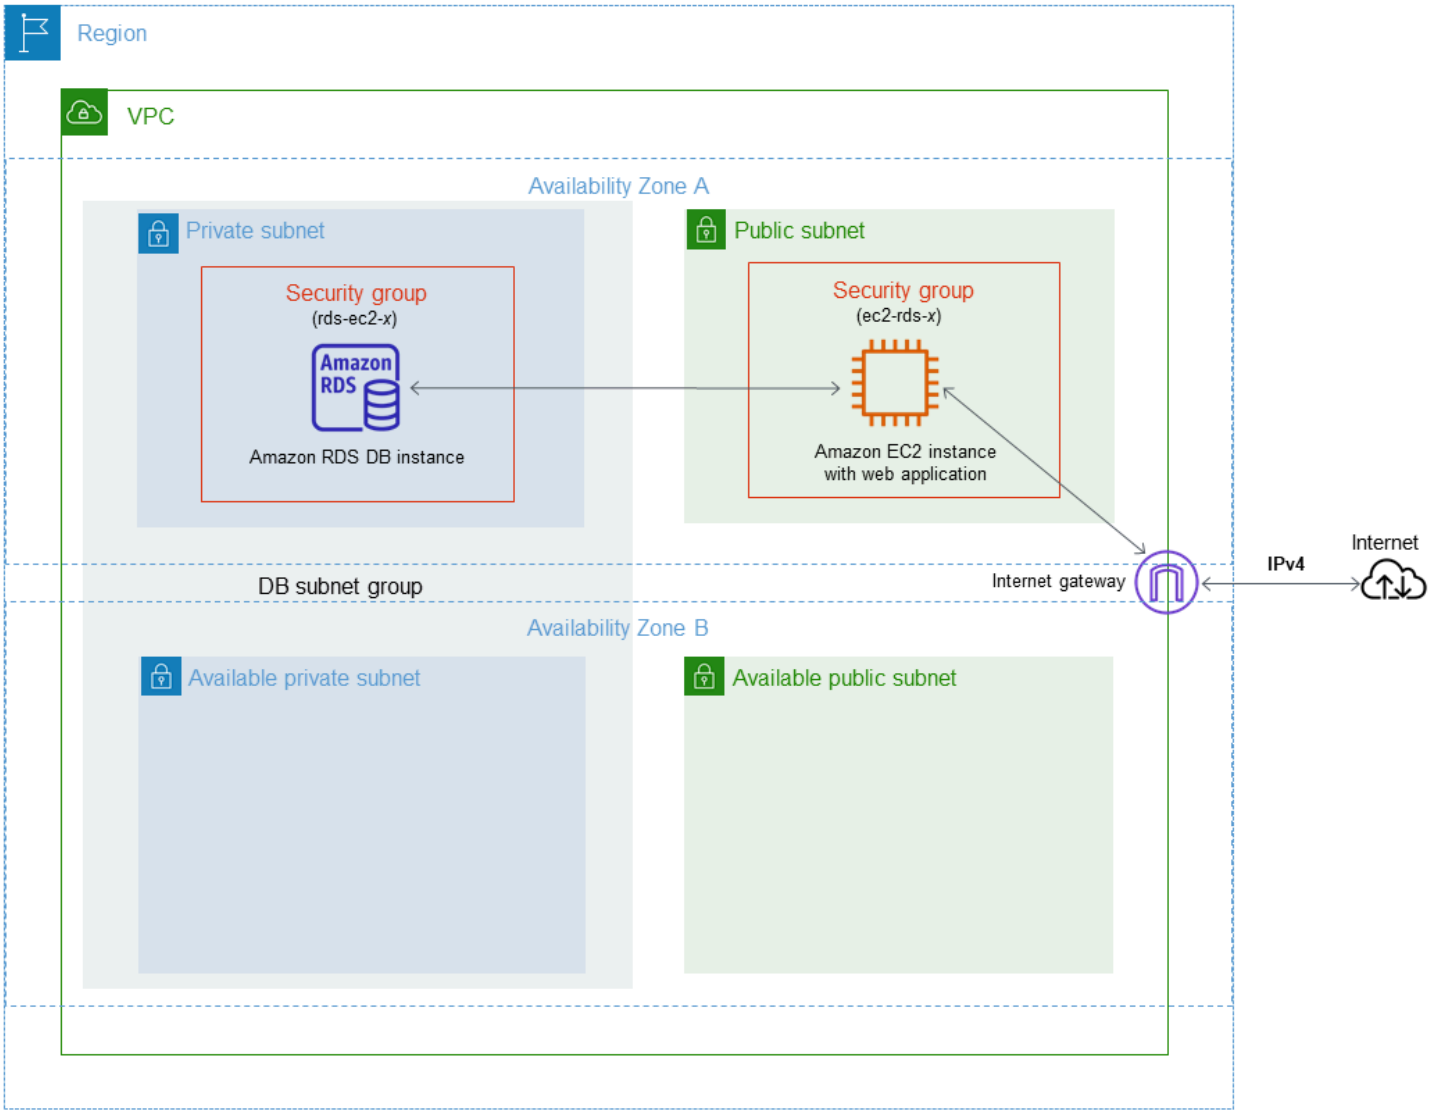


For more information, see Configuring and managing a Multi-AZ deployment.

Access control with security groups

A *security group* controls the access to a DB instance by allowing access to IP address ranges or Amazon EC2 instances that you specify. You can apply a security group to one or more DB instances.

A common use of a DB instance in a VPC is to share data with an application server in the same VPC. The following example uses VPC security group `ec2-rds-`*x* to define inbound rules that use the IP addresses of the client application as the source. The application server belongs to this security group. A second security group named `rds-ec2-`*x* specifies `ec2-rds-`*x* as the source and attaches to an RDS DB instance. According to the security group rules, client applications can't directly access the DB instance, but the EC2 instance can access the DB instance.



For more information about security groups, see Security in Amazon RDS.

Amazon RDS monitoring

Monitoring is an important part of maintaining the reliability, availability, and performance of Amazon RDS and your other AWS solutions. AWS provides various monitoring tools to watch Amazon RDS, report when something is wrong, and take automatic actions when appropriate.

You can track the performance and health of your DB instances using various automated and manual tools:

Amazon RDS DB instance status and recommendations

View details about the current status of your instance by using the Amazon RDS console, AWS CLI, or RDS API. You can also respond to automated recommendations for database resources, such as DB instances, read replicas, and DB parameter groups. For more information, see Recommendations from Amazon RDS.

Amazon CloudWatch metrics for Amazon RDS

You can use the Amazon CloudWatch service to monitor the performance and health of a DB instance. CloudWatch performance charts are shown in the Amazon RDS console. Amazon RDS automatically sends metrics to CloudWatch every minute for each active database. You don't get additional charges for Amazon RDS metrics in CloudWatch.

Using Amazon CloudWatch alarms, you can watch a single Amazon RDS metric over a specific time period. You can then perform one or more actions based on the value of the metric relative to a threshold that you set. For more information, see Monitoring Amazon RDS metrics with Amazon CloudWatch.

Amazon RDS Performance Insights and operating-system monitoring

Performance Insights assesses the load on your database, and determine when and where to take action. For more information, see Monitoring DB load with Performance Insights on Amazon RDS. Amazon RDS Enhanced Monitoring looks at metrics in real time for the operating system. For more information, see Monitoring OS metrics with Enhanced Monitoring.

Integrated AWS services

Amazon RDS is integrated with Amazon EventBridge, Amazon CloudWatch Logs, and Amazon DevOps Guru. For more information, see Monitoring metrics in an Amazon RDS instance.

User interfaces to Amazon RDS

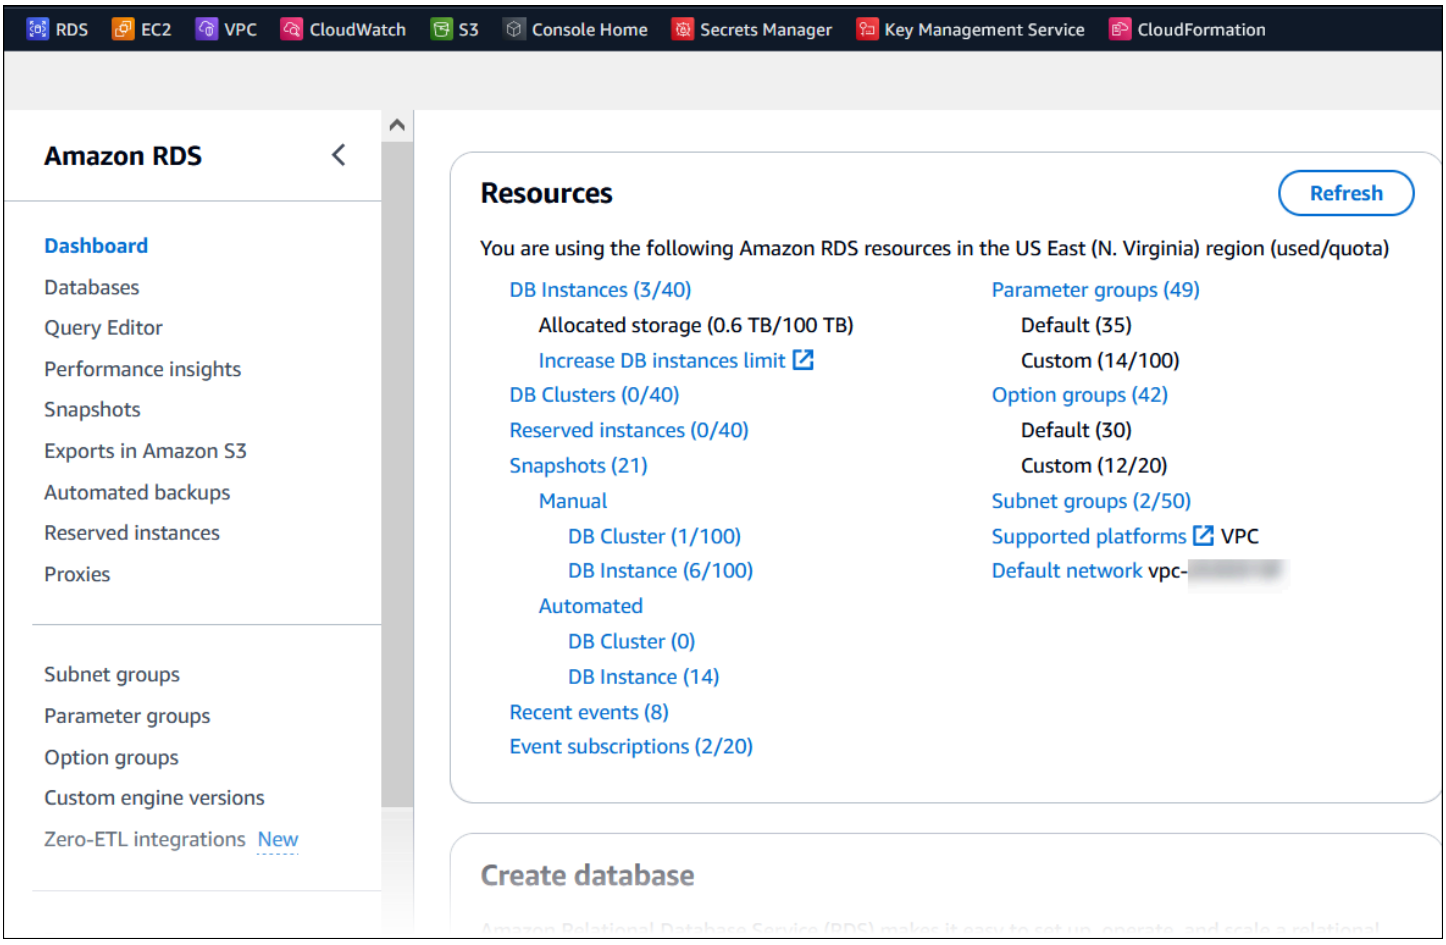
You can interact with Amazon RDS in multiple ways.

Topics

- AWS Management Console
- Command line interface
- Amazon RDS APIs

AWS Management Console

The AWS Management Console is a simple web-based user interface. You can manage your DB instances from the console with no programming required. To access the Amazon RDS console, sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.



Command line interface

You can use the AWS Command Line Interface (AWS CLI) to access the Amazon RDS API interactively. To install the AWS CLI, see Installing the AWS Command Line Interface. To begin using the AWS CLI for RDS, see AWS Command Line Interface reference for Amazon RDS.

Amazon RDS APIs

If you are a developer, you can access the Amazon RDS programmatically using APIs. For more information, see Amazon RDS API reference.

For application development, we recommend that you use one of the AWS Software Development Kits (SDKs). The AWS SDKs handle low-level details such as authentication, retry logic, and error handling, so that you can focus on your application logic. AWS SDKs are available for a wide variety of languages. For more information, see Tools for Amazon web services .

AWS also provides libraries, sample code, tutorials, and other resources to help you get started more easily. For more information, see Sample code & libraries.

How you are charged for Amazon RDS

When you use Amazon RDS, you can choose to use on-demand DB instances or reserved DB instances. For more information, see DB instance billing for Amazon RDS.

For Amazon RDS pricing information, see the Amazon RDS product page.

What's next?

The preceding section introduced you to the basic infrastructure components that RDS offers. What should you do next?

Getting started

Create a DB instance using instructions in Getting started with Amazon RDS.

Topics specific to database engines

You can review information specific to a particular DB engine in the following sections:

- Amazon RDS for Db2
- Amazon RDS for MariaDB
- Amazon RDS for Microsoft SQL Server
- Amazon RDS for MySQL
- Amazon RDS for Oracle
- Amazon RDS for PostgreSQL

Amazon RDS DB instances

A *DB instance* is an isolated database environment running in the cloud. It is the basic building block of Amazon RDS. A DB instance can contain multiple user-created databases, and can be accessed using the same client tools and applications you might use to access a standalone database instance. DB instances are simple to create and modify with the AWS command line tools, Amazon RDS API operations, or the AWS Management Console.

> **Note**
>
> Amazon RDS supports access to databases using any standard SQL client application. Amazon RDS does not allow direct host access.

You can have up to 40 Amazon RDS DB instances, with the following limitations:

- 10 for each SQL Server edition (Enterprise, Standard, Web, and Express) under the "license-included" model
- 10 for Oracle under the "license-included" model
- 40 for Db2 under the "bring-your-own-license" (BYOL) licensing model
- 40 for MySQL, MariaDB, or PostgreSQL
- 40 for Oracle under the "bring-your-own-license" (BYOL) licensing model

> **Note**
>
> If your application requires more DB instances, you can request additional DB instances by using this form.

Each DB instance has a DB instance identifier. This customer-supplied name uniquely identifies the DB instance when interacting with the Amazon RDS API and AWS CLI commands. The DB instance identifier must be unique for that customer in an AWS Region.

The DB instance identifier forms part of the DNS hostname allocated to your instance by RDS. For example, if you specify db1 as the DB instance identifier, then RDS will automatically allocate a DNS endpoint for your instance. An example endpoint is *db1*`.`*abcdefghijkl*`.`*us-east-1*`.rds.amazonaws.com`, where *db1* is your instance ID.

In the example endpoint *db1*.*abcdefghijkl*.*us-east-1*.rds.amazonaws.com, the string *abcdefghijkl* is a unique identifier for a specific combination of AWS Region and AWS account. The identifier *abcdefghijkl* in the example is internally generated by RDS and doesn't change for the specified combination of Region and account. Thus, all your DB instances in this Region share the same fixed identifier. Consider the following features of the fixed identifier:

- If you rename your DB instance, the endpoint is different but the fixed identifier is the same. For example, if you rename *db1* to *renamed-db1*, the new instance endpoint is *renamed-db1*.*abcdefghijkl*.*us-east-1*.rds.amazonaws.com.
- If you delete and re-create a DB instance with the same DB instance identifier, the endpoint is the same.
- If you use the same account to create a DB instance in a different Region, the internally generated identifier is different because the Region is different, as in *db2*.*mnopqrstuvwx*.*us-west-1*.rds.amazonaws.com.

Each DB instance supports a database engine. Amazon RDS currently supports Db2, MySQL, MariaDB, PostgreSQL, Oracle, Microsoft SQL Server, and Amazon Aurora database engines.

When creating a DB instance, some database engines require that a database name be specified. A DB instance can host multiple databases, a single Db2 database, or a single Oracle database with multiple schemas. The database name value depends on the database engine:

- For the Db2 database engine, the database name is the name of the database hosted in your DB instance. If you want to use Amazon RDS stored procedures to create or drop a database, then don't enter a database name when you create a DB instance.
- For the MySQL and MariaDB database engines, the database name is the name of a database hosted in your DB instance. Databases hosted by the same DB instance must have a unique name within that instance.
- For the Oracle database engine, database name is used to set the value of ORACLE_SID, which must be supplied when connecting to the Oracle RDS instance.
- For the Microsoft SQL Server database engine, database name is not a supported parameter.
- For the PostgreSQL database engine, the database name is the name of a database hosted in your DB instance. A database name is not required when creating a DB instance. Databases hosted by the same DB instance must have a unique name within that instance.

Amazon RDS creates a master user account for your DB instance as part of the creation process. This master user has permissions to create databases and to perform create, delete, select, update, and insert operations on tables the master user creates. You must set the master user password when you create a DB instance, but you can change it at any time using the AWS CLI, Amazon RDS API operations, or the AWS Management Console. You can also change the master user password and manage users using standard SQL commands.

Note

This guide covers non-Aurora Amazon RDS database engines. For information about using Amazon Aurora, see the *Amazon Aurora User Guide*.

DB instance classes

The DB instance class determines the computation and memory capacity of an Amazon RDS DB instance. The DB instance class that you need depends on your processing power and memory requirements.

A DB instance class consists of both the DB instance class type and the size. For example, db.r6g is a memory-optimized DB instance class type powered by AWS Graviton2 processors. Within the db.r6g instance class type, db.r6g.2xlarge is a DB instance class. The size of this class is 2xlarge.

For more information about instance class pricing, see Amazon RDS pricing.

For more information about DB instance class types, supported DB engines, supported AWS Regions, changing your DB instance class, configuring the processor for RDS for Oracle, or hardware specifications for DB instance classes, see the following sections.

Topics

DB instance class types

Amazon RDS supports DB instance classes for the following use cases:

- General-purpose
- Memory-optimized
- Compute-optimized
- Burstable-performance
- Optimized Reads

For more information about Amazon EC2 instance types, see Instance types in the Amazon EC2 documentation.

General-purpose instance class type

The following general-purpose DB instance classes are available:

- **db.m7g** – General-purpose DB instance classes powered by AWS Graviton3 processors. These instance classes deliver balanced compute, memory, and networking for a broad range of general-purpose workloads.

  You can modify a DB instance to use one of the DB instance classes powered by AWS Graviton3 processors. To do so, complete the same steps as with any other DB instance modification.
- **db.m6g** – General-purpose DB instance classes powered by AWS Graviton2 processors. These instances deliver balanced compute, memory, and networking for a broad range of general-purpose workloads. The db.m6gd instance classes have local NVMe-based SSD block-level storage for applications that need high-speed, low latency local storage.

  You can modify a DB instance to use one of the DB instance classes powered by AWS Graviton2 processors. To do so, complete the same steps as with any other DB instance modification.
- **db.m6i** – General-purpose DB instance classes powered by 3rd Generation Intel Xeon Scalable processors. These instances are SAP Certified and ideal for workloads such as backend servers supporting enterprise applications, gaming servers, caching fleets, and application development environments. The db.m6id and db.m6idn instance classes offer up to 7.6 TB of local NVMe-based SSD storage, whereas db.m6in offers EBS-only storage. The db.m6in and db.m6idn classes offer up to 200 Gbps of network bandwidth.
- **db.m5** –General-purpose DB instance classes that provide a balance of compute, memory, and network resources, and are a good choice for many applications. The db.m5d instance class offers NVMe-based SSD storage that is physically connected to the host server. The db.m5 instance classes provide more computing capacity than the previous db.m4 instance classes. They are powered by the AWS Nitro System, a combination of dedicated hardware and lightweight hypervisor.
- **db.m4** – General-purpose DB instance classes that provide more computing capacity than the previous db.m3 instance classes.

  For the RDS for Oracle DB engines, Amazon RDS no longer supports db.m4 DB instance classes. If you had previously created RDS for Oracle db.m4 DB instances, Amazon RDS automatically upgrades those DB instances to equivalent db.m5 DB instance classes.

  For the RDS for MariaDB, RDS for MySQL, RDS for SQL Server, and RDS for PostgreSQL DB engines, Amazon RDS has started the end-of-support process for this DB instance class using the

following schedule. For all RDS DB instances that use this instance class, we recommend that you upgrade to a newer generation DB instance class as soon as possible.

Action or recommendation	Date
Starting on this date, Amazon RDS began automatically upgrading instances using db.m4 to the newer generation db.m5 instance class. Creating DB instances using the db.m4 instance class is no longer supported.	June 1, 2024
Amazon RDS ends support for db.m4.	December 31, 2024

- **db.m3** – General-purpose DB instance classes that provide more computing capacity than the previous db.m1 instance classes.

  For the RDS for MariaDB, RDS for MySQL, and RDS for PostgreSQL DB engines, Amazon RDS has started the end-of-life process for db.m3 DB instance classes using the following schedule, which includes upgrade recommendations. For all RDS DB instances that use db.m3 DB instance classes, we recommend that you upgrade to a higher generation DB instance class as soon as possible.

Action or recommendation	Dates
You can no longer create RDS DB instances that use db.m3 DB instance classes.	Now
Amazon RDS started automatic upgrades of RDS DB instances that use db.m3 DB instance classes to equivalent db.m5 DB instance classes.	February 1, 2023

Memory-optimized instance class type

The memory-optimized Z family supports the following instance classes:

- **db.z1d** – Instance classes optimized for memory-intensive applications. These instance classes offer both high compute capacity and a high memory footprint. High frequency z1d instances deliver a sustained all-core frequency of up to 4.0 GHz.

The memory-optimized X family supports the following instance classes:

- **db.x2g** – Instance classes optimized for memory-intensive applications and powered by AWS Graviton2 processors. These instance classes offer low cost per GiB of memory.

  You can modify a DB instance to use one of the DB instance classes powered by AWS Graviton2 processors. To do so, complete the same steps as with any other DB instance modification.
- **db.x2i** – Instance classes optimized for memory-intensive applications. The **db.x2iedn** and **db.x2idn** instance class types are powered by third-generation Intel Xeon Scalable processors (Ice Lake). They include up to 3.8 TB of local NVMe SSD storage, up to 100 Gbps of networking bandwidth, and up to 4 TiB (db.x2iden) or 2 TiB (db.x2idn) of memory. The **db.x2iezn** type is powered by second-generation Intel Xeon Scalable processors (Cascade Lake) with an all-core turbo frequency of up to 4.5 GHz and up to 1.5 TiB of memory.
- **db.x1** – Instance classes optimized for memory-intensive applications. These instance classes offer one of the lowest price per GiB of RAM among the DB instance classes and up to 1,952 GiB of DRAM-based instance memory. The **db.x1e** instance class type offers up to 3,904 GiB of DRAM-based instance memory.

The memory-optimized R family supports the following instance class types:

- **db.r7g** – Instance classes powered by AWS Graviton3 processors. These instance classes are ideal for running memory-intensive workloads in open-source databases such as MySQL and PostgreSQL.

  You can modify a DB instance to use one of the DB instance classes powered by AWS Graviton3 processors. To do so, complete the same steps as with any other DB instance modification.
- **db.r6g** – Instance classes powered by AWS Graviton2 processors. These instance classes are ideal for running memory-intensive workloads in open-source databases such as MySQL and PostgreSQL. The **db.r6gd** type offers local NVMe-based SSD block-level storage for applications that need high-speed, low latency local storage.

  You can modify a DB instance to use one of the DB instance classes powered by AWS Graviton2 processors. To do so, complete the same steps as with any other DB instance modification.
- **db.r6i** – Instance classes powered by 3rd Generation Intel Xeon Scalable processors. These instance classes are SAP-Certified and are an ideal fit for memory-intensive workloads in open-source databases such as MySQL and PostgreSQL. The **db.r6id**, **db.r6in**, and **db.r6idn** instance classes have a memory-to-vCPU ratio of 8:1 and a maximum memory of 1 TiB. The db.r6id and

db.r6idn classes offer up to 7.6 TB of direct-attached NVMe-based SSD storage, whereas db.r6in offers EBS-only storage. The db.r6idn and db.r6in classes offer up to 200 Gbps of network bandwidth.

- **db.r5b** – Instance classes that are memory-optimized for throughput-intensive applications. Powered by the AWS Nitro System, db.r5b instances deliver up to 60 Gbps bandwidth and 260,000 IOPS of EBS performance. This is the fastest block storage performance on EC2.
- **db.r5d** – Instance classes that are optimized for low latency, very high random I/O performance, and high sequential read throughput.
- **db.r5** – Instance classes optimized for memory-intensive applications. These instance classes offer improved networking performance. They are powered by the AWS Nitro System, a combination of dedicated hardware and lightweight hypervisor.
- **db.r4** – Instance classes that provide improved networking over previous db.r3 instance classes.

  For the RDS for Oracle DB engines, Amazon RDS has started the end-of-life process for db.r4 DB instance classes using the following schedule, which includes upgrade recommendations. For RDS for Oracle DB instances that use db.r4 instance classes, we recommend that you upgrade to a higher generation instance class as soon as possible.

Action or recommendation	Dates
You can no longer create RDS for Oracle DB instances that use db.r4 DB instance classes.	Now
Amazon RDS started automatic upgrades of RDS for Oracle DB instances that use db.r4 DB instance classes to equivalent db.r5 DB instance classes.	April 17, 2023

  For the RDS for MariaDB, RDS for MySQL, RDS for SQL Server, and RDS for PostgreSQL DB engines, Amazon RDS has started the end-of-support process for this DB instance class using the following schedule. For all RDS DB instances that use this instance class, we recommend that you upgrade to a newer generation DB instance class as soon as possible.

Action or recommendation	Dates
Starting on this date, Amazon RDS began automatically upgrading instances using db.r4 to the newer generation db.r5 instance class. Creating DB instances using the db.m4 instance class is no longer supported.	June 1, 2024
Amazon RDS ends support for db.r4.	December 31, 2024

- **db.r3** – Instance classes that provide memory optimization.

  For the RDS for MariaDB, RDS for MySQL, and RDS for PostgreSQL DB engines, Amazon RDS has started the end-of-life process for db.r3 DB instance classes using the following schedule, which includes upgrade recommendations. For all RDS DB instances that use db.r3 DB instance classes, we recommend that you upgrade to a higher generation DB instance class as soon as possible.

Action or recommendation	Dates
You can no longer create RDS DB instances that use db.r3 DB instance classes.	Now
Amazon RDS started automatic upgrades of RDS DB instances that use db.r3 DB instance classes to equivalent db.r5 DB instance classes.	February 1, 2023

Compute-optimized instance class type

The following compute-optimized instance class types are available:

- **db.c6gd** – Instance classes that are ideal for running advanced compute-intensive workloads. Powered by AWS Graviton2 processors, these instance classes offer local NVMe-based SSD block-level storage for applications that need high-speed, low latency local storage.

> **Note**
>
> The c6gd instance classes are supported only for Multi-AZ DB cluster deployments. They're the only instance class supported for Multi-AZ DB clusters that offer the `medium` instance size. For more information, see the section called "Multi-AZ DB cluster deployments".

Burstable-performance instance class types

The following burstable-performance DB instance class types are available:

- **db.t4g** – General-purpose instance classes powered by Arm-based AWS Graviton2 processors. These instance classes deliver better price performance than previous burstable-performance DB instance classes for a broad set of burstable general-purpose workloads. Amazon RDS db.t4g instances are configured for Unlimited mode. This means that they can burst beyond the baseline over a 24-hour window for an additional charge.

  You can modify a DB instance to use one of the DB instance classes powered by AWS Graviton2 processors. To do so, complete the same steps as with any other DB instance modification.
- **db.t3** – Instance classes that provide a baseline performance level, with the ability to burst to full CPU usage. The db.t3 instances are configured for Unlimited mode. These instance classes provide more computing capacity than the previous db.t2 instance classes. They are powered by the AWS Nitro System, a combination of dedicated hardware and lightweight hypervisor.
- **db.t2** – Instance classes that provide a baseline performance level, with the ability to burst to full CPU usage. The db.t2 instances are configured for Unlimited mode. We recommend using these instance classes only for development and test servers, or other non-production servers.

  For the RDS for MariaDB, RDS for MySQL, RDS for SQL Server, and RDS for PostgreSQL DB engines, Amazon RDS has started the end-of-support process for this DB instance class using the following schedule. For all RDS DB instances that use this instance class, we recommend that you upgrade to a newer generation DB instance class as soon as possible.

Action or recommendation	Dates
Starting on this date, Amazon RDS began automatically upgrading instances using db.t2 to	June 1, 2024

Action or recommendation	Dates
the newer generation db.t3 instance class. Creating DB instances using the db.t2 instance class is no longer supported.	
Amazon RDS ends support for db.t2.	December 31, 2024

> **Note**
>
> The DB instance classes that use the AWS Nitro System (db.m5, db.r5, db.t3) are throttled on combined read plus write workload.

For DB instance class hardware specifications, see Hardware specifications for DB instance classes.

Optimized Reads instance class type

The following Optimized Reads instance class types are available:

- **db.r6gd** – Instance classes powered by AWS Graviton2 processors. These instance classes are ideal for running memory-intensive workloads and offer local NVMe-based SSD block-level storage for applications that need high-speed, low latency local storage.
- **db.r6id** – Instance classes powered by 3rd Generation Intel Xeon Scalable processors. These instance classes are SAP-Certified and are an ideal fit for memory-intensive workloads. They offer a maximum memory of 1 TiB and up to 7.6 TB of direct-attached NVMe-based SSD storage.

Supported DB engines for DB instance classes

The following are DB engine–specific considerations for DB instance classes:

Db2

DB instance class support varies according to the version and edition of Db2. For instance class support by version and edition, see Amazon RDS for Db2 instance classes.

Microsoft SQL Server

DB instance class support varies according to the version and edition of SQL Server. For instance class support by version and edition, see DB instance class support for Microsoft SQL Server.

Oracle

DB instance class support varies according to the Oracle Database version and edition. RDS for Oracle supports additional memory-optimized instance classes. These classes have names of the form db.r5.*instance_size*.tpc*threads_per_core*.mem*ratio*. For the vCPU count and memory allocation for each optimized class, see Supported RDS for Oracle DB instance classes.

RDS Custom

For information about the DB instance classes supported in RDS Custom, see DB instance class support for RDS Custom for Oracle and DB instance class support for RDS Custom for SQL Server.

In the following table, you can find details about supported Amazon RDS DB instance classes for each Amazon RDS DB engine. The cell for each engine contains one of the following values:

Yes

The instance class is supported for all versions of the DB engine.

No

The instance class isn't supported for the DB engine.

specific-versions

The instance class is supported only for the specified database versions of the DB engine.

Amazon RDS periodically deprecates major and minor DB engine versions. Not all AWS Regions might have support for earlier engine versions. For information about current supported versions, see topics for the individual DB engines: MariaDB versions, Microsoft SQL Server versions, MySQL versions, Oracle versions, and PostgreSQL versions.

Topics

- Supported DB engines for general-purpose instance classes

- Supported DB engines for memory-optimized instance classes
- Supported DB engines for compute-optimized instance classes
- Supported DB engines for burstable-performance instance classes
- Supported DB engines for Optimized Reads instance classes

Supported DB engines for general-purpose instance classes

The following tables show the supported databases and database versions for the general-purpose instance classes.

db.m7g – general-purpose instance classes powered by AWS Graviton3 processors

Instance class	Db2	MariaDB	Micros SQL Server	MySQL	Orac	PostgreSQL
db.m7g.1 xlarge	No	MariaDB 10.11 versions, 10.6.10 and higher 10.6 versions, 10.5.17 and higher 10.5 versions, and 10.4.26 and higher 10.4 versions	No	MySQL 8.0.28 and higher	No	All PostgreSQL 16 and 15 versions, 14.5 and higher 14 versions, and 13.4 and higher 13 versions
db.m7g.1 xlarge	No	MariaDB 10.11 versions, 10.6.10 and higher 10.6 versions, 10.5.17 and higher 10.5 versions, and 10.4.26 and higher 10.4 versions	No	MySQL 8.0.28 and higher	No	All PostgreSQL 16 and 15 versions, 14.5 and higher 14 versions, and 13.4 and higher 13 versions
db.m7g.8 large	No	MariaDB 10.11 versions, 10.6.10 and higher 10.6 versions, 10.5.17 and higher 10.5 versions, and 10.4.26 and higher 10.4 versions	No	MySQL 8.0.28 and higher	No	All PostgreSQL 16 and 15 versions, 14.5 and higher 14 versions, and 13.4 and higher 13 versions

Instance class	Db2	MariaDB	Micros SQL Server	MySQL	Orac	PostgreSQL
db.m7g.4 large	No	MariaDB 10.11 versions, 10.6.10 and higher 10.6 versions, 10.5.17 and higher 10.5 versions, and 10.4.26 and higher 10.4 versions	No	MySQL 8.0.28 and higher	No	All PostgreSQL 16 and 15 versions, 14.5 and higher 14 versions, and 13.4 and higher 13 versions
db.m7g.2 large	No	MariaDB 10.11 versions, 10.6.10 and higher 10.6 versions, 10.5.17 and higher 10.5 versions, and 10.4.26 and higher 10.4 versions	No	MySQL 8.0.28 and higher	No	All PostgreSQL 16 and 15 versions, 14.5 and higher 14 versions, and 13.4 and higher 13 versions
db.m7g.xl arge	No	MariaDB 10.11 versions, 10.6.10 and higher 10.6 versions, 10.5.17 and higher 10.5 versions, and 10.4.26 and higher 10.4 versions	No	MySQL 8.0.28 and higher	No	All PostgreSQL 16 and 15 versions, 14.5 and higher 14 versions, and 13.4 and higher 13 versions
db.m7g.la rge	No	MariaDB 10.11 versions, 10.6.10 and higher 10.6 versions, 10.5.17 and higher 10.5 versions, and 10.4.26 and higher 10.4 versions	No	MySQL 8.0.28 and higher	No	All PostgreSQL 16 and 15 versions, 14.5 and higher 14 versions, and 13.4 and higher 13 versions

db.m6g – general-purpose instance classes powered by AWS Graviton2 processors

Instance class	Db2	MariaDB	Micros SQL Server	MySQL	Ora	PostgreSQL
db.m6g.1 xlarge	No	All MariaDB 10.11, 10.6, 10.5, and 10.4 versions	No	MySQL 8.0.23 and higher	No	All PostgreSQL 16, 15, 14, and 13 versions; and 12.7 and higher 12 versions
db.m6g.1 xlarge	No	All MariaDB 10.11, 10.6, 10.5, and 10.4 versions	No	MySQL 8.0.23 and higher	No	All PostgreSQL 16, 15, 14, and 13 versions; and 12.7 and higher 12 versions

db.r3.2xlarge	No	All MariaDB 10.6, 10.5, 10.4, and 10.3 versions	Deprecated	Yes	Deprecated	Deprecated
db.r3.xlarge	No	All MariaDB 10.6, 10.5, 10.4, and 10.3 versions	Deprecated	Yes	Deprecated	Deprecated

Instance class	Db2	MariaDB	Microsoft SQL Server	MySQ	Oracle	PostgreSQL
db.r3.large	No	All MariaDB 10.6, 10.5, 10.4, and 10.3 versions	Deprecated	Yes	Deprecated	Deprecated

Supported DB engines for compute-optimized instance classes

The following tables show the supported databases and database versions for the compute-optimized instance classes.

db.c6gd – compute-optimized instance classes (for Multi-AZ DB cluster deployments only)

Instance class	Db2	Maria	Microsoft SQL Server	MySQL	Orac	PostgreSQL
db.c6gd.16xlarge	No	No	No	MySQL 8.0.28 and higher	No	All PostgreSQL 16 and 15 versions; 14.5 and higher 14 versions; 13.4 and 13.7 and higher 13 versions
db.c6gd.12xlarge	No	No	No	MySQL 8.0.28 and higher	No	All PostgreSQL 16 and 15 versions; 14.5 and higher 14 versions; 13.4 and 13.7 and higher 13 versions
db.c6gd.8xlarge	No	No	No	MySQL 8.0.28 and higher	No	All PostgreSQL 16 and 15 versions; 14.5 and higher 14 versions; 13.4 and 13.7 and higher 13 versions
db.c6gd.4xlarge	No	No	No	MySQL 8.0.28 and higher	No	All PostgreSQL 16 and 15 versions; 14.5 and higher 14 versions; 13.4 and 13.7 and higher 13 versions

Instance class	Db2	Maria	Microsoft SQL Server	MySQL	Orac	PostgreSQL
db.c6gd.2xlarge	No	No	No	MySQL 8.0.28 and higher	No	All PostgreSQL 16 and 15 versions; 14.5 and higher 14 versions; 13.4 and 13.7 and higher 13 versions
db.c6gd.xlarge	No	No	No	MySQL 8.0.28 and higher	No	All PostgreSQL 16 and 15 versions; 14.5 and higher 14 versions; 13.4 and 13.7 and higher 13 versions
db.c6gd.large	No	No	No	MySQL 8.0.28 and higher	No	All PostgreSQL 16 and 15 versions; 14.5 and higher 14 versions; 13.4 and 13.7 and higher 13 versions
db.c6gd.medium	No	No	No	MySQL 8.0.28 and higher	No	All PostgreSQL 16 and 15 versions; 14.5 and higher 14 versions; 13.4 and 13.7 and higher 13 versions

Supported DB engines for burstable-performance instance classes

The following tables show the supported databases and database versions for the burstable-performance instance classes.

db.t4g – burstable-performance instance classes powered by AWS Graviton2 processors

Instance class	Db2	MariaDB	Microsoft SQL Server	MySQL	Orac	PostgreSQL
db.t4g.2xlarge	No	All MariaDB 10.11, 10.6, 10.5, and 10.4 versions	No	MySQL 8.0.25	No	All PostgreSQL 16, 15, 14, and 13 versions;

Instance class	Db2	MariaDB	Microsoft SQL Server	MySQL	Orac	PostgreSQL
				and higher		and 12.7 and higher 12 versions
db.t4g.xlarge	No	All MariaDB 10.11, 10.6, 10.5, and 10.4 versions	No	MySQL 8.0.25 and higher	No	All PostgreSQL 16, 15, 14, and 13 versions; and 12.7 and higher 12 versions
db.t4g.large	No	All MariaDB 10.11, 10.6, 10.5, and 10.4 versions	No	MySQL 8.0.25 and higher	No	All PostgreSQL 16, 15, 14, and 13 versions; and 12.7 and higher 12 versions
db.t4g.medium	No	All MariaDB 10.11, 10.6, 10.5, and 10.4 versions	No	MySQL 8.0.25 and higher	No	All PostgreSQL 16, 15, 14, and 13 versions; and 12.7 and higher 12 versions
db.t4g.small	No	All MariaDB 10.11, 10.6, 10.5, and 10.4 versions	No	MySQL 8.0.25 and higher	No	All PostgreSQL 16, 15, 14, and 13 versions; and 12.7 and higher 12 versions
db.t4g.micro	No	All MariaDB 10.11, 10.6, 10.5, and 10.4 versions	No	MySQL 8.0.25 and higher	No	All PostgreSQL 16, 15, 14, and 13 versions; and 12.7 and higher 12 versions

db.t3 – burstable-performance instance classes

Instance class	Db2	Maria	Microsoft SQL Server	MySQ	Oracle	PostgreSQL
db.t3.2xlarge	Yes	Yes	Yes	Yes	Yes	All PostgreSQL 16, 15, 14, 13, 12, 11, and 10 versions; and 9.6.22 and higher 9 versions
db.t3.xlarge	Yes	Yes	Yes	Yes	Yes	All PostgreSQL 16, 15, 14, 13, 12, 11, and 10 versions; and 9.6.22 and higher 9 versions
db.t3.large	Yes	Yes	Yes	Yes	Yes	All PostgreSQL 16, 15, 14, 13, 12, 11, and 10 versions; and 9.6.22 and higher 9 versions
db.t3.medium	Yes	Yes	Yes	Yes	Yes	All PostgreSQL 16, 15, 14, 13, 12, 11, and 10 versions; and 9.6.22 and higher 9 versions
db.t3.small	Yes	Yes	Yes	Yes	Yes	All PostgreSQL 16, 15, 14, 13, 12, 11, and 10 versions; and 9.6.22 and higher 9 versions
db.t3.micro	No	Yes	Yes	Yes	Only on Oracle Database 12c Release 1 (12.1.0.2), which is deprecated	All PostgreSQL 16, 15, 14, 13, 12, 11, and 10 versions; and 9.6.22 and higher 9 versions

db.t2 – burstable-performance instance classes

Instance class	Db2	MariaDB	Microsof SQL Server	MySQL	Oracle	PostgreSQL
db.t2.2xlarge	No	Deprecated	No	Deprecated	Deprecated	Deprecated
db.t2.xlarge	No	Deprecated	No	Deprecated	Deprecated	Deprecated

Determining DB instance class support in AWS Regions

To determine the DB instance classes supported by each DB engine in a specific AWS Region, you can take one of several approaches. You can use the AWS Management Console, the Amazon RDS Pricing page, or the describe-orderable-db-instance-options command for the AWS Command Line Interface (AWS CLI).

> **Note**
>
> When you perform operations with the AWS Management Console, it automatically shows the supported DB instance classes for a specific DB engine, DB engine version, and AWS Region. Examples of the operations that you can perform include creating and modifying a DB instance.

Contents

Using the Amazon RDS pricing page to determine DB instance class support in AWS Regions

You can use the Amazon RDS Pricing page to determine the DB instance classes supported by each DB engine in a specific AWS Region.

To use the pricing page to determine the DB instance classes supported by each engine in a Region

1. Go to Amazon RDS Pricing.
2. In the **AWS Pricing Calculator for Amazon RDS** section, choose **Create your custom estimate now**.
3. In **Choose a Region**, choose an AWS Region.
4. In **Find a Service**, enter **`Amazon RDS`**.

5. Choose **Configure** for your configuration option and DB engine.
6. Use the section for compatible instances to view the supported DB instance classes.
7. (Optional) Choose other options in the calculator, and then choose **Save and view summary** or **Save and add service**.

Using the AWS CLI to determine DB instance class support in AWS Regions

You can use the AWS CLI to determine which DB instance classes are supported for specific DB engines and DB engine versions in an AWS Region. The following table shows the valid DB engine values.

Engine names	Engine values in CLI commands	More information about versions
Db2	`db2-ae` `db2-se`	Db2 on Amazon RDS versions
MariaDB	`mariadb`	MariaDB on Amazon RDS versions

Microsoft SQL Server	`sqlserver-ee`
	`sqlserver-se`
	`sqlserver-ex`
	`sqlserver-web`
		Microsoft SQL Server versions on Amazon RDS

MySQL	`mysql`	MySQL on Amazon RDS versions
Oracle	`oracle-ee` `oracle-se2`	*Amazon RDS for Oracle Release Notes*
PostgreSQL	`postgres`	Available PostgreSQL database versions

For information about AWS Region names, see AWS Regions.

The following examples demonstrate how to determine DB instance class support in an AWS Region using the describe-orderable-db-instance-options AWS CLI command.

> **Note**
>
> To limit the output, these examples show results only for the General Purpose SSD (gp2) storage type. If necessary, you can change the storage type to General Purpose SSD (gp3), Provisioned IOPS (`io1`), or magnetic (`standard`) in the commands.

Topics

- Listing the DB instance classes that are supported by a specific DB engine version in an AWS Region
- Listing the DB engine versions that support a specific DB instance class in an AWS Region

Listing the DB instance classes that are supported by a specific DB engine version in an AWS Region

To list the DB instance classes that are supported by a specific DB engine version in an AWS Region, run the following command.

For Linux, macOS, or Unix:

```
aws rds describe-orderable-db-instance-options --engine engine --engine-version version
 \
    --query "*[].{DBInstanceClass:DBInstanceClass,StorageType:StorageType}|[?
StorageType=='gp2']|[].{DBInstanceClass:DBInstanceClass}" \
    --output text \
    --region region
```

For Windows:

```
aws rds describe-orderable-db-instance-options --engine engine --engine-version version
 ^
    --query "*[].{DBInstanceClass:DBInstanceClass,StorageType:StorageType}|[?
StorageType=='gp2']|[].{DBInstanceClass:DBInstanceClass}" ^
    --output text ^
    --region region
```

For example, the following command lists the supported DB instance classes for version 13.6 of the RDS for PostgreSQL DB engine in US East (N. Virginia).

For Linux, macOS, or Unix:

```
aws rds describe-orderable-db-instance-options --engine postgres --engine-version 15.4
 \
    --query "*[].{DBInstanceClass:DBInstanceClass,StorageType:StorageType}|[?
StorageType=='gp2']|[].{DBInstanceClass:DBInstanceClass}" \
    --output text \
    --region us-east-1
```

For Windows:

```
aws rds describe-orderable-db-instance-options --engine postgres --engine-version 15.4
 ^
    --query "*[].{DBInstanceClass:DBInstanceClass,StorageType:StorageType}|[?
StorageType=='gp2']|[].{DBInstanceClass:DBInstanceClass}" ^
    --output text ^
    --region us-east-1
```

Listing the DB engine versions that support a specific DB instance class in an AWS Region

To list the DB engine versions that support a specific DB instance class in an AWS Region, run the following command.

For Linux, macOS, or Unix:

```
aws rds describe-orderable-db-instance-options --engine engine --db-instance-
class DB_instance_class \
    --query "*[].{EngineVersion:EngineVersion,StorageType:StorageType}|[?
StorageType=='gp2']|[].{EngineVersion:EngineVersion}" \
    --output text \
    --region region
```

For Windows:

```
aws rds describe-orderable-db-instance-options --engine engine --db-instance-
class DB_instance_class ^
    --query "*[].{EngineVersion:EngineVersion,StorageType:StorageType}|[?
StorageType=='gp2']|[].{EngineVersion:EngineVersion}" ^
    --output text ^
```

```
    --region region
```

For example, the following command lists the DB engine versions of the RDS for PostgreSQL DB engine that support the db.r5.large DB instance class in US East (N. Virginia).

For Linux, macOS, or Unix:

```
aws rds describe-orderable-db-instance-options --engine postgres --db-instance-class
 db.m7g.large \
    --query "*[].{EngineVersion:EngineVersion,StorageType:StorageType}|[?
StorageType=='gp2']|[].{EngineVersion:EngineVersion}" \
    --output text \
    --region us-east-1
```

For Windows:

```
aws rds describe-orderable-db-instance-options --engine postgres --db-instance-class
 db.m7g.large ^
    --query "*[].{EngineVersion:EngineVersion,StorageType:StorageType}|[?
StorageType=='gp2']|[].{EngineVersion:EngineVersion}" ^
    --output text ^
    --region us-east-1
```

Changing your DB instance class

You can change the CPU and memory available to a DB instance by changing its DB instance class. To change the DB instance class, modify your DB instance by following the instructions in Modifying an Amazon RDS DB instance.

Configuring the processor for a DB instance class in RDS for Oracle

Amazon RDS DB instance classes support Intel Hyper-Threading Technology, which enables multiple threads to run concurrently on a single Intel Xeon CPU core. Each thread is represented as a virtual CPU (vCPU) on the DB instance. A DB instance has a default number of CPU cores, which varies according to DB instance class. For example, a db.m4.xlarge DB instance class has two CPU cores and two threads per core by default—four vCPUs in total.

> **Note**
>
> Each vCPU is a hyperthread of an Intel Xeon CPU core.

Topics

Overview of processor configuration for RDS for Oracle

When you use RDS for Oracle, you can usually find a DB instance class that has a combination of memory and number of vCPUs to suit your workloads. However, you can also specify the following processor features to optimize your RDS for Oracle DB instance for specific workloads or business needs:

- **Number of CPU cores** – You can customize the number of CPU cores for the DB instance. You might do this to potentially optimize the licensing costs of your software with a DB instance that has sufficient amounts of RAM for memory-intensive workloads but fewer CPU cores.
- **Threads per core** – You can disable Intel Hyper-Threading Technology by specifying a single thread per CPU core. You might do this for certain workloads, such as high-performance computing (HPC) workloads.

You can control the number of CPU cores and threads for each core separately. You can set one or both in a request. After a setting is associated with a DB instance, the setting persists until you change it.

The processor settings for a DB instance are associated with snapshots of the DB instance. When a snapshot is restored, its restored DB instance uses the processor feature settings used when the snapshot was taken.

If you modify the DB instance class for a DB instance with nondefault processor settings, either specify default processor settings or explicitly specify processor settings at modification. This requirement ensures that you are aware of the third-party licensing costs that might be incurred when you modify the DB instance.

There is no additional or reduced charge for specifying processor features on an RDS for Oracle DB instance. You're charged the same as for DB instances that are launched with default CPU configurations.

DB instance classes that support processor configuration

You can configure the number of CPU cores and threads per core only when the following conditions are met:

- You're configuring an RDS for Oracle DB instance. For information about the DB instance classes supported by different Oracle Database editions, see RDS for Oracle DB instance classes.
- Your DB instance is using the Bring Your Own License (BYOL) licensing option of RDS for Oracle. For more information about Oracle licensing options, see RDS for Oracle licensing options.
- Your DB instance doesn't belong to one of the db.r5 or db.r5b instance classes that have predefined processor configurations. These instance classes have names in the form db.r5.*instance_size*.tpc*threads_per_core*.mem*ratio* or db.r5b.*instance_size*.tpc*threads_per_core*.mem*ratio*. For example, db.r5b.xlarge.tpc2.mem4x is preconfigured with 2 threads per core (tpc2) and 4x as much memory as the standard db.r5b.xlarge instance class. You can't configure the processor features of these optimized instance classes. For more information, see Supported RDS for Oracle DB instance classes.

In the following table, you can find the DB instance classes that support setting a number of CPU cores and CPU threads per core. You can also find the default value and the valid values for the number of CPU cores and CPU threads per core for each DB instance class.

DB instance class	Default vCPUs	Default CPU cores	Default threads per core	Valid number of CPU cores	Valid number of threads per core
db.m6i – memory-optimized instance classes					
db.m6i.large	2	1	2	1	1, 2
db.m6i.xlarge	4	2	2	2	1, 2
db.m6i.2xlarge	8	4	2	2, 4	1, 2
db.m6i.4xlarge	16	8	2	2, 4, 6, 8	1, 2
db.m6i.4xlarge	16	8	2	2, 4, 6, 8	1, 2

DB instance class	Default vCPUs	Default CPU cores	Default threads per core	Valid number of CPU cores	Valid number of threads per core
db.m6i.8xlarge	32	16	2	2, 4, 6, 8, 10, 12, 14, 16	1, 2
db.m6i.12xlarge	48	24	2	2, 4, 6, 8, 10, 12, 14, 16, 18, 20, 22, 24	1, 2
db.m6i.16xlarge	64	32	2	2, 4, 6, 8, 10, 12, 14, 16, 18, 20, 22, 24, 26, 28, 30, 32	1, 2
db.m6i.24xlarge	96	48	2	2, 4, 6, 8, 10, 12, 14, 16, 18, 20, 22, 24, 26, 28, 30, 32, 34, 36, 38, 40, 42, 44, 46, 48	1, 2

DB instance class	Default vCPUs	Default CPU cores	Default threads per core	Valid number of CPU cores	Valid number of threads per core
db.m6i.32xlarge	128	64	2	2, 4, 6, 8, 10, 12, 14, 16, 18, 20, 22, 24, 26, 28, 30, 32, 34, 36, 38, 40, 42, 44, 46, 48, 50, 52, 54, 56, 58, 60, 62, 64	1, 2
db.m5 – general-purpose instance classes					
db.m5.large	2	1	2	1	1, 2
db.m5.xlarge	4	2	2	2	1, 2
db.m5.2xlarge	8	4	2	2, 4	1, 2

> **Note**
>
> You can use AWS CloudTrail to monitor and audit changes to the process configuration of Amazon RDS for Oracle DB instances. For more information about using CloudTrail, see Monitoring Amazon RDS API calls in AWS CloudTrail.

Setting the CPU cores and threads per CPU core for a DB instance class

You can configure the number of CPU cores and threads per core for the DB instance class when you perform the following operations:

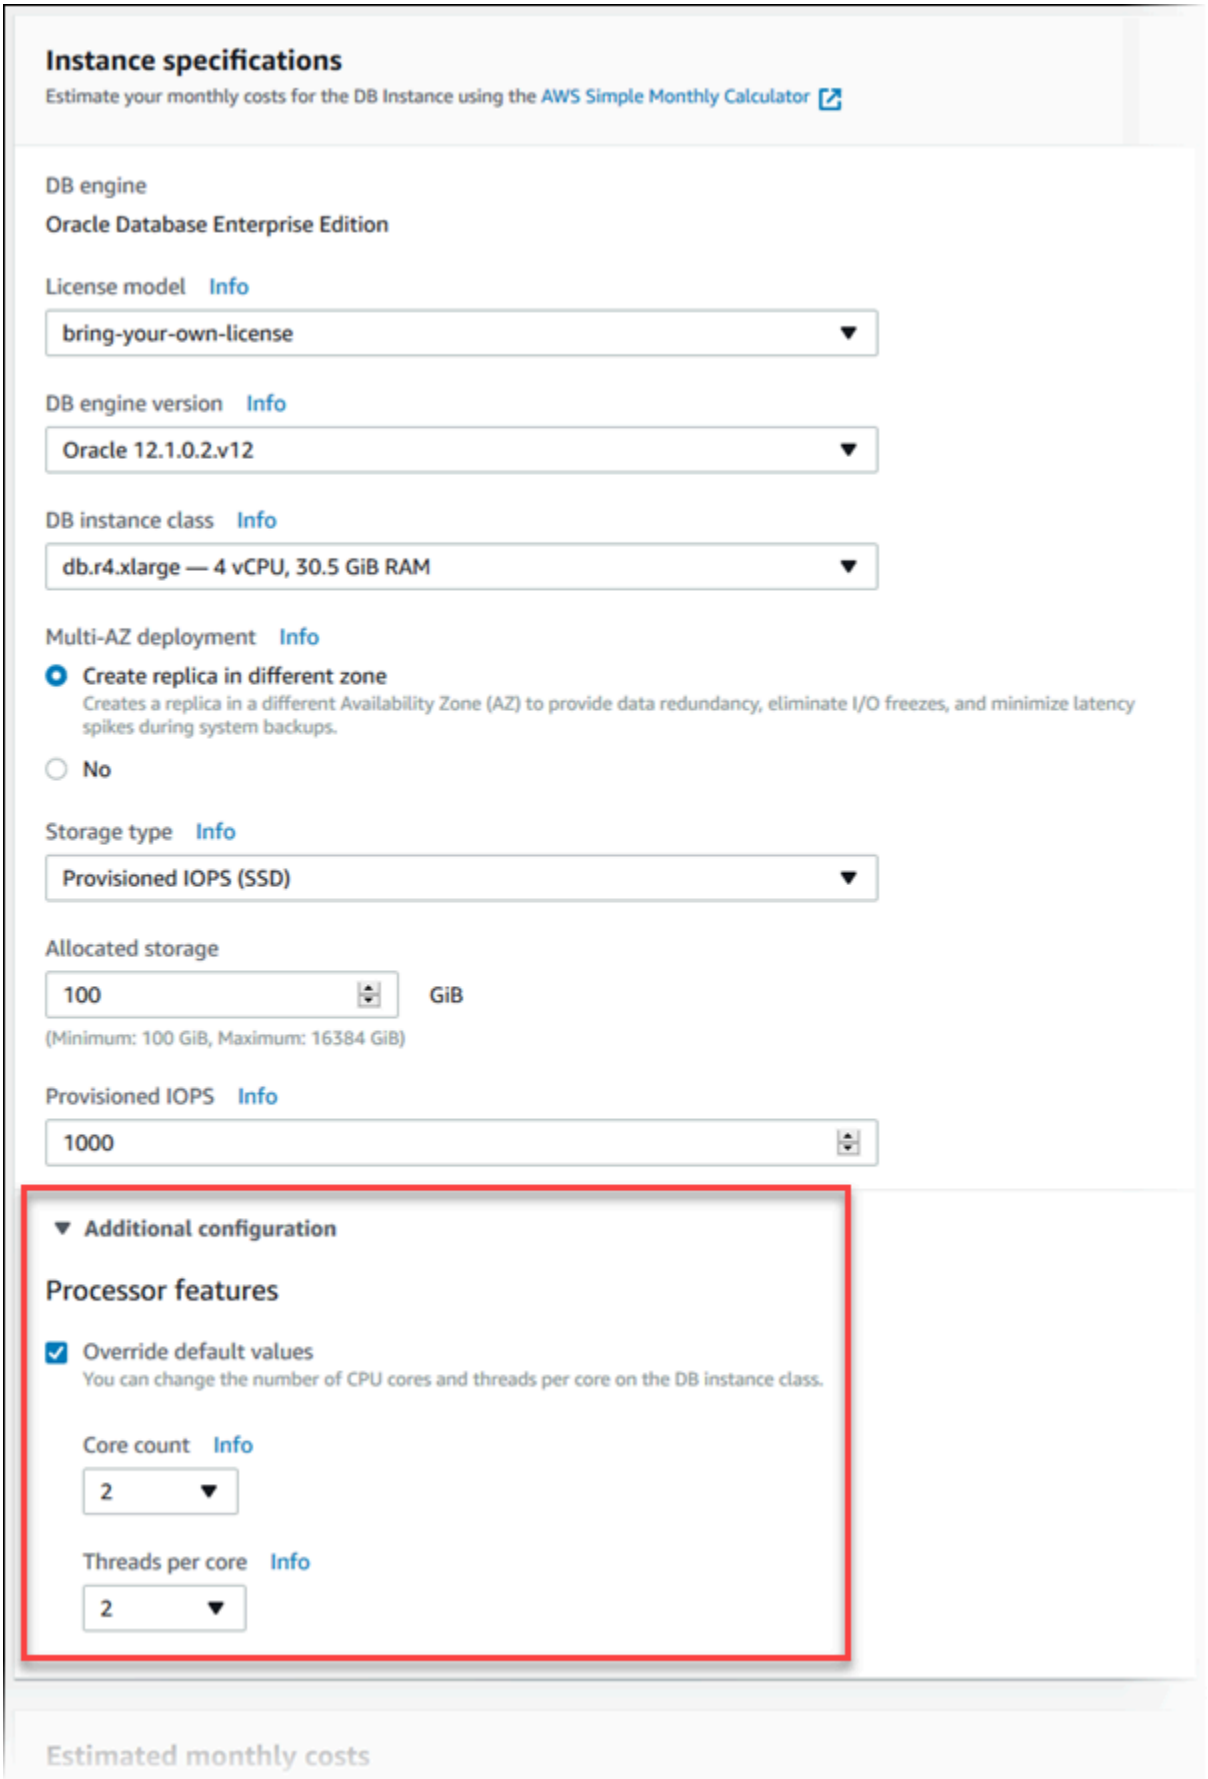
- Creating an Amazon RDS DB instance
- Modifying an Amazon RDS DB instance
- Restoring to a DB instance
- Restoring a DB instance to a specified time

> **Note**
>
> When you modify a DB instance to configure the number of CPU cores or threads per core, there is a brief DB instance outage.

You can set the CPU cores and the threads per CPU core for a DB instance class using the AWS Management Console, the AWS CLI, or the RDS API.

Console

When you are creating, modifying, or restoring a DB instance, you set the DB instance class in the AWS Management Console. The **Instance specifications** section shows options for the processor. The following image shows the processor features options.



Instance specifications
Estimate your monthly costs for the DB Instance using the AWS Simple Monthly Calculator

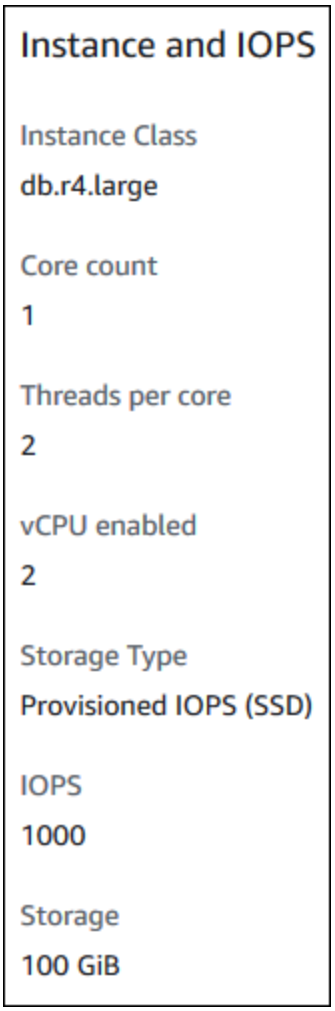
Estimated monthly costs

Set the following options to the appropriate values for your DB instance class under **Processor features**:

- **Core count –** Set the number of CPU cores using this option. The value must be equal to or less than the maximum number of CPU cores for the DB instance class.
- **Threads per core** – Specify **2** to enable multiple threads per core, or specify **1** to disable multiple threads per core.

When you modify or restore a DB instance, you can also set the CPU cores and the threads per CPU core to the defaults for the instance class.

When you view the details for a DB instance in the console, you can view the processor information for its DB instance class on the **Configuration** tab. The following image shows a DB instance class with one CPU core and multiple threads per core enabled.



For Oracle DB instances, the processor information only appears for Bring Your Own License (BYOL) DB instances.

AWS CLI

You can set the processor features for a DB instance when you run one of the following AWS CLI commands:

- create-db-instance
- modify-db-instance
- restore-db-instance-from-db-snapshot
- restore-db-instance-from-s3
- restore-db-instance-to-point-in-time

To configure the processor of a DB instance class for a DB instance by using the AWS CLI, include the `--processor-features` option in the command. Specify the number of CPU cores with the `coreCount` feature name, and specify whether multiple threads per core are enabled with the `threadsPerCore` feature name.

The option has the following syntax.

```
--processor-features "Name=coreCount,Value=<value>" "Name=threadsPerCore,Value=<value>"
```

The following are examples that configure the processor:

Examples

- Setting the number of CPU cores for a DB instance
- Setting the number of CPU cores and disabling multiple threads for a DB instance
- Viewing the valid processor values for a DB instance class
- Returning to default processor settings for a DB instance
- Returning to the default number of CPU cores for a DB instance
- Returning to the default number of threads per core for a DB instance

Setting the number of CPU cores for a DB instance

Example

The following example modifies `mydbinstance` by setting the number of CPU cores to 4. The changes are applied immediately by using `--apply-immediately`. If you want to apply the changes during the next scheduled maintenance window, omit the `--apply-immediately` option.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier mydbinstance \
    --processor-features "Name=coreCount,Value=4" \
    --apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier mydbinstance ^
    --processor-features "Name=coreCount,Value=4" ^
    --apply-immediately
```

Setting the number of CPU cores and disabling multiple threads for a DB instance

Example

The following example modifies `mydbinstance` by setting the number of CPU cores to 4 and disabling multiple threads per core. The changes are applied immediately by using `--apply-immediately`. If you want to apply the changes during the next scheduled maintenance window, omit the `--apply-immediately` option.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier mydbinstance \
    --processor-features "Name=coreCount,Value=4" "Name=threadsPerCore,Value=1" \
    --apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier mydbinstance ^
    --processor-features "Name=coreCount,Value=4" "Name=threadsPerCore,Value=1" ^
    --apply-immediately
```

Viewing the valid processor values for a DB instance class

Example

You can view the valid processor values for a particular DB instance class by running the describe-orderable-db-instance-options command and specifying the instance class for the `--db-instance-class` option. For example, the output for the following command shows the processor options for the db.r3.large instance class.

```
aws rds describe-orderable-db-instance-options --engine oracle-ee --db-instance-class
 db.r3.large
```

Following is sample output for the command in JSON format.

```
    {
                "SupportsIops": true,
                "MaxIopsPerGib": 50.0,
                "LicenseModel": "bring-your-own-license",
                "DBInstanceClass": "db.r3.large",
                "SupportsIAMDatabaseAuthentication": false,
                "MinStorageSize": 100,
                "AvailabilityZones": [
                    {
                        "Name": "us-west-2a"
                    },
                    {
                        "Name": "us-west-2b"
                    },
                    {
                        "Name": "us-west-2c"
                    }
                ],
                "EngineVersion": "12.1.0.2.v2",
                "MaxStorageSize": 32768,
                "MinIopsPerGib": 1.0,
                "MaxIopsPerDbInstance": 40000,
                "ReadReplicaCapable": false,
```

```
                "AvailableProcessorFeatures": [
                    {
                        "Name": "coreCount",
                        "DefaultValue": "1",
                        "AllowedValues": "1"
                    },
                    {
                        "Name": "threadsPerCore",
                        "DefaultValue": "2",
                        "AllowedValues": "1,2"
                    }
                ],
                "SupportsEnhancedMonitoring": true,
                "SupportsPerformanceInsights": false,
                "MinIopsPerDbInstance": 1000,
                "StorageType": "io1",
                "Vpc": false,
                "SupportsStorageEncryption": true,
                "Engine": "oracle-ee",
                "MultiAZCapable": true
    }
```

In addition, you can run the following commands for DB instance class processor information:

- describe-db-instances – Shows the processor information for the specified DB instance.
- describe-db-snapshots – Shows the processor information for the specified DB snapshot.
- describe-valid-db-instance-modifications – Shows the valid modifications to the processor for the specified DB instance.

In the output of the preceding commands, the values for the processor features are not null only if the following conditions are met:

- You are using an RDS for Oracle DB instance.
- Your RDS for Oracle DB instance supports changing processor values.
- The current CPU core and thread settings are set to nondefault values.

If the preceding conditions aren't met, you can get the instance type using describe-db-instances. You can get the processor information for this instance type by running the EC2 operation describe-instance-types.

Returning to default processor settings for a DB instance

Example

The following example modifies `mydbinstance` by returning its DB instance class to the default processor values for it. The changes are applied immediately by using `--apply-immediately`. If you want to apply the changes during the next scheduled maintenance window, omit the `--apply-immediately` option.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier mydbinstance \
    --use-default-processor-features \
    --apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier mydbinstance ^
    --use-default-processor-features ^
    --apply-immediately
```

Returning to the default number of CPU cores for a DB instance

Example

The following example modifies `mydbinstance` by returning its DB instance class to the default number of CPU cores for it. The threads per core setting isn't changed. The changes are applied immediately by using `--apply-immediately`. If you want to apply the changes during the next scheduled maintenance window, omit the `--apply-immediately` option.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier mydbinstance \
    --processor-features "Name=coreCount,Value=DEFAULT" \
    --apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier mydbinstance ^
    --processor-features "Name=coreCount,Value=DEFAULT" ^
    --apply-immediately
```

Returning to the default number of threads per core for a DB instance

Example

The following example modifies `mydbinstance` by returning its DB instance class to the default number of threads per core for it. The number of CPU cores setting isn't changed. The changes are applied immediately by using `--apply-immediately`. If you want to apply the changes during the next scheduled maintenance window, omit the `--apply-immediately` option.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier mydbinstance \
    --processor-features "Name=threadsPerCore,Value=DEFAULT" \
    --apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier mydbinstance ^
    --processor-features "Name=threadsPerCore,Value=DEFAULT" ^
    --apply-immediately
```

RDS API

You can set the processor features for a DB instance when you call one of the following Amazon RDS API operations:

- CreateDBInstance
- ModifyDBInstance
- RestoreDBInstanceFromDBSnapshot
- RestoreDBInstanceFromS3
- RestoreDBInstanceToPointInTime

To configure the processor features of a DB instance class for a DB instance by using the Amazon RDS API, include the `ProcessFeatures` parameter in the call.

The parameter has the following syntax.

```
ProcessFeatures "Name=coreCount,Value=<value>" "Name=threadsPerCore,Value=<value>"
```

Specify the number of CPU cores with the `coreCount` feature name, and specify whether multiple threads per core are enabled with the `threadsPerCore` feature name.

You can view the valid processor values for a particular DB instance class by running the DescribeOrderableDBInstanceOptions operation and specifying the instance class for the `DBInstanceClass` parameter. You can also use the following operations:

- DescribeDBInstances – Shows the processor information for the specified DB instance.
- DescribeDBSnapshots – Shows the processor information for the specified DB snapshot.
- DescribeValidDBInstanceModifications – Shows the valid modifications to the processor for the specified DB instance.

In the output of the preceding operations, the values for the processor features are not null only if the following conditions are met:

- You are using an RDS for Oracle DB instance.
- Your RDS for Oracle DB instance supports changing processor values.
- The current CPU core and thread settings are set to nondefault values.

If the preceding conditions aren't met, you can get the instance type using DescribeDBInstances. You can get the processor information for this instance type by running the EC2 operation DescribeInstanceTypes.

Hardware specifications for DB instance classes

In the tables in this section, you can find hardware details about the Amazon RDS DB instance classes.

For information about Amazon RDS DB engine support for each DB instance class, see Supported DB engines for DB instance classes.

Topics

Hardware terminology for DB instance classes

The following terminology is used to describe hardware specifications for DB instance classes:

vCPU

The number of virtual central processing units (CPUs). A *virtual CPU* is a unit of capacity that you can use to compare DB instance classes. Instead of purchasing or leasing a particular processor to use for several months or years, you are renting capacity by the hour. Our goal is to make a consistent and specific amount of CPU capacity available, within the limits of the actual underlying hardware.

ECU

The relative measure of the integer processing power of an Amazon EC2 instance. To make it easy for developers to compare CPU capacity between different instance classes, we have defined an Amazon EC2 Compute Unit. The amount of CPU that is allocated to a particular instance is expressed in terms of these EC2 Compute Units. One ECU currently provides CPU capacity equivalent to a 1.0–1.2 GHz 2007 Opteron or 2007 Xeon processor.

Memory (GiB)

The RAM, in gibibytes, allocated to the DB instance. There is often a consistent ratio between memory and vCPU. As an example, take the db.r4 instance class, which has a memory to vCPU ratio similar to the db.r5 instance class. However, for most use cases the db.r5 instance class provides better, more consistent performance than the db.r4 instance class.

EBS-optimized

The DB instance uses an optimized configuration stack and provides additional, dedicated capacity for I/O. This optimization provides the best performance by minimizing contention between I/O and other traffic from your instance. For more information about Amazon EBS–optimized instances, see Amazon EBS–Optimized instances in the *Amazon EC2 User Guide.*

EBS-optimized instances have a baseline and maximum IOPS rate. The maximum IOPS rate is enforced at the DB instance level. A set of EBS volumes that combine to have an IOPS rate that is higher than the maximum can't exceed the instance-level threshold. For example, if the maximum IOPS for a particular DB instance class is 40,000, and you attach four 64,000 IOPS EBS volumes, the maximum IOPS is 40,000 rather than 256,000. For the IOPS maximum specific to each EC2 instance type, see Supported instance types in the *Amazon EC2 User Guide for Linux Instances*.

Max. EBS bandwidth (Mbps)

The maximum EBS bandwidth in megabits per second. Divide by 8 to get the expected throughput in megabytes per second.

> **Important**
>
> General Purpose SSD (gp2) volumes for Amazon RDS DB instances have a throughput limit of 250 MiB/s in most cases. However, the throughput limit can vary depending on volume size. For more information, see Amazon EBS volume types in the *Amazon EC2 User Guide.*

Network bandwidth

The network speed relative to other DB instance classes.

Hardware specifications for the general-purpose instance classes

The following tables show the compute, memory, storage, and bandwidth specifications for the general-purpose instance classes.

db.m7g – general-purpose instance classes powered by AWS Graviton3 processors

Instance class	vCPU	ECU	Memory (GiB)	Instance storage (GiB)	Max. EBS bandwidth (Mbps)	Network bandwidth (Gbps)
db.m7g.16xlarge	64	—	256	EBS-optimized only	20,000	30

Instance class	vCPU	ECU	Memory (GiB)	Instance storage (GiB)	Max. EBS bandwidth (Mbps)	Network bandwidth (Gbps)
db.m7g.12xlarge	48	—	192	EBS-optimized only	15,000	22.5
db.m7g.8xlarge	32	—	128	EBS-optimized only	10,000	15
db.m7g.4xlarge	16	—	64	EBS-optimized only	Up to 10,000	Up to 15
db.m7g.2xlarge*	8	—	32	EBS-optimized only	Up to 10,000	Up to 15
db.m7g.xlarge*	4	—	16	EBS-optimized only	Up to 10,000	Up to 12.5
db.m7g.large*	2	—	8	EBS-optimized only	Up to 10,000	Up to 12.5

db.m6g – general-purpose instance classes powered by AWS Graviton2 processors

Instance class	vCPU	ECU	Memory (GiB)	Instance storage (GiB)	Max. EBS bandwidth (Mbps)	Network bandwidth (Gbps)
db.m6g.16xlarge	64	—	256	EBS-optimized only	19,000	25
db.m6g.12xlarge	48	—	192	EBS-optimized only	13,500	20
db.m6g.8xlarge	32	—	128	EBS-optimized only	9,000	12

Instance class	vCPU	ECU	Memory (GiB)	Instance storage (GiB)	Max. EBS bandwidth (Mbps)	Network bandwidth (Gbps)
db.m6g.4xlarge	16	—	64	EBS-optimized only	4,750	Up to 10
db.m6g.2xlarge*	8	—	32	EBS-optimized only	Up to 4,750	Up to 10
db.m6g.xlarge*	4	—	16	EBS-optimized only	Up to 4,750	Up to 10
db.m6g.large*	2	—	8	EBS-optimized only	Up to 4,750	Up to 10

db.m6gd – general-purpose instance classes powered by AWS Graviton2 processors and SSD storage

Instance class	vCPU	ECU	Memory (GiB)	Instance storage (GiB)	Max. EBS bandwidth (Mbps)	Network bandwidth (Gbps)
db.m6gd.16xlarge	64	—	256	2 x 1900 NVMe SSD	19,000	25
db.m6gd.12xlarge	48	—	192	2 x 1425 NVMe SSD	13,500	20
db.m6gd.8xlarge	32	—	128	1 x 1900 NVMe SSD	9,000	12
db.m6gd.4xlarge	16	—	64	1 x 950 NVMe SSD	4,750	Up to 10
db.m6gd.2xlarge	8	—	32	1 x 474 NVMe SSD	Up to 4,750	Up to 10

Instance class	vCPU	ECU	Memory (GiB)	Instance storage (GiB)	Max. EBS bandwidth (Mbps)	Network bandwidth (Gbps)
db.m6gd.xlarge	4	—	16	1 x 237 NVMe SSD	Up to 4,750	Up to 10
db.m6gd.large	2	—	8	1 x 118 NVMe SSD	Up to 4,750	Up to 10

db.m6id – general-purpose instance classes powered by 3rd generation Intel Xeon Scalable processors and SSD storage

Instance class	vCPU	ECU	Memory (GiB)	Instance storage (GiB)	Max. EBS bandwidth (Mbps)	Network bandwidth (Gbps)
db.m6id.32xlarge	128	—	512	4 x 1900 NVMe SSD	40,000	50
db.m6id.24xlarge	96	—	384	4 x 1425 NVMe SSD	30,000	37.5
db.m6id.16xlarge	64	—	256	2 x 1900 NVMe SSD	20,000	25
db.m6id.12xlarge	48	—	192	2 x 1425 NVMe SSD	15,000	18.75
db.m6id.8xlarge	32	—	128	1 x 1900 NVMe SSD	10,000	12.5
db.m6id.4xlarge*	16	—	64	1 x 950 NVMe SSD	Up to 10,000	Up to 12.5
db.m6id.2xlarge*	8	—	32	1 x 474 NVMe SSD	Up to 10,000	Up to 12.5

Instance class	vCPU	ECU	Memory (GiB)	Instance storage (GiB)	Max. EBS bandwidth (Mbps)	Network bandwidth (Gbps)
db.m6id.xlarge*	4	—	16	1 x 237 NVMe SSD	Up to 10,000	Up to 12.5
db.m6id.large*	2	—	8	1 x 118 NVMe SSD	Up to 10,000	Up to 12.5

db.m6idn – general-purpose instance classes with 3rd Generation Intel Xeon Scalable processors, SSD storage, and network optimization

Instance class	vCPU	ECU	Memory (GiB)	Instance storage (GiB)	Max. EBS bandwidth (Mbps)	Network bandwidth (Gbps)
db.m6idn.32xlarge	128	—	512	4 x 1900 NVMe SSD	80,000	200
db.m6idn.24xlarge	96	—	384	4 x 1425 NVMe SSD	60,000	150
db.m6idn.16xlarge	64	—	256	2 x 1900 NVMe SSD	40,000	100
db.m6idn.12xlarge	48	—	192	2 x 1425 NVMe SSD	30,000	75
db.m6idn.8xlarge	32	—	128	1 x 1900 NVMe SSD	20,000	50
db.m6idn.4xlarge*	16	—	64	1 x 950 NVMe SSD	Up to 20,000	Up to 50
db.m6idn.2xlarge*	8	—	32	1 x 474 NVMe SSD	Up to 20,000	Up to 40

Instance class	vCPU	ECU	Memory (GiB)	Instance storage (GiB)	Max. EBS bandwidth (Mbps)	Network bandwidth (Gbps)
db.m6idn.xlarge*	4	—	16	1 x 237 NVMe SSD	Up to 20,000	Up to 30
db.m6idn.large*	2	—	8	1 x 118 NVMe SSD	Up to 20,000	Up to 25

db.m6in – general-purpose instance classes powered by 3rd generation Intel Xeon Scalable processors and network optimization

Instance class	vCPU	ECU	Memory (GiB)	Instance storage (GiB)	Max. EBS bandwidth (Mbps)	Network bandwidth (Gbps)
db.m6in.32xlarge	128	—	512	EBS-optimized only	80,000	200
db.m6in.24xlarge	96	—	384	EBS-optimized only	60,000	150
db.m6in.16xlarge	64	—	256	EBS-optimized only	40,000	100
db.m6in.12xlarge	48	—	192	EBS-optimized only	30,000	75
db.m6in.8xlarge	32	—	128	EBS-optimized only	20,000	50
db.m6in.4xlarge*	16	—	64	EBS-optimized only	Up to 20,000	Up to 50
db.m6in.2xlarge*	8	—	32	EBS-optimized only	Up to 20,000	Up to 40

Instance class	vCPU	ECU	Memory (GiB)	Instance storage (GiB)	Max. EBS bandwidth (Mbps)	Network bandwidth (Gbps)
db.m6in.xlarge*	4	—	16	EBS-optimized only	Up to 20,000	Up to 30
db.m6in.large*	2	—	8	EBS-optimized only	Up to 20,000	Up to 25

db.m6i – general-purpose instance classes powered by 3rd generation Intel Xeon Scalable processors

Instance class	vCPU	ECU	Memory (GiB)	Instance storage (GiB)	Max. EBS bandwidth (Mbps)	Network bandwidth (Gbps)
db.m6i.32xlarge	128	—	512	EBS-optimized only	40,000	50
db.m6i.24xlarge	96	—	384	EBS-optimized only	30,000	37.5
db.m6i.16xlarge	64	—	256	EBS-optimized only	20,000	25
db.m6i.12xlarge	48	—	192	EBS-optimized only	15,000	18.75
db.m6i.8xlarge	32	—	128	EBS-optimized only	10,000	12.5
db.m6i.4xlarge*	16	—	64	EBS-optimized only	Up to 10,000	Up to 12.5
db.m6i.2xlarge*	8	—	32	EBS-optimized only	Up to 10,000	Up to 12.5

Instance class	vCPU	ECU	Memory (GiB)	Instance storage (GiB)	Max. EBS bandwidth (Mbps)	Network bandwidth (Gbps)
db.m6i.xlarge*	4	—	16	EBS-optimized only	Up to 10,000	Up to 12.5
db.m6i.large*	2	—	8	EBS-optimized only	Up to 10,000	Up to 12.5

db.m5d – general-purpose instance classes powered by Intel Xeon Platinum processors and SSD storage

Instance class	vCPU	ECU	Memory (GiB)	Instance storage (GiB)	Max. EBS bandwidth (Mbps)	Network bandwidth (Gbps)
db.m5d.24xlarge	96	345	384	4 x 900 NVMe SSD	19,000	25
db.m5d.16xlarge	64	262	256	4 x 600 NVMe SSD	13,600	20
db.m5d.12xlarge	48	173	192	2 x 900 NVMe SSD	9,500	10
db.m5d.8xlarge	32	131	128	2 x 600 NVMe SSD	6,800	10
db.m5d.4xlarge	16	61	64	2 x 300 NVMe SSD	4,750	Up to 10
db.m5d.2xlarge*	8	31	32	1 x 300 NVMe SSD	Up to 4,750	Up to 10
db.m5d.xlarge*	4	15	16	1 x 150 NVMe SSD	Up to 4,750	Up to 10

Instance class	vCPU	ECU	Memory (GiB)	Instance storage (GiB)	Max. EBS bandwidth (Mbps)	Network bandwidth (Gbps)
db.m5d.large*	2	10	8	1 x 75 NVMe SSD	Up to 4,750	Up to 10

db.m5 – general-purpose instance classes with Intel Xeon Platinum processors

Instance class	vCPU	ECU	Memory (GiB)	Instance storage (GiB)	Max. EBS bandwidth (Mbps)	Network bandwidth (Gbps)
db.m5.24xlarge	96	345	384	EBS-optimized only	19,000	25
db.m5.16xlarge	64	262	256	EBS-optimized only	13,600	20
db.m5.12xlarge	48	173	192	EBS-optimized only	9,500	10
db.m5.8xlarge	32	131	128	EBS-optimized only	6,800	10
db.m5.4xlarge	16	61	64	EBS-optimized only	4,750	Up to 10
db.m5.2xlarge*	8	31	32	EBS-optimized only	Up to 4,750	Up to 10
db.m5.xlarge*	4	15	16	EBS-optimized only	Up to 4,750	Up to 10
db.m5.large*	2	10	8	EBS-optimized only	Up to 4,750	Up to 10

db.m4 – general-purpose instance classes with Intel Xeon Scalable processors

Instance class	vCPU	ECU	Memory (GiB)	Instance storage (GiB)	Max. EBS bandwidth (Mbps)	Network bandwidth (Gbps)
db.m4.16xlarge	64	188	256	EBS-optimized only	10,000	25
db.m4.10xlarge	40	124.5	160	EBS-optimized only	4,000	10
db.m4.4xlarge	16	53.5	64	EBS-optimized only	2,000	High
db.m4.2xlarge	8	25.5	32	EBS-optimized only	1,000	High
db.m4.xlarge	4	13	16	EBS-optimized only	750	High
db.m4.large	2	6.5	8	EBS-optimized only	450	Moderate

db.m3 – general-purpose instance classes

Instance class	vCPU	ECU	Memory (GiB)	Instance storage (GiB)	Max. EBS bandwidth (Mbps)	Network bandwidth (Gbps)
db.m3.2xlarge	8	26	30	EBS-optimized only	1,000	High
db.m3.xlarge	4	13	15	EBS-optimized only	500	High
db.m3.large	2	6.5	7.5	EBS only	—	Moderate

Instance class	vCPU	ECU	Memory (GiB)	Instance storage (GiB)	Max. EBS bandwidth (Mbps)	Network bandwidth (Gbps)
db.m3.medium	1	3	3.75	EBS only	—	Moderate

* These DB instance classes can support maximum performance for 30 minutes at least once every 24 hours. For more information on baseline performance of the underlying EC2 instance types, see Amazon EBS-optimized instances in the *Amazon EC2 User Guide.*

Hardware specifications for the memory-optimized instance classes

The following tables show the compute, memory, storage, and bandwidth specifications for the memory-optimized instance classes.

db.z1d – memory-optimized instance classes

Instance class	vCPU	ECU	Memory (GiB)	Instance storage (GiB)	Max. EBS bandwidth (Mbps)	Network bandwidth (Gbps)
db.z1d.12xlarge	48	271	384	2 x 900 NVMe SSD	14,000	25
db.z1d.6xlarge	24	134	192	1 x 900 NVMe SSD	7,000	10
db.z1d.3xlarge	12	75	96	1 x 450 NVMe SSD	3,500	Up to 10
db.z1d.2xlarge	8	53	64	1 x 300 NVMe SSD	2,333	Up to 10
db.z1d.xlarge*	4	28	32	1 x 150 NVMe SSD	Up to 2,333	Up to 10
db.z1d.large*	2	15	16	1 x 75 NVMe SSD	Up to 2,333	Up to 10

db.x2g – memory-optimized instance classes with AWS Graviton2 processors

Instance class	vCPU	ECU	Memory (GiB)	Instance storage (GiB)	Max. EBS bandwidth (Mbps)	Network bandwidth (Gbps)
db.x2g.16xlarge	64	—	1024	EBS-optimized only	19,000	25
db.x2g.12xlarge	48	—	768	EBS-optimized only	14,250	20
db.x2g.8xlarge	32	—	512	EBS-optimized only	9,500	12
db.x2g.4xlarge	16	—	256	EBS-optimized only	4,750	Up to 10
db.x2g.2xlarge	8	—	128	EBS-optimized only	Up to 4,750	Up to 10
db.x2g.xlarge	4	—	64	EBS-optimized only	Up to 4,750	Up to 10
db.x2g.large	2	—	32	EBS-optimized only	Up to 4,750	Up to 10

db.x2idn – memory-optimized instance classes with 3rd generation Intel Xeon Scalable processors

Instance class	vCPU	ECU	Memory (GiB)	Instance storage (GiB)	Max. EBS bandwidth (Mbps)	Network bandwidth (Gbps)
db.x2idn.32xlarge	128	—	2,048	2 x 1900 NVMe SSD	80,000	100

Instance class	vCPU	ECU	Memory (GiB)	Instance storage (GiB)	Max. EBS bandwidth (Mbps)	Network bandwidth (Gbps)
db.x2idn.24xlarge	96	—	1,536	2 x 1425 NVMe SSD	60,000	75
db.x2idn.16xlarge	64	—	1,024	1 x 1900 NVMe SSD	40,000	50

db.x2iedn – memory-optimized instance classes with local NVMe-based SSDs, with 3rd generation Intel Xeon Scalable processors

Instance class	vCPU	ECU	Memory (GiB)	Instance storage (GiB)	Max. EBS bandwidth (Mbps)	Network bandwidth (Gbps)
db.x2iedn.32xlarge	128	—	4,096	2 x 1900 NVMe SSD	80,000	100
db.x2iedn.24xlarge	96	—	3,072	2 x 1425 NVMe SSD	60,000	75
db.x2iedn.16xlarge	64	—	2,048	1 x 1900 NVMe SSD	40,000	50
db.x2iedn.8xlarge	32	—	1,024	1 x 950 NVMe SSD	20,000	25
db.x2iedn.4xlarge	16	—	512	1 x 475 NVMe SSD	Up to 20,000	Up to 25
db.x2iedn.2xlarge	8	—	256	1 x 237 NVMe SSD	Up to 20,000	Up to 25
db.x2iedn.xlarge	4	—	128	1 x 118 NVMe SSD	Up to 20,000	Up to 25

db.x2iezn – memory-optimized instance classes with 2nd generation Intel Xeon Scalable processors

Instance class	vCPU	ECU	Memory (GiB)	Instance storage (GiB)	Max. EBS bandwidth (Mbps)	Network bandwidth (Gbps)
db.x2iezn.12xlarge	>48	—	1,536	EBS-optimized only	19,000	100
db.x2iezn.8xlarge	32	—	1,024	EBS-optimized only	12,000	75
db.x2iezn.6xlarge	24	—	768	EBS-optimized only	Up to 9,500	50
db.x2iezn.4xlarge	16	—	512	EBS-optimized only	Up to 4,750	Up to 25
db.x2iezn.2xlarge	8	—	256	EBS-optimized only	Up to 3,170	Up to 25

db.x1e – memory-optimized instance classes

Instance class	vCPU	ECU	Memory (GiB)	Instance storage (GiB)	Max. EBS bandwidth (Mbps)	Network bandwidth (Gbps)
db.x1e.32xlarge	128	340	3,904	EBS-optimized only	14,000	25
db.x1e.16xlarge	64	179	1,952	EBS-optimized only	7,000	10
db.x1e.8xlarge	32	91	976	EBS-optimized only	3,500	Up to 10

Instance class	vCPU	ECU	Memory (GiB)	Instance storage (GiB)	Max. EBS bandwidth (Mbps)	Network bandwidth (Gbps)
db.x1e.4xlarge	16	47	488	EBS-optimized only	1,750	Up to 10
db.x1e.2xlarge	8	23	244	EBS-optimized only	1,000	Up to 10
db.x1e.xlarge	4	12	122	EBS-optimized only	500	Up to 10

db.x1 – memory-optimized instance classes

Instance class	vCPU	ECU	Memory (GiB)	Instance storage (GiB)	Max. EBS bandwidth (Mbps)	Network bandwidth (Gbps)
db.x1.32xlarge	128	349	1,952	EBS-optimized only	14,000	25
db.x1.16xlarge	64	174.5	976	EBS-optimized only	7,000	10

db.r7g – memory-optimized instance classes with AWS Graviton3 processors

Instance class	vCPU	ECU	Memory (GiB)	Instance storage (GiB)	Max. EBS bandwidth (Mbps)	Network bandwidth (Gbps)
db.r7g.16xlarge	64	—	512	EBS-optimized only	20,000	30
db.r7g.12xlarge	48	—	384	EBS-optimized only	15,000	22.5

Instance class	vCPU	ECU	Memory (GiB)	Instance storage (GiB)	Max. EBS bandwidth (Mbps)	Network bandwidth (Gbps)
db.r7g.8xlarge	32	—	256	EBS-optimized only	10,000	15
db.r7g.4xlarge	16	—	128	EBS-optimized only	Up to 10,000	Up to 15
db.r7g.2xlarge*	8	—	64	EBS-optimized only	Up to 10,000	Up to 15
db.r7g.xlarge*	4	—	32	EBS-optimized only	Up to 10,000	Up to 12.5
db.r7g.large*	2	—	16	EBS-optimized only	Up to 10,000	Up to 12.5

db.r6g – memory-optimized instance classes with AWS Graviton2 processors

Instance class	vCPU	ECU	Memory (GiB)	Instance storage (GiB)	Max. EBS bandwidth (Mbps)	Network bandwidth (Gbps)
db.r6g.16xlarge	64	—	512	EBS-optimized only	19,000	25
db.r6g.12xlarge	48	—	384	EBS-optimized only	13,500	20
db.r6g.8xlarge	32	—	256	EBS-optimized only	9,000	12
db.r6g.4xlarge	16	—	128	EBS-optimized only	4,750	Up to 10

Instance class	vCPU	ECU	Memory (GiB)	Instance storage (GiB)	Max. EBS bandwidth (Mbps)	Network bandwidth (Gbps)
db.r6g.2xlarge*	8	—	64	EBS-optimized only	Up to 4,750	Up to 10
db.r6g.xlarge*	4	—	32	EBS-optimized only	Up to 4,750	Up to 10
db.r6g.large*	2	—	16	EBS-optimized only	Up to 4,750	Up to 10

db.r6gd – memory-optimized instance classes with AWS Graviton2 processors and SSD storage

Instance class	vCPU	ECU	Memory (GiB)	Instance storage (GiB)	Max. EBS bandwidth (Mbps)	Network bandwidth (Gbps)
db.r6gd.16xlarge	64	—	512	2 x 1900 NVMe SSD	19,000	25
db.r6gd.12xlarge	48	—	384	2 x 1425 NVMe SSD	13,500	20
db.r6gd.8xlarge	32	—	256	1 x 1900 NVMe SSD	9,000	12
db.r6gd.4xlarge	16	—	128	1 x 950 NVMe SSD	4,750	Up to 10
db.r6gd.2xlarge	8	—	64	1 x 474 NVMe SSD	Up to 4,750	Up to 10
db.r6gd.xlarge	4	—	32	1 x 237 NVMe SSD	Up to 4,750	Up to 10

Instance class	vCPU	ECU	Memory (GiB)	Instance storage (GiB)	Max. EBS bandwidth (Mbps)	Network bandwidth (Gbps)
db.r6gd.large	2	—	16	1 x 118 NVMe SSD	Up to 4,750	Up to 10

db.r6id – memory-optimized instance classes with 3rd generation Intel Xeon Scalable processors and SSD storage

Instance class	vCPU	ECU	Memory (GiB)	Instance storage (GiB)	Max. EBS bandwidth (Mbps)	Network bandwidth (Gbps)
db.r6id.32xlarge	128	—	1,024	4x1900 NVMe SSD	40,000	50
db.r6id.24xlarge	96	—	768	4x1425 NVMe SSD	30,000	37.5
db.r6id.16xlarge	64	—	512	2x1900 NVMe SSD	20,000	25
db.r6id.12xlarge	48	—	384	2x1425 NVMe SSD	15,000	18.75
db.r6id.8xlarge	32	—	256	1x1900 NVMe SSD	10,000	12.5
db.r6id.4xlarge*	16	—	128	1x950 NVMe SSD	Up to 10,000	Up to 12.5
db.r6id.2xlarge*	8	—	64	1x474 NVMe SSD	Up to 10,000	Up to 12.5
db.r6id.xlarge*	4	—	32	1x237 NVMe SSD	Up to 10,000	Up to 12.5

Instance class	vCPU	ECU	Memory (GiB)	Instance storage (GiB)	Max. EBS bandwidth (Mbps)	Network bandwidth (Gbps)
db.r6id.large*	2	—	16	1x118 NVMe SSD	Up to 10,000	Up to 12.5

db.r6idn – memory-optimized instance classes with 3rd generation Intel Xeon Scalable processors, SSD storage, and network optimization

Instance class	vCPU	ECU	Memory (GiB)	Instance storage (GiB)	Max. EBS bandwidth (Mbps)	Network bandwidth (Gbps)
db.r6idn.32xlarge	128	—	1,024	4x1900 NVMe SSD	80,000	200
db.r6idn.24xlarge	96	—	768	4x1425 NVMe SSD	60,000	150
db.r6idn.16xlarge	64	—	512	2x1900 NVMe SSD	40,000	100
db.r6idn.12xlarge	48	—	384	2x1425 NVMe SSD	30,000	75
db.r6idn.8xlarge	32	—	256	1x1900 NVMe SSD	20,000	50
db.r6idn.4xlarge*	16	—	128	1x950 NVMe SSD	Up to 20,000	Up to 50
db.r6idn.2xlarge*	8	—	64	1x474 NVMe SSD	Up to 20,000	Up to 40
db.r6idn.xlarge*	4	—	32	1x237 NVMe SSD	Up to 20,000	Up to 30

Instance class	vCPU	ECU	Memory (GiB)	Instance storage (GiB)	Max. EBS bandwidth (Mbps)	Network bandwidth (Gbps)
db.r6idn.large*	2	—	16	1x118 NVMe SSD	Up to 20,000	Up to 25

db.r6in – memory-optimized instance classes with 3rd generation Intel Xeon Scalable processors and network optimization

Instance class	vCPU	ECU	Memory (GiB)	Instance storage (GiB)	Max. EBS bandwidth (Mbps)	Network bandwidth (Gbps)
db.r6in.32xlarge	128	—	1,024	EBS-optimized only	80,000	200
db.r6in.24xlarge	96	—	768	EBS-optimized only	60,000	150
db.r6in.16xlarge	64	—	512	EBS-optimized only	40,000	100
db.r6in.12xlarge	48	—	384	EBS-optimized only	30,000	75
db.r6in.8xlarge	32	—	256	EBS-optimized only	20,000	50
db.r6in.4xlarge*	16	—	128	EBS-optimized only	Up to 20,000	Up to 50
db.r6in.2xlarge*	8	—	64	EBS-optimized only	Up to 20,000	Up to 40
db.r6in.xlarge*	4	—	32	EBS-optimized only	Up to 20,000	Up to 30

Instance class	vCPU	ECU	Memory (GiB)	Instance storage (GiB)	Max. EBS bandwidth (Mbps)	Network bandwidth (Gbps)
db.r6in.large*	2	—	16	EBS-optimized only	Up to 20,000	Up to 25

db.r6i – Oracle memory-optimized instance classes preconfigured for high memory, storage, and I/O

Instance class	vCPU	ECU	Memory (GiB)	Instance storage (GiB)	Max. EBS bandwidth (Mbps)	Network bandwidth (Gbps)
db.r6i.8xlarge.tpc2.mem4x	32	—	1024	EBS-optimized only	40,000	50
db.r6i.8xlarge.tpc2.mem3x	32	—	768	EBS-optimized only	30,000	37.5
db.r6i.6xlarge.tpc2.mem4x	24	—	768	EBS-optimized only	30,000	37.5
db.r6i.4xlarge.tpc2.mem4x	16	—	512	EBS-optimized only	20,000	25
db.r6i.4xlarge.tpc2.mem3x	16	—	384	EBS-optimized only	15,000	18.75
db.r6i.4xlarge.tpc2.mem2x	16	—	256	EBS-optimized only	10,000	12.5
db.r6i.2xlarge.tpc2.mem8x	8	—	512	EBS-optimized only	20,000	12.5
db.r6i.2xlarge.tpc2.mem4x	8	—	256	EBS-optimized only	10,000	12.5

Instance class	vCPU	ECU	Memory (GiB)	Instance storage (GiB)	Max. EBS bandwidth (Mbps)	Network bandwidth (Gbps)
db.r6i.2xlarge.tpc1.mem2x	8	—	128	EBS-optimized only	Up to 10,000	12.5
db.r6i.xlarge.tpc2.mem4x	4	—	128	EBS-optimized only	Up to 10,000	12.5
db.r6i.xlarge.tpc2.mem2x	4	—	64	EBS-optimized only	Up to 10,000	12.5
db.r6i.large.tpc1.mem2x	2	—	32	EBS-optimized only	Up to 10,000	12.5

db.r6i – memory-optimized instance classes with 3rd Generation Intel Xeon Scalable processors

Instance class	vCPU	ECU	Memory (GiB)	Instance storage (GiB)	Max. EBS bandwidth (Mbps)	Network bandwidth (Gbps)
db.r6i.32xlarge	128	—	1,024	EBS-optimized only	40,000	50
db.r6i.24xlarge	96	—	768	EBS-optimized only	30,000	37.5
db.r6i.16xlarge	64	—	512	EBS-optimized only	20,000	25
db.r6i.12xlarge	48	—	384	EBS-optimized only	15,000	18.75
db.r6i.8xlarge	32	—	256	EBS-optimized only	10,000	12.5

Instance class	vCPU	ECU	Memory (GiB)	Instance storage (GiB)	Max. EBS bandwidth (Mbps)	Network bandwidth (Gbps)
db.r6i.4xlarge*	16	—	128	EBS-optimized only	Up to 10,000	Up to 12.5
db.r6i.2xlarge*	8	—	64	EBS-optimized only	Up to 10,000	Up to 12.5
db.r6i.xlarge*	4	—	32	EBS-optimized only	Up to 10,000	Up to 12.5
db.r6i.large*	2	—	16	EBS-optimized only	Up to 10,000	Up to 12.5

db.r5d – memory-optimized instance classes with Intel Xeon Platinum processors and SSD storage

Instance class	vCPU	ECU	Memory (GiB)	Instance storage (GiB)	Max. EBS bandwidth (Mbps)	Network bandwidth (Gbps)
db.r5d.24xlarge	96	347	768	4 x 900 NVMe SSD	19,000	25
db.r5d.16xlarge	64	264	512	4 x 600 NVMe SSD	13,600	20
db.r5d.12xlarge	48	173	384	2 x 900 NVMe SSD	9,500	10
db.r5d.8xlarge	32	132	256	2 x 600 NVMe SSD	6,800	10
db.r5d.4xlarge	16	71	128	2 x 300 NVMe SSD	4,750	Up to 10

Instance class	vCPU	ECU	Memory (GiB)	Instance storage (GiB)	Max. EBS bandwidth (Mbps)	Network bandwidth (Gbps)
db.r5d.2xlarge*	8	38	64	1 x 300 NVMe SSD	Up to 4,750	Up to 10
db.r5d.xlarge*	4	19	32	1 x 150 NVMe SSD	Up to 4,750	Up to 10
db.r5d.large*	2	10	16	1 x 75 NVMe SSD	Up to 4,750	Up to 10

db.r5b – Oracle memory-optimized instance classes preconfigured for high memory, storage, and I/O

Instance class	vCPU	ECU	Memory (GiB)	Instance storage (GiB)	Max. EBS bandwidth (Mbps)	Network bandwidth (Gbps)
db.r5b.8xlarge.tpc2.mem3x	32	—	768	EBS-optimized only	60,000	25
db.r5b.6xlarge.tpc2.mem4x	24	—	768	EBS-optimized only	60,000	25
db.r5b.4xlarge.tpc2.mem4x	16	—	512	EBS-optimized only	40,000	20
db.r5b.4xlarge.tpc2.mem3x	16	—	384	EBS-optimized only	30,000	10
db.r5b.4xlarge.tpc2.mem2x	16	—	256	EBS-optimized only	20,000	10
db.r5b.2xlarge.tpc2.mem8x	8	—	512	EBS-optimized only	40,000	20

Instance class	vCPU	ECU	Memory (GiB)	Instance storage (GiB)	Max. EBS bandwidth (Mbps)	Network bandwidth (Gbps)
db.r5b.2xlarge.tpc2.mem4x	8	—	256	EBS-optimized only	20,000	10
db.r5b.2xlarge.tpc1.mem2x	8	—	128	EBS-optimized only	10,000	Up to 10
db.r5b.xlarge.tpc2.mem4x	4	—	128	EBS-optimized only	10,000	Up to 10
db.r5b.xlarge.tpc2.mem2x	4	—	64	EBS-optimized only	Up to 10,000	Up to 10
db.r5b.large.tpc1.mem2x	2	—	32	EBS-optimized only	Up to 10,000	Up to 10

db.r5b – memory-optimized instance classes with Intel Xeon Platinum processors and EBS optimization

Instance class	vCPU	ECU	Memory (GiB)	Instance storage (GiB)	Max. EBS bandwidth (Mbps)	Network bandwidth (Gbps)
db.r5b.24xlarge	96	347	768	EBS-optimized only	60,000	25
db.r5b.16xlarge	64	264	512	EBS-optimized only	40,000	20
db.r5b.12xlarge	48	173	384	EBS-optimized only	30,000	10
db.r5b.8xlarge	32	132	256	EBS-optimized only	20,000	10

Instance class	vCPU	ECU	Memory (GiB)	Instance storage (GiB)	Max. EBS bandwidth (Mbps)	Network bandwidth (Gbps)
db.r5b.4xlarge	16	71	128	EBS-optimized only	10,000	Up to 10
db.r5b.2xlarge*	8	38	64	EBS-optimized only	Up to 10,000	Up to 10
db.r5b.xlarge*	4	19	32	EBS-optimized only	Up to 10,000	Up to 10
db.r5b.large*	2	10	16	EBS-optimized only	Up to 10,000	Up to 10

db.r5 – Oracle memory-optimized instance classes preconfigured for high memory, storage, and I/O

Instance class	vCPU	ECU	Memory (GiB)	Instance storage (GiB)	Max. EBS bandwidth (Mbps)	Network bandwidth (Gbps)
db.r5.12xlarge.tpc2.mem2x	48	—	768	EBS-optimized only	19,000	25
db.r5.8xlarge.tpc2.mem3x	32	—	768	EBS-optimized only	19,000	25
db.r5.6xlarge.tpc2.mem4x	24	—	768	EBS-optimized only	19,000	25
db.r5.4xlarge.tpc2.mem4x	16	—	512	EBS-optimized only	13,600	20
db.r5.4xlarge.tpc2.mem3x	16	—	384	EBS-optimized only	9,500	10

Instance class	vCPU	ECU	Memory (GiB)	Instance storage (GiB)	Max. EBS bandwidth (Mbps)	Network bandwidth (Gbps)
db.r5.4xlarge.tpc2.mem2x	16	—	256	EBS-optimized only	6,800	10
db.r5.2xlarge.tpc2.mem8x	8	—	512	EBS-optimized only	13,600	20
db.r5.2xlarge.tpc2.mem4x	8	—	256	EBS-optimized only	6,800	10
db.r5.2xlarge.tpc1.mem2x	8	—	128	EBS-optimized only	4,750	Up to 10
db.r5.xlarge.tpc2.mem4x	4	—	128	EBS-optimized only	4,750	Up to 10
db.r5.xlarge.tpc2.mem2x	4	—	64	EBS-optimized only	Up to 4,750	Up to 10
db.r5.large.tpc1.mem2x	2	—	32	EBS-optimized only	Up to 4,750	Up to 10

db.r5 – memory-optimized instance classes

Instance class	vCPU	ECU	Memory (GiB)	Instance storage (GiB)	Max. EBS bandwidth (Mbps)	Network bandwidth (Gbps)
db.r5.24xlarge	96	347	768	EBS-optimized only	19,000	25
db.r5.16xlarge	64	264	512	EBS-optimized only	13,600	20

Instance class	vCPU	ECU	Memory (GiB)	Instance storage (GiB)	Max. EBS bandwidth (Mbps)	Network bandwidth (Gbps)
db.r5.12xlarge	48	173	384	EBS-optimized only	9,500	12
db.r5.8xlarge	32	132	256	EBS-optimized only	6,800	10
db.r5.4xlarge	16	71	128	EBS-optimized only	4,750	Up to 10
db.r5.2xlarge*	8	38	64	EBS-optimized only	Up to 4,750	Up to 10
db.r5.xlarge*	4	19	32	EBS-optimized only	Up to 4,750	Up to 10
db.r5.large*	2	10	16	EBS-optimized only	Up to 4,750	Up to 10

db.r4 – memory-optimized instance classes with Intel Xeon Scalable processors

Instance class	vCPU	ECU	Memory (GiB)	Instance storage (GiB)	Max. EBS bandwidth (Mbps)	Network bandwidth (Gbps)
db.r4.16xlarge	64	195	488	EBS-optimized only	14,000	25
db.r4.8xlarge	32	99	244	EBS-optimized only	7,000	10
db.r4.4xlarge	16	53	122	EBS-optimized only	3,500	Up to 10

Instance class	vCPU	ECU	Memory (GiB)	Instance storage (GiB)	Max. EBS bandwidth (Mbps)	Network bandwidth (Gbps)
db.r4.2xlarge	8	27	61	EBS-optimized only	1,700	Up to 10
db.r4.xlarge	4	13.5	30.5	EBS-optimized only	850	Up to 10
db.r4.large	2	7	15.25	EBS-optimized only	425	Up to 10

db.r3 – memory-optimized instance classes

Instance class	vCPU	ECU	Memory (GiB)	Instance storage (GiB)	Max. EBS bandwidth (Mbps)	Network bandwidth (Gbps)
db.r3.8xlarge**	32	104	244	EBS only	—	10
db.r3.4xlarge	16	52	122	EBS-optimized only	2,000	High
db.r3.2xlarge	8	26	61	EBS-optimized only	1,000	High
db.r3.xlarge	4	13	30.5	EBS-optimized only	500	Moderate
db.r3.large	2	6.5	15.25	EBS-optimized only	—	Moderate

* These DB instance classes can support maximum performance for 30 minutes at least once every 24 hours. For more information on baseline performance of the underlying EC2 instance types, see Amazon EBS-optimized instances in the *Amazon EC2 User Guide.*

** The r3.8xlarge DB instance class doesn't have dedicated EBS bandwidth and therefore doesn't offer EBS optimization. For this instance class, network traffic and Amazon EBS traffic share the same 10-gigabit network interface.

Hardware specifications for the compute-optimized instance classes

The following tables show the compute, memory, storage, and bandwidth specifications for the compute-optimized instance classes.

db.c6gd – compute-optimized instance classes (for Multi-AZ DB cluster deployments only)

Instance class	vCPU	ECU	Memory (GiB)	Instance storage (GiB)	Max. EBS bandwidth (Mbps)	Network bandwidth (Gbps)
db.c6gd.16xlarge	64	—	128	2 x 1900 NVMe SSD	19,000	25
db.c6gd.12xlarge	48	—	96	2 x 1425 NVMe SSD	13,500	20
db.c6gd.8xlarge	32	—	64	1 x 1900 NVMe SSD	9,000	12
db.c6gd.4xlarge	16	—	32	1 x 950 NVMe SSD	4,750	Up to 10
db.c6gd.2xlarge	8	—	16	1 x 474 NVMe SSD	Up to 4,750	Up to 10
db.c6gd.xlarge	4	—	8	1 x 237 NVMe SSD	Up to 4,750	Up to 10
db.c6gd.large	2	—	4	1 x 118 NVMe SSD	Up to 4,750	Up to 10
db.c6gd.medium	1	—	2	1 x 59 NVMe SSD	Up to 4,750	Up to 10

Hardware specifications for the burstable-performance instance classes

The following tables show the compute, memory, storage, and bandwidth specifications for the burstable-performance instance classes.

db.t4g – burstable-performance instance classes powered by AWS Graviton2 processors

Instance class	vCPU	ECU	Memory (GiB)	Instance storage (GiB)	Max. EBS bandwidth (Mbps)	Network bandwidth (Gbps)
db.t4g.2xlarge*	8	—	32	EBS-optimized only	Up to 2,780	Up to 5
db.t4g.xlarge*	4	—	16	EBS-optimized only	Up to 2,780	Up to 5
db.t4g.large*	2	—	8	EBS-optimized only	Up to 2,780	Up to 5
db.t4g.medium*	2	—	4	EBS-optimized only	Up to 2,085	Up to 5
db.t4g.small*	2	—	2	EBS-optimized only	Up to 2,085	Up to 5
db.t4g.micro*	2	—	1	EBS-optimized only	Up to 2,085	Up to 5

db.t3 – burstable-performance instance classes

Instance class	vCPU	ECU	Memory (GiB)	Instance storage (GiB)	Max. EBS bandwidth (Mbps)	Network bandwidth (Gbps)
db.t3.2xlarge*	8	Variab	32	EBS-optimized only	Up to 2,048	Up to 5

Instance class	vCPU	ECU	Memory (GiB)	Instance storage (GiB)	Max. EBS bandwidth (Mbps)	Network bandwidth (Gbps)
db.t3.xlarge*	4	Variab	16	EBS-optimized only	Up to 2,048	Up to 5
db.t3.large*	2	Variab	8	EBS-optimized only	Up to 2,048	Up to 5
db.t3.medium*	2	Variab	4	EBS-optimized only	Up to 1,536	Up to 5
db.t3.small*	2	Variab	2	EBS-optimized only	Up to 1,536	Up to 5
db.t3.micro*	2	Variab	1	EBS-optimized only	Up to 1,536	Up to 5

db.t2 – burstable-performance instance classes

Instance class	vCPU	ECU	Memory (GiB)	Instance storage (GiB)	Max. EBS bandwidth (Mbps)	Network bandwidth (Gbps)
db.t2.2xlarge	8	Variab	32	EBS only	—	Moderate
db.t2.xlarge	4	Variab	16	EBS only	—	Moderate
db.t2.large	2	Variab	8	EBS only	—	Moderate
db.t2.medium	2	Variab	4	EBS only	—	Moderate
db.t2.small	1	Variab	2	EBS only	—	Low
db.t2.micro	1	Variab	1	EBS only	—	Low

* These DB instance classes can support maximum performance for 30 minutes at least once every 24 hours. For more information on baseline performance of the underlying EC2 instance types, see Amazon EBS-optimized instances in the *Amazon EC2 User Guide.*

* These DB instance classes can support maximum performance for 30 minutes at least once every 24 hours. For more information on baseline performance of the underlying EC2 instance types, see Amazon EBS-optimized instances in the *Amazon EC2 User Guide.*

** The r3.8xlarge DB instance class doesn't have dedicated EBS bandwidth and therefore doesn't offer EBS optimization. For this instance class, network traffic and Amazon EBS traffic share the same 10-gigabit network interface.

Amazon RDS DB instance storage

DB instances for Amazon RDS for Db2, MariaDB, MySQL, PostgreSQL, Oracle, and Microsoft SQL Server use Amazon Elastic Block Store (Amazon EBS) volumes for database and log storage.

In some cases, your database workload might not be able to achieve 100 percent of the IOPS that you have provisioned. For more information, see Factors that affect storage performance.

For more information about instance storage pricing, see Amazon RDS pricing.

Amazon RDS storage types

Amazon RDS provides three storage types: Provisioned IOPS SSD (also known as io1 and io2 Block Express), General Purpose SSD (also known as gp2 and gp3), and magnetic (also known as standard). They differ in performance characteristics and price, which means that you can tailor your storage performance and cost to the needs of your database workload. You can create Db2, MySQL, MariaDB, Oracle, SQL Server, and PostgreSQL RDS DB instances with up to 64 tebibytes (TiB) of storage. RDS for Db2 doesn't support the gp2 and magnetic storage types.

The following list briefly describes the three storage types:

- **Provisioned IOPS SSD** – Provisioned IOPS storage is designed to meet the needs of I/O-intensive workloads, particularly database workloads, that require low I/O latency and consistent I/O throughput. Provisioned IOPS storage is best suited for production environments.

  For more information about Provisioned IOPS storage, including the storage size ranges, see Provisioned IOPS SSD storage.
- **General Purpose SSD** – General Purpose SSD volumes offer cost-effective storage that is ideal for a broad range of workloads running on medium-sized DB instances. General Purpose storage is best suited for development and testing environments.

  For more information about General Purpose SSD storage, including the storage size ranges, see General Purpose SSD storage.
- **Magnetic** – Amazon RDS also supports magnetic storage for backward compatibility. We recommend that you use General Purpose SSD or Provisioned IOPS SSD for any new storage needs. The maximum amount of storage allowed for DB instances on magnetic storage is 3 TiB. For more information, see Magnetic storage (legacy, not recommended).

When you select General Purpose SSD or Provisioned IOPS SSD, depending on the engine selected and the amount of storage requested, Amazon RDS automatically stripes across multiple volumes to enhance performance, as shown in the following table.

Database engine	Amazon RDS storage size	Number of volumes provisioned
Db2	Less than 400 GiB	1
Db2	400–65,536 GiB	4
MariaDB, MySQL, and PostgreSQL	Less than 400 GiB	1
MariaDB, MySQL, and PostgreSQL	400–65,536 GiB	4
Oracle	Less than 200 GiB	1
Oracle	200–65,536 GiB	4
SQL Server	Any	1

When you modify a General Purpose SSD or Provisioned IOPS SSD volume, it goes through a sequence of states. While the volume is in the `optimizing` state, your volume performance is between the source and target configuration specifications. Transitional volume performance will be no less than the lower of the two specifications.

Important

When you modify an instance's storage so that it goes from one volume to four volumes, or when you modify an instance using magnetic storage, Amazon RDS doesn't use the Elastic Volumes feature. Instead, Amazon RDS provisions new volumes and transparently moves the data from the old volume to the new volumes. This operation consumes a significant amount of IOPS and throughput of both the old and new volumes. Depending on the size of the volume and the amount of database workload present during the modification, this operation can consume a high amount of IOPS, significantly increase I/O latency, and take several hours to complete, while the RDS instance remains in the `Modifying` state.

Provisioned IOPS SSD storage

For a production application that requires fast and consistent I/O performance, we recommend Provisioned IOPS storage. Provisioned IOPS storage is a storage type that delivers predictable performance, and consistently low latency. Provisioned IOPS storage is optimized for online transaction processing (OLTP) workloads that require consistent performance. Provisioned IOPS helps performance tuning of these workloads.

When you create a DB instance, you specify the IOPS rate and the size of the volume. Amazon RDS provides that IOPS rate for the DB instance until you change it.

Amazon RDS offers two types of Provisioned IOPS SSD storage: io2 Block Express storage (recommended) and io1 storage (previous generation).

io2 Block Express storage (recommended)

For I/O-intensive and latency-sensitive workloads, you can use Provisioned IOPS SSD io2 Block Express storage to achieve up to 256,000 I/O operations per second (IOPS). The throughput of io2 Block Express volumes varies based on the amount of IOPS provisioned per volume and on the size of the I/O operations being run.

All RDS io2 volumes based on the AWS Nitro System are io2 Block Express volumes and provide sub-millisecond average latency. DB instances not based on the AWS Nitro System are io2 volumes.

The following table shows the range of Provisioned IOPS and maximum throughput for each database engine and storage size range.

Database engine	Range of storage size	Range of Provisioned IOPS	Maximum throughput
Db2, MariaDB, MySQL, and PostgreSQL	100–65,536 GiB	1,000–256,000 IOPS	16,000 MiB/s
Oracle	100–199 GiB	1,000–199,000 IOPS	16,000 MiB/s
Oracle	200–65,536 GiB	1,000–256,000 IOPS	16,000 MiB/s
SQL Server	20–65,536 GiB	1,000–256,000 IOPS	16,000 MiB/s

The IOPS and storage size ranges have the following constraints:

- The ratio of IOPS to allocated storage (in GiB) must be not more than 1000:1. For DB instances not based on the AWS Nitro System, the ratio is 500:1.
- Maximum IOPS can be provisioned with volumes 256 GiB and larger (1,000 IOPS × 256 GiB = 256,000 IOPS). For DB instances not based on the AWS Nitro System, maximum IOPS are achieved at 512 GiB (500 IOPS x 512 GiB = 256,000 IOPS).
- Throughput scales proportionally up to 0.256 MiB/s per provisioned IOPS. Maximum throughput of 4,000 MiB/s can be achieved at 256,000 IOPS with a 16-KiB I/O size and 16,000 IOPS or higher with a 256-KiB I/O size. For DB instances not based on the AWS Nitro System, maximum throughput of 2,000 MiB/s can be achieved at 128,000 IOPS with a 16-KiB I/O size.
- If you're using storage autoscaling, the same ratios between IOPS and maximum storage threshold (in GiB) also apply. For more information on storage autoscaling, see Managing capacity automatically with Amazon RDS storage autoscaling.

Amazon RDS io2 Block Express volumes are available in the following AWS Regions:

- Asia Pacific (Hong Kong)
- Asia Pacific (Mumbai)
- Asia Pacific (Seoul)
- Asia Pacific (Singapore)
- Asia Pacific (Sydney)
- Asia Pacific (Tokyo)
- Canada (Central)
- Europe (Frankfurt)
- Europe (Ireland)
- Europe (London)
- Europe (Stockholm)
- Middle East (Bahrain)
- US East (Ohio)
- US East (N. Virginia)
- US West (N. California)
- US West (Oregon)

io1 storage (previous generation)

For I/O-intensive workloads, you can use Provisioned IOPS SSD io1 storage and achieve up to 256,000 I/O operations per second (IOPS). The throughput of io1 volumes varies based on the amount of IOPS provisioned per volume and on the size of the I/O operations being run. We recommend using io2 Block Express storage where it's available.

The following table shows the range of Provisioned IOPS and maximum throughput for each database engine and storage size range.

Database engine	Range of storage size	Range of Provisioned IOPS	Maximum throughput
Db2, MariaDB, MySQL, and PostgreSQL	100–399 GiB	1,000–19,950 IOPS	500 MiB/s
Db2, MariaDB, MySQL, and PostgreSQL	400–65,536 GiB	1,000–256,000 IOPS	4,000 MiB/s
Oracle	100–199 GiB	1,000–9,950 IOPS	500 MiB/s
Oracle	200–65,536 GiB	1,000–256,000 IOPS[1]	4,000 MiB/s
SQL Server	20–16,384 GiB	1,000–64,000 IOPS[2]	1,000 MiB/s

Note

[1] For Oracle, you can provision the maximum 256,000 IOPS only on the r5b instance type.
[2] For SQL Server, the maximum 64,000 IOPS is guaranteed only on Nitro-based instances that are on the m5*, m6i, r5*, r6i, and z1d instance types. Other instance types guarantee performance up to 32,000 IOPS.

The IOPS and storage size ranges have the following constraints:

- The ratio of IOPS to allocated storage (in GiB) must be from 1–50 on RDS for SQL Server, and 0.5–50 on other RDS DB engines.

- If you're using storage autoscaling, the same ratios between IOPS and maximum storage threshold (in GiB) also apply.

  For more information on storage autoscaling, see Managing capacity automatically with Amazon RDS storage autoscaling.

Combining Provisioned IOPS storage with Multi-AZ deployments or read replicas

For production OLTP use cases, we recommend that you use Multi-AZ deployments for enhanced fault tolerance with Provisioned IOPS storage for fast and predictable performance.

You can also use Provisioned IOPS storage with read replicas for MySQL, MariaDB or PostgreSQL. The type of storage for a read replica is independent of that on the primary DB instance. For example, you might use General Purpose SSD for read replicas with a primary DB instance that uses Provisioned IOPS SSD storage to reduce costs. However, your read replica's performance in this case might differ from that of a configuration where both the primary DB instance and the read replicas use Provisioned IOPS storage.

Provisioned IOPS storage costs

With Provisioned IOPS storage, you are charged for the provisioned resources whether or not you use them in a given month.

For more information about pricing, see Amazon RDS pricing.

Getting the best performance from Amazon RDS Provisioned IOPS storage

If your workload is I/O constrained, using Provisioned IOPS storage can increase the number of I/O requests that the system can process concurrently. Increased concurrency allows for decreased latency because I/O requests spend less time in a queue. Decreased latency allows for faster database commits, which improves response time and allows for higher database throughput.

Provisioned IOPS storage provides a way to reserve I/O capacity by specifying IOPS. However, as with any other system capacity attribute, its maximum throughput under load is constrained by the resource that is consumed first. That resource might be network bandwidth, CPU, memory, or database internal resources.

General Purpose SSD storage

General Purpose storage offers cost-effective storage that is acceptable for most database workloads that aren't latency or performance sensitive.

> **Note**
>
> DB instances that use General Purpose storage can experience much longer latency than instances that use Provisioned IOPS storage. If you need a DB instance with minimum latency after these operations, we recommend using Provisioned IOPS SSD storage.

Amazon RDS offers two types of General Purpose storage: gp3 storage (recommended) and gp2 storage (previous generation).

gp3 storage (recommended)

By using General Purpose gp3 storage volumes, you can customize storage performance independently of storage capacity. *Storage performance* is the combination of I/O operations per second (IOPS) and how fast the storage volume can perform reads and writes (storage throughput). On gp3 storage volumes, Amazon RDS provides a baseline storage performance of 3000 IOPS and 125 MiB/s.

For every RDS DB engine except RDS for SQL Server, when the storage size for gp3 volumes reaches a certain threshold, the baseline storage performance increases. This is because of *volume striping*, where the storage uses four volumes instead of one. RDS for SQL Server doesn't support volume striping, and therefore doesn't have a threshold value. For striped volumes, Amazon RDS provides a baseline storage performance of 12,000 IOPS and 500 MiB/s.

Storage performance for gp3 volumes on Amazon RDS DB engines, including the threshold, is shown in the following table.

DB engine	Storage size	Baseline storage performance	Range of Provisioned IOPS	Range of provisioned storage throughput
Db2, MariaDB, MySQL, and PostgreSQL	20–399 GiB	3,000 IOPS/125 MiB/s	N/A	N/A
Db2, MariaDB, MySQL, and PostgreSQL	400–65,536 GiB	12,000 IOPS/500 MiB/s	12,000–64,000 IOPS	500–4,000 MiB/s
Oracle	20–199 GiB	3,000 IOPS/125 MiB/s	N/A	N/A
Oracle	200–65,536 GiB	12,000 IOPS/500 MiB/s	12,000–64,000 IOPS	500–4,000 MiB/s
SQL Server	20–16,384 GiB	3,000 IOPS/125 MiB/s	3,000–16,000 IOPS	125–1,000 MiB/s

For every DB engine except RDS for SQL Server, you can provision additional IOPS and storage throughput when storage size is at or above the threshold value. For RDS for SQL Server, you can provision additional IOPS and storage throughput for any available storage size. For all DB engines, you pay for only the additional provisioned storage performance. For more information, see Amazon RDS pricing.

Although the added Provisioned IOPS and storage throughput aren't dependent on the storage size, they are related to each other. When you raise the IOPS above 32,000 for MariaDB and MySQL, the storage throughput value automatically increases from 500 MiBps. For example, when you set the IOPS to 40,000 on RDS for MySQL, the storage throughput must be at least 625 MiBps. The automatic increase doesn't happen for Db2, Oracle, PostgreSQL, and SQL Server DB instances.

For Multi-AZ DB clusters, Amazon RDS automatically sets the throughput value based on the IOPS that you provision. You can't modify the throughput value.

Storage performance values for gp3 volumes on RDS have the following constraints:

- The maximum ratio of storage throughput to IOPS is 0.25 for all supported DB engines.
- The minimum ratio of IOPS to allocated storage (in GiB) is 0.5 on RDS for SQL Server. There is no minimum ratio for the other supported DB engines.
- The maximum ratio of IOPS to allocated storage is 500 for all supported DB engines.
- If you're using storage autoscaling, the same ratios between IOPS and maximum storage threshold (in GiB) also apply.

  For more information on storage autoscaling, see Managing capacity automatically with Amazon RDS storage autoscaling.

gp2 storage (previous generation)

When your applications don't need high storage performance, you can use General Purpose SSD gp2 storage. Baseline I/O performance for gp2 storage is 3 IOPS for each GiB, with a minimum of 100 IOPS. This relationship means that larger volumes have better performance. For example, baseline performance for one 100-GiB volume is 300 IOPS. Baseline performance for one 1,000 GiB volume is 3,000 IOPS.

Individual gp2 volumes below 1,000 GiB in size also have the ability to burst to 3,000 IOPS for extended periods of time. Volume I/O credit balance determines burst performance. For a more detailed description of how baseline performance and I/O credit balance affect performance, see the post Understanding burst vs. baseline performance with Amazon RDS and gp2 on the AWS Database Blog.

Many workloads never deplete the burst balance. However, some workloads can exhaust the 3,000 IOPS burst storage credit balance, so you should plan your storage capacity to meet the needs of your workloads.

For gp2 volumes larger than 4,000 GiB, the baseline performance is greater than the burst performance. For such volumes, burst is irrelevant because the baseline performance is better than the 3,000 IOPS burst performance. However, for DB instances of certain engines and sizes, storage is *striped* across four volumes providing four times the baseline throughput, and four times the burst IOPS of a single volume.

Storage performance for gp2 volumes of various storage sizes on Amazon RDS DB engines is shown in the following table.

DB engine	RDS storage size	Range of baseline IOPS	Range of baseline throughput	Burst IOPS
MariaDB, MySQL, and PostgreSQL	5–399 GiB[1]	100-1197 IOPS	128-250 MiB/s	3,000
MariaDB, MySQL, and PostgreSQL	400–1,335 GiB	1,200-4,005 IOPS	512-1,000 MiB/s	12,000
MariaDB, MySQL, and PostgreSQL	1,336–3,999 GiB	4008-11,997 IOPS	1,000 MiB/s	12,000
MariaDB, MySQL, and PostgreSQL	4,000–65,536 GiB	12,000-64,000 IOPS	1,000 MiB/s	N/A[2]
Oracle	20–199 GiB	100-597 IOPS	128-250 MiB/s	3,000
Oracle	200–1,335 GiB	600-4,005 IOPS	500-1,000 MiB/s	12,000
Oracle	1,336–3,999 GiB	4008-11,997 IOPS	1,000 MiB/s	12,000
Oracle	4,000–65,536 GiB	12,000-64,000 IOPS	1,000 MiB/s	N/A[2]
SQL Server	20–333 GiB	100-999 IOPS	128-250 MiB/s	3,000
SQL Server	334–999 GiB	1,002-2,997 IOPS	250 MiB/s	3,000
SQL Server	1,000–16,384 GiB	3,000-16,000 IOPS	250 MiB/s	N/A[2]

Note

[1] Using the AWS Management Console, you can create DB instances with a minimum storage size of 5 GiB in the Free tier for the db.t3.micro and db.t4g.micro DB instance classes. Otherwise, the minimum storage size is 20 GiB. This limitation doesn't apply to the AWS CLI and RDS API.
[2] The baseline performance of the volume exceeds the maximum burst performance.

Comparing solid-state drive (SSD) storage types

The following table shows use cases and performance characteristics for the SSD storage volumes used by Amazon RDS.

Characteristic	Provisioned IOPS (io2 Block Express)	Provisioned IOPS (io1)	General Purpose (gp3)	General Purpose (gp2)
Description	Highest performance within the RDS storage portfolio (IOPS, throughput, latency) Designed for latency-sensitive, transactional workloads	Consistent storage performance (IOPS, throughput, latency) Designed for latency-sensitive, transactional workloads	Flexibility in provisioning storage, IOPS, and throughput independently Balances price performance for a wide variety of transactional workloads	Provides burstable IOPS Balances price performance for a wide variety of transactional workloads
Use cases	Business-critical transactional workloads that require sub-millisecond latency and sustained	Transactional workloads that require sustained IOPS performance up to 256,000 IOPS	Broad range of workloads running on medium-sized relational databases in	Broad range of workloads running on medium-sized relational databases in

Characteristic	Provisioned IOPS (io2 Block Express)	Provisioned IOPS (io1)	General Purpose (gp3)	General Purpose (gp2)
	IOPS performance up to 256,000 IOPS		development/test environments	development/test environments
Latency	Sub-millisecond, provided consistently 99.9% of the time	Single-digit millisecond, provided consistently 99.9% of the time	Single-digit millisecond, provided consistently 99% of the time	Single-digit millisecond, provided consistently 99% of the time
Volume size	100–65,536 GiB	100–65,536 GiB (20–16,384 GiB on RDS for SQL Server)	20–65,536 GiB (16,384 GiB on RDS for SQL Server)	20–65,536 GiB (16,384 GiB on RDS for SQL Server)

Characteristic	Provisioned IOPS (io2 Block Express)	Provisioned IOPS (io1)	General Purpose (gp3)	General Purpose (gp2)
Maximum IOPS	256,000	256,000 (64,000 on RDS for SQL Server)	64,000 (16,000 on RDS for SQL Server)	64,000 (16,000 on RDS for SQL Server) **Note** You can't provision IOPS directly on gp2 storage. IOPS varies with the allocated storage size.

Characteristic	Provisioned IOPS (io2 Block Express)	Provisioned IOPS (io1)	General Purpose (gp3)	General Purpose (gp2)
Maximum throughput	Scales based on Provisioned IOPS up to 4,000 MB/s Throughput scales proportionally up to 0.256 MiB/s per provisioned IOPS. Maximum throughput of 4,000 MiB/s can be achieved at 256,000 IOPS with a 16-KiB I/O size and 16,000 IOPS or higher with a 256-KiB I/O size. For instances not based on the AWS Nitro System, maximum throughput of 2,000 MiB/s can be achieved at 128,000 IOPS with a 16-KiB I/O size.	Scales based on Provisioned IOPS up to 4,000 MB/s	Provision additional throughput up to 4,000 MB/s (1000 MB/s on RDS for SQL Server)	1000 MB/s (250 MB/s on RDS for SQL Server)

Characteristic	Provisioned IOPS (io2 Block Express)	Provisioned IOPS (io1)	General Purpose (gp3)	General Purpose (gp2)
AWS CLI and RDS API name	io2	io1	gp3	gp2

Magnetic storage (legacy, not recommended)

Amazon RDS also supports magnetic storage for backward compatibility. We recommend that you use General Purpose SSD or Provisioned IOPS SSD for any new storage needs. The following are some limitations for magnetic storage:

- Doesn't allow you to scale storage when using the SQL Server database engine.
- Doesn't allow you to convert to a different storage type when using the SQL Server database engine.
- Doesn't support storage autoscaling.
- Doesn't support elastic volumes.
- Limited to a maximum size of 3 TiB.
- Limited to a maximum of 1,000 IOPS.

Dedicated log volume (DLV)

You can use a dedicated log volume (DLV) for a DB instance that uses Provisioned IOPS (PIOPS) storage by using the Amazon RDS console, AWS CLI, or Amazon RDS API. A DLV moves PostgreSQL database transaction logs and MySQL/MariaDB redo logs and binary logs to a storage volume that's separate from the volume containing the database tables. A DLV makes transaction write logging more efficient and consistent. DLVs are ideal for databases with large allocated storage, high I/O per second (IOPS) requirements, or latency-sensitive workloads.

DLVs are supported for PIOPS storage (io1 and io2 Block Express), and are created with a fixed size of 1,000 GiB and 3,000 Provisioned IOPS.

> **Note**
>
> DLVs aren't supported for General Purpose storage (gp2 and gp3).

Amazon RDS supports DLVs in all AWS Regions for the following versions:

- MariaDB 10.6.7 and higher 10 versions
- MySQL 8.0.28 and higher 8 versions
- PostgreSQL 13.10 and higher 13 versions, 14.7 and higher 14 versions, 15.2 and higher 15 versions, and 16.1 and higher 16 versions

RDS supports DLVs with Multi-AZ deployments. When you modify or create a Multi-AZ instance, A DLV is created for both the primary and the secondary.

RDS supports DLVs with read replicas. If the primary DB instance has a DLV enabled, all read replicas created after enabling DLV will also have a DLV. Any read replicas created before the switch to DLV will not have it enabled unless explicitly modified to do so. We recommend all read replicas attached to a primary instance before DLV was enabled also be manually modified to have A DLV.

After you modify the DLV setting for a DB instance, the DB instance must be rebooted.

For information on enabling a DLV, see Using a dedicated log volume (DLV).

Monitoring storage performance

Amazon RDS provides several metrics that you can use to determine how your DB instance is performing. You can view the metrics on the summary page for your instance in Amazon RDS Management Console. You can also use Amazon CloudWatch to monitor these metrics. For more information, see Viewing metrics in the Amazon RDS console. Enhanced Monitoring provides more detailed I/O metrics; for more information, see Monitoring OS metrics with Enhanced Monitoring.

The following metrics are useful for monitoring storage for your DB instance:

- **IOPS** – The number of I/O operations completed each second. This metric is reported as the average IOPS for a given time interval. Amazon RDS reports read and write IOPS separately at 1-minute intervals. Total IOPS is the sum of the read and write IOPS. Typical values for IOPS range from zero to tens of thousands per second.

- **Latency** – The elapsed time between the submission of an I/O request and its completion. This metric is reported as the average latency for a given time interval. Amazon RDS reports read and write latency separately at 1-minute intervals. Typical values for latency are in milliseconds (ms).
- **Throughput** – The number of bytes each second that are transferred to or from disk. This metric is reported as the average throughput for a given time interval. Amazon RDS reports read and write throughput separately at 1-minute intervals using units of bytes per second (B/s). Typical values for throughput range from zero to the I/O channel's maximum bandwidth.
- **Queue Depth** – The number of I/O requests in the queue waiting to be serviced. These are I/O requests that have been submitted by the application but have not been sent to the device because the device is busy servicing other I/O requests. Time spent waiting in the queue is a component of latency and service time (not available as a metric). This metric is reported as the average queue depth for a given time interval. Amazon RDS reports queue depth at 1-minute intervals. Typical values for queue depth range from zero to several hundred.

Measured IOPS values are independent of the size of the individual I/O operation. This means that when you measure I/O performance, make sure to look at the throughput of the instance, not simply the number of I/O operations.

Factors that affect storage performance

System activities, database workload, and DB instance class can affect storage performance.

System activities

The following system-related activities consume I/O capacity and might reduce DB instance performance while in progress:

- Multi-AZ standby creation
- Read replica creation
- Changing storage types

Database workload

In some cases, your database or application design results in concurrency issues, locking, or other forms of database contention. In these cases, you might not be able to use all the provisioned bandwidth directly. In addition, you might encounter the following workload-related situations:

- The throughput limit of the underlying instance type is reached.
- Queue depth is consistently less than 1 because your application isn't driving enough I/O operations.
- You experience query contention in the database even though some I/O capacity is unused.

In some cases, there isn't a system resource that is at or near a limit, and adding threads doesn't increase the database transaction rate. In such cases, the bottleneck is most likely contention in the database. The most common forms are row lock and index page lock contention, but there are many other possibilities. If this is your situation, seek the advice of a database performance tuning expert.

DB instance class

To get the most performance out of your Amazon RDS DB instance, choose a current generation instance type with enough bandwidth to support your storage type. For example, you can choose Amazon EBS–optimized instances and instances with 10-gigabit network connectivity.

> **Important**
>
> Depending on the instance class you're using, you might see lower IOPS performance than the maximum that you can provision with RDS. For specific information on IOPS performance for DB instance classes, see Amazon EBS–optimized instances in the *Amazon EC2 User Guide*. We recommend that you determine the maximum IOPS for the instance class before setting a Provisioned IOPS value for your DB instance.

We encourage you to use the latest generation of instances to get the best performance. Previous generation DB instances can also have lower maximum storage.

Some older 32-bit file systems might have lower storage capacities. To determine the storage capacity of your DB instance, you can use the describe-valid-db-instance-modifications AWS CLI command.

The following list shows the maximum storage that most DB instance classes can scale to for each database engine:

- Db2 – 64 TiB
- MariaDB – 64 TiB

- Microsoft SQL Server – 64 TiB
- MySQL – 64 TiB
- Oracle – 64 TiB
- PostgreSQL – 64 TiB

The following table shows some exceptions for maximum storage (in TiB). All RDS for Microsoft SQL Server DB instances apart from io2 Block Express storage have a maximum storage of 16 TiB, so there are no entries for SQL Server.

Instance class	Db2	MariaDB	MySQL	Oracle	PostgreSQL
db.m3 – standard instance classes					
db.t4g – burstable-performance instance classes					
db.t4g.medium	N/A	16	16	N/A	32
db.t4g.small	N/A	16	16	N/A	16
db.t4g.micro	N/A	6	6	N/A	6
db.t3 – burstable-performance instance classes					
db.t3.medium	32	16	16	32	32
db.t3.small	32	16	16	32	16
db.t3.micro	N/A	6	6	32	6
db.t2 – burstable-performance instance classes					

For more details about all instance classes supported, see Previous generation DB instances.

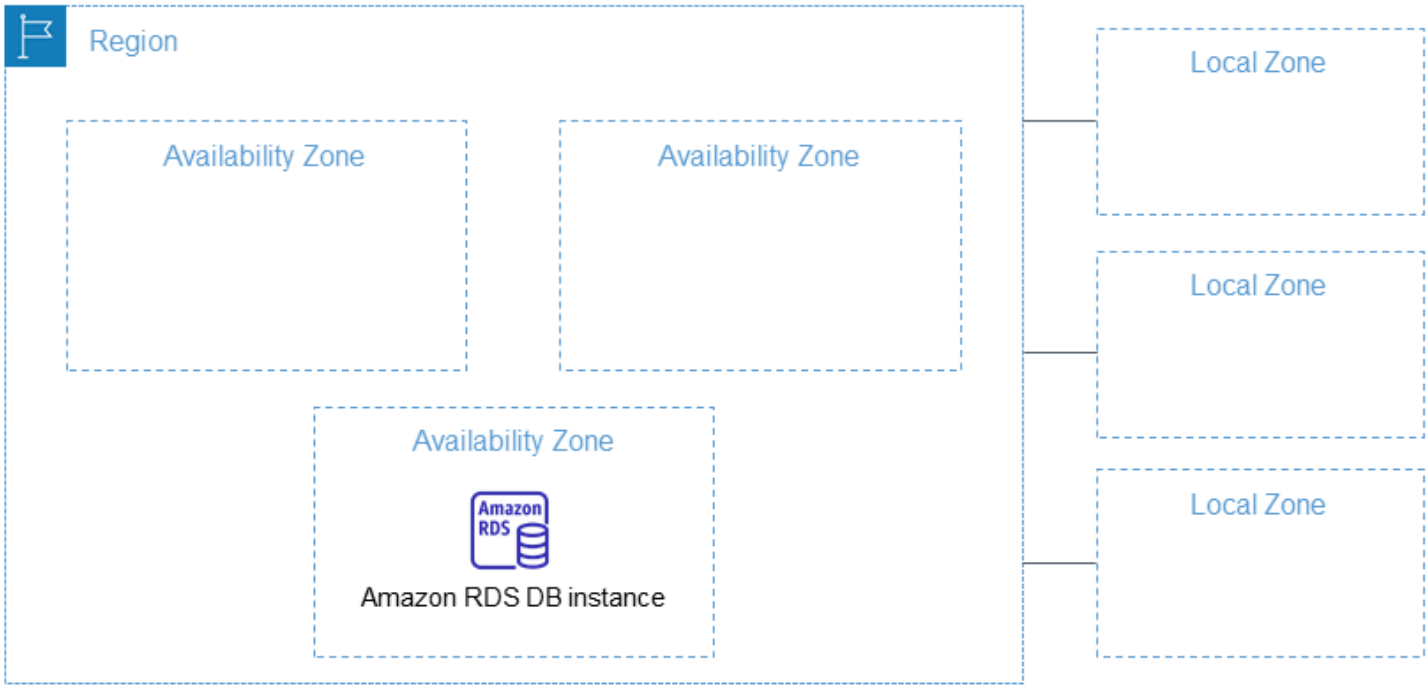
Regions, Availability Zones, and Local Zones

Amazon cloud computing resources are hosted in multiple locations world-wide. These locations are composed of AWS Regions, Availability Zones, and Local Zones. Each *AWS Region* is a separate geographic area. Each AWS Region has multiple, isolated locations known as *Availability Zones*.

> **Note**
>
> For information about finding the Availability Zones for an AWS Region, see Describe your Availability Zones in the Amazon EC2 documentation.

By using Local Zones, you can place resources, such as compute and storage, in multiple locations closer to your users. Amazon RDS enables you to place resources, such as DB instances, and data in multiple locations. Resources aren't replicated across AWS Regions unless you do so specifically.

Amazon operates state-of-the-art, highly-available data centers. Although rare, failures can occur that affect the availability of DB instances that are in the same location. If you host all your DB instances in one location that is affected by such a failure, none of your DB instances will be available.



It is important to remember that each AWS Region is completely independent. Any Amazon RDS activity you initiate (for example, creating database instances or listing available database

instances) runs only in your current default AWS Region. The default AWS Region can be changed in the console, or by setting the `AWS_DEFAULT_REGION` environment variable. Or it can be overridden by using the `--region` parameter with the AWS Command Line Interface (AWS CLI). For more information, see Configuring the AWS Command Line Interface, specifically the sections about environment variables and command line options.

Amazon RDS supports special AWS Regions called AWS GovCloud (US). These are designed to allow US government agencies and customers to move more sensitive workloads into the cloud. The AWS GovCloud (US) Regions address the US government's specific regulatory and compliance requirements. For more information, see What is AWS GovCloud (US)?

To create or work with an Amazon RDS DB instance in a specific AWS Region, use the corresponding regional service endpoint.

AWS Regions

Each AWS Region is designed to be isolated from the other AWS Regions. This design achieves the greatest possible fault tolerance and stability.

When you view your resources, you see only the resources that are tied to the AWS Region that you specified. This is because AWS Regions are isolated from each other, and we don't automatically replicate resources across AWS Regions.

Region availability

The following table shows the AWS Regions where Amazon RDS is currently available and the endpoint for each Region.

Region Name	Region	Endpoint	Protocol	
US East (Ohio)	us-east-2	rds.us-east-2.amazonaws.com	HTTPS	
		rds-fips.us-east-2.api.aws	HTTPS	
		rds.us-east-2.api.aws	HTTPS	
		rds-fips.us-east-2.amazonaws.com	HTTPS	

Region Name	Region	Endpoint	Protocol
US East (N. Virginia)	us-east-1	rds.us-east-1.amazonaws.com	HTTPS
		rds-fips.us-east-1.api.aws	HTTPS
		rds-fips.us-east-1.amazonaws.com	HTTPS
		rds.us-east-1.api.aws	HTTPS
US West (N. California)	us-west-1	rds.us-west-1.amazonaws.com	HTTPS
		rds.us-west-1.api.aws	HTTPS
		rds-fips.us-west-1.amazonaws.com	HTTPS
		rds-fips.us-west-1.api.aws	HTTPS
US West (Oregon)	us-west-2	rds.us-west-2.amazonaws.com	HTTPS
		rds-fips.us-west-2.amazonaws.com	HTTPS
		rds.us-west-2.api.aws	HTTPS
		rds-fips.us-west-2.api.aws	HTTPS
Africa (Cape Town)	af-south-1	rds.af-south-1.amazonaws.com	HTTPS
		rds.af-south-1.api.aws	HTTPS
Asia Pacific (Hong Kong)	ap-east-1	rds.ap-east-1.amazonaws.com	HTTPS
		rds.ap-east-1.api.aws	HTTPS
Asia Pacific (Hyderabad)	ap-south-2	rds.ap-south-2.amazonaws.com	HTTPS
		rds.ap-south-2.api.aws	HTTPS

Region Name	Region	Endpoint	Protocol
Asia Pacific (Jakarta)	ap-southeast-3	rds.ap-southeast-3.amazonaws.com rds.ap-southeast-3.api.aws	HTTPS HTTPS
Asia Pacific (Malaysia)	ap-southeast-5	rds.ap-southeast-5.amazonaws.com	HTTPS
Asia Pacific (Melbourne)	ap-southeast-4	rds.ap-southeast-4.amazonaws.com rds.ap-southeast-4.api.aws	HTTPS HTTPS
Asia Pacific (Mumbai)	ap-south-1	rds.ap-south-1.amazonaws.com rds.ap-south-1.api.aws	HTTPS HTTPS
Asia Pacific (Osaka)	ap-northeast-3	rds.ap-northeast-3.amazonaws.com rds.ap-northeast-3.api.aws	HTTPS HTTPS
Asia Pacific (Seoul)	ap-northeast-2	rds.ap-northeast-2.amazonaws.com rds.ap-northeast-2.api.aws	HTTPS HTTPS
Asia Pacific (Singapore)	ap-southeast-1	rds.ap-southeast-1.amazonaws.com rds.ap-southeast-1.api.aws	HTTPS HTTPS
Asia Pacific (Sydney)	ap-southeast-2	rds.ap-southeast-2.amazonaws.com rds.ap-southeast-2.api.aws	HTTPS HTTPS

Region Name	Region	Endpoint	Protocol
Asia Pacific (Tokyo)	ap-northeast-1	rds.ap-northeast-1.amazonaws.com	HTTPS
		rds.ap-northeast-1.api.aws	HTTPS
Canada (Central)	ca-central-1	rds.ca-central-1.amazonaws.com	HTTPS
		rds.ca-central-1.api.aws	HTTPS
		rds-fips.ca-central-1.api.aws	HTTPS
		rds-fips.ca-central-1.amazonaws.com	HTTPS
Canada West (Calgary)	ca-west-1	rds.ca-west-1.amazonaws.com	HTTPS
		rds-fips.ca-west-1.amazonaws.com	HTTPS
Europe (Frankfurt)	eu-central-1	rds.eu-central-1.amazonaws.com	HTTPS
		rds.eu-central-1.api.aws	HTTPS
Europe (Ireland)	eu-west-1	rds.eu-west-1.amazonaws.com	HTTPS
		rds.eu-west-1.api.aws	HTTPS
Europe (London)	eu-west-2	rds.eu-west-2.amazonaws.com	HTTPS
		rds.eu-west-2.api.aws	HTTPS
Europe (Milan)	eu-south-1	rds.eu-south-1.amazonaws.com	HTTPS
		rds.eu-south-1.api.aws	HTTPS
Europe (Paris)	eu-west-3	rds.eu-west-3.amazonaws.com	HTTPS
		rds.eu-west-3.api.aws	HTTPS

Region Name	Region	Endpoint	Protocol
Europe (Spain)	eu-south-2	rds.eu-south-2.amazonaws.com rds.eu-south-2.api.aws	HTTPS HTTPS
Europe (Stockholm)	eu-north-1	rds.eu-north-1.amazonaws.com rds.eu-north-1.api.aws	HTTPS HTTPS
Europe (Zurich)	eu-central-2	rds.eu-central-2.amazonaws.com rds.eu-central-2.api.aws	HTTPS HTTPS
Israel (Tel Aviv)	il-central-1	rds.il-central-1.amazonaws.com rds.il-central-1.api.aws	HTTPS HTTPS
Middle East (Bahrain)	me-south-1	rds.me-south-1.amazonaws.com rds.me-south-1.api.aws	HTTPS HTTPS
Middle East (UAE)	me-central-1	rds.me-central-1.amazonaws.com rds.me-central-1.api.aws	HTTPS HTTPS
South America (São Paulo)	sa-east-1	rds.sa-east-1.amazonaws.com rds.sa-east-1.api.aws	HTTPS HTTPS
AWS GovCloud (US-East)	us-gov-east-1	rds.us-gov-east-1.amazonaws.com rds.us-gov-east-1.api.aws	HTTPS HTTPS
AWS GovCloud (US-West)	us-gov-west-1	rds.us-gov-west-1.amazonaws.com rds.us-gov-west-1.api.aws	HTTPS HTTPS

If you do not explicitly specify an endpoint, the US West (Oregon) endpoint is the default.

When you work with a DB instance using the AWS CLI or API operations, make sure that you specify its regional endpoint.

Availability Zones

When you create a DB instance, you can choose an Availability Zone or have Amazon RDS choose one for you randomly. An Availability Zone is represented by an AWS Region code followed by a letter identifier (for example, `us-east-1a`).

Use the describe-availability-zones Amazon EC2 command as follows to describe the Availability Zones within the specified Region that are enabled for your account.

```
aws ec2 describe-availability-zones --region region-name
```

For example, to describe the Availability Zones within the US East (N. Virginia) Region (us-east-1) that are enabled for your account, run the following command:

```
aws ec2 describe-availability-zones --region us-east-1
```

You can't choose the Availability Zones for the primary and secondary DB instances in a Multi-AZ DB deployment. Amazon RDS chooses them for you randomly. For more information about Multi-AZ deployments, see Configuring and managing a Multi-AZ deployment.

> **Note**
>
> Random selection of Availability Zones by RDS doesn't guarantee an even distribution of DB instances among Availability Zones within a single account or DB subnet group. You can request a specific AZ when you create or modify a Single-AZ instance, and you can use more-specific DB subnet groups for Multi-AZ instances. For more information, see Creating an Amazon RDS DB instance and Modifying an Amazon RDS DB instance.

Local Zones

A *Local Zone* is an extension of an AWS Region that is geographically close to your users. You can extend any VPC from the parent AWS Region into Local Zones. To do so, create a new subnet and

assign it to the AWS Local Zone. When you create a subnet in a Local Zone, your VPC is extended to that Local Zone. The subnet in the Local Zone operates the same as other subnets in your VPC.

When you create a DB instance, you can choose a subnet in a Local Zone. Local Zones have their own connections to the internet and support AWS Direct Connect. Thus, resources created in a Local Zone can serve local users with very low-latency communications. For more information, see AWS Local Zones.

A Local Zone is represented by an AWS Region code followed by an identifier that indicates the location, for example `us-west-2-lax-1a`.

> **Note**
>
> A Local Zone can't be included in a Multi-AZ deployment.

To use a Local Zone

1. Enable the Local Zone in the Amazon EC2 console.

   For more information, see Enabling Local Zones in the *Amazon EC2 User Guide.*
2. Create a subnet in the Local Zone.

   For more information, see Creating a subnet in your VPC in the *Amazon VPC User Guide.*
3. Create a DB subnet group in the Local Zone.

   When you create a DB subnet group, choose the Availability Zone group for the Local Zone.

   For more information, see Creating a DB instance in a VPC.
4. Create a DB instance that uses the DB subnet group in the Local Zone.

   For more information, see Creating an Amazon RDS DB instance.

> **Important**
>
> Currently, the only AWS Local Zone where Amazon RDS is available is Los Angeles in the US West (Oregon) Region.

Supported features in Amazon RDS by AWS Region and DB engine

Support for Amazon RDS features and options varies across AWS Regions and specific versions of each DB engine. To identify RDS DB engine version support and availability in a given AWS Region, you can use the following sections.

Amazon RDS features are different from engine-native features and options. For more information on engine-native features and options, see Engine-native features.

Supported Regions and DB engines

- Table conventions
- Feature quick reference
- Supported Regions and DB engines for Amazon RDS Blue/Green Deployments
- Supported Regions and DB engines for cross-Region automated backups in Amazon RDS
- Supported Regions and DB engines for cross-Region read replicas in Amazon RDS
- Supported Regions and DB engines for database activity streams in Amazon RDS
- Supported Regions and DB engines for dual-stack mode in Amazon RDS
- Supported Regions and DB engines for exporting snapshots to S3 in Amazon RDS
- Supported Regions and DB engines for IAM database authentication in Amazon RDS
- Supported Regions and DB engines for Kerberos authentication in Amazon RDS
- Supported Regions and DB engines for Multi-AZ DB clusters in Amazon RDS
- Supported Regions and DB engines for Performance Insights in Amazon RDS
- Supported Regions and DB engines for RDS Custom
- Supported Regions and DB engines for Amazon RDS Proxy
- Supported Regions and DB engines for the Secrets Manager integration with Amazon RDS
- Supported Regions and DB engines for Amazon RDS zero-ETL integrations with Amazon Redshift
- Engine-native features in Amazon RDS

Table conventions

The tables in the feature sections use these patterns to specify version numbers and level of availability:

- **Version x.y** – The specific version alone is available.
- **Version x.y and higher** – The specified version and all higher minor versions of its major version are supported. For example, "version 10.11 and higher" means that versions 10.11, 10.11.1, and 10.12 are available.

Feature quick reference

The following quick reference table lists each feature and available RDS DB engine. Region and specific version availability appears in the later feature sections.

Featu	RDS for Db2	RDS for MariaDB	RDS for MySQL	RDS for Oracle	RDS for PostgreSQL	RDS for SQL Server
Blue/ Gree n Deplo ts	Not available	Available	Available	Not available	Available	Not available

Supported Regions and DB engines for Amazon RDS Blue/Green Deployments

A blue/green deployment copies a production database environment in a separate, synchronized staging environment. By using Amazon RDS Blue/Green Deployments, you can make changes to the database in the staging environment without affecting the production environment. For example, you can upgrade the major or minor DB engine version, change database parameters, or make schema changes in the staging environment. When you are ready, you can promote the staging environment to be the new production database environment. For more information, see Using Amazon RDS Blue/Green Deployments for database updates.

The Blue/Green Deployments feature is supported in all AWS Regions.

The Blue/Green Deployments feature is supported for the following engines:

- RDS for MariaDB version 10.2 and higher
- RDS for MySQL version 5.7 and higher
- RDS for MySQL version 8.0.15 and higher
- RDS for PostgreSQL version 11.21 and higher
- RDS for PostgreSQL version 12.16 and higher
- RDS for PostgreSQL version 13.12 and higher
- RDS for PostgreSQL version 14.9 and higher
- RDS for PostgreSQL version 15.4 and higher
- RDS for PostgreSQL version 16.1 and higher

The Blue/Green Deployments feature isn't supported with the following engines:

- RDS for Db2
- RDS for SQL Server
- RDS for Oracle

Supported Regions and DB engines for cross-Region automated backups in Amazon RDS

By using backup replication in Amazon RDS, you can configure your RDS DB instance to replicate snapshots and transaction logs to a destination Region. When backup replication is configured for a DB instance, RDS starts a cross-Region copy of all snapshots and transaction logs when they're ready. For more information, see Replicating automated backups to another AWS Region.

Backup replication is available in all AWS Regions except the following:

- Africa (Cape Town)
- Asia Pacific (Hong Kong)
- Asia Pacific (Hyderabad)
- Asia Pacific (Jakarta)
- Europe (Milan)
- Europe (Spain)
- Europe (Zurich)
- Middle East (Bahrain)
- Middle East (UAE)

For more detailed information on limitations for source and destination backup Region, see Replicating automated backups to another AWS Region.

Topics

- Backup replication with RDS for Db2
- Backup replication with RDS for MariaDB
- Backup replication with RDS for MySQL

- Backup replication with RDS for Oracle
- Backup replication with RDS for PostgreSQL
- Backup replication with RDS for SQL Server

Backup replication with RDS for Db2

Amazon RDS supports backup replication for all currently available versions of RDS for Db2.

Backup replication with RDS for MariaDB

Amazon RDS supports backup replication for all currently available versions of RDS for MariaDB.

Backup replication with RDS for MySQL

Amazon RDS supports backup replication for all currently available versions of RDS for MySQL.

Backup replication with RDS for Oracle

Amazon RDS supports backup replication for all currently available versions of RDS for Oracle.

Backup replication with RDS for PostgreSQL

Amazon RDS supports backup replication for all currently available versions of RDS for PostgreSQL.

Backup replication with RDS for SQL Server

Amazon RDS supports backup replication for all currently available versions of RDS for SQL Server.

Supported Regions and DB engines for cross-Region read replicas in Amazon RDS

By using cross-Region read replicas in Amazon RDS, you can create a MariaDB, MySQL, Oracle, PostgreSQL, or SQL Server read replica in a different Region from the source DB instance. For more information about cross-Region read replicas, including source and destination Region considerations, see Creating a read replica in a different AWS Region.

Cross-Region read replicas are not available for the following engines:

- RDS for Db2

Topics

Cross-Region read replicas with RDS for MariaDB

Cross-Region read replicas with RDS for MariaDB are available in all Regions for the following versions:

- RDS for MariaDB 10.11 (All available versions)
- RDS for MariaDB 10.6 (All available versions)
- RDS for MariaDB 10.5 (All available versions)
- RDS for MariaDB 10.4 (All available versions)
- RDS for MariaDB 10.3 (All available versions)

Cross-Region read replicas with RDS for MySQL

Cross-Region read replicas with RDS for MySQL are available in all Regions for the following versions:

- RDS for MySQL 8.0 (All available versions)
- RDS for MySQL 5.7 (All available versions)

Cross-Region read replicas with RDS for Oracle

Cross-Region read replicas for RDS for Oracle are available in all AWS Regions for all supported database versions using Enterprise Edition. Replicas are supported only in non-CDBs and in the single-tenant configuration of the CDB architecture. Cross-Region read replicas aren't supported in the multi-tenant configuration of the CDB architecture.

For more information on additional requirements for cross-Region read replicas with RDS for Oracle, see Requirements and considerations for RDS for Oracle replicas.

Cross-Region read replicas with RDS for PostgreSQL

Cross-Region read replicas with RDS for PostgreSQL are available in all Regions for the following versions:

- RDS for PostgreSQL 16 (All available versions)
- RDS for PostgreSQL 15 (All available versions)
- RDS for PostgreSQL 14 (All available versions)
- RDS for PostgreSQL 13 (All available versions)
- RDS for PostgreSQL 12 (All available versions)
- RDS for PostgreSQL 11 (All available versions)
- RDS for PostgreSQL 10 (All available versions)

Cross-Region read replicas with RDS for SQL Server

Cross-Region read replicas with RDS for SQL Server are available in all Regions except the following:

- Africa (Cape Town)
- Asia Pacific (Hong Kong)
- Asia Pacific (Hyderabad)
- Asia Pacific (Jakarta)
- Asia Pacific (Melbourne)
- Canada West (Calgary)
- Europe (Milan)
- Europe (Spain)
- Europe (Zurich)
- Israel (Tel Aviv)
- Middle East (Bahrain)
- Middle East (UAE)

Cross-Region read replicas with RDS for SQL Server are available for the following versions using Microsoft SQL Server Enterprise Edition:

- RDS for SQL Server 2022
- RDS for SQL Server 2019 (Version 15.00.4073.23 and higher)
- RDS for SQL Server 2017 (Version 14.00.3281.6 and higher)
- RDS for SQL Server 2016 (Version 13.00.6300.2 and higher)

Supported Regions and DB engines for database activity streams in Amazon RDS

By using database activity streams in Amazon RDS, you can monitor and set alarms for auditing activity in your Oracle database and SQL Server database. For more information, see Overview of Database Activity Streams.

Database activity streams aren't available with the following engines:

- RDS for Db2
- RDS for MariaDB
- RDS for MySQL
- RDS for PostgreSQL

Topics

- Database activity streams with RDS for Oracle
- Database activity streams with RDS for SQL Server

Database activity streams with RDS for Oracle

The following Regions and engine versions are available for database activity streams with RDS for Oracle.

For more information on additional requirements for database activity streams with RDS for Oracle, see Overview of Database Activity Streams.

Region	RDS for Oracle 21c	RDS for Oracle 19c

Supported Regions and DB engines for dual-stack mode in Amazon RDS

By using dual-stack mode in RDS, resources can communicate with a DB instance over Internet Protocol version 4 (IPv4), Internet Protocol version 6 (IPv6), or both. For more information, see Dual-stack mode.

Topics

- Dual-stack mode with RDS for Db2
- Dual-stack mode with RDS for MariaDB
- Dual-stack mode with RDS for MySQL
- Dual-stack mode with RDS for Oracle
- Dual-stack mode with RDS for PostgreSQL
- Dual-stack mode with RDS for SQL Server

Dual-stack mode with RDS for Db2

The following Regions and engine versions are available for dual-stack mode with RDS for Db2.

Region	RDS for Db2 11.5				
US East (N. Virginia)	All available versions

Supported Regions and DB engines for exporting snapshots to S3 in Amazon RDS

You can export RDS DB snapshot data to an Amazon S3 bucket. You can export all types of DB snapshots—including manual snapshots, automated system snapshots, and snapshots created by AWS Backup. After the data is exported, you can analyze the exported data directly through tools like Amazon Athena or Amazon Redshift Spectrum. For more information, see Exporting DB snapshot data to Amazon S3.

Exporting snapshots to S3 is not available for the following engines:

- RDS for Db2
- RDS for Oracle
- RDS for SQL Server

Topics

Supported Regions and DB engines for IAM database authentication in Amazon RDS

By using IAM database authentication in Amazon RDS, you can authenticate without a password when you connect to a DB instance. Instead, you use an authentication token. For more information, see IAM database authentication for MariaDB, MySQL, and PostgreSQL.

IAM database authentication isn't available with the following engines:

- RDS for Db2
- RDS for Oracle
- RDS for SQL Server

Topics

IAM database authentication with RDS for MariaDB

The following Regions and engine versions are available for IAM database authentication with RDS for MariaDB.

Region	RDS for MariaDB 10.11	RDS for MariaDB 10.6	RDS for MariaDB 10.5	RDS for MariaDB 10.4	RDS for MariaDB 10.3

IAM database authentication with RDS for MySQL

IAM database authentication with RDS for MySQL is available in all Regions for the following versions:

- RDS for MySQL 8.0 – All available versions
- RDS for MySQL 5.7 – All available versions

IAM database authentication with RDS for PostgreSQL

IAM database authentication with RDS for PostgreSQL is available in all Regions for the following versions:

- RDS for PostgreSQL 16 – All available versions
- RDS for PostgreSQL 15 – All available versions
- RDS for PostgreSQL 14 – All available versions
- RDS for PostgreSQL 13 – All available versions
- RDS for PostgreSQL 12 – All available versions
- RDS for PostgreSQL 11 – All available versions
- RDS for PostgreSQL 10 – All available versions

Supported Regions and DB engines for Kerberos authentication in Amazon RDS

By using Kerberos authentication in Amazon RDS, you can support external authentication of database users using Kerberos and Microsoft Active Directory. Using Kerberos and Active Directory provides the benefits of single sign-on and centralized authentication of database users.

Kerberos authentication isn't available with the following engines:

- RDS for MariaDB

Although most AWS Regions are active by default for your AWS account, certain Regions are activated only when you manually select them. These Regions are referred to as *opt-in Regions*. In contrast, Regions that are active by default, as soon as your AWS account is created, are referred to as *commercial Regions*, or simply, *Regions*. For opt-in Regions, you must use a regionalized service principal of the form `directoryservice.rds.region_name.amazonaws.com`. For example, for Africa (Cape Town), you must add service principal `directoryservice.rds.region-af-south-1.amazonaws.com` to your trust policy. For more information, see Kerberos authentication.

Supported Regions and DB engines for Multi-AZ DB clusters in Amazon RDS

A Multi-AZ DB cluster deployment in Amazon RDS provides a high availability deployment mode of Amazon RDS with two readable standby DB instances. A Multi-AZ DB cluster has a writer DB instance and two reader DB instances in three separate Availability Zones in the same Region. Multi-AZ DB clusters provide high availability, increased capacity for read workloads, and lower write latency when compared to Multi-AZ DB instance deployments. For more information, see Multi-AZ DB cluster deployments.

Multi-AZ DB clusters aren't available with the following engines:

- RDS for Db2
- RDS for MariaDB
- RDS for Oracle
- RDS for SQL Server

Topics

Multi-AZ DB clusters with RDS for MySQL

The following Regions and engine versions are available for Multi-AZ DB clusters with RDS for MySQL.

Region	RDS for MySQL 8.0
US East (N. Virginia)	All available versions
US East (Ohio)	All available versions
US West (N. California)	Not available
US West (Oregon)	All available versions
Africa (Cape Town)	All available versions

Region	RDS for MySQL 8.0
Asia Pacific (Hong Kong)	All available versions
Asia Pacific (Hyderabad)	All available versions
Asia Pacific (Jakarta)	All available versions
Asia Pacific (Malaysia)	All available versions
Asia Pacific (Melbourne)	All available versions
Asia Pacific (Mumbai)	All available versions
Asia Pacific (Osaka)	All available versions
Asia Pacific (Seoul)	All available versions
Asia Pacific (Singapore)	All available versions
Asia Pacific (Sydney)	All available versions
Asia Pacific (Tokyo)	All available versions
Canada (Central)	All available versions
Canada (Central)	All available versions
Canada West (Calgary)	All available versions
China (Beijing)	All available versions
China (Ningxia)	All available versions
Europe (Frankfurt)	All available versions
Europe (Ireland)	All available versions
Europe (London)	All available versions
Europe (Milan)	All available versions

Region	RDS for MySQL 8.0
Europe (Paris)	All available versions
Europe (Spain)	All available versions
Europe (Stockholm)	All available versions
Europe (Zurich)	All available versions
Israel (Tel Aviv)	All available versions
Middle East (Bahrain)	All available versions
Middle East (UAE)	All available versions
South America (São Paulo)	All available versions
AWS GovCloud (US-East)	Not available
AWS GovCloud (US-West)	Not available

You can list the available versions in a Region for a given DB instance class using the AWS CLI. Change the DB instance class to show the available engine versions for it.

For Linux, macOS, or Unix:

```
aws rds describe-orderable-db-instance-options \
--engine mysql \
--db-instance-class db.r5d.large \
--query '*[]|[?SupportsClusters == `true`].[EngineVersion]'  \
--output text
```

For Windows:

```
aws rds describe-orderable-db-instance-options ^
--engine mysql ^
--db-instance-class db.r5d.large ^
--query "*[]|[?SupportsClusters == `true`].[EngineVersion]"  ^
--output text
```

Multi-AZ DB clusters with RDS for PostgreSQL

The following Regions and engine versions are available for Multi-AZ DB clusters with RDS for PostgreSQL.

Region	RDS for PostgreSQL 16	RDS for PostgreSQL 15	RDS for PostgreSQL 14	RDS for PostgreSQL 13
US East (N. Virginia)	All PostgreSQL 16 versions	All PostgreSQL 15 versions	Version 14.5 and higher	Version 13.4 and version 13.7 and higher

You can list the available versions in a Region for a given DB instance class using the AWS CLI. Change the DB instance class to show the available engine versions for it.

For Linux, macOS, or Unix:

```
aws rds describe-orderable-db-instance-options \
```

```
--engine postgres \
--db-instance-class db.r5d.large \
--query '*[]|[?SupportsClusters == `true`].[EngineVersion]'  \
--output text
```

For Windows:

```
aws rds describe-orderable-db-instance-options ^
--engine postgres ^
--db-instance-class db.r5d.large ^
--query "*[]|[?SupportsClusters == `true`].[EngineVersion]"  ^
--output text
```

Supported Regions and DB engines for Performance Insights in Amazon RDS

Performance Insights in Amazon RDS expands on existing Amazon RDS monitoring features to illustrate and help you analyze your database performance. With the Performance Insights dashboard, you can visualize the database load on your Amazon RDS DB instance. You can also filter the load by waits, SQL statements, hosts, or users. For more information, see Monitoring DB load with Performance Insights on Amazon RDS.

Performance Insights is available for all RDS DB engines, except RDS for Db2.

For the available DB engines, Performance Insights is available with all of the available engine versions and in all AWS Regions.

For the Region, DB engine, and instance class support information for Performance Insights features, see Amazon RDS DB engine, Region, and instance class support for Performance Insights features.

Supported Regions and DB engines for RDS Custom

Amazon RDS Custom automates database administration tasks and operations. By using RDS Custom, as a database administrator you can access and customize your database environment and operating system. With RDS Custom, you can customize to meet the requirements of legacy, custom, and packaged applications. For more information, see Working with Amazon RDS Custom.

RDS Custom is supported for the following DB engines only:

Topics

Supported Regions and DB engines for RDS Custom for Oracle

The following Regions and engine versions are available for RDS Custom for Oracle.

Region	Oracle Database 19c	Oracle Database 18c	Oracle Database 12c

Supported Regions and DB engines for RDS Custom for SQL Server

You can deploy RDS Custom for SQL Server by using either an RDS provided engine version (RPEV) or a custom engine version (CEV):

- If you use an RPEV, it includes the default Amazon Machine Image (AMI) and SQL Server installation. If you customize or modify the operating system (OS), your changes might not persist during patching, snapshot restore, or automatic recovery.
- If you use a CEV, you choose your own AMI with either pre-installed Microsoft SQL Server or SQL Server that you install using your own media. When using an AWS provided CEV, you choose the latest Amazon EC2 image (AMI) available by AWS, which has the cumulative update (CU) supported by RDS Custom for SQL Server. With a CEV, you can customize both the OS and SQL Server configuration to meet your enterprise needs.

The following AWS Regions and DB engine versions are available for RDS Custom for SQL Server. The engine version support depends on whether you're using RDS Custom for SQL Server with an RPEV, AWS provided CEV, or customer-provided CEV.

Region	RPEV	AWS provided CEV	Customer-provided CEV
US East (N. Virginia)	SQL Server 2022 Enterprise, Standard, or Web, with CU9, CU13. SQL Server 2019 Enterprise,	SQL Server 2022 Enterprise, Standard, or Web, with CU9, CU13. SQL Server 2019 Enterprise,	SQL Server 2022 Enterprise, Standard, or Developer, with CU9, CU13. SQL Server 2019 Enterpris

Region	RPEV	AWS provided CEV	Customer-provided CEV

Supported Regions and DB engines for Amazon RDS Proxy

Amazon RDS Proxy is a fully managed, highly available database proxy that makes applications more scalable by pooling and sharing established database connections. For more information, see Using Amazon RDS Proxy.

RDS Proxy isn't available for the following engines:

- RDS for Db2
- RDS for Oracle

Topics

- RDS Proxy with RDS for MariaDB
- RDS Proxy with RDS for MySQL
- RDS Proxy with RDS for PostgreSQL
- RDS Proxy with RDS for SQL Server

RDS Proxy with RDS for MariaDB

The following Regions and engine versions are available for RDS Proxy with RDS for MariaDB.

Supported Regions and DB engines for the Secrets Manager integration with Amazon RDS

With AWS Secrets Manager, you can replace hard-coded credentials in your code, including database passwords, with an API call to Secrets Manager to retrieve the secret programmatically. For more information about Secrets Manager, see AWS Secrets Manager User Guide.

You can specify that Amazon RDS manages the master user password in Secrets Manager for an Amazon RDS DB instance or Multi-AZ DB cluster. RDS generates the password, stores it in Secrets Manager, and rotates it regularly. For more information, see Password management with Amazon RDS and AWS Secrets Manager.

Secrets Manager integration is available in all AWS Regions.

Supported Regions and DB engines for Amazon RDS zero-ETL integrations with Amazon Redshift

RDS zero-ETL integrations with Amazon Redshift is a fully managed solution for making transactional data available in Amazon Redshift after it's written to an Amazon RDS DB instance. For more information, see *Working with zero-ETL integrations*.

Engine-native features in Amazon RDS

Amazon RDS database engines also support many of the most common engine-native features and functionality. These features are different than the Amazon RDS-native features listed on this page. Some engine-native features might have limited support or restricted privileges.

For more information on engine-native features, see:

- Amazon RDS for Db2 features
- MariaDB feature support on Amazon RDS
- MySQL feature support on Amazon RDS
- RDS for Oracle features
- Working with PostgreSQL features supported by Amazon RDS for PostgreSQL
- Microsoft SQL Server features on Amazon RDS

DB instance billing for Amazon RDS

Amazon RDS instances are billed based on the following components:

- DB instance hours (per hour) – Based on the DB instance class of the DB instance (for example, db.t2.small or db.m4.large). Pricing is listed on a per-hour basis, but bills are calculated down to the second and show times in decimal form. RDS usage is billed in 1-second increments, with a minimum of 10 minutes. For more information, see DB instance classes.
- Storage (per GiB per month) – Storage capacity that you have provisioned to your DB instance. If you scale your provisioned storage capacity within the month, your bill is prorated. For more information, see Amazon RDS DB instance storage.
- Input/output (I/O) requests (per 1 million requests) – Total number of storage I/O requests that you have made in a billing cycle, for Amazon RDS magnetic storage only.
- Provisioned IOPS (per IOPS per month) – Provisioned IOPS rate, regardless of IOPS consumed, for Amazon RDS Provisioned IOPS (SSD) and General Purpose (SSD) gp3 storage. Provisioned storage for EBS volumes are billed in 1-second increments, with a minimum of 10 minutes.
- Backup storage (per GiB per month) – *Backup storage* is the storage that is associated with automated database backups and any active database snapshots that you have taken. Increasing your backup retention period or taking additional database snapshots increases the backup storage consumed by your database. Per second billing doesn't apply to backup storage (metered in GB-month).

  For more information, see Backing up, restoring, and exporting data.
- Data transfer (per GB) – Data transfer in and out of your DB instance from or to the internet and other AWS Regions. For useful examples, see the AWS blog post Exploring Data Transfer Costs for AWS Managed Databases.

Amazon RDS provides the following purchasing options to enable you to optimize your costs based on your needs:

- **On-Demand instances** – Pay by the hour for the DB instance hours that you use. Pricing is listed on a per-hour basis, but bills are calculated down to the second and show times in decimal form. RDS usage is now billed in 1-second increments, with a minimum of 10 minutes.
- **Reserved instances** – Reserve a DB instance for a one-year or three-year term and get a significant discount compared to the on-demand DB instance pricing. With Reserved Instance

usage, you can launch, delete, start, or stop multiple instances within an hour and get the Reserved Instance benefit for all of the instances.

For Amazon RDS pricing information, see the Amazon RDS pricing page.

Topics

- On-Demand DB instances for Amazon RDS
- Reserved DB instances for Amazon RDS

On-Demand DB instances for Amazon RDS

Amazon RDS on-demand DB instances are billed based on the class of the DB instance (for example, db.t3.small or db.m5.large). For Amazon RDS pricing information, see the Amazon RDS product page.

Billing starts for a DB instance as soon as the DB instance is available. Pricing is listed on a per-hour basis, but bills are calculated down to the second and show times in decimal form. Amazon RDS usage is billed in one-second increments, with a minimum of 10 minutes. In the case of billable configuration change, such as scaling compute or storage capacity, you're charged a 10-minute minimum. Billing continues until the DB instance terminates, which occurs when you delete the DB instance or if the DB instance fails.

If you no longer want to be charged for your DB instance, you must stop or delete it to avoid being billed for additional DB instance hours. For more information about the DB instance states for which you are billed, see Viewing Amazon RDS DB instance status.

Stopped DB instances

While your DB instance is stopped, you're charged for provisioned storage, including Provisioned IOPS. You are also charged for backup storage, including storage for manual snapshots and automated backups within your specified retention window. You aren't charged for DB instance hours.

Multi-AZ DB instances

If you specify that your DB instance should be a Multi-AZ deployment, you're billed according to the Multi-AZ pricing posted on the Amazon RDS pricing page.

Reserved DB instances for Amazon RDS

Using reserved DB instances, you can reserve a DB instance for a one- or three-year term. Reserved DB instances provide you with a significant discount compared to on-demand DB instance pricing. Reserved DB instances are not physical instances, but rather a billing discount applied to the use of certain on-demand DB instances in your account. Discounts for reserved DB instances are tied to instance type and AWS Region.

The general process for working with reserved DB instances is: First get information about available reserved DB instance offerings, then purchase a reserved DB instance offering, and finally get information about your existing reserved DB instances.

For information about purchasing reserved DB instances and viewing the billing for reserved DB instances, see the following sections.

- Purchasing reserved DB instances for Amazon RDS
- Viewing the billing for reserved DB instances for Amazon RDS

Overview of reserved DB instances

When you purchase a reserved DB instance in Amazon RDS, you purchase a commitment to getting a discounted rate, on a specific DB instance type, for the duration of the reserved DB instance. To use an Amazon RDS reserved DB instance, you create a new DB instance just like you do for an on-demand instance.

The new DB instance that you create must have the same specifications as the reserved DB instance for the following:

- AWS Region
- DB engine (The DB engine's version number doesn't need to match.)
- DB instance type
- DB instance size (RDS for Microsoft SQL Server and Amazon RDS for Oracle License Included)
- Edition (RDS for SQL Server and RDS for Oracle)
- License type (license-included or bring-your-own-license)

If the specifications of the new DB instance match an existing reserved DB instance for your account, you are billed at the discounted rate offered for the reserved DB instance. Otherwise, the DB instance is billed at an on-demand rate.

You can modify a DB instance that you're using as a reserved DB instance. If the modification is within the specifications of the reserved DB instance, part or all of the discount still applies to the modified DB instance. If the modification is outside the specifications, such as changing the instance class, the discount no longer applies. For more information, see Size-flexible reserved DB instances.

Topics

For more information about reserved DB instances, including pricing, see Amazon RDS reserved instances.

Offering types

Reserved DB instances are available in three varieties—No Upfront, Partial Upfront, and All Upfront—that let you optimize your Amazon RDS costs based on your expected usage.

No Upfront

This option provides access to a reserved DB instance without requiring an upfront payment. Your No Upfront reserved DB instance bills a discounted hourly rate for every hour within the term, regardless of usage, and no upfront payment is required. This option is only available as a one-year reservation.

Partial Upfront

This option requires a part of the reserved DB instance to be paid upfront. The remaining hours in the term are billed at a discounted hourly rate, regardless of usage. This option is the replacement for the previous Heavy Utilization option.

All Upfront

Full payment is made at the start of the term, with no other costs incurred for the remainder of the term regardless of the number of hours used.

If you are using consolidated billing, all the accounts in the organization are treated as one account. This means that all accounts in the organization can receive the hourly cost benefit of reserved DB instances that are purchased by any other account. For more information about consolidated billing, see Amazon RDS reserved DB instances in the *AWS Billing and Cost Management User Guide*.

Size-flexible reserved DB instances

When you purchase a reserved DB instance, one thing that you specify is the instance class, for example db.r5.large. For more information about DB instance classes, see DB instance classes.

If you have a DB instance, and you need to scale it to larger capacity, your reserved DB instance is automatically applied to your scaled DB instance. That is, your reserved DB instances are automatically applied across all DB instance class sizes. Size-flexible reserved DB instances are available for DB instances with the same AWS Region and database engine. Size-flexible reserved DB instances can only scale in their instance class type. For example, a reserved DB instance for a db.r5.large can apply to a db.r5.xlarge, but not to a db.r6g.large, because db.r5 and db.r6g are different instance class types.

Reserved DB instance benefits also apply for both Multi-AZ and Single-AZ configurations. Flexibility means that you can move freely between configurations within the same DB instance class type. For example, you can move from a Single-AZ deployment running on one large DB instance (four normalized units per hour) to a Multi-AZ deployment running on two medium DB instances (2+2 = 4 normalized units per hour).

Size-flexible reserved DB instances are available for the following Amazon RDS database engines:

- RDS for MariaDB
- RDS for MySQL
- RDS for Oracle, Bring Your Own License
- RDS for PostgreSQL

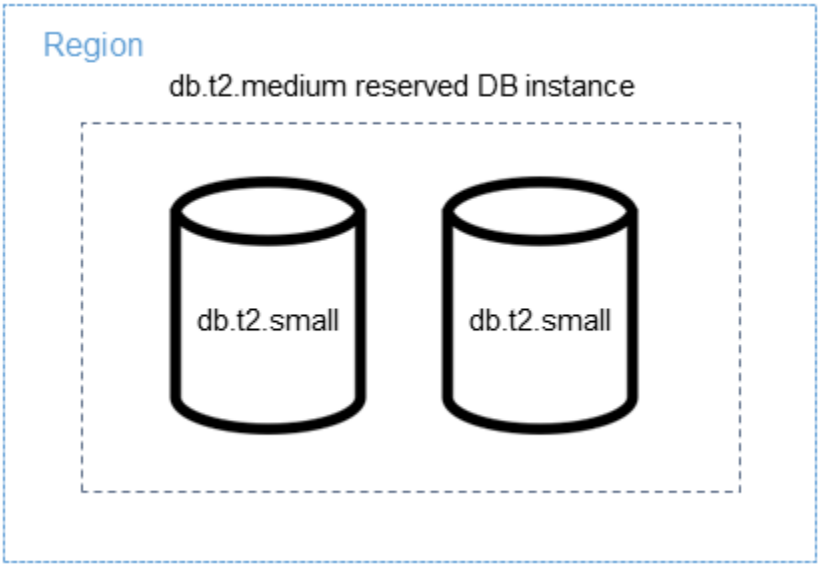
Size flexibility does not apply to RDS for SQL Server and RDS for Oracle License Included.

For details about using size-flexible reserved instances with Aurora, see Reserved DB instances for Aurora.

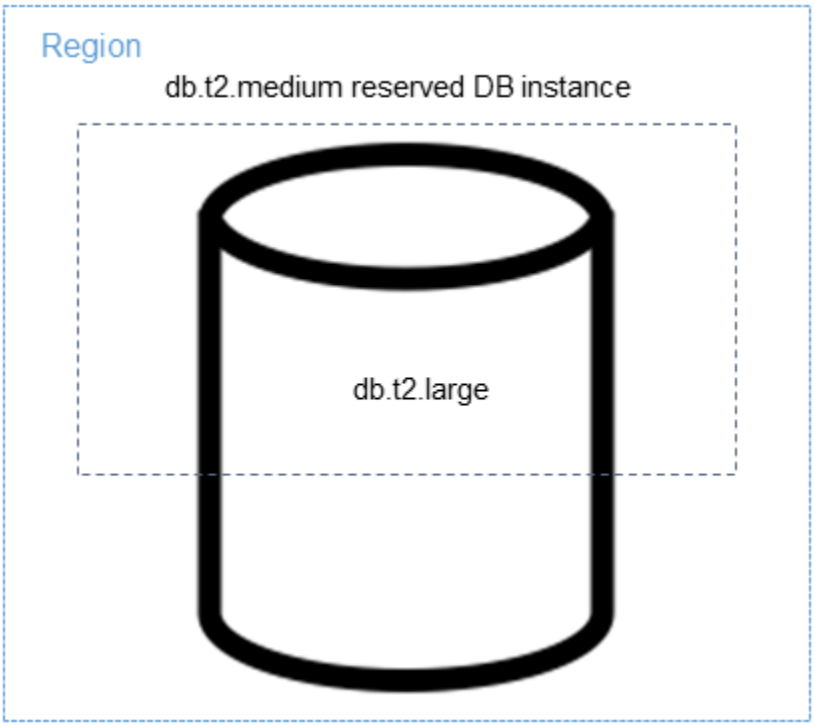
You can compare usage for different reserved DB instance sizes by using normalized units per hour. For example, one unit of usage on two db.r3.large DB instances is equivalent to eight normalized units per hour of usage on one db.r3.small. The following table shows the number of normalized units per hour for each DB instance size.

Instance size	Single-AZ normalized units per hour (deployment with one DB instance)	Multi-AZ DB instance normalized units per hour (deployment with one DB instance and one standby)	Multi-AZ DB cluster normalized units per hour (deployment with one DB instance and two standbys)
micro	0.5	1	1.5
small	1	2	3
medium	2	4	6
large	4	8	12
xlarge	8	16	24
2xlarge	16	32	48
4xlarge	32	64	96
6xlarge	48	96	144
8xlarge	64	128	192
10xlarge	80	160	240
12xlarge	96	192	288
16xlarge	128	256	384
24xlarge	192	384	576
32xlarge	256	512	768

For example, suppose that you purchase a `db.t2.medium` reserved DB instance, and you have two running `db.t2.small` DB instances in your account in the same AWS Region. In this case, the billing benefit is applied in full to both instances.



Alternatively, if you have one `db.t2.large` instance running in your account in the same AWS Region, the billing benefit is applied to 50 percent of the usage of the DB instance.



Reserved DB instance billing example

The price for a reserved DB instance doesn't provide a discount for the costs associated with storage, backups, and I/O. It provides a discount only on the hourly, on-demand instance usage. The following example illustrates the total cost per month for a reserved DB instance:

- An RDS for MySQL reserved Single-AZ db.r5.large DB instance class in US East (N. Virginia) with the No Upfront option at a cost of $0.12 for the instance, or $90 per month
- 400 GiB of General Purpose SSD (gp2) storage at a cost of 0.115 per GiB per month, or $45.60 per month
- 600 GiB of backup storage at $0.095, or $19 per month (400 GiB free)

Add all of these charges ($90 + $45.60 + $19) with the reserved DB instance, and the total cost per month is $154.60.

If you choose to use an on-demand DB instance instead of a reserved DB instance, an RDS for MySQL Single-AZ db.r5.large DB instance class in US East (N. Virginia) costs $0.1386 per hour, or $101.18 per month. So, for an on-demand DB instance, add all of these options ($101.18 + $45.60 + $19), and the total cost per month is $165.78. You save a little over $11 per month by using the reserved DB instance.

> **Note**
>
> The prices in this example are sample prices and might not match actual prices. For Amazon RDS pricing information, see Amazon RDS pricing.

Reserved DB instances for a Multi-AZ DB cluster

To purchase the equivalent reserved DB instances for a Multi-AZ DB cluster, you can do one of the following:

- Reserve three Single-AZ DB instances that are the same size as the instances in the cluster.
- Reserve one Multi-AZ DB instance and one Single-AZ DB instance that are the same size as the DB instances in the cluster.

For example, suppose that you have one cluster consisting of three db.m6gd.large DB instances. In this case, you can either purchase three db.m6gd.large Single-AZ reserved DB instances, or

one db.m6gd.large Multi-AZ reserved DB instance and one db.m6gd.large Single-AZ reserved DB instance. Either of these options reserves the maximum reserved instance discount for the Multi-AZ DB cluster.

Alternately, you can use size-flexible DB instances and purchase a larger DB instance to cover smaller DB instances in one or more clusters. For example, if you have two clusters with six total db.m6gd.large DB instances, you can purchase three db.m6gd.xl Single-AZ reserved DB instances. Doing so reserves all six DB instances in the two clusters. For more information, see Size-flexible reserved DB instances.

You might reserve DB instances that are the same size as the DB instances in the cluster, but reserve fewer DB instances than the total number of DB instances in the cluster. However, if you do so, the cluster is only partially reserved. For example, suppose that you have one cluster with three db.m6gd.large DB instances, and you purchase one db.m6gd.large Multi-AZ reserved DB instance. In this case, the cluster is only partially reserved, because only two of the three instances in the cluster are covered by reserved DB instances. The remaining DB instance is charged at the on-demand db.m6gd.large hourly rate.

For more information about Multi-AZ DB clusters, see Multi-AZ DB cluster deployments.

Deleting a reserved DB instance

The terms for a reserved DB instance involve a one-year or three-year commitment. You can't cancel a reserved DB instance. However, you can delete a DB instance that is covered by a reserved DB instance discount. The process for deleting a DB instance that is covered by a reserved DB instance discount is the same as for any other DB instance.

You're billed for the upfront costs regardless of whether you use the resources.

If you delete a DB instance that is covered by a reserved DB instance discount, you can launch another DB instance with compatible specifications. In this case, you continue to get the discounted rate during the reservation term (one or three years).

Purchasing reserved DB instances for Amazon RDS

You can use the AWS Management Console, the AWS CLI, and the RDS API to work with reserved DB instances.

Console

You can use the AWS Management Console to work with reserved DB instances as shown in the following procedures.

To get pricing and information about available reserved DB instance offerings

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Reserved instances**.
3. Choose **Purchase Reserved DB Instance**.
4. For **Product description**, choose the DB engine and licensing type.
5. For **DB instance class**, choose the DB instance class.
6. For **Deployment Option**, choose whether you want a Single-AZ or Multi-AZ DB instance deployment.

   > **Note**
   >
   > To purchase the equivalent reserved DB instances for a Multi-AZ DB cluster deployment, either purchase three Single-AZ reserved DB instances, or one Multi-AZ and one Single-AZ reserved DB instance. For more information, see Reserved DB instances for a Multi-AZ DB cluster.

7. For **Term**, choose the length of time to reserve the the DB instance.
8. For **Offering type**, choose the offering type.

   After you select the offering type, you can see the pricing information.

   > **Important**
   >
   > Choose **Cancel** to avoid purchasing the reserved DB instance and incurring any charges.

After you have information about the available reserved DB instance offerings, you can use the information to purchase an offering as shown in the following procedure.

To purchase a reserved DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Reserved instances**.
3. Choose **Purchase reserved DB instance**.
4. For **Product description**, choose the DB engine and licensing type.
5. For **DB instance class**, choose the DB instance class.
6. For **Multi-AZ deployment**, choose whether you want a Single-AZ or Multi-AZ DB instance deployment.

   > **Note**
   >
   > To purchase the equivalent reserved DB instances for a Multi-AZ DB cluster deployment, either purchase three Single-AZ reserved DB instances, or one Multi-AZ and one Single-AZ reserved DB instance. For more information, see Reserved DB instances for a Multi-AZ DB cluster.

7. For **Term**, choose the length of time you want the DB instance reserved.
8. For **Offering type**, choose the offering type.

   After you choose the offering type, you can see the pricing information.
9. (Optional) You can assign your own identifier to the reserved DB instances that you purchase to help you track them. For **Reserved Id**, type an identifier for your reserved DB instance.
10. Choose **Submit**.

    Your reserved DB instance is purchased, then displayed in the **Reserved instances** list.

After you have purchased reserved DB instances, you can get information about your reserved DB instances as shown in the following procedure.

To get information about reserved DB instances for your AWS account

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the **Navigation** pane, choose **Reserved instances**.

The reserved DB instances for your account appear. To see detailed information about a particular reserved DB instance, choose that instance in the list. You can then see detailed information about that instance in the detail pane at the bottom of the console.

AWS CLI

You can use the AWS CLI to work with reserved DB instances as shown in the following examples.

Example of getting available reserved DB instance offerings

To get information about available reserved DB instance offerings, call the AWS CLI command `describe-reserved-db-instances-offerings`.

```
aws rds describe-reserved-db-instances-offerings
```

This call returns output similar to the following:

```
OFFERING  OfferingId                            Class         Multi-AZ  Duration  Fixed
 Price  Usage Price  Description  Offering Type
OFFERING  438012d3-4052-4cc7-b2e3-8d3372e0e706  db.r3.large   y         1y
 1820.00 USD  0.368 USD    mysql        Partial  Upfront
OFFERING  649fd0c8-cf6d-47a0-bfa6-060f8e75e95f  db.r3.small   n         1y
 227.50 USD  0.046 USD    mysql        Partial  Upfront
OFFERING  123456cd-ab1c-47a0-bfa6-12345667232f  db.r3.small   n         1y
 162.00 USD   0.00 USD    mysql        All      Upfront
    Recurring Charges:   Amount  Currency  Frequency
    Recurring Charges:   0.123   USD       Hourly
OFFERING  123456cd-ab1c-37a0-bfa6-12345667232d  db.r3.large   y         1y
 700.00 USD   0.00 USD    mysql        All      Upfront
    Recurring Charges:   Amount  Currency  Frequency
    Recurring Charges:   1.25    USD       Hourly
OFFERING  123456cd-ab1c-17d0-bfa6-12345667234e  db.r3.xlarge  n         1y
 4242.00 USD   2.42 USD    mysql        No       Upfront
```

After you have information about the available reserved DB instance offerings, you can use the information to purchase an offering.

To purchase a reserved DB instance, use the AWS CLI command `purchase-reserved-db-instances-offering` with the following parameters:

- `--reserved-db-instances-offering-id` – The ID of the offering that you want to purchase. See the preceding example to get the offering ID.
- `--reserved-db-instance-id` – You can assign your own identifier to the reserved DB instances that you purchase to help track them.

Example of purchasing a reserved DB instance

The following example purchases the reserved DB instance offering with ID *649fd0c8-cf6d-47a0-bfa6-060f8e75e95f*, and assigns the identifier of *MyReservation*.

For Linux, macOS, or Unix:

```
aws rds purchase-reserved-db-instances-offering \
    --reserved-db-instances-offering-id 649fd0c8-cf6d-47a0-bfa6-060f8e75e95f \
    --reserved-db-instance-id MyReservation
```

For Windows:

```
aws rds purchase-reserved-db-instances-offering ^
    --reserved-db-instances-offering-id 649fd0c8-cf6d-47a0-bfa6-060f8e75e95f ^
    --reserved-db-instance-id MyReservation
```

The command returns output similar to the following:

```
RESERVATION  ReservationId      Class        Multi-AZ  Start Time
 Duration  Fixed Price  Usage Price  Count  State           Description  Offering Type
RESERVATION  MyReservation      db.r3.small  y         2011-12-19T00:30:23.247Z  1y
    455.00 USD   0.092 USD    1      payment-pending  mysql        Partial  Upfront
```

After you have purchased reserved DB instances, you can get information about your reserved DB instances.

To get information about reserved DB instances for your AWS account, call the AWS CLI command `describe-reserved-db-instances`, as shown in the following example.

Example of getting your reserved DB instances

```
aws rds describe-reserved-db-instances
```

The command returns output similar to the following:

```
RESERVATION  ReservationId     Class        Multi-AZ  Start Time
 Duration  Fixed Price  Usage Price  Count  State    Description  Offering Type
RESERVATION  MyReservation     db.r3.small  y         2011-12-09T23:37:44.720Z  1y
   455.00 USD   0.092 USD    1      retired  mysql        Partial  Upfront
```

RDS API

You can use the RDS API to work with reserved DB instances:

- To get information about available reserved DB instance offerings, call the Amazon RDS API operation `DescribeReservedDBInstancesOfferings`.
- After you have information about the available reserved DB instance offerings, you can use the information to purchase an offering. Call the `PurchaseReservedDBInstancesOffering` RDS API operation with the following parameters:
  - `--reserved-db-instances-offering-id` – The ID of the offering that you want to purchase.
  - `--reserved-db-instance-id` – You can assign your own identifier to the reserved DB instances that you purchase to help track them.
- After you have purchased reserved DB instances, you can get information about your reserved DB instances. Call the `DescribeReservedDBInstances` RDS API operation.

Viewing the billing for reserved DB instances for Amazon RDS

You can view the billing for your reserved DB instances in the Billing Dashboard in the AWS Management Console.

To view reserved DB instance billing

1. Sign in to the AWS Management Console.
2. From the **account menu** at the upper right, choose **Billing Dashboard**.
3. Choose **Bill Details** at the upper right of the dashboard.
4. Under **AWS Service Charges**, expand **Relational Database Service**.
5. Expand the AWS Region where your reserved DB instances are, for example **US West (Oregon)**.

   Your reserved DB instances and their hourly charges for the current month are shown under **Amazon Relational Database Service for *Database Engine* Reserved Instances**.

Amazon Relational Database Service for MySQL Community Edition Reserved Instances		$0.00
MySQL, db.t3.micro reserved instance applied, db.t3.micro instance used	395.000 Hrs	$0.00
USD 0.0 hourly fee per MySQL, db.t3.micro instance	720.000 Hrs	$0.00

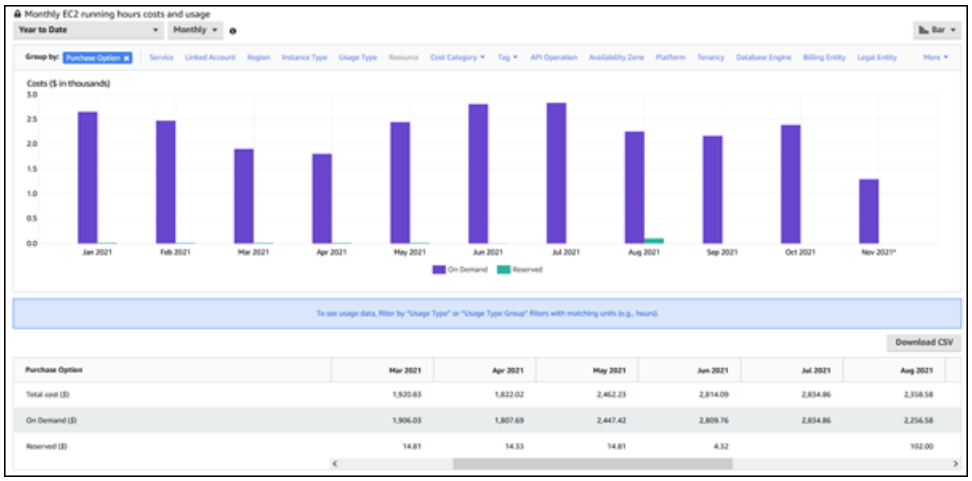
The reserved DB instance in this example was purchased All Upfront, so there are no hourly charges.

6. Choose the **Cost Explorer** (bar graph) icon next to the **Reserved Instances** heading.

   The Cost Explorer displays the **Monthly EC2 running hours costs and usage** graph.

7. Clear the **Usage Type Group** filter to the right of the graph.
8. Choose the time period and time unit for which you want to examine usage costs.

   The following example shows usage costs for on-demand and reserved DB instances for the year to date by month.



The reserved DB instance costs from January through June 2021 are monthly charges for a Partial Upfront instance, while the cost in August 2021 is a one-time charge for an All Upfront instance.

The reserved instance discount for the Partial Upfront instance expired in June 2021, but the DB instance wasn't deleted. After the expiration date, it was simply charged at the on-demand rate.

Setting up your Amazon RDS environment

This page provides a comprehensive guide for setting up Amazon Relational Database Service, including account configuration, security, and resource management. It walks you through the essential steps to create, manage, and secure your database environments efficiently. Whether you're new to Amazon RDS or setting up for specific requirements, these sections help ensure your setup is optimized and compliant with best practices.

Topics

If you already have an AWS account, know your Amazon RDS requirements, and prefer to use the defaults for IAM and VPC security groups, skip ahead to Getting started with Amazon RDS.

Sign up for an AWS account

If you do not have an AWS account, complete the following steps to create one.

To sign up for an AWS account

1. Open https://portal.aws.amazon.com/billing/signup.
2. Follow the online instructions.

   Part of the sign-up procedure involves receiving a phone call and entering a verification code on the phone keypad.

   When you sign up for an AWS account, an *AWS account root user* is created. The root user has access to all AWS services and resources in the account. As a security best practice, assign administrative access to a user, and use only the root user to perform tasks that require root user access.

AWS sends you a confirmation email after the sign-up process is complete. At any time, you can view your current account activity and manage your account by going to https://aws.amazon.com/ and choosing **My Account**.

Create a user with administrative access

After you sign up for an AWS account, secure your AWS account root user, enable AWS IAM Identity Center, and create an administrative user so that you don't use the root user for everyday tasks.

Secure your AWS account root user

1. Sign in to the AWS Management Console as the account owner by choosing **Root user** and entering your AWS account email address. On the next page, enter your password.

   For help signing in by using root user, see Signing in as the root user in the *AWS Sign-In User Guide*.

2. Turn on multi-factor authentication (MFA) for your root user.

   For instructions, see Enable a virtual MFA device for your AWS account root user (console) in the *IAM User Guide*.

Create a user with administrative access

1. Enable IAM Identity Center.

   For instructions, see Enabling AWS IAM Identity Center in the *AWS IAM Identity Center User Guide*.

2. In IAM Identity Center, grant administrative access to a user.

   For a tutorial about using the IAM Identity Center directory as your identity source, see Configure user access with the default IAM Identity Center directory in the *AWS IAM Identity Center User Guide*.

Sign in as the user with administrative access

- To sign in with your IAM Identity Center user, use the sign-in URL that was sent to your email address when you created the IAM Identity Center user.

For help signing in using an IAM Identity Center user, see Signing in to the AWS access portal in the *AWS Sign-In User Guide*.

Assign access to additional users

1. In IAM Identity Center, create a permission set that follows the best practice of applying least-privilege permissions.

   For instructions, see Create a permission set in the *AWS IAM Identity Center User Guide*.
2. Assign users to a group, and then assign single sign-on access to the group.

   For instructions, see Add groups in the *AWS IAM Identity Center User Guide*.

Grant programmatic access

Users need programmatic access if they want to interact with AWS outside of the AWS Management Console. The way to grant programmatic access depends on the type of user that's accessing AWS.

To grant users programmatic access, choose one of the following options.

Which user needs programmatic access?	To	By
Workforce identity (Users managed in IAM Identity Center)	Use temporary credentials to sign programmatic requests to the AWS CLI, AWS SDKs, or AWS APIs.	Following the instructions for the interface that you want to use. • For the AWS CLI, see Configuring the AWS CLI to use AWS IAM Identity Center in the *AWS Command Line Interface User Guide*. • For AWS SDKs, tools, and AWS APIs, see IAM Identity Center authentication in

Which user needs programmatic access?	To	By
		the *AWS SDKs and Tools Reference Guide*.
IAM	Use temporary credentials to sign programmatic requests to the AWS CLI, AWS SDKs, or AWS APIs.	Following the instructions in Using temporary credentials with AWS resources in the *IAM User Guide*.
IAM	(Not recommended) Use long-term credentials to sign programmatic requests to the AWS CLI, AWS SDKs, or AWS APIs.	Following the instructions for the interface that you want to use. • For the AWS CLI, see Authenticating using IAM user credentials in the *AWS Command Line Interface User Guide*. • For AWS SDKs and tools, see Authenticate using long-term credentials in the *AWS SDKs and Tools Reference Guide*. • For AWS APIs, see Managing access keys for IAM users in the *IAM User Guide*.

Determine requirements

The basic building block of Amazon RDS is the DB instance. In a DB instance, you create your databases. A DB instance provides a network address called an *endpoint*. Your applications use this endpoint to connect to your DB instance. When you create a DB instance, you specify details like storage, memory, database engine and version, network configuration, security, and maintenance periods. You control network access to a DB instance through a security group.

Before you create a DB instance and a security group, you must know your DB instance and network needs. Here are some important things to consider:

- **Resource requirements** – What are the memory and processor requirements for your application or service? You use these settings to help you determine what DB instance class to use. For specifications about DB instance classes, see DB instance classes.
- **VPC, subnet, and security group –** Your DB instance will most likely be in a virtual private cloud (VPC). To connect to your DB instance, you need to set up security group rules. These rules are set up differently depending on what kind of VPC you use and how you use it. For example, you can use: a default VPC or a user-defined VPC.

  The following list describes the rules for each VPC option:

  - **Default VPC** – If your AWS account has a default VPC in the current AWS Region, that VPC is configured to support DB instances. If you specify the default VPC when you create the DB instance, do the following:
    - Make sure to create a *VPC security group* that authorizes connections from the application or service to the Amazon RDS DB instance. Use the **Security Group** option on the VPC console or the AWS CLI to create VPC security groups. For information, see Step 3: Create a VPC security group.
    - Specify the default DB subnet group. If this is the first DB instance you have created in this AWS Region, Amazon RDS creates the default DB subnet group when it creates the DB instance.
  - **User-defined VPC –** If you want to specify a user-defined VPC when you create a DB instance, be aware of the following:
    - Make sure to create a *VPC security group* that authorizes connections from the application or service to the Amazon RDS DB instance. Use the **Security Group** option on the VPC console or the AWS CLI to create VPC security groups. For information, see Step 3: Create a VPC security group.
    - The VPC must meet certain requirements in order to host DB instances, such as having at least two subnets, each in a separate Availability Zone. For information, see Amazon VPC and Amazon RDS.
    - Make sure to specify a DB subnet group that defines which subnets in that VPC can be used by the DB instance. For information, see the DB subnet group section in Working with a DB instance in a VPC.

- **High availability –** Do you need failover support? On Amazon RDS, a Multi-AZ deployment creates a primary DB instance and a secondary standby DB instance in another Availability Zone for failover support. We recommend Multi-AZ deployments for production workloads to maintain high availability. For development and test purposes, you can use a deployment that isn't Multi-AZ. For more information, see Configuring and managing a Multi-AZ deployment.
- **IAM policies** – Does your AWS account have policies that grant the permissions needed to perform Amazon RDS operations? If you are connecting to AWS using IAM credentials, your IAM account must have IAM policies that grant the permissions required to perform Amazon RDS operations. For more information, see Identity and access management for Amazon RDS.
- **Open ports** – What TCP/IP port does your database listen on? The firewalls at some companies might block connections to the default port for your database engine. If your company firewall blocks the default port, choose another port for the new DB instance. When you create a DB instance that listens on a port you specify, you can change the port by modifying the DB instance.
- **AWS Region** – What AWS Region do you want your database in? Having your database in close proximity to your application or web service can reduce network latency. For more information, see Regions, Availability Zones, and Local Zones.
- **DB disk subsystem** – What are your storage requirements? Amazon RDS provides three storage types:
  - General Purpose (SSD)
  - Provisioned IOPS (PIOPS)
  - Magnetic (also known as standard storage)

  For more information on Amazon RDS storage, see Amazon RDS DB instance storage.

When you have the information you need to create the security group and the DB instance, continue to the next step.

Provide access to your DB instance in your VPC by creating a security group

VPC security groups provide access to DB instances in a VPC. They act as a firewall for the associated DB instance, controlling both inbound and outbound traffic at the DB instance level. DB instances are created by default with a firewall and a default security group that protect the DB instance.

Before you can connect to your DB instance, you must add rules to a security group that enable you to connect. Use your network and configuration information to create rules to allow access to your DB instance.

For example, suppose that you have an application that accesses a database on your DB instance in a VPC. In this case, you must add a custom TCP rule that specifies the port range and IP addresses that your application uses to access the database. If you have an application on an Amazon EC2 instance, you can use the security group that you set up for the Amazon EC2 instance.

You can configure connectivity between an Amazon EC2 instance a DB instance when you create the DB instance. For more information, see Configure automatic network connectivity with an EC2 instance.

> **Tip**
>
> You can set up network connectivity between an Amazon EC2 instance and a DB instance automatically when you create the DB instance. For more information, see Configure automatic network connectivity with an EC2 instance.

For information about common scenarios for accessing a DB instance, see Scenarios for accessing a DB instance in a VPC.

To create a VPC security group

1. Sign in to the AWS Management Console and open the Amazon VPC console at https://console.aws.amazon.com/vpc.

   > **Note**
   >
   > Make sure you are in the VPC console, not the RDS console.

2. In the upper-right corner of the AWS Management Console, choose the AWS Region where you want to create your VPC security group and DB instance. In the list of Amazon VPC resources for that AWS Region, you should see at least one VPC and several subnets. If you don't, you don't have a default VPC in that AWS Region.
3. In the navigation pane, choose **Security Groups**.
4. Choose **Create security group**.

The **Create security group** page appears.

5. In **Basic details**, enter the **Security group name** and **Description**. For **VPC**, choose the VPC that you want to create your DB instance in.
6. In **Inbound rules**, choose **Add rule**.
   a. For **Type**, choose **Custom TCP**.
   b. For **Port range**, enter the port value to use for your DB instance.
   c. For **Source**, choose a security group name or type the IP address range (CIDR value) from where you access the DB instance. If you choose **My IP**, this allows access to the DB instance from the IP address detected in your browser.
7. If you need to add more IP addresses or different port ranges, choose **Add rule** and enter the information for the rule.
8. (Optional) In **Outbound rules**, add rules for outbound traffic. By default, all outbound traffic is allowed.
9. Choose **Create security group**.

You can use the VPC security group that you just created as the security group for your DB instance when you create it.

> **Note**
>
> If you use a default VPC, a default subnet group spanning all of the VPC's subnets is created for you. When you create a DB instance, you can select the default VPC and use **default** for **DB Subnet Group**.

After you have completed the setup requirements, you can create a DB instance using your requirements and security group. To do so, follow the instructions in Creating an Amazon RDS DB instance. For information about getting started by creating a DB instance that uses a specific DB engine, see the relevant documentation in the following table.

Database engine	Documentation
MariaDB	Creating and connecting to a MariaDB DB instance

Database engine	Documentation
Microsoft SQL Server	Creating and connecting to a Microsoft SQL Server DB instance
MySQL	Creating and connecting to a MySQL DB instance
Oracle	Creating and connecting to an Oracle DB instance
PostgreSQL	Creating and connecting to a PostgreSQL DB instance

Note

If you can't connect to a DB instance after you create it, see the troubleshooting information in Can't connect to Amazon RDS DB instance.

Getting started with Amazon RDS

In the following examples, you can find how to create and connect to a DB instance using Amazon Relational Database Service (Amazon RDS). You can create a DB instance that uses Db2, MariaDB, MySQL, Microsoft SQL Server, Oracle, or PostgreSQL.

> **Important**
>
> Before you can create or connect to a DB instance, make sure to complete the tasks in Setting up your Amazon RDS environment.

Creating a DB instance and connecting to a database on a DB instance is slightly different for each of the DB engines. Choose one of the following DB engines that you want to use for detailed information on creating and connecting to the DB instance. After you have created and connected to your DB instance, there are instructions to help you delete the DB instance.

Topics

Creating and connecting to a MariaDB DB instance

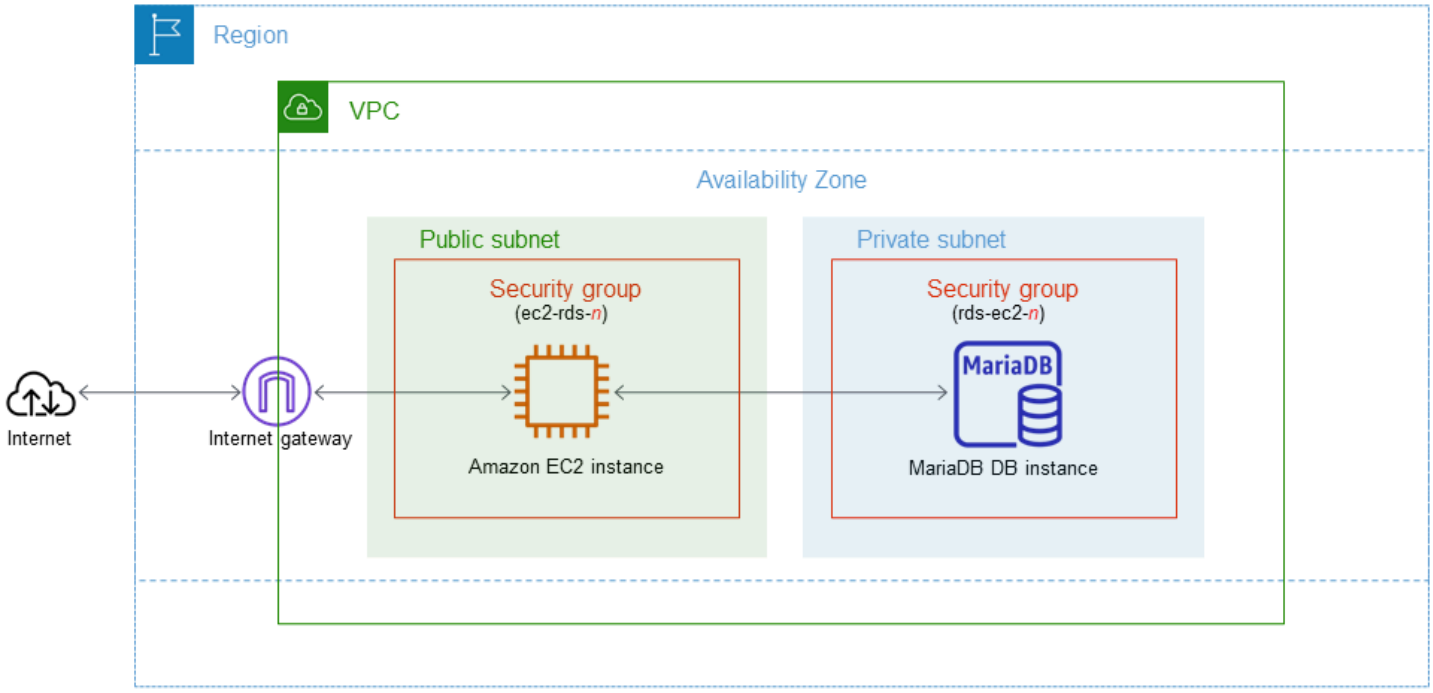
This tutorial creates an EC2 instance and an RDS for MariaDB DB instance. The tutorial shows you how to access the DB instance from the EC2 instance using a standard MySQL client. As a best practice, this tutorial creates a private DB instance in a virtual private cloud (VPC). In most cases, other resources in the same VPC, such as EC2 instances, can access the DB instance, but resources outside of the VPC can't access it.

After you complete the tutorial, there is a public and private subnet in each Availability Zone in your VPC. In one Availability Zone, the EC2 instance is in the public subnet, and the DB instance is in the private subnet.

Important

There's no charge for creating an AWS account. However, by completing this tutorial, you might incur costs for the resources you use. You can delete these resources after you complete the tutorial if they are no longer needed.

The following diagram shows the configuration when the tutorial is complete.



This tutorial allows you to create your resources by using one of the following methods:

1. Use the AWS Management Console - Step 1: Create an EC2 instance and Step 2: Create a MariaDB DB instance
2. Use AWS CloudFormation to create the database instance and EC2 instance - (Optional) Create VPC, EC2 instance, and MariaDB instance using AWS CloudFormation

The first method uses **Easy create** to create a private MariaDB DB instance with the AWS Management Console. Here, you specify only the DB engine type, DB instance size, and DB instance identifier. **Easy create** uses the default settings for the other configuration options.

When you use **Standard create** instead, you can specify more configuration options when you create a DB instance. These options include settings for availability, security, backups, and maintenance. To create a public DB instance, you must use **Standard create**. For information, see Creating an Amazon RDS DB instance.

Topics

Prerequisites

Before you begin, complete the steps in the following sections:

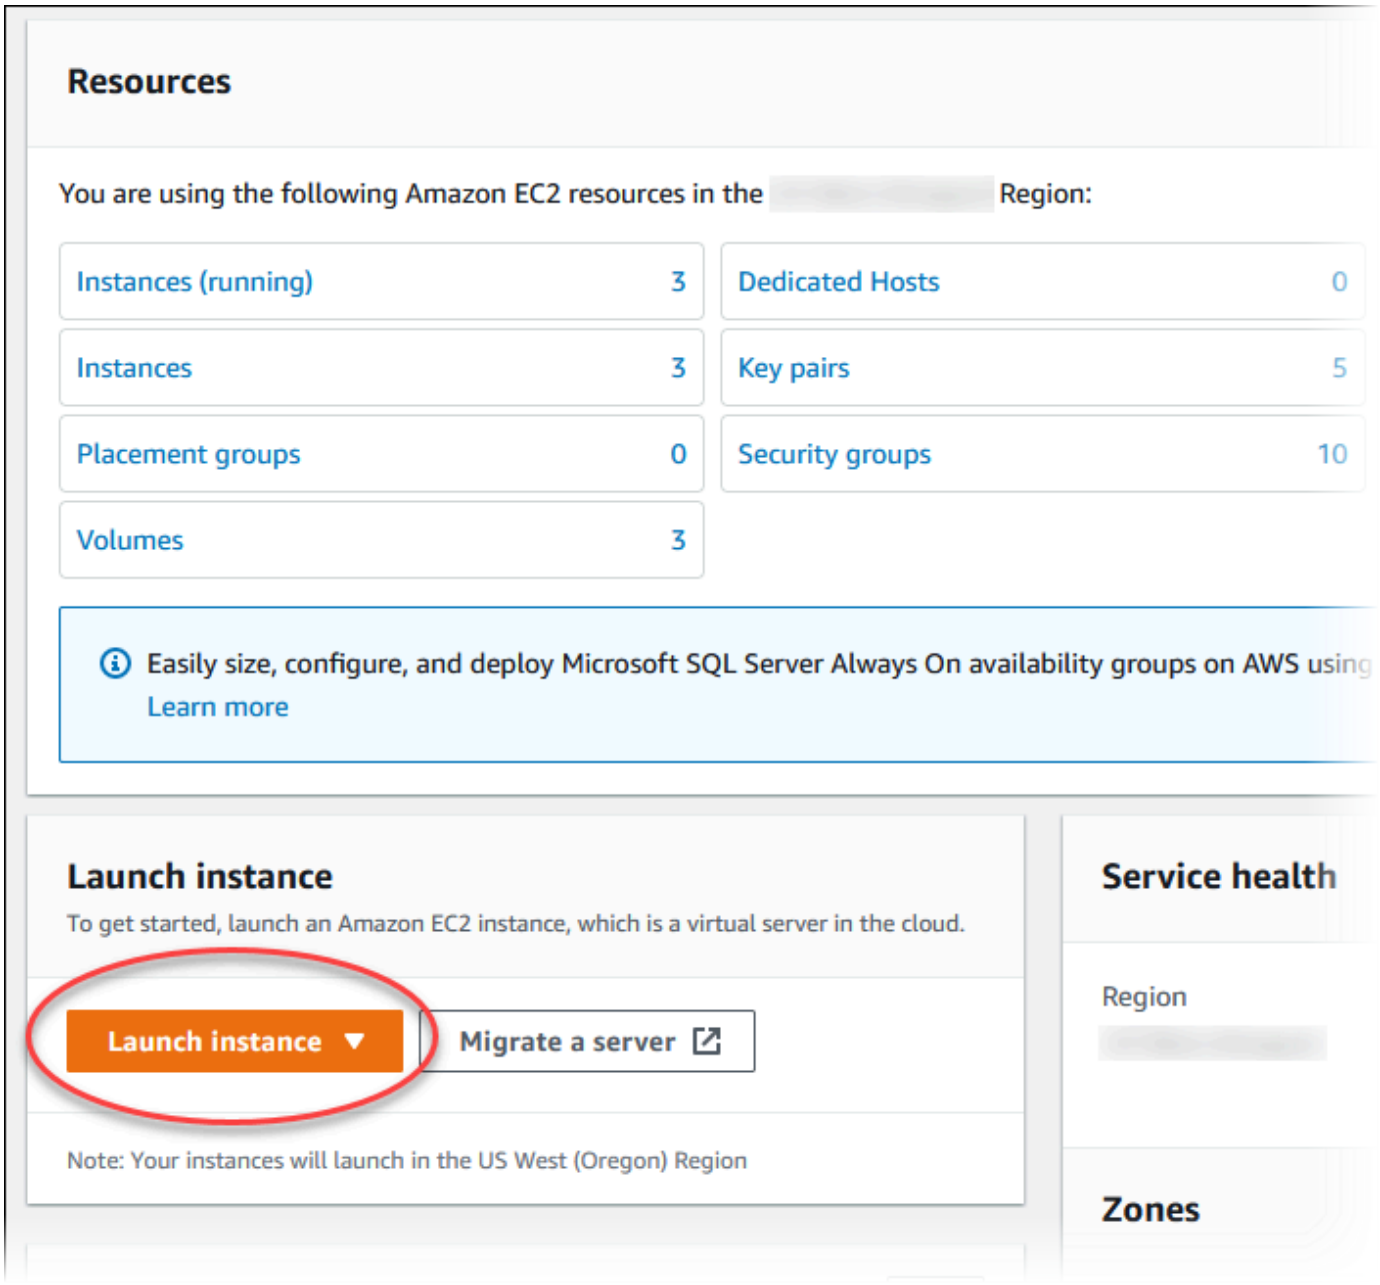
- Sign up for an AWS account
- Create a user with administrative access

Step 1: Create an EC2 instance

Create an Amazon EC2 instance that you will use to connect to your database.

To create an EC2 instance

1. Sign in to the AWS Management Console and open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the upper-right corner of the AWS Management Console, choose the AWS Region in which you want to create the EC2 instance.
3. Choose **EC2 Dashboard**, and then choose **Launch instance**, as shown in the following image.



The **Launch an instance** page opens.

4. Choose the following settings on the **Launch an instance** page.

   a. Under **Name and tags**, for **Name**, enter **`ec2-database-connect`**.

   b. Under **Application and OS Images (Amazon Machine Image)**, choose **Amazon Linux**, and then choose the **Amazon Linux 2023 AMI**. Keep the default selections for the other choices.

   c. Under **Instance type**, choose **t2.micro**.

   d. Under **Key pair (login)**, choose a **Key pair name** to use an existing key pair. To create a new key pair for the Amazon EC2 instance, choose **Create new key pair** and then use the **Create key pair** window to create it.

For more information about creating a new key pair, see Create a key pair in the *Amazon EC2 User Guide*.

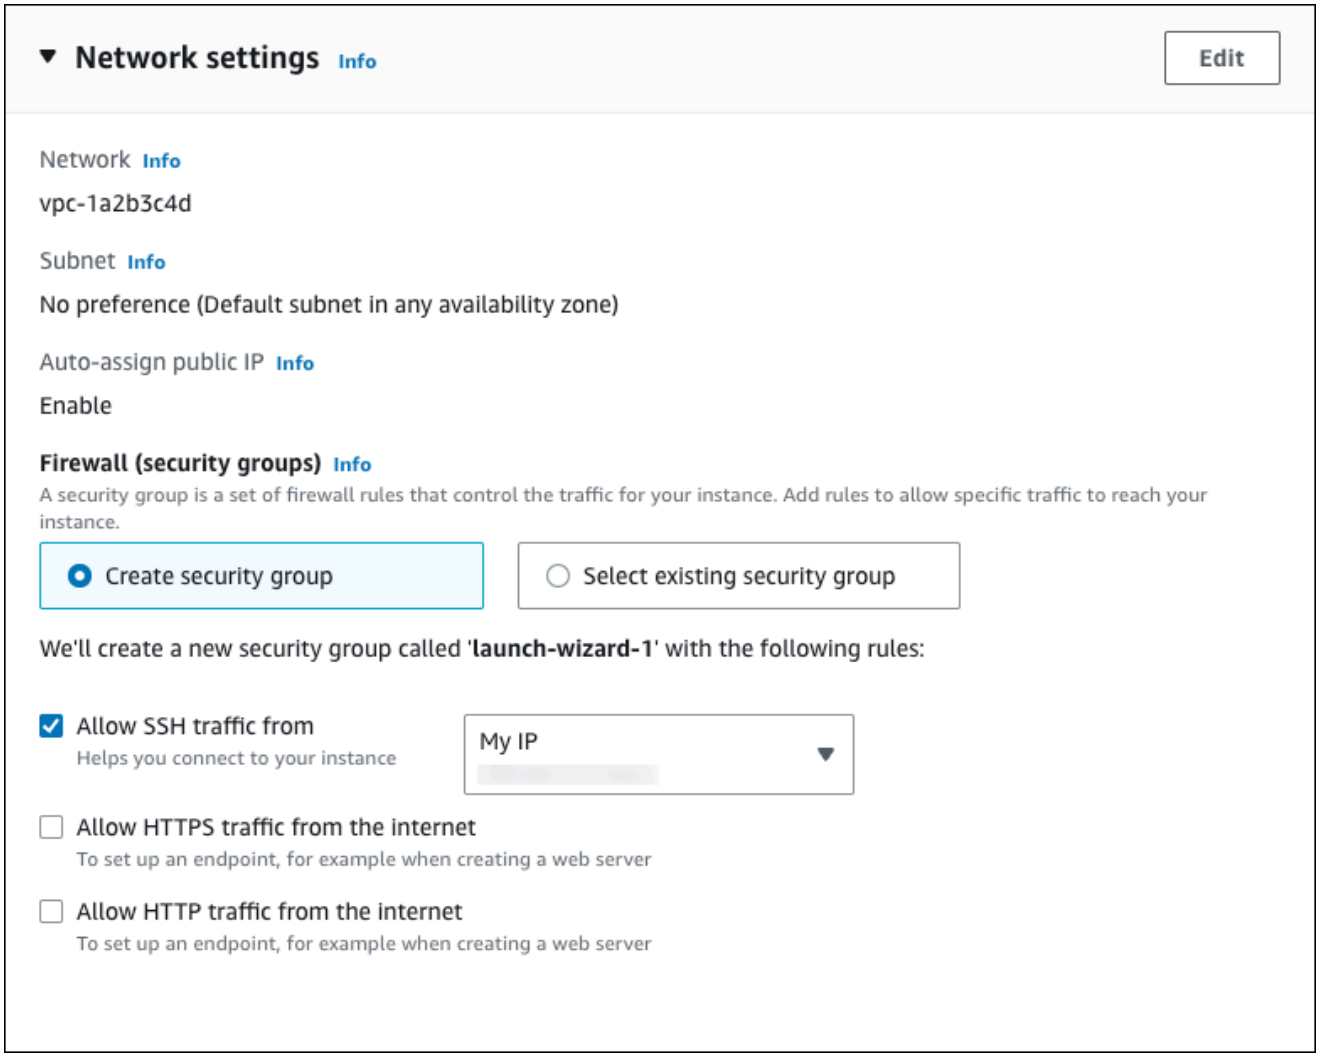
e. For **Allow SSH traffic** in **Network settings**, choose the source of SSH connections to the EC2 instance.

You can choose **My IP** if the displayed IP address is correct for SSH connections. Otherwise, you can determine the IP address to use to connect to EC2 instances in your VPC using Secure Shell (SSH). To determine your public IP address, in a different browser window or tab, you can use the service at https://checkip.amazonaws.com. An example of an IP address is 192.0.2.1/32.

In many cases, you might connect through an internet service provider (ISP) or from behind your firewall without a static IP address. If so, make sure to determine the range of IP addresses used by client computers.

> **Warning**
>
> If you use `0.0.0.0/0` for SSH access, you make it possible for all IP addresses to access your public EC2 instances using SSH. This approach is acceptable for a short time in a test environment, but it's unsafe for production environments. In production, authorize only a specific IP address or range of addresses to access your EC2 instances using SSH.

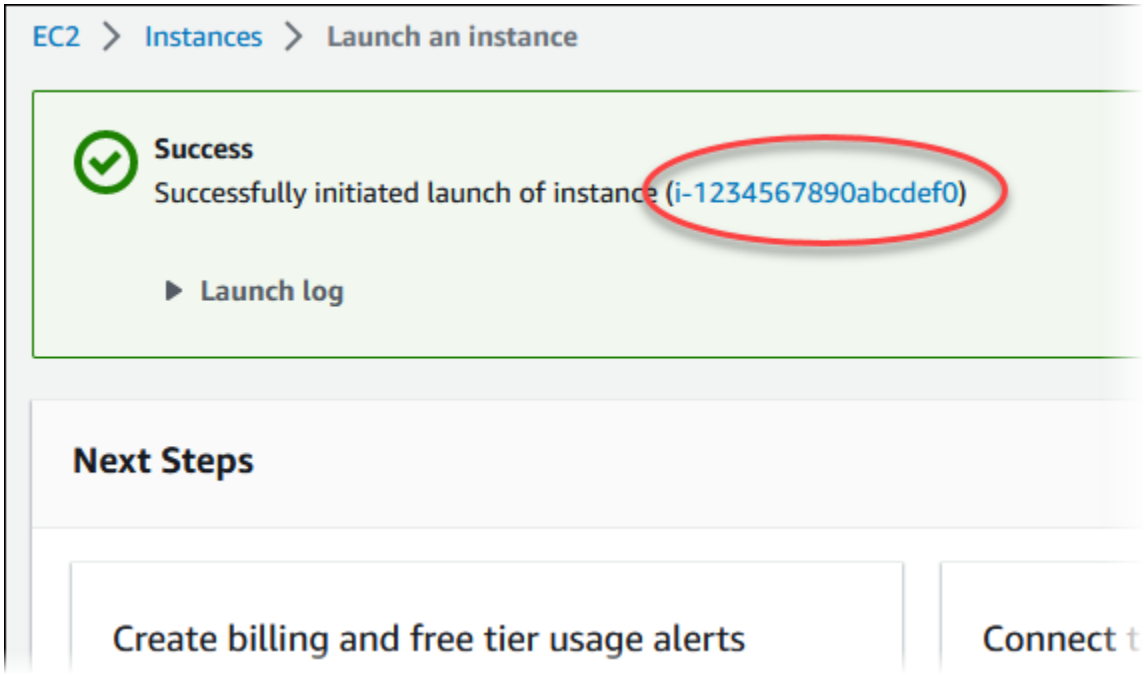
The following image shows an example of the **Network settings** section.



f. Leave the default values for the remaining sections.

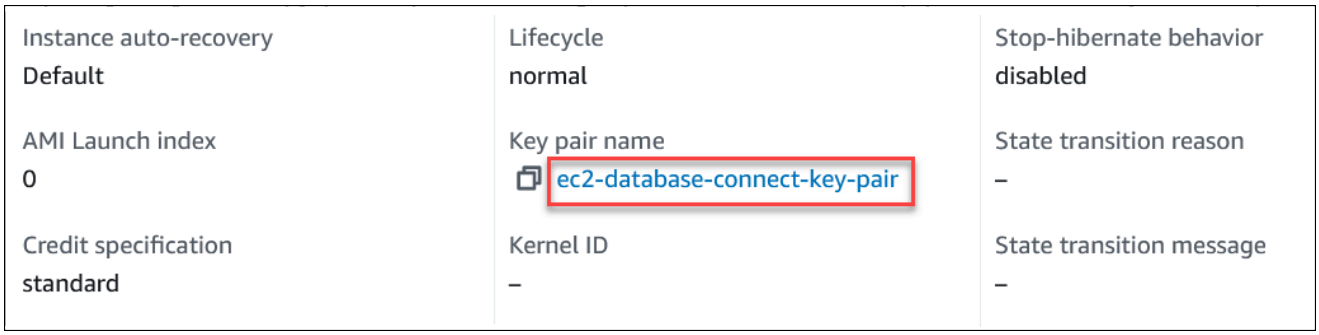
g. Review a summary of your EC2 instance configuration in the **Summary** panel, and when you're ready, choose **Launch instance**.

5. On the **Launch Status** page, note the identifier for your new EC2 instance, for example: `i-1234567890abcdef0`.



6. Choose the EC2 instance identifier to open the list of EC2 instances, and then select your EC2 instance.
7. In the **Details** tab, note the following values, which you need when you connect using SSH:
   a. In **Instance summary**, note the value for **Public IPv4 DNS**.

   b. In **Instance details**, note the value for **Key pair name**.



8. Wait until the **Instance state** for your EC2 instance has a status of **Running** before continuing.

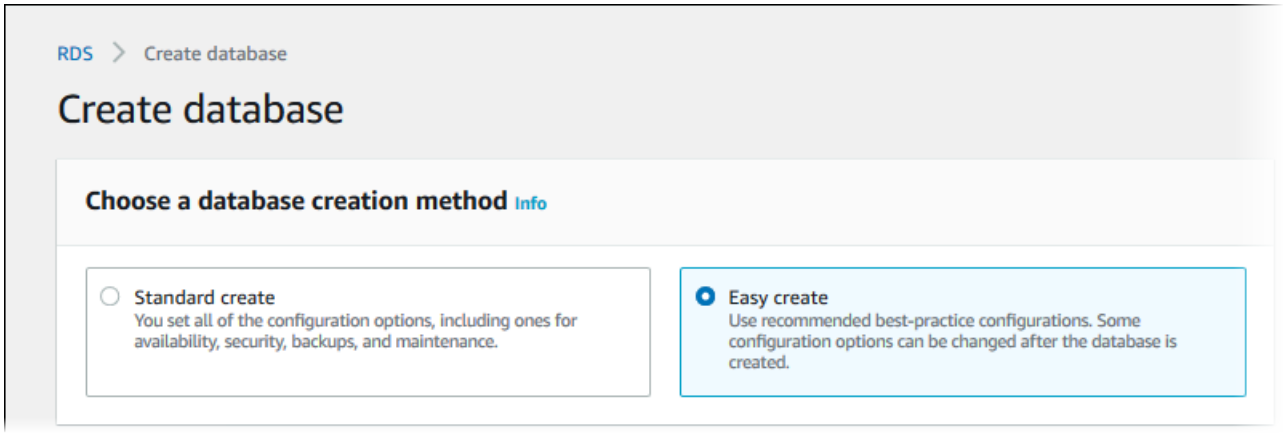
Step 2: Create a MariaDB DB instance

The basic building block of Amazon RDS is the DB instance. This environment is where you run your MariaDB databases.

In this example, you use **Easy create** to create a DB instance running the MariaDB database engine with a db.t3.micro DB instance class.

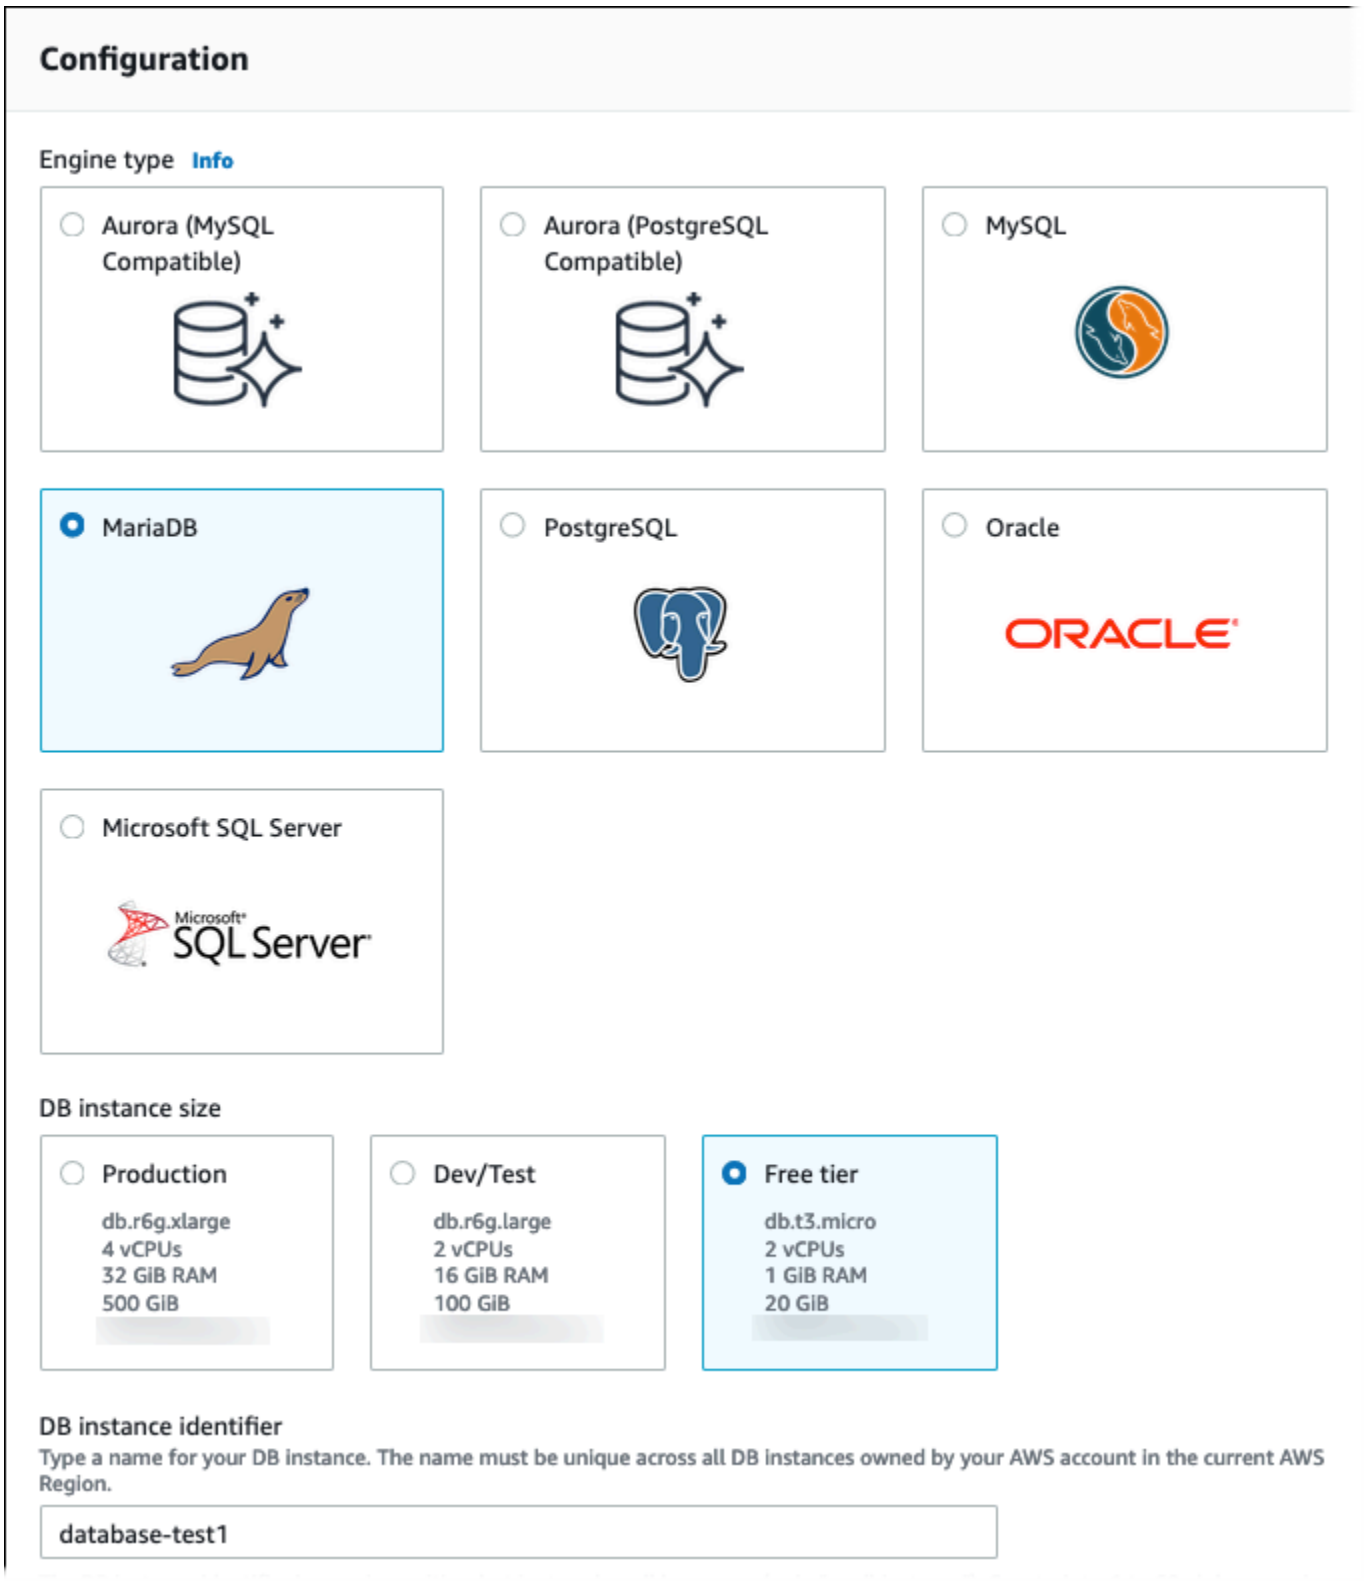
To create a MariaDB DB instance with Easy create

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the upper-right corner of the Amazon RDS console, choose the AWS Region in which you want to create the DB instance.
3. In the navigation pane, choose **Databases**.
4. Choose **Create database** and make sure that **Easy create** is chosen.



5. In **Configuration**, choose **MariaDB**.
6. For **DB instance size**, choose **Free tier**.
7. For **DB instance identifier**, enter **`database-test1`**.
8. For **Master username**, enter a name for the master user, or keep the default name.

   The **Create database** page should look similar to the following image.

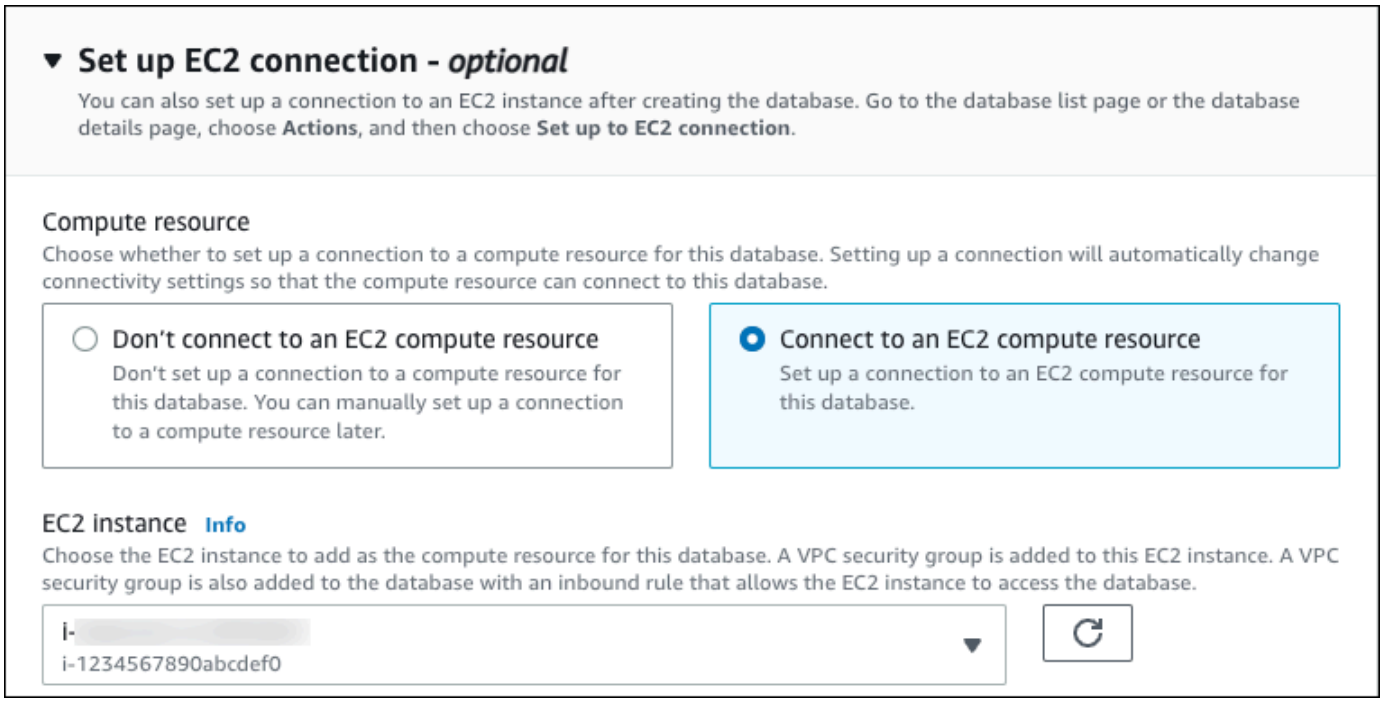


9. To use an automatically generated master password for the DB instance, select **Auto generate a password**.

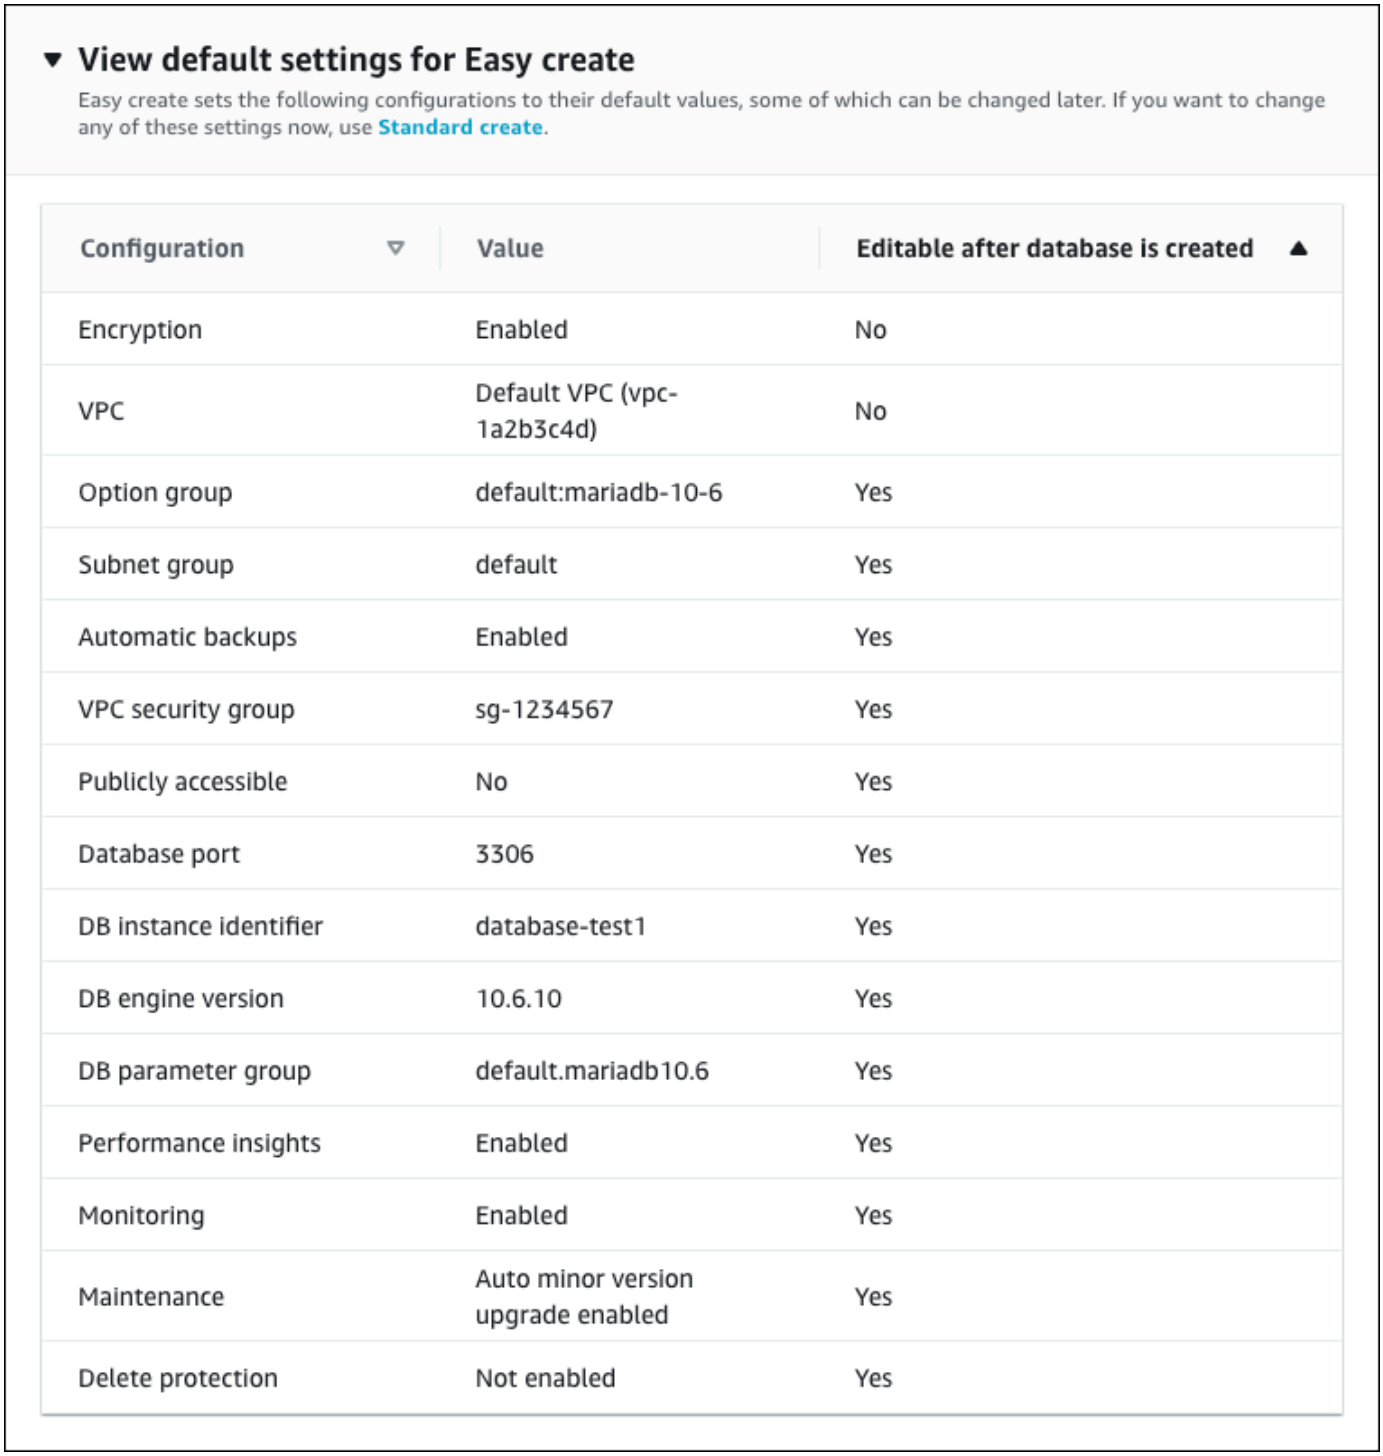
To enter your master password, make sure **Auto generate a password** is cleared, and then enter the same password in **Master password** and **Confirm password**.

10. To set up a connection with the EC2 instance you created previously, open **Set up EC2 connection - *optional***.

    Select **Connect to an EC2 compute resource**. Choose the EC2 instance you created previously.



11. Open **View default settings for Easy create**.



View default settings for Easy create

Easy create sets the following configurations to their default values, some of which can be changed later. If you want to change any of these settings now, use **Standard create**.

Configuration	Value	Editable after database is created
Encryption	Enabled	No
VPC	Default VPC (vpc-1a2b3c4d)	No
Option group	default:mariadb-10-6	Yes
Subnet group	default	Yes
Automatic backups	Enabled	Yes
VPC security group	sg-1234567	Yes
Publicly accessible	No	Yes
Database port	3306	Yes
DB instance identifier	database-test1	Yes
DB engine version	10.6.10	Yes
DB parameter group	default.mariadb10.6	Yes
Performance insights	Enabled	Yes
Monitoring	Enabled	Yes
Maintenance	Auto minor version upgrade enabled	Yes
Delete protection	Not enabled	Yes

You can examine the default settings used with **Easy create**. The **Editable after database is created** column shows which options you can change after you create the database.

- If a setting has **No** in that column, and you want a different setting, you can use **Standard create** to create the DB instance.

- If a setting has **Yes** in that column, and you want a different setting, you can either use **Standard create** to create the DB instance, or modify the DB instance after you create it to change the setting.

12. Choose **Create database**.

    To view the master username and password for the DB instance, choose **View credential details**.

    You can use the username and password that appears to connect to the DB instance as the master user.

    > **Important**
    >
    > You can't view the master user password again. If you don't record it, you might have to change it.
    > If you need to change the master user password after the DB instance is available, you can modify the DB instance to do so. For more information about modifying a DB instance, see Modifying an Amazon RDS DB instance.

13. In the **Databases** list, choose the name of the new MariaDB DB instance to show its details.

    The DB instance has a status of **Creating** until it is ready to use.

    When the status changes to **Available**, you can connect to the DB instance. Depending on the DB instance class and the amount of storage, it can take up to 20 minutes before the new instance is available.

(Optional) Create VPC, EC2 instance, and MariaDB instance using AWS CloudFormation

Instead of using the console to create your VPC, EC2 instance, and MariaDB instance, you can use AWS CloudFormation to provision AWS resources by treating infrastructure as code. To help you organize your AWS resources into smaller and more manageable units, you can use the AWS CloudFormation nested stack functionality. For more information, see Creating a stack on the AWS CloudFormation console and Working with nested stacks.

> **Important**
>
> AWS CloudFormation is free, but the resources that CloudFormation creates are live. You incur the standard usage fees for these resources until you terminate them. The total charges will be minimal. For information about how you might minimize any charges, go to AWS Free Tier.

To create your resources using the AWS CloudFormation console, complete the following steps:

- Step 1: Download the CloudFormation template
- Step 2: Configure your resources using CloudFormation

Download the CloudFormation template

A CloudFormation template is a JSON or YAML text file that contains the configuration information about the resources you want to create in the stack. This template also creates a VPC and a bastion host for you along with the RDS instance.

To download the template file, open the following link, MariaDB CloudFormation template.

In the Github page, click the *Download raw file* button to save the template YAML file.

Configure your resources using CloudFormation

> **Note**
>
> Before starting this process, make sure you have a Key pair for an EC2 instance in your AWS account. For more information, see Amazon EC2 key pairs and Linux instances.

When you use the AWS CloudFormation template, you must select the correct parameters to make sure your resources are created properly. Follow the steps below:

1. Sign in to the AWS Management Console and open the AWS CloudFormation console at https://console.aws.amazon.com/cloudformation.
2. Choose **Create Stack**.
3. In the Specify template section, select **Upload a template file from your computer**, and then choose **Next**.
4. In the **Specify stack details** page, set the following parameters:
   a. Set **Stack name** to **MariaDBTestStack**.
   b. Under **Parameters**, set **Availability Zones** by selecting three availability zones.
   c. Under **Linux Bastion Host configuration**, for **Key Name**, select a key pair to login to your EC2 instance.
   d. In **Linux Bastion Host configuration** settings, set the **Permitted IP range** to your IP address. To connect to EC2 instances in your VPC using Secure Shell (SSH), determine your public IP address using the service at https://checkip.amazonaws.com. An example of an IP address is 192.0.2.1/32.

      > **Warning**
      >
      > If you use `0.0.0.0/0` for SSH access, you make it possible for all IP addresses to access your public EC2 instances using SSH. This approach is acceptable for a short time in a test environment, but it's unsafe for production environments. In production, authorize only a specific IP address or range of addresses to access your EC2 instances using SSH.

   e. Under **Database General configuration**, set **Database instance class** to **db.t3.micro**.
   f. Set **Database name** to **`database-test1`**.
   g. For **Database master username**, enter a name for the master user.
   h. Set **Manage DB master user password with Secrets Manager** to `false` for this tutorial.
   i. For **Database password**, set a password of your choice. Remember this password for further steps in the tutorial.
   j. Under **Database Storage configuration**, set **Database storage type** to **gp2**.
   k. Under **Database Monitoring configuration**, set **Enable RDS Performance Insights** to false.

l. Leave all other settings as the default values. Click **Next** to continue.

5. In the **Review stack** page, select **Submit** after checking the database and Linux bastion host options.

After the stack creation process completes, view the stacks with names *BastionStack* and *RDSNS* to note the information you need to connect to the database. For more information, see Viewing AWS CloudFormation stack data and resources on the AWS Management Console.

Step 3: Connect to a MariaDB DB instance

You can use any standard SQL client application to connect to the DB instance. In this example, you connect to a MariaDB DB instance using the mysql command-line client.

To connect to a MariaDB DB instance

1. Find the endpoint (DNS name) and port number for your DB instance.

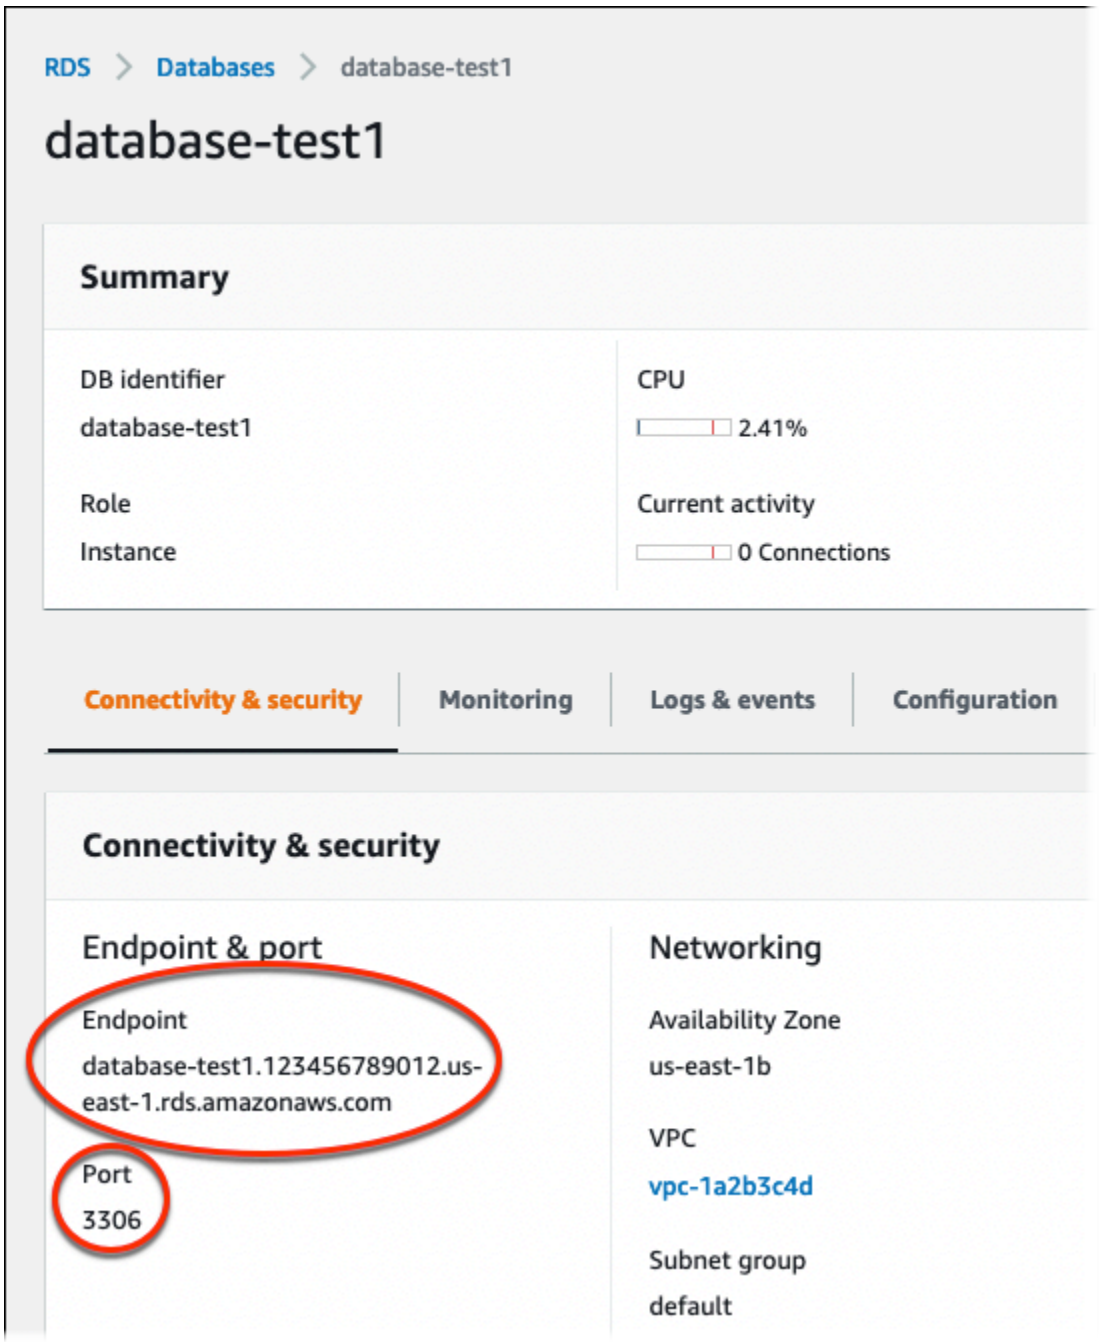
   a. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.

   b. In the upper-right corner of the Amazon RDS console, choose the AWS Region for the DB instance.

   c. In the navigation pane, choose **Databases**.

   d. Choose the MariaDB DB instance name to display its details.

   e. On the **Connectivity & security** tab, copy the endpoint. Also note the port number. You need both the endpoint and the port number to connect to the DB instance.



2. Connect to the EC2 instance that you created earlier by following the steps in Connect to your Linux instance in the *Amazon EC2 User Guide*.

   We recommend that you connect to your EC2 instance using SSH. If the SSH client utility is installed on Windows, Linux, or Mac, you can connect to the instance using the following command format:

```
ssh -i location_of_pem_file ec2-user@ec2-instance-public-dns-name
```

For example, assume that `ec2-database-connect-key-pair.pem` is stored in `/dir1` on Linux, and the public IPv4 DNS for your EC2 instance is `ec2-12-345-678-90.compute-1.amazonaws.com`. Your SSH command would look as follows:

```
ssh -i /dir1/ec2-database-connect-key-pair.pem ec2-
user@ec2-12-345-678-90.compute-1.amazonaws.com
```

3. Get the latest bug fixes and security updates by updating the software on your EC2 instance. To do this, use the following command.

   > **Note**
   >
   > The `-y` option installs the updates without asking for confirmation. To examine updates before installing, omit this option.

   ```
   sudo dnf update -y
   ```

4. Install the mysql command-line client from MariaDB.

   To install the MariaDB command-line client on Amazon Linux 2023, run the following command:

   ```
   sudo dnf install mariadb105
   ```

5. Connect to the MariaDB DB instance. For example, enter the following command. This action lets you connect to the MariaDB DB instance using the MySQL client.

   Substitute the DB instance endpoint (DNS name) for *`endpoint`*, and substitute the master username that you used for *`admin`*. Provide the master password that you used when prompted for a password.

   ```
   mysql -h endpoint -P 3306 -u admin -p
   ```

   After you enter the password for the user, you should see output similar to the following.

   ```
   Welcome to the MariaDB monitor.  Commands end with ; or \g.
   ```

```
Your MariaDB connection id is 156
Server version: 10.6.10-MariaDB-log managed by https://aws.amazon.com/rds/

Copyright (c) 2000, 2018, Oracle, MariaDB Corporation Ab and others.

Type 'help;' or '\h' for help. Type '\c' to clear the current input statement.

MariaDB [(none)]>
```

For more information about connecting to a MariaDB DB instance, see Connecting to a DB instance running the MariaDB database engine. If you can't connect to your DB instance, see Can't connect to Amazon RDS DB instance.

For security, it is a best practice to use encrypted connections. Only use an unencrypted MariaDB connection when the client and server are in the same VPC and the network is trusted. For information about using encrypted connections, see Connecting from the MySQL command-line client with SSL/TLS (encrypted).

6. Run SQL commands.

   For example, the following SQL command shows the current date and time:

```
SELECT CURRENT_TIMESTAMP;
```

Step 4: Delete the EC2 instance and DB instance

After you connect to and explore the sample EC2 instance and DB instance that you created, delete them so you're no longer charged for them.

If you used AWS CloudFormation to create resources, skip this step and go to the next step.

To delete the EC2 instance

1. Sign in to the AWS Management Console and open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select the EC2 instance, and choose **Instance state, Terminate instance**.
4. Choose **Terminate** when prompted for confirmation.

For more information about deleting an EC2 instance, see Terminate your instance in the *Amazon EC2 User Guide*.

To delete the DB instance with no final DB snapshot

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.
3. Choose the DB instance you want to delete.
4. For **Actions**, choose **Delete**.
5. Clear **Create final snapshot?** and **Retain automated backups**.
6. Complete the acknowledgement and choose **Delete**.

(Optional) Delete the EC2 instance and DB instance created with CloudFormation

If you used AWS CloudFormation to create resources, delete the CloudFormation stack after you connect to and explore the sample EC2 instance and DB instance, so you're no longer charged for them.

To delete the CloudFormation resources

1. Open the AWS CloudFormation console.
2. On the **Stacks** page in the CloudFormationconsole, select the root stack (the stack without the name VPCStack, BastionStack or RDSNS).
3. Choose **Delete**.
4. Select **Delete stack** when prompted for confirmation.

For more information about deleting a stack in CloudFormation, see Deleting a stack on the AWS CloudFormation console in the *AWS CloudFormation User Guide*.

(Optional) Connect your DB instance to a Lambda function

You can also connect your RDS for MariaDB DB instance to a Lambda serverless compute resource. Lambda functions allow you to run code without provisioning or managing infrastructure. A Lambda function also allows you to automatically respond to code execution requests at any scale,

from a dozen events a day to hundreds of per second. For more information, see Automatically connecting a Lambda function and a DB instance.

Creating and connecting to a Microsoft SQL Server DB instance

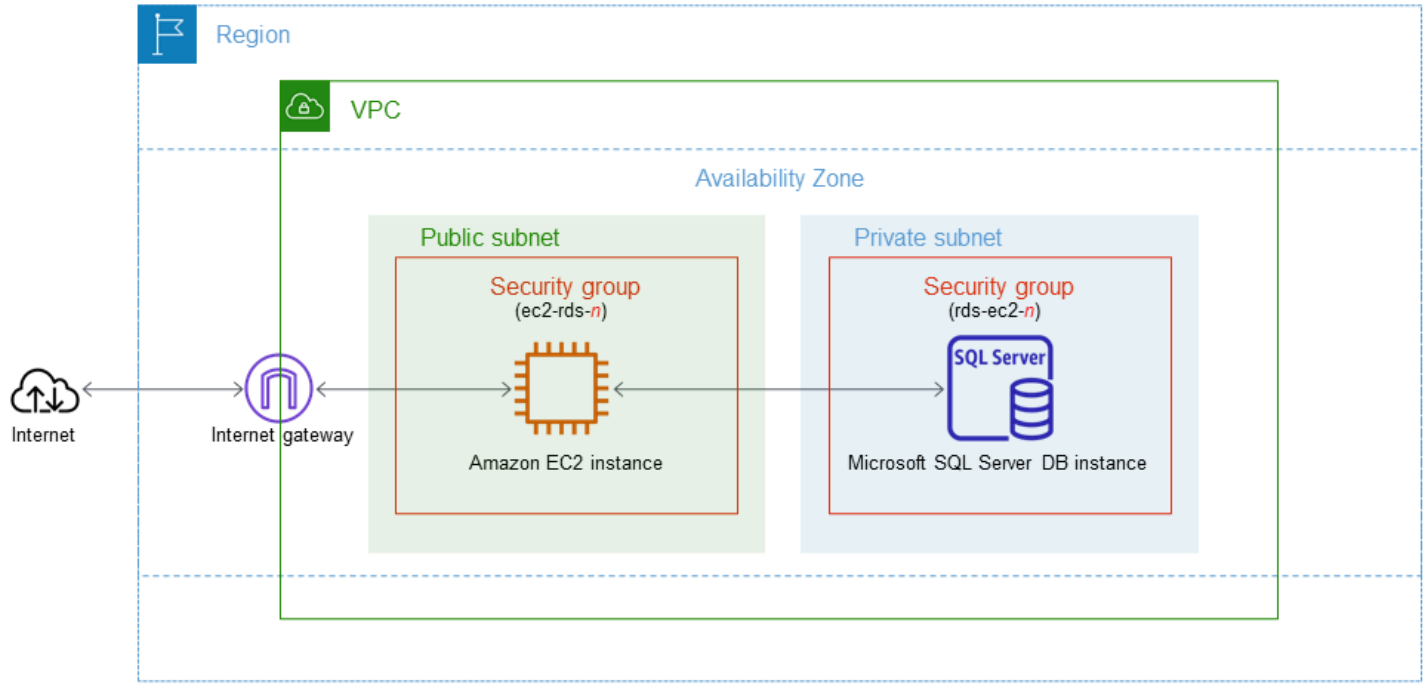
This tutorial creates an EC2 instance and an RDS for Microsoft SQL Server DB instance. The tutorial shows you how to access the DB instance from the EC2 instance using the Microsoft SQL Server Management Studio client. As a best practice, this tutorial creates a private DB instance in a virtual private cloud (VPC). In most cases, other resources in the same VPC, such as EC2 instances, can access the DB instance, but resources outside of the VPC can't access it.

After you complete the tutorial, there is a public and private subnet in each Availability Zone in your VPC. In one Availability Zone, the EC2 instance is in the public subnet, and the DB instance is in the private subnet.

Important

There's no charge for creating an AWS account. However, by completing this tutorial, you might incur costs for the AWS resources you use. You can delete these resources after you complete the tutorial if they are no longer needed.

The following diagram shows the configuration when the tutorial is complete.



This tutorial allows you to create your resources by using one of the following methods:

1. Use the AWS Management Console - Step 2: Create a SQL Server DB instance and Step 1: Create an EC2 instance
2. Use AWS CloudFormation to create the database instance and EC2 instance - (Optional) Create VPC, EC2 instance, and SQL Server instance using AWS CloudFormation

The first method uses **Easy create** to create a private SQL Server DB instance with the AWS Management Console. Here, you specify only the DB engine type, DB instance size, and DB instance identifier. **Easy create** uses the default settings for the other configuration options.

When you use **Standard create** instead, you can specify more configuration options when you create a DB instance. These options include settings for availability, security, backups, and maintenance. To create a public DB instance, you must use **Standard create**. For information, see Creating an Amazon RDS DB instance.

Topics

Prerequisites

Before you begin, complete the steps in the following sections:

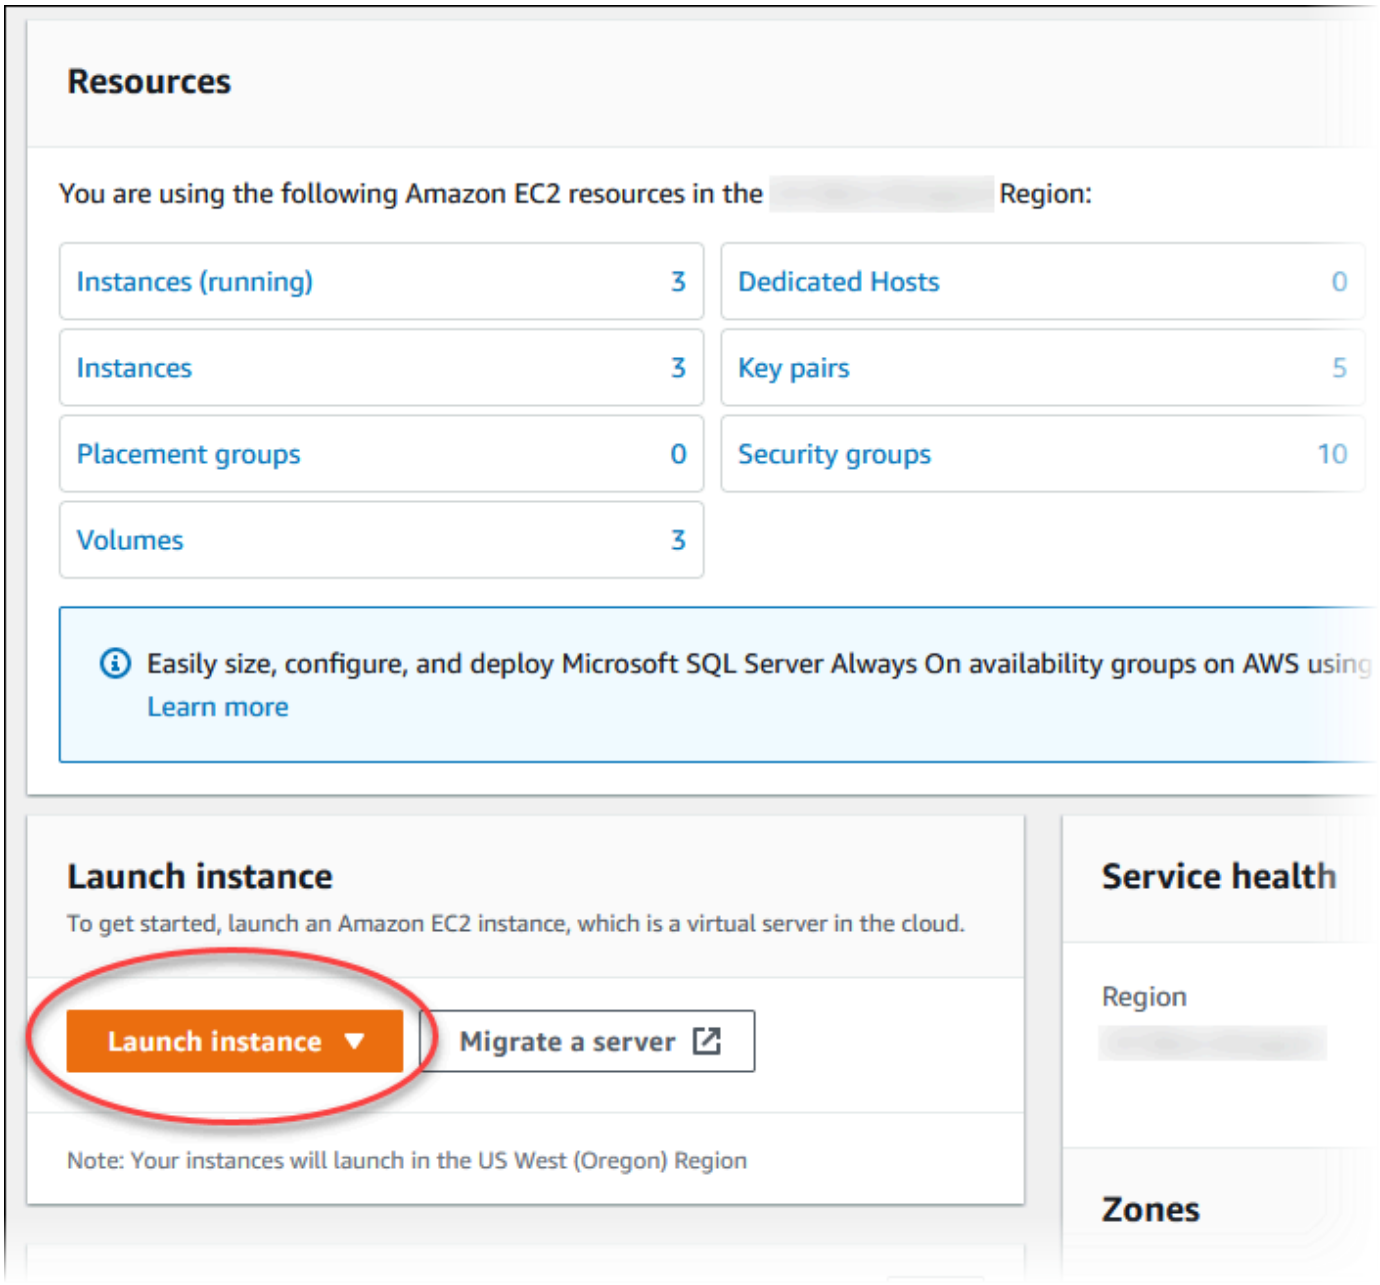
- Sign up for an AWS account
- Create a user with administrative access

Step 1: Create an EC2 instance

Create an Amazon EC2 instance that you will use to connect to your database.

To create an EC2 instance

1. Sign in to the AWS Management Console and open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the upper-right corner of the AWS Management Console, choose the AWS Region you used for the database previously.
3. Choose **EC2 Dashboard**, and then choose **Launch instance**, as shown in the following image.



The **Launch an instance** page opens.

4. Choose the following settings on the **Launch an instance** page.

   a. Under **Name and tags**, for **Name**, enter **`ec2-database-connect`**.

   b. Under **Application and OS Images (Amazon Machine Image)**, choose **Windows**, and then choose the **Microsoft Windows Server 2022 Base**. Keep the default selections for the other choices.

   c. Under **Instance type**, choose **t2.micro**.

   d. Under **Key pair (login)**, choose a **Key pair name** to use an existing key pair. To create a new key pair for the Amazon EC2 instance, choose **Create new key pair** and then use the **Create key pair** window to create it.

For more information about creating a new key pair, see Create a key pair in the *Amazon EC2 User Guide for Windows Instances*.

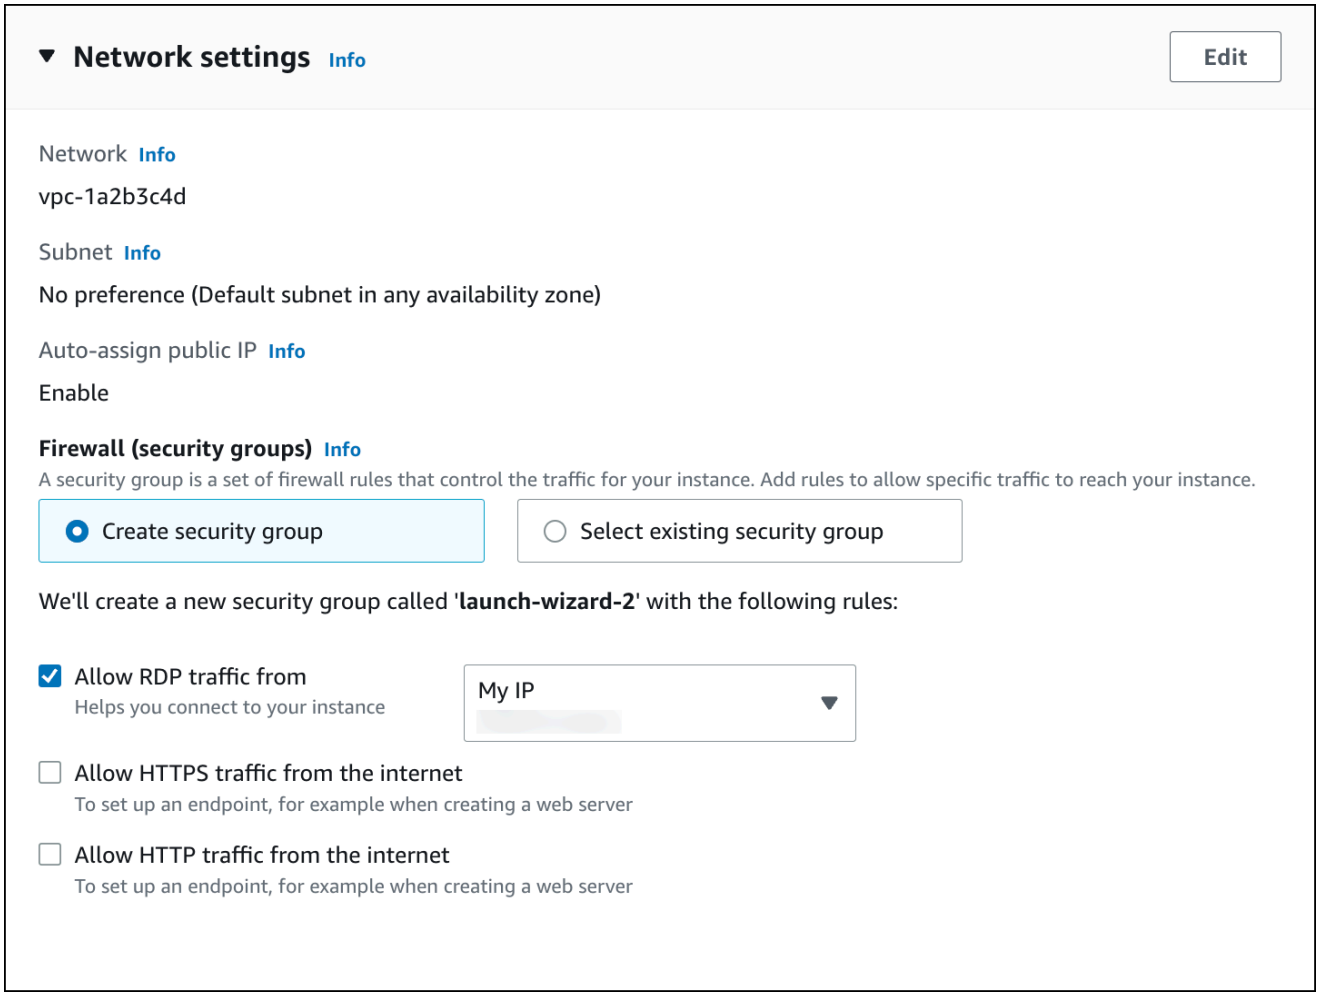
e. For **Firewall (security groups)** in **Network settings**, choose **Allow RDP traffic from** to connect to the EC2 instance.

You can choose **My IP** if the displayed IP address is correct for RDP connections. Otherwise, you can determine the IP address to use to connect to EC2 instances in your VPC using RDP. To determine your public IP address, in a different browser window or tab, you can use the service at https://checkip.amazonaws.com. An example of an IP address is 192.0.2.1/32.

In many cases, you might connect through an internet service provider (ISP) or from behind your firewall without a static IP address. If so, make sure to determine the range of IP addresses used by client computers.

> **Warning**
>
> If you use `0.0.0.0/0` for RDP access, you make it possible for all IP addresses to access your public EC2 instances using RDP. This approach is acceptable for a short time in a test environment, but it's unsafe for production environments. In production, authorize only a specific IP address or range of addresses to access your EC2 instances using RDP.

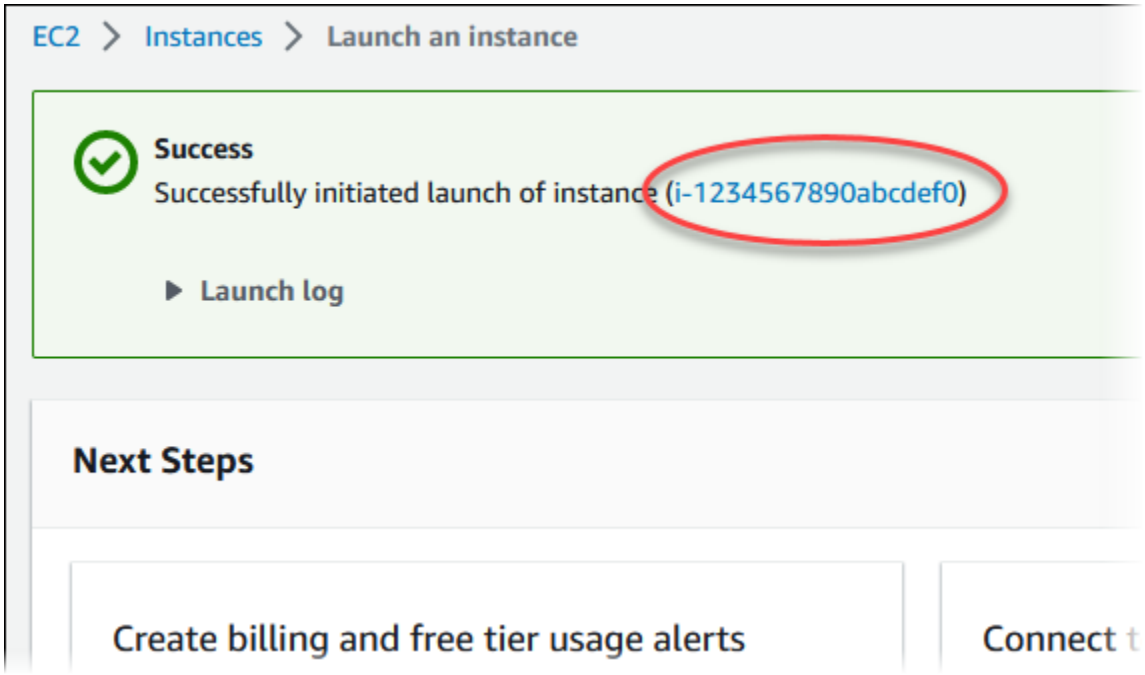
The following image shows an example of the **Network settings** section.



f. Keep the default values for the remaining sections.

g. Review a summary of your EC2 instance configuration in the **Summary** panel, and when you're ready, choose **Launch instance**.

5. On the **Launch Status** page, note the identifier for your new EC2 instance, for example: `i-1234567890abcdef0`.



6. Choose the EC2 instance identifier to open the list of EC2 instances.
7. Wait until the **Instance state** for your EC2 instance has a status of **Running** before continuing.

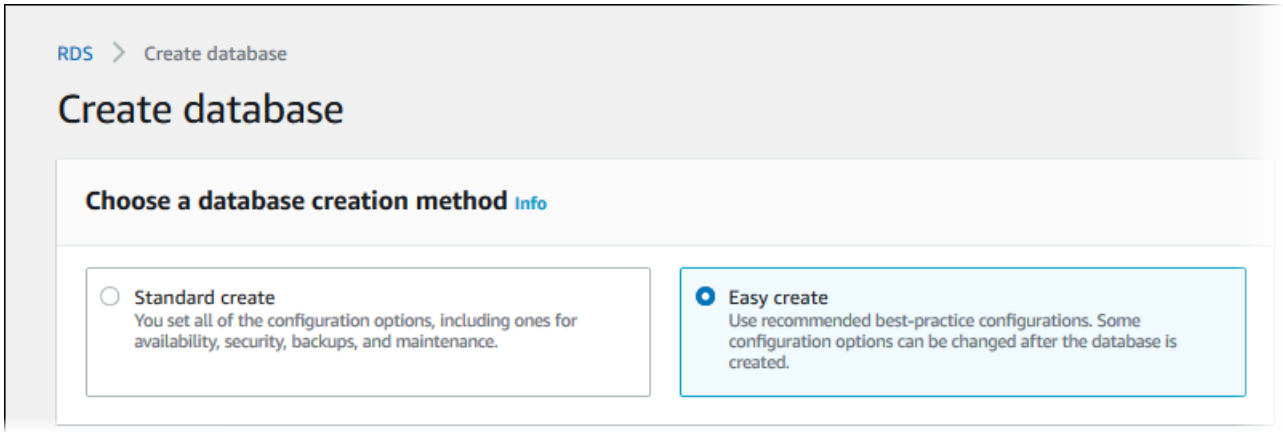
Step 2: Create a SQL Server DB instance

The basic building block of Amazon RDS is the DB instance. This environment is where you run your SQL Server databases.

In this example, you use **Easy create** to create a DB instance running the SQL Server database engine with a db.t2.micro DB instance class.

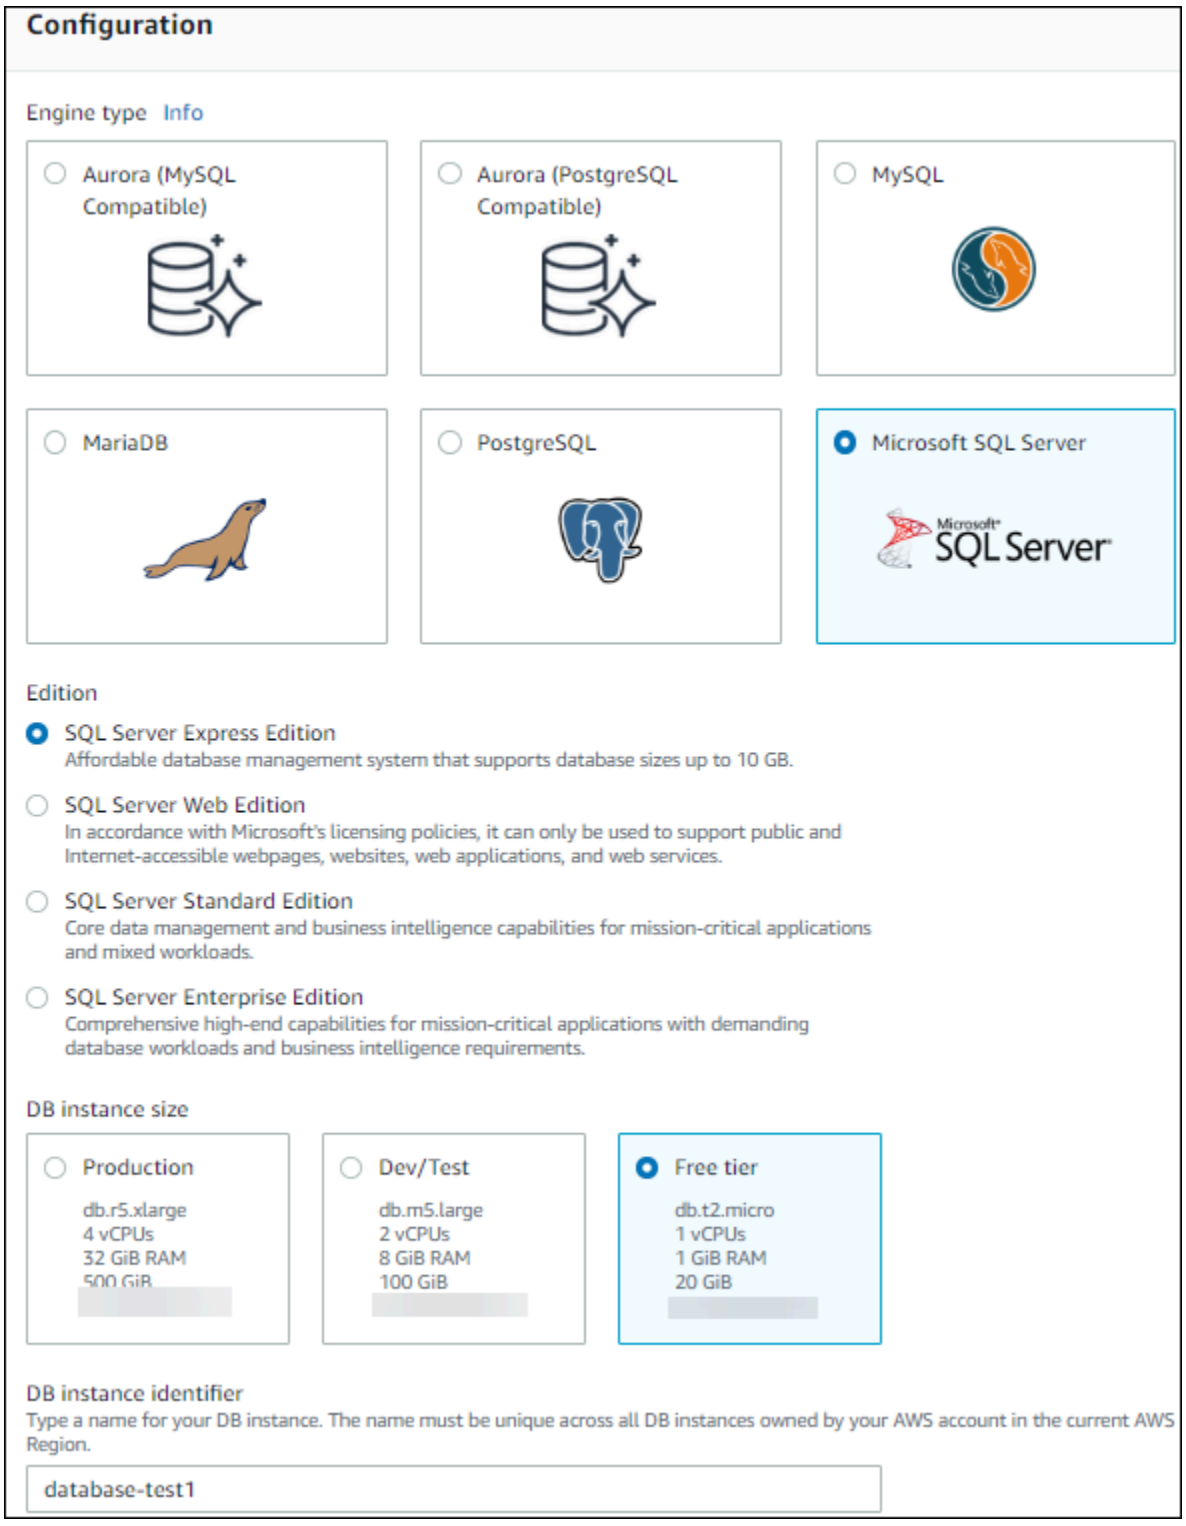
To create a Microsoft SQL Server DB instance with Easy create

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the upper-right corner of the Amazon RDS console, choose the AWS Region in which you want to create the DB instance.
3. In the navigation pane, choose **Databases**.
4. Choose **Create database** and make sure that **Easy create** is chosen.



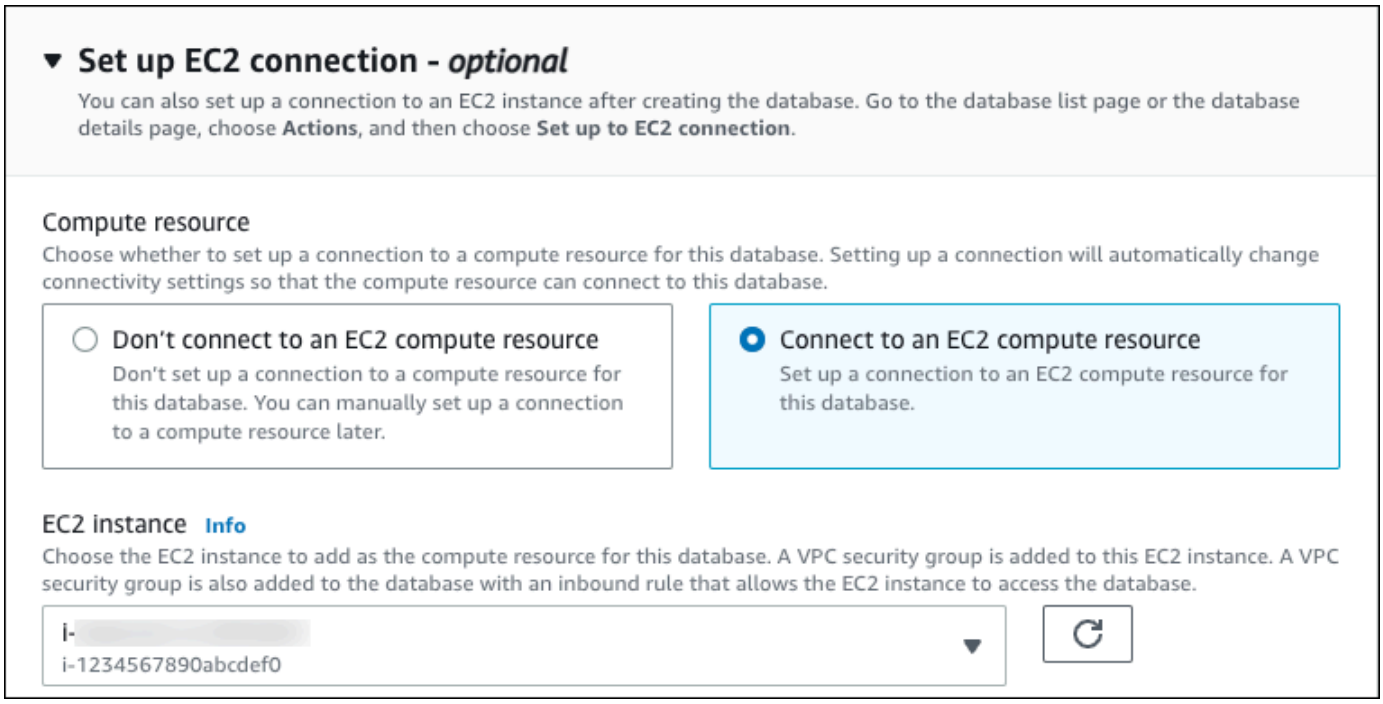
5. In **Configuration**, choose **Microsoft SQL Server**.
6. For **Edition**, choose **SQL Server Express Edition**.
7. For **DB instance size**, choose **Free tier**.
8. For **DB instance identifier**, enter **`database-test1`**.

   The **Create database** page should look similar to the following image.



9. For **Master username**, enter a name for the master user, or keep the default name.
10. To set up a connection with the EC2 instance you created previously, open **Set up EC2 connection - *optional***.

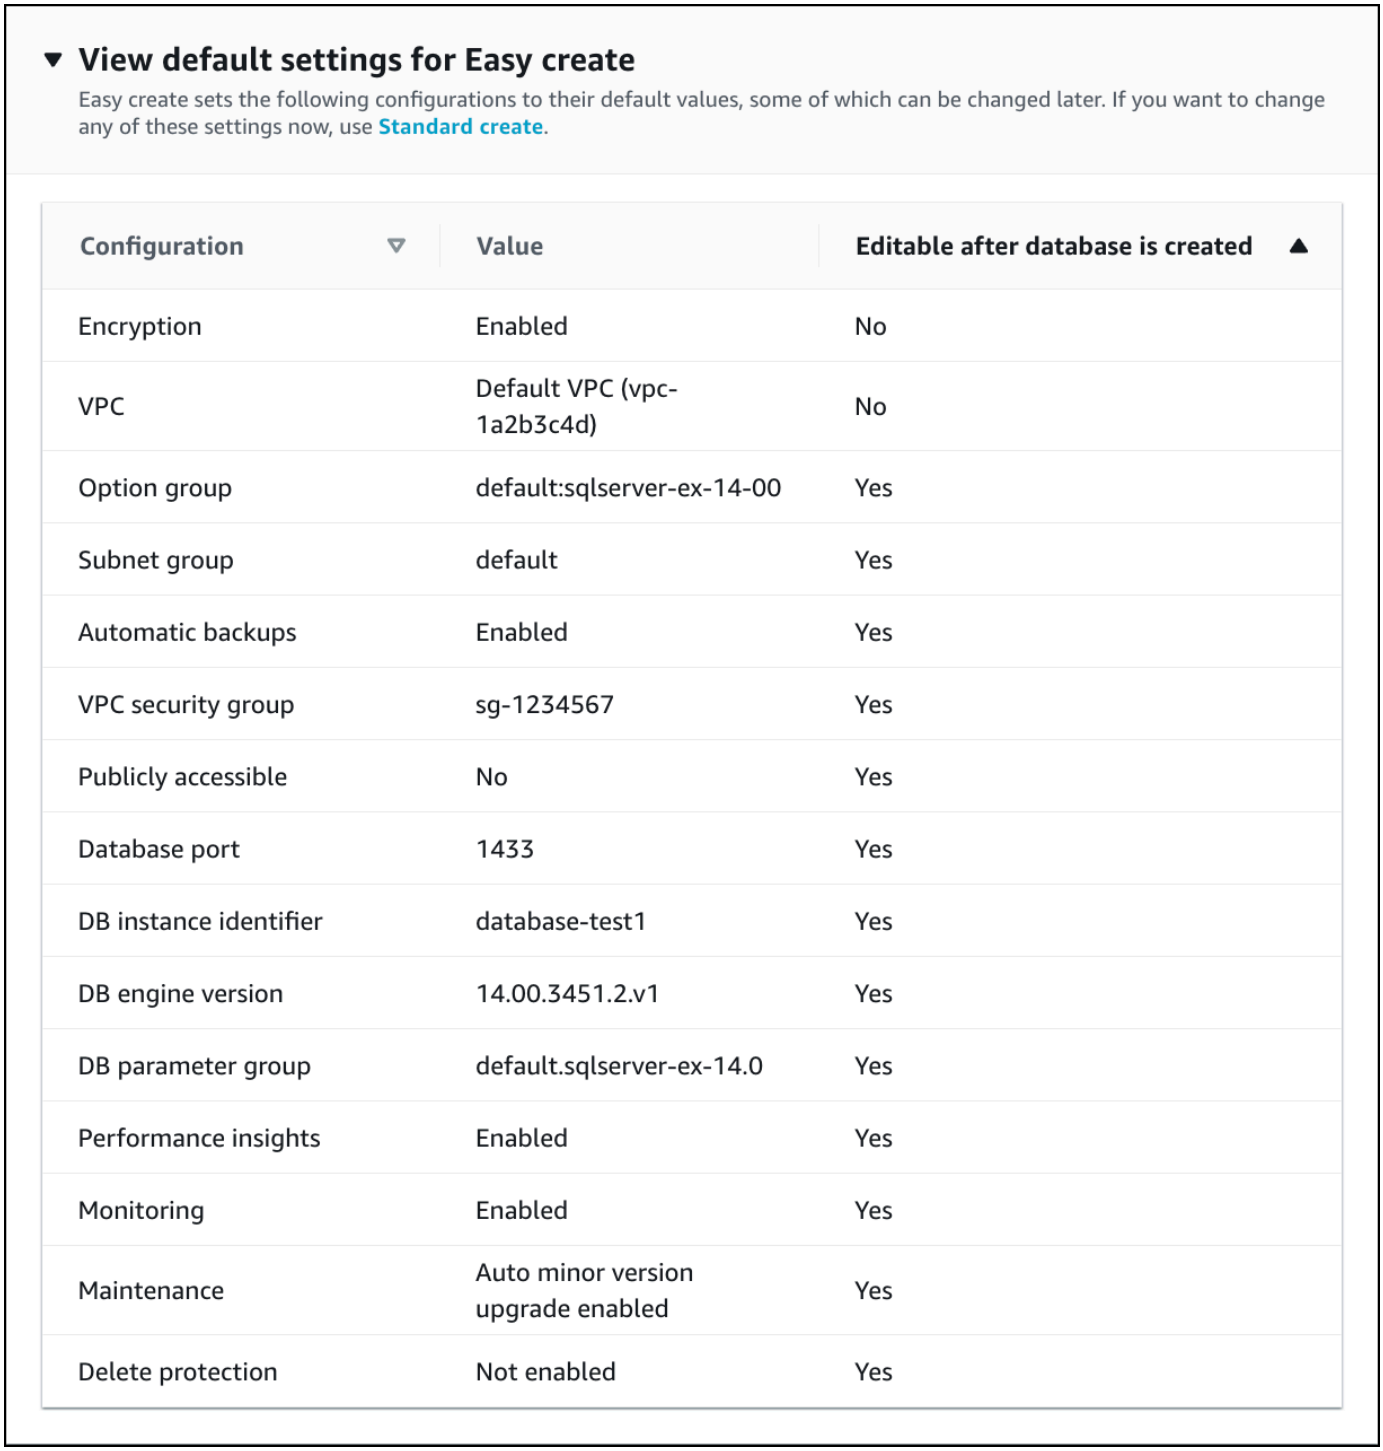
Select **Connect to an EC2 compute resource**. Choose the EC2 instance you created previously.



11. To use an automatically generated master password for the DB instance, select the **Auto generate a password** box.

    To enter your master password, clear the **Auto generate a password** box, and then enter the same password in **Master password** and **Confirm password**.

12. Open **View default settings for Easy create**.



View default settings for Easy create

Easy create sets the following configurations to their default values, some of which can be changed later. If you want to change any of these settings now, use **Standard create**.

Configuration	Value	Editable after database is created
Encryption	Enabled	No
VPC	Default VPC (vpc-1a2b3c4d)	No
Option group	default:sqlserver-ex-14-00	Yes
Subnet group	default	Yes
Automatic backups	Enabled	Yes
VPC security group	sg-1234567	Yes
Publicly accessible	No	Yes
Database port	1433	Yes
DB instance identifier	database-test1	Yes
DB engine version	14.00.3451.2.v1	Yes
DB parameter group	default.sqlserver-ex-14.0	Yes
Performance insights	Enabled	Yes
Monitoring	Enabled	Yes
Maintenance	Auto minor version upgrade enabled	Yes
Delete protection	Not enabled	Yes

You can examine the default settings used with **Easy create**. The **Editable after database is created** column shows which options you can change after you create the database.

- If a setting has **No** in that column, and you want a different setting, you can use **Standard create** to create the DB instance.

- If a setting has **Yes** in that column, and you want a different setting, you can either use **Standard create** to create the DB instance, or modify the DB instance after you create it to change the setting.

13. Choose **Create database**.

    To view the master username and password for the DB instance, choose **View credential details**.

    You can use the username and password that appears to connect to the DB instance as the master user.

    > **Important**
    >
    > You can't view the master user password again. If you don't record it, you might have to change it.
    > If you need to change the master user password after the DB instance is available, you can modify the DB instance to do so. For more information about modifying a DB instance, see Modifying an Amazon RDS DB instance.

14. In the **Databases** list, choose the name of the new SQL Server DB instance to show its details.

    The DB instance has a status of **Creating** until it is ready to use.

    When the status changes to **Available**, you can connect to the DB instance. Depending on the DB instance class and the amount of storage, it can take up to 20 minutes before the new instance is available.

(Optional) Create VPC, EC2 instance, and SQL Server instance using AWS CloudFormation

Instead of using the console to create your VPC, EC2 instance, and SQL Server instance, you can use AWS CloudFormation to provision AWS resources by treating infrastructure as code. To help you organize your AWS resources into smaller and more manageable units, you can use the AWS CloudFormation nested stack functionality. For more information, see Creating a stack on the AWS CloudFormation console and Working with nested stacks..

> **Important**
>
> AWS CloudFormation is free, but the resources that CloudFormation creates are live. You incur the standard usage fees for these resources until you terminate them. The total charges will be minimal. For information about how you might minimize any charges, go to AWS Free Tier.

To create your resources using the AWS CloudFormation console, complete the following steps:

- Step 1: Download the CloudFormation template
- Step 2: Configure your resources using CloudFormation

Download the CloudFormation template

A CloudFormation template is a JSON or YAML text file that contains the configuration information about the resources you want to create in the stack. This template also creates a VPC and a bastion host for you along with the RDS instance.

To download the template file, open the following link, SQL Server CloudFormation template.

In the Github page, click the *Download raw file* button to save the template YAML file.

Configure your resources using CloudFormation

> **Note**
>
> Before starting this process, make sure you have a Key pair for an EC2 instance in your AWS account. For more information, see Amazon EC2 key pairs and Linux instances.

When you use the AWS CloudFormation template, you must select the correct parameters to make sure your resources are created properly. Follow the steps below:

1. Sign in to the AWS Management Console and open the AWS CloudFormation console at https://console.aws.amazon.com/cloudformation.
2. Choose **Create Stack**.
3. In the Specify template section, select **Upload a template file from your computer**, and then choose **Next**.
4. In the **Specify stack details** page, set the following parameters:
   a. Set **Stack name** to **SQLServerTestStack**.
   b. Under **Parameters**, set **Availability Zones** by selecting three availability zones.
   c. Under **Linux Bastion Host configuration**, for **Key Name**, select a key pair to login to your EC2 instance.
   d. In **Linux Bastion Host configuration** settings, set the **Permitted IP range** to your IP address. To connect to EC2 instances in your VPC using Secure Shell (SSH), determine your public IP address using the service at https://checkip.amazonaws.com. An example of an IP address is 192.0.2.1/32.

      > **Warning**
      >
      > If you use `0.0.0.0/0` for SSH access, you make it possible for all IP addresses to access your public EC2 instances using SSH. This approach is acceptable for a short time in a test environment, but it's unsafe for production environments. In production, authorize only a specific IP address or range of addresses to access your EC2 instances using SSH.

   e. Under **Database General configuration**, set **Database instance class** to **db.t3.micro**.
   f. Set **Database name** to **`database-test1`**.
   g. For **Database master username**, enter a name for the master user.
   h. Set **Manage DB master user password with Secrets Manager** to `false` for this tutorial.
   i. For **Database password**, set a password of your choice. Remember this password for further steps in the tutorial.
   j. Under **Database Storage configuration**, set **Database storage type** to **gp2**.
   k. Under **Database Monitoring configuration**, set **Enable RDS Performance Insights** to false.

l. Leave all other settings as the default values. Click **Next** to continue.

5. In the **Configure stack options** page, leave all the default options. Click **Next** to continue.
6. In the **Review stack** page, select **Submit** after checking the database and Linux bastion host options.

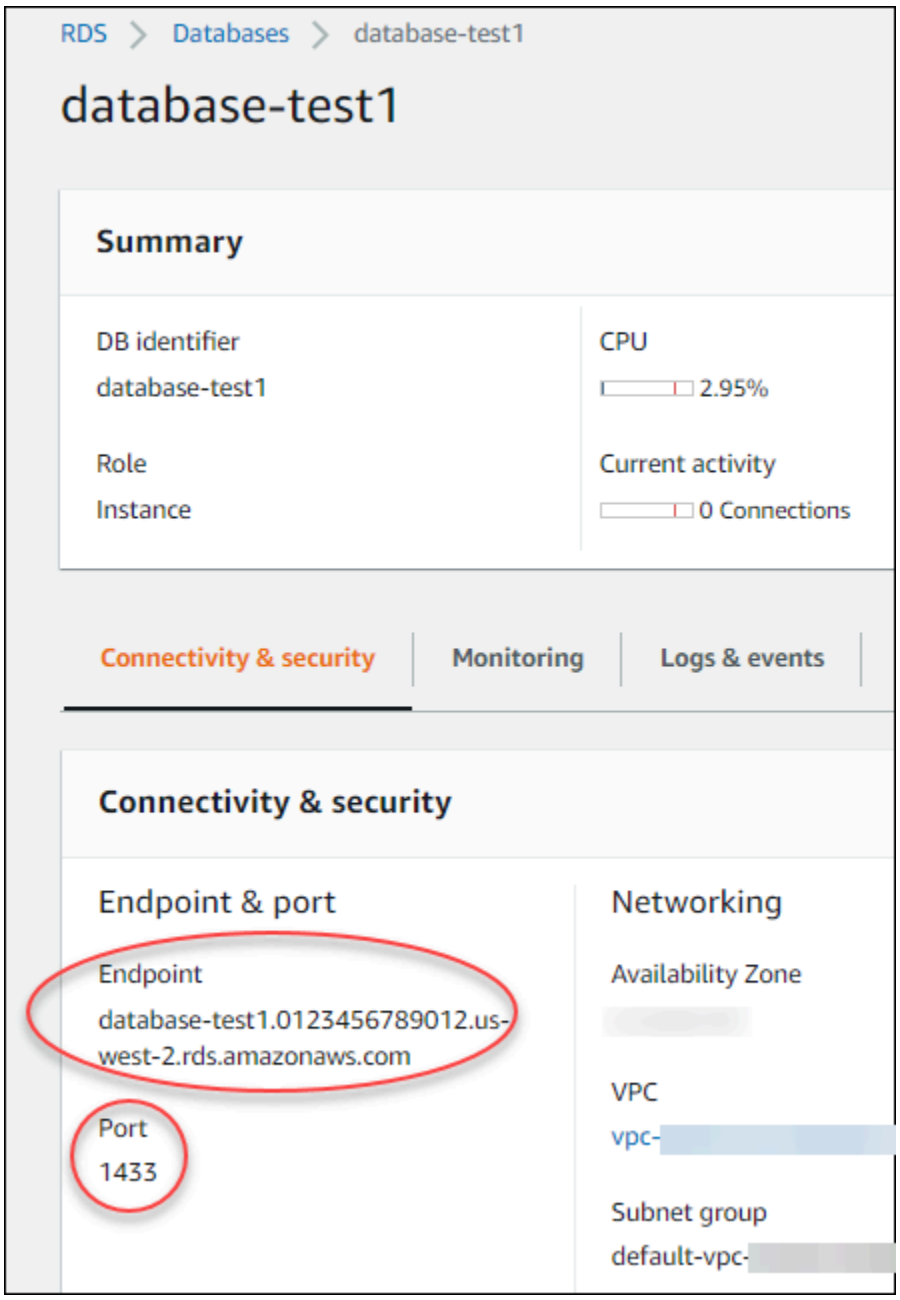
After the stack creation process completes, view the stacks with names *BastionStack* and *RDSNS* to note the information you need to connect to the database. For more information, see Viewing AWS CloudFormation stack data and resources on the AWS Management Console.

Step 3: Connect to your SQL Server DB instance

In the following procedure, you connect to your DB instance by using Microsoft SQL Server Management Studio (SSMS).

To connect to an RDS for SQL Server DB instance using SSMS

1. Find the endpoint (DNS name) and port number for your DB instance.
   a. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
   b. In the upper-right corner of the Amazon RDS console, choose the AWS Region for the DB instance.
   c. In the navigation pane, choose **Databases**.
   d. Choose the SQL Server DB instance name to display its details.
   e. On the **Connectivity** tab, copy the endpoint. Also, note the port number. You need both the endpoint and the port number to connect to the DB instance.



2. Connect to the EC2 instance that you created earlier by following the steps in Connect to your Microsoft Windows instance in the *Amazon EC2 User Guide for Windows Instances*.
3. Install the SQL Server Management Studio (SSMS) client from Microsoft.

   To download a standalone version of SSMS to your EC2 instance, see Download SQL Server Management Studio (SSMS) in the Microsoft documentation.

   a. Use the Start menu to open Internet Explorer.

b. Use Internet Explorer to download and install a standalone version of SSMS. If you are prompted that the site isn't trusted, add the site to the list of trusted sites.

4. Start SQL Server Management Studio (SSMS).

   The **Connect to Server** dialog box appears.

5. Provide the following information for your sample DB instance:

   a. For **Server type**, choose **Database Engine**.

   b. For **Server name**, enter the DNS name, followed by a comma and the port number (the default port is 1433). For example, your server name should look as follows:

   ```
   database-test1.0123456789012.us-west-2.rds.amazonaws.com,1433
   ```

   c. For **Authentication**, choose **SQL Server Authentication**.

   d. For **Login**, enter the username that you chose to use for your sample DB instance. This is also known as the master username.

   e. For **Password**, enter the password that you chose earlier for your sample DB instance. This is also known as the master user password.

6. Choose **Connect**.

   After a few moments, SSMS connects to your DB instance. For security, it is a best practice to use encrypted connections. Only use an unencrypted SQL Server connection when the client and server are in the same VPC and the network is trusted. For information about using encrypted connections, see Using SSL with a Microsoft SQL Server DB instance

For more information about connecting to a Microsoft SQL Server DB instance, see Connecting to a DB instance running the Microsoft SQL Server database engine.

For information about connection issues, see Can't connect to Amazon RDS DB instance.

Step 4: Explore your sample SQL Server DB instance

You can explore your sample DB instance by using Microsoft SQL Server Management Studio (SSMS).

To explore a DB instance using SSMS

1. Your SQL Server DB instance comes with SQL Server's standard built-in system databases (master, model, msdb, and tempdb). To explore the system databases, do the following:

   a. In SSMS, on the **View** menu, choose **Object Explorer**.

   b. Expand your DB instance, expand **Databases**, and then expand **System Databases** as shown.

   Your SQL Server DB instance also comes with a database named `rdsadmin`. Amazon RDS uses this database to store the objects that it uses to manage your database. The `rdsadmin` database also includes stored procedures that you can run to perform advanced tasks.

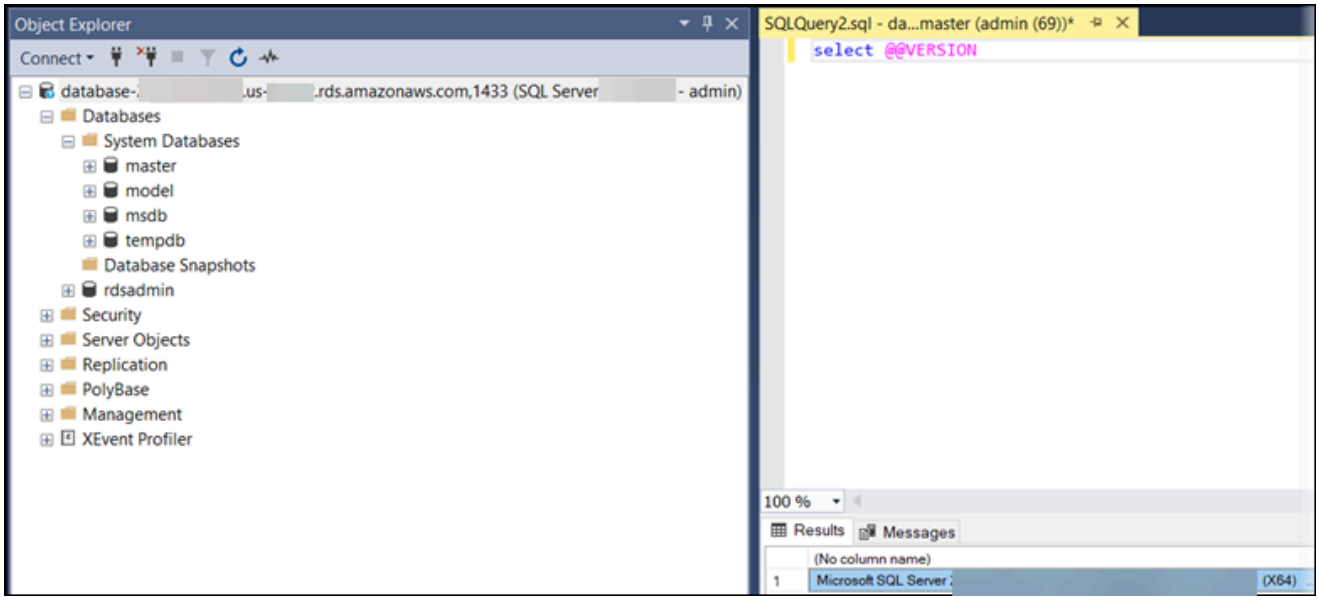
2. Start creating your own databases and running queries against your DB instance and databases as usual. To run a test query against your sample DB instance, do the following:

   a. In SSMS, on the **File** menu, point to **New** and then choose **Query with Current Connection**.

   b. Enter the following SQL query:

```
select @@VERSION
```

c. Run the query. SSMS returns the SQL Server version of your Amazon RDS DB instance.



Step 5: Delete the EC2 instance and DB instance

After you connect to and explore the sample EC2 instance and DB instance that you created, delete them so you're no longer charged for them.

If you used AWS CloudFormation to create resources, skip this step and go to the next step.

To delete the EC2 instance

1. Sign in to the AWS Management Console and open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select the EC2 instance, and choose **Instance state, Terminate instance**.
4. Choose **Terminate** when prompted for confirmation.

For more information about deleting an EC2 instance, see Terminate your instance in the *User Guide for Windows Instances*.

To delete the DB instance with no final DB snapshot

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.
3. Choose the DB instance that you want to delete.
4. For **Actions**, choose **Delete**.
5. Clear **Create final snapshot?** and **Retain automated backups**.
6. Complete the acknowledgement and choose **Delete**.

(Optional) Delete the EC2 instance and DB instance created with CloudFormation

If you used AWS CloudFormation to create resources, delete the CloudFormation stack after you connect to and explore the sample EC2 instance and DB instance, so you're no longer charged for them.

To delete the CloudFormation resources

1. Open the AWS CloudFormation console.
2. On the **Stacks** page in the CloudFormationconsole, select the root stack (the stack without the name VPCStack, BastionStack or RDSNS).
3. Choose **Delete**.
4. Select **Delete stack** when prompted for confirmation.

For more information about deleting a stack in CloudFormation, see Deleting a stack on the AWS CloudFormation console in the *AWS CloudFormation User Guide*.

(Optional) Connect your DB instance to a Lambda function

You can also connect your RDS for SQL Server DB instance to a Lambda serverless compute resource. Lambda functions allow you to run code without provisioning or managing infrastructure. A Lambda function also allows you to automatically respond to code execution requests at any scale, from a dozen events a day to hundreds of per second. For more information, see Automatically connecting a Lambda function and a DB instance.

Creating and connecting to a MySQL DB instance

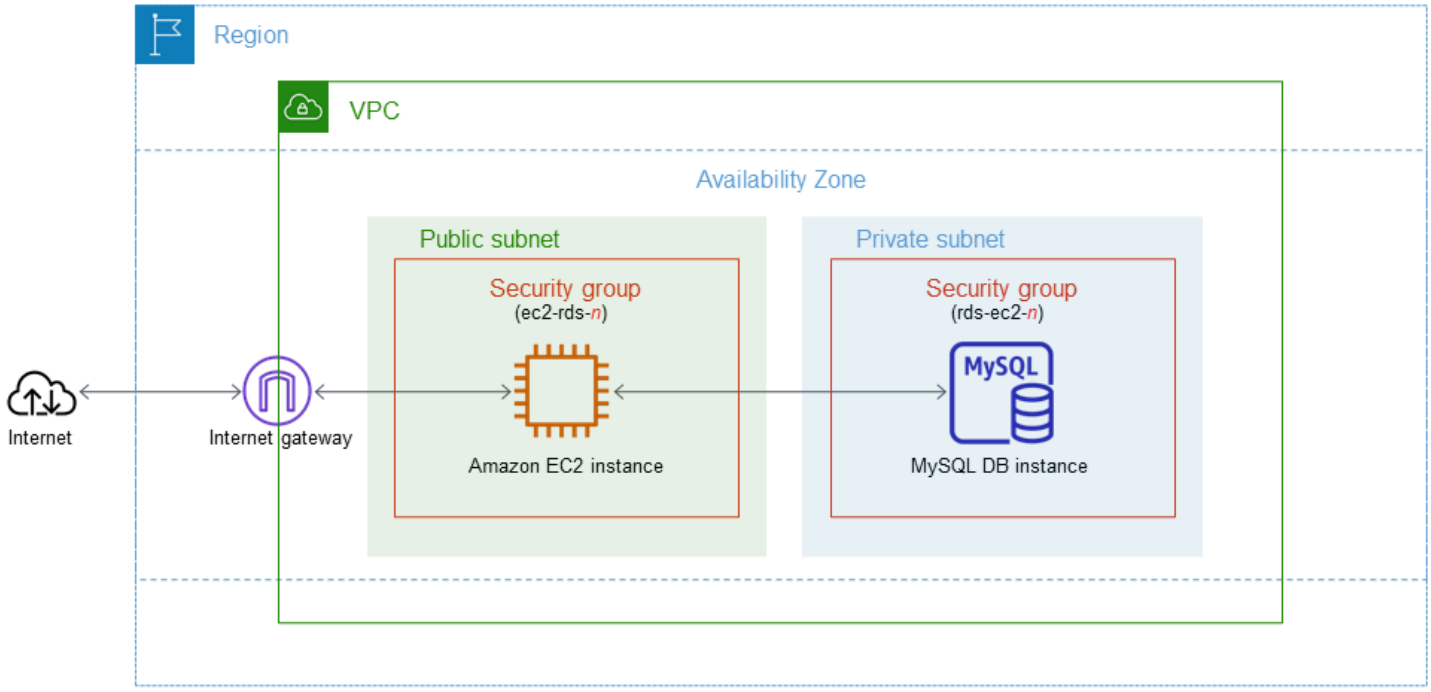
This tutorial creates an EC2 instance and an RDS for MySQL DB instance. The tutorial shows you how to access the DB instance from the EC2 instance using a standard MySQL client. As a best practice, this tutorial creates a private DB instance in a virtual private cloud (VPC). In most cases, other resources in the same VPC, such as EC2 instances, can access the DB instance, but resources outside of the VPC can't access it.

After you complete the tutorial, there is a public and private subnet in each Availability Zone in your VPC. In one Availability Zone, the EC2 instance is in the public subnet, and the DB instance is in the private subnet.

Important

There's no charge for creating an AWS account. However, by completing this tutorial, you might incur costs for the AWS resources you use. You can delete these resources after you complete the tutorial if they are no longer needed.

The following diagram shows the configuration when the tutorial is complete.



This tutorial allows you to create your resources by using one of the following methods:

1. Use the AWS Management Console - Step 2: Create a MySQL DB instance and Step 1: Create an EC2 instance
2. Use AWS CloudFormation to create the database instance and EC2 instance - (Optional) Create VPC, EC2 instance, and MySQL instance using AWS CloudFormation

The first method uses **Easy create** to create a private MySQL DB instance with the AWS Management Console. Here, you specify only the DB engine type, DB instance size, and DB instance identifier. **Easy create** uses the default settings for the other configuration options.

When you use **Standard create** instead, you can specify more configuration options when you create a DB instance. These options include settings for availability, security, backups, and maintenance. To create a public DB instance, you must use **Standard create**. For information, see Creating an Amazon RDS DB instance.

Topics

Prerequisites

Before you begin, complete the steps in the following sections:

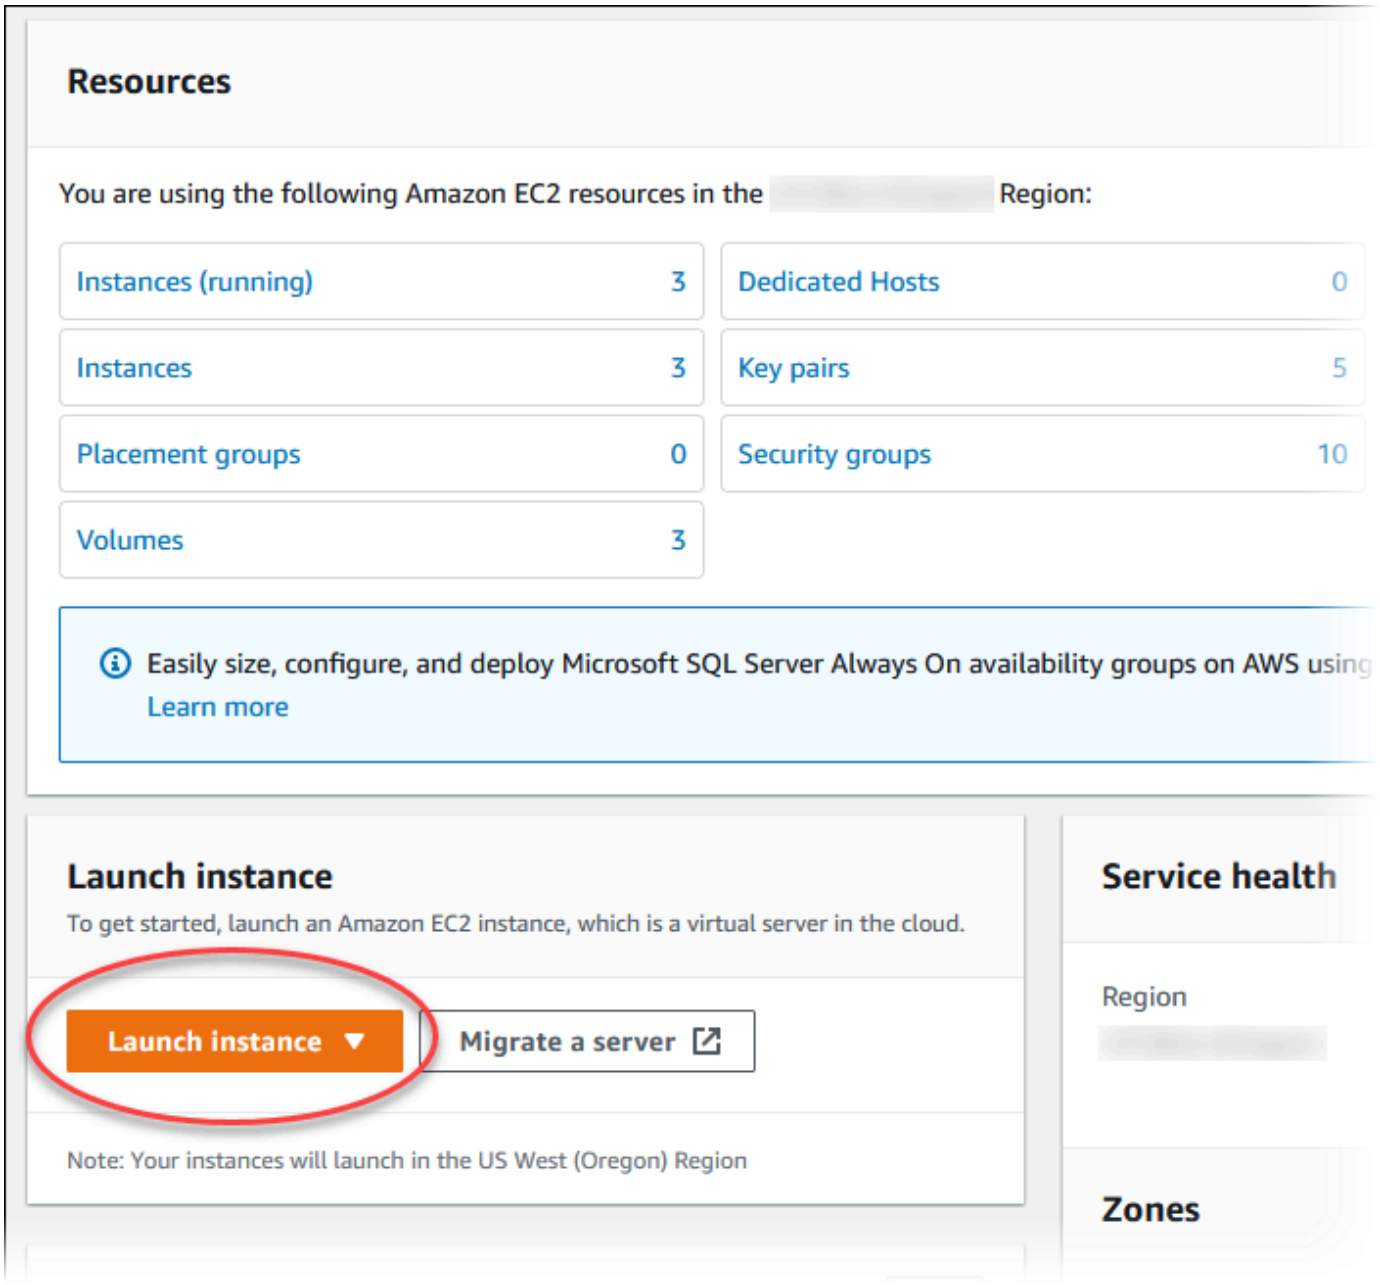
- Sign up for an AWS account
- Create a user with administrative access

Step 1: Create an EC2 instance

Create an Amazon EC2 instance that you will use to connect to your database.

To create an EC2 instance

1. Sign in to the AWS Management Console and open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the upper-right corner of the AWS Management Console, choose the AWS Region in which you want to create the EC2 instance.
3. Choose **EC2 Dashboard**, and then choose **Launch instance**, as shown in the following image.



The **Launch an instance** page opens.

4. Choose the following settings on the **Launch an instance** page.

   a. Under **Name and tags**, for **Name**, enter **`ec2-database-connect`**.

   b. Under **Application and OS Images (Amazon Machine Image)**, choose **Amazon Linux**, and then choose the **Amazon Linux 2023 AMI**. Keep the default selections for the other choices.

   c. Under **Instance type**, choose **t2.micro**.

   d. Under **Key pair (login)**, choose a **Key pair name** to use an existing key pair. To create a new key pair for the Amazon EC2 instance, choose **Create new key pair** and then use the **Create key pair** window to create it.

For more information about creating a new key pair, see Create a key pair in the *Amazon EC2 User Guide*.

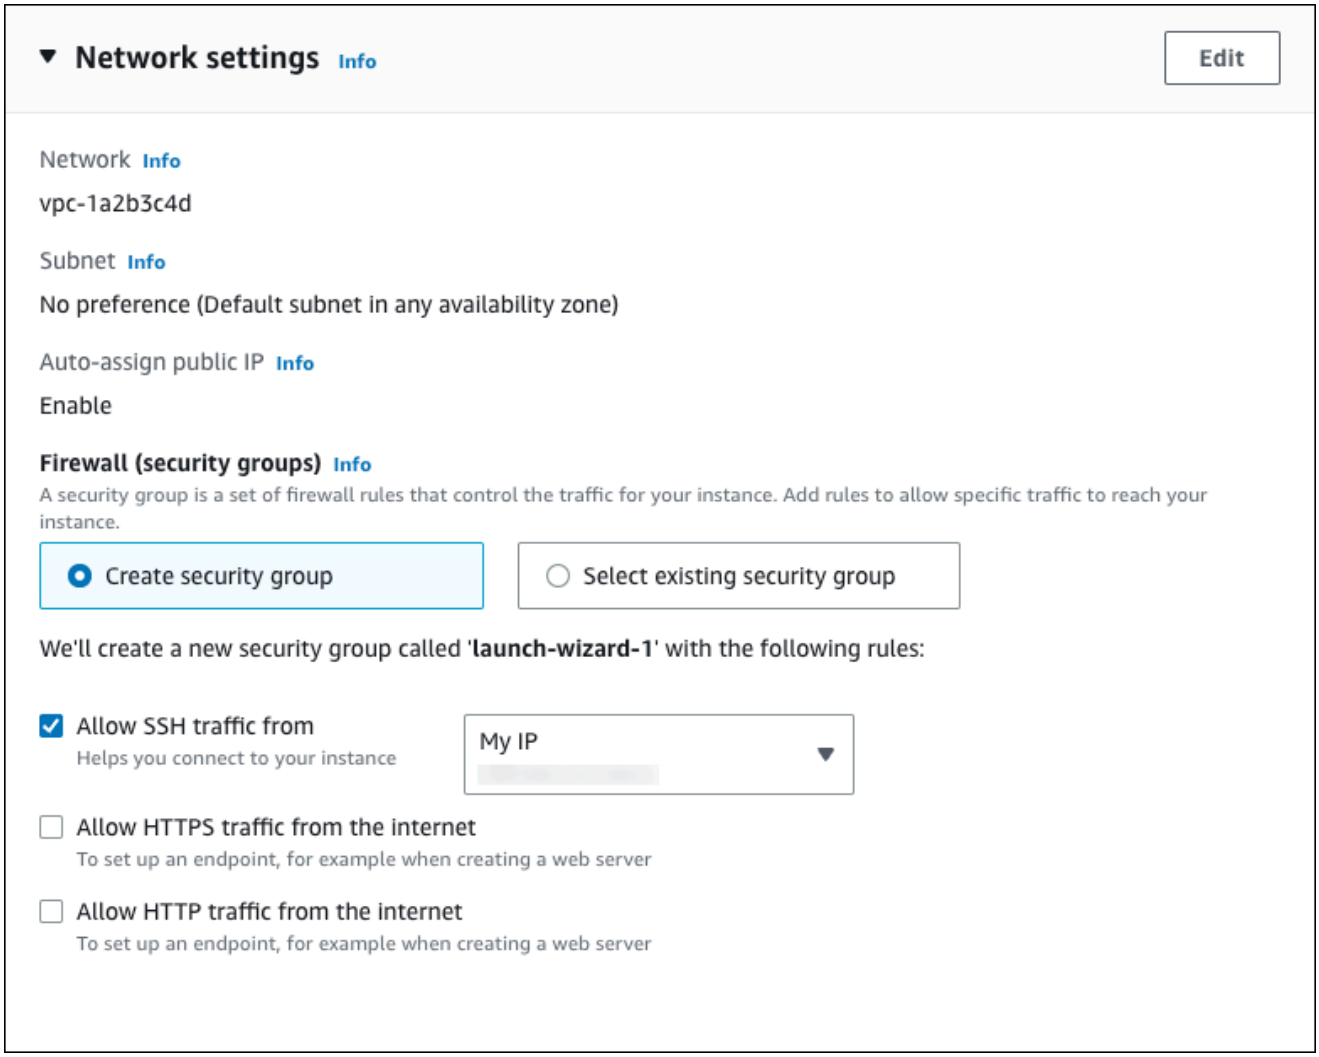
e. For **Allow SSH traffic** in **Network settings**, choose the source of SSH connections to the EC2 instance.

You can choose **My IP** if the displayed IP address is correct for SSH connections. Otherwise, you can determine the IP address to use to connect to EC2 instances in your VPC using Secure Shell (SSH). To determine your public IP address, in a different browser window or tab, you can use the service at https://checkip.amazonaws.com. An example of an IP address is 192.0.2.1/32.

In many cases, you might connect through an internet service provider (ISP) or from behind your firewall without a static IP address. If so, make sure to determine the range of IP addresses used by client computers.

> **Warning**
>
> If you use `0.0.0.0/0` for SSH access, you make it possible for all IP addresses to access your public EC2 instances using SSH. This approach is acceptable for a short time in a test environment, but it's unsafe for production environments. In production, authorize only a specific IP address or range of addresses to access your EC2 instances using SSH.

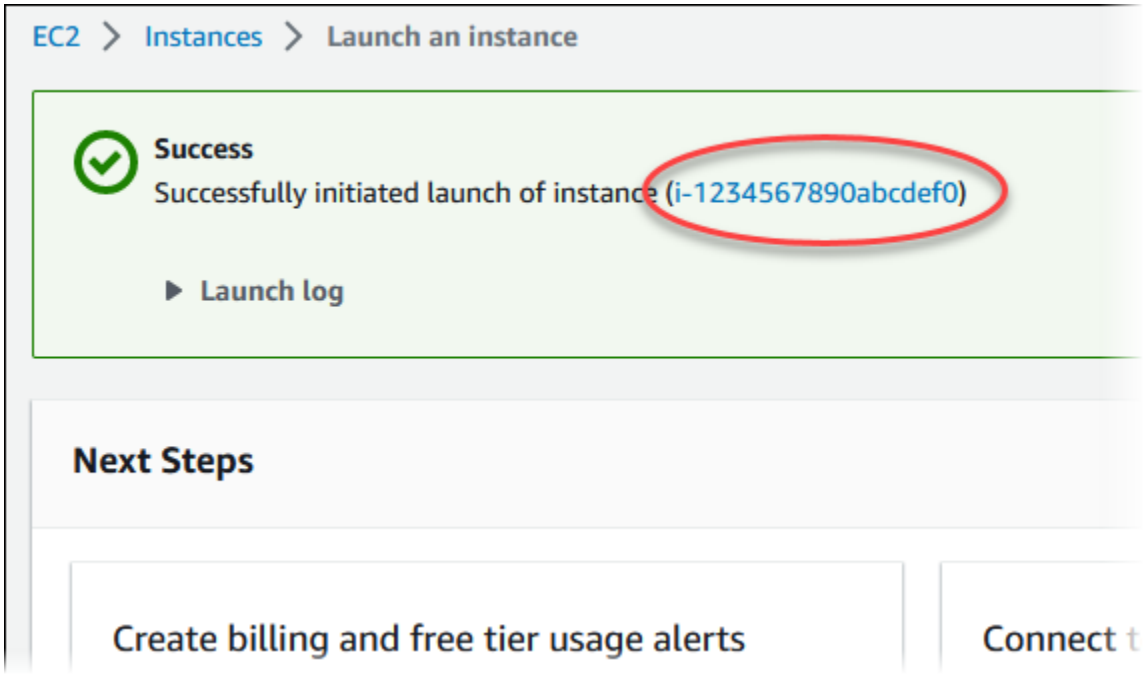
The following image shows an example of the **Network settings** section.



f. Leave the default values for the remaining sections.

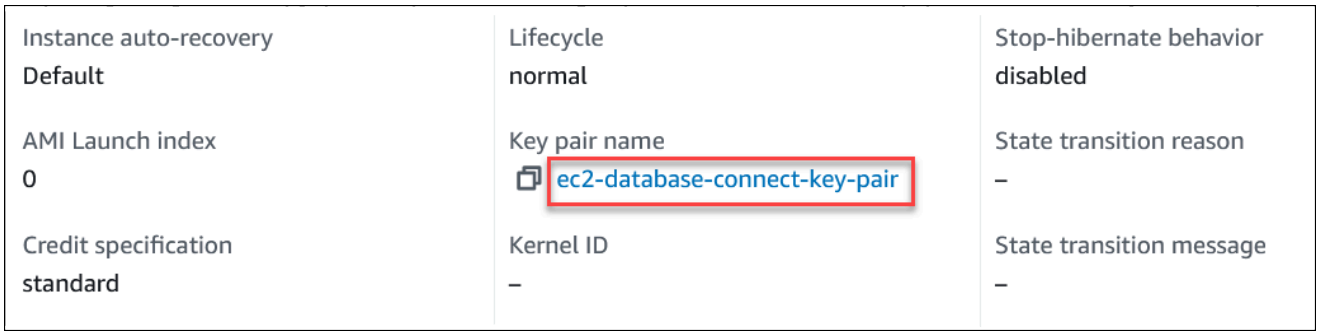
g. Review a summary of your EC2 instance configuration in the **Summary** panel, and when you're ready, choose **Launch instance**.

5. On the **Launch Status** page, note the identifier for your new EC2 instance, for example: `i-1234567890abcdef0`.



6. Choose the EC2 instance identifier to open the list of EC2 instances, and then select your EC2 instance.
7. In the **Details** tab, note the following values, which you need when you connect using SSH:
   a. In **Instance summary**, note the value for **Public IPv4 DNS**.

   b. In **Instance details**, note the value for **Key pair name**.



8. Wait until the **Instance state** for your EC2 instance has a status of **Running** before continuing.

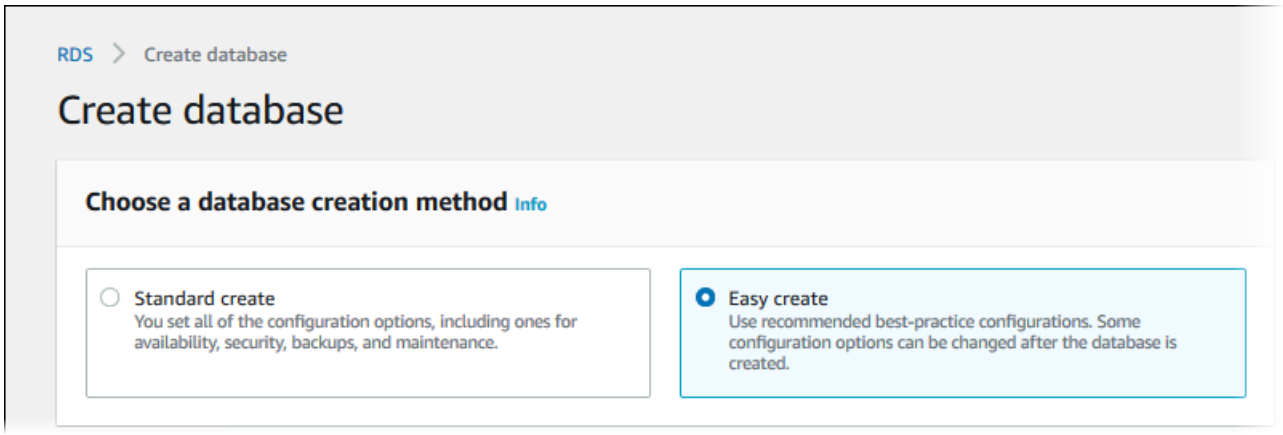
Step 2: Create a MySQL DB instance

The basic building block of Amazon RDS is the DB instance. This environment is where you run your MySQL databases.

In this example, you use **Easy create** to create a DB instance running the MySQL database engine with a db.t3.micro DB instance class.

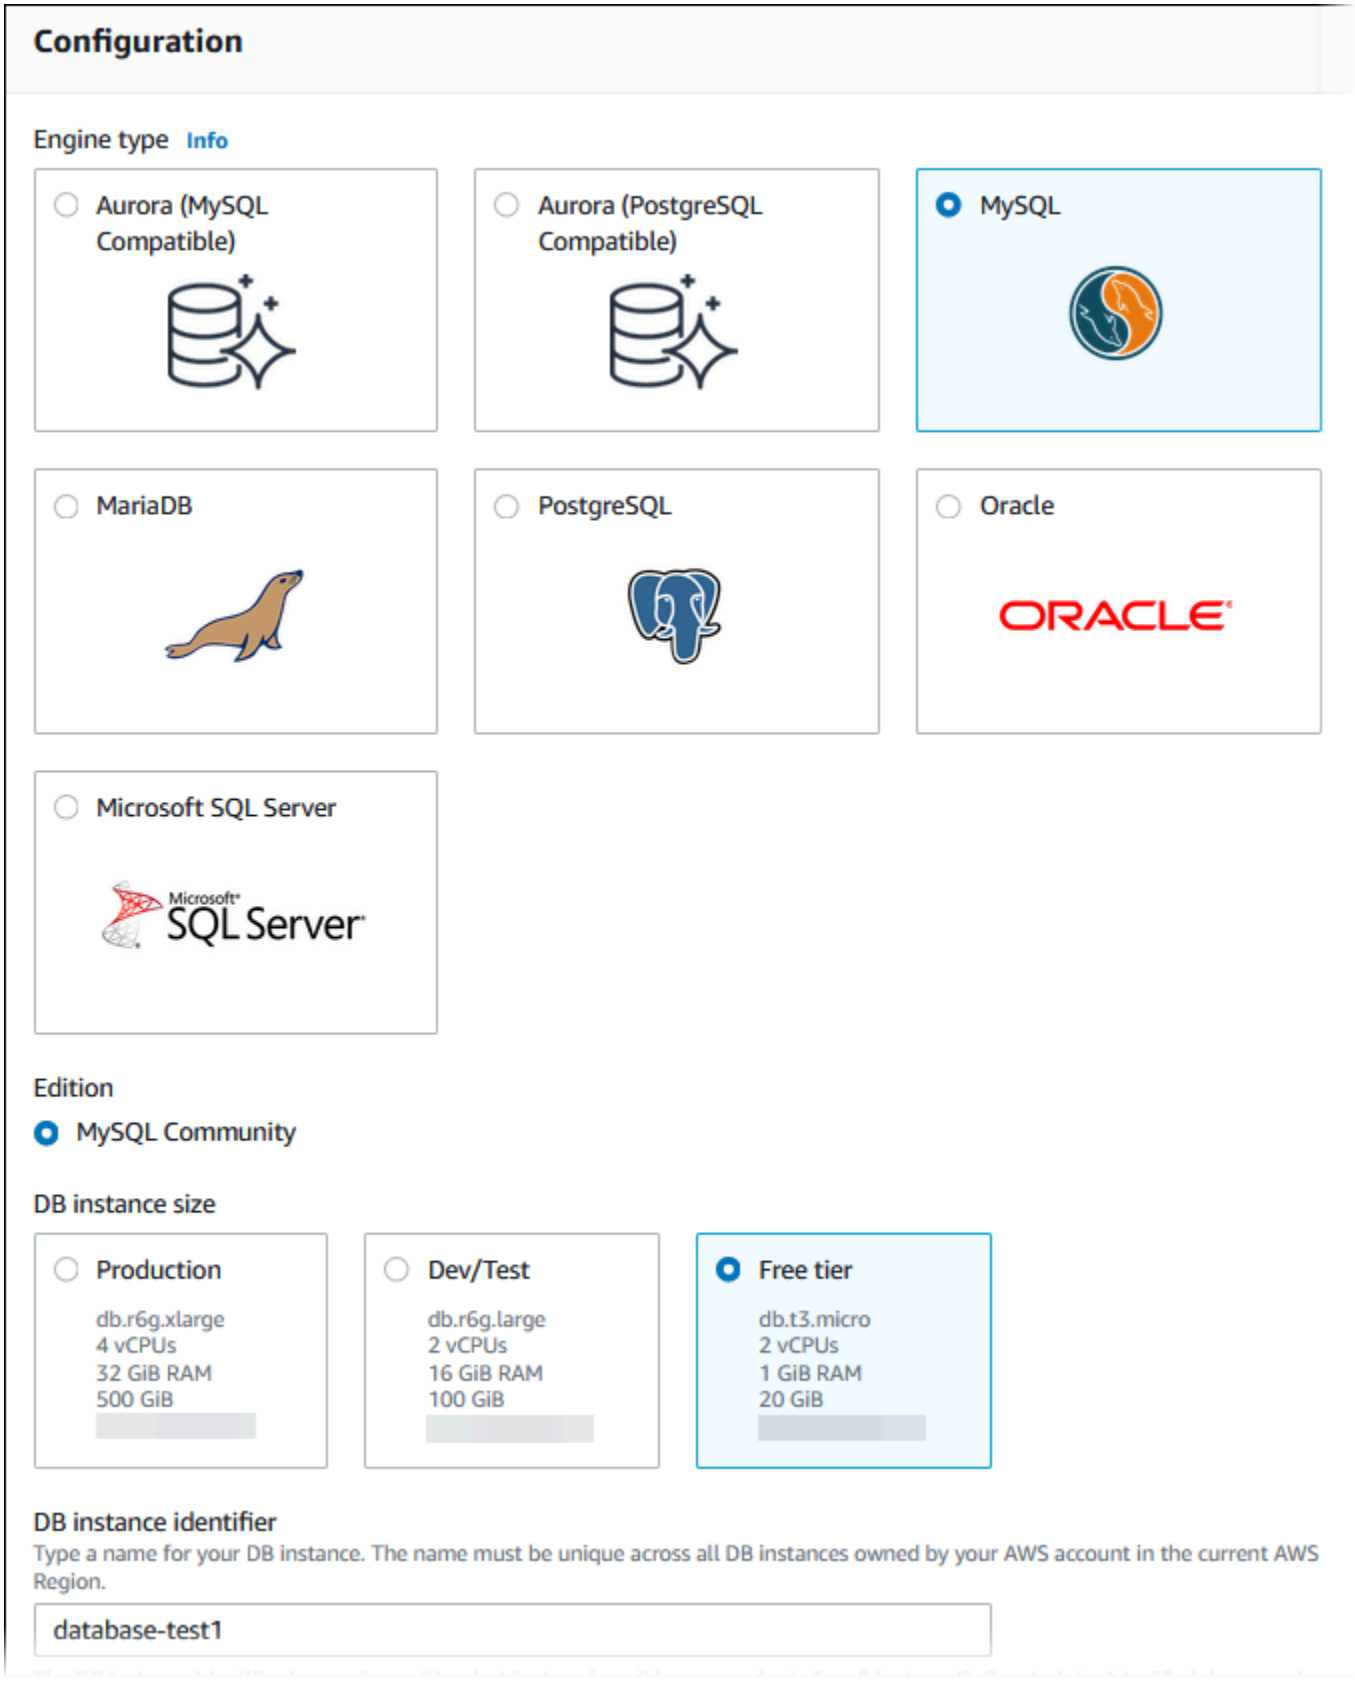
To create a MySQL DB instance with Easy create

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the upper-right corner of the Amazon RDS console, choose the AWS Region you used for the EC2 instance previously.
3. In the navigation pane, choose **Databases**.
4. Choose **Create database** and make sure that **Easy create** is chosen.



5. In **Configuration**, choose **MySQL**.
6. For **DB instance size**, choose **Free tier**.
7. For **DB instance identifier**, enter **`database-test1`**.
8. For **Master username**, enter a name for the master user, or keep the default name.

   The **Create database** page should look similar to the following image.



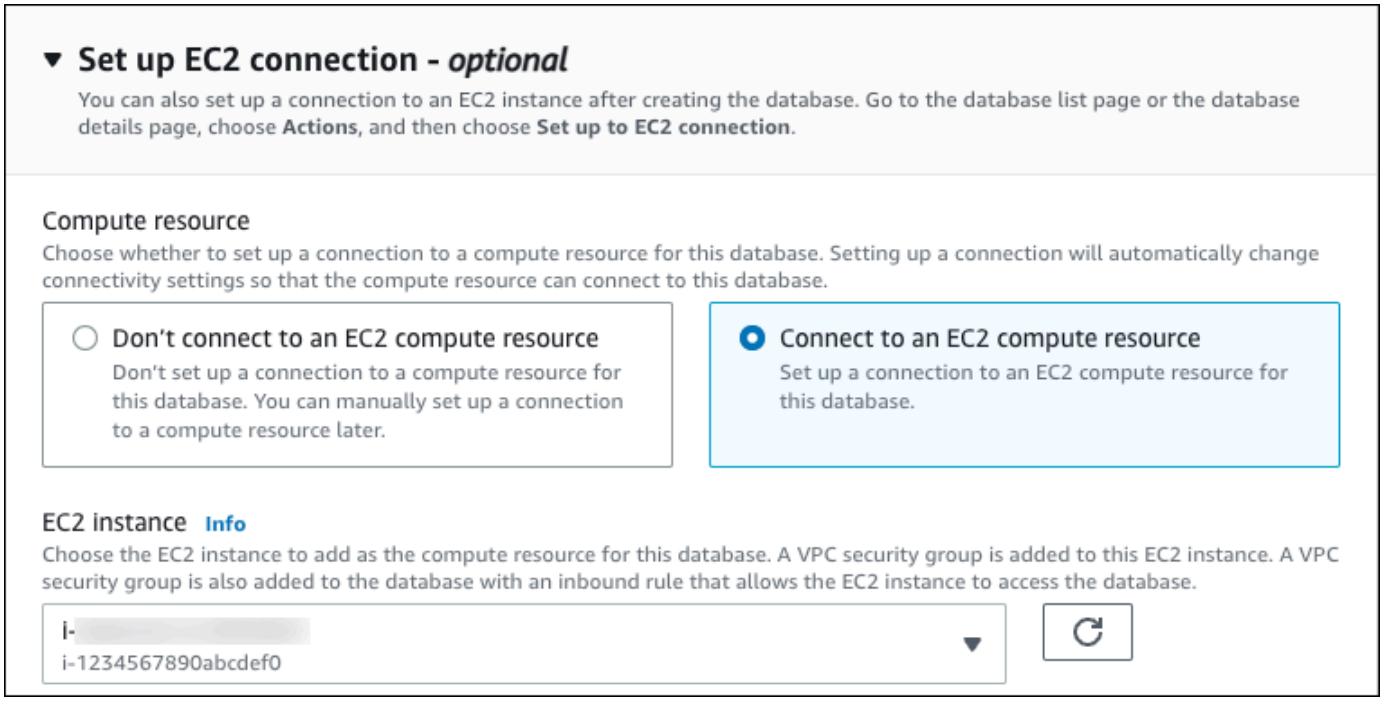
Configuration
Engine type Info
Aurora (MySQL Compatible)
Aurora (PostgreSQL Compatible)
MySQL
MariaDB
PostgreSQL
Oracle
ORACLE
Microsoft SQL Server
Microsoft SQL Server
Edition
MySQL Community
DB instance size
Production
db.r6g.xlarge
4 vCPUs
32 GiB RAM
500 GiB
Dev/Test
db.r6g.large
2 vCPUs
16 GiB RAM
100 GiB
Free tier
db.t3.micro
2 vCPUs
1 GiB RAM
20 GiB
DB instance identifier
Type a name for your DB instance. The name must be unique across all DB instances owned by your AWS account in the current AWS Region.
database-test1

9. To use an automatically generated master password for the DB instance, select **Auto generate a password**.

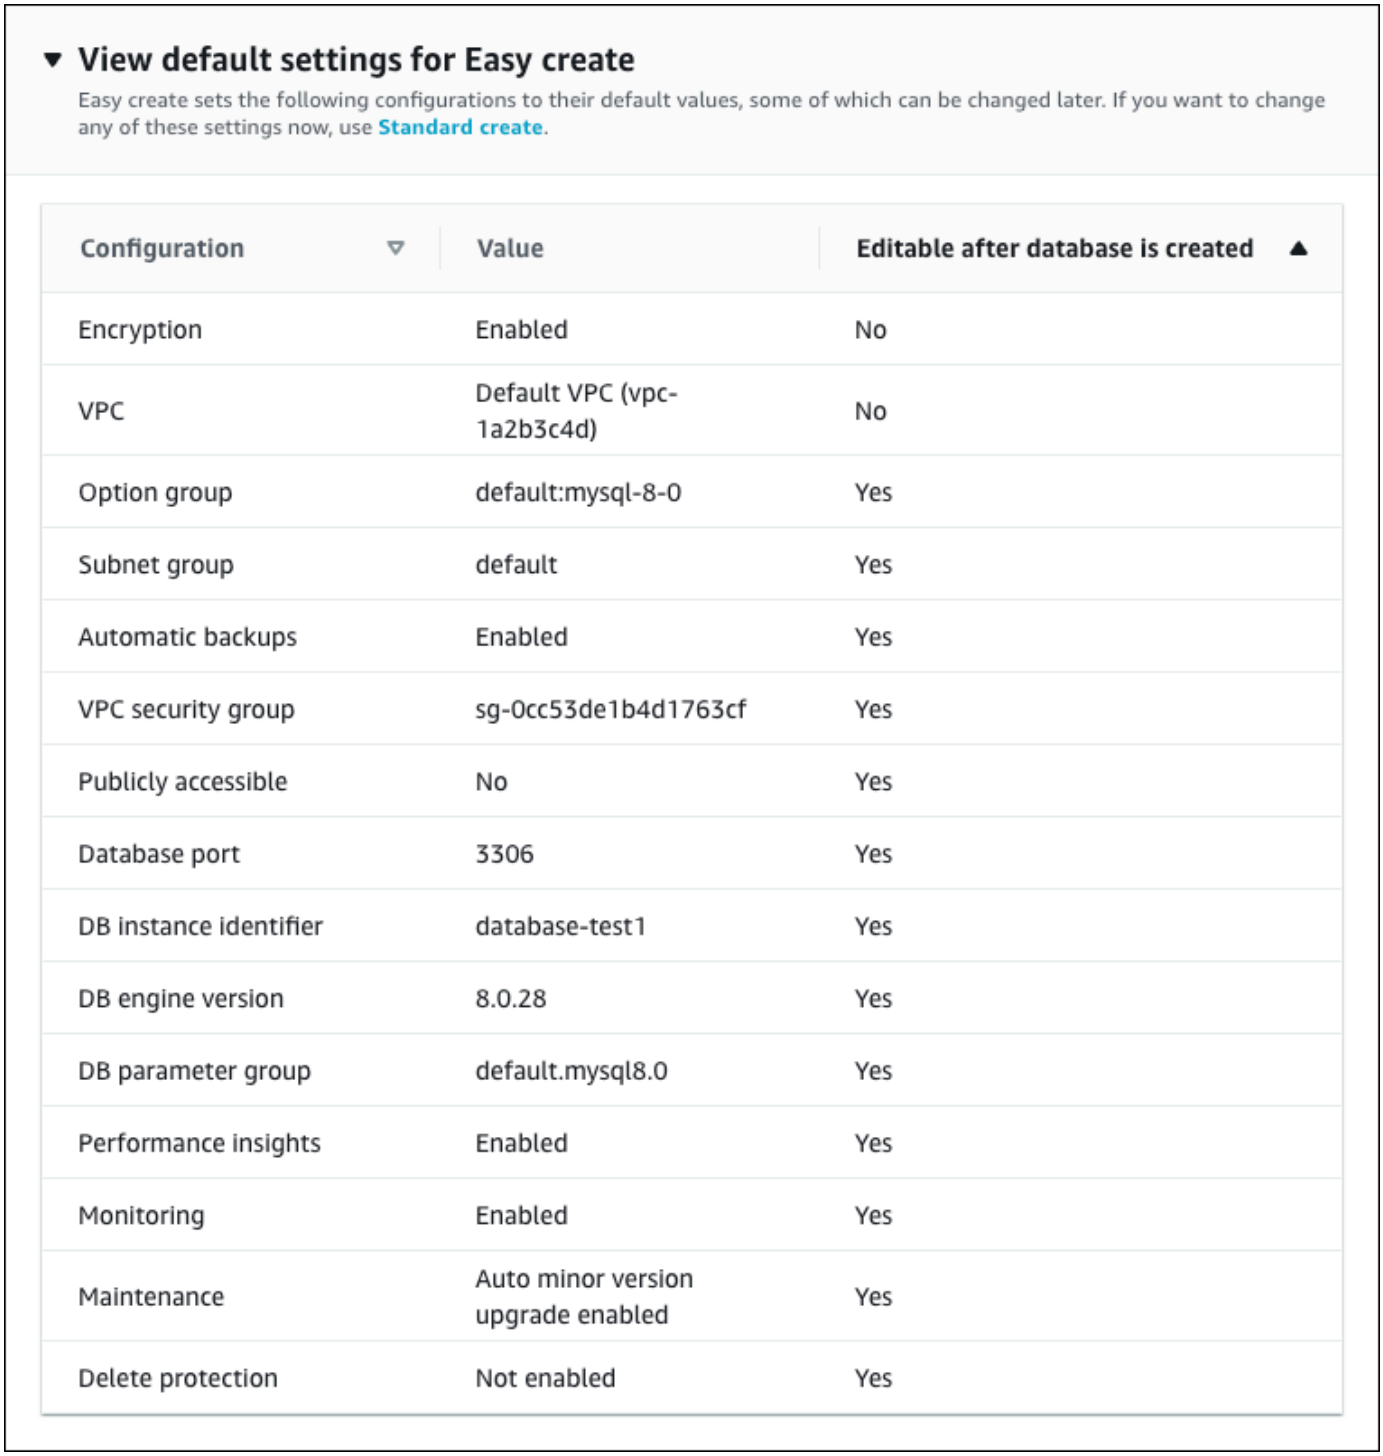
   To enter your master password, make sure **Auto generate a password** is cleared, and then enter the same password in **Master password** and **Confirm password**.

10. To set up a connection with the EC2 instance you created previously, open **Set up EC2 connection - *optional***.

    Select **Connect to an EC2 compute resource**. Choose the EC2 instance you created previously.



11. (Optional) Open **View default settings for Easy create**.



View default settings for Easy create

Easy create sets the following configurations to their default values, some of which can be changed later. If you want to change any of these settings now, use **Standard create**.

Configuration	Value	Editable after database is created
Encryption	Enabled	No
VPC	Default VPC (vpc-1a2b3c4d)	No
Option group	default:mysql-8-0	Yes
Subnet group	default	Yes
Automatic backups	Enabled	Yes
VPC security group	sg-0cc53de1b4d1763cf	Yes
Publicly accessible	No	Yes
Database port	3306	Yes
DB instance identifier	database-test1	Yes
DB engine version	8.0.28	Yes
DB parameter group	default.mysql8.0	Yes
Performance insights	Enabled	Yes
Monitoring	Enabled	Yes
Maintenance	Auto minor version upgrade enabled	Yes
Delete protection	Not enabled	Yes

You can examine the default settings used with **Easy create**. The **Editable after database is created** column shows which options you can change after you create the database.

- If a setting has **No** in that column, and you want a different setting, you can use **Standard create** to create the DB instance.

- If a setting has **Yes** in that column, and you want a different setting, you can either use **Standard create** to create the DB instance, or modify the DB instance after you create it to change the setting.

12. Choose **Create database**.

    To view the master username and password for the DB instance, choose **View credential details**.

    You can use the username and password that appears to connect to the DB instance as the master user.

    > **Important**
    >
    > You can't view the master user password again. If you don't record it, you might have to change it.
    > If you need to change the master user password after the DB instance is available, you can modify the DB instance to do so. For more information about modifying a DB instance, see Modifying an Amazon RDS DB instance.

13. In the **Databases** list, choose the name of the new MySQL DB instance to show its details.

    The DB instance has a status of **Creating** until it is ready to use.

    When the status changes to **Available**, you can connect to the DB instance. Depending on the DB instance class and the amount of storage, it can take up to 20 minutes before the new instance is available.

(Optional) Create VPC, EC2 instance, and MySQL instance using AWS CloudFormation

Instead of using the console to create your VPC, EC2 instance, and MySQL instance, you can use AWS CloudFormation to provision AWS resources by treating infrastructure as code. To help you organize your AWS resources into smaller and more manageable units, you can use the AWS CloudFormation nested stack functionality. For more information, see Creating a stack on the AWS CloudFormation console and Working with nested stacks.

Important

AWS CloudFormation is free, but the resources that CloudFormation creates are live. You incur the standard usage fees for these resources until you terminate them. The total charges will be minimal. For information about how you might minimize any charges, go to AWS Free Tier.

To create your resources using the AWS CloudFormation console, complete the following steps:

- Step 1: Download the CloudFormation template
- Step 2: Configure your resources using CloudFormation

Download the CloudFormation template

A CloudFormation template is a JSON or YAML text file that contains the configuration information about the resources you want to create in the stack. This template also creates a VPC and a bastion host for you along with the RDS instance.

To download the template file, open the following link, MySQL CloudFormation template.

In the Github page, click the *Download raw file* button to save the template YAML file.

Configure your resources using CloudFormation

Note

Before starting this process, make sure you have a Key pair for an EC2 instance in your AWS account. For more information, see Amazon EC2 key pairs and Linux instances.

When you use the AWS CloudFormation template, you must select the correct parameters to make sure your resources are created properly. Follow the steps below:

1. Sign in to the AWS Management Console and open the AWS CloudFormation console at https://console.aws.amazon.com/cloudformation.
2. Choose **Create Stack**.
3. In the Specify template section, select **Upload a template file from your computer**, and then choose **Next**.
4. In the **Specify stack details** page, set the following parameters:
   a. Set **Stack name** to **MySQLTestStack**.
   b. Under **Parameters**, set **Availability Zones** by selecting three availability zones.
   c. Under **Linux Bastion Host configuration**, for **Key Name**, select a key pair to login to your EC2 instance.
   d. In **Linux Bastion Host configuration** settings, set the **Permitted IP range** to your IP address. To connect to EC2 instances in your VPC using Secure Shell (SSH), determine your public IP address using the service at https://checkip.amazonaws.com. An example of an IP address is 192.0.2.1/32.

      > **Warning**
      >
      > If you use `0.0.0.0/0` for SSH access, you make it possible for all IP addresses to access your public EC2 instances using SSH. This approach is acceptable for a short time in a test environment, but it's unsafe for production environments. In production, authorize only a specific IP address or range of addresses to access your EC2 instances using SSH.

   e. Under **Database General configuration**, set **Database instance class** to **db.t3.micro**.
   f. Set **Database name** to **`database-test1`**.
   g. For **Database master username**, enter a name for the master user.
   h. Set **Manage DB master user password with Secrets Manager** to `false` for this tutorial.
   i. For **Database password**, set a password of your choice. Remember this password for further steps in the tutorial.
   j. Under **Database Storage configuration**, set **Database storage type** to **gp2**.
   k. Under **Database Monitoring configuration**, set **Enable RDS Performance Insights** to false.

l. Leave all other settings as the default values. Click **Next** to continue.

5. In the **Configure stack options** page, leave all the default options. Click **Next** to continue.
6. In the **Review stack** page, select **Submit** after checking the database and Linux bastion host options.

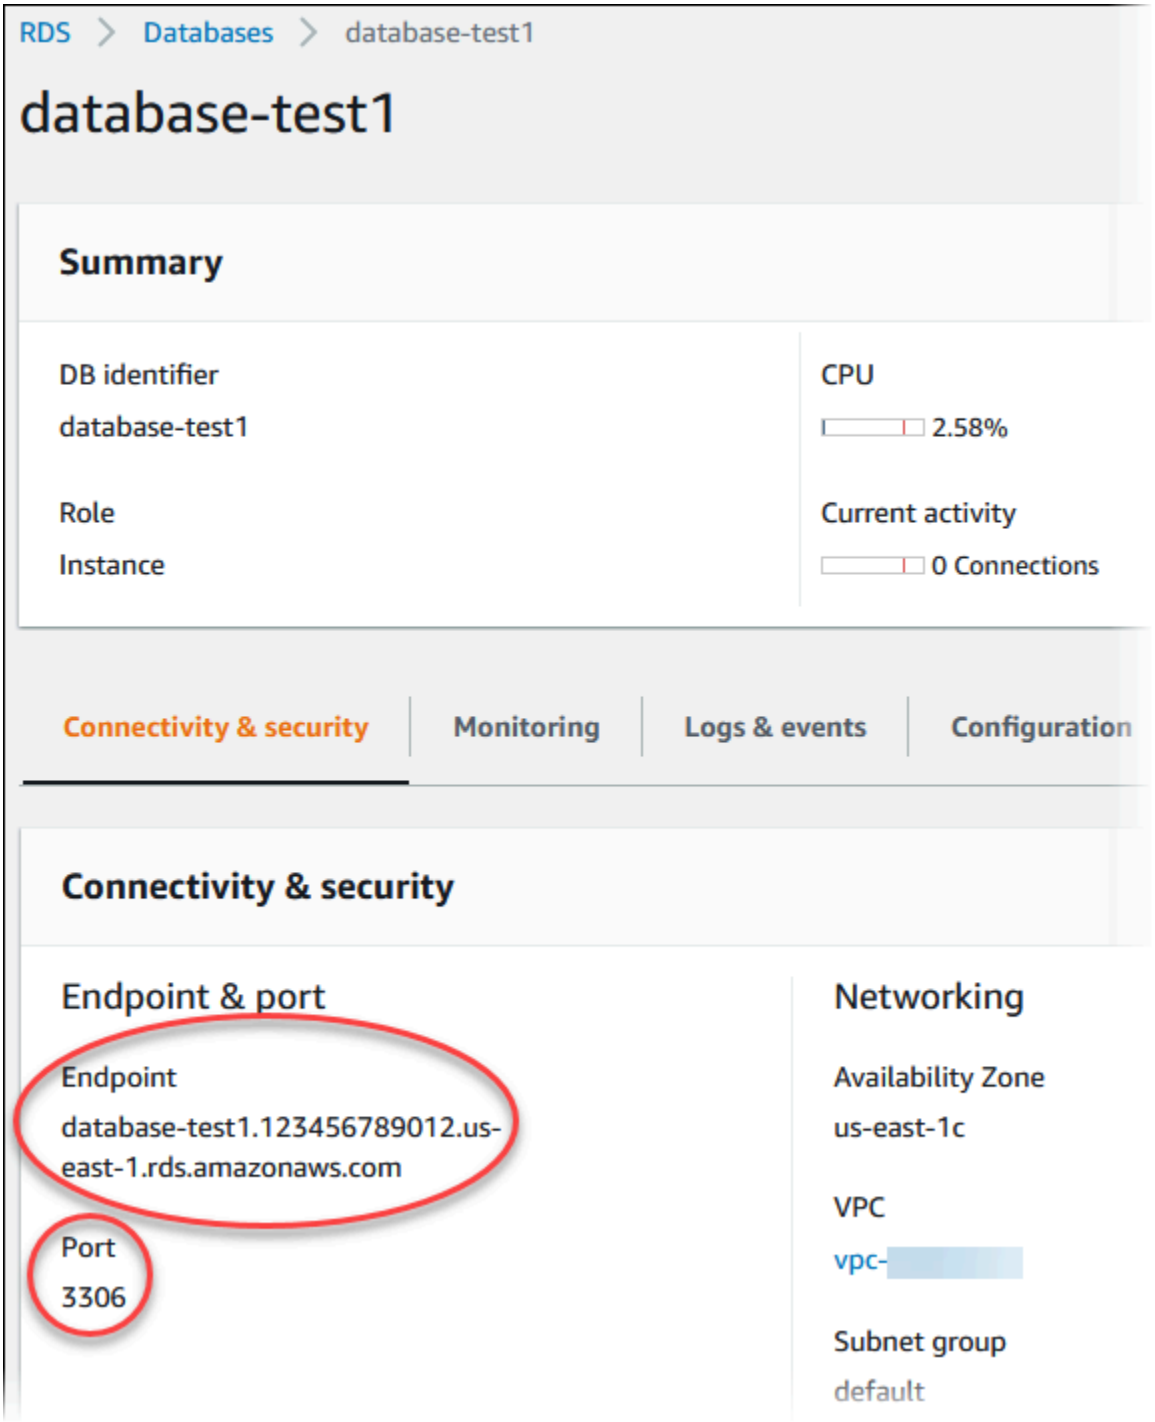
After the stack creation process completes, view the stacks with names *BastionStack* and *RDSNS* to note the information you need to connect to the database. For more information, see Viewing AWS CloudFormation stack data and resources on the AWS Management Console.

Step 3: Connect to a MySQL DB instance

You can use any standard SQL client application to connect to the DB instance. In this example, you connect to a MySQL DB instance using the mysql command-line client.

To connect to a MySQL DB instance

1. Find the endpoint (DNS name) and port number for your DB instance.
   a. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
   b. In the upper-right corner of the Amazon RDS console, choose the AWS Region for the DB instance.
   c. In the navigation pane, choose **Databases**.
   d. Choose the MySQL DB instance name to display its details.
   e. On the **Connectivity & security** tab, copy the endpoint. Also, note the port number. You need both the endpoint and the port number to connect to the DB instance.



2. Connect to the EC2 instance that you created earlier by following the steps in Connect to your Linux instance in the *Amazon EC2 User Guide*.

   We recommend that you connect to your EC2 instance using SSH. If the SSH client utility is installed on Windows, Linux, or Mac, you can connect to the instance using the following command format:

```
ssh -i location_of_pem_file ec2-user@ec2-instance-public-dns-name
```

For example, assume that `ec2-database-connect-key-pair.pem` is stored in `/dir1` on Linux, and the public IPv4 DNS for your EC2 instance is `ec2-12-345-678-90.compute-1.amazonaws.com`. Your SSH command would look as follows:

```
ssh -i /dir1/ec2-database-connect-key-pair.pem ec2-
user@ec2-12-345-678-90.compute-1.amazonaws.com
```

3. Get the latest bug fixes and security updates by updating the software on your EC2 instance. To do this, use the following command.

   Note

   The `-y` option installs the updates without asking for confirmation. To examine updates before installing, omit this option.

   ```
   sudo dnf update -y
   ```

4. To install the mysql command-line client from MariaDB on Amazon Linux 2023, run the following command:

   ```
   sudo dnf install mariadb105
   ```

5. Connect to the MySQL DB instance. For example, enter the following command. This action lets you connect to the MySQL DB instance using the MySQL client.

   Substitute the DB instance endpoint (DNS name) for *endpoint*, and substitute the master username that you used for *admin*. Provide the master password that you used when prompted for a password.

   ```
   mysql -h endpoint -P 3306 -u admin -p
   ```

   After you enter the password for the user, you should see output similar to the following.

```
Welcome to the MariaDB monitor.  Commands end with ; or \g.
Your MySQL connection id is 3082
Server version: 8.0.28 Source distribution

Copyright (c) 2000, 2018, Oracle, MariaDB Corporation Ab and others.

Type 'help;' or '\h' for help. Type '\c' to clear the current input statement.

MySQL [(none)]>
```

For more information about connecting to a MySQL DB instance, see Connecting to a DB instance running the MySQL database engine. If you can't connect to your DB instance, see Can't connect to Amazon RDS DB instance.

For security, it is a best practice to use encrypted connections. Only use an unencrypted MySQL connection when the client and server are in the same VPC and the network is trusted. For information about using encrypted connections, see Connecting from the MySQL command-line client with SSL/TLS (encrypted).

6. Run SQL commands.

   For example, the following SQL command shows the current date and time:

```
SELECT CURRENT_TIMESTAMP;
```

Step 4: Delete the EC2 instance and DB instance

After you connect to and explore the sample EC2 instance and DB instance that you created, delete them so you're no longer charged for them.

If you used AWS CloudFormation to create resources, skip this step and go to the next step.

To delete the EC2 instance

1. Sign in to the AWS Management Console and open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select the EC2 instance, and choose **Instance state, Terminate instance**.

4. Choose **Terminate** when prompted for confirmation.

For more information about deleting an EC2 instance, see Terminate your instance in the *Amazon EC2 User Guide*.

To delete the DB instance with no final DB snapshot

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.
3. Choose the DB instance that you want to delete.
4. For **Actions**, choose **Delete**.
5. Clear **Create final snapshot?** and **Retain automated backups**.
6. Complete the acknowledgement and choose **Delete**.

(Optional) Delete the EC2 instance and DB instance created with CloudFormation

If you used AWS CloudFormation to create resources, delete the CloudFormation stack after you connect to and explore the sample EC2 instance and DB instance, so you're no longer charged for them.

To delete the CloudFormation resources

1. Open the AWS CloudFormation console.
2. On the **Stacks** page in the CloudFormationconsole, select the root stack (the stack without the name VPCStack, BastionStack or RDSNS).
3. Choose **Delete**.
4. Select **Delete stack** when prompted for confirmation.

For more information about deleting a stack in CloudFormation, see Deleting a stack on the AWS CloudFormation console in the *AWS CloudFormation User Guide*.

(Optional) Connect your DB instance to a Lambda function

You can also connect your RDS for MySQL DB instance to a Lambda serverless compute resource. Lambda functions allow you to run code without provisioning or managing infrastructure. A Lambda function also allows you to automatically respond to code execution requests at any scale, from a dozen events a day to hundreds of per second. For more information, see Automatically connecting a Lambda function and a DB instance.

Creating and connecting to an Oracle DB instance

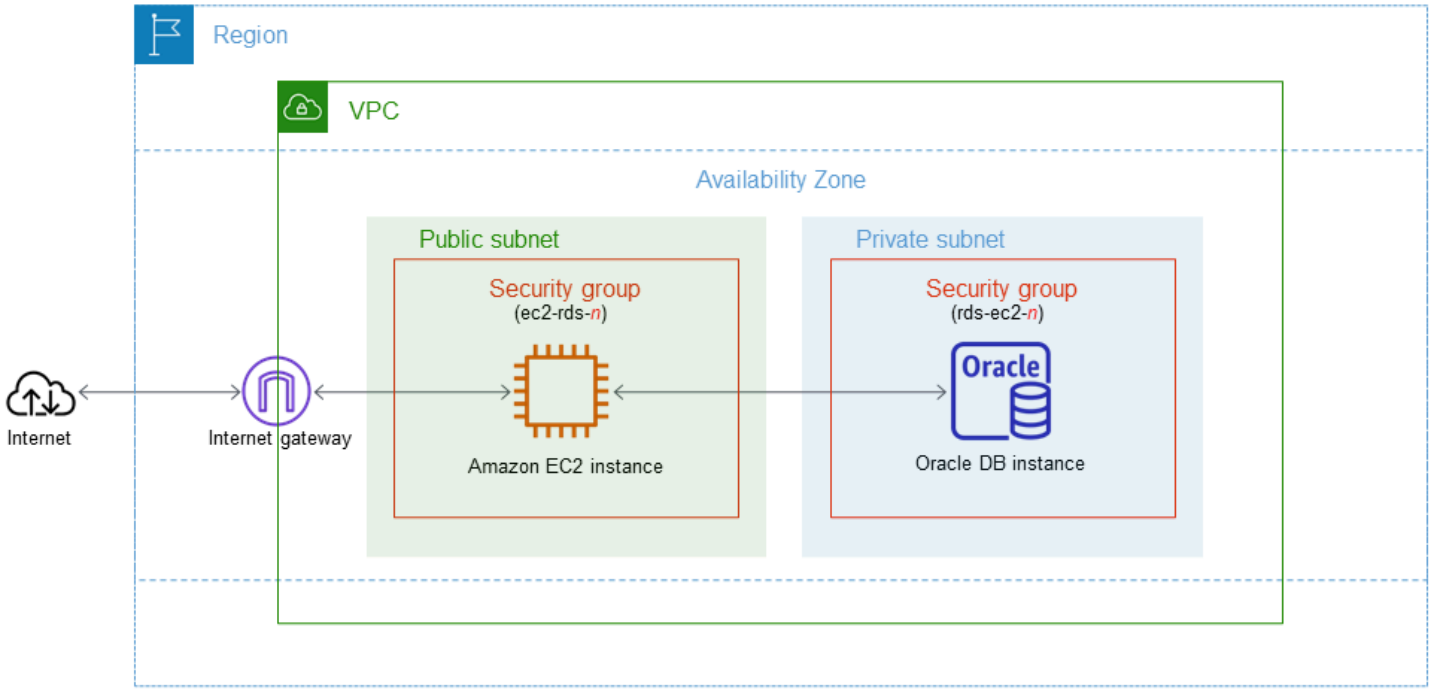
This tutorial creates an EC2 instance and an RDS for Oracle DB instance. The tutorial shows you how to access the DB instance from the EC2 instance using a standard Oracle client. As a best practice, this tutorial creates a private DB instance in a virtual private cloud (VPC). In most cases, other resources in the same VPC, such as EC2 instances, can access the DB instance, but resources outside of the VPC can't access it.

After you complete the tutorial, there is a public and private subnet in each Availability Zone in your VPC. In one Availability Zone, the EC2 instance is in the public subnet, and the DB instance is in the private subnet.

Important

There's no charge for creating an AWS account. However, by completing this tutorial, you might incur costs for the AWS resources you use. You can delete these resources after you complete the tutorial if they are no longer needed.

The following diagram shows the configuration when the tutorial is complete.



This tutorial allows you to create your resources by using one of the following methods:

1. Use the AWS Management Console - Step 2: Create an Oracle DB instance and Step 1: Create an EC2 instance
2. Use AWS CloudFormation to create the database instance and EC2 instance - (Optional) Create VPC, EC2 instance, and Oracle DB instance using AWS CloudFormation

The first method uses **Easy create** to create a private Oracle DB instance with the AWS Management Console. Here, you specify only the DB engine type, DB instance size, and DB instance identifier. **Easy create** uses the default settings for the other configuration options.

When you use **Standard create** instead, you can specify more configuration options when you create a DB instance. These options include settings for availability, security, backups, and maintenance. To create a public DB instance, you must use **Standard create**. For information, see Creating an Amazon RDS DB instance.

Topics

Prerequisites

Before you begin, complete the steps in the following sections:

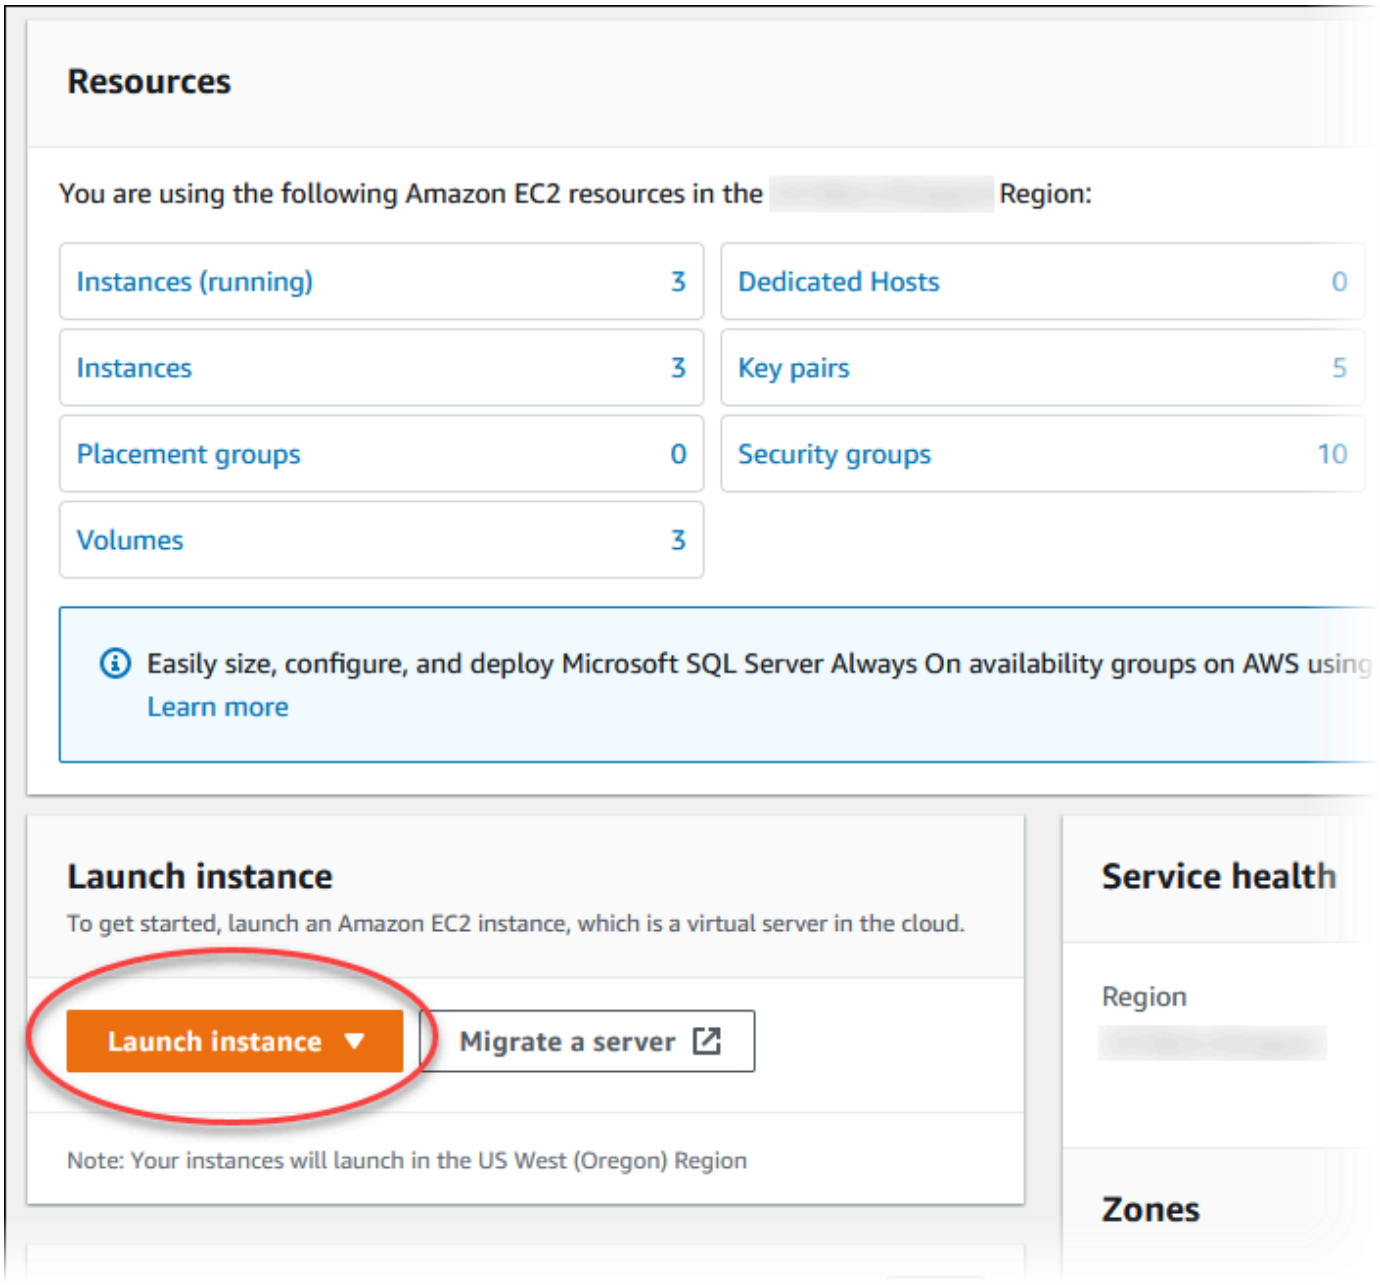
- Sign up for an AWS account
- Create a user with administrative access

Step 1: Create an EC2 instance

Create an Amazon EC2 instance that you will use to connect to your database.

To create an EC2 instance

1. Sign in to the AWS Management Console and open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the upper-right corner of the AWS Management Console, choose the AWS Region in which you want to create the EC2 instance.
3. Choose **EC2 Dashboard**, and then choose **Launch instance**, as shown in the following image.



The **Launch an instance** page opens.

4. Choose the following settings on the **Launch an instance** page.

   a. Under **Name and tags**, for **Name**, enter **`ec2-database-connect`**.

   b. Under **Application and OS Images (Amazon Machine Image)**, choose **Amazon Linux**, and then choose the **Amazon Linux 2023 AMI**. Keep the default selections for the other choices.

   c. Under **Instance type**, choose **t2.micro**.

   d. Under **Key pair (login)**, choose a **Key pair name** to use an existing key pair. To create a new key pair for the Amazon EC2 instance, choose **Create new key pair** and then use the **Create key pair** window to create it.

For more information about creating a new key pair, see Create a key pair in the *Amazon EC2 User Guide*.

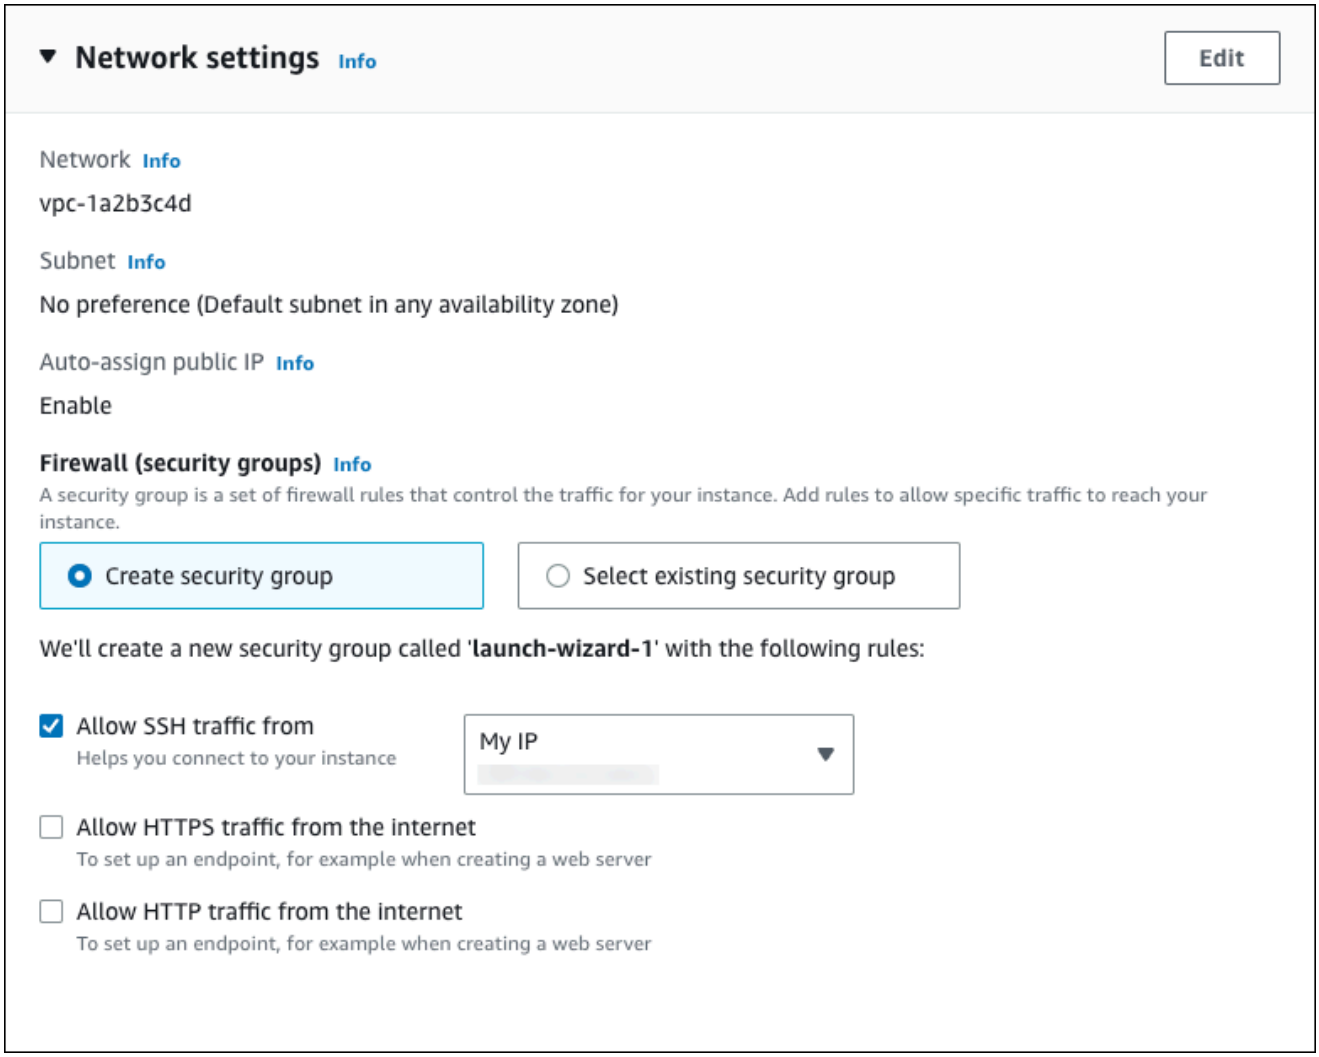
e. For **Allow SSH traffic** in **Network settings**, choose the source of SSH connections to the EC2 instance.

You can choose **My IP** if the displayed IP address is correct for SSH connections. Otherwise, you can determine the IP address to use to connect to EC2 instances in your VPC using Secure Shell (SSH). To determine your public IP address, in a different browser window or tab, you can use the service at https://checkip.amazonaws.com. An example of an IP address is 192.0.2.1/32.

In many cases, you might connect through an internet service provider (ISP) or from behind your firewall without a static IP address. If so, make sure to determine the range of IP addresses used by client computers.

> **Warning**
>
> If you use `0.0.0.0/0` for SSH access, you make it possible for all IP addresses to access your public EC2 instances using SSH. This approach is acceptable for a short time in a test environment, but it's unsafe for production environments. In production, authorize only a specific IP address or range of addresses to access your EC2 instances using SSH.

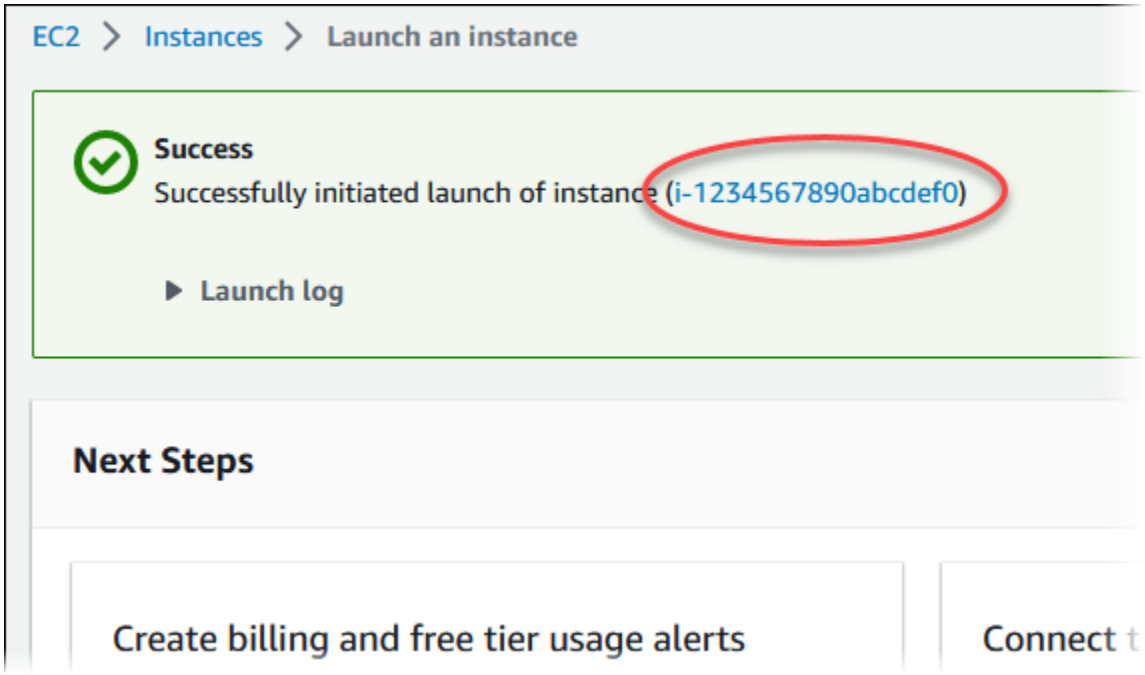
The following image shows an example of the **Network settings** section.



f. Leave the default values for the remaining sections.

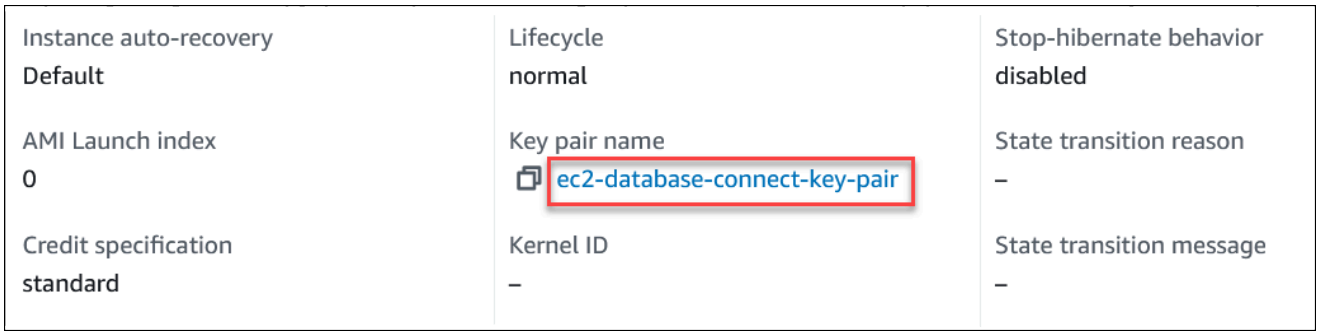
g. Review a summary of your EC2 instance configuration in the **Summary** panel, and when you're ready, choose **Launch instance**.

5. On the **Launch Status** page, note the identifier for your new EC2 instance, for example: `i-1234567890abcdef0`.



6. Choose the EC2 instance identifier to open the list of EC2 instances, and then select your EC2 instance.
7. In the **Details** tab, note the following values, which you need when you connect using SSH:
   a. In **Instance summary**, note the value for **Public IPv4 DNS**.

   b. In **Instance details**, note the value for **Key pair name**.



8. Wait until the **Instance state** for your EC2 instance has a status of **Running** before continuing.

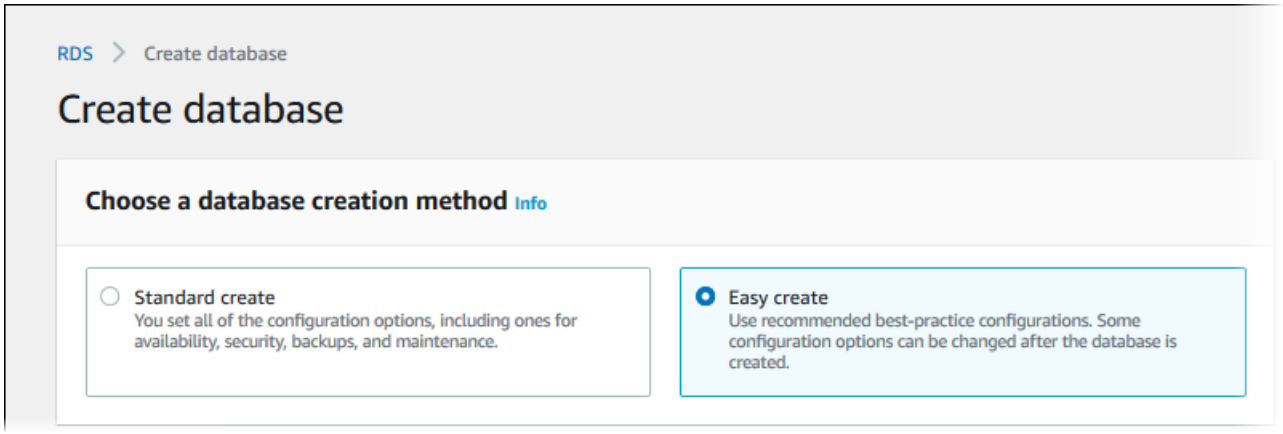
Step 2: Create an Oracle DB instance

The basic building block of Amazon RDS is the DB instance. This environment is where you run your Oracle databases.

In this example, you use **Easy create** to create a DB instance running the Oracle database engine with a db.m5.large DB instance class.

To create an Oracle DB instance with Easy create

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the upper-right corner of the Amazon RDS console, choose the AWS Region in which you want to create the DB instance.
3. In the navigation pane, choose **Databases**.
4. Choose **Create database** and make sure that **Easy create** is chosen.



5. In **Configuration**, choose **Oracle**.
6. For **DB instance size**, choose **Dev/Test**.
7. For **DB instance identifier**, enter **`database-test1`**.
8. For **Master username**, enter a name for the master user, or keep the default name.

   The **Create database** page should look similar to the following image.

Configuration

Engine type Info

- Aurora (MySQL Compatible)
- Aurora (PostgreSQL Compatible)
- MySQL
- MariaDB
- PostgreSQL
- Oracle
- Microsoft SQL Server

Edition

- Oracle Enterprise Edition
  Affordable and full-featured database management system supporting up to 16 vCPUs.
- Oracle Standard Edition Two
  Affordable and full-featured database management system supporting up to 16 vCPUs. Oracle Database Standard Edition Two is a replacement for Standard Edition and Standard Edition One.

DB instance size

- Production
  db.r5.large
  2 vCPUs
  16 GiB RAM
  500 GiB
- Dev/Test
  db.m5.large
  2 vCPUs
  8 GiB RAM
  100 GiB

DB instance identifier

Type a name for your DB instance. The name must be unique across all DB instances owned by your AWS account in the current AWS Region.

database-test1

The DB instance identifier is case-insensitive, but is stored as all lowercase (as in "mydbinstance"). Constraints: 1 to 60 alphanumeric characters or hyphens. First character must be a letter. Can't contain two consecutive hyphens. Can't end with a hyphen.

Master username Info

Type a login ID for the master user of your DB instance.

admin

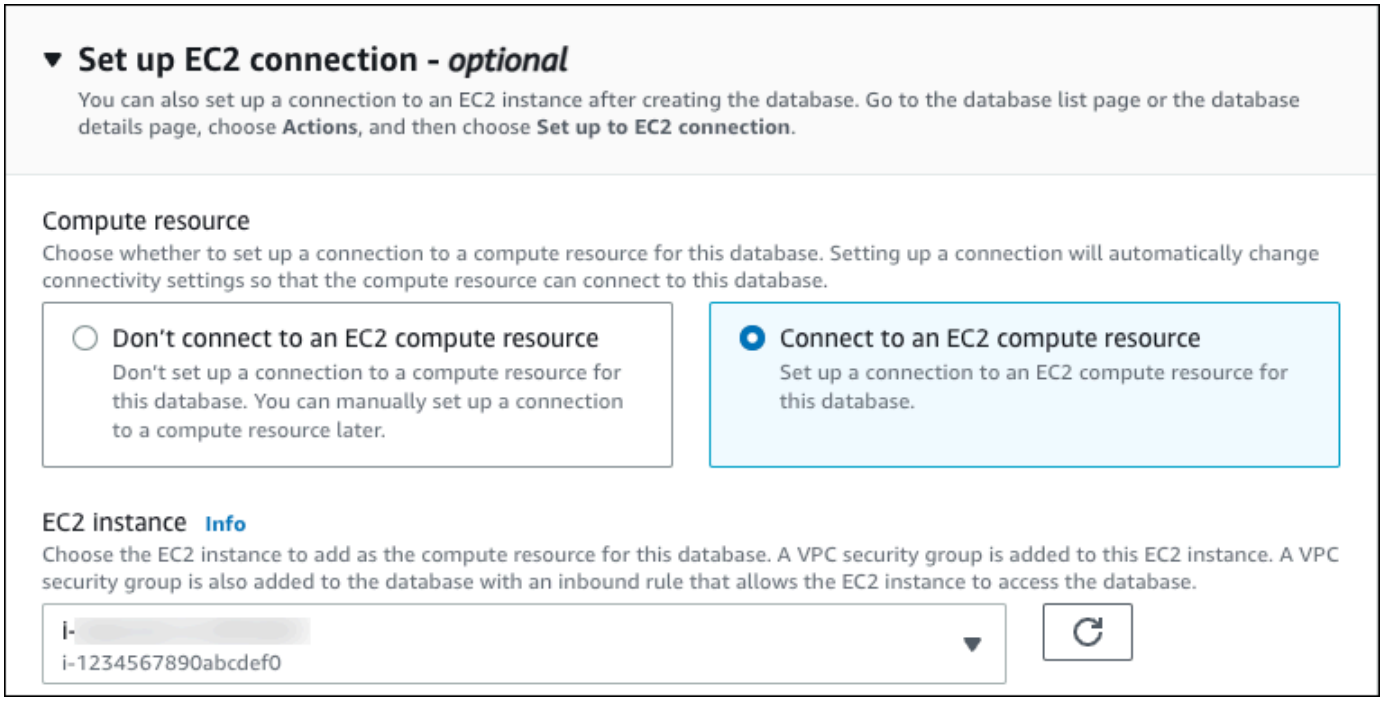
1 to 16 alphanumeric characters. First character must be a letter.

9. To use an automatically generated master password for the DB instance, select **Auto generate a password**.

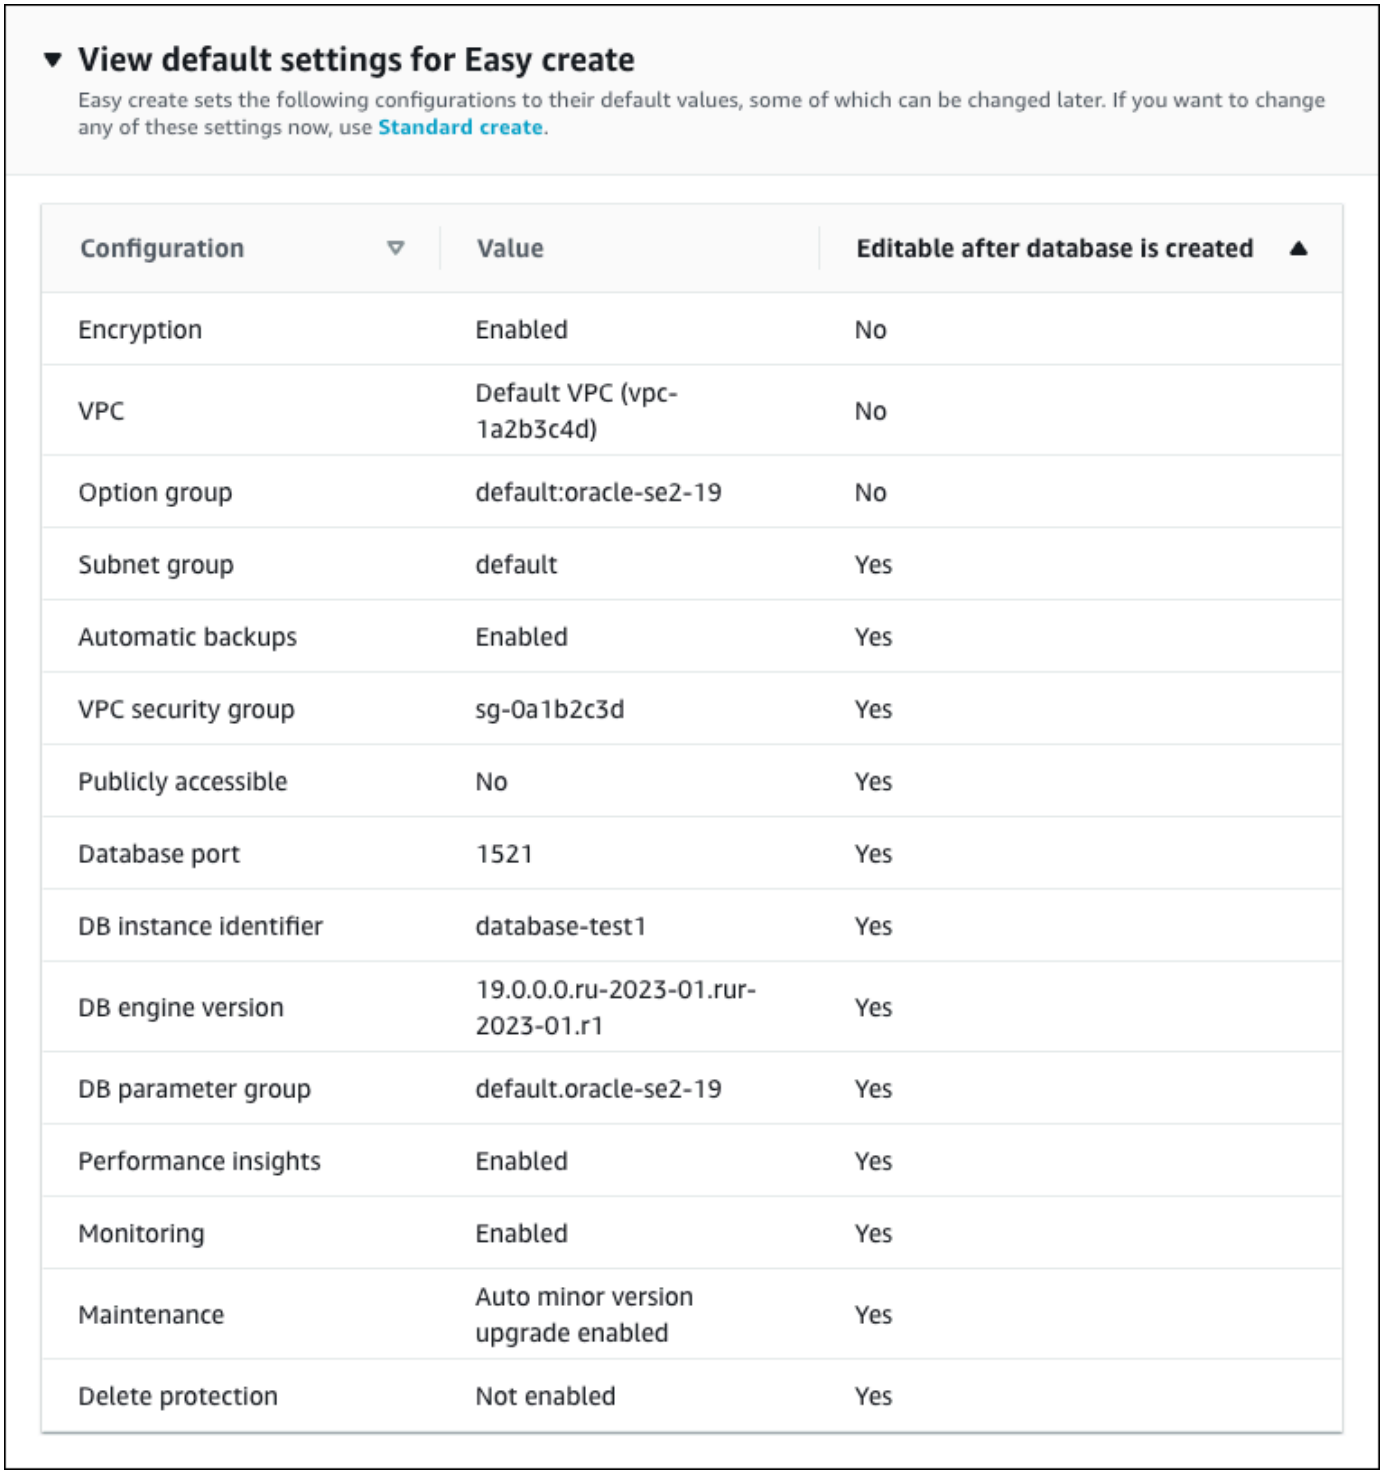
   To enter your master password, make sure **Auto generate a password** is cleared, and then enter the same password in **Master password** and **Confirm password**.

10. To set up a connection with the EC2 instance you created previously, open **Set up EC2 connection - *optional***.

    Select **Connect to an EC2 compute resource**. Choose the EC2 instance you created previously.



11. Open **View default settings for Easy create**.



View default settings for Easy create

Easy create sets the following configurations to their default values, some of which can be changed later. If you want to change any of these settings now, use **Standard create**.

Configuration	Value	Editable after database is created
Encryption	Enabled	No
VPC	Default VPC (vpc-1a2b3c4d)	No
Option group	default:oracle-se2-19	No
Subnet group	default	Yes
Automatic backups	Enabled	Yes
VPC security group	sg-0a1b2c3d	Yes
Publicly accessible	No	Yes
Database port	1521	Yes
DB instance identifier	database-test1	Yes
DB engine version	19.0.0.0.ru-2023-01.rur-2023-01.r1	Yes
DB parameter group	default.oracle-se2-19	Yes
Performance insights	Enabled	Yes
Monitoring	Enabled	Yes
Maintenance	Auto minor version upgrade enabled	Yes
Delete protection	Not enabled	Yes

You can examine the default settings used with **Easy create**. The **Editable after database is created** column shows which options you can change after you create the database.

- If a setting has **No** in that column, and you want a different setting, you can use **Standard create** to create the DB instance.

- If a setting has **Yes** in that column, and you want a different setting, you can either use **Standard create** to create the DB instance, or modify the DB instance after you create it to change the setting.

12. Choose **Create database**.

    To view the master username and password for the DB instance, choose **View credential details**.

    You can use the username and password that appears to connect to the DB instance as the master user.

    > **Important**
    >
    > You can't view the master user password again. If you don't record it, you might have to change it.
    > If you need to change the master user password after the DB instance is available, you can modify the DB instance to do so. For more information about modifying a DB instance, see Modifying an Amazon RDS DB instance.

13. In the **Databases** list, choose the name of the new Oracle DB instance to show its details.

    The DB instance has a status of **Creating** until it is ready to use.

    When the status changes to **Available**, you can connect to the DB instance. Depending on the DB instance class and the amount of storage, it can take up to 20 minutes before the new instance is available. While the DB instance is being created, you can move on to the next step and create an EC2 instance.

(Optional) Create VPC, EC2 instance, and Oracle DB instance using AWS CloudFormation

Instead of using the console to create your VPC, EC2 instance, and Oracle DB instance, you can use AWS CloudFormation to provision AWS resources by treating infrastructure as code. To help you organize your AWS resources into smaller and more manageable units, you can use the AWS CloudFormation nested stack functionality. For more information, see Creating a stack on the AWS CloudFormation console and Working with nested stacks.

> **Important**
>
> AWS CloudFormation is free, but the resources that CloudFormation creates are live. You incur the standard usage fees for these resources until you terminate them. The total charges will be minimal. For information about how you might minimize any charges, go to AWS Free Tier.

To create your resources using the AWS CloudFormation console, complete the following steps:

- Step 1: Download the CloudFormation template
- Step 2: Configure your resources using CloudFormation

Download the CloudFormation template

A CloudFormation template is a JSON or YAML text file that contains the configuration information about the resources you want to create in the stack. This template also creates a VPC and a bastion host for you along with the RDS instance.

To download the template file, open the following link, Oracle CloudFormation template.

In the Github page, click the *Download raw file* button to save the template YAML file.

Configure your resources using CloudFormation

> **Note**
>
> Before starting this process, make sure you have a Key pair for an EC2 instance in your AWS account. For more information, see Amazon EC2 key pairs and Linux instances.

When you use the AWS CloudFormation template, you must select the correct parameters to make sure your resources are created properly. Follow the steps below:

1. Sign in to the AWS Management Console and open the AWS CloudFormation console at https://console.aws.amazon.com/cloudformation.
2. Choose **Create Stack**.
3. In the Specify template section, select **Upload a template file from your computer**, and then choose **Next**.
4. In the **Specify stack details** page, set the following parameters:
   a. Set **Stack name** to **OracleTestStack**.
   b. Under **Parameters**, set **Availability Zones** by selecting three availability zones.
   c. Under **Linux Bastion Host configuration**, for **Key Name**, select a key pair to login to your EC2 instance.
   d. In **Linux Bastion Host configuration** settings, set the **Permitted IP range** to your IP address. To connect to EC2 instances in your VPC using Secure Shell (SSH), determine your public IP address using the service at https://checkip.amazonaws.com. An example of an IP address is 192.0.2.1/32.

      > **Warning**
      >
      > If you use `0.0.0.0/0` for SSH access, you make it possible for all IP addresses to access your public EC2 instances using SSH. This approach is acceptable for a short time in a test environment, but it's unsafe for production environments. In production, authorize only a specific IP address or range of addresses to access your EC2 instances using SSH.

   e. Under **Database General configuration**, set **Database instance class** to **db.t3.micro**.
   f. Set **Database name** to **`database-test1`**.
   g. For **Database master username**, enter a name for the master user.
   h. Set **Manage DB master user password with Secrets Manager** to `false` for this tutorial.
   i. For **Database password**, set a password of your choice. Remember this password for further steps in the tutorial.
   j. Under **Database Storage configuration**, set **Database storage type** to **gp2**.
   k. Under **Database Monitoring configuration**, set **Enable RDS Performance Insights** to false.

l. Leave all other settings as the default values. Click **Next** to continue.

5. In the **Configure stack options** page, leave all the default options. Click **Next** to continue.
6. In the **Review stack** page, select **Submit** after checking the database and Linux bastion host options.

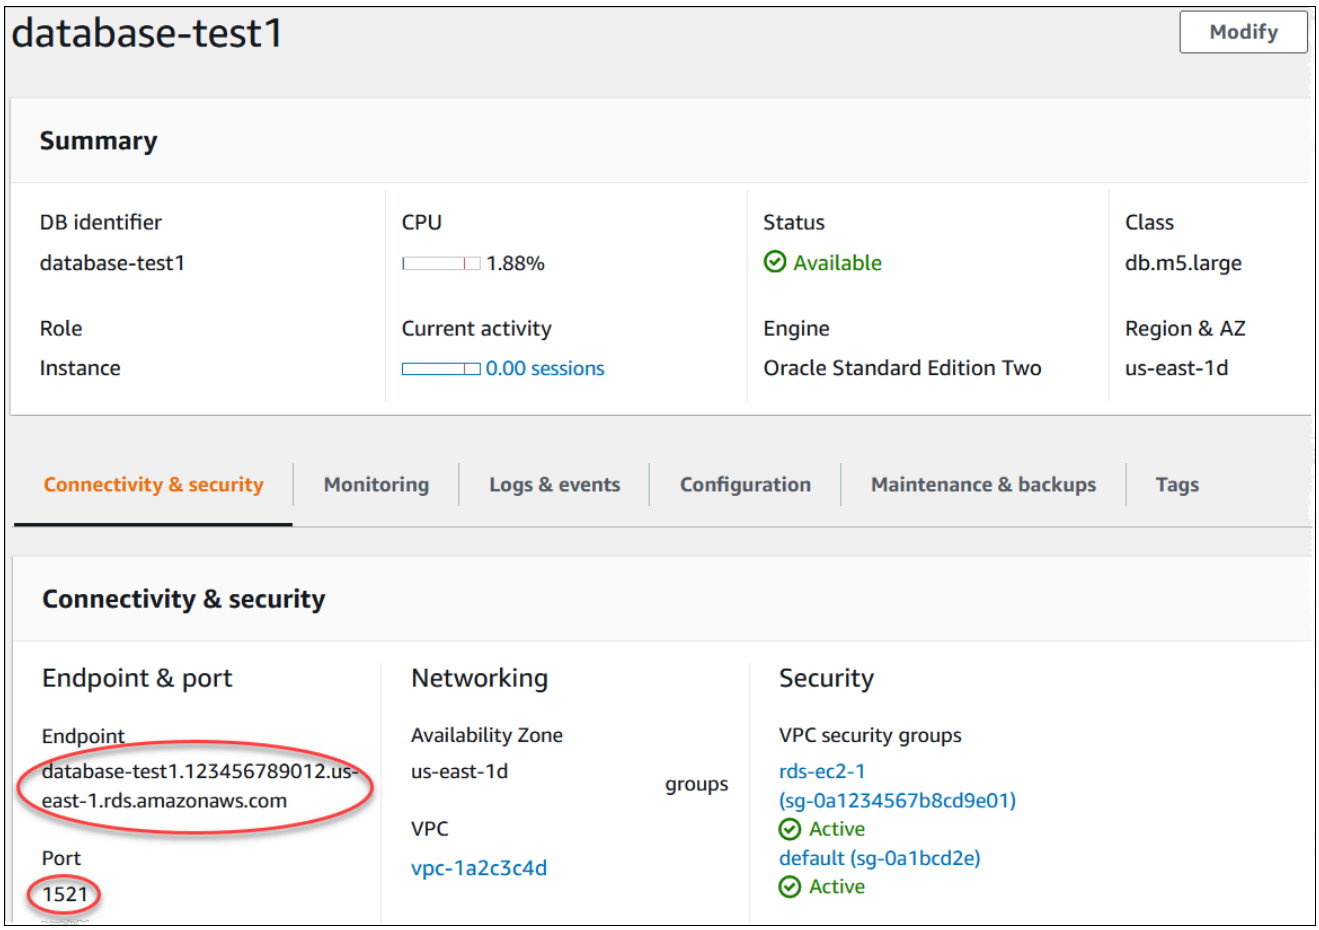
After the stack creation process completes, view the stacks with names *BastionStack* and *RDSNS* to note the information you need to connect to the database. For more information, see Viewing AWS CloudFormation stack data and resources on the AWS Management Console.

Step 3: Connect your SQL client to an Oracle DB instance

You can use any standard SQL client application to connect to your DB instance. In this example, you connect to an Oracle DB instance using the Oracle command-line client.

To connect to an Oracle DB instance

1. Find the endpoint (DNS name) and port number for your DB instance.
   a. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
   b. In the upper-right corner of the Amazon RDS console, choose the AWS Region for the DB instance.
   c. In the navigation pane, choose **Databases**.
   d. Choose the Oracle DB instance name to display its details.
   e. On the **Connectivity & security** tab, copy the endpoint. Also, note the port number. You need both the endpoint and the port number to connect to the DB instance.



2. Connect to the EC2 instance that you created earlier by following the steps in Connect to your Linux instance in the *Amazon EC2 User Guide*.

   We recommend that you connect to your EC2 instance using SSH. If the SSH client utility is installed on Windows, Linux, or Mac, you can connect to the instance using the following command format:

   ```
   ssh -i location_of_pem_file ec2-user@ec2-instance-public-dns-name
   ```

   For example, assume that `ec2-database-connect-key-pair.pem` is stored in `/dir1` on Linux, and the public IPv4 DNS for your EC2 instance is `ec2-12-345-678-90.compute-1.amazonaws.com`. Your SSH command would look as follows:

   ```
   ssh -i /dir1/ec2-database-connect-key-pair.pem ec2-
   user@ec2-12-345-678-90.compute-1.amazonaws.com
   ```

3. Get the latest bug fixes and security updates by updating the software on your EC2 instance. To do so, use the following command.

   > **Note**
   >
   > The `-y` option installs the updates without asking for confirmation. To examine updates before installing, omit this option.

   ```
   sudo dnf update -y
   ```

4. In a web browser, go to https://www.oracle.com/database/technologies/instant-client/linux-x86-64-downloads.html.
5. For the latest database version that appears on the web page, copy the .rpm links (not the .zip links) for the Instant Client Basic Package and SQL*Plus Package. For example, the following links are for Oracle Database version 21.9:

   - https://download.oracle.com/otn_software/linux/instantclient/219000/oracle-instantclient-basic-21.9.0.0.0-1.el8.x86_64.rpm
   - https://download.oracle.com/otn_software/linux/instantclient/219000/oracle-instantclient-sqlplus-21.9.0.0.0-1.el8.x86_64.rpm

6. In your SSH session, run the `wget` command to the download the .rpm files from the links that you obtained in the previous step. The following example downloads the .rpm files for Oracle Database version 21.9:

   ```
   wget https://download.oracle.com/otn_software/linux/instantclient/219000/oracle-instantclient-basic-21.9.0.0.0-1.el8.x86_64.rpm
   wget https://download.oracle.com/otn_software/linux/instantclient/219000/oracle-instantclient-sqlplus-21.9.0.0.0-1.el8.x86_64.rpm
   ```

7. Install the packages by running the `dnf` command as follows:

   ```
   sudo dnf install oracle-instantclient-*.rpm
   ```

8. Start SQL*Plus and connect to the Oracle DB instance. For example, enter the following command.

Substitute the DB instance endpoint (DNS name) for *oracle-db-instance-endpoint* and substitute the master user name that you used for *admin*. When you use **Easy create** for Oracle, the database name is DATABASE. Provide the master password that you used when prompted for a password.

```
sqlplus admin@oracle-db-instance-endpoint:1521/DATABASE
```

After you enter the password for the user, you should see output similar to the following.

```
SQL*Plus: Release 21.0.0.0.0 - Production on Wed Mar 1 16:41:28 2023
Version 21.9.0.0.0

Copyright (c) 1982, 2022, Oracle.  All rights reserved.

Enter password:
Last Successful login time: Wed Mar 01 2023 16:30:52 +00:00

Connected to:
Oracle Database 19c Standard Edition 2 Release 19.0.0.0.0 - Production
Version 19.18.0.0.0

SQL>
```

For more information about connecting to an RDS for Oracle DB instance, see Connecting to your RDS for Oracle DB instance. If you can't connect to your DB instance, see Can't connect to Amazon RDS DB instance.

For security, it is a best practice to use encrypted connections. Only use an unencrypted Oracle connection when the client and server are in the same VPC and the network is trusted. For information about using encrypted connections, see Securing Oracle DB instance connections.

9. Run SQL commands.

   For example, the following SQL command shows the current date:

```
SELECT SYSDATE FROM DUAL;
```

Step 4: Delete the EC2 instance and DB instance

After you connect to and explore the sample EC2 instance and DB instance that you created, delete them so you're no longer charged for them.

If you used AWS CloudFormation to create resources, skip this step and go to the next step.

To delete the EC2 instance

1. Sign in to the AWS Management Console and open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select the EC2 instance, and choose **Instance state, Terminate instance**.
4. Choose **Terminate** when prompted for confirmation.

For more information about deleting an EC2 instance, see Terminate your instance in the *Amazon EC2 User Guide*.

To delete the DB instance with no final DB snapshot

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.
3. Choose the DB instance that you want to delete.
4. For **Actions**, choose **Delete**.
5. Clear **Create final snapshot?** and **Retain automated backups**.
6. Complete the acknowledgement and choose **Delete**.

(Optional) Delete the EC2 instance and DB instance created with CloudFormation

If you used AWS CloudFormation to create resources, delete the CloudFormation stack after you connect to and explore the sample EC2 instance and DB instance, so you're no longer charged for them.

To delete the CloudFormation resources

1. Open the AWS CloudFormation console.
2. On the **Stacks** page in the CloudFormationconsole, select the root stack (the stack without the name VPCStack, BastionStack or RDSNS).
3. Choose **Delete**.
4. Select **Delete stack** when prompted for confirmation.

For more information about deleting a stack in CloudFormation, see Deleting a stack on the AWS CloudFormation console in the *AWS CloudFormation User Guide*.

(Optional) Connect your DB instance to a Lambda function

You can also connect your RDS for Oracle DB instance to a Lambda serverless compute resource. Lambda functions allow you to run code without provisioning or managing infrastructure. A Lambda function also allows you to automatically respond to code execution requests at any scale, from a dozen events a day to hundreds of per second. For more information, see Automatically connecting a Lambda function and a DB instance.

Creating and connecting to a PostgreSQL DB instance

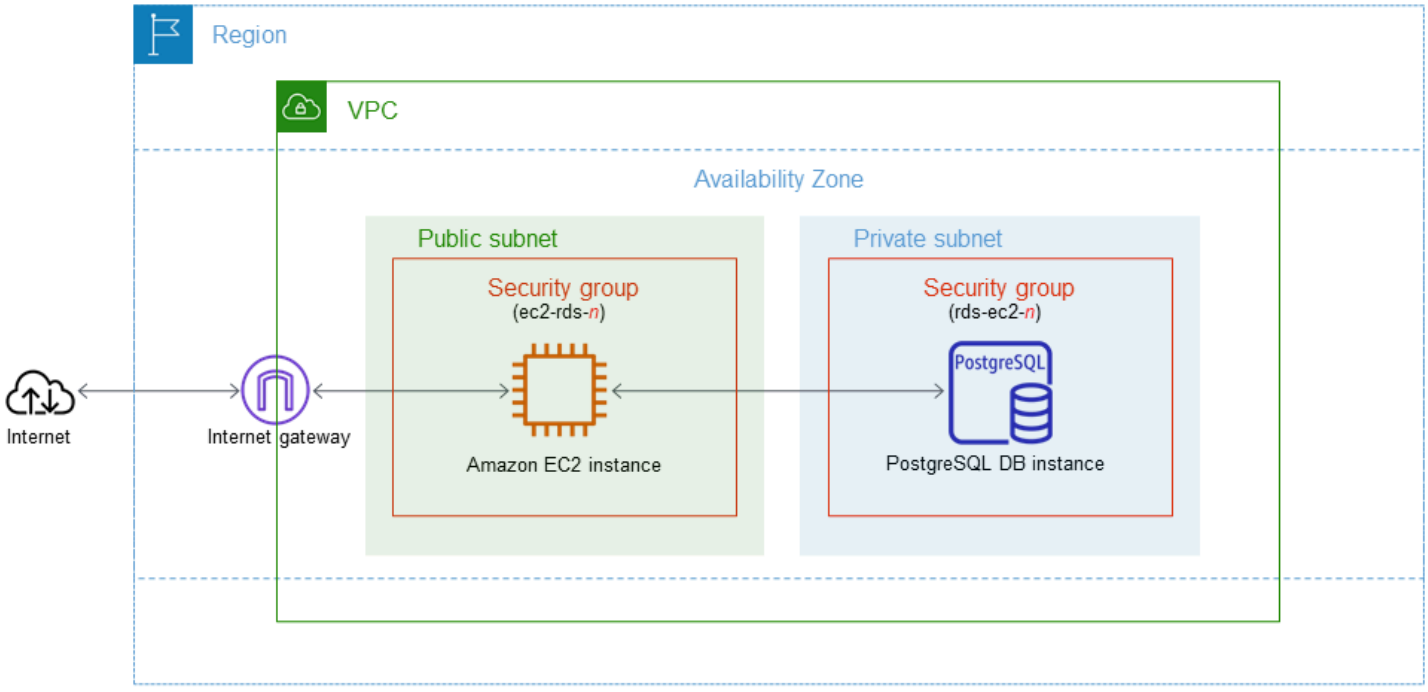
This tutorial creates an EC2 instance and an RDS for PostgreSQL DB instance. The tutorial shows you how to access the DB instance from the EC2 instance using a standard PostgreSQL client. As a best practice, this tutorial creates a private DB instance in a virtual private cloud (VPC). In most cases, other resources in the same VPC, such as EC2 instances, can access the DB instance, but resources outside of the VPC can't access it.

After you complete the tutorial, there is a public and private subnet in each Availability Zone in your VPC. In one Availability Zone, the EC2 instance is in the public subnet, and the DB instance is in the private subnet.

Important

There's no charge for creating an AWS account. However, by completing this tutorial, you might incur costs for the AWS resources you use. You can delete these resources after you complete the tutorial if they are no longer needed.

The following diagram shows the configuration when the tutorial is complete.



This tutorial allows you to create your resources by using one of the following methods:

1. Use the AWS Management Console - Step 1: Create an EC2 instance and Step 2: Create a PostgreSQL DB instance
2. Use AWS CloudFormation to create the database instance and EC2 instance - (Optional) Create VPC, EC2 instance, and PostgreSQL instance using AWS CloudFormation

The first method uses **Easy create** to create a private PostgreSQL DB instance with the AWS Management Console. Here, you specify only the DB engine type, DB instance size, and DB instance identifier. **Easy create** uses the default settings for the other configuration options.

When you use **Standard create** instead, you can specify more configuration options when you create a DB instance. These options include settings for availability, security, backups, and maintenance. To create a public DB instance, you must use **Standard create**. For information, see Creating an Amazon RDS DB instance.

Topics

Prerequisites

Before you begin, complete the steps in the following sections:

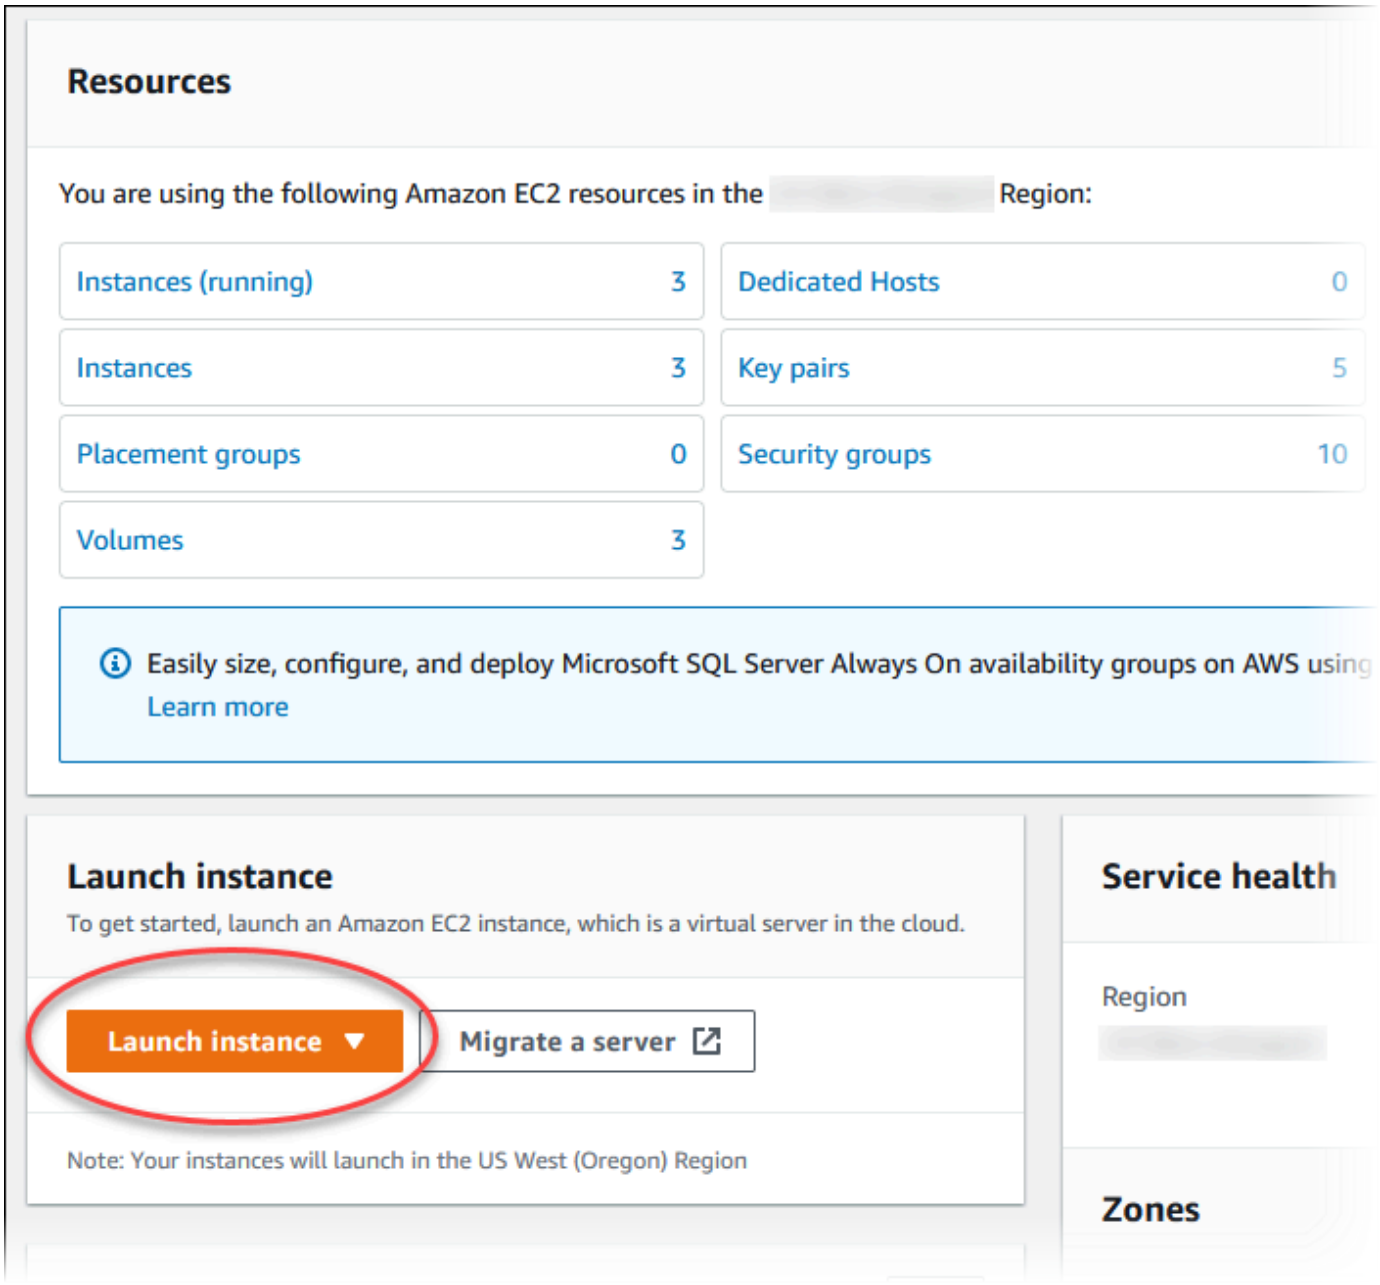
- Sign up for an AWS account
- Create a user with administrative access

Step 1: Create an EC2 instance

Create an Amazon EC2 instance that you will use to connect to your database.

To create an EC2 instance

1. Sign in to the AWS Management Console and open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the upper-right corner of the AWS Management Console, choose the AWS Region in which you want to create the EC2 instance.
3. Choose **EC2 Dashboard**, and then choose **Launch instance**, as shown in the following image.



The **Launch an instance** page opens.

4. Choose the following settings on the **Launch an instance** page.

   a. Under **Name and tags**, for **Name**, enter **`ec2-database-connect`**.

   b. Under **Application and OS Images (Amazon Machine Image)**, choose **Amazon Linux**, and then choose the **Amazon Linux 2023 AMI**. Keep the default selections for the other choices.

   c. Under **Instance type**, choose **t2.micro**.

   d. Under **Key pair (login)**, choose a **Key pair name** to use an existing key pair. To create a new key pair for the Amazon EC2 instance, choose **Create new key pair** and then use the **Create key pair** window to create it.

For more information about creating a new key pair, see Create a key pair in the *Amazon EC2 User Guide*.

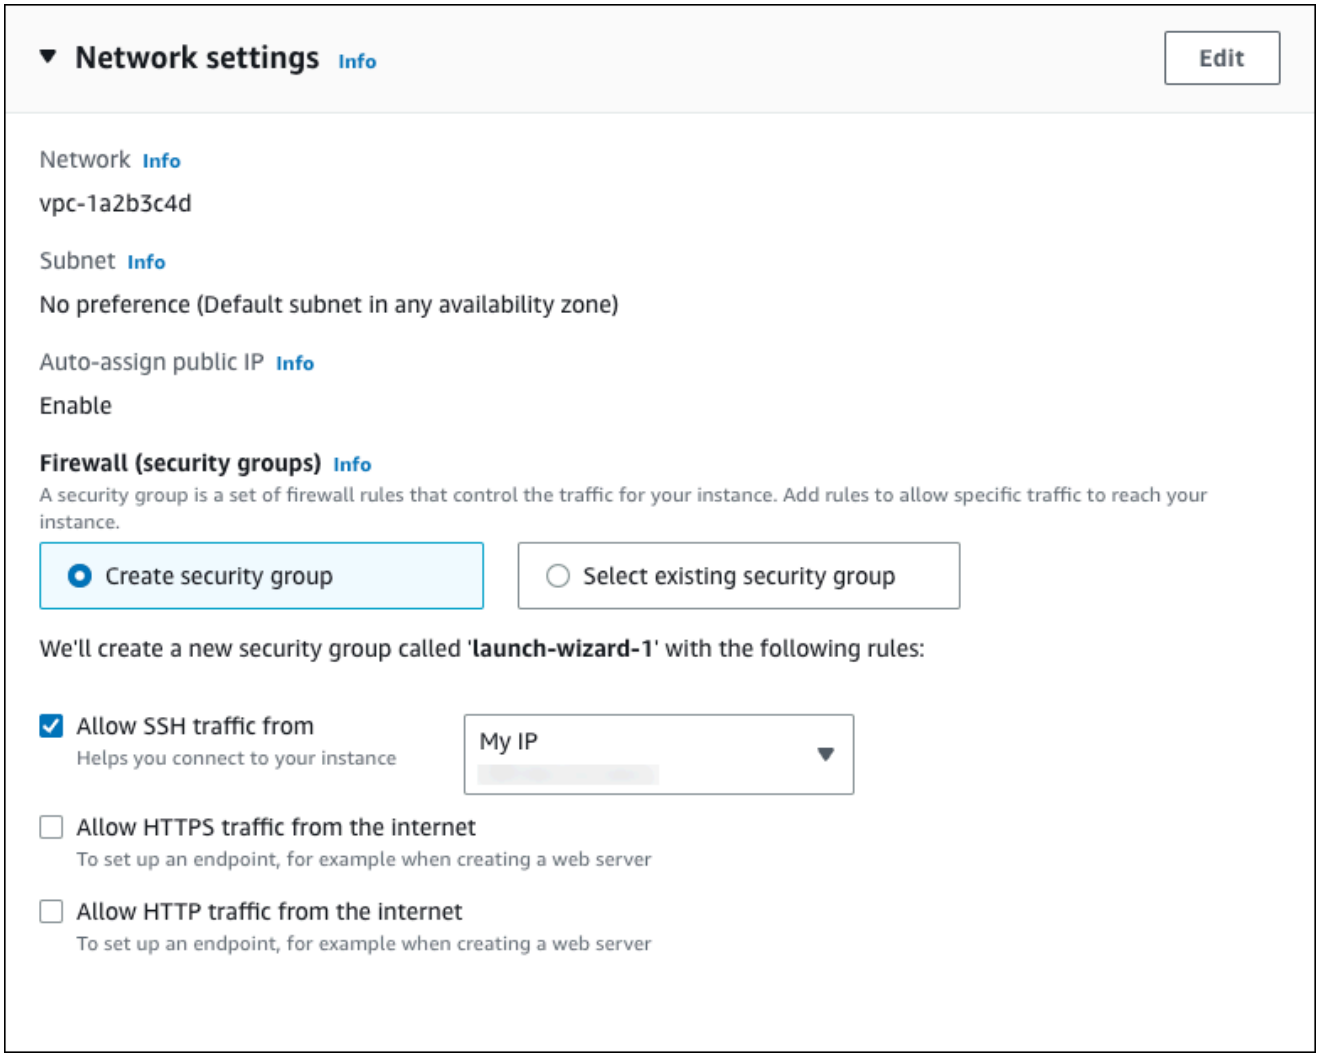
e. For **Allow SSH traffic** in **Network settings**, choose the source of SSH connections to the EC2 instance.

You can choose **My IP** if the displayed IP address is correct for SSH connections. Otherwise, you can determine the IP address to use to connect to EC2 instances in your VPC using Secure Shell (SSH). To determine your public IP address, in a different browser window or tab, you can use the service at https://checkip.amazonaws.com. An example of an IP address is 192.0.2.1/32.

In many cases, you might connect through an internet service provider (ISP) or from behind your firewall without a static IP address. If so, make sure to determine the range of IP addresses used by client computers.

> **Warning**
>
> If you use `0.0.0.0/0` for SSH access, you make it possible for all IP addresses to access your public EC2 instances using SSH. This approach is acceptable for a short time in a test environment, but it's unsafe for production environments. In production, authorize only a specific IP address or range of addresses to access your EC2 instances using SSH.

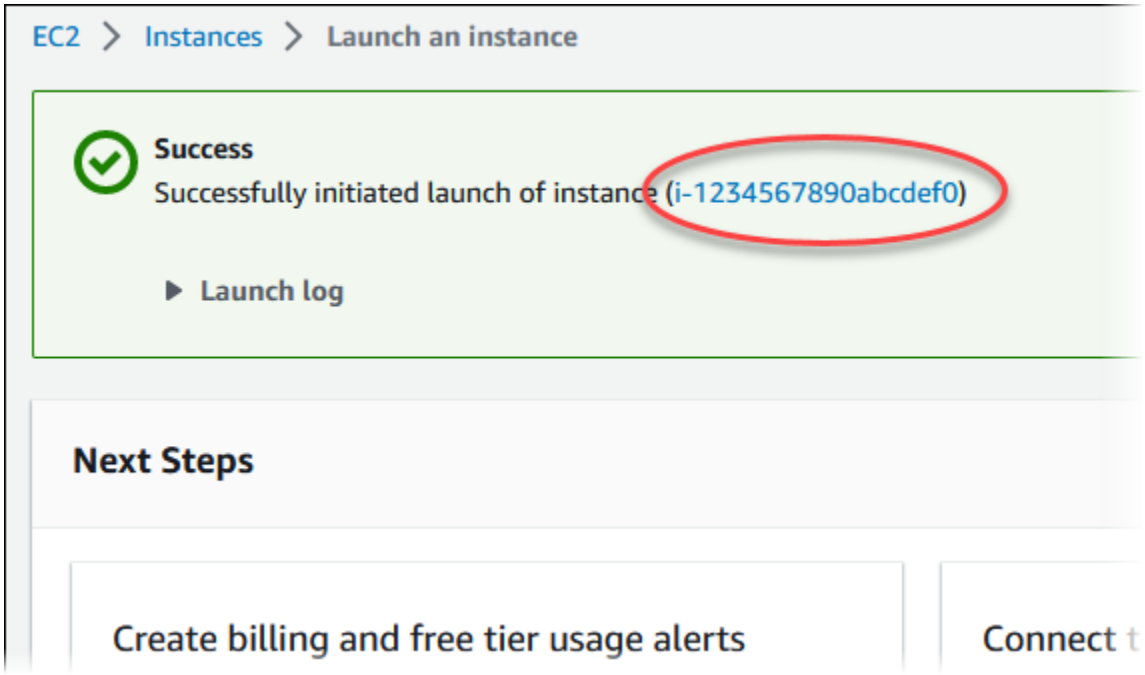
The following image shows an example of the **Network settings** section.



f. Leave the default values for the remaining sections.

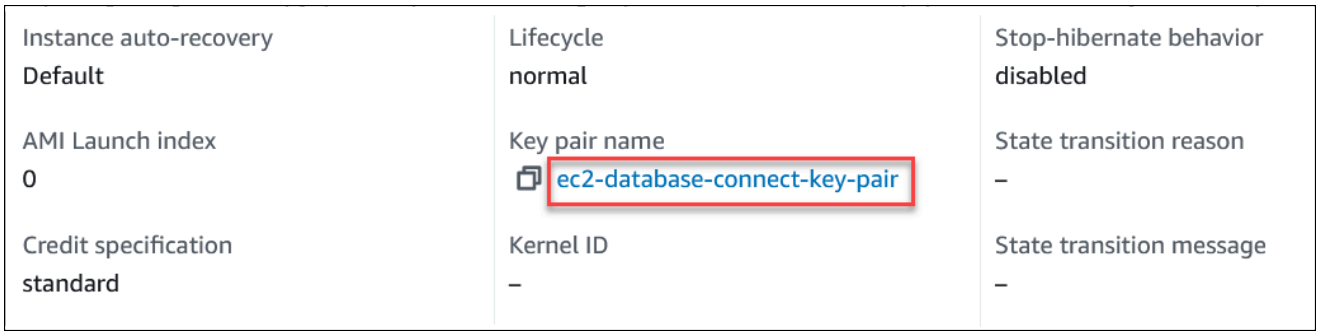
g. Review a summary of your EC2 instance configuration in the **Summary** panel, and when you're ready, choose **Launch instance**.

5. On the **Launch Status** page, note the identifier for your new EC2 instance, for example: `i-1234567890abcdef0`.



6. Choose the EC2 instance identifier to open the list of EC2 instances, and then select your EC2 instance.
7. In the **Details** tab, note the following values, which you need when you connect using SSH:
   a. In **Instance summary**, note the value for **Public IPv4 DNS**.

   b. In **Instance details**, note the value for **Key pair name**.



8. Wait until the **Instance state** for your EC2 instance has a status of **Running** before continuing.

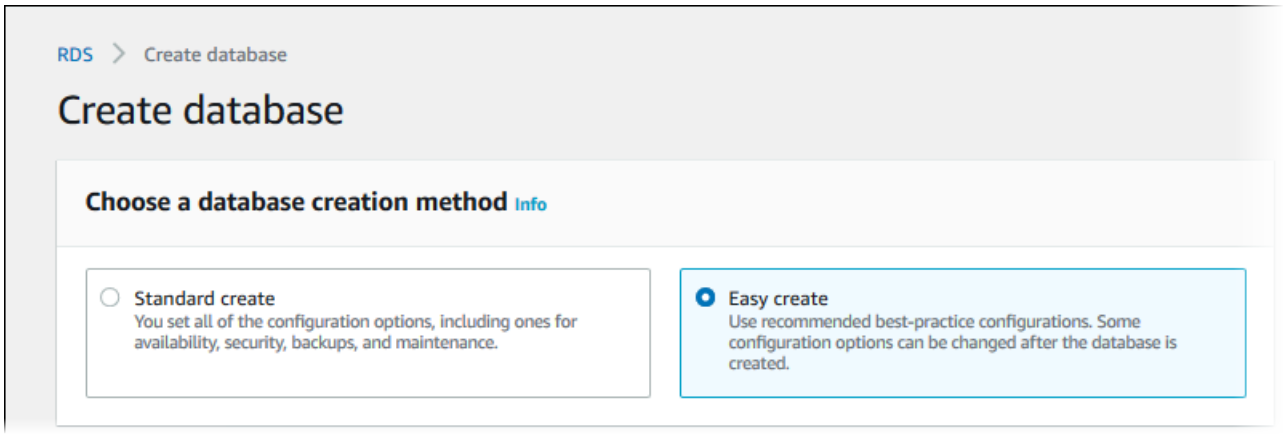
Step 2: Create a PostgreSQL DB instance

The basic building block of Amazon RDS is the DB instance. This environment is where you run your PostgreSQL databases.

In this example, you use **Easy create** to create a DB instance running the PostgreSQL database engine with a db.t3.micro DB instance class.

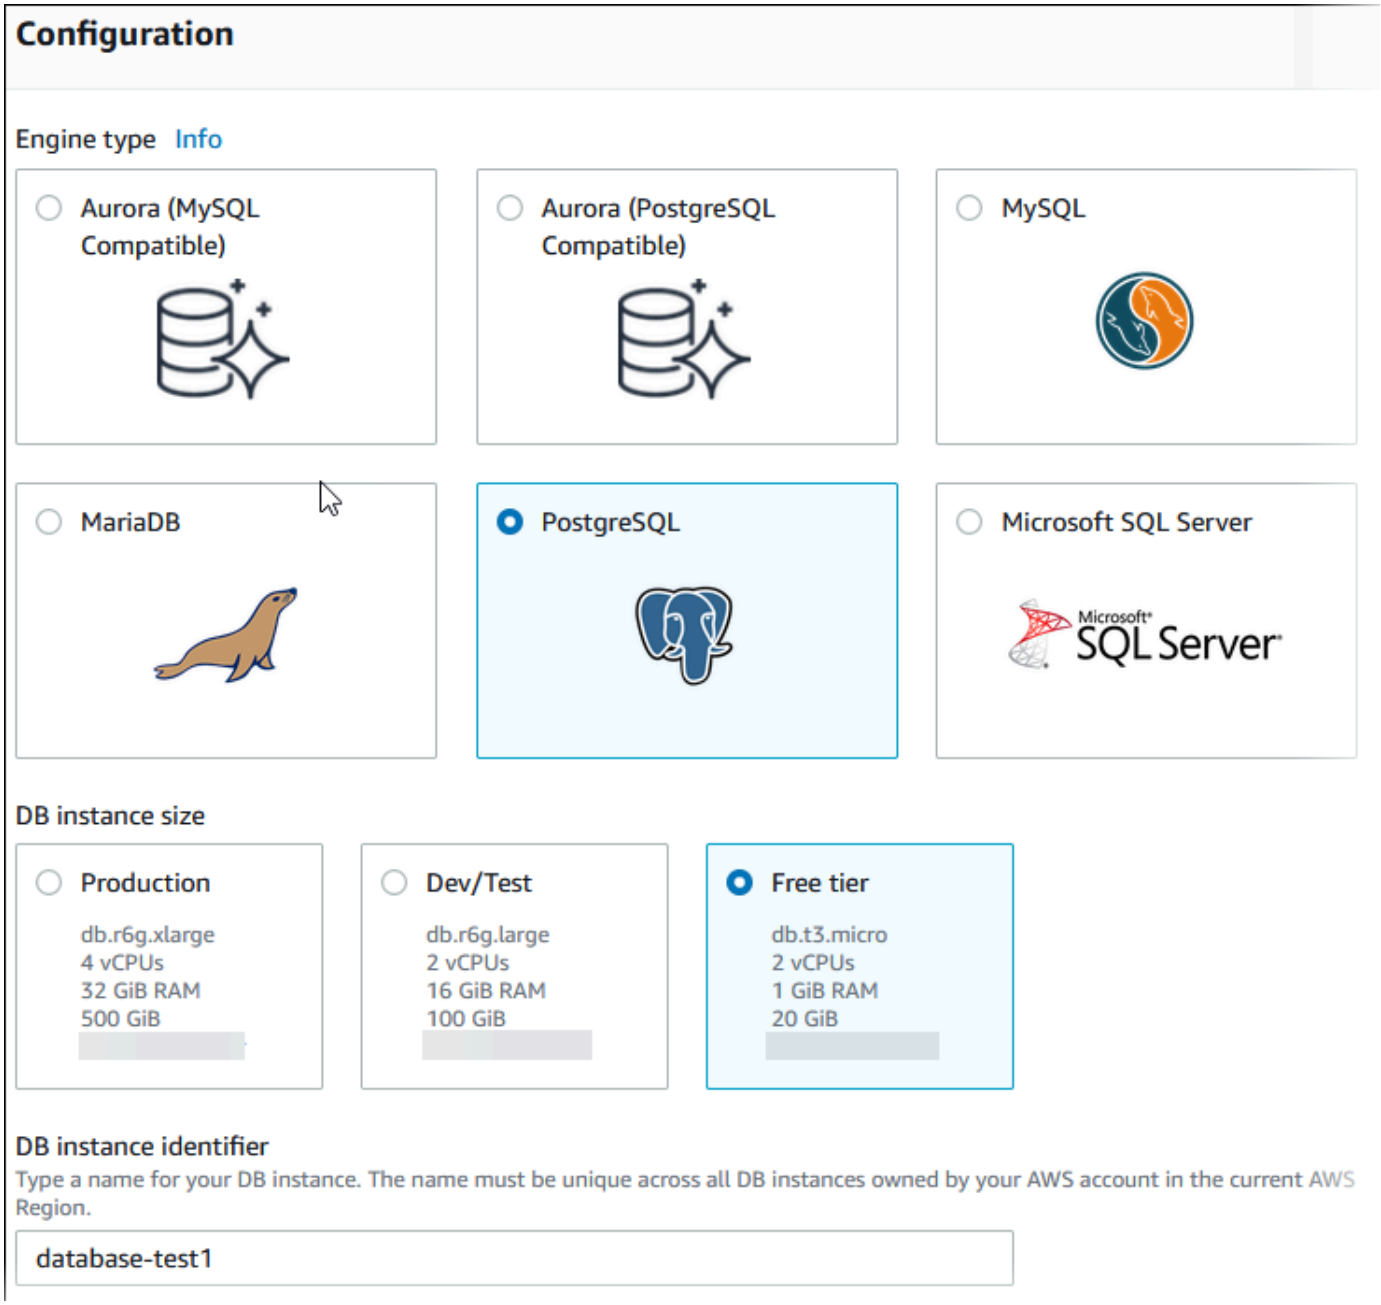
To create a PostgreSQL DB instance with Easy create

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the upper-right corner of the Amazon RDS console, choose the AWS Region in which you want to create the DB instance.
3. In the navigation pane, choose **Databases**.
4. Choose **Create database** and make sure that **Easy create** is chosen.



5. In **Configuration**, choose **PostgreSQL**.
6. For **DB instance size**, choose **Free tier**.
7. For **DB instance identifier**, enter **`database-test1`**.
8. For **Master username**, enter a name for the master user, or keep the default name (**`postgres`**).

   The **Create database** page should look similar to the following image.

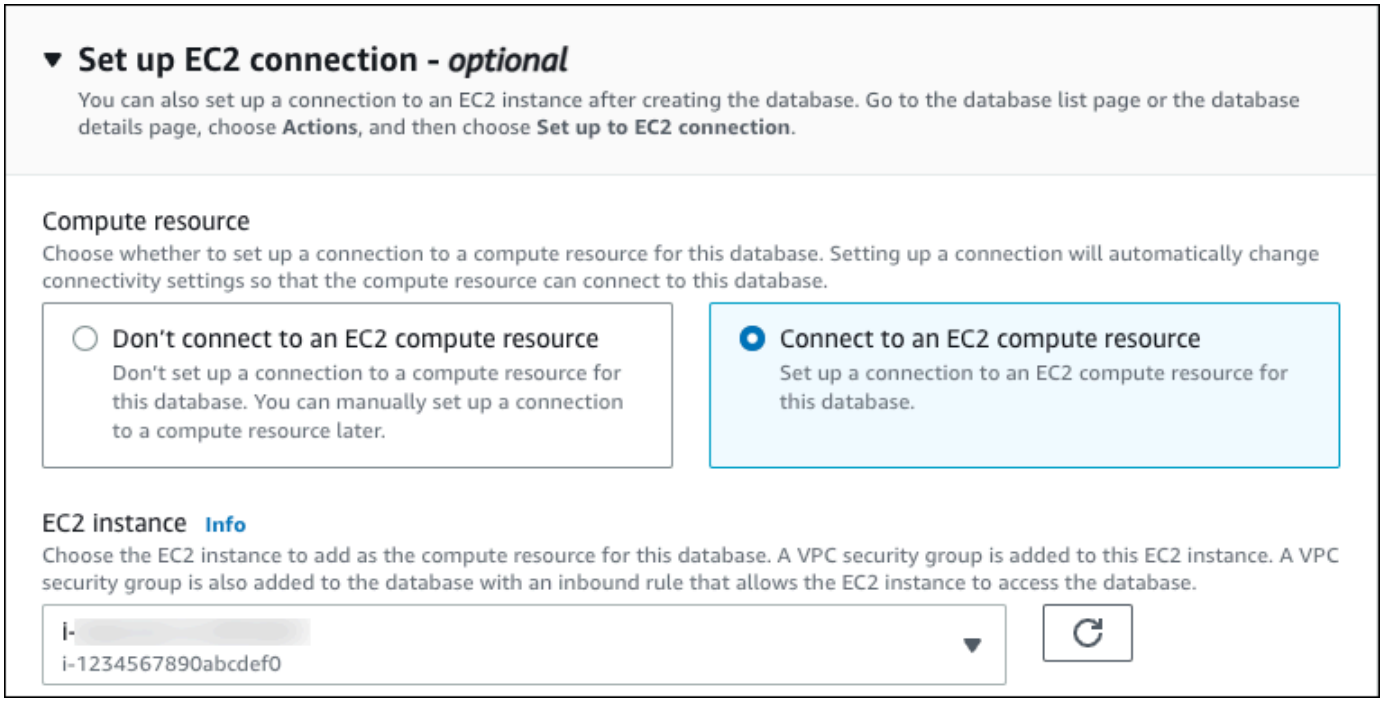


9. To use an automatically generated master password for the DB instance, select **Auto generate a password**.

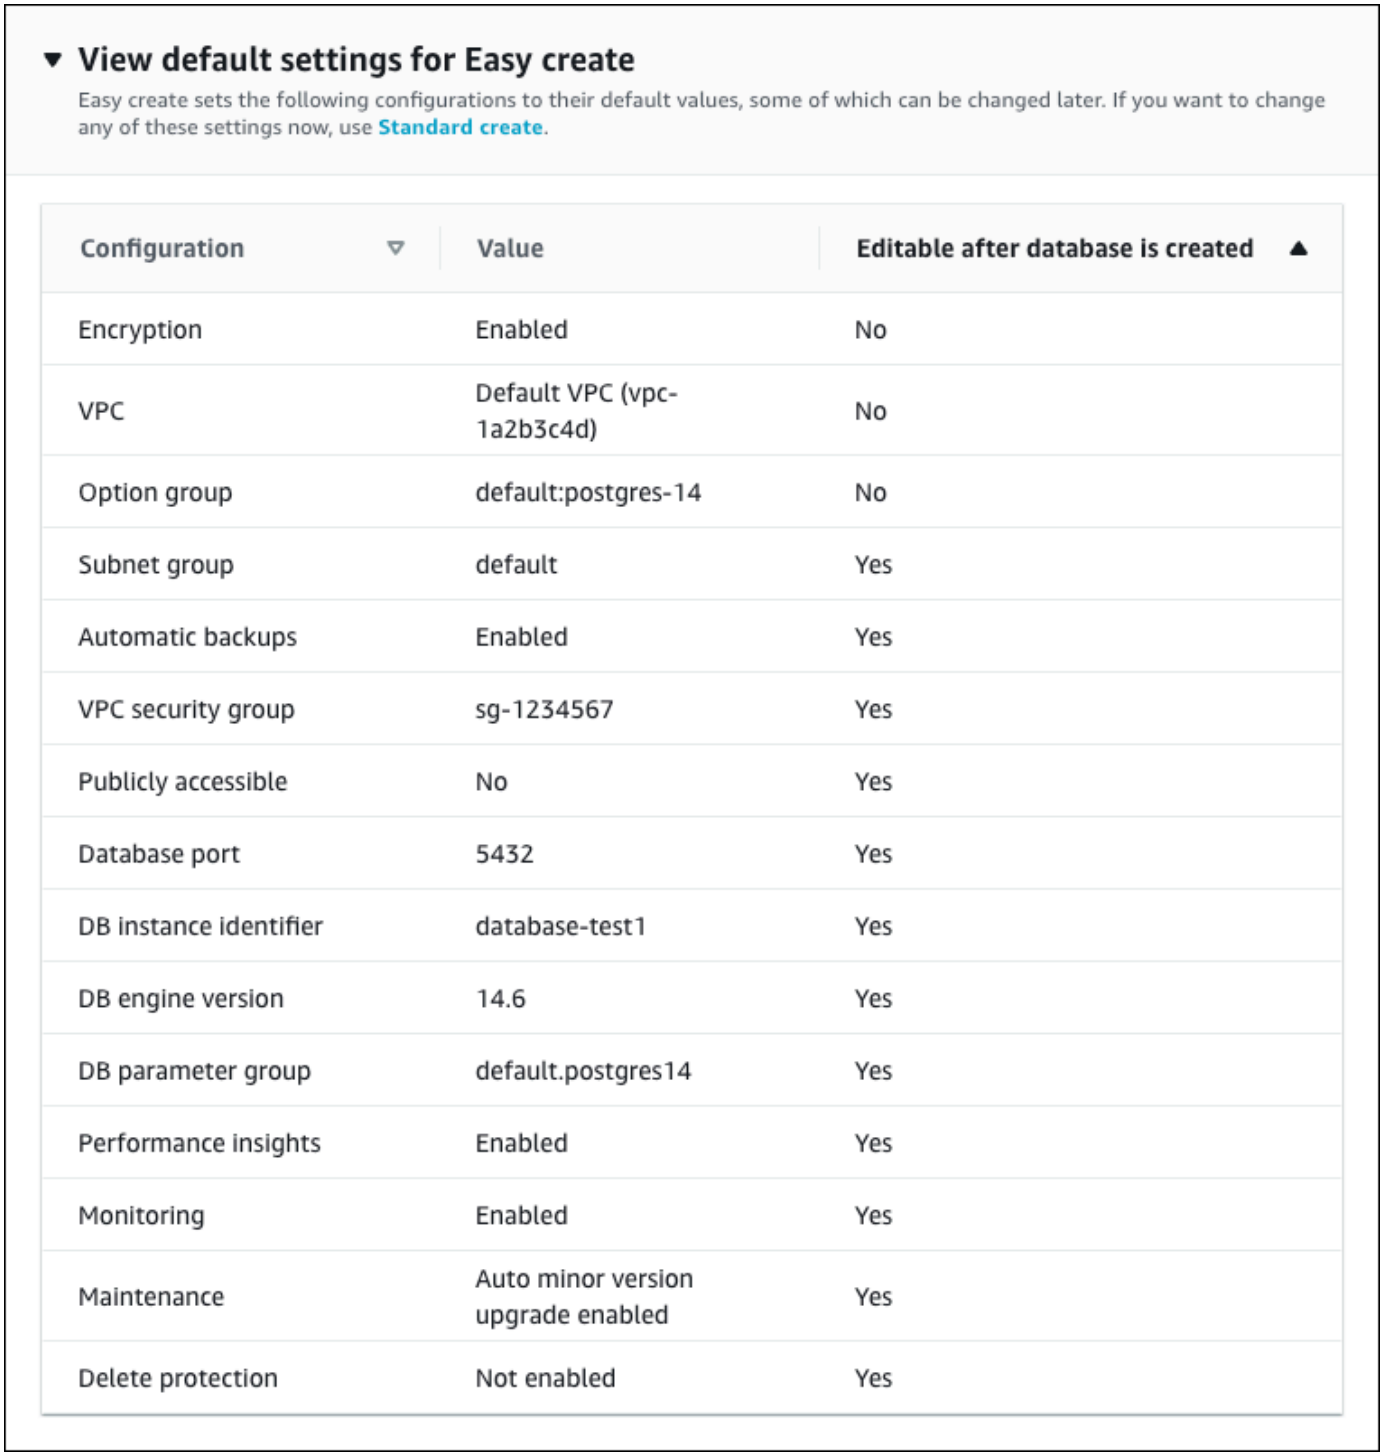
   To enter your master password, make sure **Auto generate a password** is cleared, and then enter the same password in **Master password** and **Confirm password**.

10. To set up a connection with the EC2 instance you created previously, open **Set up EC2 connection - *optional***.

    Select **Connect to an EC2 compute resource**. Choose the EC2 instance you created previously.



11. Open **View default settings for Easy create**.



View default settings for Easy create

Easy create sets the following configurations to their default values, some of which can be changed later. If you want to change any of these settings now, use **Standard create**.

Configuration	Value	Editable after database is created
Encryption	Enabled	No
VPC	Default VPC (vpc-1a2b3c4d)	No
Option group	default:postgres-14	No
Subnet group	default	Yes
Automatic backups	Enabled	Yes
VPC security group	sg-1234567	Yes
Publicly accessible	No	Yes
Database port	5432	Yes
DB instance identifier	database-test1	Yes
DB engine version	14.6	Yes
DB parameter group	default.postgres14	Yes
Performance insights	Enabled	Yes
Monitoring	Enabled	Yes
Maintenance	Auto minor version upgrade enabled	Yes
Delete protection	Not enabled	Yes

You can examine the default settings used with **Easy create**. The **Editable after database is created** column shows which options you can change after you create the database.

- If a setting has **No** in that column, and you want a different setting, you can use **Standard create** to create the DB instance.

- If a setting has **Yes** in that column, and you want a different setting, you can either use **Standard create** to create the DB instance, or modify the DB instance after you create it to change the setting.

12. Choose **Create database**.

    To view the master username and password for the DB instance, choose **View credential details**.

    You can use the username and password that appears to connect to the DB instance as the master user.

    > **Important**
    >
    > You can't view the master user password again. If you don't record it, you might have to change it.
    > If you need to change the master user password after the DB instance is available, you can modify the DB instance to do so. For more information about modifying a DB instance, see Modifying an Amazon RDS DB instance.

13. In the **Databases** list, choose the name of the new PostgreSQL DB instance to show its details.

    The DB instance has a status of **Creating** until it is ready to use.

    When the status changes to **Available**, you can connect to the DB instance. Depending on the DB instance class and the amount of storage, it can take up to 20 minutes before the new instance is available.

(Optional) Create VPC, EC2 instance, and PostgreSQL instance using AWS CloudFormation

Instead of using the console to create your VPC, EC2 instance, and PostgreSQL instance, you can use AWS CloudFormation to provision AWS resources by treating infrastructure as code. To help you organize your AWS resources into smaller and more manageable units, you can use the AWS CloudFormation nested stack functionality. For more information, see Creating a stack on the AWS CloudFormation console and Working with nested stacks.

Important

AWS CloudFormation is free, but the resources that CloudFormation creates are live. You incur the standard usage fees for these resources until you terminate them. The total charges will be minimal. For information about how you might minimize any charges, go to AWS Free Tier.

To create your resources using the AWS CloudFormation console, complete the following steps:

- Step 1: Download the CloudFormation template
- Step 2: Configure your resources using CloudFormation

Download the CloudFormation template

A CloudFormation template is a JSON or YAML text file that contains the configuration information about the resources you want to create in the stack. This template also creates a VPC and a bastion host for you along with the RDS instance.

To download the template file, open the following link, PostgreSQL CloudFormation template.

In the Github page, click the *Download raw file* button to save the template YAML file.

Configure your resources using CloudFormation

Note

Before starting this process, make sure you have a Key pair for an EC2 instance in your AWS account. For more information, see Amazon EC2 key pairs and Linux instances.

When you use the AWS CloudFormation template, you must select the correct parameters to make sure your resources are created properly. Follow the steps below:

1. Sign in to the AWS Management Console and open the AWS CloudFormation console at https://console.aws.amazon.com/cloudformation.
2. Choose **Create Stack**.
3. In the Specify template section, select **Upload a template file from your computer**, and then choose **Next**.
4. In the **Specify stack details** page, set the following parameters:
   a. Set **Stack name** to **PostgreSQLTestStack**.
   b. Under **Parameters**, set **Availability Zones** by selecting three availability zones.
   c. Under **Linux Bastion Host configuration**, for **Key Name**, select a key pair to login to your EC2 instance.
   d. In **Linux Bastion Host configuration** settings, set the **Permitted IP range** to your IP address. To connect to EC2 instances in your VPC using Secure Shell (SSH), determine your public IP address using the service at https://checkip.amazonaws.com. An example of an IP address is 192.0.2.1/32.

      > **Warning**
      >
      > If you use `0.0.0.0/0` for SSH access, you make it possible for all IP addresses to access your public EC2 instances using SSH. This approach is acceptable for a short time in a test environment, but it's unsafe for production environments. In production, authorize only a specific IP address or range of addresses to access your EC2 instances using SSH.

   e. Under **Database General configuration**, set **Database instance class** to **db.t3.micro**.
   f. Set **Database name** to **`database-test1`**.
   g. For **Database master username**, enter a name for the master user.
   h. Set **Manage DB master user password with Secrets Manager** to `false` for this tutorial.
   i. For **Database password**, set a password of your choice. Remember this password for further steps in the tutorial.
   j. Under **Database Storage configuration**, set **Database storage type** to **gp2**.
   k. Under **Database Monitoring configuration**, set **Enable RDS Performance Insights** to false.

l. Leave all other settings as the default values. Click **Next** to continue.

5. In the **Configure stack options** page, leave all the default options. Click **Next** to continue.
6. In the **Review stack** page, select **Submit** after checking the database and Linux bastion host options.

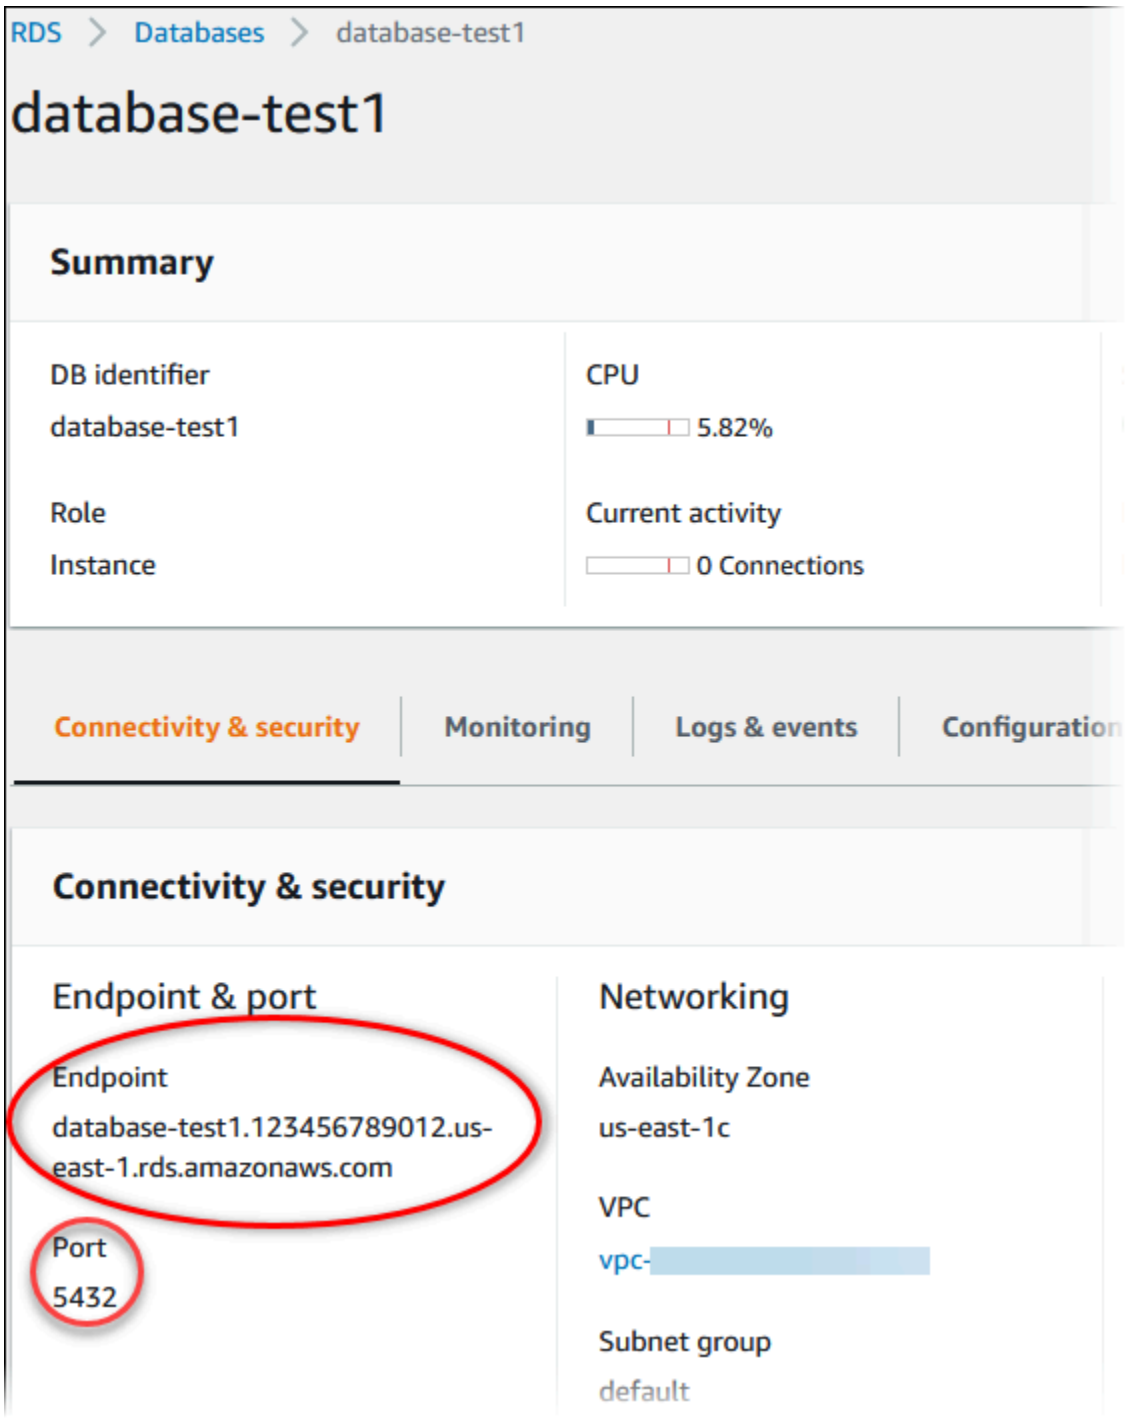
After the stack creation process completes, view the stacks with names *BastionStack* and *RDSNS* to note the information you need to connect to the database. For more information, see Viewing AWS CloudFormation stack data and resources on the AWS Management Console.

Step 3: Connect to a PostgreSQL DB instance

You can connect to the DB instance using pgadmin or psql. This example explains how to connect to a PostgreSQL DB instance using the psql command-line client.

To connect to a PostgreSQL DB instance using psql

1. Find the endpoint (DNS name) and port number for your DB instance.
   a. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
   b. In the upper-right corner of the Amazon RDS console, choose the AWS Region for the DB instance.
   c. In the navigation pane, choose **Databases**.
   d. Choose the PostgreSQL DB instance name to display its details.
   e. On the **Connectivity & security** tab, copy the endpoint. Also note the port number. You need both the endpoint and the port number to connect to the DB instance.



2. Connect to the EC2 instance that you created earlier by following the steps in Connect to your Linux instance in the *Amazon EC2 User Guide*.

   We recommend that you connect to your EC2 instance using SSH. If the SSH client utility is installed on Windows, Linux, or Mac, you can connect to the instance using the following command format:

```
ssh -i location_of_pem_file ec2-user@ec2-instance-public-dns-name
```

For example, assume that `ec2-database-connect-key-pair.pem` is stored in `/dir1` on Linux, and the public IPv4 DNS for your EC2 instance is `ec2-12-345-678-90.compute-1.amazonaws.com`. Your SSH command would look as follows:

```
ssh -i /dir1/ec2-database-connect-key-pair.pem ec2-
user@ec2-12-345-678-90.compute-1.amazonaws.com
```

3. Get the latest bug fixes and security updates by updating the software on your EC2 instance. To do this, use the following command.

> **Note**
>
> The `-y` option installs the updates without asking for confirmation. To examine updates before installing, omit this option.

```
sudo dnf update -y
```

4. To install the psql command-line client from PostgreSQL on Amazon Linux 2023, run the following command:

```
sudo dnf install postgresql15
```

5. Connect to the PostgreSQL DB instance. For example, enter the following command at a command prompt on a client computer. This action lets you connect to the PostgreSQL DB instance using the psql client.

   Substitute the DB instance endpoint (DNS name) for *`endpoint`*, substitute the database name `--dbname` that you want to connect to for *`postgres`*, and substitute the master username that you used for *`postgres`*. Provide the master password that you used when prompted for a password.

```
psql --host=endpoint --port=5432 --dbname=postgres --username=postgres
```

After you enter the password for the user, you should see output similar to the following:

```
psql (14.3, server 14.6)
SSL connection (protocol: TLSv1.2, cipher: ECDHE-RSA-AES256-GCM-SHA384, bits: 256,
 compression: off)
Type "help" for help.

postgres=>
```

For more information on connecting to a PostgreSQL DB instance, see Connecting to a DB instance running the PostgreSQL database engine. If you can't connect to your DB instance, see Troubleshooting connections to your RDS for PostgreSQL instance.

For security, it is a best practice to use encrypted connections. Only use an unencrypted PostgreSQL connection when the client and server are in the same VPC and the network is trusted. For information about using encrypted connections, see Connecting to a PostgreSQL DB instance over SSL.

6. Run SQL commands.

   For example, the following SQL command shows the current date and time:

   ```
   SELECT CURRENT_TIMESTAMP;
   ```

Step 4: Delete the EC2 instance and DB instance

After you connect to and explore the sample EC2 instance and DB instance that you created, delete them so you're no longer charged for them.

If you used AWS CloudFormation to create resources, skip this step and go to the next step.

To delete the EC2 instance

1. Sign in to the AWS Management Console and open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select the EC2 instance, and choose **Instance state, Terminate instance**.
4. Choose **Terminate** when prompted for confirmation.

For more information about deleting an EC2 instance, see Terminate your instance in the *Amazon EC2 User Guide*.

To delete a DB instance with no final DB snapshot

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.
3. Choose the DB instance that you want to delete.
4. For **Actions**, choose **Delete**.
5. Clear **Create final snapshot?** and **Retain automated backups**.
6. Complete the acknowledgement and choose **Delete**.

(Optional) Delete the EC2 instance and DB instance created with CloudFormation

If you used AWS CloudFormation to create resources, delete the CloudFormation stack after you connect to and explore the sample EC2 instance and DB instance, so you're no longer charged for them.

To delete the CloudFormation resources

1. Open the AWS CloudFormation console.
2. On the **Stacks** page in the CloudFormationconsole, select the root stack (the stack without the name VPCStack, BastionStack or RDSNS).
3. Choose **Delete**.
4. Select **Delete stack** when prompted for confirmation.

For more information about deleting a stack in CloudFormation, see Deleting a stack on the AWS CloudFormation console in the *AWS CloudFormation User Guide*.

(Optional) Connect your DB instance to a Lambda function

You can also connect your RDS for PostgreSQL DB instance to a Lambda serverless compute resource. Lambda functions allow you to run code without provisioning or managing infrastructure. A Lambda function also allows you to automatically respond to code execution requests at

any scale, from a dozen events a day to hundreds of per second. For more information, see Automatically connecting a Lambda function and a DB instance.

Tutorial: Create a web server and an Amazon RDS DB instance

This tutorial shows you how to install an Apache web server with PHP and create a MariaDB, MySQL, or PostgreSQL database. The web server runs on an Amazon EC2 instance using Amazon Linux 2023, and you can choose between a MySQL or PostgreSQL DB instance. Both the Amazon EC2 instance and the DB instance run in a virtual private cloud (VPC) based on the Amazon VPC service.

Important

There's no charge for creating an AWS account. However, by completing this tutorial, you might incur costs for the AWS resources you use. You can delete these resources after you complete the tutorial if they are no longer needed.

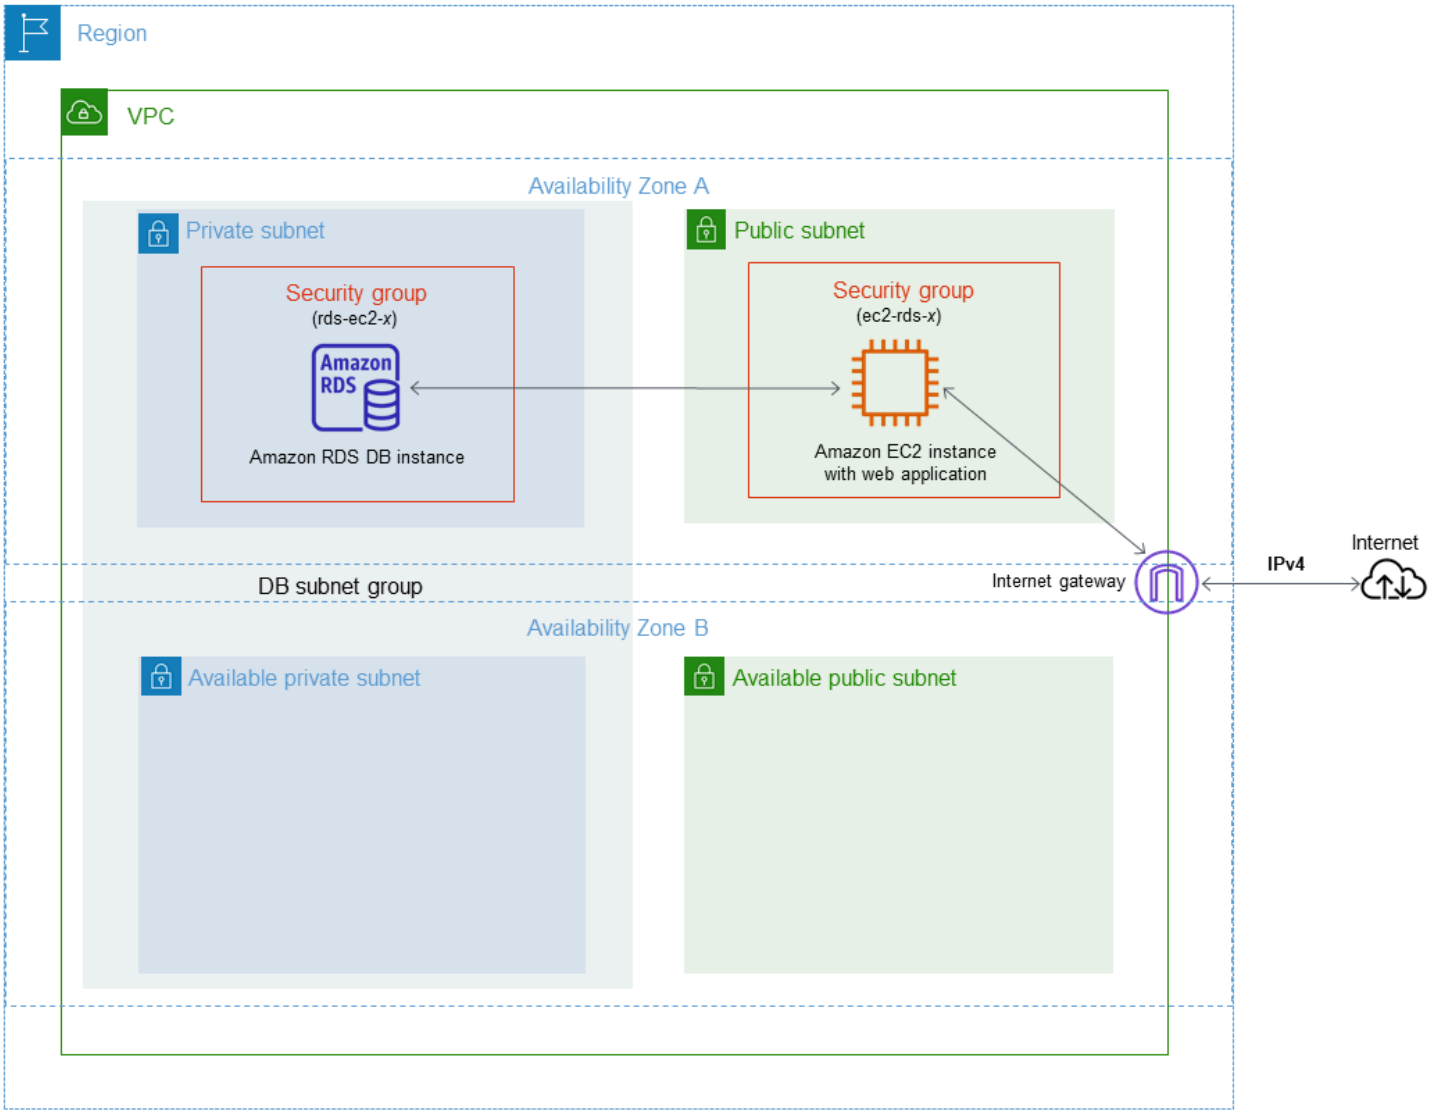
Note

This tutorial works with Amazon Linux 2023 and might not work for other versions of Linux.

In the tutorial that follows, you create an EC2 instance that uses the default VPC, subnets, and security group for your AWS account. This tutorial shows you how to create the DB instance and automatically set up connectivity with the EC2 instance that you created. The tutorial then shows you how to install the web server on the EC2 instance. You connect your web server to your DB instance in the VPC using the DB instance endpoint.

1. Launch an EC2 instance to connect with your DB instance
2. Create an Amazon RDS DB instance
3. Install a web server on your EC2 instance

The following diagram shows the configuration when the tutorial is complete.



Note

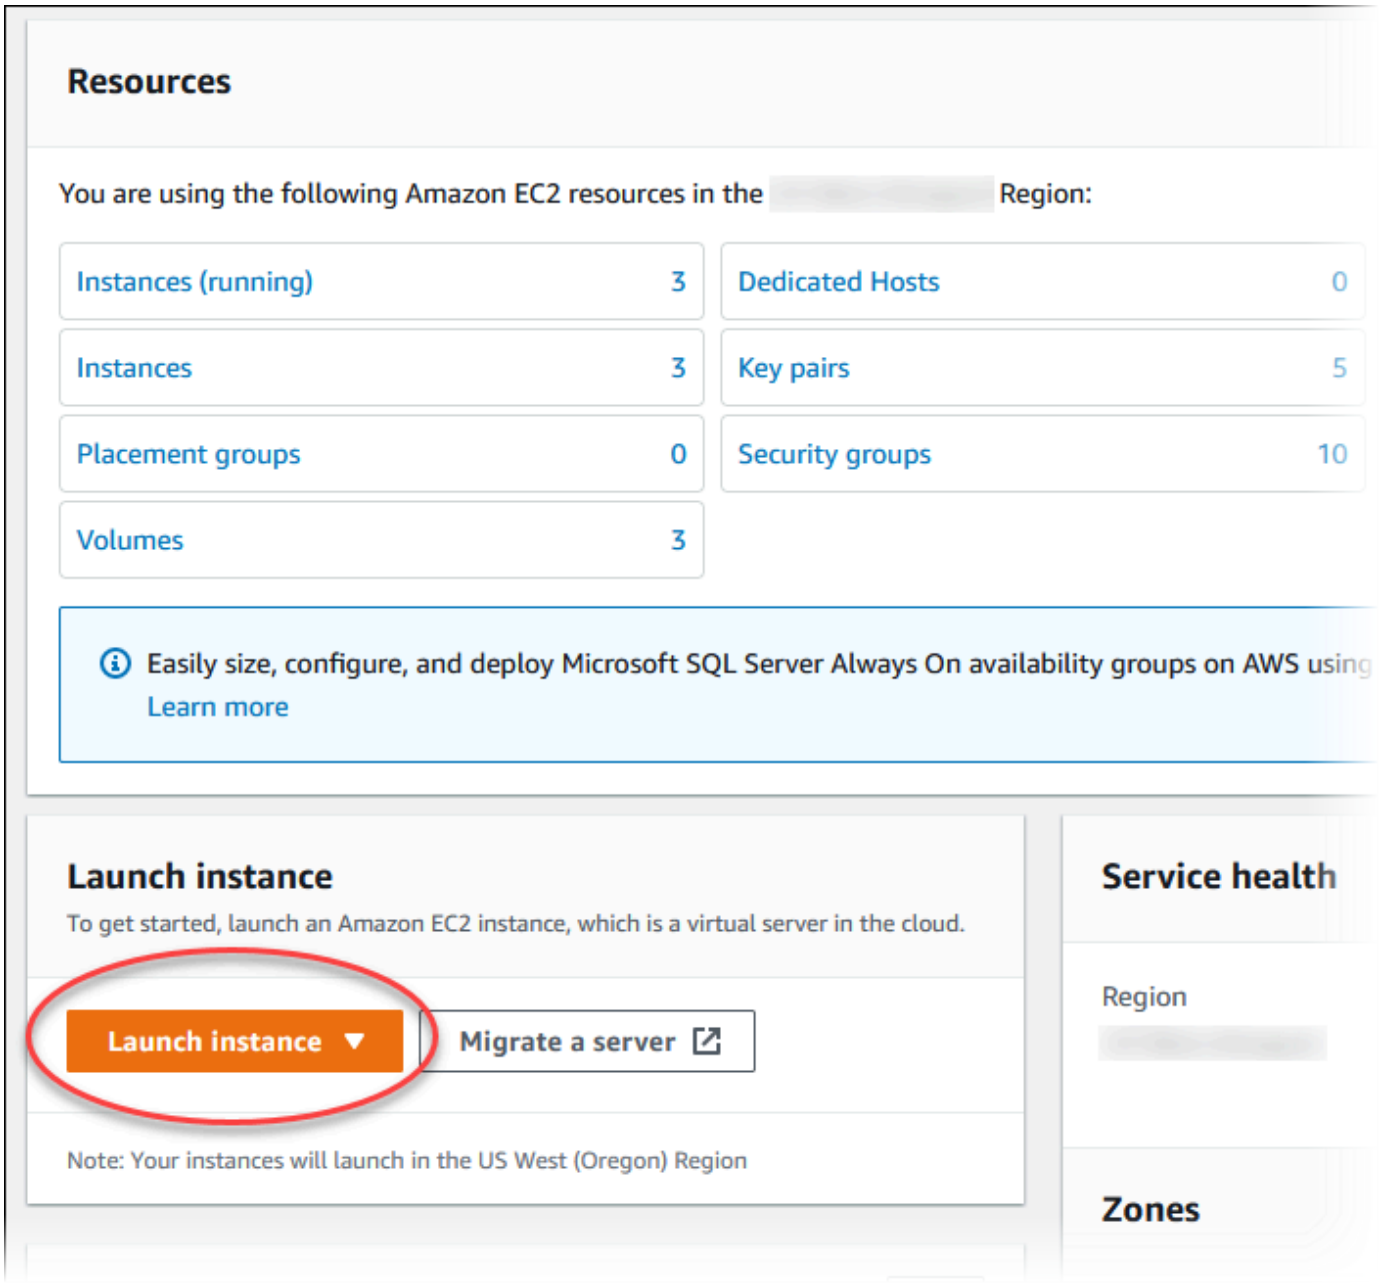
After you complete the tutorial, there is a public and private subnet in each Availability Zone in your VPC. This tutorial uses the default VPC for your AWS account and automatically sets up connectivity between your EC2 instance and DB instance. If you would rather configure a new VPC for this scenario instead, complete the tasks in Tutorial: Create a VPC for use with a DB instance (IPv4 only).

Launch an EC2 instance to connect with your DB instance

Create an Amazon EC2 instance in the public subnet of your VPC.

To launch an EC2 instance

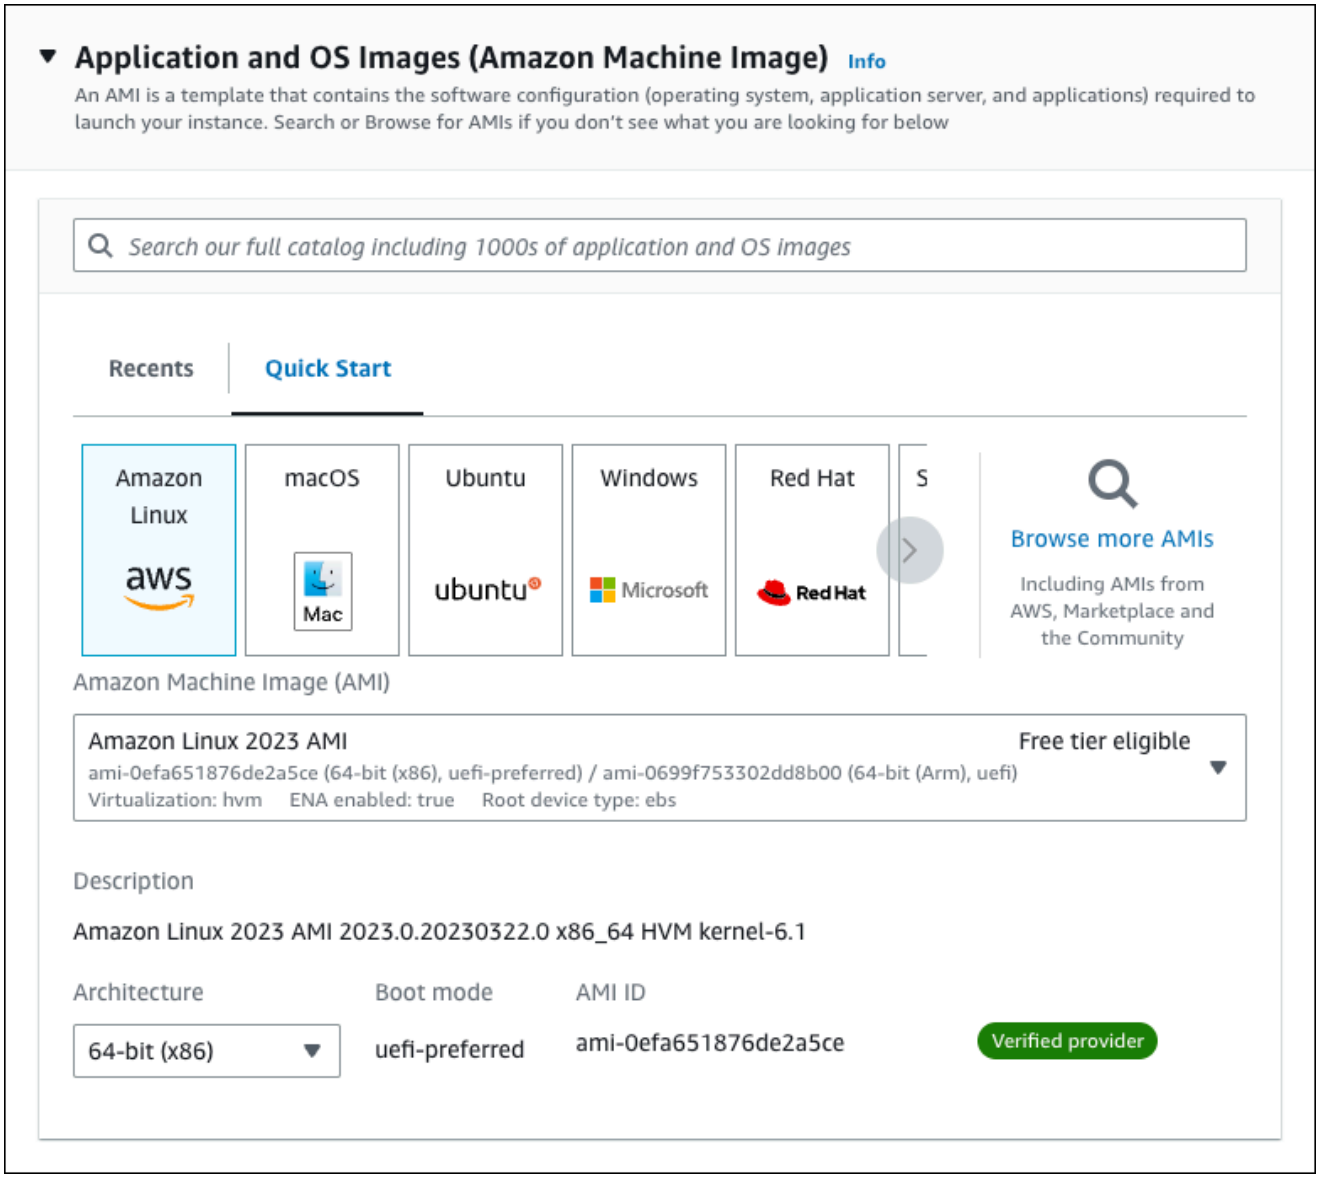
1. Sign in to the AWS Management Console and open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the upper-right corner of the AWS Management Console, choose the AWS Region where you want to create the EC2 instance.
3. Choose **EC2 Dashboard**, and then choose **Launch instance**, as shown following.



4. Choose the following settings in the **Launch an instance** page.

a. Under **Name and tags**, for **Name**, enter **`tutorial-ec2-instance-web-server`**.

b. Under **Application and OS Images (Amazon Machine Image)**, choose **Amazon Linux**, and then choose the **Amazon Linux 2023 AMI**. Keep the defaults for the other choices.



c. Under **Instance type**, choose **t2.micro**.

d. Under **Key pair (login)**, choose a **Key pair name** to use an existing key pair. To create a new key pair for the Amazon EC2 instance, choose **Create new key pair** and then use the **Create key pair** window to create it.

   For more information about creating a new key pair, see Create a key pair in the *Amazon EC2 User Guide*.

e. Under **Network settings**, set these values and keep the other values as their defaults:

- For **Allow SSH traffic from**, choose the source of SSH connections to the EC2 instance.

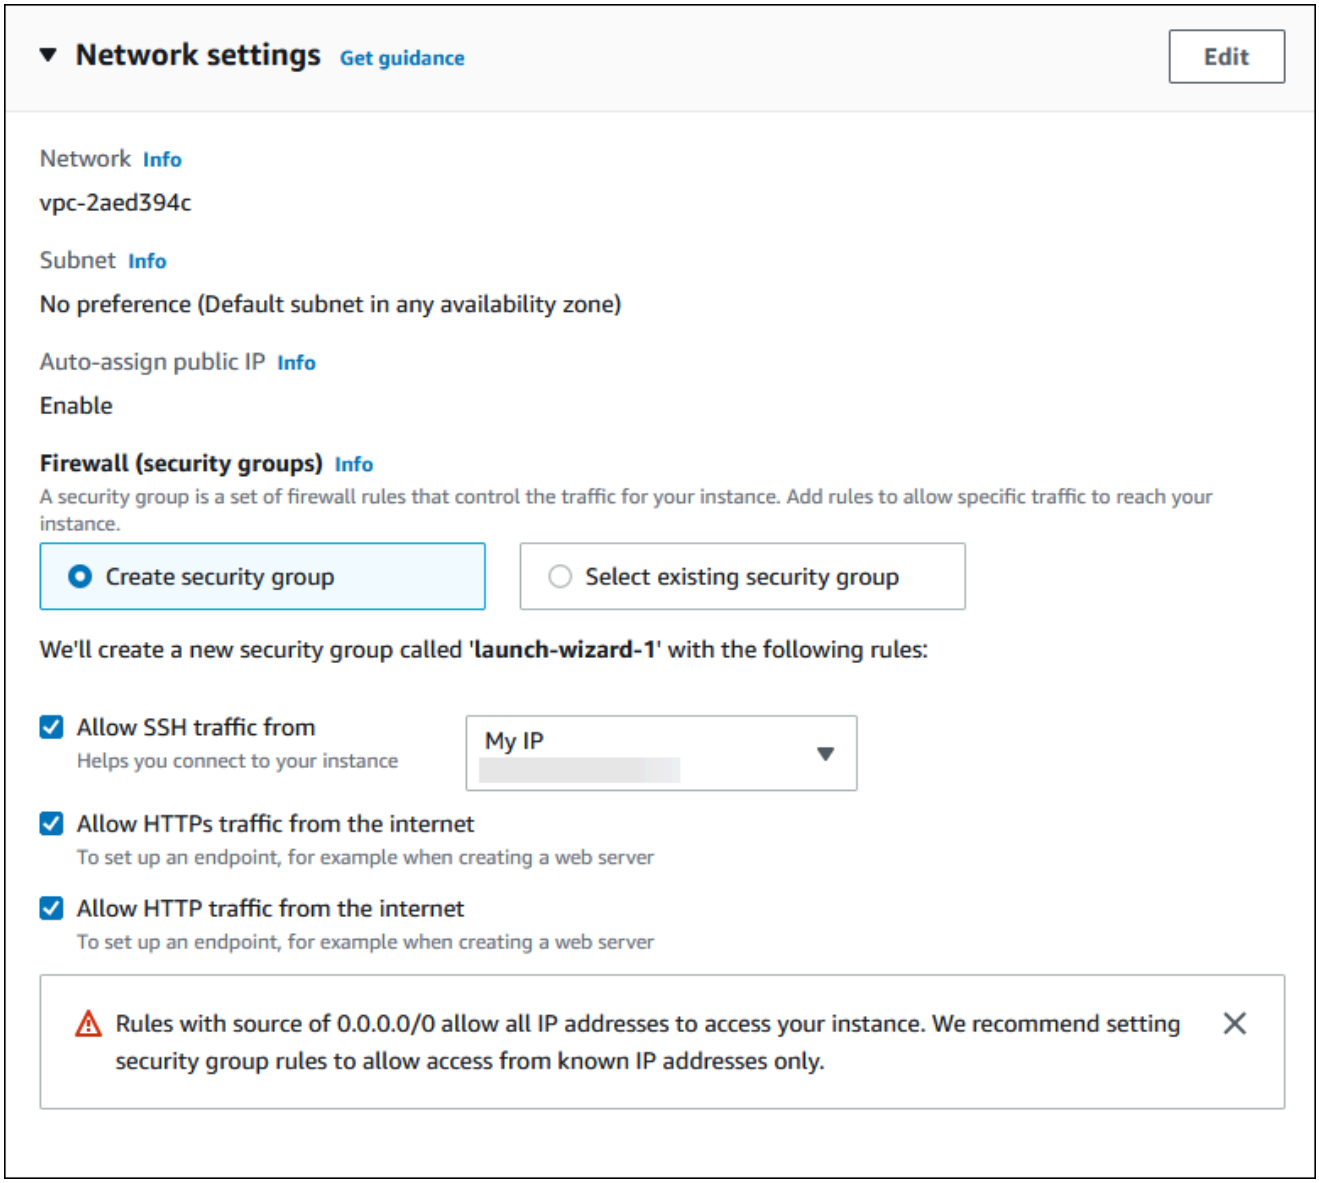
  You can choose **My IP** if the displayed IP address is correct for SSH connections.

  Otherwise, you can determine the IP address to use to connect to EC2 instances in your VPC using Secure Shell (SSH). To determine your public IP address, in a different browser window or tab, you can use the service at https://checkip.amazonaws.com. An example of an IP address is `203.0.113.25/32`.

  In many cases, you might connect through an internet service provider (ISP) or from behind your firewall without a static IP address. If so, make sure to determine the range of IP addresses used by client computers.

  > **Warning**
  >
  > If you use `0.0.0.0/0` for SSH access, you make it possible for all IP addresses to access your public instances using SSH. This approach is acceptable for a short time in a test environment, but it's unsafe for production environments. In production, authorize only a specific IP address or range of addresses to access your instances using SSH.

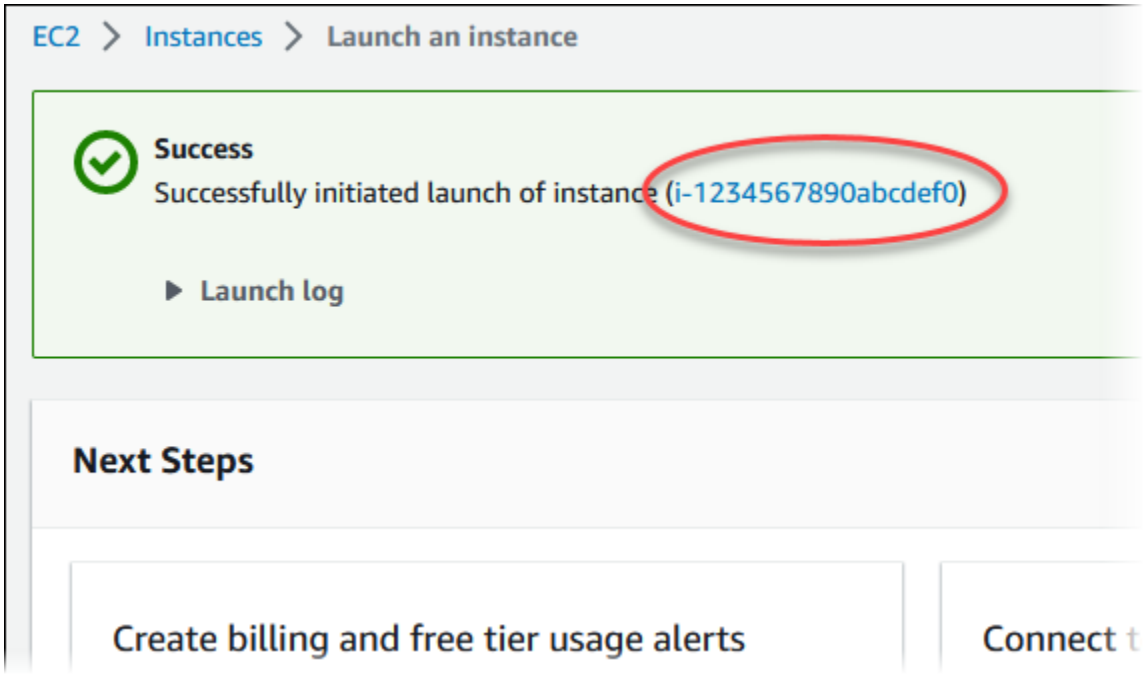
- Turn on **Allow HTTPs traffic from the internet**.
- Turn on **Allow HTTP traffic from the internet**.



f. Leave the default values for the remaining sections.

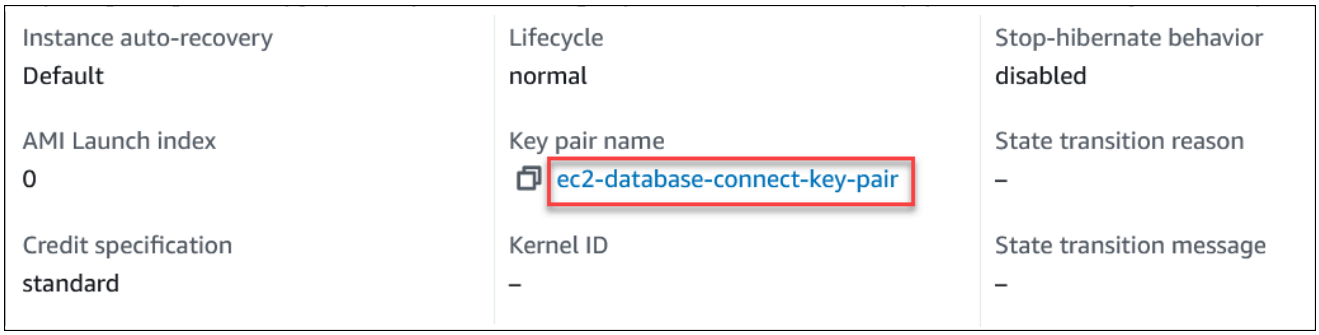
g. Review a summary of your instance configuration in the **Summary** panel, and when you're ready, choose **Launch instance**.

5. On the **Launch Status** page, note the identifier for your new EC2 instance, for example: `i-1234567890abcdef0`.



6. Choose the EC2 instance identifier to open the list of EC2 instances, and then select your EC2 instance.
7. In the **Details** tab, note the following values, which you need when you connect using SSH:
   a. In **Instance summary**, note the value for **Public IPv4 DNS**.

   b. In **Instance details**, note the value for **Key pair name**.



8. Wait until **Instance state** for your instance is **Running** before continuing.
9. Complete Create an Amazon RDS DB instance.

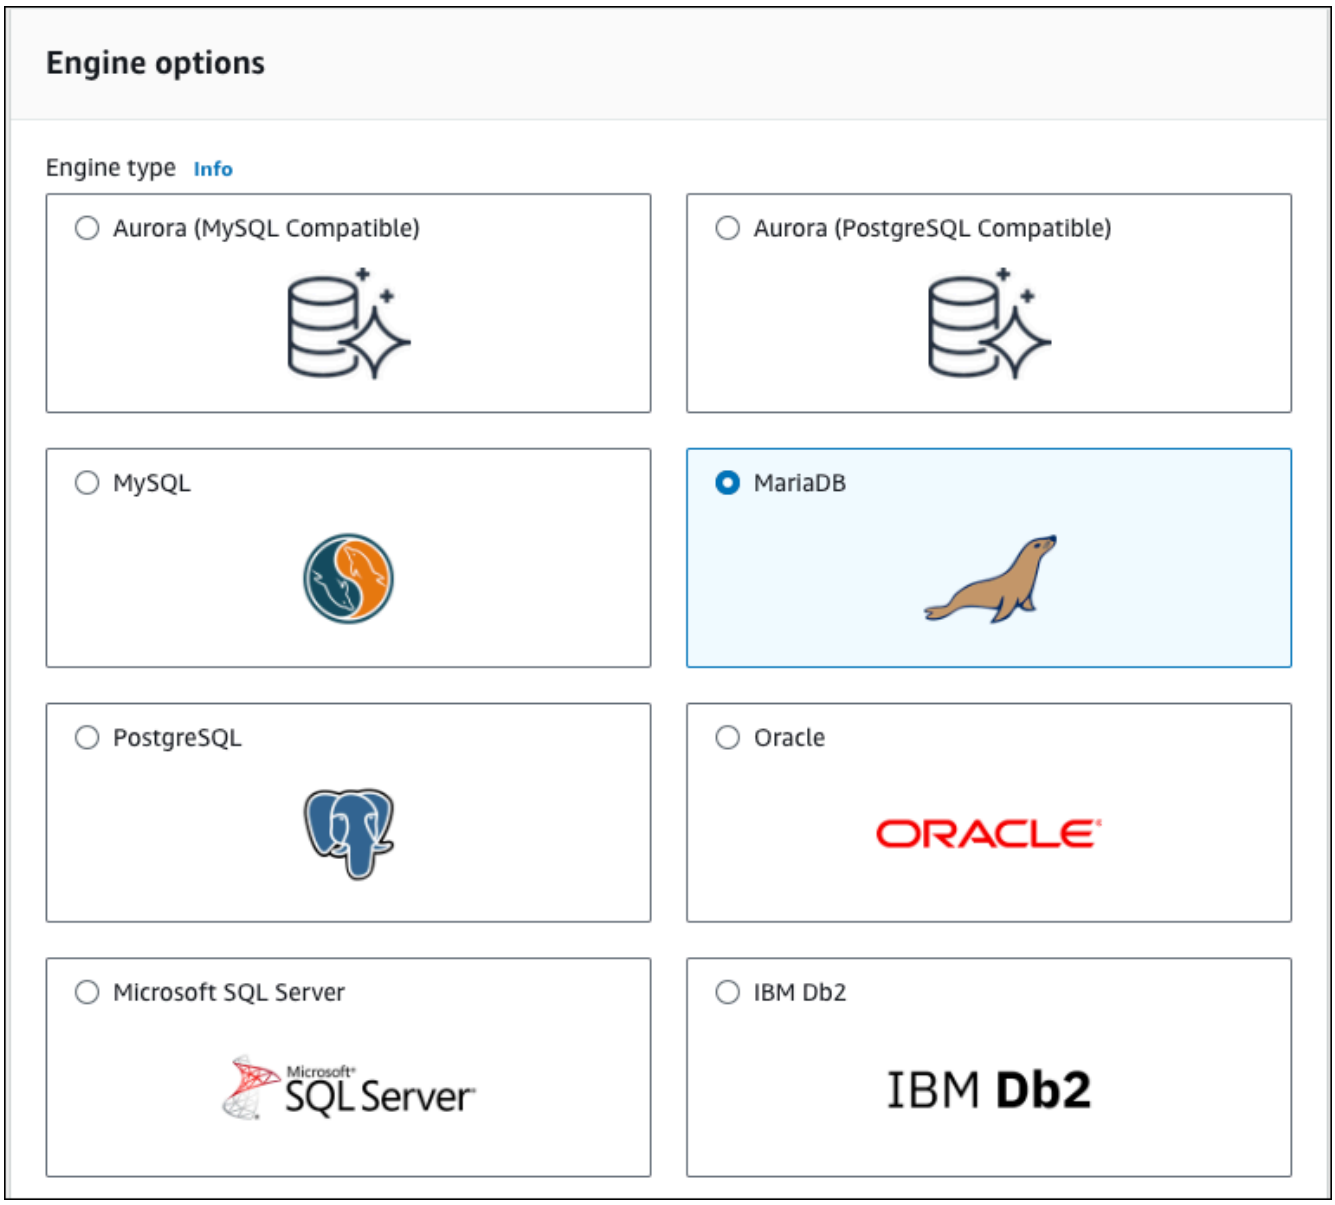
Create an Amazon RDS DB instance

Create an RDS for MariaDB, RDS for MySQL, or RDS for PostgreSQL DB instance that maintains the data used by a web application.

RDS for MariaDB

To create a MariaDB instance

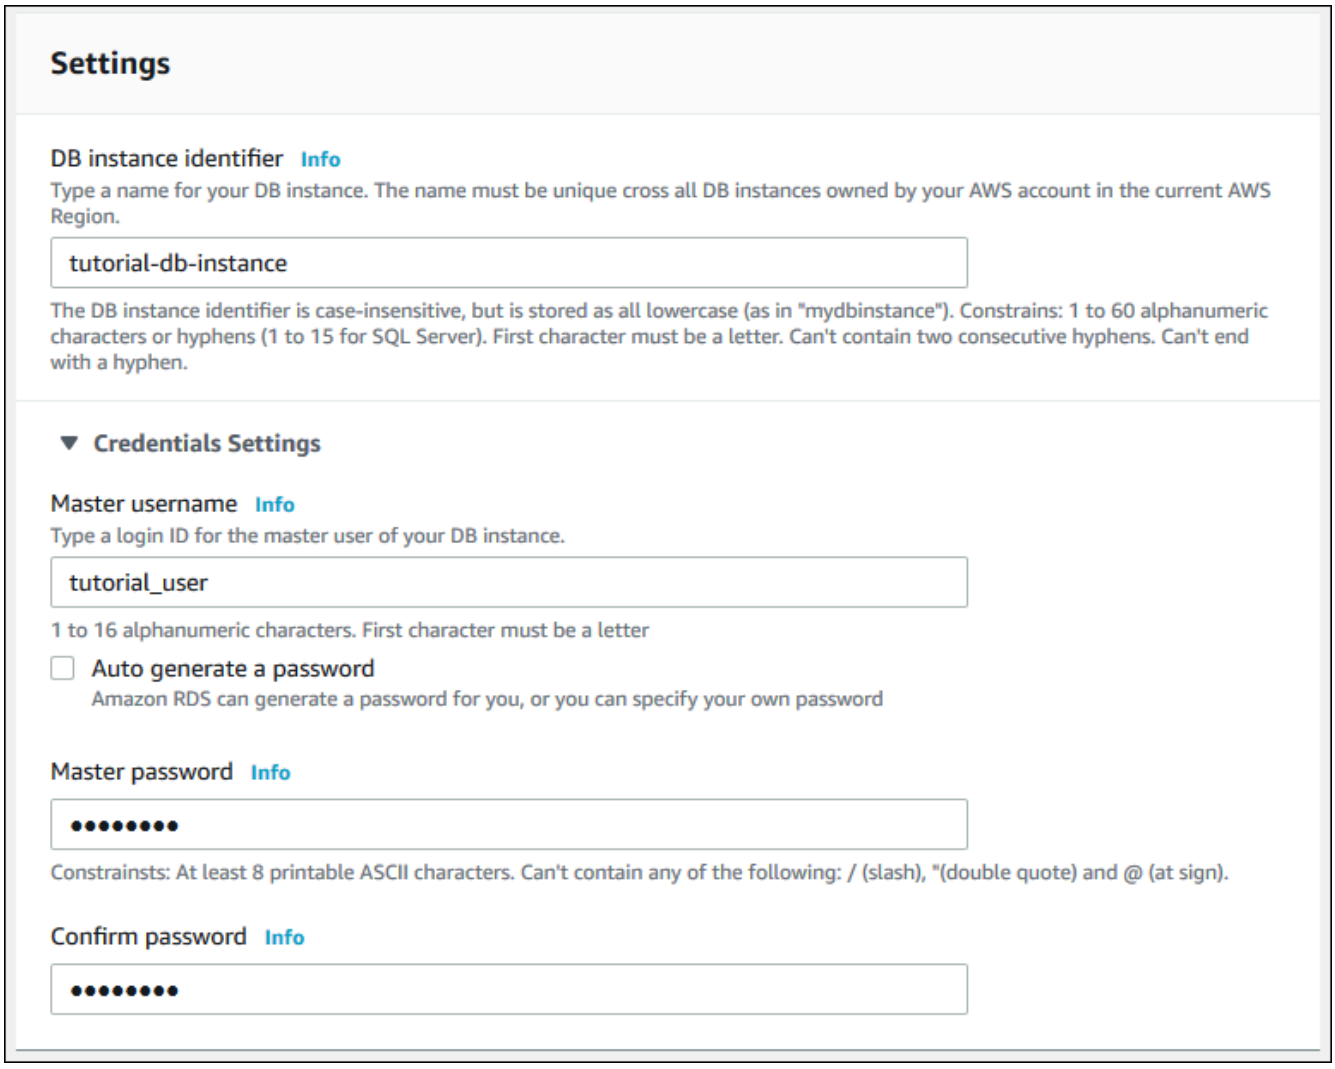
1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the upper-right corner of the AWS Management Console, check the AWS Region. It should be the same as the one where you created your EC2 instance.
3. In the navigation pane, choose **Databases**.
4. Choose **Create database**.
5. On the **Create database** page, choose **Standard create**.
6. For **Engine options**, choose **MariaDB**.



7. For **Templates**, choose **Free tier**.

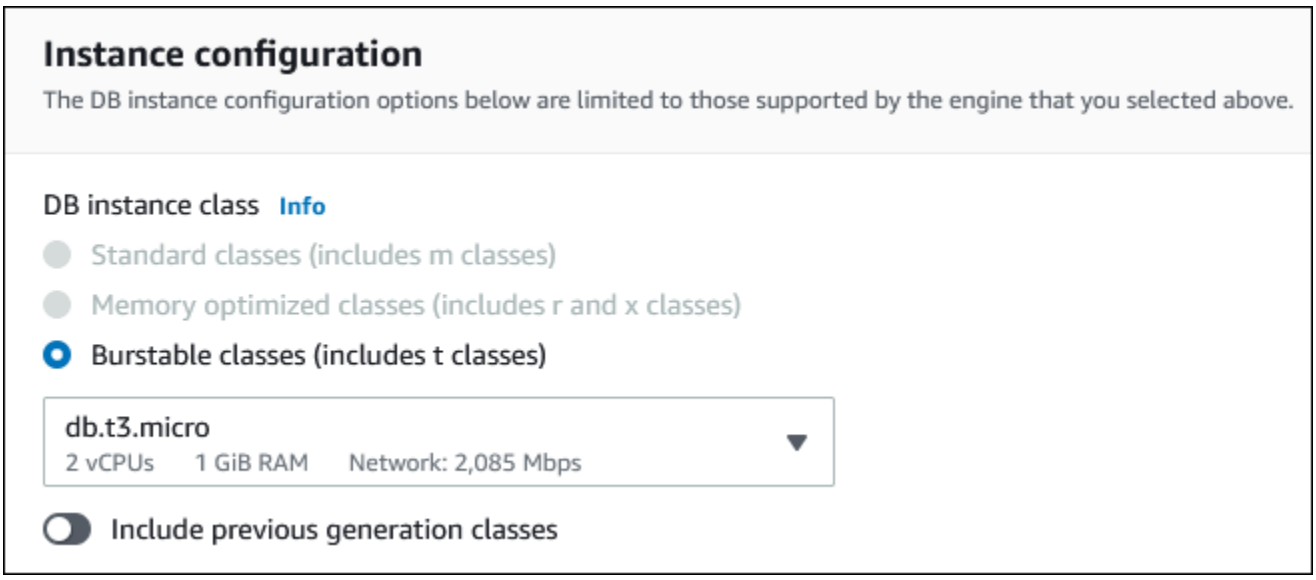
8. In the **Availability and durability** section, keep the defaults.
9. In the **Settings** section, set these values:

   - **DB instance identifier** – Type **`tutorial-db-instance`**.
   - **Master username** – Type **`tutorial_user`**.
   - **Auto generate a password** – Leave the option turned off.
   - **Master password** – Type a password.
   - **Confirm password** – Retype the password.

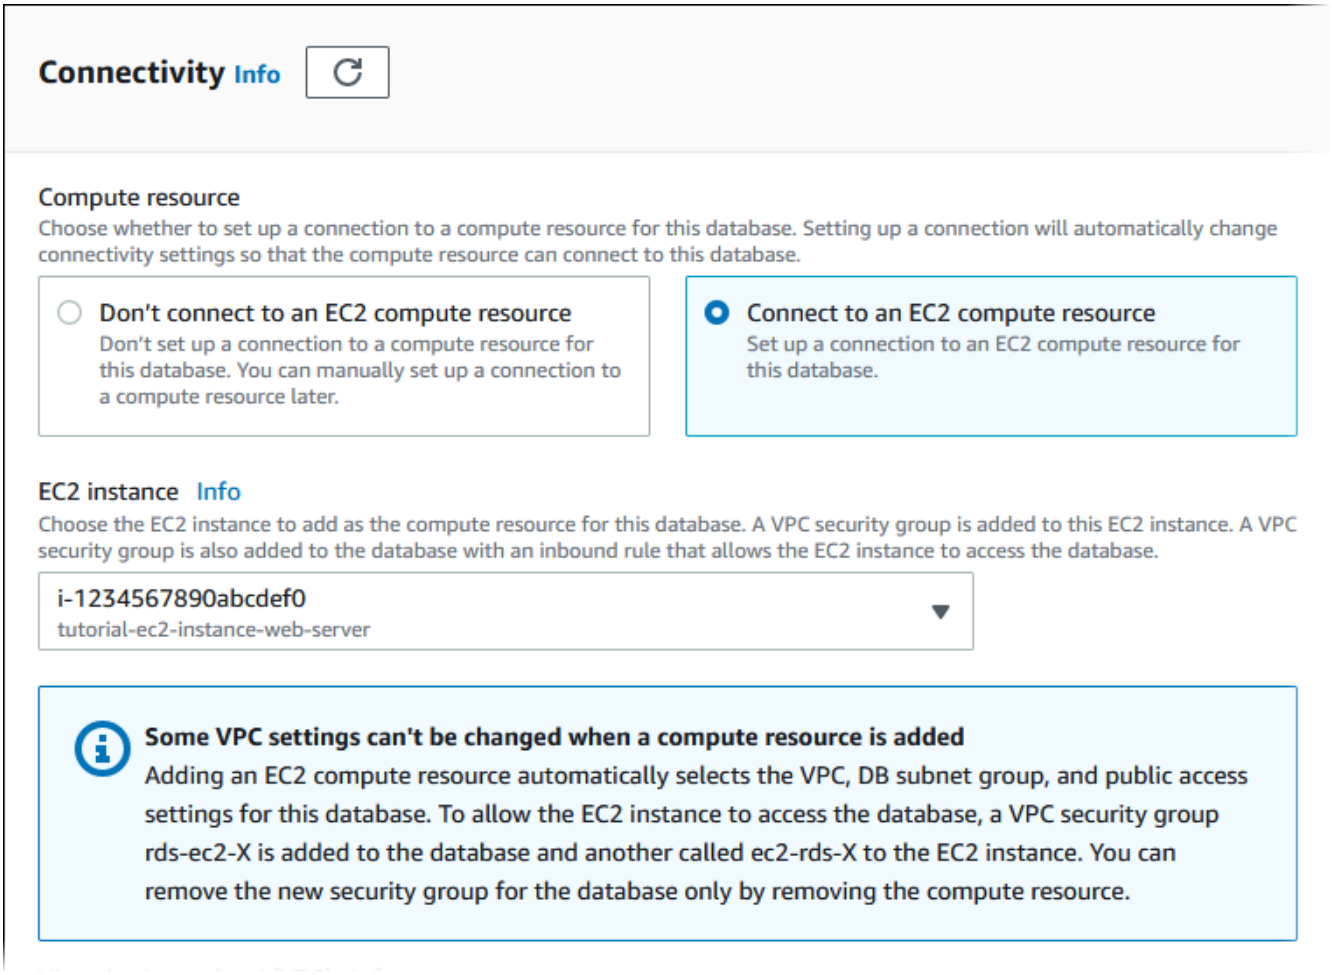


10. In the **Instance configuration** section, set these values:

    - **Burstable classes (includes t classes)**
    - **db.t3.micro**

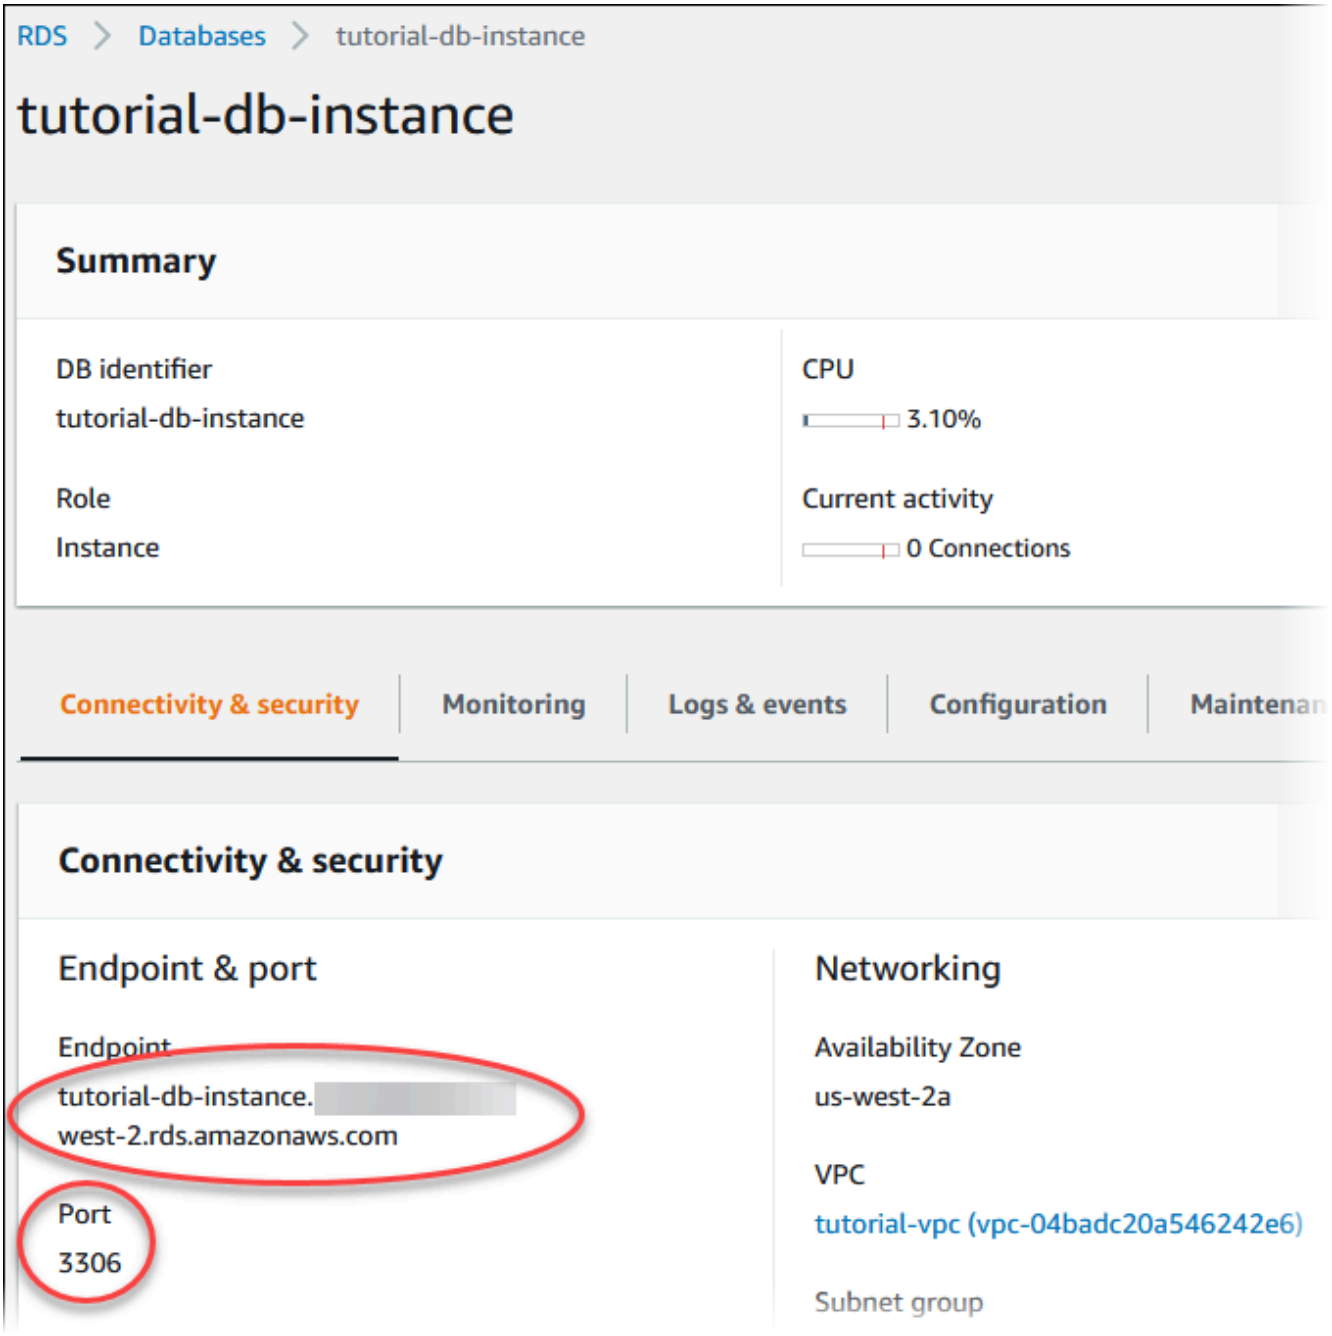


11. In the **Storage** section, keep the defaults.
12. In the **Connectivity** section, set these values and keep the other values as their defaults:
    - For **Compute resource**, choose **Connect to an EC2 compute resource**.
    - For **EC2 instance**, choose the EC2 instance you created previously, such as **tutorial-ec2-instance-web-server**.



13. In the **Database authentication** section, make sure **Password authentication** is selected.
14. Open the **Additional configuration** section, and enter **`sample`** for **Initial database name**. Keep the default settings for the other options.
15. To create your MariaDB instance, choose **Create database**.

    Your new DB instance appears in the **Databases** list with the status **Creating**.
16. Wait for the **Status** of your new DB instance to show as **Available**. Then choose the DB instance name to show its details.
17. In the **Connectivity & security** section, view the **Endpoint** and **Port** of the DB instance.



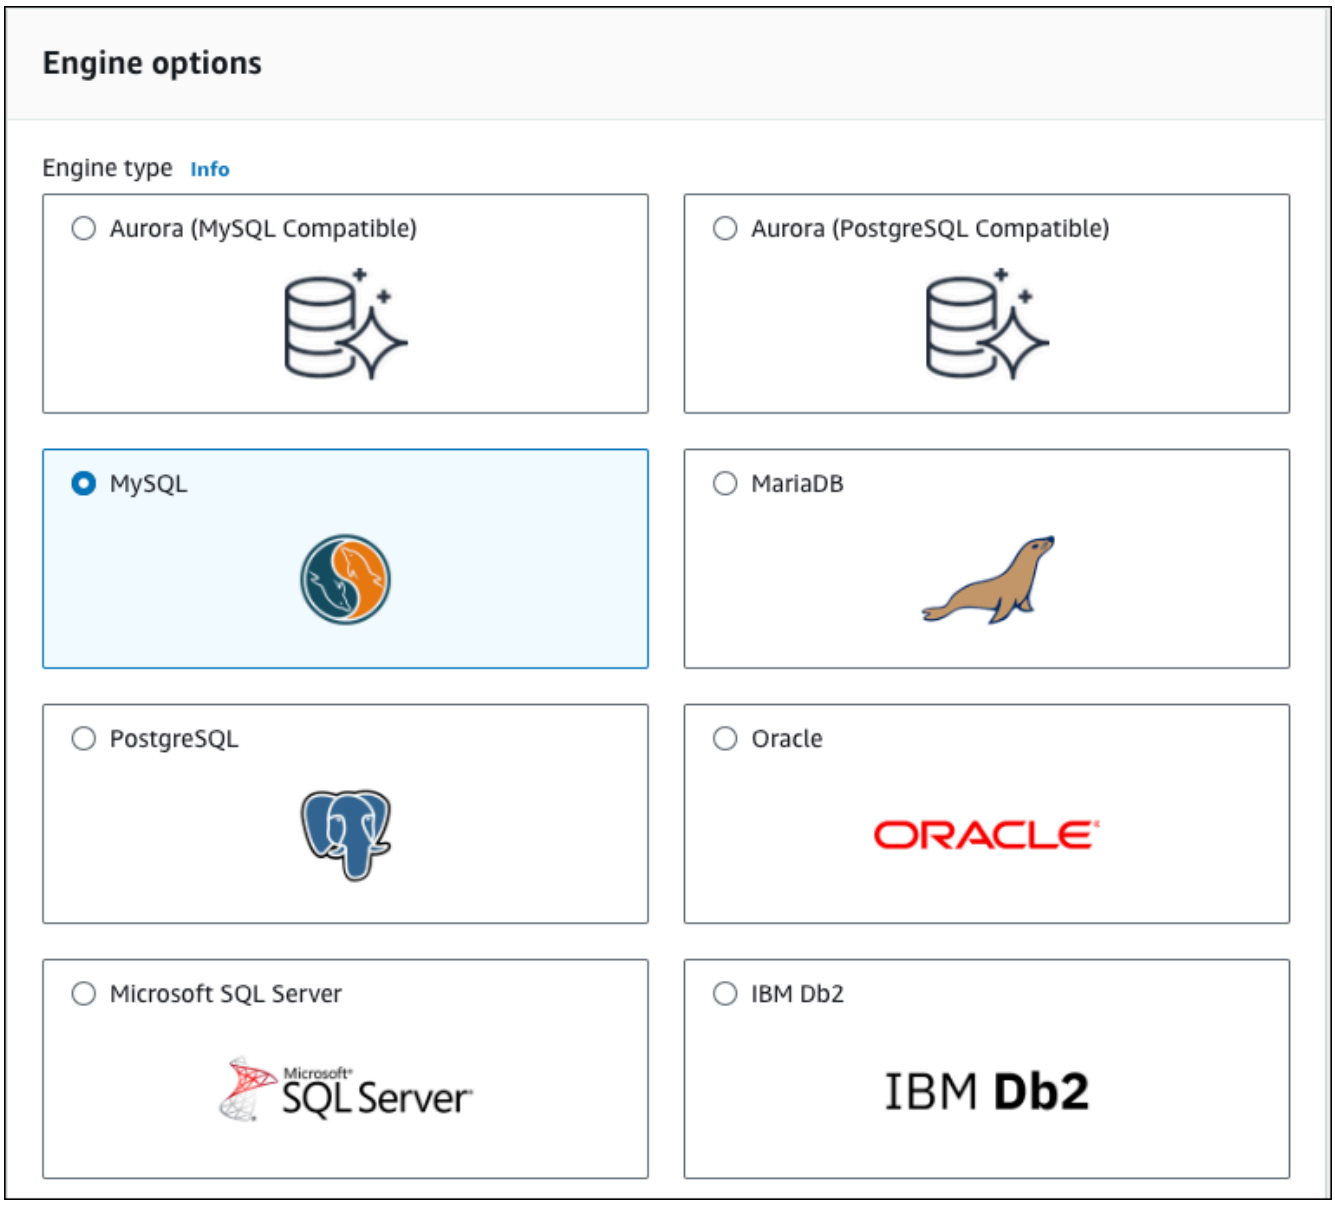
Note the endpoint and port for your DB instance. You use this information to connect your web server to your DB instance.

18. Complete Install a web server on your EC2 instance.

RDS for MySQL

To create a MySQL DB instance

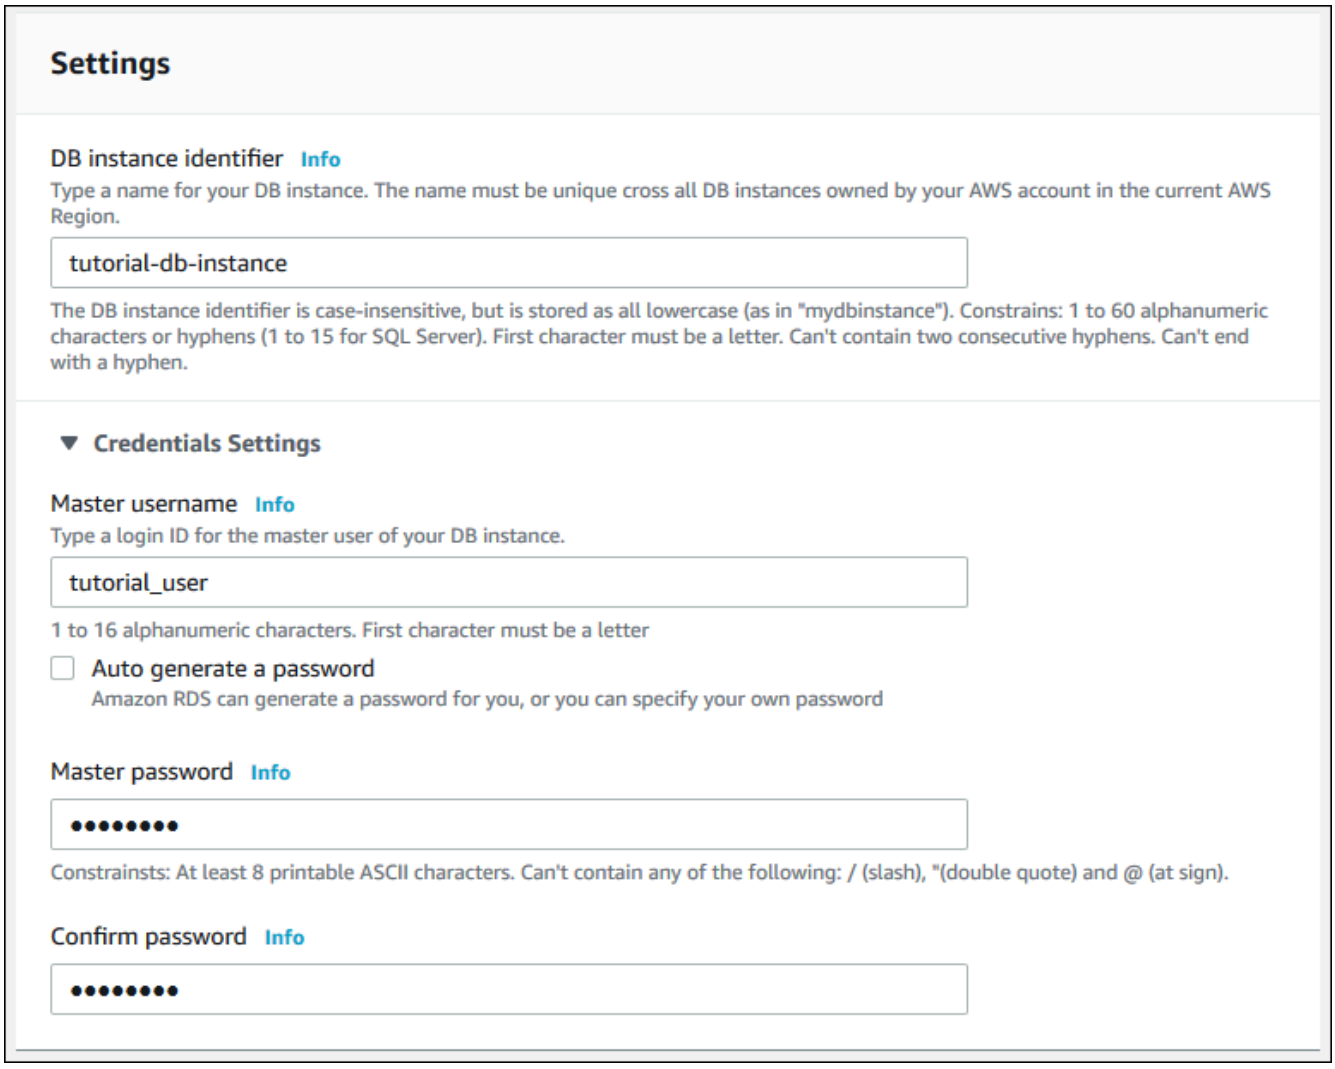
1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the upper-right corner of the AWS Management Console, check the AWS Region. It should be the same as the one where you created your EC2 instance.
3. In the navigation pane, choose **Databases**.
4. Choose **Create database**.
5. On the **Create database** page, choose **Standard create**.
6. For **Engine options**, choose **MySQL**.



7. For **Templates**, choose **Free tier**.

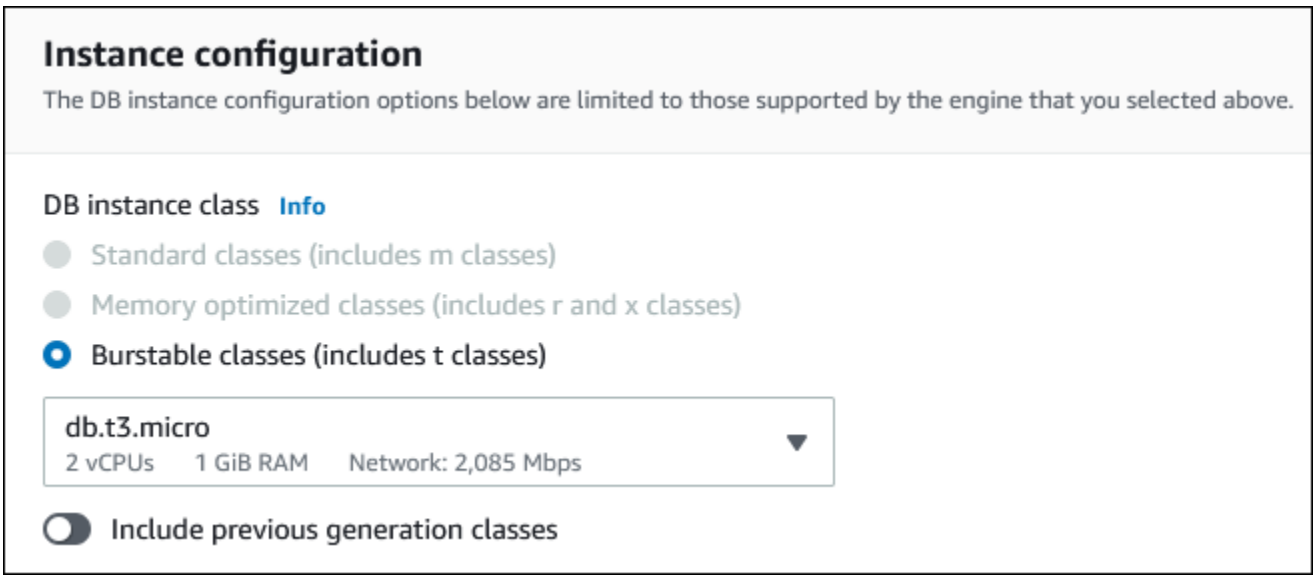
8. In the **Availability and durability** section, keep the defaults.
9. In the **Settings** section, set these values:

   - **DB instance identifier** – Type **`tutorial-db-instance`**.
   - **Master username** – Type **`tutorial_user`**.
   - **Auto generate a password** – Leave the option turned off.
   - **Master password** – Type a password.
   - **Confirm password** – Retype the password.

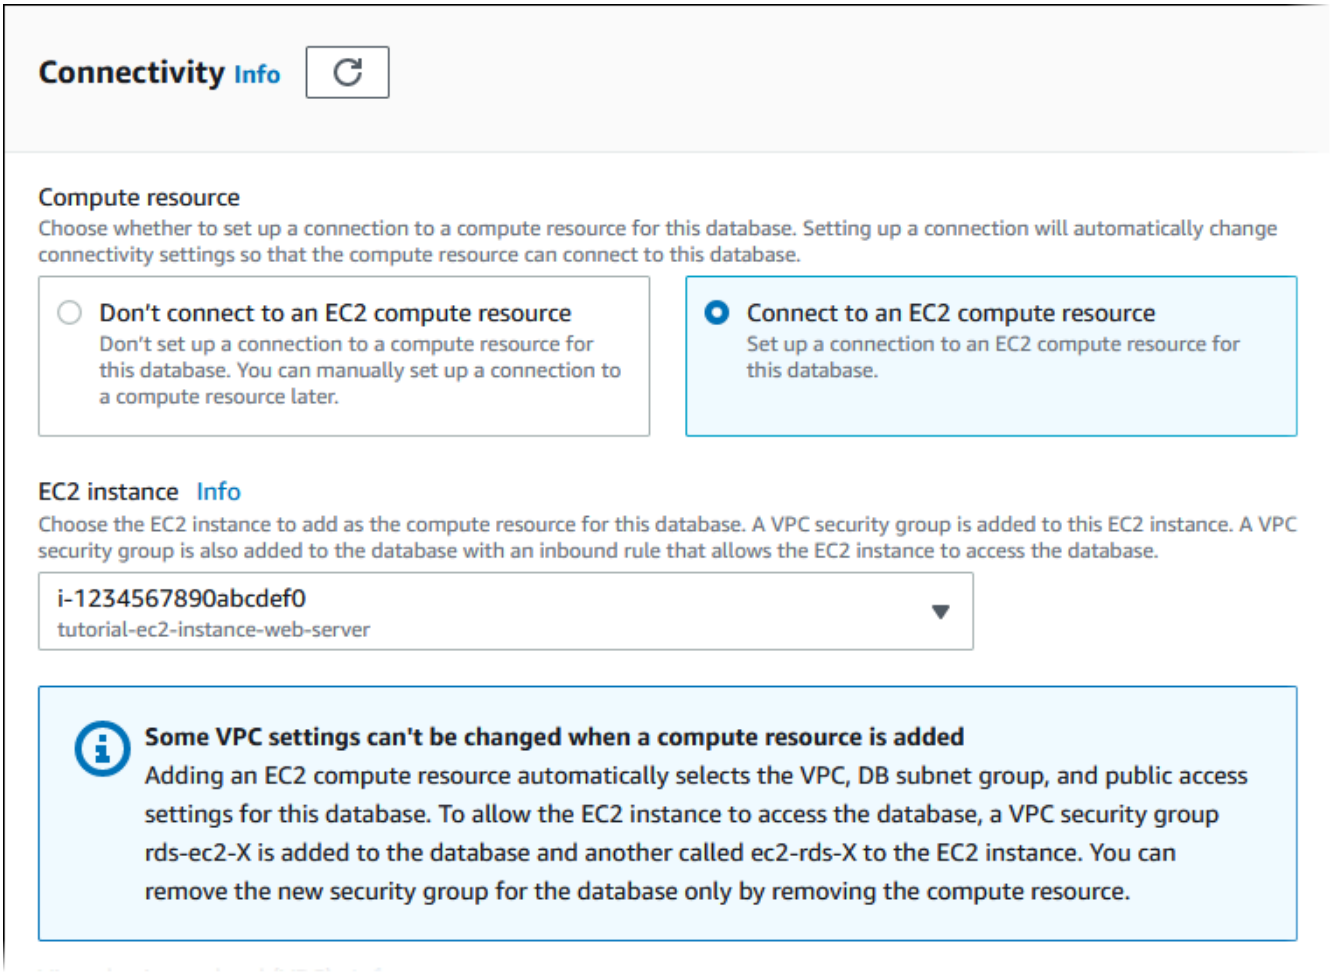


10. In the **Instance configuration** section, set these values:

    - **Burstable classes (includes t classes)**
    - **db.t3.micro**

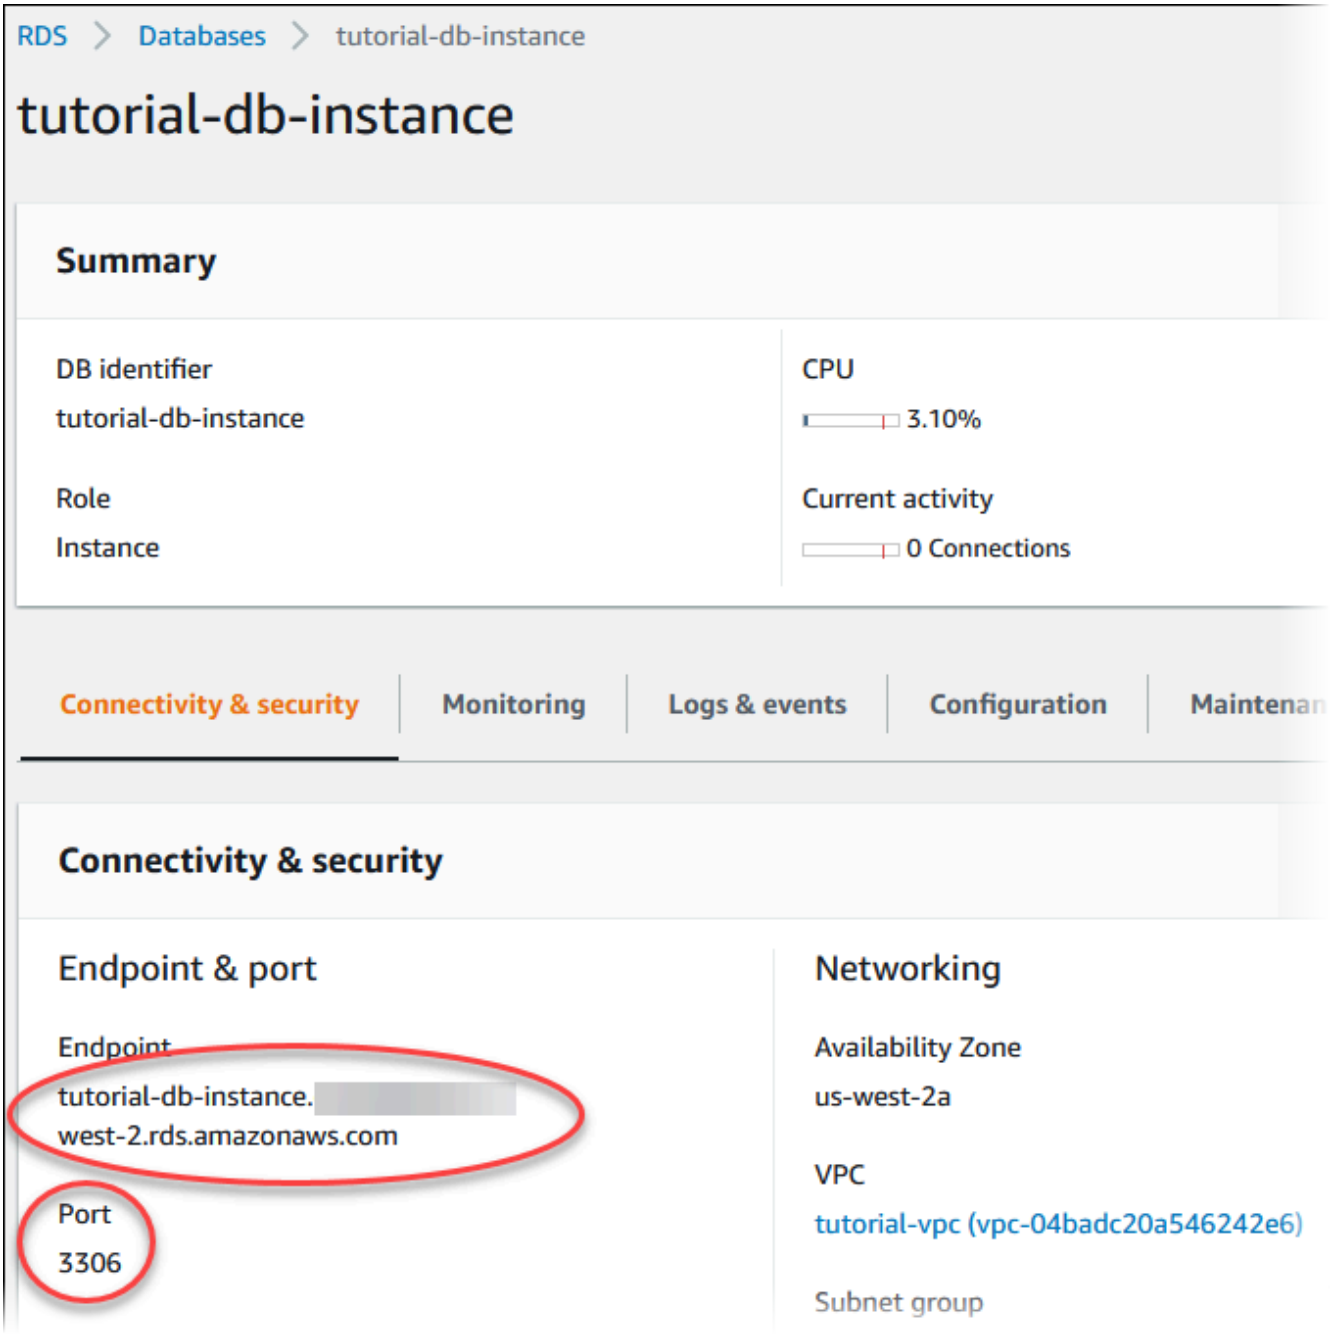


11. In the **Storage** section, keep the defaults.
12. In the **Connectivity** section, set these values and keep the other values as their defaults:
    - For **Compute resource**, choose **Connect to an EC2 compute resource**.
    - For **EC2 instance**, choose the EC2 instance you created previously, such as **tutorial-ec2-instance-web-server**.



13. In the **Database authentication** section, make sure **Password authentication** is selected.
14. Open the **Additional configuration** section, and enter **`sample`** for **Initial database name**. Keep the default settings for the other options.
15. To create your MySQL DB instance, choose **Create database**.

    Your new DB instance appears in the **Databases** list with the status **Creating**.
16. Wait for the **Status** of your new DB instance to show as **Available**. Then choose the DB instance name to show its details.
17. In the **Connectivity & security** section, view the **Endpoint** and **Port** of the DB instance.



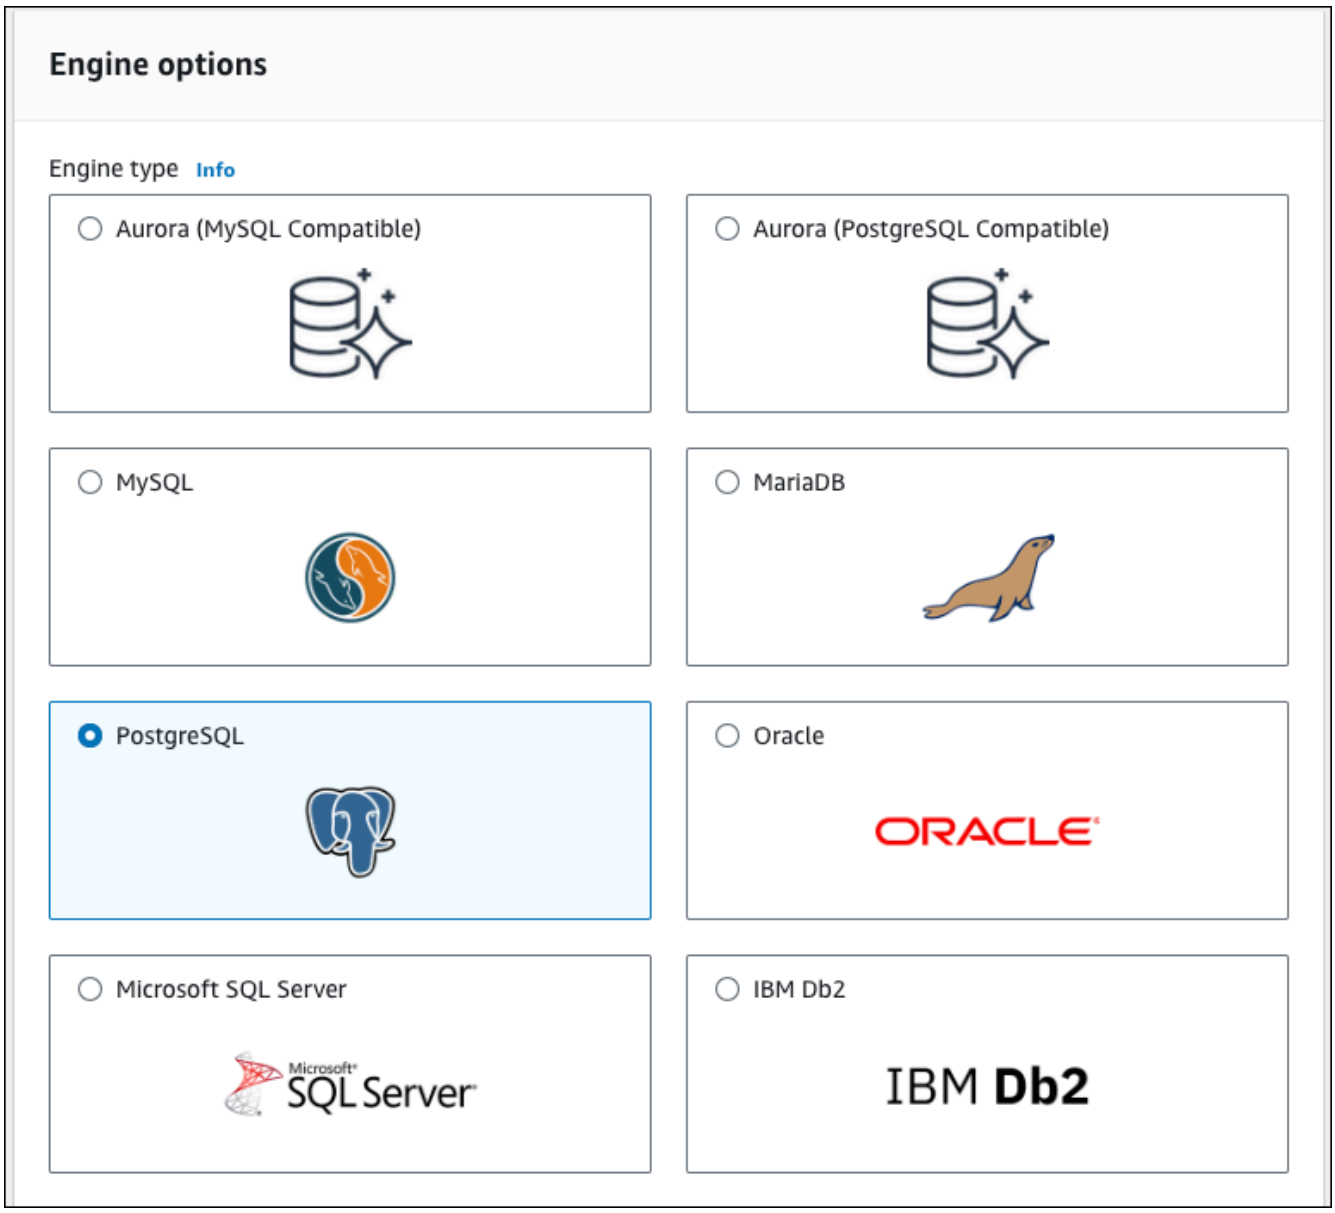
Note the endpoint and port for your DB instance. You use this information to connect your web server to your DB instance.

18. Complete Install a web server on your EC2 instance.

RDS for PostgreSQL

To create a PostgreSQL DB instance

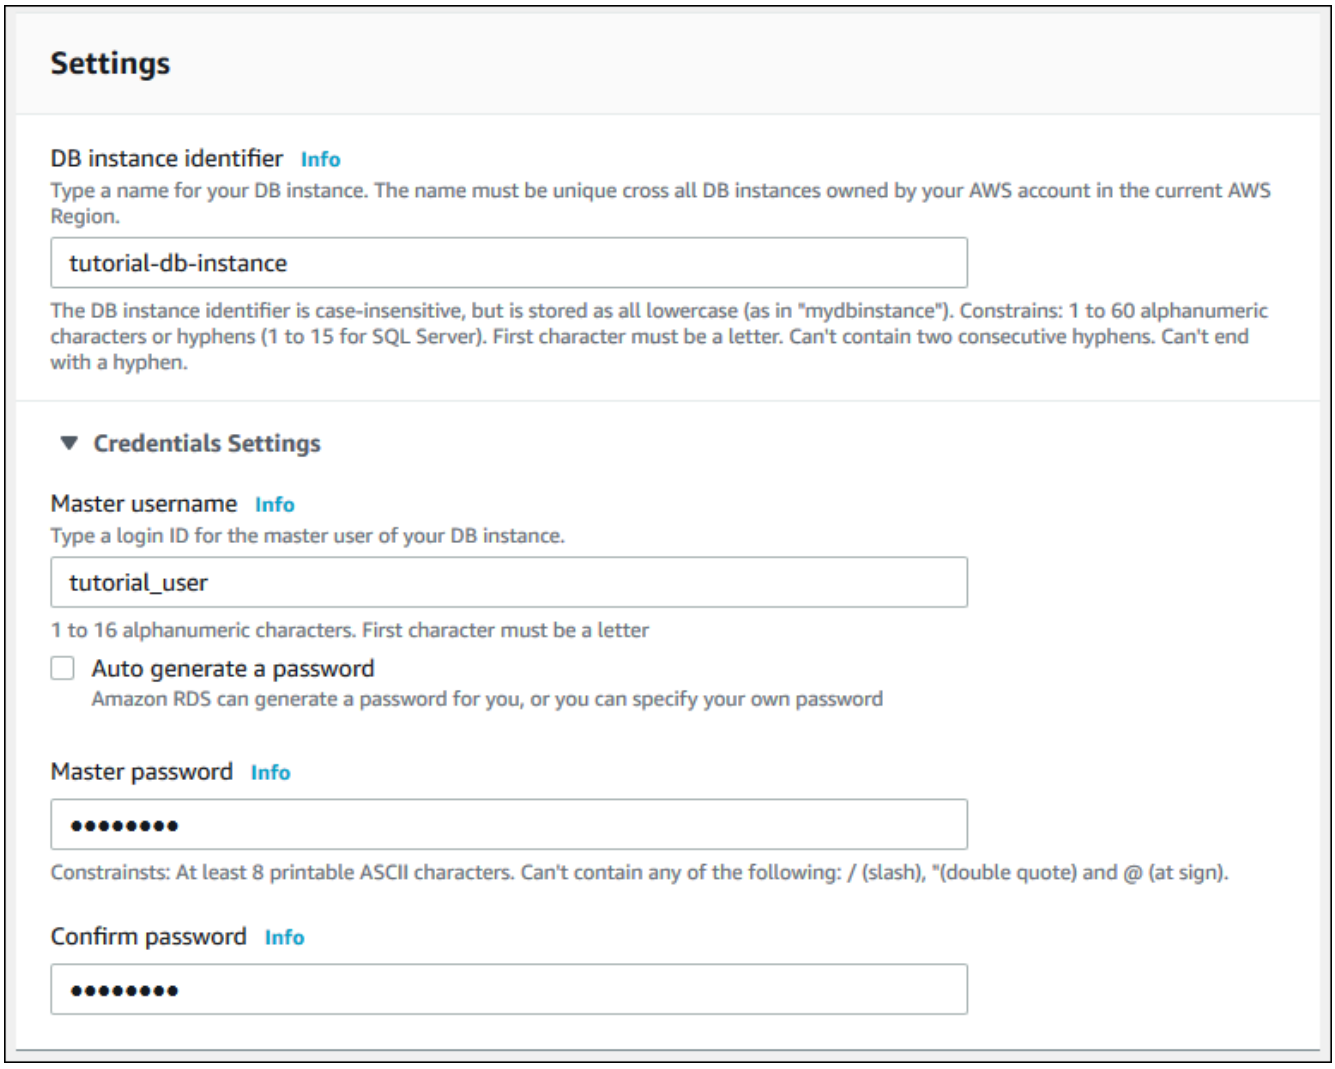
1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the upper-right corner of the AWS Management Console, check the AWS Region. It should be the same as the one where you created your EC2 instance.
3. In the navigation pane, choose **Databases**.
4. Choose **Create database**.
5. On the **Create database** page, choose **Standard create**.
6. For **Engine options**, choose **PostgreSQL**.



7. For **Templates**, choose **Free tier**.

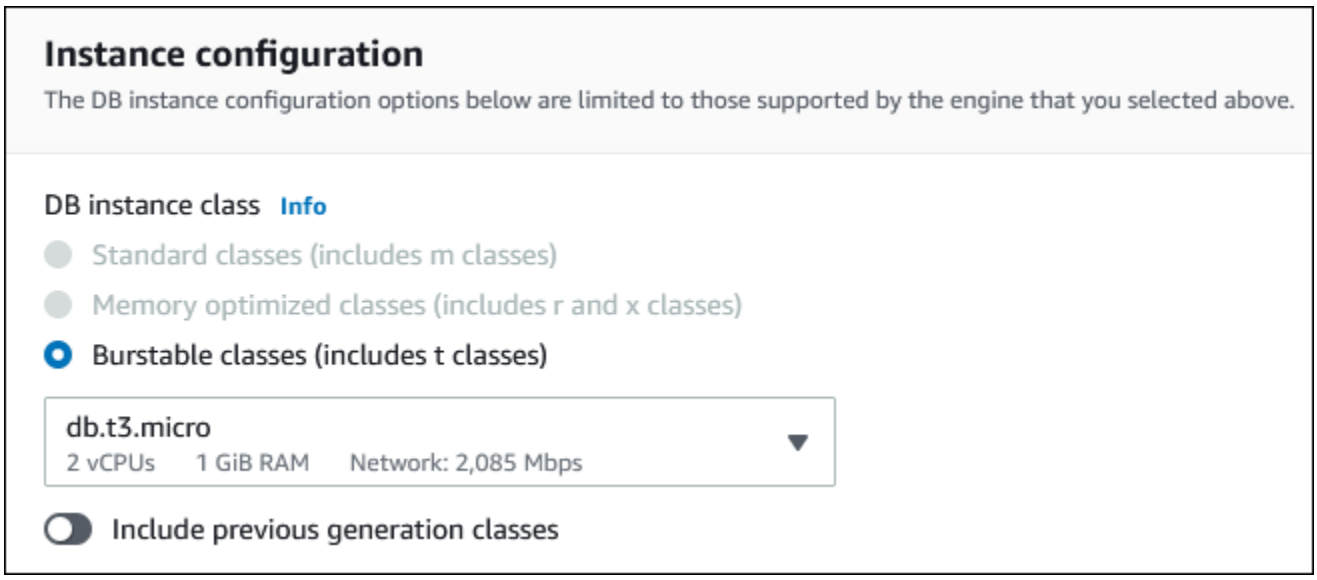
8. In the **Availability and durability** section, keep the defaults.
9. In the **Settings** section, set these values:

   - **DB instance identifier** – Type **`tutorial-db-instance`**.
   - **Master username** – Type **`tutorial_user`**.
   - **Auto generate a password** – Leave the option turned off.
   - **Master password** – Type a password.
   - **Confirm password** – Retype the password.

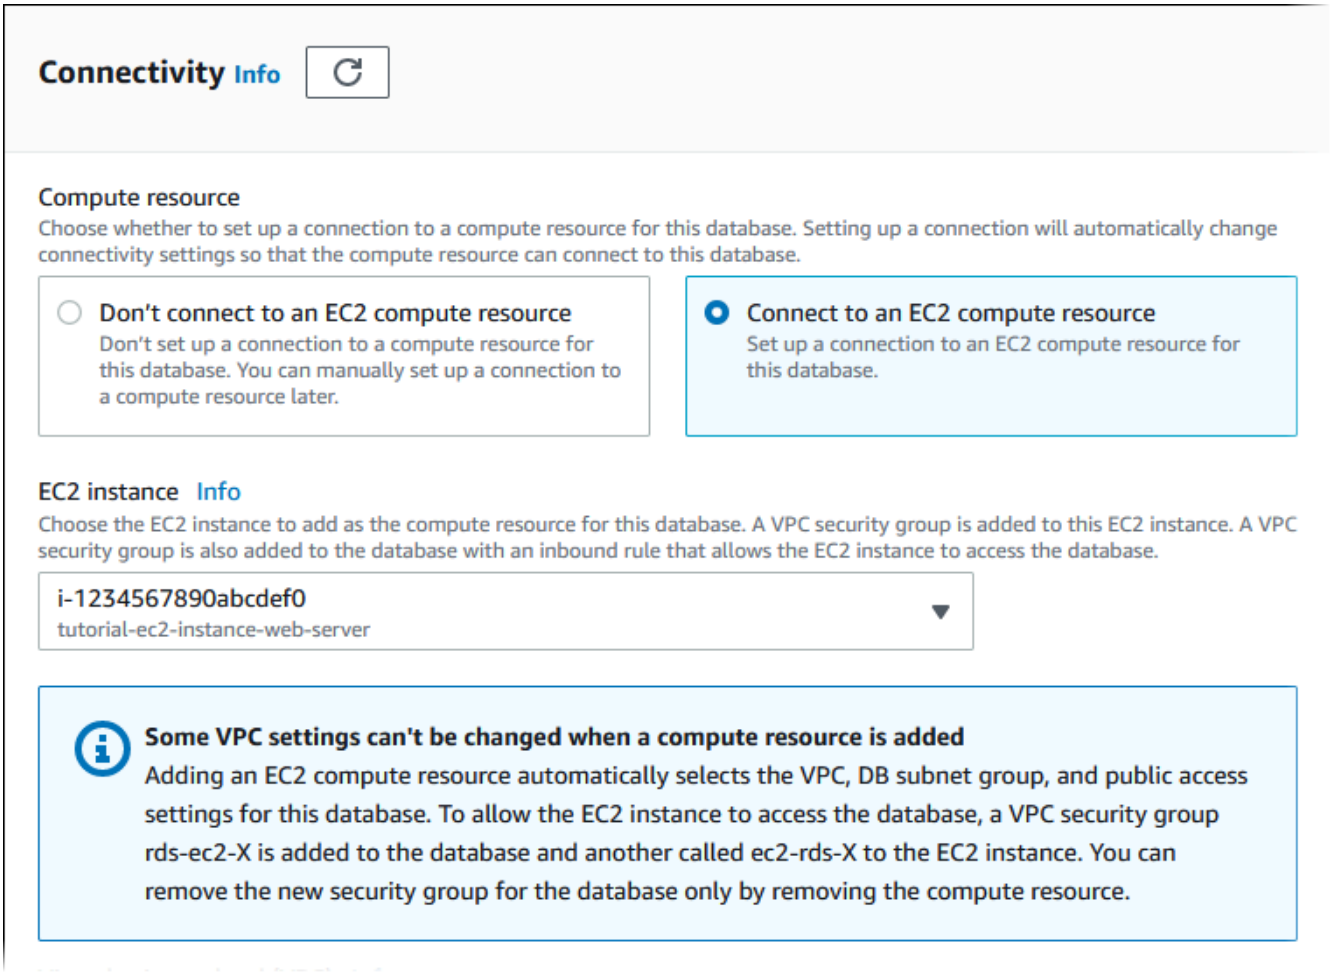


10. In the **Instance configuration** section, set these values:

    - **Burstable classes (includes t classes)**
    - **db.t3.micro**

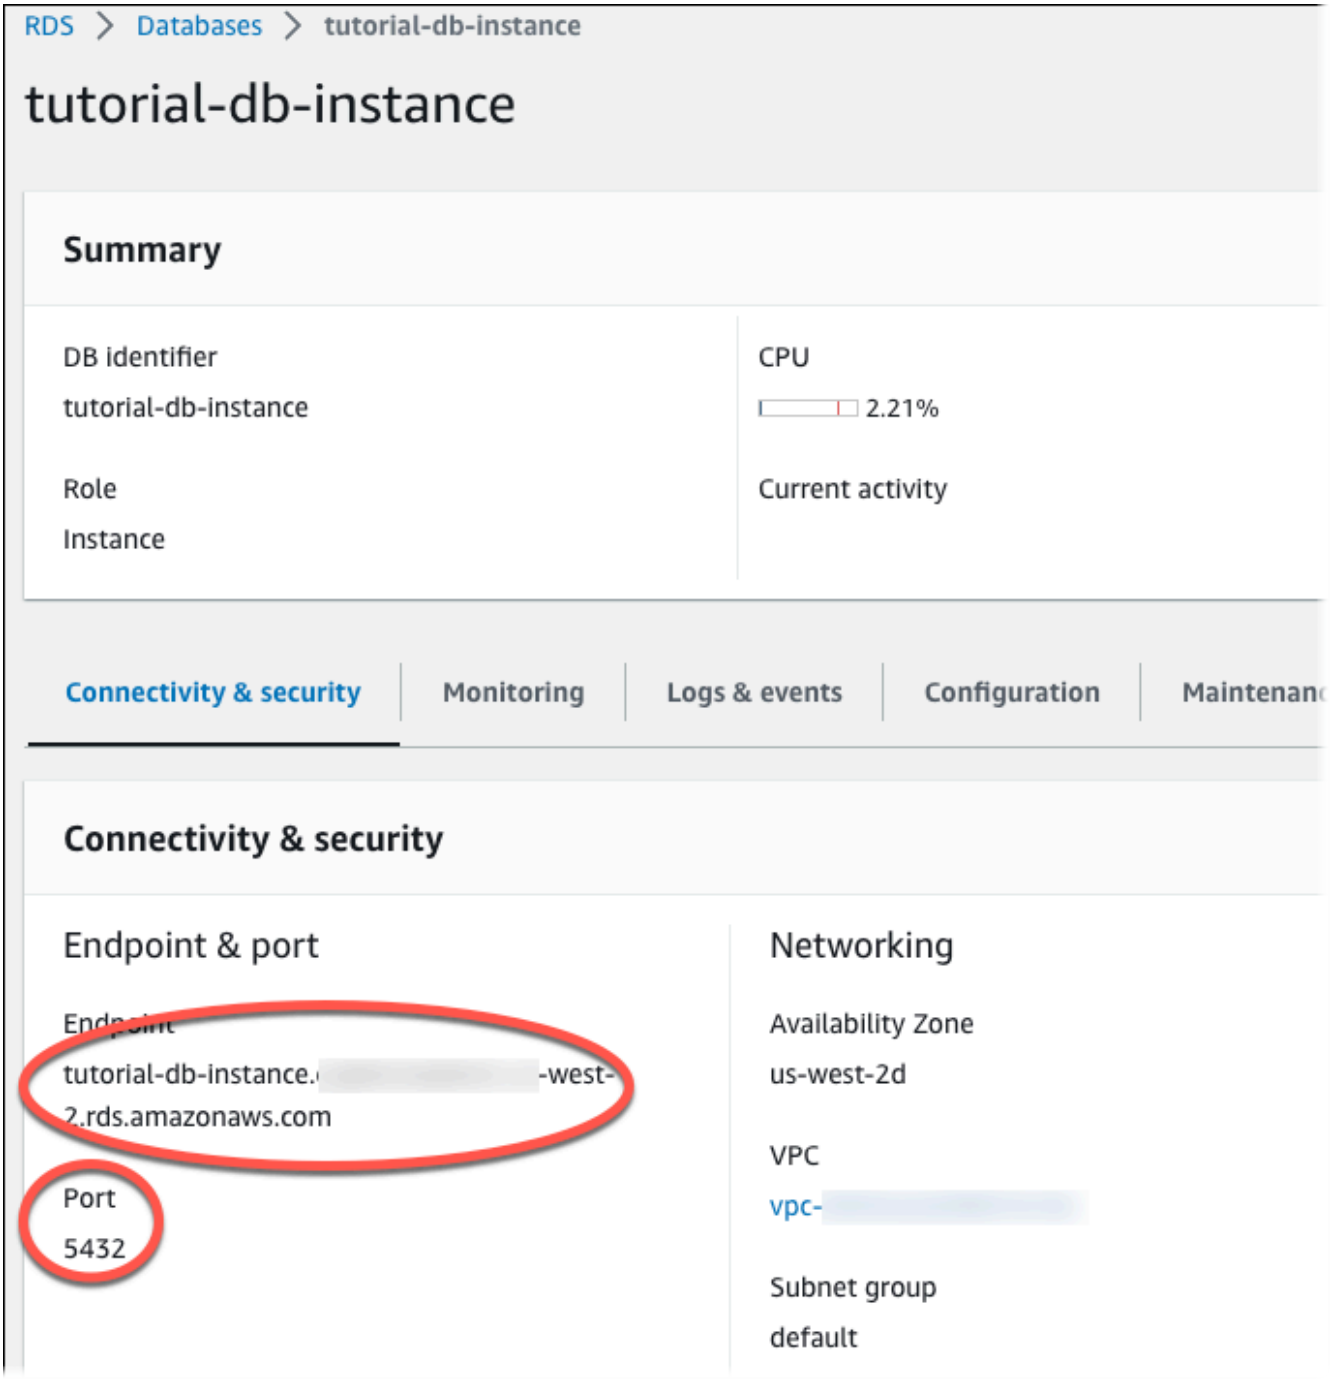


11. In the **Storage** section, keep the defaults.
12. In the **Connectivity** section, set these values and keep the other values as their defaults:
    - For **Compute resource**, choose **Connect to an EC2 compute resource**.
    - For **EC2 instance**, choose the EC2 instance you created previously, such as **tutorial-ec2-instance-web-server**.



13. In the **Database authentication** section, make sure **Password authentication** is selected.
14. Open the **Additional configuration** section, and enter **`sample`** for **Initial database name**. Keep the default settings for the other options.
15. To create your PostgreSQL DB instance, choose **Create database**.

    Your new DB instance appears in the **Databases** list with the status **Creating**.
16. Wait for the **Status** of your new DB instance to show as **Available**. Then choose the DB instance name to show its details.
17. In the **Connectivity & security** section, view the **Endpoint** and **Port** of the DB instance.



Note the endpoint and port for your DB instance. You use this information to connect your web server to your DB instance.

18. Complete Install a web server on your EC2 instance.

Install a web server on your EC2 instance

Install a web server on the EC2 instance you created in Launch an EC2 instance to connect with your DB instance. The web server connects to the Amazon RDS DB instance that you created in Create an Amazon RDS DB instance.

Install an Apache web server with PHP and MariaDB

Connect to your EC2 instance and install the web server.

To connect to your EC2 instance and install the Apache web server with PHP

1. Connect to the EC2 instance that you created earlier by following the steps in Connect to your Linux instance in the *Amazon EC2 User Guide*.

   We recommend that you connect to your EC2 instance using SSH. If the SSH client utility is installed on Windows, Linux, or Mac, you can connect to the instance using the following command format:

   ```
   ssh -i location_of_pem_file ec2-user@ec2-instance-public-dns-name
   ```

   For example, assume that `ec2-database-connect-key-pair.pem` is stored in `/dir1` on Linux, and the public IPv4 DNS for your EC2 instance is `ec2-12-345-678-90.compute-1.amazonaws.com`. Your SSH command would look as follows:

   ```
   ssh -i /dir1/ec2-database-connect-key-pair.pem ec2-
   user@ec2-12-345-678-90.compute-1.amazonaws.com
   ```

2. Get the latest bug fixes and security updates by updating the software on your EC2 instance. To do this, use the following command.

   > **Note**
   >
   > The `-y` option installs the updates without asking for confirmation. To examine updates before installing, omit this option.

   ```
   sudo dnf update -y
   ```

3. After the updates complete, install the Apache web server, PHP, and MariaDB or PostgreSQL software using the following commands. This command installs multiple software packages and related dependencies at the same time.

   MariaDB & MySQL

   ```
   sudo dnf install -y httpd php php-mysqli mariadb105
   ```

   PostgreSQL

   ```
   sudo dnf install -y httpd php php-pgsql postgresql15
   ```

   If you receive an error, your instance probably wasn't launched with an Amazon Linux 2023 AMI. You might be using the Amazon Linux 2 AMI instead. You can view your version of Amazon Linux using the following command.

   ```
   cat /etc/system-release
   ```

   For more information, see Updating instance software.

4. Start the web server with the command shown following.

   ```
   sudo systemctl start httpd
   ```

   You can test that your web server is properly installed and started. To do this, enter the public Domain Name System (DNS) name of your EC2 instance in the address bar of a web browser, for example: `http://ec2-42-8-168-21.us-west-1.compute.amazonaws.com`. If your web server is running, then you see the Apache test page.

   If you don't see the Apache test page, check your inbound rules for the VPC security group that you created in Tutorial: Create a VPC for use with a DB instance (IPv4 only). Make sure that your inbound rules include one allowing HTTP (port 80) access for the IP address to connect to the web server.

   Note

   The Apache test page appears only when there is no content in the document root directory, `/var/www/html`. After you add content to the document root directory,

your content appears at the public DNS address of your EC2 instance. Before this point, it appears on the Apache test page.

5. Configure the web server to start with each system boot using the `systemctl` command.

```
sudo systemctl enable httpd
```

To allow `ec2-user` to manage files in the default root directory for your Apache web server, modify the ownership and permissions of the `/var/www` directory. There are many ways to accomplish this task. In this tutorial, you add `ec2-user` to the `apache` group, to give the `apache` group ownership of the `/var/www` directory and assign write permissions to the group.

To set file permissions for the Apache web server

1. Add the `ec2-user` user to the `apache` group.

```
sudo usermod -a -G apache ec2-user
```

2. Log out to refresh your permissions and include the new `apache` group.

```
exit
```

3. Log back in again and verify that the `apache` group exists with the `groups` command.

```
groups
```

Your output looks similar to the following:

```
ec2-user adm wheel apache systemd-journal
```

4. Change the group ownership of the `/var/www` directory and its contents to the `apache` group.

```
sudo chown -R ec2-user:apache /var/www
```

5. Change the directory permissions of `/var/www` and its subdirectories to add group write permissions and set the group ID on subdirectories created in the future.

```
sudo chmod 2775 /var/www
```

```
find /var/www -type d -exec sudo chmod 2775 {} \;
```

6. Recursively change the permissions for files in the `/var/www` directory and its subdirectories to add group write permissions.

```
find /var/www -type f -exec sudo chmod 0664 {} \;
```

Now, `ec2-user` (and any future members of the `apache` group) can add, delete, and edit files in the Apache document root. This makes it possible for you to add content, such as a static website or a PHP application.

> **Note**
>
> A web server running the HTTP protocol provides no transport security for the data that it sends or receives. When you connect to an HTTP server using a web browser, much information is visible to eavesdroppers anywhere along the network pathway. This information includes the URLs that you visit, the content of web pages that you receive, and the contents (including passwords) of any HTML forms.
> The best practice for securing your web server is to install support for HTTPS (HTTP Secure). This protocol protects your data with SSL/TLS encryption. For more information, see Tutorial: Configure SSL/TLS with the Amazon Linux AMI in the *Amazon EC2 User Guide*.

Connect your Apache web server to your DB instance

Next, you add content to your Apache web server that connects to your Amazon RDS DB instance.

To add content to the Apache web server that connects to your DB instance

1. While still connected to your EC2 instance, change the directory to `/var/www` and create a new subdirectory named `inc`.

```
cd /var/www
mkdir inc
cd inc
```

2. Create a new file in the `inc` directory named `dbinfo.inc`, and then edit the file by calling nano (or the editor of your choice).

```
>dbinfo.inc
nano dbinfo.inc
```

3. Add the following contents to the `dbinfo.inc` file. Here, *db_instance_endpoint* is your DB instance endpoint, without the port, for your DB instance.

> **Note**
>
> We recommend placing the user name and password information in a folder that isn't part of the document root for your web server. Doing this reduces the possibility of your security information being exposed.
> Make sure to change `master password` to a suitable password in your application.

```
<?php

define('DB_SERVER', 'db_instance_endpoint');
define('DB_USERNAME', 'tutorial_user');
define('DB_PASSWORD', 'master password');
define('DB_DATABASE', 'sample');
?>
```

4. Save and close the `dbinfo.inc` file. If you are using nano, save and close the file by using Ctrl +S and Ctrl+X.
5. Change the directory to `/var/www/html`.

```
cd /var/www/html
```

6. Create a new file in the `html` directory named `SamplePage.php`, and then edit the file by calling nano (or the editor of your choice).

```
>SamplePage.php
nano SamplePage.php
```

7. Add the following contents to the `SamplePage.php` file:

   MariaDB & MySQL

```
<?php include "../inc/dbinfo.inc"; ?>
```

```
<html>
<body>
<h1>Sample page</h1>
<?php

  /* Connect to MySQL and select the database. */
  $connection = mysqli_connect(DB_SERVER, DB_USERNAME, DB_PASSWORD);

  if (mysqli_connect_errno()) echo "Failed to connect to MySQL: " .
 mysqli_connect_error();

  $database = mysqli_select_db($connection, DB_DATABASE);

  /* Ensure that the EMPLOYEES table exists. */
  VerifyEmployeesTable($connection, DB_DATABASE);

  /* If input fields are populated, add a row to the EMPLOYEES table. */
  $employee_name = htmlentities($_POST['NAME']);
  $employee_address = htmlentities($_POST['ADDRESS']);

  if (strlen($employee_name) || strlen($employee_address)) {
    AddEmployee($connection, $employee_name, $employee_address);
  }
?>

<!-- Input form -->
<form action="<?PHP echo $_SERVER['SCRIPT_NAME'] ?>" method="POST">
  <table border="0">
    <tr>
      <td>NAME</td>
      <td>ADDRESS</td>
    </tr>
    <tr>
      <td>
        <input type="text" name="NAME" maxlength="45" size="30" />
      </td>
      <td>
        <input type="text" name="ADDRESS" maxlength="90" size="60" />
      </td>
      <td>
        <input type="submit" value="Add Data" />
      </td>
    </tr>
  </table>
```

```
</form>

<!-- Display table data. -->
<table border="1" cellpadding="2" cellspacing="2">
  <tr>
    <td>ID</td>
    <td>NAME</td>
    <td>ADDRESS</td>
  </tr>

<?php

$result = mysqli_query($connection, "SELECT * FROM EMPLOYEES");

while($query_data = mysqli_fetch_row($result)) {
  echo "<tr>";
  echo "<td>",$query_data[0], "</td>",
       "<td>",$query_data[1], "</td>",
       "<td>",$query_data[2], "</td>";
  echo "</tr>";
}
?>

</table>

<!-- Clean up. -->
<?php

  mysqli_free_result($result);
  mysqli_close($connection);

?>

</body>
</html>

<?php

/* Add an employee to the table. */
function AddEmployee($connection, $name, $address) {
   $n = mysqli_real_escape_string($connection, $name);
   $a = mysqli_real_escape_string($connection, $address);
```

```
   $query = "INSERT INTO EMPLOYEES (NAME, ADDRESS) VALUES ('$n', '$a');";

   if(!mysqli_query($connection, $query)) echo("<p>Error adding employee data.</
p>");
}

/* Check whether the table exists and, if not, create it. */
function VerifyEmployeesTable($connection, $dbName) {
  if(!TableExists("EMPLOYEES", $connection, $dbName))
  {
     $query = "CREATE TABLE EMPLOYEES (
         ID int(11) UNSIGNED AUTO_INCREMENT PRIMARY KEY,
         NAME VARCHAR(45),
         ADDRESS VARCHAR(90)
       )";

     if(!mysqli_query($connection, $query)) echo("<p>Error creating table.</
p>");
  }
}

/* Check for the existence of a table. */
function TableExists($tableName, $connection, $dbName) {
  $t = mysqli_real_escape_string($connection, $tableName);
  $d = mysqli_real_escape_string($connection, $dbName);

  $checktable = mysqli_query($connection,
      "SELECT TABLE_NAME FROM information_schema.TABLES WHERE TABLE_NAME = '$t'
 AND TABLE_SCHEMA = '$d'");

  if(mysqli_num_rows($checktable) > 0) return true;

  return false;
}
?>
```

PostgreSQL

```
<?php include "../inc/dbinfo.inc"; ?>

<html>
<body>
```

```
<h1>Sample page</h1>
<?php

/* Connect to PostgreSQL and select the database. */
$constring = "host=" . DB_SERVER . " dbname=" . DB_DATABASE . " user=" .
 DB_USERNAME . " password=" . DB_PASSWORD ;
$connection = pg_connect($constring);

if (!$connection){
 echo "Failed to connect to PostgreSQL";
 exit;
}

/* Ensure that the EMPLOYEES table exists. */
VerifyEmployeesTable($connection, DB_DATABASE);

/* If input fields are populated, add a row to the EMPLOYEES table. */
$employee_name = htmlentities($_POST['NAME']);
$employee_address = htmlentities($_POST['ADDRESS']);

if (strlen($employee_name) || strlen($employee_address)) {
  AddEmployee($connection, $employee_name, $employee_address);
}

?>

<!-- Input form -->
<form action="<?PHP echo $_SERVER['SCRIPT_NAME'] ?>" method="POST">
  <table border="0">
    <tr>
      <td>NAME</td>
      <td>ADDRESS</td>
    </tr>
    <tr>
      <td>
    <input type="text" name="NAME" maxlength="45" size="30" />
      </td>
      <td>
    <input type="text" name="ADDRESS" maxlength="90" size="60" />
      </td>
      <td>
    <input type="submit" value="Add Data" />
      </td>
    </tr>
```

```
  </table>
</form>
<!-- Display table data. -->
<table border="1" cellpadding="2" cellspacing="2">
  <tr>
    <td>ID</td>
    <td>NAME</td>
    <td>ADDRESS</td>
  </tr>

<?php

$result = pg_query($connection, "SELECT * FROM EMPLOYEES");

while($query_data = pg_fetch_row($result)) {
  echo "<tr>";
  echo "<td>",$query_data[0], "</td>",
       "<td>",$query_data[1], "</td>",
       "<td>",$query_data[2], "</td>";
  echo "</tr>";
}
?>
</table>

<!-- Clean up. -->
<?php

  pg_free_result($result);
  pg_close($connection);
?>
</body>
</html>

<?php

/* Add an employee to the table. */
function AddEmployee($connection, $name, $address) {
   $n = pg_escape_string($name);
   $a = pg_escape_string($address);
   echo "Forming Query";
   $query = "INSERT INTO EMPLOYEES (NAME, ADDRESS) VALUES ('$n', '$a');";
```

```
   if(!pg_query($connection, $query)) echo("<p>Error adding employee data.</
p>");
}

/* Check whether the table exists and, if not, create it. */
function VerifyEmployeesTable($connection, $dbName) {
  if(!TableExists("EMPLOYEES", $connection, $dbName))
  {
     $query = "CREATE TABLE EMPLOYEES (
         ID serial PRIMARY KEY,
         NAME VARCHAR(45),
         ADDRESS VARCHAR(90)
       )";

     if(!pg_query($connection, $query)) echo("<p>Error creating table.</p>");
  }
}
/* Check for the existence of a table. */
function TableExists($tableName, $connection, $dbName) {
  $t = strtolower(pg_escape_string($tableName)); //table name is case sensitive
  $d = pg_escape_string($dbName); //schema is 'public' instead of 'sample' db
 name so not using that

  $query = "SELECT TABLE_NAME FROM information_schema.TABLES WHERE TABLE_NAME =
 '$t';";
  $checktable = pg_query($connection, $query);

  if (pg_num_rows($checktable) >0) return true;
  return false;

}
?>
```

8. Save and close the `SamplePage.php` file.
9. Verify that your web server successfully connects to your DB instance by opening a web browser and browsing to `http://`*`EC2 instance endpoint`*`/SamplePage.php`, for example: `http://ec2-12-345-67-890.us-west-2.compute.amazonaws.com/SamplePage.php`.

You can use `SamplePage.php` to add data to your DB instance. The data that you add is then displayed on the page. To verify that the data was inserted into the table, install MySQL client on the Amazon EC2 instance. Then connect to the DB instance and query the table.

For information about installing the MySQL client and connecting to a DB instance, see Connecting to a DB instance running the MySQL database engine.

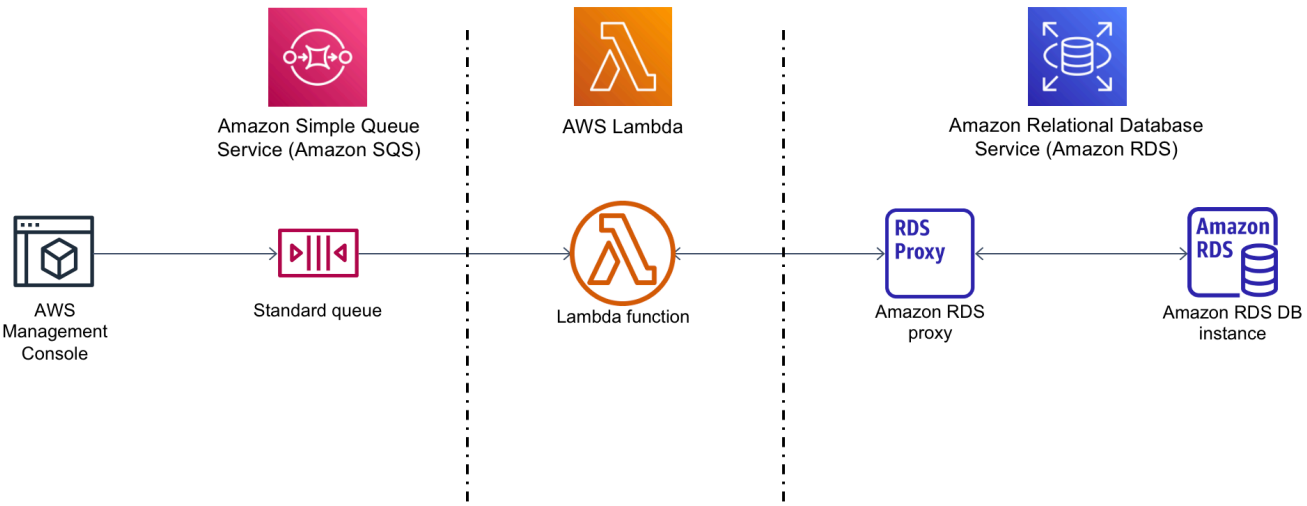
To make sure that your DB instance is as secure as possible, verify that sources outside of the VPC can't connect to your DB instance.

After you have finished testing your web server and your database, you should delete your DB instance and your Amazon EC2 instance.

- To delete a DB instance, follow the instructions in Deleting a DB instance. You don't need to create a final snapshot.
- To terminate an Amazon EC2 instance, follow the instruction in Terminate your instance in the *Amazon EC2 User Guide*.

Tutorial: Using a Lambda function to access an Amazon RDS database

In this tutorial, you use a Lambda function to write data to an Amazon Relational Database Service (Amazon RDS) database through RDS Proxy. Your Lambda function reads records from an Amazon Simple Queue Service (Amazon SQS) queue and writes a new item to a table in your database whenever a message is added. In this example, you use the AWS Management Console to manually add messages to your queue. The following diagram shows the AWS resources you use to complete the tutorial.



With Amazon RDS, you can run a managed relational database in the cloud using common database products like Microsoft SQL Server, MariaDB, MySQL, Oracle Database, and PostgreSQL. By using Lambda to access your database, you can read and write data in response to events, such as a new customer registering with your website. Your function, database instance, and proxy scale automatically to meet periods of high demand.

To complete this tutorial, you carry out the following tasks:

1. Launch an RDS for MySQL database instance and a proxy in your AWS account's default VPC.
2. Create and test a Lambda function that creates a new table in your database and writes data to it.

3. Create an Amazon SQS queue and configure it to invoke your Lambda function whenever a new message is added.
4. Test the complete setup by adding messages to your queue using the AWS Management Console and monitoring the results using CloudWatch Logs.

By completing these steps, you learn:

- How to use Amazon RDS to create a database instance and a proxy, and connect a Lambda function to the proxy.
- How to use Lambda to perform create and read operations on an Amazon RDS database.
- How to use Amazon SQS to invoke a Lambda function.

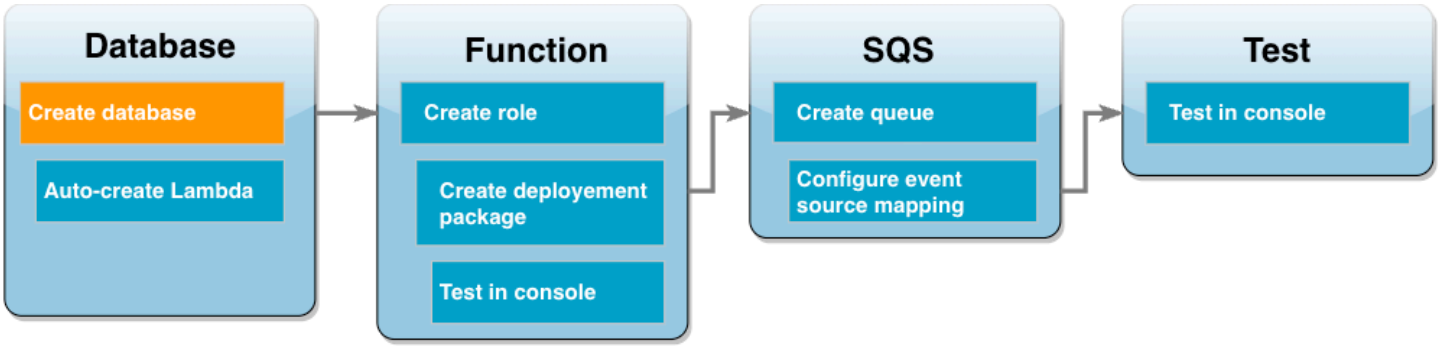
You can complete this tutorial using the AWS Management Console or the AWS Command Line Interface (AWS CLI).

Prerequisites

Before you begin, complete the steps in the following sections:

- Sign up for an AWS account
- Create a user with administrative access

Create an Amazon RDS DB instance



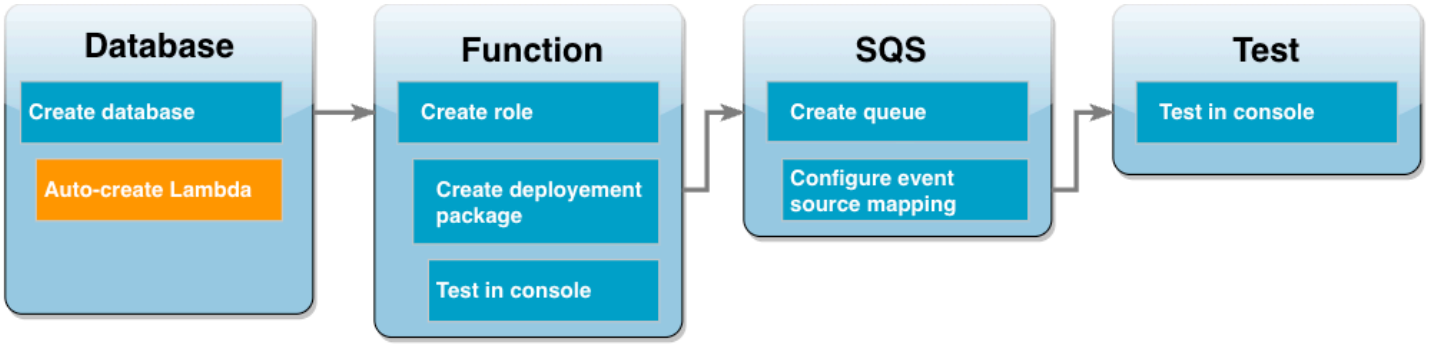
An Amazon RDS DB instance is an isolated database environment running in the AWS Cloud. An instance can contain one or more user-created databases. Unless you specify otherwise, Amazon RDS creates new database instances in the default VPC included in your AWS account. For more information about Amazon VPC, see the Amazon Virtual Private Cloud User Guide.

In this tutorial, you create a new instance in your AWS account's default VPC and create a database named `ExampleDB` in that instance. You can create your DB instance and database using either the AWS Management Console or the AWS CLI.

To create a database instance

1. Open the Amazon RDS console and choose **Create database**.
2. Leave the **Standard create** option selected, then in **Engine options**, choose **MySQL**.
3. In **Templates**, choose **Free tier**.
4. In **Settings**, for **DB instance identifier**, enter **`MySQLForLambda`**.
5. Set your username and password by doing the following:
   a. In **Credentials settings**, leave **Master username** set to `admin`.
   b. For **Master password**, enter and confirm a password to access your database.
6. Specify the database name by doing the following:
   - Leave all the remaining default options selected and scroll down to the **Additional configuration** section.
   - Expand this section and enter **`ExampleDB`** as the **Initial database name**.
7. Leave all the remaining default options selected and choose **Create database**.

Create Lambda function and proxy



You can use the RDS console to create a Lambda function and a proxy in the same VPC as the database.

> **Note**
>
> You can only create these associated resources when your database has completed creation and is in **Available** status.

To create an associated function and proxy

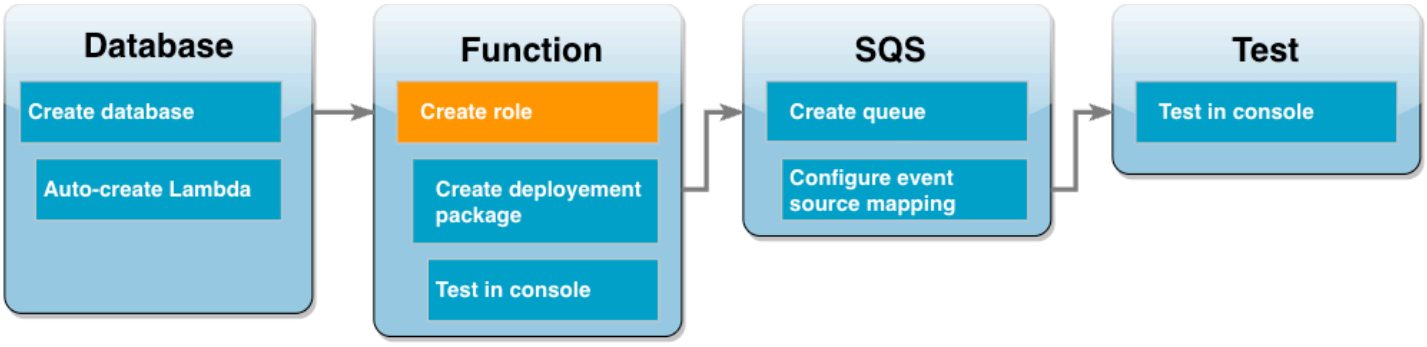
1. From the **Databases** page, check if your database is in the **Available** status. If so, proceed to the next step. Else, wait till your database is available.
2. Select your database and choose **Set up Lambda connection** from **Actions**.
3. In the **Set up Lambda connection** page, choose **Create new function**.

   Set the **New Lambda function name** to **`LambdaFunctionWithRDS`**.
4. In the **RDS Proxy** section, select the **Connect using RDS Proxy** option. Further choose **Create new proxy**.

   - For **Database credentials**, choose **Database username and password**.
   - For **Username**, specify `admin`.
   - For **Password**, enter the password you created for your database instance.
5. Select **Set up** to complete the proxy and Lambda function creation.

The wizard completes the set up and provides a link to the Lambda console to review your new function. Note the proxy endpoint before switching to the Lambda console.

Create a function execution role



Before you create your Lambda function, you create an execution role to give your function the necessary permissions. For this tutorial, Lambda needs permission to manage the network

connection to the VPC containing your database instance and to poll messages from an Amazon SQS queue.

To give your Lambda function the permissions it needs, this tutorial uses IAM managed policies. These are policies that grant permissions for many common use cases and are available in your AWS account. For more information about using managed policies, see Policy best practices.

To create the Lambda execution role

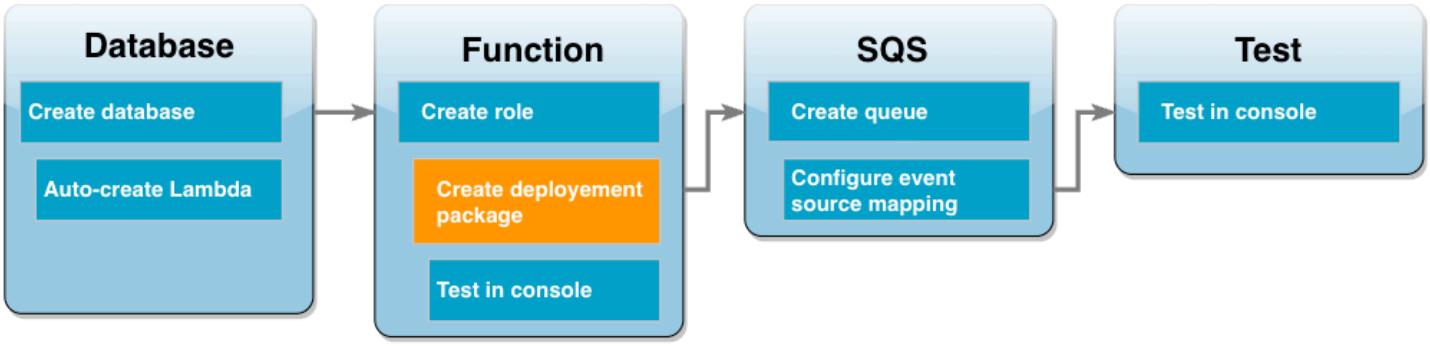
1. Open the Roles page of the IAM console and choose **Create role**.
2. For the **Trusted entity type**, choose **AWS service**, and for the **Use case**, choose **Lambda**.
3. Choose **Next**.
4. Add the IAM managed policies by doing the following:
    a. Using the policy search box, search for **`AWSLambdaSQSQueueExecutionRole`**.
    b. In the results list, select the check box next to the role, then choose **Clear filters**.
    c. Using the policy search box, search for **`AWSLambdaVPCAccessExecutionRole`**.
    d. In the results list, select the check box next to the role, then choose **Next**.
5. For the **Role name**, enter **`lambda-vpc-sqs-role`**, then choose **Create role**.

Later in the tutorial, you need the Amazon Resource Name (ARN) of the execution role you just created.

To find the execution role ARN

1. Open the Roles page of the IAM console and choose your role (`lambda-vpc-sqs-role`).
2. Copy the **ARN** displayed in the **Summary** section.

Create a Lambda deployment package



The following example Python code uses the PyMySQL package to open a connection to your database. The first time you invoke your function, it also creates a new table called `Customer`. The table uses the following schema, where `CustID` is the primary key:

```
Customer(CustID, Name)
```

The function also uses PyMySQL to add records to this table. The function adds records using customer IDs and names specified in messages you will add to your Amazon SQS queue.

The code creates the connection to your database outside of the handler function. Creating the connection in the initialization code allows the connection to be re-used by subsequent invocations of your function and improves performance. In a production application, you can also use provisioned concurrency to initialize a requested number of database connections. These connections are available as soon as your function is invoked.

```
import sys
import logging
import pymysql
import json
import os

# rds settings
user_name = os.environ['USER_NAME']
password = os.environ['PASSWORD']
rds_proxy_host = os.environ['RDS_PROXY_HOST']
db_name = os.environ['DB_NAME']

logger = logging.getLogger()
logger.setLevel(logging.INFO)
```

```
# create the database connection outside of the handler to allow connections to be
# re-used by subsequent function invocations.
try:
        conn = pymysql.connect(host=rds_proxy_host, user=user_name, passwd=password,
 db=db_name, connect_timeout=5)
except pymysql.MySQLError as e:
    logger.error("ERROR: Unexpected error: Could not connect to MySQL instance.")
    logger.error(e)
    sys.exit(1)

logger.info("SUCCESS: Connection to RDS for MySQL instance succeeded")

def lambda_handler(event, context):
    """
    This function creates a new RDS database table and writes records to it
    """
    message = event['Records'][0]['body']
    data = json.loads(message)
    CustID = data['CustID']
    Name = data['Name']

    item_count = 0
    sql_string = f"insert into Customer (CustID, Name) values(%s, %s)"

    with conn.cursor() as cur:
        cur.execute("create table if not exists Customer ( CustID  int NOT NULL, Name
 varchar(255) NOT NULL, PRIMARY KEY (CustID))")
        cur.execute(sql_string, (CustID, Name))
        conn.commit()
        cur.execute("select * from Customer")
        logger.info("The following items have been added to the database:")
        for row in cur:
            item_count += 1
            logger.info(row)
    conn.commit()

    return "Added %d items to RDS for MySQL table" %(item_count)
```

Note

In this example, your database access credentials are stored as environment variables. In production applications, we recommend that you use AWS Secrets Manager as a more

secure option. Note that if your Lambda function is in a VPC, to connect to Secrets Manager you need to create a VPC endpoint. See How to connect to Secrets Manager service within a Virtual Private Cloud to learn more.

To include the PyMySQL dependency with your function code, create a .zip deployment package. The following commands work for Linux, macOS, or Unix:

To create a .zip deployment package

1. Save the example code as a file named `lambda_function.py`.
2. In the same directory in which you created your `lambda_function.py` file, create a new directory named `package` and install the PyMySQL library.

```
mkdir package
pip install --target package pymysql
```

3. Create a zip file containing your application code and the PyMySQL library. In Linux or MacOS, run the following CLI commands. In Windows, use your preferred zip tool to create the `lambda_function.zip` file. Your `lambda_function.py` source code file and the folders containing your dependencies must be installed at the root of the .zip file.

```
cd package
zip -r ../lambda_function.zip .
cd ..
zip lambda_function.zip lambda_function.py
```

You can also create your deployment package using a Python virtual environment. See Deploy Python Lambda functions with .zip file archives.

Update the Lambda function

Using the .zip package you just created, you now update your Lambda function using the Lambda console. To enable your function to access your database, you also need to configure environment variables with your access credentials.

To update the Lambda function

1. Open the Functions page of the Lambda console and choose your function `LambdaFunctionWithRDS`.
2. In the **Runtime settings** tab, select **Edit** to change the **Runtime** of the function to **Python 3.10**.
3. Change the **Handler** to `lambda_function.lambda_handler`.
4. In the **Code** tab, choose **Upload from** and then **.zip file**.
5. Select the `lambda_function.zip` file you created in the previous stage and choose **Save**.

Now configure the function with the execution role you created earlier. This grants the function the permissions it needs to access your database instance and poll an Amazon SQS queue.

To configure the function's execution role

1. In the Functions page of the Lambda console, select the **Configuration** tab, then choose **Permissions**.
2. In **Execution role**, choose **Edit**.
3. In **Existing role**, choose your execution role (`lambda-vpc-sqs-role`).
4. Choose **Save**.

To configure your function's environment variables

1. In the Functions page of the Lambda console, select the **Configuration** tab, then choose **Environment variables**.
2. Choose **Edit**.
3. To add your database access credentials, do the following:

    a. Choose **Add environment variable**, then for **Key** enter **`USER_NAME`** and for **Value** enter **`admin`**.

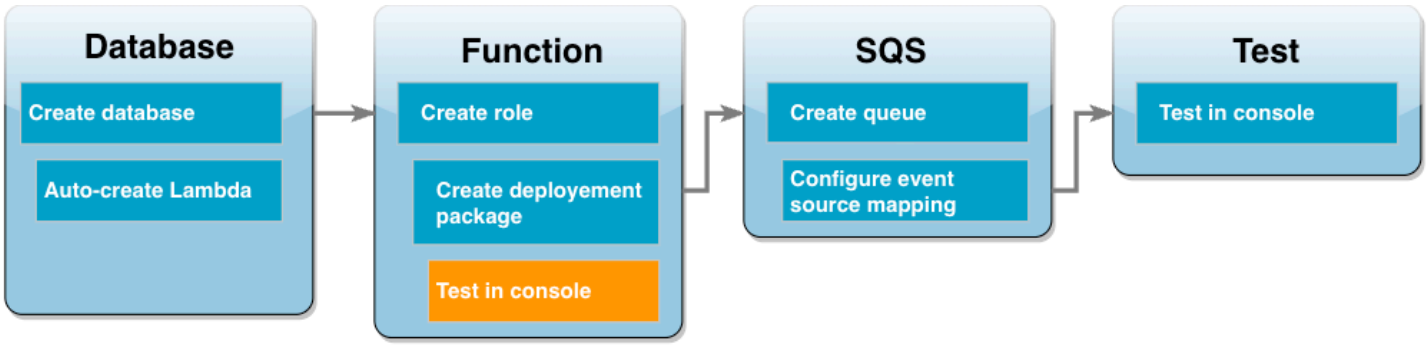
    b. Choose **Add environment variable**, then for **Key** enter **`DB_NAME`** and for **Value** enter **`ExampleDB`**.

    c. Choose **Add environment variable**, then for **Key** enter **`PASSWORD`** and for **Value** enter the password you chose when you created your database.

d. Choose **Add environment variable**, then for **Key** enter **`RDS_PROXY_HOST`** and for **Value** enter the RDS Proxy endpoint you noted earlier.

e. Choose **Save**.

Test your Lambda function in the console



You can now use the Lambda console to test your function. You create a test event which mimics the data your function will receive when you invoke it using Amazon SQS in the final stage of the tutorial. Your test event contains a JSON object specifying a customer ID and customer name to add to the `Customer` table your function creates.

To test the Lambda function

1. Open the Functions page of the Lambda console and choose your function.
2. Choose the **Test** section.
3. Choose **Create new event** and enter **`myTestEvent`** for the event name.
4. Copy the following code into **Event JSON** and choose **Save**.

```
{
  "Records": [
    {
      "messageId": "059f36b4-87a3-44ab-83d2-661975830a7d",
      "receiptHandle": "AQEBwJnKyrHigUMZj6rYigCgxlaS3SLy0a...",
      "body": "{\n     \"CustID\": 1021,\n     \"Name\": \"Martha Rivera\"\n}",
      "attributes": {
        "ApproximateReceiveCount": "1",
        "SentTimestamp": "1545082649183",
        "SenderId": "AIDAIENQZJOLO23YVJ4VO",
        "ApproximateFirstReceiveTimestamp": "1545082649185"
      },
```

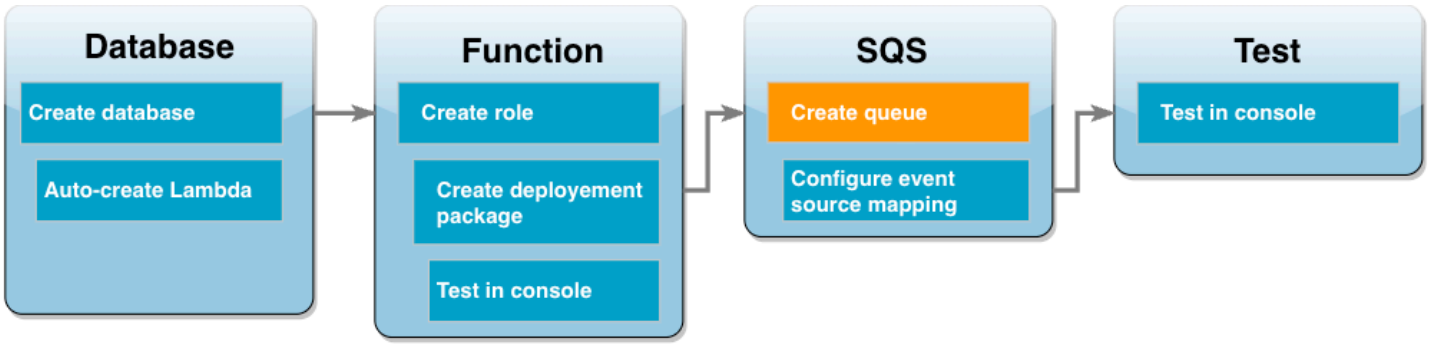
```
      "messageAttributes": {},
      "md5OfBody": "e4e68fb7bd0e697a0ae8f1bb342846b3",
      "eventSource": "aws:sqs",
      "eventSourceARN": "arn:aws:sqs:us-west-2:123456789012:my-queue",
      "awsRegion": "us-west-2"
    }
  ]
}
```

5. Choose **Test**.

In the **Execution results** tab, you should see results similar to the following displayed in the **Function Logs**:

```
[INFO] 2023-02-14T19:31:35.149Z bdd06682-00c7-4d6f-9abb-89f4bbb4a27f The following
 items have been added to the database:
[INFO] 2023-02-14T19:31:35.149Z bdd06682-00c7-4d6f-9abb-89f4bbb4a27f (1021, 'Martha
 Rivera')
```

Create an Amazon SQS queue

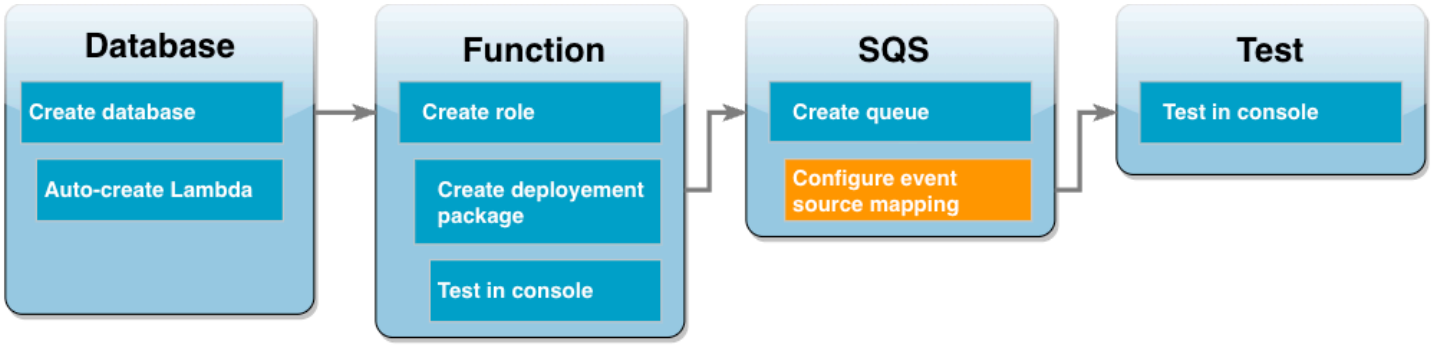


You have successfully tested the integration of your Lambda function and Amazon RDS database instance. Now you create the Amazon SQS queue you will use to invoke your Lambda function in the final stage of the tutorial.

To create the Amazon SQS queue (console)

1. Open the Queues page of the Amazon SQS console and select **Create queue**.
2. Leave the **Type** as **Standard** and enter **`LambdaRDSQueue`** for the name of your queue.
3. Leave all the default options selected and choose **Create queue**.

Create an event source mapping to invoke your Lambda function



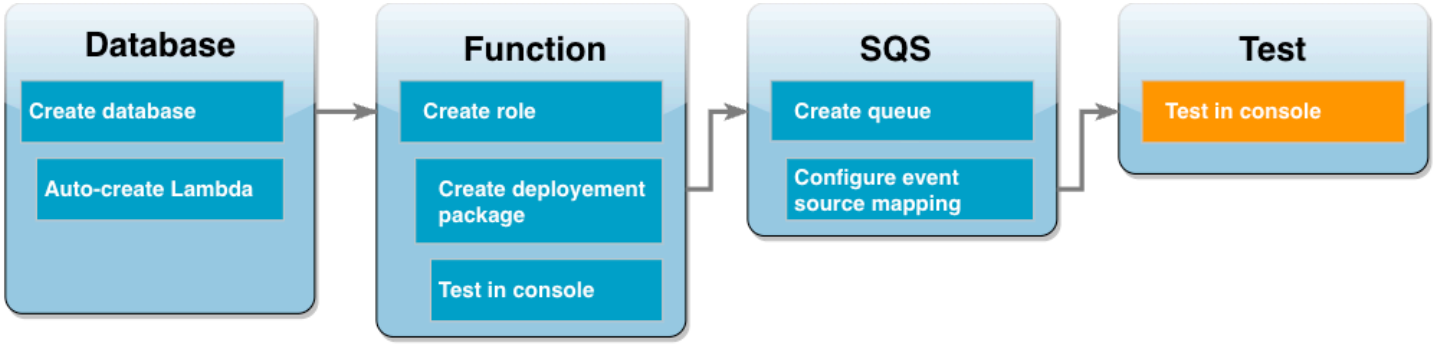
An event source mapping is a Lambda resource which reads items from a stream or queue and invokes a Lambda function. When you configure an event source mapping, you can specify a batch size so that records from your stream or queue are batched together into a single payload. In this example, you set the batch size to 1 so that your Lambda function is invoked every time you send a message to your queue. You can configure the event source mapping using either the AWS CLI or the Lambda console.

To create an event source mapping (console)

1. Open the Functions page of the Lambda console and select your function (`LambdaFunctionWithRDS`).
2. In the **Function overview** section, choose **Add trigger**.
3. For the source, select **Amazon SQS**, then select the name of your queue (`LambdaRDSQueue`).
4. For **Batch size**, enter **1**.
5. Leave all the other options set to the default values and choose **Add**.

You are now ready to test your complete setup by adding a message to your Amazon SQS queue.

Test and monitor your setup



To test your complete setup, add messages to your Amazon SQS queue using the console. You then use CloudWatch Logs to confirm that your Lambda function is writing records to your database as expected.

To test and monitor your setup

1. Open the Queues page of the Amazon SQS console and select your queue (`LambdaRDSQueue`).
2. Choose **Send and receive messages** and paste the following JSON into the **Message body** in the **Send message** section.

   ```
   {
       "CustID": 1054,
       "Name": "Richard Roe"
   }
   ```

3. Choose **Send message**.

   Sending your message to the queue will cause Lambda to invoke your function through your event source mapping. To confirm that Lambda has invoked your function as expected, use CloudWatch Logs to verify that the function has written the customer name and ID to your database table.

4. Open the Log groups page of the CloudWatch console and select the log group for your function (`/aws/lambda/LambdaFunctionWithRDS`).
5. In the **Log streams** section, choose the most recent log stream.

   Your table should contain two customer records, one from each invocation of your function. In the log stream, you should see messages similar to the following:

   ```
   [INFO] 2023-02-14T19:06:43.873Z 45368126-3eee-47f7-88ca-3086ae6d3a77 The following
    items have been added to the database:
   [INFO] 2023-02-14T19:06:43.873Z 45368126-3eee-47f7-88ca-3086ae6d3a77 (1021, 'Martha
    Rivera')
   [INFO] 2023-02-14T19:06:43.873Z 45368126-3eee-47f7-88ca-3086ae6d3a77 (1054,
    'Richard Roe')
   ```

Clean up your resources

You can now delete the resources that you created for this tutorial, unless you want to retain them. By deleting AWS resources that you're no longer using, you prevent unnecessary charges to your AWS account.

To delete the Lambda function

1. Open the Functions page of the Lambda console.
2. Select the function that you created.
3. Choose **Actions**, **Delete**.
4. Choose **Delete**.

To delete the execution role

1. Open the Roles page of the IAM console.
2. Select the execution role that you created.
3. Choose **Delete role**.
4. Choose **Yes, delete**.

To delete the MySQL DB instance

1. Open the Databases page of the Amazon RDS console.
2. Select the database you created.
3. Choose **Actions**, **Delete**.
4. Clear the **Create final snapshot** check box.
5. Enter **`delete me`** in the text box.
6. Choose **Delete**.

To delete the Amazon SQS queue

1. Sign in to the AWS Management Console and open the Amazon SQS console at https://console.aws.amazon.com/sqs/.
2. Select the queue you created.
3. Choose **Delete**.

4. Enter **`delete`** in the text box.
5. Choose **Delete**.

Amazon RDS tutorials and sample code

The AWS documentation includes several tutorials that guide you through common Amazon RDS use cases. Many of these tutorials show you how to use Amazon RDS with other AWS services. In addition, you can access sample code in GitHub.

> **Note**
>
> You can find more tutorials at the AWS Database Blog. For information about training, see AWS Training and Certification.

Topics

Tutorials in this guide

The following tutorials in this guide show you how to perform common tasks with Amazon RDS:

- Tutorial: Create a VPC for use with a DB instance (IPv4 only)

  Learn how to include a DB instance in a virtual private cloud (VPC) based on the Amazon VPC service. In this case, the VPC shares data with a web server that is running on an Amazon EC2 instance in the same VPC.
- Tutorial: Create a VPC for use with a DB instance (dual-stack mode)

  Learn how to include a DB instance in a virtual private cloud (VPC) based on the Amazon VPC service. In this case, the VPC shares data with an Amazon EC2 instance in the same VPC. In this tutorial, you create the VPC for this scenario that works with a database running in dual-stack mode.

- Tutorial: Create a web server and an Amazon RDS DB instance

  Learn how to install an Apache web server with PHP and create a MySQL database. The web server runs on an Amazon EC2 instance using Amazon Linux, and the MySQL database is a MySQL DB instance. Both the Amazon EC2 instance and the DB instance run in an Amazon VPC.

- Tutorial: Restore an Amazon RDS DB instance from a DB snapshot

  Learn how to restore a DB instance from a DB snapshot.

- Tutorial: Using a Lambda function to access an Amazon RDS database

  Learn how to create a Lambda function from the RDS console to access a database through a proxy, create a table, add a few records, and retrieve the records from the table. You also learn how to invoke the Lambda function and verify the query results.

- Tutorial: Specify which DB instances to stop by using tags

  Learn how to use tags to specify which DB instances to stop.

- Tutorial: Log DB instance state changes using Amazon EventBridge

  Learn how to log a DB instance state change using Amazon EventBridge and AWS Lambda.

- Tutorial: Creating an Amazon CloudWatch alarm for Multi-AZ DB cluster replica lag

  Learn how to create a CloudWatch alarm that sends an Amazon SNS message when replica lag for a Multi-AZ DB cluster has exceeded a threshold. An alarm watches the `ReplicaLag` metric over a time period that you specify. The action is a notification sent to an Amazon SNS topic or Amazon EC2 Auto Scaling policy.

Tutorials in other AWS guides

The following tutorials in other AWS guides show you how to perform common tasks with Amazon RDS:

- Tutorial: Rotating a Secret for an AWS Database in the *AWS Secrets Manager User Guide*

  Learn how to create a secret for an AWS database and configure the secret to rotate on a schedule. You trigger one rotation manually, and then confirm that the new version of the secret continues to provide access.

- Tutorials and samples in the *AWS Elastic Beanstalk Developer Guide*

Learn how to deploy applications that use Amazon RDS databases with AWS Elastic Beanstalk.

- Using Data from an Amazon RDS Database to Create an Amazon ML Datasource in the *Amazon Machine Learning Developer Guide*

  Learn how to create an Amazon Machine Learning (Amazon ML) datasource object from data stored in a MySQL DB instance.

- Manually Enabling Access to an Amazon RDS Instance in a VPC in the *Amazon QuickSight User Guide*

  Learn how to enable Amazon QuickSight access to an Amazon RDS DB instance in a VPC.

AWS workshop and lab content portal for Amazon RDS PostgreSQL

The following collection of workshops and other hands-on content helps you to gain an understanding of the Amazon RDS PostgreSQL features and capabilities:

- Creating a DB instance

  Learn how to create the DB instance.

- Performance Monitoring with RDS Tools

  Learn how to use AWS and SQL tools(Cloudwatch, Enhanced Monitoring, Slow Query Logs, Performance Insights, PostgreSQL Catalog Views) to understand performance issues and identify ways to improve performance of your database.

AWS workshop and lab content portal for Amazon RDS MySQL

The following collection of workshops and other hands-on content helps you to gain an understanding of the Amazon RDS MySQL features and capabilities:

- Creating a DB instance

  Learn how to create the DB instance.

- Using Performance Insights

Learn how to monitor and tune your DB instance using Performance insights.

Tutorials and sample code in GitHub

The following tutorials and sample code in GitHub show you how to perform common tasks with Amazon RDS:

- Creating the Amazon Relational Database Service item tracker

  Learn how to create an application that tracks and reports on work items. This application uses Amazon RDS, Amazon Simple Email Service, Elastic Beanstalk, and SDK for Java 2.x.

Using this service with an AWS SDK

AWS software development kits (SDKs) are available for many popular programming languages. Each SDK provides an API, code examples, and documentation that make it easier for developers to build applications in their preferred language.

SDK documentation	Code examples
AWS SDK for C++	AWS SDK for C++ code examples
AWS CLI	AWS CLI code examples
AWS SDK for Go	AWS SDK for Go code examples
AWS SDK for Java	AWS SDK for Java code examples
AWS SDK for JavaScript	AWS SDK for JavaScript code examples
AWS SDK for Kotlin	AWS SDK for Kotlin code examples
AWS SDK for .NET	AWS SDK for .NET code examples
AWS SDK for PHP	AWS SDK for PHP code examples
AWS Tools for PowerShell	Tools for PowerShell code examples

SDK documentation	Code examples
AWS SDK for Python (Boto3)	AWS SDK for Python (Boto3) code examples
AWS SDK for Ruby	AWS SDK for Ruby code examples
AWS SDK for Rust	AWS SDK for Rust code examples
AWS SDK for SAP ABAP	AWS SDK for SAP ABAP code examples
AWS SDK for Swift	AWS SDK for Swift code examples

For examples specific to this service, see Code examples for Amazon RDS using AWS SDKs.

Example availability

Best practices for Amazon RDS

Learn best practices for working with Amazon RDS. As new best practices are identified, we will keep this section up to date.

Topics

> **Note**
>
> For common recommendations for Amazon RDS, see Recommendations from Amazon RDS.

Amazon RDS basic operational guidelines

The following are basic operational guidelines that everyone should follow when working with Amazon RDS. Note that the Amazon RDS Service Level Agreement requires that you follow these guidelines:

- Use metrics to monitor your memory, CPU, replica lag, and storage usage. You can set up Amazon CloudWatch to notify you when the usage patterns change or when your deployment approaches capacity limits. This allows you to maintain system performance and availability.
- Scale up your DB instance when you are approaching storage capacity limits. You should have some buffer in storage and memory to accommodate unforeseen increases in demand from your applications.
- Enable automatic backups and set the backup window to occur during the daily low in write IOPS. That's when a backup is least disruptive to your database usage.
- If your database workload requires more I/O than you have provisioned, recovery after a failover or database failure will be slow. To increase the I/O capacity of a DB instance, do any or all of the following:
  - Migrate to a different DB instance class with high I/O capacity.
  - Convert from magnetic storage to either General Purpose or Provisioned IOPS storage, depending on how much of an increase you need. For information on available storage types, see Amazon RDS storage types.

    If you convert to Provisioned IOPS storage, make sure you also use a DB instance class that is optimized for Provisioned IOPS. For information on Provisioned IOPS, see Provisioned IOPS SSD storage.
  - If you are already using Provisioned IOPS storage, provision additional throughput capacity.
- If your client application is caching the Domain Name Service (DNS) data of your DB instances, set a time-to-live (TTL) value of less than 30 seconds. The underlying IP address of a DB instance can change after a failover. Caching the DNS data for an extended time can thus lead to connection failures. Your application might try to connect to an IP address that's no longer in service.
- Test failover for your DB instance to understand how long the process takes for your particular use case. Also test failover to ensure that the application that accesses your DB instance can automatically connect to the new DB instance after failover occurs.

DB instance RAM recommendations

An Amazon RDS performance best practice is to allocate enough RAM so that your *working set* resides almost completely in memory. The working set is the data and indexes that are frequently in use on your instance. The more you use the DB instance, the more the working set will grow.

To tell if your working set is almost all in memory, check the ReadIOPS metric (using Amazon CloudWatch) while the DB instance is under load. The value of ReadIOPS should be small and stable. In some cases, scaling up the DB instance class to a class with more RAM results in a dramatic drop in ReadIOPS. In these cases, your working set was not almost completely in memory. Continue to scale up until ReadIOPS no longer drops dramatically after a scaling operation, or ReadIOPS is reduced to a very small amount. For information on monitoring a DB instance's metrics, see Viewing metrics in the Amazon RDS console.

AWS database drivers

We recommend the AWS suite of drivers for application connectivity. The drivers have been designed to provide support for faster switchover and failover times, and authentication with AWS Secrets Manager, AWS Identity and Access Management (IAM), and Federated Identity. The AWS drivers rely on monitoring DB instance status and being aware of the instance topology to determine the new writer. This approach reduces switchover and failover times to single-digit seconds, compared to tens of seconds for open-source drivers.

As new service features are introduced, the goal of the AWS suite of drivers is to have built-in support for these service features.

For more information, see Connecting to DB instances with the AWS drivers.

Using Enhanced Monitoring to identify operating system issues

When Enhanced Monitoring is enabled, Amazon RDS provides metrics in real time for the operating system (OS) that your DB instance runs on. You can view the metrics for your DB instance using the console. You can also consume the Enhanced Monitoring JSON output from Amazon CloudWatch Logs in a monitoring system of your choice. For more information about Enhanced Monitoring, see Monitoring OS metrics with Enhanced Monitoring.

Using metrics to identify performance issues

To identify performance issues caused by insufficient resources and other common bottlenecks, you can monitor the metrics available for your Amazon RDS DB instance.

Viewing performance metrics

You should monitor performance metrics on a regular basis to see the average, maximum, and minimum values for a variety of time ranges. If you do so, you can identify when performance is

degraded. You can also set Amazon CloudWatch alarms for particular metric thresholds so you are alerted if they are reached.

To troubleshoot performance issues, it's important to understand the baseline performance of the system. When you set up a DB instance and run it with a typical workload, capture the average, maximum, and minimum values of all performance metrics. Do so at a number of different intervals (for example, one hour, 24 hours, one week, two weeks). This can give you an idea of what is normal. It helps to get comparisons for both peak and off-peak hours of operation. You can then use this information to identify when performance is dropping below standard levels.

If you use Multi-AZ DB clusters, monitor the time difference between the latest transaction on the writer DB instance and the latest applied transaction on a reader DB instance. This difference is called *replica lag*. For more information, see Replica lag and Multi-AZ DB clusters.

You can view the combined Performance Insights and CloudWatch metrics in the Performance Insights dashboard and monitor your DB instance. To use this monitoring view, Performance Insights must be turned on for your DB instance. For information about this monitoring view, see Viewing combined metrics with the Performance Insights dashboard.

You can create a performance analysis report for a specific time period and view the insights identified and the recommendations to resolve the issues. For more information see, Creating a performance analysis report in Performance Insights.

To view performance metrics

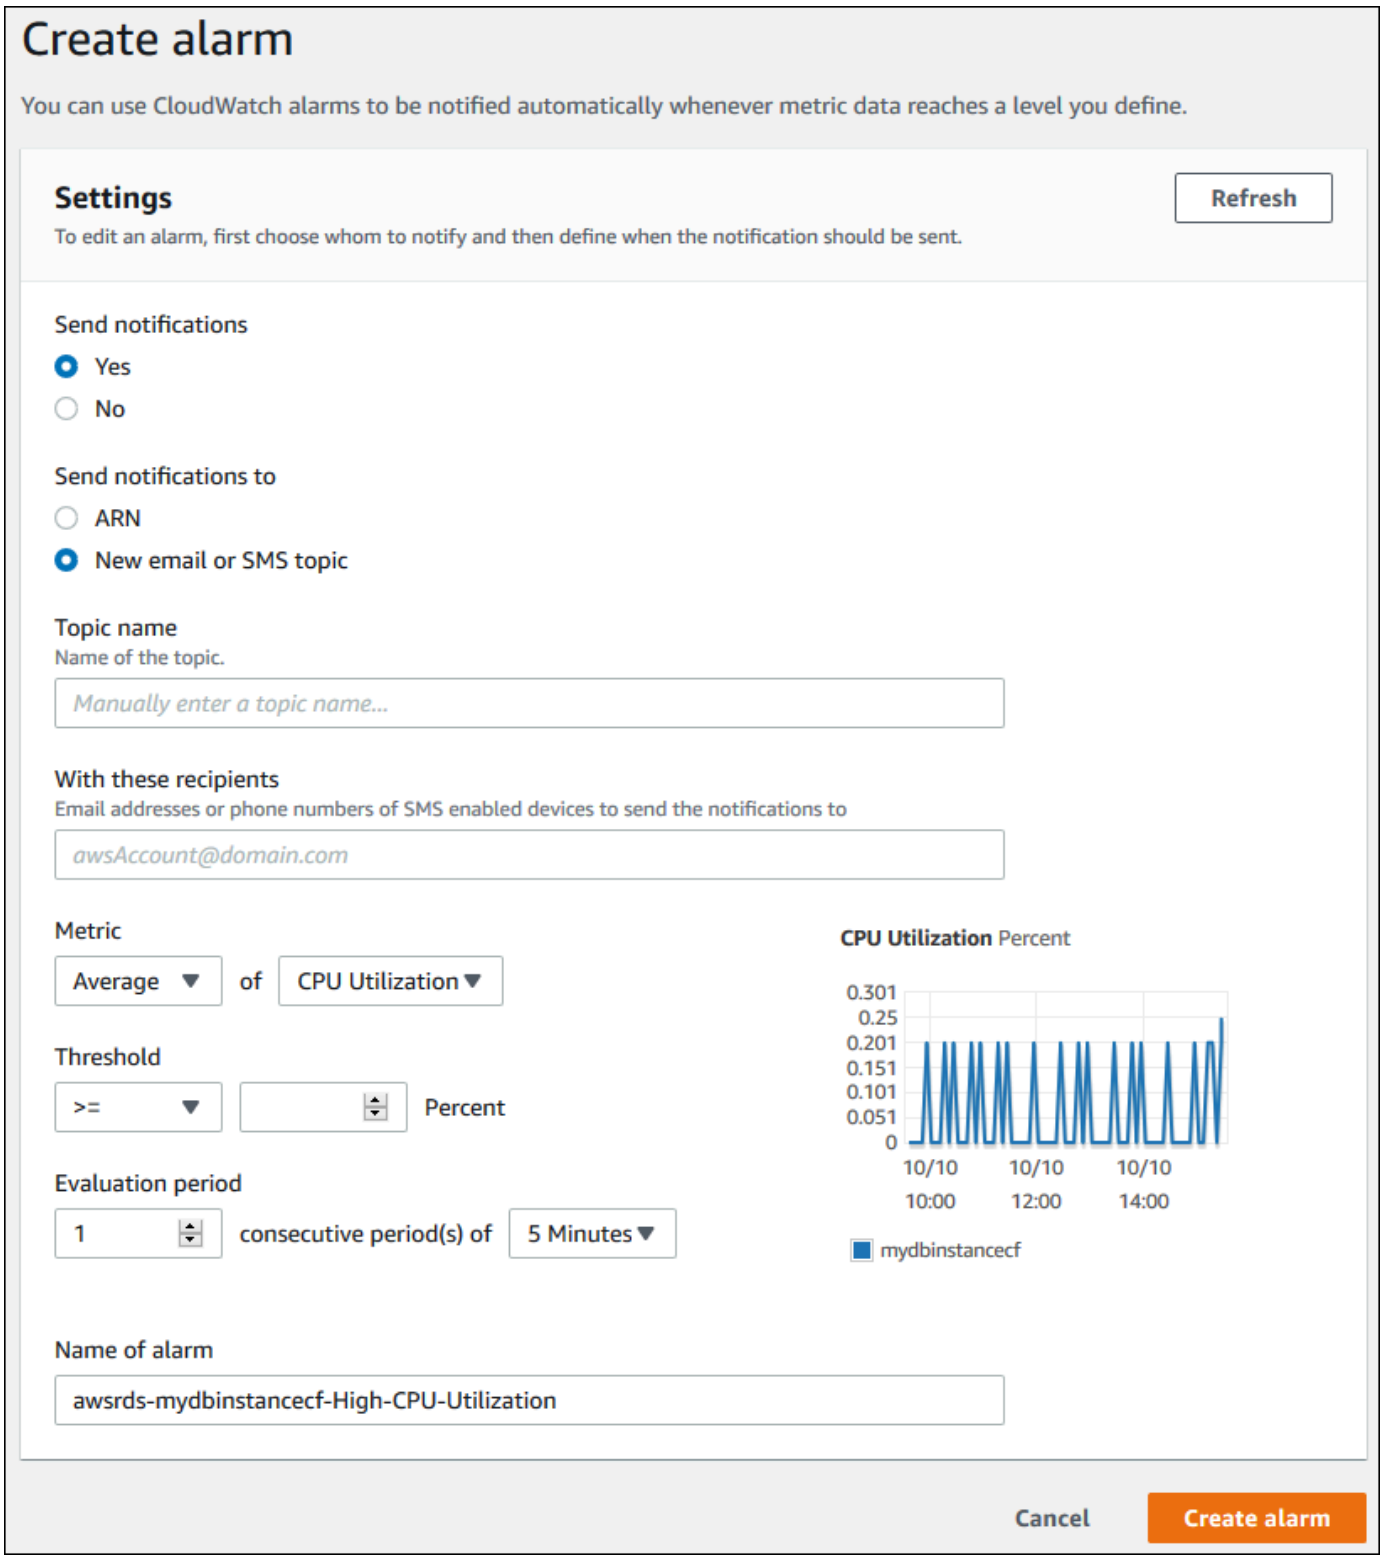
1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**, and then choose a DB instance.
3. Choose **Monitoring**.

   The dashboard provides the performance metrics. The metrics default to show the information for the last three hours.
4. Use the numbered buttons in the upper-right to page through the additional metrics, or adjust the settings to see more metrics.
5. Choose a performance metric to adjust the time range in order to see data for other than the current day. You can change the **Statistic**, **Time Range**, and **Period** values to adjust the information displayed. For example, you might want to see the peak values for a metric for each day of the last two weeks. If so, set **Statistic** to **Maximum**, **Time Range** to **Last 2 Weeks**, and **Period** to **Day**.

You can also view performance metrics using the CLI or API. For more information, see Viewing metrics in the Amazon RDS console.

To set a CloudWatch alarm

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**, and then choose a DB instance.
3. Choose **Logs & events**.
4. In the **CloudWatch alarms** section, choose **Create alarm**.



5. For **Send notifications**, choose **Yes**, and for **Send notifications to**, choose **New email or SMS topic**.

6. For **Topic name**, enter a name for the notification, and for **With these recipients**, enter a comma-separated list of email addresses and phone numbers.
7. For **Metric**, choose the alarm statistic and metric to set.
8. For **Threshold**, specify whether the metric must be greater than, less than, or equal to the threshold, and specify the threshold value.
9. For **Evaluation period**, choose the evaluation period for the alarm. For **consecutive period(s) of**, choose the period during which the threshold must have been reached in order to trigger the alarm.
10. For **Name of alarm**, enter a name for the alarm.
11. Choose **Create Alarm**.

The alarm appears in the **CloudWatch alarms** section.

Evaluating performance metrics

A DB instance has a number of different categories of metrics, and how to determine acceptable values depends on the metric.

CPU

- CPU Utilization – Percentage of computer processing capacity used.

Memory

- Freeable Memory – How much RAM is available on the DB instance, in bytes. The red line in the Monitoring tab metrics is marked at 75% for CPU, Memory and Storage Metrics. If instance memory consumption frequently crosses that line, then this indicates that you should check your workload or upgrade your instance.
- Swap Usage – How much swap space is used by the DB instance, in bytes.

Disk space

- Free Storage Space – How much disk space is not currently being used by the DB instance, in megabytes.

Input/output operations

- Read IOPS, Write IOPS – The average number of disk read or write operations per second.
- Read Latency, Write Latency – The average time for a read or write operation in milliseconds.
- Read Throughput, Write Throughput – The average number of megabytes read from or written to disk per second.
- Queue Depth – The number of I/O operations that are waiting to be written to or read from disk.

Network traffic

- Network Receive Throughput, Network Transmit Throughput – The rate of network traffic to and from the DB instance in bytes per second.

Database connections

- DB Connections – The number of client sessions that are connected to the DB instance.

For more detailed individual descriptions of the performance metrics available, see Monitoring Amazon RDS metrics with Amazon CloudWatch.

Generally speaking, acceptable values for performance metrics depend on what your baseline looks like and what your application is doing. Investigate consistent or trending variances from your baseline. Advice about specific types of metrics follows:

- **High CPU or RAM consumption –** High values for CPU or RAM consumption might be appropriate. For example, they might be so if they are in keeping with your goals for your application (like throughput or concurrency) and are expected.
- **Disk space consumption –** Investigate disk space consumption if space used is consistently at or above 85 percent of the total disk space. See if it is possible to delete data from the instance or archive data to a different system to free up space.
- **Network traffic –** For network traffic, talk with your system administrator to understand what expected throughput is for your domain network and internet connection. Investigate network traffic if throughput is consistently lower than expected.
- **Database connections –** Consider constraining database connections if you see high numbers of user connections in conjunction with decreases in instance performance and response time. The best number of user connections for your DB instance will vary based on your instance class

and the complexity of the operations being performed. To determine the number of database connections, associate your DB instance with a parameter group. In this group, set the *User Connections* parameter to other than 0 (unlimited). You can either use an existing parameter group or create a new one. For more information, see Parameter groups for Amazon RDS.

- **IOPS metrics –** The expected values for IOPS metrics depend on disk specification and server configuration, so use your baseline to know what is typical. Investigate if values are consistently different than your baseline. For best IOPS performance, make sure your typical working set will fit into memory to minimize read and write operations.

For issues with performance metrics, a first step to improve performance is to tune the most used and most expensive queries. Tune them to see if doing so lowers the pressure on system resources. For more information, see Tuning queries.

If your queries are tuned and an issue persists, consider upgrading your Amazon RDS DB instance classes. You might upgrade it to one with more of the resource (CPU, RAM, disk space, network bandwidth, I/O capacity) that is related to the issue.

Tuning queries

One of the best ways to improve DB instance performance is to tune your most commonly used and most resource-intensive queries. Here, you tune them to make them less expensive to run. For information on improving queries, use the following resources:

- MySQL – See Optimizing SELECT statements in the MySQL documentation. For additional query tuning resources, see MySQL performance tuning and optimization resources.
- Oracle – See Database SQL Tuning Guide in the Oracle Database documentation.
- SQL Server – See Analyzing a query in the Microsoft documentation. You can also use the execution-, index-, and I/O-related data management views (DMVs) described in System Dynamic Management Views in the Microsoft documentation to troubleshoot SQL Server query issues.

  A common aspect of query tuning is creating effective indexes. For potential index improvements for your DB instance, see Database Engine Tuning Advisor in the Microsoft documentation. For information on using Tuning Advisor on RDS for SQL Server, see Analyzing your database workload on an Amazon RDS for SQL Server DB instance with Database Engine Tuning Advisor.
- PostgreSQL – See Using EXPLAIN in the PostgreSQL documentation to learn how to analyze a query plan. You can use this information to modify a query or underlying tables in order to improve query performance.

For information about how to specify joins in your query for the best performance, see Controlling the planner with explicit JOIN clauses.

- MariaDB – See Query optimizations in the MariaDB documentation.

Best practices for working with MySQL

Both table sizes and number of tables in a MySQL database can affect performance.

Table size

Typically, operating system constraints on file sizes determine the effective maximum table size for MySQL databases. So, the limits usually aren't determined by internal MySQL constraints.

On a MySQL DB instance, avoid tables in your database growing too large. Although the general storage limit is 64 TiB, provisioned storage limits restrict the maximum size of a MySQL table file to 16 TiB. Partition your large tables so that file sizes are well under the 16 TiB limit. This approach can also improve performance and recovery time. For more information, see MySQL file size limits in Amazon RDS.

Very large tables (greater than 100 GB in size) can negatively affect performance for both reads and writes (including DML statements and especially DDL statements). Indexes on larges tables can significantly improve select performance, but they can also degrade the performance of DML statements. DDL statements, such as `ALTER TABLE`, can be significantly slower for the large tables because those operations might completely rebuild a table in some cases. These DDL statements might lock the tables for the duration of the operation.

The amount of memory required by MySQL for reads and writes depends on the tables involved in the operations. It is a best practice to have at least enough RAM to the hold the indexes of *actively* used tables. To find the ten largest tables and indexes in a database, use the following query:

```
select table_schema, TABLE_NAME, dat, idx from
(SELECT table_schema, TABLE_NAME,
       ( data_length ) / 1024 / 1024 as dat,
       ( index_length ) / 1024 / 1024 as idx
FROM information_schema.TABLES
order by 3 desc ) a
order by 3 desc
limit 10;
```

Number of tables

Your underlying file system might have a limit on the number of files that represent tables. However, MySQL has no limit on the number of tables. Despite this, the total number of tables in the MySQL InnoDB storage engine can contribute to the performance degradation, regardless of the size of those tables. To limit the operating system impact, you can split the tables across multiple databases in the same MySQL DB instance. Doing so might limit the number of files in a directory but won't solve the overall problem.

When there is performance degradation because of a large number of tables (more than 10 thousand), it is caused by MySQL working with storage files, including opening and closing them. To address this issue, you can increase the size of the `table_open_cache` and `table_definition_cache` parameters. However, increasing the values of those parameters might significantly increase the amount of memory MySQL uses, and might even use all of the available memory. For more information, see How MySQL Opens and Closes Tables in the MySQL documentation.

In addition, too many tables can significantly affect MySQL startup time. Both a clean shutdown and restart and a crash recovery can be affected, especially in versions prior to MySQL 8.0.

We recommend having fewer than 10,000 tables total across all of the databases in a DB instance. For a use case with a large number of tables in a MySQL database, see One Million Tables in MySQL 8.0.

Storage engine

The point-in-time restore and snapshot restore features of Amazon RDS for MySQL require a crash-recoverable storage engine. These features are supported for the InnoDB storage engine only. Although MySQL supports multiple storage engines with varying capabilities, not all of them are optimized for crash recovery and data durability. For example, the MyISAM storage engine doesn't support reliable crash recovery and might prevent a point-in-time restore or snapshot restore from working as intended. This might result in lost or corrupt data when MySQL is restarted after a crash.

InnoDB is the recommended and supported storage engine for MySQL DB instances on Amazon RDS. InnoDB instances can also be migrated to Aurora, while MyISAM instances can't be migrated. However, MyISAM performs better than InnoDB if you require intense, full-text search capability. If you still choose to use MyISAM with Amazon RDS, following the steps outlined in Automated

backups with unsupported MySQL storage engines can be helpful in certain scenarios for snapshot restore functionality.

If you want to convert existing MyISAM tables to InnoDB tables, you can use the process outlined in Converting Tables from MyISAM to InnoDB in the MySQL documentation. MyISAM and InnoDB have different strengths and weaknesses, so you should fully evaluate the impact of making this switch on your applications before doing so.

In addition, Federated Storage Engine is currently not supported by Amazon RDS for MySQL.

Best practices for working with MariaDB

Both table sizes and number of tables in a MariaDB database can affect performance.

Table size

Typically, operating system constraints on file sizes determine the effective maximum table size for MariaDB databases. So, the limits usually aren't determined by internal MariaDB constraints.

On a MariaDB DB instance, avoid tables in your database growing too large. Although the general storage limit is 64 TiB, provisioned storage limits restrict the maximum size of a MariaDB table file to 16 TiB. Partition your large tables so that file sizes are well under the 16 TiB limit. This approach can also improve performance and recovery time.

Very large tables (greater than 100 GB in size) can negatively affect performance for both reads and writes (including DML statements and especially DDL statements). Indexes on larges tables can significantly improve select performance, but they can also degrade the performance of DML statements. DDL statements, such as `ALTER TABLE`, can be significantly slower for the large tables because those operations might completely rebuild a table in some cases. These DDL statements might lock the tables for the duration of the operation.

The amount of memory required by MariaDB for reads and writes depends on the tables involved in the operations. It is a best practice to have at least enough RAM to the hold the indexes of *actively* used tables. To find the ten largest tables and indexes in a database, use the following query:

```
select table_schema, TABLE_NAME, dat, idx from
(SELECT table_schema, TABLE_NAME,
```

```
       ( data_length ) / 1024 / 1024 as dat,
       ( index_length ) / 1024 / 1024 as idx
FROM information_schema.TABLES
order by 3 desc ) a
order by 3 desc
limit 10;
```

Number of tables

Your underlying file system might have a limit on the number of files that represent tables. However, MariaDB has no limit on the number of tables. Despite this, the total number of tables in the MariaDB InnoDB storage engine can contribute to the performance degradation, regardless of the size of those tables. To limit the operating system impact, you can split the tables across multiple databases in the same MariaDB DB instance. Doing so might limit the number of files in a directory but doesn't solve the overall problem.

When there is performance degradation because of a large number of tables (more than 10,000), it's caused by MariaDB working with storage files. This work includes MariaDB opening and closing storage files. To address this issue, you can increase the size of the `table_open_cache` and `table_definition_cache` parameters. However, increasing the values of those parameters might significantly increase the amount of memory MariaDB uses. It might even use all of the available memory. For more information, see Optimizing table_open_cache in the MariaDB documentation.

In addition, too many tables can significantly affect MariaDB startup time. Both a clean shutdown and restart and a crash recovery can be affected. We recommend having fewer than ten thousand tables total across all of the databases in a DB instance.

Storage engine

The point-in-time restore and snapshot restore features of Amazon RDS for MariaDB require a crash-recoverable storage engine. Although MariaDB supports multiple storage engines with varying capabilities, not all of them are optimized for crash recovery and data durability. For example, although Aria is a crash-safe replacement for MyISAM, it might still prevent a point-in-time restore or snapshot restore from working as intended. This might result in lost or corrupt data when MariaDB is restarted after a crash. InnoDB is the recommended and supported storage engine for MariaDB DB instances on Amazon RDS. If you still choose to use Aria with Amazon RDS, following the steps outlined in Automated backups with unsupported MariaDB storage engines can be helpful in certain scenarios for snapshot restore functionality.

If you want to convert existing MyISAM tables to InnoDB tables, you can use the process outlined in Converting Tables from MyISAM to InnoDB in the MariaDB documentation. MyISAM and InnoDB have different strengths and weaknesses, so you should fully evaluate the impact of making this switch on your applications before doing so.

Best practices for working with Oracle

For information about best practices for working with Amazon RDS for Oracle, see Best practices for running Oracle database on Amazon Web Services.

A 2020 AWS virtual workshop included a presentation on running production Oracle databases on Amazon RDS. A video of the presentation is available here.

Best practices for working with PostgreSQL

Of two important areas where you can improve performance with RDS for PostgreSQL, one is when loading data into a DB instance. Another is when using the PostgreSQL autovacuum feature. The following sections cover some of the practices we recommend for these areas.

For information on how Amazon RDS implements other common PostgreSQL DBA tasks, see Common DBA tasks for Amazon RDS for PostgreSQL.

Loading data into a PostgreSQL DB instance

When loading data into an Amazon RDS for PostgreSQL DB instance, modify your DB instance settings and your DB parameter group values. Set these to allow for the most efficient importing of data into your DB instance.

Modify your DB instance settings to the following:

- Disable DB instance backups (set backup_retention to 0)
- Disable Multi-AZ

Modify your DB parameter group to include the following settings. Also, test the parameter settings to find the most efficient settings for your DB instance.

- Increase the value of the `maintenance_work_mem` parameter. For more information about PostgreSQL resource consumption parameters, see the PostgreSQL documentation.

- Increase the value of the `max_wal_size` and `checkpoint_timeout` parameters to reduce the number of writes to the write-ahead log (WAL) log.
- Disable the `synchronous_commit` parameter.
- Disable the PostgreSQL autovacuum parameter.
- Make sure that none of the tables you're importing are unlogged. Data stored in unlogged tables can be lost during a failover. For more information, see CREATE TABLE UNLOGGED.

Use the `pg_dump -Fc` (compressed) or `pg_restore -j` (parallel) commands with these settings.

After the load operation completes, return your DB instance and DB parameters to their normal settings.

Working with the PostgreSQL autovacuum feature

The autovacuum feature for PostgreSQL databases is a feature that we strongly recommend you use to maintain the health of your PostgreSQL DB instance. Autovacuum automates the execution of the VACUUM and ANALYZE command Using autovacuum is required by PostgreSQL, not imposed by Amazon RDS, and its use is critical to good performance. The feature is enabled by default for all new Amazon RDS for PostgreSQL DB instances, and the related configuration parameters are appropriately set by default.

Your database administrator needs to know and understand this maintenance operation. For the PostgreSQL documentation on autovacuum, see The Autovacuum Daemon.

Autovacuum is not a "resource free" operation, but it works in the background and yields to user operations as much as possible. When enabled, autovacuum checks for tables that have had a large number of updated or deleted tuples. It also protects against loss of very old data due to transaction ID wraparound. For more information, see Preventing transaction ID wraparound failures.

Autovacuum should not be thought of as a high-overhead operation that can be reduced to gain better performance. On the contrary, tables that have a high velocity of updates and deletes will quickly deteriorate over time if autovacuum is not run.

> **Important**
>
> Not running autovacuum can result in an eventual required outage to perform a much more intrusive vacuum operation. In some cases, an RDS for PostgreSQL DB instance might

become unavailable because of an over-conservative use of autovacuum. In these cases, the PostgreSQL database shuts down to protect itself. At that point, Amazon RDS must perform a single-user-mode full vacuum directly on the DB instance. This full vacuum can result in a multi-hour outage. Thus, we strongly recommend that you do not turn off autovacuum, which is turned on by default.

The autovacuum parameters determine when and how hard autovacuum works. The`autovacuum_vacuum_threshold` and `autovacuum_vacuum_scale_factor` parameters determine when autovacuum is run. The `autovacuum_max_workers`, `autovacuum_nap_time`, `autovacuum_cost_limit`, and `autovacuum_cost_delay` parameters determine how hard autovacuum works. For more information about autovacuum, when it runs, and what parameters are required, see Routine Vacuuming in the PostgreSQL documentation.

The following query shows the number of "dead" tuples in a table named table1:

```
SELECT relname, n_dead_tup, last_vacuum, last_autovacuum FROM
pg_catalog.pg_stat_all_tables
WHERE n_dead_tup > 0 and relname = 'table1';
```

The results of the query will resemble the following:

```
relname | n_dead_tup | last_vacuum | last_autovacuum
---------+------------+-------------+-----------------
 tasks   |   81430522 |             |
(1 row)
```

Amazon RDS for PostgreSQL best practices video

The 2020 AWS re:Invent conference included a presentation on new features and best practices for working with PostgreSQL on Amazon RDS. A video of the presentation is available here.

Best practices for working with SQL Server

Best practices for a Multi-AZ deployment with a SQL Server DB instance include the following:

- Use Amazon RDS DB events to monitor failovers. For example, you can be notified by text message or email when a DB instance fails over. For more information about Amazon RDS events, see Working with Amazon RDS event notification.

- If your application caches DNS values, set time to live (TTL) to less than 30 seconds. Setting TTL as so is a good practice in case there is a failover. In a failover, the IP address might change and the cached value might no longer be in service.
- We recommend that you *do not* enable the following modes because they turn off transaction logging, which is required for Multi-AZ:
  - Simple recover mode
  - Offline mode
  - Read-only mode
- Test to determine how long it takes for your DB instance to failover. Failover time can vary due to the type of database, the instance class, and the storage type you use. You should also test your application's ability to continue working if a failover occurs.
- To shorten failover time, do the following:
  - Ensure that you have sufficient Provisioned IOPS allocated for your workload. Inadequate I/O can lengthen failover times. Database recovery requires I/O.
  - Use smaller transactions. Database recovery relies on transactions, so if you can break up large transactions into multiple smaller transactions, your failover time should be shorter.
- Take into consideration that during a failover, there will be elevated latencies. As part of the failover process, Amazon RDS automatically replicates your data to a new standby instance. This replication means that new data is being committed to two different DB instances. So there might be some latency until the standby DB instance has caught up to the new primary DB instance.
- Deploy your applications in all Availability Zones. If an Availability Zone does go down, your applications in the other Availability Zones will still be available.

When working with a Multi-AZ deployment of SQL Server, remember that Amazon RDS creates replicas for all SQL Server databases on your instance. If you don't want specific databases to have secondary replicas, set up a separate DB instance that doesn't use Multi-AZ for those databases.

Amazon RDS for SQL Server best practices video

The 2019 AWS re:Invent conference included a presentation on new features and best practices for working with SQL Server on Amazon RDS. A video of the presentation is available here.

Working with DB parameter groups

We recommend that you try out DB parameter group changes on a test DB instance before applying parameter group changes to your production DB instances. Improperly setting DB engine parameters in a DB parameter group can have unintended adverse effects, including degraded performance and system instability. Always exercise caution when modifying DB engine parameters and back up your DB instance before modifying a DB parameter group.

For information about backing up your DB instance, see Backing up, restoring, and exporting data.

Best practices for automating DB instance creation

It's an Amazon RDS best practice to create a DB instance with the preferred minor version of the database engine. You can use the AWS CLI, Amazon RDS API, or AWS CloudFormation to automate DB instance creation. When you use these methods, you can specify only the major version and Amazon RDS automatically creates the instance with the preferred minor version. For example, if PostgreSQL 12.5 is the preferred minor version, and if you specify version 12 with `create-db-instance`, the DB instance will be version 12.5.

To determine the preferred minor version, you can run the `describe-db-engine-versions` command with the `--default-only` option as shown in the following example.

```
aws rds describe-db-engine-versions --default-only --engine postgres

{
    "DBEngineVersions": [
        {
            "Engine": "postgres",
            "EngineVersion": "12.5",
            "DBParameterGroupFamily": "postgres12",
            "DBEngineDescription": "PostgreSQL",
            "DBEngineVersionDescription": "PostgreSQL 12.5-R1",
            ...some output truncated...
        }
    ]
}
```

For information on creating DB instances programmatically, see the following resources:

- Using the AWS CLI – create-db-instance

- Using the Amazon RDS API – CreateDBInstance
- Using AWS CloudFormation – AWS::RDS::DBInstance

Amazon RDS new features video

The 2023 AWS re:Invent conference included a presentation on new Amazon RDS features. A video of the presentation is available here.

Configuring an Amazon RDS DB instance

This section shows how to set up your Amazon RDS DB instance. Before creating a DB instance, decide on the DB instance class that will run the DB instance. Also, decide where the DB instance will run by choosing an AWS Region. Next, create the DB instance.

You can configure a DB instance with an option group and a DB parameter group.

- An *option group* specifies features, called options, that are available for a particular Amazon RDS DB instance.
- A *DB parameter group* acts as a container for engine configuration values that are applied to one or more DB instances.

The options and parameters that are available depend on the DB engine and DB engine version. You can specify an option group and a DB parameter group when you create a DB instance. You can also modify a DB instance to specify them.

Topics

Creating an Amazon RDS DB instance

The basic building block of Amazon RDS is the DB instance, where you create your databases. You choose the engine-specific characteristics of the DB instance when you create it. You also choose the storage capacity, CPU, memory, and so on of the AWS instance on which the database server runs.

Topics

DB instance prerequisites

> **Important**
>
> Before you can create an Amazon RDS DB instance, complete the tasks in Setting up your Amazon RDS environment.

The following are prerequisites for creating an RDS DB instance.

Topics

Configure the network for the DB instance

You can create an Amazon RDS DB instance only in a virtual private cloud (VPC) based on the Amazon VPC service. Also, it must be in an AWS Region that has at least two Availability Zones. The DB subnet group that you choose for the DB instance must cover at least two Availability Zones. This configuration ensures that you can configure a Multi-AZ deployment when you create the DB instance or easily move to one in the future.

To set up connectivity between your new DB instance and an Amazon EC2 instance in the same VPC, do so when you create the DB instance. To connect to your DB instance from resources other than EC2 instances in the same VPC, configure the network connections manually.

Topics

Configure automatic network connectivity with an EC2 instance

When you create an RDS DB instance, you can use the AWS Management Console to set up connectivity between an EC2 instance and the new DB instance. When you do so, RDS configures your VPC and network settings automatically. The DB instance is created in the same VPC as the EC2 instance so that the EC2 instance can access the DB instance.

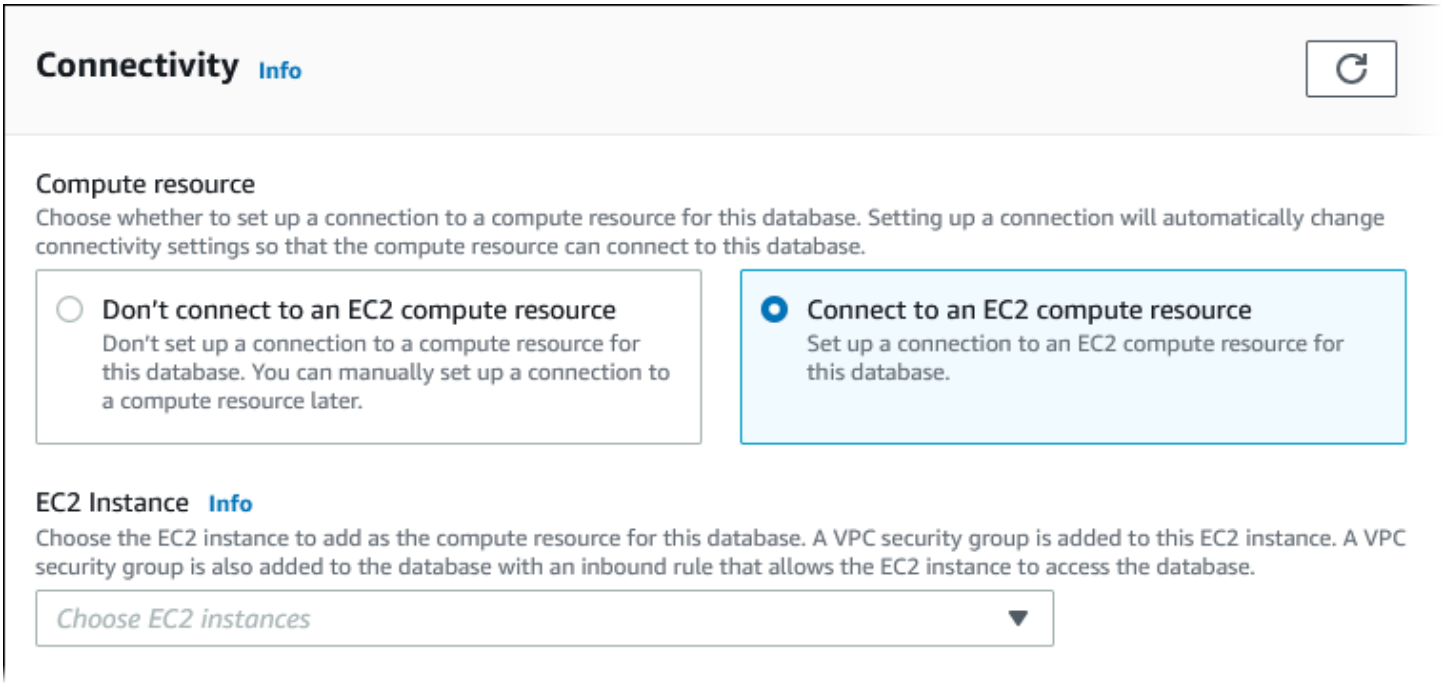
The following are requirements for connecting an EC2 instance with the DB instance:

- The EC2 instance must exist in the AWS Region before you create the DB instance.

  If no EC2 instances exist in the AWS Region, the console provides a link to create one.
- The user who is creating the DB instance must have permissions to perform the following operations:
  - `ec2:AssociateRouteTable`
  - `ec2:AuthorizeSecurityGroupEgress`
  - `ec2:AuthorizeSecurityGroupIngress`
  - `ec2:CreateRouteTable`
  - `ec2:CreateSubnet`
  - `ec2:CreateSecurityGroup`
  - `ec2:DescribeInstances`
  - `ec2:DescribeNetworkInterfaces`
  - `ec2:DescribeRouteTables`
  - `ec2:DescribeSecurityGroups`
  - `ec2:DescribeSubnets`
  - `ec2:ModifyNetworkInterfaceAttribute`
  - `ec2:RevokeSecurityGroupEgress`

Using this option creates a private DB instance. The DB instance uses a DB subnet group with only private subnets to restrict access to resources within the VPC.

To connect an EC2 instance to the DB instance, choose **Connect to an EC2 compute resource** in the **Connectivity** section on the **Create database** page.



When you choose **Connect to an EC2 compute resource**, RDS sets the following options automatically. You can't change these settings unless you choose not to set up connectivity with an EC2 instance by choosing **Don't connect to an EC2 compute resource**.

Console option	Automatic setting
Network type	RDS sets network type to **IPv4**. Currently, dual-stack mode isn't supported when you set up a connection between an EC2 instance and the DB instance.
Virtual Private Cloud (VPC)	RDS sets the VPC to the one associated with the EC2 instance.
DB subnet group	RDS requires a DB subnet group with a private subnet in the same Availability Zone as the EC2 instance. If a DB subnet group that meets this requirement exists, then RDS uses the

Console option	Automatic setting
	existing DB subnet group. By default, this option is set to **Automatic setup**. When you choose **Automatic setup** and there is no DB subnet group that meets this requirement, the following action happens. RDS uses three available private subnets in three Availability Zones where one of the Availability Zones is the same as the EC2 instance. If a private subnet isn't available in an Availability Zone, RDS creates a private subnet in the Availability Zone. Then RDS creates the DB subnet group. When a private subnet is available, RDS uses the route table associated with the subnet and adds any subnets it creates to this route table. When no private subnet is available, RDS creates a route table without internet gateway access and adds the subnets it creates to the route table. RDS also allows you to use existing DB subnet groups. Select **Choose existing** if you want to use an existing DB subnet group of your choice.
Public access	RDS chooses **No** so that the DB instance isn't publicly accessible. For security, it is a best practice to keep the database private and make sure it isn't accessible from the internet.

Console option	Automatic setting
VPC security group (firewall)	RDS creates a new security group that is associated with the DB instance. The security group is named `rds-ec2-`*n*, where *n* is a number. This security group includes an inbound rule with the EC2 VPC security group (firewall) as the source. This security group that is associated with the DB instance allows the EC2 instance to access the DB instance. RDS also creates a new security group that is associated with the EC2 instance. The security group is named `ec2-rds-`*n*, where *n* is a number. This security group includes an outbound rule with the VPC security group of the DB instance as the source. This security group allows the EC2 instance to send traffic to the DB instance. You can add another new security group by choosing **Create new** and typing the name of the new security group. You can add existing security groups by choosing **Choose existing** and selecting security groups to add.
Availability Zone	When you choose **Single DB instance** in **Availability & durability** (Single-AZ deployment), RDS chooses the Availability Zone of the EC2 instance. When you choose **Multi-AZ DB instance** in **Availability & durability** (Multi-AZ DB instance deployment), RDS chooses the Availability Zone of the EC2 instance for one DB instance in the deployment. RDS randomly chooses a different Availability Zone for the other DB instance. Either the primary DB instance or the standby replica is created in the same Availability Zone as the EC2 instance. When you choose **Multi-AZ DB instance**, there is the possibility of cross Availability Zone costs if the DB instance and EC2 instance are in different Availability Zones.

For more information about these settings, see Settings for DB instances.

If you change these settings after the DB instance is created, the changes might affect the connection between the EC2 instance and the DB instance.

Configure the network manually

To connect to your DB instance from resources other than EC2 instances in the same VPC, configure the network connections manually. If you use the AWS Management Console to create your DB instance, you can have Amazon RDS automatically create a VPC for you. Or you can use an existing VPC or create a new VPC for your DB instance. With any approach, your VPC requires at least one subnet in each of at least two Availability Zones for use with an RDS DB instance.

By default, Amazon RDS creates the DB instance an Availability Zone automatically for you. To choose a specific Availability Zone, you need to change the **Availability & durability** setting to **Single DB instance**. Doing so exposes an **Availability Zone** setting that lets you choose from among the Availability Zones in your VPC. However, if you choose a Multi-AZ deployment, RDS chooses the Availability Zone of the primary or writer DB instance automatically, and the **Availability Zone** setting doesn't appear.

In some cases, you might not have a default VPC or haven't created a VPC. In these cases, you can have Amazon RDS automatically create a VPC for you when you create a DB instance using the console. Otherwise, do the following:

- Create a VPC with at least one subnet in each of at least two of the Availability Zones in the AWS Region where you want to deploy your DB instance. For more information, see Working with a DB instance in a VPC and Tutorial: Create a VPC for use with a DB instance (IPv4 only).
- Specify a VPC security group that authorizes connections to your DB instance. For more information, see Provide access to your DB instance in your VPC by creating a security group and Controlling access with security groups.
- Specify an RDS DB subnet group that defines at least two subnets in the VPC that can be used by the DB instance. For more information, see Working with DB subnet groups.

If you want to connect to a resource that isn't in the same VPC as the DB instance, see the appropriate scenarios in Scenarios for accessing a DB instance in a VPC.

Additional prerequisites

Before you create your DB instance, consider the following additional prerequisites:

- If you are connecting to AWS using AWS Identity and Access Management (IAM) credentials, your AWS account must have certain IAM policies. These grant the permissions required to perform Amazon RDS operations. For more information, see Identity and access management for Amazon RDS.

  To use IAM to access the RDS console, sign in to the AWS Management Console with your IAM user credentials. Then go to the Amazon RDS console at https://console.aws.amazon.com/rds/.

- To tailor the configuration parameters for your DB instance, specify a DB parameter group with the required parameter settings. For information about creating or modifying a DB parameter group, see Parameter groups for Amazon RDS.

  > **Important**
  >
  > If you are using the BYOL model for Amazon RDS for Db2, before creating a DB instance, you must first create a custom parameter group that contains your IBM Site ID and IBM Customer ID. For more information, see Bring Your Own License for Db2.

- Determine the TCP/IP port number to specify for your DB instance. The firewalls at some companies block connections to the default ports for RDS DB instances. If your company firewall blocks the default port, choose another port for your DB instance. The default ports for Amazon RDS DB engines are:

RDS for Db2	RDS for MariaDB	RDS for MySQL	RDS for Oracle	RDS for PostgreSQL	RDS for SQL Server
50000	3306	3306	1521	5432	1433

  For RDS for SQL Server, the following ports are reserved, and you can't use them when you create a DB instance: `1234`, `1434`, `3260`, `3343`, `3389`, `47001`, and `49152-49156`.

Creating a DB instance

You can create an Amazon RDS DB instance using the AWS Management Console, the AWS CLI, or the RDS API.

> **Note**
>
> For RDS for Db2, we recommend that you set up items needed for your license model before you create an RDS for Db2 DB instance. For more information, see Amazon RDS for Db2 licensing options.

Console

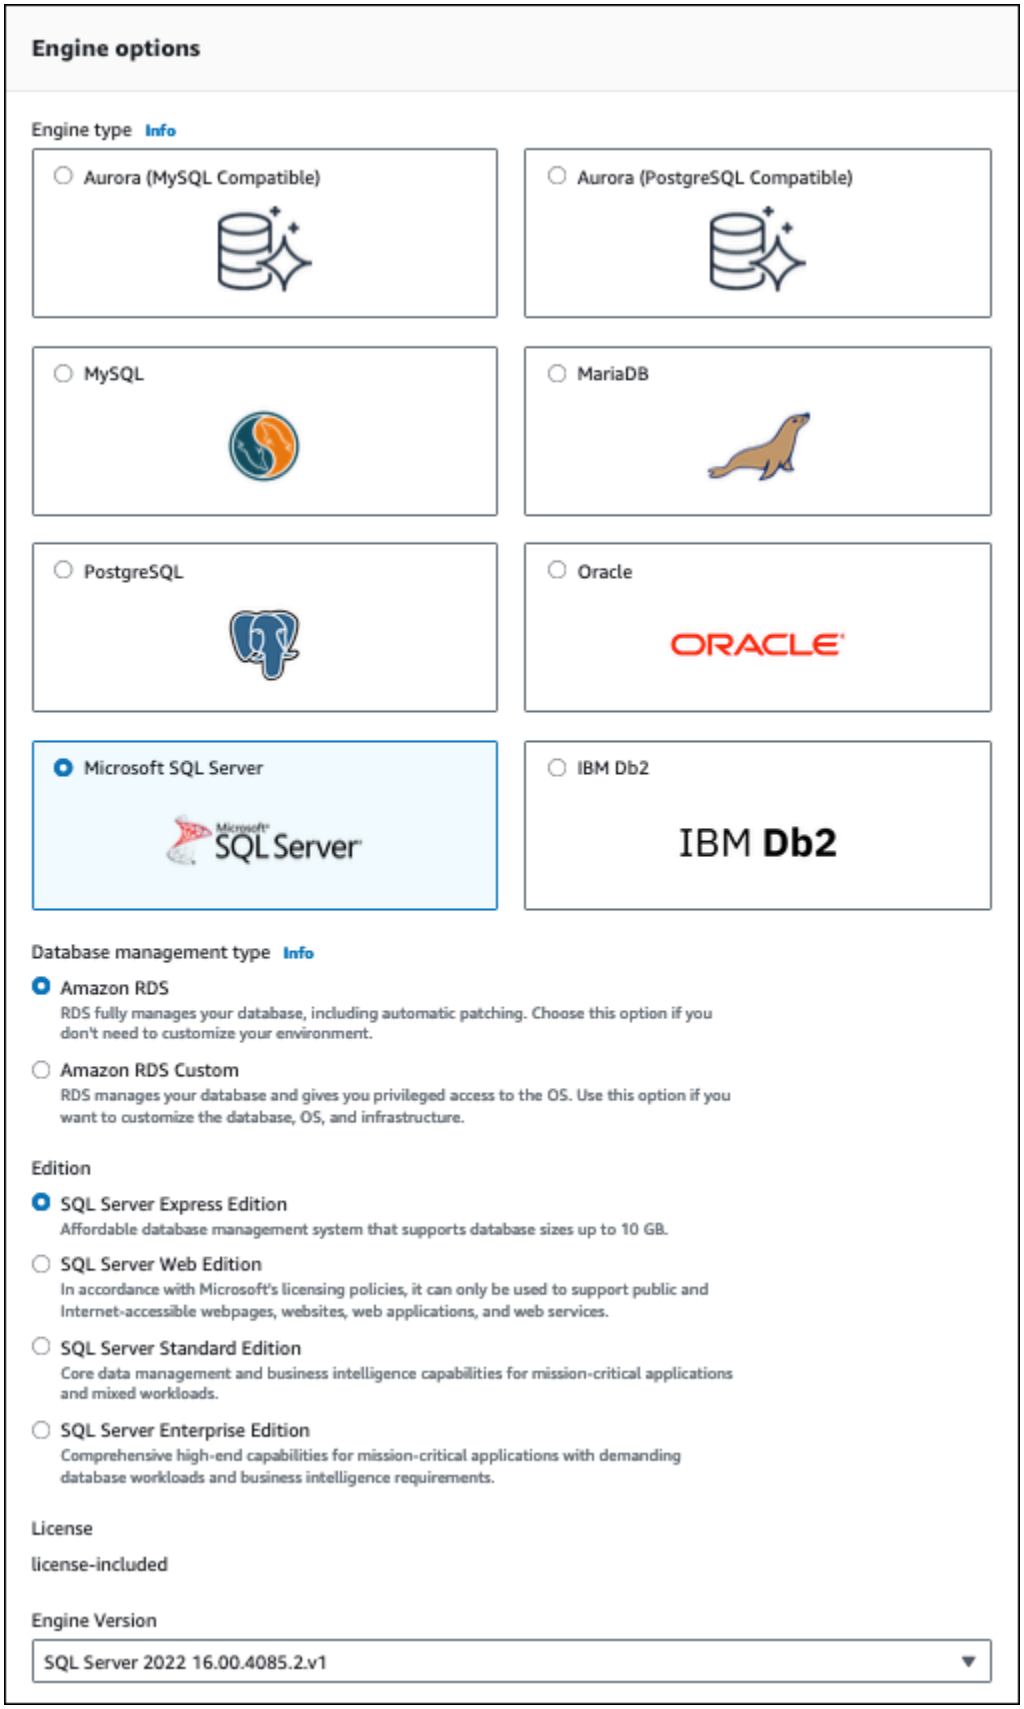
You can create a DB instance by using the AWS Management Console with **Easy create** enabled or not enabled. With **Easy create** enabled, you specify only the DB engine type, DB instance size, and DB instance identifier. **Easy create** uses the default setting for other configuration options. With **Easy create** not enabled, you specify more configuration options when you create a database, including ones for availability, security, backups, and maintenance.

> **Note**
>
> In the following procedure, **Standard create** is enabled, and **Easy create** isn't enabled. This procedure uses Microsoft SQL Server as an example.
> For examples that use **Easy create** to walk you through creating and connecting to sample DB instances for each engine, see Getting started with Amazon RDS.

To create a DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the upper-right corner of the Amazon RDS console, choose the AWS Region in which you want to create the DB instance.
3. In the navigation pane, choose **Databases**.
4. Choose **Create database**, then choose **Standard create**.
5. For **Engine type**, choose IBM Db2, MariaDB, Microsoft SQL Server, MySQL, Oracle, or PostgreSQL.

   Microsoft SQL Server is shown here.



Engine options
Engine type Info
Aurora (MySQL Compatible)
Aurora (PostgreSQL Compatible)
MySQL
MariaDB
PostgreSQL
Oracle
ORACLE
Microsoft SQL Server
Microsoft SQL Server
IBM Db2
IBM Db2
Database management type Info
Amazon RDS
RDS fully manages your database, including automatic patching. Choose this option if you don't need to customize your environment.
Amazon RDS Custom
RDS manages your database and gives you privileged access to the OS. Use this option if you want to customize the database, OS, and infrastructure.
Edition
SQL Server Express Edition
Affordable database management system that supports database sizes up to 10 GB.
SQL Server Web Edition
In accordance with Microsoft's licensing policies, it can only be used to support public and Internet-accessible webpages, websites, web applications, and web services.
SQL Server Standard Edition
Core data management and business intelligence capabilities for mission-critical applications and mixed workloads.
SQL Server Enterprise Edition
Comprehensive high-end capabilities for mission-critical applications with demanding database workloads and business intelligence requirements.
License
license-included
Engine Version
SQL Server 2022 16.00.4085.2.v1

6. For **Database management type**, if you're using Oracle or SQL Server choose **Amazon RDS** or **Amazon RDS Custom**.

   Amazon RDS is shown here. For more information on RDS Custom, see *Working with Amazon RDS Custom*.

7. For **Edition**, if you're using Db2, Oracle, or SQL Server, choose the DB engine edition that you want to use.

   MySQL has only one option for the edition, and MariaDB and PostgreSQL have none.

8. For **Version**, choose the engine version.

9. In **Templates**, choose the template that matches your use case. If you choose **Production**, the following are preselected in a later step:

   - **Multi-AZ** failover option
   - **Provisioned IOPS SSD (io1)** storage option
   - **Enable deletion protection** option

   We recommend these features for any production environment.

   > **Note**
   >
   > Template choices vary by edition.

10. To enter your master password, do the following:

    a. In the **Settings** section, open **Credential Settings**.

    b. If you want to specify a password, clear the **Auto generate a password** check box if it is selected.

    c. (Optional) Change the **Master username** value.

    d. Enter the same password in **Master password** and **Confirm password**.

11. (Optional) Set up a connection to a compute resource for this DB instance.

    You can configure connectivity between an Amazon EC2 instance and the new DB instance during DB instance creation. For more information, see Configure automatic network connectivity with an EC2 instance.

12. In the **Connectivity** section under **VPC security group (firewall)**, if you select **Create new**, a VPC security group is created with an inbound rule that allows your local computer's IP address to access the database.
13. For the remaining sections, specify your DB instance settings. For information about each setting, see Settings for DB instances.
14. Choose **Create database**.

    If you chose to use an automatically generated password, the **View credential details** button appears on the **Databases** page.

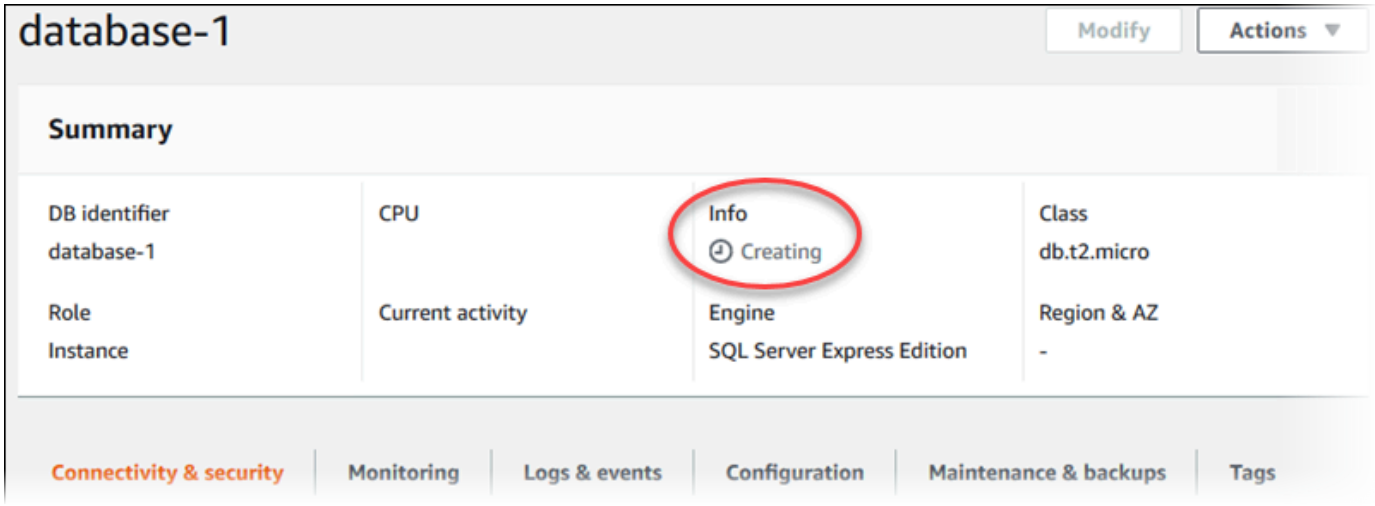
    To view the master username and password for the DB instance, choose **View credential details**.

    To connect to the DB instance as the master user, use the username and password that appear.

    > **Important**
    >
    > You can't view the master user password again. If you don't record it, you might have to change it. If you need to change the master user password after the DB instance is available, modify the DB instance to do so. For more information about modifying a DB instance, see Modifying an Amazon RDS DB instance.

15. For **Databases**, choose the name of the new DB instance.

    On the RDS console, the details for the new DB instance appear. The DB instance has a status of **Creating** until the DB instance is created and ready for use. When the state changes to **Available**, you can connect to the DB instance. Depending on the DB instance class and storage allocated, it can take several minutes for the new instance to be available.



AWS CLI

> **Note**
>
> If you want to use Db2 license through AWS Marketplace, you must first subscribe to AWS Marketplace and register with IBM by using the AWS Management Console. For more information, see Subscribing to Db2 Marketplace listings and registering with IBM.

To create a DB instance by using the AWS CLI, call the create-db-instance command with the following parameters:

- `--db-instance-identifier`
- `--db-instance-class`
- `--vpc-security-group-ids`
- `--db-subnet-group`
- `--engine`
- `--master-username`
- `--master-user-password`
- `--allocated-storage`
- `--backup-retention-period`

For information about each setting, see Settings for DB instances.

This example uses Microsoft SQL Server.

Example

For Linux, macOS, or Unix:

```
aws rds create-db-instance \
    --engine sqlserver-se \
    --db-instance-identifier mymsftsqlserver \
    --allocated-storage 250 \
    --db-instance-class db.t3.large \
    --vpc-security-group-ids mysecuritygroup \
    --db-subnet-group mydbsubnetgroup \
    --master-username masterawsuser \
    --manage-master-user-password \
    --backup-retention-period 3
```

For Windows:

```
aws rds create-db-instance ^
    --engine sqlserver-se ^
    --db-instance-identifier mydbinstance ^
    --allocated-storage 250 ^
    --db-instance-class db.t3.large ^
    --vpc-security-group-ids mysecuritygroup ^
    --db-subnet-group mydbsubnetgroup ^
    --master-username masterawsuser ^
    --manage-master-user-password ^
    --backup-retention-period 3
```

This command produces output similar to the following.

```
DBINSTANCE  mydbinstance  db.t3.large  sqlserver-se  250  sa  creating  3  ****  n
 10.50.2789
SECGROUP  default  active
PARAMGRP  default.sqlserver-se-14  in-sync
```

RDS API

> **Note**
>
> If you want to use Db2 license through AWS Marketplace, you must first subscribe to AWS Marketplace and register with IBM by using the AWS Management Console. For more information, see Subscribing to Db2 Marketplace listings and registering with IBM.

To create a DB instance by using the Amazon RDS API, call the CreateDBInstance operation.

For information about each setting, see Settings for DB instances.

Settings for DB instances

In the following table, you can find details about settings that you choose when you create a DB instance. The table also shows the DB engines for which each setting is supported.

You can create a DB instance using the console, the create-db-instance CLI command, or the CreateDBInstance RDS API operation.

Console setting	Setting description	CLI option and RDS API parameter	Supported DB engines

Allocated storage	The amount of storage to allocate for your DB instance (in gibibytes). In some cases, allocating a higher amount of storage for your DB instance than the size of your database can improve I/O performance.
	
	For more information, see Amazon RDS DB instance storage.
		CLI option:
		
		`--allocated-storage`
		
		API parameter:
		
		`AllocatedStorage`
			All

Architecture settings	If you choose **Oracle multitenant architecture**, RDS for Oracle creates a container database (CDB). If you don't choose this option, RDS for Oracle	**CLI option:**	Oracle

Console setting	Setting description	CLI option and RDS API parameter	Supported DB engines
	creates a non-CDB. A non-CDB uses the traditional Oracle database architecture. A CDB can contain pluggable databases (PDBs) whereas a non-CDB cannot. Oracle Database 21c uses the CDB architecture only. Oracle Database 19c can use either the CDB or non-CDB architecture. Releases lower than Oracle Database 19c use the non-CDB architecture only. For more information, see Overview of RDS for Oracle CDBs.	`--engine oracle-ee-cdb` (Oracle multitenant) `--engine oracle-se2-cdb` (Oracle multitenant) `--engine oracle-ee` (traditional) `--engine oracle-se2` (traditional) **API parameter:** `Engine`	

Console setting	Setting description	CLI option and RDS API parameter	Supported DB engines
Architecture configuration	These settings are only valid when you choose **Oracle multitenant architecture** for **Architecture settings**. Choose either of the following additional settings: • With the **Multi-tenant configuration**, your RDS for Oracle CDB instance can contain 1–30 tenant databases, depending on the database edition and any required option licenses. In the context of an Oracle database, a tenant database is a PDB. Application PDBs and proxy PDBs aren't supported. Your DB instance is created with 1 initial tenant database. Choose values for **Tenant database name**, **Tenant database master username**, **Tenant database master password**, and **Tenant database character set**. The multi-tenant configuration is permanent. Thus, you can't convert the multi-tenant configuration back to the single-tenant configuration. The minimum supported release update (RU) for the multi-tenant configuration is 19.0.0.0.ru-2022-01.rur-2022.r1.	**CLI option:** `--multi-tenant` (multi-tenant configuration) `--no-multi-tenant` (single-tenant configuration) **API parameter:** `MultiTenant`	Oracle

Console setting	Setting description	CLI option and RDS API parameter	Supported DB engines
	Note The Amazon RDS feature is called "multi-tenant" rather than "multitenant" because it is a capability of the RDS platform, not just the Oracle DB engine. The term "Oracle multitenant" refers exclusively to the Oracle database architecture, which is compatible with both on-premises and RDS deployments. • With the **Single-tenant configuration**, your RDS for Oracle CDB contains 1 PDB. This is the default configuration when you create a CDB. You can't delete the initial PDB or add more PDBs. You can later convert the single-tenant configuration of your CDB to the multi-tenant configuration, but you can't then convert back to the single-tenant configuration. Regardless of which configuration you choose, your CDB contains a single initial PDB. In the multi-tenant		

Console setting	Setting description	CLI option and RDS API parameter	Supported DB engines
	configuration, you can create more PDBs later using RDS APIs. For more information, see Overview of RDS for Oracle CDBs.		

Auto minor version upgrade	Choose **Enable auto minor version upgrade** to enable your DB instance to receive preferred minor DB engine version upgrades automatically when they become available. This is the default behavior. Amazon RDS performs automatic minor version upgrades in the maintenance window. If you don't choose **Enable auto minor version upgrade**, your DB instance isn't upgraded automatically when new minor versions become available.
	
	For more information, see Automatically upgrading the minor engine version.
		CLI option:
		
		`--auto-minor-version-upgrade`
		
		`--no-auto-minor-version-upgrade`
		
		API parameter:
		
		`AutoMinorVersionUpgrade`
			All

Availability zone	The Availability Zone for your DB instance. Use the default value of **No Preference** unless you want to specify an Availability Zone.
	
	For more information, see Regions, Availability Zones, and Local Zones.
		CLI option:
		
		`--availability-zone`
		
		API parameter:
		
		`AvailabilityZone`
			All

Console setting	Setting description	CLI option and RDS API parameter	Supported DB engines

AWS KMS key	Only available if **Encryption** is set to **Enable encryption**. Choose the AWS KMS key to use for encrypting this DB instance. For more information, see Encrypting Amazon RDS resources.	**CLI option:**
		`--kms-key-id`
		API parameter:
		`KmsKeyId`
			All

AWS License Manager configuration	Enter a name for an AWS License Manager license configuration. The name must be 100 characters or less, and only include a-z, A-Z, and 0-9. For more information, see the section called "Integrating with AWS License Manager".	**CLI option:** For more information, see AWS License Manager CLI. **API parameter:** For more information, see AWS License Manager API.	Db2
Backup replication	Choose **Enable replication in another AWS Region** to create backups in an additional Region for disaster recovery. Then choose the **Destination Region** for the additional backups.	Not available when creating a DB instance. For information on enabling cross-Region backups using the AWS CLI or RDS API, see Enabling cross-Region automated backups.	Oracle PostgreSQL SQL Server

Console setting	Setting description	CLI option and RDS API parameter	Supported DB engines

Backup retention period	The number of days that you want automatic backups of your DB instance to be retained. For any nontrivial DB instance, set this value to **1** or greater.
	
	For more information, see Introduction to backups.
		CLI option:
		
		`--backup-retention-period`
		
		API parameter:
		
		`BackupRetentionPeriod`
			All

Backup target	Choose **AWS Cloud** to store automated backups and manual snapshots in the parent AWS Region. Choose **Outposts (on-premises)** to store them locally on your Outpost.
	
	This option setting applies only to RDS on Outposts. For more information, see Creating DB instances for Amazon RDS on AWS Outposts.
		CLI option:
		
		`--backup-target`
		
		API parameter:
		
		`BackupTarget`
			MySQL, PostgreSQL, SQL Server

Backup window	The time period during which Amazon RDS automatically takes a backup of your DB instance. Unless you have a specific time that you want to have your database backed up, use the default of **No Preference**.
	
	For more information, see Introduction to backups.
		CLI option:
		
		`--preferred-backup-window`
		
		API parameter:
		
		`PreferredBackupWindow`
			All

Console setting	Setting description	CLI option and RDS API parameter	Supported DB engines

Certificate authority	The certificate authority (CA) for the server certificate used by the DB instance.
	
	For more information, see Using SSL/TLS to encrypt a connection to a DB instance or cluster.
		CLI option:
		
		`--ca-certificate-identifier`
		
		RDS API parameter:
		
		`CACertificateIdentifier`
			All

Character set	The character set for your DB instance. The default value of **AL32UTF8** for the DB character set is for the Unicode 5.0 UTF-8 Universal character set. You can't change the DB character set after you create the DB instance.
	
	In a single-tenant configuration, a non-default DB character set affects only the PDB, not the CDB. For more information, see Single-tenant configuration of the CDB architecture.
	
	The DB character set is different from the national character set, which is called the NCHAR character set. Unlike the DB character set, the NCHAR character set specifies the encoding for NCHAR data types (NCHAR, NVARCHAR2, and NCLOB) columns without affecting database metadata.
	
	For more information, see RDS for Oracle character sets.
		CLI option:
		
		`--character-set-name`
		
		API parameter:
		
		`CharacterSetName`
			Oracle

Console setting	Setting description	CLI option and RDS API parameter	Supported DB engines

Collation	A server-level collation for your DB instance.
	
	For more information, see Server-level collation for Microsoft SQL Server.
		CLI option:
		
		`--character-set-name`
		
		API parameter:
		
		`CharacterSetName`
			SQL Server

Copy tags to snapshots	This option copies any DB instance tags to a DB snapshot when you create a snapshot.
	
	For more information, see Tagging Amazon RDS resources.
		CLI option:
		
		`--copy-tags-to-snapshot`
		
		`--no-copy-tags-to-snapshot`
		
		RDS API parameter:
		
		`CopyTagsToSnapshot`
			All

Console setting	Setting description	CLI option and RDS API parameter	Supported DB engines

Database authentication	The database authentication option that you want to use.
	
	Choose **Password authentication** to authenticate database users with database passwords only.
	
	Choose **Password and IAM DB authentication** to authenticate database users with database passwords and user credentials through users and roles. For more information, see IAM database authentication for MariaDB, MySQL, and PostgreSQL. This option is only supported for MySQL and PostgreSQL.
	
	Choose **Password and Kerberos authentication** to authenticate database users with database passwords and Kerberos authentication through an AWS Managed Microsoft AD created with AWS Directory Service. Next, choose the directory or choose **Create a new Directory**.
	
	For more information, see one of the following:
	
	• Using Kerberos authentication for Amazon RDS for Db2
	• Using Kerberos authentication for MySQL
		IAM:
		
		CLI option:
		
		`--enable-iam-database-authentication`
		
		`--no-enable-iam-database-authentication`
		
		RDS API parameter:
		
		`EnableIAMDatabaseAuthentication`
		
		Kerberos:
		
		CLI option:
		
		`--domain`
		
		`--domain-iam-role-name`
		
		RDS API parameter:
		
		`Domain`
		
		`DomainIAMRoleName`
			Varies by authentication type

Console setting	Setting description	CLI option and RDS API parameter	Supported DB engines
	• Configuring Kerberos authentication for Amazon RDS for Oracle • Using Kerberos authentication with Amazon RDS for PostgreSQL		
Database management type	Choose **Amazon RDS** if you don't need to customize your environment. Choose **Amazon RDS Custom** if you want to customize the database, OS, and infrastructure. For more information, see Working with Amazon RDS Custom.	For the CLI and API, you specify the database engine type.	Oracle SQL Server

Database port	The port that you want to access the DB instance through. The default port is shown.
	
	Note
	The firewalls at some companies block connections to the default MariaDB, MySQL, and PostgreSQL ports. If your company firewall blocks the default port, enter another port for your DB instance.
		CLI option:
		
		`--port`
		
		RDS API parameter:
		
		`Port`
			All

Console setting	Setting description	CLI option and RDS API parameter	Supported DB engines

DB engine version	The version of database engine that you want to use.	**CLI option:**
		`--engine-version`
		RDS API parameter:
		`EngineVersion`
			All

DB instance class	The configuration for your DB instance. For example, a **db.t3.small** DB instance class has 2 GiB memory, 2 vCPUs, 1 virtual core, a variable ECU, and a moderate I/O capacity.
	If possible, choose a DB instance class large enough that a typical query working set can be held in memory. When working sets are held in memory, the system can avoid writing to disk, which improves performance. For more information, see DB instance classes.
	In RDS for Oracle, you can select **Include additional memory configurations**. These configurations are optimized for a high ratio of memory to vCPU. For example, **db.r5.6xlarge.tpc2.mem4x** is a db.r5.8x DB instance that has 2 threads per core (tpc2) and 4x the memory of a standard db.r5.6xlarge DB instance. For more information, see RDS for Oracle DB instance classes.
		CLI option:
		`--db-instance-class`
		RDS API parameter:
		`DBInstanceClass`
			All

Console setting	Setting description	CLI option and RDS API parameter	Supported DB engines

DB instance identifier	The name for your DB instance. Name your DB instances in the same way that you name your on-premises servers. Your DB instance identifier can contain up to 63 alphanumeric characters, and must be unique for your account in the AWS Region you chose.	**CLI option:**
		`--db-instance-identifier`
		RDS API parameter:
		`DBInstanceIdentifier`
			All

DB parameter group	A parameter group for your DB instance. You can choose the default parameter group, or you can create a custom parameter group.
	If you are using the BYOL model for RDS for Db2, before creating a DB instance, you must first create a custom parameter group that contains your IBM Site ID and IBM Customer ID. For more information, see Bring Your Own License for Db2.
	For more information, see Parameter groups for Amazon RDS.
		CLI option:
		`--db-parameter-group-name`
		RDS API parameter:
		`DBParameterGroupName`
			All

Console setting	Setting description	CLI option and RDS API parameter	Supported DB engines

DB subnet group	The DB subnet group you want to use for the DB cluster.
	Select **Choose existing** to use an existing DB subnet group. Then choose the required subnet group from the **Existing DB subnet groups** dropdown list.
	
	Choose **Automatic setup** to let RDS select a compatible DB subnet group. If none exist, RDS creates a new subnet group for your cluster.
	
	For more information, see Working with DB subnet groups.
		CLI option:
		
		`--db-subnet-group-name`
		
		RDS API parameter:
		
		`DBSubnetGroupName`
			All

Dedicated Log Volume	Use a dedicated log volume (DLV) to store database transaction logs on a storage volume that's separate from the volume containing the database tables.
	
	For more information, see Using a dedicated log volume (DLV).
		CLI option:
		
		`--dedicated-log-volume`
		
		RDS API parameter:
		
		`DedicatedLogVolume`
			All

Console setting	Setting description	CLI option and RDS API parameter	Supported DB engines

Deletion protection	**Enable deletion protection** to prevent your DB instance from being deleted. If you create a production DB instance with the AWS Management Console, deletion protection is enabled by default.
	
	For more information, see Deleting a DB instance.
		CLI option:
		
		`--deletion-protection`
		
		`--no-deletion-protection`
		
		RDS API parameter:
		
		`DeletionProtection`
			All

Encryption	**Enable Encryption** to enable encryption at rest for this DB instance.
	
	For more information, see Encrypting Amazon RDS resources.
		CLI option:
		
		`--storage-encrypted`
		
		`--no-storage-encrypted`
		
		RDS API parameter:
		
		`StorageEncrypted`
			All

Console setting	Setting description	CLI option and RDS API parameter	Supported DB engines

Enhanced Monitoring	**Enable enhanced monitoring** to enable gathering metrics in real time for the operating system that your DB instance runs on.
	
	For more information, see Monitoring OS metrics with Enhanced Monitoring.
		CLI options:
		
		`--monitoring-interval`
		
		`--monitoring-role-arn`
		
		RDS API parameters:
		
		`MonitoringInterval`
		
		`MonitoringRoleArn`
			All

Engine type	Choose the database engine to be used for this DB instance.	**CLI option:**
		
		`--engine`
		
		RDS API parameter:
		
		`Engine`
			All

Console setting	Setting description	CLI option and RDS API parameter	Supported DB engines

Initial database name	The name for the database on your DB instance. If you don't provide a name, Amazon RDS doesn't create a database on the DB instance (except for Oracle and PostgreSQL). The name can't be a word reserved by the database engine, and has other constraints depending on the DB engine.
	
	Db2:
	
	• It must contain 1–8 alphanumeric characters.
	• It must start with a-z, A-Z, @, $, or #, and be followed by a-z, A-Z, 0-9, _, @, #, or $.
	• It can't contain spaces.
	• For more information, see Additional considerations.
	
	MariaDB and MySQL:
	
	• It must contain 1–64 alphanumeric characters.
	
	Oracle:
	
	•
		CLI option:
		
		`--db-name`
		
		RDS API parameter:
		
		`DBName`
			All except SQL Server

Console setting	Setting description	CLI option and RDS API parameter	Supported DB engines
	It must contain 1–8 alphanumeric characters. • It can't be `NULL`. The default value is `ORCL`. • It must begin with a letter. PostgreSQL: • It must contain 1–63 alphanumeric characters. • It must begin with a letter or an underscore. Subsequent characters can be letters, underscores, or digits (0-9). • The initial database name is `postgres`.		

Console setting	Setting description	CLI option and RDS API parameter	Supported DB engines

License	Valid values for the license model:
	• **bring-your-own-license** or **marketplace-license** for Db2.
	• **general-public-license** for MariaDB.
	• **license-included** for Microsoft SQL Server.
	• **general-public-license** for MySQL.
	• **license-included** or **bring-your-own-license** for Oracle.
	• **postgresql-license** for PostgreSQL.
		CLI option:
		`--license-model`
		RDS API parameter:
		`LicenseModel`
			All

Log exports	The types of database log files to publish to Amazon CloudWatch Logs.
	For more information, see Publishing database logs to Amazon CloudWatch Logs.
		CLI option:
		`--enable-cloudwatch-logs-exports`
		RDS API parameter:
		`EnableCloudwatchLogsExports`
			All

Console setting	Setting description	CLI option and RDS API parameter	Supported DB engines

Maintenance window	The 30-minute window in which pending modifications to your DB instance are applied. If the time period doesn't matter, choose **No Preference**.
	
	For more information, see The Amazon RDS maintenance window.
		CLI option:
		
		`--preferred-maintenance-window`
		
		RDS API parameter:
		
		`PreferredMaintenanceWindow`
			All

Manage master credentials in AWS Secrets Manager	Select **Manage master credentials in AWS Secrets Manager** to manage the master user password in a secret in Secrets Manager.
	
	Optionally, choose a KMS key to use to protect the secret. Choose from the KMS keys in your account, or enter the key from a different account.
	
	For more information, see Password management with Amazon RDS and AWS Secrets Manager.
		CLI option:
		
		`--manage-master-user-password | --no-manage-master-user-password`
		
		`--master-user-secret-kms-key-id`
		
		RDS API parameter:
		
		`ManageMasterUserPassword`
		
		`MasterUserSecretKmsKeyId`
			All

Console setting	Setting description	CLI option and RDS API parameter	Supported DB engines

Master password	The password for your master user account. The password has the following number of printable ASCII characters (excluding /, ", a space, and @) depending on the DB engine:
	• Db2: 8–255
	• Oracle: 8–30
	• MariaDB and MySQL: 8–41
	• SQL Server and PostgreSQL: 8–128
		CLI option:
		`--master-user-password`
		RDS API parameter:
		`MasterUserPassword`
			All

Console setting	Setting description	CLI option and RDS API parameter	Supported DB engines

Master username	The name that you use as the master username to log in to your DB instance with all database privileges. Note the following naming restrictions:
	• The name can contain 1–16 alphanumeric characters and underscores.
	• The first character must be a letter.
	• The name can't be a word reserved by the database engine.
	
	You can't change the master username after you create the DB instance.
	
	For Db2, we recommend that you use the same master username as your self-managed Db2 instance name.
	
	For more information on privileges granted to the master user, see Master user account privileges.
		CLI option:
		`--master-username`
		RDS API parameter:
		`MasterUsername`
			All

Console setting	Setting description	CLI option and RDS API parameter	Supported DB engines

Microsoft SQL Server Windows Aut hentication	**Enable Microsoft SQL Server Windows authentication**, then **Browse Directory** to choose the directory where you want to allow authorized domain users to authenticate with this SQL Server ins tance using Windows Authentication.	**CLI options:**
		`--domain`
		`--domain-iam-role-name`
		RDS API parameters:
		`Domain`
		`DomainIAMRoleName`
			SQL Server

Multi-AZ deploymen t	**Create a standby instance** to create a passive secondary replica of your DB instance in another Availability Zone for failover support. We recommend Multi-AZ for production workloads to maintai n high availability.
	For development and testing, you can choose **Do not create a standby instance**.
	For more information, see Configuring and managing a Multi-AZ deployment.
		CLI option:
		`--multi-az`
		`--no-multi-az`
		RDS API parameter:
		`MultiAZ`
			All

Console setting	Setting description	CLI option and RDS API parameter	Supported DB engines

National character set (NCHAR)	The national character set for your DB instance, commonly called the NCHAR character set. You can set the national character set to either AL16UTF16 (default) or UTF-8. You can't change the national character set after you create the DB instance.
	
	The national character set is different from the DB character set. Unlike the DB character set, the national character set specifies the encoding only for NCHAR data types (NCHAR, NVARCHAR2, and NCLOB) columns without affecting database metadata.
	
	For more information, see RDS for Oracle character sets.
		CLI option:
		
		`--nchar-character-set-name`
		
		API parameter:
		
		`NcharCharacterSetName`
			Oracle

Console setting	Setting description	CLI option and RDS API parameter	Supported DB engines

Network type	The IP addressing protocols supported by the DB instance.
	
	IPv4 (the default) to specify that resources can communicate with the DB instance only over the Internet Protocol version 4 (IPv4) addressing protocol.
	
	Dual-stack mode to specify that resources can communicate with the DB instance over IPv4, Internet Protocol version 6 (IPv6), or both. Use dual-stack mode if you have any resources that must communicate with your DB instance over the IPv6 addressing protocol. Also, make sure that you associate an IPv6 CIDR block with all subnets in the DB subnet group that you specify.
	
	For more information, see Amazon RDS IP addressing.
		CLI option:
		
		`--network-type`
		
		RDS API parameter:
		
		`NetworkType`
			All

Option group	An option group for your DB instance. You can choose the default option group or you can create a custom option group.
	
	For more information, see Working with option groups.
		CLI option:
		
		`--option-group-name`
		
		RDS API parameter:
		
		`OptionGroupName`
			All

Console setting	Setting description	CLI option and RDS API parameter	Supported DB engines

Performance Insights	**Enable Performance Insights** to monitor your DB instance load so that you can analyze and troubleshoot your database performance.
	
	Choose a retention period to determine how much Performance Insights data history to keep. The retention setting in the free tier is **Default (7 days)**. To retain your performance data for longer, specify 1–24 months. For more information about retention periods, see Pricing and data retention for Performance Insights.
	
	Choose a KMS key to use to protect the key used to encrypt this database volume. Choose from the KMS keys in your account, or enter the key from a different account.
	
	For more information, see Monitoring DB load with Performance Insights on Amazon RDS.
		CLI options:
		
		`--enable-performance-insights`
		
		`--no-enable-performance-insights`
		
		`--performance-insights-retention-period`
		
		`--performance-insights-kms-key-id`
		
		RDS API parameters:
		
		`EnablePerformanceInsights`
		
		`PerformanceInsightsRetentionPeriod`
		
		`PerformanceInsightsKMSKeyId`
			All except Db2

Console setting	Setting description	CLI option and RDS API parameter	Supported DB engines

Provisioned IOPS	The Provisioned IOPS (I/O operations per second) value for the DB instance. This setting is available only if you choose one of the following for **Storage type**:
	• **General purpose SSD (gp3)**
	• **Provisioned IOPS SSD (io1)**
	• **Provisioned IOPS SSD (io2)**
	
	For more information, see Amazon RDS DB instance storage.
		CLI option:
		`--iops`
		RDS API parameter:
		`Iops`
			All

Console setting	Setting description	CLI option and RDS API parameter	Supported DB engines

Public access	**Yes** to give the DB instance a public IP address, meaning that it's accessible outside the VPC. To be publicly accessible, the DB instance also has to be in a public subnet in the VPC.
	
	No to make the DB instance accessible only from inside the VPC.
	
	For more information, see Hiding a DB instance in a VPC from the internet.
	
	To connect to a DB instance from outside of its VPC, the DB instance must be publicly accessible. Also, access must be granted using the inbound rules of the DB instance's security group. In addition, other requirements must be met. For more information, see Can't connect to Amazon RDS DB instance.
	
	If your DB instance isn't publicly accessible, use an AWS Site-to-Site VPN connection or an AWS Direct Connect connection to access it from a private network. For more information, see Internetwork traffic privacy.
		CLI option:
		
		`--publicly-accessible`
		
		`--no-publicly-accessible`
		
		RDS API parameter:
		
		`PubliclyAccessible`
			All

Console setting	Setting description	CLI option and RDS API parameter	Supported DB engines

RDS Extended Support	Select **Enable RDS Extended Support** to allow supported major engine versions to continue running past the RDS end of standard support date.
	
	When you create a DB instance, Amazon RDS defaults to RDS Extended Support. To prevent the creation of a new DB instance after the RDS end of standard support date and to avoid charges for RDS Extended Support, disable this setting. Your existing DB instances won't incur charges until the RDS Extended Support pricing start date.
	
	For more information, see Using Amazon RDS Extended Support.
		CLI option:
		
		`--engine-lifecycle-support`
		
		RDS API parameter:
		
		`EngineLifecycleSupport`
			MySQL
			
			PostgreSQL

RDS Proxy	Choose **Create an RDS Proxy** to create a proxy for your DB instance. Amazon RDS automatically creates an IAM role and a Secrets Manager secret for the proxy. For more information, see Using Amazon RDS Proxy.	Not available when creating a DB instance.	MariaDB MySQL PostgreSQL

Console setting	Setting description	CLI option and RDS API parameter	Supported DB engines

Storage autoscaling	**Enable storage autoscaling** to enable Amazon RDS to automatically increase storage when needed to avoid having your DB instance run out of storage space.
	
	Use **Maximum storage threshold** to set the upper limit for Amazon RDS to automatically increase storage for your DB instance. The default is 1,000 GiB.
	
	For more information, see Managing capacity automatically with Amazon RDS storage autoscaling.
		CLI option:
		
		`--max-allocated-storage`
		
		RDS API parameter:
		
		`MaxAllocatedStorage`
			All

Storage throughput	The storage throughput value for the DB instance. This setting is available only if you choose **General purpose SSD (gp3)** for **Storage type**.
	
	For more information, see gp3 storage (recommended).
		CLI option:
		
		`--storage-throughput`
		
		RDS API parameter:
		
		`StorageThroughput`
			All

Console setting	Setting description	CLI option and RDS API parameter	Supported DB engines

Storage type	The storage type for your DB instance.
	
	If you choose **General Purpose SSD (gp3)**, you can provision additional provisioned IOPS and storage throughput under **Advanced settings**.
	
	If you choose **Provisioned IOPS SSD (io1)** or **Provisioned IOPS SSD (io2)**, enter the **Provisioned IOPS** value.
	
	For more information, see Amazon RDS storage types.
		CLI option:
		
		`--storage-type`
		
		RDS API parameter:
		
		`StorageType`
			All

Subnet group	A DB subnet group to associate with this DB instance.
	
	For more information, see Working with DB subnet groups.
		CLI option:
		
		`--db-subnet-group-name`
		
		RDS API parameter:
		
		`DBSubnetGroupName`
			All

Tenant database name	The name of your initial PDB in the multi-tenant configuration of the Oracle architecture. This setting is available only if you choose **Multi-tenant configuration** for **Architecture configuration**.
	
	The tenant database name must differ from the name of your CDB, which is named RDSCDB. You can't change the CDB name.
		CLI option:
		
		`--db-name`
		
		RDS API parameter:
		
		`DBName`
			Oracle

Console setting	Setting description	CLI option and RDS API parameter	Supported DB engines

Tenant database master username	The name that you use as the master username to log in to your tenant database (PDB) with all database privileges. This setting is available only if you choose **Multi-tenant configuration** for **Architecture configuration**.
	
	Note the following naming restrictions:
	
	• The name can contain 1–16 alphanumeric characters and underscores.
	• The first character must be a letter.
	• The name can't be a word reserved by the database engine.
	
	You can't do the following:
	
	• Change the tenant master username after you create the tenant database.
	• Log in with the tenant master username to the CDB.
		CLI option:
		
		`--master-username`
		
		RDS API parameter:
		
		`MasterUsername`
			Oracle

Console setting	Setting description	CLI option and RDS API parameter	Supported DB engines

Tenant database master password	The password for the master user account of your tenant database (PDB). This setting is available only if you choose **Multi-tenant configuration** for **Architecture configuration**.
	
	The password has 8–30 printable ASCII characters, excluding /, ", a space, and @.
		CLI option:
		
		`--master-password`
		
		RDS API parameter:
		
		`MasterPassword`
			Oracle

Tenant database character set	The character set of the initial tenant database. This setting is available only if you choose **Multi-tenant configuration** for **Architecture configuration**. Only RDS for Oracle CDB instances are supported.
	
	The default value of **AL32UTF8** for the tenant database character set is for the Unicode 5.0 UTF-8 Universal character set. You can choose a tenant database character set that is different from the character set of the CDB.
	
	For more information, see RDS for Oracle character sets.
		CLI option:
		
		`--character-set-name`
		
		RDS API parameter:
		
		`CharacterSetName`
			Oracle

Console setting	Setting description	CLI option and RDS API parameter	Supported DB engines

Tenant database national character set	The national character set for your tenant database, commonly called the NCHAR character set. This setting is available only if you choose **Multi-tenant configuration** for **Architecture configuration**. Only RDS for Oracle CDB instances are supported.
	
	You can set the national character set to either **AL16UTF16** (default) or **UTF-8**. You can't change the national character set after you create the tenant database.
	
	The tenant database national character set is different from the tenant database character set. The national character set specifies the encoding only for columns that use the NCHAR data type (NCHAR, NVARCHAR2, and NCLOB) and doesn't affect database metadata.
	
	For more information, see RDS for Oracle character sets.
		CLI option:
		
		`--nchar-character-set-name`
		
		API parameter:
		
		`NcharCharacterSetName`
			Oracle

Time zone	The time zone for your DB instance. If you don't choose a time zone, your DB instance uses the default time zone. You can't change the time zone after the DB instance is created.
	
	For more information, see Local time zone for Amazon RDS for Db2 DB instances and Local time zone for Microsoft SQL Server DB instances.
		CLI option:
		
		`--timezone`
		
		RDS API parameter:
		
		`Timezone`
			Db2
			
			SQL Server
			
			RDS Custom for SQL Server

Console setting	Setting description	CLI option and RDS API parameter	Supported DB engines
Virtual Private Cloud (VPC)	A VPC based on the Amazon VPC service to associate with this DB instance. For more information, see Amazon VPC and Amazon RDS.	For the CLI and API, you specify the VPC security group IDs.	All

VPC security group (firewall)	The security group to associate with the DB instance.
	
	For more information, see Overview of VPC security groups.
		CLI option:
		
		`--vpc-security-group-ids`
		
		RDS API parameter:
		
		`VpcSecurityGroupIds`
			All

Creating Amazon RDS resources with AWS CloudFormation

Amazon RDS is integrated with AWS CloudFormation, a service that helps you to model and set up your AWS resources so that you can spend less time creating and managing your resources and infrastructure. You create a template that describes all the AWS resources that you want (such as DB instances and DB parameter groups), and AWS CloudFormation provisions and configures those resources for you.

When you use AWS CloudFormation, you can reuse your template to set up your RDS resources consistently and repeatedly. Describe your resources once, and then provision the same resources over and over in multiple AWS accounts and Regions.

RDS and AWS CloudFormation templates

AWS CloudFormation templates are formatted text files in JSON or YAML. These templates describe the resources that you want to provision in your AWS CloudFormation stacks. If you're unfamiliar with JSON or YAML, you can use AWS CloudFormation Designer to help you get started with AWS CloudFormation templates. For more information, see What is AWS CloudFormation Designer? in the *AWS CloudFormation User Guide*.

RDS supports creating resources in AWS CloudFormation. For more information, including examples of JSON and YAML templates for these resources, see the RDS resource type reference in the *AWS CloudFormation User Guide*.

Learn more about AWS CloudFormation

To learn more about AWS CloudFormation, see the following resources:

- AWS CloudFormation
- AWS CloudFormation User Guide
- AWS CloudFormation API Reference
- AWS CloudFormation Command Line Interface User Guide

Connecting to an Amazon RDS DB instance

Before you can connect to a DB instance, you must create the DB instance. For information, see Creating an Amazon RDS DB instance. After Amazon RDS provisions your DB instance, use any standard client application or utility for your DB engine to connect to the DB instance. In the connection string, specify the DNS address from the DB instance endpoint as the host parameter. Also, specify the port number from the DB instance endpoint as the port parameter.

Topics

Finding the connection information for an Amazon RDS DB instance

The connection information for a DB instance includes its endpoint, port, and a valid database user, such as the master user. For example, for a MySQL DB instance, suppose that the endpoint value is `mydb.123456789012.us-east-1.rds.amazonaws.com`. In this case, the port value is `3306`, and the database user is `admin`. Given this information, you specify the following values in a connection string:

- For host or host name or DNS name, specify `mydb.123456789012.us-east-1.rds.amazonaws.com`.
- For port, specify `3306`.
- For user, specify `admin`.

The endpoint is unique for each DB instance, and the values of the port and user can vary. The following list shows the most common port for each DB engine:

- Db2 – 50000
- MariaDB – 3306

- Microsoft SQL Server – 1433
- MySQL – 3306
- Oracle – 1521
- PostgreSQL – 5432

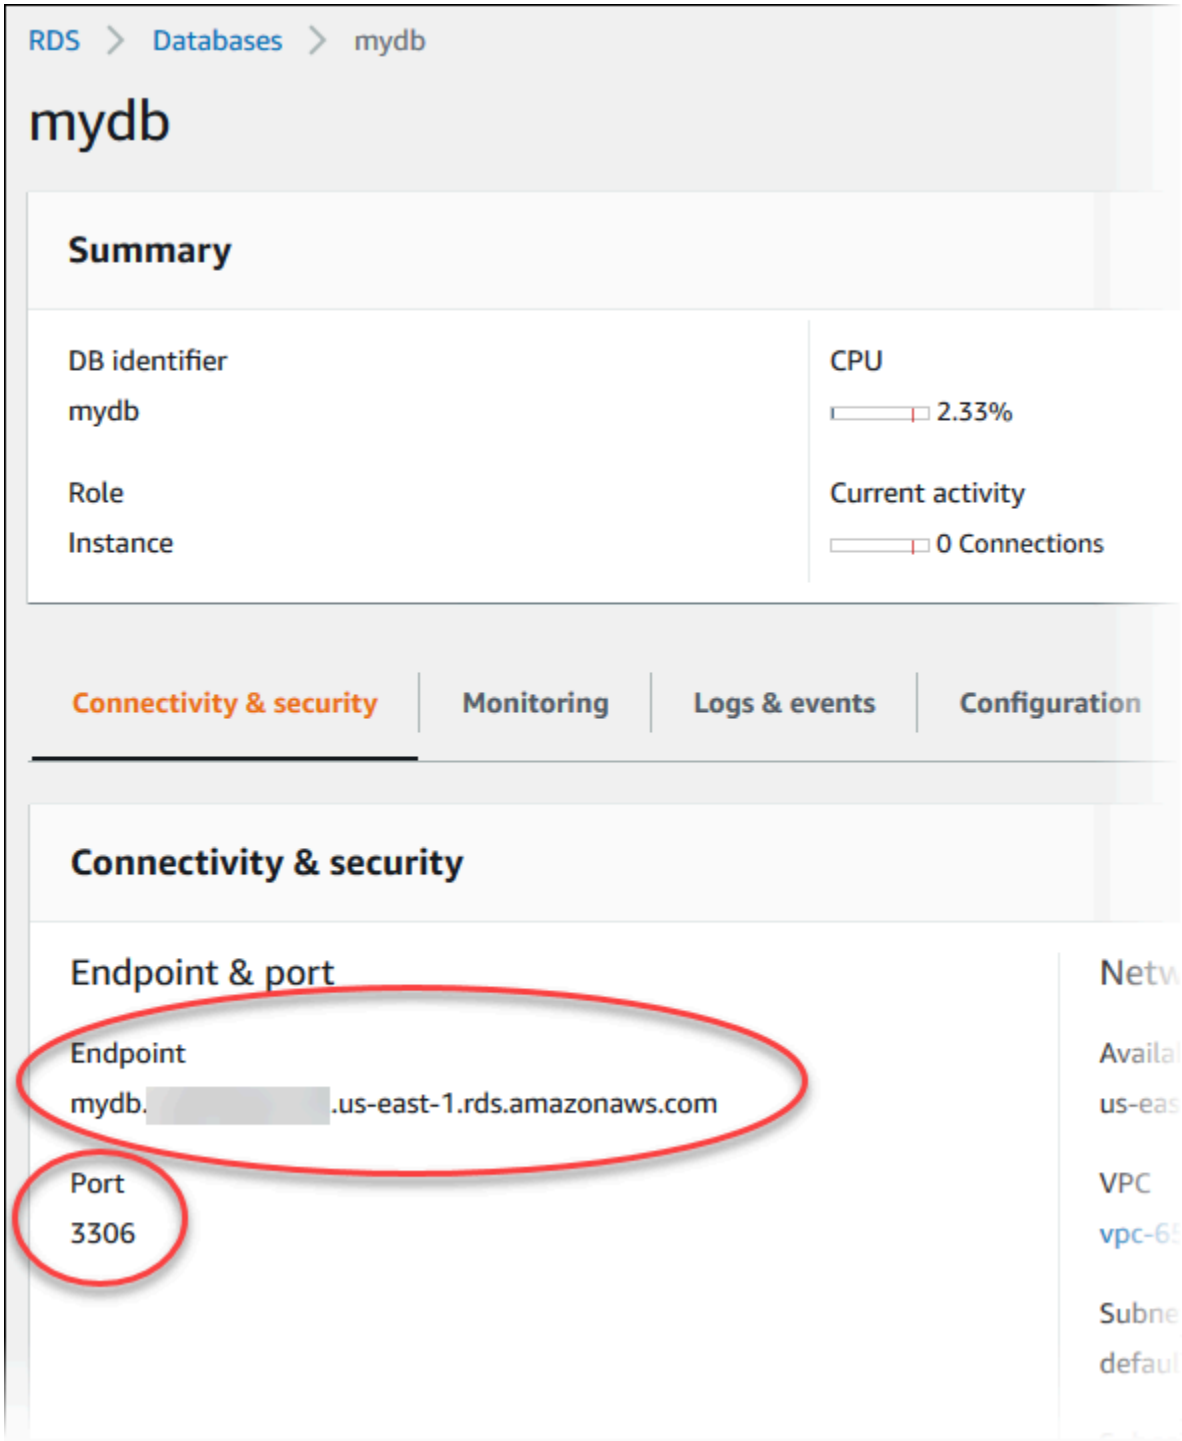
To connect to a DB instance, use any client for a DB engine. For example, you might use the mysql utility to connect to a MariaDB or MySQL DB instance. You might use Microsoft SQL Server Management Studio to connect to a SQL Server DB instance. You might use Oracle SQL Developer to connect to an Oracle DB instance. Similarly, you might use the psql command line utility to connect to a PostgreSQL DB instance.

To find the connection information for a DB instance, use the AWS Management Console. You can also use the AWS Command Line Interface (AWS CLI) describe-db-instances command or the RDS API DescribeDBInstances operation.

Console

To find the connection information for a DB instance in the AWS Management Console

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases** to display a list of your DB instances.
3. Choose the name of the DB instance to display its details.
4. On the **Connectivity & security** tab, copy the endpoint. Also, note the port number. You need both the endpoint and the port number to connect to the DB instance.



5. If you need to find the master user name, choose the **Configuration** tab and view the **Master username** value.

AWS CLI

To find the connection information for a DB instance by using the AWS CLI, call the describe-db-instances command. In the call, query for the DB instance ID, endpoint, port, and master user name.

For Linux, macOS, or Unix:

```
aws rds describe-db-instances \
  --query "*[].[DBInstanceIdentifier,Endpoint.Address,Endpoint.Port,MasterUsername]"
```

For Windows:

```
aws rds describe-db-instances ^
  --query "*[].[DBInstanceIdentifier,Endpoint.Address,Endpoint.Port,MasterUsername]"
```

Your output should be similar to the following.

```
[
    [
        "mydb",
        "mydb.123456789012.us-east-1.rds.amazonaws.com",
        3306,
        "admin"
    ],
    [
        "myoracledb",
        "myoracledb.123456789012.us-east-1.rds.amazonaws.com",
        1521,
        "dbadmin"
    ],
    [
        "mypostgresqldb",
        "mypostgresqldb.123456789012.us-east-1.rds.amazonaws.com",
        5432,
        "postgresadmin"
    ]
]
```

RDS API

To find the connection information for a DB instance by using the Amazon RDS API, call the DescribeDBInstances operation. In the output, find the values for the endpoint address, endpoint port, and master user name.

Database authentication options

Amazon RDS supports the following ways to authenticate database users:

- **Password authentication** – Your DB instance performs all administration of user accounts. You create users and specify passwords with SQL statements. The SQL statements you can use depend on your DB engine.
- **AWS Identity and Access Management (IAM) database authentication** – You don't need to use a password when you connect to a DB instance. Instead, you use an authentication token.
- **Kerberos authentication** – You use external authentication of database users using Kerberos and Microsoft Active Directory. Kerberos is a network authentication protocol that uses tickets and symmetric-key cryptography to eliminate the need to transmit passwords over the network. Kerberos has been built into Active Directory and is designed to authenticate users to network resources, such as databases.

IAM database authentication and Kerberos authentication are available only for specific DB engines and versions.

For more information, see Database authentication with Amazon RDS.

Encrypted connections

You can use Secure Socket Layer (SSL) or Transport Layer Security (TLS) from your application to encrypt a connection to a DB instance. Each DB engine has its own process for implementing SSL/TLS. For more information, see Using SSL/TLS to encrypt a connection to a DB instance or cluster.

Scenarios for accessing a DB instance in a VPC

Using Amazon Virtual Private Cloud (Amazon VPC), you can launch AWS resources, such as Amazon RDS DB instances, into a virtual private cloud (VPC). When you use Amazon VPC, you have control over your virtual networking environment. You can choose your own IP address range, create subnets, and configure routing and access control lists.

A VPC security group controls access to DB instances inside a VPC. Each VPC security group rule enables a specific source to access a DB instance in a VPC that is associated with that VPC security group. The source can be a range of addresses (for example, 203.0.113.0/24), or another VPC security group. By specifying a VPC security group as the source, you allow incoming traffic from all instances (typically application servers) that use the source VPC security group.

Before attempting to connect to your DB instance, configure your VPC for your use case. The following are common scenarios for accessing a DB instance in a VPC:

- **A DB instance in a VPC accessed by an Amazon EC2 instance in the same VPC** – A common use of a DB instance in a VPC is to share data with an application server that is running in an EC2 instance in the same VPC. The EC2 instance might run a web server with an application that interacts with the DB instance.
- **A DB instance in a VPC accessed by an EC2 instance in a different VPC** – In some cases, your DB instance is in a different VPC from the EC2 instance that you're using to access it. If so, you can use VPC peering to access the DB instance.
- **A DB instance in a VPC accessed by a client application through the internet** – To access a DB instance in a VPC from a client application through the internet, you configure a VPC with a single public subnet. You also configure an internet gateway to enable communication over the internet.

  To connect to a DB instance from outside of its VPC, the DB instance must be publicly accessible. Also, access must be granted using the inbound rules of the DB instance's security group, and other requirements must be met. For more information, see Can't connect to Amazon RDS DB instance.
- **A DB instance in a VPC accessed by a private network** – If your DB instance isn't publicly accessible, you can use one of the following options to access it from a private network:
  - An AWS Site-to-Site VPN connection
  - An AWS Direct Connect connection
  - An AWS Client VPN connection

For more information, see Scenarios for accessing a DB instance in a VPC.

Connecting to DB instances with the AWS drivers

The AWS suite of drivers has been designed to provide support for faster switchover and failover times, and authentication with AWS Secrets Manager, AWS Identity and Access Management (IAM),

and Federated Identity. The AWS drivers rely on monitoring DB instance status and being aware of the instance topology to determine the new primary instance. This approach reduces switchover and failover times to single-digit seconds, compared to tens of seconds for open-source drivers.

The following table lists the features supported for each of the drivers. As new service features are introduced, the goal of the AWS suite of drivers is to have built-in support for these service features.

Feature	AWS JDBC Driver	AWS Python Driver	AWS ODBC Driver for MySQL
Failover support	Yes	Yes	Yes
Enhanced failover monitoring	Yes	Yes	Yes
Read/write splitting	Yes	Yes	No
Driver metadata connection	Yes	N/A	N/A
Telemetry	Yes	Yes	No
Secrets Manager	Yes	Yes	Yes
IAM authentication	Yes	Yes	Yes
Federated Identity (AD FS)	Yes	Yes	No
Federated Identity (Okta)	Yes	No	No
Multi-AZ DB clusters	Yes	Yes	No

For more information on the AWS drivers, see the corresponding language driver for your RDS for MariaDB, RDS for MySQL, or RDS for PostgreSQL DB instance.

> **Note**
>
> The only features supported for RDS for MariaDB are authentication with AWS Secrets Manager, AWS Identity and Access Management (IAM), and Federated Identity.

Connecting to a DB instance that's running a specific DB engine

To learn how to connect to a DB instance that is running a specific DB engine, follow the instructions for your DB engine:

- RDS for Db2
- RDS for MariaDB
- RDS for SQL Server
- RDS for MySQL
- RDS for Oracle
- RDS for PostgreSQL

Managing connections with RDS Proxy

You can also use Amazon RDS Proxy to manage connections to RDS for MariaDB, RDS for Microsoft SQL Server, RDS for MySQL, and RDS for PostgreSQL DB instances. RDS Proxy allows applications to pool and share database connections to improve scalability. For more information, see Using Amazon RDS Proxy.

Working with option groups

Some DB engines offer additional features that make it easier to manage data and databases, and to provide additional security for your database. Amazon RDS uses option groups to enable and configure these features. An *option group* can specify features, called options, that are available for a particular Amazon RDS DB instance. Options can have settings that specify how the option works. When you associate a DB instance with an option group, the specified options and option settings are enabled for that DB instance.

Amazon RDS supports options for the following database engines:

Database engine	Relevant documentation
`Db2`	Options for RDS for Db2 DB instances
`MariaDB`	Options for MariaDB database engine
`Microsoft SQL Server`	Options for the Microsoft SQL Server database engine
`MySQL`	Options for MySQL DB instances
`Oracle`	Adding options to Oracle DB instances
`PostgreSQL`	PostgreSQL does not use options and option groups. PostgreSQL uses extensions and modules to provide additional features. For more information, see Supported PostgreSQL extension versions.

Option groups overview

Amazon RDS provides an empty default option group for each new DB instance. You can't modify or delete this default option group, but any new option group that you create derives its settings from the default option group. To apply an option to a DB instance, you must do the following:

1. Create a new option group, or copy or modify an existing option group.
2. Add one or more options to the option group.
3. Associate the option group with the DB instance.

To associate an option group with a DB instance, modify the DB instance. For more information, see Modifying an Amazon RDS DB instance.

Both DB instances and DB snapshots can be associated with an option group. In some cases, you might restore from a DB snapshot or perform a point-in-time restore for a DB instance. In these cases, the option group associated with the DB snapshot or DB instance is, by default, associated with the restored DB instance. You can associate a different option group with a restored DB instance. However, the new option group must contain any persistent or permanent options that were included in the original option group. Persistent and permanent options are described following.

Options require additional memory to run on a DB instance. Thus, you might need to launch a larger instance to use them, depending on your current use of your DB instance. For example, Oracle Enterprise Manager Database Control uses about 300 MB of RAM. If you enable this option for a small DB instance, you might encounter performance problems or out-of-memory errors.

Persistent and permanent options

Two types of options, persistent and permanent, require special consideration when you add them to an option group.

Persistent options can't be removed from an option group while DB instances are associated with the option group. An example of a persistent option is the TDE option for Microsoft SQL Server transparent data encryption (TDE). You must disassociate all DB instances from the option group before a persistent option can be removed from the option group. In some cases, you might restore or perform a point-in-time restore from a DB snapshot. In these cases, if the option group associated with that DB snapshot contains a persistent option, you can only associate the restored DB instance with that option group.

Permanent options, such as the TDE option for Oracle Advanced Security TDE, can never be removed from an option group. You can change the option group of a DB instance that is using the permanent option. However, the option group associated with the DB instance must include the same permanent option. In some cases, you might restore or perform a point-in-time restore from a DB snapshot. In these cases, if the option group associated with that DB snapshot contains a permanent option, you can only associate the restored DB instance with an option group with that permanent option.

For Oracle DB instances, you can copy shared DB snapshots that have the options `Timezone` or `OLS` (or both). To do so, specify a target option group that includes these options when you copy the DB snapshot. The OLS option is permanent and persistent only for Oracle DB instances running Oracle version 12.2 or higher. For more information about these options, see Oracle time zone and Oracle Label Security.

VPC considerations

The option group associated with the DB instance is linked to the DB instance's VPC. This means that you can't use the option group assigned to a DB instance if you try to restore the instance to a different VPC. If you restore a DB instance to a different VPC, you can do one of the following:

- Assign the default option group to the DB instance.
- Assign an option group that is linked to that VPC.
- Create a new option group and assign it to the DB instance.

With persistent or permanent options, such as Oracle TDE, you must create a new option group. This option group must include the persistent or permanent option when restoring a DB instance into a different VPC.

Option settings control the behavior of an option. For example, the Oracle Advanced Security option `NATIVE_NETWORK_ENCRYPTION` has a setting that you can use to specify the encryption algorithm for network traffic to and from the DB instance. Some options settings are optimized for use with Amazon RDS and cannot be changed.

Mutually exclusive options

Some options are mutually exclusive. You can use one or the other, but not both at the same time. The following options are mutually exclusive:

- Oracle Enterprise Manager Database Express and Oracle Management Agent for Enterprise Manager Cloud Control.
- Oracle native network encryption and Oracle Secure Sockets Layer.

Creating an option group

You can create a new option group that derives its settings from the default option group. You then add one or more options to the new option group. Or, if you already have an existing option

group, you can copy that option group with all of its options to a new option group. For more information, see Copying an option group.

After you create a new option group, it has no options. To learn how to add options to the option group, see Adding an option to an option group. After you have added the options you want, you can then associate the option group with a DB instance. This way, the options become available on the DB instance. For information about associating an option group with a DB instance, see the documentation for your engine in Working with option groups.

Console

One way of creating an option group is by using the AWS Management Console.

To create a new option group by using the console

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Option groups**.
3. Choose **Create group**.
4. In the **Create option group** window, do the following:
    a. For **Name**, type a name for the option group that is unique within your AWS account. The name can contain only letters, digits, and hyphens.
    b. For **Description**, type a brief description of the option group. The description is used for display purposes.
    c. For **Engine**, choose the DB engine that you want.
    d. For **Major engine version**, choose the major version of the DB engine that you want.
5. To continue, choose **Create**. To cancel the operation instead, choose **Cancel**.

AWS CLI

To create an option group, use the AWS CLI `create-option-group` command with the following required parameters.

- `--option-group-name`
- `--engine-name`
- `--major-engine-version`

- `--option-group-description`

Example

The following example creates an option group named `testoptiongroup`, which is associated with the Oracle Enterprise Edition DB engine. The description is enclosed in quotation marks.

For Linux, macOS, or Unix:

```
aws rds create-option-group \
    --option-group-name testoptiongroup \
    --engine-name oracle-ee \
    --major-engine-version 19 \
    --option-group-description "Test option group for Oracle Database 19c EE"
```

For Windows:

```
aws rds create-option-group ^
    --option-group-name testoptiongroup ^
    --engine-name oracle-ee ^-
    --major-engine-version 19 ^
    --option-group-description "Test option group for Oracle Database 19c EE"
```

RDS API

To create an option group, call the Amazon RDS API `CreateOptionGroup` operation. Include the following parameters:

- `OptionGroupName`
- `EngineName`
- `MajorEngineVersion`
- `OptionGroupDescription`

Copying an option group

You can use the AWS CLI or the Amazon RDS API copy an option group. Copying an option group can be convenient. An example is when you have an existing option group and want to include most of its custom parameters and values in a new option group. You can also make a copy of an option group that you use in production and then modify the copy to test other option settings.

> **Note**
>
> Currently, you can't copy an option group to a different AWS Region.

AWS CLI

To copy an option group, use the AWS CLI copy-option-group command. Include the following required options:

- `--source-option-group-identifier`
- `--target-option-group-identifier`
- `--target-option-group-description`

Example

The following example creates an option group named `new-option-group`, which is a local copy of the option group `my-option-group`.

For Linux, macOS, or Unix:

```
aws rds copy-option-group \
    --source-option-group-identifier my-option-group \
    --target-option-group-identifier new-option-group \
    --target-option-group-description "My new option group"
```

For Windows:

```
aws rds copy-option-group ^
    --source-option-group-identifier my-option-group ^
    --target-option-group-identifier new-option-group ^
    --target-option-group-description "My new option group"
```

RDS API

To copy an option group, call the Amazon RDS API CopyOptionGroup operation. Include the following required parameters.

- `SourceOptionGroupIdentifier`
- `TargetOptionGroupIdentifier`
- `TargetOptionGroupDescription`

Adding an option to an option group

You can add an option to an existing option group. After you have added the options you want, you can then associate the option group with a DB instance so that the options become available on the DB instance. For information about associating an option group with a DB instance, see the documentation for your specific DB engine listed at Working with option groups.

Option group changes must be applied immediately in two cases:

- When you add an option that adds or updates a port value, such as the `OEM` option.
- When you add or remove an option group with an option that includes a port value.

In these cases, choose the **Apply Immediately** option in the console. Or you can include the `--apply-immediately` option when using the AWS CLI or set the `ApplyImmediately` parameter to `true` when using the Amazon RDS API. Options that don't include port values can be applied immediately, or can be applied during the next maintenance window for the DB instance.

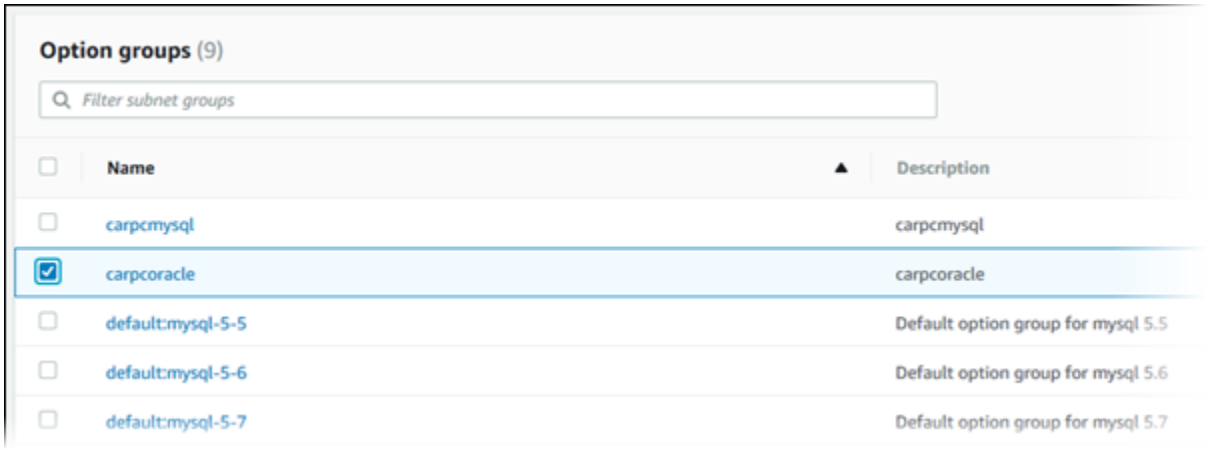
> **Note**
>
> If you specify a security group as a value for an option in an option group, manage the security group by modifying the option group. You can't change or remove this security group by modifying a DB instance. Also, the security group doesn't appear in the DB instance details in the AWS Management Console or in the output for the AWS CLI command `describe-db-instances`.

Console

You can use the AWS Management Console to add an option to an option group.

To add an option to an option group by using the console

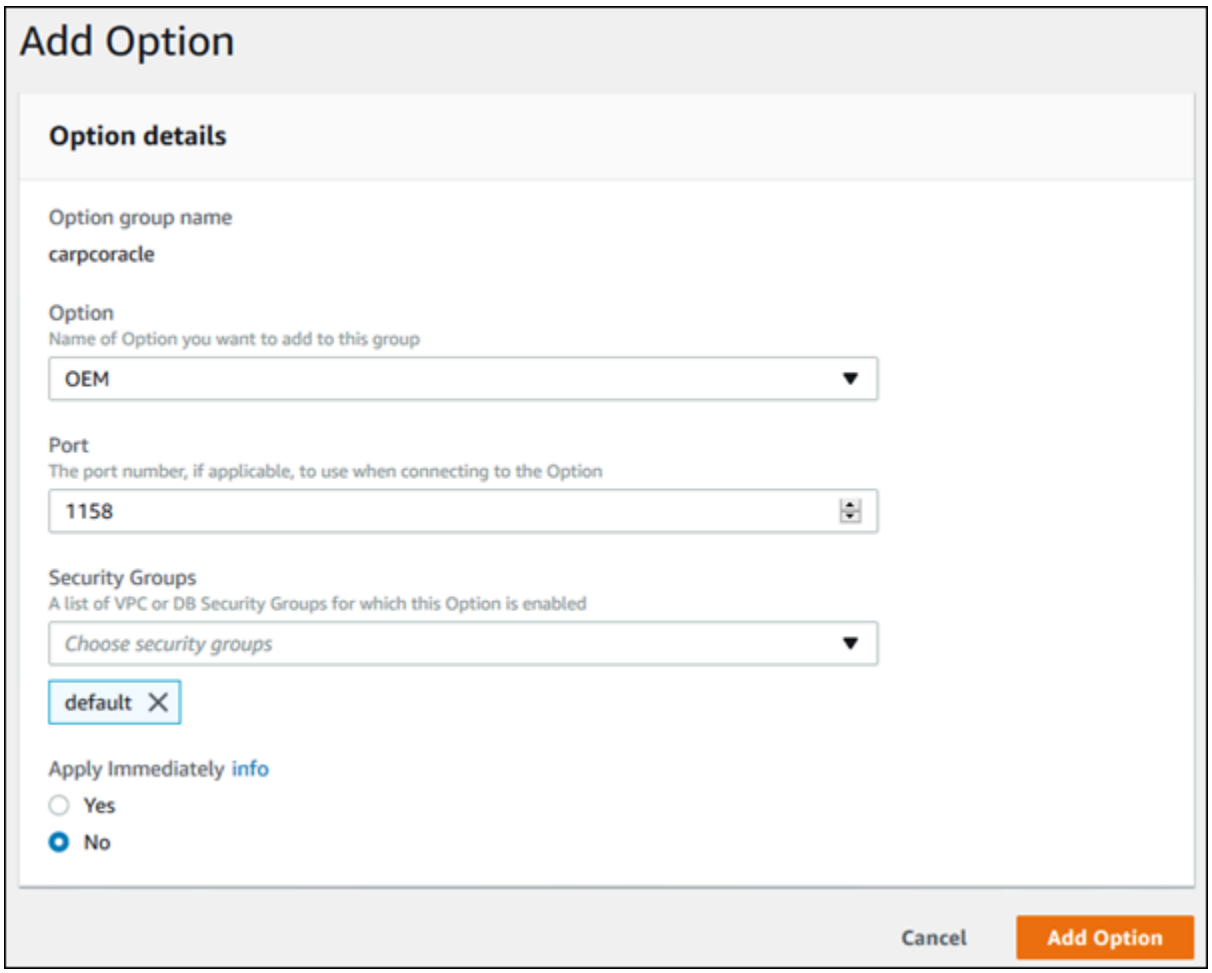
1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Option groups**.
3. Choose the option group that you want to modify, and then choose **Add option**.



4. In the **Add option** window, do the following:

   a. Choose the option that you want to add. You might need to provide additional values, depending on the option that you select. For example, when you choose the `OEM` option, you must also type a port value and specify a security group.

   b. To enable the option on all associated DB instances as soon as you add it, for **Apply Immediately**, choose **Yes**. If you choose **No** (the default), the option is enabled for each associated DB instance during its next maintenance window.



5. When the settings are as you want them, choose **Add option**.

AWS CLI

To add an option to an option group, run the AWS CLI add-option-to-option-group command with the option that you want to add. To enable the new option immediately on all associated DB instances, include the `--apply-immediately` parameter. By default, the option is enabled for each associated DB instance during its next maintenance window. Include the following required parameter:

- `--option-group-name`

Example

The following example adds the `Timezone` option, with the `America/Los_Angeles` setting, to an option group named `testoptiongroup` and immediately enables it.

For Linux, macOS, or Unix:

```
aws rds add-option-to-option-group \
    --option-group-name testoptiongroup \
    --options "OptionName=Timezone,OptionSettings=[{Name=TIME_ZONE,Value=America/
Los_Angeles}]" \
    --apply-immediately
```

For Windows:

```
aws rds add-option-to-option-group ^
    --option-group-name testoptiongroup ^
    --options "OptionName=Timezone,OptionSettings=[{Name=TIME_ZONE,Value=America/
Los_Angeles}]" ^
    --apply-immediately
```

Command output is similar to the following:

```
...{
       "OptionName": "Timezone",
       "OptionDescription": "Change time zone",
       "Persistent": true,
       "Permanent": false,
       "OptionSettings": [
           {
               "Name": "TIME_ZONE",
               "Value": "America/Los_Angeles",
               "DefaultValue": "UTC",
               "Description": "Specifies the timezone the user wants to change the
 system time to",
               "ApplyType": "DYNAMIC",
               "DataType": "STRING",
               "AllowedValues": "Africa/Cairo,...",
               "IsModifiable": true,
               "IsCollection": false
           }
       ],
```

```
        "DBSecurityGroupMemberships": [],
        "VpcSecurityGroupMemberships": []
    }...
```

Example

The following example adds the Oracle OEM option to an option group. It also specifies a custom port and a pair of Amazon EC2 VPC security groups to use for that port.

For Linux, macOS, or Unix:

```
aws rds add-option-to-option-group \
    --option-group-name testoptiongroup \
    --options OptionName=OEM,Port=5500,VpcSecurityGroupMemberships="sg-test1,sg-test2"
 \
    --apply-immediately
```

For Windows:

```
aws rds add-option-to-option-group ^
    --option-group-name testoptiongroup ^
    --options OptionName=OEM,Port=5500,VpcSecurityGroupMemberships="sg-test1,sg-test2"
 ^
    --apply-immediately
```

Command output is similar to the following:

```
OPTIONGROUP  False  oracle-ee  19 arn:aws:rds:us-east-1:1234567890:og:testoptiongroup
 Test Option Group  testoptiongroup vpc-test
OPTIONS Oracle 12c EM Express   OEM     False   False   5500
VPCSECURITYGROUPMEMBERSHIPS     active  sg-test1
VPCSECURITYGROUPMEMBERSHIPS     active  sg-test2
```

Example

The following example adds the Oracle option `NATIVE_NETWORK_ENCRYPTION` to an option group and specifies the option settings. If no option settings are specified, default values are used.

For Linux, macOS, or Unix:

```
aws rds add-option-to-option-group \
```

```
    --option-group-name testoptiongroup \
    --options '[{"OptionSettings":
[{"Name":"SQLNET.ENCRYPTION_SERVER","Value":"REQUIRED"},
{"Name":"SQLNET.ENCRYPTION_TYPES_SERVER","Value":"AES256,AES192,DES"}],"OptionName":"NATIVE_NET
 \
    --apply-immediately
```

For Windows:

```
aws rds add-option-to-option-group ^
    --option-group-name testoptiongroup ^
    --options "OptionSettings"=[{"Name"="SQLNET.ENCRYPTION_SERVER","Value"="REQUIRED"},
{"Name"="SQLNET.ENCRYPTION_TYPES_SERVER","Value"="AES256\,AES192\,DES"}],"OptionName"="NATIVE_N
 ^
    --apply-immediately
```

Command output is similar to the following:

```
...{
    "OptionName": "NATIVE_NETWORK_ENCRYPTION",
    "OptionDescription": "Native Network Encryption",
    "Persistent": false,
    "Permanent": false,
    "OptionSettings": [
        {
            "Name": "SQLNET.ENCRYPTION_TYPES_SERVER",
             "Value": "AES256,AES192,DES",
            "DefaultValue":
 "RC4_256,AES256,AES192,3DES168,RC4_128,AES128,3DES112,RC4_56,DES,RC4_40,DES40",
            "Description": "Specifies list of encryption algorithms in order of
 intended use",
            "ApplyType": "STATIC",
            "DataType": "STRING",
            "AllowedValues":
 "RC4_256,AES256,AES192,3DES168,RC4_128,AES128,3DES112,RC4_56,DES,RC4_40,DES40",
            "IsModifiable": true,
            "IsCollection": true
        },
        {
            "Name": "SQLNET.ENCRYPTION_SERVER",
            "Value": "REQUIRED",
            "DefaultValue": "REQUESTED",
            "Description": "Specifies the desired encryption behavior",
```

```
            "ApplyType": "STATIC",
            "DataType": "STRING",
            "AllowedValues": "ACCEPTED,REJECTED,REQUESTED,REQUIRED",
            "IsModifiable": true,
            "IsCollection": false
        },...
```

RDS API

To add an option to an option group using the Amazon RDS API, call the ModifyOptionGroup operation with the option that you want to add. To enable the new option immediately on all associated DB instances, include the `ApplyImmediately` parameter and set it to `true`. By default, the option is enabled for each associated DB instance during its next maintenance window. Include the following required parameter:

- `OptionGroupName`

Listing the options and option settings for an option group

You can list all the options and option settings for an option group.

Console

You can use the AWS Management Console to list all of the options and option settings for an option group.

To list the options and option settings for an option group

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Option groups**.
3. Choose the name of the option group to display its details. The options and option settings in the option group are listed.

AWS CLI

To list the options and option settings for an option group, use the AWS CLI `describe-option-groups` command. Specify the name of the option group whose options and settings you want to view. If you don't specify an option group name, all option groups are described.

Example

The following example lists the options and option settings for all option groups.

```
aws rds describe-option-groups
```

Example

The following example lists the options and option settings for an option group named `testoptiongroup`.

```
aws rds describe-option-groups --option-group-name testoptiongroup
```

RDS API

To list the options and option settings for an option group, use the Amazon RDS API `DescribeOptionGroups` operation. Specify the name of the option group whose options and settings you want to view. If you don't specify an option group name, all option groups are described.

Modifying an option setting

After you have added an option that has modifiable option settings, you can modify the settings at any time. If you change options or option settings in an option group, those changes are applied to all DB instances that are associated with that option group. For more information on what settings are available for the various options, see the documentation for your engine in Working with option groups.

Option group changes must be applied immediately in two cases:

- When you add an option that adds or updates a port value, such as the `OEM` option.
- When you add or remove an option group with an option that includes a port value.

In these cases, choose the **Apply Immediately** option in the console. Or you can include the `--apply-immediately` option when using the AWS CLI or set the `ApplyImmediately` parameter to `true` when using the RDS API. Options that don't include port values can be applied immediately, or can be applied during the next maintenance window for the DB instance.

> **Note**
>
> If you specify a security group as a value for an option in an option group, you manage the security group by modifying the option group. You can't change or remove this security group by modifying a DB instance. Also, the security group doesn't appear in the DB instance details in the AWS Management Console or in the output for the AWS CLI command `describe-db-instances`.

Console

You can use the AWS Management Console to modify an option setting.

To modify an option setting by using the console

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Option groups**.
3. Select the option group whose option that you want to modify, and then choose **Modify option**.
4. In the **Modify option** window, from **Installed Options**, choose the option whose setting you want to modify. Make the changes that you want.
5. To enable the option as soon as you add it, for **Apply Immediately**, choose **Yes**. If you choose **No** (the default), the option is enabled for each associated DB instance during its next maintenance window.
6. When the settings are as you want them, choose **Modify Option**.

AWS CLI

To modify an option setting, use the AWS CLI `add-option-to-option-group` command with the option group and option that you want to modify. By default, the option is enabled for each associated DB instance during its next maintenance window. To apply the change immediately to all associated DB instances, include the `--apply-immediately` parameter. To modify an option setting, use the `--settings` argument.

Example

The following example modifies the port that the Oracle Enterprise Manager Database Control (OEM) uses in an option group named `testoptiongroup` and immediately applies the change.

For Linux, macOS, or Unix:

```
aws rds add-option-to-option-group \
    --option-group-name testoptiongroup \
    --options OptionName=OEM,Port=5432,DBSecurityGroupMemberships=default \
    --apply-immediately
```

For Windows:

```
aws rds add-option-to-option-group ^
    --option-group-name testoptiongroup ^
    --options OptionName=OEM,Port=5432,DBSecurityGroupMemberships=default ^
    --apply-immediately
```

Command output is similar to the following:

```
OPTIONGROUP   False  oracle-ee  19  arn:aws:rds:us-east-1:1234567890:og:testoptiongroup
   Test Option Group    testoptiongroup
OPTIONS Oracle 12c EM Express   OEM     False   False   5432
DBSECURITYGROUPMEMBERSHIPS   default  authorized
```

Example

The following example modifies the Oracle option `NATIVE_NETWORK_ENCRYPTION` and changes the option settings.

For Linux, macOS, or Unix:

```
aws rds add-option-to-option-group \
    --option-group-name testoptiongroup \
    --options '[{"OptionSettings":
[{"Name":"SQLNET.ENCRYPTION_SERVER","Value":"REQUIRED"},
{"Name":"SQLNET.ENCRYPTION_TYPES_SERVER","Value":"AES256,AES192,DES,RC4_256"}],"OptionName":"NA
 \
    --apply-immediately
```

For Windows:

```
aws rds add-option-to-option-group ^
    --option-group-name testoptiongroup ^
    --options "OptionSettings"=[{"Name"="SQLNET.ENCRYPTION_SERVER","Value"="REQUIRED"},
{"Name"="SQLNET.ENCRYPTION_TYPES_SERVER","Value"="AES256\,AES192\,DES
\,RC4_256"}],"OptionName"="NATIVE_NETWORK_ENCRYPTION" ^
    --apply-immediately
```

Command output is similar to the following:

```
OPTIONGROUP   False  oracle-ee  19  arn:aws:rds:us-east-1:1234567890:og:testoptiongroup
   Test Option Group    testoptiongroup
OPTIONS Oracle Advanced Security - Native Network Encryption
 NATIVE_NETWORK_ENCRYPTION       False   False
OPTIONSETTINGS
 RC4_256,AES256,AES192,3DES168,RC4_128,AES128,3DES112,RC4_56,DES,RC4_40,DES40 STATIC
 STRING
   RC4_256,AES256,AES192,3DES168,RC4_128,AES128,3DES112,RC4_56,DES,RC4_40,DES40
 Specifies list of encryption algorithms in order of intended use
   True     True    SQLNET.ENCRYPTION_TYPES_SERVER  AES256,AES192,DES,RC4_256
OPTIONSETTINGS  ACCEPTED,REJECTED,REQUESTED,REQUIRED    STATIC  STRING  REQUESTED
 Specifies the desired encryption behavior  False   True  SQLNET.ENCRYPTION_SERVER
 REQUIRED
OPTIONSETTINGS  SHA1,MD5   STATIC  STRING  SHA1,MD5    Specifies list of
 checksumming algorithms in order of intended use      True    True
 SQLNET.CRYPTO_CHECKSUM_TYPES_SERVER  SHA1,MD5
OPTIONSETTINGS  ACCEPTED,REJECTED,REQUESTED,REQUIRED  STATIC  STRING
 REQUESTED     Specifies the desired data integrity behavior   False   True
 SQLNET.CRYPTO_CHECKSUM_SERVER  REQUESTED
```

RDS API

To modify an option setting, use the Amazon RDS API `ModifyOptionGroup` command with the option group and option that you want to modify. By default, the option is enabled for each associated DB instance during its next maintenance window. To apply the change immediately to all associated DB instances, include the `ApplyImmediately` parameter and set it to `true`.

Removing an option from an option group

Some options can be removed from an option group, and some cannot. A persistent option cannot be removed from an option group until all DB instances associated with that option group are disassociated. A permanent option can never be removed from an option group. For more

information about what options are removable, see the documentation for your specific engine listed at Working with option groups.

If you remove all options from an option group, Amazon RDS doesn't delete the option group. DB instances that are associated with the empty option group continue to be associated with it; they just won't have any active options. Alternatively, to remove all options from a DB instance, you can associate the DB instance with the default (empty) option group.

Console

You can use the AWS Management Console to remove an option from an option group.

To remove an option from an option group by using the console

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Option groups**.
3. Select the option group whose option you want to remove, and then choose **Delete option**.
4. In the **Delete option** window, do the following:
   - Select the check box for the option that you want to delete.
   - For the deletion to take effect as soon as you make it, for **Apply immediately**, choose **Yes**. If you choose **No** (the default), the option is deleted for each associated DB instance during its next maintenance window.

5. When the settings are as you want them, choose **Yes, Delete**.

AWS CLI

To remove an option from an option group, use the AWS CLI `remove-option-from-option-group` command with the option that you want to delete. By default, the option is removed from each associated DB instance during its next maintenance window. To apply the change immediately, include the `--apply-immediately` parameter.

Example

The following example removes the Oracle Enterprise Manager Database Control (OEM) option from an option group named `testoptiongroup` and immediately applies the change.

For Linux, macOS, or Unix:

```
aws rds remove-option-from-option-group \
    --option-group-name testoptiongroup \
    --options OEM \
    --apply-immediately
```

For Windows:

```
aws rds remove-option-from-option-group ^
    --option-group-name testoptiongroup ^
    --options OEM ^
    --apply-immediately
```

Command output is similar to the following:

```
OPTIONGROUP    testoptiongroup oracle-ee   19    Test option group
```

RDS API

To remove an option from an option group, use the Amazon RDS API `ModifyOptionGroup` action. By default, the option is removed from each associated DB instance during its next maintenance window. To apply the change immediately, include the `ApplyImmediately` parameter and set it to `true`.

Include the following parameters:

- `OptionGroupName`
- `OptionsToRemove.OptionName`

Deleting an option group

You can delete an option group only if it meets the following criteria:

- It is not associated with any Amazon RDS resource. An option group can be associated with a DB instance, a manual DB snapshot, or an automated DB snapshot.
- It is not a default option group.

To identify the option groups used by your DB instances and DB snapshots, you can use the following CLI commands:

```
aws rds describe-db-instances \
    --query 'DBInstances[*].
[DBInstanceIdentifier,OptionGroupMemberships[].OptionGroupName]'

aws rds describe-db-snapshots | jq -r '.DBSnapshots[] | "\(.DBInstanceIdentifier),
\(.OptionGroupName)"' | sort | uniq
```

If you try to delete an option group that is associated with an RDS resource, an error like the following is returned.

```
An error occurred (InvalidOptionGroupStateFault) when calling the DeleteOptionGroup
 operation: The option group 'optionGroupName' cannot be deleted because it is in use.
```

To find the Amazon RDS resources associated with an option group

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Option groups**.
3. Choose the name of the option group to show its details.

4. Check the **Associated Instances and Snapshots** section for the associated Amazon RDS resources.

If a DB instance is associated with the option group, modify the DB instance to use a different option group. For more information, see Modifying an Amazon RDS DB instance.

If a manual DB snapshot is associated with the option group, modify the DB snapshot to use a different option group. You can do so using the AWS CLI `modify-db-snapshot` command.

> **Note**
>
> You can't modify the option group of an automated DB snapshot.

Console

One way of deleting an option group is by using the AWS Management Console.

To delete an option group by using the console

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Option groups**.
3. Choose the option group.
4. Choose **Delete group**.
5. On the confirmation page, choose **Delete** to finish deleting the option group, or choose **Cancel** to cancel the deletion.

AWS CLI

To delete an option group, use the AWS CLI `delete-option-group` command with the following required parameter.

- `--option-group-name`

Example

The following example deletes an option group named `testoptiongroup`.

For Linux, macOS, or Unix:

```
aws rds delete-option-group \
    --option-group-name testoptiongroup
```

For Windows:

```
aws rds delete-option-group ^
    --option-group-name testoptiongroup
```

RDS API

To delete an option group, call the Amazon RDS API `DeleteOptionGroup` operation. Include the following parameter:

- `OptionGroupName`

Parameter groups for Amazon RDS

Database parameters specify how the database is configured. For example, database parameters can specify the amount of resources, such as memory, to allocate to a database.

You manage your database configuration by associating your DB instances and Multi-AZ DB clusters with parameter groups. Amazon RDS defines parameter groups with default settings. You can also define your own parameter groups with customized settings.

> **Note**
>
> Some DB engines offer additional features that you can add to your database as options in an option group. For information about option groups, see Working with option groups.

Topics

Overview of parameter groups

A *DB parameter group* acts as a container for engine configuration values that are applied to one or more DB instances.

DB cluster parameter groups apply to Multi-AZ DB clusters only. In a Multi-AZ DB cluster, the settings in the DB cluster parameter group apply to all of the DB instances in the cluster. The default DB parameter group for the DB engine and DB engine version is used for each DB instance in the DB cluster.

Topics

- Static and dynamic DB cluster parameters
- Character set parameters
- Supported parameters and parameter values

Default and custom parameter groups

If you create a DB instance without specifying a DB parameter group, the DB instance uses a default DB parameter group. Likewise, if you create a Multi-AZ DB cluster without specifying a DB cluster parameter group, the DB cluster uses a default DB cluster parameter group. Each default parameter group contains database engine defaults and Amazon RDS system defaults based on the engine, compute class, and allocated storage of the instance.

You can't modify the parameter settings of a default parameter group. Instead, you can do the following:

1. Create a new parameter group.
2. Change the settings of your desired parameters. Not all DB engine parameters in a parameter group are eligible to be modified.
3. Modify your DB instance or DB cluster to associate the new parameter group.

   When you associate a new DB parameter group with a DB instance, the association happens immediately. For information about modifying a DB instance, see Modifying an Amazon RDS DB instance. For information about modifying a Multi-AZ DB clusters, see Modifying a Multi-AZ DB cluster.

   > **Note**
   >
   > If you have modified your DB instance to use a custom parameter group, and you start the DB instance, RDS automatically reboots the DB instance as part of the startup process.

RDS applies the modified static and dynamic parameters in a newly associated parameter group only after the DB instance is rebooted. However, if you modify dynamic parameters in the DB parameter group after you associate it with the DB instance, these changes are applied immediately without a reboot. For more information about changing the DB parameter group, see Modifying an Amazon RDS DB instance.

If you update parameters within a DB parameter group, the changes apply to all DB instances that are associated with that parameter group. Likewise, if you update parameters within a Multi-AZ DB cluster parameter group, the changes apply to all Aurora DB clusters that are associated with that DB cluster parameter group.

If you don't want to create a parameter group from scratch, you can copy an existing parameter group with the AWS CLI copy-db-parameter-group command or copy-db-cluster-parameter-group command. You might find that copying a parameter group is useful in some cases. For example, you might want to include most of an existing DB parameter group's custom parameters and values in a new DB parameter group.

Static and dynamic DB instance parameters

DB instance parameters are either static or dynamic. They differ as follows:

- When you change a static parameter and save the DB parameter group, the parameter change takes effect after you manually reboot the associated DB instances. For static parameters, the console always uses `pending-reboot` for the `ApplyMethod`.
- When you change a dynamic parameter, by default the parameter change takes effect immediately, without requiring a reboot. When you use the AWS Management Console to change DB instance parameter values, it always uses `immediate` for the `ApplyMethod` for dynamic parameters. To defer the parameter change until after you reboot an associated DB instance, use the AWS CLI or RDS API. Set the `ApplyMethod` to `pending-reboot` for the parameter change.

> **Note**
>
> Using `pending-reboot` with dynamic parameters in the AWS CLI or RDS API on RDS for SQL Server DB instances generates an error. Use `apply-immediately` on RDS for SQL Server.

For more information about using the AWS CLI to change a parameter value, see modify-db-parameter-group. For more information about using the RDS API to change a parameter value, see ModifyDBParameterGroup.

If a DB instance isn't using the latest changes to its associated DB parameter group, the console shows a status of **pending-reboot** for the DB parameter group. This status doesn't result in an automatic reboot during the next maintenance window. To apply the latest parameter changes to that DB instance, manually reboot the DB instance.

Static and dynamic DB cluster parameters

DB cluster parameters are either static or dynamic. They differ as follows:

- When you change a static parameter and save the DB cluster parameter group, the parameter change takes effect after you manually reboot the associated DB clusters. For static parameters, the console always uses `pending-reboot` for the `ApplyMethod`.
- When you change a dynamic parameter, by default the parameter change takes effect immediately, without requiring a reboot. When you use the AWS Management Console to change DB cluster parameter values, it always uses `immediate` for the `ApplyMethod` for dynamic parameters. To defer the parameter change until after an associated DB cluster is rebooted, use the AWS CLI or RDS API. Set the `ApplyMethod` to `pending-reboot` for the parameter change.

For more information about using the AWS CLI to change a parameter value, see modify-db-cluster-parameter-group. For more information about using the RDS API to change a parameter value, see ModifyDBClusterParameterGroup.

Character set parameters

Before you create a DB instance or Multi-AZ DB cluster, set any parameters that relate to the character set or collation of your database in your parameter group. Also do so before you create a database in it. In this way, you ensure that the default database and new databases use the character set and collation values that you specify. If you change character set or collation parameters, the parameter changes aren't applied to existing databases.

For some DB engines, you can change character set or collation values for an existing database using the `ALTER DATABASE` command, for example:

```
ALTER DATABASE database_name CHARACTER SET character_set_name COLLATE collation;
```

For more information about changing the character set or collation values for a database, check the documentation for your DB engine.

Supported parameters and parameter values

To determine the supported parameters for your DB engine, view the parameters in the DB parameter group and DB cluster parameter group used by the DB instance or DB cluster. For more information, see Viewing parameter values for a DB parameter group in Amazon RDS and Viewing parameter values for a DB cluster parameter group.

In many cases, you can specify integer and Boolean parameter values using expressions, formulas, and functions. Functions can include a mathematical log expression. However, not all parameters support expressions, formulas, and functions for parameter values. For more information, see Specifying DB parameters.

Improperly setting parameters in a parameter group can have unintended adverse effects, including degraded performance and system instability. Always be cautious when modifying database parameters, and back up your data before modifying a parameter group. Try parameter group setting changes on a test DB instance or DB cluster before applying those parameter group changes to a production DB instance or DB cluster.

DB parameter groups for Amazon RDS DB instances

DB instances use DB parameter groups. The following sections describe configuring and managing DB instance parameter groups.

Topics

Creating a DB parameter group in Amazon RDS

You can create a new DB parameter group using the AWS Management Console, the AWS CLI, or the RDS API.

The following limitations apply to the DB parameter group name:

- The name must be 1 to 255 letters, numbers, or hyphens.

  Default parameter group names can include a period, such as `default.mysql8.0`. However, custom parameter group names can't include a period.

- The first character must be a letter.
- The name can't end with a hyphen or contain two consecutive hyphens.

Console

To create a DB parameter group

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Parameter groups**.
3. Choose **Create parameter group**.
4. For **Parameter group name**, enter the name of your new DB parameter group.
5. For **Description**, enter a description for your new DB parameter group.
6. For **Engine type**, choose your DB engine.
7. For **Parameter group family**, choose a DB parameter group family.
8. For **Type**, if applicable, choose **DB Parameter Group**.
9. Choose **Create**.

AWS CLI

To create a DB parameter group, use the AWS CLI `create-db-parameter-group` command. The following example creates a DB parameter group named *mydbparametergroup* for MySQL version 8.0 with a description of "*My new parameter group*."

Include the following required parameters:

- `--db-parameter-group-name`
- `--db-parameter-group-family`
- `--description`

To list all of the available parameter group families, use the following command:

```
aws rds describe-db-engine-versions --query "DBEngineVersions[].DBParameterGroupFamily"
```

> **Note**
>
> The output contains duplicates.

Example

For Linux, macOS, or Unix:

```
aws rds create-db-parameter-group \
    --db-parameter-group-name mydbparametergroup \
    --db-parameter-group-family MySQL8.0 \
    --description "My new parameter group"
```

For Windows:

```
aws rds create-db-parameter-group ^
    --db-parameter-group-name mydbparametergroup ^
    --db-parameter-group-family MySQL8.0 ^
    --description "My new parameter group"
```

This command produces output similar to the following:

```
DBPARAMETERGROUP  mydbparametergroup  mysql8.0  My new parameter group
```

RDS API

To create a DB parameter group, use the RDS API `CreateDBParameterGroup` operation.

Include the following required parameters:

- `DBParameterGroupName`
- `DBParameterGroupFamily`
- `Description`

Associating a DB parameter group with a DB instance in Amazon RDS

You can create your own DB parameter groups with customized settings. You can associate a DB parameter group with a DB instance using the AWS Management Console, the AWS CLI, or the RDS API. You can do so when you create or modify a DB instance.

For information about creating a DB parameter group, see Creating a DB parameter group in Amazon RDS. For information about creating a DB instance, see Creating an Amazon RDS DB instance. For information about modifying a DB instance, see Modifying an Amazon RDS DB instance.

> **Note**
>
> When you associate a new DB parameter group with a DB instance, the modified static and dynamic parameters are applied only after the DB instance is rebooted. However, if you modify dynamic parameters in the DB parameter group after you associate it with the DB instance, these changes are applied immediately without a reboot.

Console

To associate a DB parameter group with a DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**, and then choose the DB instance that you want to modify.
3. Choose **Modify**. The **Modify DB instance** page appears.
4. Change the **DB parameter group** setting.
5. Choose **Continue** and check the summary of modifications.
6. (Optional) Choose **Apply immediately** to apply the changes immediately. Choosing this option can cause an outage in some cases. For more information, see Schedule modifications setting.
7. On the confirmation page, review your changes. If they are correct, choose **Modify DB instance** to save your changes.

   Or choose **Back** to edit your changes or **Cancel** to cancel your changes.

AWS CLI

To associate a DB parameter group with a DB instance, use the AWS CLI `modify-db-instance` command with the following options:

- `--db-instance-identifier`

- `--db-parameter-group-name`

The following example associates the `mydbpg` DB parameter group with the `database-1` DB instance. The changes are applied immediately by using `--apply-immediately`. Use `--no-apply-immediately` to apply the changes during the next maintenance window. For more information, see Schedule modifications setting.

Example

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier database-1 \
    --db-parameter-group-name mydbpg \
    --apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier database-1 ^
    --db-parameter-group-name mydbpg ^
    --apply-immediately
```

RDS API

To associate a DB parameter group with a DB instance, use the RDS API `ModifyDBInstance` operation with the following parameters:

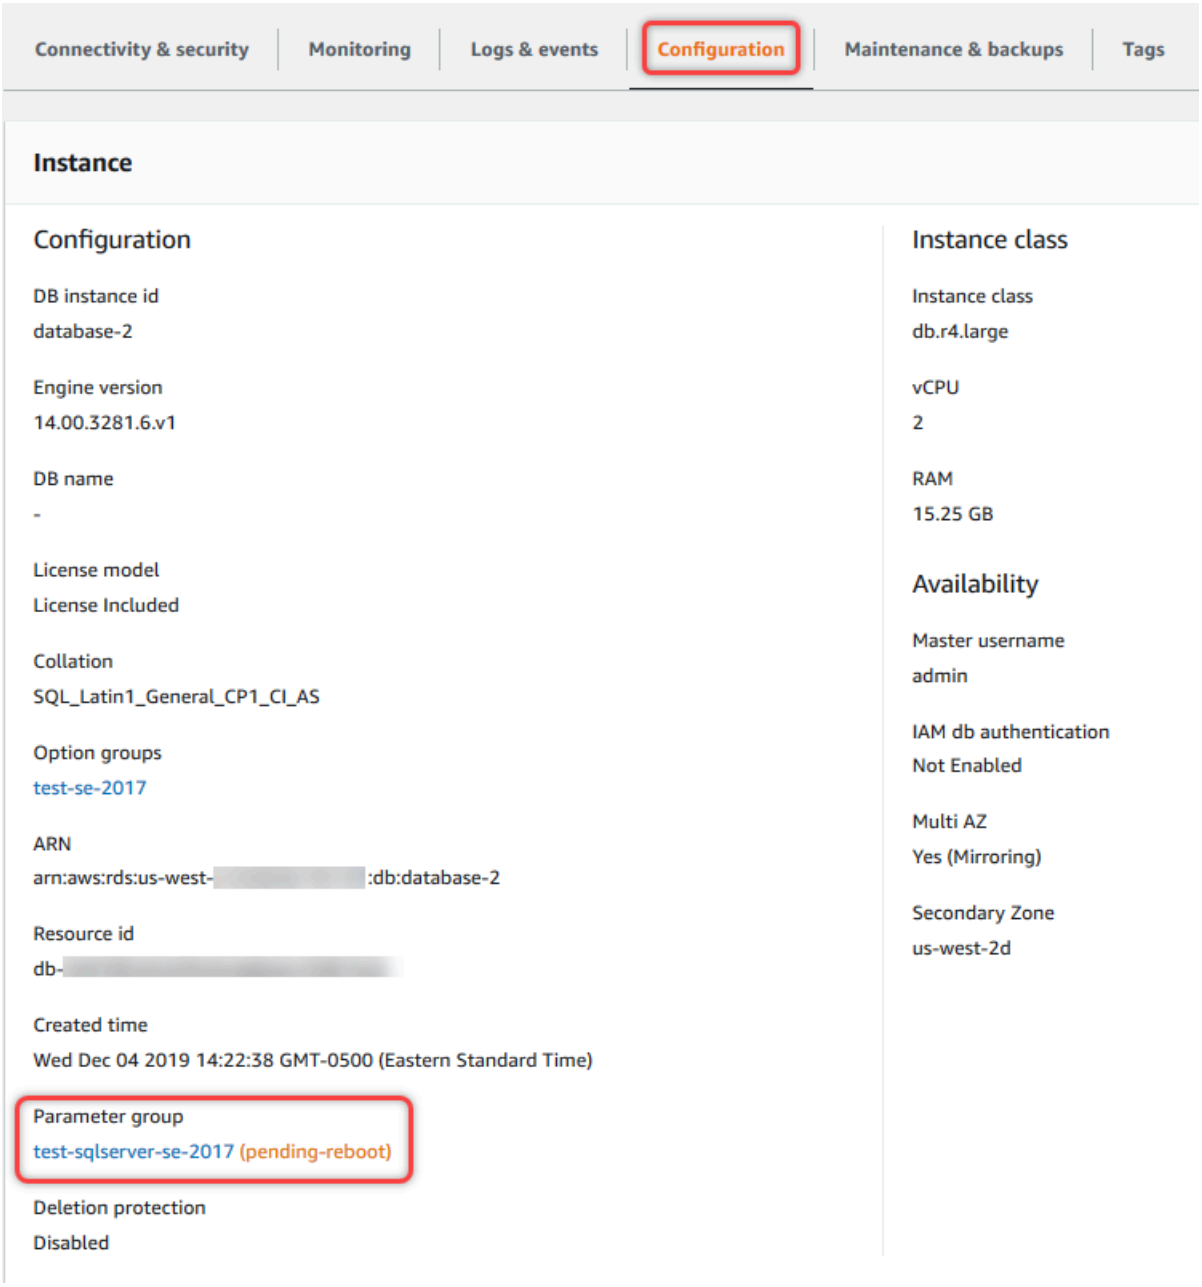
- `DBInstanceName`
- `DBParameterGroupName`

Modifying parameters in a DB parameter group in Amazon RDS

You can modify parameter values in a customer-created DB parameter group; you can't change the parameter values in a default DB parameter group. Changes to parameters in a customer-created DB parameter group are applied to all DB instances that are associated with the DB parameter group.

Changes to some parameters are applied to the DB instance immediately without a reboot. Changes to other parameters are applied only after the DB instance is rebooted. The RDS console

shows the status of the DB parameter group associated with a DB instance on the **Configuration** tab. For example, suppose that the DB instance isn't using the latest changes to its associated DB parameter group. If so, the RDS console shows the DB parameter group with a status of **pending-reboot**. To apply the latest parameter changes to that DB instance, manually reboot the DB instance.



Console

To modify the parameters in a DB parameter group

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Parameter groups**.
3. In the list, choose the name of the parameter group that you want to modify.
4. For **Parameter group actions**, choose **Edit**.
5. Change the values of the parameters that you want to modify. You can scroll through the parameters using the arrow keys at the top right of the dialog box.

   You can't change values in a default parameter group.
6. Choose **Save changes**.

AWS CLI

To modify a DB parameter group, use the AWS CLI `modify-db-parameter-group` command with the following required options:

- `--db-parameter-group-name`
- `--parameters`

The following example modifies the `max_connections` and `max_allowed_packet` values in the DB parameter group named *mydbparametergroup*.

Example

For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group \
    --db-parameter-group-name mydbparametergroup \
    --parameters
 "ParameterName=max_connections,ParameterValue=250,ApplyMethod=immediate" \

 "ParameterName=max_allowed_packet,ParameterValue=1024,ApplyMethod=immediate"
```

For Windows:

```
aws rds modify-db-parameter-group ^
    --db-parameter-group-name mydbparametergroup ^
    --parameters
 "ParameterName=max_connections,ParameterValue=250,ApplyMethod=immediate" ^

 "ParameterName=max_allowed_packet,ParameterValue=1024,ApplyMethod=immediate"
```

The command produces output like the following:

```
DBPARAMETERGROUP  mydbparametergroup
```

RDS API

To modify a DB parameter group, use the RDS API ModifyDBParameterGroup operation with the following required parameters:

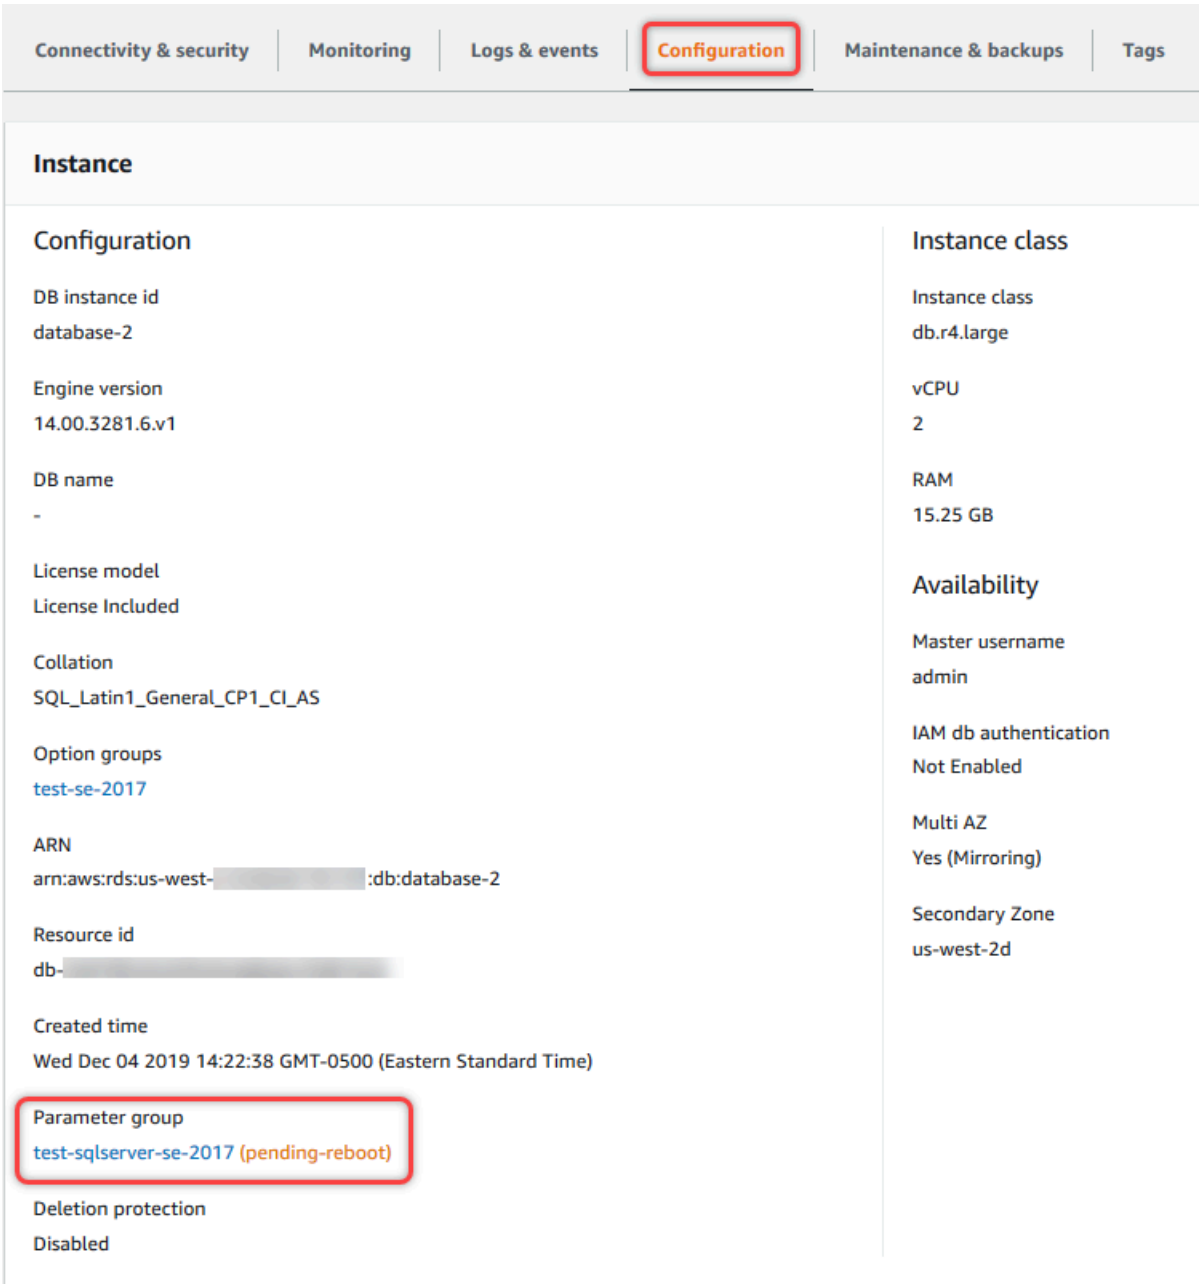
- DBParameterGroupName
- Parameters

Resetting parameters in a DB parameter group to their default values in Amazon RDS

You can reset parameter values in a customer-created DB parameter group to their default values. Changes to parameters in a customer-created DB parameter group are applied to all DB instances that are associated with the DB parameter group.

When you use the console, you can reset specific parameters to their default values. However, you can't easily reset all of the parameters in the DB parameter group at once. When you use the AWS CLI or RDS API, you can reset specific parameters to their default values. You can also reset all of the parameters in the DB parameter group at once.

Changes to some parameters are applied to the DB instance immediately without a reboot. Changes to other parameters are applied only after the DB instance is rebooted. The RDS console shows the status of the DB parameter group associated with a DB instance on the **Configuration** tab. For example, suppose that the DB instance isn't using the latest changes to its associated DB parameter group. If so, the RDS console shows the DB parameter group with a status of **pending-reboot**. To apply the latest parameter changes to that DB instance, manually reboot the DB instance.



Note

In a default DB parameter group, parameters are always set to their default values.

Console

To reset parameters in a DB parameter group to their default values

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Parameter groups**.
3. In the list, choose the parameter group.
4. For **Parameter group actions**, choose **Edit**.
5. Choose the parameters that you want to reset to their default values. You can scroll through the parameters using the arrow keys at the top right of the dialog box.

   You can't reset values in a default parameter group.
6. Choose **Reset** and then confirm by choosing **Reset parameters**.

AWS CLI

To reset some or all of the parameters in a DB parameter group, use the AWS CLI `reset-db-parameter-group` command with the following required option: `--db-parameter-group-name`.

To reset all of the parameters in the DB parameter group, specify the `--reset-all-parameters` option. To reset specific parameters, specify the `--parameters` option.

The following example resets all of the parameters in the DB parameter group named *mydbparametergroup* to their default values.

Example

For Linux, macOS, or Unix:

```
aws rds reset-db-parameter-group \
    --db-parameter-group-name mydbparametergroup \
    --reset-all-parameters
```

For Windows:

```
aws rds reset-db-parameter-group ^
```

```
    --db-parameter-group-name mydbparametergroup ^
    --reset-all-parameters
```

The following example resets the `max_connections` and `max_allowed_packet` options to their default values in the DB parameter group named *mydbparametergroup*.

Example

For Linux, macOS, or Unix:

```
aws rds reset-db-parameter-group \
    --db-parameter-group-name mydbparametergroup \
    --parameters "ParameterName=max_connections,ApplyMethod=immediate" \
                 "ParameterName=max_allowed_packet,ApplyMethod=immediate"
```

For Windows:

```
aws rds reset-db-parameter-group ^
    --db-parameter-group-name mydbparametergroup ^
    --parameters "ParameterName=max_connections,ApplyMethod=immediate" ^
                 "ParameterName=max_allowed_packet,ApplyMethod=immediate"
```

The command produces output like the following:

```
DBParameterGroupName  mydbparametergroup
```

RDS API

To reset parameters in a DB parameter group to their default values, use the RDS API `ResetDBParameterGroup` command with the following required parameter: `DBParameterGroupName`.

To reset all of the parameters in the DB parameter group, set the `ResetAllParameters` parameter to `true`. To reset specific parameters, specify the `Parameters` parameter.

Copying a DB parameter group in Amazon RDS

You can copy custom DB parameter groups that you create. Copying a parameter group can be convenient solution. An example is when you have created a DB parameter group and want to include most of its custom parameters and values in a new DB parameter group. You can copy a DB

parameter group by using the AWS Management Console. You can also use the AWS CLI copy-db-parameter-group command or the RDS API CopyDBParameterGroup operation.

After you copy a DB parameter group, wait at least 5 minutes before creating your first DB instance that uses that DB parameter group as the default parameter group. Doing this allows Amazon RDS to fully complete the copy action before the parameter group is used. This is especially important for parameters that are critical when creating the default database for a DB instance. An example is the character set for the default database defined by the `character_set_database` parameter. Use the **Parameter Groups** option of the Amazon RDS console or the describe-db-parameters command to verify that your DB parameter group is created.

> **Note**
>
> You can't copy a default parameter group. However, you can create a new parameter group that is based on a default parameter group.
> You can't copy a DB parameter group to a different AWS account or AWS Region.

Console

To copy a DB parameter group

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Parameter groups**.
3. In the list, choose the custom parameter group that you want to copy.
4. For **Parameter group actions**, choose **Copy**.
5. In **New DB parameter group identifier**, enter a name for the new parameter group.
6. In **Description**, enter a description for the new parameter group.
7. Choose **Copy**.

AWS CLI

To copy a DB parameter group, use the AWS CLI `copy-db-parameter-group` command with the following required options:

- `--source-db-parameter-group-identifier`

- `--target-db-parameter-group-identifier`
- `--target-db-parameter-group-description`

The following example creates a new DB parameter group named `mygroup2` that is a copy of the DB parameter group `mygroup1`.

Example

For Linux, macOS, or Unix:

```
aws rds copy-db-parameter-group \
    --source-db-parameter-group-identifier mygroup1 \
    --target-db-parameter-group-identifier mygroup2 \
    --target-db-parameter-group-description "DB parameter group 2"
```

For Windows:

```
aws rds copy-db-parameter-group ^
    --source-db-parameter-group-identifier mygroup1 ^
    --target-db-parameter-group-identifier mygroup2 ^
    --target-db-parameter-group-description "DB parameter group 2"
```

RDS API

To copy a DB parameter group, use the RDS API `CopyDBParameterGroup` operation with the following required parameters:

- `SourceDBParameterGroupIdentifier`
- `TargetDBParameterGroupIdentifier`
- `TargetDBParameterGroupDescription`

Listing DB parameter groups in Amazon RDS

You can list the DB parameter groups you've created for your AWS account.

> **Note**
>
> Default parameter groups are automatically created from a default parameter template when you create a DB instance for a particular DB engine and version. These default

parameter groups contain preferred parameter settings and can't be modified. When you create a custom parameter group, you can modify parameter settings.

Console

To list all DB parameter groups for an AWS account

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Parameter groups**.

   The DB parameter groups appear in a list.

AWS CLI

To list all DB parameter groups for an AWS account, use the AWS CLI `describe-db-parameter-groups` command.

Example

The following example lists all available DB parameter groups for an AWS account.

```
aws rds describe-db-parameter-groups
```

The command returns a response like the following:

```
DBPARAMETERGROUP  default.mysql8.0     mysql8.0  Default parameter group for MySQL8.0
DBPARAMETERGROUP  mydbparametergroup   mysql8.0  My new parameter group
```

The following example describes the *mydbparamgroup1* parameter group.

For Linux, macOS, or Unix:

```
aws rds describe-db-parameter-groups \
    --db-parameter-group-name mydbparamgroup1
```

For Windows:

```
aws rds describe-db-parameter-groups ^
    --db-parameter-group-name mydbparamgroup1
```

The command returns a response like the following:

```
DBPARAMETERGROUP  mydbparametergroup1  mysql8.0  My new parameter group
```

RDS API

To list all DB parameter groups for an AWS account, use the RDS API `DescribeDBParameterGroups` operation.

Viewing parameter values for a DB parameter group in Amazon RDS

You can get a list of all parameters in a DB parameter group and their values.

Console

To view the parameter values for a DB parameter group

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Parameter groups**.

   The DB parameter groups appear in a list.
3. Choose the name of the parameter group to see its list of parameters.

AWS CLI

To view the parameter values for a DB parameter group, use the AWS CLI `describe-db-parameters` command with the following required parameter.

- `--db-parameter-group-name`

Example

The following example lists the parameters and parameter values for a DB parameter group named *mydbparametergroup.*

```
aws rds describe-db-parameters --db-parameter-group-name mydbparametergroup
```

The command returns a response like the following:

```
DBPARAMETER  Parameter Name            Parameter Value  Source           Data Type
 Apply Type  Is Modifiable
DBPARAMETER  allow-suspicious-udfs                      engine-default   boolean
 static      false
DBPARAMETER  auto_increment_increment                   engine-default   integer
 dynamic     true
DBPARAMETER  auto_increment_offset                      engine-default   integer
 dynamic     true
DBPARAMETER  binlog_cache_size         32768            system           integer
 dynamic     true
DBPARAMETER  socket                    /tmp/mysql.sock  system           string
 static      false
```

RDS API

To view the parameter values for a DB parameter group, use the RDS API `DescribeDBParameters` command with the following required parameter.

- `DBParameterGroupName`

Deleting a DB parameter group in Amazon RDS

You can delete a DB parameter group using the AWS Management Console, AWS CLI, or RDS API. A parameter group is eligible for deletion only if it isn't associated with a DB instance.

Console

To delete a DB parameter group

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Parameter groups**.

   The DB parameter groups appear in a list.
3. Choose the name of the parameter groups to be deleted.

4. Choose **Actions** and then **Delete**.
5. Review the parameter group names and then choose **Delete**.

AWS CLI

To delete a DB parameter group, use the AWS CLI `delete-db-parameter-group` command with the following required parameter.

- `--db-parameter-group-name`

Example

The following example deletes a DB parameter group named *mydbparametergroup.*

```
aws rds delete-db-parameter-group --db-parameter-group-name mydbparametergroup
```

RDS API

To delete a DB parameter group, use the RDS API `DeleteDBParameterGroup` command with the following required parameter.

- `DBParameterGroupName`

Working with DB cluster parameter groups for Multi-AZ DB clusters

Multi-AZ DB clusters use DB cluster parameter groups. The following sections describe configuring and managing DB cluster parameter groups.

Topics

- Creating a DB cluster parameter group
- Modifying parameters in a DB cluster parameter group
- Resetting parameters in a DB cluster parameter group
- Copying a DB cluster parameter group
- Listing DB cluster parameter groups
- Viewing parameter values for a DB cluster parameter group

- Deleting a DB cluster parameter group

Creating a DB cluster parameter group

You can create a new DB cluster parameter group using the AWS Management Console, the AWS CLI, or the RDS API.

After you create a DB cluster parameter group, wait at least 5 minutes before creating a DB cluster that uses that DB cluster parameter group. Doing this allows Amazon RDS to fully create the parameter group before it is used by the new DB cluster. You can use the **Parameter groups** page in the Amazon RDS console or the describe-db-cluster-parameters command to verify that your DB cluster parameter group is created.

The following limitations apply to the DB cluster parameter group name:

- The name must be 1 to 255 letters, numbers, or hyphens.

  Default parameter group names can include a period, such as `default.mysql5.7`. However, custom parameter group names can't include a period.
- The first character must be a letter.
- The name can't end with a hyphen or contain two consecutive hyphens.

Console

To create a DB cluster parameter group

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Parameter groups**.
3. Choose **Create parameter group**.

   The **Create parameter group** window appears.
4. In the **Parameter group family** list, select a DB parameter group family
5. In the **Type** list, select **DB cluster parameter group**.
6. In the **Group name** box, enter the name of the new DB cluster parameter group.
7. In the **Description** box, enter a description for the new DB cluster parameter group.
8. Choose **Create**.

AWS CLI

To create a DB cluster parameter group, use the AWS CLI `create-db-cluster-parameter-group` command.

The following example creates a DB cluster parameter group named *mydbclusterparametergroup* for RDS for MySQL version 8.0 with a description of "*My new cluster parameter group*."

Include the following required parameters:

- `--db-cluster-parameter-group-name`
- `--db-parameter-group-family`
- `--description`

To list all of the available parameter group families, use the following command:

```
aws rds describe-db-engine-versions --query "DBEngineVersions[].DBParameterGroupFamily"
```

> **Note**
>
> The output contains duplicates.

Example

For Linux, macOS, or Unix:

```
aws rds create-db-cluster-parameter-group \
    --db-cluster-parameter-group-name mydbclusterparametergroup \
    --db-parameter-group-family mysql8.0 \
    --description "My new cluster parameter group"
```

For Windows:

```
aws rds create-db-cluster-parameter-group ^
    --db-cluster-parameter-group-name mydbclusterparametergroup ^
    --db-parameter-group-family mysql8.0 ^
    --description "My new cluster parameter group"
```

This command produces output similar to the following:

```
{
    "DBClusterParameterGroup": {
        "DBClusterParameterGroupName": "mydbclusterparametergroup",
        "DBParameterGroupFamily": "mysql8.0",
        "Description": "My new cluster parameter group",
        "DBClusterParameterGroupArn": "arn:aws:rds:us-east-1:123456789012:cluster-
pg:mydbclusterparametergroup2"
    }
}
```

RDS API

To create a DB cluster parameter group, use the RDS API `CreateDBClusterParameterGroup` action.

Include the following required parameters:

- `DBClusterParameterGroupName`
- `DBParameterGroupFamily`
- `Description`

Modifying parameters in a DB cluster parameter group

You can modify parameter values in a customer-created DB cluster parameter group. You can't change the parameter values in a default DB cluster parameter group. Changes to parameters in a customer-created DB cluster parameter group are applied to all DB clusters that are associated with the DB cluster parameter group.

Console

To modify a DB cluster parameter group

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Parameter groups**.
3. In the list, choose the parameter group that you want to modify.
4. For **Parameter group actions**, choose **Edit**.

5. Change the values of the parameters you want to modify. You can scroll through the parameters using the arrow keys at the top right of the dialog box.

   You can't change values in a default parameter group.
6. Choose **Save changes**.
7. Reboot the cluster to apply the changes to it.

AWS CLI

To modify a DB cluster parameter group, use the AWS CLI `modify-db-cluster-parameter-group` command with the following required parameters:

- `--db-cluster-parameter-group-name`
- `--parameters`

The following example modifies the `server_audit_logging` and `server_audit_logs_upload` values in the DB cluster parameter group named *mydbclusterparametergroup*.

Example

For Linux, macOS, or Unix:

```
aws rds modify-db-cluster-parameter-group \
    --db-cluster-parameter-group-name mydbclusterparametergroup \
    --parameters
 "ParameterName=server_audit_logging,ParameterValue=1,ApplyMethod=immediate" \

 "ParameterName=server_audit_logs_upload,ParameterValue=1,ApplyMethod=immediate"
```

For Windows:

```
aws rds modify-db-cluster-parameter-group ^
    --db-cluster-parameter-group-name mydbclusterparametergroup ^
    --parameters
 "ParameterName=server_audit_logging,ParameterValue=1,ApplyMethod=immediate" ^

 "ParameterName=server_audit_logs_upload,ParameterValue=1,ApplyMethod=immediate"
```

The command produces output like the following:

```
DBCLUSTERPARAMETERGROUP  mydbclusterparametergroup
```

RDS API

To modify a DB cluster parameter group, use the RDS API `ModifyDBClusterParameterGroup` command with the following required parameters:

- `DBClusterParameterGroupName`
- `Parameters`

Resetting parameters in a DB cluster parameter group

You can reset parameters to their default values in a customer-created DB cluster parameter group. Changes to parameters in a customer-created DB cluster parameter group are applied to all DB clusters that are associated with the DB cluster parameter group.

> **Note**
>
> In a default DB cluster parameter group, parameters are always set to their default values.

Console

To reset parameters in a DB cluster parameter group to their default values

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Parameter groups**.
3. In the list, choose the parameter group.
4. For **Parameter group actions**, choose **Edit**.
5. Choose the parameters that you want to reset to their default values. You can scroll through the parameters using the arrow keys at the top right of the dialog box.

   You can't reset values in a default parameter group.
6. Choose **Reset** and then confirm by choosing **Reset parameters**.

7. Reboot the DB cluster.

AWS CLI

To reset parameters in a DB cluster parameter group to their default values, use the AWS CLI `reset-db-cluster-parameter-group` command with the following required option: `--db-cluster-parameter-group-name`.

To reset all of the parameters in the DB cluster parameter group, specify the `--reset-all-parameters` option. To reset specific parameters, specify the `--parameters` option.

The following example resets all of the parameters in the DB parameter group named *mydbparametergroup* to their default values.

Example

For Linux, macOS, or Unix:

```
aws rds reset-db-cluster-parameter-group \
    --db-cluster-parameter-group-name mydbparametergroup \
    --reset-all-parameters
```

For Windows:

```
aws rds reset-db-cluster-parameter-group ^
    --db-cluster-parameter-group-name mydbparametergroup ^
    --reset-all-parameters
```

The following example resets the `server_audit_logging` and `server_audit_logs_upload` to their default values in the DB cluster parameter group named *mydbclusterparametergroup*.

Example

For Linux, macOS, or Unix:

```
aws rds reset-db-cluster-parameter-group \
    --db-cluster-parameter-group-name mydbclusterparametergroup \
    --parameters "ParameterName=server_audit_logging,ApplyMethod=immediate" \
                 "ParameterName=server_audit_logs_upload,ApplyMethod=immediate"
```

For Windows:

```
aws rds reset-db-cluster-parameter-group ^
    --db-cluster-parameter-group-name mydbclusterparametergroup ^
    --parameters
 "ParameterName=server_audit_logging,ParameterValue=1,ApplyMethod=immediate" ^

 "ParameterName=server_audit_logs_upload,ParameterValue=1,ApplyMethod=immediate"
```

The command produces output like the following:

```
DBClusterParameterGroupName  mydbclusterparametergroup
```

RDS API

To reset parameters in a DB cluster parameter group to their default values, use the RDS API `ResetDBClusterParameterGroup` command with the following required parameter: `DBClusterParameterGroupName`.

To reset all of the parameters in the DB cluster parameter group, set the `ResetAllParameters` parameter to `true`. To reset specific parameters, specify the `Parameters` parameter.

Copying a DB cluster parameter group

You can copy custom DB cluster parameter groups that you create. Copying a parameter group is a convenient solution when you have already created a DB cluster parameter group and you want to include most of the custom parameters and values from that group in a new DB cluster parameter group. You can copy a DB cluster parameter group by using the AWS CLI copy-db-cluster-parameter-group command or the RDS API CopyDBClusterParameterGroup operation.

After you copy a DB cluster parameter group, wait at least 5 minutes before creating a DB cluster that uses that DB cluster parameter group. Doing this allows Amazon RDS to fully copy the parameter group before it is used by the new DB cluster. You can use the **Parameter groups** page in the Amazon RDS console or the describe-db-cluster-parameters command to verify that your DB cluster parameter group is created.

> **Note**
>
> You can't copy a default parameter group. However, you can create a new parameter group that is based on a default parameter group.
> You can't copy a DB cluster parameter group to a different AWS account or AWS Region.

Console

To copy a DB cluster parameter group

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Parameter groups**.
3. In the list, choose the custom parameter group that you want to copy.
4. For **Parameter group actions**, choose **Copy**.
5. In **New DB parameter group identifier**, enter a name for the new parameter group.
6. In **Description**, enter a description for the new parameter group.
7. Choose **Copy**.

AWS CLI

To copy a DB cluster parameter group, use the AWS CLI `copy-db-cluster-parameter-group` command with the following required parameters:

- `--source-db-cluster-parameter-group-identifier`
- `--target-db-cluster-parameter-group-identifier`
- `--target-db-cluster-parameter-group-description`

The following example creates a new DB cluster parameter group named `mygroup2` that is a copy of the DB cluster parameter group `mygroup1`.

Example

For Linux, macOS, or Unix:

```
aws rds copy-db-cluster-parameter-group \
    --source-db-cluster-parameter-group-identifier mygroup1 \
    --target-db-cluster-parameter-group-identifier mygroup2 \
    --target-db-cluster-parameter-group-description "DB parameter group 2"
```

For Windows:

```
aws rds copy-db-cluster-parameter-group ^
```

```
    --source-db-cluster-parameter-group-identifier mygroup1 ^
    --target-db-cluster-parameter-group-identifier mygroup2 ^
    --target-db-cluster-parameter-group-description "DB parameter group 2"
```

RDS API

To copy a DB cluster parameter group, use the RDS API `CopyDBClusterParameterGroup` operation with the following required parameters:

- `SourceDBClusterParameterGroupIdentifier`
- `TargetDBClusterParameterGroupIdentifier`
- `TargetDBClusterParameterGroupDescription`

Listing DB cluster parameter groups

You can list the DB cluster parameter groups you've created for your AWS account.

> **Note**
>
> Default parameter groups are automatically created from a default parameter template when you create a DB cluster for a particular DB engine and version. These default parameter groups contain preferred parameter settings and can't be modified. When you create a custom parameter group, you can modify parameter settings.

Console

To list all DB cluster parameter groups for an AWS account

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Parameter groups**.

   The DB cluster parameter groups appear in the list with **DB cluster parameter group** for **Type**.

AWS CLI

To list all DB cluster parameter groups for an AWS account, use the AWS CLI `describe-db-cluster-parameter-groups` command.

Example

The following example lists all available DB cluster parameter groups for an AWS account.

```
aws rds describe-db-cluster-parameter-groups
```

The following example describes the *mydbclusterparametergroup* parameter group.

For Linux, macOS, or Unix:

```
aws rds describe-db-cluster-parameter-groups \
    --db-cluster-parameter-group-name mydbclusterparametergroup
```

For Windows:

```
aws rds describe-db-cluster-parameter-groups ^
    --db-cluster-parameter-group-name mydbclusterparametergroup
```

The command returns a response like the following:

```
{
    "DBClusterParameterGroups": [
        {
            "DBClusterParameterGroupName": "mydbclusterparametergroup2",
            "DBParameterGroupFamily": "mysql8.0",
            "Description": "My new cluster parameter group",
            "DBClusterParameterGroupArn": "arn:aws:rds:us-east-1:123456789012:cluster-
pg:mydbclusterparametergroup"
        }
    ]
}
```

RDS API

To list all DB cluster parameter groups for an AWS account, use the RDS API `DescribeDBClusterParameterGroups` action.

Viewing parameter values for a DB cluster parameter group

You can get a list of all parameters in a DB cluster parameter group and their values.

Console

To view the parameter values for a DB cluster parameter group

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Parameter groups**.

   The DB cluster parameter groups appear in the list with **DB cluster parameter group** for **Type**.
3. Choose the name of the DB cluster parameter group to see its list of parameters.

AWS CLI

To view the parameter values for a DB cluster parameter group, use the AWS CLI `describe-db-cluster-parameters` command with the following required parameter.

- `--db-cluster-parameter-group-name`

Example

The following example lists the parameters and parameter values for a DB cluster parameter group named *mydbclusterparametergroup*, in JSON format.

The command returns a response like the following:

```
aws rds describe-db-cluster-parameters --db-cluster-parameter-group-
name mydbclusterparametergroup
```

```
{
    "Parameters": [
        {
            "ParameterName": "activate_all_roles_on_login",
            "ParameterValue": "0",
            "Description": "Automatically set all granted roles as active after the
 user has authenticated successfully.",
            "Source": "engine-default",
            "ApplyType": "dynamic",
            "DataType": "boolean",
            "AllowedValues": "0,1",
            "IsModifiable": true,
```

```
            "ApplyMethod": "pending-reboot",
            "SupportedEngineModes": [
                "provisioned"
            ]
        },
        {
            "ParameterName": "allow-suspicious-udfs",
            "Description": "Controls whether user-defined functions that have only an
 xxx symbol for the main function can be loaded",
            "Source": "engine-default",
            "ApplyType": "static",
            "DataType": "boolean",
            "AllowedValues": "0,1",
            "IsModifiable": false,
            "ApplyMethod": "pending-reboot",
            "SupportedEngineModes": [
                "provisioned"
            ]
        },
...
```

RDS API

To view the parameter values for a DB cluster parameter group, use the RDS API `DescribeDBClusterParameters` command with the following required parameter.

- `DBClusterParameterGroupName`

In some cases, the allowed values for a parameter aren't shown. These are always parameters where the source is the database engine default.

To view the values of these parameters, you can run the following SQL statements:

- MySQL:

```
-- Show the value of a particular parameter
mysql$ SHOW VARIABLES LIKE '%parameter_name%';

-- Show the values of all parameters
mysql$ SHOW VARIABLES;
```

- PostgreSQL:

```
-- Show the value of a particular parameter
postgresql=> SHOW parameter_name;

-- Show the values of all parameters
postgresql=> SHOW ALL;
```

Deleting a DB cluster parameter group

You can delete a DB cluster parameter group using the AWS Management Console, AWS CLI, or RDS API. A DB cluster parameter group parameter group is eligible for deletion only if it isn't associated with a DB cluster.

Console

To delete parameter groups

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Parameter groups**.

   The parameter groups appear in a list.
3. Choose the name of the DB cluster parameter groups to be deleted.
4. Choose **Actions** and then **Delete**.
5. Review the parameter group names and then choose **Delete**.

AWS CLI

To delete a DB cluster parameter group, use the AWS CLI `delete-db-cluster-parameter-group` command with the following required parameter.

- `--db-parameter-group-name`

Example

The following example deletes a DB cluster parameter group named *mydbparametergroup.*

```
aws rds delete-db-cluster-parameter-group --db-parameter-group-name mydbparametergroup
```

RDS API

To delete a DB cluster parameter group, use the RDS API `DeleteDBClusterParameterGroup` command with the following required parameter.

- `DBParameterGroupName`

Comparing DB parameter groups

You can use the AWS Management Console to view the differences between two DB parameter groups.

The specified parameter groups must both be DB parameter groups, or they both must be DB cluster parameter groups. This is true even when the DB engine and version are the same. For example, you can't compare an `aurora-mysql8.0` (Aurora MySQL version 3) DB parameter group and an `aurora-mysql8.0` DB cluster parameter group.

You can compare Aurora MySQL and RDS for MySQL DB parameter groups, even for different versions, but you can't compare Aurora PostgreSQL and RDS for PostgreSQL DB parameter groups.

To compare two DB parameter groups

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Parameter groups**.
3. In the list, choose the two parameter groups that you want to compare.

   > **Note**
   >
   > To compare a default parameter group to a custom parameter group, first choose the default parameter group on the **Default** tab, then choose the custom parameter group on the **Custom** tab.

4. From **Actions**, choose **Compare**.

Specifying DB parameters

DB parameter types include the following:

- Integer
- Boolean
- String
- Long
- Double
- Timestamp
- Object of other defined data types
- Array of values of type integer, Boolean, string, long, double, timestamp, or object

You can also specify integer and Boolean parameters using expressions, formulas, and functions.

For the Oracle engine, you can use the `DBInstanceClassHugePagesDefault` formula variable to specify a Boolean DB parameter. See DB parameter formula variables.

For the PostgreSQL engine, you can use an expression to specify a Boolean DB parameter. See Boolean DB parameter expressions.

Contents

DB parameter formulas

A DB parameter formula is an expression that resolves to an integer value or a Boolean value. You enclose the expression in braces: {}. You can use a formula for either a DB parameter value or as an argument to a DB parameter function.

Syntax

```
{FormulaVariable}
```

```
{FormulaVariable*Integer}
{FormulaVariable*Integer/Integer}
{FormulaVariable/Integer}
```

DB parameter formula variables

Each formula variable returns an integer or a Boolean value. The names of the variables are case-sensitive.

AllocatedStorage

Returns an integer representing the size, in bytes, of the data volume.

DBInstanceClassHugePagesDefault

Returns a Boolean value. Currently, it's only supported for Oracle engines.

For more information, see Turning on HugePages for an RDS for Oracle instance.

DBInstanceClassMemory

Returns an integer for the number of bytes of memory available to the database process. This number is internally calculated by starting with the total amount of memory for the DB instance class. From this, the calculation subtracts memory reserved for the operating system and the RDS processes that manage the instance. Therefore, the number is always somewhat lower than the memory figures shown in the instance class tables in DB instance classes. The exact value depends on a combination of factors. These include instance class, DB engine, and whether it applies to an RDS instance or an instance that's part of an Aurora cluster.

DBInstanceVCPU

Returns an integer representing the number of virtual central processing units (vCPUs) used by Amazon RDS to manage the instance.

EndPointPort

Returns an integer representing the port used when connecting to the DB instance.

TrueIfReplica

Returns `1` if the DB instance is a read replica and `0` if it is not. This is the default value for the `read_only` parameter in MySQL.

DB parameter formula operators

DB parameter formulas support two operators: division and multiplication.

Division operator: /

Divides the dividend by the divisor, returning an integer quotient. Decimals in the quotient are truncated, not rounded.

Syntax

```
dividend / divisor
```

The dividend and divisor arguments must be integer expressions.

*Multiplication operator: **

Multiplies the expressions, returning the product of the expressions. Decimals in the expressions are truncated, not rounded.

Syntax

```
expression * expression
```

Both expressions must be integers.

DB parameter functions

You specify the arguments of DB parameter functions as either integers or formulas. Each function must have at least one argument. Specify multiple arguments as a comma-separated list. The list can't have any empty members, such as *argument1*,,*argument3*. Function names are case-insensitive.

IF

Returns an argument.

Currently, it's only supported for Oracle engines, and the only supported first argument is `{DBInstanceClassHugePagesDefault}`. For more information, see Turning on HugePages for an RDS for Oracle instance.

Syntax

```
IF(argument1, argument2, argument3)
```

Returns the second argument if the first argument evaluates to true. Returns the third argument otherwise.

GREATEST

Returns the largest value from a list of integers or parameter formulas.

Syntax

```
GREATEST(argument1, argument2,...argumentn)
```

Returns an integer.

LEAST

Returns the smallest value from a list of integers or parameter formulas.

Syntax

```
LEAST(argument1, argument2,...argumentn)
```

Returns an integer.

SUM

Adds the values of the specified integers or parameter formulas.

Syntax

```
SUM(argument1, argument2,...argumentn)
```

Returns an integer.

Boolean DB parameter expressions

A Boolean DB parameter expression resolves to a Boolean value of 1 or 0. The expression is enclosed in quotation marks.

> **Note**
>
> Boolean DB parameter expressions are only supported for the PostgreSQL engine.

Syntax

```
"expression operator expression"
```

Both expressions must resolve to integers. An expression can be the following:

- integer constant
- DB parameter formula
- DB parameter function
- DB parameter variable

Boolean DB parameter expressions support the following inequality operators:

The greater than operator: >

Syntax

```
"expression > expression"
```

The less than operator: <

Syntax

```
"expression < expression"
```

The greater than or equal to operators: >=, =>

Syntax

```
"expression >= expression"
"expression => expression"
```

The less than or equal to operators: <=, =<

Syntax

```
"expression <= expression"
"expression =< expression"
```

Example using a Boolean DB parameter expression

The following Boolean DB parameter expression example compares the result of a parameter formula with an integer. It does so to modify the Boolean DB parameter `wal_compression` for a PostgreSQL DB instance. The parameter expression compares the number of vCPUs with the value 2. If the number of vCPUs is greater than 2, then the `wal_compression` DB parameter is set to true.

```
aws rds modify-db-parameter-group --db-parameter-group-name group-name \
--parameters "ParameterName=wal_compression,ParameterValue=\"{DBInstanceVCPU} > 2\" "
```

DB parameter log expressions

You can set an integer DB parameter value to a log expression. You enclose the expression in braces: {}. For example:

```
{log(DBInstanceClassMemory/8187281418)*1000}
```

The `log` function represents log base 2. This example also uses the `DBInstanceClassMemory` formula variable. See DB parameter formula variables.

> **Note**
>
> Currently, you can't specify the MySQL `innodb_log_file_size` parameter with any value other than an integer.

DB parameter value examples

These examples show using formulas, functions, and expressions for the values of DB parameters.

> **Warning**
>
> Improperly setting parameters in a DB parameter group can have unintended adverse effects. These might include degraded performance and system instability. Use caution

when modifying database parameters and back up your data before modifying your DB parameter group. Try out parameter group changes on a test DB instance, created using point-in-time-restores, before applying those parameter group changes to your production DB instances.

Example using the DB parameter function GREATEST

You can specify the `GREATEST` function in an Oracle processes parameter. Use it to set the number of user processes to the larger of either 80 or `DBInstanceClassMemory` divided by 9,868,951.

```
GREATEST({DBInstanceClassMemory/9868951},80)
```

Example using the DB parameter function LEAST

You can specify the `LEAST` function in a MySQL `max_binlog_cache_size` parameter value. Use it to set the maximum cache size a transaction can use in a MySQL instance to the lesser of 1 MB or `DBInstanceClass/256`.

```
LEAST({DBInstanceClassMemory/256},10485760)
```

Creating an Amazon ElastiCache cache using Amazon RDS DB instance settings

ElastiCache is a fully managed, in-memory caching service that provides microsecond read and write latencies that support flexible, real-time use cases. ElastiCache can help you accelerate application and database performance. You can use ElastiCache as a primary data store for use cases that don't require data durability, such as gaming leaderboards, streaming, and data analytics. ElastiCache helps remove the complexity associated with deploying and managing a distributed computing environment. For more information, see Common ElastiCache Use Cases and How ElastiCache Can Help for Memcached and Common ElastiCache Use Cases and How ElastiCache Can Help for Redis OSS. You can use the Amazon RDS console for creating ElastiCache cache.

You can operate Amazon ElastiCache in two formats. You can get started with a serverless cache or choose to design your own cache cluster. If you choose to design your own cache cluster, ElastiCache works with both the Redis OSS and Memcached engines. If you're unsure which engine you want to use, see Comparing Memcached and Redis OSS. For more information about Amazon ElastiCache, see the Amazon ElastiCache User Guide.

Topics

Overview of ElastiCache cache creation with RDS DB instance settings

You can create an ElastiCache cache from Amazon RDS using the same configuration settings as a newly created or existing RDS DB instance.

Some use cases to associate an ElastiCache cache with your DB instance:

- You can save costs and improve your performance by using ElastiCache with RDS versus running on RDS alone.

  For example, you can save up to 55% in cost and gain up to 80x faster read performance by using ElastiCache with RDS for MySQL versus RDS for MySQL alone.

- You can use the ElastiCache cache as a primary data store for applications that don't require data durability. Your applications that use Redis OSS or Memcached can use ElastiCache with almost no modification.

When you create an ElastiCache cache from RDS, the ElastiCache cache inherits the following settings from the associated RDS DB instance:

- ElastiCache connectivity settings
- ElastiCache security settings

You can also set the cache configuration settings according to your requirements.

Setting up ElastiCache in your applications

Your applications must be set up to utilize ElastiCache cache. You can also optimize and improve cache performance by setting up your applications to use caching strategies depending on your requirements.

- To access your ElastiCache cache and get started, see Getting started with ElastiCache (Redis OSS) and Getting started with ElastiCache (Memcached).
- For more information about caching strategies, see Caching strategies and best practices for Memcached and Caching strategies and best practices for Redis OSS.
- For more information about high availability in ElastiCache (Redis OSS) clusters, see High availability using replication groups.
- You might incur costs associated with backup storage, data transfer within or across regions, or use of AWS Outposts. For pricing details, see Amazon ElastiCache pricing.

Creating an ElastiCache cache with settings from an RDS DB instance

You can create an ElastiCache cache for your RDS DB instances with settings for inherited from the DB instance.

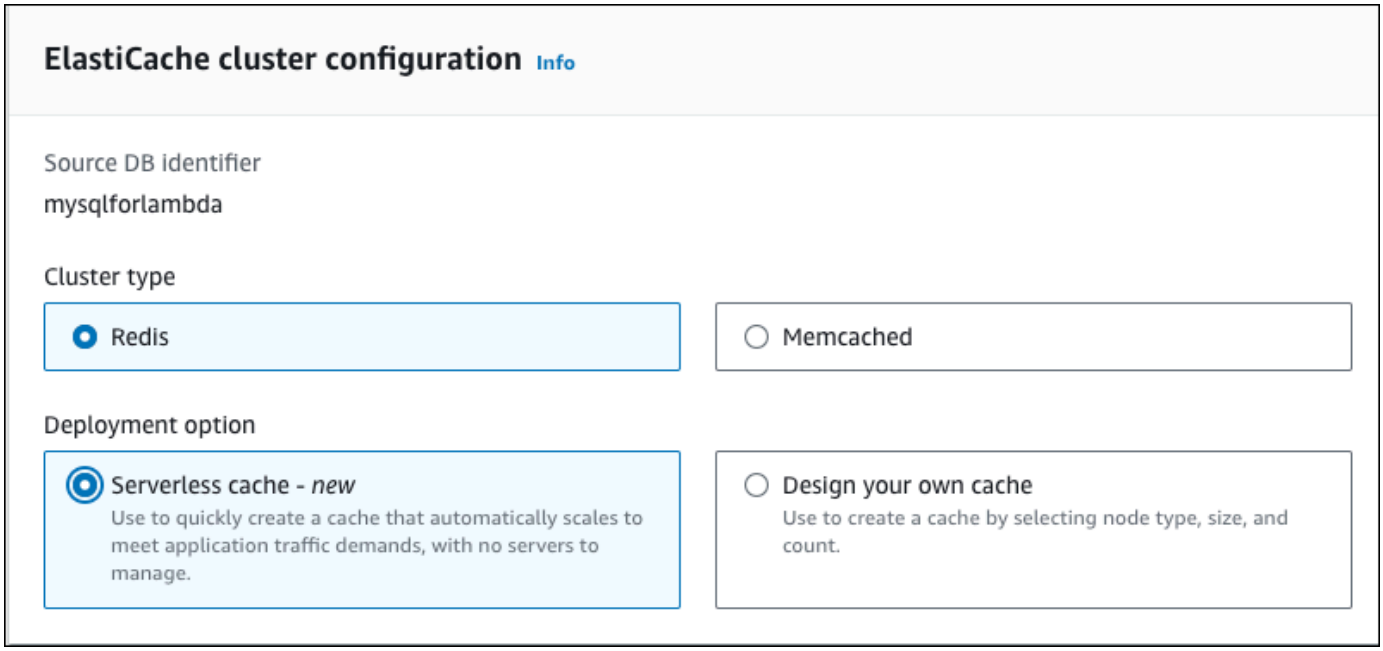
Create an ElastiCache cache with settings from a DB instance

1. To create a DB instance, follow the instructions in Creating an Amazon RDS DB instance.
2. After creating an RDS DB instance, the console displays the **Suggested add-ons** window. Select **Create an ElastiCache cluster from RDS using your DB settings**.

For an existing database, in the **Databases** page, select the required DB instance. In the **Actions** dropdown menu, choose **Create ElastiCache cluster** to create an ElastiCache cache in RDS that has the same settings as your existing RDS DB instance.

In the **ElastiCache configuration section**, the **Source DB identifier** displays which DB instance the ElastiCache cache inherits settings from.

3. Choose whether you want to create a Redis OSS or Memcached cluster. For more information, see Comparing Memcached and Redis OSS.



4. After this, choose whether you want to create a **Serverless cache** or **Design your own cache**. For more information, see Choosing between deployment options.

   If you choose **Serverless cache**:

   a. In **Cache settings**, enter values for **Name** and **Description**.

   b. Under **View default settings**, leave the default settings to establish the connection between your cache and DB instance.

   c. You can also edit the default settings by choosing **Customize default settings**. Select the **ElastiCache connectivity settings**, **ElastiCache security settings**, and **Maximum usage limits**.

5. If you choose **Design your own cache**:

a. If you chose **Redis OSS cluster**, choose whether you want to keep the cluster mode **Enabled** or **Disabled**. For more information, see Replication: Redis OSS (Cluster Mode Disabled) vs. Redis OSS (Cluster Mode Enabled).

b. Enter values for **Name**, **Description**, and **Engine version**.

   For **Engine version**, the recommended default value is the latest engine version. You can also choose an **Engine version** for the ElastiCache cache that best meets your requirements.

c. Choose the node type in the **Node type** option. For more information, see Managing nodes.

   If you choose to create a Redis OSS cluster with the **Cluster mode** set to **Enabled**, then enter the number of shards (partitions/node groups) in the **Number of shards** option.

   Enter the number of replicas of each shard in **Number of replicas**.

   > **Note**
   >
   > The selected node type, the number of shards, and the number of replicas all affect your cache performance and resource costs. Be sure these settings match your database needs. For pricing information, see Amazon ElastiCache pricing.

d. Select the **ElastiCache connectivity settings** and **ElastiCache security settings**. You can keep the default settings or customize these settings per your requirements.

6. Verify the default and inherited settings of your ElastiCache cache. Some settings can't be changed after creation.

   > **Note**
   >
   > RDS might adjust the backup window of your ElastiCache cache to meet the minimum window requirement of 60 minutes. The backup window of your source database remains the same.

7. When you're ready, choose **Create ElastiCache cache**.

The console displays a confirmation banner for the ElastiCache cache creation. Follow the link in the banner to the ElastiCache console to view the cache details. The ElastiCache console displays the newly created ElastiCache cache.

Tutorial: Creating a MySQL DB instance with a custom parameter and custom option group

In this tutorial, you create a MySQL DB instance with a custom parameter and custom option group. For more information about custom parameter and option groups, see Parameter groups for Amazon RDS and Working with option groups .

Topics

Introduction

To create DB instances with custom configurations and settings, you can use custom parameter and option groups. Custom parameter and option groups are particularly helpful if you work with multiple databases and want to uniformly configure settings for your fleet.

By completing these steps, you learn:

- How to use Amazon RDS to create a MySQL DB instances with custom parameter and option groups.
- How to use specific custom parameters and option for MySQL DB instances.

To complete this tutorial, carry out the following tasks:

1. Create a custom parameter group with the MySQL parameters default_password_lifetime and disconnect_on_expired_password.
2. Create a custom option group with MySQL option feature MariaDB Audit Plugin. For steps to create an option group, see Working with option groups.

3. Create a MySQL DB instances with the custom parameters group and custom option group that you created.

Prerequisites

Before you begin, complete the steps in the following sections:

- Sign up for an AWS account
- Create a user with administrative access

Create an Amazon RDS custom parameter group;

In this tutorial, you learn how to create a custom parameter group; for a MySQL DB instance in the console. If you don't specify a custom parameter group, Amazon RDS creates DB instances with a default parameter group. The custom parameter group uses default_password_lifetime and disconnect_on_expired_password. The default_password_lifetime parameter determines the length of time until the client password expires. The disconnect_on_expired_password parameter rejects a client connection when the DB instance detects an expired password from the client.. For more information on other custom parameters available for MySQL DB instances, see MySQL documentation.

1. Open the Amazon RDS console and choose **Parameter groups**.
2. In Custom Parameter groups, select **Create parameter group**.
3. Set the parameter group details.
   a. Select a name for the parameter group.
   b. Write a description of the parameter group.
   c. In Engine type, select **MySQL Community** .
   d. In Parameter group family, select **MySQL 8.0** .
4. Select **Create**.

The new parameter group appears on the **Parameter groups** page in the Amazon RDS console. The following steps illustrate how to add specific parameters to the parameter group.

Add custom parameters to your custom parameter group

Use the following steps to add specific parameters to the parameter group that you created in Create an Amazon RDS custom parameter group;.

1. Open the Amazon RDS console and choose **Parameter groups**.
2. In Custom parameter groups, select the name of the parameter group you created.
3. Click **Edit**.
4. In the Filter parameters search box, search for the custom parameter **Default_password_lifetime**.
5. Select the check box next to the parameter and select **Save Changes**.
6. Repeat the same steps for the custom parameter **Disconnect_on_expired_password**.

The custom parameter group is now available to associate with Amazon RDS for MySQL 8.0 DB instance. Next,create a custom option group for your DB instance.

Create an Amazon RDS custom option group

Create a custom option group with the option MariaDB Audit Plugin. This plugin logs server activity for security and compliance. For more information on other options available for MySQL DB instances, see Options for MySQL DB instances.

1. Open the Amazon RDS console and choose **Option groups**.
2. In Option Groups, select **Create group**.
3. Set the Option group details.
   - Select a name for the option group.
   - Write a description of the option group.
   - In Engine type, select **mysql**.
   - In Major Engine Version, select **8.0**.
4. Select **Create**.

The new option group appears on the **Option groups** page in the Amazon RDS console. The following steps illustrate how to add specific options to the option group.

Add options to your custom option group

Use the following steps to add specific options to the option group that you created in Create an Amazon RDS custom option group.

1. Open the Amazon RDS console and choose **Option groups**.
2. In Option groups, select the name of the option group you created.
3. Under Options, select **Add option**.
4. Set the Option group details.
   - In Option name, choose the option MariaDB Audit Plugin, **MARIADB_AUDIT_PLUGIN**.
   - In Option settings, leave all the default options selected.
   - Check the option **Yes** to apply immediately.
5. Choose **Create option**.

The option should now be available for all associated DB instances. Next, create a MySQL DB instance with the custom parameters and custom option group.

Create a MySQL DB instance with a custom parameter and a custom option group

Finally, create a MySQL DB instance with the custom parameter and option group you made in the steps above. The following steps illustrate how to create the MySQL DB instance with a custom parameter and option group.

1. Open the Amazon RDS console and choose **Databases**.
2. Select **Create database**.
3. In Choose a database creation method, select **Standard Create**.
4. In Engine options, select **MySQL** .
5. In **Availability and durability**, select **Single DB instance.** This step is necessary to support a custom parameter or option group.
6. Select Additional Configuration.
   - In Initial database name, choose a name for your DB instance.
   - Under the DB parameter group dropdown, select the name of the custom parameter group you created previously.

- Under Option group dropdown, select the name of custom option group you created previously.

7. For this tutorial, you can leave the default settings for any other DB settings or modify them as your use case requires.
8. Select**Create database**.

RDS creates a new MySQL DB instance with a custom parameter group and a custom option group. To see more information on this database, see the Databases page of the Amazon RDS console.

In this tutorial, you configure a MySQL DB instance with tailored settings using a custom parameter group and a custom option group. This newly created MySQL DB instance manages the user password lifetime by using the default_password_lifetime parameter. This instance also disconnects users that connect with an expired password by using the disconnect_on_expired_password parameter. You also use the MariaDB Audit Plugin to keep track of server activity. Additional settings can be applied to MySQL DB instance with a customparameter and option group in order to optimize your database.

Managing an Amazon RDS DB instance

Following, you can find instructions for managing and maintaining your Amazon RDS DB instance.

Topics

Stopping an Amazon RDS DB instance temporarily

You can stop your DB instance intermittently for temporary testing or for a daily development activity. The most common use case is cost optimization.

The time to stop your DB instance varies depending on factors such as the instance class, network state, DB engine type, and database state. The process can take several minutes. The service must perform the following actions:

- Shut down database engine processes.
- Shut down RDS platform processes.
- Detach the EBS storage volumes associated with your DB instance.
- Terminate the underlying Amazon EC2 instance.

> **Warning**
>
> Starting a DB instance requires instance recovery and can take from minutes to hours. Therefore, if instance availability is a concern, be cautious about stopping a production instance temporarily. For more information, see Starting an Amazon RDS DB instance that was previously stopped.

To stop and start your DB instance in the same operation, reboot the DB instance. For more information, see Rebooting a DB instance.

Topics

Use cases for stopping your DB instance

Stopping and starting a DB instance is faster than creating a DB snapshot, deleting your DB instance, and then restoring the snapshot when you want to access the instance. Common use cases for stopping an instance include the following:

- **Cost optimization** – For non-production databases, you can stop your Amazon RDS DB instance temporarily to save money. While the instance is stopped, you're not charged for DB instance hours.

  > **Important**
  >
  > While your DB instance is stopped, you are charged for provisioned storage (including Provisioned IOPS). You're also charged for backup storage, including manual snapshots and automated backups within your specified retention window. However, you're not charged for DB instance hours. For more information, see Billing FAQs.

- **Daily development** – If you maintain a DB instance for development purposes, you can start the instance when it's needed and then shut down the instance when it's not needed.
- **Testing** – You might need a temporary DB instance to test backup and recovery procedures, migrations, application upgrades, or related activities. In these use cases, you can stop the DB instance when it's not needed.
- **Training** – If you're conducting training in RDS, you might need to start DB instances during the training session and shut them down afterward.

Supported DB engines, instance classes, and Regions

You can stop and start Amazon RDS DB instances that are running the following DB engines:

- Db2
- MariaDB
- Microsoft SQL Server, including RDS Custom for SQL Server
- MySQL
- Oracle
- PostgreSQL

Stopping and starting a DB instance is supported for all DB instance classes, and in all AWS Regions.

Stopping a DB instance in a Multi-AZ deployment

You can stop and start a DB instance in a Multi-AZ deployment. Note the following limitations:

- You can only create a Multi-AZ deployment if your database engine supports it. For more information about engine support, see Supported Regions and DB engines for Multi-AZ DB clusters in Amazon RDS.
- RDS for SQL Server doesn't support stopping a DB instance in a Multi-AZ deployment. For more information, see Microsoft SQL Server Multi-AZ deployment limitations, notes, and recommendations.
- A long time might be required to stop a DB instance. If you have at least one backup after a previous failover, then you can speed up the stop operation by performing a reboot with failover operation. For more information, see Rebooting a DB instance.

How stopping a DB instance works

The stopping operation occurs in the following stages:

1. The DB instance initiates the normal shutdown process.

   The status of the DB instance changes to `stopping`.
2. The instance stops running, up to a maximum of 7 consecutive days.

   The status of the DB instance changes to `stopped`.

Characteristics of a stopped DB instance

When in a stopped state, your DB instance has the following characteristics:

- Your stopped DB instance retains the following:
  - Instance ID
  - Domain Name Server (DNS) endpoint
  - Parameter group
  - Security group

- Option group
- Amazon S3 transaction logs (necessary for a point-in-time restore)

When you restart a DB instance, it has the same configuration as when you stopped it.

- Any storage volumes remain attached to the DB instance, and their data is kept. RDS deletes any data stored in the RAM of the DB instance.

  While your DB instance is stopped, you are charged for provisioned storage (including Provisioned IOPS). You're also charged for backup storage, including manual snapshots and automated backups within your specified retention window.
- RDS removes pending actions, including scheduled maintenance updates, except for pending actions for the option group or DB parameter group of the DB instance.

> **Note**
>
> Occasionally, an RDS for PostgreSQL DB instance doesn't shut down cleanly. If this happens, you see that the instance goes through a recovery process when you restart it later. This is expected behavior of the database engine, intended to protect database integrity. Some memory-based statistics and counters don't retain history and are re-initialized after restart, to capture the operational workload moving forward.

Automatic restart of a stopped DB instance

If you don't manually start your DB instance after it is stopped for seven consecutive days, RDS automatically starts your DB instance for you. This way, your instance doesn't fall behind any required maintenance updates. To learn how to stop and start your instance on a schedule, see How can I use Step Functions to stop an Amazon RDS instance for longer than 7 days?.

Limitations of stopping your DB instance

The following are some limitations of the stopping operation:

- You can't stop a DB instance that has a read replica, or that is a read replica.
- You can't modify a stopped DB instance.
- You can't delete an option group that is associated with a stopped DB instance.

- You can't delete a DB parameter group that is associated with a stopped DB instance.
- In a Multi-AZ deployment, note the following limitations:
  - You can't stop an RDS for SQL Server DB instance.
  - The primary and secondary Availability Zones might be switched after you start the DB instance.

Additional limitations apply to RDS Custom for SQL Server. For more information, see Starting and stopping an RDS Custom for SQL Server DB instance.

Option and parameter group considerations

You can't remove persistent options (including permanent options) from an option group if there are DB instances associated with that option group. This functionality is also true of any DB instance with a state of `stopping`, `stopped`, or `starting`.

You can change the option group or DB parameter group that is associated with a stopped DB instance. However, the change doesn't occur until the next time you start the DB instance. If you chose to apply changes immediately, the change occurs when you start the DB instance. Otherwise the change occurs during the next maintenance window after you start the DB instance.

Public IP address considerations

When you stop a DB instance, it retains its DNS endpoint. If you stop a DB instance that has a public IP address, Amazon RDS releases its public IP address. When the DB instance is restarted, it has a different public IP address.

> **Note**
>
> You should always connect to a DB instance using the DNS endpoint, not the IP address.

Stopping a DB instance temporarily: basic steps

You can stop a DB using the AWS Management Console, the AWS CLI, or the RDS API.

Console

To stop a DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**, and then choose the DB instance that you want to stop.
3. For **Actions**, choose **Stop temporarily**.
4. In the **Stop DB instance temporarily** window, select the acknowledgement that the DB instance will restart automatically after 7 days.
5. (Optional) Select **Save the DB instance in a snapshot** and enter the snapshot name for **Snapshot name**. Choose this option if you want to create a snapshot of the DB instance before stopping it.
6. Choose **Stop temporarily** to stop the DB instance, or choose **Cancel** to cancel the operation.

AWS CLI

To stop a DB instance by using the AWS CLI, call the stop-db-instance command with the following option:

- `--db-instance-identifier` – the name of the DB instance.

Example

```
aws rds stop-db-instance --db-instance-identifier mydbinstance
```

RDS API

To stop a DB instance by using the Amazon RDS API, call the StopDBInstance operation with the following parameter:

- `DBInstanceIdentifier` – the name of the DB instance.

Starting an Amazon RDS DB instance that was previously stopped

This topic explains how to start an Amazon RDS DB instance that was previously stopped, outlining the necessary steps and key considerations for resuming use of the database.

You can stop your Amazon RDS DB instance temporarily to save money. After you stop your DB instance, you can restart it to begin using it again. For more information about stopping a DB instance, see Stopping an Amazon RDS DB instance temporarily.

When you start a DB instance that you previously stopped, the DB instance retains information such as the following:

- Instance ID
- Domain Name Server (DNS) endpoint
- DB parameter group
- VPC security group
- DB option group

Amazon RDS bills in one-second increments for database instances and attached storage. There is a 10-minute minimum charge when an instance is started.

To start the instance, the Amazon RDS service performs actions such as the following:

- Provisioning the underlying Amazon EC2 instance
- Starting the RDS processes
- Starting the database engine processes
- Attaching the EBS storage volumes
- Enabling Performance Insights if it was previously enabled
- Recovering the DB instance (recovery occurs even after a normal shutdown)

The time to start your DB instance varies depending on factors such as the instance class, network state, DB engine type, database size, and the database state when the instance was shut down. The startup process can take minutes to hours. We recommend that you consider the variability in startup time when creating your availability plan.

Console

To start a DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**, and then choose the DB instance that you want to start.
3. For **Actions**, choose **Start**.

AWS CLI

To start a DB instance by using the AWS CLI, call the start-db-instance command with the following option:

- `--db-instance-identifier` – The name of the DB instance.

Example

```
aws rds start-db-instance --db-instance-identifier mydbinstance
```

RDS API

To start a DB instance by using the Amazon RDS API, call the StartDBInstance operation with the following parameter:

- `DBInstanceIdentifier` – The name of the DB instance.

Rebooting a DB instance

You can stop and start the database service on your RDS DB instance in a single operation, called *rebooting*. Rebooting might be necessary to apply configuration changes, address minor issues, or resolve network problems without having to perform a full restart or migration of your database.

> **Note**
>
> This topic applies only to rebooting a Single-AZ or Multi-AZ DB *instance*. For instructions to reboot a Multi-AZ DB cluster, see the section called "Rebooting a Multi-AZ DB cluster".

Topics

Use cases for rebooting a DB instance

Typically, you reboot your DB instance for maintenance reasons so that your changes take effect. The following use cases are common:

- **Associating a new DB parameter group** – When you associate a new DB parameter group with a DB instance, RDS applies the modified static and dynamic parameters only after the DB instance is rebooted. However, if you modify dynamic parameters in the DB parameter group after you have associated it with the DB instance, these changes are applied immediately without a reboot. For more information, see Parameter groups for Amazon RDS.
- **Applying a change to a static parameter in an existing DB parameter group** – When you change a static parameter and save the DB parameter group, the status of DB instances associated with this parameter group in the console changes to **pending-reboot**. The parameter change takes effect only after the associated DB instances are rebooted. When you change a

dynamic parameter in an existing parameter group, the change takes effect immediately by default, without requiring a reboot.

> **Note**
>
> The **pending-reboot** status doesn't result in an automatic reboot during the next maintenance window. To apply the latest parameter changes to your DB instance, reboot the DB instance manually. For more information about parameter groups, see Parameter groups for Amazon RDS.

- **Troubleshooting** – You might encounter performance or other operational issues that necessitate a reboot. For example, your DB instance might be unresponsive.

How rebooting a DB instance works

When Amazon RDS reboots your DB instance it performs the following sequential tasks:

1. Stops the database service on your DB instance
2. Starts the database service on your DB instance

The reboot process leads to a brief outage. During this outage, the DB instance status is *rebooting*. An outage occurs for both a Single-AZ deployment and a Multi-AZ DB instance deployment, even when you reboot with a failover.

How rebooting a DB instance in a Multi-AZ deployment works

If the Amazon RDS DB instance is in a Multi-AZ deployment, you can reboot with a failover. This operation is useful to simulate a failure of a DB instance or restore operations to the original Availability Zone after a failover.

During the reboot with failover, Amazon RDS does the following

- Interrupts the database abruptly. The DB instance and its client sessions might not have time to shut down gracefully.

> **Warning**
>
> To avoid the possibility of data loss, we recommend stopping transactions on your DB instance before rebooting with a failover.

- Switches to a standby replica in another AZ automatically. The AZ change might not be reflected in the AWS Management Console, and in calls to the AWS CLI and RDS API, for several minutes.
- Updates the DNS record for the DB instance to point to the standby DB instance. As a result, you need to clean up and re-establish any existing connections to your DB instance. For more information, see Configuring and managing a Multi-AZ deployment.
- Creates an Amazon RDS event after the reboot.

On RDS for Microsoft SQL Server, the failover reboots only the primary DB instance. After the failover, the primary DB instance becomes the new secondary DB instance. Parameters might not be updated for Multi-AZ instances. For reboot without failover, both the primary and secondary DB instances reboot, and parameters are updated after the reboot. If the DB instance is unresponsive, we recommend reboot without failover.

Considerations when rebooting a DB instance

Before you reboot your instance, consider the following:

- For a DB instance with read replicas, you can reboot the source DB instance and its read replicas independently. After a reboot completes, replication resumes automatically.
- The reboot time depends on the crash recovery process, database activity at the time of reboot, and the behavior of your specific DB engine. To improve the reboot time, we recommend that you reduce database activity as much as possible during the reboot. This technique reduces rollback activity for in-transit transactions.

Prerequisites for rebooting a DB instance

Make sure that you meet the following prerequisites:

- Your DB instance must be in the `available` state. Your database can be unavailable for several reasons, such as an in-progress backup, a previously requested modification, or a maintenance window operation.

- If you force a failover to a different AZ, your DB instance must be configured for Multi-AZ.
- If you force a failover to a different AZ, we recommend first stopping transactions on your DB instance to prevent possible data loss.

Rebooting a DB instance: basic steps

You can reboot your DB instance using the AWS Management Console, AWS CLI, or RDS API.

Console

To reboot a DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**, and then choose the DB instance that you want to reboot.
3. For **Actions**, choose **Reboot**.

   The **Reboot DB instance** page appears.
4. (Optional) Choose **Reboot with failover?** to force a failover from one AZ to another.
5. Choose **Reboot** to reboot your DB instance.

   Alternatively, choose **Cancel**.

AWS CLI

To reboot a DB instance by using the AWS CLI, call the `reboot-db-instance` command.

Example Simple reboot

For Linux, macOS, or Unix:

```
aws rds reboot-db-instance \
    --db-instance-identifier mydbinstance
```

For Windows:

```
aws rds reboot-db-instance ^
```

```
    --db-instance-identifier mydbinstance
```

Example Reboot with failover

To force a failover from one AZ to the other in a Multi-AZ DB cluster, use the `--force-failover` parameter.

For Linux, macOS, or Unix:

```
aws rds reboot-db-instance \
    --db-instance-identifier mydbinstance \
    --force-failover
```

For Windows:

```
aws rds reboot-db-instance ^
    --db-instance-identifier mydbinstance ^
    --force-failover
```

RDS API

To reboot a DB instance by using the Amazon RDS API, call the `RebootDBInstance` operation.

Automatically connecting an EC2 instance and a DB instance

You can use the Amazon RDS console to simplify setting up a connection between an Amazon Elastic Compute Cloud (Amazon EC2) instance and a DB instance. Often, your DB instance is in a private subnet and your EC2 instance is in a public subnet within a VPC. You can use a SQL client on your EC2 instance to connect to your DB instance. The EC2 instance can also run web servers or applications that access your private DB instance. For instructions on setting up a connection between an EC2 instance and a Multi-AZ DB cluster, see the section called “Connecting an EC2 instance and a Multi-AZ DB cluster”.

If you want to connect to an EC2 instance that isn't in the same VPC as the DB instance, see the scenarios in Scenarios for accessing a DB instance in a VPC.

Topics

- Connecting to a DB instance that is running a specific DB engine

Overview of automatic connectivity with an EC2 instance

When you set up a connection between an EC2 instance and an RDS database, Amazon RDSautomatically configures the VPC security group for your EC2 instance and for your RDS database.

The following are requirements for connecting an EC2 instance with an RDS database:

- The EC2 instance must exist in the same VPC as the RDS database.

  If no EC2 instances exist in the same VPC, then the console provides a link to create one.
- The user who sets up connectivity must have permissions to perform the following Amazon EC2 operations:
  - `ec2:AuthorizeSecurityGroupEgress`
  - `ec2:AuthorizeSecurityGroupIngress`
  - `ec2:CreateSecurityGroup`
  - `ec2:DescribeInstances`
  - `ec2:DescribeNetworkInterfaces`
  - `ec2:DescribeSecurityGroups`
  - `ec2:ModifyNetworkInterfaceAttribute`
  - `ec2:RevokeSecurityGroupEgress`

If the DB instance and EC2 instance are in different Availability Zones, your account may incur cross-Availability Zone costs.

When you set up a connection to an EC2 instance, Amazon RDS acts according to the current configuration of the security groups associated with the RDS database and EC2 instance, as described in the following table.

Current RDS security group configuration	Current EC2 security group configuration	RDS action
There are one or more security groups associated	There are one or more security groups associated	RDS takes no action.

Current RDS security group configuration	Current EC2 security group configuration	RDS action
with the RDS database with a name that matches the pattern `rds-ec2-`*n* (where *n* is a number). A security group that matches the pattern hasn't been modified. This security group has only one inbound rule with the VPC security group of the EC2 instance as the source.	with the EC2 instance with a name that matches the pattern `ec2-rds-`*n* (where *n* is a number). A security group that matches the pattern hasn't been modified. This security group has only one outbound rule with the VPC security group of the RDS database as the source.	A connection was already configured automatically between the EC2 instance and RDS database. Because a connection already exists between the EC2 instance and the RDS database, the security groups aren't modified.

Current RDS security group configuration	Current EC2 security group configuration	RDS action
Either of the following conditions apply: • There is no security group associated with the RDS database with a name that matches the pattern `rds-ec2-`*n*. • There are one or more security groups associated with the RDS database with a name that matches the pattern `rds-ec2-`*n*. However, Amazon RDS can't use any of these security groups for the connection with the EC2 instance. Amazon RDS can't use a security group that doesn't have one inbound rule with the VPC security group of the EC2 instance as the source. Amazon RDS also can't use a security group that has been modified. Examples of modifications include adding a rule or changing the port of an existing rule.	Either of the following conditions apply: • There is no security group associated with the EC2 instance with a name that matches the pattern `ec2-rds-`*n*. • There are one or more security groups associated with the EC2 instance with a name that matches the pattern `ec2-rds-`*n*. However, Amazon RDS can't use any of these security groups for the connection with the RDS database. Amazon RDS can't use a security group that doesn't have one outbound rule with the VPC security group of the RDS database as the source. Amazon RDS also can't use a security group that has been modified.	RDS action: create new security groups

Current RDS security group configuration	Current EC2 security group configuration	RDS action
There are one or more security groups associated with the RDS database with a name that matches the pattern `rds-ec2-`*n*. A security group that matches the pattern hasn't been modified. This security group has only one inbound rule with the VPC security group of the EC2 instance as the source.	There are one or more security groups associated with the EC2 instance with a name that matches the pattern `ec2-rds-`*n*. However, Amazon RDS can't use any of these security groups for the connection with the RDS database. Amazon RDS can't use a security group that doesn't have one outbound rule with the VPC security group of the RDS database as the source. Amazon RDS also can't use a security group that has been modified.	RDS action: create new security groups
There are one or more security groups associated with the RDS database with a name that matches the pattern `rds-ec2-`*n*. A security group that matches the pattern hasn't been modified. This security group has only one inbound rule with the VPC security group of the EC2 instance as the source.	A valid EC2 security group for the connection exists, but it is not associated with the EC2 instance. This security group has a name that matches the pattern `ec2-rds-`*n*. It hasn't been modified. It has only one outbound rule with the VPC security group of the RDS database as the source.	RDS action: associate EC2 security group

Current RDS security group configuration	Current EC2 security group configuration	RDS action
Either of the following conditions apply: • There is no security group associated with the RDS database with a name that matches the pattern `rds-ec2-`*n*. • There are one or more security groups associated with the RDS database with a name that matches the pattern `rds-ec2-`*n*. However, Amazon RDS can't use any of these security groups for the connection with the EC2 instance. Amazon RDS can't use a security group that doesn't have one inbound rule with the VPC security group of the EC2 instance as the source. Amazon RDS also can't use security group that has been modified.	There are one or more security groups associated with the EC2 instance with a name that matches the pattern `ec2-rds-`*n*. A security group that matches the pattern hasn't been modified. This security group has only one outbound rule with the VPC security group of the RDS database as the source.	RDS action: create new security groups

RDS action: create new security groups

Amazon RDS takes the following actions:

- Creates a new security group that matches the pattern `rds-ec2-`*n*. This security group has an inbound rule with the VPC security group of the EC2 instance as the source. This security group is associated with the RDS database and allows the EC2 instance to access the RDS database.

- Creates a new security group that matches the pattern `ec2-rds-`*n*. This security group has an outbound rule with the VPC security group of the RDS database as the target. This security group is associated with the EC2 instance and allows the EC2 instance to send traffic to the RDS database.

RDS action: associate EC2 security group

Amazon RDS associates the valid, existing EC2 security group with the EC2 instance. This security group allows the EC2 instance to send traffic to the RDS database.

Automatically connecting an EC2 instance and an RDS database

Before setting up a connection between an EC2 instance and an RDS database, make sure you meet the requirements described in Overview of automatic connectivity with an EC2 instance.

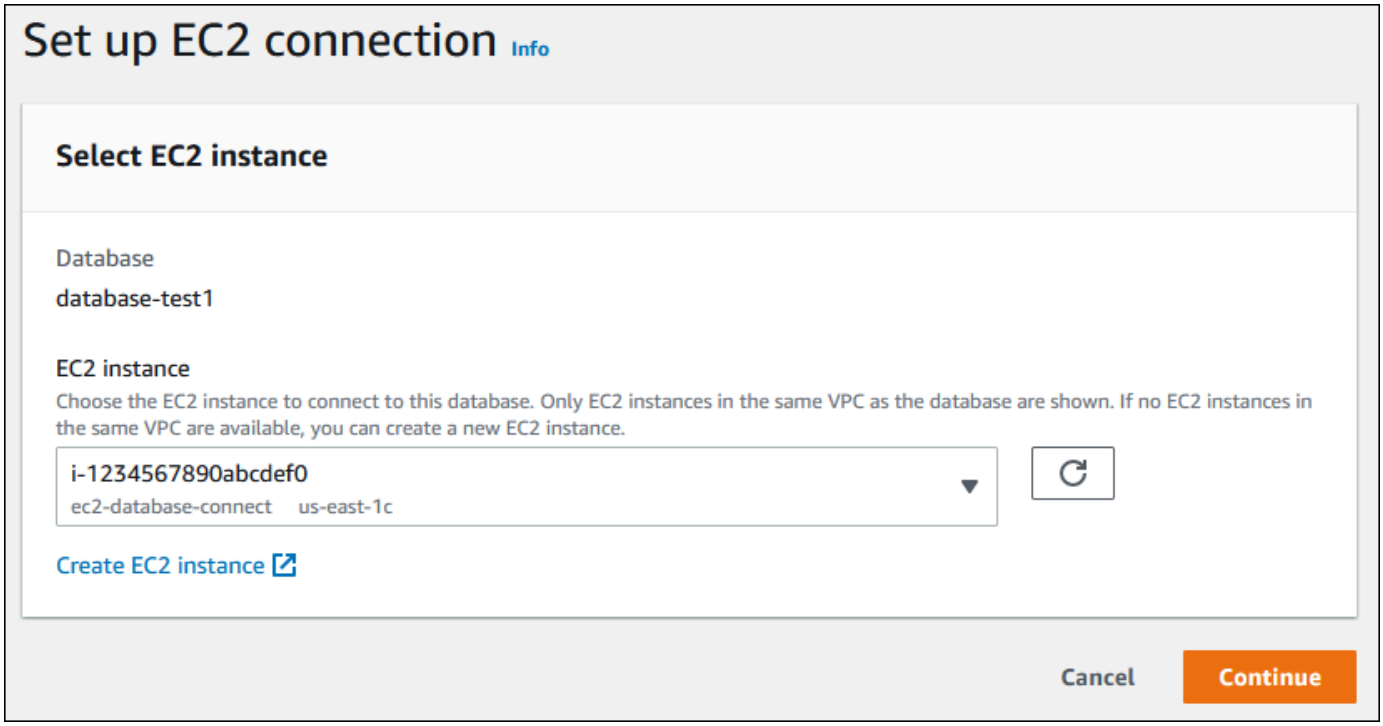
If you make changes to security groups after you configure connectivity, the changes might affect the connection between the EC2 instance and the RDS database.

> **Note**
>
> You can only set up a connection between an EC2 instance and an RDS database automatically by using the AWS Management Console. You can't set up a connection automatically with the AWS CLI or RDS API.

To connect an EC2 instance and an RDS database automatically

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**, and then choose the RDS database.
3. From **Actions**, choose **Set up EC2 connection**.

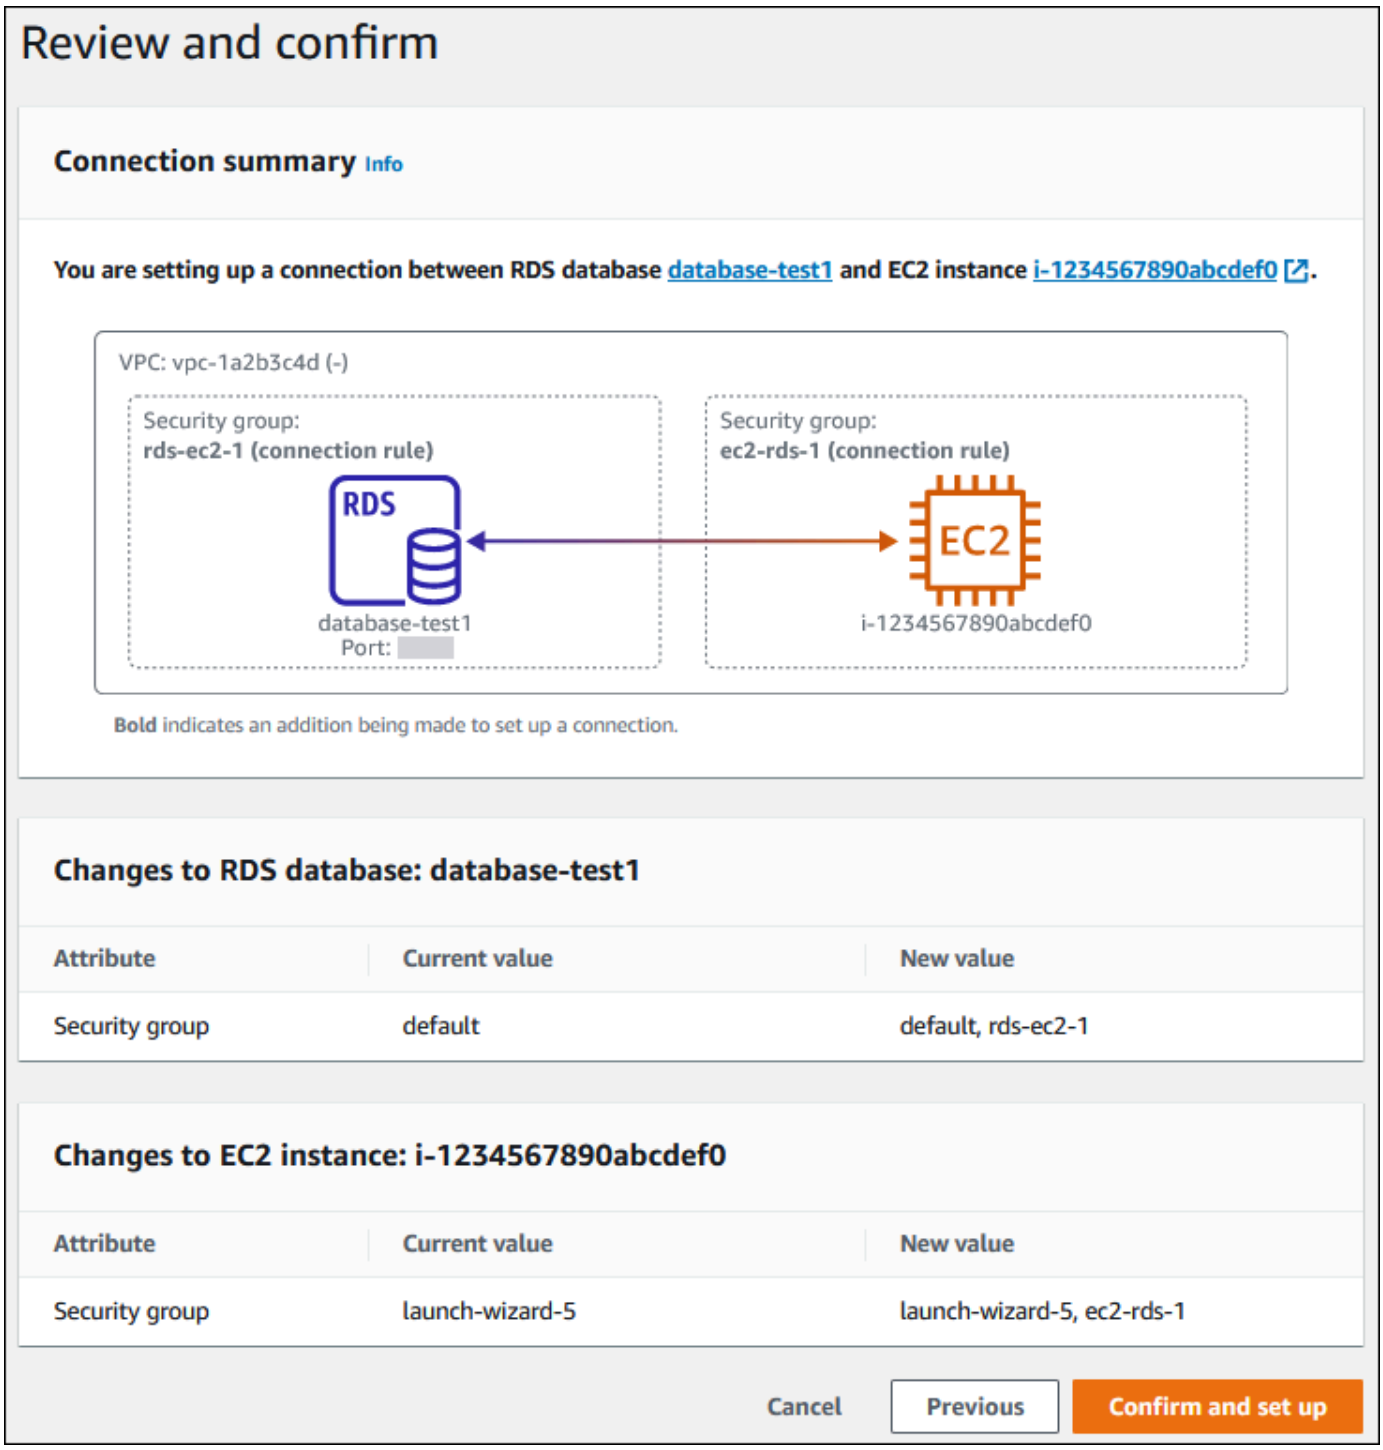
   The **Set up EC2 connection** page appears.
4. On the **Set up EC2 connection** page, choose the EC2 instance.



If no EC2 instances exist in the same VPC, choose **Create EC2 instance** to create one. In this case, make sure the new EC2 instance is in the same VPC as the RDS database.

5. Choose **Continue**.

   The **Review and confirm** page appears.



6. On the **Review and confirm** page, review the changes that RDS will make to set up connectivity with the EC2 instance.

   If the changes are correct, choose **Confirm and set up**.

   If the changes aren't correct, choose **Previous** or **Cancel**.

Viewing connected compute resources

You can use the AWS Management Console to view the compute resources that are connected to an RDS database. The resources shown include compute resource connections that were set up automatically. You can set up connectivity with compute resources automatically in the following ways:

- You can select the compute resource when you create the database.

  For more information, see Creating an Amazon RDS DB instance and Creating a Multi-AZ DB cluster.
- You can set up connectivity between an existing database and a compute resource.

  For more information, see Automatically connecting an EC2 instance and an RDS database.

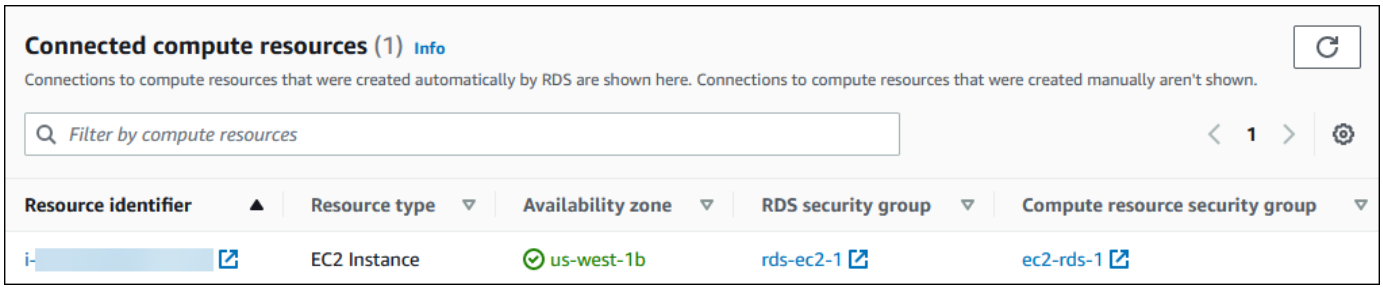
The listed compute resources don't include ones that were connected to the database manually. For example, you can allow a compute resource to access a database manually by adding a rule to the VPC security group associated with the database.

For a compute resource to be listed, the following conditions must apply:

- The name of the security group associated with the compute resource matches the pattern `ec2-rds-`*n* (where *n* is a number).
- The security group associated with the compute resource has an outbound rule with the port range set to the port that the RDS database uses.
- The security group associated with the compute resource has an outbound rule with the source set to a security group associated with the RDS database.
- The name of the security group associated with the RDS database matches the pattern `rds-ec2-`*n* (where *n* is a number).
- The security group associated with the RDS database has an inbound rule with the port range set to the port that the RDS database uses.
- The security group associated with the RDS database has an inbound rule with the source set to a security group associated with the compute resource.

To view compute resources connected to an RDS database

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**, and then choose the name of the RDS database.
3. On the **Connectivity & security** tab, view the compute resources in the **Connected compute resources**.



Connecting to a DB instance that is running a specific DB engine

For information about connecting to a DB instance that is running a specific DB engine, follow the instructions for your DB engine:

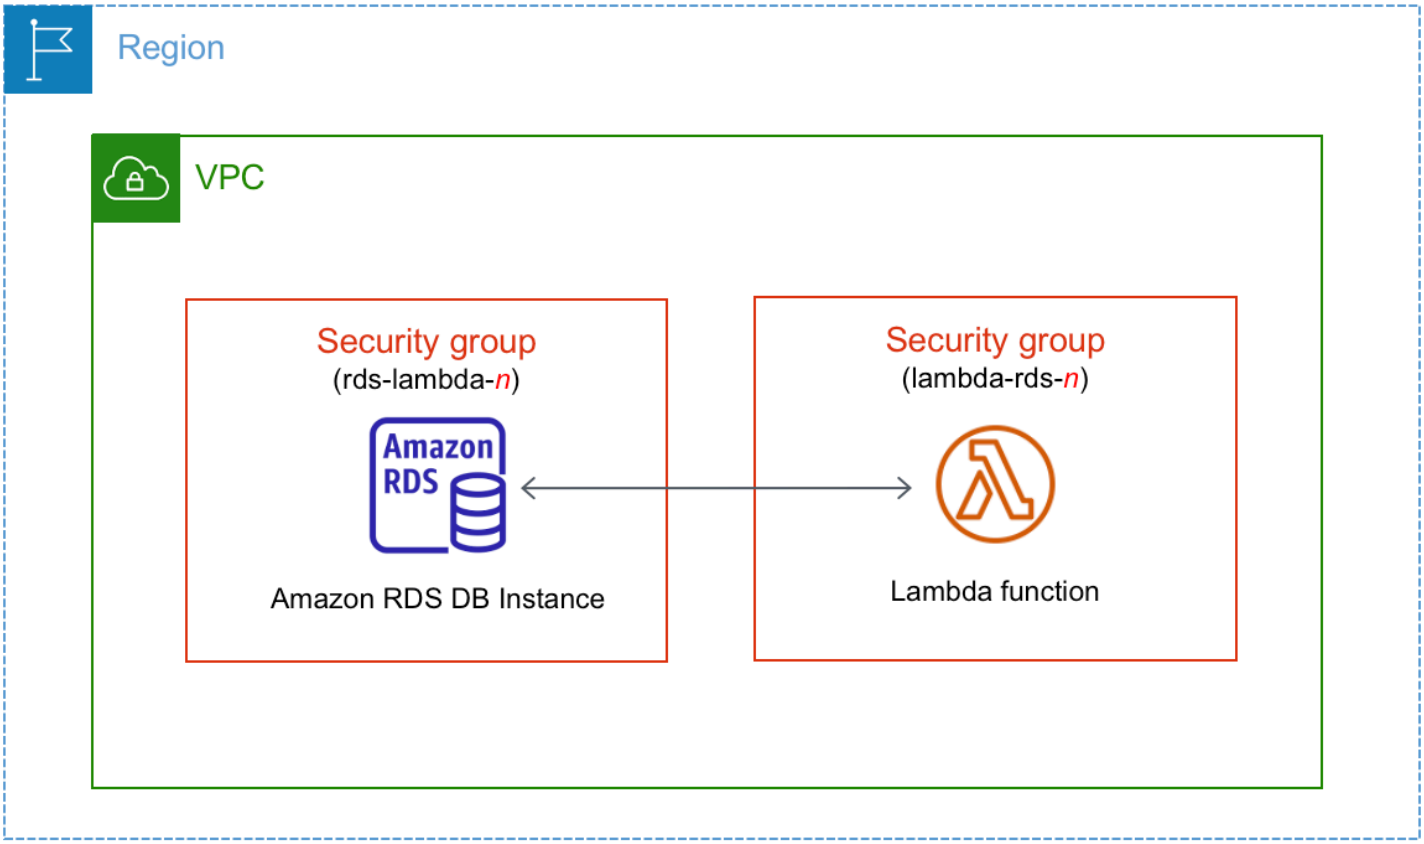
- Connecting to a DB instance running the MariaDB database engine
- Connecting to a DB instance running the Microsoft SQL Server database engine
- Connecting to a DB instance running the MySQL database engine
- Connecting to your RDS for Oracle DB instance
- Connecting to a DB instance running the PostgreSQL database engine

Automatically connecting a Lambda function and a DB instance

You can use the Amazon RDS console to simplify setting up a connection between a Lambda function and a DB instance. Often, your DB instance is in a private subnet within a VPC. The Lambda function can be used by applications to access your private DB instance.

For instructions on setting up a connection between a Lambda function and a Multi-AZ DB cluster, see the section called “Connecting a Lambda function and a Multi-AZ DB cluster”.

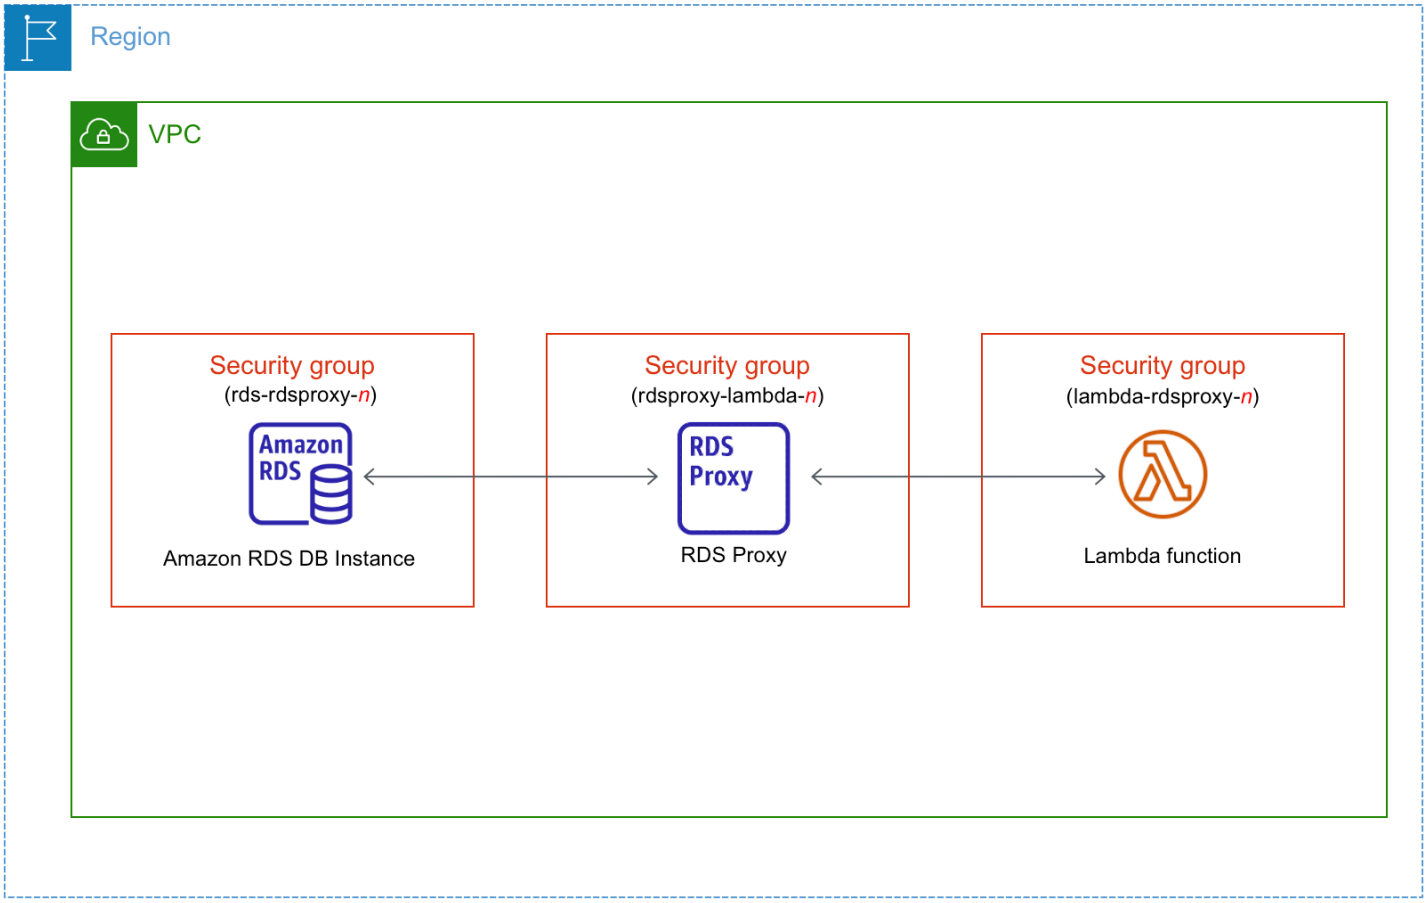
The following image shows a direct connection between your DB instance and your Lambda function.



You can set up the connection between your Lambda function and your DB instance through RDS Proxy to improve your database performance and resiliency. Often, Lambda functions make frequent, short database connections that benefit from connection pooling that RDS Proxy offers. You can take advantage of any AWS Identity and Access Management (IAM) authentication that you already have for Lambda functions, instead of managing database credentials in your Lambda application code. For more information, see Using Amazon RDS Proxy.

When you use the console to connect with an existing proxy, Amazon RDS updates the proxy security group to allow connections from your DB instance and Lambda function.

You can also create a new proxy from the same console page. When you create a proxy in the console, to access the DB instance, you must input your database credentials or select an AWS Secrets Manager secret.



Topics

- Overview of automatic connectivity with a Lambda function
- Automatically connecting a Lambda function and an RDS database
- Viewing connected compute resources

Overview of automatic connectivity with a Lambda function

The following are requirements for connecting a Lambda function with an RDS DB instance:

- The Lambda function must exist in the same VPC as the DB instance.

- The user who sets up connectivity must have permissions to perform the following Amazon RDS, Amazon EC2, Lambda, Secrets Manager, and IAM operations:
  - Amazon RDS
    - `rds:CreateDBProxies`
    - `rds:DescribeDBInstances`
    - `rds:DescribeDBProxies`
    - `rds:ModifyDBInstance`
    - `rds:ModifyDBProxy`
    - `rds:RegisterProxyTargets`
  - Amazon EC2
    - `ec2:AuthorizeSecurityGroupEgress`
    - `ec2:AuthorizeSecurityGroupIngress`
    - `ec2:CreateSecurityGroup`
    - `ec2:DeleteSecurityGroup`
    - `ec2:DescribeSecurityGroups`
    - `ec2:RevokeSecurityGroupEgress`
    - `ec2:RevokeSecurityGroupIngress`
  - Lambda
    - `lambda:CreateFunctions`
    - `lambda:ListFunctions`
    - `lambda:UpdateFunctionConfiguration`
  - Secrets Manager
    - `secretsmanager:CreateSecret`
    - `secretsmanager:DescribeSecret`
  - IAM
    - `iam:AttachPolicy`
    - `iam:CreateRole`
    - `iam:CreatePolicy`
  - AWS KMS
    - `kms:describeKey`

> **Note**
>
> If the DB instance and Lambda function are in different Availability Zones, your account might incur cross-Availability Zone costs.

When you set up a connection between a Lambda function and an RDS database, Amazon RDS configures the VPC security group for your function and for your DB instance. If you use RDS Proxy, then Amazon RDS also configures the VPC security group for the proxy. Amazon RDS acts according to the current configuration of the security groups associated with the DB instance, Lambda function, and proxy, as described in the following table.

Current RDS security group configuration	Current Lambda security group configuration	Current proxy security group configuration	RDS action
There are one or more security groups associated with the DB instance with a name that matches the pattern `rds-lambda-` *n* or if a proxy is already connected to your DB instance, RDS checks if the `TargetHealth` of an associated proxy is `AVAILABLE` . Either of the following conditions apply: • There is no security group associated with the DB instance with a name that matches the pattern `rds-lambda-`*n* or if the `TargetHealth` of an associated proxy is `AVAILABLE`. • There are one or more security groups associated with the DB instance with a name that matches the pattern `rds-lambda-`*n* or if the `TargetHealth` of an associated proxy is `AVAILABLE`. However, Amazon RDS can't use any of these security groups for the connectio	Either of the following conditions apply: • There is no security group associated with the Lambda function with a name that matches the pattern `lambda-rds-`*n* or `lambda-rdsproxy-`*n*. • There are one or more security groups associated with the Lambda function with a name that matches the pattern `lambda-rds-`*n* or `lambda-rdsproxy-`*n*. However, Amazon RDS can't use any of these security groups for the connection with the DB instance. Amazon RDS can't use a security group	Either of the following conditions apply: • There is no security group associated with the proxy with a name that matches the pattern `rdsproxy-lambda-`*n*. • There are one or more security groups associated with the proxy with a name that matches `rdsproxy-lambda-`*n*. However, Amazon RDS can't use any of these security groups for the connection with the DB instance or Lambda function. Amazon RDS can't use a security group that doesn't have inbound and	RDS action: create new security groups

Current RDS security group configuration	Current Lambda security group configuration	Current proxy security group configuration	RDS action
n with the Lambda function or proxy. Amazon RDS can't use a security group that doesn't have one inbound rule with the VPC security group of the Lambda function or proxy as the source. Amazon RDS also can't use a security group that has been modified.	that doesn't have one outbound rule with the VPC security group of the DB instance or proxy as the source. Amazon RDS also can't use a security group that has been modified.	outbound rules with the VPC security group of the DB instance and the Lambda function. Amazon RDS also can't use a security group that has been modified.	

RDS action: create new security groups

Amazon RDS takes the following actions:

- Creates a new security group that matches the pattern `rds-lambda-`*n* or `rds-rdsproxy-`*n* (if you choose to use RDS Proxy). This security group has an inbound rule with the VPC security group of the Lambda function or proxy as the source. This security group is associated with the DB instance and allows the function or proxy to access the DB instance.
- Creates a new security group that matches the pattern `lambda-rds-`*n* or `lambda-rdsproxy-`*n*. This security group has an outbound rule with the VPC security group of the DB instance or proxy as the destination. This security group is associated with the Lambda function and allows the function to send traffic to the DB instance or send traffic through a proxy.
- Creates a new security group that matches the pattern `rdsproxy-lambda-`*n*. This security group has inbound and outbound rules with the VPC security group of the DB instance and the Lambda function.

RDS action: associate Lambda security group

Amazon RDS associates the valid, existing Lambda security group with the Lambda function. This security group allows the function to send traffic to the DB instance or send traffic through a proxy.

Automatically connecting a Lambda function and an RDS database

You can use the Amazon RDS console to automatically connect a Lambda function to your DB instance. This simplifies the process of setting up a connection between these resources.

You can also use RDS Proxy to include a proxy in your connection. Lambda functions make frequent short database connections that benefit from the connection pooling that RDS Proxy offers. You can also use any IAM authentication that you've already set up for your Lambda function, instead of managing database credentials in your Lambda application code.

You can connect an existing DB instance to new and existing Lambda functions using the **Set up Lambda connection** page. The setup process automatically sets up the required security groups for you.

Before setting up a connection between a Lambda function and a DB instance, make sure that:

- Your Lambda function and DB instance are in the same VPC.
- You have the right permissions for your user account. For more information about the requirements, see Overview of automatic connectivity with a Lambda function.

If you change security groups after you configure connectivity, the changes might affect the connection between the Lambda function and the DB instance.

> **Note**
>
> You can automatically set up a connection between a DB instance and a Lambda function only in the AWS Management Console. To connect a Lambda function, the DB instance must be in the **Available** state.

To automatically connect a Lambda function and a DB instance

<result>

After you confirm the setup, Amazon RDS begins the process of connecting your Lambda function, RDS Proxy (if you used a proxy), and DB instance. The console shows the **Connection details** dialog box, which lists the security group changes that allow connections between your resources.

</result>

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**, and then choose the DB instance that you want to connect to a Lambda function.
3. For **Actions**, choose **Set up Lambda connection**.
4. On the **Set up Lambda connection** page, under **Select Lambda function**, do either of the following:
   - If you have an existing Lambda function in the same VPC as your DB instance, choose **Choose existing function**, and then choose the function.
   - If you don't have a Lambda function in the same VPC, choose **Create new function**, and then enter a **Function name**. The default runtime is set to Nodejs.18. You can modify the settings for your new Lambda function in the Lambda console after you complete the connection setup.
5. (Optional) Under **RDS Proxy**, select **Connect using RDS Proxy**, and then do any of the following:
   - If you have an existing proxy that you want to use, choose **Choose existing proxy**, and then choose the proxy.
   - If you don't have a proxy, and you want Amazon RDS to automatically create one for you, choose **Create new proxy**. Then, for **Database credentials**, do either of the following:

     a. Choose **Database username and password**, and then enter the **Username** and **Password** for your DB instance.

     b. Choose **Secrets Manager secret**. Then, for **Select secret**, choose an AWS Secrets Manager secret. If you don't have a Secrets Manager secret, choose **Create new Secrets Manager secret** to create a new secret. After you create the secret, for **Select secret**, choose the new secret.

     After you create the new proxy, choose **Choose existing proxy**, and then choose the proxy. Note that it might take some time for your proxy to be available for connection.
6. (Optional) Expand **Connection summary** and verify the highlighted updates for your resources.
7. Choose **Set up**.

Viewing connected compute resources

You can use the AWS Management Console to view the Lambda functions that are connected to your DB instance. The resources shown include compute resource connections that Amazon RDS set up automatically.

The listed compute resources don't include those that are manually connected to the DB instance. For example, you can allow a compute resource to access your DB instance manually by adding a rule to your VPC security group associated with the database.

For the console to list a Lambda function, the following conditions must apply:

- The name of the security group associated with the compute resource matches the pattern `lambda-rds-`*n* or `lambda-rdsproxy-`*n* (where *n* is a number).
- The security group associated with the compute resource has an outbound rule with the port range set to the port of the DB instance or an associated proxy. The destination for the outbound rule must be set to a security group associated with the DB instance or an associated proxy.
- If the configuration includes a proxy, the name of the security group attached to the proxy associated with your database matches the pattern `rdsproxy-lambda-`*n* (where *n* is a number).
- The security group associated with the function has an outbound rule with the port set to the port that the DB instance or associated proxy uses. The destination must be set to a security group associated with the DB instance or associated proxy.

To view compute resources automatically connected to an DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**, and then choose the DB instance.
3. On the **Connectivity & security** tab, view the compute resources under **Connected compute resources**.

Modifying an Amazon RDS DB instance

You can change the settings of a DB instance to accomplish tasks such as adding additional storage or changing the DB instance class. In this topic, you can find out how to modify an Amazon RDS DB instance and learn about the settings for DB instances.

We recommend that you test any changes on a test instance before modifying a production instance. Doing this helps you to fully understand the impact of each change. Testing is especially important when upgrading database versions.

Most modifications to a DB instance you can either apply immediately or defer until the next maintenance window. Some modifications, such as parameter group changes, require that you manually reboot your DB instance for the change to take effect.

> **Important**
>
> Some modifications result in downtime because Amazon RDS must reboot your DB instance for the change to take effect. Review the impact to your database and applications before modifying your DB instance settings.

Console

To modify a DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**, and then choose the DB instance that you want to modify.
3. Choose **Modify**. The **Modify DB instance** page appears.
4. Change any of the settings that you want. For information about each setting, see Settings for DB instances.
5. When all the changes are as you want them, choose **Continue** and check the summary of modifications.
6. (Optional) Choose **Apply immediately** to apply the changes immediately. Choosing this option can cause downtime in some cases. For more information, see Schedule modifications setting.

7. On the confirmation page, review your changes. If they are correct, choose **Modify DB instance** to save your changes.

   Or choose **Back** to edit your changes or **Cancel** to cancel your changes.

AWS CLI

To modify a DB instance by using the AWS CLI, call the modify-db-instance command. Specify the DB instance identifier and the values for the options that you want to modify. For information about each option, see Settings for DB instances.

Example

The following code modifies `mydbinstance` by setting the backup retention period to 1 week (7 days). The code enables deletion protection by using `--deletion-protection`. To disable deletion protection, use `--no-deletion-protection`. The changes are applied during the next maintenance window by using `--no-apply-immediately`. Use `--apply-immediately` to apply the changes immediately. For more information, see Schedule modifications setting.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier mydbinstance \
    --backup-retention-period 7 \
    --deletion-protection \
    --no-apply-immediately
```

For Windows:

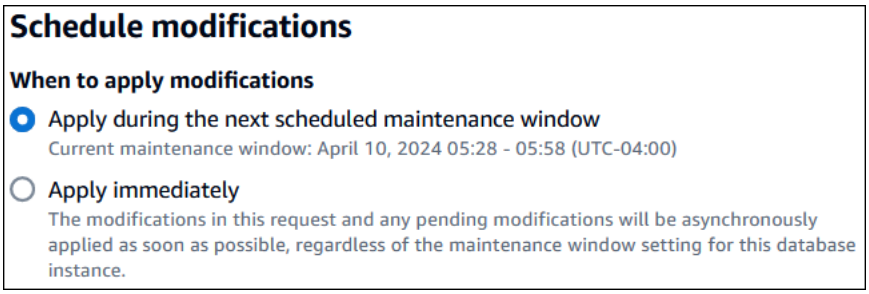
```
aws rds modify-db-instance ^
    --db-instance-identifier mydbinstance ^
    --backup-retention-period 7 ^
    --deletion-protection ^
    --no-apply-immediately
```

RDS API

To modify a DB instance by using the Amazon RDS API, call the ModifyDBInstance operation. Specify the DB instance identifier, and the parameters for the settings that you want to modify. For information about each parameter, see Settings for DB instances.

Schedule modifications setting

When you modify your DB instance, you decide when you want the modifications to occur.



To apply changes immediately rather than in the next maintenance window, choose the **Apply Immediately** option in the AWS Management Console. Or you use the `--apply-immediately` parameter when calling the AWS CLI or set the `ApplyImmediately` parameter to `true` when using the Amazon RDS API.

If you don't choose to apply changes immediately, RDS puts the changes into the pending modifications queue. During the next maintenance window, RDS applies any pending changes in the queue. If you choose to apply changes immediately, your new changes and any changes in the pending modifications queue are applied.

To see the modifications that are pending for the next maintenance window, use the describe-db-instances AWS CLI command and check the `PendingModifiedValues` field.

> **Important**
>
> If any of the pending modifications require the DB instance to be temporarily unavailable (*downtime*), choosing the apply immediately option can cause unexpected downtime. When you choose to apply a change immediately, any pending modifications are also applied immediately, instead of during the next maintenance window.
> If you don't want a pending change to be applied in the next maintenance window, you can modify the DB instance to revert the change. You can do this by using the AWS CLI and specifying the `--apply-immediately` option.

Changes to some database settings are applied immediately, even if you choose to defer your changes. To see how the different database settings interact with the apply immediately setting, see Settings for DB instances.

Settings for DB instances

In the following table, you can find details about which settings you can and can't modify. You can also find when changes can be applied and whether the changes cause downtime for your DB instance. By using Amazon RDS features such as Multi-AZ, you can minimize downtime if you later modify the DB instance. For more information, see Configuring and managing a Multi-AZ deployment.

You can modify a DB instance using the console, the `modify-db-instance` CLI command, or the `ModifyDBInstance` RDS API operation.

Console setting and description	CLI option and RDS API parameter	When the change occurs	Downtime notes	Supported DB engines

Allocated storage
 	
The storage, in gibibytes, that you want to allocate for your DB instance. You can only increase the allocated storage. You can't reduce the allocated storage.
 	
You can't modify the storage of some older DB instances, or DB instances restored from older DB snapshots. The **Allocated storage** setting is disabled in the console if your DB instance isn't eligible. You can check whether you can allocate more storage by using the CLI command describe-valid-db-instance-modifications. This command returns the valid storage options for your DB instance.
	CLI option:
	
	`--allocated-storage`
	
	RDS API parameter:
	
	`AllocatedStorage`
		If you choose to apply the change immediately, it occurs immediately.
		
		If you don't choose to apply the change immediately, it occurs during the next maintenance window.
			Downtime doesn't occur during this change. Performance might be degraded during the change.	All DB engines

Console setting and description	CLI option and RDS API parameter	When the change occurs	Downtime notes	Supported DB engines
You can't modify allocated storage if the DB instance status is **storage-optimization**. You also can't modify allocated storage for a DB instance if it's been modified in the last six hours. The maximum storage allowed depends on your DB engine and the storage type. For more information, see Amazon RDS DB instance storage.				

Console setting and description	CLI option and RDS API parameter	When the change occurs	Downtime notes	Supported DB engines
Architecture configuration A configuration that allows multiple tenant databases to reside in your DB instance. Currently, only RDS for Oracle container databases (CDBs) support this setting. If your CDB is in the single-tenant configuration, you can modify it to use the **Multi-tenant configuration**. In this configuration, you can use RDS APIs to create 1–30 tenant databases, depending on the database edition and any required option licenses. Application PDBs and proxy PDBs aren't supported. The multi-tenant configuration is permanent, which means that you can't later convert your CDB back to the single-tenant configuration. **Note** The Amazon RDS feature is called "multi-tenant" rather than "multitenant" because it is a capability of the RDS platform,	**CLI option:** `--multi-tenant` (multi-tenant configuration of the CDB architecture) `--no-multi-tenant` (single-tenant configuration of the CDB architecture) **API parameter:** `MultiTenant`	The change occurs immediately.	Downtime doesn't occur during this change.	Oracle

Console setting and description	CLI option and RDS API parameter	When the change occurs	Downtime notes	Supported DB engines
not just the Oracle DB engine. The term "Oracle multitenant" refers exclusively to the Oracle database architecture, which is compatible with both on-premises and RDS deployments. For more information, see Overview of RDS for Oracle CDBs.				

Console setting and description	CLI option and RDS API parameter	When the change occurs	Downtime notes	Supported DB engines
Architecture settings The architecture of the Oracle database: CDB or non-CDB. If you choose **Oracle multitenant architecture**, RDS for Oracle converts your non-CDB into a CDB that uses the single-tenant configuration. This setting is supported only if your database is a non-CDB running Oracle Database 19c with the April 2021 or higher RU. After conversion, your CDB contains one initial pluggable database (PDB). The architecture change is permanent, which means that you can't convert your CDB back to a non-CDB. **Note** To convert a CDB in the single-tenant configuration to the multi-tenant configuration, modify your CDB instance again and choose **Multi-tenant configuration** for your **Architecture configuration**.	**CLI option:** `--engine oracle-ee-cdb` (Oracle multitenant) `--engine oracle-se2-cdb` (Oracle multitenant) **API parameter:** `Engine`	If you choose to apply the change immediately, it occurs immediately. If you don't choose to apply the change immediately, it occurs during the next maintenance window.	Downtime occurs during this change.	Oracle

Console setting and description	CLI option and RDS API parameter	When the change occurs	Downtime notes	Supported DB engines
For more information, see Single-tenant configuration of the CDB architecture.				

Auto minor version upgrade
 	
Choose **Enable auto minor version upgrade** to enable your DB instance to receive preferred minor DB engine version upgrades automatically when they become available. This is the default behavior. Amazon RDS performs automatic minor version upgrades in the maintenance window. If you don't choose **Enable auto minor version upgrade**, your DB instance isn't upgraded automatically when new minor versions become available.
 	
For more information, see Automatically upgrading the minor engine version.
	CLI option:
	
	`--auto-minor-version-upgrade | --no-auto-minor-version-upgrade`
	
	RDS API parameter:
	
	`AutoMinorVersionUpgrade`
		The change occurs immediately. This setting ignores the apply immediately setting.	Downtime doesn't occur during this change.	All DB engines

Console setting and description	CLI option and RDS API parameter	When the change occurs	Downtime notes	Supported DB engines
Backup replication Choose **Enable replication to another AWS Region** to create backups in an additional Region for disaster recovery. Then choose the **Destination Region** for the additional backups.	Not available when modifying a DB instance. For information on enabling cross-Region backups using the AWS CLI or RDS API, see Enabling cross-Region automated backups.	The change is applied asynchronously, as soon as possible.	Downtime doesn't occur during this change.	Oracle, PostgreSQL, SQL Server

Console setting and description	CLI option and RDS API parameter	When the change occurs	Downtime notes	Supported DB engines

Backup retention period
 	
The number of days that automatic backups are retained. To disable automatic backups, set the backup retention period to 0.
 	
For more information, see Introduction to backups.
 	
Note
If you use AWS Backup to manage your backups, this option doesn't apply. For information about AWS Backup, see the *AWS Backup Developer Guide*.
	CLI option:
	
	`--backup-retention-period`
	
	RDS API parameter:
	
	`BackupRetentionPeriod`
		If you choose to apply the change immediately, it occurs immediately.
		
		If you don't choose to apply the change immediately, and you change the setting from a nonzero value to another nonzero value, the change is applied asynchronously, as soon as possible. Otherwise, the change occurs during the next maintenance window.
			Downtime occurs if you change from 0 to a nonzero value, or from a nonzero value to 0.
			
			This applies to both Single-AZ and Multi-AZ DB instances.
				All DB engines

Console setting and description	CLI option and RDS API parameter	When the change occurs	Downtime notes	Supported DB engines

Backup window
 	
The time range during which automated backups of your databases occur. The backup window is a start time in Universal Coordinated Time (UTC), and a duration in hours.
 	
For more information, see Introduction to backups.
 	
Note
If you use AWS Backup to manage your backups, this option doesn't appear. For information about AWS Backup, see the *AWS Backup Developer Guide*.
	CLI option:
	
	`--preferred-backup-window`
	
	RDS API parameter:
	
	`PreferredBackupWindow`
		The change is applied asynchronously, as soon as possible.	Downtime doesn't occur during this change.	All DB engines

Console setting and description	CLI option and RDS API parameter	When the change occurs	Downtime notes	Supported DB engines

Certificate authority
 	
The certificate authority (CA) for the server certificate used by the DB instance.
 	
For more information, see Using SSL/TLS to encrypt a connection to a DB instance or cluster.
	CLI option:
	
	`--ca-certificate-identifier`
	
	RDS API parameter:
	
	`CACertificateIdentifier`
		If you choose to apply the change immediately, it occurs immediately.
		
		If you don't choose to apply the change immediately, it occurs during the next maintenance window.
			Downtime only occurs if the DB engine doesn't support rotation without restart. You can use the describe-db-engine-versions AWS CLI command to determine whether the DB engine supports rotation without restart.	All DB engines

Console setting and description	CLI option and RDS API parameter	When the change occurs	Downtime notes	Supported DB engines

Copy tags to snapshots
 	
If you have any DB instance tags, enable this option to copy them when you create a DB snapshot.
 	
For more information, see Tagging Amazon RDS resources.
	CLI option:
	
	`--copy-tags-to-snapshot` or `--no-copy-tags-to-snapshot`
	
	RDS API parameter:
	
	`CopyTagsToSnapshot`
		The change occurs immediately. This setting ignores the apply immediately setting.	Downtime doesn't occur during this change.	All DB engines

Database port
 	
The port that you want to use to access the DB instance.
 	
The port value must not match any of the port values specified for options in the option group that is associated with the DB instance.
 	
For more information, see Connecting to an Amazon RDS DB instance.
	CLI option:
	
	`--db-port-number`
	
	RDS API parameter:
	
	`DBPortNumber`
		The change occurs immediately. This setting ignores the apply immediately setting.	The DB instance is rebooted immediately.	All DB engines

Console setting and description	CLI option and RDS API parameter	When the change occurs	Downtime notes	Supported DB engines

DB engine version
 	
The version of the DB engine that you want to use. Before you upgrade your production DB instance, we recommend that you test the upgrade process on a test DB instance. Doing this helps verify its duration and validate your applications.
 	
For more information, see Upgrading a DB instance engine version.
	CLI option:
	
	`--engine-version`
	
	RDS API parameter:
	
	`EngineVersion`
		If you choose to apply the change immediately, it occurs immediately.
		
		If you don't choose to apply the change immediately, it occurs during the next maintenance window.
			Downtime occurs during this change.	All DB engines

DB instance class
 	
The DB instance class that you want to use.
 	
For more information, see DB instance classes.
	CLI option:
	
	`--db-instance-class`
	
	RDS API parameter:
	
	`DBInstanceClass`
		If you choose to apply the change immediately, it occurs immediately.
		
		If you don't choose to apply the change immediately, it occurs during the next maintenance window.
			Downtime occurs during this change.	All DB engines

Console setting and description	CLI option and RDS API parameter	When the change occurs	Downtime notes	Supported DB engines

DB instance identifier
 	
The new DB instance identifier. This value is stored as a lowercase string.
 	
For more information about the effects of renaming a DB instance, see Renaming a DB instance.
	CLI option:
	
	`--new-db-instance-identifier`
	
	RDS API parameter:
	
	`NewDBInstanceIdentifier`
		If you choose to apply the change immediately, it occurs immediately.
		
		If you don't choose to apply the change immediately, it occurs during the next maintenance window.
			Downtime occurs during this change unless your DB engine version supports dynamic SSL upload. To determine whether your version requires a restart, run the following AWS CLI command:
			
			`aws rds describe-db-engine-versions \ --default-only \ --engine your-db-engine \ --query 'DBEngineVersions[*].SupportsCertificateRotationWithoutRestart'`
				All DB engines

Console setting and description	CLI option and RDS API parameter	When the change occurs	Downtime notes	Supported DB engines

DB parameter group
 	
The DB parameter group that you want associated with the DB instance.
 	
For more information, see Parameter groups for Amazon RDS.
	CLI option:
	
	`--db-parameter-group-name`
	
	RDS API parameter:
	
	`DBParameterGroupName`
		The association of the new DB parameter group with the DB instance occurs immediately.	Downtime doesn't occur when you associate a new DB parameter group with your DB instance.
			
			The association of a DB parameter group is different from the application of parameter changes within a parameter group. RDS applies modified static and dynamic parameter settings in the newly associated group only after you manually reboot the DB instance. However, if
				All DB engines

Console setting and description	CLI option and RDS API parameter	When the change occurs	Downtime notes	Supported DB engines
			you modify dynamic parameters in the DB parameter group after you associate it with the DB instance, these parameter settings are applied immediately without requiring a reboot. For more information, see Parameter groups for Amazon RDS and Rebooting a DB instance.	

Console setting and description	CLI option and RDS API parameter	When the change occurs	Downtime notes	Supported DB engines

Dedicated Log Volume
 	
Use a dedicated log volume (DLV) to store database transaction logs on a storage volume that's separate from the volume containing the database tables.
 	
For more information, see Using a dedicated log volume (DLV).
	CLI option:
	
	`-dedicated-log-volume`
	
	RDS API parameter:
	
	`DedicatedLogVolume`
		The change is applied when the DB instance is rebooted.	Downtime occurs while the DB instance is rebooted.	MariaDB, MySQL, PostgreSQL

Deletion protection
 	
Enable deletion protection to prevent your DB instance from being deleted.
 	
For more information, see Deleting a DB instance.
	CLI option:
	
	`--deletion-protection|--no-deletion-protection`
	
	RDS API parameter:
	
	`DeletionProtection`
		The change occurs immediately. This setting ignores the apply immediately setting.	Downtime doesn't occur during this change.	All DB engines

Console setting and description	CLI option and RDS API parameter	When the change occurs	Downtime notes	Supported DB engines

Enhanced Monitoring
 	
Enable Enhanced Monitoring to enable gathering metrics in real time for the operating system that your DB instance runs on.
 	
For more information, see Monitoring OS metrics with Enhanced Monitoring.
	CLI option:
	
	`--monitoring-interval` and `--monitoring-role-arn`
	
	RDS API parameter:
	
	`MonitoringInterval` and `MonitoringRoleArn`
		The change occurs immediately. This setting ignores the apply immediately setting.	Downtime doesn't occur during this change.	All DB engines

Console setting and description	CLI option and RDS API parameter	When the change occurs	Downtime notes	Supported DB engines

IAM DB authentication
 	
Enable IAM DB authentication to authenticate database users through users and roles.
 	
For more information, see IAM database authentication for MariaDB, MySQL, and PostgreSQL.
	CLI option:
	
	`--enable-iam-database-authentication|--no-enable-iam-database-authentication`
	
	RDS API parameter:
	
	`EnableIAMDatabaseAuthentication`
		If you choose to apply the change immediately, it occurs immediately.
		
		If you don't choose to apply the change immediately, it occurs during the next maintenance window.
			Downtime doesn't occur during this change.	Only MariaDB, MySQL, and PostgreSQL

Console setting and description	CLI option and RDS API parameter	When the change occurs	Downtime notes	Supported DB engines

Kerberos authentication
 	
Choose the Active Directory to move the DB instance to. The directory must exist prior to this operation. If a directory is already selected, you can specify **None** to remove the DB instance from its current directory.
 	
For more information, see Kerberos authentication.
	CLI option:
	
	`--domain` and `--domain-iam-role-name`
	
	RDS API parameter:
	
	`Domain` and `DomainIAMRoleName`
		If you choose to apply the change immediately, it occurs immediately.
		
		If you don't choose to apply the change immediately, it occurs during the next maintenance window.
			A brief downtime occurs during this change.	Only Microsoft SQL Server, MySQL, Oracle, and PostgreSQL

License model
 	
Choose **bring-your-own-license** to use your license for Db2 and Oracle.
 	
Choose **license-included** to use the general license agreement for Microsoft SQL Server or Oracle.
 	
For more information, see Amazon RDS for Db2 licensing options, Licensing Microsoft SQL Server on Amazon RDS, and RDS for Oracle licensing options.
	CLI option:
	
	`--license-model`
	
	RDS API parameter:
	
	`LicenseModel`
		If you choose to apply the change immediately, it occurs immediately.
		
		If you don't choose to apply the change immediately, it occurs during the next maintenance window.
			Downtime occurs during this change.	Only Microsoft SQL Server and Oracle

Console setting and description	CLI option and RDS API parameter	When the change occurs	Downtime notes	Supported DB engines

Log exports
 	
The types of database log files to publish to Amazon CloudWatch Logs.
 	
For more information, see Publishing database logs to Amazon CloudWatch Logs.
	CLI option:
	
	`--cloudwatch-logs-export-configuration`
	
	RDS API parameter:
	
	`CloudwatchLogsExportConfiguration`
		The change occurs immediately. This setting ignores the apply immediately setting.	Downtime doesn't occur during this change.	All DB engines

Console setting and description	CLI option and RDS API parameter	When the change occurs	Downtime notes	Supported DB engines

Maintenance window
 	
The time range during which system maintenance occurs. System maintenance includes upgrades, if applicable. The maintenance window is a start time in Universal Coordinated Time (UTC), and a duration in hours.
 	
If you set the window to the current time, there must be at least 30 minutes between the current time and the end of the window. This timing helps ensure that any pending changes are applied.
 	
For more information, see The Amazon RDS maintenance window.
	CLI option:
	
	`--preferred-maintenance-window`
	
	RDS API parameter:
	
	`PreferredMaintenanceWindow`
		The change occurs immediately. This setting ignores the apply immediately setting.	If there are one or more pending actions that cause downtime, and the maintenance window is changed to include the current time, those pending actions are applied immediately and downtime occurs.	All DB engines

Console setting and description	CLI option and RDS API parameter	When the change occurs	Downtime notes	Supported DB engines

Manage master credentials in AWS Secrets Manager
 	
Select **Manage master credentials in AWS Secrets Manager** to manage the master user password in a secret in Secrets Manager.
 	
Optionally, choose a KMS key to use to protect the secret. Choose from the KMS keys in your account, or enter the key from a different account.
 	
If RDS is already managing the master user password for the DB instance, you can rotate the master user password by choosing **Rotate secret immediately**.
 	
For more information, see Password management with Amazon RDS and AWS Secrets Manager.
	CLI option:
	
	`--manage-master-user-password | --no-manage-master-user-password`
	
	`--master-user-secret-kms-key-id`
	
	`--rotate-master-user-password | --no-rotate-master-user-password`
	
	RDS API parameter:
	
	`ManageMasterUserPassword`
		If you are turning on or turning off automatic master user password management, the change occurs immediately. This change ignores the apply immediately setting.
		
		If you are rotating the master user password, you must specify that the change is applied immediately.
			Downtime doesn't occur during this change.	All DB engines

Console setting and description	CLI option and RDS API parameter	When the change occurs	Downtime notes	Supported DB engines

	`MasterUserSecretKmsKeyId`
	
	`RotateMasterUserPassword`			

Multi-AZ deployment
 	
Yes to deploy your DB instance in multiple Availability Zones. Otherwise, **No**.
 	
For more information, see Configuring and managing a Multi-AZ deployment.
	CLI option:
	
	`--multi-az|--no-multi-az`
	
	RDS API parameter:
	
	`MultiAZ`
		If you choose to apply the change immediately, it occurs immediately.
		
		If you don't choose to apply the change immediately, it occurs during the next maintenance window.
			Downtime doesn't occur during this change. However, there is a possible performance impact. For more information, see Modifying a DB instance to be a Multi-AZ DB instance deployment.	All DB engines

Console setting and description	CLI option and RDS API parameter	When the change occurs	Downtime notes	Supported DB engines

Network type
 	
The IP addressing protocols supported by the DB instance.
 	
IPv4 to specify that resources can communicate with the DB instance only over the Internet Protocol version 4 (IPv4) addressing protocol.
 	
Dual-stack mode to specify that resources can communicate with the DB instance over IPv4, Internet Protocol version 6 (IPv6), or both. Use dual-stack mode if you have any resources that must communicate with your DB instance over the IPv6 addressing protocol. Also, make sure that you associate an IPv6 CIDR block with all subnets in the DB subnet group that you specify.
 	
For more information, see Amazon RDS IP addressing.
	CLI option:
	
	`--network-type`
	
	RDS API parameter:
	
	`NetworkType`
		If you choose to apply the change immediately, it occurs immediately.
		
		If you don't choose to apply the change immediately, it occurs during the next maintenance window.
			Downtime is possible during this change.	All DB engines

Console setting and description	CLI option and RDS API parameter	When the change occurs	Downtime notes	Supported DB engines

New master password
 	
The password for your master user. The password must contain 8–41 alphanumeric characters.
	CLI option:
	
	`--master-user-password`
	
	RDS API parameter:
	
	`MasterUserPassword`
		The change is applied asynchronously, as soon as possible. This setting ignores the apply immediately setting.	Downtime doesn't occur during this change.	All DB engines

Option group
 	
The option group that you want associated with the DB instance.
 	
For more information, see Working with option groups.
	CLI option:
	
	`--option-group-name`
	
	RDS API parameter:
	
	`OptionGroupName`
		If you choose to apply the change immediately, it occurs immediately.
		
		If you don't choose to apply the change immediately, it occurs during the next maintenance window.
			Downtime doesn't occur during this change. One exception is adding the MariaDB Audit Plugin to an RDS for MariaDB or RDS for MySQL DB instance, which might cause an outage.	All DB engines

Console setting and description	CLI option and RDS API parameter	When the change occurs	Downtime notes	Supported DB engines

Performance Insights
 	
Enable Performance Insights to monitor your DB instance load so that you can analyze and troubleshoot your database performance.
 	
Performance Insights isn't available for some DB engine versions and DB instance classes. The **Performance Insights** section doesn't appear in the console if it isn't available for your DB instance.
 	
For more information, see Monitoring DB load with Performance Insights on Amazon RDS and Amazon RDS DB engine, Region, and instance class support for Performance Insights.
	CLI option:
	
	`--enable-performance-insights| --no-enable-performance-insights`
	
	RDS API parameter:
	
	`EnablePerformanceInsights`
		The change occurs immediately. This setting ignores the apply immediately setting.	Downtime doesn't occur during this change.	All except Db2

Console setting and description	CLI option and RDS API parameter	When the change occurs	Downtime notes	Supported DB engines

Performance Insights AWS KMS key
 	
The AWS KMS key identifier for the AWS KMS key for encryption of Performance Insights data. The key identifier is the Amazon Resource Name (ARN), AWS KMS key identifier, or the key alias for the KMS key.
 	
For more information, see Turning Performance Insights on and off for Amazon RDS.
	CLI option:
	
	`--performance-insights-kms-key-id`
	
	RDS API parameter:
	
	`PerformanceInsightsKMSKeyId`
		The change occurs immediately. This setting ignores the apply immediately setting.	Downtime doesn't occur during this change.	All except Db2

Performance Insights Retention period
 	
The amount of time, in days, to retain Performance Insights data. The retention setting in the free tier is **Default (7 days)**. To retain your performance data for longer, specify 1–24 months. For more information about retention periods, see Pricing and data retention for Performance Insights.
 	
For more information, see Turning Performance Insights on and off for Amazon RDS.
	CLI option:
	
	`--performance-insights-retention-period`
	
	RDS API parameter:
	
	`PerformanceInsightsRetentionPeriod`
		The change occurs immediately. This setting ignores the apply immediately setting.	Downtime doesn't occur during this change.	All except Db2

Console setting and description	CLI option and RDS API parameter	When the change occurs	Downtime notes	Supported DB engines

Processor features
 	
The number of CPU cores and the number of threads per core for the DB instance class of the DB instance.
 	
For more information, see Configuring the processor for a DB instance class in RDS for Oracle.
	CLI option:
	
	`--processor-features` and `--use-default-processor-features` | `--no-use-default-processor-features`
	
	RDS API parameter:
	
	`ProcessorFeatures` and `UseDefaultProcessorFeatures`
		If you choose to apply the change immediately, it occurs immediately.
		
		If you don't choose to apply the change immediately, it occurs during the next maintenance window.
			Downtime occurs during this change.	Only Oracle

Console setting and description	CLI option and RDS API parameter	When the change occurs	Downtime notes	Supported DB engines

Provisioned IOPS
 	
The Provisioned IOPS (I/O operations per second) value for the DB instance. This setting is available only if you choose one of the following for **Storage type**:
 	
• **General purpose SSD (gp3)**
• **Provisioned IOPS SSD (io1)**
• **Provisioned IOPS SSD (io2)**
 	
For more information, see the section called “Provisioned IOPS storage” and the section called “gp3 storage (recommended)”.
	CLI option:
	
	`--iops`
	
	RDS API parameter:
	
	`Iops`
		If you choose to apply the change immediately, it occurs immediately.
		
		If you don't choose to apply the change immediately, it occurs during the next maintenance window.
			Downtime doesn't occur during this change.	All DB engines

Console setting and description	CLI option and RDS API parameter	When the change occurs	Downtime notes	Supported DB engines

Public access
 	
Publicly accessible to give the DB instance a public IP address, meaning that it's accessible outside the VPC. To be publicly accessible, the DB instance also has to be in a public subnet in the VPC.
 	
Not publicly accessible to make the DB instance accessible only from inside the VPC.
 	
For more information, see Hiding a DB instance in a VPC from the internet.
 	
To connect to a DB instance from outside its VPC, the DB instance must be publicly accessible. Also, access must be granted using the inbound rules of the DB instance's security group. In addition, other requirements must be met. For more information, see Can't connect to Amazon RDS DB instance.
 	
If your DB instance isn't publicly accessible, you can also use an AWS Site-to-Site VPN connection or an AWS Direct Connect connection to access it from
	CLI option:
	
	`--publicly-accessible | --no-publicly-accessible`
	
	RDS API parameter:
	
	`PubliclyAccessible`
		The change occurs immediately. This setting ignores the apply immediately setting.	Downtime doesn't occur during this change.	All DB engines

Console setting and description	CLI option and RDS API parameter	When the change occurs	Downtime notes	Supported DB engines
a private network. For more information, see Internetwork traffic privacy.				

Security group
 	
The VPC security group that you want associated with the DB instance.
 	
For more information, see Controlling access with security groups.
	CLI option:
	
	`--vpc-security-group-ids`
	
	RDS API parameter:
	
	`VpcSecurityGroupIds`
		The change is applied asynchronously, as soon as possible. This setting ignores the apply immediately setting.	Downtime doesn't occur during this change.	All DB engines

Console setting and description	CLI option and RDS API parameter	When the change occurs	Downtime notes	Supported DB engines

Storage autoscaling
 	
Enable storage autoscaling to enable Amazon RDS to automatically increase storage when needed to avoid having your DB instance run out of storage space.
 	
Use **Maximum storage threshold** to set the upper limit for Amazon RDS to automatic ally increase storage for your DB instance. The default is 1,000 GiB.
 	
For more information, see Managing capacity automatic ally with Amazon RDS storage autoscaling.
	CLI option:
	
	`--max-all ocated-st orage`
	
	RDS API parameter:
	
	`MaxAlloca tedStorag e`
		The change occurs immediately. This setting ignores the apply immediately setting.	Downtime doesn't occur during this change.	All DB engines

Console setting and description	CLI option and RDS API parameter	When the change occurs	Downtime notes	Supported DB engines

Storage throughput
 	
The new storage throughput value for the DB instance. This setting is available only if you choose **General purpose SSD (gp3)** for **Storage type**.
 	
For more information, see the section called “gp3 storage (recommended)”.
	CLI option:
	
	`--storage-throughput`
	
	RDS API parameter:
	
	`StorageThroughput`
		If you choose to apply the change immediately, it occurs immediately.
		
		If you don't choose to apply the change immediately, it occurs during the next maintenance window.
			Downtime doesn't occur during this change.	All DB engines

Console setting and description	CLI option and RDS API parameter	When the change occurs	Downtime notes	Supported DB engines

Storage type
 	
The storage type that you want to use.
 	
If you choose **General Purpose SSD (gp3)**, you can provision additional **Provisioned IOPS** and **Storage throughput** under **Advanced settings**.
 	
If you choose **Provisioned IOPS SSD (io1)** or **Provisioned IOPS SSD (io2)**, enter the **Provisioned IOPS** value.
 	
After Amazon RDS begins to modify your DB instance to change the storage size or type, you can't submit another request to change the storage size, performance, or type for six hours.
 	
For more information, see Amazon RDS storage types.
	CLI option:
	
	`--storage-type`
	
	RDS API parameter:
	
	`StorageType`
		If you choose to apply the change immediately, it occurs immediately.
		
		If you don't choose to apply the change immediately, it occurs during the next maintenance window.
			The following changes all result in a brief downtime while the process starts. After that, you can use your database normally while the change takes place.
			
			• From **General Purpose (SSD)** or **Provisioned IOPS (SSD)** to **Magnetic**.
			• From **Magnetic** to **General Purpose (SSD)** or **Provisioned IOPS (SSD)**.
				All DB engines

Console setting and description	CLI option and RDS API parameter	When the change occurs	Downtime notes	Supported DB engines

DB subnet group
 	
The DB subnet group for the DB instance. You can use this setting to move your DB instance to a different VPC.
 	
For more information, see Amazon VPC and Amazon RDS.
	CLI option:
	
	`--db-subnet-group-name`
	
	RDS API parameter:
	
	`DBSubnetGroupName`
		If you choose to apply the change immediately, it occurs immediately.
		
		If you don't choose to apply the change immediately, it occurs during the next maintenance window.
			Downtime occurs during this change.	All DB engines

Maintaining a DB instance

Periodically, Amazon RDS performs maintenance on Amazon RDS resources.

Topics

Overview of DB instance maintenance updates

Maintenance most often involves updates to the following resources in your DB instance:

- Underlying hardware
- Underlying operating system (OS)
- Database engine version

Updates to the operating system most often occur for security issues. We recommend that you do them as soon as possible. For more information about operating system updates, see Applying updates for a DB instance.

Topics

Offline resources during maintenance updates

Some maintenance items require that Amazon RDS take your DB instance offline for a short time. Maintenance items that require a resource to be offline include required operating system or

database patching. Required patching is automatically scheduled only for patches that are related to security and instance reliability. Such patching occurs infrequently, typically once every few months. It seldom requires more than a fraction of your maintenance window.

Deferred DB instance modifications

Deferred DB instance modifications that you have chosen not to apply immediately are applied during the maintenance window. For example, you might choose to change the DB instance class or parameter group during the maintenance window. Such modifications that you specify using the **pending reboot** setting don't show up in the **Pending maintenance** list. For information about modifying a DB instance, see Modifying an Amazon RDS DB instance.

To see the modifications that are pending for the next maintenance window, use the describe-db-instances AWS CLI command and check the `PendingModifiedValues` field.

Eventual consistency for the DescribePendingMaintenanceActions API

The Amazon RDS `DescribePendingMaintenanceActions` API follows an eventual consistency model. This means that the result of the `DescribePendingMaintenanceActions` command might not be immediately visible to all subsequent RDS commands. Keep this in mind when you use `DescribePendingMaintenanceActions` immediately after using a previous API command.

Eventual consistency can affect the way you managed your maintenance updates.
For example, if you run the `ApplyPendingMaintenanceActions` command
to update the database engine version for a DB instance, it will eventually
be visible to `DescribePendingMaintenanceActions`. In this scenario,
`DescribePendingMaintenanceActions` might show that the maintenance action wasn't applied even though it was.

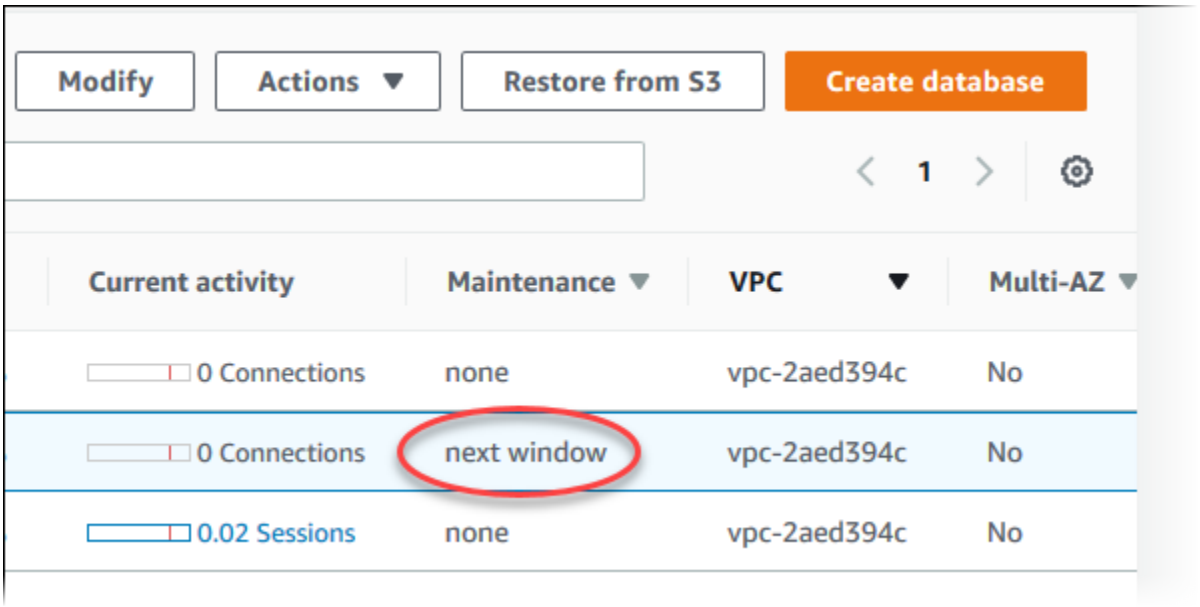
To manage eventual consistency, you can do the following:

- Confirm the state of your DB instance before you run a command to modify it. Run the appropriate `DescribePendingMaintenanceActions` command using an exponential backoff algorithm to ensure that you allow enough time for the previous command to propagate through the system. To do this, run the `DescribePendingMaintenanceActions` command repeatedly, starting with a couple of seconds of wait time, and increasing gradually up to five minutes of wait time.
- Add wait time between subsequent commands, even if a `DescribePendingMaintenanceActions` command returns an accurate response. Apply

an exponential backoff algorithm starting with a couple of seconds of wait time, and increase gradually up to about five minutes of wait time.

Viewing pending maintenance updates

View whether a maintenance update is available for your DB instance by using the RDS console, the AWS CLI, or the RDS API. If an update is available, it is indicated in the **Maintenance** column for the DB instance on the Amazon RDS console, as shown following.



If no maintenance update is available for a DB instance, the column value is **none** for it.

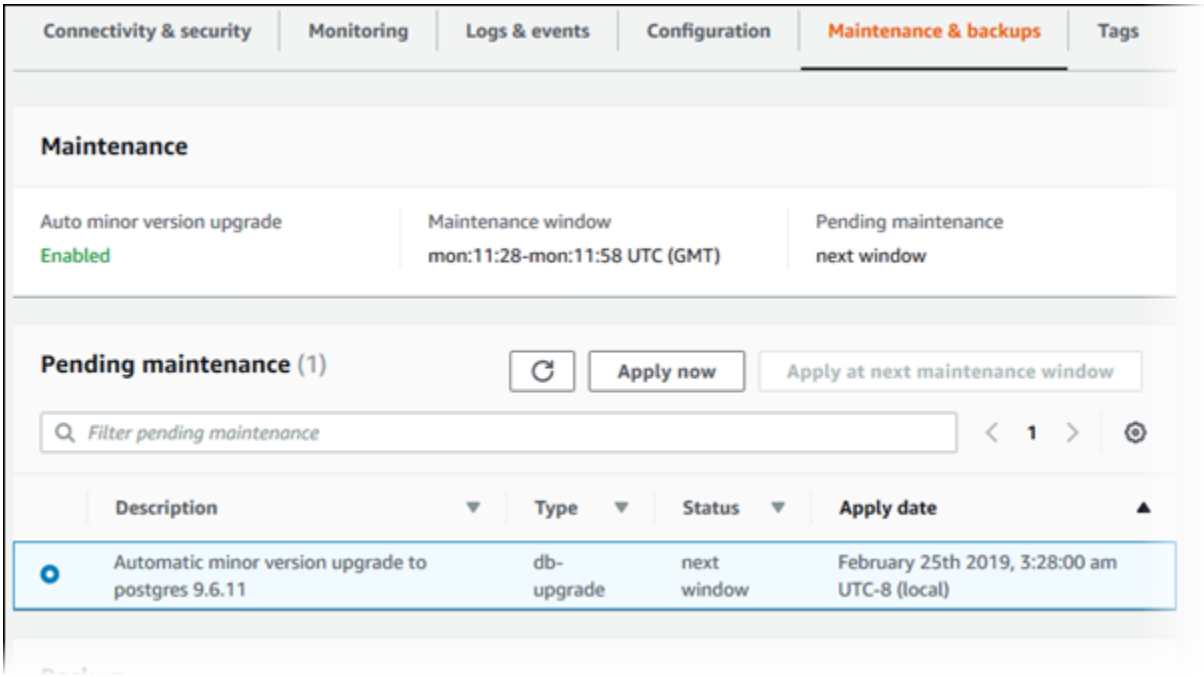
If a maintenance update is available for a DB instance, the following column values are possible:

- **required** – The maintenance action will be applied to the resource and can't be deferred indefinitely.
- **available** – The maintenance action is available, but it will not be applied to the resource automatically. You can apply it manually.
- **next window** – The maintenance action will be applied to the resource during the next maintenance window.
- **In progress** – The maintenance action is in the process of being applied to the resource.

If an update is available, you can take one of the actions:

- If the maintenance value is **next window**, defer the maintenance items by choosing **Defer upgrade** from **Actions**. You can't defer a maintenance action if it has already started.
- Apply the maintenance items immediately.
- Schedule the maintenance items to start during your next maintenance window.
- Take no action.

To take an action, choose the DB instance to show its details, then choose **Maintenance & backups**. The pending maintenance items appear.



The maintenance window determines when pending operations start, but doesn't limit the total run time of these operations. Maintenance operations aren't guaranteed to finish before the maintenance window ends, and can continue beyond the specified end time. For more information, see The Amazon RDS maintenance window.

You can also view whether a maintenance update is available for your DB instance by running the `describe-pending-maintenance-actions` AWS CLI command.

For information about applying maintenance updates, see Applying updates for a DB instance.

Applying updates for a DB instance

With Amazon RDS, you can choose when to apply maintenance operations. You can decide when Amazon RDS applies updates by using the RDS console, AWS Command Line Interface (AWS CLI), or RDS API.

> **Note**
>
> For RDS for SQL Server, an update to the underlying operating system can be applied by stopping and starting your DB instance, or by scaling your DB instance class up and then down again.

Console

To manage an update for a DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.
3. Choose the DB instance that has a required update.
4. For **Actions**, choose one of the following:

   - **Upgrade now**
   - **Upgrade at next window**

   > **Note**
   >
   > If you choose **Upgrade at next window** and later want to delay the update, you can choose **Defer upgrade**. You can't defer a maintenance action if it has already started. To cancel a maintenance action, modify the DB instance and disable **Auto minor version upgrade**.

AWS CLI

To apply a pending update to a DB instance, use the apply-pending-maintenance-action AWS CLI command.

Example

For Linux, macOS, or Unix:

```
aws rds apply-pending-maintenance-action \
    --resource-identifier arn:aws:rds:us-west-2:001234567890:db:mysql-db \
    --apply-action system-update \
    --opt-in-type immediate
```

For Windows:

```
aws rds apply-pending-maintenance-action ^
    --resource-identifier arn:aws:rds:us-west-2:001234567890:db:mysql-db ^
    --apply-action system-update ^
    --opt-in-type immediate
```

> **Note**
>
> To defer a maintenance action, specify `undo-opt-in` for `--opt-in-type`. You can't specify `undo-opt-in` for `--opt-in-type` if the maintenance action has already started. To cancel a maintenance action, run the modify-db-instance AWS CLI command and specify `--no-auto-minor-version-upgrade`.

To return a list of resources that have at least one pending update, use the describe-pending-maintenance-actions AWS CLI command.

Example

For Linux, macOS, or Unix:

```
aws rds describe-pending-maintenance-actions \
    --resource-identifier arn:aws:rds:us-west-2:001234567890:db:mysql-db
```

For Windows:

```
aws rds describe-pending-maintenance-actions ^
    --resource-identifier arn:aws:rds:us-west-2:001234567890:db:mysql-db
```

You can also return a list of resources for a DB instance by specifying the `--filters` parameter of the `describe-pending-maintenance-actions` AWS CLI command. The format for the `--filters` command is `Name=`*`filter-name`*`,Value=`*`resource-id`*`,...`.

The following are the accepted values for the `Name` parameter of a filter:

- `db-instance-id` – Accepts a list of DB instance identifiers or Amazon Resource Names (ARNs). The returned list only includes pending maintenance actions for the DB instances identified by these identifiers or ARNs.
- `db-cluster-id` – Accepts a list of DB cluster identifiers or ARNs for Amazon Aurora. The returned list only includes pending maintenance actions for the DB clusters identified by these identifiers or ARNs.

For example, the following example returns the pending maintenance actions for the `sample-instance1` and `sample-instance2` DB instances.

Example

For Linux, macOS, or Unix:

```
aws rds describe-pending-maintenance-actions \
 --filters Name=db-instance-id,Values=sample-instance1,sample-instance2
```

For Windows:

```
aws rds describe-pending-maintenance-actions ^
 --filters Name=db-instance-id,Values=sample-instance1,sample-instance2
```

RDS API

To apply an update to a DB instance, call the Amazon RDS API `ApplyPendingMaintenanceAction` operation.

To return a list of resources that have at least one pending update, call the Amazon RDS API `DescribePendingMaintenanceActions` operation.

Maintenance for Multi-AZ deployments

Running a DB instance as a Multi-AZ deployment can further reduce the impact of a maintenance event. This result is because Amazon RDS applies operating system updates by following these steps:

1. Perform maintenance on the standby.
2. Promote the standby to primary.
3. Perform maintenance on the old primary, which becomes the new standby.

If you upgrade the database engine for your DB instance in a Multi-AZ deployment, Amazon RDS modifies both primary and secondary DB instances at the same time. In this case, both the primary and secondary DB instances in the Multi-AZ deployment are unavailable during the upgrade. This operation causes downtime until the upgrade is complete. The duration of the downtime varies based on the size of your DB instance.

If there are underlying operating system patches that need to be applied, a short Multi-AZ failover is required to apply the patches to the primary DB instance. This failover typically lasts less than a minute.

If your DB instance runs RDS for MySQL, RDS for PostgreSQL, or RDS for MariaDB, you can minimize the downtime required for an upgrade by using a blue/green deployment. For more information, see Using Amazon RDS Blue/Green Deployments for database updates. If you upgrade an RDS for SQL Server or RDS Custom for SQL Server DB instance in a Multi-AZ deployment, then Amazon RDS performs rolling upgrades, so you have an outage only for the duration of a failover. For more information, see Multi-AZ and in-memory optimization considerations.

If your DB instance runs RDS for SQL Server in a Multi-AZ deployment, you can apply an update to the underlying operating system by using one of the following methods:

- Modify the DB instance class to a different size and then modify it back to the original size.
- Scale up the DB instance size and the scale back down to the original size.
- Modify the DB instance from Multi-AZ to Single-AZ, stop and start the DB instance, and then change the instance back to Multi-AZ.

For more information about Multi-AZ deployments, see Configuring and managing a Multi-AZ deployment.

The Amazon RDS maintenance window

The *maintenance windows* is a weekly time interval during which any system changes are applied. Every DB instance has a weekly maintenance window. The maintenance window is an opportunity to control when modifications and software patching occur. For more information about adjusting the maintenance window, see Adjusting the preferred DB instance maintenance window.

RDS consumes some of the resources on your DB instance while maintenance is being applied. You might observe a minimal effect on performance. For a DB instance, on rare occasions, a Multi-AZ failover might be required for a maintenance update to complete.

If a maintenance event is scheduled for a given week, it's initiated during the 30-minute maintenance window you identify. Most maintenance events also complete during the 30-minute maintenance window, although larger maintenance events may take more than 30 minutes to complete. The maintenance window is paused when the DB instance is stopped.

The 30-minute maintenance window is selected at random from an 8-hour block of time per region. If you don't specify a maintenance window when you create the DB instance, RDS assigns a 30-minute maintenance window on a randomly selected day of the week.

Following, you can find the time blocks for each region from which default maintenance windows are assigned.

Region Name	Region	Time Block
US East (N. Virginia)	us-east-1	03:00–11:00 UTC
US East (Ohio)	us-east-2	03:00–11:00 UTC
US West (N. Californi a)	us-west-1	06:00–14:00 UTC
US West (Oregon)	us-west-2	06:00–14:00 UTC
Africa (Cape Town)	af-south-1	03:00–11:00 UTC
Asia Pacific (Hong Kong)	ap-east-1	06:00–14:00 UTC

Region Name	Region	Time Block
Asia Pacific (Hyderabad)	ap-south-2	06:30–14:30 UTC
Asia Pacific (Jakarta)	ap-southeast-3	08:00–16:00 UTC
Asia Pacific (Malaysia)	ap-southeast-5	09:00–17:00 UTC
Asia Pacific (Melbourne)	ap-southeast-4	11:00–19:00 UTC
Asia Pacific (Mumbai)	ap-south-1	06:00–14:00 UTC
Asia Pacific (Osaka)	ap-northeast-3	22:00–23:59 UTC
Asia Pacific (Seoul)	ap-northeast-2	13:00–21:00 UTC
Asia Pacific (Singapore)	ap-southeast-1	14:00–22:00 UTC
Asia Pacific (Sydney)	ap-southeast-2	12:00–20:00 UTC
Asia Pacific (Tokyo)	ap-northeast-1	13:00–21:00 UTC
Canada (Central)	ca-central-1	03:00–11:00 UTC
Canada West (Calgary)	ca-west-1	18:00–02:00 UTC
China (Beijing)	cn-north-1	06:00–14:00 UTC
China (Ningxia)	cn-northwest-1	06:00–14:00 UTC
Europe (Frankfurt)	eu-central-1	21:00–05:00 UTC
Europe (Ireland)	eu-west-1	22:00–06:00 UTC
Europe (London)	eu-west-2	22:00–06:00 UTC

Region Name	Region	Time Block
Europe (Milan)	eu-south-1	02:00–10:00 UTC
Europe (Paris)	eu-west-3	23:59–07:29 UTC
Europe (Spain)	eu-south-2	02:00–10:00 UTC
Europe (Stockholm)	eu-north-1	23:00–07:00 UTC
Europe (Zurich)	eu-central-2	02:00–10:00 UTC
Israel (Tel Aviv)	il-central-1	03:00–11:00 UTC
Middle East (Bahrain)	me-south-1	06:00–14:00 UTC
Middle East (UAE)	me-central-1	05:00–13:00 UTC
South America (São Paulo)	sa-east-1	00:00–08:00 UTC
AWS GovCloud (US-East)	us-gov-east-1	17:00–01:00 UTC
AWS GovCloud (US-West)	us-gov-west-1	06:00–14:00 UTC

Adjusting the preferred DB instance maintenance window

The maintenance window should fall at the time of lowest usage and thus might need modification from time to time. Your DB instance is unavailable during this time only if the system changes, such as a change in DB instance class, are being applied and require an outage. Your DB instance is unavailable only for the minimum amount of time required to make the necessary changes.

In the following example, you adjust the preferred maintenance window for a DB instance.

For this example, we assume that a DB instance named *mydbinstance* exists and has a preferred maintenance window of "Sun:05:00-Sun:06:00" UTC.

Console

To adjust the preferred maintenance window

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**, and then select the DB instance that you want to modify.
3. Choose **Modify**. The **Modify DB instance** page appears.
4. In the **Maintenance** section, update the maintenance window.

   > **Note**
   >
   > The maintenance window and the backup window for the DB instance cannot overlap. If you enter a value for the maintenance window that overlaps the backup window, an error message appears.

5. Choose **Continue**.

   On the confirmation page, review your changes.
6. To apply the changes to the maintenance window immediately, select **Apply immediately**.
7. Choose **Modify DB instance** to save your changes.

   Alternatively, choose **Back** to edit your changes, or choose **Cancel** to cancel your changes.

AWS CLI

To adjust the preferred maintenance window, use the AWS CLI `modify-db-instance` command with the following parameters:

- `--db-instance-identifier`
- `--preferred-maintenance-window`

Example

The following code example sets the maintenance window to Tuesdays from 4:00-4:30AM UTC.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
--db-instance-identifier mydbinstance \
--preferred-maintenance-window Tue:04:00-Tue:04:30
```

For Windows:

```
aws rds modify-db-instance ^
--db-instance-identifier mydbinstance ^
--preferred-maintenance-window Tue:04:00-Tue:04:30
```

RDS API

To adjust the preferred maintenance window, use the Amazon RDS API `ModifyDBInstance` operation with the following parameters:

- `DBInstanceIdentifier`
- `PreferredMaintenanceWindow`

Operating system updates in Amazon RDS

RDS for Db2, RDS for MariaDB, RDS for MySQL, RDS for PostgreSQL, and RDS for Oracle DB instances occasionally require operating system updates. Amazon RDS upgrades the operating system to a newer version to improve database performance and customers' overall security posture. Typically, the updates take about 10 minutes. Operating system updates don't change the DB engine version or DB instance class of a DB instance.

Operating system updates can be either optional or mandatory:

- An **optional update** can be applied at any time. While these updates are optional, we recommend that you apply them periodically to keep your RDS fleet up to date. RDS *does not* apply these updates automatically.

  To be notified when a new, optional operating system patch becomes available, you can subscribe to RDS-EVENT-0230 in the security patching event category. For information about subscribing to RDS events, see Subscribing to Amazon RDS event notification.

> **Note**
>
> `RDS-EVENT-0230` doesn't apply to operating system distribution upgrades.

> **Note**
>
> If you received `RDS-EVENT-0230` for an RDS for SQL Server DB instance, the OS update can't be applied via the `apply-pending-maintenance` action. For more information, see Applying updates for a DB instance.

- A **mandatory update** is required and has an apply date. Plan to schedule your update before this apply date. After the specified apply date, Amazon RDS automatically upgrades the operating system for your DB instance to the latest version during one of your assigned maintenance windows.

> **Note**
>
> Staying current on all optional and mandatory updates might be required to meet various compliance obligations. We recommend that you apply all updates made available by RDS routinely during your maintenance windows.

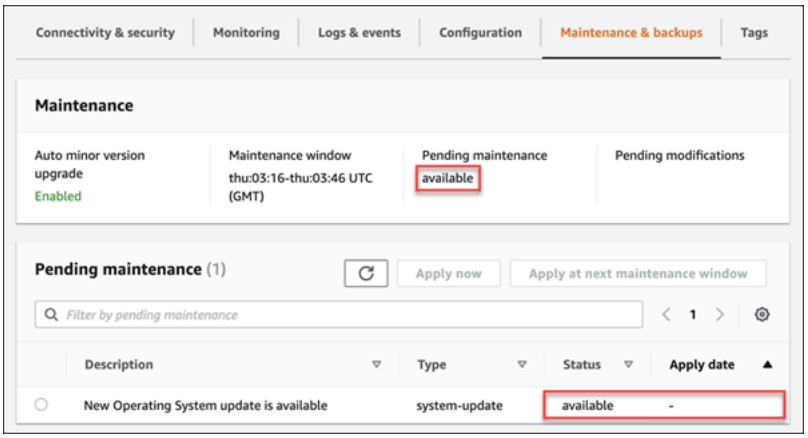
You can use the AWS Management Console or the AWS CLI to get information about the type of operating system upgrade.

Console

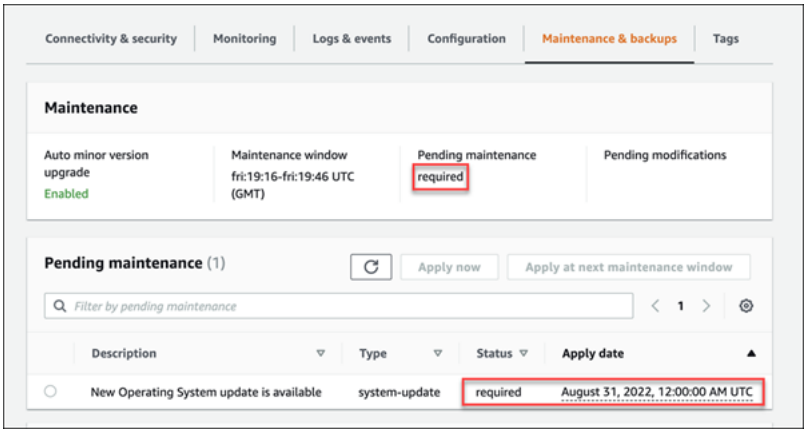
To get update information using the AWS Management Console

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**, and then select the DB instance.
3. Choose **Maintenance & backups**.
4. In the **Pending maintenance** section, find the operating system update, and check the **Status** value.

In the AWS Management Console, an optional update has its maintenance **Status** set to **available** and doesn't have an **Apply date**, as shown in the following image.



A mandatory update has its maintenance **Status** set to **required** and has an **Apply date**, as shown in the following image.



AWS CLI

To get update information from the AWS CLI, use the describe-pending-maintenance-actions command.

```
aws rds describe-pending-maintenance-actions
```

A mandatory operating system update includes an `AutoAppliedAfterDate` value and a `CurrentApplyDate` value. An optional operating system update doesn't include these values.

The following output shows a mandatory operating system update.

```
{
  "ResourceIdentifier": "arn:aws:rds:us-east-1:123456789012:db:mydb1",
```

```
  "PendingMaintenanceActionDetails": [
    {
      "Action": "system-update",
      "AutoAppliedAfterDate": "2022-08-31T00:00:00+00:00",
      "CurrentApplyDate": "2022-08-31T00:00:00+00:00",
      "Description": "New Operating System update is available"
    }
  ]
}
```

The following output shows an optional operating system update.

```
{
  "ResourceIdentifier": "arn:aws:rds:us-east-1:123456789012:db:mydb2",
  "PendingMaintenanceActionDetails": [
    {
      "Action": "system-update",
      "Description": "New Operating System update is available"
    }
  ]
}
```

Availability of operating system updates

Operating system updates are specific to DB engine version and DB instance class. Therefore, DB instances receive or require updates at different times. When an operating system update is available for your DB instance based on its engine version and instance class, the update appears in the console. It can also be viewed by running AWS CLI describe-pending-maintenance-actions command or by calling the RDS DescribePendingMaintenanceActions API operation. If an update is available for your instance, you can update your operating system by following the instructions in Applying updates for a DB instance.

Upgrading a DB instance engine version

Amazon RDS provides newer versions of each supported database engine so you can keep your DB instance up-to-date. Newer versions can include bug fixes, security enhancements, and other improvements for the database engine. When Amazon RDS supports a new version of a database engine, you can choose how and when to upgrade your database DB instances.

There are two kinds of upgrades: major version upgrades and minor version upgrades. In general, a *major engine version upgrade* can introduce changes that are not compatible with existing applications. In contrast, a *minor version upgrade* includes only changes that are backward-compatible with existing applications.

For Multi-AZ DB clusters, major version upgrades are only supported for RDS for PostgreSQL. Minor version upgrades are supported for all engines that support Multi-AZ DB clusters. For more information, see the section called “Upgrading the engine version of a Multi-AZ DB cluster”.

The version numbering sequence is specific to each database engine. For example, RDS for MySQL 5.7 and 8.0 are major engine versions and upgrading from any 5.7 version to any 8.0 version is a major version upgrade. RDS for MySQL version 5.7.22 and 5.7.23 are minor versions and upgrading from 5.7.22 to 5.7.23 is a minor version upgrade.

> **Important**
>
> You can't modify a DB instance when it is being upgraded. During an upgrade, the DB instance status is `upgrading`.

For more information about major and minor version upgrades for a specific DB engine, see the following documentation for your DB engine:

- Upgrading the MariaDB DB engine
- Upgrading the Microsoft SQL Server DB engine
- Upgrading the MySQL DB engine
- Upgrading the RDS for Oracle DB engine
- Upgrading the PostgreSQL DB engine for Amazon RDS

For major version upgrades, you must manually modify the DB engine version through the AWS Management Console, AWS CLI, or RDS API. For minor version upgrades, you can manually modify the engine version, or you can choose to enable the **Auto minor version upgrade** option.

> **Note**
>
> Database engine upgrades require downtime. You can minimize the downtime required for DB instance upgrade by using a blue/green deployment. For more information, see Using Amazon RDS Blue/Green Deployments for database updates.

Topics

Manually upgrading the engine version

To manually upgrade the engine version of a DB instance, you can use the AWS Management Console, the AWS CLI, or the RDS API.

Console

To upgrade the engine version of a DB instance by using the console

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**, and then choose the DB instance that you want to upgrade.
3. Choose **Modify**. The **Modify DB instance** page appears.
4. For **DB engine version**, choose the new version.
5. Choose **Continue** and check the summary of modifications.
6. Decide when to schedule your upgrade. To apply the changes immediately, choose **Apply immediately**. Choosing this option can cause an outage in some cases. For more information, see Schedule modifications setting.
7. On the confirmation page, review your changes. If they are correct, choose **Modify DB instance** to save your changes.

Alternatively, choose **Back** to edit your changes, or choose **Cancel** to cancel your changes.

AWS CLI

To upgrade the engine version of a DB instance, use the CLI modify-db-instance command. Specify the following parameters:

- `--db-instance-identifier` – the name of the DB instance.
- `--engine-version` – the version number of the database engine to upgrade to.

  For information about valid engine versions, use the AWS CLI describe-db-engine-versions command.
- `--allow-major-version-upgrade` – to upgrade the major version.
- `--no-apply-immediately` – to apply changes during the next maintenance window. To apply changes immediately, use `--apply-immediately`.

Example

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier mydbinstance \
    --engine-version new_version \
    --allow-major-version-upgrade \
    --no-apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier mydbinstance ^
    --engine-version new_version ^
    --allow-major-version-upgrade ^
    --no-apply-immediately
```

RDS API

To upgrade the engine version of a DB instance, use the ModifyDBInstance action. Specify the following parameters:

- `DBInstanceIdentifier` – the name of the DB instance, for example *`mydbinstance`*.
- `EngineVersion` – the version number of the database engine to upgrade to. For information about valid engine versions, use the DescribeDBEngineVersions operation.
- `AllowMajorVersionUpgrade` – whether to allow a major version upgrade. To do so, set the value to `true`.
- `ApplyImmediately` – whether to apply changes immediately or during the next maintenance window. To apply changes immediately, set the value to `true`. To apply changes during the next maintenance window, set the value to `false`.

Automatically upgrading the minor engine version

A *minor engine version* is an update to a DB engine version within a major engine version. For example, a major engine version might be 9.6 with the minor engine versions 9.6.11 and 9.6.12 within it.

If you want Amazon RDS to upgrade the DB engine version of a database automatically, you can enable auto minor version upgrades for the database.

RDS for SQL Server currently does not support automatic minor version updates.

Topics

- How automatic minor version upgrades work
- Turning on automatic minor version upgrades
- Determining the availability of maintenance updates
- Finding automatic minor version upgrade targets

How automatic minor version upgrades work

Amazon RDS designates a minor engine version as the preferred minor engine version when the following conditions are met:

- The database is running a minor version of the DB engine that is lower than the preferred minor engine version.

  You can find your current engine version for your DB instance by looking on the **Configuration** tab of the database details page or running the CLI command `describe-db-instances`.

- The database has auto minor version upgrade enabled.

RDS schedules the upgrades to run automatically in the maintenance window. During the upgrade, RDS performs the following basic steps:

1. Runs a precheck to make sure the database is healthy and ready to be upgraded
2. Upgrades the DB engine
3. Runs post-upgrade checks
4. Marks the database upgrade as complete

Automatic upgrades incur downtime. The length of the downtime depends on various factors, including the DB engine type and the size of the database.

Turning on automatic minor version upgrades

You can control whether auto minor version upgrade is enabled for a DB instance when you perform the following tasks:

- Creating a DB instance
- Modifying a DB instance
- Creating a read replica
- Restoring a DB instance from a snapshot
- Restoring a DB instance to a specific time
- Importing a DB instance from Amazon S3 (for a MySQL backup on Amazon S3)

When you perform these tasks, you can control whether auto minor version upgrade is enabled for the DB instance in the following ways:

- Using the console, set the **Auto minor version upgrade** option.
- Using the AWS CLI, set the `--auto-minor-version-upgrade|--no-auto-minor-version-upgrade` option.
- Using the RDS API, set the `AutoMinorVersionUpgrade` parameter.

Determining the availability of maintenance updates

To determine whether a maintenance update, such as a DB engine version upgrade, is available for your DB instance, you can use the console, AWS CLI, or RDS API. You can also upgrade the DB engine version manually and adjust the maintenance window. For more information, see Maintaining a DB instance.

Finding automatic minor version upgrade targets

You can use the following AWS CLI command to determine the current automatic minor upgrade target version for a specified minor DB engine version in a specific AWS Region. You can find the possible `--engine` values for this command in the description for the `Engine` parameter in CreateDBInstance.

For Linux, macOS, or Unix:

```
aws rds describe-db-engine-versions \
--engine engine \
--engine-version minor-version \
--region region \
--query "DBEngineVersions[*].ValidUpgradeTarget[*].
{AutoUpgrade:AutoUpgrade,EngineVersion:EngineVersion}" \
--output text
```

For Windows:

```
aws rds describe-db-engine-versions ^
--engine engine ^
--engine-version minor-version ^
--region region ^
--query "DBEngineVersions[*].ValidUpgradeTarget[*].
{AutoUpgrade:AutoUpgrade,EngineVersion:EngineVersion}" ^
--output text
```

For example, the following AWS CLI command determines the automatic minor upgrade target for MySQL minor version 8.0.11 in the US East (Ohio) AWS Region (us-east-2).

For Linux, macOS, or Unix:

```
aws rds describe-db-engine-versions \
--engine mysql \
```

```
--engine-version 8.0.11 \
--region us-east-2 \
--query "DBEngineVersions[*].ValidUpgradeTarget[*].
{AutoUpgrade:AutoUpgrade,EngineVersion:EngineVersion}" \
--output table
```

For Windows:

```
aws rds describe-db-engine-versions ^
--engine mysql ^
--engine-version 8.0.11 ^
--region us-east-2 ^
--query "DBEngineVersions[*].ValidUpgradeTarget[*].
{AutoUpgrade:AutoUpgrade,EngineVersion:EngineVersion}" ^
--output table
```

Your output is similar to the following.

```
---------------------------------
|    DescribeDBEngineVersions    |
+--------------+-----------------+
|  AutoUpgrade |  EngineVersion  |
+--------------+-----------------+
|  False       |  8.0.15         |
|  False       |  8.0.16         |
|  False       |  8.0.17         |
|  False       |  8.0.19         |
|  False       |  8.0.20         |
|  False       |  8.0.21         |
|  True        |  8.0.23         |
|  False       |  8.0.25         |
+--------------+-----------------+
```

In this example, the `AutoUpgrade` value is `True` for MySQL version 8.0.23. So, the automatic minor upgrade target is MySQL version 8.0.23, which is highlighted in the output.

Important

If you plan to migrate an RDS for PostgreSQL DB instance to an Aurora PostgreSQL DB cluster soon, we strongly recommend that you turn off auto minor version upgrades for the DB instance early during planning. Migration to Aurora PostgreSQL might be delayed if

the RDS for PostgreSQL version isn't yet supported by Aurora PostgreSQL. For information about Aurora PostgreSQL versions, see Engine versions for Amazon Aurora PostgreSQL.

Renaming a DB instance

You can rename a DB instance by using the AWS Management Console, the AWS CLI `modify-db-instance` command, or the Amazon RDS API `ModifyDBInstance` action. Renaming a DB instance can have far-reaching effects. The following is a list of considerations before you rename a DB instance.

- When you rename a DB instance, the endpoint for the DB instance changes, because the URL includes the name you assigned to the DB instance. You should always redirect traffic from the old URL to the new one.
- When you rename a DB instance, the old DNS name that was used by the DB instance is immediately deleted, although it could remain cached for a few minutes. The new DNS name for the renamed DB instance becomes effective in about 10 minutes. The renamed DB instance is not available until the new name becomes effective.
- You cannot use an existing DB instance name when renaming an instance.
- All read replicas associated with a DB instance remain associated with that instance after it is renamed. For example, suppose you have a DB instance that serves your production database and the instance has several associated read replicas. If you rename the DB instance and then replace it in the production environment with a DB snapshot, the DB instance that you renamed will still have the read replicas associated with it.
- Metrics and events associated with the name of a DB instance are maintained if you reuse a DB instance name. For example, if you promote a read replica and rename it to be the name of the previous primary DB instance, the events and metrics associated with the primary DB instance are associated with the renamed instance.
- DB instance tags remain with the DB instance, regardless of renaming.
- DB snapshots are retained for a renamed DB instance.

> **Note**
>
> A DB instance is an isolated database environment running in the cloud. A DB instance can host multiple databases, or a single Oracle database with multiple schemas. For information about changing a database name, see the documentation for your DB engine.

Renaming to replace an existing DB instance

The most common reasons for renaming a DB instance are that you are promoting a read replica or you are restoring data from a DB snapshot or point-in-time recovery (PITR). By renaming the database, you can replace the DB instance without having to change any application code that references the DB instance. In these cases, you would do the following:

1. Stop all traffic going to the primary DB instance. This can involve redirecting traffic from accessing the databases on the DB instance or some other way you want to use to prevent traffic from accessing your databases on the DB instance.
2. Rename the primary DB instance to a name that indicates it is no longer the primary DB instance as described later in this topic.
3. Create a new primary DB instance by restoring from a DB snapshot or by promoting a read replica, and then give the new instance the name of the previous primary DB instance.
4. Associate any read replicas with the new primary DB instance.

If you delete the old primary DB instance, you are responsible for deleting any unwanted DB snapshots of the old primary DB instance.

For information about promoting a read replica, see Promoting a read replica to be a standalone DB instance.

> **Important**
>
> The DB instance is rebooted when it is renamed.

Console

To rename a DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.
3. Choose the DB instance that you want to rename.
4. Choose **Modify**.
5. In **Settings**, enter a new name for **DB instance identifier**.

6. Choose **Continue**.
7. To apply the changes immediately, choose **Apply immediately**. Choosing this option can cause an outage in some cases. For more information, see Modifying an Amazon RDS DB instance.
8. On the confirmation page, review your changes. If they are correct, choose **Modify DB Instance** to save your changes.

   Alternatively, choose **Back** to edit your changes, or choose **Cancel** to cancel your changes.

AWS CLI

To rename a DB instance, use the AWS CLI command `modify-db-instance`. Provide the current `--db-instance-identifier` value and `--new-db-instance-identifier` parameter with the new name of the DB instance.

Example

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier DBInstanceIdentifier \
    --new-db-instance-identifier NewDBInstanceIdentifier
```

For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier DBInstanceIdentifier ^
    --new-db-instance-identifier NewDBInstanceIdentifier
```

RDS API

To rename a DB instance, call Amazon RDS API operation `ModifyDBInstance` with the following parameters:

- `DBInstanceIdentifier` — existing name for the instance
- `NewDBInstanceIdentifier` — new name for the instance

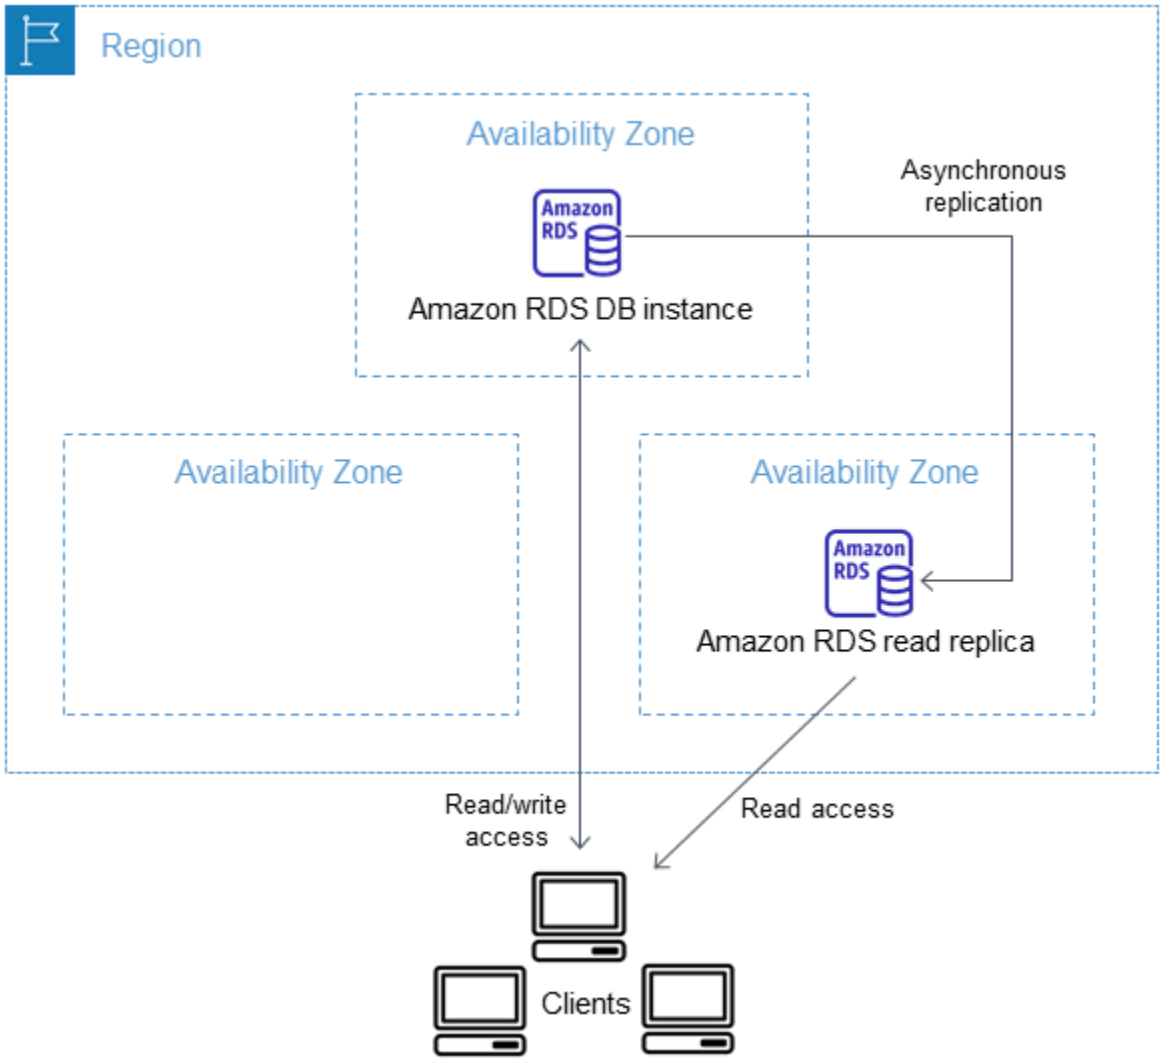
Working with DB instance read replicas

A *read replica* is a read-only copy of a DB instance. You can reduce the load on your primary DB instance by routing queries from your applications to the read replica. In this way, you can elastically scale out beyond the capacity constraints of a single DB instance for read-heavy database workloads.

To create a read replica from a source DB instance, Amazon RDS uses the built-in replication features of the DB engine. For information about using read replicas with a specific engine, see the following sections:

- Working with MariaDB read replicas
- Working with read replicas for Microsoft SQL Server in Amazon RDS
- Working with MySQL read replicas
- Working with read replicas for Amazon RDS for Oracle
- Working with read replicas for Amazon RDS for PostgreSQL

After you create a read replica from a source DB instance, the source becomes the primary DB instance. When you make updates to the primary DB instance, Amazon RDS copies them asynchronously to the read replica. The following diagram shows a source DB instance replicating to a read replica in a different Availability Zone (AZ). Clients have read/write access to the primary DB instance and read-only access to the replica.



Read replicas are billed as standard DB instances at the same rates as the DB instance class used for the replica. You aren't charged for the data transfer incurred in replicating data between the source DB instance and a read replica within the same AWS Region. For more information, see Cross-Region replication costs and DB instance billing for Amazon RDS.

Topics

- Overview of Amazon RDS read replicas
- Creating a read replica
- Promoting a read replica to be a standalone DB instance
- Monitoring read replication
- Creating a read replica in a different AWS Region

Overview of Amazon RDS read replicas

The following sections discuss DB *instance* read replicas. For information about Multi-AZ DB *cluster* read replicas, see the section called "Working with Multi-AZ DB cluster read replicas".

Topics

Use cases for read replicas

Deploying one or more read replicas for a given source DB instance might make sense in a variety of scenarios, including the following:

- Scaling beyond the compute or I/O capacity of a single DB instance for read-heavy database workloads. You can direct this excess read traffic to one or more read replicas.
- Serving read traffic while the source DB instance is unavailable. In some cases, your source DB instance might not be able to take I/O requests, for example due to I/O suspension for backups or scheduled maintenance. In these cases, you can direct read traffic to your read replicas. For this use case, keep in mind that the data on the read replica might be "stale" because the source DB instance is unavailable.
- Business reporting or data warehousing scenarios where you might want business reporting queries to run against a read replica, rather than your production DB instance.
- Implementing disaster recovery. You can promote a read replica to a standalone instance as a disaster recovery solution if the primary DB instance fails.

How read replicas work

When you create a read replica, you first specify an existing DB instance as the source. Then Amazon RDS takes a snapshot of the source instance and creates a read-only instance from the snapshot. Amazon RDS then uses the asynchronous replication method for the DB engine to update the read replica whenever there is a change to the primary DB instance.

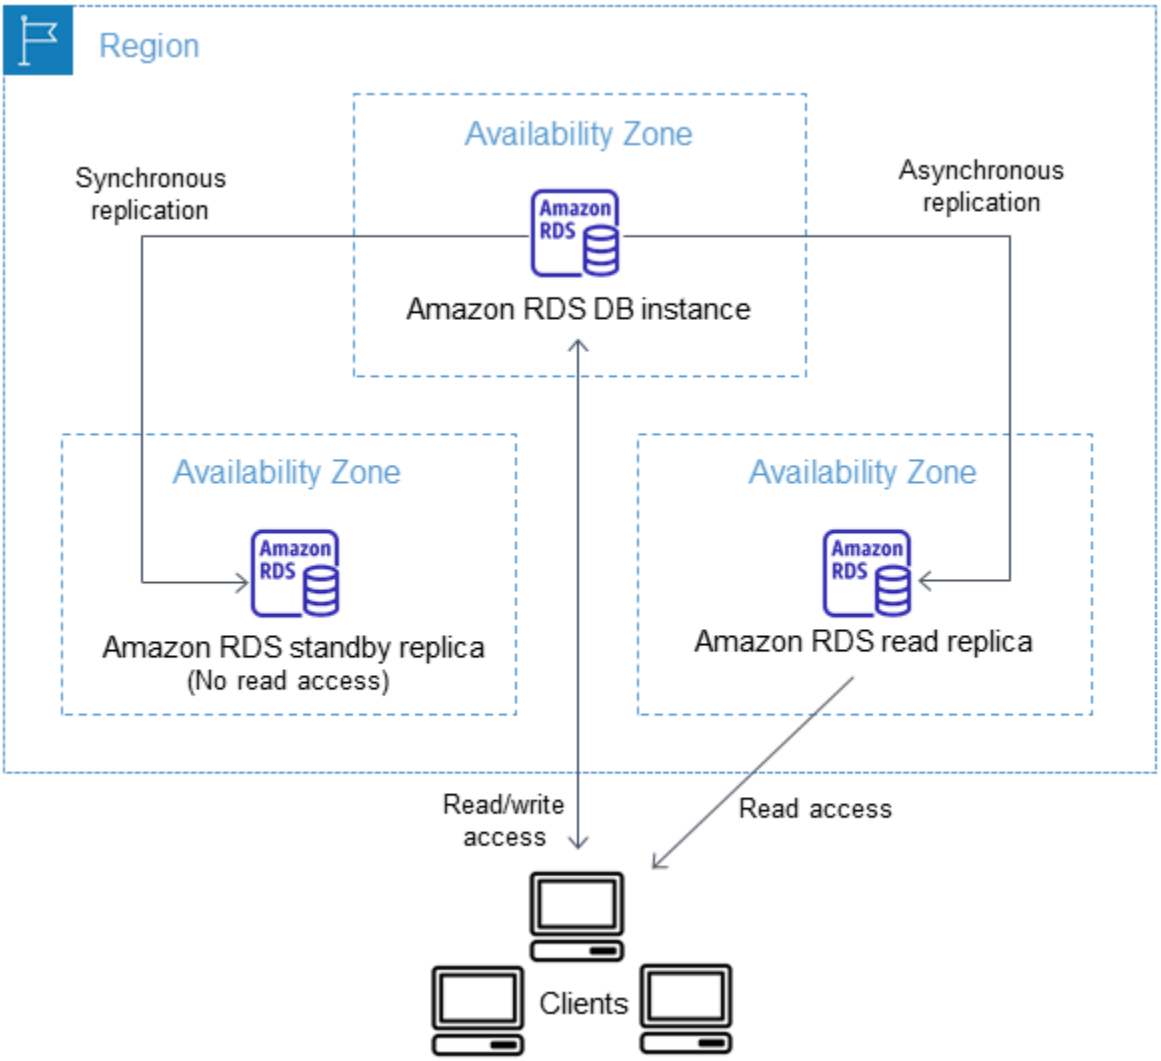
The read replica operates as a DB instance that allows only read-only connections. An exception is the RDS for Oracle DB engine, which supports replica databases in mounted mode. A mounted replica doesn't accept user connections and so can't serve a read-only workload. The primary use for mounted replicas is cross-Region disaster recovery. For more information, see Working with read replicas for Amazon RDS for Oracle.

Applications connect to a read replica just as they do to any DB instance. Amazon RDS replicates all databases from the source DB instance.

Read replicas in a Multi-AZ deployment

You can configure a read replica for a DB instance that also has a standby replica configured for high availability in a Multi-AZ deployment. Replication with the standby replica is synchronous. Unlike a read replica, a standby replica can't serve read traffic.

In the following scenario, clients have read/write access to a primary DB instance in one AZ. The primary instance copies updates asynchronously to a read replica in a second AZ and also copies them synchronously to a standby replica in a third AZ. Clients have read access only to the read replica.



For more information about high availability and standby replicas, see Configuring and managing a Multi-AZ deployment.

Cross-Region read replicas

In some cases, a read replica resides in a different AWS Region from its primary DB instance. In these cases, Amazon RDS sets up a secure communications channel between the primary DB instance and the read replica. Amazon RDS establishes any AWS security configurations needed to enable the secure channel, such as adding security group entries. For more information about cross-Region read replicas, see Creating a read replica in a different AWS Region.

The information in this chapter applies to creating Amazon RDS read replicas either in the same AWS Region as the source DB instance, or in a separate AWS Region. The following information

doesn't apply to setting up replication with an instance that is running on an Amazon EC2 instance or that is on-premises.

Differences among read replicas for DB engines

Because Amazon RDS DB engines implement replication differently, there are several significant differences you should know about, as shown in the following table.

Feature or behavior	MySQL and MariaDB	Oracle	PostgreSQL	SQL Server
What is the replication method?	Logical replication.	Physical replication.	Physical replication.	Physical replication.
How are transacti on logs purged?	RDS for MySQL and RDS for MariaDB keep any binary logs that haven't been applied.	If a primary DB instance has no cross-Region read replicas, Amazon RDS for Oracle keeps a minimum of two hours of transaction logs on the source DB instance. Logs are purged from the source DB instance after two hours or after the archive log retention hours setting has passed, whichever is longer. Logs are purged from the read replica after the archive log retention hours	PostgreSQL has the parameter `wal_keep_segments` that dictates how many write ahead log (WAL) files are kept to provide data to the read replicas. The parameter value specifies the number of logs to keep.	The Virtual Log File (VLF) of the transaction log file on the primary replica can be truncated after it is no longer required for the secondary replicas. The VLF can only be marked as inactive when the log records have been

Feature or behavior	MySQL and MariaDB	Oracle	PostgreSQL	SQL Server
		setting has passed only if they have been successfu lly applied to the database. In some cases, a primary DB instance might have one or more cross-Region read replicas. If so, Amazon RDS for Oracle keeps the transaction logs on the source DB instance until they have been transmitted and applied to all cross-Region read replicas. For information about setting archive log retention hours, see Retaining archived redo logs.		hardened in the replicas. Regardles s of how fast the disk subsystem s are in the primary replica, the transacti on log will keep the VLFs until the slowest replica has hardened it.

Feature or behavior	MySQL and MariaDB	Oracle	PostgreSQL	SQL Server
Can a replica be made writable?	Yes. You can enable the MySQL or MariaDB read replica to be writable.	No. An Oracle read replica is a physical copy, and Oracle doesn't allow for writes in a read replica. You can promote the read replica to make it writable. The promoted read replica has the replicated data to the point when the request was made to promote it.	No. A PostgreSQL read replica is a physical copy, and PostgreSQL doesn't allow for a read replica to be made writable.	No. A SQL Server read replica is a physical copy and also doesn't allow for writes. You can promote the read replica to make it writable. The promoted read replica has the replicated data up to the point when the request was made to promote it.

Feature or behavior	MySQL and MariaDB	Oracle	PostgreSQL	SQL Server
Can backups be performed on the replica?	Yes. Automatic backups and manual snapshots are supported on RDS for MySQL or RDS for MariaDB read replicas.	Yes. Automatic backups and manual snapshots are supported on RDS for Oracle read replicas.	Yes, you can create a manual snapshot of RDS for PostgreSQL read replicas. Automated backups for read replicas are supported for RDS for PostgreSQL 14.1 and higher versions only. You can't turn on automated backups for PostgreSQL read replicas for RDS for PostgreSQL versions earlier than 14.1. For RDS for PostgreSQL 13 and earlier versions, create a snapshot from a read replica if you want a backup of it.	No. Automatic backups and manual snapshots aren't supported on RDS for SQL Server read replicas.

Feature or behavior	MySQL and MariaDB	Oracle	PostgreSQL	SQL Server
Can you use parallel replication?	Yes. All supported MariaDB and MySQL versions allow for parallel replication threads.	Yes. Redo log data is always transmitted in parallel from the primary database to all of its read replicas.	No. PostgreSQL has a single process handling replication.	Yes. Redo log data is always transmitted in parallel from the primary database to all of its read replicas.
Can you maintain a replica in a mounted rather than a read-only state?	No.	Yes. The primary use for mounted replicas is cross-Region disaster recovery. An Active Data Guard license isn't required for mounted replicas. For more information, see Working with read replicas for Amazon RDS for Oracle.	No.	No.

Read replica storage types

By default, a read replica is created with the same storage type as the source DB instance. However, you can create a read replica that has a different storage type from the source DB instance based on the options listed in the following table.

Source DB instance storage type	Source DB instance storage allocation	Read replica storage type options
Provisioned IOPS	100 GiB–64 TiB	Provisioned IOPS, General Purpose, Magnetic
General Purpose	100 GiB–64 TiB	Provisioned IOPS, General Purpose, Magnetic
General Purpose	<100 GiB	General Purpose, Magnetic
Magnetic	100 GiB–6 TiB	Provisioned IOPS, General Purpose, Magnetic
Magnetic	<100 GiB	General Purpose, Magnetic

Note

When you increase the allocated storage of a read replica, it must be by at least 10 percent. If you try to increase the value by less than 10 percent, you get an error.

Restrictions for creating a replica from a replica

Amazon RDS doesn't support circular replication. You can't configure a DB instance to serve as a replication source for an existing DB instance. You can only create a new read replica from an existing DB instance. For example, if **`MySourceDBInstance`** replicates to **`ReadReplica1`**, you can't configure **`ReadReplica1`** to replicate back to **`MySourceDBInstance`**.

For RDS for MariaDB and RDS for MySQL, and for certain versions of RDS for PostgreSQL, you can create a read replica from an existing read replica. For example, you can create new read replica **`ReadReplica2`** from existing replica **`ReadReplica1`**. For RDS for Oracle and RDS for SQL Server, you can't create a read replica from an existing read replica.

Considerations when deleting replicas

If you no longer need read replicas, you can explicitly delete them using the same mechanisms for deleting a DB instance. If you delete a source DB instance without deleting its read replicas in

the same AWS Region, each read replica is promoted to a standalone DB instance. For information about deleting a DB instance, see Deleting a DB instance. For information about read replica promotion, see Promoting a read replica to be a standalone DB instance.

If you have cross-Region read replicas, see Cross-Region replication considerations for information related to deleting the source DB instance for a cross-Region read replica.

Creating a read replica

You can create a read replica from an existing DB instance using the AWS Management Console, AWS CLI, or RDS API. You create a read replica by specifying `SourceDBInstanceIdentifier`, which is the DB instance identifier of the source DB instance that you want to replicate from.

When you create a read replica, Amazon RDS takes a DB snapshot of your source DB instance and begins replication. The source DB instance experiences a very brief I/O suspension when the DB snapshot operation begins. The I/O suspension typically lasts about one second. You can avoid the I/O suspension if the source DB instance is a Multi-AZ deployment, because in that case the snapshot is taken from the secondary DB instance.

An active, long-running transaction can slow the process of creating the read replica. We recommend that you wait for long-running transactions to complete before creating a read replica. If you create multiple read replicas in parallel from the same source DB instance, Amazon RDS takes only one snapshot at the start of the first create action.

When creating a read replica, there are a few things to consider. First, you must enable automatic backups on the source DB instance by setting the backup retention period to a value other than 0. This requirement also applies to a read replica that is the source DB instance for another read replica. To enable automatic backups on an RDS for MySQL read replica, first create the read replica, then modify the read replica to enable automatic backups.

> **Note**
>
> Within an AWS Region, we strongly recommend that you create all read replicas in the same virtual private cloud (VPC) based on Amazon VPC as the source DB instance. If you create a read replica in a different VPC from the source DB instance, classless inter-domain routing (CIDR) ranges can overlap between the replica and the RDS system. CIDR overlap makes the replica unstable, which can negatively impact applications connecting to it.
> If you receive an error when creating the read replica, choose a different destination DB subnet group. For more information, see Working with a DB instance in a VPC.

There is no direct way to create a read replica in another AWS account using the console or AWS CLI.

Console

To create a read replica from a source DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.
3. Choose the DB instance that you want to use as the source for a read replica.
4. For **Actions**, choose **Create read replica**.
5. For **DB instance identifier**, enter a name for the read replica.
6. Choose your instance configuration. We recommend that you use the same or larger DB instance class and storage type as the source DB instance for the read replica.
7. For **AWS Region**, specify the destination Region for the read replica.
8. For **Storage**, specify the allocated storage size and whether you want to use storage autoscaling.

   If your source DB instance isn't on the latest storage configuration, the **Upgrade storage file system configuration** option is available. You can enable this setting to upgrade the storage file system of the read replica to the preferred configuration. For more information, see the section called “Upgrading the storage file system”.
9. For **Availability**, choose whether to create a standby of your replica in another Availability Zone for failover support for the replica.

   Note

   Creating your read replica as a Multi-AZ DB instance is independent of whether the source database is a Multi-AZ DB instance.
10. Specify other DB instance settings. For information about each available setting, see Settings for DB instances.
11. To create an encrypted read replica, expand **Additional configuration** and specify the following settings:

a. Choose **Enable encryption**.

b. For **AWS KMS key**, choose the AWS KMS key identifier of the KMS key.

> **Note**
>
> The source DB instance must be encrypted. To learn more about encrypting the source DB instance, see Encrypting Amazon RDS resources.

12. Choose **Create read replica**.

After the read replica is created, you can see it on the **Databases** page in the RDS console. It shows **Replica** in the **Role** column.

AWS CLI

To create a read replica from a source DB instance, use the AWS CLI command create-db-instance-read-replica. This example also sets the allocated storage size, enables storage autoscaling, and upgrades the file system to the preferred configuration.

You can specify other settings. For information about each setting, see Settings for DB instances.

Example

For Linux, macOS, or Unix:

```
aws rds create-db-instance-read-replica \
    --db-instance-identifier myreadreplica \
    --source-db-instance-identifier mydbinstance \
    --allocated-storage 100 \
    --max-allocated-storage 1000 \
    --upgrade-storage-config
```

For Windows:

```
aws rds create-db-instance-read-replica ^
    --db-instance-identifier myreadreplica ^
    --source-db-instance-identifier mydbinstance ^
    --allocated-storage 100 ^
```

```
    --max-allocated-storage 1000 ^
    --upgrade-storage-config
```

RDS API

To create a read replica from a source MySQL, MariaDB, Oracle, PostgreSQL, or SQL Server DB instance, call the Amazon RDS API `CreateDBInstanceReadReplica` operation with the following required parameters:

- `DBInstanceIdentifier`
- `SourceDBInstanceIdentifier`

Promoting a read replica to be a standalone DB instance

You can promote a read replica into a standalone DB instance. If a source DB instance has several read replicas, promoting one of the read replicas to a DB instance has no effect on the other replicas.

When you promote a read replica, RDS reboots the DB instance before making it available. The promotion process can take several minutes or longer to complete, depending on the size of the read replica.

Use cases for promoting a read replica

You might want to promote a read replica to a standalone DB instance for any of the following reasons:

- **Implementing failure recovery** – You can use read replica promotion as a data recovery scheme if the primary DB instance fails. This approach complements synchronous replication, automatic failure detection, and failover.

If you are aware of the ramifications and limitations of asynchronous replication and you still want to use read replica promotion for data recovery, you can. To do this, first create a read replica and then monitor the primary DB instance for failures. In the event of a failure, do the following:

1. Promote the read replica.
2. Direct database traffic to the promoted DB instance.
3. Create a replacement read replica with the promoted DB instance as its source.

- **Upgrading storage configuration** – If your source DB instance isn't on the preferred storage configuration, you can create a read replica of the instance and upgrade the storage file system configuration. This option migrates the file system of the read replica to the preferred configuration. You can then promote the read replica to a standalone instance.

  You can use this option to overcome the scaling limitations on storage and file size for older 32-bit file systems. For more information, see the section called “Upgrading the storage file system”.

  This option is only available if your source DB instance is *not* on the latest storage configuration, or if you're modifying the DB instance class within the same request.
- **Sharding** – Sharding embodies the "share-nothing" architecture and essentially involves breaking a large database into several smaller databases. One common way to split a database is splitting tables that are not joined in the same query onto different hosts. Another method is duplicating a table across multiple hosts and then using a hashing algorithm to determine which host receives a given update. You can create read replicas corresponding to each of your shards (smaller databases) and promote them when you decide to convert them into standalone shards. You can then carve out the key space (if you are splitting rows) or distribution of tables for each of the shards depending on your requirements.
- **Performing DDL operations (MySQL and MariaDB only)** – DDL operations, such as creating or rebuilding indexes, can take time and impose a significant performance penalty on your DB instance. You can perform these operations on a MySQL or MariaDB read replica once the read replica is in sync with its primary DB instance. Then you can promote the read replica and direct your applications to use the promoted instance.

> **Note**
>
> If your read replica is an RDS for Oracle DB instance, you can perform a *switchover* instead of a promotion. In a switchover, the source DB instance becomes the new replica, and the

replica becomes the new source DB instance. For more information, see Performing an Oracle Data Guard switchover.

Characteristics of a promoted read replica

After you promote the read replica, it ceases to function as a read replica and becomes a standalone DB instance. The new standalone DB instance has the following characteristics:

- The standalone DB instance retains the option group and the parameter group of the pre-promotion read replica.
- You can create read replicas from the standalone DB instance and perform point-in-time restore operations.
- You can't use the DB instance as a replication target because it is no longer a read replica.

Prerequisites for promoting a read replica

Before you promote a read replica, do the following:

- Review your backup strategy:
  - We recommend that you enable backups and complete at least one backup. Backup duration is a function of the number of changes to the database since the previous backup.
  - If you have enabled backups on your read replica, configure the automated backup window so that daily backups don't interfere with read replica promotion.
  - Make sure that your read replica doesn't have the `backing-up` status. You can't promote a read replica when it is in this state.
- Stop any transactions from being written to the primary DB instance, and then wait for RDS to apply all updates to the read replica.

  Database updates occur on the read replica after they have occurred on the primary DB instance. Replication lag can vary significantly. Use the `Replica Lag` metric to determine when all updates have been made to the read replica.
- (MySQL and MariaDB only) To make changes to a MySQL or MariaDB read replica before you promote it, set the `read_only` parameter to `0` in the DB parameter group for the read replica. You can then perform all needed DDL operations, such as creating indexes, on the read replica. Actions taken on the read replica don't affect the performance of the primary DB instance.

Promoting a read replica: basic steps

The following steps show the general process for promoting a read replica to a DB instance:

1. Promote the read replica by using the **Promote** option on the Amazon RDS console, the AWS CLI command `promote-read-replica`, or the `PromoteReadReplica` Amazon RDS API operation.

   > **Note**
   >
   > The promotion process takes a few minutes to complete. When you promote a read replica, RDS stops replication and reboots the read replica. When the reboot is complete, the read replica is available as a new DB instance.

2. (Optional) Modify the new DB instance to be a Multi-AZ deployment. For more information, see Modifying an Amazon RDS DB instance and Configuring and managing a Multi-AZ deployment.

Console

To promote a read replica to a standalone DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the Amazon RDS console, choose **Databases**.

   The **Databases** pane appears. Each read replica shows **Replica** in the **Role** column.
3. Choose the read replica that you want to promote.
4. For **Actions**, choose **Promote**.
5. On the **Promote Read Replica** page, enter the backup retention period and the backup window for the newly promoted DB instance.
6. When the settings are as you want them, choose **Continue**.
7. On the acknowledgment page, choose **Promote Read Replica**.

AWS CLI

To promote a read replica to a standalone DB instance, use the AWS CLI `promote-read-replica` command.

Example

For Linux, macOS, or Unix:

```
aws rds promote-read-replica \
    --db-instance-identifier myreadreplica
```

For Windows:

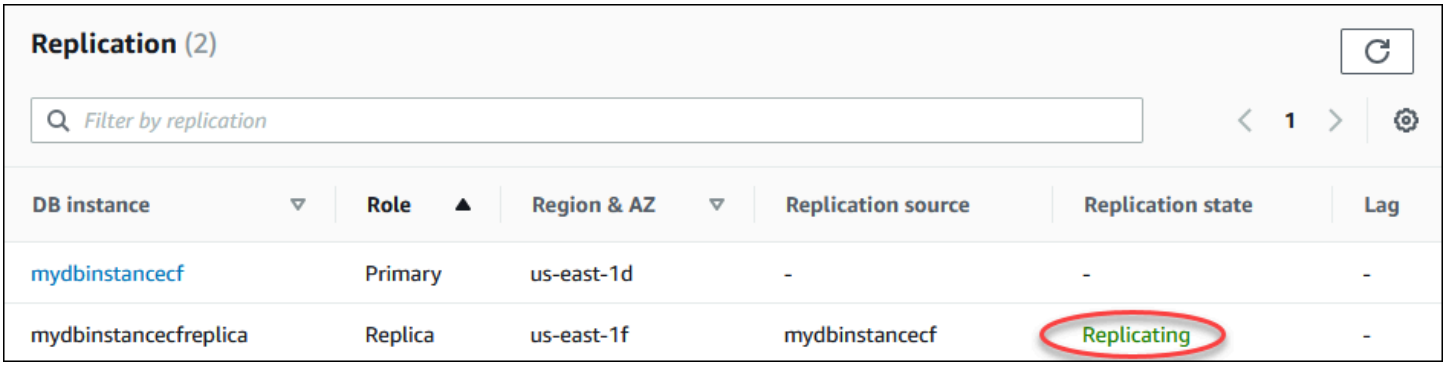
```
aws rds promote-read-replica ^
    --db-instance-identifier myreadreplica
```

RDS API

To promote a read replica to a standalone DB instance, call the Amazon RDS API `PromoteReadReplica` operation with the required parameter `DBInstanceIdentifier`.

Monitoring read replication

You can monitor the status of a read replica in several ways. The Amazon RDS console shows the status of a read replica in the **Replication** section of the **Connectivity & security** tab in the read replica details. To view the details for a read replica, choose the name of the read replica in the list of DB instances in the Amazon RDS console.



You can also see the status of a read replica using the AWS CLI `describe-db-instances` command or the Amazon RDS API `DescribeDBInstances` operation.

The status of a read replica can be one of the following:

- **replicating** – The read replica is replicating successfully.
- **replication degraded (SQL Server and PostgreSQL only) –** Replicas are receiving data from the primary instance, but one or more databases might be not getting updates. This can occur, for

example, when a replica is in the process of setting up newly created databases. It can also occur when unsupported DDL or large object changes are made in the blue environment of a blue/green deployment.

The status doesn't transition from `replication degraded` to `error`, unless an error occurs during the degraded state.

- **error** – An error has occurred with the replication. Check the **Replication Error** field in the Amazon RDS console or the event log to determine the exact error. For more information about troubleshooting a replication error, see Troubleshooting a MySQL read replica problem.
- **terminated (MariaDB, MySQL, or PostgreSQL only)** – Replication is terminated. This occurs if replication is stopped for more than 30 consecutive days, either manually or due to a replication error. In this case, Amazon RDS terminates replication between the primary DB instance and all read replicas. Amazon RDS does this to prevent increased storage requirements on the source DB instance and long failover times.

  Broken replication can affect storage because the logs can grow in size and number due to the high volume of errors messages being written to the log. Broken replication can also affect failure recovery due to the time Amazon RDS requires to maintain and process the large number of logs during recovery.
- **terminated (Oracle only)** – Replication is terminated. This occurs if replication is stopped for more than 8 hours because there isn't enough storage remaining on the read replica. In this case, Amazon RDS terminates replication between the primary DB instance and the affected read replica. This status is a terminal state, and the read replica must be re-created.
- **stopped (MariaDB or MySQL only)** – Replication has stopped because of a customer-initiated request.
- **replication stop point set (MySQL only)** – A customer-initiated stop point was set using the mysql.rds_start_replication_until stored procedure and the replication is in progress.
- **replication stop point reached (MySQL only)** – A customer-initiated stop point was set using the mysql.rds_start_replication_until stored procedure and replication is stopped because the stop point was reached.

You can see where a DB instance is being replicated and if so, check its replication status. On the **Databases** page in the RDS console, it shows **Primary** in the **Role** column. Choose its DB instance name. On its detail page, on the **Connectivity & security** tab, its replication status is under **Replication**.

Monitoring replication lag

You can monitor replication lag in Amazon CloudWatch by viewing the Amazon RDS `ReplicaLag` metric.

For MariaDB and MySQL, the `ReplicaLag` metric reports the value of the `Seconds_Behind_Master` field of the `SHOW REPLICA STATUS` command. Common causes for replication lag for MySQL and MariaDB are the following:

- A network outage.
- Writing to tables with indexes on a read replica. If the `read_only` parameter is not set to 0 on the read replica, it can break replication.
- Using a nontransactional storage engine such as MyISAM. Replication is only supported for the InnoDB storage engine on MySQL and the XtraDB storage engine on MariaDB.

> **Note**
>
> Previous versions of MariaDB and MySQL used `SHOW SLAVE STATUS` instead of `SHOW REPLICA STATUS`. If you are using a MariaDB version before 10.5 or a MySQL version before 8.0.23, then use `SHOW SLAVE STATUS`.

When the `ReplicaLag` metric reaches 0, the replica has caught up to the primary DB instance. If the `ReplicaLag` metric returns `-1`, then replication is currently not active. `ReplicaLag = -1` is equivalent to `Seconds_Behind_Master = NULL`.

For Oracle, the `ReplicaLag` metric is the sum of the `Apply Lag` value and the difference between the current time and the apply lag's `DATUM_TIME` value. The `DATUM_TIME` value is the last time the read replica received data from its source DB instance. For more information, see V$DATAGUARD_STATS in the Oracle documentation.

For SQL Server, the `ReplicaLag` metric is the maximum lag of databases that have fallen behind, in seconds. For example, if you have two databases that lag 5 seconds and 10 seconds, respectively, then `ReplicaLag` is 10 seconds. The `ReplicaLag` metric returns the value of the following query.

```
SELECT MAX(secondary_lag_seconds) max_lag FROM sys.dm_hadr_database_replica_states;
```

For more information, see secondary_lag_seconds in the Microsoft documentation.

`ReplicaLag` returns `-1` if RDS can't determine the lag, such as during replica setup, or when the read replica is in the `error` state.

> **Note**
>
> New databases aren't included in the lag calculation until they are accessible on the read replica.

For PostgreSQL, the `ReplicaLag` metric returns the value of the following query.

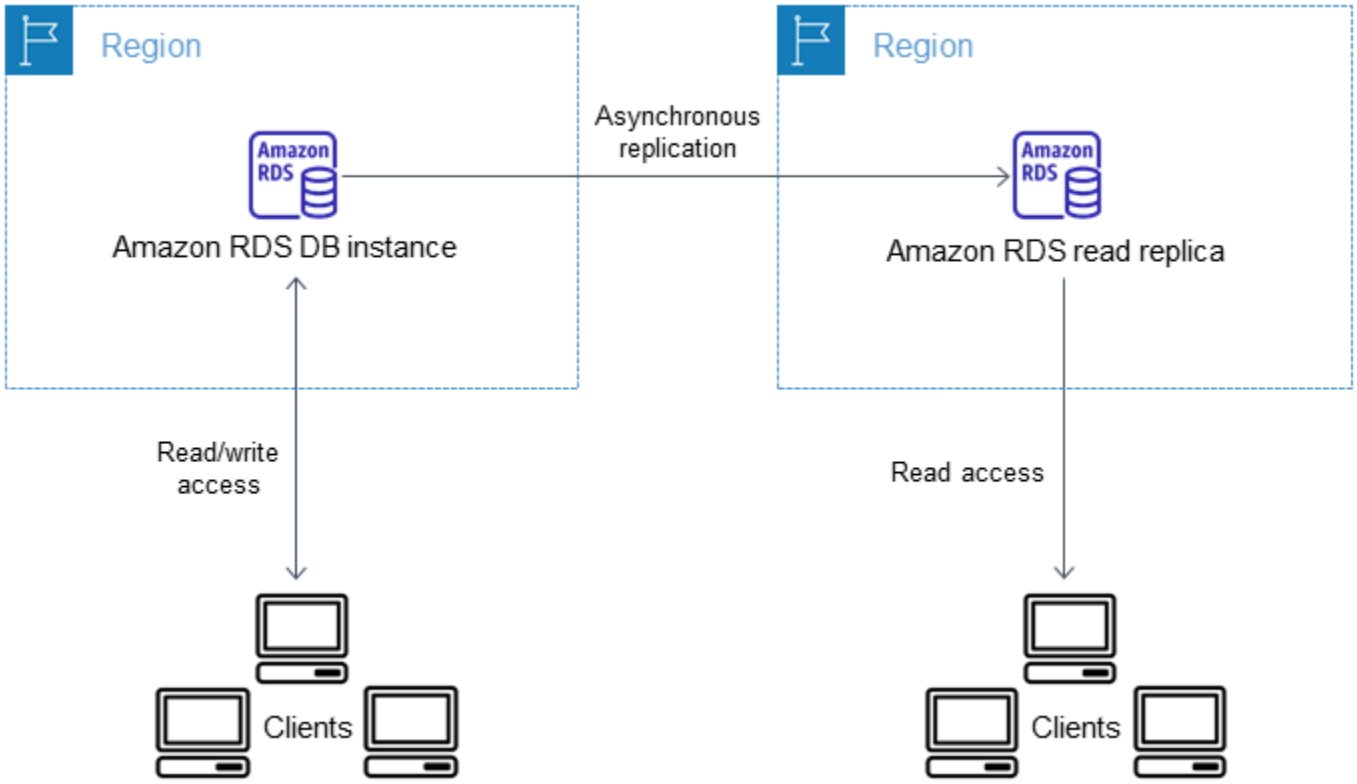
```
SELECT extract(epoch from now() - pg_last_xact_replay_timestamp()) AS reader_lag
```

PostgreSQL versions 9.5.2 and later use physical replication slots to manage write ahead log (WAL) retention on the source instance. For each cross-Region read replica instance, Amazon RDS creates a physical replication slot and associates it with the instance. Two Amazon CloudWatch metrics, `Oldest Replication Slot Lag` and `Transaction Logs Disk Usage`, show how far behind the most lagging replica is in terms of WAL data received and how much storage is being used for WAL data. The `Transaction Logs Disk Usage` value can substantially increase when a cross-Region read replica is lagging significantly.

For more information about monitoring a DB instance with CloudWatch, see Monitoring Amazon RDS metrics with Amazon CloudWatch.

Creating a read replica in a different AWS Region

With Amazon RDS, you can create a read replica in a different AWS Region from the source DB instance.



You create a read replica in a different AWS Region to do the following:

- Improve your disaster recovery capabilities.
- Scale read operations into an AWS Region closer to your users.
- Make it easier to migrate from a data center in one AWS Region to a data center in another AWS Region.

Creating a read replica in a different AWS Region from the source instance is similar to creating a replica in the same AWS Region. You can use the AWS Management Console, run the `create-db-instance-read-replica` command, or call the `CreateDBInstanceReadReplica` API operation.

> **Note**
>
> To create an encrypted read replica in a different AWS Region from the source DB instance, the source DB instance must be encrypted.

Topics

- Region and version availability
- Creating a cross-Region read replica
- How Amazon RDS does cross-Region replication
- Cross-Region replication considerations
- Cross-Region replication costs

Region and version availability

Feature availability and support varies across specific versions of each database engine, and across AWS Regions. For more information on version and Region availability with cross-Region replication, see Supported Regions and DB engines for cross-Region read replicas in Amazon RDS.

Creating a cross-Region read replica

The following procedures show how to create a read replica from a source MariaDB, Microsoft SQL Server, MySQL, Oracle, or PostgreSQL DB instance in a different AWS Region.

Console

You can create a read replica across AWS Regions using the AWS Management Console.

To create a read replica across AWS Regions with the console

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.
3. Choose the MariaDB, Microsoft SQL Server, MySQL, Oracle, or PostgreSQL DB instance that you want to use as the source for a read replica.
4. For **Actions**, choose **Create read replica**.
5. For **DB instance identifier**, enter a name for the read replica.
6. Choose the **Destination Region**.
7. Choose the instance specifications that you want to use. We recommend that you use the same or larger DB instance class and storage type for the read replica.
8. To create an encrypted read replica in another AWS Region:

    a. Choose **Enable encryption**.

b. For **AWS KMS key**, choose the AWS KMS key identifier of the KMS key in the destination AWS Region.

> **Note**
>
> To create an encrypted read replica, the source DB instance must be encrypted. To learn more about encrypting the source DB instance, see Encrypting Amazon RDS resources.

9. Choose other options, such as storage autoscaling.
10. Choose **Create read replica**.

AWS CLI

To create a read replica from a source MySQL, Microsoft SQL Server, MariaDB, Oracle, or PostgreSQL DB instance in a different AWS Region, you can use the `create-db-instance-read-replica` command. In this case, you use `create-db-instance-read-replica` from the AWS Region where you want the read replica (destination Region) and specify the Amazon Resource Name (ARN) for the source DB instance. An ARN uniquely identifies a resource created in Amazon Web Services.

For example, if your source DB instance is in the US East (N. Virginia) Region, the ARN looks similar to this example:

```
arn:aws:rds:us-east-1:123456789012:db:mydbinstance
```

For information about ARNs, see Amazon Resource Names (ARNs) in Amazon RDS.

To create a read replica in a different AWS Region from the source DB instance, you can use the AWS CLI `create-db-instance-read-replica` command from the destination AWS Region. The following parameters are required for creating a read replica in another AWS Region:

- `--region` – The destination AWS Region where the read replica is created.
- `--source-db-instance-identifier` – The DB instance identifier for the source DB instance. This identifier must be in the ARN format for the source AWS Region.
- `--db-instance-identifier` – The identifier for the read replica in the destination AWS Region.

Example of a cross-Region read replica

The following code creates a read replica in the US West (Oregon) Region from a source DB instance in the US East (N. Virginia) Region.

For Linux, macOS, or Unix:

```
aws rds create-db-instance-read-replica \
    --db-instance-identifier myreadreplica \
    --region us-west-2 \
    --source-db-instance-identifier arn:aws:rds:us-east-1:123456789012:db:mydbinstance
```

For Windows:

```
aws rds create-db-instance-read-replica ^
    --db-instance-identifier myreadreplica ^
    --region us-west-2 ^
    --source-db-instance-identifier arn:aws:rds:us-east-1:123456789012:db:mydbinstance
```

The following parameter is also required for creating an encrypted read replica in another AWS Region:

- `--kms-key-id` – The AWS KMS key identifier of the KMS key to use to encrypt the read replica in the destination AWS Region.

Example of an encrypted cross-Region read replica

The following code creates an encrypted read replica in the US West (Oregon) Region from a source DB instance in the US East (N. Virginia) Region.

For Linux, macOS, or Unix:

```
aws rds create-db-instance-read-replica \
    --db-instance-identifier myreadreplica \
    --region us-west-2 \
    --source-db-instance-identifier arn:aws:rds:us-east-1:123456789012:db:mydbinstance
 \
    --kms-key-id my-us-west-2-key
```

For Windows:

```
aws rds create-db-instance-read-replica ^
    --db-instance-identifier myreadreplica ^
    --region us-west-2 ^
    --source-db-instance-identifier arn:aws:rds:us-east-1:123456789012:db:mydbinstance
 ^
    --kms-key-id my-us-west-2-key
```

The `--source-region` option is required when you're creating an encrypted read replica between the AWS GovCloud (US-East) and AWS GovCloud (US-West) Regions. For `--source-region`, specify the AWS Region of the source DB instance.

If `--source-region` isn't specified, specify a `--pre-signed-url` value. A *presigned URL* is a URL that contains a Signature Version 4 signed request for the `create-db-instance-read-replica` command that's called in the source AWS Region. To learn more about the `pre-signed-url` option, see create-db-instance-read-replica in the *AWS CLI Command Reference*.

RDS API

To create a read replica from a source MySQL, Microsoft SQL Server, MariaDB, Oracle, or PostgreSQL DB instance in a different AWS Region, you can call the Amazon RDS API operation CreateDBInstanceReadReplica. In this case, you call CreateDBInstanceReadReplica from the AWS Region where you want the read replica (destination Region) and specify the Amazon Resource Name (ARN) for the source DB instance. An ARN uniquely identifies a resource created in Amazon Web Services.

To create an encrypted read replica in a different AWS Region from the source DB instance, you can use the Amazon RDS API `CreateDBInstanceReadReplica` operation from the destination AWS Region. To create an encrypted read replica in another AWS Region, you must specify a value for `PreSignedURL`. `PreSignedURL` should contain a request for the `CreateDBInstanceReadReplica` operation to call in the source AWS Region where the read replica is created in. To learn more about `PreSignedUrl`, see `CreateDBInstanceReadReplica`.

For example, if your source DB instance is in the US East (N. Virginia) Region, the ARN looks similar to the following.

```
arn:aws:rds:us-east-1:123456789012:db:mydbinstance
```

For information about ARNs, see Amazon Resource Names (ARNs) in Amazon RDS.

Example

```
https://us-west-2.rds.amazonaws.com/
    ?Action=CreateDBInstanceReadReplica
    &KmsKeyId=my-us-east-1-key
    &PreSignedUrl=https%253A%252F%252Frds.us-west-2.amazonaws.com%252F
         %253FAction%253DCreateDBInstanceReadReplica
         %2526DestinationRegion%253Dus-east-1

    &Signature=<Signature>
```

How Amazon RDS does cross-Region replication

Amazon RDS uses the following process to create a cross-Region read replica. Depending on the AWS Regions involved and the amount of data in the databases, this process can take hours to complete. You can use this information to determine how far the process has proceeded when you create a cross-Region read replica:

1. Amazon RDS begins configuring the source DB instance as a replication source and sets the status to *modifying*.

2. Amazon RDS begins setting up the specified read replica in the destination AWS Region and sets the status to *creating*.
3. Amazon RDS creates an automated DB snapshot of the source DB instance in the source AWS Region. The format of the DB snapshot name is `rds:<InstanceID>-<timestamp>`, where `<InstanceID>` is the identifier of the source instance, and `<timestamp>` is the date and time the copy started. For example, `rds:mysourceinstance-2013-11-14-09-24` was created from the instance `mysourceinstance` at `2013-11-14-09-24`. During the creation of an automated DB snapshot, the source DB instance status remains *modifying*, the read replica status remains *creating*, and the DB snapshot status is *creating*. The progress column of the DB snapshot page in the console reports how far the DB snapshot creation has progressed. When the DB snapshot is complete, the status of both the DB snapshot and source DB instance are set to *available*.
4. Amazon RDS begins a cross-Region snapshot copy for the initial data transfer. The snapshot copy is listed as an automated snapshot in the destination AWS Region with a status of *creating*. It has the same name as the source DB snapshot. The progress column of the DB snapshot display indicates how far the copy has progressed. When the copy is complete, the status of the DB snapshot copy is set to *available*.
5. Amazon RDS then uses the copied DB snapshot for the initial data load on the read replica. During this phase, the read replica is in the list of DB instances in the destination, with a status of *creating*. When the load is complete, the read replica status is set to *available*, and the DB snapshot copy is deleted.
6. When the read replica reaches the available status, Amazon RDS starts by replicating the changes made to the source instance since the start of the create read replica operation. During this phase, the replication lag time for the read replica is greater than 0.

   For information about replication lag time, see Monitoring read replication.

Cross-Region replication considerations

All of the considerations for performing replication within an AWS Region apply to cross-Region replication. The following extra considerations apply when replicating between AWS Regions:

- A source DB instance can have cross-Region read replicas in multiple AWS Regions. Because of the limit on the number of access control list (ACL) entries for the source VPC, RDS can't guarantee more than five cross-Region read replica DB instances.

- You can replicate between the GovCloud (US-East) and GovCloud (US-West) Regions, but not into or out of GovCloud (US).
- For Microsoft SQL Server, Oracle, and PostgreSQL DB instances, you can only create a cross-Region Amazon RDS read replica from a source Amazon RDS DB instance that is not a read replica of another Amazon RDS DB instance. This limitation doesn't apply to MariaDB and MySQL DB instances.
- You can expect to see a higher level of lag time for any read replica that is in a different AWS Region than the source instance. This lag time comes from the longer network channels between regional data centers.
- For cross-Region read replicas, any of the create read replica commands that specify the `--db-subnet-group-name` parameter must specify a DB subnet group from the same VPC.
- In most cases, the read replica uses the default DB parameter group and DB option group for the specified DB engine.

  For the MySQL and Oracle DB engines, you can specify a custom parameter group for the read replica in the `--db-parameter-group-name` option of the AWS CLI command `create-db-instance-read-replica`. You can't specify a custom parameter group when you use the AWS Management Console.
- The read replica uses the default security group.
- For MariaDB, Microsoft SQL Server, MySQL, and Oracle DB instances, when the source DB instance for a cross-Region read replica is deleted, the read replica is promoted.
- For PostgreSQL DB instances, when the source DB instance for a cross-Region read replica is deleted, the replication status of the read replica is set to `terminated`. The read replica isn't promoted.

  You have to promote the read replica manually or delete it.

Requesting a cross-Region read replica

To communicate with the source Region to request the creation of a cross-Region read replica, the requester (IAM role or IAM user) must have access to the source DB instance and the source Region.

Certain conditions in the requester's IAM policy can cause the request to fail. The following examples assume that the source DB instance is in US East (Ohio) and the read replica is created in US East (N. Virginia). These examples show conditions in the requester's IAM policy that cause the request to fail:

- The requester's policy has a condition for `aws:RequestedRegion`.

```
...
"Effect": "Allow",
"Action": "rds:CreateDBInstanceReadReplica",
"Resource": "*",
"Condition": {
    "StringEquals": {
        "aws:RequestedRegion": "us-east-1"
    }
}
```

  The request fails because the policy doesn't allow access to the source Region. For a successful request, specify both the source and destination Regions.

```
...
"Effect": "Allow",
"Action": "rds:CreateDBInstanceReadReplica",
"Resource": "*",
"Condition": {
    "StringEquals": {
        "aws:RequestedRegion": [
            "us-east-1",
            "us-east-2"
        ]
    }
}
```

- The requester's policy doesn't allow access to the source DB instance.

```
...
"Effect": "Allow",
"Action": "rds:CreateDBInstanceReadReplica",
"Resource": "arn:aws:rds:us-east-1:123456789012:db:myreadreplica"
...
```

  For a successful request, specify both the source instance and the replica.

```
...
"Effect": "Allow",
"Action": "rds:CreateDBInstanceReadReplica",
```

```
"Resource": [
    "arn:aws:rds:us-east-1:123456789012:db:myreadreplica",
    "arn:aws:rds:us-east-2:123456789012:db:mydbinstance"
]
...
```

- The requester's policy denies `aws:ViaAWSService`.

  ```
  ...
  "Effect": "Allow",
  "Action": "rds:CreateDBInstanceReadReplica",
  "Resource": "*",
  "Condition": {
      "Bool": {"aws:ViaAWSService": "false"}
  }
  ```

  Communication with the source Region is made by RDS on the requester's behalf. For a successful request, don't deny calls made by AWS services.

- The requester's policy has a condition for `aws:SourceVpc` or `aws:SourceVpce`.

  These requests might fail because when RDS makes the call to the remote Region, it isn't from the specified VPC or VPC endpoint.

If you need to use one of the previous conditions that would cause a request to fail, you can include a second statement with `aws:CalledVia` in your policy to make the request succeed. For example, you can use `aws:CalledVia` with `aws:SourceVpce` as shown here:

```
...
"Effect": "Allow",
"Action": "rds:CreateDBInstanceReadReplica",
"Resource": "*",
"Condition": {
    "Condition" : {
        "ForAnyValue:StringEquals" : {
          "aws:SourceVpce": "vpce-1a2b3c4d"
        }
     }
},
{
    "Effect": "Allow",
    "Action": [
```

```
            "rds:CreateDBInstanceReadReplica"
        ],
        "Resource": "*",
        "Condition": {
            "ForAnyValue:StringEquals": {
                "aws:CalledVia": [
                    "rds.amazonaws.com"
                ]
            }
        }
    }
```

For more information, see Policies and permissions in IAM in the *IAM User Guide*.

Authorizing the read replica

After a cross-Region DB read replica creation request returns `success`, RDS starts the replica creation in the background. An authorization for RDS to access the source DB instance is created. This authorization links the source DB instance to the read replica, and allows RDS to copy only to the specified read replica.

The authorization is verified by RDS using the `rds:CrossRegionCommunication` permission in the service-linked IAM role. If the replica is authorized, RDS communicates with the source Region and completes the replica creation.

RDS doesn't have access to DB instances that weren't authorized previously by a `CreateDBInstanceReadReplica` request. The authorization is revoked when read replica creation completes.

RDS uses the service-linked role to verify the authorization in the source Region. If you delete the service-linked role during the replication creation process, the creation fails.

For more information, see Using service-linked roles in the *IAM User Guide*.

Using AWS Security Token Service credentials

Session tokens from the global AWS Security Token Service (AWS STS) endpoint are valid only in AWS Regions that are enabled by default (commercial Regions). If you use credentials from the `assumeRole` API operation in AWS STS, use the regional endpoint if the source Region is an opt-in Region. Otherwise, the request fails. This happens because your credentials must be valid in both Regions, which is true for opt-in Regions only when the regional AWS STS endpoint is used.

To use the global endpoint, make sure that it's enabled for both Regions in the operations. Set the global endpoint to `Valid in all AWS Regions` in the AWS STS account settings.

The same rule applies to credentials in the presigned URL parameter.

For more information, see Managing AWS STS in an AWS Region in the *IAM User Guide*.

Cross-Region replication costs

The data transferred for cross-Region replication incurs Amazon RDS data transfer charges. These cross-Region replication actions generate charges for the data transferred out of the source AWS Region:

- When you create a read replica, Amazon RDS takes a snapshot of the source instance and transfers the snapshot to the read replica AWS Region.
- For each data modification made in the source databases, Amazon RDS transfers data from the source AWS Region to the read replica AWS Region.

For more information about data transfer pricing, see Amazon RDS pricing.

For MySQL and MariaDB instances, you can reduce your data transfer costs by reducing the number of cross-Region read replicas that you create. For example, suppose that you have a source DB instance in one AWS Region and want to have three read replicas in another AWS Region. In this case, you create only one of the read replicas from the source DB instance. You create the other two replicas from the first read replica instead of the source DB instance.

For example, if you have `source-instance-1` in one AWS Region, you can do the following:

- Create `read-replica-1` in the new AWS Region, specifying `source-instance-1` as the source.
- Create `read-replica-2` from `read-replica-1`.
- Create `read-replica-3` from `read-replica-1`.

In this example, you are only charged for the data transferred from `source-instance-1` to `read-replica-1`. You aren't charged for the data transferred from `read-replica-1` to the other two replicas because they are all in the same AWS Region. If you create all three replicas directly from `source-instance-1`, you are charged for the data transfers to all three replicas.

Tagging Amazon RDS resources

An Amazon RDS *tag* is a name-value pair that you define and associate with an Amazon RDS resource such as a DB instance or DB snapshot. The name is referred to as the *key*. Optionally, you can supply a value for the key.

You can use the AWS Management Console, the AWS CLI, or the Amazon RDS API to add, list, and delete tags on Amazon RDS resources. When using the CLI or API, make sure to provide the Amazon Resource Name (ARN) for the RDS resource to work with. For more information about constructing an ARN, see Constructing an ARN for Amazon RDS.

Topics

Why use Amazon RDS resource tags?

You can use tags to do the following:

- Categorize your RDS resources by application, project, department, environment, and so on. For example, you could use a tag key to define a category, where the tag value is an item in this category. You might create the tag `environment=prod`. Or you might define a tag key of `project` and a tag value of `Salix`, which indicates that an Amazon RDS resource is assigned to the Salix project.
- Automate resource management tasks. For example, you could create a maintenance window for instances tagged `environment=prod` that differs from the window for instances tagged `environment=test`. You could also configure automatic DB snapshots for instances tagged `environment=prod`.
- Control access to RDS resources within an IAM policy. You can do this by using the global `aws:ResourceTag/`*`tag-key`* condition key. For example, a policy might allow only users in the `DBAdmin` group to modify DB instances tagged with `environment=prod`. For information about

managing access to tagged resources with IAM policies, see Identity and access management for Amazon RDS and Controlling access to AWS resources in the *AWS Identity and Access Management User Guide*.

- Monitor resources based on a tag. For example, you can create an Amazon CloudWatch dashboard for DB instances tagged with `environment=prod`.
- Track costs by grouping expenses for similarly tagged resources. For example, if you tag RDS resources associated with the Salix project with `project=Salix`, you can generate cost reports for and allocate expenses to this project. For more information, see How AWS billing works with tags in Amazon RDS.

How Amazon RDS resource tags work

AWS doesn't apply any semantic meaning to your tags. Tags are interpreted strictly as character strings.

Topics

- Tag sets in Amazon RDS
- Tag structure in Amazon RDS
- Amazon RDS resources eligible for tagging
- How AWS billing works with tags in Amazon RDS

Tag sets in Amazon RDS

Every Amazon RDS resource has a container called a *tag set*. The container includes all the tags that are assigned to the resource. A resource has exactly one tag set.

A tag set contains 0—50 tags. If you add a tag to an RDS resource with the same key as an existing resource tag, the new value overwrites the old.

Tag structure in Amazon RDS

The structure of an RDS tag is as follows:

Tag key

The key is the required name of the tag. The string value must be 1—128 Unicode characters in length and cannot be prefixed with `aws:` or `rds:`. The string can contain only the set of

Unicode letters, digits, whitespace, _, ., :, /, =, +, -, and @. The Java regex is "^([\\p{L}\\p{Z}\\p{N}_.:/=+\\-@]*)$". Tag keys are case-sensitive. Thus, the keys `project` and `Project` are distinct.

A key is unique to a tag set. For example, you cannot have a key-pair in a tag set with the key the same but with different values, such as `project=Trinity` and `project=Xanadu`.

Tag value

The value is an optional string value of the tag. The string value must be 1—256 Unicode characters in length. The string can contain only the set of Unicode letters, digits, whitespace, _, ., :, /, =, +, -, and @. The Java regex is "^([\\p{L}\\p{Z}\\p{N}_.:/=+\\-@]*)$". Tag values are case-sensitive. Thus, the values `prod` and `Prod` are distinct.

Values don't need to be unique in a tag set and can be null. For example, you can have a key-value pair in a tag set of `project=Trinity` and `cost-center=Trinity`.

Amazon RDS resources eligible for tagging

You can tag the following Amazon RDS resources:

- DB instances
- DB clusters
- DB cluster endpoints
- Read replicas
- DB snapshots
- DB cluster snapshots
- Reserved DB instances
- Event subscriptions
- DB option groups
- DB parameter groups
- DB cluster parameter groups
- DB subnet groups
- RDS Proxies
- RDS Proxy endpoints

> **Note**
>
> Currently, you can't tag RDS Proxies and RDS Proxy endpoints by using the AWS Management Console.

- Blue/green deployments
- Zero-ETL integrations (preview)

How AWS billing works with tags in Amazon RDS

Use tags to organize your AWS bill to reflect your own cost structure. To do this, sign up to get your AWS account bill with tag key values included. Then, to see the cost of combined resources, organize your billing information according to resources with the same tag key values. For example, you can tag several resources with a specific application name, and then organize your billing information to see the total cost of that application across several services. For more information, see Using Cost Allocation Tags in the *AWS Billing User Guide*.

How cost allocation tags work with DB snapshots

You can add a tag to a DB snapshot. However, your bill won't reflect this grouping. For cost allocation tags to apply to DB snapshots, the following conditions must be met:

- The tags must be attached to the parent DB instance.
- The parent DB instance must exist in the same AWS account as the DB snapshot.
- The parent DB instance must exist in the same AWS Region as the DB snapshot.

DB snapshots are considered orphaned if they don't exist in the same Region as the parent DB instance, or if the parent DB instance is deleted. Orphaned DB snapshots don't support cost allocation tags. Costs for orphaned snapshots are aggregated in a single untagged line item. Cross-account DB snapshots aren't considered orphaned when the following conditions are met:

- They exist in the same Region as the parent DB instance.
- The parent DB instance is owned by the source account.

> **Note**
>
> If the parent DB instance is owned by a different account, cost allocation tags don't apply to cross-account snapshots in the destination account.

Best practices for tagging Amazon RDS resources

When you use tags, we recommend that you adhere to the following best practices:

- Document conventions for tag use that are followed by all teams in your organization. In particular, ensure the names are both descriptive and consistent. For example, standardize on the format `environment:prod` rather than tagging some resources with `env:production`.

  > **Important**
  >
  > Do not store personally identifiable information (PII) or other confidential or sensitive information in tags.

- Automate tagging to ensure consistency. For example, you can use the following techniques:
  - Include tags in an AWS CloudFormation template. When you create resources with the template, the resources are tagged automatically.
  - Define and apply tags using AWS Lambda functions.
  - Create an SSM document that includes steps to add tags to your RDS resources.
- Use tags only when necessary. You can add up to 50 tags for a single RDS resource, but a best practice is to avoid unnecessary tag proliferation and complexity.
- Review tags periodically for relevance and accuracy. Remove or modify outdated tags as needed.
- Consider creating tags with the AWS Tag Editor in the AWS Management Console. You can use the Tag Editor to add tags to multiple supported AWS resources, including RDS resources, at the same time. For more information, see Tag Editor in the *AWS Resource Groups User Guide*.

Copying tags to DB snapshots

When you create or restore a DB instance, you can specify that the tags from the DB instance are copied to snapshots of the DB instance. Copying tags ensures that the metadata for the DB

snapshots matches that of the source DB instance. It also ensures that any access policies for the DB snapshots also match those of the source DB instance.

You can specify that tags are copied to DB snapshots for the following actions:

- Creating a DB instance.
- Restoring a DB instance.
- Creating a read replica.
- Copying a DB snapshot.

In most cases, tags aren't copied by default. However, when you restore a DB instance from a DB snapshot, RDS checks whether you specify new tags. If yes, the new tags are added to the restored DB instance. If there are no new tags, RDS adds the tags from the source DB instance at the time of snapshot creation to the restored DB instance.

To prevent tags from source DB instances from being added to restored DB instances, we recommend that you specify new tags when restoring a DB instance.

> **Note**
>
> In some cases, you might include a value for the `--tags` parameter of the create-db-snapshot AWS CLI command. Or you might supply at least one tag to the CreateDBSnapshot API operation. In these cases, RDS doesn't copy tags from the source DB instance to the new DB snapshot. This functionality applies even if the source DB instance has the `--copy-tags-to-snapshot` (`CopyTagsToSnapshot`) option turned on.
> If you take this approach, you can create a copy of a DB instance from a DB snapshot. This approach avoids adding tags that don't apply to the new DB instance. You create your DB snapshot using the AWS CLI `create-db-snapshot` command (or the `CreateDBSnapshot` RDS API operation). After you create your DB snapshot, you can add tags as described later in this topic.

Adding and deleting tags in Amazon RDS

You can do the following:

- Create tags when you create a resource, for example, when you run the AWS CLI command `create-db-instance`.

- Add tags to an existing resource using the command `add-tags-to-resource`.
- List tags associated with a specific resource using the command `list-tags-for-resource`.
- Update tags using the command `add-tags-to-resource`.
- Remove tags from a resource using the command `remove-tags-from-resource`.

The following procedures show how you can perform typical tagging operations on resources related to DB instances. Note that tags are cached for authorization purposes. For this reason, when you add or update tags on Amazon RDS resources, several minutes can pass before the modifications are available.

Console

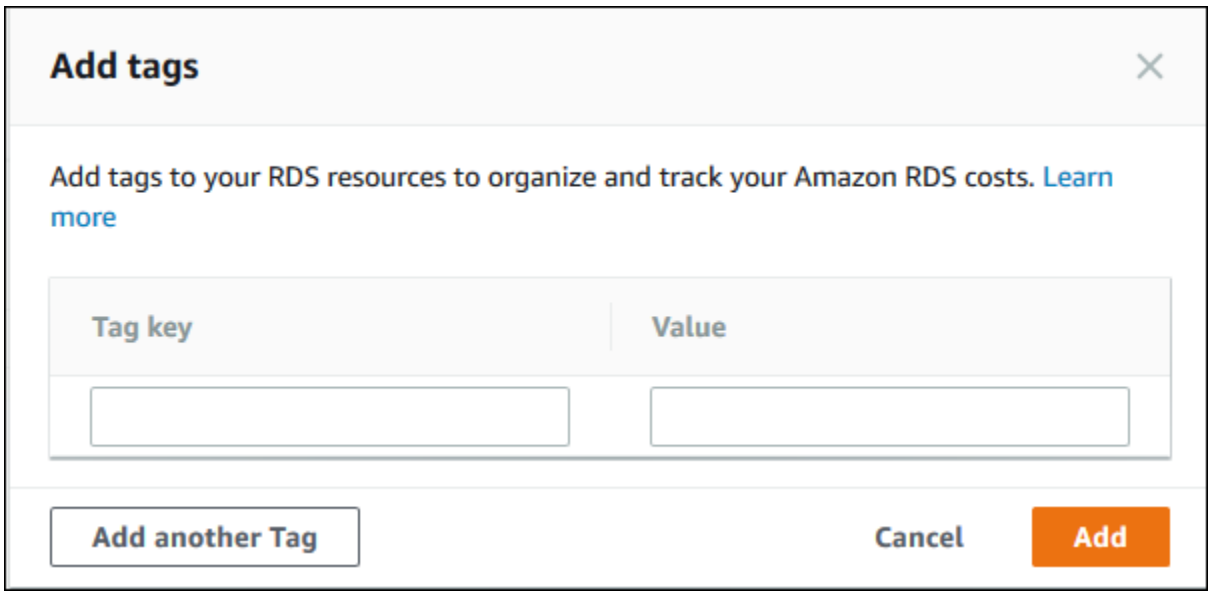
The process to tag an Amazon RDS resource is similar for all resources. The following procedure shows how to tag an Amazon RDS DB instance.

To add a tag to a DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.

   > **Note**
   >
   > To filter the list of DB instances in the **Databases** pane, enter a text string for **Filter databases**. Only DB instances that contain the string appear.

3. Choose the name of the DB instance that you want to tag to show its details.
4. In the details section, scroll down to the **Tags** section.
5. Choose **Add**. The **Add tags** window appears.



6. Enter a value for **Tag key** and **Value**.
7. To add another tag, you can choose **Add another Tag** and enter a value for its **Tag key** and **Value**.

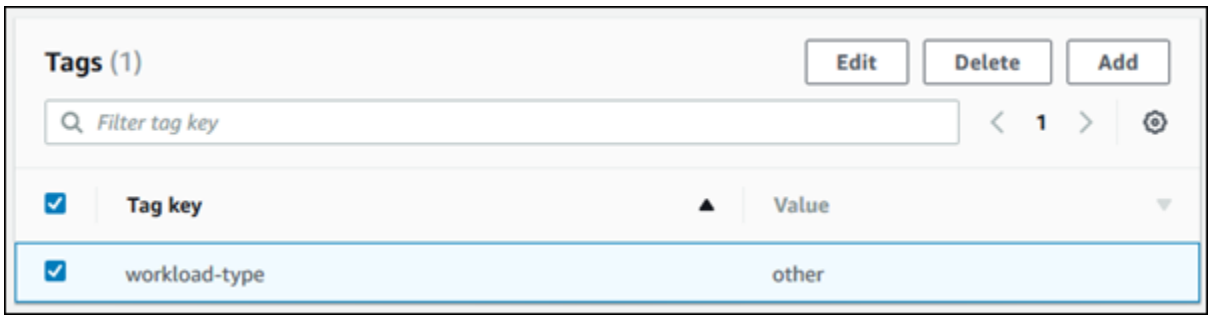
   Repeat this step as many times as necessary.
8. Choose **Add**.

To delete a tag from a DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.

   > **Note**
   >
   > To filter the list of DB instances in the **Databases** pane, enter a text string in the **Filter databases** box. Only DB instances that contain the string appear.

3. Choose the name of the DB instance to show its details.
4. In the details section, scroll down to the **Tags** section.
5. Choose the tag you want to delete.



6. Choose **Delete**, and then choose **Delete** in the **Delete tags** window.

AWS CLI

You can add, list, or remove tags for a DB instance using the AWS CLI.

- To add one or more tags to an Amazon RDS resource, use the AWS CLI command `add-tags-to-resource`.
- To list the tags on an Amazon RDS resource, use the AWS CLI command `list-tags-for-resource`.
- To remove one or more tags from an Amazon RDS resource, use the AWS CLI command `remove-tags-from-resource`.

To learn more about how to construct the required ARN, see Constructing an ARN for Amazon RDS.

RDS API

You can add, list, or remove tags for a DB instance using the Amazon RDS API.

- To add a tag to an Amazon RDS resource, use the `AddTagsToResource` operation.
- To list tags that are assigned to an Amazon RDS resource, use the `ListTagsForResource`.
- To remove tags from an Amazon RDS resource, use the `RemoveTagsFromResource` operation.

To learn more about how to construct the required ARN, see Constructing an ARN for Amazon RDS.

When working with XML using the Amazon RDS API, tags use the following schema:

```
<Tagging>
      <TagSet>
          <Tag>
```

```
            <Key>Project</Key>
            <Value>Trinity</Value>
        </Tag>
        <Tag>
            <Key>User</Key>
            <Value>Jones</Value>
        </Tag>
    </TagSet>
</Tagging>
```

The following table provides a list of the allowed XML tags and their characteristics. Values for `Key` and `Value` are case-sensitive. For example, `project=Trinity` and `PROJECT=Trinity` are distinct tags.

Tagging element	Description
TagSet	A tag set is a container for all tags assigned to an Amazon RDS resource. There can be only one tag set per resource. You work with a TagSet only through the Amazon RDS API.
Tag	A tag is a user-defined key-value pair. There can be from 1 to 50 tags in a tag set.
Key	A key is the required name of the tag. For restrictions, see Tag structure in Amazon RDS. The string value can be from 1 to 128 Unicode characters in length and cannot be prefixed with `aws:` or `rds:`. The string can only contain only the set of Unicode letters, digits, white space, '_', '.', '/', '=', '+', '-' (Java regex: "^([\\p{L}\\p{Z}\\p{N}_.:/=+\\-]*)$"). Keys must be unique to a tag set. For example, you cannot have a key-pair in a tag set with the key the same but with different values, such as project/Trinity and project/Xanadu.
Value	A value is the optional value of the tag. For restrictions, see Tag structure in Amazon RDS. The string value can be from 1 to 256 Unicode characters in length and cannot be prefixed with `aws:` or `rds:`. The string can only contain only the set of

Tagging element	Description
	Unicode letters, digits, white space, '_', '.', '/', '=', '+', '-' (Java regex: "^([\\p{L}\\p{Z}\\p{N}_.:/=+\\-]*)$"). Values do not have to be unique in a tag set and can be null. For example, you can have a key-value pair in a tag set of project/Trinity and cost-center/Trinity.

Tutorial: Specify which DB instances to stop by using tags

This tutorial assumes that you have several DB instances in a development or test environment. You need to keep these DB instances for several days. Some DB instances run tests overnight, whereas others can be stopped overnight and started again the next day.

The following tutorial shows how to assign a tag to DB instances that are suitable to stop overnight. The tutorial shows how a script can detect which DB instances have the tag and then stop the tagged DB instances. In this example, the value portion of the key-value pair doesn't matter. The presence of the `stoppable` tag signifies that the DB instance has this user-defined property.

In the following tutorial, the commands and APIs for tagging work with ARNs, which allow RDS to work seamlessly across AWS Regions, AWS accounts, and different types of resources that might have identical short names. You can specify the ARN instead of the DB instance ID in CLI commands that operate on DB instances.

To specify which DB instances to stop

1. Determine the ARN of a DB instance that you want to designate as stoppable.

   In the following example, substitute the name of your own DB instances for *`dev-test-db-instance`*. In subsequent commands that use ARN parameters, substitute the ARN of your own DB instance. The ARN includes your own AWS account ID and the name of the AWS Region where your DB instance is located.

   ```
   $ aws rds describe-db-instances --db-instance-identifier dev-test-db-instance \
     --query "*[].{DBInstance:DBInstanceArn}" --output text
   arn:aws:rds:us-east-1:123456789102:db:dev-test-db-instance
   ```

2. Add the tag `stoppable` to this DB instance.

   You choose the name for this tag. Because this example treats the tag as an attribute that is either present or absent, it omits the `Value=` part of the `--tags` parameter. This approach means that you can avoid devising a naming convention that encodes all relevant information in names. In such a convention, you might encode information in the DB instance name or names of other resources.

   ```
   $ aws rds add-tags-to-resource \
     --resource-name arn:aws:rds:us-east-1:123456789102:db:dev-test-db-instance \
     --tags Key=stoppable
   ```

3. Confirm that the tag is present in the DB instance.

   The following commands retrieve the tag information for the DB instance in JSON format and in plain tab-separated text.

   ```
   $ aws rds list-tags-for-resource \
     --resource-name arn:aws:rds:us-east-1:123456789102:db:dev-test-db-instance
   {
       "TagList": [
           {
               "Key": "stoppable",
               "Value": ""

           }
       ]
   }
   aws rds list-tags-for-resource \
     --resource-name arn:aws:rds:us-east-1:123456789102:db:dev-test-db-instance --
   output text
   TAGLIST stoppable
   ```

4. Stop all the DB instances that are designated as `stoppable`.

   The following example create a text file that lists all your DB instances. The shell command loops through the list and checks if each DB instance is tagged with the relevant attribute and performs runs the command `aws rds stop-db-instance` for each DB instance.

   ```
   $ aws rds describe-db-instances --query "*[].[DBInstanceArn]" --output text >/tmp/
   db_instance_arns.lst
   $ for arn in $(cat /tmp/db_instance_arns.lst)
   ```

```
do
  match="$(aws rds list-tags-for-resource --resource-name $arn --output text | grep
 stoppable)"
  if [[ ! -z "$match" ]]
  then
      echo "DB instance $arn is tagged as stoppable. Stopping it now."
# Note that you need to get the DB instance identifier from the ARN.
      dbid=$(echo $arn | sed -e 's/.*://')
      aws rds stop-db-instance --db-instance-identifier $dbid
  fi
done

DB instance arn:arn:aws:rds:us-east-1:123456789102:db:dev-test-db-instance is
 tagged as stoppable. Stopping it now.
{
    "DBInstance": {
        "DBInstanceIdentifier": "dev-test-db-instance",
        "DBInstanceClass": "db.t3.medium",
        ...
```

You can run a script like the preceding one at the end of every day to make sure that nonessential DB instances are stopped. You might also schedule a job using a utility such as `cron` to perform such a check each night. For example, you might do this in case some DB instances were left running by mistake. Here, you might fine-tune the command that prepares the list of DB instances to check.

The following command produces a list of your DB instances, but only the ones in `available` state. The script can ignore DB instances that are already stopped, because they will have different status values such as `stopped` or `stopping`.

```
$ aws rds describe-db-instances \
  --query '*[].{DBInstanceArn:DBInstanceArn,DBInstanceStatus:DBInstanceStatus}|[?
DBInstanceStatus == `available`]|[].{DBInstanceArn:DBInstanceArn}' \
  --output text
arn:aws:rds:us-east-1:123456789102:db:db-instance-2447
arn:aws:rds:us-east-1:123456789102:db:db-instance-3395
arn:aws:rds:us-east-1:123456789102:db:dev-test-db-instance
arn:aws:rds:us-east-1:123456789102:db:pg2-db-instance
```

Tip

You can use assigning tags and finding DB instances with those tags to reduce costs in other ways. For example, take this scenario with DB instances used for development and testing. In this case, you might designate some DB instances to be deleted at the end of each day. Or you might designate them to have their DB instances changed to small DB instance classes during times of expected low usage.

Amazon Resource Names (ARNs) in Amazon RDS

Resources created in Amazon Web Services are each uniquely identified with an Amazon Resource Name (ARN). For certain Amazon RDS operations, you must uniquely identify an Amazon RDS resource by specifying its ARN. For example, when you create an RDS DB instance read replica, you must supply the ARN for the source DB instance.

For information about constructing an ARN and getting an existing ARN, see the following topics.

Topics

Constructing an ARN for Amazon RDS

Resources created in Amazon Web Services are each uniquely identified with an Amazon Resource Name (ARN). You can construct an ARN for an Amazon RDS resource using the following syntax.

`arn:aws:rds:<region>:<account number>:<resourcetype>:<name>`

Region Name	Region	Endpoint	Protocol	
US East (Ohio)	us-east-2	rds.us-east-2.amazonaws.com	HTTPS	
		rds-fips.us-east-2.api.aws	HTTPS	
		rds.us-east-2.api.aws	HTTPS	
		rds-fips.us-east-2.amazonaws.com	HTTPS	
US East (N. Virginia)	us-east-1	rds.us-east-1.amazonaws.com	HTTPS	
		rds-fips.us-east-1.api.aws	HTTPS	
		rds-fips.us-east-1.amazonaws.com	HTTPS	
		rds.us-east-1.api.aws	HTTPS	

Region Name	Region	Endpoint	Protocol
US West (N. California)	us-west-1	rds.us-west-1.amazonaws.com	HTTPS
		rds.us-west-1.api.aws	HTTPS
		rds-fips.us-west-1.amazonaws.com	HTTPS
		rds-fips.us-west-1.api.aws	HTTPS
US West (Oregon)	us-west-2	rds.us-west-2.amazonaws.com	HTTPS
		rds-fips.us-west-2.amazonaws.com	HTTPS
		rds.us-west-2.api.aws	HTTPS
		rds-fips.us-west-2.api.aws	HTTPS
Africa (Cape Town)	af-south-1	rds.af-south-1.amazonaws.com	HTTPS
		rds.af-south-1.api.aws	HTTPS
Asia Pacific (Hong Kong)	ap-east-1	rds.ap-east-1.amazonaws.com	HTTPS
		rds.ap-east-1.api.aws	HTTPS
Asia Pacific (Hyderabad)	ap-south-2	rds.ap-south-2.amazonaws.com	HTTPS
		rds.ap-south-2.api.aws	HTTPS
Asia Pacific (Jakarta)	ap-southeast-3	rds.ap-southeast-3.amazonaws.com	HTTPS
		rds.ap-southeast-3.api.aws	HTTPS

Region Name	Region	Endpoint	Protocol
Asia Pacific (Malaysia)	ap-southeast-5	rds.ap-southeast-5.amazonaws.com	HTTPS
Asia Pacific (Melbourne)	ap-southeast-4	rds.ap-southeast-4.amazonaws.com rds.ap-southeast-4.api.aws	HTTPS HTTPS
Asia Pacific (Mumbai)	ap-south-1	rds.ap-south-1.amazonaws.com rds.ap-south-1.api.aws	HTTPS HTTPS

The following table shows the format that you should use when constructing an ARN for a particular Amazon RDS resource type.

Resource type	ARN format
DB instance	arn:aws:rds:*<region>*:*<account>* :db:*<name>* For example: `arn:aws:rds: us-east-2 :123456789012 :db:my-mysql-instance-1`
DB cluster	arn:aws:rds:*<region>*:*<account>* :cluster:*<name>* For example: `arn:aws:rds: us-east-2 :123456789012 :cluster: my-aurora-cluster-1`
Event subscription	arn:aws:rds:*<region>*:*<account>* :es:*<name>* For example: `arn:aws:rds: us-east-2 :123456789012 :es:my-subscription`
DB option group	arn:aws:rds:*<region>*:*<account>* :og:*<name>* For example: `arn:aws:rds: us-east-2 :123456789012 :og:my-og`
DB parameter group	arn:aws:rds:*<region>*:*<account>* :pg:*<name>* For example: `arn:aws:rds: us-east-2 :123456789012 :pg:my-param-enable-logs`
DB cluster parameter group	arn:aws:rds:*<region>*:*<account>* :cluster-pg:*<name>* For example:

Resource type	ARN format
	`arn:aws:rds: us-east-2 :123456789012 :cluster-pg: my-cluster-param-timezone`
Reserved DB instance	arn:aws:rds:*<region>*:*<account>* :ri:*<name>* For example: `arn:aws:rds: us-east-2 :123456789012 :ri:my-reserved-postgresql`
DB security group	arn:aws:rds:*<region>*:*<account>* :secgrp:*<name>* For example: `arn:aws:rds: us-east-2 :123456789012 :secgrp:my-public`
Automated DB snapshot	arn:aws:rds:*<region>*:*<account>* :snapshot:rds:*<name>* For example: `arn:aws:rds: us-east-2 :123456789012 :snapshot:rds: my-mysql-db-2019-07-22-07-23`
Automated DB cluster snapshot	arn:aws:rds:*<region>*:*<account>* :cluster-snapshot:rds:*<name>* For example: `arn:aws:rds: us-east-2 :123456789012 :cluster-snapshot:rds: my-aurora-cluster-2019-07-22-16-16`

Resource type	ARN format
Manual DB snapshot	arn:aws:rds:*<region>*:*<account>* :snapshot:*<name>* For example: `arn:aws:rds: us-east-2 :123456789012 :snapshot: my-mysql-db-snap`
Manual DB cluster snapshot	arn:aws:rds:*<region>*:*<account>* :cluster-snapshot:*<name>* For example: `arn:aws:rds: us-east-2 :123456789012 :cluster-snapshot: my-aurora-cluster-snap`
DB subnet group	arn:aws:rds:*<region>*:*<account>* :subgrp:*<name>* For example: `arn:aws:rds: us-east-2 :123456789012 :subgrp:my-subnet-10`

Getting an existing ARN for Amazon RDS

You can get the ARN of an RDS resource by using the AWS Management Console, AWS Command Line Interface (AWS CLI), or RDS API.

Console

To get an ARN from the AWS Management Console, navigate to the resource you want an ARN for, and view the details for that resource.

For example, you can get the ARN for a DB instance from the **Configuration** tab of the DB instance details.

AWS CLI

To get an ARN from the AWS CLI for a particular RDS resource, you use the `describe` command for that resource. The following table shows each AWS CLI command, and the ARN property used with the command to get an ARN.

AWS CLI command	ARN property
describe-event-subscriptions	EventSubscriptionArn
describe-certificates	CertificateArn
describe-db-parameter-groups	DBParameterGroupArn
describe-db-cluster-parameter-groups	DBClusterParameterGroupArn
describe-db-instances	DBInstanceArn
describe-db-security-groups	DBSecurityGroupArn
describe-db-snapshots	DBSnapshotArn
describe-events	SourceArn
describe-reserved-db-instances	ReservedDBInstanceArn
describe-db-subnet-groups	DBSubnetGroupArn
describe-option-groups	OptionGroupArn
describe-db-clusters	DBClusterArn
describe-db-cluster-snapshots	DBClusterSnapshotArn

For example, the following AWS CLI command gets the ARN for a DB instance.

Example

For Linux, macOS, or Unix:

```
aws rds describe-db-instances \
--db-instance-identifier DBInstanceIdentifier \
--region us-west-2 \
--query "*[].{DBInstanceIdentifier:DBInstanceIdentifier,DBInstanceArn:DBInstanceArn}"
```

For Windows:

```
aws rds describe-db-instances ^
--db-instance-identifier DBInstanceIdentifier ^
--region us-west-2 ^
--query "*[].{DBInstanceIdentifier:DBInstanceIdentifier,DBInstanceArn:DBInstanceArn}"
```

The output of that command is like the following:

```
[
    {
        "DBInstanceArn": "arn:aws:rds:us-west-2:account_id:db:instance_id",
        "DBInstanceIdentifier": "instance_id"
    }
]
```

RDS API

To get an ARN for a particular RDS resource, you can call the following RDS API operations and use the ARN properties shown following.

RDS API operation	ARN property
DescribeEventSubscriptions	EventSubscriptionArn
DescribeCertificates	CertificateArn
DescribeDBParameterGroups	DBParameterGroupArn
DescribeDBClusterParameterGroups	DBClusterParameterGroupArn
DescribeDBInstances	DBInstanceArn

RDS API operation	ARN property
DescribeDBSecurityGroups	DBSecurityGroupArn
DescribeDBSnapshots	DBSnapshotArn
DescribeEvents	SourceArn
DescribeReservedDBInstances	ReservedDBInstanceArn
DescribeDBSubnetGroups	DBSubnetGroupArn
DescribeOptionGroups	OptionGroupArn
DescribeDBClusters	DBClusterArn
DescribeDBClusterSnapshots	DBClusterSnapshotArn

Working with storage for Amazon RDS DB instances

To specify how you want your data stored in Amazon RDS, choose a storage type and provide a storage size when you create or modify a DB instance. Later, you can increase the amount or change the type of storage by modifying the DB instance. For more information about which storage type to use for your workload, see Amazon RDS storage types.

Topics

Increasing DB instance storage capacity

If you need space for additional data, you can scale up the storage of an existing DB instance. To do so, you can use the Amazon RDS Management Console, the Amazon RDS API, or the AWS Command Line Interface (AWS CLI). For information about storage limits, see Amazon RDS DB instance storage.

> **Note**
>
> You can't reduce the amount of storage for a DB instance after storage has been allocated. When you increase the allocated storage, it must be by at least 10 percent. If you try to increase the value by less than 10 percent, you get an error.
> Scaling storage for RDS for SQL Server DB instances is supported only for the General Purpose SSD and Provisioned IOPS SSD storage types.

To monitor the amount of free storage for your DB instance so you can respond when necessary, we recommend that you create an Amazon CloudWatch alarm. For more information on setting CloudWatch alarms, see Using CloudWatch alarms.

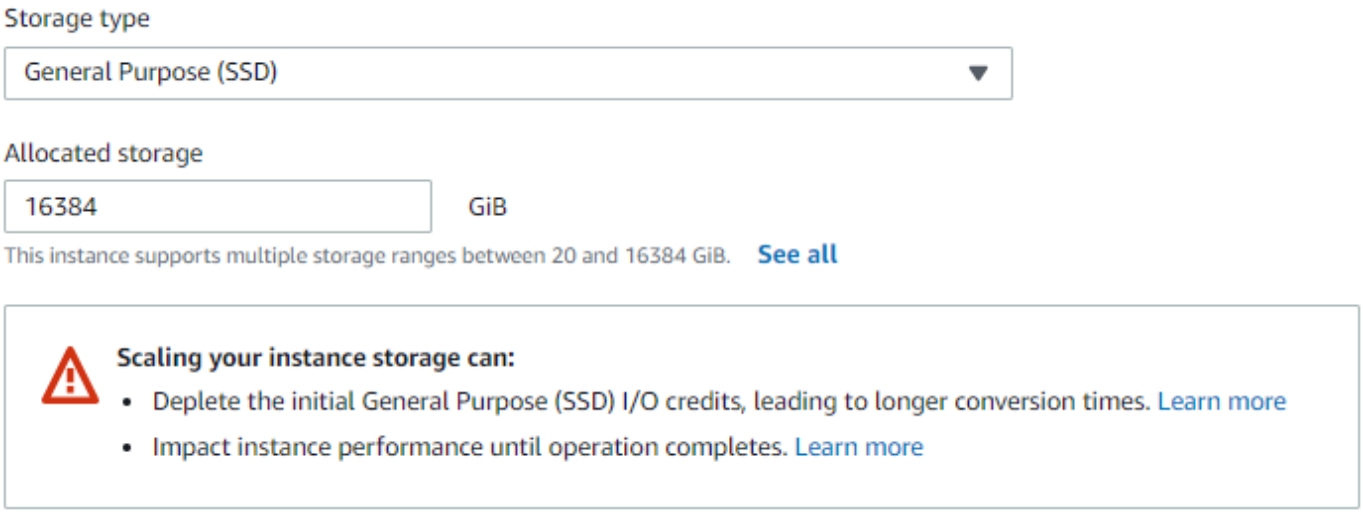
Scaling storage usually doesn't cause any outage or performance degradation of the DB instance. After you modify the storage size for a DB instance, the status of the DB instance is **storage-optimization**.

> **Note**
>
> Storage optimization can take several hours. You can't make further storage modifications for either six (6) hours or until storage optimization has completed on the instance, whichever is longer. You can view the storage optimization progress in the AWS Management Console or by using the describe-db-instances AWS CLI command.

Console

To increase storage for a DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.
3. Choose the DB instance that you want to modify.
4. Choose **Modify**.
5. Enter a new value for **Allocated storage**. It must be greater than the current value.



6. Choose **Continue** to move to the next screen.
7. Choose **Apply immediately** in the **Scheduling of modifications** section to apply the storage changes to the DB instance immediately.

Or choose **Apply during the next scheduled maintenance window** to apply the changes during the next maintenance window.

8. When the settings are as you want them, choose **Modify DB instance**.

AWS CLI

To increase the storage for a DB instance, use the AWS CLI command `modify-db-instance`. Set the following parameters:

- `--allocated-storage` – Amount of storage to be allocated for the DB instance, in gibibytes.
- `--apply-immediately` – Use `--apply-immediately` to apply the storage changes immediately.

  Or use `--no-apply-immediately` (the default) to apply the changes during the next maintenance window. An immediate outage occurs when the changes are applied.

For more information about storage, see Amazon RDS DB instance storage.

RDS API

To increase storage for a DB instance, use the Amazon RDS API operation `ModifyDBInstance`. Set the following parameters:

- `AllocatedStorage` – Amount of storage to be allocated for the DB instance, in gibibytes.
- `ApplyImmediately` – Set this option to `True` to apply the storage changes immediately. Set this option to `False` (the default) to apply the changes during the next maintenance window. An immediate outage occurs when the changes are applied.

For more information about storage, see Amazon RDS DB instance storage.

Managing capacity automatically with Amazon RDS storage autoscaling

If your workload is unpredictable, you can enable storage autoscaling for an Amazon RDS DB instance. To do so, you can use the Amazon RDS console, the Amazon RDS API, or the AWS CLI.

For example, you might use this feature for a new mobile gaming application that users are adopting rapidly. In this case, a rapidly increasing workload might exceed the available database

storage. To avoid having to manually scale up database storage, you can use Amazon RDS storage autoscaling.

With storage autoscaling enabled, when Amazon RDS detects that you are running out of free database space it automatically scales up your storage. Amazon RDS starts a storage modification for an autoscaling-enabled DB instance when these factors apply:

- Free available space is less than or equal to 10 percent of the allocated storage.
- The low-storage condition lasts at least five minutes.
- At least six hours have passed since the last storage modification, or storage optimization has completed on the instance, whichever is longer.

The additional storage is in increments of whichever of the following is greater:

- 10 GiB
- 10 percent of currently allocated storage
- Predicted storage growth exceeding the current allocated storage size in the next 7 hours based on the `FreeStorageSpace` metrics from the past hour. For more information on metrics, see Monitoring with Amazon CloudWatch.

The maximum storage threshold is the limit that you set for autoscaling the DB instance. It has the following constraints:

- You must set the maximum storage threshold to at least 10% more than the current allocated storage. We recommend setting it to at least 26% more to avoid receiving an event notification that the storage size is approaching the maximum storage threshold.

  For example, if you have DB instance with 1000 GiB of allocated storage, then set the maximum storage threshold to at least 1100 GiB. If you don't, you get an error such as Invalid max storage size for *`engine_name`*. However, we recommend that you set the maximum storage threshold to at least 1260 GiB to avoid the event notification.
- For a DB instance that uses Provisioned IOPS (io1 or io2 Block Express) storage, the ratio of IOPS to maximum storage threshold (in GiB) must be within a certain range. For more information, see Provisioned IOPS SSD storage.
- You can't set the maximum storage threshold for autoscaling-enabled instances to a value greater than the maximum allocated storage for the database engine and DB instance class.

For example, SQL Server Standard Edition on db.m5.xlarge has a default allocated storage for the instance of 20 GiB (the minimum) and a maximum allocated storage of 16,384 GiB. The default maximum storage threshold for autoscaling is 1,000 GiB. If you use this default, the instance doesn't autoscale above 1,000 GiB. This is true even though the maximum allocated storage for the instance is 16,384 GiB.

Note

We recommend that you carefully choose the maximum storage threshold based on usage patterns and customer needs. If there are any aberrations in the usage patterns, the maximum storage threshold can prevent scaling storage to an unexpectedly high value when autoscaling predicts a very high threshold. After a DB instance has been autoscaled, its allocated storage can't be reduced.

Topics

Limitations

The following limitations apply to storage autoscaling:

- Autoscaling doesn't occur if the maximum storage threshold would be exceeded by the storage increment.
- When autoscaling, RDS predicts the storage size for subsequent autoscaling operations. If a subsequent operation is predicted to exceed the maximum storage threshold, then RDS autoscales to the maximum storage threshold.
- Autoscaling can't completely prevent storage-full situations for large data loads. This is because further storage modifications can't be made for either six (6) hours or until storage optimization has completed on the instance, whichever is longer.

If you perform a large data load, and autoscaling doesn't provide enough space, the database might remain in the storage-full state for several hours. This can harm the database.

- If you start a storage scaling operation at the same time that Amazon RDS starts an autoscaling operation, your storage modification takes precedence. The autoscaling operation is canceled.
- Autoscaling can't decrease the allocated storage. You can't reduce the amount of storage for a DB instance after storage has been allocated.
- Autoscaling can't be used with magnetic storage.
- Autoscaling can't be used with the following previous-generation instance classes that have less than 6 TiB of orderable storage: db.m3.large, db.m3.xlarge, and db.m3.2xlarge.
- Autoscaling operations aren't logged by AWS CloudTrail. For more information on CloudTrail, see Monitoring Amazon RDS API calls in AWS CloudTrail.

Although automatic scaling helps you to increase storage on your Amazon RDS DB instance dynamically, you should still configure the initial storage for your DB instance to an appropriate size for your typical workload.

Enabling storage autoscaling for a new DB instance

When you create a new Amazon RDS DB instance, you can choose whether to enable storage autoscaling. You can also set an upper limit on the storage that Amazon RDS can allocate for the DB instance.

> **Note**
>
> When you clone an Amazon RDS DB instance that has storage autoscaling enabled, that setting isn't automatically inherited by the cloned instance. The new DB instance has the same amount of allocated storage as the original instance. You can turn storage autoscaling on again for the new instance if the cloned instance continues to increase its storage requirements.

Console

To enable storage autoscaling for a new DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.

2. In the upper-right corner of the Amazon RDS console, choose the AWS Region where you want to create the DB instance.
3. In the navigation pane, choose **Databases**.
4. Choose **Create database**. On the **Select engine** page, choose your database engine and specify your DB instance information as described in Getting started with Amazon RDS.
5. In the **Storage autoscaling** section, set the **Maximum storage threshold** value for the DB instance.
6. Specify the rest of your DB instance information as described in Getting started with Amazon RDS.

AWS CLI

To enable storage autoscaling for a new DB instance, use the AWS CLI command `create-db-instance`. Set the following parameter:

- `--max-allocated-storage` – Turns on storage autoscaling and sets the upper limit on storage size, in gibibytes.

To verify that Amazon RDS storage autoscaling is available for your DB instance, use the AWS CLI `describe-valid-db-instance-modifications` command. To check based on the instance class before creating an instance, use the `describe-orderable-db-instance-options` command. Check the following field in the return value:

- `SupportsStorageAutoscaling` – Indicates whether the DB instance or instance class supports storage autoscaling.

For more information about storage, see Amazon RDS DB instance storage.

RDS API

To enable storage autoscaling for a new DB instance, use the Amazon RDS API operation `CreateDBInstance`. Set the following parameter:

- `MaxAllocatedStorage` – Turns on Amazon RDS storage autoscaling and sets the upper limit on storage size, in gibibytes.

To verify that Amazon RDS storage autoscaling is available for your DB instance, use the Amazon RDS API `DescribeValidDbInstanceModifications` operation for an existing instance, or the `DescribeOrderableDBInstanceOptions` operation before creating an instance. Check the following field in the return value:

- `SupportsStorageAutoscaling` – Indicates whether the DB instance supports storage autoscaling.

For more information about storage, see Amazon RDS DB instance storage.

Changing the storage autoscaling settings for a DB instance

You can turn storage autoscaling on for an existing Amazon RDS DB instance. You can also change the upper limit on the storage that Amazon RDS can allocate for the DB instance.

Console

To change the storage autoscaling settings for a DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.
3. Choose the DB instance that you want to modify, and choose **Modify**. The **Modify DB instance** page appears.
4. Change the storage limit in the **Autoscaling** section. For more information, see Modifying an Amazon RDS DB instance.
5. When all the changes are as you want them, choose **Continue** and check your modifications.
6. On the confirmation page, review your changes. If they're correct, choose **Modify DB Instance** to save your changes. If they aren't correct, choose **Back** to edit your changes or **Cancel** to cancel your changes.

   Changing the storage autoscaling limit occurs immediately. This setting ignores the **Apply immediately** setting.

AWS CLI

To change the storage autoscaling settings for a DB instance, use the AWS CLI command `modify-db-instance`. Set the following parameter:

- `--max-allocated-storage` – Sets the upper limit on storage size, in gibibytes. If the value is greater than the `--allocated-storage` parameter, storage autoscaling is turned on. If the value is the same as the `--allocated-storage` parameter, storage autoscaling is turned off.

To verify that Amazon RDS storage autoscaling is available for your DB instance, use the AWS CLI `describe-valid-db-instance-modifications` command. To check based on the instance class before creating an instance, use the `describe-orderable-db-instance-options` command. Check the following field in the return value:

- `SupportsStorageAutoscaling` – Indicates whether the DB instance supports storage autoscaling.

For more information about storage, see Amazon RDS DB instance storage.

RDS API

To change the storage autoscaling settings for a DB instance, use the Amazon RDS API operation `ModifyDBInstance`. Set the following parameter:

- `MaxAllocatedStorage` – Sets the upper limit on storage size, in gibibytes.

To verify that Amazon RDS storage autoscaling is available for your DB instance, use the Amazon RDS API `DescribeValidDbInstanceModifications` operation for an existing instance, or the `DescribeOrderableDBInstanceOptions` operation before creating an instance. Check the following field in the return value:

- `SupportsStorageAutoscaling` – Indicates whether the DB instance supports storage autoscaling.

For more information about storage, see Amazon RDS DB instance storage.

Turning off storage autoscaling for a DB instance

If you no longer need Amazon RDS to automatically increase the storage for an Amazon RDS DB instance, you can turn off storage autoscaling. After you do, you can still manually increase the amount of storage for your DB instance.

Console

To turn off storage autoscaling for a DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.
3. Choose the DB instance that you want to modify and choose **Modify**. The **Modify DB instance** page appears.
4. Clear the **Enable storage autoscaling** check box in the **Storage autoscaling** section. For more information, see Modifying an Amazon RDS DB instance.
5. When all the changes are as you want them, choose **Continue** and check the modifications.
6. On the confirmation page, review your changes. If they're correct, choose **Modify DB Instance** to save your changes. If they aren't correct, choose **Back** to edit your changes or **Cancel** to cancel your changes.

Changing the storage autoscaling limit occurs immediately. This setting ignores the **Apply immediately** setting.

AWS CLI

To turn off storage autoscaling for a DB instance, use the AWS CLI command `modify-db-instance` and the following parameter:

- `--max-allocated-storage` – Specify a value equal to the `--allocated-storage` setting to prevent further Amazon RDS storage autoscaling for the specified DB instance.

For more information about storage, see Amazon RDS DB instance storage.

RDS API

To turn off storage autoscaling for a DB instance, use the Amazon RDS API operation `ModifyDBInstance`. Set the following parameter:

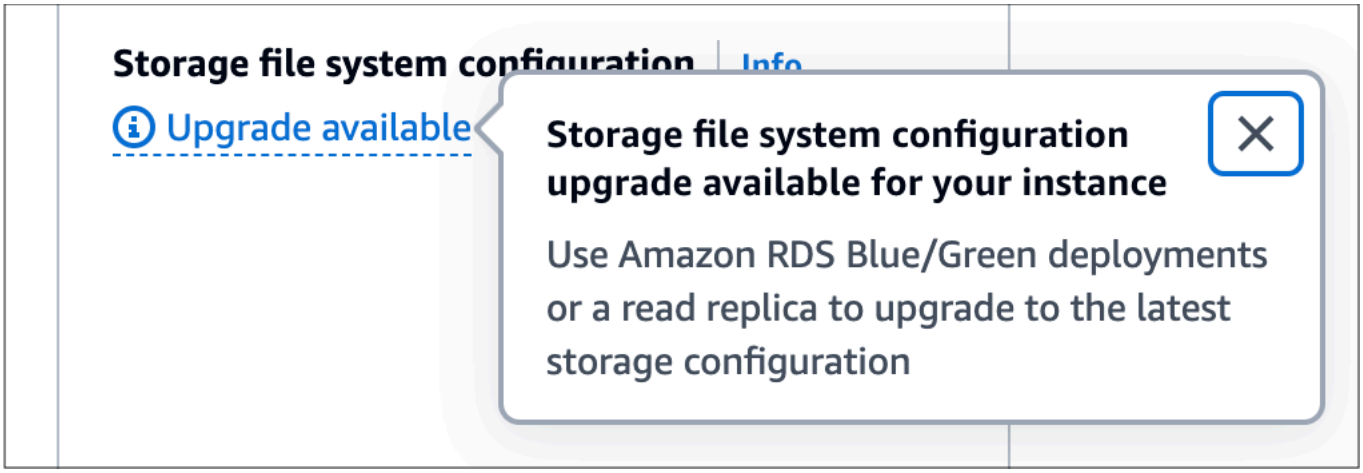
- `MaxAllocatedStorage` – Specify a value equal to the `AllocatedStorage` setting to prevent further Amazon RDS storage autoscaling for the specified DB instance.

For more information about storage, see Amazon RDS DB instance storage.

Upgrading the storage file system for a DB instance

Most RDS DB instances offer a maximum storage size of 64 TiB for RDS for MariaDB, MySQL, and PostgreSQL databases. However, some older 32-bit file systems have lower storage capacities. To determine the storage capacity of your DB instance, you can use the describe-valid-db-instance-modifications AWS CLI command.

If RDS detects that one of your DB instances is running an older file system (one that has a 16 TiB storage size, a file size limit of 2 TiB, or non-optimized writes), the RDS console informs you that your file system configuration is eligible for an upgrade. You can check the upgrade eligibility of your DB instance on the **Storage** panel of the DB instance details page.



If your DB instance is eligible for a file system upgrade, you can perform the upgrade in one of two ways:

- Create a blue/green deployment and specify **Upgrade storage file system configuration**. This option upgrades the file system in the green environment to the preferred configuration. You can then switch over the blue/green deployment, which promotes the green environment to be the new production environment. For detailed instructions, see the section called “Creating a blue/green deployment”.
- Create a DB instance read replica and specify **Upgrade storage file system configuration**. This option upgrades the file system of the read replica to the preferred configuration. You can then promote the read replica to be a standalone instance. For detailed instructions, see the section called “Creating a read replica”.

Upgrading the storage configuration is an I/O-intensive operation and leads to longer creation times for read replicas and blue/green deployments. The storage upgrade process is faster if

the source DB instance uses Provisioned IOPS SSD (io1 or io2 Block Express) storage and you provisioned the green environment or read replica with an instance size of 4xlarge or larger. Storage upgrades involving General Purpose SSD (gp2) storage can deplete your I/O credit balance, resulting in longer upgrade times. For more information, see the section called “DB instance storage”.

During the storage upgrade process, the database engine isn't available. If the storage consumption on your source DB instance is greater than or equal to 90% of the allocated storage size, and if storage autoscaling is enabled, the storage upgrade process increases the allocated storage size by 10% for the green instance or read replica. If storage autoscaling is disabled, the storage size doesn't increase during the upgrade.

Modifying settings for Provisioned IOPS SSD storage

You can modify the settings for a DB instance that uses Provisioned IOPS SSD storage by using the Amazon RDS console, AWS CLI, or Amazon RDS API. Specify the storage type, allocated storage, and the amount of Provisioned IOPS that you require. The range depends on your database engine and instance type.

Although you can reduce the amount of IOPS provisioned for your instance, you can't reduce the storage size.

In most cases, scaling storage doesn't require any outage and doesn't degrade performance of the server. After you modify the storage IOPS for a DB instance, the status of the DB instance is **storage-optimization**.

> **Note**
>
> Storage optimization can take several hours. You can't make further storage modifications for either six (6) hours or until storage optimization has completed on the instance, whichever is longer.

For information on the ranges of allocated storage and Provisioned IOPS available for each database engine, see Provisioned IOPS SSD storage.

Console

To change the Provisioned IOPS settings for a DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.

   To filter the list of DB instances, for **Filter databases** enter a text string for Amazon RDS to use to filter the results. Only DB instances whose names contain the string appear.
3. Choose the DB instance with Provisioned IOPS that you want to modify.
4. Choose **Modify**.
5. On the **Modify DB instance** page, choose **Provisioned IOPS SSD (io1)** or **Provisioned IOPS SSD (io2)** for **Storage type**.
6. For **Provisioned IOPS**, enter a value.

   If the value that you specify for either **Allocated storage** or **Provisioned IOPS** is outside the limits supported by the other parameter, a warning message is displayed. This message gives the range of values required for the other parameter.
7. Choose **Continue**.
8. Choose **Apply immediately** in the **Scheduling of modifications** section to apply the changes to the DB instance immediately. Or choose **Apply during the next scheduled maintenance window** to apply the changes during the next maintenance window.
9. Review the parameters to be changed, and choose **Modify DB instance** to complete the modification.

   The new value for allocated storage or for Provisioned IOPS appears in the **Status** column.

AWS CLI

To change the Provisioned IOPS setting for a DB instance, use the AWS CLI command `modify-db-instance`. Set the following parameters:

- `--storage-type` – Set to `io1` or `io2` for Provisioned IOPS.
- `--allocated-storage` – Amount of storage to be allocated for the DB instance, in gibibytes.
- `--iops` – The new amount of Provisioned IOPS for the DB instance, expressed in I/O operations per second.

- `--apply-immediately` – Use `--apply-immediately` to apply changes immediately. Use `--no-apply-immediately` (the default) to apply changes during the next maintenance window.

RDS API

To change the Provisioned IOPS settings for a DB instance, use the Amazon RDS API operation `ModifyDBInstance`. Set the following parameters:

- `StorageType` – Set to `io1` or `io2` for Provisioned IOPS.
- `AllocatedStorage` – Amount of storage to be allocated for the DB instance, in gibibytes.
- `Iops` – The new IOPS rate for the DB instance, expressed in I/O operations per second.
- `ApplyImmediately` – Set this option to `True` to apply changes immediately. Set this option to `False` (the default) to apply changes during the next maintenance window.

I/O-intensive storage modifications

Amazon RDS DB instances use Amazon Elastic Block Store (EBS) volumes for database and log storage. Depending on the amount of storage requested, RDS (except for RDS for SQL Server) automatically *stripes* across multiple Amazon EBS volumes to enhance performance. RDS DB instances with SSD storage types are backed by either one or four striped Amazon EBS volumes in a RAID 0 configuration. By design, storage modification operations for an RDS DB instance have minimal impact on ongoing database operations.

In most cases, storage scaling modifications are completely offloaded to the Amazon EBS layer and are transparent to the database. This process is typically completed within a few minutes. However, some older RDS storage volumes require a different process for modifying the size, Provisioned IOPS, or storage type. This involves making a full copy of the data using a potentially I/O-intensive operation.

Storage modification uses an I/O-intensive operation if any of the following factors apply:

- The source storage type is magnetic. Magnetic storage doesn't support elastic volume modification.
- The RDS DB instance isn't on a one- or four-volume Amazon EBS layout. You can view the number of Amazon EBS volumes in use on your RDS DB instances by using Enhanced Monitoring metrics. For more information, see Viewing OS metrics in the RDS console.

- The target size of the modification request increases the allocated storage above 400 GiB for RDS for MariaDB, MySQL, and PostgreSQL instances, and 200 GiB for RDS for Oracle. Storage autoscaling operations have the same effect when they increase the allocated storage size of your DB instance above these thresholds.

If your storage modification involves an I/O-intensive operation, it consumes I/O resources and increases the load on your DB instance. Storage modifications with I/O-intensive operations involving General Purpose SSD (gp2) storage can deplete your I/O credit balance, resulting in longer conversion times.

We recommend as a best practice to schedule these storage modification requests outside of peak hours to help reduce the time required to complete the storage modification operation. Alternatively, you can create a read replica of the DB instance and perform the storage modification on the read replica. Then promote the read replica to be the primary DB instance. For more information, see Working with DB instance read replicas.

For more information, see Why is an Amazon RDS DB instance stuck in the modifying state when I try to increase the allocated storage?

Modifying settings for General Purpose SSD (gp3) storage

You can modify the settings for a DB instance that uses General Purpose SSD (gp3) storage by using the Amazon RDS console, AWS CLI, or Amazon RDS API. Specify the storage type, allocated storage, amount of Provisioned IOPS, and storage throughput that you require.

Although you can reduce the amount of Provisioned IOPS and storage throughput for your DB instance, you can't reduce the storage size.

In most cases, scaling storage doesn't require any outage. After you modify the storage IOPS for a DB instance, the status of the DB instance is **storage-optimization**. You can expect elevated latencies, but still within the single-digit millisecond range, during storage optimization. The DB instance is fully operational after a storage modification.

> **Note**
>
> You can't make further storage modifications until six (6) hours after storage optimization has completed on the instance.

For information on the ranges of allocated storage, Provisioned IOPS, and storage throughput available for each database engine, see gp3 storage (recommended).

Console

To change the storage performance settings for a DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.

   To filter the list of DB instances, for **Filter databases** enter a text string for Amazon RDS to use to filter the results. Only DB instances whose names contain the string appear.
3. Choose the DB instance with gp3 storage that you want to modify.
4. Choose **Modify**.
5. On the **Modify DB Instance page**, choose **General Purpose SSD (gp3)** for **Storage type**, then do the following:

   a. For **Provisioned IOPS**, choose a value.

      If the value that you specify for either **Allocated storage** or **Provisioned IOPS** is outside the limits supported by the other parameter, a warning message appears. This message gives the range of values required for the other parameter.

   b. For **Storage throughput**, choose a value.

      If the value that you specify for either **Provisioned IOPS** or **Storage throughput** is outside the limits supported by the other parameter, a warning message appears. This message gives the range of values required for the other parameter.
6. Choose **Continue**.
7. Choose **Apply immediately** in the **Scheduling of modifications** section to apply the changes to the DB instance immediately. Or choose **Apply during the next scheduled maintenance window** to apply the changes during the next maintenance window.
8. Review the parameters to be changed, and choose **Modify DB instance** to complete the modification.

   The new value for Provisioned IOPS appears in the **Status** column.

AWS CLI

To change the storage performance settings for a DB instance, use the AWS CLI command `modify-db-instance`. Set the following parameters:

- `--storage-type` – Set to gp3 for General Purpose SSD (gp3).
- `--allocated-storage` – Amount of storage to be allocated for the DB instance, in gibibytes.
- `--iops` – The new amount of Provisioned IOPS for the DB instance, expressed in I/O operations per second.
- `--storage-throughput` – The new storage throughput for the DB instance, expressed in MiBps.
- `--apply-immediately` – Use `--apply-immediately` to apply changes immediately. Use `--no-apply-immediately` (the default) to apply changes during the next maintenance window.

RDS API

To change the storage performance settings for a DB instance, use the Amazon RDS API operation `ModifyDBInstance`. Set the following parameters:

- `StorageType` – Set to gp3 for General Purpose SSD (gp3).
- `AllocatedStorage` – Amount of storage to be allocated for the DB instance, in gibibytes.
- `Iops` – The new IOPS rate for the DB instance, expressed in I/O operations per second.
- `StorageThroughput` – The new storage throughput for the DB instance, expressed in MiBps.
- `ApplyImmediately` – Set this option to `True` to apply changes immediately. Set this option to `False` (the default) to apply changes during the next maintenance window.

Using a dedicated log volume (DLV)

You can use a dedicated log volume (DLV) for a DB instance that uses Provisioned IOPS (PIOPS) storage. A DLV moves PostgreSQL database transaction logs and MySQL/MariaDB redo logs and binary logs to a storage volume that's separate from the volume containing the database tables. A DLV makes transaction write logging more efficient and consistent. DLVs are ideal for databases with large allocated storage, high I/O per second (IOPS) requirements, or latency-sensitive workloads.

DLVs are supported for PIOPS storage (io1 and io2 Block Express) and are created with a fixed size of 1,000 GiB and 3,000 Provisioned IOPS.

Amazon RDS supports DLVs in all AWS Regions for the following versions:

- MariaDB 10.6.7 and higher 10 versions
- MySQL 8.0.28 and higher 8 versions
- PostgreSQL 13.10 and higher 13 versions, 14.7 and higher 14 versions, and 15.2 and higher 15 versions

RDS supports DLVs with Multi-AZ deployments. When you modify or create a Multi-AZ instance, a DLV is created for both the primary and the secondary.

RDS supports DLVs with read replicas. If the primary DB instance has a DLV enabled, all read replicas created after enabling DLV will also have a DLV. Any read replicas created before the switch to DLV will not have it enabled unless explicitly modified to do so. We recommend all read replicas attached to a primary instance before DLV was enabled also be manually modified to have A DLV.

> **Note**
>
> Dedicated log volumes are recommended for database configurations of 5 TiB or greater.

For information on the ranges of allocated storage, Provisioned IOPS, and storage throughput available for each database engine, see Provisioned IOPS SSD storage.

Topics

Considerations when enabling and disabling DLV

Enabling and disabling DLV can be time consuming and cause downtime. The process involves copying all transaction logs or redo and binary logs (depending on the database engine) to the

new volume when enabling, or back to the original storage when disabling. The duration of this operation is influenced by several factors:

- Number of transaction logs:
  - Larger databases with more transactions generate more logs, increasing the time required for copying.
  - Transaction logs can accumulate on the primary DB instance if replication slots are inactive or if replication is lagging, increasing the time required for copying. Make sure that replication is current, and remove any unnecessary slots.
- Storage configuration:
  - DB instance EBS bandwidth – Higher bandwidth allows for faster data transfer.
  - Number of Provisioned IOPS – More input/output operations per second (IOPS) can speed up the copying process.
- Database activity – High levels of database activity during configuration can slow down the process.

To minimize downtime, we recommend that you plan and schedule during periods of low activity or maintenance windows.

Enabling DLV when you create a DB instance

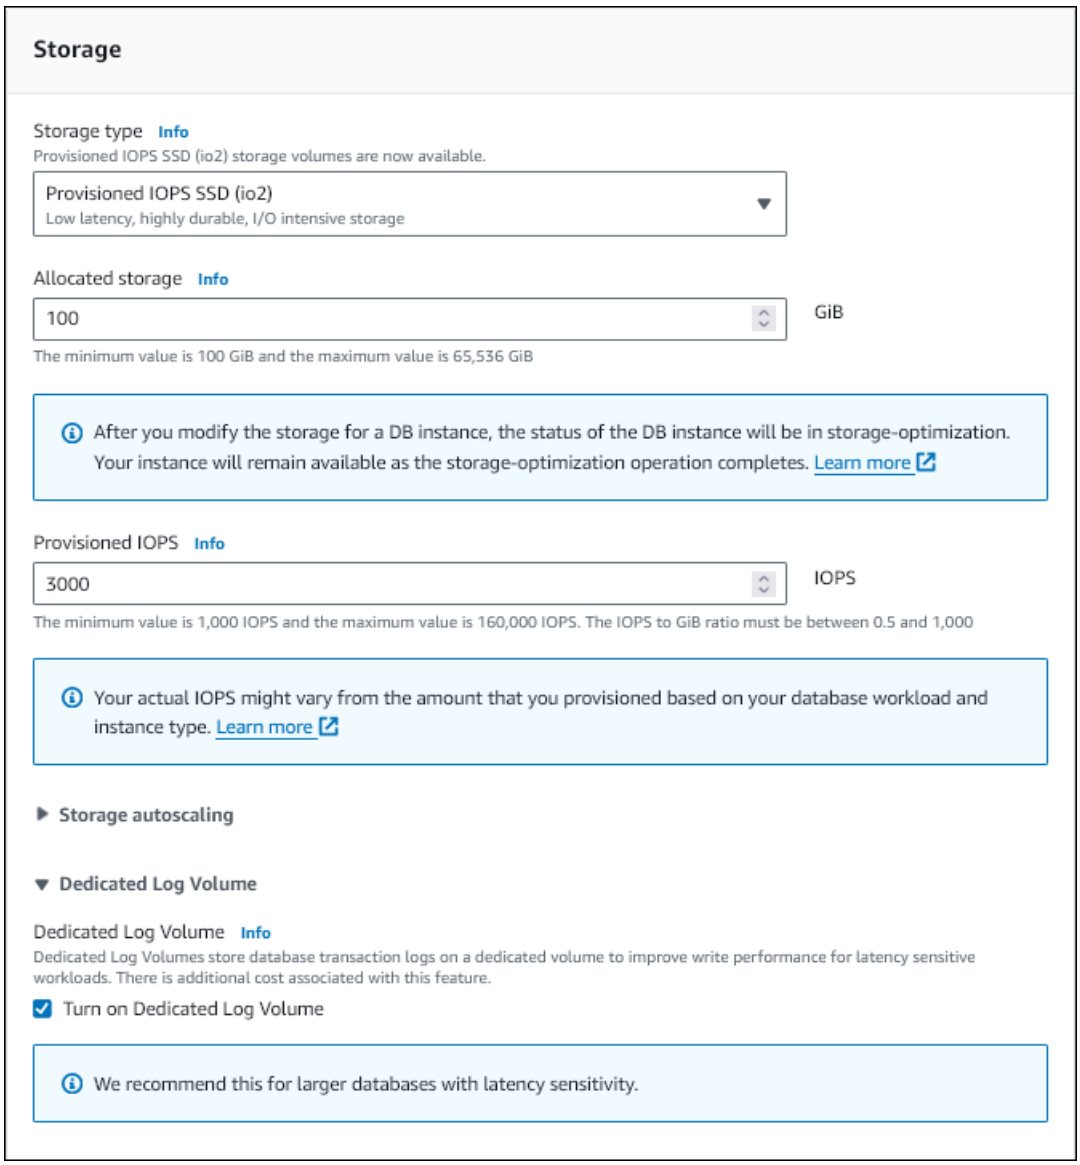
You can use the AWS Management Console, AWS CLI, or RDS API to create a DB instance with DLV enabled.

Console

To enable DLV on a new DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Choose **Create database**.
3. On the **Create DB instance page**, choose a DB engine that supports DLV.
4. For **Storage**:
   a. Choose either **Provisioned IOPS SSD (io1)** or **Provisioned IOPS SSD (io2)**.
   b. Enter the **Allocated storage** and **Provisioned IOPS** that you want.

c. Expand **Dedicated Log Volume**, then select **Turn on Dedicated Log Volume**.



5. Choose other settings as needed.
6. Choose **Create database**.

After the database is created, the value for Dedicated Log Volume appears on the **Configuration** tab of the database details page.

CLI

To enable DLV when you create a DB instance using Provisioned IOPS storage, use the AWS CLI command create-db-instance. Set the following parameters:

- `--dedicated-log-volume` – Enables a dedicated log volume.
- `--storage-type` – Set to `io1` or `io2` for Provisioned IOPS.
- `--allocated-storage` – Amount of storage to be allocated for the DB instance, in gibibytes.
- `--iops` – The amount of Provisioned IOPS for the DB instance, expressed in I/O operations per second.

RDS API

To enable DLV when you create a DB instance using Provisioned IOPS storage, use the Amazon RDS API operation CreateDBInstance. Set the following parameters:

- `DedicatedLogVolume` – Set to `true` to enable a dedicated log volume.
- `StorageType` – Set to `io1` or `io2` for Provisioned IOPS.
- `AllocatedStorage` – Amount of storage to be allocated for the DB instance, in gibibytes.
- `Iops` – The IOPS rate for the DB instance, expressed in I/O operations per second.

Enabling DLV on an existing DB instance

You can use the AWS Management Console, AWS CLI, or RDS API to modify a DB instance to enable DLV.

After you modify the DLV setting for a DB instance, you must reboot the DB instance.

Console

To enable DLV on an existing DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.

   To filter the list of DB instances, for **Filter databases** enter a text string for Amazon RDS to use to filter the results. Only DB instances whose names contain the string appear.
3. Choose the DB instance with Provisioned IOPS storage that you want to modify.
4. Choose **Modify**.
5. On the **Modify DB instance page**:

- For **Storage**, expand **Dedicated Log Volume**, then select **Turn on Dedicated Log Volume**.

6. Choose **Continue**.
7. Choose **Apply immediately** to apply the changes to the DB instance immediately. Or choose **Apply during the next scheduled maintenance window** to apply the changes during the next maintenance window.
8. Review the parameters to be changed, and choose **Modify DB instance** to complete the modification.

The new value for Dedicated Log Volume appears on the **Configuration** tab of the database details page.

CLI

To enable or disable DLV on an existing DB instance using Provisioned IOPS storage, use the AWS CLI command `modify-db-instance`. Set the following parameters:

- `--dedicated-log-volume` – Enables a dedicated log volume.

  Use `--no-dedicated-log-volume` (the default) to disable a dedicated log volume.
- `--apply-immediately` – Use `--apply-immediately` to apply changes immediately.

  Use `--no-apply-immediately` (the default) to apply changes during the next maintenance window.

RDS API

To enable or disable DLV on an existing DB instance using Provisioned IOPS storage, use the Amazon RDS API operation `ModifyDBInstance`. Set the following parameters:

- `DedicatedLogVolume` – Set this option to `true` to enable a dedicated log volume.

  Set this option to `false` to disable a dedicated log volume. This is the default value.
- `ApplyImmediately` – Set this option to `True` to apply changes immediately.

  Set this option to `False` (the default) to apply changes during the next maintenance window.

Monitoring DLV storage

You can monitor the DLV storage usage by using the `FreeStorageSpaceLogVolume` metric in CloudWatch.

You can use the following query for RDS for PostgreSQL to find the size occupied by transaction logs:

```
SELECT pg_size_pretty(COALESCE(sum(size), 0)) AS total_wal_generated_size
FROM pg_catalog.pg_ls_waldir();
```

If the DLV runs out of storage, the DB instance will enter the `storage-full` state, causing downtime.

Deleting a DB instance

You can delete a DB instance using the AWS Management Console, the AWS CLI, or the RDS API. If you want to delete a DB instance in an Aurora DB cluster, see Deleting Aurora DB clusters and DB instances.

Topics

Prerequisites for deleting a DB instance

Before you try to delete your DB instance, make sure that deletion protection is turned off. By default, deletion protection is turned on for a DB instance that was created with the console.

If your DB instance has deletion protection turned on, you can turn it off by modifying your instance settings. Choose **Modify** in the database details page or call the modify-db-instance command. This operation doesn't cause an outage. For more information, see Settings for DB instances.

Considerations when deleting a DB instance

Deleting a DB instance has an effect on instance recoverability, backup availability, and read replica status. Consider the following issues:

- You can choose whether to create a final DB snapshot. You have the following options:
  - If you take a final snapshot, you can use it to restore your deleted DB instance. RDS retains both the final snapshot and any manual snapshots that you took previously. You can't create a final DB snapshot of your DB instance if it isn't in the `Available` state. For more information, see Viewing Amazon RDS DB instance status.
  - If you don't take a final snapshot, deletion of your instance is faster. The disadvantage is that no final snapshot exists that you can restore later. If you decide to restore your deleted DB instance, either retain automated backups or use an earlier manual snapshot to restore your DB instance to the point in time of the earlier snapshot.
- You can choose whether to retain automated backups. You have the following options:

- If you retain automated backups, RDS keeps them for the retention period that is in effect for the DB instance at the time when you delete it. You can use automated backups to restore your DB instance to a time during but not after your retention period. The retention period is in effect regardless of whether you create a final DB snapshot. To delete a retained automated backup, see Deleting retained automated backups.
- Retained automated backups and manual snapshots incur billing charges until they're deleted. For more information, see Retention costs.
- If you don't retain automated backups, RDS deletes the automated backups that reside in the same AWS Region as your DB instance. You can't recover these backups. If your automated backups have been replicated to another AWS Region, RDS keeps them even if you don't choose to retain automated backups. For more information, see Replicating automated backups to another AWS Region.

  > **Note**
  >
  > Typically, if you create a final DB snapshot, you don't need to retain automated backups.

- When you delete your DB instance, RDS doesn't delete manual DB snapshots. For more information, see Creating a DB snapshot for a Single-AZ DB instance.
- If you want to delete all RDS resources, note that the following resources incur billing charges:
  - DB instances
  - DB snapshots
  - DB clusters

  If you purchased reserved instances, then they are billed according to contract that you agreed to when you purchased the instance. For more information, see Reserved DB instances for Amazon RDS. You can get billing information for all your AWS resources by using the AWS Cost Explorer. For more information, see Analyzing your costs with AWS Cost Explorer.
- If you delete a DB instance that has read replicas in the same AWS Region, each read replica is automatically promoted to a standalone DB instance. For more information, see Promoting a read replica to be a standalone DB instance. If your DB instance has read replicas in different AWS Regions, see Cross-Region replication considerations for information related to deleting the source DB instance for a cross-Region read replica.

- When the status for a DB instance is `deleting`, its CA certificate value doesn't appear in the RDS console or in output for AWS CLI commands or RDS API operations. For more information about CA certificates, see Using SSL/TLS to encrypt a connection to a DB instance or cluster.
- The time required to delete a DB instance varies depending on the backup retention period (that is, how many backups to delete), how much data is deleted, and whether a final snapshot is taken.

Deleting a DB instance

You can delete a DB instance using the AWS Management Console, the AWS CLI, or the RDS API. You must do the following:

- Provide the name of the DB instance
- Enable or disable the option to take a final DB snapshot of the instance
- Enable or disable the option to retain automated backups

> **Note**
>
> You can't delete a DB instance when deletion protection is turned on. For more information, see Prerequisites for deleting a DB instance.

Console

To delete a DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**, and then choose the DB instance that you want to delete.
3. For **Actions**, choose **Delete**.
4. To create a final DB snapshot for the DB instance, choose **Create final snapshot?**.
5. If you chose to create a final snapshot, enter the **Final snapshot name**.
6. To retain automated backups, choose **Retain automated backups**.
7. Enter **`delete me`** in the box.

8. Choose **Delete**.

AWS CLI

To find the instance IDs of the DB instances in your account, call the describe-db-instances command:

```
aws rds describe-db-instances --query 'DBInstances[*].[DBInstanceIdentifier]' --output
 text
```

To delete a DB instance by using the AWS CLI, call the delete-db-instance command with the following options:

- `--db-instance-identifier`
- `--final-db-snapshot-identifier` or `--skip-final-snapshot`

Example With a final snapshot and no retained automated backups

For Linux, macOS, or Unix:

```
aws rds delete-db-instance \
    --db-instance-identifier mydbinstance \
    --final-db-snapshot-identifier mydbinstancefinalsnapshot \
    --delete-automated-backups
```

For Windows:

```
aws rds delete-db-instance ^
    --db-instance-identifier mydbinstance ^
    --final-db-snapshot-identifier mydbinstancefinalsnapshot ^
    --delete-automated-backups
```

Example With retained automated backups and no final snapshot

For Linux, macOS, or Unix:

```
aws rds delete-db-instance \
    --db-instance-identifier mydbinstance \
    --skip-final-snapshot \
```

```
    --no-delete-automated-backups
```

For Windows:

```
aws rds delete-db-instance ^
    --db-instance-identifier mydbinstance ^
    --skip-final-snapshot ^
    --no-delete-automated-backups
```

RDS API

To delete a DB instance by using the Amazon RDS API, call the `DeleteDBInstance` operation with the following parameters:

- `DBInstanceIdentifier`
- `FinalDBSnapshotIdentifier` or `SkipFinalSnapshot`

Tutorial: Managing a MySQL DB instance environment from development to production

Topics

Introduction

A common scenario when managing an Amazon RDS DB instance involves the oversight of its lifecycle from initial development through to production deployment. This tutorial offers guidance to handle key tasks to ensure your database performs optimally and adapts to meet your evolving operational needs. Additionally, it outlines options to synchronize changes made between your development and production environments to ensure consistency and reliability.

By completing these steps, you learn:

- How to perform specific tasks with MySQL DB instances, such as adding and updating Amazon RDS tags, expanding storage, creating read replicas, and deleting resources.
- How to synchronize updates from a production environment to a development environment for comprehensive testing and validation.

To complete this tutorial, carry out the following tasks:

1. Create a MySQL DB instance.
2. Add Amazon RDS tags to categorize your DB instance as a development environment.
3. Increase the storage capacity of your DB instance to accommodate increased workloads.
4. Create read replicas to enhance the resilience and availability of your DB instance.
5. Update Amazon RDS tags to categorize your DB instance as a production environment.
6. Delete DB instance that you no longer need so that they don't incur additional costs.

7. Next Steps: Synchronize your development instance with production for consistency across environments

Prerequisites

Before you begin, complete the steps in the following sections:

- Sign up for an AWS account
- Create a user with administrative access

Add Amazon RDS tags to categorize your DB instance as a development environment

To categorize the DB instance as a development environment, add an Amazon RDS tag to the instance you created. An Amazon RDS tag is a key-value pair that you define and associate with your RDS instance. Tagging your AWS resources helps distinguish between your development and production AWS resources. For more information on Amazon RDS tags, see Tagging Amazon RDS resources.

1. In the Amazon RDS console, choose **Databases**.
2. Select the DB instance you want to tag.
3. In the details section, scroll to the **Tags** section.
4. Choose **Manage tags** and select**dd new tag**.
5. Enter a value for **Tag key** and **Value**. For instance, you might use the tag key environment with the value dev to specify that the database instance is part of the development environment.
6. Choose **Add new tag**and **Save changes**.

Your DB instance is now tagged as a development environment. This makes it easier to identify the DB instance and to manage costs associated with this resource.

Increase the storage capacity of a DB instance to accommodate growing data needs

Next, modify the storage capacity of the MySQL DB instance to accommodate additional data. Initially, the storage capacity of your DB instance is set to meet the immediate needs of your

application. However, as data volumes grow, it might be necessary to adjust the storage settings to ensure the database's continued performance and stability. This process involves increasing the allocated storage of your DB instance. For more information on modifying the storage capacity of your DB instance, see Working with storage for Amazon RDS DB instances.

1. In the Amazon RDS console, choose **Databases**.
2. Select the DB instance you want to modify.
3. Choose **Modify.**.
4. In Storage, increase the **Allocated Storage**.The modified storage value must be greater than the current one.
5. Choose **Continue**.
6. In **Scheduling of modifications**, you can either choose **Apply immediately** to apply the storage changes to the DB instance immediately or choose **Apply during the next scheduled maintenance window** to apply the changes during the next maintenance window.
7. When the settings are as you want them, choose **Modify DB instance**.

The storage capacity of your DB instance is now increased. This enables it to effectively handle larger data volumes and ensures continued performance and stability as your application's data needs grow.

Create read replicas to enhance the resilience and availability of a DB instance

Create a read replica of the MySQL DB instance. Read replicas enhance the resilience and availability of your DB instance. To reduce the read traffic on your primary DB instance, create a read replica of your DB instance. This routes queries to the read replica, which can help distribute the load and improve overall database performance. For more information on DB instance read replicas, see Working with DB instance read replicas.

Before a MySQL DB instance can serve as a replication source, automatic backups must be enabled on the source DB instance. This can be done by setting the backup retention period to a value other than 0. For more information on MySQL read replicas, see Working with MySQL read replicas.

1. In the Amazon RDS console, choose **Databases**.
2. Select the DB instance you want to use as the source for the read replica

3. In Actions, select **Create read replica**.
4. For **DB instance identifier**, enter a name for the read replica in all lowercase letters.
5. Choose your instance configuration. We recommend that you use the same or larger DB instance class and storage type as the source DB instance for the read replica.
6. Forw **AWS Region**, specify the destination Region for the read replica.
7. Leave the default settings or modify them as your use case requires. For information about each available setting, see Creating an Amazon RDS DB instance.
8. Choose **Create read replica.**.

The read replica appears underneath your source DB instance on the Databases page in the RDS console. It shows Replica in the Role column.

Update Amazon RDS tags to categorize a DB instance as a production environment

When your DB instance is ready to move from the development phase to production, it is important to update its tags to reflect its transition. To align your DB instance with your operational and monitoring strategies, update the initial tags to indicate that the DB instance is now part of the production environment. This ensures better visibility and management of the database.

1. In the Amazon RDS console, choose **Databases**.
2. Select the DB instance you want to update
3. In the details section, scroll to the **Tags** section.
4. Select **Manage Tags**.
5. **Remove** your initial tag signifying a development environment.
6. Select**Add new tag**.
7. Enter a new value for **Tag key** and **Value**. For instance, you might use the tag key environment with the value prod to specify that the DB instance is part of the production environment.
8. Choose **Add new tag** and **Save changes**.

The tag on your DB instance is updated to signify the database's transition to a production environment.

Delete a DB instance when it is no longer needed to avoid incurring additional costs

Before the end of this tutorial, it is crucial to address the management of your resources. If you have any resources that are no longer required, you should proceed to delete them to prevent incurring additional costs and optimize your cloud environment.

1. In the Amazon RDS console, choose **Databases**.
2. Select the DB instance you want to delete
3. In Actions, select **Delete**. Deleting a DB instance will permanently delete the instance with all its content and related resources. .
4. Confirm the deletion of the DB instance and select **Delete**.

Alternatively, if you choose to maintain your DB instance for future use, you can continue to manage it as part of your production environment. This involves maintaining a synchronized development environment to facilitate comprehensive testing and validation. For more information, see Next Steps: Synchronize your development instance with production for consistency across environments.

Next Steps: Synchronize your development instance with production for consistency across environments

Create a development environment

To manage a production environment, it's important to maintain a synchronized development environment for comprehensive testing and validation. To create a new development environment, first create a DB snapshot of the current production DB instance. A DB snapshot captures the entire DB instance by creating a storage volume snapshot. For instructions on how to create a DB snapshot on the Amazon RDS console, see Creating a DB snapshot for a Single-AZ DB instance.

After you create the DB snapshot of your production environment, create a new DB instance for your development environment by restoring a DB snapshot. Restored DB instances are automatically associated with the default DB parameter and option groups. However, you can apply a custom parameter group and option group by specifying them during a restore. For instructions on restoring a DB snapshot, see Tutorial: Restore an Amazon RDS DB instance from a DB snapshot.

Finally, designate the new DB instance as your new development environment by updating its Amazon RDS tags. For guidance on updating Amazon RDS tags to reflect this change, see the previous section Update Amazon RDS tags to categorize a DB instance as a production environment.

You now have a new development environment that mirrors the database configuration of your production environment.

Synchronize a development environment with production environment

Once your new development environment is established, it is necessary to keep it synchronized with any changes that occur in the production environment. This ensures that your development environment accurately reflects the current state of production, which is essential for effective testing, validation, and troubleshooting. Amazon RDS provides a variety of different ways to keep your development environment up to date with your production environment. For more information on these options, see Orchestrating database refreshes for Amazon RDS and Amazon Aurora.

One of the primary ways in which you can synchronize your development and production environments is through creating and restoring DB snapshots. A DB snapshot allows you to create a development environment that reflects the database configuration of the production environment during the time the snapshot was created. For more information on DB snapshots, see Managing manual backups. For more information on restoring a DB instance, see Restoring to a DB instance.

DB snapshots are particularly valuable for the following use cases.

- Initial setup of a development environment: DB snapshots are useful to create the initial development environment for testing as it provides a consistent baseline that mirrors the exact state of the production environment at the time of the snapshot.
- High traffic applications: In production environments where continuous operation is critical, using Multi-AZ deployments for snapshots avoids I/O suspension on the primary database, ensuring uninterrupted performance and high availability.
- Sharing data across different RDS accounts: DB snapshots can be shared across different AWS accounts, facilitating the transfer of data between accounts or regions. This is useful for collaborative projects or scenarios where data needs to be shared for various purposes. For more information, see Sharing a DB snapshot.

In this tutorial, you explored essential tasks for managing your DB instance throughout its lifecycle. You learned how to create a DB instance, add and update Amazon RDS tags, expand storage, and create read replicas. You also learned ways to build on these fundamental operations and manage your production environment effectively. This included establishing a development environment for testing and synchronizing it with the production environment for consistency. These tasks help maintain a resilient and scalable database infrastructure, ensuring your Amazon RDS environment operates efficiently.

Configuring and managing a Multi-AZ deployment

Multi-AZ deployments can have one standby or two standby DB instances. When the deployment has one standby DB instance, it's called a *Multi-AZ DB instance deployment*. A Multi-AZ DB instance deployment has one standby DB instance that provides failover support, but doesn't serve read traffic. When the deployment has two standby DB instances, it's called a *Multi-AZ DB cluster deployment*. A Multi-AZ DB cluster deployment has standby DB instances that provide failover support and can also serve read traffic.

You can use the AWS Management Console to determine whether a Multi-AZ deployment is a Multi-AZ DB instance deployment or a Multi-AZ DB cluster deployment. In the navigation pane, choose **Databases**, and then choose a **DB identifier**.

- A Multi-AZ DB instance deployment has the following characteristics:
  - There is only one row for the DB instance.
  - The value of **Role** is **Instance** or **Primary**.
  - The value of **Multi-AZ** is **Yes**.
- A Multi-AZ DB cluster deployment has the following characteristics:
  - There is a cluster-level row with three DB instance rows under it.
  - For the cluster-level row, the value of **Role** is **Multi-AZ DB cluster**.
  - For each instance-level row, the value of **Role** is **Writer instance** or **Reader instance**.
  - For each instance-level row, the value of **Multi-AZ** is **3 Zones**.

Topics

In addition, the following topics apply to both DB instances and Multi-AZ DB clusters:

- the section called “Tagging RDS resources”
- the section called “ARNs in Amazon RDS”
- the section called “Working with storage”
- the section called “Maintaining a DB instance”

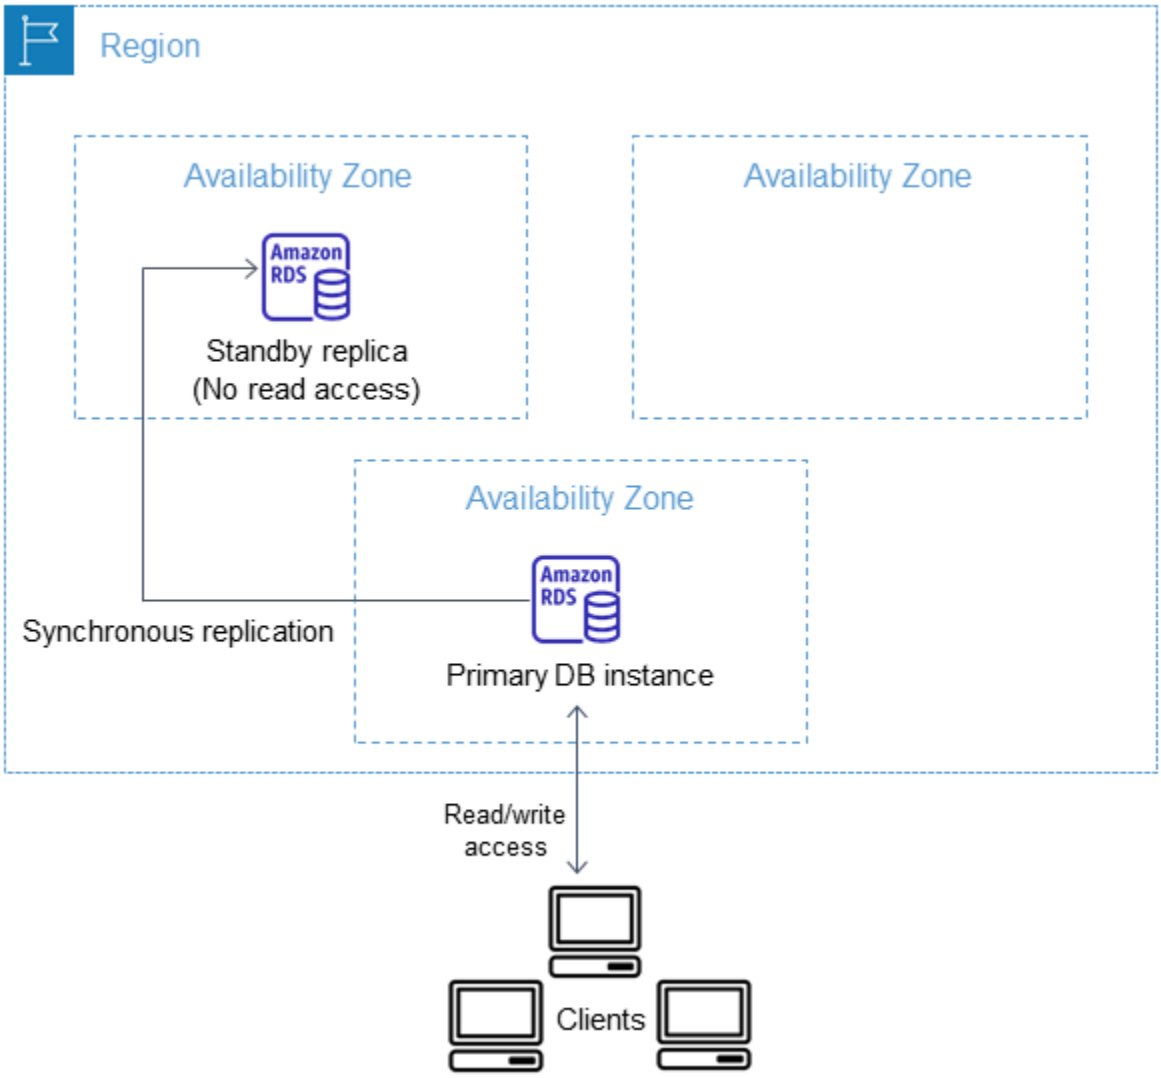
- the section called “Upgrading the engine version”

Multi-AZ DB instance deployments

Amazon RDS provides high availability and failover support for DB instances using Multi-AZ deployments with a single standby DB instance. This type of deployment is called a *Multi-AZ DB instance deployment*. Amazon RDS uses several different technologies to provide this failover support. Multi-AZ deployments for MariaDB, MySQL, Oracle, PostgreSQL, and RDS Custom for SQL Server DB instances use the Amazon failover technology. Microsoft SQL Server DB instances use SQL Server Database Mirroring (DBM) or Always On Availability Groups (AGs). For information on SQL Server version support for Multi-AZ, see Multi-AZ deployments for Amazon RDS for Microsoft SQL Server. For information on working with RDS Custom for SQL Server for Multi-AZ, see Managing a Multi-AZ deployment for RDS Custom for SQL Server.

In a Multi-AZ DB instance deployment, Amazon RDS automatically provisions and maintains a synchronous standby replica in a different Availability Zone. The primary DB instance is synchronously replicated across Availability Zones to a standby replica to provide data redundancy and minimize latency spikes during system backups. Running a DB instance with high availability can enhance availability during planned system maintenance. It can also help protect your databases against DB instance failure and Availability Zone disruption. For more information on Availability Zones, see Regions, Availability Zones, and Local Zones.

> **Note**
>
> The high availability option isn't a scaling solution for read-only scenarios. You can't use a standby replica to serve read traffic. To serve read-only traffic, use a Multi-AZ DB cluster or a read replica instead. For more information about Multi-AZ DB clusters, see Multi-AZ DB cluster deployments. For more information about read replicas, see Working with DB instance read replicas.



Using the RDS console, you can create a Multi-AZ DB instance deployment by simply specifying Multi-AZ when creating a DB instance. You can use the console to convert existing DB instances to Multi-AZ DB instance deployments by modifying the DB instance and specifying the Multi-AZ option. You can also specify a Multi-AZ DB instance deployment with the AWS CLI or Amazon RDS API. Use the create-db-instance or modify-db-instance CLI command, or the CreateDBInstance or ModifyDBInstance API operation.

The RDS console shows the Availability Zone of the standby replica (called the secondary AZ). You can also use the describe-db-instances CLI command or the DescribeDBInstances API operation to find the secondary AZ.

DB instances using Multi-AZ DB instance deployments can have increased write and commit latency compared to a Single-AZ deployment. This can happen because of the synchronous data replication that occurs. You might have a change in latency if your deployment fails over to the

standby replica, although AWS is engineered with low-latency network connectivity between Availability Zones. For production workloads, we recommend that you use Provisioned IOPS (input/output operations per second) for fast, consistent performance. For more information about DB instance classes, see DB instance classes.

Modifying a DB instance to be a Multi-AZ DB instance deployment

If you have a DB instance in a Single-AZ deployment and modify it to a Multi-AZ DB instance deployment (for engines other than Amazon Aurora), Amazon RDS performs several actions:

1. Takes a snapshot of the primary DB instance's Amazon Elastic Block Store (EBS) volumes.
2. Creates new volumes for the standby replica from the snapshot. These volumes initialize in the background, and maximum volume performance is achieved after the data is fully initialized.
3. Turns on synchronous block-level replication between the volumes of the primary and standby replicas.

> **Important**
>
> Using a snapshot to create the standby instance avoids downtime when you convert from Single-AZ to Multi-AZ, but you can experience a performance impact during and after converting to Multi-AZ. This impact can be significant for workloads that are sensitive to write latency.
>
> While this capability lets large volumes be restored from snapshots quickly, it can cause a significant increase in the latency of I/O operations because of the synchronous replication. This latency can impact your database performance. We highly recommend as a best practice not to perform Multi-AZ conversion on a production DB instance.
>
> To avoid the performance impact on the DB instance currently serving the sensitive workload, create a read replica and enable backups on the read replica. Convert the read replica to Multi-AZ, and run queries that load the data into the read replica's volumes (on both AZs). Then promote the read replica to be the primary DB instance. For more information, see Working with DB instance read replicas.

There are two ways to modify a DB instance to be a Multi-AZ DB instance deployment:

Topics

- Convert to a Multi-AZ DB instance deployment with the RDS console

- Modifying a DB instance to be a Multi-AZ DB instance deployment

Convert to a Multi-AZ DB instance deployment with the RDS console

You can use the RDS console to convert a DB instance to a Multi-AZ DB instance deployment.

You can only use the console to complete the conversion. To use the AWS CLI or RDS API, follow the instructions in Modifying a DB instance to be a Multi-AZ DB instance deployment.

To convert to a Multi-AZ DB instance deployment with the RDS console

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**, and then choose the DB instance that you want to modify.
3. From **Actions**, choose **Convert to Multi-AZ deployment**.
4. On the confirmation page, choose **Apply immediately** to apply the changes immediately. Choosing this option doesn't cause downtime, but there is a possible performance impact. Alternatively, you can choose to apply the update during the next maintenance window. For more information, see Schedule modifications setting.
5. Choose **Convert to Multi-AZ**.

Modifying a DB instance to be a Multi-AZ DB instance deployment

You can modify a DB instance to be a MultiAZ DB instance deployment in the following ways:

- Using the RDS console, modify the DB instance, and set **Multi-AZ deployment** to **Yes**.
- Using the AWS CLI, call the modify-db-instance command, and set the `--multi-az` option.
- Using the RDS API, call the ModifyDBInstance operation, and set the `MultiAZ` parameter to `true`.

For information about modifying a DB instance, see Modifying an Amazon RDS DB instance. After the modification is complete, Amazon RDS triggers an event (RDS-EVENT-0025) that indicates the process is complete. You can monitor Amazon RDS events. For more information about events, see Working with Amazon RDS event notification.

Failover process for Amazon RDS

If a planned or unplanned outage of your DB instance results from an infrastructure defect, Amazon RDS automatically switches to a standby replica in another Availability Zone if you have turned on Multi-AZ. The time that it takes for the failover to complete depends on the database activity and other conditions at the time the primary DB instance became unavailable. Failover times are typically 60–120 seconds. However, large transactions or a lengthy recovery process can increase failover time. When the failover is complete, it can take additional time for the RDS console to reflect the new Availability Zone.

> **Note**
>
> You can force a failover manually when you reboot a DB instance. For more information, see Rebooting a DB instance.

Amazon RDS handles failovers automatically so you can resume database operations as quickly as possible without administrative intervention. The primary DB instance switches over automatically to the standby replica if any of the conditions described in the following table occurs. You can view these failover reasons in the event log.

Failover reason	Description
The operating system underlying the RDS database instance is being patched in an offline operation.	A failover was triggered during the maintenance window for an OS patch or a security update. For more information, see Maintaining a DB instance.
The primary host of the RDS Multi-AZ instance is unhealthy.	The Multi-AZ DB instance deployment detected an impaired primary DB instance and failed over.
The primary host of the RDS Multi-AZ instance is unreachable due to loss of network connectivity.	RDS monitoring detected a network reachability failure to the primary DB instance and triggered a failover.

Failover reason	Description
The RDS instance was modified by customer.	An RDS DB instance modification triggered a failover. For more information, see Modifying an Amazon RDS DB instance.

Failover reason	Description
The RDS Multi-AZ primary instance is busy and unresponsive.	The primary DB instance is unresponsive. We recommend that you do the following: • Examine the event and CloudWatch logs for excessive CPU, memory, or swap space usage. For more information, see Working with Amazon RDS event notification and Creating a rule that triggers on an Amazon RDS event. • Evaluate your workload to determine whether you're using the appropriate DB instance class. For more information, see DB instance classes. • Use Enhanced Monitoring for real-time operating system metrics. For more information, see Monitoring OS metrics with Enhanced Monitoring. • Use Performance Insights to help analyze any issues that affect your DB instance's performance. For more information, see Monitoring DB load with Performance Insights on Amazon RDS. For more information on these recommend ations, see Monitoring tools for Amazon RDS and Best practices for Amazon RDS.
The storage volume underlying the primary host of the RDS Multi-AZ instance experienced a failure.	The Multi-AZ DB instance deployment detected a storage issue on the primary DB instance and failed over.

Failover reason	Description
The user requested a failover of the DB instance.	You rebooted the DB instance and chose **Reboot with failover**. For more information, see Rebooting a DB instance.

To determine if your Multi-AZ DB instance has failed over, you can do the following:

- Set up DB event subscriptions to notify you by email or SMS that a failover has been initiated. For more information about events, see Working with Amazon RDS event notification.
- View your DB events by using the RDS console or API operations.
- View the current state of your Multi-AZ DB instance deployment by using the RDS console or API operations.

For information on how you can respond to failovers, reduce recovery time, and other best practices for Amazon RDS, see Best practices for Amazon RDS.

Setting the JVM TTL for DNS name lookups

The failover mechanism automatically changes the Domain Name System (DNS) record of the DB instance to point to the standby DB instance. As a result, you need to re-establish any existing connections to your DB instance. In a Java virtual machine (JVM) environment, due to how the Java DNS caching mechanism works, you might need to reconfigure JVM settings.

The JVM caches DNS name lookups. When the JVM resolves a host name to an IP address, it caches the IP address for a specified period of time, known as the *time-to-live* (TTL).

Because AWS resources use DNS name entries that occasionally change, we recommend that you configure your JVM with a TTL value of no more than 60 seconds. Doing this makes sure that when a resource's IP address changes, your application can receive and use the resource's new IP address by requerying the DNS.

On some Java configurations, the JVM default TTL is set so that it never refreshes DNS entries until the JVM is restarted. Thus, if the IP address for an AWS resource changes while your application is still running, it can't use that resource until you manually restart the JVM and the cached IP

information is refreshed. In this case, it's crucial to set the JVM's TTL so that it periodically refreshes its cached IP information.

You can get the JVM default TTL by retrieving the `networkaddress.cache.ttl` property value:

```
String ttl = java.security.Security.getProperty("networkaddress.cache.ttl");
```

> **Note**
>
> The default TTL can vary according to the version of your JVM and whether a security manager is installed. Many JVMs provide a default TTL less than 60 seconds. If you're using such a JVM and not using a security manager, you can ignore the rest of this topic. For more information on security managers in Oracle, see The security manager in the Oracle documentation.

To modify the JVM's TTL, set the `networkaddress.cache.ttl` property value. Use one of the following methods, depending on your needs:

- To set the property value globally for all applications that use the JVM, set `networkaddress.cache.ttl` in the `$JAVA_HOME/jre/lib/security/java.security` file.

  ```
  networkaddress.cache.ttl=60
  ```

- To set the property locally for your application only, set `networkaddress.cache.ttl` in your application's initialization code before any network connections are established.

  ```
  java.security.Security.setProperty("networkaddress.cache.ttl" , "60");
  ```

Multi-AZ DB cluster deployments

A *Multi-AZ DB cluster deployment* is a semisynchronous, high availability deployment mode of Amazon RDS with two readable replica DB instances. A Multi-AZ DB cluster has a writer DB instance and two reader DB instances in three separate Availability Zones in the same AWS Region. Multi-AZ DB clusters provide high availability, increased capacity for read workloads, and lower write latency when compared to Multi-AZ DB instance deployments.

You can import data from an on-premises database to a Multi-AZ DB cluster by following the instructions in Importing data to an Amazon RDS MariaDB or MySQL database with reduced downtime.

You can purchase reserved DB instances for a Multi-AZ DB cluster. For more information, see Reserved DB instances for a Multi-AZ DB cluster.

Feature availability and support varies across specific versions of each database engine, and across AWS Regions. For more information on version and Region availability of Amazon RDS with Multi-AZ DB clusters, see Supported Regions and DB engines for Multi-AZ DB clusters in Amazon RDS.

Topics

- Renaming a Multi-AZ DB cluster
- Rebooting a Multi-AZ DB cluster and reader DB instances
- Working with Multi-AZ DB cluster read replicas
- Using PostgreSQL logical replication with Multi-AZ DB clusters
- Deleting a Multi-AZ DB cluster
- Limitations of Multi-AZ DB clusters

Important

Multi-AZ DB clusters aren't the same as Aurora DB clusters. For information about Aurora DB clusters, see the Amazon Aurora User Guide.

Instance class availability for Multi-AZ DB clusters

Multi-AZ DB cluster deployments are supported for the following DB instance classes: `db.m5d`, `db.m6gd`, `db.m6id`, `db.m6idn`, `db.r5d`, `db.r6gd`, `db.x2iedn`, `db.r6id`, and `db.r6idn`, and `db.c6gd`.

Note

The c6gd instance classes are the only ones that support the `medium` instance size.

For more information about DB instance classes, see the section called “DB instance classes”.

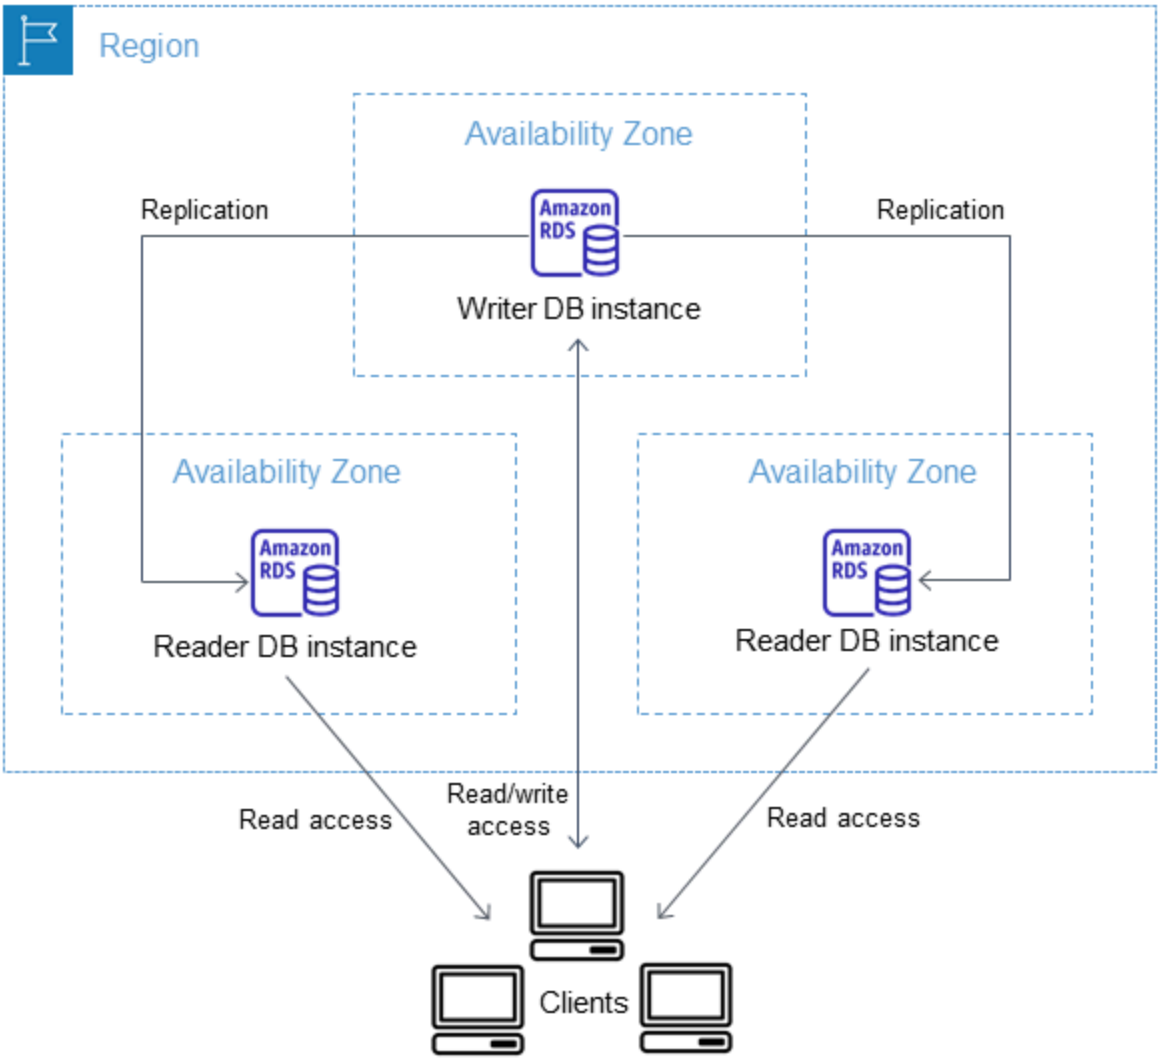
Overview of Multi-AZ DB clusters

With a Multi-AZ DB cluster, Amazon RDS replicates data from the writer DB instance to both of the reader DB instances using the DB engine's native replication capabilities. When a change is made on the writer DB instance, it's sent to each reader DB instance.

Multi-AZ DB cluster deployments use semisynchronous replication, which requires acknowledgment from at least one reader DB instance in order for a change to be committed. It doesn't require acknowledgment that events have been fully executed and committed on *all* replicas.

Reader DB instances act as automatic failover targets and also serve read traffic to increase application read throughput. If an outage occurs on your writer DB instance, RDS manages failover to one of the reader DB instances. RDS does this based on which reader DB instance has the most recent change record.

The following diagram shows a Multi-AZ DB cluster.



Multi-AZ DB clusters typically have lower write latency when compared to Multi-AZ DB instance deployments. They also allow read-only workloads to run on reader DB instances. The RDS console shows the Availability Zone of the writer DB instance and the Availability Zones of the reader DB instances. You can also use the describe-db-clusters CLI command or the DescribeDBClusters API operation to find this information.

Important

To prevent replication errors in RDS for MySQL Multi-AZ DB clusters, we strongly recommend that all tables have a primary key.

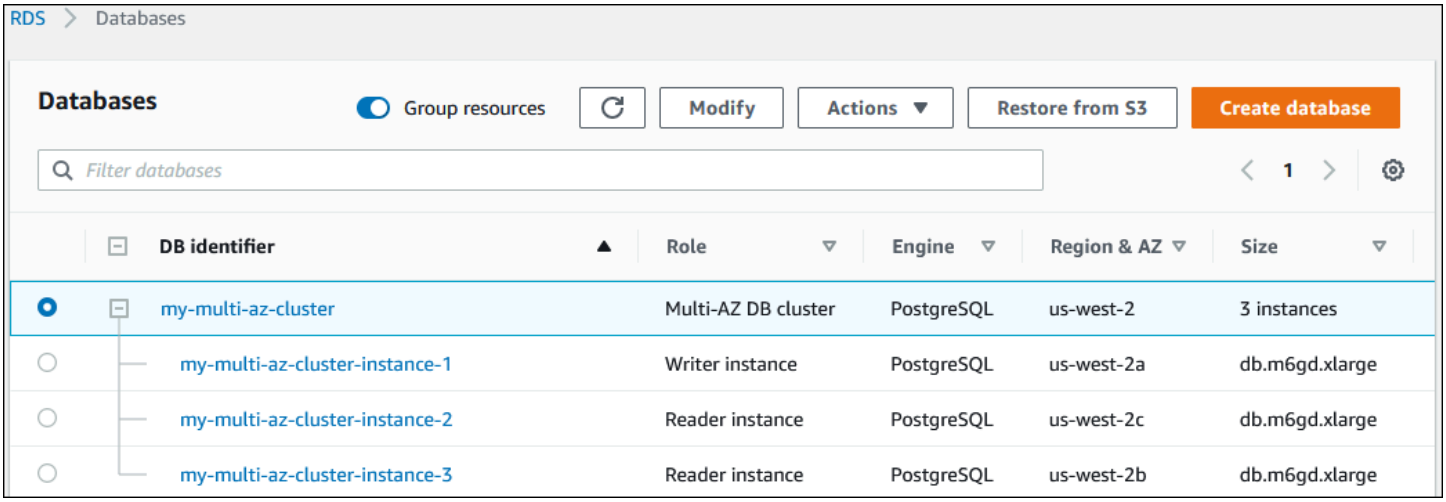
Managing a Multi-AZ DB cluster with the AWS Management Console

You can manage a Multi-AZ DB cluster with the console.

To manage a Multi-AZ DB cluster with the console

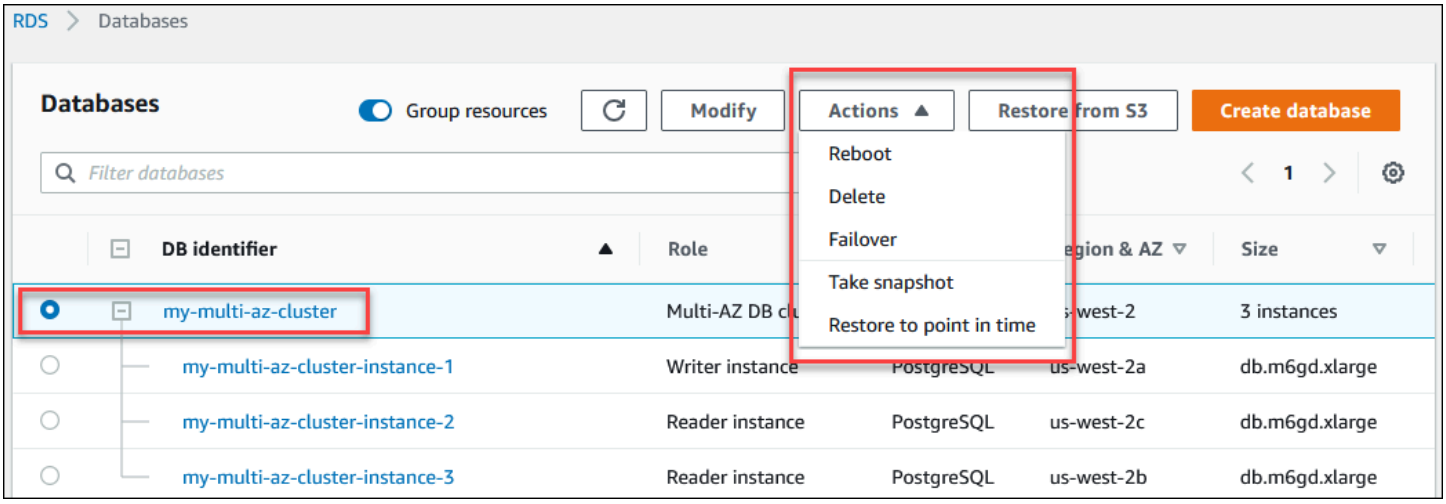
1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**, and then choose the Multi-AZ DB cluster that you want to manage.

The following image shows a Multi-AZ DB cluster in the console.

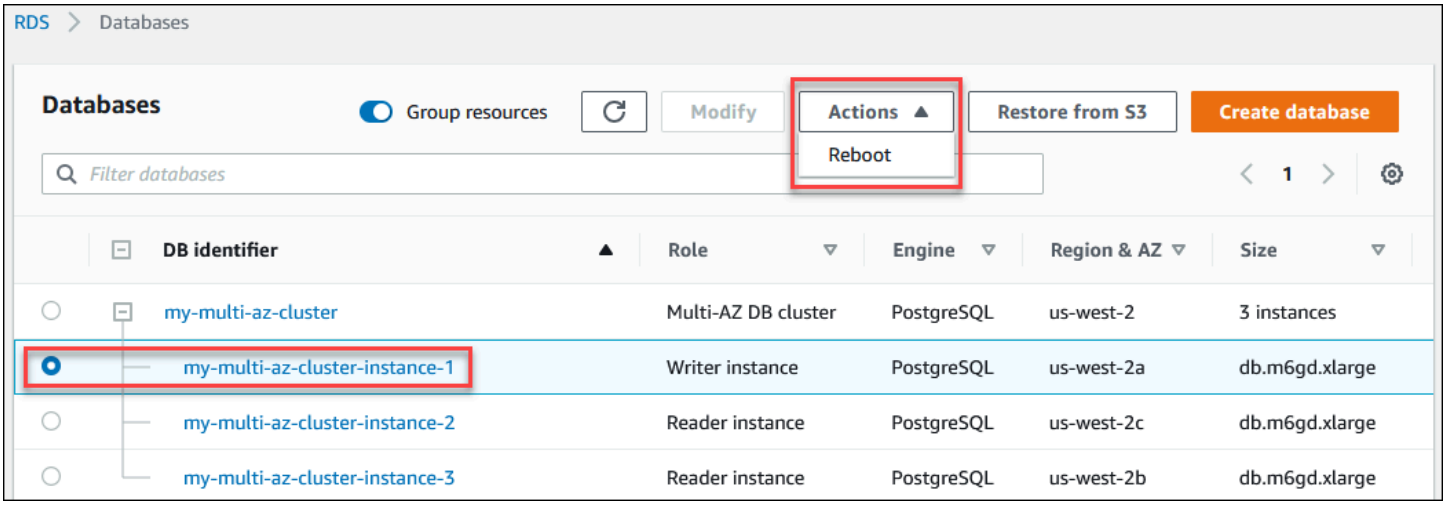


The available actions in the **Actions** menu depend on whether the Multi-AZ DB cluster is selected or a DB instance in the cluster is selected.

Choose the Multi-AZ DB cluster to view the cluster details and perform actions at the cluster level.



Choose a DB instance in a Multi-AZ DB cluster to view the DB instance details and perform actions at the DB instance level.



Working with parameter groups for Multi-AZ DB clusters

In a Multi-AZ DB cluster, a *DB cluster parameter group* acts as a container for engine configuration values that are applied to every DB instance in the Multi-AZ DB cluster.

In a Multi-AZ DB cluster, a *DB parameter group* is set to the default DB parameter group for the DB engine and DB engine version. The settings in the DB cluster parameter group are used for all of the DB instances in the cluster.

For information about parameter groups, see the section called “DB cluster parameter groups”.

Upgrading the engine version of a Multi-AZ DB cluster

Amazon RDS provides newer versions of each supported database engine so that you can keep your Multi-AZ DB cluster up to date. When Amazon RDS supports a new version of a database engine, you can choose how and when to upgrade your Multi-AZ DB cluster.

There are two kinds of upgrades that you can perform:

Major version upgrades

A *major engine version upgrade* can introduce changes that aren't compatible with existing applications. When you initiate a major version upgrade, Amazon RDS simultaneously upgrades the reader and writer instances. Therefore, your DB cluster might not be available until the upgrade completes.

Minor version upgrades

A *minor version upgrade* includes only changes that are backward-compatible with existing applications. When you initiate a minor version upgrade, Amazon RDS first upgrades the reader DB instances one at a time. Then, one of the reader DB instances switches to be the new writer DB instance. Amazon RDS then upgrades the old writer instance (which is now a reader instance).

Downtime during the upgrade is limited to the time it takes for one of the reader DB instances to become the new writer DB instance. This downtime acts like an automatic failover. For more information, see the section called “Failover process for Multi-AZ DB clusters”. Note that the replica lag of your Multi-AZ DB cluster might affect the downtime. For more information, see the section called “Replica lag and Multi-AZ DB clusters”.

For RDS for PostgreSQL Multi-AZ DB cluster read replicas, Amazon RDS upgrades the cluster member instances one at a time. The reader and writer cluster roles don't switch during the upgrade. Therefore, your DB cluster might experience downtime while Amazon RDS upgrades the cluster writer instance.

> **Note**
>
> The downtime for a Multi-AZ DB cluster minor version upgrade is typically 35 seconds. When used with RDS Proxy, you can further reduce downtime to one second or less. For more information, see *Using RDS Proxy*. Alternately, you can use an open source database proxy such as ProxySQL,PgBouncer, or the AWS JDBC Driver for MySQL.

Currently, Amazon RDS supports major version upgrades only for RDS for PostgreSQL Multi-AZ DB clusters. Amazon RDS supports minor version upgrades for all DB engines that support Multi-AZ DB clusters.

Amazon RDS doesn't automatically upgrade Multi-AZ DB cluster read replicas. For *minor* version upgrades, you must first manually upgrade all read replicas and then upgrade the cluster. Otherwise, the upgrade is blocked. When you perform a *major* version upgrade of a cluster, the replication state of all read replicas changes to **terminated**. You must delete and recreate the read replicas after the upgrade completes. For more information, see the section called "Monitoring read replication".

The process for upgrading the engine version of a Multi-AZ DB cluster is the same as the process for upgrading a DB instance engine version. For instructions, see the section called "Upgrading the engine version". The only difference is that when using the AWS Command Line Interface (AWS CLI), you use the modify-db-cluster command and specify the `--db-cluster-identifier` parameter (along with the `--allow-major-version-upgrade` parameter).

For more information about major and minor version upgrades, see the following documentation for your DB engine:

- the section called "Upgrading the PostgreSQL DB engine"
- the section called "Upgrading the MySQL DB engine"

Using RDS Proxy with Multi-AZ DB clusters

You can use Amazon RDS Proxy to create a proxy for your Multi-AZ DB clusters. By using RDS Proxy, your applications can pool and share database connections to improve their ability to scale. Each proxy performs connection *multiplexing*, also known as connection reuse. With multiplexing, RDS Proxy performs all the operations for a transaction using one underlying database connection. RDS Proxy can also reduce the downtime for a minor version upgrade of a Multi-AZ DB cluster to one second or less. For more information about the benefits of RDS Proxy, see *Using RDS Proxy*.

To set up a proxy for a Multi-AZ DB cluster, choose **Create an RDS Proxy** when creating the cluster. For instructions to create and manage RDS Proxy endpoints, see the section called "Working with RDS Proxy endpoints".

Configuring external replication from Multi-AZ DB clusters

You can set up replication between an Multi-AZ DB cluster and a database that is external to Amazon RDS. See the instructions in the following sections depending on your DB engine.

RDS for MySQL

To set up external replication for an RDS for MySQL Multi-AZ DB cluster, you must retain binary log files on the DB instances within the cluster for long enough to ensure that the changes are applied to the replica before Amazon RDS deletes the binlog file. To do so, configure binary log retention by calling the `mysql.rds_set_configuration` stored procedure and specifying the `binlog retention hours` parameter. For more information, see the section called “binlog retention hours”.

The default value for `binlog retention hours` is `NULL`, which means that binary logs aren't retained (0 hours). If you want to set up external replication for a Multi-AZ DB cluster, you must set the parameter to a value other than `NULL`.

You can only configure binary log retention from the writer DB instance of the Multi-AZ DB cluster, and the setting is propagated to all reader DB instances asynchronously.

In addition, we highly recommend enabling GTID-based replication on your external replica. Then, if one of the DB instances fails, you can resume replication from another healthy DB instance within the cluster. For more information, see Replication with Global Transaction Identifiers in the MySQL documentation.

RDS for PostgreSQL

To set up external replication for an RDS for PostgreSQL Multi-AZ DB cluster, you must enable logical replication. For instructions, see the section called “Using PostgreSQL logical replication with Multi-AZ DB clusters”.

Replica lag and Multi-AZ DB clusters

Replica lag is the difference in time between the latest transaction on the writer DB instance and the latest applied transaction on a reader DB instance. The Amazon CloudWatch metric `ReplicaLag` represents this time difference. For more information about CloudWatch metrics, see Monitoring Amazon RDS metrics with Amazon CloudWatch.

Although Multi-AZ DB clusters allow for high write performance, replica lag can still occur due to the nature of engine-based replication. Because any failover must first resolve the replica lag before it promotes a new writer DB instance, monitoring and managing this replica lag is a consideration.

For RDS for MySQL Multi-AZ DB clusters, failover time depends on replica lag of both remaining reader DB instances. Both the reader DB instances must apply unapplied transactions before one of them is promoted to the new writer DB instance.

For RDS for PostgreSQL Multi-AZ DB clusters, failover time depends on the lowest replica lag of the two remaining reader DB instances. The reader DB instance with the lowest replica lag must apply unapplied transactions before it is promoted to the new writer DB instance.

For a tutorial that shows you how to create a CloudWatch alarm when replica lag exceeds a set amount of time, see Tutorial: Creating an Amazon CloudWatch alarm for Multi-AZ DB cluster replica lag.

Common causes of replica lag

In general, replica lag occurs when the write workload is too high for the reader DB instances to apply the transactions efficiently. Various workloads can incur temporary or continuous replica lag. Some examples of common causes are the following:

- High write concurrency or heavy batch updating on the writer DB instance, causing the apply process on the reader DB instances to fall behind.
- Heavy read workload that is using resources on one or more reader DB instances. Running slow or large queries can affect the apply process and can cause replica lag.
- Transactions that modify large amounts of data or DDL statements can sometimes cause a temporary increase in replica lag because the database must preserve commit order.

Mitigating replica lag

For Multi-AZ DB clusters for RDS for MySQL and RDS for PostgreSQL, you can mitigate replica lag by reducing the load on your writer DB instance. You can also use flow control to reduce replica lag. *Flow control* works by throttling writes on the writer DB instance, which ensures that replica lag doesn't continue to grow unbounded. Write throttling is accomplished by adding a delay into the end of a transaction, which decreases the write throughput on the writer DB instance. Although flow control doesn't guarantee lag elimination, it can help reduce overall lag in many workloads.

The following sections provide information about using flow control with RDS for MySQL and RDS for PostgreSQL.

Mitigating replica lag with flow control for RDS for MySQL

When you are using RDS for MySQL Multi-AZ DB clusters, flow control is turned on by default using the dynamic parameter `rpl_semi_sync_master_target_apply_lag`. This parameter specifies the upper limit that you want for replica lag. As replica lag approaches this configured limit, flow control throttles the write transactions on the writer DB instance to try to contain the replica lag below the specified value. In some cases, replica lag can exceed the specified limit. By default, this parameter is set to 120 seconds. To turn off flow control, set this parameter to its maximum value of 86,400 seconds (one day).

To view the current delay injected by flow control, show the parameter `Rpl_semi_sync_master_flow_control_current_delay` by running the following query.

```
SHOW GLOBAL STATUS like '%flow_control%';
```

Your output should look similar to the following.

```
+-----------------------------------------------+-------+
| Variable_name                                 | Value |
+-----------------------------------------------+-------+
| Rpl_semi_sync_master_flow_control_current_delay | 2010  |
+-----------------------------------------------+-------+
1 row in set (0.00 sec)
```

> **Note**
>
> The delay is shown in microseconds.

When you have Performance Insights turned on for an RDS for MySQL Multi-AZ DB cluster, you can monitor the wait event corresponding to a SQL statement indicating that the queries were delayed by a flow control. When a delay was introduced by a flow control, you can view the wait event `/wait/synch/cond/semisync/semi_sync_flow_control_delay_cond` corresponding to the SQL statement on the Performance Insights dashboard. To view these metrics, make sure that the Performance Schema is turned on. For information about Performance Insights, see Monitoring DB load with Performance Insights on Amazon RDS.

Mitigating replica lag with flow control for RDS for PostgreSQL

When you are using RDS for PostgreSQL Multi-AZ DB clusters, flow control is deployed as an extension. It turns on a background worker for all DB instances in the DB cluster. By default, the background workers on the reader DB instances communicate the current replica lag with the background worker on the writer DB instance. If the lag exceeds two minutes on any reader DB instance, the background worker on the writer DB instance adds a delay at the end of a transaction. To control the lag threshold, use the parameter `flow_control.target_standby_apply_lag`.

When a flow control throttles a PostgreSQL process, the `Extension` wait event in `pg_stat_activity` and Performance Insights indicates that. The function `get_flow_control_stats` displays details about how much delay is currently being added.

Flow control can benefit most online transaction processing (OLTP) workloads that have short but highly concurrent transactions. If the lag is caused by long-running transactions, such as batch operations, flow control doesn't provide as strong a benefit.

You can turn off flow control by removing the extension from the `shared_preload_libraries` and rebooting your DB instance.

Failover process for Multi-AZ DB clusters

If there is a planned or unplanned outage of your writer DB instance in a Multi-AZ DB cluster, Amazon RDS automatically fails over to a reader DB instance in different Availability Zone. The time it takes for the failover to complete depends on the database activity and other conditions when the writer DB instance became unavailable. Failover times are typically under 35 seconds. Failover completes when both reader DB instances have applied outstanding transactions from the failed writer. When the failover is complete, it can take additional time for the RDS console to reflect the new Availability Zone.

Topics

- Automatic failovers
- Manually failing over a Multi-AZ DB cluster
- Determining whether a Multi-AZ DB cluster has failed over
- Setting the JVM TTL for DNS name lookups

Automatic failovers

Amazon RDS handles failovers automatically so you can resume database operations as quickly as possible without administrative intervention. To fail over, the writer DB instance switches automatically to a reader DB instance.

Manually failing over a Multi-AZ DB cluster

If you manually fail over a Multi-AZ DB cluster, RDS first terminates the primary DB instance. Then, the internal monitoring system detects that the primary DB instance is unhealthy and promotes a readable replica DB instance. Failover times are typically under 35 seconds.

You can fail over a Multi-AZ DB cluster manually using the AWS Management Console, the AWS CLI, or the RDS API.

Console

To fail over a Multi-AZ DB cluster manually

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.
3. Choose the Multi-AZ DB cluster that you want to fail over.
4. For **Actions**, choose **Failover**.

   The **Failover DB cluster** page appears.
5. Choose **Failover** to confirm the manual failover.

AWS CLI

To fail over a Multi-AZ DB cluster manually, use the AWS CLI command failover-db-cluster.

Example

```
aws rds failover-db-cluster --db-cluster-identifier mymultiazdbcluster
```

RDS API

To fail over a Multi-AZ DB cluster manually, call the Amazon RDS API FailoverDBCluster and specify the `DBClusterIdentifier`.

Determining whether a Multi-AZ DB cluster has failed over

To determine if your Multi-AZ DB cluster has failed over, you can do the following:

- Set up DB event subscriptions to notify you by email or SMS that a failover has been initiated. For more information about events, see Working with Amazon RDS event notification.
- View your DB events by using the Amazon RDS console or API operations.
- View the current state of your Multi-AZ DB cluster by using the Amazon RDS console, the AWS CLI, and the RDS API.

For information on how you can respond to failovers, reduce recovery time, and other best practices for Amazon RDS, see Best practices for Amazon RDS.

Setting the JVM TTL for DNS name lookups

The failover mechanism automatically changes the Domain Name System (DNS) record of the DB instance to point to the reader DB instance. As a result, you need to re-establish any existing connections to your DB instance. In a Java virtual machine (JVM) environment, due to how the Java DNS caching mechanism works, you might need to reconfigure JVM settings.

The JVM caches DNS name lookups. When the JVM resolves a host name to an IP address, it caches the IP address for a specified period of time, known as the *time-to-live* (TTL).

Because AWS resources use DNS name entries that occasionally change, we recommend that you configure your JVM with a TTL value of no more than 60 seconds. Doing this makes sure that when a resource's IP address changes, your application can receive and use the resource's new IP address by requerying the DNS.

On some Java configurations, the JVM default TTL is set so that it never refreshes DNS entries until the JVM is restarted. Thus, if the IP address for an AWS resource changes while your application is still running, it can't use that resource until you manually restart the JVM and the cached IP information is refreshed. In this case, it's crucial to set the JVM's TTL so that it periodically refreshes its cached IP information.

> **Note**
>
> The default TTL can vary according to the version of your JVM and whether a security manager is installed. Many JVMs provide a default TTL less than 60 seconds. If you're using such a JVM and not using a security manager, you can ignore the rest of this topic. For

more information on security managers in Oracle, see The security manager in the Oracle documentation.

To modify the JVM's TTL, set the `networkaddress.cache.ttl` property value. Use one of the following methods, depending on your needs:

- To set the property value globally for all applications that use the JVM, set `networkaddress.cache.ttl` in the `$JAVA_HOME/jre/lib/security/java.security` file.

```
networkaddress.cache.ttl=60
```

- To set the property locally for your application only, set `networkaddress.cache.ttl` in your application's initialization code before any network connections are established.

```
java.security.Security.setProperty("networkaddress.cache.ttl" , "60");
```

Multi-AZ DB cluster snapshots

Amazon RDS creates and saves automated backups of your Multi-AZ DB cluster during the configured backup window. RDS creates a storage volume snapshot of your DB cluster, backing up the entire cluster and not just individual instances.

You can also take manual backups of your Multi-AZ DB cluster. For very long-term backups, consider exporting the snapshot data to Amazon S3. For more information, see the section called "Creating a Multi-AZ DB cluster snapshot".

You can restore a Multi-AZ DB cluster to a specific point in time, creating a new Multi-AZ DB cluster. For instructions, see the section called "Restoring a Multi-AZ DB cluster to a specified time".

Alternately, you can restore a Multi-AZ DB cluster snapshot to a Single-AZ deployment or Multi-AZ DB instance deployment. For instructions, see the section called "Restoring from a Multi-AZ DB cluster snapshot to a DB instance".

Creating a Multi-AZ DB cluster

A Multi-AZ DB cluster has a writer DB instance and two reader DB instances in three separate Availability Zones. Multi-AZ DB clusters provide high availability, increased capacity for read workloads, and lower latency when compared to Multi-AZ deployments. For more information about Multi-AZ DB clusters, see Multi-AZ DB cluster deployments.

Note

Multi-AZ DB clusters are supported only for the MySQL and PostgreSQL DB engines.

DB cluster prerequisites

Important

Before you can create a Multi-AZ DB cluster, you must complete the tasks in Setting up your Amazon RDS environment.

The following are prerequisites to complete before creating a Multi-AZ DB cluster.

Topics

- Configure the network for the DB cluster
- Additional prerequisites

Configure the network for the DB cluster

You can create a Multi-AZ DB cluster only in a virtual private cloud (VPC) based on the Amazon VPC service. It must be in an AWS Region that has at least three Availability Zones. The DB subnet group that you choose for the DB cluster must cover at least three Availability Zones. This configuration ensures that each DB instance in the DB cluster is in a different Availability Zone.

To set up connectivity between your new DB cluster and an Amazon EC2 instance in the same VPC, do so when you create the DB cluster. To connect to your DB cluster from resources other than EC2 instances in the same VPC, configure the network connections manually.

Topics

- Configure automatic network connectivity with an EC2 instance
- Configure the network manually

Configure automatic network connectivity with an EC2 instance

When you create a Multi-AZ DB cluster, you can use the AWS Management Console to set up connectivity between an EC2 instance and the new DB cluster. When you do so, RDS configures your VPC and network settings automatically. The DB cluster is created in the same VPC as the EC2 instance so that the EC2 instance can access the DB cluster.

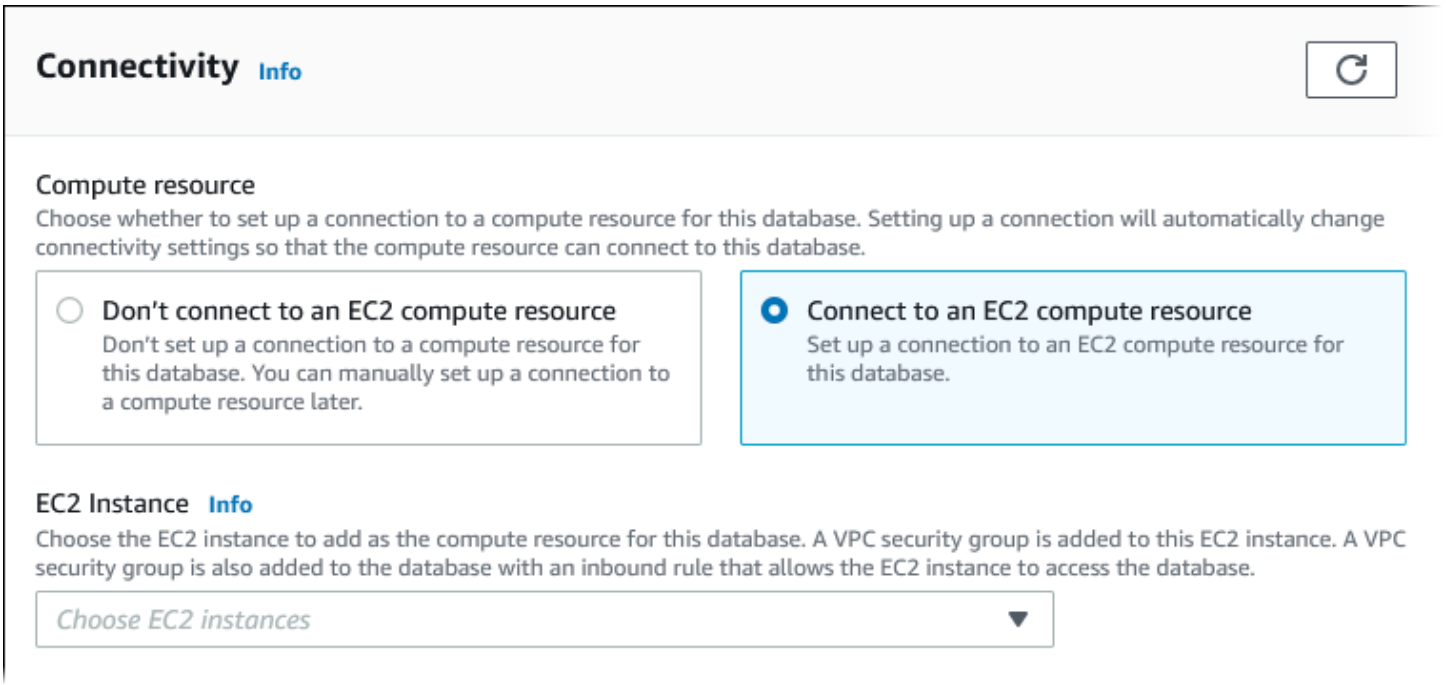
The following are requirements for connecting an EC2 instance with the DB cluster:

- The EC2 instance must exist in the AWS Region before you create the DB cluster.

  If no EC2 instances exist in the AWS Region, the console provides a link to create one.
- The user who is creating the DB cluster must have permissions to perform the following operations:
  - `ec2:AssociateRouteTable`
  - `ec2:AuthorizeSecurityGroupEgress`
  - `ec2:AuthorizeSecurityGroupIngress`
  - `ec2:CreateRouteTable`
  - `ec2:CreateSubnet`
  - `ec2:CreateSecurityGroup`
  - `ec2:DescribeInstances`
  - `ec2:DescribeNetworkInterfaces`
  - `ec2:DescribeRouteTables`
  - `ec2:DescribeSecurityGroups`
  - `ec2:DescribeSubnets`
  - `ec2:ModifyNetworkInterfaceAttribute`
  - `ec2:RevokeSecurityGroupEgress`

Using this option creates a private DB cluster. The DB cluster uses a DB subnet group with only private subnets to restrict access to resources within the VPC.

To connect an EC2 instance to the DB cluster, choose **Connect to an EC2 compute resource** in the **Connectivity** section on the **Create database** page.



When you choose **Connect to an EC2 compute resource**, RDS sets the following options automatically. You can't change these settings unless you choose not to set up connectivity with an EC2 instance by choosing **Don't connect to an EC2 compute resource**.

Console option	Automatic setting
Virtual Private Cloud (VPC)	RDS sets the VPC to the one associated with the EC2 instance.
DB subnet group	RDS requires a DB subnet group with a private subnet in the same Availability Zone as the EC2 instance. If a DB subnet group that meets this requirement exists, then RDS uses the existing DB subnet group. By default, this option is set to **Automatic setup**. When you choose **Automatic setup** and there is no DB subnet group that meets this requirement, the following action happens. RDS uses three available private subnets in three Availability Zones where one of the Availability Zones is the same as the EC2 instance. If a private subnet isn't available in

Console option	Automatic setting
	an Availability Zone, RDS creates a private subnet in the Availability Zone. Then RDS creates the DB subnet group. When a private subnet is available, RDS uses the route table associated with the subnet and adds any subnets it creates to this route table. When no private subnet is available, RDS creates a route table without internet gateway access and adds the subnets it creates to the route table. RDS also allows you to use existing DB subnet groups. Select **Choose existing** if you want to use an existing DB subnet group of your choice.
Public access	RDS chooses **No** so that the DB cluster isn't publicly accessible. For security, it is a best practice to keep the database private and make sure it isn't accessible from the internet.

Console option	Automatic setting
VPC security group (firewall)	RDS creates a new security group that is associated with the DB cluster. The security group is named `rds-ec2-`*n*, where *n* is a number. This security group includes an inbound rule with the EC2 VPC security group (firewall) as the source. This security group that is associated with the DB cluster allows the EC2 instance to access the DB cluster. RDS also creates a new security group that is associated with the EC2 instance. The security group is named `ec2-rds-`*n*, where *n* is a number. This security group includes an outbound rule with the VPC security group of the DB cluster as the source. This security group allows the EC2 instance to send traffic to the DB cluster. You can add another new security group by choosing **Create new** and typing the name of the new security group. You can add existing security groups by choosing **Choose existing** and selecting security groups to add.
Availability Zone	RDS chooses the Availability Zone of the EC2 instance for one DB instance in the Multi-AZ DB cluster deployment. RDS randomly chooses a different Availability Zone for both of the other DB instances. The writer DB instance is created in the same Availability Zone as the EC2 instance. There is the possibility of cross Availability Zone costs if a failover occurs and the writer DB instance is in a different Availability Zone.

For more information about these settings, see Settings for creating Multi-AZ DB clusters.

If you change these settings after the DB cluster is created, the changes might affect the connection between the EC2 instance and the DB cluster.

Configure the network manually

To connect to your DB cluster from resources other than EC2 instances in the same VPC, configure the network connections manually. If you use the AWS Management Console to create your Multi-AZ DB cluster, you can have Amazon RDS automatically create a VPC for you. Or you can use an existing VPC or create a new VPC for your Multi-AZ DB cluster. Your VPC must have at least one subnet in each of at least three Availability Zones for you to use it with a Multi-AZ DB cluster. For information on VPCs, see Amazon VPC and Amazon RDS.

If you don't have a default VPC or you haven't created a VPC, and you don't plan to use the console, do the following:

- Create a VPC with at least one subnet in each of at least three of the Availability Zones in the AWS Region where you want to deploy your DB cluster. For more information, see Working with a DB instance in a VPC.
- Specify a VPC security group that authorizes connections to your DB cluster. For more information, see Provide access to your DB instance in your VPC by creating a security group and Controlling access with security groups.
- Specify an RDS DB subnet group that defines at least three subnets in the VPC that can be used by the Multi-AZ DB cluster. For more information, see Working with DB subnet groups.

For information about limitations that apply to Multi-AZ DB clusters, see Limitations of Multi-AZ DB clusters.

If you want to connect to a resource that isn't in the same VPC as the Multi-AZ DB cluster, see the appropriate scenarios in Scenarios for accessing a DB instance in a VPC.

Additional prerequisites

Before you create your Multi-AZ DB cluster, consider the following additional prerequisites:

- To connect to AWS using AWS Identity and Access Management (IAM) credentials, your AWS account must have certain IAM policies. These grant the permissions required to perform Amazon RDS operations. For more information, see Identity and access management for Amazon RDS.

  If you use IAM to access the RDS console, first sign in to the AWS Management Console with your IAM user credentials. Then go to the RDS console at https://console.aws.amazon.com/rds/.

- To tailor the configuration parameters for your DB cluster, specify a DB cluster parameter group with the required parameter settings. For information about creating or modifying a DB cluster parameter group, see Working with parameter groups for Multi-AZ DB clusters.
- Determine the TCP/IP port number to specify for your DB cluster. The firewalls at some companies block connections to the default ports. If your company firewall blocks the default port, choose another port for your DB cluster. All DB instances in a DB cluster use the same port.
- If the major engine version for your database reached the RDS end of standard support date, you must use the Extended Support CLI option or the RDS API parameter. For more information, see RDS Extended Support in Settings for creating Multi-AZ DB clusters.

Creating a DB cluster

You can create a Multi-AZ DB cluster using the AWS Management Console, the AWS CLI, or the RDS API.

Console

You can create a Multi-AZ DB cluster by choosing **Multi-AZ DB cluster** in the **Availability and durability** section.

To create a Multi-AZ DB cluster using the console

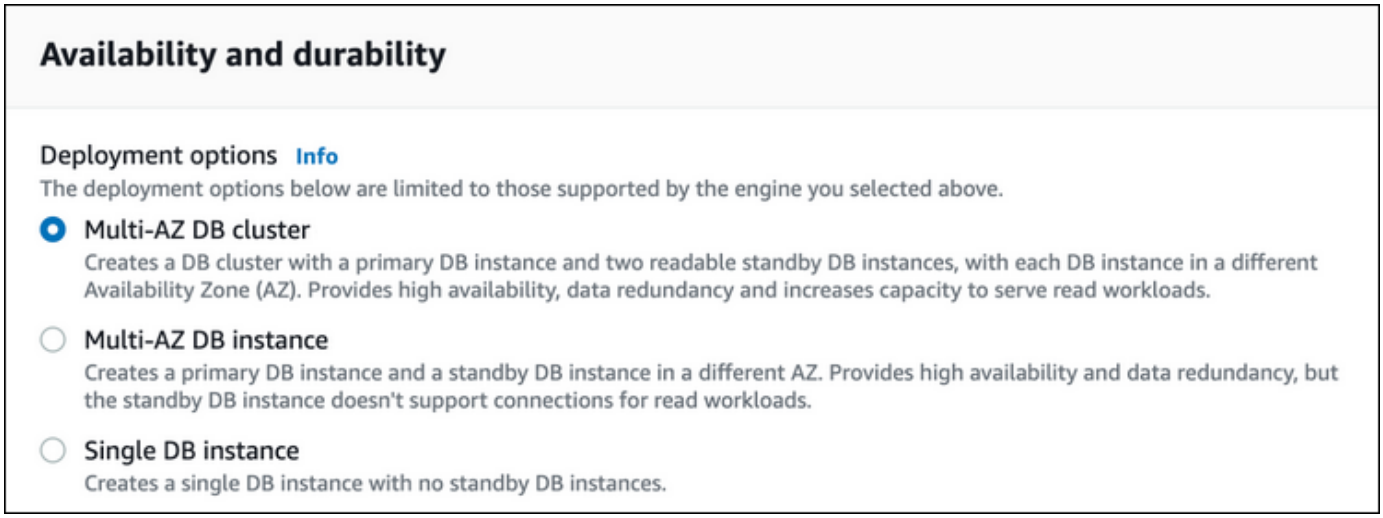
1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the upper-right corner of the AWS Management Console, choose the AWS Region in which you want to create the DB cluster.

   For information about the AWS Regions that support Multi-AZ DB clusters, see Limitations of Multi-AZ DB clusters.
3. In the navigation pane, choose **Databases**.
4. Choose **Create database**.

   To create a Multi-AZ DB cluster, make sure that **Standard Create** is selected and **Easy Create** isn't.
5. In **Engine type**, choose **MySQL** or **PostgreSQL**.
6. For **Version**, choose the DB engine version.

For information about the DB engine versions that support Multi-AZ DB clusters, see Limitations of Multi-AZ DB clusters.

7. In **Templates**, choose the appropriate template for your deployment.
8. In **Availability and durability**, choose **Multi-AZ DB cluster**.



9. In **DB cluster identifier**, enter the identifier for your DB cluster.
10. In **Master username**, enter your master user name, or keep the default setting.
11. Enter your master password:
    a. In the **Settings** section, open **Credential Settings**.
    b. If you want to specify a password, clear the **Auto generate a password** box if it is selected.
    c. (Optional) Change the **Master username** value.
    d. Enter the same password in **Master password** and **Confirm password**.
12. For **DB instance class**, choose a DB instance class. For a list of supported DB instance classes, see the section called “Instance class availability for Multi-AZ DB clusters”.
13. (Optional) Set up a connection to a compute resource for this DB cluster.

    You can configure connectivity between an Amazon EC2 instance and the new DB cluster during DB cluster creation. For more information, see Configure automatic network connectivity with an EC2 instance.
14. In the **Connectivity** section under **VPC security group (firewall)**, if you select **Create new**, a VPC security group is created with an inbound rule that allows your local computer's IP address to access the database.

15. For the remaining sections, specify your DB cluster settings. For information about each setting, see Settings for creating Multi-AZ DB clusters.
16. Choose **Create database**.

    If you chose to use an automatically generated password, the **View credential details** button appears on the **Databases** page.

    To view the master user name and password for the DB cluster, choose **View credential details**.

    To connect to the DB cluster as the master user, use the user name and password that appear.

    > **Important**
    >
    > You can't view the master user password again.

17. For **Databases**, choose the name of the new DB cluster.

On the RDS console, the details for the new DB cluster appear. The DB cluster has a status of **Creating** until the DB cluster is created and ready for use. When the state changes to **Available**, you can connect to the DB cluster. Depending on the DB cluster class and storage allocated, it can take several minutes for the new DB cluster to be available.

AWS CLI

Before you create a Multi-AZ DB cluster using the AWS CLI, make sure to fulfill the required prerequisites. These include creating a VPC and an RDS DB subnet group. For more information, see DB cluster prerequisites.

To create a Multi-AZ DB cluster by using the AWS CLI, call the create-db-cluster command. Specify the `--db-cluster-identifier`. For the `--engine` option, specify either `mysql` or `postgres`.

For information about each option, see Settings for creating Multi-AZ DB clusters.

For information about the AWS Regions, DB engines, and DB engine versions that support Multi-AZ DB clusters, see Limitations of Multi-AZ DB clusters.

The `create-db-cluster` command creates the writer DB instance for your DB cluster, and two reader DB instances. Each DB instance is in a different Availability Zone.

For example, the following command creates a MySQL 8.0 Multi-AZ DB cluster named `mysql-multi-az-db-cluster`.

Example

For Linux, macOS, or Unix:

```
aws rds create-db-cluster \
   --db-cluster-identifier mysql-multi-az-db-cluster \
   --engine mysql \
   --engine-version 8.0.32  \
   --master-username admin \
   --manage-master-user-password  \
   --port 3306 \
   --backup-retention-period 1  \
   --db-subnet-group-name default \
   --allocated-storage 4000 \
   --storage-type io1 \
   --iops 10000 \
   --db-cluster-instance-class db.m5d.xlarge
```

For Windows:

```
aws rds create-db-cluster ^
   --db-cluster-identifier mysql-multi-az-db-cluster ^
   --engine mysql ^
   --engine-version 8.0.32 ^
   --manage-master-user-password ^
   --master-username admin ^
   --port 3306 ^
   --backup-retention-period 1 ^
   --db-subnet-group-name default ^
   --allocated-storage 4000 ^
   --storage-type io1 ^
   --iops 10000 ^
   --db-cluster-instance-class db.m5d.xlarge
```

The following command creates a PostgreSQL 13.4 Multi-AZ DB cluster named `postgresql-multi-az-db-cluster`.

Example

For Linux, macOS, or Unix:

```
aws rds create-db-cluster \
   --db-cluster-identifier postgresql-multi-az-db-cluster \
   --engine postgres \
   --engine-version 13.4 \
   --manage-master-user-password \
   --master-username postgres \
   --port 5432 \
   --backup-retention-period 1  \
   --db-subnet-group-name default \
   --allocated-storage 4000 \
   --storage-type io1 \
   --iops 10000 \
   --db-cluster-instance-class db.m5d.xlarge
```

For Windows:

```
aws rds create-db-cluster ^
   --db-cluster-identifier postgresql-multi-az-db-cluster ^
   --engine postgres ^
   --engine-version 13.4 ^
   --manage-master-user-password ^
   --master-username postgres ^
   --port 5432 ^
   --backup-retention-period 1 ^
   --db-subnet-group-name default ^
   --allocated-storage 4000 ^
   --storage-type io1 ^
   --iops 10000 ^
   --db-cluster-instance-class db.m5d.xlarge
```

RDS API

Before you can create a Multi-AZ DB cluster using the RDS API, make sure to fulfill the required prerequisites, such as creating a VPC and an RDS DB subnet group. For more information, see DB cluster prerequisites.

To create a Multi-AZ DB cluster by using the RDS API, call the CreateDBCluster operation. Specify the `DBClusterIdentifier`. For the `Engine` parameter, specify either `mysql` or `postgresql`.

For information about each option, see Settings for creating Multi-AZ DB clusters.

The `CreateDBCluster` operation creates the writer DB instance for your DB cluster, and two reader DB instances. Each DB instance is in a different Availability Zone.

Settings for creating Multi-AZ DB clusters

For details about settings that you choose when you create a Multi-AZ DB cluster, see the following table. For more information about the AWS CLI options, see create-db-cluster. For more information about the RDS API parameters, see CreateDBCluster.

Console setting	Setting description	CLI option and RDS API parameter

Allocated storage	The amount of storage to allocate for each DB instance in your DB cluster (in gibibyte). For more information, see Amazon RDS DB instance storage.	**CLI option:**
		`--allocated-storage`
		API parameter:
		`AllocatedStorage`

Auto minor version upgrade	**Enable auto minor version upgrade** to have your DB cluster receive preferred minor DB engine version upgrades automatically when they become available. Amazon RDS performs automatic minor version upgrades in the maintenance window.	**CLI option:**
		`--auto-minor-version-upgrade`
		`--no-auto-minor-version-upgrade`
		API parameter:
		`AutoMinorVersionUpgrade`

Backup retention period	The number of days that you want automatic backups of your DB cluster to be retained. For a Multi-AZ DB cluster, this value must be set to **1** or greater.
	For more information, see Introduction to backups.
		CLI option:
		`--backup-retention-period`
		API parameter:
		`BackupRetentionPeriod`

Console setting	Setting description	CLI option and RDS API parameter

Backup window	The time period during which Amazon RDS automatically takes a backup of your DB cluster. U nless you have a specific time that you want to have your database backed up, use the default of **No preference**.
	
	For more information, see Introduction to backups.
		CLI option:
		
		`--preferred-backup-window`
		
		API parameter:
		
		`PreferredBackupWindow`

Certificate authority	The certificate authority (CA) for the server certificate used by the DB cluster.
	
	For more information, see Using SSL/TLS to encrypt a connection to a DB instance or cluster.
		CLI option:
		
		`--ca-certificate-identifier`
		
		RDS API parameter:
		
		`CACertificateIdentifier`

Copy tags to snapshots	This option copies any DB cluster tags to a DB snapshot when you create a snapshot.
	
	For more information, see Tagging Amazon RDS resources.
		CLI option:
		
		`-copy-tags-to-snapshot`
		
		`-no-copy-tags-to-snapshot`
		
		RDS API parameter:
		
		`CopyTagsToSnapshot`

Database authentication	For Multi-AZ DB clusters, only **Password authentication** is supported.	None because password authentication is the default.

Console setting	Setting description	CLI option and RDS API parameter

Database port	The port that you want to access the DB cluster through. The default port is shown.
	
	The port can't be changed after the DB cluster is created.
	
	The firewalls at some companies block connections to the default ports. If your company firewall blocks the default port, enter another port for your DB cluster.
		CLI option:
		
		`--port`
		
		RDS API parameter:
		
		`Port`

DB cluster identifier	The name for your DB cluster. Name your DB clusters in the same way that you name your on-premises servers. Your DB cluster identifier can contain up to 63 alphanumeric characters, and must be unique for your account in the AWS Region you chose.	**CLI option:**
		
		`--db-cluster-identifier`
		
		RDS API parameter:
		
		`DBClusterIdentifier`

Console setting	Setting description	CLI option and RDS API parameter

DB instance class	The compute and memory capacity of each DB instance in the Multi-AZ DB cluster, for example `db.m5d.xlarge` .
	
	If possible, choose a DB instance class large enough that a typical query working set can be held in memory. When working sets are held in memory the system can avoid writing to disk, which improves performance.
	
	For a list of supported DB instance classes, see the section called "Instance class availability for Multi-AZ DB clusters".
		CLI option:
		
		`--db-cluster-instance-class`
		
		RDS API parameter:
		
		`DBClusterInstanceClass`

DB cluster parameter group	The DB cluster parameter group that you want associated with the DB cluster.
	
	For more information, see Working with parameter groups for Multi-AZ DB clusters.
		CLI option:
		
		`--db-cluster-parameter-group-name`
		
		RDS API parameter:
		
		`DBClusterParameterGroupName`

DB engine version	The version of database engine that you want to use.	**CLI option:**
		
		`--engine-version`
		
		RDS API parameter:
		
		`EngineVersion`

Console setting	Setting description	CLI option and RDS API parameter
DB cluster parameter group	The DB instance parameter group to associate with the DB cluster. For more information, see Working with parameter groups for Multi-AZ DB clusters.	**CLI option:** `--db-cluster-parameter-group-name` **RDS API parameter:** **`DBClusterParameterGroupName`**

DB subnet group	The DB subnet group you want to use for the DB cluster.
	Select **Choose existing** to use an existing DB subnet group. Then choose the required subnet group from the **Existing DB subnet groups** dropdown list.
	
	Choose **Automatic setup** to let RDS select a compatible DB subnet group. If none exist, RDS creates a new subnet group for your cluster.
	
	For more information, see Working with DB subnet groups.
		CLI option:
		
		`--db-subnet-group-name`
		
		RDS API parameter:
		
		`DBSubnetGroupName`

Deletion protection	**Enable deletion protection** to prevent your DB cluster from being deleted. If you create a production DB cluster with the console, deletion protection is turned on by default.
	
	For more information, see Deleting a DB instance.
		CLI option:
		
		`--deletion-protection`
		
		`--no-deletion-protection`
		
		RDS API parameter:
		
		`DeletionProtection`

Console setting	Setting description	CLI option and RDS API parameter

Encryption	**Enable Encryption** to turn on encryption at rest for this DB cluster.
	
	Encryption is turned on by default for Multi-AZ DB clusters.
	
	For more information, see Encrypting Amazon RDS resources.
		CLI options:
		
		`--kms-key-id`
		
		`--storage-encrypted`
		
		`--no-storage-encrypted`
		
		RDS API parameters:
		
		`KmsKeyId`
		
		`StorageEncrypted`

Enhanced Monitoring	**Enable enhanced monitoring** to turn on metrics gathering in real time for the operating system that your DB cluster runs on.
	
	For more information, see Monitoring OS metrics with Enhanced Monitoring.
		CLI options:
		
		`--monitoring-interval`
		
		`--monitoring-role-arn`
		
		RDS API parameters:
		
		`MonitoringInterval`
		
		`MonitoringRoleArn`

Console setting	Setting description	CLI option and RDS API parameter

Initial database name	The name for the database on your DB cluster. If you don't provide a name, Amazon RDS doesn't create a database on the DB cluster for MySQL. However, it does create a database on the DB cluster for PostgreSQL. The name can't be a word reserved by the database engine. It has other constraints depending on the DB engine.
	
	MySQL:
	
	• It must contain 1–64 alphanumeric characters.
	
	PostgreSQL:
	
	• It must contain 1–63 alphanumeric characters.
	• It must begin with a letter or an underscore. Subsequent characters can be letters, underscores, or digits (0-9).
	• The initial database name is `postgres`.
		CLI option:
		
		`--database-name`
		
		RDS API parameter:
		
		`DatabaseName`

Console setting	Setting description	CLI option and RDS API parameter

Log exports	The types of database log files to publish to Amazon CloudWatch Logs.
	
	For more information, see Publishing database logs to Amazon CloudWatch Logs.
		CLI option:
		
		`-enable-cloudwatch-logs-exports`
		
		RDS API parameter:
		
		`EnableCloudwatchLogsExports`

Maintenance window	The 30-minute window in which pending modifications to your DB cluster are applied. If the time period doesn't matter, choose **No preference**.
	
	For more information, see The Amazon RDS maintenance window.
		CLI option:
		
		`--preferred-maintenance-window`
		
		RDS API parameter:
		
		`PreferredMaintenanceWindow`

Manage master credentials in AWS Secrets Manager	Select **Manage master credentials in AWS Secrets Manager** to manage the master user password in a secret in Secrets Manager.
	
	Optionally, choose a KMS key to use to protect the secret. Choose from the KMS keys in your account, or enter the key from a different account.
	
	For more information, see Password management with Amazon RDS and AWS Secrets Manager.
		CLI option:
		
		`--manage-master-user-password | --no-manage-master-user-password`
		
		`--master-user-secret-kms-key-id`
		
		RDS API parameter:
		
		`ManageMasterUserPassword`
		
		`MasterUserSecretKmsKeyId`

Console setting	Setting description	CLI option and RDS API parameter

Master password	The password for your master user account.	**CLI option:**
		`--master-user-password`
		RDS API parameter:
		`MasterUserPassword`

Master username	The name that you use as the master user name to log on to your DB cluster with all database privileges.
	• It can contain 1–16 alphanumeric characters and underscores.
	• Its first character must be a letter.
	• It can't be a word reserved by the database engine.
	You can't change the master user name after the Multi-AZ DB cluster is created.
	For more information on privileges granted to the master user, see Master user account privileges.
		CLI option:
		`--master-username`
		RDS API parameter:
		`MasterUsername`

Console setting	Setting description	CLI option and RDS API parameter

Performance Insights	**Enable Performance Insights** to monitor your DB cluster load so that you can analyze and troubleshoot your database performance.
	
	Choose a retention period to determine how much Performance Insights data history to keep. The retention setting in the free tier is **Default (7 days)**. To retain your performance data for longer, specify 1–24 months. For more information about retention periods, see Pricing and data retention for Performance Insights.
	
	Choose a master key to use to protect the key used to encrypt this database volume. Choose from the master keys in your account, or enter the key from a different account.
	
	For more information, see Monitoring DB load with Performance Insights on Amazon RDS.
		CLI options:
		
		`--enable-performance-insights`
		
		`--no-enable-performance-insights`
		
		`--performance-insights-retention-period`
		
		`--performance-insights-kms-key-id`
		
		RDS API parameters:
		
		`EnablePerformanceInsights`
		
		`PerformanceInsightsRetentionPeriod`
		
		`PerformanceInsightsKMSKeyId`

Provisioned IOPS	The amount of Provisioned IOPS (input/output operations per second) to be initially allocated for the DB cluster.	**CLI option:**
		
		`--iops`
		
		RDS API parameter:
		
		`Iops`

Console setting	Setting description	CLI option and RDS API parameter

Public access	**Publicly accessible** to give the DB cluster a public IP address, meaning that it's accessible outside the VPC. To be publicly accessible, the DB cluster also has to be in a public subnet in the VPC.
	
	Not publicly accessible to make the DB cluster accessible only from inside the VPC.
	
	For more information, see Hiding a DB instance in a VPC from the internet.
	
	To connect to a DB cluster from outside of its VPC, the DB cluster must be publicly accessible. Also, access must be granted using the inbound rules of the DB cluster's security group, and other requirements must be met. For more information, see Can't connect to Amazon RDS DB instance.
	
	If your DB cluster isn't publicly accessible, you can use an AWS Site-to-Site VPN connection or an AWS Direct Connect connection to access it from a private network. For more information, see Internetwork traffic privacy.
		CLI option:
		
		`--publicly-accessible`
		
		`--no-publicly-accessible`
		
		RDS API parameter:
		
		`PubliclyAccessible`

Console setting	Setting description	CLI option and RDS API parameter

RDS Extended Support	Select **Enable RDS Extended Support** to allow supported major engine versions to continue running past the RDS end of standard support date.
	
	When you create a DB cluster, Amazon RDS defaults to RDS Extended Support. To prevent the creation of a new DB cluster after the RDS end of standard support date and to avoid charges for RDS Extended Support, disable this setting. Your existing DB clusters won't incur charges until the RDS Extended Support pricing start date.
	
	For more information, see Using Amazon RDS Extended Support.
		CLI option:
		
		`--engine-lifecycle-support`
		
		RDS API parameter:
		
		`EngineLifecycleSupport`

Storage throughput	The storage throughput value for the DB cluster. This setting is visible only if you choose General Purpose SSD (gp3) for the storage type. This setting is not configurable and is automatically set based on the IOPS that you specify. For more information, see gp3 storage (recommended).	This value is automatically calculated and doesn't have a CLI option.

Console setting	Setting description	CLI option and RDS API parameter
RDS Proxy	Choose **Create an RDS Proxy** to create a proxy for your DB cluster. Amazon RDS automatically creates an IAM role and a Secrets Manager secret for the proxy.	Not available when creating a DB cluster.

Storage type	The storage type for your DB cluster.
	
	Only General Purpose SSD (gp3), Provisioned IOPS (io1), and Provisioned IOPS SSD (io2) stor age are supported.
	
	For more information, see Amazon RDS storage types.
		CLI option:
		
		`--storage-type`
		
		RDS API parameter:
		
		`StorageType`

Virtual Private Cloud (VPC)	A VPC based on the Amazon VPC service to associate with this DB cluster. For more information, see Amazon VPC and Amazon RDS.	For the CLI and API, you specify the VPC security group IDs.

VPC security group (firewall)	The security groups to associate with the DB cluster.
	
	For more information, see Overview of VPC security groups.
		CLI option:
		
		`--vpc-security-group-ids`
		
		RDS API parameter:
		
		`VpcSecurityGroupIds`

Settings that don't apply when creating Multi-AZ DB clusters

The following settings in the AWS CLI command `create-db-cluster` and the RDS API operation `CreateDBCluster` don't apply to Multi-AZ DB clusters.

You also can't specify these settings for Multi-AZ DB clusters in the console.

AWS CLI setting	RDS API setting
`--availability-zones`	`AvailabilityZones`
`--backtrack-window`	`BacktrackWindow`
`--character-set-name`	`CharacterSetName`
`--domain`	`Domain`
`--domain-iam-role-name`	`DomainIAMRoleName`
`--enable-global-write-forwarding | --no-enable-global-write-fo rwarding`	`EnableGlobalWriteForwarding`
`--enable-http-endpoint | --no-enable-http-endpoint`	`EnableHttpEndpoint`
`--enable-iam-database-authe ntication | --no-enable-iam-da tabase-authentication`	`EnableIAMDatabaseAuthentication`
`--global-cluster-identifier`	`GlobalClusterIdentifier`
`--option-group-name`	`OptionGroupName`
`--pre-signed-url`	`PreSignedUrl`
`--replication-source-identifier`	`ReplicationSourceIdentifier`
`--scaling-configuration`	`ScalingConfiguration`

Connecting to a Multi-AZ DB cluster

A Multi-AZ DB cluster has three DB instances instead of a single DB instance. Each connection is handled by a specific DB instance. When you connect to a Multi-AZ DB cluster, the hostname and port that you specify point to a fully qualified domain name called an *endpoint*. The Multi-AZ DB cluster uses the endpoint mechanism to abstract these connections so that you don't need to specify exactly which DB instance in the DB cluster to connect to. Thus, you don't have to hardcode all the hostnames or write your own logic for rerouting connections when some DB instances aren't available.

The writer endpoint connects to the writer DB instance of the DB cluster, which supports both read and write operations. The reader endpoint connects to either of the two reader DB instances, which support only read operations.

Using endpoints, you can map each connection to the appropriate DB instance or group of DB instances based on your use case. For example, to perform DDL and DML statements, you can connect to whichever DB instance is the writer DB instance. To perform queries, you can connect to the reader endpoint, with the Multi-AZ DB cluster automatically managing connections among the reader DB instances. For diagnosis or tuning, you can connect to a specific DB instance endpoint to examine details about a specific DB instance.

For information about connecting to a DB instance, see Connecting to an Amazon RDS DB instance.

Topics

Types of Multi-AZ DB cluster endpoints

An endpoint is represented by a unique identifier that contains a host address. The following types of endpoints are available from a Multi-AZ DB cluster:

Cluster endpoint

A *cluster endpoint* (or *writer endpoint*) for a Multi-AZ DB cluster connects to the current writer DB instance for that DB cluster. This endpoint is the only one that can perform write operations such as DDL and DML statements. This endpoint can also perform read operations.

Each Multi-AZ DB cluster has one cluster endpoint and one writer DB instance.

You use the cluster endpoint for all write operations on the DB cluster, including inserts, updates, deletes, and DDL changes. You can also use the cluster endpoint for read operations, such as queries.

If the current writer DB instance of a DB cluster fails, the Multi-AZ DB cluster automatically fails over to a new writer DB instance. During a failover, the DB cluster continues to serve connection requests to the cluster endpoint from the new writer DB instance, with minimal interruption of service.

The following example illustrates a cluster endpoint for a Multi-AZ DB cluster.

```
mydbcluster.cluster-123456789012.us-east-1.rds.amazonaws.com
```

Reader endpoint

A *reader endpoint* for a Multi-AZ DB cluster provides support for read-only connections to the DB cluster. Use the reader endpoint for read operations, such as `SELECT` queries. By processing those statements on the reader DB instances, this endpoint reduces the overhead on the writer DB instance. It also helps the cluster to scale the capacity to handle simultaneous `SELECT` queries. Each Multi-AZ DB cluster has one reader endpoint.

The reader endpoint sends each connection request to one of the reader DB instances. When you use the reader endpoint for a session, you can only perform read-only statements such as `SELECT` in that session.

The following example illustrates a reader endpoint for a Multi-AZ DB cluster. The read-only intent of a reader endpoint is denoted by the `-ro` within the cluster endpoint name.

```
mydbcluster.cluster-ro-123456789012.us-east-1.rds.amazonaws.com
```

Instance endpoint

An *instance endpoint* connects to a specific DB instance within a Multi-AZ DB cluster. Each DB instance in a DB cluster has its own unique instance endpoint. So there is one instance endpoint

for the current writer DB instance of the DB cluster, and there is one instance endpoint for each of the reader DB instances in the DB cluster.

The instance endpoint provides direct control over connections to the DB cluster. This control can help you address scenarios where using the cluster endpoint or reader endpoint might not be appropriate. For example, your client application might require more fine-grained load balancing based on workload type. In this case, you can configure multiple clients to connect to different reader DB instances in a DB cluster to distribute read workloads.

The following example illustrates an instance endpoint for a DB instance in a Multi-AZ DB cluster.

`mydbinstance.123456789012.us-east-1.rds.amazonaws.com`

Viewing the endpoints for a Multi-AZ DB cluster

In the AWS Management Console, you see the cluster endpoint and the reader endpoint on the details page for each Multi-AZ DB cluster. You see the instance endpoint in the details page for each DB instance.

With the AWS CLI, you see the writer and reader endpoints in the output of the describe-db-clusters command. For example, the following command shows the endpoint attributes for all clusters in your current AWS Region.

```
aws rds describe-db-cluster-endpoints
```

With the Amazon RDS API, you retrieve the endpoints by calling the DescribeDBClusterEndpoints action. The output also shows Amazon Aurora DB cluster endpoints, if any exist.

Using the cluster endpoint

Each Multi-AZ DB cluster has a single built-in cluster endpoint, whose name and other attributes are managed by Amazon RDS. You can't create, delete, or modify this kind of endpoint.

You use the cluster endpoint when you administer your DB cluster, perform extract, transform, load (ETL) operations, or develop and test applications. The cluster endpoint connects to the writer DB instance of the cluster. The writer DB instance is the only DB instance where you can create tables and indexes, run `INSERT` statements, and perform other DDL and DML operations.

The physical IP address pointed to by the cluster endpoint changes when the failover mechanism promotes a new DB instance to be the writer DB instance for the cluster. If you use any form of connection pooling or other multiplexing, be prepared to flush or reduce the time-to-live for any cached DNS information. Doing so ensures that you don't try to establish a read/write connection to a DB instance that became unavailable or is now read-only after a failover.

Using the reader endpoint

You use the reader endpoint for read-only connections to your Multi-AZ DB cluster. This endpoint helps your DB cluster handle a query-intensive workload. The reader endpoint is the endpoint that you supply to applications that do reporting or other read-only operations on the cluster. The reader endpoint sends connections to available reader DB instances in a Multi-AZ DB cluster.

Each Multi-AZ cluster has a single built-in reader endpoint, whose name and other attributes are managed by Amazon RDS. You can't create, delete, or modify this kind of endpoint.

Using the instance endpoints

Each DB instance in a Multi-AZ DB cluster has its own built-in instance endpoint, whose name and other attributes are managed by Amazon RDS. You can't create, delete, or modify this kind of endpoint. With a Multi-AZ DB cluster, you typically use the writer and reader endpoints more often than the instance endpoints.

In day-to-day operations, the main way that you use instance endpoints is to diagnose capacity or performance issues that affect one specific DB instance in a Multi-AZ DB cluster. While connected to a specific DB instance, you can examine its status variables, metrics, and so on. Doing this can help you determine what's happening for that DB instance that's different from what's happening for other DB instances in the cluster.

How Multi-AZ DB endpoints work with high availability

For Multi-AZ DB clusters where high availability is important, use the writer endpoint for read/write or general-purpose connections and the reader endpoint for read-only connections. The writer and reader endpoints manage DB instance failover better than instance endpoints do. Unlike the instance endpoints, the writer and reader endpoints automatically change which DB instance they connect to if a DB instance in your cluster becomes unavailable.

If the writer DB instance of a DB cluster fails, Amazon RDS automatically fails over to a new writer DB instance. It does so by promoting a reader DB instance to a new writer DB instance. If a failover occurs, you can use the writer endpoint to reconnect to the newly promoted writer DB instance. Or

you can use the reader endpoint to reconnect to one of the reader DB instances in the DB cluster. During a failover, the reader endpoint might direct connections to the new writer DB instance of a DB cluster for a short time after a reader DB instance is promoted to the new writer DB instance. If you design your own application logic to manage instance endpoint connections, you can manually or programmatically discover the resulting set of available DB instances in the DB cluster.

Connecting to Multi-AZ DB clusters with the AWS drivers

The AWS suite of drivers has been designed to provide support for faster switchover and failover times, and authentication with AWS Secrets Manager, AWS Identity and Access Management (IAM), and Federated Identity. The AWS drivers rely on monitoring DB cluster status and being aware of the cluster topology to determine the new writer. This approach reduces switchover and failover times to single-digit seconds, compared to tens of seconds for open-source drivers.

As new service features are introduced, the goal of the AWS suite of drivers is to have built-in support for these service features.

Connecting to Multi-AZ DB clusters with the Amazon Web Services (AWS) JDBC Driver

The Amazon Web Services (AWS) JDBC Driver is designed as an advanced JDBC wrapper to help applications take advantage of the features of clustered databases. This wrapper is complementary to and extends the functionality of an existing JDBC driver. The driver is drop-in compatible with the following community drivers:

- MySQL Connector/J
- MariaDB Connector/J
- pgJDBC

To install the AWS JDBC Driver, append the AWS JDBC Driver .jar file (located in the application CLASSPATH), and keep references to the respective community driver. Update the respective connection URL prefix as follows:

- `jdbc:mysql://` to `jdbc:aws-wrapper:mysql://`
- `jdbc:mariadb://` to `jdbc:aws-wrapper:mariadb://`
- `jdbc:postgresql://` to `jdbc:aws-wrapper:postgresql://`

For more information about the AWS JDBC Driver and complete instructions for using it, see the Amazon Web Services (AWS) JDBC Driver GitHub repository.

Connecting to Multi-AZ DB clusters with the Amazon Web Services (AWS) Python Driver

The Amazon Web Services (AWS) Python Driver is designed as an advanced Python wrapper. This wrapper is complementary to and extends the functionality of the open-source Psycopg driver. The AWS Python Driver supports Python versions 3.8 and higher. You can install the `aws-advanced-python-wrapper` package using the `pip` command, along with the `psycopg` open-source packages.

For more information about the AWS Python Driver and complete instructions for using it, see the Amazon Web Services (AWS) Python Driver GitHub repository.

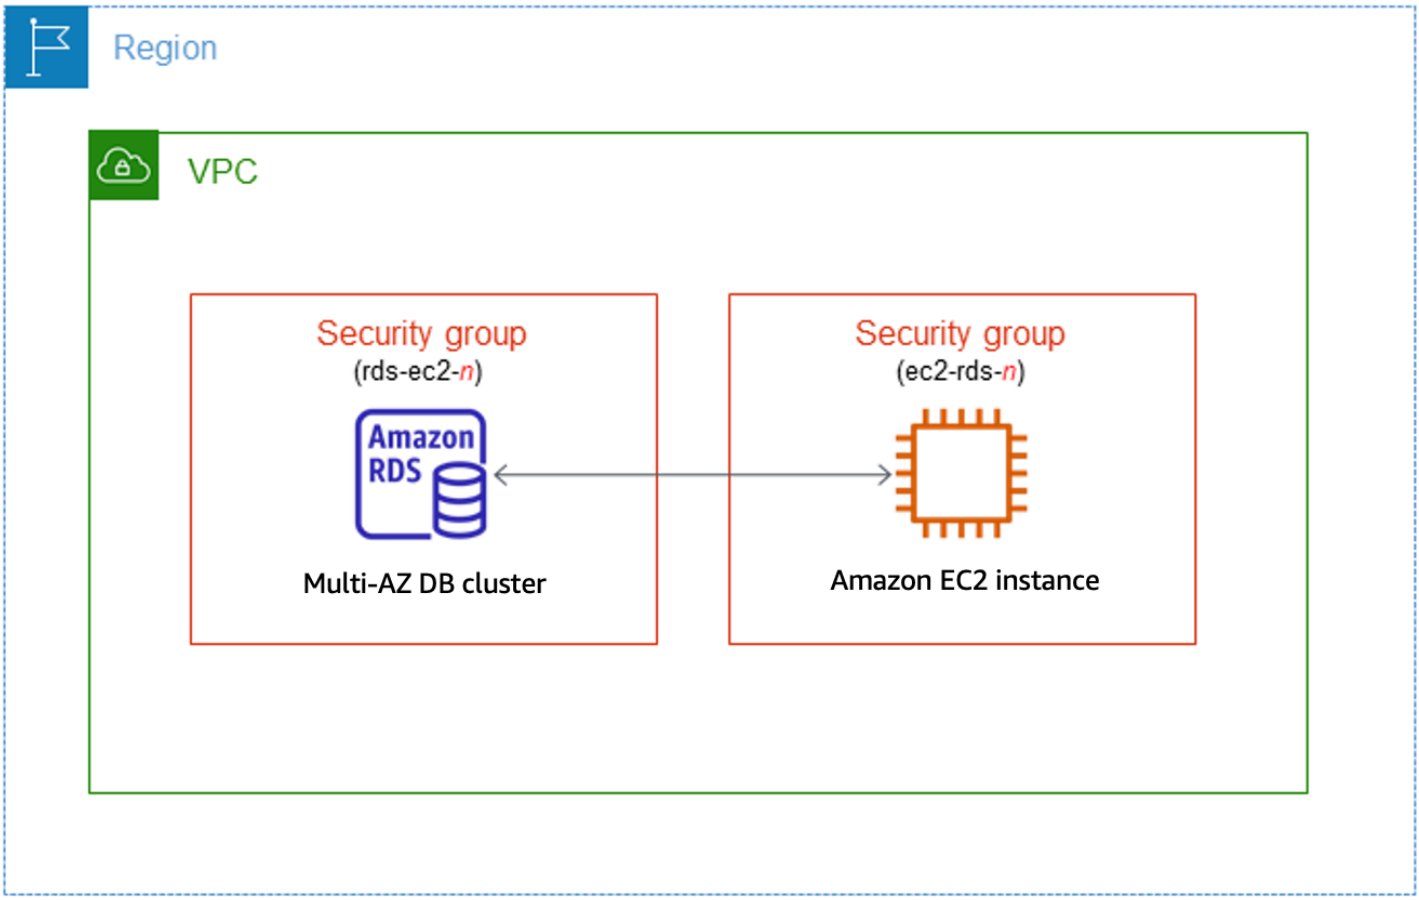
Automatically connecting an AWS compute resource and a Multi-AZ DB cluster

You can automatically connect a Multi-AZ DB cluster and AWS compute resources such as Amazon Elastic Compute Cloud (Amazon EC2) instances and AWS Lambda functions.

Topics

Automatically connecting an EC2 instance and a Multi-AZ DB cluster

You can use the Amazon RDS console to simplify setting up a connection between an Amazon Elastic Compute Cloud (Amazon EC2) instance and a Multi-AZ DB cluster. Often, your Multi-AZ DB cluster is in a private subnet and your EC2 instance is in a public subnet within a VPC. You can use a SQL client on your EC2 instance to connect to your Multi-AZ DB cluster. The EC2 instance can also run web servers or applications that access your private Multi-AZ DB cluster.



If you want to connect to an EC2 instance that isn't in the same VPC as the Multi-AZ DB cluster, see the scenarios in the section called "Scenarios for accessing a DB instance in a VPC".

Topics

- Overview of automatic connectivity with an EC2 instance
- Connecting an EC2 instance and a Multi-AZ DB cluster automatically
- Viewing connected compute resources

Overview of automatic connectivity with an EC2 instance

When you set up a connection between an EC2 instance and a Multi-AZ DB cluster automatically, Amazon RDS configures the VPC security group for your EC2 instance and for your DB cluster.

The following are requirements for connecting an EC2 instance with a Multi-AZ DB cluster:

- The EC2 instance must exist in the same VPC as the Multi-AZ DB cluster.

  If no EC2 instances exist in the same VPC, the console provides a link to create one.
- The user who is setting up connectivity must have permissions to perform the following EC2 operations:
  - `ec2:AuthorizeSecurityGroupEgress`
  - `ec2:AuthorizeSecurityGroupIngress`
  - `ec2:CreateSecurityGroup`
  - `ec2:DescribeInstances`
  - `ec2:DescribeNetworkInterfaces`
  - `ec2:DescribeSecurityGroups`
  - `ec2:ModifyNetworkInterfaceAttribute`
  - `ec2:RevokeSecurityGroupEgress`

When you set up a connection to an EC2 instance, Amazon RDS acts according to the current configuration of the security groups associated with the Multi-AZ DB cluster and EC2 instance, as described in the following table.

Current RDS security group configuration	Current EC2 security group configuration	RDS action
There are one or more security groups associated with the Multi-AZ DB cluster with a name that matches the pattern `rds-ec2-`*n* (where *n* is a number). A security group that matches the pattern hasn't been modified. This security group has only one inbound rule with the VPC security group of the EC2 instance as the source.	There are one or more security groups associated with the EC2 instance with a name that matches the pattern `rds-ec2-`*n* (where *n* is a number). A securit y group that matches the pattern hasn't been modified. This security group has only one outbound rule with the VPC security group of the Multi-AZ DB cluster as the source.	Amazon RDS takes no action. A connection was already configured automatically between the EC2 instance and Multi-AZ DB cluster. Because a connection already exists between the EC2 instance and the RDS database, the security groups aren't mo dified.
Either of the following conditions apply: • There is no security group associated with the Multi-AZ DB cluster with a name that matches the pattern `rds-ec2-`*n*. • There are one or more security groups associate d with the Multi-AZ DB cluster with a name that matches the pattern `rds-ec2-`*n*. However, none of these security groups can be used for the connection with the EC2 instance. A	Either of the following conditions apply: • There is no security group associated with the EC2 instance with a name that matches the pattern `ec2-rds-`*n*. • There are one or more security groups associate d with the EC2 instance with a name that matches the pattern `ec2-rds-`*n*. However, none of these security groups can be used for the connection with the Multi-AZ DB cluster.	RDS action: create new security groups

Current RDS security group configuration	Current EC2 security group configuration	RDS action
security group can't be used if it doesn't have one inbound rule with the VPC security group of the EC2 instance as the source. A security group also can't be used if it has been modified. Examples of modifications include adding a rule or changing the port of an existing rule.	A security group can't be used if it doesn't have one outbound rule with the VPC security group of the Multi-AZ DB cluster as the source. A security group also can't be used if it has been modified.	
There are one or more security groups associated with the Multi-AZ DB cluster with a name that matches the pattern `rds-ec2-`*n*. A security group that matches the pattern hasn't been modified. There are one or more security groups associated with the EC2 instance with a name that matches the pattern `ec2-rds-`*n*. However, none of these security groups can be used for the connection with the Multi-AZ DB cluster. A security group can't be used if it doesn't have one outbound rule with the VPC security group of the Multi-AZ DB cluster as the source. A security group also can't be used if it has been modified.	RDS action: create new security groups

Current RDS security group configuration	Current EC2 security group configuration	RDS action
There are one or more security groups associated with the Multi-AZ DB cluster with a name that matches the pattern `rds-ec2-`*n*. A security group that matches the pattern hasn't been modified. This security group has only one inbound rule with the VPC security group of the EC2 instance as the source.	A valid EC2 security group for the connection exists, but it is not associated with the EC2 instance. This security group has a name that matches the pattern `rds-ec2-`*n*. It hasn't been modified. It has only one outbound rule with the VPC security group of the Multi-AZ DB cluster as the source.	RDS action: associate EC2 security group

Current RDS security group configuration	Current EC2 security group configuration	RDS action
Either of the following conditions apply: • There is no security group associated with the Multi-AZ DB cluster with a name that matches the pattern `rds-ec2-`*n*. • There are one or more security groups associated with the Multi-AZ DB cluster with a name that matches the pattern `rds-ec2-`*n*. However, none of these security groups can be used for the connection with the EC2 instance. A security group can't be used if it doesn't have one inbound rule with the VPC security group of the EC2 instance as the source. A security group also can't be used if it has been modified.	There are one or more security groups associated with the EC2 instance with a name that matches the pattern `rds-ec2-`*n*. A security group that matches the pattern hasn't been modified. This security group has only one outbound rule with the VPC security group of the Multi-AZ DB cluster as the source.	RDS action: create new security groups

RDS action: create new security groups

Amazon RDS takes the following actions:

- Creates a new security group that matches the pattern `rds-ec2-`*n*. This security group has an inbound rule with the VPC security group of the EC2 instance as the source. This security group is associated with the Multi-AZ DB cluster and allows the EC2 instance to access the Multi-AZ DB cluster.
- Creates a new security group that matches the pattern `ec2-rds-`*n*. This security group has an outbound rule with the VPC security group of the Multi-AZ DB cluster as the source. This security group is associated with the EC2 instance and allows the EC2 instance to send traffic to the Multi-AZ DB cluster.

RDS action: associate EC2 security group

Amazon RDS associates the valid, existing EC2 security group with the EC2 instance. This security group allows the EC2 instance to send traffic to the Multi-AZ DB cluster.

Connecting an EC2 instance and a Multi-AZ DB cluster automatically

Before setting up a connection between an EC2 instance and an RDS database, make sure you meet the requirements described in Overview of automatic connectivity with an EC2 instance.

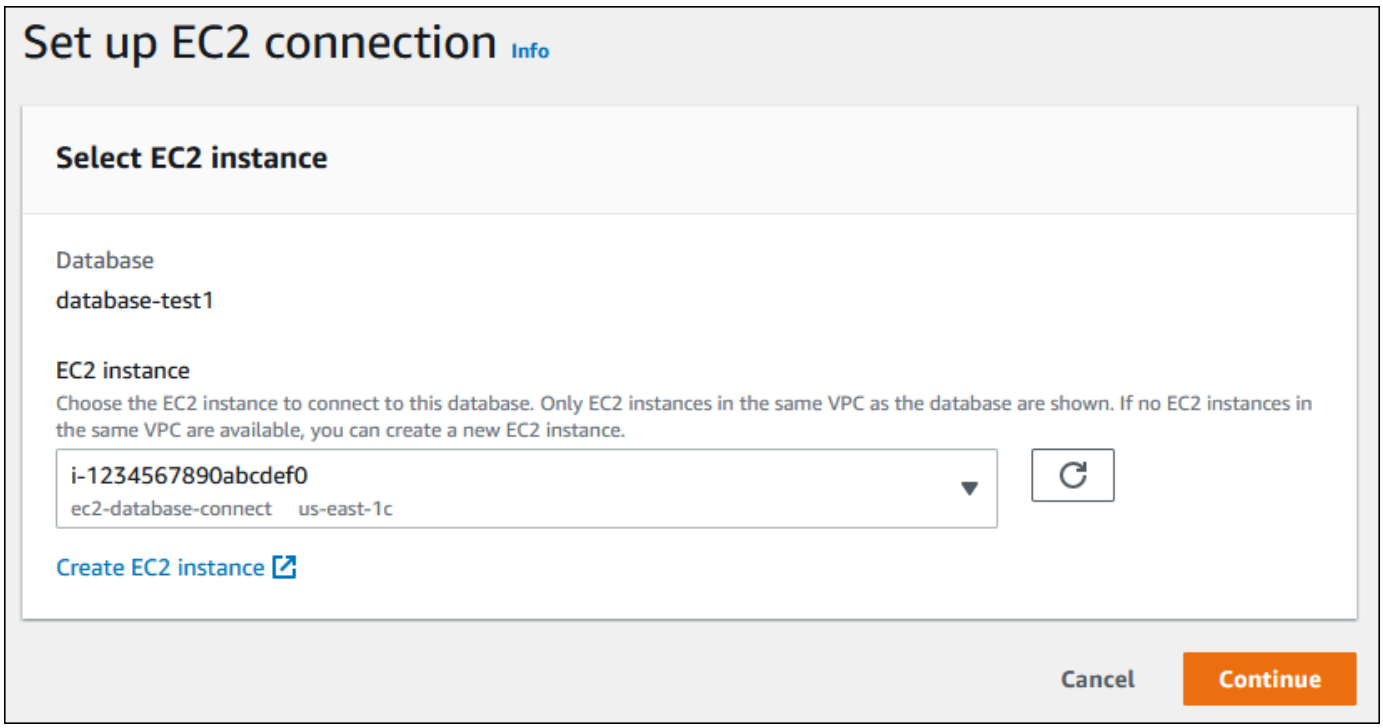
If you make changes to security groups after you configure connectivity, the changes might affect the connection between the EC2 instance and the RDS database.

> **Note**
>
> You can only set up a connection between an EC2 instance and an RDS database automatically by using the AWS Management Console. You can't set up a connection automatically with the AWS CLI or RDS API.

To connect an EC2 instance and an RDS database automatically

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**, and then choose the RDS database.
3. From **Actions**, choose **Set up EC2 connection**.

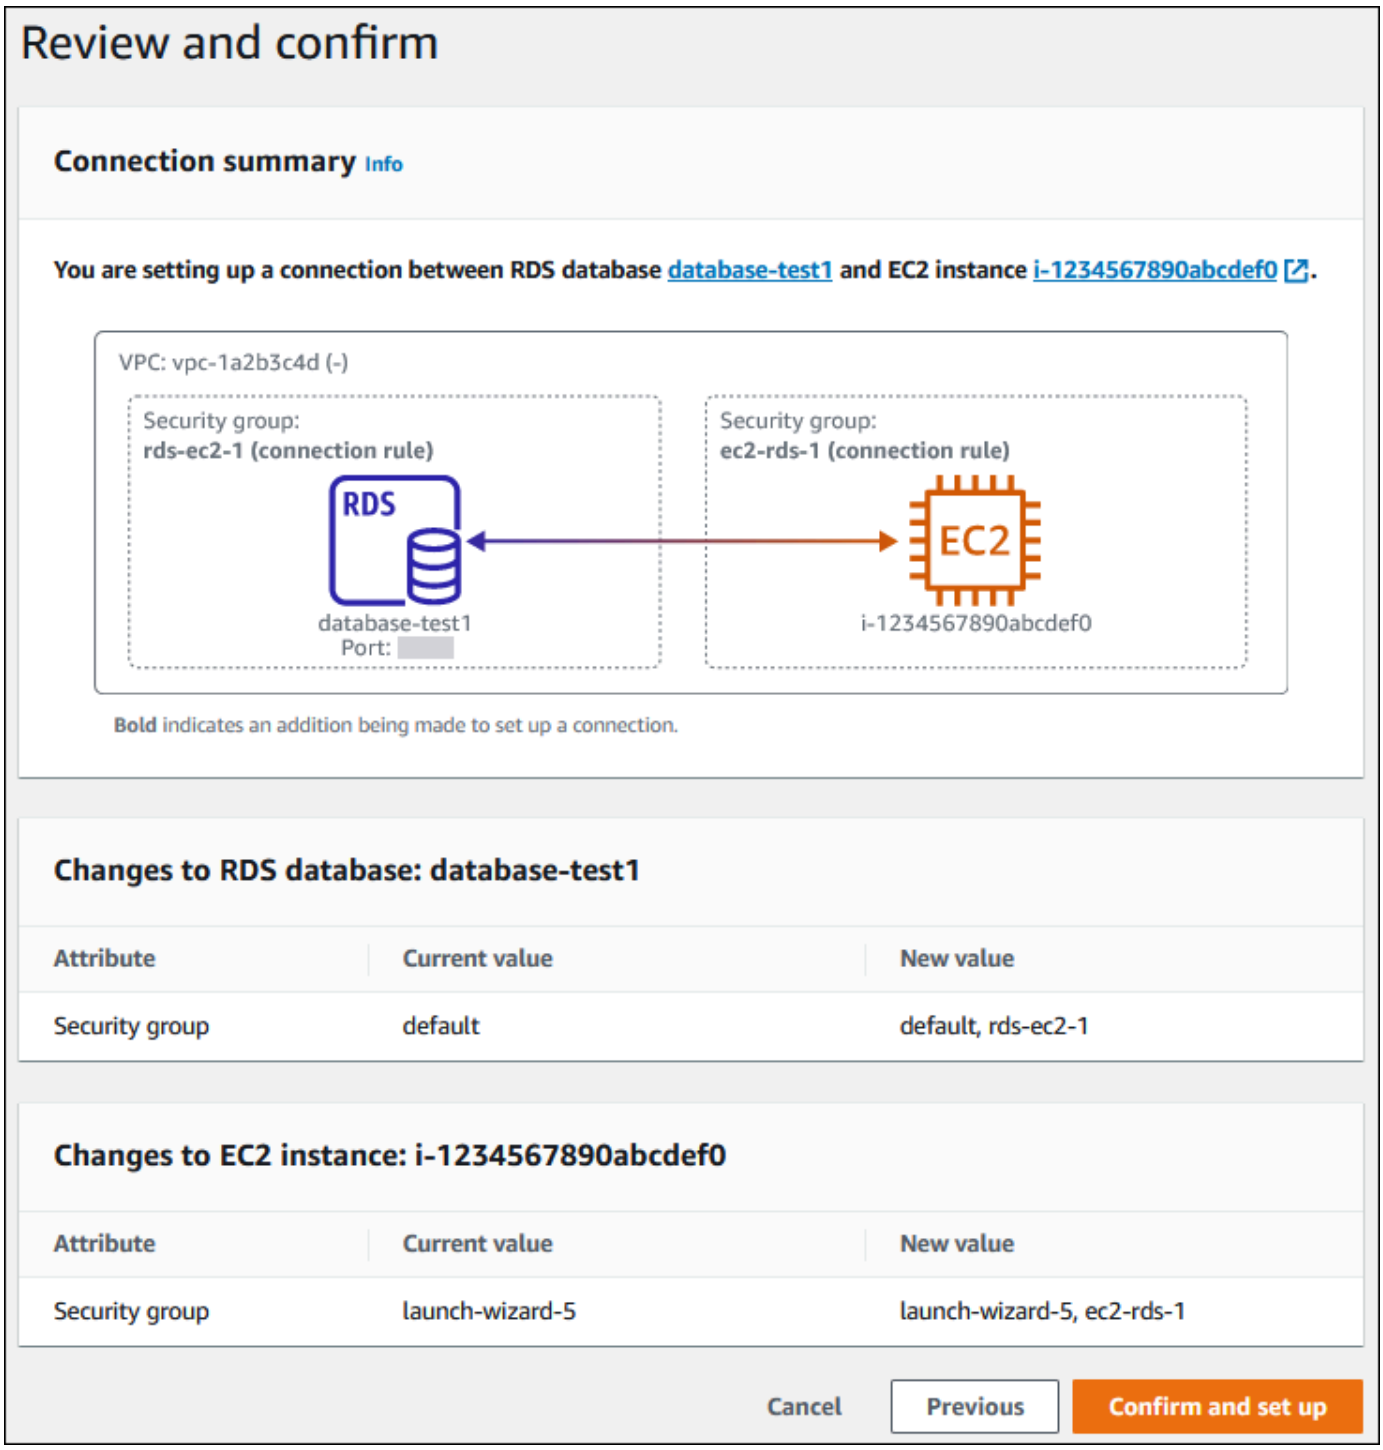
   The **Set up EC2 connection** page appears.
4. On the **Set up EC2 connection** page, choose the EC2 instance.



If no EC2 instances exist in the same VPC, choose **Create EC2 instance** to create one. In this case, make sure the new EC2 instance is in the same VPC as the RDS database.

5. Choose **Continue**.

   The **Review and confirm** page appears.



6. On the **Review and confirm** page, review the changes that RDS will make to set up connectivity with the EC2 instance.

   If the changes are correct, choose **Confirm and set up**.

   If the changes aren't correct, choose **Previous** or **Cancel**.

Viewing connected compute resources

You can use the AWS Management Console to view the compute resources that are connected to an RDS database. The resources shown include compute resource connections that were set up automatically. You can set up connectivity with compute resources automatically in the following ways:

- You can select the compute resource when you create the database.

  For more information, see Creating an Amazon RDS DB instance and Creating a Multi-AZ DB cluster.
- You can set up connectivity between an existing database and a compute resource.

  For more information, see Automatically connecting an EC2 instance and an RDS database.

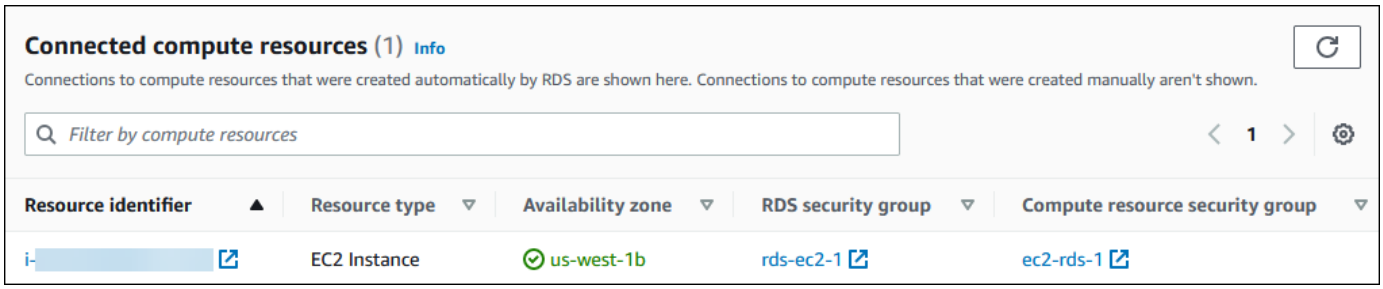
The listed compute resources don't include ones that were connected to the database manually. For example, you can allow a compute resource to access a database manually by adding a rule to the VPC security group associated with the database.

For a compute resource to be listed, the following conditions must apply:

- The name of the security group associated with the compute resource matches the pattern `ec2-rds-`*n* (where *n* is a number).
- The security group associated with the compute resource has an outbound rule with the port range set to the port that the RDS database uses.
- The security group associated with the compute resource has an outbound rule with the source set to a security group associated with the RDS database.
- The name of the security group associated with the RDS database matches the pattern `rds-ec2-`*n* (where *n* is a number).
- The security group associated with the RDS database has an inbound rule with the port range set to the port that the RDS database uses.
- The security group associated with the RDS database has an inbound rule with the source set to a security group associated with the compute resource.

To view compute resources connected to an RDS database

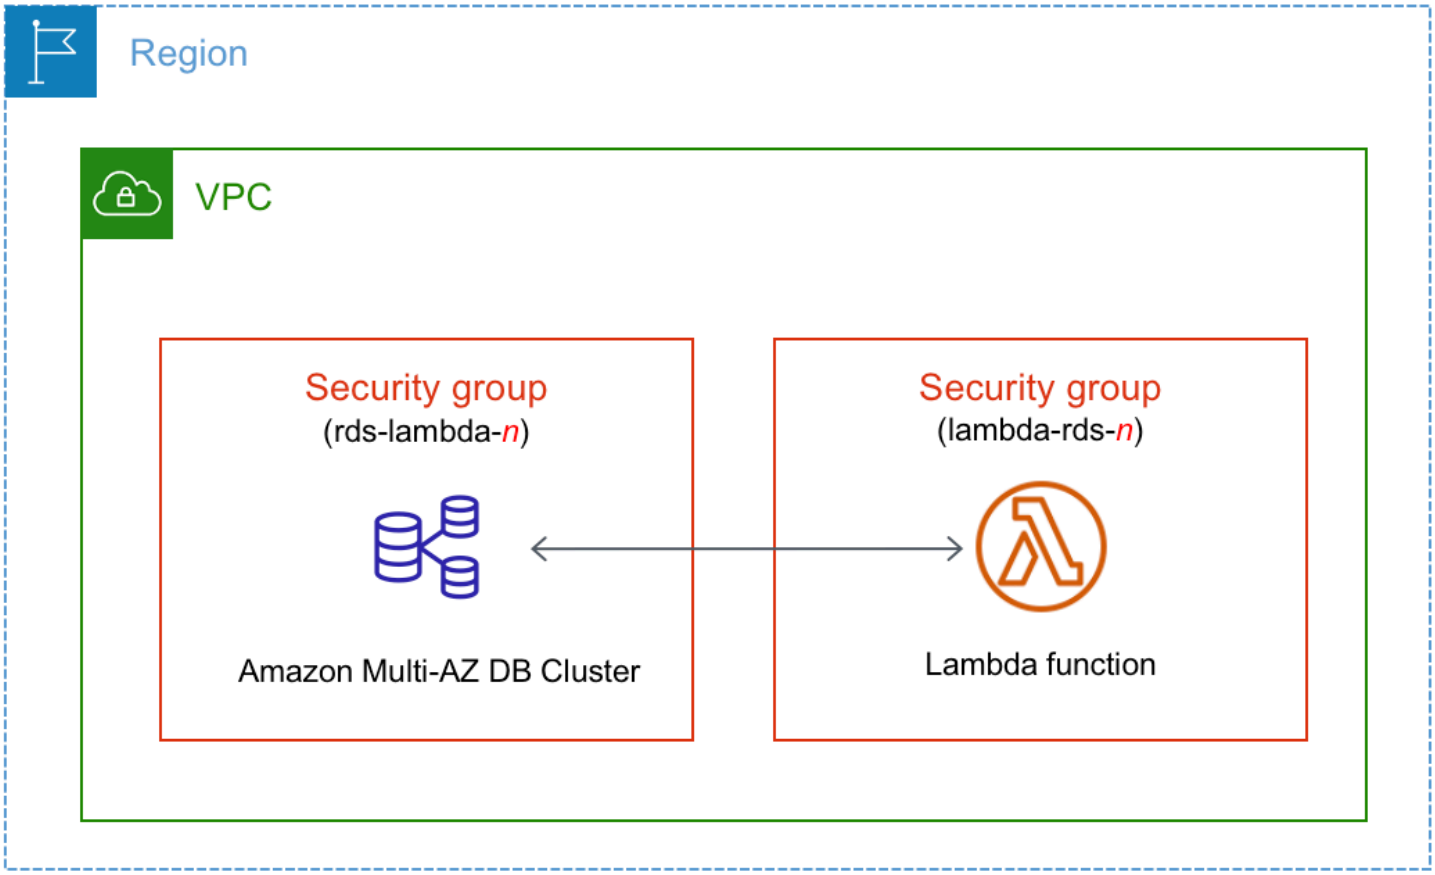
1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**, and then choose the name of the RDS database.
3. On the **Connectivity & security** tab, view the compute resources in the **Connected compute resources**.



Automatically connecting a Lambda function and a Multi-AZ DB cluster

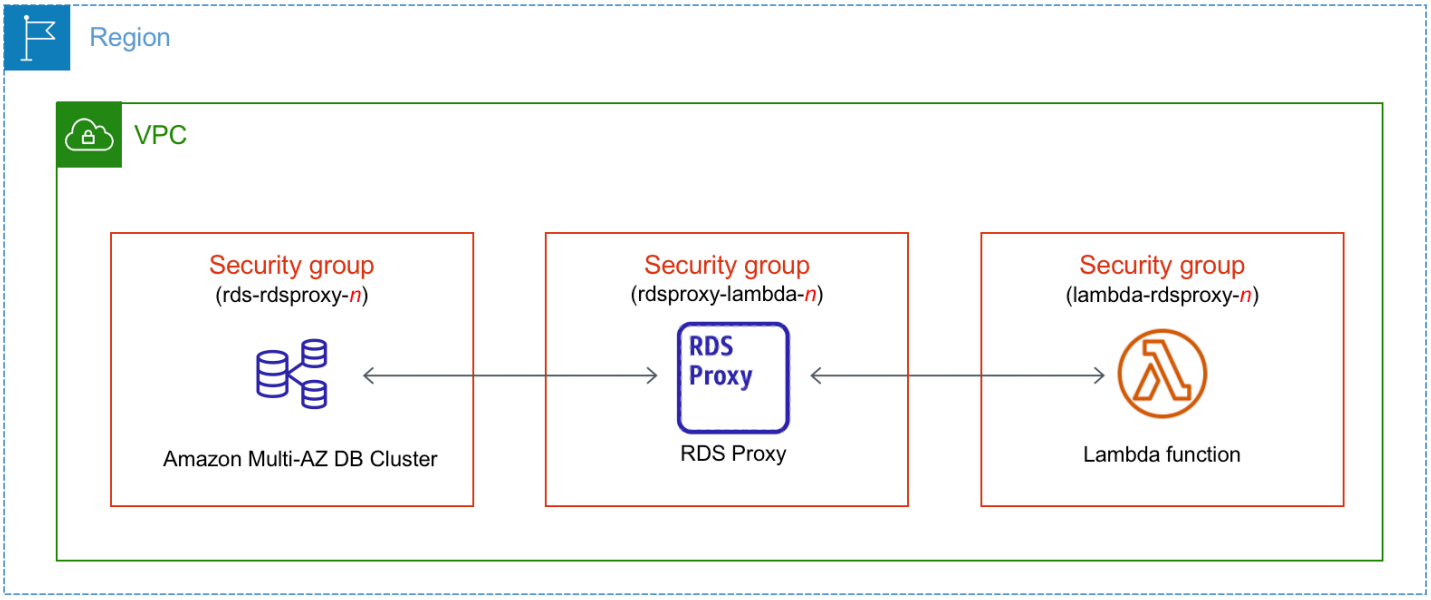
You can use the RDS console to simplify setting up a connection between a Lambda function and a Multi-AZ DB cluster. You can use the RDS console to simplify setting up a connection between a Lambda function and a Multi-AZ DB cluster. Often, your Multi-AZ DB cluster is in a private subnet within a VPC. The Lambda function can be used by applications to access your private Multi-AZ DB cluster.

The following image shows a direct connection between your Multi-AZ DB cluster and your Lambda function.



You can set up the connection between your Lambda function and your database through RDS Proxy to improve your database performance and resiliency. Often, Lambda functions make frequent, short database connections that benefit from connection pooling that RDS Proxy offers. You can take advantage of any IAM authentication that you already have for Lambda functions, instead of managing database credentials in your Lambda application code. For more information, see Using Amazon RDS Proxy.

You can use the console to automatically create a proxy for your connection. You can also select existing proxies. The console updates the proxy security group to allow connections from your database and Lambda function. You can input your database credentials or select the Secrets Manager secret you require to access the database.



Topics

- Overview of automatic connectivity with a Lambda function
- Automatically connecting a Lambda function and a Multi-AZ DB cluster

Overview of automatic connectivity with a Lambda function

When you set up a connection between a Lambda function and a Multi-AZ DB cluster automatically, Amazon RDS configures the VPC security group for your Lambda function and for your DB cluster.

The following are requirements for connecting a Lambda function with a Multi-AZ DB cluster:

- The Lambda function must exist in the same VPC as the Multi-AZ DB cluster.

  If no Lambda function exists in the same VPC, the console provides a link to create one.
- The user who sets up connectivity must have permissions to perform the following Amazon RDS, Amazon EC2, Lambda, Secrets Manager, and IAM operations:
  - Amazon RDS
    - `rds:CreateDBProxies`
    - `rds:DescribeDBInstances`
    - `rds:DescribeDBProxies`

    - rds:ModifyDBInstance
    - rds:ModifyDBProxy
    - rds:RegisterProxyTargets
- Amazon EC2
    - ec2:AuthorizeSecurityGroupEgress
    - ec2:AuthorizeSecurityGroupIngress
    - ec2:CreateSecurityGroup
    - ec2:DeleteSecurityGroup
    - ec2:DescribeSecurityGroups
    - ec2:RevokeSecurityGroupEgress
    - ec2:RevokeSecurityGroupIngress
- Lambda
    - lambda:CreateFunctions
    - lambda:ListFunctions
    - lambda:UpdateFunctionConfiguration
- Secrets Manager
    - sercetsmanager:CreateSecret
    - secretsmanager:DescribeSecret
- IAM
    - iam:AttachPolicy
    - iam:CreateRole
    - iam:CreatePolicy
- AWS KMS
    - kms:describeKey

When you set up a connection between a Lambda function and a Multi-AZ DB cluster, Amazon RDS configures the VPC security group for your function and for your Multi-AZ DB cluster. If you use RDS Proxy, then Amazon RDS also configures the VPC security group for the proxy. Amazon RDS acts according to the current configuration of the security groups associated with the Multi-AZ DB cluster and Lambda function, and proxy, as described in the following table.

Current RDS security group configuration	Current Lambda security group configuration	Current proxy security group configuration	RDS action
Amazon RDS takes no action because security groups of all resources follow the correct naming pattern and have the right inbound and outbound rules.	There are one or more security groups associated with the Multi-AZ DB cluster with a name that matches the pattern `rds-lambda-` *n* (where *n* is a number) or if the `TargetHealth` of an associated proxy is `AVAILABLE`. A security group that matches the pattern hasn't been modified. This security group has only one inbound rule with the VPC security group of the Lambda function or proxy as the source.	There are one or more security groups associated with the Lambda function with a name that matches the pattern `lambda-rds-` *n* or `lambda-rdsproxy-` *n* (where *n* is a number). A security group that matches the pattern hasn't been modified. This security group has only one outbound rule with either the VPC security group of the Multi-AZ DB cluster or the proxy as the destination.	There are one or more security groups associated with the proxy with a name that matches the pattern `rdsproxy-lambda-` *n* (where *n* is a number). A security group that matches the pattern hasn't been modified. This security group has inbound and outbound rules with the VPC security groups of the Lambda function and the Multi-AZ DB cluster.

Amazon RDS also can't use a security group that has been modified.	that doesn't have inbound and outbound rules with the VPC security group of the Multi-AZ DB cluster and the Lambda function. Amazon RDS also can't use a security group that has been modified.	

RDS action: create new security groups

Amazon RDS takes the following actions:

- Creates a new security group that matches the pattern `rds-lambda-`*n*.This security group has an inbound rule with the VPC security group of the Lambda function or proxy as the source. This security group is associated with the Multi-AZ DB cluster and allows the function or proxy to access the Multi-AZ DB cluster.
- Creates a new security group that matches the pattern `lambda-rds-`*n*. This security group has an outbound rule with the VPC security group of the Multi-AZ DB cluster or proxy as the destination. This security group is associated with the Lambda function and allows the Lambda function to send traffic to the Multi-AZ DB cluster or send traffic through a proxy.
- Creates a new security group that matches the pattern `rdsproxy-lambda-`*n*. This security group has inbound and outbound rules with the VPC security group of the Multi-AZ DB cluster and the Lambda function.

RDS action: associate Lambda security group

Amazon RDS associates the valid, existing Lambda security group with the Lambda function. This security group allows the function to send traffic to the Multi-AZ DB cluster or send traffic through a proxy.

Automatically connecting a Lambda function and a Multi-AZ DB cluster

You can use the Amazon RDS console to automatically connect a Lambda function to your Multi-AZ DB cluster. This simplifies the process of setting up a connection between these resources.

You can also use RDS Proxy to include a proxy in your connection. Lambda functions make frequent short database connections that benefit from the connection pooling that RDS Proxy offers. You can also use any IAM authentication that you've already set up for your Lambda function, instead of managing database credentials in your Lambda application code.

You can connect an existing Multi-AZ DB cluster to new and existing Lambda functions using the **Set up Lambda connection** page. The setup process automatically sets up the required security groups for you.

Before setting up a connection between a Lambda function and a Multi-AZ DB cluster, make sure that:

- Your Lambda function and Multi-AZ DB cluster are in the same VPC.
- You have the right permissions for your user account. For more information about the requirements, see Overview of automatic connectivity with a Lambda function.

If you change security groups after you configure connectivity, the changes might affect the connection between the Lambda function and the Multi-AZ DB cluster.

> **Note**
>
> You can automatically set up a connection between a Multi-AZ DB cluster and a Lambda function only in the AWS Management Console. To connect a Lambda function, all instances in the Multi-AZ DB cluster must be in the **Available** state.

To automatically connect a Lambda function and a Multi-AZ DB cluster

<result>

After you confirm the setup, Amazon RDS begins the process of connecting your Lambda function, RDS Proxy (if you used a proxy), and Multi-AZ DB cluster. The console shows the **Connection details** dialog box, which lists the security group changes that allow connections between your resources.
</result>

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**, and then choose the Multi-AZ DB cluster that you want to connect to a Lambda function.
3. For **Actions**, choose **Set up Lambda connection**.
4. On the **Set up Lambda connection** page, under **Select Lambda function**, do either of the following:
   - If you have an existing Lambda function in the same VPC as your Multi-AZ DB cluster, choose **Choose existing function**, and then choose the function.
   - If you don't have a Lambda function in the same VPC, choose **Create new function**, and then enter a **Function name**. The default runtime is set to Nodejs.18. You can modify the settings for your new Lambda function in the Lambda console after you complete the connection setup.
5. (Optional) Under **RDS Proxy**, select **Connect using RDS Proxy**, and then do any of the following:
   - If you have an existing proxy that you want to use, choose **Choose existing proxy**, and then choose the proxy.
   - If you don't have a proxy, and you want Amazon RDS to automatically create one for you, choose **Create new proxy**. Then, for **Database credentials**, do either of the following:
     a. Choose **Database username and password**, and then enter the **Username** and **Password** for your Multi-AZ DB cluster.
     b. Choose **Secrets Manager secret**. Then, for **Select secret**, choose an AWS Secrets Manager secret. If you don't have a Secrets Manager secret, choose **Create new Secrets Manager secret** to create a new secret. After you create the secret, for **Select secret**, choose the new secret.

     After you create the new proxy, choose **Choose existing proxy**, and then choose the proxy. Note that it might take some time for your proxy to be available for connection.

6. (Optional) Expand **Connection summary** and verify the highlighted updates for your resources.
7. Choose **Set up**.

Viewing connected compute resources

You can use the AWS Management Console to view the compute resources that are connected to your Multi-AZ DB cluster. The resources shown include compute resource connections that Amazon RDS set up automatically.

The listed compute resources don't include those that are manually connected to the Multi-AZ DB cluster. For example, you can allow a compute resource to access your Multi-AZ DB cluster manually by adding a rule to your VPC security group associated with the cluster.

For the console to list a Lambda function, the following conditions must apply:

- The name of the security group associated with the compute resource matches the pattern `lambda-rds-`*n* or `lambda-rdsproxy-`*n* (where *n* is a number).
- The security group associated with the compute resource has an outbound rule with the port range set to the port of the Multi-AZ DB cluster or an associated proxy. The destination for the outbound rule must be set to a security group associated with the Multi-AZ DB cluster or an associated proxy.
- The name of the security group attached to the proxy associated with your database matches the pattern `rds-rdsproxy-`*n* (where *n* is a number).
- The security group associated with the function has an outbound rule with the port set to the port that the Multi-AZ DB cluster or associated proxy uses. The destination must be set to a security group associated with the Multi-AZ DB cluster or associated proxy.

To view compute resources automatically connected to a Multi-AZ DB cluster

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**, and then choose the Multi-AZ DB cluster.
3. On the **Connectivity & security** tab, view the compute resources under **Connected compute resources**.

Modifying a Multi-AZ DB cluster

A Multi-AZ DB cluster has a writer DB instance and two reader DB instances in three separate Availability Zones. Multi-AZ DB clusters provide high availability, increased capacity for read workloads, and lower latency when compared to Multi-AZ deployments. For more information about Multi-AZ DB clusters, see Multi-AZ DB cluster deployments.

You can modify a Multi-AZ DB cluster to change its settings. You can also perform operations on a Multi-AZ DB cluster, such as taking a snapshot of it.

> **Important**
>
> You can't modify the DB instances within a Multi-AZ DB cluster. All modifications must be done at the DB cluster level. The only operation you can perform on a DB instance within a Multi-AZ DB cluster is rebooting it.

You can modify a Multi-AZ DB cluster using the AWS Management Console, the AWS CLI, or the RDS API.

Console

To modify a Multi-AZ DB cluster

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**, and then choose the Multi-AZ DB cluster that you want to modify.
3. Choose **Modify**. The **Modify DB cluster** page appears.
4. Change any of the settings that you want. For information about each setting, see Settings for modifying Multi-AZ DB clusters.
5. When all the changes are as you want them, choose **Continue** and check the summary of modifications.
6. (Optional) Choose **Apply immediately** to apply the changes immediately. Choosing this option can cause downtime in some cases. For more information, see Applying changes immediately.
7. On the confirmation page, review your changes. If they're correct, choose **Modify DB cluster** to save your changes.

Or choose **Back** to edit your changes or **Cancel** to cancel your changes.

AWS CLI

To modify a Multi-AZ DB cluster by using the AWS CLI, call the modify-db-cluster command. Specify the DB cluster identifier and the values for the options that you want to modify. For information about each option, see Settings for modifying Multi-AZ DB clusters.

Example

The following code modifies `my-multi-az-dbcluster` by setting the backup retention period to 1 week (7 days). The code turns on deletion protection by using `--deletion-protection`. To turn off deletion protection, use `--no-deletion-protection`. The changes are applied during the next maintenance window by using `--no-apply-immediately`. Use `--apply-immediately` to apply the changes immediately. For more information, see Applying changes immediately.

For Linux, macOS, or Unix:

```
aws rds modify-db-cluster \
    --db-cluster-identifier my-multi-az-dbcluster \
    --backup-retention-period 7 \
    --deletion-protection \
    --no-apply-immediately
```

For Windows:

```
aws rds modify-db-cluster ^
    --db-cluster-identifier my-multi-az-dbcluster ^
    --backup-retention-period 7 ^
    --deletion-protection ^
    --no-apply-immediately
```

RDS API

To modify a Multi-AZ DB cluster by using the Amazon RDS API, call the ModifyDBCluster operation. Specify the DB cluster identifier, and the parameters for the settings that you want to modify. For information about each parameter, see Settings for modifying Multi-AZ DB clusters.

Applying changes immediately

When you modify a Multi-AZ DB cluster, you can apply the changes immediately. To apply changes immediately, you choose the **Apply Immediately** option in the AWS Management Console. Or you use the `--apply-immediately` option when calling the AWS CLI or set the `ApplyImmediately` parameter to `true` when using the Amazon RDS API.

If you don't choose to apply changes immediately, the changes are put into the pending modifications queue. During the next maintenance window, any pending changes in the queue are applied. If you choose to apply changes immediately, your new changes and any changes in the pending modifications queue are applied.

> **Important**
>
> If any of the pending modifications require the DB cluster to be temporarily unavailable (*downtime*), choosing the apply immediately option can cause unexpected downtime. When you choose to apply a change immediately, any pending modifications are also applied immediately, instead of during the next maintenance window.
> If you don't want a pending change to be applied in the next maintenance window, you can modify the DB instance to revert the change. You can do this by using the AWS CLI and specifying the `--apply-immediately` option.

Changes to some database settings are applied immediately, even if you choose to defer your changes. To see how the different database settings interact with the apply immediately setting, see Settings for modifying Multi-AZ DB clusters.

Settings for modifying Multi-AZ DB clusters

For details about settings that you can use to modify a Multi-AZ DB cluster, see the following table. For more information about the AWS CLI options, see modify-db-cluster. For more information about the RDS API parameters, see ModifyDBCluster.

Console setting	Setting description	CLI option and RDS API parameter	When the change occurs	Downtime notes
Allocated storage	The amount of storage to allocate for each	**CLI option:**	If you choose to apply the change immediately,	Downtime doesn't occur during this change.

Console setting	Setting description	CLI option and RDS API parameter	When the change occurs	Downtime notes

	DB instance in your DB cluster (in gibibyte). For more information, see Amazon RDS DB instance storage.	`--allocated-storage`
		
		RDS API parameter:
		
		`AllocatedStorage`
			it occurs immediately.
			
			If you don't choose to apply the change immediately, it occurs during the next maintenance window.	

Auto minor version upgrade	**Enable auto minor version upgrade** to have your DB cluster receive preferred minor DB engine version upgrades automatically when they become available. Amazon RDS performs automatic minor version upgrades in the maintenance window.	**CLI option:**
		
		`--auto-minor-version-upgrade`
		
		`--no-auto-minor-version-upgrade`
		
		RDS API parameter:
		
		`AutoMinorVersionUpgrade`
			The change occurs immediately. This setting ignores the apply immediately setting.	Downtime occurs during this change.

Console setting	Setting description	CLI option and RDS API parameter	When the change occurs	Downtime notes

Backup retention period	The number of days that you want automatic backups of your DB cluster to be retained. For any nontrivial DB cluster, set this value to **1** or greater.
	
	For more information, see Introduction to backups.
		CLI option:
		
		`--backup-retention-period`
		
		RDS API parameter:
		
		`BackupRetentionPeriod`
			If you choose to apply the change immediately, it occurs immediately.
			
			If you don't choose to apply the change immediately, and you change the setting from a nonzero value to another nonzero value, the change is applied asynchronously, as soon as possible. Otherwise, the change occurs during the next maintenance window.
				Downtime occurs if you change from 0 to a nonzero value, or from a nonzero value to 0.

Console setting	Setting description	CLI option and RDS API parameter	When the change occurs	Downtime notes

Backup window	The time period during which Amazon RDS automatically takes a backup of your DB cluster. Unless you have a specific time that you want to have your database backed up, use the default of **No preference**.
	
	For more information, see Introduction to backups.
		CLI option:
		
		`--preferred-backup-window`
		
		RDS API parameter:
		
		`PreferredBackupWindow`
			The change is applied asynchronously, as soon as possible.	Downtime doesn't occur during this change.

Certificate authority	The certificate authority (CA) for the server certificate used by the DB cluster.
	
	For more information, see Using SSL/TLS to encrypt a connection to a DB instance or cluster.
		CLI option:
		
		`--ca-certificate-identifier`
		
		RDS API parameter:
		
		`CACertificateIdentifier`
			If you choose to apply the change immediately, it occurs immediately.
			
			If you don't choose to apply the change immediately, it occurs during the next maintenance window.
				Downtime only occurs if the DB engine doesn't support rotation without restart. You can use the describe-db-engine-versions AWS CLI command to determine whether the DB engine supports rotation without restart.

Console setting	Setting description	CLI option and RDS API parameter	When the change occurs	Downtime notes

Copy tags to snapshot	This option copies any DB cluster tags to a DB snapshot when you create a snapshot.
	
	For more information, see Tagging Amazon RDS resources.
		CLI option:
		
		`-copy-tags-to-snapshot`
		
		`-no-copy-tags-to-snapshot`
		
		RDS API parameter:
		
		`CopyTagsToSnapshot`
			The change occurs immediately. This setting ignores the apply immediately setting.	Downtime doesn't occur during this change.

Database authentication	For Multi-AZ DB clusters, only **Password authentication** is supported.	None because password authentication is the default.	If you choose to apply the change immediately, it occurs immediately. If you don't choose to apply the change immediately, it occurs during the next maintenance window.	Downtime doesn't occur during this change.

Console setting	Setting description	CLI option and RDS API parameter	When the change occurs	Downtime notes

DB cluster identifier	The DB cluster identifier. This value is stored as a lowercase string.
	
	When you change the DB cluster identifier, the DB cluster endpoint changes. The identifiers and endpoints of the DB instances in the DB cluster also change. The new DB cluster name must be unique. The maximum length is 63 characters.
	
	The names of the DB instances in the DB cluster are changed to correspond with the new name of the DB cluster. A new DB instance name can't be the same as the name
		CLI option:
		
		`--new-db-cluster-identifier`
		
		RDS API parameter:
		
		`NewDBClusterIdentifier`
			If you choose to apply the change immediately, it occurs immediately.
			
			If you don't choose to apply the change immediately, it occurs during the next maintenance window.
				Downtime doesn't occur during this change.

Console setting	Setting description	CLI option and RDS API parameter	When the change occurs	Downtime notes
	of an existing DB instance. For example, if you change the DB cluster name to `maz`, a DB instance name might be changed to `maz-instance-1` . In this case, there can't be an existing DB instance named `maz-instance-1` . For more information, see Renaming a Multi-AZ DB cluster.			

Console setting	Setting description	CLI option and RDS API parameter	When the change occurs	Downtime notes

DB cluster instance class	The compute and memory capacity of each DB instance in the Multi-AZ DB cluster, for example `db.r6gd.xlarge`.
	
	If possible, choose a DB instance class large enough that a typical query working set can be held in memory. When working sets are held in memory, the system can avoid writing to disk, which improves performance.
	
	For more information, see the section called "Instance class availability for Multi-AZ DB clusters".
		CLI option:
		
		`--db-cluster-instance-class`
		
		RDS API parameter:
		
		`DBClusterInstanceClass`
			If you choose to apply the change immediately, it occurs immediately.
			
			If you don't choose to apply the change immediately, it occurs during the next maintenance window.
				Downtime occurs during this change.

Console setting	Setting description	CLI option and RDS API parameter	When the change occurs	Downtime notes

DB cluster parameter group	The DB cluster parameter group that you want associated with the DB cluster.
	
	For more information, see Working with parameter groups for Multi-AZ DB clusters.
		CLI option:
		
		`--db-cluster-parameter-group-name`
		
		RDS API parameter:
		
		`DBClusterParameterGroupName`
			The parameter group change occurs immediately.	Downtime doesn't occur during this change. When you change the parameter group, changes to some parameters are applied to the DB instances in the Multi-AZ DB cluster immediately without a reboot. Changes to other parameters are applied only after the DB instances are rebooted.

DB engine version	The version of database engine that you want to use.	**CLI option:**
		
		`--engine-version`
		
		RDS API parameter:
		
		`EngineVersion`
			If you choose to apply the change immediately, it occurs immediately.
			
			If you don't choose to apply the change immediately, it occurs during the next maintenance window.
				Downtime occurs during this change.

Console setting	Setting description	CLI option and RDS API parameter	When the change occurs	Downtime notes

Deletion protection	**Enable deletion protection** to prevent your DB cluster from being deleted.
	
	For more information, see Deleting a DB instance.
		CLI option:
		
		`--deletion-protection`
		
		`--no-deletion-protection`
		
		RDS API parameter:
		
		`DeletionProtection`
			The change occurs immediately. This setting ignores the apply immediately setting.	Downtime doesn't occur during this change.

Maintenance window	The 30-minute window in which pending modifications to your DB cluster are applied. If the time period doesn't matter, choose **No preference**.
	
	For more information, see The Amazon RDS maintenance window.
		CLI option:
		
		`--preferred-maintenance-window`
		
		RDS API parameter:
		
		`PreferredMaintenanceWindow`
			The change occurs immediately. This setting ignores the apply immediately setting.	If there are one or more pending actions that cause downtime, and the maintenance window is changed to include the current time, those pending actions are applied immediately and downtime occurs.

Console setting	Setting description	CLI option and RDS API parameter	When the change occurs	Downtime notes

Manage master credentials in AWS Secrets Manager	Select **Manage master credentials in AWS Secrets Manager** to manage the master user password in a secret in Secrets Manager.
	
	Optionally, choose a KMS key to use to protect the secret. Choose from the KMS keys in your account, or enter the key from a different account.
	
	If RDS is already managing the master user password for the DB cluster, you can rotate the master user password by choosing **Rotate secret immediately**.
		CLI option:
		
		`--manage-master-user-password | --no-manage-master-user-password`
		
		`--master-user-secret-kms-key-id`
		
		`--rotate-master-user-password | --no-rotate-master-user-password`
		
		RDS API parameter:
		
		`ManageMasterUserPassword`
		
		`MasterUserSecretKmsKeyId`
		
		`RotateMasterUserPassword`
			If you are turning on or turning off automatic master user password management, the change occurs immediately. This change ignores the apply immediately setting.
			
			If you are rotating the master user password, you must specify that the change is applied immediately.
				Downtime doesn't occur during this change.

Console setting	Setting description	CLI option and RDS API parameter	When the change occurs	Downtime notes
	For more information, see Password management with Amazon RDS and AWS Secrets Manager.			

New master password	The password for your master user account.	**CLI option:**
		`--master-user-password`
		RDS API parameter:
		`MasterUserPassword`
			The change is applied asynchronously, as soon as possible. This setting ignores the apply immediately setting.	Downtime doesn't occur during this change.

Provisioned IOPS	The amount of Provisioned IOPS (input/output operations per second) to be initially allocated for the DB cluster.	**CLI option:**
		`--iops`
		RDS API parameter:
		`Iops`
			If you choose to apply the change immediately, it occurs immediately.
			If you don't choose to apply the change immediately, it occurs during the next maintenance window.
				Downtime doesn't occur during this change.

Console setting	Setting description	CLI option and RDS API parameter	When the change occurs	Downtime notes
Public access	**Publicly accessible** to give the DB cluster a public IP address, meaning that it's accessible outside its virtual private cloud (VPC). To be publicly accessible, the DB cluster also has to be in a public subnet in the VPC. **Not publicly accessible** to make the DB cluster accessible only from inside the VPC. For more information, see Hiding a DB instance in a VPC from the internet. To connect to a DB cluster from outside of its VPC, the	Not available when modifying a DB cluster.	The change occurs immediately. This setting ignores the apply immediately setting.	Downtime doesn't occur during this change.

Console setting	Setting description	CLI option and RDS API parameter	When the change occurs	Downtime notes
	DB cluster must be publicly accessible. Also, access must be granted using the inbound rules of the DB cluster's security group, and other requirements must be met. For more information, see Can't connect to Amazon RDS DB instance. If your DB cluster isn't publicly accessible, you can use an AWS Site-to-Site VPN connection or an AWS Direct Connect connection to access it from a private network. For more information, see Internetwork traffic privacy.			

Console setting	Setting description	CLI option and RDS API parameter	When the change occurs	Downtime notes

Storage type	The storage type for your DB cluster.
	
	Only General Purpose SSD (gp3), Provisioned IOPS (io1), and Provisioned IOPS SSD (io2) storage are supported.
	
	For more information, see Amazon RDS storage types.
		CLI option:
		
		`--storage-type`
		
		RDS API parameter:
		
		`StorageType`
			If you choose to apply the change immediately, it occurs immediately.
			
			If you don't choose to apply the change immediately, it occurs during the next maintenance window.
				Downtime doesn't occur during this change.

VPC security group	The security groups to associate with the DB cluster.
	
	For more information, see Overview of VPC security groups.
		CLI option:
		
		`--vpc-security-group-ids`
		
		RDS API parameter:
		
		`VpcSecurityGroupIds`
			The change is applied asynchronously, as soon as possible. This setting ignores the apply immediately setting.	Downtime doesn't occur during this change.

Settings that don't apply when modifying Multi-AZ DB clusters

The following settings in the AWS CLI command modify-db-cluster and the RDS API operation ModifyDBCluster don't apply to Multi-AZ DB clusters.

You also can't modify these settings for Multi-AZ DB clusters in the console.

AWS CLI setting	RDS API setting
--backtrack-window	BacktrackWindow
--cloudwatch-logs-export-configuration	CloudwatchLogsExportConfiguration
--copy-tags-to-snapshot | --no-copy-tags-to-snapshot	CopyTagsToSnapshot
--db-instance-parameter-group-name	DBInstanceParameterGroupName
--domain	Domain
--domain-iam-role-name	DomainIAMRoleName
--enable-global-write-forwarding | --no-enable-global-write-forwarding	EnableGlobalWriteForwarding
--enable-http-endpoint | --no-enable-http-endpoint	EnableHttpEndpoint
--enable-iam-database-authentication | --no-enable-iam-database-authentication	EnableIAMDatabaseAuthentication
--option-group-name	OptionGroupName
--port	Port
--scaling-configuration	ScalingConfiguration
--storage-type	StorageType

Renaming a Multi-AZ DB cluster

You can rename a Multi-AZ DB cluster by using the AWS Management Console, the AWS CLI `modify-db-cluster` command, or the Amazon RDS API `ModifyDBCluster` operation. Renaming a Multi-AZ DB cluster can have significant effects. The following is a list of considerations before you rename a Multi-AZ DB cluster.

- When you rename a Multi-AZ DB cluster, the cluster endpoints for the Multi-AZ DB cluster change. These endpoints change because they include the name you assigned to the Multi-AZ DB cluster. You can redirect traffic from an old endpoint to a new one. For more information about Multi-AZ DB cluster endpoints, see Connecting to a Multi-AZ DB cluster.
- When you rename a Multi-AZ DB cluster, the old DNS name that was used by the Multi-AZ DB cluster is deleted, although it could remain cached for a few minutes. The new DNS name for the renamed Multi-AZ DB cluster becomes effective in about two minutes. The renamed Multi-AZ DB cluster isn't available until the new name becomes effective.
- You can't use an existing Multi-AZ DB cluster name when renaming a cluster.
- Metrics and events associated with the name of a Multi-AZ DB cluster are maintained if you reuse a DB cluster name.
- Multi-AZ DB cluster tags remain with the Multi-AZ DB cluster, regardless of renaming.
- DB cluster snapshots are retained for a renamed Multi-AZ DB cluster.

> **Note**
>
> A Multi-AZ DB cluster is an isolated database environment running in the cloud. A Multi-AZ DB cluster can host multiple databases. For information about changing a database name, see the documentation for your DB engine.

Renaming to replace an existing Multi-AZ DB cluster

The most common scenarios for renaming a Multi-AZ DB cluster include restoring data from a DB cluster snapshot or performing point-in-time recovery (PITR). By renaming the Multi-AZ DB cluster, you can replace the Multi-AZ DB cluster without changing any application code that references the Multi-AZ DB cluster. In these cases, complete the following steps:

1. Stop all traffic going to the Multi-AZ DB cluster. You can redirect traffic from accessing the databases on the Multi-AZ DB cluster, or choose another way to prevent traffic from accessing your databases on the Multi-AZ DB cluster.
2. Rename the existing Multi-AZ DB cluster.
3. Create a new Multi-AZ DB cluster by restoring from a DB cluster snapshot or recovering to a point in time. Then, give the new Multi-AZ DB cluster the name of the previous Multi-AZ DB cluster.

If you delete the old Multi-AZ DB cluster, you are responsible for deleting any unwanted DB cluster snapshots of the old Multi-AZ DB cluster.

Console

To rename a Multi-AZ DB cluster

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.
3. Choose the Multi-AZ DB cluster that you want to rename.
4. Choose **Modify**.
5. In **Settings**, enter a new name for **DB cluster identifier**.
6. Choose **Continue**.
7. To apply the changes immediately, choose **Apply immediately**. Choosing this option can cause an outage in some cases. For more information, see Applying changes immediately.
8. On the confirmation page, review your changes. If they are correct, choose **Modify cluster** to save your changes.

   Alternatively, choose **Back** to edit your changes, or choose **Cancel** to discard your changes.

AWS CLI

To rename a Multi-AZ DB cluster, use the AWS CLI command modify-db-cluster. Provide the current `--db-cluster-identifier` value and `--new-db-cluster-identifier` parameter with the new name of the Multi-AZ DB cluster.

Example

For Linux, macOS, or Unix:

```
aws rds modify-db-cluster \
    --db-cluster-identifier DBClusterIdentifier \
    --new-db-cluster-identifier NewDBClusterIdentifier
```

For Windows:

```
aws rds modify-db-cluster ^
    --db-cluster-identifier DBClusterIdentifier ^
    --new-db-cluster-identifier NewDBClusterIdentifier
```

RDS API

To rename a Multi-AZ DB cluster, call the Amazon RDS API operation ModifyDBCluster with the following parameters:

- `DBClusterIdentifier` – The existing name of the DB cluster.
- `NewDBClusterIdentifier` – The new name of the DB cluster.

Rebooting a Multi-AZ DB cluster and reader DB instances

You might need to reboot your Multi-AZ DB cluster, usually for maintenance reasons. For example, if you make certain modifications or change the DB cluster parameter group associated with a DB cluster, you reboot the DB cluster. Doing so causes the changes to take effect.

If a DB cluster isn't using the latest changes to its associated DB cluster parameter group, the AWS Management Console shows the DB cluster parameter group with a status of **pending-reboot**. The **pending-reboot** parameter groups status doesn't result in an automatic reboot during the next maintenance window. To apply the latest parameter changes to that DB cluster, manually reboot the DB cluster. For more information about parameter groups, see Working with parameter groups for Multi-AZ DB clusters.

Rebooting a DB cluster restarts the database engine service. Rebooting a DB cluster results in a momentary outage, during which the DB cluster status is set to **rebooting**.

You can't reboot your DB cluster if it isn't in the **Available** state. Your database can be unavailable for several reasons, such as an in-progress backup, a previously requested modification, or a maintenance-window action.

The time required to reboot your DB cluster depends on the crash recovery process, the database activity at the time of reboot, and the behavior of your specific DB cluster. To improve the reboot time, we recommend that you reduce database activity as much as possible during the reboot process. Reducing database activity reduces rollback activity for in-transit transactions.

> **Important**
>
> Multi-AZ DB clusters don't support reboot with a failover. When you reboot the writer instance of a Multi-AZ DB cluster, it doesn't affect the reader DB instances in that DB cluster and no failover occurs. When you reboot a reader DB instance, no failover occurs. To fail over a Multi-AZ DB cluster, choose **Failover** in the console, call the AWS CLI command `failover-db-cluster`, or call the API operation `FailoverDBCluster`.

Console

To reboot a DB cluster

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.

2. In the navigation pane, choose **Databases**, and then choose the Multi-AZ DB cluster that you want to reboot.
3. For **Actions**, choose **Reboot**.

   The **Reboot DB cluster** page appears.
4. Choose **Reboot** to reboot your DB cluster.

   Or choose **Cancel**.

AWS CLI

To reboot a Multi-AZ DB cluster by using the AWS CLI, call the reboot-db-cluster command.

```
aws rds reboot-db-cluster --db-cluster-identifier mymultiazdbcluster
```

RDS API

To reboot a Multi-AZ DB cluster by using the Amazon RDS API, call the RebootDBCluster operation.

Working with Multi-AZ DB cluster read replicas

A DB cluster read replica is a special type of cluster that you create from a source DB instance. After you create a read replica, any updates made to the primary DB instance are asynchronously copied to the Multi-AZ DB cluster read replica. You can reduce the load on your primary DB instance by routing read queries from your applications to the read replica. Using read replicas, you can elastically scale out beyond the capacity constraints of a single DB instance for read-heavy database workloads.

You can also create one or more DB instance read replicas from a Multi-AZ DB cluster. DB instance read replicas let you scale beyond the compute or I/O capacity of the source Multi-AZ DB cluster by directing excess read traffic to the read replicas. Currently, you can't create a Multi-AZ DB cluster read replica from an existing Multi-AZ DB cluster.

Topics

Migrating to a Multi-AZ DB cluster using a read replica

To migrate a Single-AZ deployment or Multi-AZ DB instance deployment to a Multi-AZ DB cluster deployment with reduced downtime, you can create a Multi-AZ DB cluster read replica. For the source, you specify the DB instance in the Single-AZ deployment or the primary DB instance in the Multi-AZ DB instance deployment. The DB instance can process write transactions during the migration to a Multi-AZ DB cluster.

Consider the following before you create a Multi-AZ DB cluster read replica:

- The source DB instance must be on a version that supports Multi-AZ DB clusters. For more information, see Supported Regions and DB engines for Multi-AZ DB clusters in Amazon RDS.
- The Multi-AZ DB cluster read replica must be on the same major version as its source, and the same or higher minor version.
- You must turn on automatic backups on the source DB instance by setting the backup retention period to a value other than 0.
- The allocated storage of the source DB instance must be 100 GiB or higher.

- For RDS for MySQL, both the `gtid-mode` and `enforce_gtid_consistency` parameters must be set to `ON` for the source DB instance. You must use a custom parameter group, not the default parameter group. For more information, see the section called "DB parameter groups".
- An active, long-running transaction can slow the process of creating the read replica. We recommend that you wait for long-running transactions to complete before creating a read replica.
- If you delete the source DB instance for a Multi-AZ DB cluster read replica, the read replica is promoted to a standalone Multi-AZ DB cluster.

Creating and promoting the Multi-AZ DB cluster read replica

You can create and promote a Multi-AZ DB cluster read replica using the AWS Management Console, AWS CLI, or RDS API.

> **Note**
>
> We strongly recommend that you create all read replicas in the same virtual private cloud (VPC) based on Amazon VPC of the source DB instance.
> If you create a read replica in a different VPC from the source DB instance, Classless Inter-Domain Routing (CIDR) ranges can overlap between the replica and the Amazon RDS system. CIDR overlap makes the replica unstable, which can negatively impact applications connecting to it. If you receive an error when creating the read replica, choose a different destination DB subnet group. For more information, see Working with a DB instance in a VPC.

Console

To migrate a Single-AZ deployment or Multi-AZ DB instance deployment to a Multi-AZ DB cluster using a read replica, complete the following steps using the AWS Management Console.

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Create the Multi-AZ DB cluster read replica.
    a. In the navigation pane, choose **Databases**.
    b. Choose the DB instance that you want to use as the source for a read replica.

c. For **Actions**, choose **Create read replica**.

d. For **Availability and durability**, choose **Multi-AZ DB cluster**.

e. For **DB instance identifier**, enter a name for the read replica.

f. For the remaining sections, specify your DB cluster settings. For information about a setting, see Settings for creating Multi-AZ DB clusters.

g. Choose **Create read replica**.

3. When you are ready, promote the read replica to be a standalone Multi-AZ DB cluster:

a. Stop any transactions from being written to the source DB instance, and then wait for all updates to be made to the read replica.

Database updates occur on the read replica after they have occurred on the primary DB instance. This replication lag can vary significantly. Use the `ReplicaLag` metric to determine when all updates have been made to the read replica. For more information about replica lag, see Monitoring read replication.

b. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.

c. In the Amazon RDS console, choose **Databases**.

The **Databases** pane appears. Each read replica shows **Replica** in the **Role** column.

d. Choose the Multi-AZ DB cluster read replica that you want to promote.

e. For **Actions**, choose **Promote**.

f. On the **Promote read replica** page, enter the backup retention period and the backup window for the newly promoted Multi-AZ DB cluster.

g. When the settings are as you want them, choose **Promote read replica**.

h. Wait for the status of the promoted Multi-AZ DB cluster to be `Available`.

i. Direct your applications to use the promoted Multi-AZ DB cluster.

Optionally, delete the Single-AZ deployment or Multi-AZ DB instance deployment if it is no longer needed. For instructions, see Deleting a DB instance.

AWS CLI

To migrate a Single-AZ deployment or Multi-AZ DB instance deployment to a Multi-AZ DB cluster using a read replica, complete the following steps using the AWS CLI.

1. Create the Multi-AZ DB cluster read replica.

   To create a read replica from the source DB instance, use the AWS CLI command `create-db-cluster`. For `--replication-source-identifier`, specify the Amazon Resource Name (ARN) of the source DB instance.

   For Linux, macOS, or Unix:

```
aws rds create-db-cluster \
  --db-cluster-identifier mymultiazdbcluster \
  --replication-source-identifier arn:aws:rds:us-
east-2:123456789012:db:mydbinstance
  --engine postgres \
  --db-cluster-instance-class db.m5d.large \
  --storage-type io1 \
  --iops 1000 \
  --db-subnet-group-name defaultvpc \
  --backup-retention-period 1
```

   For Windows:

```
aws rds create-db-cluster ^
  --db-cluster-identifier mymultiazdbcluster ^
  --replication-source-identifier arn:aws:rds:us-
east-2:123456789012:db:mydbinstance
  --engine postgres ^
  --db-cluster-instance-class db.m5d.large ^
  --storage-type io1 ^
  --iops 1000 ^
  --db-subnet-group-name defaultvpc ^
  --backup-retention-period 1
```

2. Stop any transactions from being written to the source DB instance, and then wait for all updates to be made to the read replica.

   Database updates occur on the read replica after they have occurred on the primary DB instance. This replication lag can vary significantly. Use the `Replica Lag` metric to determine

when all updates have been made to the read replica. For more information about replica lag, see Monitoring read replication.

3. When you are ready, promote the read replica to be a standalone Multi-AZ DB cluster.

   To promote a Multi-AZ DB cluster read replica, use the AWS CLI command `promote-read-replica-db-cluster`. For `--db-cluster-identifier`, specify the identifier of the Multi-AZ DB cluster read replica.

   ```
   aws rds promote-read-replica-db-cluster --db-cluster-identifier mymultiazdbcluster
   ```

4. Wait for the status of the promoted Multi-AZ DB cluster to be `Available`.
5. Direct your applications to use the promoted Multi-AZ DB cluster.

Optionally, delete the Single-AZ deployment or Multi-AZ DB instance deployment if it is no longer needed. For instructions, see Deleting a DB instance.

RDS API

To migrate a Single-AZ deployment or Multi-AZ DB instance deployment to a Multi-AZ DB cluster using a read replica, complete the following steps using the RDS API.

1. Create the Multi-AZ DB cluster read replica.

   To create a Multi-AZ DB cluster read replica, use the `CreateDBCluster` operation with the required parameter `DBClusterIdentifier`. For `ReplicationSourceIdentifier`, specify the Amazon Resource Name (ARN) of the source DB instance.

2. Stop any transactions from being written to the source DB instance, and then wait for all updates to be made to the read replica.

   Database updates occur on the read replica after they have occurred on the primary DB instance. This replication lag can vary significantly. Use the `Replica Lag` metric to determine when all updates have been made to the read replica. For more information about replica lag, see Monitoring read replication.

3. When you are ready, promote read replica to be a standalone Multi-AZ DB cluster.

   To promote a Multi-AZ DB cluster read replica, use the `PromoteReadReplicaDBCluster` operation with the required parameter `DBClusterIdentifier`. Specify the identifier of the Multi-AZ DB cluster read replica.

4. Wait for the status of the promoted Multi-AZ DB cluster to be `Available`.
5. Direct your applications to use the promoted Multi-AZ DB cluster.

Optionally, delete the Single-AZ deployment or Multi-AZ DB instance deployment if it is no longer needed. For instructions, see Deleting a DB instance.

Limitations for creating a Multi-AZ DB cluster read replica

The following limitations apply to creating a Multi-AZ DB cluster read replica from a Single-AZ deployment or Multi-AZ DB instance deployment.

- You can't create a Multi-AZ DB cluster read replica in an AWS account that is different from the AWS account that owns the source DB instance.
- You can't create a Multi-AZ DB cluster read replica in a different AWS Region from the source DB instance.
- You can't recover a Multi-AZ DB cluster read replica to a point in time.
- Storage encryption must have the same settings on the source DB instance and Multi-AZ DB cluster.
- If the source DB instance is encrypted, the Multi-AZ DB cluster read replica must be encrypted using the same KMS key.
- If the source DB instance uses General Purpose SSD (gp3) storage and has less than 400 GiB of allocated storage, you can't modify the provisioned IOPS for the Multi-AZ DB cluster read replica.
- To perform a minor version upgrade on the source DB instance, you must first perform the minor version upgrade on the Multi-AZ DB cluster read replica.
- When you perform a minor version upgrade on an RDS for PostgreSQL Multi-AZ DB cluster read replica, the reader DB instance doesn't switch to the writer DB instance after the upgrade. Therefore, your DB cluster might experience downtime while Amazon RDS upgrades the writer instance.
- You can't perform a major version upgrade on a Multi-AZ DB cluster read replica.
- You can perform a major version upgrade on the source DB instance of a Multi-AZ DB cluster read replica, but replication to the read replica stops and can't be restarted.
- The Multi-AZ DB cluster read replica doesn't support cascading read replicas.
- For RDS for PostgreSQL, Multi-AZ DB cluster read replicas can't fail over.

Creating a DB instance read replica from a Multi-AZ DB cluster

You can create a DB instance read replica from a Multi-AZ DB cluster in order to scale beyond the compute or I/O capacity of the cluster for read-heavy database workloads. You can direct this excess read traffic to one or more DB instance read replicas. You can also use read replicas to migrate from a Multi-AZ DB cluster to a DB instance.

To create a read replica, specify a Multi-AZ DB cluster as the replication source. One of the reader instances of the Multi-AZ DB cluster is always the source of replication, not the writer instance. This condition ensures that the replica is always in sync with the source cluster, even in cases of failover.

Topics

Comparing reader DB instances and DB instance read replicas

A *DB instance read replica* of a Multi-AZ DB cluster is different than the *reader DB instances* of the Multi-AZ DB cluster in the following ways:

- The reader DB instances act as automatic failover targets, while DB instance read replicas do not.
- Reader DB instances must acknowledge a change from the writer DB instance before the change can be committed. For DB instance read replicas, however, updates are asynchronously copied to the read replica without requiring acknowledgement.
- Reader DB instances always share the same instance class, storage type, and engine version as the writer DB instance of the Multi-AZ DB cluster. DB instance read replicas, however, don't necessarily have to share the same configurations as the source cluster.
- You can promote a DB instance read replica to a standalone DB instance. You can't promote a reader DB instance of a Multi-AZ DB cluster to a standalone instance.
- The reader endpoint only routes requests to the reader DB instances of the Multi-AZ DB cluster. It never routes requests to a DB instance read replica.

For more information about reader and writer DB instances, see the section called "Overview of Multi-AZ DB clusters".

Considerations

Consider the following before you create a DB instance read replica from a Multi-AZ DB cluster:

- When you create the DB instance read replica, it must be on the same major version as its source cluster, and the same or higher minor version. After you create it, you can optionally upgrade the read replica to a higher minor version than the source cluster.
- When you create the DB instance read replica, the allocated storage must be the same as the allocated storage of the source Multi-AZ DB cluster. You can change the allocated storage after the read replica is created.
- For RDS for MySQL, the `gtid-mode` parameter must be set to `ON` for the source Multi-AZ DB cluster. For more information, see the section called "DB cluster parameter groups".
- An active, long-running transaction can slow the process of creating the read replica. We recommend that you wait for long-running transactions to complete before creating a read replica.
- If you delete the source Multi-AZ DB cluster for a DB instance read replica, any read replicas that it's writing to are promoted to standalone DB instances.

Creating a DB instance read replica

You can create a DB instance read replica from a Multi-AZ DB cluster using the AWS Management Console, AWS CLI, or RDS API.

> **Note**
>
> We strongly recommend that you create all read replicas in the same virtual private cloud (VPC) based on Amazon VPC of the source Multi-AZ DB cluster.
> If you create a read replica in a different VPC from the source Multi-AZ DB cluster, Classless Inter-Domain Routing (CIDR) ranges can overlap between the replica and the RDS system. CIDR overlap makes the replica unstable, which can negatively impact applications connecting to it. If you receive an error when creating the read replica, choose a different destination DB subnet group. For more information, see the section called "Working with a DB instance in a VPC".

Console

To create a DB instance read replica from a Multi-AZ DB cluster, complete the following steps using the AWS Management Console.

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.
3. Choose the Multi-AZ DB cluster that you want to use as the source for a read replica.
4. For **Actions**, choose **Create read replica**.
5. For **Replica source**, make sure that the correct Multi-AZ DB cluster is selected.
6. For **DB identifier**, enter a name for the read replica.
7. For the remaining sections, specify your DB instance settings. For information about a setting, see the section called "Available settings".

   > **Note**
   >
   > The allocated storage for the DB instance read replica must be the same as the allocated storage for the source Multi-AZ DB cluster.

8. Choose **Create read replica**.

AWS CLI

To create a DB instance read replica from a Multi-AZ DB cluster, use the AWS CLI command `create-db-instance-read-replica`. For `--source-db-cluster-identifier`, specify the identifier of the Multi-AZ DB cluster.

For Linux, macOS, or Unix:

```
aws rds create-db-instance-read-replica \
  --db-instance-identifier myreadreplica \
  --source-db-cluster-identifier mymultiazdbcluster
```

For Windows:

```
aws rds create-db-instance-read-replica ^
```

```
  --db-instance-identifier myreadreplica ^
  --source-db-cluster-identifier mymultiazdbcluster
```

RDS API

To create a DB instance read replica from a Multi-AZ DB cluster, use the `CreateDBInstanceReadReplica` operation.

Promoting the DB instance read replica

If you no longer need the DB instance read replica, you can promote it into a standalone DB instance. When you promote a read replica, the DB instance is rebooted before it becomes available. For instructions, see the section called “Promoting a read replica”.

If you're using the read replica to migrate a Multi-AZ DB cluster deployment to a Single-AZ or Multi-AZ DB instance deployment, make sure to stop any transactions that are being written to the source DB cluster. Then, wait for all updates to be made to the read replica. Database updates occur on the read replica after they occur on one of the reader DB instances of the Multi-AZ DB cluster. This replication lag can vary significantly. Use the `ReplicaLag` metric to determine when all updates have been made to the read replica. For more information about replica lag, see the section called “Monitoring read replication”.

After you promote the read replica, wait for the status of the promoted DB instance to be `Available` before you direct your applications to use the promoted DB instance. Optionally, delete the Multi-AZ DB cluster deployment if you no longer need it. For instructions, see the section called “Deleting a Multi-AZ DB cluster”.

Limitations for creating a DB instance read replica from a Multi-AZ DB cluster

The following limitations apply to creating a DB instance read replica from a Multi-AZ DB cluster deployment.

- You can't create a DB instance read replica in an AWS account that's different from the AWS account that owns the source Multi-AZ DB cluster.
- You can't create a DB instance read replica in a different AWS Region from the source Multi-AZ DB cluster.
- You can't recover a DB instance read replica to a point in time.
- Storage encryption must have the same settings on the source Multi-AZ DB cluster and DB instance read replica.

- If the source Multi-AZ DB cluster is encrypted, the DB instance read replica must be encrypted using the same KMS key.
- To perform a minor version upgrade on the source Multi-AZ DB cluster, you must first perform the minor version upgrade on the DB instance read replica.
- The DB instance read replica doesn't support cascading read replicas.
- For RDS for PostgreSQL, the source Multi-AZ DB cluster must be running PostgreSQL version 13.11, 14.8, or 15.2.R2 or higher in order to create a DB instance read replica.
- You can perform a major version upgrade on the source Multi-AZ DB cluster of a DB instance read replica, but replication to the read replica stops and can't be restarted.

Using PostgreSQL logical replication with Multi-AZ DB clusters

By using PostgreSQL logical replication with your Multi-AZ DB cluster, you can replicate and synchronize individual tables rather than the entire database instance. Logical replication uses a publish and subscribe model to replicate changes from a source to one or more recipients. It works by using change records from the PostgreSQL write-ahead log (WAL). For more information, see the section called "Logical replication".

When you create a new logical replication slot on the writer DB instance of a Multi-AZ DB cluster, the slot is asynchronously copied to each reader DB instance in the cluster. The slots on the reader DB instances are continuously synchronized with those on the writer DB instance.

Logical replication is supported for Multi-AZ DB clusters running RDS for PostgreSQL version 14.8-R2 and higher, and 15.3-R2 and higher.

> **Note**
>
> In addition to the native PostgreSQL logical replication feature, Multi-AZ DB clusters running RDS for PostgreSQL also support the `pglogical` extension.

For more information about PostgreSQL logical replication, see Logical replication in the PostgreSQL documentation.

Topics

Prerequisites

To configure PostgreSQL logical replication for Multi-AZ DB clusters, you must meet the following prerequisites.

- Your user account must be a member of the `rds_superuser` group and have `rds_superuser` privileges. For more information, see the section called "Understanding PostgreSQL roles and permissions".

- Your Multi-AZ DB cluster must be associated with a custom DB cluster parameter group so that you can configure the parameter values described in the following procedure. For more information, see the section called "DB cluster parameter groups".

Setting up logical replication

To set up logical replication for a Multi-AZ DB cluster, you enable specific parameters within the associated DB cluster parameter group, then create logical replication slots.

> **Note**
>
> Starting with PostgreSQL version 16, you can use reader DB instances of the Multi-AZ DB cluster for logical replication.

To set up logical replication for an RDS for PostgreSQL Multi-AZ DB cluster

1. Open the custom DB cluster parameter group associated with your RDS for PostgreSQL Multi-AZ DB cluster.
2. In the **Parameters** search field, locate the `rds.logical_replication` static parameter and set its value to 1. This parameter change can increase WAL generation, so enable it only when you're using logical slots.
3. As part of this change, configure the following DB cluster parameters.

   - `max_wal_senders`
   - `max_replication_slots`
   - `max_connections`

   Depending on your expected usage, you might also need to change the values of the following parameters. However, in many cases, the default values are sufficient.

   - `max_logical_replication_workers`
   - `max_sync_workers_per_subscription`
4. Reboot the Multi-AZ DB cluster for the parameter values to take effect. For instructions, see the section called "Rebooting a Multi-AZ DB cluster".

5. Create a logical replication slot on the writer DB instance of the Multi-AZ DB cluster as explained in the section called "Working with logical replication slots". This process requires that you specify a decoding plugin. Currently, RDS for PostgreSQL supports the `test_decoding`, `wal2json`, and `pgoutput` plugins that ship with PostgreSQL.

   The slot is asynchronously copied to each reader DB instance in the cluster.

6. Verify the state of the slot on all reader DB instances of the Multi-AZ DB cluster. To do so, inspect the `pg_replication_slots` view on all reader DB instances and make sure that the `confirmed_flush_lsn` state is making progress while the application is actively consuming logical changes.

   The following commands demonstrate how to inspect the replication state on the reader DB instances.

```
% psql -h test-postgres-instance-2.abcdefabcdef.us-west-2.rds.amazonaws.com

postgres=> select slot_name, slot_type, confirmed_flush_lsn from
 pg_replication_slots;
  slot_name   | slot_type | confirmed_flush_lsn
--------------+-----------+---------------------
 logical_slot | logical   | 32/D0001700
(1 row)

postgres=> select slot_name, slot_type, confirmed_flush_lsn from
 pg_replication_slots;
  slot_name   | slot_type | confirmed_flush_lsn
--------------+-----------+---------------------
 logical_slot | logical   | 32/D8003628
(1 row)

% psql -h test-postgres-instance-3.abcdefabcdef.us-west-2.rds.amazonaws.com

postgres=> select slot_name, slot_type, confirmed_flush_lsn from
 pg_replication_slots;
  slot_name   | slot_type | confirmed_flush_lsn
--------------+-----------+---------------------
 logical_slot | logical   | 32/D0001700
(1 row)

postgres=> select slot_name, slot_type, confirmed_flush_lsn from
 pg_replication_slots;
  slot_name   | slot_type | confirmed_flush_lsn
```

```
--------------+-----------+--------------------
 logical_slot | logical   | 32/D8003628
(1 row)
```

After you complete your replication tasks, stop the replication process, drop replication slots, and turn off logical replication. To turn off logical replication, modify your DB cluster parameter group and set the value of `rds.logical_replication` back to `0`. Reboot the cluster for the parameter change to take effect.

Limitations and recommendations

The following limitations and recommendations apply to using logical replication with Multi-AZ DB clusters running PostgreSQL version 16:

- You can use only writer DB instances to create or drop logical replication slots. For example, the `CREATE SUBSCRIPTION` command must use the cluster writer endpoint in the host connection string.
- You must use the cluster writer endpoint during any table synchronization or resynchronization. For example, you can use the following commands to resynchronize a newly added table:

  ```
  Postgres=>ALTER SUBSCRIPTION subscription-name CONNECTION host=writer-endpoint
  Postgres=>ALTER SUBSCRIPTION subscription-name REFRESH PUBLICATION
  ```

- You must wait for table synchronization to complete before using the reader DB instances for logical replication. You can use the pg_subscription_rel catalog table to monitor table synchronization. Table synchronization is complete when the `srsubstate` column is set to ready (`r`).
- We recommend using instance endpoints for the logical replication connection once initial table synchronization is complete. The following command reduces load on the writer DB instance by offloading replication to one of the reader DB instances:

  ```
  Postgres=>ALTER SUBSCRITPION subscription-name CONNECTION host=reader-instance-
  endpoint
  ```

  You can't use the same slot on more than one DB instance at a time. When two or more applications are replicating logical changes from different DB instances in the cluster, some changes might be lost due to a cluster failover or network issue. In these situations, you can use

instance endpoints for logical replication in the host connection string. The other application using the same configuration will show the following error message:

```
replication slot slot_name is already active for PID x providing immediate feedback.
```

- While using the `pglogical` extension, you can only use the cluster writer endpoint. The extension has known limitations that can create unused logical replication slots during table synchronization. Stale replication slots reserve write-ahead log (WAL) files and can lead to disk space problems.

Deleting a Multi-AZ DB cluster

You can delete a DB Multi-AZ DB cluster using the AWS Management Console, the AWS CLI, or the RDS API.

The time required to delete a Multi-AZ DB cluster can vary depending on the following factors:

- Thee backup retention period (that is, how many backups to delete).
- How much data is deleted.
- Whether a final snapshot is taken.

Deletion protection must be disabled on the Multi-AZ DB cluster before you can delete it. For more information, see the section called "Prerequisites for deleting a DB instance". You can disable deletion protection by modifying the Multi-AZ DB cluster. For more information, see the section called "Modifying a Multi-AZ DB cluster".

Console

To delete a Multi-AZ DB cluster

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**, and then choose the Multi-AZ DB cluster that you want to delete.
3. For **Actions**, choose **Delete**.
4. Choose **Create final snapshot?** to create a final DB snapshot for the Multi-AZ DB cluster.

   If you create a final snapshot, enter a name for **Final snapshot name**.
5. Choose **Retain automated backups** to retain automated backups.
6. Enter **`delete me`** in the box.
7. Choose **Delete**.

AWS CLI

To delete a Multi-AZ DB cluster by using the AWS CLI, call the delete-db-cluster command with the following options:

- `--db-cluster-identifier`
- `--final-db-snapshot-identifier` or `--skip-final-snapshot`

Example With a final snapshot

For Linux, macOS, or Unix:

```
aws rds delete-db-cluster \
    --db-cluster-identifier mymultiazdbcluster \
    --final-db-snapshot-identifier mymultiazdbclusterfinalsnapshot
```

For Windows:

```
aws rds delete-db-cluster ^
    --db-cluster-identifier mymultiazdbcluster ^
    --final-db-snapshot-identifier mymultiazdbclusterfinalsnapshot
```

Example With no final snapshot

For Linux, macOS, or Unix:

```
aws rds delete-db-cluster \
    --db-cluster-identifier mymultiazdbcluster \
    --skip-final-snapshot
```

For Windows:

```
aws rds delete-db-cluster ^
    --db-cluster-identifier mymultiazdbcluster ^
    --skip-final-snapshot
```

RDS API

To delete a Multi-AZ DB cluster by using the Amazon RDS API, call the DeleteDBCluster operation with the following parameters:

- `DBClusterIdentifier`
- `FinalDBSnapshotIdentifier` or `SkipFinalSnapshot`

Limitations of Multi-AZ DB clusters

A Multi-AZ DB cluster has a writer DB instance and two reader DB instances in three separate Availability Zones. Multi-AZ DB clusters provide high availability, increased capacity for read workloads, and lower latency when compared to Multi-AZ deployments. For more information about Multi-AZ DB clusters, see Multi-AZ DB cluster deployments.

The following limitations apply to Multi-AZ DB clusters.

- Multi-AZ DB clusters don't support the following features:
  - IPv6 connections (dual-stack mode)
  - Cross-Region automated backups
  - IAM DB authentication and Kerberos authentication
  - Modifying the port. As an alternative, you can restore a Multi-AZ DB cluster to a point in time and specify a different port.
  - Option groups
  - Point-in-time-recovery (PITR) for deleted clusters
  - Storage autoscaling by setting the maximum allocated storage. As an alternative, you can scale storage manually.
  - Stopping and starting the Multi-AZ DB cluster
  - Copying a snapshot of a Multi-AZ DB cluster
  - Encrypting an unencrypted Multi-AZ DB cluster
- RDS for MySQL Multi-AZ DB clusters don't support replication to an external target database.
- RDS for MySQL Multi-AZ DB clusters support only the following system stored procedures:
  - `mysql.rds_rotate_general_log`
  - `mysql.rds_rotate_slow_log`
  - `mysql.rds_show_configuration`
  - `mysql.rds_set_external_master_with_auto_position`
  - `mysql.rds_set_configuration`
- RDS for PostgreSQL Multi-AZ DB clusters don't support the following extensions: `aws_s3` and `pg_transport`.
- RDS for PostgreSQL Multi-AZ DB clusters don't support using a custom DNS server for outbound network access.

Using Amazon RDS Extended Support

With Amazon RDS Extended Support, you can continue running your database on a major engine version past the RDS end of standard support date for an additional cost. On the RDS end of standard support date, Amazon RDS automatically enrolls your databases in RDS Extended Support. Automatic enrollment into RDS Extended Support doesn't change the database engine and doesn't impact the uptime or performance of your DB instance.

This paid offering gives you more time to upgrade to a supported major engine version.

For example, the RDS end of standard support date for RDS for MySQL version 5.7 is February 29, 2024. However, you aren't ready to manually upgrade to RDS for MySQL version 8.0 before that date. In this case, Amazon RDS automatically enrolls your databases in RDS Extended Support on February 29, 2024, and you can continue to run RDS for MySQL version 5.7. Starting March 1, 2024, Amazon RDS automatically charges you for RDS Extended Support.

RDS Extended Support is available for up to 3 years past the RDS end of standard support date for a major engine version. After this time, if you haven't upgraded your major engine version to a supported version, then Amazon RDS will automatically upgrade your major engine version. We recommend that you upgrade to a supported major engine version as soon as possible.

Topics

Overview of Amazon RDS Extended Support

After the RDS end of standard support date, if you didn't disable RDS Extended Support during the creation or restoration of your DB instances, then Amazon RDS will automatically enroll them in RDS Extended Support. Amazon RDS automatically upgrades your DB instance to the last

minor version released before the RDS end of standard support date, if you aren't already running that version. Amazon RDS won't upgrade your minor version until *after* the RDS end of standard support date for your major engine version.

You can create new databases with major engine versions that have reached the RDS end of standard support date. RDS automatically enrolls these new databases in RDS Extended Support and charges you for this offering.

If you upgrade to an engine that's still under RDS standard support *before* the RDS end of standard support date, Amazon RDS won't enroll your engine in RDS Extended Support.

If you attempt to restore a snapshot of a database compatible with an engine that's past the RDS end of standard support date but isn't enrolled in RDS Extended Support, then Amazon RDS will attempt to upgrade the snapshot to be compatible with the latest engine version that is still under RDS standard support. If the restore fails, then Amazon RDS will automatically enroll your engine in RDS Extended Support with a version that's compatible with the snapshot.

You can end enrollment in RDS Extended Support at any time. To end enrollment, upgrade each enrolled engine to a newer engine version that's still under RDS standard support. The end of RDS Extended Support enrollment will be effective the day that you complete an upgrade to a newer engine version that's still under RDS standard support.

Amazon RDS Extended Support charges

You will incur charges for all engines enrolled in RDS Extended Support beginning the day after the RDS end of standard support date. For the RDS end of standard support date, see Supported MySQL major versions and Release calendar for Amazon RDS for PostgreSQL. RDS Extended Support charges apply to standby instances in Multi-AZ deployments.

The additional charge for RDS Extended Support automatically stops when you take one of the following actions:

- Upgrade to an engine version that's covered under standard support.
- Delete the database that's running a major version past the RDS end of standard support date.

The charges will restart if your target engine version enters RDS Extended Support in the future.

For example, RDS for PostgreSQL 11 enters Extended Support on March 1, 2024, but charges don't start until April 1, 2024. You upgrade your RDS for PostgreSQL 11 database to RDS for

PostgreSQL 12 on April 30, 2024. You will only be charged for 30 days of Extended Support on RDS for PostgreSQL 11. You continue running RDS for PostgreSQL 12 on this DB instance past the RDS end of standard support date of February 28, 2025. Your database will again incur RDS Extended Support charges starting on March 1, 2025.

For more information, see Amazon RDS for MySQL pricing and Amazon RDS for PostgreSQL pricing.

Avoiding charges for Amazon RDS Extended Support

You can avoid being charged for RDS Extended Support by preventing RDS from creating or restoring a DB instance or a Multi-AZ DB cluster past the RDS end of standard support date. To do this, use the AWS CLI or the RDS API.

In the AWS CLI, specify `open-source-rds-extended-support-disabled` for the `--engine-lifecycle-support` option. In the RDS API, specify `open-source-rds-extended-support-disabled` for the `LifeCycleSupport` parameter. For more information, see Creating a DB instance or a Multi-AZ DB cluster or Restoring a DB instance or a Multi-AZ DB cluster.

Versions with Amazon RDS Extended Support

RDS Extended Support is only available for major versions. It isn't available for minor versions.

RDS Extended Support is available for RDS for MySQL 5.7 and 8.0, and for RDS for PostgreSQL 11 and higher. For more information, see Supported MySQL major versions and Release calendar for Amazon RDS for PostgreSQL in the *Amazon RDS for PostgreSQL Release Notes*.

Amazon RDS Extended Support version naming

Amazon RDS will release new minor versions with fixes and CVE patches for engines on RDS Extended Support. For more information, see Amazon RDS Extended Support versions for RDS for MySQL and Amazon RDS Extended Support updates for RDS for PostgreSQL in the *Amazon RDS for PostgreSQL Release Notes*.

The names of these minor releases will be in the form *major.minor-RDS.YYYYMMDD.patch.YYYYMMDD*, for example, 5.7.44-RDS.20240208.R2.20240210 (for RDS for MySQL) or 11.22-RDS.20240208.R2.20240210 (for RDS for PostgreSQL).

major

For MySQL, the major version number is both the integer and the first fractional part of the version number, for example, 8.0. A major version upgrade increases the major part of the version number. For example, an upgrade from 5.7.44 to 8.0.33 is a major version upgrade, where *5.7* and *8.0* are the major version numbers.

For PostgreSQL, the major version number is the integer, for example, 11.

minor-RDS.YYYYMMDD

For MySQL, the minor version number is the third part of the version number, for example, the 44-RDS.20240208 in 5.7.44-RDS.20240208.

For PostgeSQL, the minor version number is the second part of version number, for example, the 22-RDS.20240208in 11.22-RDS.20240208.

The date is when Amazon RDS created the Amazon RDS minor version.

patch

The patch version is what follows the date when Amazon RDS created the Amazon RDS minor version, for example, the R2 in 5.7.44-RDS.20240208.R2 or 11.22-RDS.20240208.R2.

An Amazon RDS patch version includes important bug fixes added to an Amazon RDS minor version after its release.

YYYYMMDD

The date is when Amazon RDS created the patch version, for example, the 20240210 in 5.7.44-RDS.20240208.R2.20240210 or 11.22-RDS.20240208.R2.20240210.

An Amazon RDS dated version is a security patch that includes important security fixes added to a minor version after its release. It doesn't include any fixes that might change an engine's behavior.

Amazon RDS and customer responsibilities with Amazon RDS Extended Support

The following content describes the responsibilities of Amazon RDS and your responsibilities with RDS Extended Support.

Topics

Amazon RDS responsibilities

After the RDS end of standard support date, Amazon RDS will supply patches, bug fixes, and upgrades for engines that are enrolled in RDS Extended Support. This will occur for up to 3 years, or until you stop using the engines, whichever happens first.

The patches will be for Critical and High CVEs as defined by the National Vulnerability Database (NVD) CVSS severity ratings. For more information, see Vulnerability Metrics.

Your responsibilities

You're responsible for applying the patches, bug fixes, and upgrades given for DB instances or Multi-AZ DB clusters enrolled in RDS Extended Support. Amazon RDS reserves the right to change, replace, or withdraw such patches, bug fixes, and upgrades at any time. If a patch is necessary to address security or critical stability issues, Amazon RDS reserves the right to update your DB instances or Multi-AZ DB clusters with the patch, or to require that you install the patch.

You're also responsible for upgrading your engine to a newer engine version *before* the RDS end of Extended Support date. The RDS end of Extended Support date is typically 3 years after the RDS standard support date. For the RDS end of Extended Support date for your database major engine version, see Supported MySQL major versions and Release calendar for Amazon RDS for PostgreSQL.

If you don't upgrade your engine, then after the RDS end of Extended Support date, Amazon RDS will attempt to upgrade your engine to the latest engine version that's supported under RDS standard support. If the upgrade fails, then Amazon RDS reserves the right to delete the DB instance or Multi-AZ DB cluster that's running the engine past the RDS end of standard support date. However, before doing so, Amazon RDS will preserve your data from that engine.

Creating a DB instance or a Multi-AZ DB cluster with Amazon RDS Extended Support

When you create a DB instance or a Multi-AZ DB cluster, select **Enable RDS Extended Support** in the console, or use the Extended Support option in the AWS CLI or the parameter in the RDS

API. When you enroll a DB instance or a Multi-AZ DB cluster in Amazon RDS Extended Support, it is permanently enrolled in RDS Extended Support for the life of the DB instance or Multi-AZ DB cluster.

If you use the console, you must select **Enable RDS Extended Support**. The setting isn't selected by default.

If you use the AWS CLI or the RDS API and don't specify the RDS Extended Support setting, Amazon RDS defaults to enabling RDS Extended Support. When you automate by using AWS CloudFormation or other services, this default behavior maintains the availability of your database past the RDS end of standard support date.

You can prevent enrollment in RDS Extended Support by using the AWS CLI or the RDS API to create a DB instance or a Multi-AZ DB cluster.

Topics

RDS Extended Support behavior

The following table summarizes what happens when a major engine version reaches the RDS end of standard support.

RDS Extended Support status*	Behavior
Enabled	Amazon RDS charges you for RDS Extended Support.
Disabled	Amazon RDS upgrades your DB instance or Multi-AZ DB cluster to a supported engine version. This upgrade takes place on or shortly after the RDS end of standard support date.

* In the RDS console, the RDS Extended Support status appears as Yes or No. In the AWS CLI or RDS API, the RDS Extended Support status appears as `open-source-rds-extended-support` or `open-source-rds-extended-support-disabled`.

Considerations for RDS Extended Support

Before creating a DB instance or a Multi-AZ DB cluster, consider the following items:

- *After* the RDS end of standard support date has passed, you can prevent the creation of a new DB instance or a new Multi-AZ DB cluster and avoid RDS Extended Support charges. To do this, use the AWS CLI or the RDS API. In the AWS CLI, specify `open-source-rds-extended-support-disabled` for the `--engine-lifecycle-support` option. In the RDS API, specify `open-source-rds-extended-support-disabled` for the `LifeCycleSupport` parameter. If you specify `open-source-rds-extended-support-disabled` and the RDS end of standard support date has passed, creating a DB instance or a Multi-AZ DB cluster will always fail.
- RDS Extended Support is set at the cluster level. Members of a cluster will always have the same setting for RDS Extended Support in the RDS console, `--engine-lifecycle-support` in the AWS CLI, and `EngineLifecycleSupport` in the RDS API.

For more information, see MySQL versions and Release calendars for Amazon RDS for PostgreSQL.

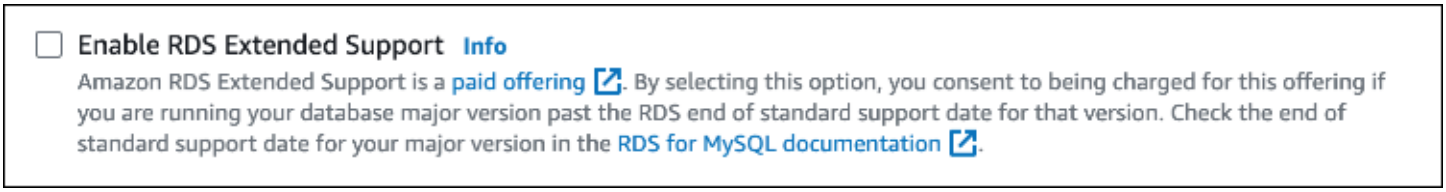
Create a DB instance or a Multi-AZ DB cluster with RDS Extended Support

You can create a DB instance or a Multi-AZ DB cluster with an RDS Extended Support version using the AWS Management Console, the AWS CLI, or the RDS API.

Console

When you create a DB instance or a Multi-AZ DB cluster, in the **Engine options** section, select **Enable RDS Extended Support**. This setting isn't selected by default.

The following image shows the **Enable RDS Extended Support** setting:



AWS CLI

When you run the create-db-instance or create-db-cluster (Multi-AZ DB cluster) AWS CLI command, select RDS Extended Support by specifying `open-source-rds-extended-support` for the

`--engine-lifecycle-support` option. By default, this option is set to `open-source-rds-extended-support`.

To prevent the creation of a new DB instance or a Multi-AZ DB cluster after the RDS end of standard support date, specify `open-source-rds-extended-support-disabled` for the `--engine-lifecycle-support` option. By doing so, you will avoid any associated RDS Extended Support charges.

RDS API

When you use the CreateDBInstance or CreateDBCluster (Multi-AZ DB cluster) Amazon RDS API operation, select RDS Extended Support by setting the `EngineLifecycleSupport` parameter to `open-source-rds-extended-support`. By default, this parameter is set to `open-source-rds-extended-support`.

To prevent the creation of a new DB instance or a Multi-AZ DB cluster after the RDS end of standard support date, specify `open-source-rds-extended-support-disabled` for the `EngineLifecycleSupport` parameter. By doing so, you will avoid any associated RDS Extended Support charges.

For more information, see the following topics:

- To create a DB instance, follow the instructions for your DB engine in Creating an Amazon RDS DB instance.
- To create a Multi-AZ DB cluster, follow the instructions for your DB engine in Creating a Multi-AZ DB cluster.

Viewing the enrollment of your DB instances or Multi-AZ DB clusters in Amazon RDS Extended Support

You can view the enrollment of your DB instances or Multi-AZ DB clusters in RDS Extended Support using the AWS Management Console, the AWS CLI, or the RDS API.

> **Note**
>
> The **RDS Extended Support** column in the console, the `--engine-lifecycle-support` option in the AWS CLI, and the `EngineLifecycleSupport` parameter in the RDS API only indicate enrollment in RDS Extended Support. Charges for RDS Extended Support only

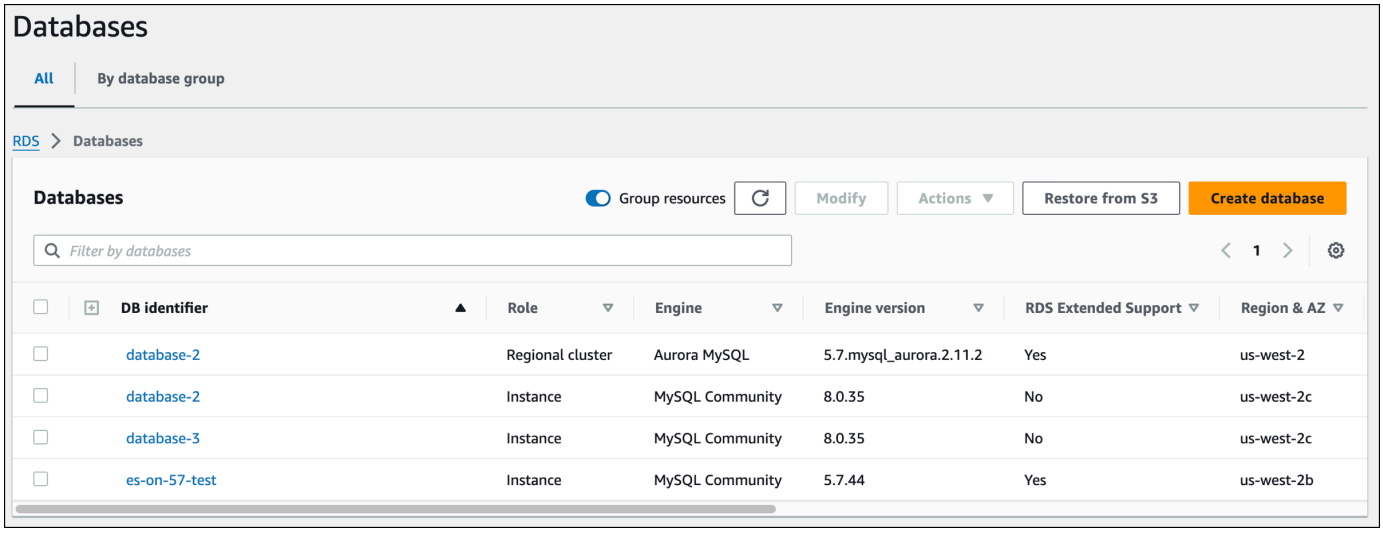
start when your DB engine version has reached the RDS end of standard support. For more information, see Supported MySQL major versions and Release calendar for Amazon RDS for PostgreSQL in the *Amazon RDS for PostgreSQL Release Notes*.
For example, you have an RDS for MySQL 5.7 database that is enrolled in RDS Extended Support. On March 1, 2024, Amazon RDS started charging you for RDS Extended Support for this database. On July 31, 2024, you upgraded this database to RDS for MySQL 8.0. The RDS Extended Support status for this database remains enabled. However, the RDS Extended Support charges for this database stopped because RDS for MySQL 8.0 hadn't reached RDS end of standard support yet. Amazon RDS won't charge you for RDS Extended Support for this database until August 1, 2026, which is when RDS standard support ends for RDS for MySQL 8.0.

Console

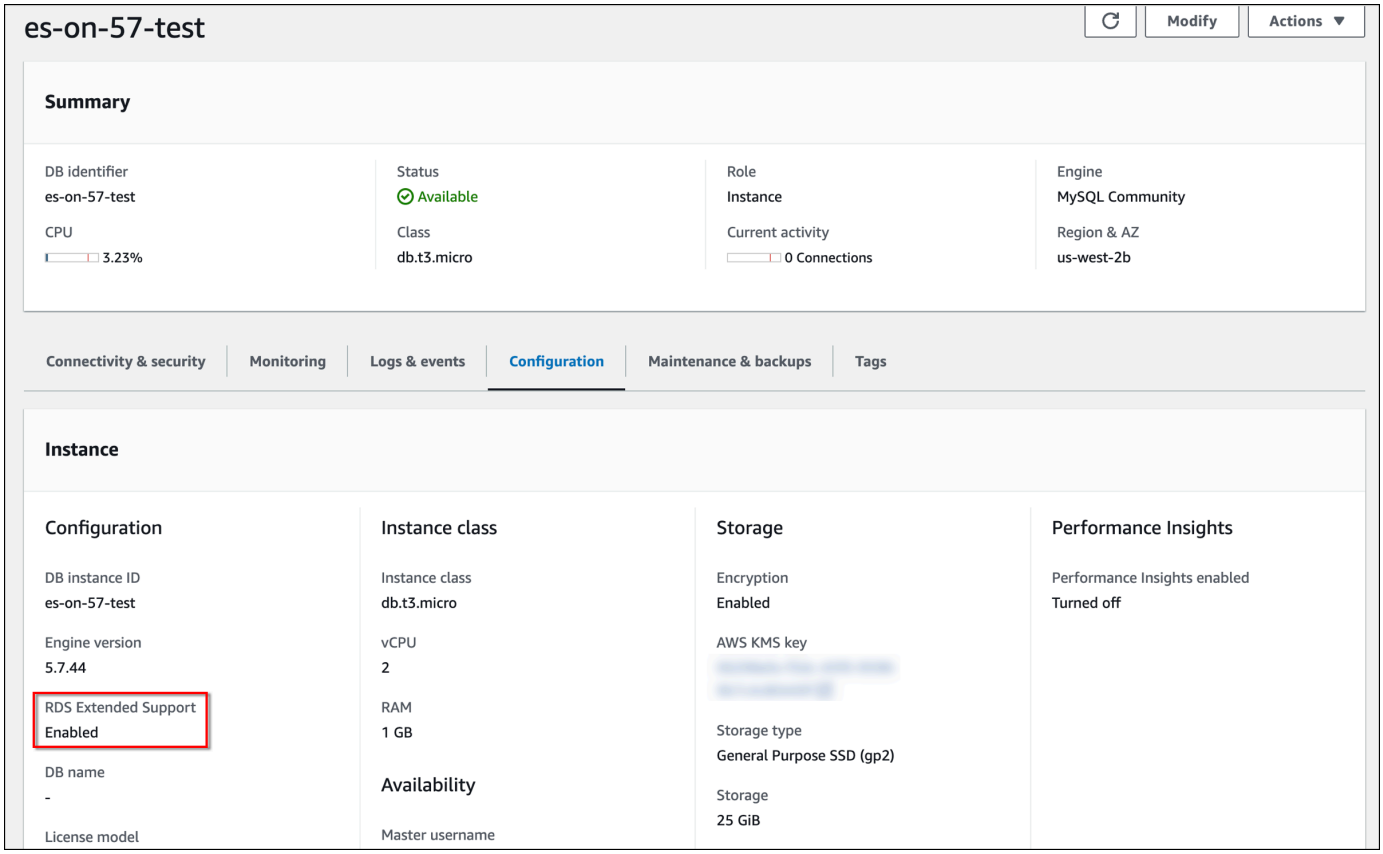
To view the enrollment of your DB instances or Multi-AZ DB clusters in RDS Extended Support

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**. The value under **RDS Extended Support** indicates if a DB instance or Multi-AZ DB cluster is enrolled in RDS Extended Support. If no value appears, then RDS Extended Support isn't available for your database.

> **Tip**
>
> If the **RDS Extended Support** column doesn't appear, choose the **Preferences** icon, and then turn on **RDS Extended Support**.



3. You can also view the enrollment on the **Configuration** tab for each database. Choose a database under **DB identifier**. On the **Configuration** tab, look under **Extended Support** to see if the database is enrolled or not.



AWS CLI

To view the enrollment of your databases in RDS Extended Support by using the AWS CLI, run the describe-db-instances or describe-db-clusters (Multi-AZ DB clusters) command.

If RDS Extended Support is available for a database, then the response includes the parameter `EngineLifecycleSupport`. The value `open-source-rds-extended-support` indicates that a DB instance or Multi-AZ DB cluster is enrolled in RDS Extended Support. The value `open-source-rds-extended-support-disabled` indicates that enrollment of the DB instance or Multi-AZ DB cluster in RDS Extended Support was disabled.

Example

The following command returns information for all of your DB instances:

```
aws rds describe-db-instances
```

The following response shows that a PostgreSQL engine running on the DB instance `database-1` is enrolled in RDS Extended Support:

```
{
    "DBInstanceIdentifier": "database-1",
    "DBInstanceClass": "db.t3.large",
    "Engine": "postgres",
    ...
    "EngineLifecycleSupport": "open-source-rds-extended-support"
}
```

RDS API

To view the enrollment of your databases in RDS Extended Support by using the Amazon RDS API, use the DescribeDBInstances or DescribeDBClusters operation.

If RDS Extended Support is available for a database, then the response includes the parameter `EngineLifecycleSupport`. The value `open-source-rds-extended-support` indicates that a DB instance or Multi-AZ DB cluster is enrolled in RDS Extended Support. The value `open-source-rds-extended-support-disabled` indicates that enrollment of the DB instance or Multi-AZ DB cluster in RDS Extended Support was disabled.

Restoring a DB instance or a Multi-AZ DB cluster with Amazon RDS Extended Support

When you restore a DB instance or a Multi-AZ DB cluster, select **Enable RDS Extended Support** in the console, or use the Extended Support option in the AWS CLI or the parameter in the RDS API. When you enroll a DB instance or Multi-AZ DB cluster in RDS Extended Support, it is permanently enrolled in RDS Extended Support for the life of the DB instance or Multi-AZ DB cluster.

The default for the RDS Extended Support setting depends on whether you use the console, the AWS CLI, or the RDS API to restore your database. If you use the console, you don't select **Enable RDS Extended Support**, and the major engine version you are restoring is past the RDS end of standard support, then Amazon RDS automatically upgrades your DB instance to a newer engine version. If you use the AWS CLI or the RDS API and you don't specify the RDS Extended Support setting, then Amazon RDS defaults to enabling RDS Extended Support. When you automate by using AWS CloudFormation or other services, this default behavior maintains the availability of your database past the RDS end of standard support date. You can disable RDS Extended Support by using the AWS CLI or the RDS API.

Topics

RDS Extended Support behavior

The following table summarizes what happens when a major engine version of a DB instance or a Multi-AZ DB cluster that you are restoring has reached the RDS end of standard support.

RDS Extended Support status*	Behavior
Enabled	Amazon RDS charges you for RDS Extended Support.
Disabled**	After the restore finishes, Amazon RDS automatically upgrades your DB instance or Multi-AZ DB cluster to a newer engine version (in a future maintenance window).

* In the RDS console, the RDS Extended Support status appears as Yes or No. In the AWS CLI or RDS API, the RDS Extended Support status appears as `open-source-rds-extended-support` or `open-source-rds-extended-support-disabled`.

** This option is only available when restoring a DB instance or a Multi-AZ DB cluster running PostgreSQL 12 and higher or MySQL 8 and higher.

Considerations for RDS Extended Support

Before restoring a DB instance or a Multi-AZ DB cluster, consider the following items:

- *After* the RDS end of standard support date has passed, if you want to restore a DB instance or a Multi-AZ DB cluster from Amazon S3, you can only do so by using the AWS CLI or the RDS API. Use the `--engine-lifecycle-support` option in the restore-db-cluster-from-s3 AWS CLI command or the `EngineLifecycleSupport` parameter in the RestoreDBClusterFromS3 RDS API operation.
- If you want to prevent RDS from restoring your databases to RDS Extended Support versions, specify `open-source-rds-extended-support-disabled` in the AWS CLI or the RDS API. By doing so, you will avoid any associated RDS Extended Support charges.

  If you specify this setting, Amazon RDS will automatically upgrade your restored database to a newer, supported major version. If the upgrade fails pre-upgrade checks, Amazon RDS will safely roll back to the RDS Extended Support engine version. This database will remain in RDS Extended Support mode, and Amazon RDS will charge you for RDS Extended Support until you manually upgrade your database.

  For example, if you restore a MySQL 5.7 snapshot without using RDS Extended Support, Amazon RDS will attempt to automatically upgrade your database to MySQL 8.0. If this upgrade fails due to an issue that you need to resolve, Amazon RDS will roll back the database to MySQL 5.7. Amazon RDS will keep the database on RDS Extended Support until you can fix the issue. For example, an upgrade might fail due to insufficient storage space. After you fix the issue, you must initiate the upgrade. After the first attempt to upgrade your database, Amazon RDS won't attempt to upgrade it again.
- RDS Extended Support is set at the cluster level. Members of a cluster will always have the same setting for RDS Extended Support in the RDS console, `--engine-lifecycle-support` in the AWS CLI, and `EngineLifecycleSupport` in the RDS API.

For more information, see MySQL versions and Release calendars for Amazon RDS for PostgreSQL.

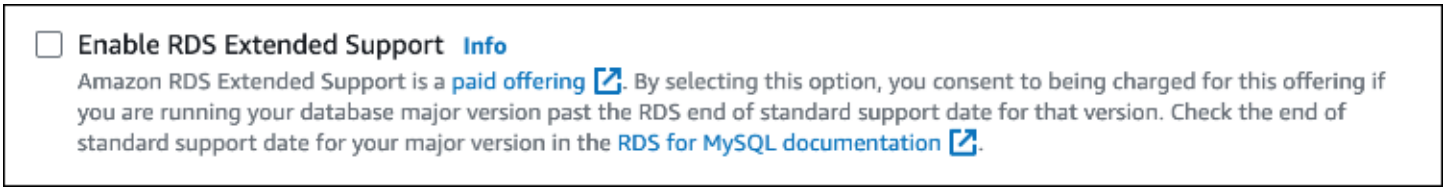
Restore a DB instance or a Multi-AZ DB cluster with RDS Extended Support

You can restore a DB instance or a Multi-AZ DB cluster with an RDS Extended Support version using the AWS Management Console, the AWS CLI, or the RDS API.

Console

When you restore a DB instance or a Multi-AZ DB cluster, select **Enable RDS Extended Support** in the **Engine options** section. If you don't select this setting and the major engine version that you are restoring is past the RDS end of standard support, then Amazon RDS automatically upgrades your DB instance or Multi-AZ DB cluster to a version under RDS standard support.

The following image shows the **Enable RDS Extended Support** setting:



AWS CLI

When you run the restore-db-instance-from-db-snapshot or restore-db-cluster-from-snapshot AWS CLI command, select RDS Extended Support by specifying `open-source-rds-extended-support` for the `--engine-lifecycle-support` option.

If you want to avoid charges associated with RDS Extended Support, set the `--engine-lifecycle-support` option to `open-source-rds-extended-support-disabled`. By default, this option is set to `open-source-rds-extended-support`.

You can also specify this value using the following AWS CLI commands:

- restore-db-cluster-from-s3
- restore-db-cluster-to-point-in-time
- restore-db-instance-from-s3
- restore-db-instance-to-point-in-time

RDS API

When you use the RestoreDBInstanceFromDBSnapshot or RestoreDBClusterFromSnapshot Amazon RDS API operation, select RDS Extended Support by setting the `EngineLifecycleSupport` parameter to `open-source-rds-extended-support`.

If you want to avoid charges associated with RDS Extended Support, set the `EngineLifecycleSupport` parameter to `open-source-rds-extended-support-disabled`. By default, this parameter is set to `open-source-rds-extended-support`.

You can also specify this value using the following RDS API operations:

- RestoreDBClusterFromS3
- RestoreDBClusterToPointInTime
- RestoreDBInstanceFromS3
- RestoreDBInstanceToPointInTime

For more information about restoring a DB instance or a Multi-AZ DB cluster, follow the instructions for your DB engine in Restoring to a DB instance.

Using Amazon RDS Blue/Green Deployments for database updates

A blue/green deployment copies a production database environment to a separate, synchronized staging environment. By using Amazon RDS Blue/Green Deployments, you can make changes to the database in the staging environment without affecting the production environment. For example, you can upgrade the major or minor DB engine version, change database parameters, or make schema changes in the staging environment. When you're ready, you can promote the staging environment to be the new production database environment, with downtime typically under one minute.

> **Note**
>
> Currently, Blue/Green Deployments are supported for RDS for MariaDB, RDS for MySQL, and RDS for PostgreSQL only. For Amazon Aurora availability, see Using Amazon RDS Blue/Green Deployments for database updates in the *Amazon Aurora User Guide*.

Topics

Overview of Amazon RDS Blue/Green Deployments

By using Amazon RDS Blue/Green Deployments, you can make and test database changes before implementing them in a production environment. A *blue/green deployment* creates a staging environment that copies the production environment. In a blue/green deployment, the *blue environment* is the current production environment. The *green environment* is the staging environment. The staging environment stays in sync with the current production environment using logical replication.

You can make changes to the RDS DB instances in the green environment without affecting production workloads. For example, you can upgrade the major or minor DB engine version, upgrade the underlying file system configuration, or change database parameters in the staging environment. You can thoroughly test changes in the green environment. When ready, you can *switch over* the environments to promote the green environment to be the new production environment. The switchover typically takes under a minute with no data loss and no need for application changes.

Because the green environment is a copy of the topology of the production environment, the green environment includes the features used by the DB instance. These features include the read replicas, the storage configuration, DB snapshots, automated backups, Performance Insights, and Enhanced Monitoring. If the blue DB instance is a Multi-AZ DB instance deployment, then the green DB instance is also a Multi-AZ DB instance deployment.

> **Note**
>
> Currently, Blue/Green Deployments are supported only for RDS for MariaDB, RDS for MySQL, and RDS for PostgreSQL. For Amazon Aurora availability, see Using Amazon RDS Blue/Green Deployments for database updates in the *Amazon Aurora User Guide*.

Topics

- Best practices for blue/green deployments

Region and version availability

Feature availability and support varies across specific versions of each database engine, and across AWS Regions. For more information, see the section called “Blue/Green Deployments”.

Benefits of using Amazon RDS Blue/Green Deployments

By using Amazon RDS Blue/Green Deployments, you can stay current on security patches, improve database performance, and adopt newer database features with short, predictable downtime. Blue/green deployments reduce the risks and downtime for database updates, such as major or minor engine version upgrades.

Blue/green deployments provide the following benefits:

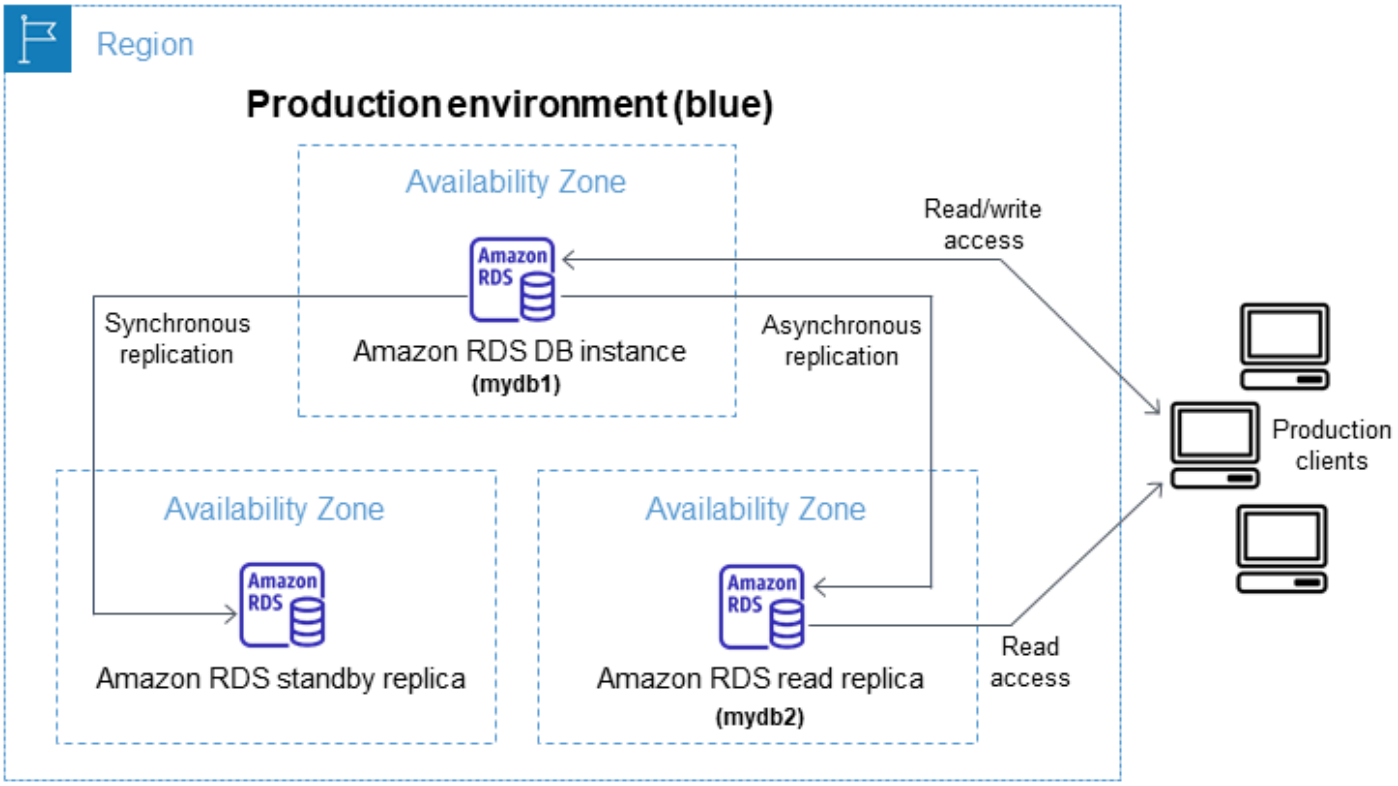
- Easily create a production-ready staging environment.
- Automatically replicate database changes from the production environment to the staging environment.
- Test database changes in a safe staging environment without affecting the production environment.
- Stay current with database patches and system updates.
- Implement and test newer database features.
- Switch over your staging environment to be the new production environment without changes to your application.
- Safely switch over through the use of built-in switchover guardrails.
- Eliminate data loss during switchover.
- Switch over quickly, typically under a minute depending on your workload.

Workflow of a blue/green deployment

Complete the following major steps when you use a blue/green deployment for database updates.

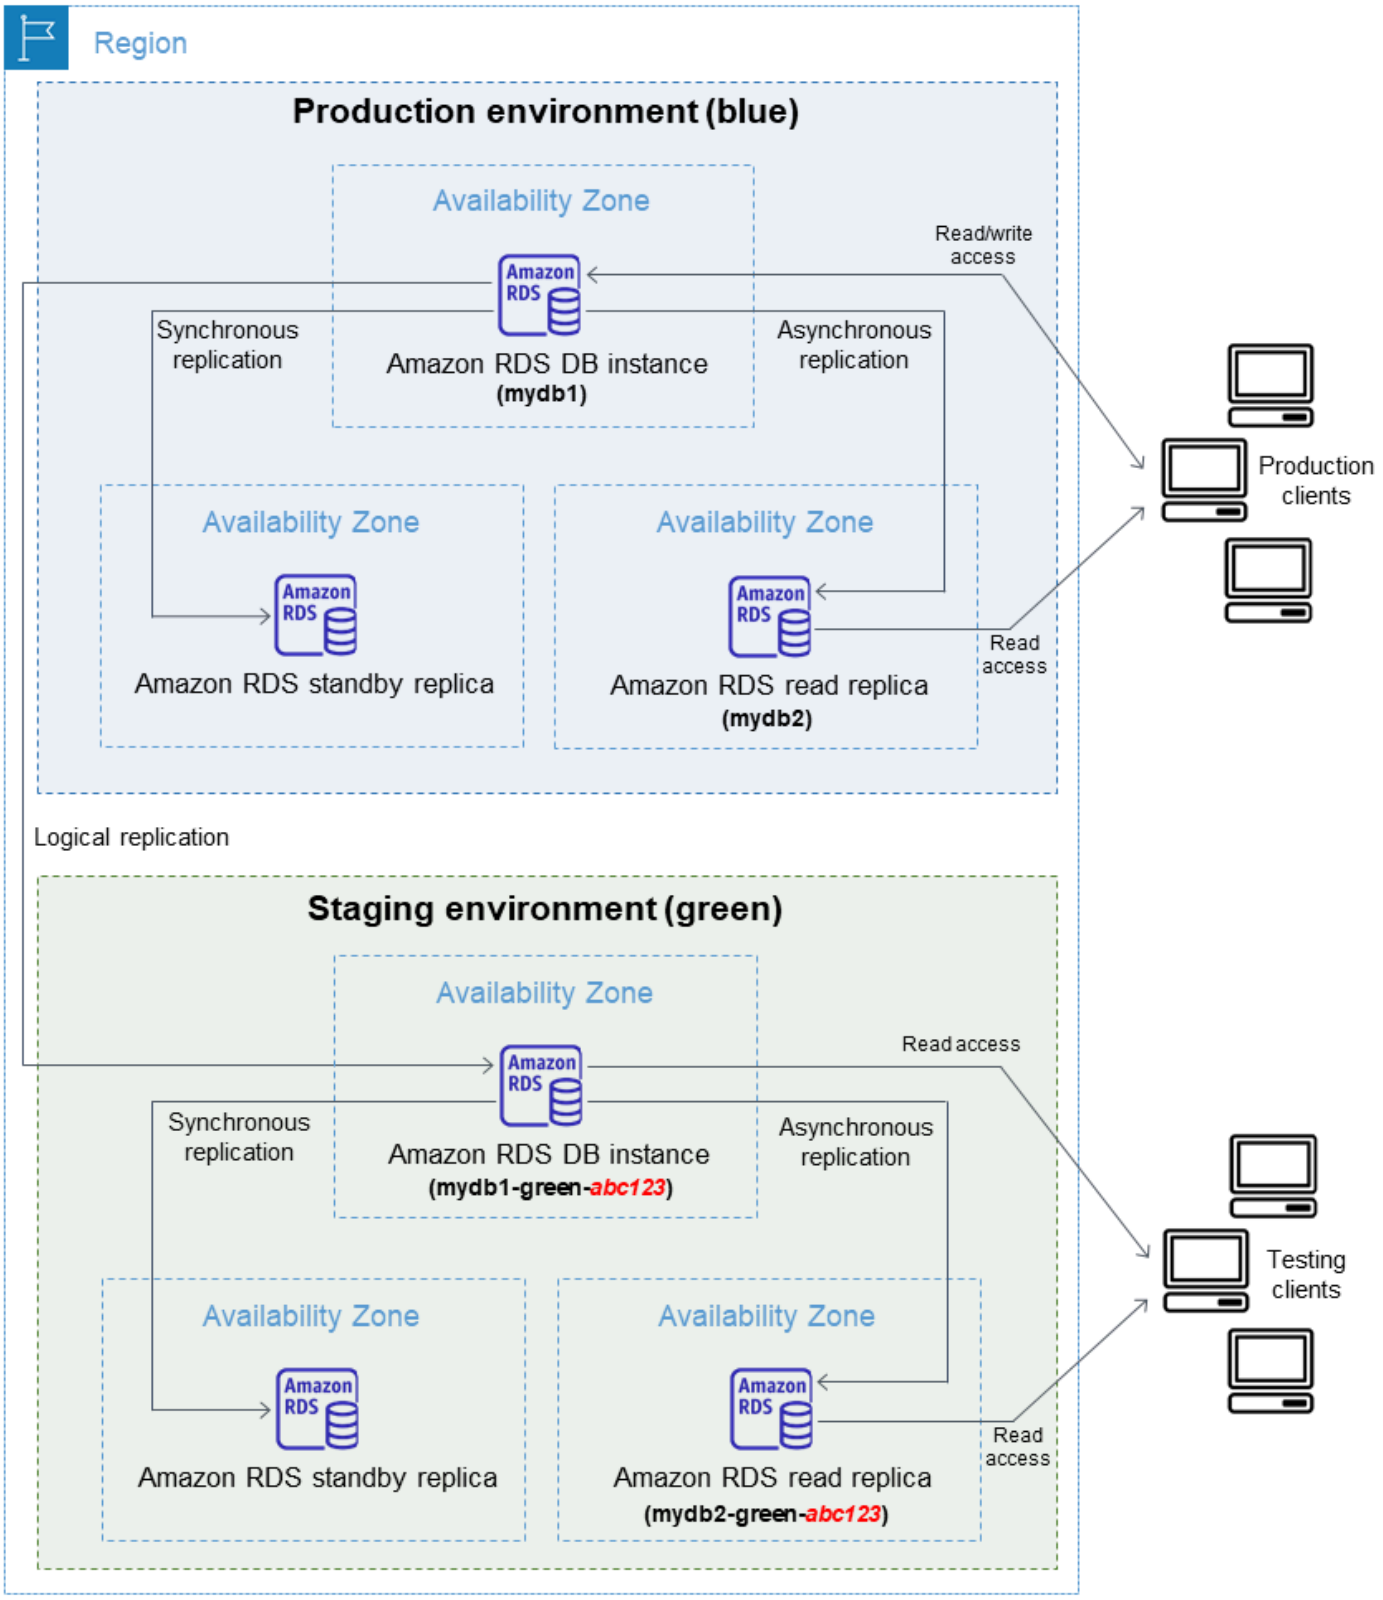
1. Identify a production environment that requires updates.

   For example, the production environment in this image has a Multi-AZ DB instance deployment (mydb1) and a read replica (mydb2).



2. Create the blue/green deployment. For instructions, see Creating a blue/green deployment.

   The following image shows an example of a blue/green deployment of the production environment from step 1. While creating the blue/green deployment, RDS copies the complete topology and configuration of the primary DB instance to create the green environment. The copied DB instance names are appended with `-green-`*`random-characters`*. The staging environment in the image contains a Multi-AZ DB instance deployment (mydb1-green-*abc123*) and a read replica (mydb2-green-*abc123*).



When you create the blue/green deployment, you can upgrade your DB engine version and specify a different DB parameter group for the DB instances in the green environment. RDS

also configures logical replication from the primary DB instance in the blue environment to the primary DB instance in the green environment.

After you create the blue/green deployment, the DB instance in the green environment is read-only by default.

3. Make additional changes to the staging environment, if required.

   For example, you might make schema changes to your database or change the DB instance class used by one or more DB instances in the green environment.

   For information about modifying a DB instance, see Modifying an Amazon RDS DB instance.

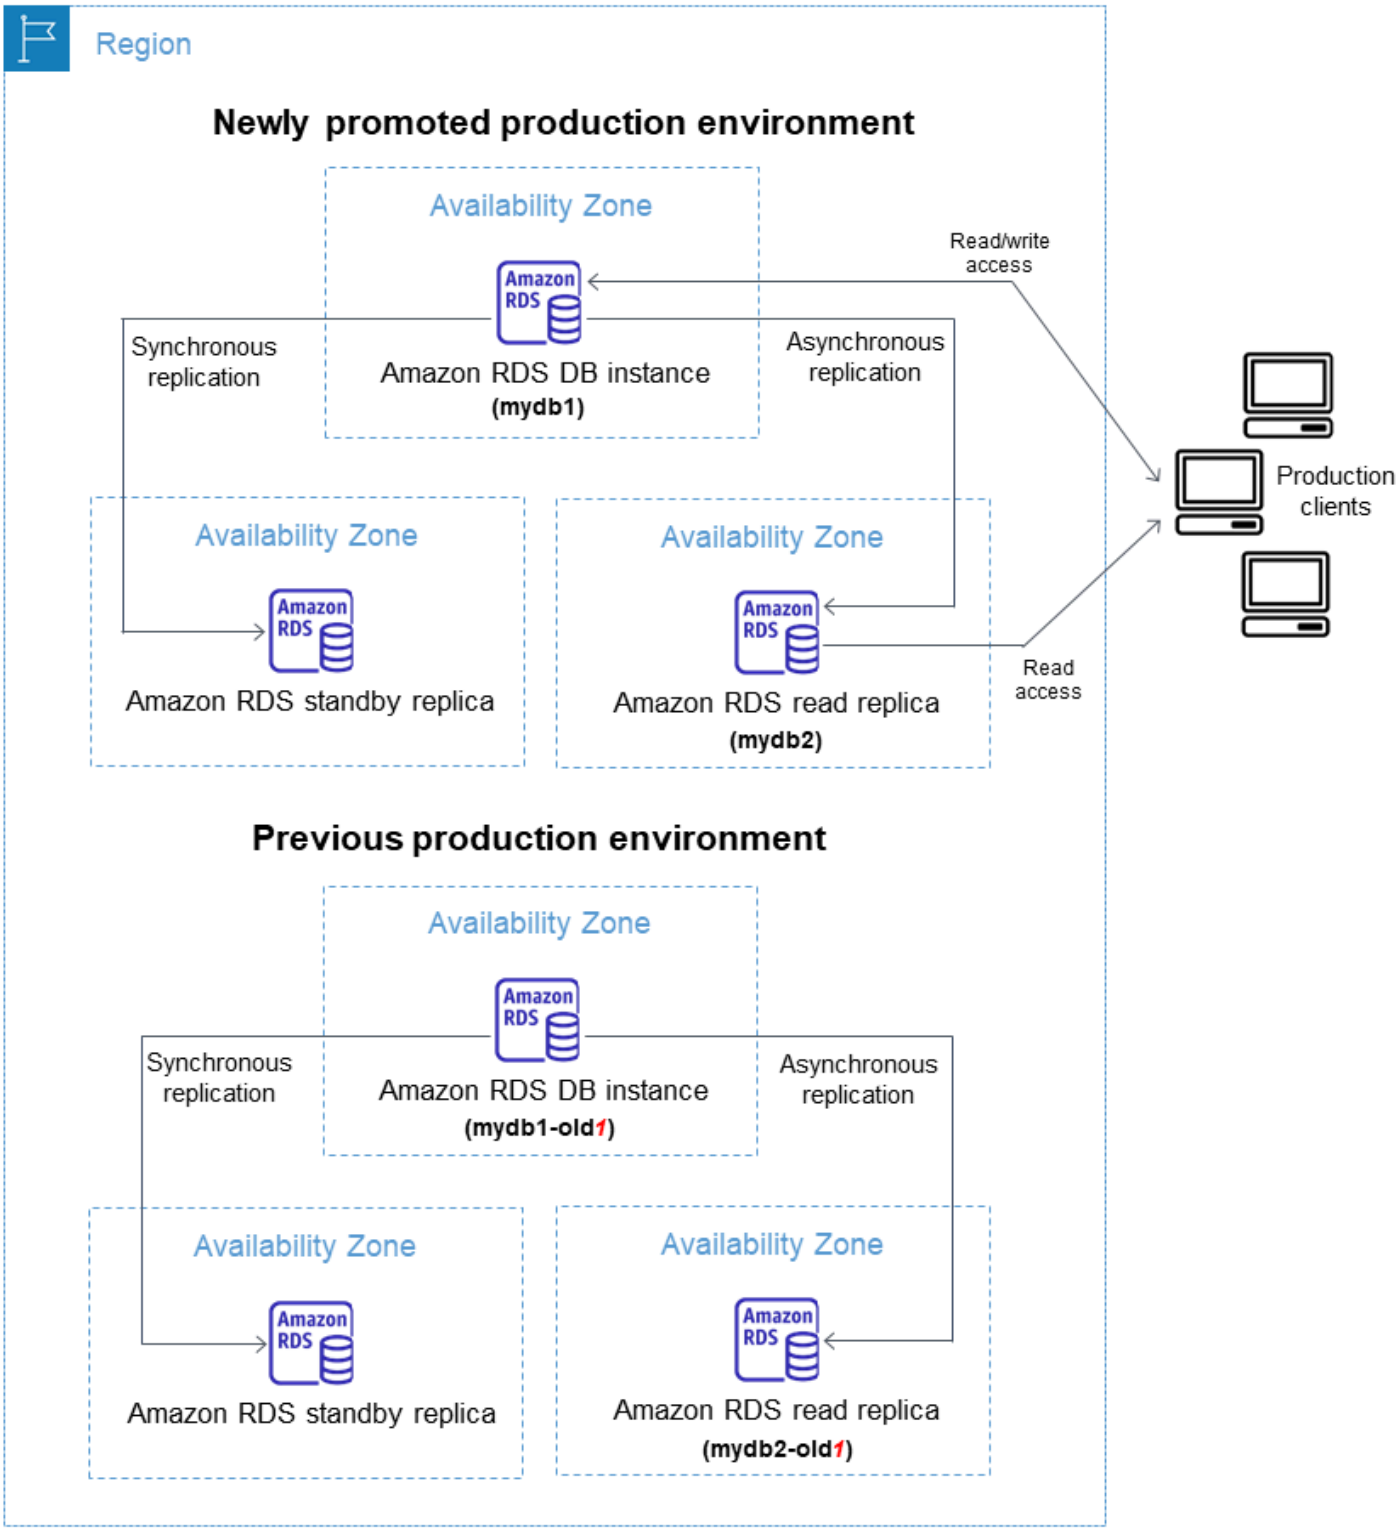
4. Test your staging environment.

   During testing, we recommend that you keep your databases in the green environment read only. Enable write operations on the green environment with caution because they can result in replication conflicts. They can also result in unintended data in the production databases after switchover. To enable write operations for RDS for MySQL, set the `read_only` parameter to `0`, then reboot the DB instance. For RDS for PostgreSQL, set the `default_transaction_read_only` parameter to `off` at the session level.

5. When ready, switch over to promote the staging environment to be the new production environment. For instructions, see Switching a blue/green deployment.

   The switchover results in downtime. The downtime is usually under one minute, but it can be longer depending on your workload.

   The following image shows the DB instances after the switchover.



After the switchover, the DB instances that were in the green environment become the new production DB instances. The names and endpoints in the current production environment are assigned to the newly promoted production environment, requiring no changes to your

application. As a result, your production traffic now flows to the new production environment. The DB instances in the previous blue environment are renamed by appending `-old`*n* to the current name, where *n* is a number. For example, assume the name of the DB instance in the blue environment is `mydb1`. After switchover, the DB instance name might be `mydb1-old1`.

In the example in the image, the following changes occur during switchover:

- The green environment Multi-AZ DB instance deployment named `mydb1-green-abc123` becomes the production Multi-AZ DB instance deployment named `mydb1`.
- The green environment read replica named `mydb2-green-abc123` becomes the production read replica `mydb2`.
- The blue environment Multi-AZ DB instance deployment named `mydb1` becomes `mydb1-old1`.
- The blue environment read replica named `mydb2` becomes `mydb2-old1`.

6. If you no longer need a blue/green deployment, you can delete it. For instructions, see Deleting a blue/green deployment.

   After switchover, the previous production environment isn't deleted so that you can use it for regression testing, if necessary.

Authorizing access to blue/green deployment operations

Users must have the required permissions to perform operations related to blue/green deployments. You can create IAM policies that grant users and roles permission to perform specific API operations on the specified resources they need. You can then attach those policies to the IAM permission sets or roles that require those permissions. For more information, see Identity and access management for Amazon RDS.

The user who creates a blue/green deployment must have permissions to perform the following RDS operations:

- `rds:AddTagsToResource`
- `rds:CreateDBInstanceReadReplica`

The user who switches over a blue/green deployment must have permissions to perform the following RDS operations:

- `rds:ModifyDBInstance`
- `rds:PromoteReadReplica`

The user who deletes a blue/green deployment must have permissions to perform the following RDS operation:

- `rds:DeleteDBInstance`

Amazon RDS provisions and modifies resources in the staging environment on your behalf. These resources include DB instances that use an internally defined naming convention. Therefore, attached IAM policies can't contain partial resource name patterns such as `my-db-prefix-*`. Only wildcards (*) are supported. In general, we recommend using resource tags and other supported attributes to control access to these resources, rather than wildcards. For more information, see Actions, resources, and condition keys for Amazon RDS.

Limitations and considerations for blue/green deployments

Blue/green deployments in Amazon RDS require careful consideration of factors such as replication slots, resource management, instance sizing, and potential impacts on database performance. The following sections provide guidance to help you optimize your deployment strategy to ensure minimal downtime, seamless transitions, and effective management of your database environment.

Topics

- Limitations for blue/green deployments
- Considerations for blue/green deployments

Limitations for blue/green deployments

The following limitations apply to blue/green deployments.

Topics

- General limitations for blue/green deployments
- RDS for MySQL limitations for blue/green deployments
- RDS for PostgreSQL limitations for blue/green deployments

General limitations for blue/green deployments

The following general limitations apply to blue/green deployments:

- Blue/green deployments don't support managing master user passwords with AWS Secrets Manager.
- If dedicated log volume (DLV) is enabled on the blue database, it must be enabled on *all* DB instances, including read replicas.
- During switchover, the blue and green environments can't have zero-ETL integrations with Amazon Redshift. You must delete the integration first and switch over, then recreate the integration.
- The Event Scheduler (`event_scheduler` parameter) must be disabled on the green environment when you create a blue/green deployment. This prevents events from being generated in the green environment and causing inconsistencies.
- You can't change an unencrypted DB instance into an encrypted DB instance. In addition, you can't change an encrypted DB instance into an unencrypted DB instance.
- You can't change a blue DB instance to a higher engine version than its corresponding green DB instance.
- The resources in the blue environment and green environment must be in the same AWS account.
- Blue/green deployments aren't supported for the following features:
  - Amazon RDS Proxy
  - Cascading read replicas
  - Cross-Region read replicas
  - AWS CloudFormation
  - Multi-AZ DB cluster deployments

    Blue/green deployments are supported for Multi-AZ DB instance deployments. For more information about Multi-AZ deployments, see Configuring and managing a Multi-AZ deployment.

RDS for MySQL limitations for blue/green deployments

The following limitations apply to MySQL blue/green deployments:

- MySQL versions 8.0.11 through 8.0.13 have a community bug that prevents them from supporting blue/green deployments.
- The blue DB instance can't be an external binlog replica.
- If the source database is associated with a custom option group, you can't specify a major version upgrade when you create the blue/green deployment.

  In this case, you can create a blue/green deployment without specifying a major version upgrade. Then, you can upgrade the database in the green environment. For more information, see Upgrading a DB instance engine version.
- Blue/green deployments don't support the AWS JDBC Driver for MySQL. For more information, see Known Limitations on GitHub.

RDS for PostgreSQL limitations for blue/green deployments

The following limitations apply to PostgreSQL blue/green deployments:

- The following versions of RDS for PostgreSQL are supported as upgrade source and target versions: 11.21 and higher, 12.16 and higher, 13.12 and higher, 14.9 and higher, 15.4 and higher, and 16.1 and higher. For lower versions, you can perform a minor version upgrade to a supported version.
- Unlogged tables aren't replicated to the green environment.
- The blue DB instance can't be a self-managed logical source (publisher) or replica (subscriber).
- If the blue DB instance is configured as the foreign server of a foreign data wrapper (FDW) extension, you must use the instance endpoint name instead of IP addresses. This allows the configuration to remain functional after switchover.
- In a blue/green deployment, each database requires a logical replication slot. As the number of databases grows, resource overhead increases and can potentially lead to replication lag, especially if the DB instance isn't sufficiently scaled. The impact depends on factors such as database workload and the number of connections. To mitigate this, consider scaling up your DB instance class or reducing the number of databases on the source instance.
- The `pg_partman` extension must be disabled on the blue environment when you create a blue/green deployment. The extension performs DDL operations such as `CREATE TABLE`, which break logical replication from the blue environment to the green environment.

- The `pg_cron` extension must remain disabled on all green databases after the blue/green deployment is created. The extension has background workers that run as superuser and bypass the read-only setting of the green environment, which might cause replication conflicts.
- The `pglogical` and `pgactive` extensions must be disabled on the blue environment when you create a blue/green deployment. After you promote the green environment to be the new production environment, you can enable the extensions again. In addition, the blue database can't be a logical subscriber of an external instance.
- If you're using the `pgAudit` extension, it must remain in the shared libraries (`shared_preload_libraries`) on the custom DB parameter groups for both the blue and the green DB instances. For more information, see the section called "Setting up the pgAudit extension".

PostgreSQL logical replication limitations for blue/green deployments

Blue/green deployments use logical replication to keep the staging environment in sync with the production environment. PostgreSQL has certain restrictions related to logical replication, which translate to limitations when creating blue/green deployments for RDS for PostgreSQL DB instances.

The following table describes logical replication limitations that apply to blue/green deployments for RDS for PostgreSQL.

Limitation	Explanation
Data definition language (DDL) statements, such as `CREATE TABLE` and `CREATE SCHEMA`, aren't replicated from the blue environment to the green environment.	If Amazon RDS detects a DDL change in the blue environment, your green databases enter a state of **Replication degraded**. You receive an event notifying you that DDL changes in the blue environment can't be replicated to the green environment. You must delete the blue/green deployment and all green databases, then recreate it. Otherwise, you won't be able to switch over the blue/green deployment.

Limitation	Explanation
NEXTVAL operations on sequence objects aren't synchronized between the blue environment and the green environment.	During switchover, Amazon RDS increments sequence values in the green environment to match those in the blue environment. If you have thousands of sequences, this can delay switchover.
Creation or modification of large objects in the blue environment aren't replicated to the green environment.	If Amazon RDS detects the creation or modification of large objects in the blue environment that are stored in the `pg_largeobject` system table, your green databases enter a state of **Replication degraded**. RDS generates an event notifying you that large object changes in the blue environment can't be replicated to the green environment. You must delete the blue/green deployment and all green databases, then recreate it. Otherwise, you won't be able to switch over the blue/green deployment.
Materialized views aren’t automatically refreshed on the green environment.	Refreshing materialized views in the blue environment doesn't refresh them in the green environment. After switchover, you can manually refresh them using the REFRESH MATERIALIZED VIEW command, or schedule a refresh.
UPDATE and DELETE operations aren't permitted on tables that don't have a primary key.	Before you create a blue/green deployment, make sure that all tables in the DB instance have a primary key.

For more information, see Restrictions in the PostgreSQL logical replication documentation.

Considerations for blue/green deployments

Amazon RDS tracks resources in blue/green deployments with the `DbiResourceId` of each resource. This resource ID is an AWS Region-unique, immutable identifier for the resource.

The *resource* ID is separate from the DB *instance* ID. Each one is listed in the database configuration in the RDS console.

The name (instance ID) of a resource changes when you switch over a blue/green deployment, but each resource keeps the same resource ID. For example, a DB instance identifier might be `mydb` in the blue environment. After switchover, the same DB instance might be renamed to `mydb-old1`. However, the resource ID of the DB instance doesn't change during switchover. So, when the green resources are promoted to be the new production resources, their resource IDs don't match the blue resource IDs that were previously in production.

After you switch over a blue/green deployment, consider updating the resource IDs to those of the newly promoted production resources for integrated features and services that you used with the production resources. Specifically, consider the following updates:

- If you perform filtering using the RDS API and resource IDs, adjust the resource IDs used in filtering after switchover.
- If you use CloudTrail for auditing resources, adjust the consumers of the CloudTrail to track the new resource IDs after switchover. For more information, see Monitoring Amazon RDS API calls in AWS CloudTrail.
- If you use the Performance Insights API, adjust the resource IDs in calls to the API after switchover. For more information, see Monitoring DB load with Performance Insights on Amazon RDS.

  You can monitor a database with the same name after switchover, but it doesn't contain the data from before the switchover.
- If you use resource IDs in IAM policies, make sure you add the resource IDs of the newly promoted resources when necessary. For more information, see Identity and access management for Amazon RDS.
- If you have IAM roles associated with your DB instance, make sure to reassociate them after switchover. Attached roles aren't automatically copied to the green environment.
- If you authenticate to your DB instance using IAM database authentication, make sure that the IAM policy used for database access has both the blue and the green databases listed under the

`Resource` element of the policy. This is required in order to connect to the green database after switchover. For more information, see the section called "Creating and using an IAM policy for IAM database access".

- If you use AWS Backup to manage automated backups of resources in a blue/green deployment, adjust the resource IDs used by AWS Backup after switchover. For more information, see Using AWS Backup to manage automated backups.
- If you want to restore a manual or automated DB snapshot for a DB instance that was part of a blue/green deployment, make sure you restore the correct DB snapshot by examining the time when the snapshot was taken. For more information, see Restoring to a DB instance.
- If you want to describe a previous blue environment DB instance automated backup or restore it to a point in time, use the resource ID for the operation.

  Because the name of the DB instance changes during switchover, you can't use its previous name for `DescribeDBInstanceAutomatedBackups` or `RestoreDBInstanceToPointInTime` operations.

  For more information, see Restoring a DB instance to a specified time.
- When you add a read replica to a DB instance in the green environment of a blue/green deployment, the new read replica won't replace a read replica in the blue environment when you switch over. However, the new read replica is retained in the new production environment after switchover.
- When you delete a DB instance in the green environment of a blue/green deployment, you can't create a new DB instance to replace it in the blue/green deployment.

  If you create a new DB instance with the same name and Amazon Resource Name (ARN) as the deleted DB instance, it has a different `DbiResourceId`, so it isn't part of the green environment.

  The following behavior results if you delete a DB instance in the green environment:

  - If the DB instance in the blue environment with the same name exists, it won't be switched over to the DB instance in the green environment. This DB instance won't be renamed by adding `-old`*n* to the DB instance name.
  - Any application that points to the DB instance in the blue environment continues to use the same DB instance after switchover.

  The same behavior applies to DB instances and read replicas.

Best practices for blue/green deployments

The following are best practices for blue/green deployments.

Topics

General best practices

- Thoroughly test the DB instances in the green environment before switching over.
- Keep your databases in the green environment read only. We recommend that you enable write operations on the green environment with caution because they can result in replication conflicts. They can also result in unintended data in the production databases after switchover.
- When using a blue/green deployment to implement schema changes, make only replication-compatible changes.

  For example, you can add new columns at the end of a table without disrupting replication from the blue deployment to the green deployment. However, schema changes, such as renaming columns or renaming tables, break replication to the green deployment.

  For more information about replication-compatible changes, see Replication with Differing Table Definitions on Source and Replica in the MySQL documentation and Restrictions in the PostgreSQL logical replication documentation.
- After you create the blue/green deployment, handle lazy loading if necessary. Make sure data loading is complete before switching over. For more information, see Handling lazy loading when you create a blue/green deployment.
- When you switch over a blue/green deployment, follow the switchover best practices. For more information, see the section called “Switchover best practices”.

RDS for MySQL best practices

- Avoid using non-transactional storage engines, such as MyISAM, that aren't optimized for replication.
- Optimize read replicas for binary log replication.

For example, if your DB engine version supports it, consider using GTID replication, parallel replication, and crash-safe replication in your production environment before deploying your blue/green deployment. These options promote consistency and durability of your data before you switch over your blue/green deployment. For more information about GTID replication for read replicas, see Using GTID-based replication.

RDS for PostgreSQL best practices

- If your database has sufficient freeable memory, increase the value of the `logical_decoding_work_mem` DB parameter in the blue environment. Doing so allows for less decoding on disk and instead uses memory. You can monitor freeable memory with the `FreeableMemory` CloudWatch metric. For more information, see the section called "Amazon CloudWatch instance-level metrics for Amazon RDS".
- Update all of your PostgreSQL extensions to the latest version before you create a blue/green deployment. For more information, see the section called "Upgrading PostgreSQL extensions".
- If you're using the `aws_s3` extension, make sure to give the green DB instance access to Amazon S3 through an IAM role after the green environment is created. This allows the import and export commands to continue functioning after switchover. For instructions, see the section called "Setting up access to an Amazon S3 bucket".
- If you specify a higher engine version for the green environment, run the `ANALYZE` operation on all databases to refresh the `pg_statistic` table. Optimizer statistics aren't transferred during a major version upgrade, so you must regenerate all statistics to avoid performance issues. For additional best practices during major version upgrades, see the section called "How to perform a major version upgrade".
- Avoid configuring triggers as `ENABLE REPLICA` or `ENABLE ALWAYS` if the trigger is used on the source to manipulate data. Otherwise, the replication system propagates changes and executes the trigger, which leads to duplication.
- Long-running transactions can cause significant replica lag. To reduce replica lag, consider doing the following:
  - Reduce long-running transactions that can be delayed until after the green environment catches up to the blue environment.
  - Initiate a manual vacuum freeze operation on busy tables prior to creating the blue/green deployment.

  - For PostgreSQL version 12 and higher, disable the `index_cleanup` parameter on large or busy tables to increase the rate of normal maintenance on blue databases. For more information, see the section called “Vacuuming a table as quickly as possible”.
- Slow replication can cause senders and receivers to restart often, which delays synchronization. To ensure that they remain active, disable timeouts by setting the `wal_sender_timeout` parameter to `0` in the blue environment, and the `wal_receiver_timeout` parameter to `0` in the green environment.
- To prevent write-ahead log (WAL) segments from being removed from the blue environment, set the `wal_keep_segments` parameter to 15625 for PostgreSQL version 13 and lower. For version 14 and higher, set the `wal_keep_size` parameter too 1 TiB, if there's enough free storage space.

Creating a blue/green deployment

When you create a blue/green deployment, you specify the source DB instance to copy in the deployment. The DB instance you choose is the production DB instance, and it becomes the primary DB instance in the blue environment. This DB instance is copied to the green environment, and RDS configures replication from the DB instance in the blue environment to the DB instance in the green environment.

RDS copies the blue environment's topology to a staging area, along with its configured features. When the blue DB instance has read replicas, the read replicas are copied as read replicas of the green DB instance in the deployment. If the blue DB instance is a Multi-AZ DB instance deployment, then the green DB instance is created as a Multi-AZ DB instance deployment.

Topics

- Preparing for a blue/green deployment
- Specifying changes when creating a blue/green deployment
- Handling lazy loading when you create a blue/green deployment
- Creating a blue/green deployment
- Settings for creating blue/green deployments

Preparing for a blue/green deployment

There are certain steps you must take before you create a blue/green deployment, depending on the engine that your DB instance is running.

Topics

Preparing an RDS for MySQL DB instance for a blue/green deployment

Before you create a blue/green deployment for an RDS for MySQL DB instance, you must enable automated backups. For instructions, see the section called “Enabling automated backups”.

Preparing an RDS for PostgreSQL DB instance for a blue/green deployment

Before you create a blue/green deployment for an RDS for PostgreSQL DB instance, make sure to do the following:

- Associate the instance with a custom DB parameter group with logical replication (`rds.logical_replication`) turned on. Logical replication is required for replication from the blue environment to the green environment. For instructions, see the section called “Modifying parameters in a DB parameter group”.

  Because blue/green deployments require at least one background worker per database, make sure to tune the following configuration settings according to your workload. For instructions to tune each setting, see Configuration Settings in the PostgreSQL documentation.

  - `max_replication_slots`
  - `max_wal_senders`
  - `max_logical_replication_workers`
  - `max_worker_processes`

  After you enable logical replication and set all configuration options, make sure to reboot the DB instance so that your changes take effect. Blue/green deployments *require* that the DB instance be in sync with the DB parameter group, otherwise creation fails. For more information, see the section called “Rebooting a DB instance”.

- Make sure that your DB instance is running a version of RDS for PostgreSQL that's compatible with RDS Blue/Green Deployments. For a list of compatible versions, see the section called "Blue/Green Deployments".
- Confirm that the DB instance isn't the source or target of external replication. For more information, see the section called "General limitations".
- Make sure that all tables in the DB instance have a primary key. PostgreSQL logical replication doesn't allow `UPDATE` or `DELETE` operations on tables that don't have a primary key.
- If you're using triggers, make sure they don't interfere with the creating, updating, and dropping of `pg_catalog.pg_publication`, `pg_catalog.pg_subscription`, and `pg_catalog.pg_replication_slots` objects whose names start with 'rds'.

Specifying changes when creating a blue/green deployment

You can make the following changes to the DB instance in the green environment when you create the blue/green deployment.

You can make other modifications to the DB instance in the green environment after it is deployed. For example, you might make schema changes to your database or change the DB instance class used by one or more DB instances in the green environment.

For information about modifying a DB instance, see Modifying an Amazon RDS DB instance.

Specify a higher engine version

You can specify a higher engine version if you want to test a DB engine upgrade. Upon switchover, the database is upgraded to the major or minor DB engine version that you specify.

Specify a different DB parameter group

You can test how parameter changes affect the DB instances in the green environment or specify a parameter group for a new major DB engine version in the case of an upgrade.

If you specify a different DB parameter group, the specified DB parameter group is associated with all of the DB instances in the green environment. If you don't specify a different parameter group, each DB instance in the green environment is associated with the parameter group of its corresponding blue DB instance.

Enable RDS Optimized Writes

You can use Blue/Green Deployments to upgrade to a DB instance class that supports RDS Optimized Writes. You can only enable RDS Optimized Writes on a database that was *created* with a supported DB instance class. Thus, this option creates a green database that uses a supported DB instance class, which enables you to turn on RDS Optimized Writes on the green DB instance.

If you're upgrading from a DB instance class that doesn't support RDS Optimized Writes to one that does, you must also upgrade the storage configuration of the green DB instance. For more information, see the section called “Upgrade the storage configuration”.

You can only upgrade the DB instance class of the *primary* green DB instance. By default, read replicas in the green environment inherit the DB instance settings from the blue environment. After the green environment is successfully created, you must manually modify the DB instance class of the read replicas in the green environment.

Some instance class upgrades aren't supported depending on the engine version and instance class of the blue DB instance. For more information about DB instance classes, see the section called “DB instance classes”.

Upgrade the storage configuration

If your blue database isn't on the latest storage configuration, RDS can migrate the green DB instance from the older storage configuration (32-bit file system) to the preferred configuration. You can use RDS Blue/Green Deployments to overcome the scaling limitations on storage and file size for older 32-bit file systems. In addition, this setting changes the storage configuration to be compatible with RDS Optimized Writes if the specified DB instance class supports Optimized Writes.

> **Note**
>
> Upgrading the storage configuration is an I/O-intensive operation and leads to longer creation times for blue/green deployments. The storage upgrade process is faster if the blue DB instance uses Provisioned IOPS SSD (io1) storage, and if you provisoned the green environment with an instance size of 4xlarge or larger. Storage upgrades involving General Purpose SSD (gp2) storage can deplete your I/O credit balance, resulting in longer upgrade times. For more information, see the section called “DB instance storage”.
> During the storage upgrade process, the database engine isn't available. If the storage consumption on your blue DB instance is greater than or equal to 90% of the allocated

storage size, the storage upgrade process will increase the allocated storage size by 10% for the green instance.

This option is only available if your blue database is *not* on the latest storage configuration, or if you're changing the DB instance class within the same request. You can only upgrade the storage configuration when initially creating a blue/green deployment.

Handling lazy loading when you create a blue/green deployment

When you create a blue/green deployment, Amazon RDS creates the primary DB instance in the green environment by restoring from a DB snapshot. After it is created, the green DB instance continues to load data in the background, which is known as *lazy loading*. If the DB instance has read replicas, these are also created from DB snapshots and are subject to lazy loading.

If you access data that hasn't been loaded yet, the DB instance immediately downloads the requested data from Amazon S3, and then continues loading the rest of the data in the background. For more information, see Amazon EBS snapshots.

To help mitigate the effects of lazy loading on tables to which you require quick access, you can perform operations that involve full-table scans, such as `SELECT *`. This operation allows Amazon RDS to download all of the backed-up table data from S3.

If an application attempts to access data that isn't loaded, the application can encounter higher latency than normal while the data is loaded. This higher latency due to lazy loading could lead to poor performance for latency-sensitive workloads.

Important

If you switch over a blue/green deployment before data loading is complete, your application could experience performance issues due to high latency.

Creating a blue/green deployment

You can create a blue/green deployment using the AWS Management Console, the AWS CLI, or the RDS API.

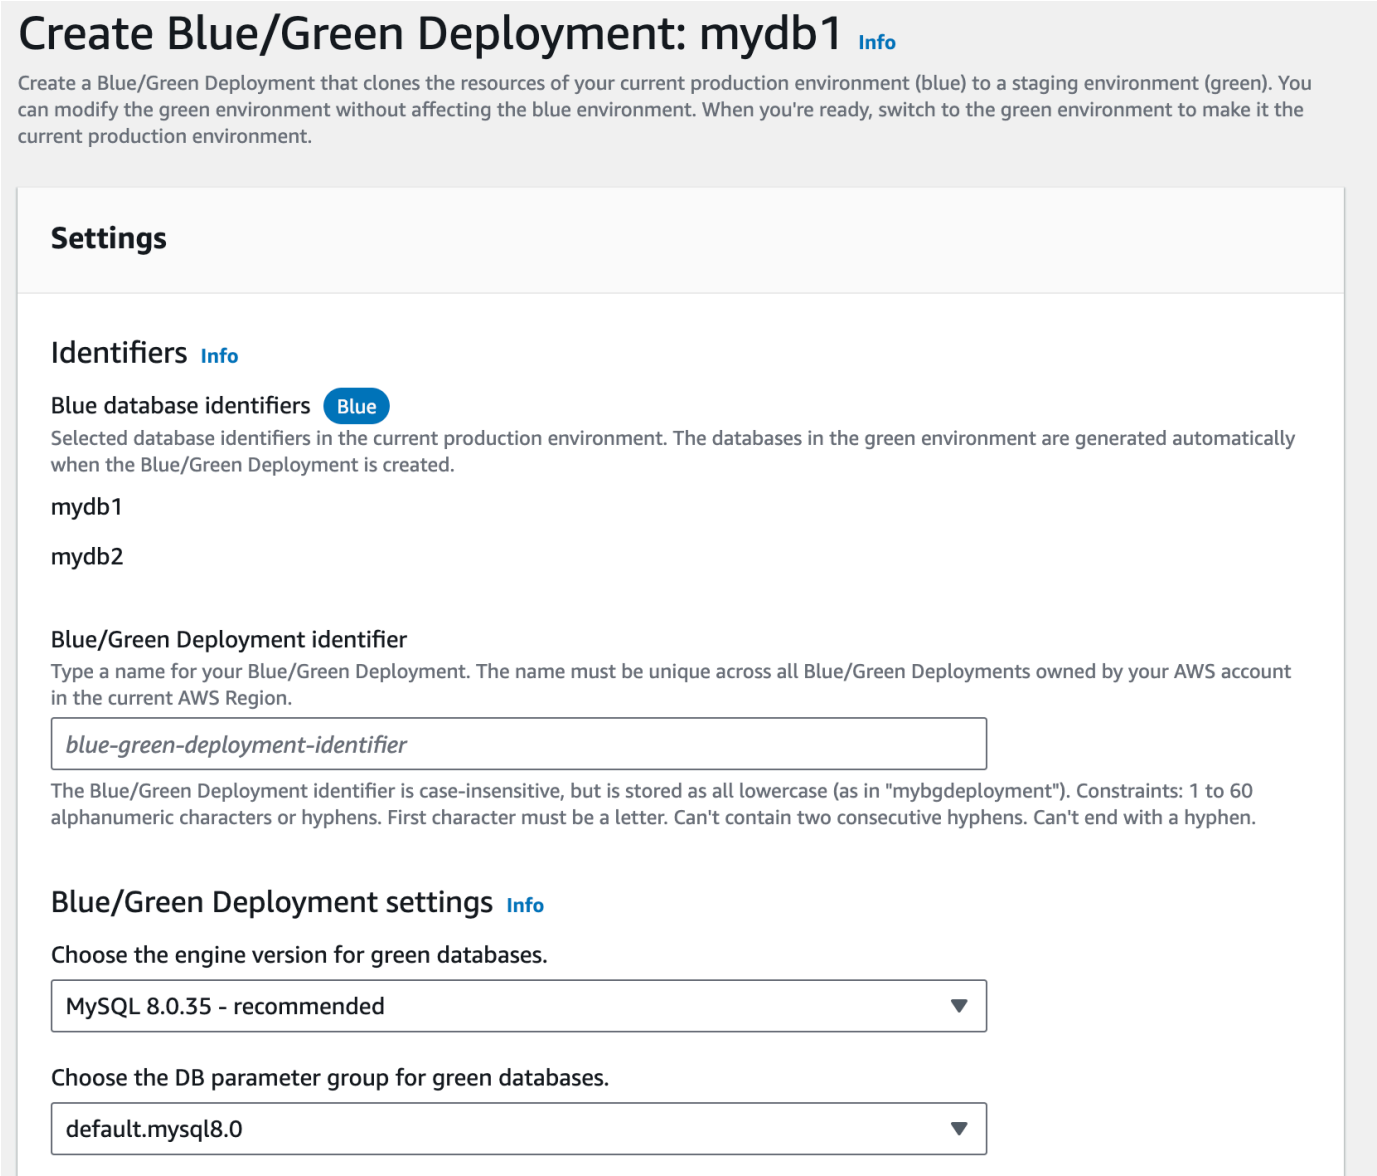
Console

To create a blue/green deployment

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**, and then choose the DB instance that you want to copy to a green environment.
3. Choose **Actions**, **Create Blue/Green Deployment**.

   If you choose an RDS for PostgreSQL DB instance, review and acknowledge the logical replication limitations. For more information, see the section called “PostgreSQL logical replication limitations”.

   The **Create Blue/Green Deployment** page appears.



4. Review the blue database identifiers. Make sure that they match the DB instances that you expect in the blue environment. If they don't, choose **Cancel**.
5. For **Blue/Green Deployment identifier**, enter a name for your blue/green deployment.
6. In the remaining sections, specify the settings for the green environment. For information about each setting, see the section called “Available settings”.

   You can make other modifications to the databases in the green environment after it is deployed.
7. Choose **Create staging environment**.

AWS CLI

To create a blue/green deployment using the AWS CLI, use the create-blue-green-deployment command. For information about each option, see the section called "Available settings".

Example

For Linux, macOS, or Unix:

```
aws rds create-blue-green-deployment \
    --blue-green-deployment-name my-blue-green-deployment \
    --source arn:aws:rds:us-east-2:123456789012:db:mydb1 \
    --target-engine-version 8.0.31 \
    --target-db-parameter-group-name mydbparametergroup
```

For Windows:

```
aws rds create-blue-green-deployment ^
    --blue-green-deployment-name my-blue-green-deployment ^
    --source arn:aws:rds:us-east-2:123456789012:db:mydb1 ^
    --target-engine-version 8.0.31 ^
    --target-db-parameter-group-name mydbparametergroup
```

RDS API

To create a blue/green deployment by using the Amazon RDS API, use the `CreateBlueGreenDeployment` operation. For information about each option, see the section called "Available settings".

Settings for creating blue/green deployments

The following table explains the settings that you can choose when you create a blue/green deployment. For more information about the AWS CLI options, see create-blue-green-deployment. For more information about the RDS API parameters, see CreateBlueGreenDeployment.

Console setting	Setting description	CLI option and RDS API parameter
Blue/Green Deployment identifier	A name for the blue/green deployment.	**CLI option:** `--blue-green-deployment-name`

Console setting	Setting description	CLI option and RDS API parameter
		API parameter: `BlueGreenDeploymentName`

Blue database identifier	The identifier of the instance that you want to copy to the green environment. When using the CLI or API, specify the instance Amazon Resource Name (ARN).	**CLI option:**
		`--source`
		API parameter:
		`Source`

DB parameter group for green databases	A parameter group to associate with the databases in the green environment.	**CLI option:**
		`--target-db-parameter-group-name`
		`--target-db-cluster-parameter-group-name`
		API parameter:
		`TargetDBParameterGroupName`
		`TargetDBClusterParameterGroupName`

Console setting	Setting description	CLI option and RDS API parameter
Enable Optimized Writes for green database	Enable RDS Optimized Writes on the green primary DB instance. For more information, see the section called "Enable RDS Optimized Writes". If you're changing from a DB instance class that doesn't support Optimized Writes to one that does, you also need to perform a storage configuration upgrade. For more information, see the section called "Upgrade the storage configuration".	For the CLI and API, specifying a target DB instance class that supports RDS Optimized Writes automatically enables it on the green primary DB instance.

Engine version for green databases	Upgrade the databases in the green environment to the specified DB engine version.
	
	If not specified, each database in the green environment is created with the same engine version as the corresponding DB instance in the blue environment.
		CLI option:
		
		`--target-engine-version`
		
		RDS API parameter:
		
		`TargetEngineVersion`

Green DB instance class	The compute and memory capacity of each DB instance in the green environment, for example `db.m5d.xlarge` .
	
	This option is only visible when you enable RDS Optimized Writes for the green database.
		CLI option:
		
		`--target-db-instance-class`
		
		RDS API parameter:
		
		`TargetDBInstanceClass`

Console setting	Setting description	CLI option and RDS API parameter

Storage configuration upgrade	Choose whether to upgrade your storage file system configuration. If you enable this setting, RDS migrates the green database from the old storage file system to the preferred configuration.
	
	This option is only available if your blue database is *not* on the latest storage configuration, or if you're enabling RDS Optimized Writes within the same request. You can only upgrade the storage configuration when initially creating a blue/green deployment.
	
	For more information, see the section called “Upgrading the storage file system”.
		CLI option:
		
		`--upgrade-target-storage-config`
		
		RDS API parameter:
		
		`UpgradeTargetStorageConfig`

Viewing a blue/green deployment

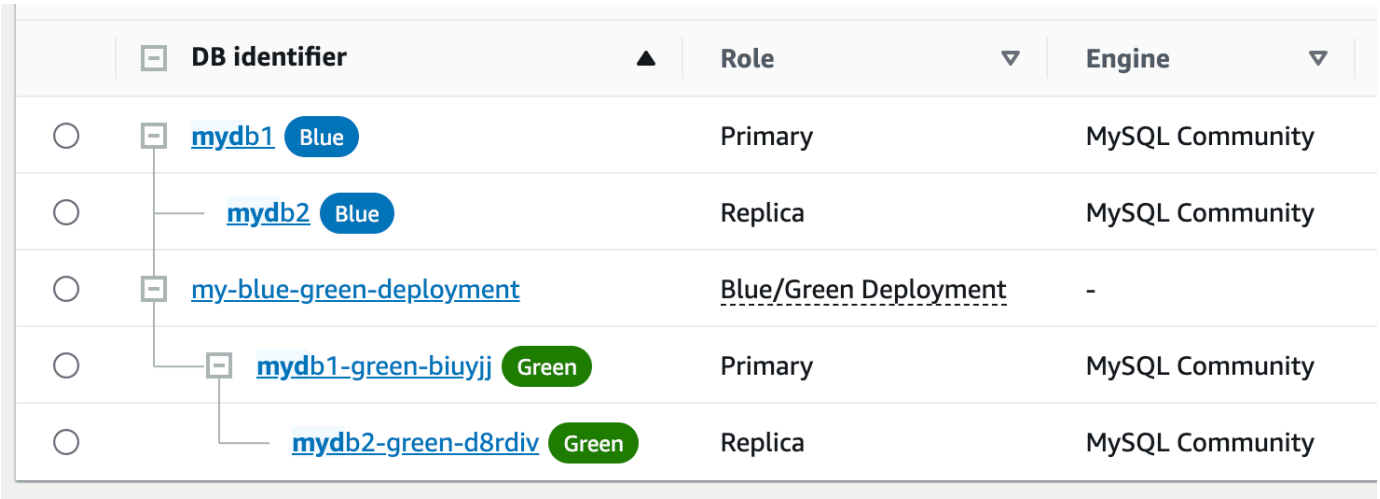
You can view the details about a blue/green deployment using the AWS Management Console, the AWS CLI, or the RDS API.

You can also view and subscribe to events for information about a blue/green deployment. For more information, see Blue/green deployment events.

Console

To view the details about a blue/green deployment

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**, and then find the blue/green deployment in the list.

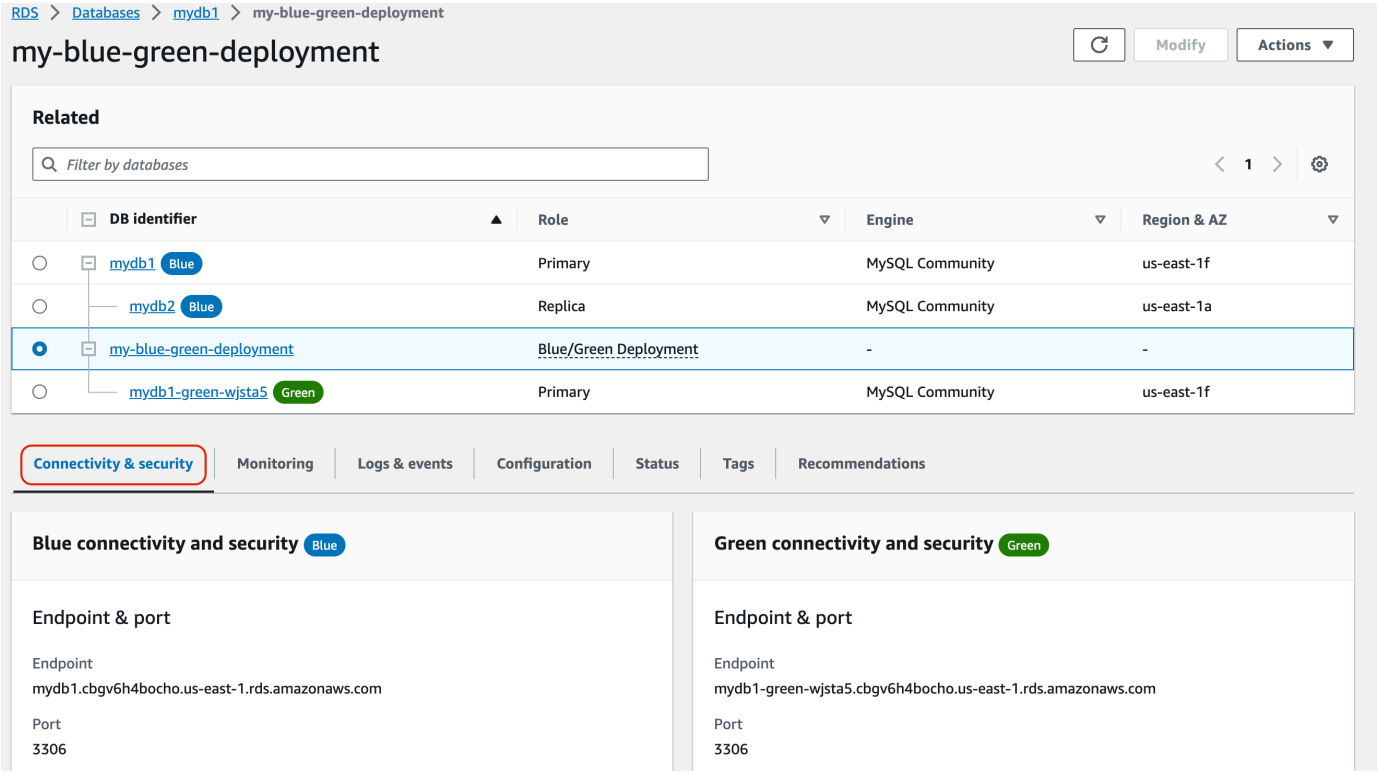


The **Role** value for the blue/green deployment is **Blue/Green Deployment**.

3. Choose the name of blue/green deployment that you want to view to display its details.

Each tab has a section for the blue deployment and a section for the green deployment. For example, on the **Configuration** tab, the DB engine version might be different in the blue environment and in the green environment if you're upgrading the DB engine version in the green environment.

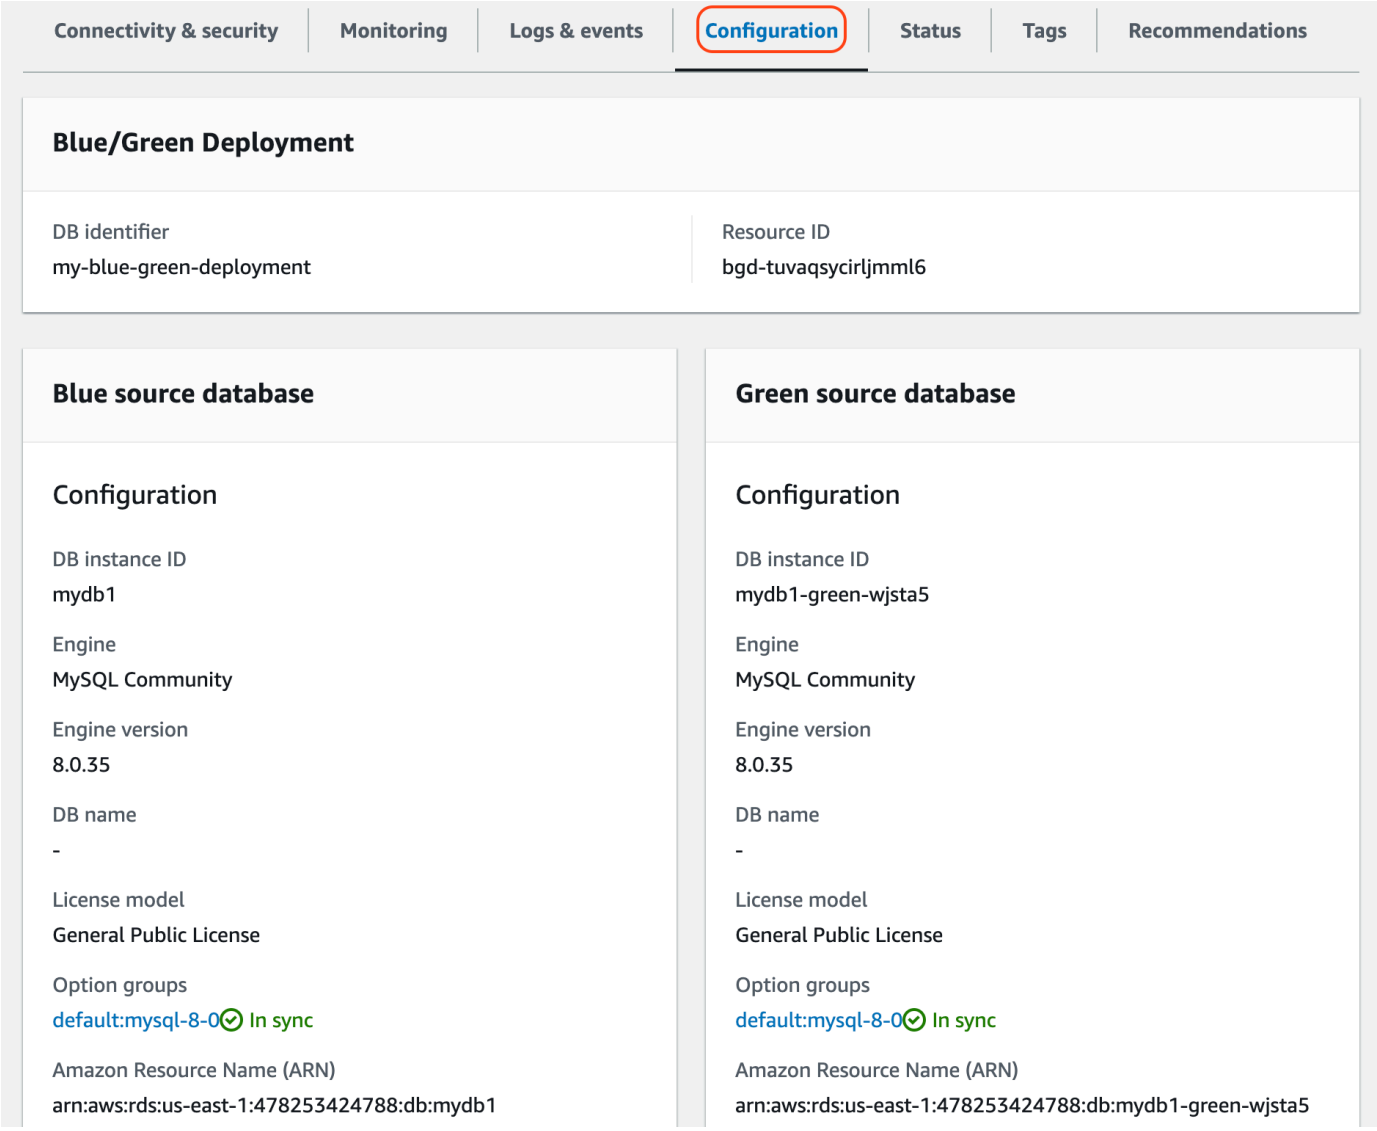
The following image shows an example of the **Connectivity & security** tab:



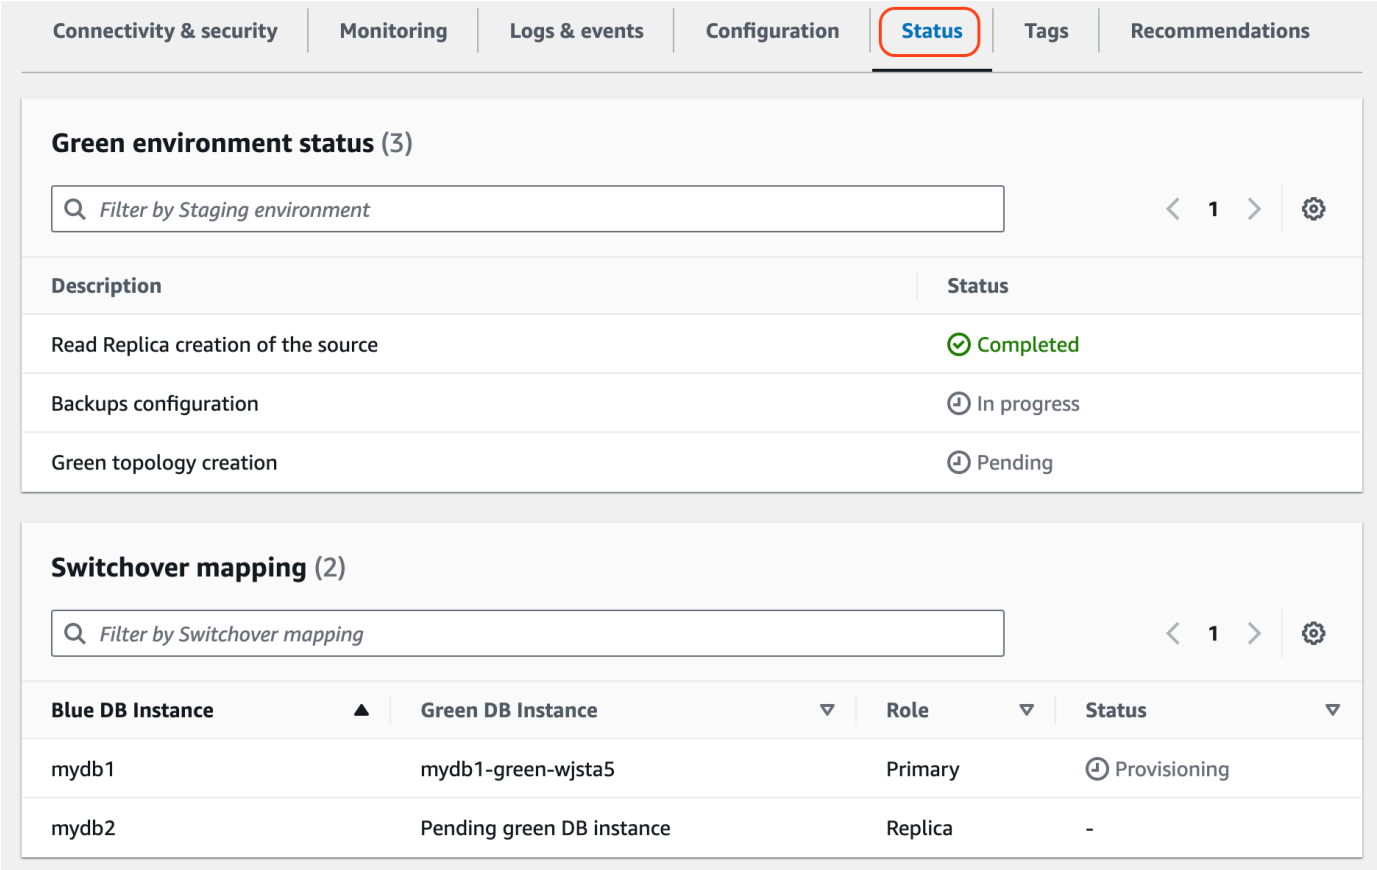
The **Connectivity & security** tab also includes a section called **Replication**, which shows the current state of logical replication and replica lag between the blue and green environments. If the replication state is `Replicating`, the blue/green deployment is replicating successfully.

For RDS for PostgreSQL blue/green deployments, the replication state can change to `Replication degraded` if you make unsupported DDL or large object changes in the blue environment. For more information, see the section called "PostgreSQL logical replication limitations".

The following image shows an example of the **Configuration** tab:



The following image shows an example of the **Status** tab:



AWS CLI

To view the details about a blue/green deployment by using the AWS CLI, use the describe-blue-green-deployments command.

Example View the details about a blue/green deployment by filtering on its name

When you use the describe-blue-green-deployments command, you can filter on the `--blue-green-deployment-name`. The following example shows the details for a blue/green deployment named *`my-blue-green-deployment`*.

```
aws rds describe-blue-green-deployments --filters Name=blue-green-deployment-
name,Values=my-blue-green-deployment
```

Example View the details about a blue/green deployment by specifying its identifier

When you use the describe-blue-green-deployments command, you can specify the `--blue-green-deployment-identifier`. The following example shows the details for a blue/green deployment with the identifier *`bgd-1234567890abcdef`*.

```
aws rds describe-blue-green-deployments --blue-green-deployment-
identifier bgd-1234567890abcdef
```

RDS API

To view the details about a blue/green deployment by using the Amazon RDS API, use the `DescribeBlueGreenDeployments` operation and specify the `BlueGreenDeploymentIdentifier`.

Switching a blue/green deployment

A *switchover* promotes the green environment to be the new production environment. When the green DB instance has read replicas, they are also promoted. Before you switch over, production traffic is routed to the DB instance and read replicas in the blue environment. After you switch over, production traffic is routed to the DB instance and read replicas in the green environment.

Switching over a blue/green deployment is not the same as *promoting* the green DB instance within the blue/green deployment. If you manually promote the green DB instance by choosing **Promote** from the **Actions** menu, replication between the blue and green environments breaks and the blue/green deployment enters a state of **Invalid configuration**.

Topics

Switchover timeout

You can specify a switchover timeout period between 30 seconds and 3,600 seconds (one hour). If the switchover takes longer than the specified duration, then any changes are rolled back and no changes are made to either environment. The default timeout period is 300 seconds (five minutes).

Switchover guardrails

When you start a switchover, Amazon RDS runs some basic checks to test the readiness of the blue and green environments for switchover. These checks are known as *switchover guardrails*. These switchover guardrails prevent a switchover if the environments aren't ready for it. Therefore, they avoid longer than expected downtime and prevent the loss of data between the blue and green environments that might result if the switchover started.

Amazon RDS runs the following guardrail checks on the green environment:

- **Replication health** – Checks if green primary DB instance replication status is healthy. The green primary DB instance is a replica of the blue primary DB instance.
- **Replication lag** – Checks if the replica lag of the green primary DB instance is within allowable limits for switchover. The allowable limits are based on the specified timeout period. Replica lag indicates how far the green primary DB instance is lagging behind its blue primary DB instance. For more information, see the section called “Diagnosing and resolving lag between read replicas” for RDS for MySQL and the section called “Monitoring and tuning the replication process” for RDS for PostgreSQL.
- **Active writes** – Makes sure there are no active writes on the green primary DB instance.

Amazon RDS runs the following guardrail checks on the blue environment:

- **External replication** – For RDS for PostgreSQL, makes sure that the blue environment isn't a self-managed logical source (publisher) or replica (subscriber). If it is, we recommend that you drop the self-managed replication slots and subscriptions across all databases in the blue environment, proceed with switchover, then recreate them to resume replication. For RDS for MySQL and RDS for MariaDB, checks whether the blue database isn't an external binlog replica. If it is, make sure that it is not actively replicating.
- **Long-running active writes** – Makes sure there are no long-running active writes on the blue primary DB instance because they can increase replica lag.
- **Long-running DDL statements** – Makes sure there are no long-running DDL statements on the blue primary DB instance because they can increase replica lag.
- **Unsupported PostgreSQL changes** – For RDS for PostgreSQL DB instances, makes sure that no DDL changes and no additions or modifications of large objects have been performed on the blue environment. For more information, see the section called “PostgreSQL logical replication limitations”.

If Amazon RDS detects unsupported PostgreSQL changes, it changes the replication state to `Replication degraded` and notifies you that switchover is not available for the blue/green deployment. To proceed with switchover, we recommend that you delete and recreate the blue/green deployment and all green databases. To do so, choose **Actions**, **Delete with green databases**.

Switchover actions

When you switch over a blue/green deployment, RDS performs the following actions:

1. Runs guardrail checks to verify if the blue and green environments are ready for switchover.
2. Stops new write operations on the primary DB instance in both environments.
3. Drops connections to the DB instances in both environments and doesn't allow new connections.
4. Waits for replication to catch up in the green environment so that the green environment is in sync with the blue environment.
5. Renames the DB instances in the both environments.

   RDS renames the DB instances in the green environment to match the corresponding DB instances in the blue environment. For example, assume the name of a DB instance in the blue environment is `mydb`. Also assume the name of the corresponding DB instance in the green environment is `mydb-green-abc123`. During switchover, the name of the DB instance in the green environment is changed to `mydb`.

   RDS renames the DB instances in the blue environment by appending `-old`*n* to the current name, where *n* is a number. For example, assume the name of a DB instance in the blue environment is `mydb`. After switchover, the DB instance name might be `mydb-old1`.

   RDS also renames the endpoints in the green environment to match the corresponding endpoints in the blue environment so that application changes aren't required.
6. Allows connections to databases in both environments.
7. Allows write operations on the primary DB instance in the new production environment.

   After switchover, the previous production primary DB instance only allows read operations until you set the `read_only` parameter to `0` and reboot the DB instance.

You can monitor the status of a switchover using Amazon EventBridge. For more information, see the section called "Blue/green deployment events".

If you have tags configured in the blue environment, these tags are copied to the new production environment during switchover. For more information about tags, see Tagging Amazon RDS resources.

If the switchover starts and then stops before finishing for any reason, then any changes are rolled back, and no changes are made to either environment.

Switchover best practices

Before you switch over, we strongly recommend that you adhere to best practices by completing the following tasks:

- Thoroughly test the resources in the green environment. Make sure they function properly and efficiently.
- Monitor relevant Amazon CloudWatch metrics. For more information, see the section called "Verifying CloudWatch metrics before switchover".
- Identify the best time for the switchover.

  During the switchover, writes are cut off from databases in both environments. Identify a time when traffic is lowest on your production environment. Long-running transactions, such as active DDLs, can increase your switchover time, resulting in longer downtime for your production workloads.

  If there's a large number of connections on your DB instances, consider manually reducing them to the minimum amount necessary for your application before you switch over the blue/green deployment. One way to achieve this is to create a script that monitors the status of the blue/green deployment and starts cleaning up connections when it detects that the status has changed to `SWITCHOVER_IN_PROGRESS`.
- Make sure the DB instances in both environments are in `Available` state.
- Make sure the primary DB instance in the green environment is healthy and replicating.
- Make sure that your network and client configurations don't increase the DNS cache Time-To-Live (TTL) beyond five seconds, which is the default for RDS DNS zones.
  Otherwise, applications will continue to send write traffic to the blue environment after switchover.

- Make sure data loading is complete before switching over. For more information, see the section called “Handling lazy loading”.
- For RDS for PostgreSQL DB instances, do the following:
  - Review the logical replication limitations and take any required actions prior to switchover. For more information, see the section called “PostgreSQL logical replication limitations”.
  - Run the `ANALYZE` operation to refresh the `pg_statistics` table. This reduces the risk of performance issues after switchover.

> **Note**
>
> During a switchover, you can't modify any DB instances included in the switchover.

Verifying CloudWatch metrics before switchover

Before you switch over a blue/green deployment, we recommend that you check the values of the following metrics within Amazon CloudWatch.

- `ReplicaLag` – Use this metric to identify the current replication lag on the green environment. To reduce downtime, make sure that this value is close to zero before you switch over.
- `DatabaseConnections` – Use this metric to estimate the level of activity on the blue/green deployment, and make sure that the value is at an acceptable level for your deployment before you switch over. If Performance Insights is turned on, `DBLoad` is a more accurate metric.

For more information about these metrics, see the section called “CloudWatch metrics for RDS”.

Switching over a blue/green deployment

You can switch over a blue/green deployment using the AWS Management Console, the AWS CLI, or the RDS API.

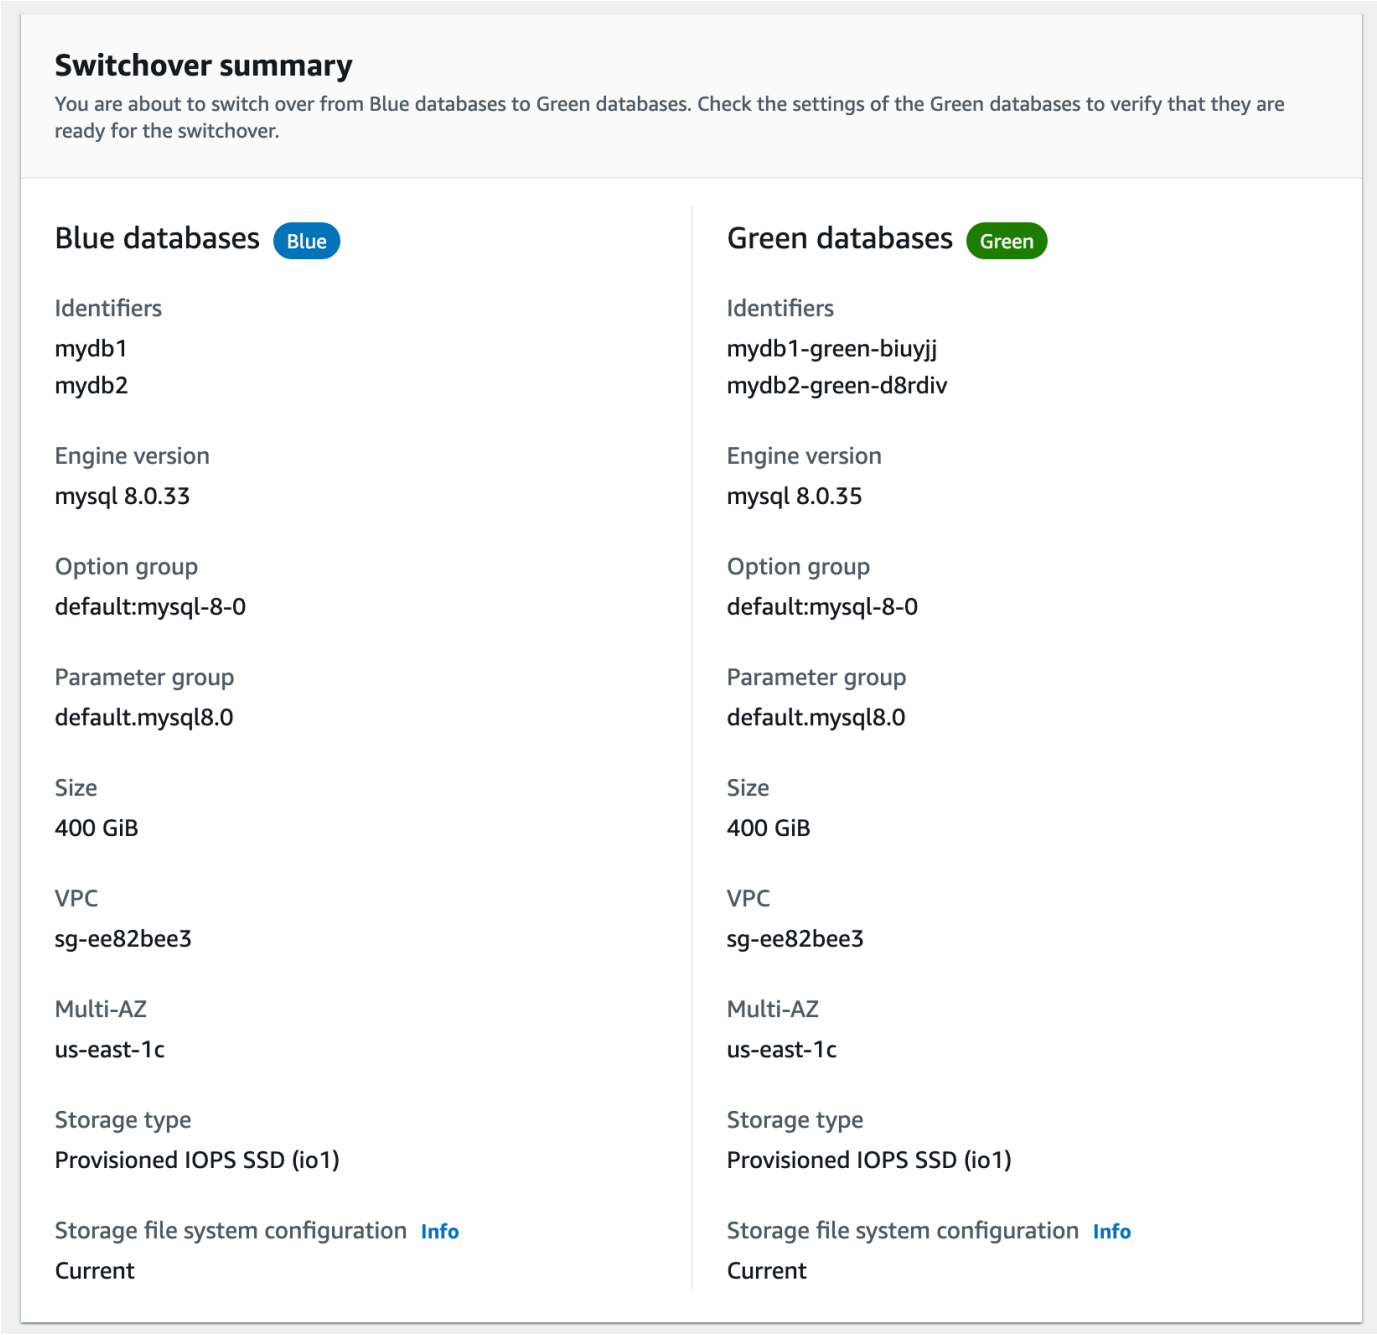
Console

To switch over a blue/green deployment

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.

2. In the navigation pane, choose **Databases**, and then choose the blue/green deployment that you want to switch over.
3. For **Actions**, choose **Switch over**.

   The **Switch over** page appears.



4. On the **Switch over** page, review the switchover summary. Make sure the resources in both environments match what you expect. If they don't, choose **Cancel**.
5. For **Timeout settings**, enter the time limit for switchover.

6. If your instance is running RDS for PostgreSQL, review and acknowledge the pre-switchover recommendations. For more information, see the section called "PostgreSQL logical replication limitations".
7. Choose **Switch over**.

AWS CLI

To switch over a blue/green deployment by using the AWS CLI, use the switchover-blue-green-deployment command with the following options:

- `--blue-green-deployment-identifier` – Specify the resource ID of the blue/green deployment.
- `--switchover-timeout` – Specify the time limit for the switchover, in seconds. The default is 300.

Example Switch over a blue/green deployment

For Linux, macOS, or Unix:

```
aws rds switchover-blue-green-deployment \
    --blue-green-deployment-identifier bgd-1234567890abcdef \
    --switchover-timeout 600
```

For Windows:

```
aws rds switchover-blue-green-deployment ^
    --blue-green-deployment-identifier bgd-1234567890abcdef ^
    --switchover-timeout 600
```

RDS API

To switch over a blue/green deployment by using the Amazon RDS API, use the `SwitchoverBlueGreenDeployment` operation with the following parameters:

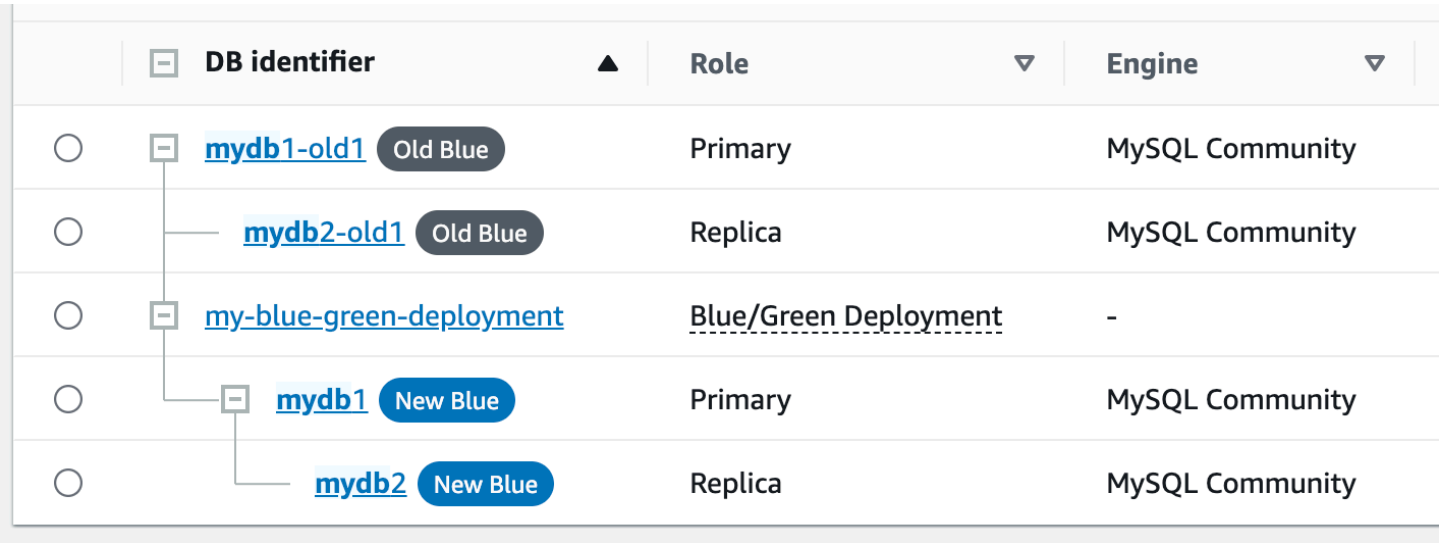
- `BlueGreenDeploymentIdentifier` – Specify the resource ID of the blue/green deployment.
- `SwitchoverTimeout` – Specify the time limit for the switchover, in seconds. The default is 300.

After switchover

After a switchover, the DB instances in the previous blue environment are retained. Standard costs apply to these resources. Replication between the blue and green environments stops.

RDS renames the DB instances in the blue environment by appending `-old`*n* to the current resource name, where *n* is a number. The DB instances are read-only until you set the `read_only` parameter to `0`. RDS names the DB instances in the green environment `-new`*n*.

If you delete the blue/green deployment resource, RDS retains the `-old`*n* and `-new`*n* resources.



Updating the parent node for consumers

After you switch over an RDS for MariaDB or RDS for MySQL blue/green deployment, if the blue DB instance had any external replicas or binary log consumers prior to switchover, you must update their parent node after switchover in order to maintain replication continuity.

After switchover, the DB instance that was previously in the green environment emits an event that contains the master log file name and master log position. For example:

```
aws rds describe-events --output json --source-type db-instance --source-identifier db-instance-identifier

{
    "Events": [
...
        {
            "SourceIdentifier": "db-instance-identifier",
```

```
            "SourceType": "db-instance",
            "Message": "Binary log coordinates in green environment after switchover:
             file mysql-bin-changelog.000003 and position 804",
            "EventCategories": [],
            "Date": "2023-11-10T01:33:41.911Z",
            "SourceArn": "arn:aws:rds:us-east-1:123456789012:db:db-instance-identifier"
        }
    ]
}
```

First, make sure that the consumer or replica has applied all binary logs from the old blue environment. Then, use the provided binary log coordinates to resume application on the consumers. For example, if you're running a MySQL replica on EC2, you can use the `CHANGE MASTER TO` command:

```
CHANGE MASTER TO MASTER_HOST='{new-writer-endpoint}', MASTER_LOG_FILE='mysql-bin-
changelog.000003', MASTER_LOG_POS=804;
```

> **Note**
>
> If the consumer is another RDS for MariaDB or RDS for MariaDB DB instance, you can run the following stored procedures in order: the section called “mysql.rds_stop_replication”, the section called “mysql.rds_reset_external_master”, the section called “mysql.rds_set_external_master”, and the section called “mysql.rds_start_replication”.

Deleting a blue/green deployment

You can delete a blue/green deployment before or after you switch it over.

When you delete a blue/green deployment before switching it over, Amazon RDS optionally deletes the DB instances in the green environment:

- If you choose to delete the DB instances in the green environment (`--delete-target`), they must have deletion protection turned off.
- If you don't delete the DB instances in the green environment (`--no-delete-target`), the instances are retained, but they're no longer part of a blue/green deployment. For RDS for MySQL, replication continues between the environments. For RDS for PostgreSQL, the green environment is promoted to a standalone environment, so replication stops.

The option to delete the green databases isn't available in the console after switchover. When you delete blue/green deployments using the AWS CLI, you can't specify the `--delete-target` option if the deployment status is `SWITCHOVER_COMPLETED`.

> **Important**
>
> Deleting a blue/green deployment doesn't affect the blue environment.

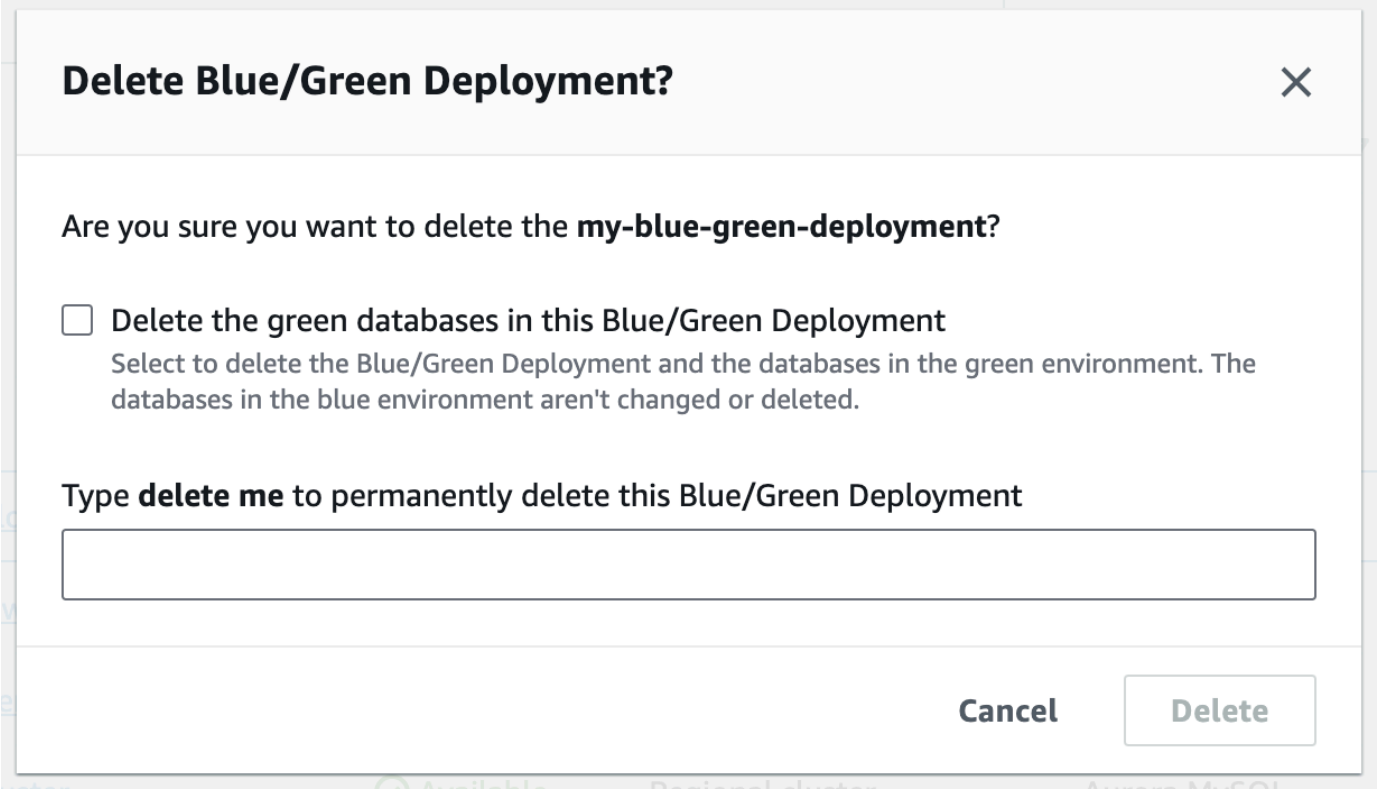
You can delete a blue/green deployment using the AWS Management Console, the AWS CLI, or the RDS API.

Console

To delete a blue/green deployment

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**, and then choose the blue/green deployment that you want to delete.
3. For **Actions**, choose **Delete**.

   The **Delete Blue/Green Deployment?** window appears.



To delete the green databases, select **Delete the green databases in this Blue/Green Deployment**.

4. Enter **`delete me`** in the box.
5. Choose **Delete**.

AWS CLI

To delete a blue/green deployment by using the AWS CLI, use the delete-blue-green-deployment command with the following options:

- `--blue-green-deployment-identifier` – The resource ID of the blue/green deployment to be deleted.
- `--delete-target` – Specifies that the DB instances in the green environment are deleted. You can't specify this option if the blue/green deployment has a status of `SWITCHOVER_COMPLETED`.
- `--no-delete-target` – Specifies that the DB instances in the green environment are retained.

Example Delete a blue/green deployment and the DB instances in the green environment

For Linux, macOS, or Unix:

```
aws rds delete-blue-green-deployment \
    --blue-green-deployment-identifier bgd-1234567890abcdef \
    --delete-target
```

For Windows:

```
aws rds delete-blue-green-deployment ^
    --blue-green-deployment-identifier bgd-1234567890abcdef ^
    --delete-target
```

Example Delete a blue/green deployment but retain the DB instances in the green environment

For Linux, macOS, or Unix:

```
aws rds delete-blue-green-deployment \
    --blue-green-deployment-identifier bgd-1234567890abcdef \
    --no-delete-target
```

For Windows:

```
aws rds delete-blue-green-deployment ^
    --blue-green-deployment-identifier bgd-1234567890abcdef ^
    --no-delete-target
```

RDS API

To delete a blue/green deployment by using the Amazon RDS API, use the `DeleteBlueGreenDeployment` operation with the following parameters:

- `BlueGreenDeploymentIdentifier` – The resource ID of the blue/green deployment to be deleted.
- `DeleteTarget` – Specify `TRUE` to delete the DB instances in the green environment or `FALSE` to retain them. Cannot be `TRUE` if the blue/green deployment has a status of `SWITCHOVER_COMPLETED`.

Backing up, restoring, and exporting data

This section shows how to back up, restore, and export data from an Amazon RDS DB instance or Multi-AZ DB cluster.

Topics

Introduction to backups

Amazon RDS creates and saves automated backups of your DB instance or Multi-AZ DB cluster during the backup window of your DB instance. RDS creates a storage volume snapshot of your DB instance, backing up the entire DB instance and not just individual databases. RDS saves the automated backups of your DB instance according to the backup retention period that you specify. If necessary, you can recover your DB instance to any point in time during the backup retention period.

Automated backups follow these rules:

- Your DB instance must be in the `available` state for automated backups to occur. Automated backups don't occur while your DB instance is in a state other than `available`, for example, `storage_full`.
- Automated backups don't occur while a DB snapshot copy is running in the same AWS Region for the same database.

You can also back up your DB instance manually by creating a DB snapshot. For more information about manually creating a DB snapshot, see Creating a DB snapshot for a Single-AZ DB instance.

The first snapshot of a DB instance contains the data for the full database. Subsequent snapshots of the same database are incremental, which means that only the data that has changed after your most recent snapshot is saved.

You can copy both automatic and manual DB snapshots, and share manual DB snapshots. For more information about copying a DB snapshot, see Copying a DB snapshot. For more information about sharing a DB snapshot, see Sharing a DB snapshot.

Backup storage

Your Amazon RDS backup storage for each AWS Region is composed of the automated backups and manual DB snapshots for that Region. Total backup storage space equals the sum of the storage for all backups in that Region. Moving a DB snapshot to another Region increases the backup storage in the destination Region. Backups are stored in Amazon S3.

For more information about backup storage costs, see Amazon RDS pricing.

If you choose to retain automated backups when you delete a DB instance, the automated backups are saved for the full retention period. If you don't choose **Retain automated backups** when you

delete a DB instance, all automated backups are deleted with the DB instance. After they are deleted, the automated backups can't be recovered. If you choose to have Amazon RDS create a final DB snapshot before it deletes your DB instance, you can use that to recover your DB instance. Optionally, you can use a previously created manual snapshot. Manual snapshots are not deleted. You can have up to 100 manual snapshots per Region.

Managing automated backups

This section shows how to manage automated backups for DB instances and Multi-AZ DB clusters.

Topics

Backup window

Automated backups occur daily during the preferred backup window. If the backup requires more time than allotted to the backup window, the backup continues after the window ends until it finishes. The backup window can't overlap with the weekly maintenance window for the DB instance or Multi-AZ DB cluster.

During the automatic backup window, storage I/O might be suspended briefly while the backup process initializes (typically under a few seconds). You might experience elevated latencies for a few minutes during backups for Multi-AZ deployments. For MariaDB, MySQL, Oracle, and PostgreSQL, I/O activity isn't suspended on your primary during backup for Multi-AZ deployments because the backup is taken from the standby. For SQL Server, I/O activity is suspended briefly during backup for both Single-AZ and Multi-AZ deployments because the backup is taken from the primary. For Db2, I/O activity is also suspended briefly during backup even though the backup is taken from the standby.

Automated backups might occasionally be skipped if the DB instance or cluster has a heavy workload at the time a backup is supposed to start. If a backup is skipped, you can still do a point-in-time-recovery (PITR), and a backup is still attempted during the next backup window. For more information on PITR, see Restoring a DB instance to a specified time.

If you don't specify a preferred backup window when you create the DB instance or Multi-AZ DB cluster, Amazon RDS assigns a default 30-minute backup window. This window is selected at random from an 8-hour block of time for each AWS Region. The following table lists the time blocks for each AWS Region from which the default backup windows are assigned.

Region Name	Region	Time Block
US East (N. Virginia)	us-east-1	03:00–11:00 UTC
US East (Ohio)	us-east-2	03:00–11:00 UTC
US West (N. California)	us-west-1	06:00–14:00 UTC
US West (Oregon)	us-west-2	06:00–14:00 UTC
Africa (Cape Town)	af-south-1	03:00–11:00 UTC
Asia Pacific (Hong Kong)	ap-east-1	06:00–14:00 UTC
Asia Pacific (Hyderabad)	ap-south-2	06:30–14:30 UTC
Asia Pacific (Jakarta)	ap-southeast-3	08:00–16:00 UTC
Asia Pacific (Malaysia)	ap-southeast-5	09:00–17:00 UTC
Asia Pacific (Melbourne)	ap-southeast-4	11:00–19:00 UTC
Asia Pacific (Mumbai)	ap-south-1	16:30–00:30 UTC
Asia Pacific (Osaka)	ap-northeast-3	00:00–08:00 UTC
Asia Pacific (Seoul)	ap-northeast-2	13:00–21:00 UTC
Asia Pacific (Singapore)	ap-southeast-1	14:00–22:00 UTC

Region Name	Region	Time Block
Asia Pacific (Sydney)	ap-southeast-2	12:00–20:00 UTC
Asia Pacific (Tokyo)	ap-northeast-1	13:00–21:00 UTC
Canada (Central)	ca-central-1	03:00–11:00 UTC
Canada West (Calgary)	ca-west-1	18:00–02:00 UTC
China (Beijing)	cn-north-1	06:00–14:00 UTC
China (Ningxia)	cn-northwest-1	06:00–14:00 UTC
Europe (Frankfurt)	eu-central-1	20:00–04:00 UTC
Europe (Ireland)	eu-west-1	22:00–06:00 UTC
Europe (London)	eu-west-2	22:00–06:00 UTC
Europe (Milan)	eu-south-1	02:00–10:00 UTC
Europe (Paris)	eu-west-3	07:29–14:29 UTC
Europe (Spain)	eu-south-2	02:00–10:00 UTC
Europe (Stockholm)	eu-north-1	23:00–07:00 UTC
Europe (Zurich)	eu-central-2	02:00–10:00 UTC
Israel (Tel Aviv)	il-central-1	03:00–11:00 UTC
Middle East (Bahrain)	me-south-1	06:00–14:00 UTC
Middle East (UAE)	me-central-1	05:00–13:00 UTC
South America (São Paulo)	sa-east-1	23:00–07:00 UTC
AWS GovCloud (US-East)	us-gov-east-1	17:00–01:00 UTC

Region Name	Region	Time Block
AWS GovCloud (US-West)	us-gov-west-1	06:00–14:00 UTC

Backup retention period

You can set the backup retention period when you create a DB instance or Multi-AZ DB cluster. If you create a DB instance using the Amazon RDS API or the AWS CLI and if you don't set the backup retention period, the default backup retention period is one day. If you create a DB instance using the console, the default backup retention period is seven days.

After you create a DB instance or cluster, you can modify the backup retention period. You can set the backup retention period of a DB instance to between 0 and 35 days. Setting the backup retention period to 0 disables automated backups. For a Multi-AZ DB cluster, you can set the backup retention period to between 1 and 35 days. Manual snapshot limits (100 per Region) don't apply to automated backups.

Important

An outage occurs if you change the backup retention period of a DB instance from 0 to a nonzero value or from a nonzero value to 0.

RDS doesn't include time spent in the `stopped` state when the backup retention period is calculated. Automated backups aren't created while a DB instance or cluster is stopped. Backups can be retained longer than the backup retention period if a DB instance has been stopped.

Enabling automated backups

If your DB instance doesn't have automated backups enabled, you can enable them at any time. You enable automated backups by setting the backup retention period to a positive nonzero value. When automated backups are turned on, your DB instance is taken offline and a backup is immediately created.

> **Note**
>
> If you manage your backups in AWS Backup, you can't enable automated backups. For more information, see Using AWS Backup to manage automated backups.

Console

To enable automated backups immediately

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**, and then choose the DB instance or Multi-AZ DB cluster that you want to modify.
3. Choose **Modify**.
4. For **Backup retention period**, choose a positive nonzero value, for example 3 days.
5. Choose **Continue**.
6. Choose **Apply immediately**.
7. Choose **Modify DB instance** or **Modify cluster** to save your changes and enable automated backups.

AWS CLI

To enable automated backups, use the AWS CLI `modify-db-instance` or `modify-db-cluster` command.

Include the following parameters:

- `--db-instance-identifier` (or `--db-cluster-identifier` for a Multi-AZ DB cluster)
- `--backup-retention-period`
- `--apply-immediately` or `--no-apply-immediately`

In the following example, we enable automated backups by setting the backup retention period to three days. The changes are applied immediately.

Example

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier mydbinstance  \
    --backup-retention-period 3 \
    --apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier mydbinstance  ^
    --backup-retention-period 3 ^
    --apply-immediately
```

RDS API

To enable automated backups, use the RDS API `ModifyDBInstance` or `ModifyDBCluster` operation with the following required parameters:

- `DBInstanceIdentifier` or `DBClusterIdentifier`
- `BackupRetentionPeriod`

Viewing automated backups

To view your automated backups, choose **Automated backups** in the navigation pane. To view individual snapshots associated with an automated backup, choose **Snapshots** in the navigation pane. Alternatively, you can describe individual snapshots associated with an automated backup. From there, you can restore a DB instance directly from one of those snapshots.

To describe the automated backups for your existing DB instances using the AWS CLI, use one of the following commands:

```
aws rds describe-db-instance-automated-backups --db-instance-
identifier DBInstanceIdentifier
```

or

```
aws rds describe-db-instance-automated-backups --dbi-resource-id DbiResourceId
```

To describe the retained automated backups for your existing DB instances using the RDS API, call the `DescribeDBInstanceAutomatedBackups` action with one of the following parameters:

- `DBInstanceIdentifier`
- `DbiResourceId`

Retaining automated backups

> **Note**
>
> You can only retain automated backups of DB instances, not Multi-AZ DB clusters.

When you delete a DB instance, you can choose to retain automated backups. Automated backups can be retained for a number of days equal to the backup retention period configured for the DB instance at the time when you delete it.

Retained automated backups contain system snapshots and transaction logs from a DB instance. They also include your DB instance properties like allocated storage and DB instance class, which are required to restore it to an active instance.

Retained automated backups and manual snapshots incur billing charges until they're deleted. For more information, see Retention costs.

You can retain automated backups for RDS instances running the Db2, MariaDB, MySQL, PostgreSQL, Oracle, and Microsoft SQL Server engines.

You can restore or remove retained automated backups using the AWS Management Console, RDS API, and AWS CLI.

Topics

- Limitations

Retention period

The system snapshots and transaction logs in a retained automated backup expire the same way that they expire for the source DB instance. Because there are no new snapshots or logs created for this instance, the retained automated backups eventually expire completely. Effectively, they live as long their last system snapshot would have done, based on the settings for retention period the source instance had when you deleted it. Retained automated backups are removed by the system after their last system snapshot expires.

You can remove a retained automated backup in the same way that you can delete a DB instance. You can remove retained automated backups using the console or the RDS API operation `DeleteDBInstanceAutomatedBackup`.

Final snapshots are independent of retained automated backups. We strongly suggest that you take a final snapshot even if you retain automated backups because the retained automated backups eventually expire. The final snapshot doesn't expire.

Viewing retained backups

To view your retained automated backups, choose **Automated backups** in the navigation pane, then choose **Retained**. To view individual snapshots associated with a retained automated backup, choose **Snapshots** in the navigation pane. Alternatively, you can describe individual snapshots associated with a retained automated backup. From there, you can restore a DB instance directly from one of those snapshots.

To describe your retained automated backups using the AWS CLI, use the following command:

```
aws rds describe-db-instance-automated-backups --dbi-resource-id DbiResourceId
```

To describe your retained automated backups using the RDS API, call the `DescribeDBInstanceAutomatedBackups` action with the `DbiResourceId` parameter.

Restoration

For information on restoring DB instances from automated backups, see Restoring a DB instance to a specified time.

Retention costs

The cost of a retained automated backup is the cost of total storage of the system snapshots that are associated with it. There is no additional charge for transaction logs or instance metadata. All other pricing rules for backups apply to restorable instances.

For example, suppose that your total allocated storage of running instances is 100 GB. Suppose also that you have 50 GB of manual snapshots plus 75 GB of system snapshots associated with a retained automated backup. In this case, you are charged only for the additional 25 GB of backup storage, like this: (50 GB + 75 GB) – 100 GB = 25 GB.

Limitations

The following limitations apply to retained automated backups:

- The maximum number of retained automated backups in one AWS Region is 40. It's not included in the DB instances quota. You can have 40 running DB instances and an additional 40 retained automated backups at the same time.
- Retained automated backups don't contain information about parameters or option groups.
- You can restore a deleted instance to a point in time that is within the retention period at the time of deletion.
- You can't modify a retained automated backup. That's because it consists of system backups, transaction logs, and the DB instance properties that existed at the time that you deleted the source instance.

Deleting retained automated backups

You can delete retained automated backups when they are no longer needed.

Console

To delete a retained automated backup

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Automated backups**.
3. On the **Retained** tab, choose the retained automated backup that you want to delete.

4. For **Actions**, choose **Delete**.
5. On the confirmation page, enter **`delete me`** and choose **Delete**.

AWS CLI

You can delete a retained automated backup by using the AWS CLI command delete-db-instance-automated-backup with the following option:

- `--dbi-resource-id` – The resource identifier for the source DB instance.

  You can find the resource identifier for the source DB instance of a retained automated backup by running the AWS CLI command describe-db-instance-automated-backups.

Example

The following example deletes the retained automated backup with source DB instance resource identifier db-123ABCEXAMPLE.

For Linux, macOS, or Unix:

```
aws rds delete-db-instance-automated-backup \
    --dbi-resource-id db-123ABCEXAMPLE
```

For Windows:

```
aws rds delete-db-instance-automated-backup ^
    --dbi-resource-id db-123ABCEXAMPLE
```

RDS API

You can delete a retained automated backup by using the Amazon RDS API operation DeleteDBInstanceAutomatedBackup with the following parameter:

- `DbiResourceId` – The resource identifier for the source DB instance.

  You can find the resource identifier for the source DB instance of a retained automated backup using the Amazon RDS API operation DescribeDBInstanceAutomatedBackups.

Disabling automated backups

You might want to temporarily disable automated backups in certain situations, for example while loading large amounts of data.

> **Important**
>
> We highly discourage disabling automated backups because it disables point-in-time recovery. Disabling automatic backups for a DB instance or Multi-AZ DB cluster deletes all existing automated backups for the database. If you disable and then re-enable automated backups, you can restore starting only from the time you re-enabled automated backups.

Console

To disable automated backups immediately

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**, and then choose the DB instance or Multi-AZ DB cluster that you want to modify.
3. Choose **Modify**.
4. For **Backup retention period**, choose **0 days**.
5. Choose **Continue**.
6. Choose **Apply immediately**.
7. Choose **Modify DB instance** or **Modify cluster** to save your changes and disable automated backups.

AWS CLI

To disable automated backups immediately, use the modify-db-instance or modify-db-cluster command and set the backup retention period to 0 with `--apply-immediately`.

Example

The following example immediately disables automatic backups on a Multi-AZ DB cluster.

For Linux, macOS, or Unix:

```
aws rds modify-db-cluster \
    --db-cluster-identifier mydbcluster \
    --backup-retention-period 0 \
    --apply-immediately
```

For Windows:

```
aws rds modify-db-cluster ^
    --db-cluster-identifier mydbcluster ^
    --backup-retention-period 0 ^
    --apply-immediately
```

To know when the modification is in effect, call `describe-db-instances` for the DB instance (or `describe-db-clusters` for a Multi-AZ DB cluster) until the value for backup retention period is 0 and `mydbcluster` status is available.

```
aws rds describe-db-clusters --db-cluster-identifier mydcluster
```

RDS API

To disable automated backups immediately, call the ModifyDBInstance or ModifyDBCluster operation with the following parameters:

- `DBInstanceIdentifier = mydbinstance` (or `DBClusterIdentifier = mydbcluster`)
- `BackupRetentionPeriod = 0`

Example

```
https://rds.amazonaws.com/
    ?Action=ModifyDBInstance
    &DBInstanceIdentifier=mydbinstance
    &BackupRetentionPeriod=0
    &SignatureVersion=2
    &SignatureMethod=HmacSHA256
    &Timestamp=2009-10-14T17%3A48%3A21.746Z
    &AWSAccessKeyId=<&AWS; Access Key ID>
    &Signature=<Signature>
```

Automated backups with unsupported MySQL storage engines

For the MySQL DB engine, automated backups are only supported for the InnoDB storage engine. Using these features with other MySQL storage engines, including MyISAM, can lead to unreliable behavior when you're restoring from backups. Specifically, since storage engines like MyISAM don't support reliable crash recovery, your tables can be corrupted in the event of a crash. For this reason, we encourage you to use the InnoDB storage engine.

- To convert existing MyISAM tables to InnoDB tables, you can use the `ALTER TABLE` command, for example: `ALTER TABLE table_name ENGINE=innodb, ALGORITHM=COPY;`
- If you choose to use MyISAM, you can attempt to manually repair tables that become damaged after a crash by using the `REPAIR` command. For more information, see REPAIR TABLE statement in the MySQL documentation. However, as noted in the MySQL documentation, there is a good chance that you might not be able to recover all your data.
- If you want to take a snapshot of your MyISAM tables before restoring, follow these steps:

  1. Stop all activity to your MyISAM tables (that is, close all sessions).

     You can close all sessions by calling the mysql.rds_kill command for each process that is returned from the `SHOW FULL PROCESSLIST` command.

  2. Lock and flush each of your MyISAM tables. For example, the following commands lock and flush two tables named `myisam_table1` and `myisam_table2`:

     ```
     mysql> FLUSH TABLES myisam_table, myisam_table2 WITH READ LOCK;
     ```

  3. Create a snapshot of your DB instance or Multi-AZ DB cluster. When the snapshot has completed, release the locks and resume activity on the MyISAM tables. You can release the locks on your tables using the following command:

     ```
     mysql> UNLOCK TABLES;
     ```

  These steps force MyISAM to flush data stored in memory to disk, which ensures a clean start when you restore from a DB snapshot. For more information on creating a DB snapshot, see Creating a DB snapshot for a Single-AZ DB instance.

Automated backups with unsupported MariaDB storage engines

For the MariaDB DB engine, automated backups are only supported with the InnoDB storage engine. Using these features with other MariaDB storage engines, including Aria, can lead to unreliable behavior when you're restoring from backups. Even though Aria is a crash-resistant alternative to MyISAM, your tables can still be corrupted in the event of a crash. For this reason, we encourage you to use the InnoDB storage engine.

- To convert existing Aria tables to InnoDB tables, you can use the `ALTER TABLE` command. For example: `ALTER TABLE table_name ENGINE=innodb, ALGORITHM=COPY;`
- If you choose to use Aria, you can attempt to manually repair tables that become damaged after a crash by using the `REPAIR TABLE` command. For more information, see http://mariadb.com/kb/en/mariadb/repair-table/.
- If you want to take a snapshot of your Aria tables before restoring, follow these steps:
  1. Stop all activity to your Aria tables (that is, close all sessions).
  2. Lock and flush each of your Aria tables.
  3. Create a snapshot of your DB instance or Multi-AZ DB cluster. When the snapshot has completed, release the locks and resume activity on the Aria tables. These steps force Aria to flush data stored in memory to disk, thereby ensuring a clean start when you restore from a DB snapshot.

Replicating automated backups to another AWS Region

For added disaster recovery capability, you can configure your Amazon RDS database instance to replicate snapshots and transaction logs to a destination AWS Region of your choice. When backup replication is configured for a DB instance, RDS initiates a cross-Region copy of all snapshots and transaction logs as soon as they are ready on the DB instance.

DB snapshot copy charges apply to the data transfer. After the DB snapshot is copied, standard charges apply to storage in the destination Region. For more details, see RDS Pricing.

For an example of using backup replication, see the AWS online tech talk Managed Disaster Recovery with Amazon RDS for Oracle Cross-Region Automated Backups.

> **Note**
>
> Automated backup replication is not supported for Multi-AZ DB clusters.

Topics

Region and version availability

Feature availability and support varies across specific versions of each database engine, and across AWS Regions. For more information on version and Region availability with cross-Region automated backups, see Supported Regions and DB engines for cross-Region automated backups in Amazon RDS.

Source and destination AWS Region support

Backup replication is supported between the following AWS Regions.

Source Region	Destination Regions available
Asia Pacific (Mumbai)	Asia Pacific (Singapore) US East (N. Virginia), US East (Ohio), US West (Oregon)
Asia Pacific (Osaka)	Asia Pacific (Tokyo)
Asia Pacific (Seoul)	Asia Pacific (Singapore), Asia Pacific (Tokyo) US East (N. Virginia), US East (Ohio), US West (Oregon)
Asia Pacific (Singapore)	Asia Pacific (Mumbai), Asia Pacific (Seoul), Asia Pacific (Sydney), Asia Pacific (Tokyo) US East (N. Virginia), US East (Ohio), US West (Oregon)
Asia Pacific (Sydney)	Asia Pacific (Singapore) US East (N. Virginia), US West (N. California), US West (Oregon)
Asia Pacific (Tokyo)	Asia Pacific (Osaka), Asia Pacific (Seoul), Asia Pacific (Singapore) US East (N. Virginia), US East (Ohio), US West (Oregon)
Canada (Central)	Europe (Ireland) US East (N. Virginia), US East (Ohio), US West (N. California), US West (Oregon)
China (Beijing)	China (Ningxia)
China (Ningxia)	China (Beijing)
Europe (Frankfurt)	Europe (Ireland), Europe (London), Europe (Paris), Europe (Stockholm) US East (N. Virginia), US East (Ohio), US West (Oregon)
Europe (Ireland)	Canada (Central)

Source Region	Destination Regions available
	Europe (Frankfurt), Europe (London), Europe (Paris), Europe (Stockholm) US East (N. Virginia), US East (Ohio), US West (N. California), US West (Oregon)
Europe (London)	Europe (Frankfurt), Europe (Ireland), Europe (Paris), Europe (Stockholm) US East (N. Virginia)
Europe (Paris)	Europe (Frankfurt), Europe (Ireland), Europe (London), Europe (Stockholm) US East (N. Virginia)
Europe (Stockholm)	Europe (Frankfurt), Europe (Ireland), Europe (London), Europe (Paris) US East (N. Virginia)
South America (São Paulo)	US East (N. Virginia), US East (Ohio)
AWS GovCloud (US-East)	AWS GovCloud (US-West)
AWS GovCloud (US-West)	AWS GovCloud (US-East)
US East (N. Virginia)	Asia Pacific (Mumbai), Asia Pacific (Seoul), Asia Pacific (Singapore), Asia Pacific (Sydney), Asia Pacific (Tokyo) Canada (Central) Europe (Frankfurt), Europe (Ireland), Europe (London), Europe (Paris), Europe (Stockholm) South America (São Paulo) US East (Ohio), US West (N. California), US West (Oregon)

Source Region	Destination Regions available
US East (Ohio)	Asia Pacific (Mumbai), Asia Pacific (Seoul), Asia Pacific (Singapore), Asia Pacific (Tokyo) Canada (Central) Europe (Frankfurt), Europe (Ireland) South America (São Paulo) US East (N. Virginia), US West (N. California), US West (Oregon)
US West (N. California)	Asia Pacific (Sydney) Canada (Central) Europe (Ireland) US East (N. Virginia), US East (Ohio), US West (Oregon)
US West (Oregon)	Asia Pacific (Mumbai), Asia Pacific (Seoul), Asia Pacific (Singapore), Asia Pacific (Sydney), Asia Pacific (Tokyo) Canada (Central) Europe (Frankfurt), Europe (Ireland) US East (N. Virginia), US East (Ohio), US West (N. California)

You can also use the `describe-source-regions` AWS CLI command to find out which AWS Regions can replicate to each other. For more information, see Finding information about replicated backups.

Enabling cross-Region automated backups

You can enable backup replication on new or existing DB instances using the Amazon RDS console. You can also use the `start-db-instance-automated-backups-replication` AWS CLI command or the `StartDBInstanceAutomatedBackupsReplication` RDS API operation. You can replicate up to 20 backups to each destination AWS Region for each AWS account.

> **Note**
>
> To be able to replicate automated backups, make sure to enable them. For more information, see Enabling automated backups.

Console

You can enable backup replication for a new or existing DB instance:

- For a new DB instance, enable it when you launch the instance. For more information, see Settings for DB instances.
- For an existing DB instance, use the following procedure.

To enable backup replication for an existing DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Automated backups**.
3. On the **Current Region** tab, choose the DB instance for which you want to enable backup replication.
4. For **Actions**, choose **Manage cross-Region replication**.
5. Under **Backup replication**, choose **Enable replication to another AWS Region**.
6. Choose the **Destination Region**.
7. Choose the **Replicated backup retention period**.
8. If you've enabled encryption on the source DB instance, choose the **AWS KMS key** for encrypting the backups or enter a key ARN.
9. Choose **Save**.

In the source Region, replicated backups are listed on the **Current Region** tab of the **Automated backups** page. In the destination Region, replicated backups are listed on the **Replicated backups** tab of the **Automated backups** page.

AWS CLI

Enable backup replication by using the `start-db-instance-automated-backups-replication` AWS CLI command.

The following CLI example replicates automated backups from a DB instance in the US West (Oregon) Region to the US East (N. Virginia) Region. It also encrypts the replicated backups, using an AWS KMS key in the destination Region.

To enable backup replication

- Run one of the following commands.

  For Linux, macOS, or Unix:

```
aws rds start-db-instance-automated-backups-replication \
--region us-east-1 \
--source-db-instance-arn "arn:aws:rds:us-west-2:123456789012:db:mydatabase" \
--kms-key-id "arn:aws:kms:us-east-1:123456789012:key/AKIAIOSFODNN7EXAMPLE" \
--backup-retention-period 7
```

  For Windows:

```
aws rds start-db-instance-automated-backups-replication ^
--region us-east-1 ^
--source-db-instance-arn "arn:aws:rds:us-west-2:123456789012:db:mydatabase" ^
--kms-key-id "arn:aws:kms:us-east-1:123456789012:key/AKIAIOSFODNN7EXAMPLE" ^
--backup-retention-period 7
```

  The `--source-region` option is required when you encrypt backups between the AWS GovCloud (US-East) and AWS GovCloud (US-West) Regions. For `--source-region`, specify the AWS Region of the source DB instance.

  If `--source-region` isn't specified, make sure to specify a `--pre-signed-url` value. A *presigned URL* is a URL that contains a Signature Version 4 signed request for the `start-db-instance-automated-backups-replication` command that is called in the source AWS Region. To learn more about the `pre-signed-url` option, see start-db-instance-automated-backups-replication in the *AWS CLI Command Reference*.

RDS API

Enable backup replication by using the `StartDBInstanceAutomatedBackupsReplication` RDS API operation with the following parameters:

- `Region` (if you aren't calling the API operation from the destination Region)
- `SourceDBInstanceArn`
- `BackupRetentionPeriod`
- `KmsKeyId` (optional)
- `PreSignedUrl` (required if you use `KmsKeyId`)

> **Note**
>
> If you encrypt the backups, you must also include a presigned URL. For more information on presigned URLs, see Authenticating Requests: Using Query Parameters (AWS Signature Version 4) in the *Amazon Simple Storage Service API Reference* and Signature Version 4 signing process in the *AWS General Reference*.

Finding information about replicated backups

You can use the following CLI commands to find information about replicated backups:

- `describe-source-regions`
- `describe-db-instances`
- `describe-db-instance-automated-backups`

The following `describe-source-regions` example lists the source AWS Regions from which automated backups can be replicated to the US West (Oregon) destination Region.

To show information about source Regions

- Run the following command.

```
aws rds describe-source-regions --region us-west-2
```

The output shows that backups can be replicated from US East (N. Virginia), but not from US East (Ohio) or US West (N. California), into US West (Oregon).

```
{
    "SourceRegions": [
        ...
        {
            "RegionName": "us-east-1",
            "Endpoint": "https://rds.us-east-1.amazonaws.com",
            "Status": "available",
            "SupportsDBInstanceAutomatedBackupsReplication": true
        },
        {
            "RegionName": "us-east-2",
            "Endpoint": "https://rds.us-east-2.amazonaws.com",
            "Status": "available",
            "SupportsDBInstanceAutomatedBackupsReplication": false
        },
            "RegionName": "us-west-1",
            "Endpoint": "https://rds.us-west-1.amazonaws.com",
            "Status": "available",
            "SupportsDBInstanceAutomatedBackupsReplication": false
        }
    ]
}
```

The following `describe-db-instances` example shows the automated backups for a DB instance.

To show the replicated backups for a DB instance

- Run one of the following commands.

  For Linux, macOS, or Unix:

  ```
  aws rds describe-db-instances \
  --db-instance-identifier mydatabase
  ```

  For Windows:

  ```
  aws rds describe-db-instances ^
  ```

```
--db-instance-identifier mydatabase
```

The output includes the replicated backups.

```
{
    "DBInstances": [
        {
            "StorageEncrypted": false,
            "Endpoint": {
                "HostedZoneId": "Z1PVIF0B656C1W",
                "Port": 1521,
            ...

            "BackupRetentionPeriod": 7,
            "DBInstanceAutomatedBackupsReplications":
 [{"DBInstanceAutomatedBackupsArn": "arn:aws:rds:us-east-1:123456789012:auto-backup:ab-
L2IJCEXJP7XQ7HOJ4SIEXAMPLE"}]
        }
    ]
}
```

The following `describe-db-instance-automated-backups` example shows the automated backups for a DB instance.

To show automated backups for a DB instance

- Run one of the following commands.

  For Linux, macOS, or Unix:

  ```
  aws rds describe-db-instance-automated-backups \
  --db-instance-identifier mydatabase
  ```

  For Windows:

  ```
  aws rds describe-db-instance-automated-backups ^
  --db-instance-identifier mydatabase
  ```

The output shows the source DB instance and automated backups in US West (Oregon), with backups replicated to US East (N. Virginia).

```
{
    "DBInstanceAutomatedBackups": [
        {
            "DBInstanceArn": "arn:aws:rds:us-west-2:868710585169:db:mydatabase",
            "DbiResourceId": "db-L2IJCEXJP7XQ7HOJ4SIEXAMPLE",
            "DBInstanceAutomatedBackupsArn": "arn:aws:rds:us-west-2:123456789012:auto-
backup:ab-L2IJCEXJP7XQ7HOJ4SIEXAMPLE",
            "BackupRetentionPeriod": 7,
            "DBInstanceAutomatedBackupsReplications":
 [{"DBInstanceAutomatedBackupsArn": "arn:aws:rds:us-east-1:123456789012:auto-backup:ab-
L2IJCEXJP7XQ7HOJ4SIEXAMPLE"}]
            "Region": "us-west-2",
            "DBInstanceIdentifier": "mydatabase",
            "RestoreWindow": {
                "EarliestTime": "2020-10-26T01:09:07Z",
                "LatestTime": "2020-10-31T19:09:53Z",
            }
            ...
        }
    ]
}
```

The following `describe-db-instance-automated-backups` example uses the `--db-instance-automated-backups-arn` option to show the replicated backups in the destination Region.

To show replicated backups

- Run one of the following commands.

  For Linux, macOS, or Unix:

  ```
  aws rds describe-db-instance-automated-backups \
  --db-instance-automated-backups-arn "arn:aws:rds:us-east-1:123456789012:auto-
  backup:ab-L2IJCEXJP7XQ7HOJ4SIEXAMPLE"
  ```

  For Windows:

  ```
  aws rds describe-db-instance-automated-backups ^
  ```

```
--db-instance-automated-backups-arn "arn:aws:rds:us-east-1:123456789012:auto-
backup:ab-L2IJCEXJP7XQ7HOJ4SIEXAMPLE"
```

The output shows the source DB instance in US West (Oregon), with replicated backups in US East (N. Virginia).

```
{
    "DBInstanceAutomatedBackups": [
        {
            "DBInstanceArn": "arn:aws:rds:us-west-2:868710585169:db:mydatabase",
            "DbiResourceId": "db-L2IJCEXJP7XQ7HOJ4SIEXAMPLE",
            "DBInstanceAutomatedBackupsArn": "arn:aws:rds:us-east-1:123456789012:auto-
backup:ab-L2IJCEXJP7XQ7HOJ4SIEXAMPLE",
            "Region": "us-west-2",
            "DBInstanceIdentifier": "mydatabase",
            "RestoreWindow": {
                "EarliestTime": "2020-10-26T01:09:07Z",
                "LatestTime": "2020-10-31T19:01:23Z"
            },
            "AllocatedStorage": 50,
            "BackupRetentionPeriod": 7,
            "Status": "replicating",
            "Port": 1521,
            ...
        }
    ]
}
```

Restoring to a specified time from a replicated backup

You can restore a DB instance to a specific point in time from a replicated backup using the Amazon RDS console. You can also use the `restore-db-instance-to-point-in-time` AWS CLI command or the `RestoreDBInstanceToPointInTime` RDS API operation.

For general information on point-in-time recovery (PITR), see Restoring a DB instance to a specified time.

> **Note**
>
> On RDS for SQL Server, option groups aren't copied across AWS Regions when automated backups are replicated. If you've associated a custom option group with your RDS for SQL

Server DB instance, you can re-create that option group in the destination Region. Then restore the DB instance in the destination Region and associate the custom option group with it. For more information, see Working with option groups.

Console

To restore a DB instance to a specified time from a replicated backup

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Choose the destination Region (where backups are replicated to) from the Region selector.
3. In the navigation pane, choose **Automated backups**.
4. On the **Replicated backups** tab, choose the DB instance that you want to restore.
5. For **Actions**, choose **Restore to point in time**.
6. Choose **Latest restorable time** to restore to the latest possible time, or choose **Custom** to choose a time.

   If you chose **Custom**, enter the date and time that you want to restore the instance to.

   > **Note**
   >
   > Times are shown in your local time zone, which is indicated by an offset from Coordinated Universal Time (UTC). For example, UTC-5 is Eastern Standard Time/ Central Daylight Time.

7. For **DB instance identifier**, enter the name of the target restored DB instance.
8. (Optional) Choose other options as needed, such as enabling autoscaling.
9. Choose **Restore to point in time**.

AWS CLI

Use the `restore-db-instance-to-point-in-time` AWS CLI command to create a new DB instance.

To restore a DB instance to a specified time from a replicated backup

- Run one of the following commands.

  For Linux, macOS, or Unix:

```
aws rds restore-db-instance-to-point-in-time \
    --source-db-instance-automated-backups-arn "arn:aws:rds:us-
east-1:123456789012:auto-backup:ab-L2IJCEXJP7XQ7HOJ4SIEXAMPLE" \
    --target-db-instance-identifier mytargetdbinstance \
    --restore-time 2020-10-14T23:45:00.000Z
```

  For Windows:

```
aws rds restore-db-instance-to-point-in-time ^
    --source-db-instance-automated-backups-arn "arn:aws:rds:us-
east-1:123456789012:auto-backup:ab-L2IJCEXJP7XQ7HOJ4SIEXAMPLE" ^
    --target-db-instance-identifier mytargetdbinstance ^
    --restore-time 2020-10-14T23:45:00.000Z
```

RDS API

To restore a DB instance to a specified time, call the `RestoreDBInstanceToPointInTime` Amazon RDS API operation with the following parameters:

- `SourceDBInstanceAutomatedBackupsArn`
- `TargetDBInstanceIdentifier`
- `RestoreTime`

Stopping automated backup replication

You can stop backup replication for DB instances using the Amazon RDS console. You can also use the `stop-db-instance-automated-backups-replication` AWS CLI command or the `StopDBInstanceAutomatedBackupsReplication` RDS API operation.

Replicated backups are retained, subject to the backup retention period set when they were created.

Console

Stop backup replication from the **Automated backups** page in the source Region.

To stop backup replication to an AWS Region

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Choose the source Region from the **Region selector**.
3. In the navigation pane, choose **Automated backups**.
4. On the **Current Region** tab, choose the DB instance for which you want to stop backup replication.
5. For **Actions**, choose **Manage cross-Region replication**.
6. Under **Backup replication**, clear the **Enable replication to another AWS Region** check box.
7. Choose **Save**.

Replicated backups are listed on the **Retained** tab of the **Automated backups** page in the destination Region.

AWS CLI

Stop backup replication by using the `stop-db-instance-automated-backups-replication` AWS CLI command.

The following CLI example stops automated backups of a DB instance from replicating in the US West (Oregon) Region.

To stop backup replication

- Run one of the following commands.

  For Linux, macOS, or Unix:

```
aws rds stop-db-instance-automated-backups-replication \
--region us-east-1 \
--source-db-instance-arn "arn:aws:rds:us-west-2:123456789012:db:mydatabase"
```

  For Windows:

```
aws rds stop-db-instance-automated-backups-replication ^
--region us-east-1 ^
--source-db-instance-arn "arn:aws:rds:us-west-2:123456789012:db:mydatabase"
```

RDS API

Stop backup replication by using the `StopDBInstanceAutomatedBackupsReplication` RDS API operation with the following parameters:

- `Region`
- `SourceDBInstanceArn`

Deleting replicated backups

You can delete replicated backups for DB instances using the Amazon RDS console. You can also use the `delete-db-instance-automated-backups` AWS CLI command or the `DeleteDBInstanceAutomatedBackup` RDS API operation.

Console

Delete replicated backups in the destination Region from the **Automated backups** page.

To delete replicated backups

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Choose the destination Region from the **Region selector**.
3. In the navigation pane, choose **Automated backups**.
4. On the **Replicated backups** tab, choose the DB instance for which you want to delete the replicated backups.
5. For **Actions**, choose **Delete**.
6. On the confirmation page, enter **`delete me`** and choose **Delete**.

AWS CLI

Delete replicated backups by using the `delete-db-instance-automated-backup` AWS CLI command.

You can use the `describe-db-instances` CLI command to find the Amazon Resource Names (ARNs) of the replicated backups. For more information, see Finding information about replicated backups.

To delete replicated backups

- Run one of the following commands.

  For Linux, macOS, or Unix:

```
aws rds delete-db-instance-automated-backup \
--db-instance-automated-backups-arn "arn:aws:rds:us-east-1:123456789012:auto-
backup:ab-L2IJCEXJP7XQ7HOJ4SIEXAMPLE"
```

  For Windows:

```
aws rds delete-db-instance-automated-backup ^
--db-instance-automated-backups-arn "arn:aws:rds:us-east-1:123456789012:auto-
backup:ab-L2IJCEXJP7XQ7HOJ4SIEXAMPLE"
```

RDS API

Delete replicated backups by using the `DeleteDBInstanceAutomatedBackup` RDS API operation with the `DBInstanceAutomatedBackupsArn` parameter.

Managing manual backups

This section shows how to manage manual backups for DB instances and DB clusters.

Topics

Creating a DB snapshot for a Single-AZ DB instance

Amazon RDS creates a storage volume snapshot of your DB instance, backing up the entire DB instance and not just individual databases. Creating this DB snapshot on a Single-AZ DB instance results in a brief I/O suspension that can last from a few seconds to a few minutes, depending on the size and class of your DB instance. For MariaDB, MySQL, Oracle, and PostgreSQL, I/O activity is not suspended on your primary during backup for Multi-AZ deployments, because the backup is taken from the standby. For SQL Server, I/O activity is suspended briefly during backup for Multi-AZ deployments.

When you create a DB snapshot, you need to identify which DB instance you are going to back up, and then give your DB snapshot a name so you can restore from it later. The amount of time it takes to create a snapshot varies with the size of your databases. Since the snapshot includes the entire storage volume, the size of files, such as temporary files, also affects the amount of time it takes to create the snapshot.

> **Note**
>
> Your DB instance must be in the `available` state to take a DB snapshot.
> For PostgreSQL DB instances, data in unlogged tables might not be restored from snapshots. For more information, see Best practices for working with PostgreSQL.

Unlike automated backups, manual snapshots aren't subject to the backup retention period. Snapshots don't expire.

For very long-term backups of MariaDB, MySQL, and PostgreSQL data, we recommend exporting snapshot data to Amazon S3. If the major version of your DB engine is no longer supported, you can't restore to that version from a snapshot. For more information, see Exporting DB snapshot data to Amazon S3.

You can create a DB snapshot using the AWS Management Console, the AWS CLI, or the RDS API.

Console

To create a DB snapshot

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.

2. In the navigation pane, choose **Snapshots**.

   The **Manual snapshots** list appears.
3. Choose **Take snapshot**.

   The **Take DB snapshot** window appears.
4. Choose the **DB instance** for which you want to take a snapshot.
5. Enter the **Snapshot name**.
6. Choose **Take snapshot**.

The **Manual snapshots** list appears, with the new DB snapshot's status shown as `Creating`. After its status is `Available`, you can see its creation time.

AWS CLI

When you create a DB snapshot using the AWS CLI, you need to identify which DB instance you are going to back up, and then give your DB snapshot a name so you can restore from it later. You can do this by using the AWS CLI `create-db-snapshot` command with the following parameters:

- `--db-instance-identifier`
- `--db-snapshot-identifier`

In this example, you create a DB snapshot called *`mydbsnapshot`* for a DB instance called *`mydbinstance`*.

Example

For Linux, macOS, or Unix:

```
aws rds create-db-snapshot \
    --db-instance-identifier mydbinstance \
    --db-snapshot-identifier mydbsnapshot
```

For Windows:

```
aws rds create-db-snapshot ^
    --db-instance-identifier mydbinstance ^
    --db-snapshot-identifier mydbsnapshot
```

RDS API

When you create a DB snapshot using the Amazon RDS API, you need to identify which DB instance you are going to back up, and then give your DB snapshot a name so you can restore from it later. You can do this by using the Amazon RDS API `CreateDBSnapshot` command with the following parameters:

- `DBInstanceIdentifier`
- `DBSnapshotIdentifier`

Creating a Multi-AZ DB cluster snapshot

When you create a Multi-AZ DB cluster snapshot, make sure to identify which Multi-AZ DB cluster you are going to back up, and then give your DB cluster snapshot a name so you can restore from it later. You can also share a Multi-AZ DB cluster snapshot. For instructions, see the section called "Sharing a DB snapshot".

You can create a Multi-AZ DB cluster snapshot using the AWS Management Console, the AWS CLI, or the RDS API.

For very long-term backups, we recommend exporting snapshot data to Amazon S3. If the major version of your DB engine is no longer supported, you can't restore to that version from a snapshot. For more information, see Exporting DB snapshot data to Amazon S3.

Console

To create a DB cluster snapshot

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.
3. In the list, choose the Multi-AZ DB cluster for which you want to take a snapshot.
4. For **Actions**, choose **Take snapshot**.

   The **Take DB snapshot** window appears.
5. For **Snapshot name**, enter the name of the snapshot.
6. Choose **Take snapshot**.

The **Snapshots** page appears, with the new Multi-AZ DB cluster snapshot's status shown as `Creating`. After its status is `Available`, you can see its creation time.

AWS CLI

You can create a Multi-AZ DB cluster snapshot by using the AWS CLI create-db-cluster-snapshot command with the following options:

- `--db-cluster-identifier`
- `--db-cluster-snapshot-identifier`

In this example, you create a Multi-AZ DB cluster snapshot called *mymultiazdbclustersnapshot* for a DB cluster called *mymultiazdbcluster*.

Example

For Linux, macOS, or Unix:

```
aws rds create-db-cluster-snapshot \
    --db-cluster-identifier mymultiazdbcluster \
    --db-cluster-snapshot-identifier mymultiazdbclustersnapshot
```

For Windows:

```
aws rds create-db-cluster-snapshot ^
    --db-cluster-identifier mymultiazdbcluster ^
    --db-cluster snapshot-identifier mymultiazdbclustersnapshot
```

RDS API

You can create a Multi-AZ DB cluster snapshot by using the Amazon RDS API CreateDBClusterSnapshot operation with the following parameters:

- `DBClusterIdentifier`
- `DBClusterSnapshotIdentifier`

Deleting a Multi-AZ DB cluster snapshot

You can delete Multi-AZ DB snapshots managed by Amazon RDS when you no longer need them. For instructions, see the section called “Deleting a DB snapshot”.

Deleting a DB snapshot

You can delete DB snapshots managed by Amazon RDS when you no longer need them.

> **Note**
>
> To delete backups managed by AWS Backup, use the AWS Backup console. For information about AWS Backup, see the *AWS Backup Developer Guide*.

Deleting a DB snapshot

You can delete a manual, shared, or public DB snapshot using the AWS Management Console, the AWS CLI, or the RDS API.

To delete a shared or public snapshot, you must sign in to the AWS account that owns the snapshot.

If you have automated DB snapshots that you want to delete without deleting the DB instance, change the backup retention period for the DB instance to 0. The automated snapshots are deleted when the change is applied. You can apply the change immediately if you don't want to wait until the next maintenance period. After the change is complete, you can then re-enable automatic backups by setting the backup retention period to a number greater than 0. For information about modifying a DB instance, see Modifying an Amazon RDS DB instance.

Retained automated backups and manual snapshots incur billing charges until they're deleted. For more information, see Retention costs.

If you deleted a DB instance, you can delete its automated DB snapshots by removing the automated backups for the DB instance. For information about automated backups, see Introduction to backups.

Console

To delete a DB snapshot

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Snapshots**.

The **Manual snapshots** list appears.

3. Choose the DB snapshot that you want to delete.
4. For **Actions**, choose **Delete snapshot**.
5. Choose **Delete** on the confirmation page.

AWS CLI

You can delete a DB snapshot by using the AWS CLI command delete-db-snapshot.

The following options are used to delete a DB snapshot.

- `--db-snapshot-identifier` – The identifier for the DB snapshot.

Example

The following code deletes the `mydbsnapshot` DB snapshot.

For Linux, macOS, or Unix:

```
aws rds delete-db-snapshot \
    --db-snapshot-identifier mydbsnapshot
```

For Windows:

```
aws rds delete-db-snapshot ^
    --db-snapshot-identifier mydbsnapshot
```

RDS API

You can delete a DB snapshot by using the Amazon RDS API operation DeleteDBSnapshot.

The following parameters are used to delete a DB snapshot.

- `DBSnapshotIdentifier` – The identifier for the DB snapshot.

Restoring to a DB instance

This section shows how to restore to a DB instance. This page shows how to restore to an Amazon RDS DB instance from a DB snapshot.

Topics

Amazon RDS creates a storage volume snapshot of your DB instance, backing up the entire DB instance and not just individual databases. You can create a new DB instance by restoring from a DB snapshot. You provide the name of the DB snapshot to restore from, and then provide a name for the new DB instance that is created from the restore. You can't restore from a DB snapshot to an existing DB instance; a new DB instance is created when you restore.

You can use the restored DB instance as soon as its status is `available`. The DB instance continues to load data in the background. This is known as *lazy loading*.

If you access data that hasn't been loaded yet, the DB instance immediately downloads the requested data from Amazon S3, and then continues loading the rest of the data in the background. For more information, see Amazon EBS snapshots.

To help mitigate the effects of lazy loading on tables to which you require quick access, you can perform operations that involve full-table scans, such as `SELECT *`. This allows Amazon RDS to download all of the backed-up table data from S3.

You can restore a DB instance and use a different storage type than the source DB snapshot. In this case, the restoration process is slower because of the additional work required to migrate the data to the new storage type. If you restore to or from magnetic storage, the migration process is the slowest. That's because magnetic storage doesn't have the IOPS capability of Provisioned IOPS or General Purpose (SSD) storage.

You can use AWS CloudFormation to restore a DB instance from a DB instance snapshot. For more information, see AWS::RDS::DBInstance in the *AWS CloudFormation User Guide*.

> **Note**
>
> You can't restore a DB instance from a DB snapshot that is both shared and encrypted. Instead, you can make a copy of the DB snapshot and restore the DB instance from the copy. For more information, see Copying a DB snapshot.

For information about restoring a DB instance with an RDS Extended Support version, see Restoring a DB instance or a Multi-AZ DB cluster with Amazon RDS Extended Support.

Parameter group considerations

We recommend that you retain the DB parameter group for any DB snapshots you create, so that you can associate your restored DB instance with the correct parameter group.

The default DB parameter group is associated with the restored instance, unless you choose a different one. No custom parameter settings are available in the default parameter group.

You can specify the parameter group when you restore the DB instance.

For more information about DB parameter groups, see Parameter groups for Amazon RDS.

Security group considerations

When you restore a DB instance, the default virtual private cloud (VPC), DB subnet group, and VPC security group are associated with the restored instance, unless you choose different ones.

- If you're using the Amazon RDS console, you can specify a custom VPC security group to associate with the instance or create a new VPC security group.
- If you're using the AWS CLI, you can specify a custom VPC security group to associate with the instance by including the `--vpc-security-group-ids` option in the `restore-db-instance-from-db-snapshot` command.
- If you're using the Amazon RDS API, you can include the `VpcSecurityGroupIds.VpcSecurityGroupId.N` parameter in the `RestoreDBInstanceFromDBSnapshot` action.

As soon as the restore is complete and your new DB instance is available, you can also change the VPC settings by modifying the DB instance. For more information, see Modifying an Amazon RDS DB instance.

Option group considerations

When you restore a DB instance, the default DB option group is associated with the restored DB instance in most cases.

The exception is when the source DB instance is associated with an option group that contains a persistent or permanent option. For example, if the source DB instance uses Oracle Transparent Data Encryption (TDE), the restored DB instance must use an option group that has the TDE option.

If you restore a DB instance into a different VPC, you must do one of the following to assign a DB option group:

- Assign the default option group for that VPC group to the instance.
- Assign another option group that is linked to that VPC.
- Create a new option group and assign it to the DB instance. With persistent or permanent options, such as Oracle TDE, you must create a new option group that includes the persistent or permanent option.

For more information about DB option groups, see Working with option groups.

Resource tagging considerations

When you restore a DB instance from a DB snapshot, RDS checks whether you specify new tags. If yes, the new tags are added to the restored DB instance. If there are no new tags, RDS adds the tags from the source DB instance at the time of snapshot creation to the restored DB instance.

For more information, see Copying tags to DB snapshots.

Db2 considerations

With the BYOL model, your Amazon RDS for Db2 DB instances must be associated with a custom parameter group that contains your IBM Site ID and your IBM Customer ID. Otherwise, attempts to restore a DB instance from a snapshot will fail. Your Amazon RDS for Db2 DB instances must also be associated with an AWS License Manager self-managed license. For more information, see Bring Your Own License for Db2.

With the Db2 license through AWS Marketplace model, you need an active AWS Marketplace subscription for the particular IBM Db2 edition that you want to use. If you don't already have one, subscribe to Db2 in AWS Marketplace for that IBM Db2 edition. For more information, see Db2 license through AWS Marketplace.

Microsoft SQL Server considerations

When you restore an RDS for Microsoft SQL Server DB snapshot to a new instance, you can always restore to the same edition as your snapshot. In some cases, you can also change the edition of the DB instance. The following limitations apply when you change editions:

- The DB snapshot must have enough storage allocated for the new edition.
- Only the following edition changes are supported:
  - From Standard Edition to Enterprise Edition
  - From Web Edition to Standard Edition or Enterprise Edition
  - From Express Edition to Web Edition, Standard Edition, or Enterprise Edition

If you want to change from one edition to a new edition that isn't supported by restoring a snapshot, you can try using the native backup and restore feature. SQL Server verifies whether your database is compatible with the new edition based on what SQL Server features you have

enabled on the database. For more information, see Importing and exporting SQL Server databases using native backup and restore.

Oracle Database considerations

When you restore an Oracle database from a DB snapshot, consider the following:

- Before you restore a DB snapshot, you can upgrade it to a later Oracle database release. For more information, see Upgrading an Oracle DB snapshot.
- If you restore a snapshot of a CDB instance that uses the single-tenant configuration, you can change the PDB name. You can't change the PDB names when your CDB instance uses the multi-tenant configuration. For more information, see Backing up and restoring a CDB.
- You can't change the CDB name, which is always RDSCDB. This CDB name is the same for all CDB instances.
- You can't directly interact with the tenant databases in a DB snapshot. If you restore a snapshot of a CDB instance that uses the multi-tenant configuration, you restore all its tenant databases. You can use describe-db-snapshot-tenant-databases to inspect the tenant databases within a DB snapshot before restoring it.
- If you use Oracle GoldenGate, always retain the parameter group with the `compatible` parameter. When you restore a DB instance from a DB snapshot, specify a parameter group that has a matching or greater `compatible` value.
- You might choose to rename your database when you restore a DB snapshot. If the total size of online redo log is greater than 20GB, RDS might reset your online redo log size to its default settings of 512MB (4 x 128MB). The smaller size allows the restore operation to complete in a reasonable time. You can re-create the online redo logs later and change the size.

Restoring from a snapshot

You can restore a DB instance from a DB snapshot using the AWS Management Console, the AWS CLI, or the RDS API.

> **Note**
>
> You can't reduce the amount of storage when you restore a DB instance. When you increase the allocated storage, it must be by at least 10 percent. If you try to increase the value

by less than 10 percent, you get an error. You can't increase the allocated storage when restoring RDS for SQL Server DB instances.

Console

To restore a DB instance from a DB snapshot

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Snapshots**.
3. Choose the DB snapshot that you want to restore from.
4. For **Actions**, choose **Restore snapshot**.
5. On the **Restore snapshot** page, for **DB instance identifier**, enter the name for your restored DB instance.
6. Specify other settings, such as allocated storage size.

   For information about each setting, see Settings for DB instances.
7. Choose **Restore DB instance**.

AWS CLI

To restore a DB instance from a DB snapshot, use the AWS CLI command restore-db-instance-from-db-snapshot.

In this example, you restore from a previously created DB snapshot named `mydbsnapshot`. You restore to a new DB instance named `mynewdbinstance`. This example also sets the allocated storage size.

You can specify other settings. For information about each setting, see Settings for DB instances.

Example

For Linux, macOS, or Unix:

```
aws rds restore-db-instance-from-db-snapshot \
    --db-instance-identifier mynewdbinstance \
    --db-snapshot-identifier mydbsnapshot \
```

```
    --allocated-storage 100
```

For Windows:

```
aws rds restore-db-instance-from-db-snapshot ^
    --db-instance-identifier mynewdbinstance ^
    --db-snapshot-identifier mydbsnapshot ^
    --allocated-storage 100
```

This command returns output similar to the following:

```
DBINSTANCE  mynewdbinstance  db.t3.small  MySQL     50       sa              creating
 3  n  8.0.28  general-public-license
```

RDS API

To restore a DB instance from a DB snapshot, call the Amazon RDS API function RestoreDBInstanceFromDBSnapshot with the following parameters:

- `DBInstanceIdentifier`
- `DBSnapshotIdentifier`

Restoring a DB instance to a specified time

You can restore a DB instance to a specific point in time, creating a new DB instance without modifying the source DB instance.

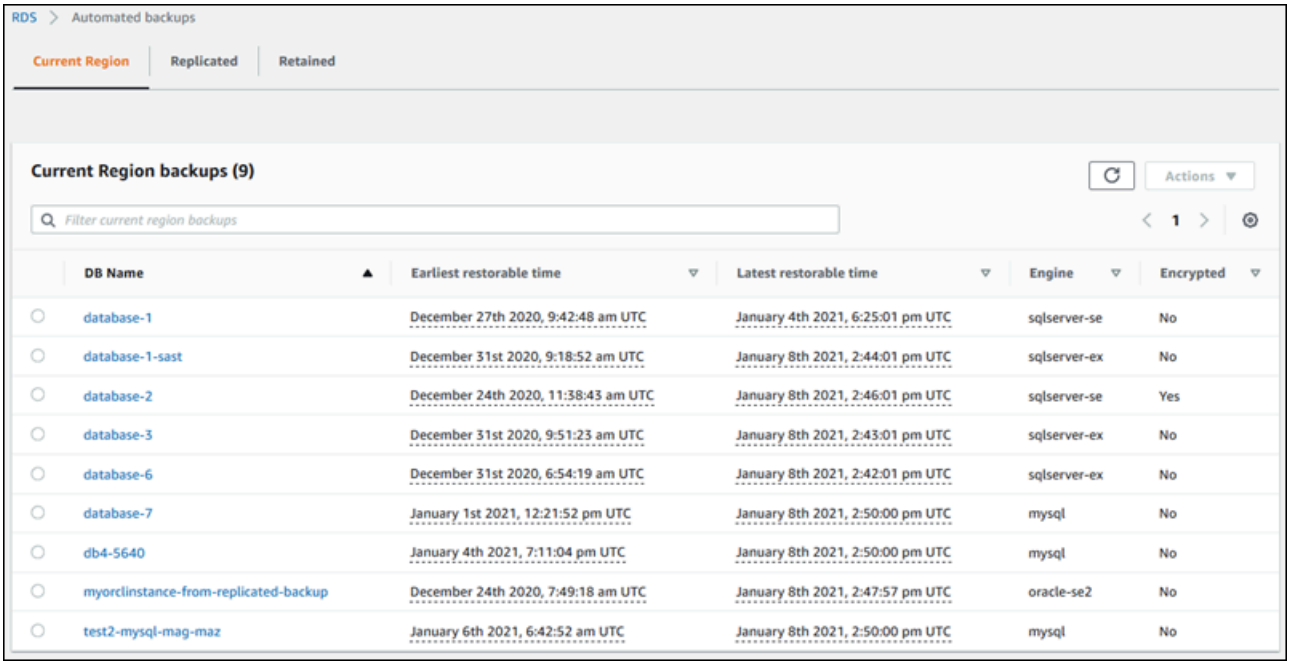
When you restore a DB instance to a point in time, you can choose the default virtual private cloud (VPC) security group. Or you can apply a custom VPC security group to your DB instance.

Restored DB instances are automatically associated with the default DB parameter and option groups. However, you can apply a custom parameter group and option group by specifying them during a restore.

If the source DB instance has resource tags, RDS adds the latest tags to the restored DB instance.

RDS uploads transaction logs for DB instances to Amazon S3 every five minutes. To see the latest restorable time for a DB instance, use the AWS CLI describe-db-instances command and look at the value returned in the `LatestRestorableTime` field for the DB instance. To see the latest restorable time for each DB instance in the Amazon RDS console, choose **Automated backups**.

You can restore to any point in time within your backup retention period. To see the earliest restorable time for each DB instance, choose **Automated backups** in the Amazon RDS console.



> **Note**
>
> We recommend that you restore to the same or similar DB instance size—and IOPS if using Provisioned IOPS storage—as the source DB instance. You might get an error if, for example, you choose a DB instance size with an incompatible IOPS value.

For information about restoring a DB instance with an RDS Extended Support version, see Restoring a DB instance or a Multi-AZ DB cluster with Amazon RDS Extended Support.

Some of the database engines used by Amazon RDS have special considerations when restoring from a point in time:

- If you use password authentication with an Amazon RDS for Db2 DB instance, user management actions, including `rdsadmin.add_user`, won't be captured in the logs. These actions require a full snapshot backup.

  With the BYOL model, your RDS for Db2 DB instances must be associated with a custom parameter group that contains your IBM Site ID and your IBM Customer ID. Otherwise, attempts to restore a DB instance to a specific point in time will fail. Your Amazon RDS for Db2 DB instances must also be associated with an AWS License Manager self-managed license. For more information, see Bring Your Own License for Db2.

  With the Db2 license through AWS Marketplace model, you need an active AWS Marketplace subscription for the particular IBM Db2 edition that you want to use. If you don't already have one, subscribe to Db2 in AWS Marketplace for that IBM Db2 edition. For more information, see Db2 license through AWS Marketplace.
- When you restore an Oracle DB instance to a point in time, you can specify a different Oracle DB engine, license model, and DBName (SID) to be used by the new DB instance.
- When you restore a Microsoft SQL Server DB instance to a point in time, each database within that instance is restored to a point in time within 1 second of each other database within the instance. Transactions that span multiple databases within the instance might be restored inconsistently.
- For a SQL Server DB instance, the `OFFLINE`, `EMERGENCY`, and `SINGLE_USER` modes aren't supported. Setting any database into one of these modes causes the latest restorable time to stop moving ahead for the whole instance.

- Some actions, such as changing the recovery model of a SQL Server database, can break the sequence of logs that are used for point-in-time recovery. In some cases, Amazon RDS can detect this issue and the latest restorable time is prevented from moving forward. In other cases, such as when a SQL Server database uses the BULK_LOGGED recovery model, the break in log sequence isn't detected. It might not be possible to restore a SQL Server DB instance to a point in time if there is a break in the log sequence. For these reasons, Amazon RDS doesn't support changing the recovery model of SQL Server databases.

You can also use AWS Backup to manage backups of Amazon RDS DB instances. If your DB instance is associated with a backup plan in AWS Backup, that backup plan is used for point-in-time recovery. Backups that were created with AWS Backup have names ending in `awsbackup:`*`AWS-Backup-job-number`*. For information about AWS Backup, see the *AWS Backup Developer Guide*.

> **Note**
>
> Information in this topic applies to Amazon RDS. For information on restoring an Amazon Aurora DB cluster, see Restoring a DB cluster to a specified time.

You can restore a DB instance to a point in time using the AWS Management Console, the AWS CLI, or the RDS API.

> **Note**
>
> You can't reduce the amount of storage when you restore a DB instance. When you increase the allocated storage, it must be by at least 10 percent. If you try to increase the value by less than 10 percent, you get an error. You can't increase the allocated storage when restoring RDS for SQL Server DB instances.

Console

To restore a DB instance to a specified time

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Automated backups**.

The automated backups are displayed on the **Current Region** tab.

3. Choose the DB instance that you want to restore.
4. For **Actions**, choose **Restore to point in time**.

   The **Restore to point in time** window appears.
5. Choose **Latest restorable time** to restore to the latest possible time, or choose **Custom** to choose a time.

   If you chose **Custom**, enter the date and time to which you want to restore the instance.

   > **Note**
   >
   > Times are shown in your local time zone, which is indicated by an offset from Coordinated Universal Time (UTC). For example, UTC-5 is Eastern Standard Time/ Central Daylight Time.
6. For **DB instance identifier**, enter the name of the target restored DB instance. The name must be unique.
7. Choose other options as needed, such as DB instance class, storage, and whether you want to use storage autoscaling.

   For information about each setting, see Settings for DB instances.
8. Choose **Restore to point in time**.

AWS CLI

To restore a DB instance to a specified time, use the AWS CLI command restore-db-instance-to-point-in-time to create a new DB instance. This example also sets the allocated storage size and enables storage autoscaling.

Resource tagging is supported for this operation. When you use the `--tags` option, the source DB instance tags are ignored and the provided ones are used. Otherwise, the latest tags from the source instance are used.

You can specify other settings. For information about each setting, see Settings for DB instances.

Example

For Linux, macOS, or Unix:

```
aws rds restore-db-instance-to-point-in-time \
    --source-db-instance-identifier mysourcedbinstance \
    --target-db-instance-identifier mytargetdbinstance \
    --restore-time 2017-10-14T23:45:00.000Z \
    --allocated-storage 100 \
    --max-allocated-storage 1000
```

For Windows:

```
aws rds restore-db-instance-to-point-in-time ^
    --source-db-instance-identifier mysourcedbinstance ^
    --target-db-instance-identifier mytargetdbinstance ^
    --restore-time 2017-10-14T23:45:00.000Z ^
    --allocated-storage 100 ^
    --max-allocated-storage 1000
```

RDS API

To restore a DB instance to a specified time, call the Amazon RDS API `RestoreDBInstanceToPointInTime` operation with the following parameters:

- `SourceDBInstanceIdentifier`
- `TargetDBInstanceIdentifier`
- `RestoreTime`

Restoring a Multi-AZ DB cluster to a specified time

You can restore a Multi-AZ DB cluster to a specific point in time, creating a new Multi-AZ DB cluster.

RDS uploads transaction logs for Multi-AZ DB clusters to Amazon S3 continuously. You can restore to any point in time within your backup retention period. To see the earliest restorable time for a Multi-AZ DB cluster, use the AWS CLI describe-db-clusters command. Look at the value returned in the `EarliestRestorableTime` field for the DB cluster. To see the latest restorable time for a Multi-AZ DB cluster, look at the value returned in the `LatestRestorableTime` field for the DB cluster.

When you restore a Multi-AZ DB cluster to a point in time, you can choose the default VPC security group for your Multi-AZ DB cluster, or you can apply a custom VPC security group to your Multi-AZ DB cluster.

Restored Multi-AZ DB clusters are automatically associated with the default DB cluster parameter group. However, you can apply a custom DB cluster parameter group by specifying it during a restore.

If the source DB cluster has resource tags, RDS adds the latest tags to the restored DB cluster.

> **Note**
>
> We recommend that you restore to the same or similar Multi-AZ DB cluster size as the source DB cluster. We also recommend that you restore with the same or similar IOPS value if you're using Provisioned IOPS storage. You might get an error if, for example, you choose a DB cluster size with an incompatible IOPS value.
> If the source Multi-AZ DB cluster uses General Purpose SSD (gp3) storage and has less than 400 GiB of allocated storage, you can't modify the provisioned IOPS for the restored DB cluster.

For information about restoring a Multi-AZ DB cluster with an RDS Extended Support version, see Restoring a DB instance or a Multi-AZ DB cluster with Amazon RDS Extended Support.

You can restore a Multi-AZ DB cluster to a point in time using the AWS Management Console, the AWS CLI, or the RDS API.

Console

To restore a Multi-AZ DB cluster to a specified time

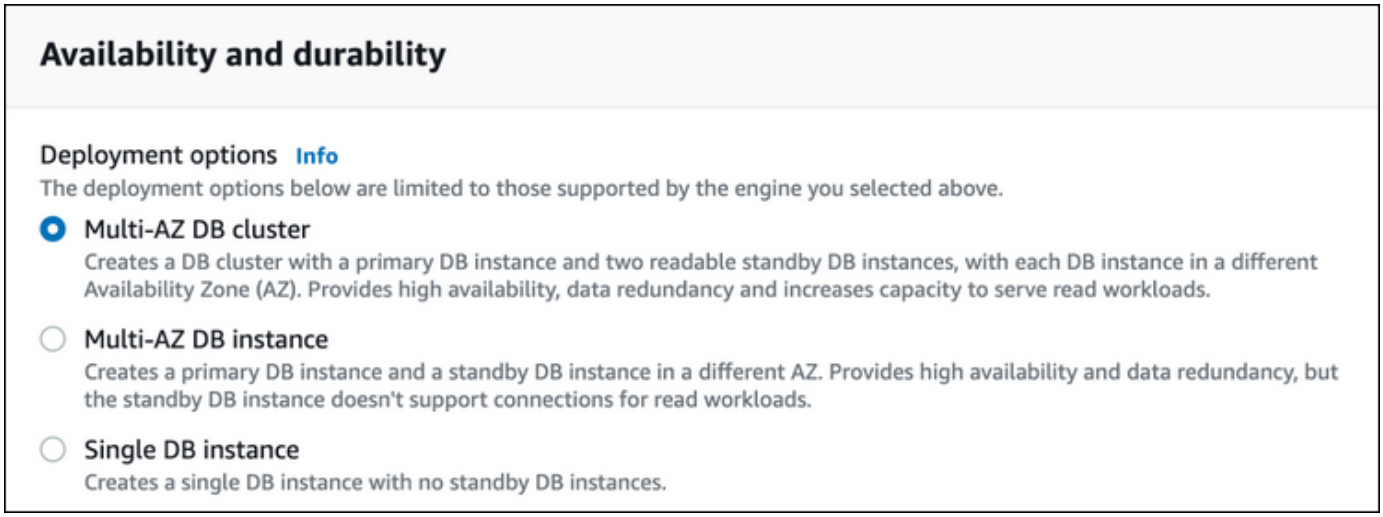
1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.
3. Choose the Multi-AZ DB cluster that you want to restore.
4. For **Actions**, choose **Restore to point in time**.

   The **Restore to point in time** window appears.
5. Choose **Latest restorable time** to restore to the latest possible time, or choose **Custom** to choose a time.

   If you chose **Custom**, enter the date and time to which you want to restore the Multi-AZ DB cluster.

   > **Note**
   >
   > Times are shown in your local time zone, which is indicated by an offset from Coordinated Universal Time (UTC). For example, UTC-5 is Eastern Standard Time/ Central Daylight Time.

6. For **DB cluster identifier**, enter the name for your restored Multi-AZ DB cluster.
7. In **Availability and durability**, choose **Multi-AZ DB cluster**.



8. In **DB instance class**, choose a DB instance class.

Currently, Multi-AZ DB clusters only support db.m6gd and db.r6gd DB instance classes. For more information about DB instance classes, see DB instance classes.

9. For the remaining sections, specify your DB cluster settings. For information about each setting, see Settings for creating Multi-AZ DB clusters.
10. Choose **Restore to point in time**.

AWS CLI

To restore a Multi-AZ DB cluster to a specified time, use the AWS CLI command restore-db-cluster-to-point-in-time to create a new Multi-AZ DB cluster.

Currently, Multi-AZ DB clusters only support db.m6gd and db.r6gd DB instance classes. For more information about DB instance classes, see DB instance classes.

Example

For Linux, macOS, or Unix:

```
aws rds restore-db-cluster-to-point-in-time \
    --source-db-cluster-identifier mysourcemultiazdbcluster \
    --db-cluster-identifier mytargetmultiazdbcluster \
    --restore-to-time 2021-08-14T23:45:00.000Z \
    --db-cluster-instance-class db.r6gd.xlarge
```

For Windows:

```
aws rds restore-db-cluster-to-point-in-time ^
    --source-db-cluster-identifier mysourcemultiazdbcluster ^
    --db-cluster-identifier mytargetmultiazdbcluster ^
    --restore-to-time 2021-08-14T23:45:00.000Z ^
    --db-cluster-instance-class db.r6gd.xlarge
```

RDS API

To restore a DB cluster to a specified time, call the Amazon RDS API RestoreDBClusterToPointInTime operation with the following parameters:

- `SourceDBClusterIdentifier`
- `DBClusterIdentifier`

- `RestoreToTime`

Restoring from a snapshot to a Multi-AZ DB cluster

You can restore a snapshot to a Multi-AZ DB cluster using the AWS Management Console, the AWS CLI, or the RDS API. You can restore each of these types of snapshots to a Multi-AZ DB cluster:

- A snapshot of a Single-AZ deployment
- A snapshot of a Multi-AZ DB cluster deployment with a single DB instance
- A snapshot of a Multi-AZ DB cluster

For information about Multi-AZ deployments, see Configuring and managing a Multi-AZ deployment.

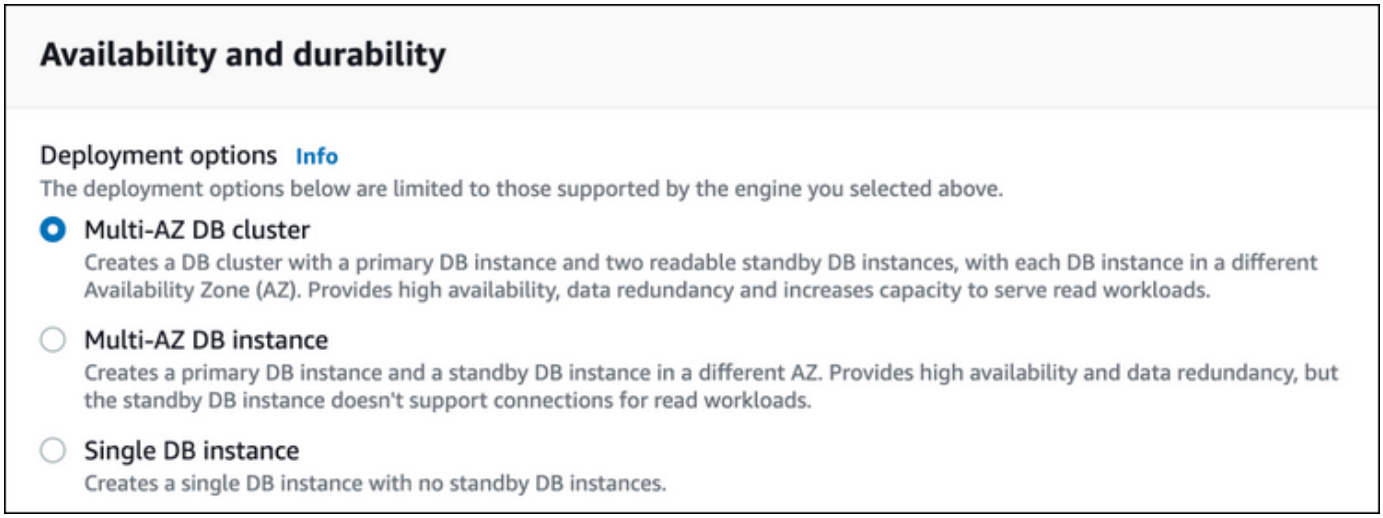
> **Tip**
>
> You can migrate a Single-AZ deployment or a Multi-AZ DB cluster deployment to a Multi-AZ DB cluster deployment by restoring a snapshot.

For information about restoring Multi-AZ DB cluster with an RDS Extended Support version, see Restoring a DB instance or a Multi-AZ DB cluster with Amazon RDS Extended Support.

Console

To restore a snapshot to a Multi-AZ DB cluster

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Snapshots**.
3. Choose the snapshot that you want to restore from.
4. For **Actions**, choose **Restore snapshot**.
5. On the **Restore snapshot** page, in **Availability and durability**, choose **Multi-AZ DB cluster**.



6. For **DB cluster identifier**, enter the name for your restored Multi-AZ DB cluster.
7. For the remaining sections, specify your DB cluster settings. For information about each setting, see Settings for creating Multi-AZ DB clusters.
8. Choose **Restore DB instance**.

AWS CLI

To restore a snapshot to a Multi-AZ DB cluster, use the AWS CLI command restore-db-cluster-from-snapshot.

In the following example, you restore from a previously created snapshot named `mysnapshot`. You restore to a new Multi-AZ DB cluster named `mynewmultiazdbcluster`. You also specify the DB instance class used by the DB instances in the Multi-AZ DB cluster. Specify either `mysql` or `postgres` for the DB engine.

For the `--snapshot-identifier` option, you can use either the name or the Amazon Resource Name (ARN) to specify a DB cluster snapshot. However, you can use only the ARN to specify a DB snapshot.

For the `--db-cluster-instance-class` option, specify the DB instance class for the new Multi-AZ DB cluster. Multi-AZ DB clusters only support specific DB instance classes, such as the db.m6gd and db.r6gd DB instance classes. For more information about DB instance classes, see DB instance classes.

You can also specify other options.

Example

For Linux, macOS, or Unix:

```
aws rds restore-db-cluster-from-snapshot \
    --db-cluster-identifier mynewmultiazdbcluster \
    --snapshot-identifier mysnapshot \
    --engine mysql|postgres \
    --db-cluster-instance-class db.r6gd.xlarge
```

For Windows:

```
aws rds restore-db-cluster-from-snapshot ^
    --db-cluster-identifier mynewmultiazdbcluster ^
    --snapshot-identifier mysnapshot ^
    --engine mysql|postgres ^
    --db-cluster-instance-class db.r6gd.xlarge
```

After you restore the DB cluster, you can add the Multi-AZ DB cluster to the security group associated with the DB cluster or DB instance that you used to create the snapshot, if applicable. Completing this action provides the same functions of the previous DB cluster or DB instance.

RDS API

To restore a snapshot to a Multi-AZ DB cluster, call the RDS API operation RestoreDBClusterFromSnapshot with the following parameters:

- `DBClusterIdentifier`
- `SnapshotIdentifier`
- `Engine`

You can also specify other optional parameters.

After you restore the DB cluster, you can add the Multi-AZ DB cluster to the security group associated with the DB cluster or DB instance that you used to create the snapshot, if applicable. Completing this action provides the same functions of the previous DB cluster or DB instance.

Restoring from a Multi-AZ DB cluster snapshot to a DB instance

A *Multi-AZ DB cluster snapshot* is a storage volume snapshot of your DB cluster, backing up the entire DB cluster and not just individual databases. You can restore a Multi-AZ DB cluster snapshot to a Single-AZ deployment or Multi-AZ DB instance deployment. For information about Multi-AZ deployments, see Configuring and managing a Multi-AZ deployment.

> **Note**
>
> You can also restore a Multi-AZ DB cluster snapshot to a new Multi-AZ DB cluster. For instructions, see Restoring from a snapshot to a Multi-AZ DB cluster.

For information about restoring a Multi-AZ DB cluster with an RDS Extended Support version, see Restoring a DB instance or a Multi-AZ DB cluster with Amazon RDS Extended Support.

Use the AWS Management Console, the AWS CLI, or the RDS API to restore a Multi-AZ DB cluster snapshot to a Single-AZ deployment or Multi-AZ DB instance deployment.

Console

To restore a Multi-AZ DB cluster snapshot to a Single-AZ deployment or Multi-AZ DB instance deployment

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Snapshots**.
3. Choose the Multi-AZ DB cluster snapshot that you want to restore from.
4. For **Actions**, choose **Restore snapshot**.
5. On the **Restore snapshot** page, in **Availability and durability**, choose one of the following:
   - **Single DB instance** – Restores the snapshot to one DB instance with no standby DB instance.
   - **Multi-AZ DB instance** – Restores the snapshot to a Multi-AZ DB instance deployment with one primary DB instance and one standby DB instance.
6. For **DB instance identifier**, enter the name for your restored DB instance.
7. For the remaining sections, specify your DB instance settings. For information about each setting, see Settings for DB instances.

8. Choose **Restore DB instance**.

AWS CLI

To restore a Multi-AZ DB cluster snapshot to a DB instance deployment, use the AWS CLI command restore-db-instance-from-db-snapshot.

In the following example, you restore from a previously created Multi-AZ DB cluster snapshot named `myclustersnapshot`. You restore to a new Multi-AZ DB instance deployment with a primary DB instance named `mynewdbinstance`. For the `--db-cluster-snapshot-identifier` option, specify the name of the Multi-AZ DB cluster snapshot.

For the `--db-instance-class` option, specify the DB instance class for the new DB instance deployment. For more information about DB instance classes, see DB instance classes.

You can also specify other options.

Example

For Linux, macOS, or Unix:

```
aws rds restore-db-instance-from-db-snapshot \
    --db-instance-identifier mynewdbinstance \
    --db-cluster-snapshot-identifier myclustersnapshot \
    --engine mysql \
    --multi-az \
    --db-instance-class db.r6g.xlarge
```

For Windows:

```
aws rds restore-db-instance-from-db-snapshot ^
    --db-instance-identifier mynewdbinstance ^
    --db-cluster-snapshot-identifier myclustersnapshot ^
    --engine mysql ^
    --multi-az ^
    --db-instance-class db.r6g.xlarge
```

After you restore the DB instance, you can add it to the security group associated with the Multi-AZ DB cluster that you used to create the snapshot, if applicable. Completing this action provides the same functions of the previous Multi-AZ DB cluster.

RDS API

To restore a Multi-AZ DB cluster snapshot to a DB instance deployment, call the RDS API operation RestoreDBInstanceFromDBSnapshot with the following parameters:

- `DBInstanceIdentifier`
- `DBClusterSnapshotIdentifier`
- `Engine`

You can also specify other optional parameters.

After you restore the DB instance, you can add it to the security group associated with the Multi-AZ DB cluster that you used to create the snapshot, if applicable. Completing this action provides the same functions of the previous Multi-AZ DB cluster.

Tutorial: Restore an Amazon RDS DB instance from a DB snapshot

Often, when working with Amazon RDS you might have a DB instance that you work with occasionally but don't need full time. For example, suppose that you have a quarterly customer survey that uses an Amazon EC2 instance to host a customer survey website. You also have a DB instance that is used to store the survey results. One way to save money on such a scenario is to take a DB snapshot of the DB instance after the survey is completed. You then delete the DB instance and restore it when you need to conduct the survey again.

When you restore the DB instance, you provide the name of the DB snapshot to restore from. You then provide a name for the new DB instance that's created from the restore operation.

For more detailed information on restoring DB instances from snapshots, see Restoring to a DB instance.

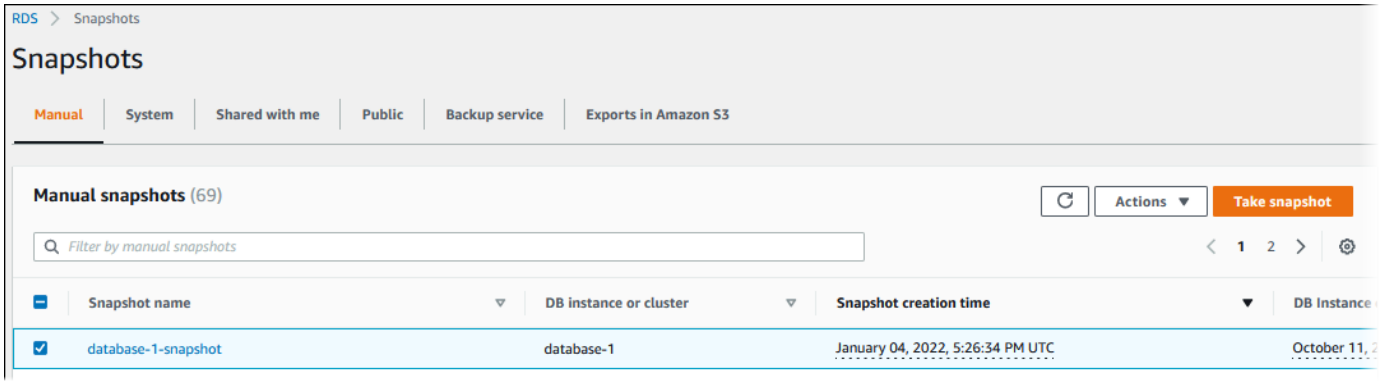
For information about AWS KMS key management for Amazon RDS, see AWS KMS key management.

Restoring a DB instance from a DB snapshot

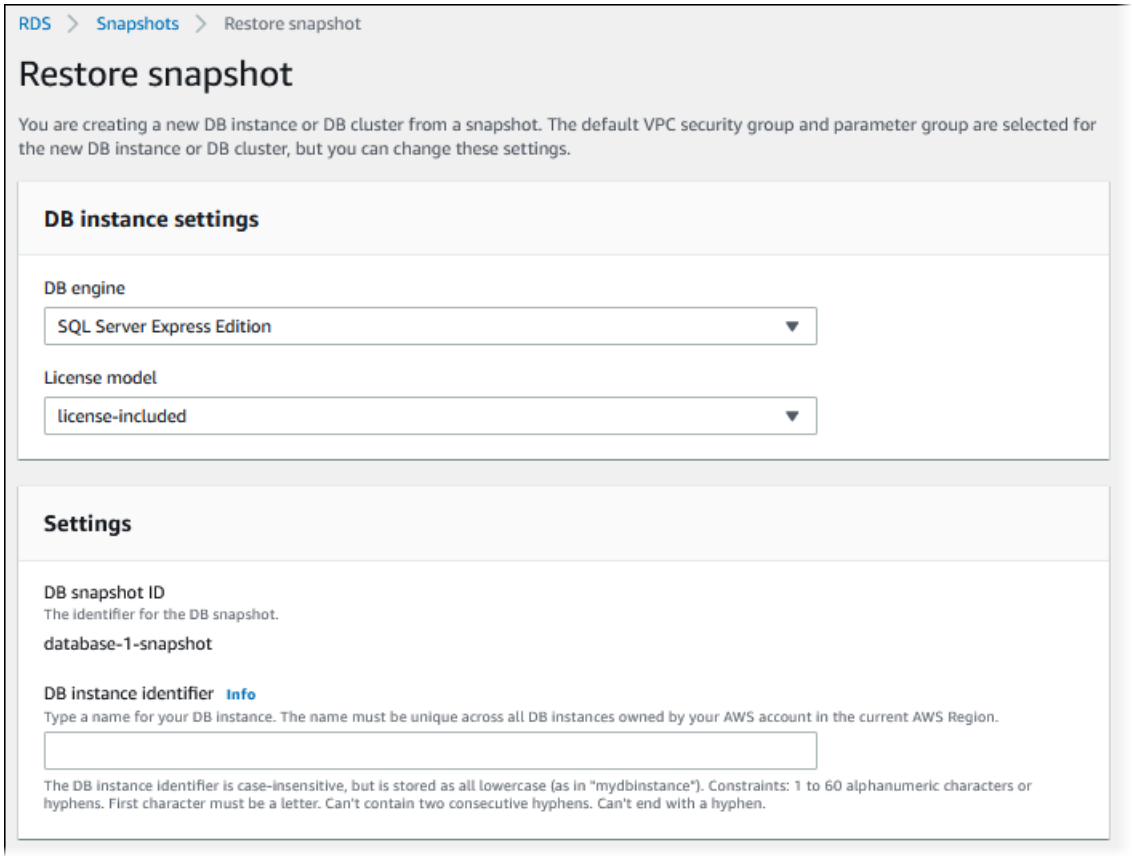
Use the following procedure to restore from a snapshot in the AWS Management Console.

To restore a DB instance from a DB snapshot

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Snapshots**.
3. Choose the DB snapshot that you want to restore from.
4. For **Actions**, choose **Restore snapshot**.



The **Restore snapshot** page appears.



5. Under **DB instance settings**, use the default settings for **DB engine** and **License model** (for Oracle or Microsoft SQL Server).
6. Under **Settings**, for **DB instance identifier** enter the unique name that you want to use for the restored DB instance, for example **`mynewdbinstance`**.

   If you're restoring from a DB instance that you deleted after you made the DB snapshot, you can use the name of that DB instance.
7. Under **Availability & durability**, choose whether to create a standby instance in another Availability Zone.

   For this tutorial, don't create a standby instance.
8. Under **Connectivity**, use the default settings for the following:

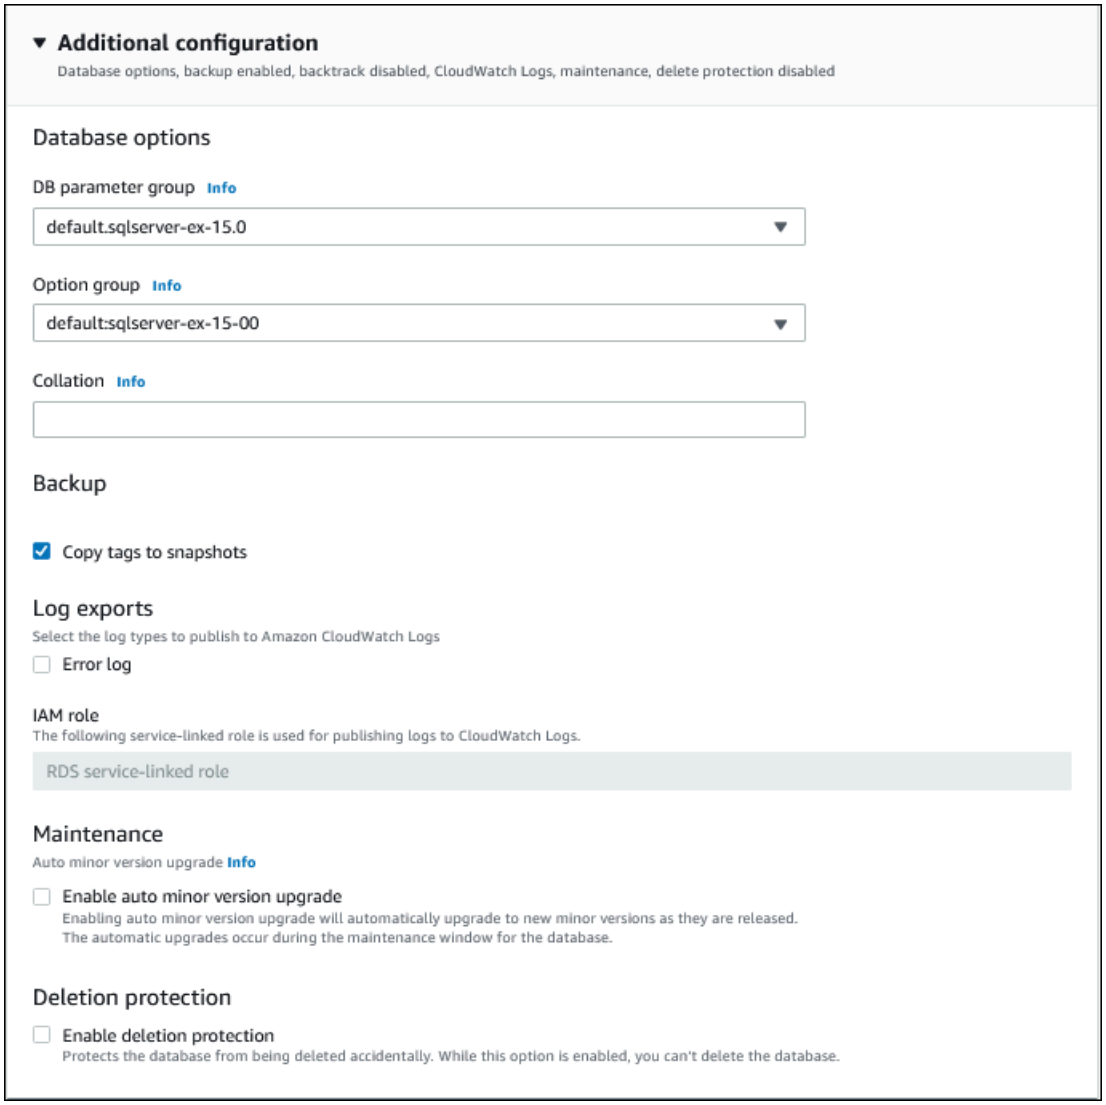
   - **Virtual private cloud (VPC)**
   - **DB subnet group**
   - **Public access**
   - **VPC security group (firewall)**
9. Choose the **DB instance class**.

For this tutorial, choose **Burstable classes (includes t classes)**, and then choose **db.t3.small**.

10. For **Encryption**, use the default settings.

    If the source DB instance for the snapshot was encrypted, the restored DB instance is also encrypted. You can't make it unencrypted.

11. Expand **Additional configuration** at the bottom of the page.



12. Do the following under **Database options**:

    a. Choose the **DB parameter group**.

       For this tutorial, use the default parameter group.

    b. Choose the **Option group**.

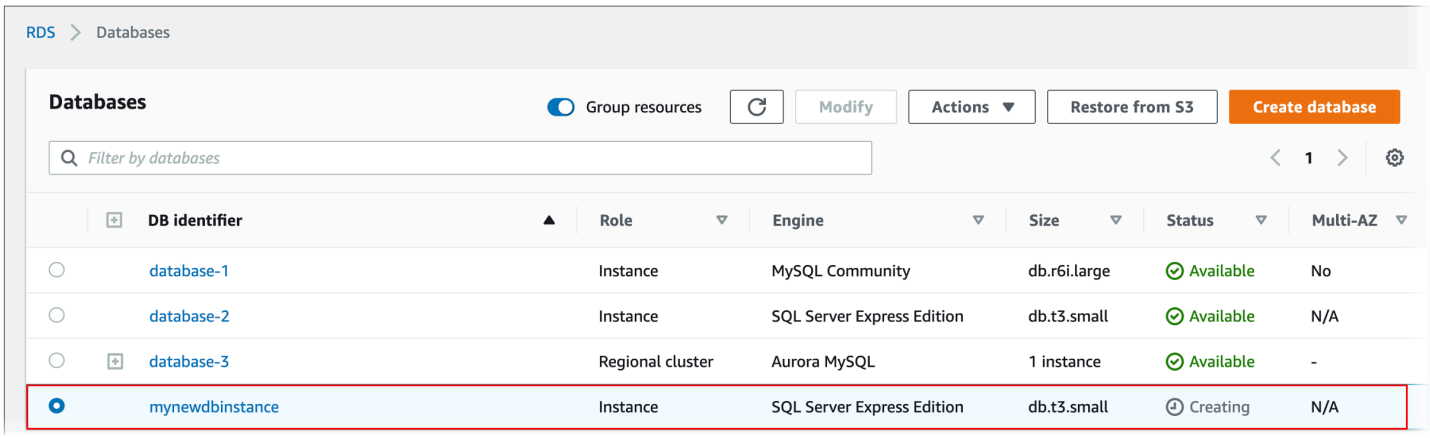
For this tutorial, use the default option group.

> **Important**
>
> In some cases, you might restore from a DB snapshot of a DB instance that uses a persistent or permanent option. If so, make sure to choose an option group that uses the same option.

c. For **Deletion protection**, choose the **Enable deletion protection** check box.

13. Choose **Restore DB instance**.

The **Databases** page displays the restored DB instance, with a status of `Creating`.



Copying a DB snapshot

With Amazon RDS, you can copy automated backups or manual DB snapshots. After you copy a snapshot, the copy is a manual snapshot. You can make multiple copies of an automated backup or manual snapshot, but each copy must have a unique identifier.

You can copy a snapshot within the same AWS Region, you can copy a snapshot across AWS Regions, and you can copy shared snapshots.

Limitations

The following are some limitations when you copy snapshots:

- You can't copy a snapshot to or from the China (Beijing) Region or the China (Ningxia) Region.
- You can copy a snapshot between AWS GovCloud (US-East) and AWS GovCloud (US-West). However, you can't copy a snapshot between these GovCloud (US) Regions and Regions that aren't GovCloud (US) Regions.
- If you delete a source snapshot before the target snapshot becomes available, the snapshot copy might fail. Verify that the target snapshot has a status of `AVAILABLE` before you delete a source snapshot.
- You can have up to 20 snapshot copy requests in progress to a single destination Region per account.
- When you request multiple snapshot copies for the same source DB instance, they're queued internally. The copies requested later won't start until the previous snapshot copies are completed. For more information, see Why is my EC2 AMI or EBS snapshot creation slow? in the AWS Knowledge Center.
- Depending on the AWS Regions involved and the amount of data to be copied, a cross-Region snapshot copy can take hours to complete. In some cases, there might be a large number of cross-Region snapshot copy requests from a given source Region. In such cases, Amazon RDS might put new cross-Region copy requests from that source Region into a queue until some in-progress copies complete. No progress information is displayed about copy requests while they are in the queue. Progress information is displayed when the copy starts.
- If a copy is still pending when you start another copy, the second copy doesn't start until the first copy finishes.
- You can't copy a snapshot of a Multi-AZ DB cluster.

- You can only copy snapshots of DB instances that use io2 volumes to AWS Regions where io2 Block Express volumes are available. For more information, see Amazon RDS DB instance storage.

Snapshot retention

Amazon RDS deletes automated backups in several situations:

- At the end of their retention period.
- When you disable automated backups for a DB instance.
- When you delete a DB instance.

If you want to keep an automated backup for a longer period, copy it to create a manual snapshot, which is retained until you delete it. Amazon RDS storage costs might apply to manual snapshots if they exceed your default storage space.

For more information about backup storage costs, see Amazon RDS pricing.

Copying shared snapshots

You can copy snapshots shared to you by other AWS accounts. In some cases, you might copy an encrypted snapshot that has been shared from another AWS account. In these cases, you must have access to the AWS KMS key that was used to encrypt the snapshot.

> **Note**
>
> Amazon RDS storage costs apply to shared snapshots you copy. Amazon RDS might attach the ARN of the source DB instance to the snapshot you copied.

You can copy a shared DB snapshot across AWS Regions if the snapshot is unencrypted. However, if the shared DB snapshot is encrypted, you can only copy it in the same Region.

> **Note**
>
> Copying shared incremental snapshots in the same AWS Region is supported when they're unencrypted, or encrypted using the same KMS key as the initial full snapshot. If you use

a different KMS key to encrypt subsequent snapshots when copying them, those shared snapshots are full snapshots. For more information, see Incremental snapshot copying.

Handling encryption

You can copy a snapshot that has been encrypted using a KMS key. If you copy an encrypted snapshot, the copy of the snapshot must also be encrypted. If you copy an encrypted snapshot within the same AWS Region, you can encrypt the copy with the same KMS key as the original snapshot. Or you can specify a different KMS key.

If you copy an encrypted snapshot across Regions, you must specify a KMS key valid in the destination AWS Region. It can be a Region-specific KMS key, or a multi-Region key. For more information on multi-Region KMS keys, see Using multi-Region keys in AWS KMS.

The source snapshot remains encrypted throughout the copy process. For more information, see Limitations of Amazon RDS encrypted DB instances.

You can also encrypt a copy of an unencrypted snapshot. This way, you can quickly add encryption to a previously unencrypted DB instance. To do this, you create a snapshot of your DB instance when you are ready to encrypt it. You then create a copy of that snapshot and specify a KMS key to encrypt that snapshot copy. You can then restore an encrypted DB instance from the encrypted snapshot.

For more information about AWS KMS key management for Amazon RDS, see AWS KMS key management.

Incremental snapshot copying

An *incremental* snapshot contains only the data that has changed after the most recent snapshot of the same DB instance. Incremental snapshot copying is faster and results in lower storage costs than full snapshot copying.

Whether a snapshot copy is incremental is determined by the most recently completed snapshot copy and the source snapshot. If the most recent snapshot copy was deleted, the next copy is a full copy, not an incremental copy. A snapshot copy will be the same type as the source snapshot. If the source snapshot is an incremental snapshot, then the snapshot copy will be an incremental snapshot.

When you copy a snapshot across AWS accounts, the copy is an incremental copy only if all of the following conditions are met:

- The most recent snapshot copy is of the same source DB instance and still exists in the destination account.
- All copies of the snapshot in the destination account are either unencrypted, or were encrypted using the same KMS key.
- If the source DB instance is a Multi-AZ instance, it hasn't failed over to another AZ since the last snapshot was taken from it.

The following examples illustrate the difference between full and incremental snapshots. They apply to both shared and unshared snapshots.

Snapshot	Encryption key	Full or incremental
S1	K1	Full
S2	K1	Incremental of S1
S3	K1	Incremental of S2
S4	K1	Incremental of S3
Copy of S1 (S1C)	K2	Full
Copy of S2 (S2C)	K3	Full
Copy of S3 (S3C)	K3	Incremental of S2C
Copy of S4 (S4C)	K3	Incremental of S3C
Copy 2 of S4 (S4C2)	K4	Full

Note

In these examples, snapshots S2, S3, and S4 are incremental only if the previous snapshot still exists.

The same applies to copies. Snapshot copies S3C and S4C are incremental only if the previous copy still exists.

For information on copying incremental snapshots across AWS Regions, see Full and incremental copies.

Cross-Region snapshot copying

You can copy DB snapshots across AWS Regions. However, there are certain constraints and considerations for cross-Region snapshot copying.

Requesting a cross-Region DB snapshot copy

To communicate with the source Region to request a cross-Region DB snapshot copy, the requester (IAM role or IAM user) must have access to the source DB snapshot and the source Region.

Certain conditions in the requester's IAM policy can cause the request to fail. The following examples assume that you're copying the DB snapshot from US East (Ohio) to US East (N. Virginia). These examples show conditions in the requester's IAM policy that cause the request to fail:

- The requester's policy has a condition for `aws:RequestedRegion`.

```
...
"Effect": "Allow",
"Action": "rds:CopyDBSnapshot",
"Resource": "*",
"Condition": {
    "StringEquals": {
        "aws:RequestedRegion": "us-east-1"
    }
}
```

The request fails because the policy doesn't allow access to the source Region. For a successful request, specify both the source and destination Regions.

```
...
"Effect": "Allow",
"Action": "rds:CopyDBSnapshot",
"Resource": "*",
```

```
"Condition": {
    "StringEquals": {
        "aws:RequestedRegion": [
            "us-east-1",
            "us-east-2"
        ]
    }
}
```

- The requester's policy doesn't allow access to the source DB snapshot.

  ```
  ...
  "Effect": "Allow",
  "Action": "rds:CopyDBSnapshot",
  "Resource": "arn:aws:rds:us-east-1:123456789012:snapshot:target-snapshot"
  ...
  ```

  For a successful request, specify both the source and target snapshots.

  ```
  ...
  "Effect": "Allow",
  "Action": "rds:CopyDBSnapshot",
  "Resource": [
      "arn:aws:rds:us-east-1:123456789012:snapshot:target-snapshot",
      "arn:aws:rds:us-east-2:123456789012:snapshot:source-snapshot"
  ]
  ...
  ```

- The requester's policy denies `aws:ViaAWSService`.

  ```
  ...
  "Effect": "Allow",
  "Action": "rds:CopyDBSnapshot",
  "Resource": "*",
  "Condition": {
      "Bool": {"aws:ViaAWSService": "false"}
  }
  ```

  Communication with the source Region is made by RDS on the requester's behalf. For a successful request, don't deny calls made by AWS services.

- The requester's policy has a condition for `aws:SourceVpc` or `aws:SourceVpce`.

These requests might fail because when RDS makes the call to the remote Region, it isn't from the specified VPC or VPC endpoint.

If you need to use one of the previous conditions that would cause a request to fail, you can include a second statement with `aws:CalledVia` in your policy to make the request succeed. For example, you can use `aws:CalledVia` with `aws:SourceVpce` as shown here:

```
...
"Effect": "Allow",
"Action": "rds:CopyDBSnapshot",
"Resource": "*",
"Condition": {
    "Condition" : {
        "ForAnyValue:StringEquals" : {
          "aws:SourceVpce": "vpce-1a2b3c4d"
        }
     }
},
{
    "Effect": "Allow",
    "Action": [
        "rds:CopyDBSnapshot"
    ],
    "Resource": "*",
    "Condition": {
        "ForAnyValue:StringEquals": {
            "aws:CalledVia": [
                "rds.amazonaws.com"
            ]
        }
    }
}
```

For more information, see Policies and permissions in IAM in the *IAM User Guide*.

Authorizing the snapshot copy

After a cross-Region DB snapshot copy request returns `success`, RDS starts the copy in the background. An authorization for RDS to access the source snapshot is created. This authorization

links the source DB snapshot to the target DB snapshot, and allows RDS to copy only to the specified target snapshot.

The authorization is verified by RDS using the `rds:CrossRegionCommunication` permission in the service-linked IAM role. If the copy is authorized, RDS communicates with the source Region and completes the copy.

RDS doesn't have access to DB snapshots that weren't authorized previously by a `CopyDBSnapshot` request. The authorization is revoked when copying completes.

RDS uses the service-linked role to verify the authorization in the source Region. If you delete the service-linked role during the copy process, the copy fails.

For more information, see Using service-linked roles in the *IAM User Guide*.

Using AWS Security Token Service credentials

Session tokens from the global AWS Security Token Service (AWS STS) endpoint are valid only in AWS Regions that are enabled by default (commercial Regions). If you use credentials from the `assumeRole` API operation in AWS STS, use the regional endpoint if the source Region is an opt-in Region. Otherwise, the request fails. This happens because your credentials must be valid in both Regions, which is true for opt-in Regions only when the regional AWS STS endpoint is used.

To use the global endpoint, make sure that it's enabled for both Regions in the operations. Set the global endpoint to `Valid in all AWS Regions` in the AWS STS account settings.

The same rule applies to credentials in the presigned URL parameter.

For more information, see Managing AWS STS in an AWS Region in the *IAM User Guide*.

Latency and multiple copy requests

Depending on the AWS Regions involved and the amount of data to be copied, a cross-Region snapshot copy can take hours to complete.

In some cases, there might be a large number of cross-Region snapshot copy requests from a given source AWS Region. In such cases, Amazon RDS might put new cross-Region copy requests from that source AWS Region into a queue until some in-progress copies complete. No progress information is displayed about copy requests while they are in the queue. Progress information is displayed when the copying starts.

Full and incremental copies

When you copy a snapshot to a different AWS Region from the source snapshot, the first copy is a full snapshot copy, even if you copy an incremental snapshot. A full snapshot copy contains all of the data and metadata required to restore the DB instance. After the first snapshot copy, you can copy incremental snapshots of the same DB instance to the same destination Region within the same AWS account. For more information on incremental snapshots, see Incremental snapshot copying.

Incremental snapshot copying across AWS Regions is supported for both unencrypted and encrypted snapshots.

When you copy a snapshot across AWS Regions, the copy is an incremental copy if the following conditions are met:

- The snapshot was previously copied to the destination Region.
- The most recent snapshot copy still exists in the destination Region.
- All copies of the snapshot in the destination Region are either unencrypted, or were encrypted using the same KMS key.

Option group considerations

DB option groups are specific to the AWS Region that they are created in, and you can't use an option group from one AWS Region in another AWS Region.

For Oracle databases, you can use the AWS CLI or RDS API to copy the custom DB option group from a snapshot that has been shared with your AWS account. You can only copy option groups within the same AWS Region. The option group isn't copied if it has already been copied to the destination account and no changes have been made to it since being copied. If the source option group has been copied before, but has changed since being copied, RDS copies the new version to the destination account. Default option groups aren't copied.

When you copy a snapshot across Regions, you can specify a new option group for the snapshot. We recommend that you prepare the new option group before you copy the snapshot. In the destination AWS Region, create an option group with the same settings as the original DB instance. If one already exists in the new AWS Region, you can use that one.

In some cases, you might copy a snapshot and not specify a new option group for the snapshot. In these cases, when you restore the snapshot the DB instance gets the default option group. To give the new DB instance the same options as the original, do the following:

1. In the destination AWS Region, create an option group with the same settings as the original DB instance. If one already exists in the new AWS Region, you can use that one.
2. After you restore the snapshot in the destination AWS Region, modify the new DB instance and add the new or existing option group from the previous step.

Parameter group considerations

When you copy a snapshot across Regions, the copy doesn't include the parameter group used by the original DB instance. When you restore a snapshot to create a new DB instance, that DB instance gets the default parameter group for the AWS Region it is created in. To give the new DB instance the same parameters as the original, do the following:

1. In the destination AWS Region, create a DB parameter group with the same settings as the original DB instance. If one already exists in the new AWS Region, you can use that one.
2. After you restore the snapshot in the destination AWS Region, modify the new DB instance and add the new or existing parameter group from the previous step.

Copying a DB snapshot

Use the procedures in this topic to copy a DB snapshot. For an overview of copying a snapshot, see Copying a DB snapshot

For each AWS account, you can copy up to 20 DB snapshots at a time from one AWS Region to another. If you copy a DB snapshot to another AWS Region, you create a manual DB snapshot that is retained in that AWS Region. Copying a DB snapshot out of the source AWS Region incurs Amazon RDS data transfer charges.

For more information about data transfer pricing, see Amazon RDS pricing.

After the DB snapshot copy has been created in the new AWS Region, the DB snapshot copy behaves the same as all other DB snapshots in that AWS Region.

You can copy a DB snapshot using the AWS Management Console, the AWS CLI, or the RDS API.

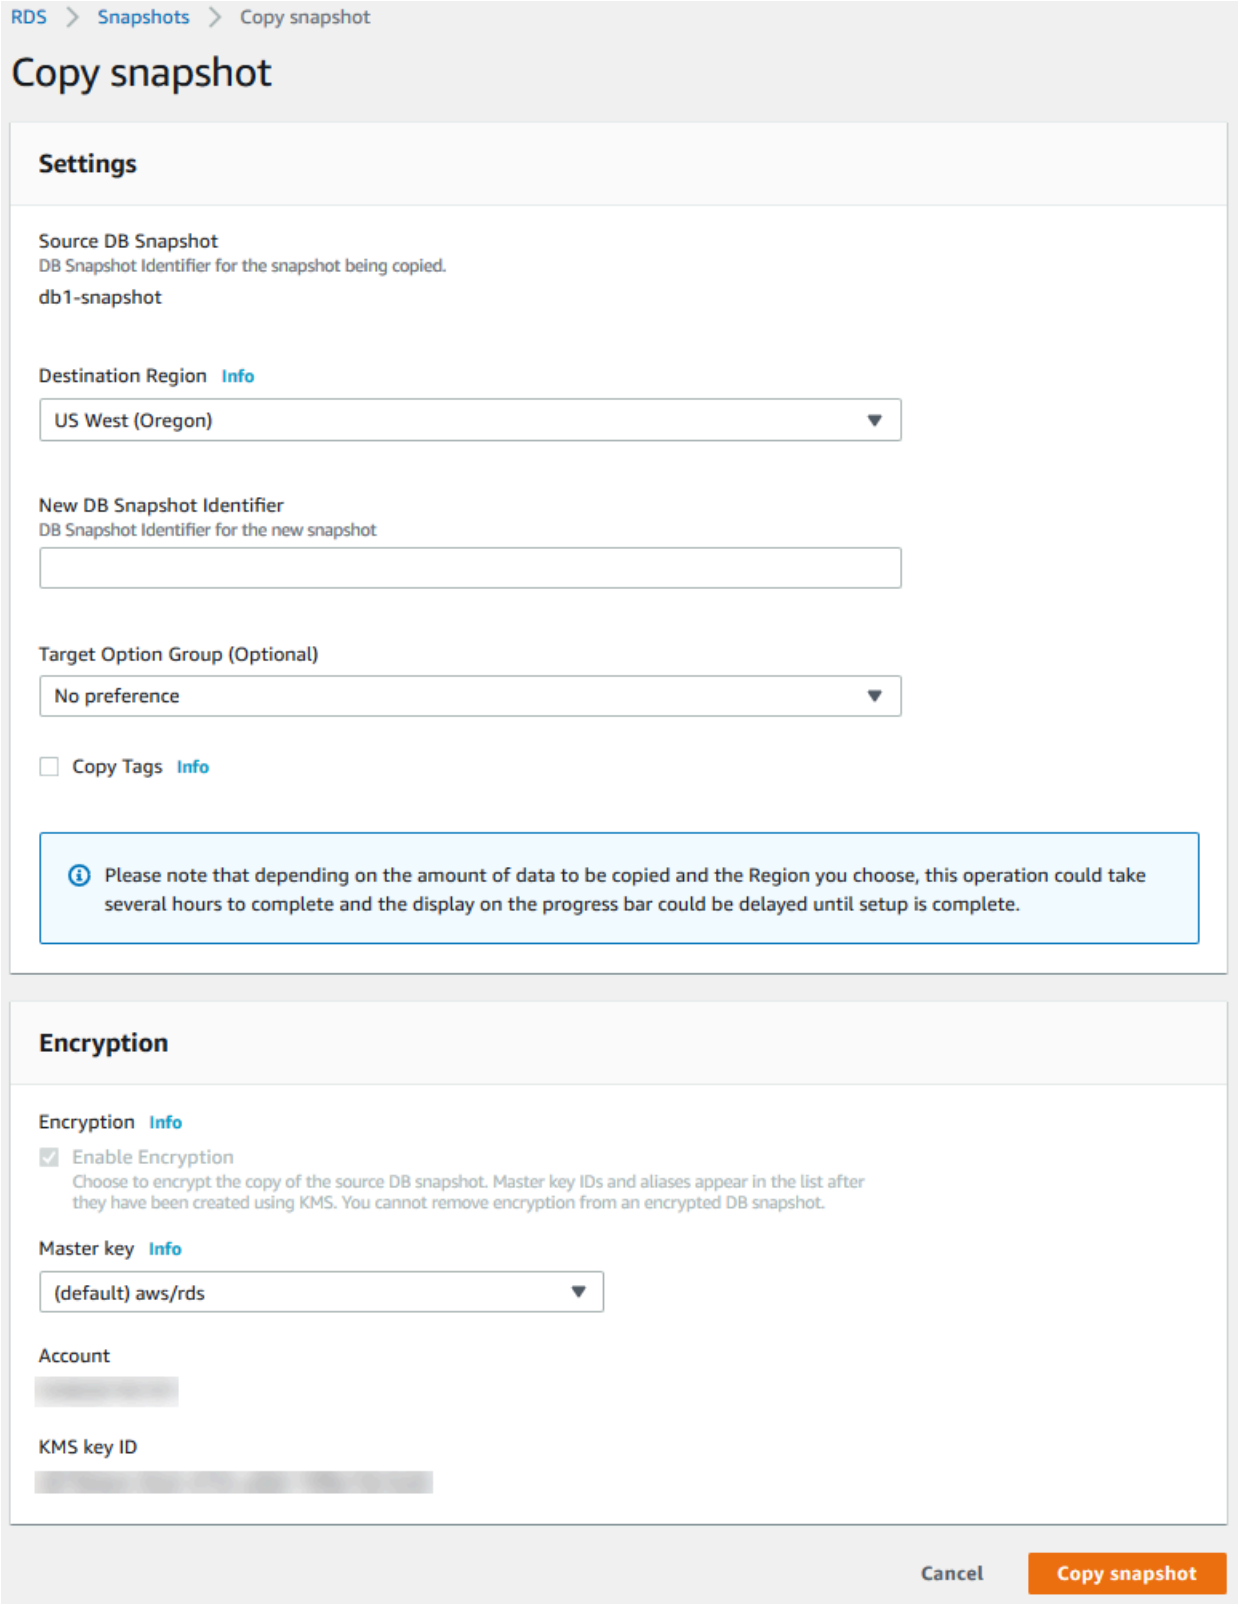
Console

The following procedure copies an encrypted or unencrypted DB snapshot, in the same AWS Region or across Regions, by using the AWS Management Console.

To copy a DB snapshot

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Snapshots**.
3. Select the DB snapshot that you want to copy.
4. For **Actions**, choose **Copy snapshot**.

   The **Copy snapshot** page appears.



5. For **Target option group (optional)**, choose a new option group if you want.

Specify this option if you are copying a snapshot from one AWS Region to another, and your DB instance uses a nondefault option group.

If your source DB instance uses Transparent Data Encryption for Oracle or Microsoft SQL Server, you must specify this option when copying across Regions. For more information, see Option group considerations.

6. (Optional) To copy the DB snapshot to a different AWS Region, for **Destination Region**, choose the new AWS Region.

   > **Note**
   >
   > The destination AWS Region must have the same database engine version available as the source AWS Region.

7. For **New DB snapshot identifier**, type the name of the DB snapshot copy.

   You can make multiple copies of an automated backup or manual snapshot, but each copy must have a unique identifier.

8. (Optional) Select **Copy Tags** to copy tags and values from the snapshot to the copy of the snapshot.

9. (Optional) For **Encryption**, do the following:

   a. Choose **Enable Encryption** if the DB snapshot isn't encrypted but you want to encrypt the copy.

      > **Note**
      >
      > If the DB snapshot is encrypted, you must encrypt the copy, so the check box is already selected.

   b. For **AWS KMS key**, specify the KMS key identifier to use to encrypt the DB snapshot copy.

10. Choose **Copy snapshot**.

AWS CLI

You can copy a DB snapshot by using the AWS CLI command copy-db-snapshot. If you are copying the snapshot to a new AWS Region, run the command in the new AWS Region.

The following options are used to copy a DB snapshot. Not all options are required for all scenarios. Use the descriptions and the examples that follow to determine which options to use.

- `--source-db-snapshot-identifier` – The identifier for the source DB snapshot.
  - If the source snapshot is in the same AWS Region as the copy, specify a valid DB snapshot identifier. For example, `rds:mysql-instance1-snapshot-20130805`.
  - If the source snapshot is in the same AWS Region as the copy, and has been shared with your AWS account, specify a valid DB snapshot ARN. For example, `arn:aws:rds:us-west-2:123456789012:snapshot:mysql-instance1-snapshot-20130805`.
  - If the source snapshot is in a different AWS Region than the copy, specify a valid DB snapshot ARN. For example, `arn:aws:rds:us-west-2:123456789012:snapshot:mysql-instance1-snapshot-20130805`.
  - If you are copying from a shared manual DB snapshot, this parameter must be the Amazon Resource Name (ARN) of the shared DB snapshot.
  - If you are copying an encrypted snapshot this parameter must be in the ARN format for the source AWS Region, and must match the `SourceDBSnapshotIdentifier` in the `PreSignedUrl` parameter.
- `--target-db-snapshot-identifier` – The identifier for the new copy of the encrypted DB snapshot.
- `--copy-option-group` – Copy the option group from a snapshot that has been shared with your AWS account.
- `--copy-tags` – Include the copy tags option to copy tags and values from the snapshot to the copy of the snapshot.
- `--option-group-name` – The option group to associate with the copy of the snapshot.

  Specify this option if you are copying a snapshot from one AWS Region to another, and your DB instance uses a non-default option group.

  If your source DB instance uses Transparent Data Encryption for Oracle or Microsoft SQL Server, you must specify this option when copying across Regions. For more information, see Option group considerations.
- `--kms-key-id` – The KMS key identifier for an encrypted DB snapshot. The KMS key identifier is the Amazon Resource Name (ARN), key identifier, or key alias for the KMS key.
  - If you copy an encrypted DB snapshot from your AWS account, you can specify a value for this parameter to encrypt the copy with a new KMS key. If you don't specify a value for this

parameter, then the copy of the DB snapshot is encrypted with the same KMS key as the source DB snapshot.

- If you copy an encrypted DB snapshot that is shared from another AWS account, then you must specify a value for this parameter.
- If you specify this parameter when you copy an unencrypted snapshot, the copy is encrypted.
- If you copy an encrypted snapshot to a different AWS Region, then you must specify a KMS key for the destination AWS Region. KMS keys are specific to the AWS Region that they are created in, and you cannot use encryption keys from one AWS Region in another AWS Region.

Example from unencrypted, to the same Region

The following code creates a copy of a snapshot, with the new name `mydbsnapshotcopy`, in the same AWS Region as the source snapshot. When the copy is made, the DB option group and tags on the original snapshot are copied to the snapshot copy.

For Linux, macOS, or Unix:

```
aws rds copy-db-snapshot \
    --source-db-snapshot-identifier arn:aws:rds:us-west-2:123456789012:snapshot:mysql-instance1-snapshot-20130805 \
    --target-db-snapshot-identifier mydbsnapshotcopy \
    --copy-option-group \
    --copy-tags
```

For Windows:

```
aws rds copy-db-snapshot ^
    --source-db-snapshot-identifier arn:aws:rds:us-west-2:123456789012:snapshot:mysql-instance1-snapshot-20130805 ^
    --target-db-snapshot-identifier mydbsnapshotcopy ^
    --copy-option-group ^
    --copy-tags
```

Example from unencrypted, across Regions

The following code creates a copy of a snapshot, with the new name `mydbsnapshotcopy`, in the AWS Region in which the command is run.

For Linux, macOS, or Unix:

```
aws rds copy-db-snapshot \
    --source-db-snapshot-identifier arn:aws:rds:us-east-1:123456789012:snapshot:mysql-instance1-snapshot-20130805 \
    --target-db-snapshot-identifier mydbsnapshotcopy
```

For Windows:

```
aws rds copy-db-snapshot ^
    --source-db-snapshot-identifier arn:aws:rds:us-east-1:123456789012:snapshot:mysql-instance1-snapshot-20130805 ^
    --target-db-snapshot-identifier mydbsnapshotcopy
```

Example from encrypted, across Regions

The following code example copies an encrypted DB snapshot from the US West (Oregon) Region in the US East (N. Virginia) Region. Run the command in the destination (us-east-1) Region.

For Linux, macOS, or Unix:

```
aws rds copy-db-snapshot \
    --source-db-snapshot-identifier arn:aws:rds:us-west-2:123456789012:snapshot:mysql-instance1-snapshot-20161115 \
    --target-db-snapshot-identifier mydbsnapshotcopy \
    --kms-key-id my-us-east-1-key \
    --option-group-name custom-option-group-name
```

For Windows:

```
aws rds copy-db-snapshot ^
    --source-db-snapshot-identifier arn:aws:rds:us-west-2:123456789012:snapshot:mysql-instance1-snapshot-20161115 ^
    --target-db-snapshot-identifier mydbsnapshotcopy ^
    --kms-key-id my-us-east-1-key ^
    --option-group-name custom-option-group-name
```

The `--source-region` parameter is required when you're copying an encrypted snapshot between the AWS GovCloud (US-East) and AWS GovCloud (US-West) Regions. For `--source-region`, specify the AWS Region of the source DB instance.

If `--source-region` isn't specified, specify a `--pre-signed-url` value. A *presigned URL* is a URL that contains a Signature Version 4 signed request for the `copy-db-snapshot` command that's

called in the source AWS Region. To learn more about the `pre-signed-url` option, see copy-db-snapshot in the *AWS CLI Command Reference*.

RDS API

You can copy a DB snapshot by using the Amazon RDS API operation CopyDBSnapshot. If you are copying the snapshot to a new AWS Region, perform the action in the new AWS Region.

The following parameters are used to copy a DB snapshot. Not all parameters are required for all scenarios. Use the descriptions and the examples that follow to determine which parameters to use.

- `SourceDBSnapshotIdentifier` – The identifier for the source DB snapshot.
  - If the source snapshot is in the same AWS Region as the copy, specify a valid DB snapshot identifier. For example, `rds:mysql-instance1-snapshot-20130805`.
  - If the source snapshot is in the same AWS Region as the copy, and has been shared with your AWS account, specify a valid DB snapshot ARN. For example, `arn:aws:rds:us-west-2:123456789012:snapshot:mysql-instance1-snapshot-20130805`.
  - If the source snapshot is in a different AWS Region than the copy, specify a valid DB snapshot ARN. For example, `arn:aws:rds:us-west-2:123456789012:snapshot:mysql-instance1-snapshot-20130805`.
  - If you are copying from a shared manual DB snapshot, this parameter must be the Amazon Resource Name (ARN) of the shared DB snapshot.
  - If you are copying an encrypted snapshot this parameter must be in the ARN format for the source AWS Region, and must match the `SourceDBSnapshotIdentifier` in the `PreSignedUrl` parameter.
- `TargetDBSnapshotIdentifier` – The identifier for the new copy of the encrypted DB snapshot.
- `CopyOptionGroup` – Set this parameter to `true` to copy the option group from a shared snapshot to the copy of the snapshot. The default is `false`.
- `CopyTags` – Set this parameter to `true` to copy tags and values from the snapshot to the copy of the snapshot. The default is `false`.
- `OptionGroupName` – The option group to associate with the copy of the snapshot.

  Specify this parameter if you are copying a snapshot from one AWS Region to another, and your DB instance uses a non-default option group.

If your source DB instance uses Transparent Data Encryption for Oracle or Microsoft SQL Server, you must specify this parameter when copying across Regions. For more information, see Option group considerations.

- `KmsKeyId` – The KMS key identifier for an encrypted DB snapshot. The KMS key identifier is the Amazon Resource Name (ARN), key identifier, or key alias for the KMS key.
  - If you copy an encrypted DB snapshot from your AWS account, you can specify a value for this parameter to encrypt the copy with a new KMS key. If you don't specify a value for this parameter, then the copy of the DB snapshot is encrypted with the same KMS key as the source DB snapshot.
  - If you copy an encrypted DB snapshot that is shared from another AWS account, then you must specify a value for this parameter.
  - If you specify this parameter when you copy an unencrypted snapshot, the copy is encrypted.
  - If you copy an encrypted snapshot to a different AWS Region, then you must specify a KMS key for the destination AWS Region. KMS keys are specific to the AWS Region that they are created in, and you can't use encryption keys from one AWS Region in another AWS Region.
- `PreSignedUrl` – The URL that contains a Signature Version 4 signed request for the `CopyDBSnapshot` API operation in the source AWS Region that contains the source DB snapshot to copy.

  Specify this parameter when you copy an encrypted DB snapshot from another AWS Region by using the Amazon RDS API. You can specify the source Region option instead of this parameter when you copy an encrypted DB snapshot from another AWS Region by using the AWS CLI.

  The presigned URL must be a valid request for the `CopyDBSnapshot` API operation that can be run in the source AWS Region containing the encrypted DB snapshot to be copied. The presigned URL request must contain the following parameter values:

  - `DestinationRegion` – The AWS Region that the encrypted DB snapshot will be copied to. This AWS Region is the same one where the `CopyDBSnapshot` operation is called that contains this presigned URL.

    For example, suppose that you copy an encrypted DB snapshot from the us-west-2 Region to the us-east-1 Region. You then call the `CopyDBSnapshot` operation in the us-east-1 Region and provide a presigned URL that contains a call to the `CopyDBSnapshot` operation in the us-west-2 Region. For this example, the `DestinationRegion` in the presigned URL must be set to the us-east-1 Region.

- `KmsKeyId` – The KMS key identifier for the key to use to encrypt the copy of the DB snapshot in the destination AWS Region. This is the same identifier for both the `CopyDBSnapshot` operation that is called in the destination AWS Region, and the operation contained in the presigned URL.
- `SourceDBSnapshotIdentifier` – The DB snapshot identifier for the encrypted snapshot to be copied. This identifier must be in the Amazon Resource Name (ARN) format for the source AWS Region. For example, if you're copying an encrypted DB snapshot from the us-west-2 Region, then your `SourceDBSnapshotIdentifier` looks like the following example: `arn:aws:rds:us-west-2:123456789012:snapshot:mysql-instance1-snapshot-20161115`.

For more information on Signature Version 4 signed requests, see the following:

- Authenticating requests: Using query parameters (AWS signature version 4) in the Amazon Simple Storage Service API Reference
- Signature version 4 signing process in the AWS General Reference

Example from unencrypted, to the same Region

The following code creates a copy of a snapshot, with the new name `mydbsnapshotcopy`, in the same AWS Region as the source snapshot. When the copy is made, all tags on the original snapshot are copied to the snapshot copy.

```
https://rds.us-west-1.amazonaws.com/
 ?Action=CopyDBSnapshot
 &CopyTags=true
 &SignatureMethod=HmacSHA256
 &SignatureVersion=4
 &SourceDBSnapshotIdentifier=mysql-instance1-snapshot-20130805
 &TargetDBSnapshotIdentifier=mydbsnapshotcopy
 &Version=2013-09-09
 &X-Amz-Algorithm=AWS4-HMAC-SHA256
 &X-Amz-Credential=AKIADQKE4SARGYLE/20140429/us-west-1/rds/aws4_request
 &X-Amz-Date=20140429T175351Z
 &X-Amz-SignedHeaders=content-type;host;user-agent;x-amz-content-sha256;x-amz-date
 &X-Amz-Signature=9164337efa99caf850e874a1cb7ef62f3cea29d0b448b9e0e7c53b288ddffed2
```

Example from unencrypted, across Regions

The following code creates a copy of a snapshot, with the new name mydbsnapshotcopy, in the US West (N. California) Region.

```
https://rds.us-west-1.amazonaws.com/
 ?Action=CopyDBSnapshot
 &SignatureMethod=HmacSHA256
 &SignatureVersion=4
 &SourceDBSnapshotIdentifier=arn%3Aaws%3Ards%3Aus-east-1%3A123456789012%3Asnapshot
%3Amysql-instance1-snapshot-20130805
 &TargetDBSnapshotIdentifier=mydbsnapshotcopy
 &Version=2013-09-09
 &X-Amz-Algorithm=AWS4-HMAC-SHA256
 &X-Amz-Credential=AKIADQKE4SARGYLE/20140429/us-west-1/rds/aws4_request
 &X-Amz-Date=20140429T175351Z
 &X-Amz-SignedHeaders=content-type;host;user-agent;x-amz-content-sha256;x-amz-date
 &X-Amz-Signature=9164337efa99caf850e874a1cb7ef62f3cea29d0b448b9e0e7c53b288ddffed2
```

Example from encrypted, across Regions

The following code creates a copy of a snapshot, with the new name mydbsnapshotcopy, in the US East (N. Virginia) Region.

```
https://rds.us-east-1.amazonaws.com/
    ?Action=CopyDBSnapshot
    &KmsKeyId=my-us-east-1-key
    &OptionGroupName=custom-option-group-name
    &PreSignedUrl=https%253A%252F%252Frds.us-west-2.amazonaws.com%252F
         %253FAction%253DCopyDBSnapshot
         %2526DestinationRegion%253Dus-east-1
         %2526KmsKeyId%253Dmy-us-east-1-key

```

Sharing a DB snapshot

Using Amazon RDS, you can share a manual DB snapshot in the following ways:

- Sharing a manual DB snapshot, whether encrypted or unencrypted, enables authorized AWS accounts to copy the snapshot.
- Sharing an unencrypted manual DB snapshot enables authorized AWS accounts to directly restore a DB instance from the snapshot instead of taking a copy of it and restoring from that. However, you can't restore a DB instance from a DB snapshot that is both shared and encrypted. Instead, you can make a copy of the DB snapshot and restore the DB instance from the copy.

> **Note**
>
> To share an automated DB snapshot, create a manual DB snapshot by copying the automated snapshot, and then share that copy. This process also applies to AWS Backup–generated resources.

For more information on copying a snapshot, see Copying a DB snapshot. For more information on restoring a DB instance from a DB snapshot, see Restoring to a DB instance.

You can share a manual snapshot with up to 20 other AWS accounts.

The following limitations apply when sharing manual snapshots with other AWS accounts:

- When you restore a DB instance from a shared snapshot using the AWS Command Line Interface (AWS CLI) or Amazon RDS API, you must specify the Amazon Resource Name (ARN) of the shared snapshot as the snapshot identifier.
- You can't share a DB snapshot that uses an option group with permanent or persistent options, except for Oracle DB instances that have the `Timezone` or `OLS` option (or both).

  A *permanent option* can't be removed from an option group. Option groups with persistent options can't be removed from a DB instance once the option group has been assigned to the DB instance.

  The following table lists permanent and persistent options and their related DB engines.

Option name	Persistent	Permanent	DB engine
TDE	Yes	No	Microsoft SQL Server Enterprise Edition
TDE	Yes	Yes	Oracle Enterprise Edition
Timezone	Yes	Yes	Oracle Enterprise Edition Oracle Standard Edition Oracle Standard Edition One Oracle Standard Edition 2

For Oracle DB instances, you can copy shared DB snapshots that have the `Timezone` or `OLS` option (or both). To do so, specify a target option group that includes these options when you copy the DB snapshot. The OLS option is permanent and persistent only for Oracle DB instances running Oracle version 12.2 or higher. For more information about these options, see Oracle time zone and Oracle Label Security.

- You can't share a snapshot of a Multi-AZ DB cluster.

Contents

Sharing a snapshot

You can share a DB snapshot using the AWS Management Console, the AWS CLI, or the RDS API.

Console

Using the Amazon RDS console, you can share a manual DB snapshot with up to 20 AWS accounts. You can also use the console to stop sharing a manual snapshot with one or more accounts.

To share a manual DB snapshot by using the Amazon RDS console

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Snapshots**.
3. Select the manual snapshot that you want to share.
4. For **Actions**, choose **Share snapshot**.
5. Choose one of the following options for **DB snapshot visibility**.

   - If the source is unencrypted, choose **Public** to permit all AWS accounts to restore a DB instance from your manual DB snapshot, or choose **Private** to permit only AWS accounts that you specify to restore a DB instance from your manual DB snapshot.

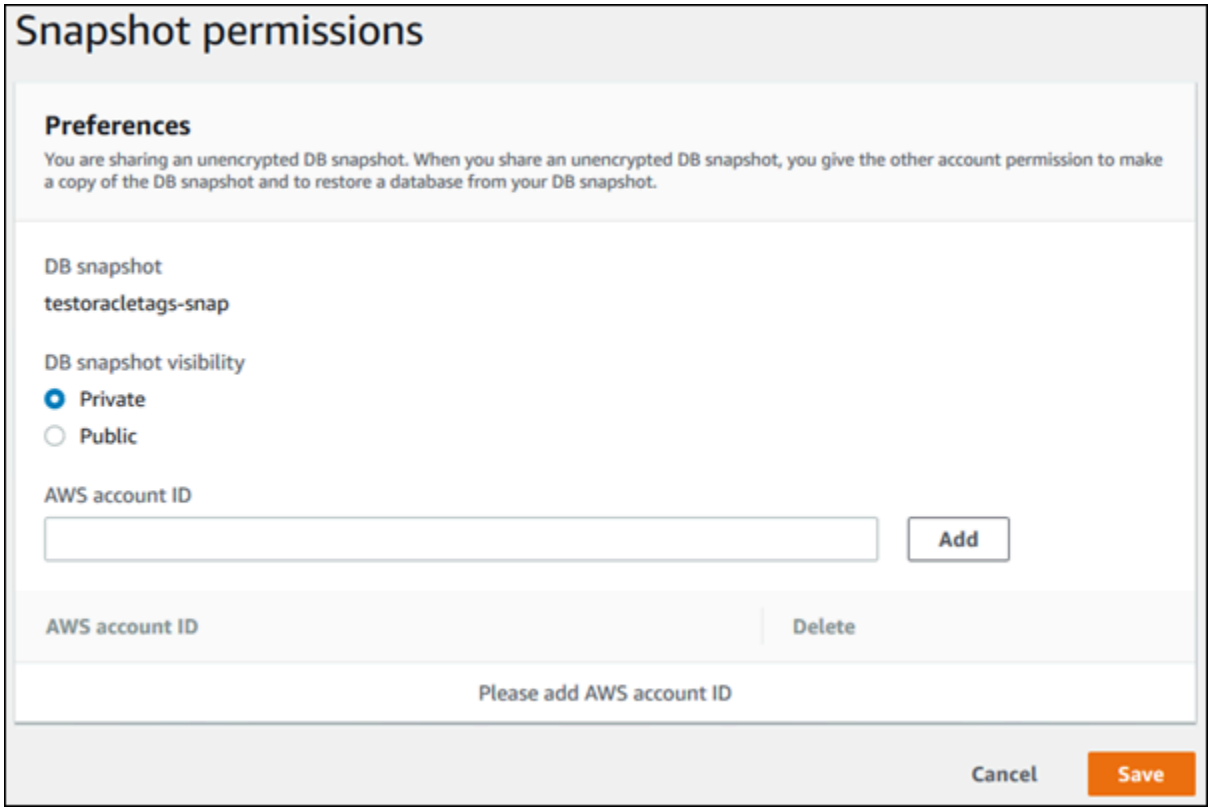
     > **Warning**
     >
     > If you set **DB snapshot visibility** to **Public**, all AWS accounts can restore a DB instance from your manual DB snapshot and have access to your data. Do not share any manual DB snapshots that contain private information as **Public**.
     > For more information, see Sharing public snapshots.

   - If the source is encrypted, **DB snapshot visibility** is set as **Private** because encrypted snapshots can't be shared as public.

     > **Note**
     >
     > Snapshots that have been encrypted with the default AWS KMS key can't be shared. For information on how to work around this issue, see Sharing encrypted snapshots.

6. For **AWS Account ID**, enter the AWS account identifier for an account that you want to permit to restore a DB instance from your manual snapshot, and then choose **Add**. Repeat to include additional AWS account identifiers, up to 20 AWS accounts.

   If you make an error when adding an AWS account identifier to the list of permitted accounts, you can delete it from the list by choosing **Delete** at the right of the incorrect AWS account identifier.



7. After you have added identifiers for all of the AWS accounts that you want to permit to restore the manual snapshot, choose **Save** to save your changes.

AWS CLI

To share a DB snapshot, use the `aws rds modify-db-snapshot-attribute` command. Use the `--values-to-add` parameter to add a list of the IDs for the AWS accounts that are authorized to restore the manual snapshot.

Example of sharing a snapshot with a single account

The following example enables AWS account identifier `123456789012` to restore the DB snapshot named `db7-snapshot`.

For Linux, macOS, or Unix:

```
aws rds modify-db-snapshot-attribute \
--db-snapshot-identifier db7-snapshot \
--attribute-name restore \
--values-to-add 123456789012
```

For Windows:

```
aws rds modify-db-snapshot-attribute ^
--db-snapshot-identifier db7-snapshot ^
--attribute-name restore ^
--values-to-add 123456789012
```

Example of sharing a snapshot with multiple accounts

The following example enables two AWS account identifiers, 111122223333 and 444455556666, to restore the DB snapshot named `manual-snapshot1`.

For Linux, macOS, or Unix:

```
aws rds modify-db-snapshot-attribute \
--db-snapshot-identifier manual-snapshot1 \
--attribute-name restore \
--values-to-add {"111122223333","444455556666"}
```

For Windows:

```
aws rds modify-db-snapshot-attribute ^
--db-snapshot-identifier manual-snapshot1 ^
--attribute-name restore ^
--values-to-add "[\"111122223333\",\"444455556666\"]"
```

> **Note**
>
> When using the Windows command prompt, you must escape double quotes (") in JSON code by prefixing them with a backslash (\).

To list the AWS accounts enabled to restore a snapshot, use the `describe-db-snapshot-attributes` AWS CLI command.

RDS API

You can also share a manual DB snapshot with other AWS accounts by using the Amazon RDS API. To do so, call the `ModifyDBSnapshotAttribute` operation. Specify `restore` for `AttributeName`, and use the `ValuesToAdd` parameter to add a list of the IDs for the AWS accounts that are authorized to restore the manual snapshot.

To make a manual snapshot public and restorable by all AWS accounts, use the value `all`. However, take care not to add the `all` value for any manual snapshots that contain private information that you don't want to be available to all AWS accounts. Also, don't specify `all` for encrypted snapshots, because making such snapshots public isn't supported.

To list all of the AWS accounts permitted to restore a snapshot, use the `DescribeDBSnapshotAttributes` API operation.

Sharing public snapshots

You can also share an unencrypted manual snapshot as public, which makes the snapshot available to all AWS accounts. Make sure when sharing a snapshot as public that none of your private information is included in the public snapshot.

When a snapshot is shared publicly, it gives all AWS accounts permission both to copy the snapshot and to create DB instances from it.

You aren't billed for the backup storage of public snapshots owned by other accounts. You're billed only for snapshots that you own.

If you copy a public snapshot, you own the copy. You're billed for the backup storage of your snapshot copy. If you create a DB instance from a public snapshot, you're billed for that DB instance. For Amazon RDS pricing information, see the Amazon RDS product page.

You can delete only the public snapshots that you own. To delete a shared or public snapshot, make sure to log into the AWS account that owns the snapshot.

Viewing public snapshots owned by other AWS accounts

You can view public snapshots owned by other accounts in a particular AWS Region on the **Public** tab of the **Snapshots** page in the Amazon RDS console. Your snapshots (those owned by your account) don't appear on this tab.

To view public snapshots

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Snapshots**.
3. Choose the **Public** tab.

   The public snapshots appear. You can see which account owns a public snapshot in the **Owner** column.

   > **Note**
   >
   > You might have to modify the page preferences, by selecting the gear icon at the upper right of the **Public snapshots** list, to see this column.

Viewing your own public snapshots

You can use the following AWS CLI command (Unix only) to view the public snapshots owned by your AWS account in a particular AWS Region.

```
aws rds describe-db-snapshots --snapshot-type public --include-public |
 grep account_number
```

The output returned is similar to the following example if you have public snapshots.

```
"DBSnapshotArn": "arn:aws:rds:us-east-1:123456789012:snapshot:mysnapshot1",
"DBSnapshotArn": "arn:aws:rds:us-east-1:123456789012:snapshot:mysnapshot2",
```

> **Note**
>
> You might see duplicate entries for `DBSnapshotIdentifier` or `SourceDBSnapshotIdentifier`.

Sharing public snapshots from deprecated DB engine versions

Restoring or copying public snapshots from deprecated DB engine versions isn't supported.

The RDS for Oracle and RDS for PostgreSQL DB engines support upgrading DB snapshot engine versions directly. You can upgrade your snapshots, then re-share them publicly. For more information, see the following:

- Upgrading an Oracle DB snapshot
- Upgrading a PostgreSQL DB snapshot engine version

For other DB engines, perform the following steps to make your existing unsupported public snapshot available to restore or copy:

1. Mark the snapshot as private.
2. Restore the snapshot.
3. Upgrade the restored DB instance to a supported engine version.
4. Create a new snapshot.
5. Re-share the snapshot publicly.

Sharing encrypted snapshots

You can share DB snapshots that have been encrypted "at rest" using the AES-256 encryption algorithm, as described in Encrypting Amazon RDS resources.

The following restrictions apply to sharing encrypted snapshots:

- You can't share encrypted snapshots as public.
- You can't share Oracle or Microsoft SQL Server snapshots that are encrypted using Transparent Data Encryption (TDE).
- You can't share a snapshot that has been encrypted using the default KMS key of the AWS account that shared the snapshot.

  For more information about AWS KMS key management for Amazon RDS, see AWS KMS key management.

To work around the default KMS key issue, perform the following tasks:

1. Create a customer managed key and give access to it.
2. Copy and share the snapshot from the source account.

3. Copy the shared snapshot in the target account.

Create a customer managed key and give access to it

First you create a custom KMS key in the same AWS Region as the encrypted DB snapshot. While creating the customer managed key, you give access to it for another AWS account.

To create a customer managed key and give access to it

1. Sign in to the AWS Management Console from the source AWS account.
2. Open the AWS KMS console at https://console.aws.amazon.com/kms.
3. To change the AWS Region, use the Region selector in the upper-right corner of the page.
4. In the navigation pane, choose **Customer managed keys**.
5. Choose **Create key**.
6. On the **Configure key** page:
    a. For **Key type**, select **Symmetric**.
    b. For **Key usage**, select **Encrypt and decrypt**.
    c. Expand **Advanced options**.
    d. For **Key material origin**, select **KMS**.
    e. For **Regionality**, select **Single-Region key**.
    f. Choose **Next**.
7. On the **Add labels** page:
    a. For **Alias**. enter a display name for your KMS key, for example **`share-snapshot`**.
    b. (Optional) Enter a description for your KMS key.
    c. (Optional) Add tags to your KMS key.
    d. Choose **Next**.
8. On the **Define key administrative permissions** page, choose **Next.**
9. On the **Define key usage permissions** page:
    a. For **Other AWS accounts**, choose **Add another AWS account**.
    b. Enter the ID of the AWS account to which you want to give access.

        You can give access to multiple AWS accounts.

c. Choose **Next**.

10. Review your KMS key, then choose **Finish**.

Copy and share the snapshot from the source account

Next you copy the source DB snapshot to a new snapshot using the customer managed key. Then you share it with the target AWS account.

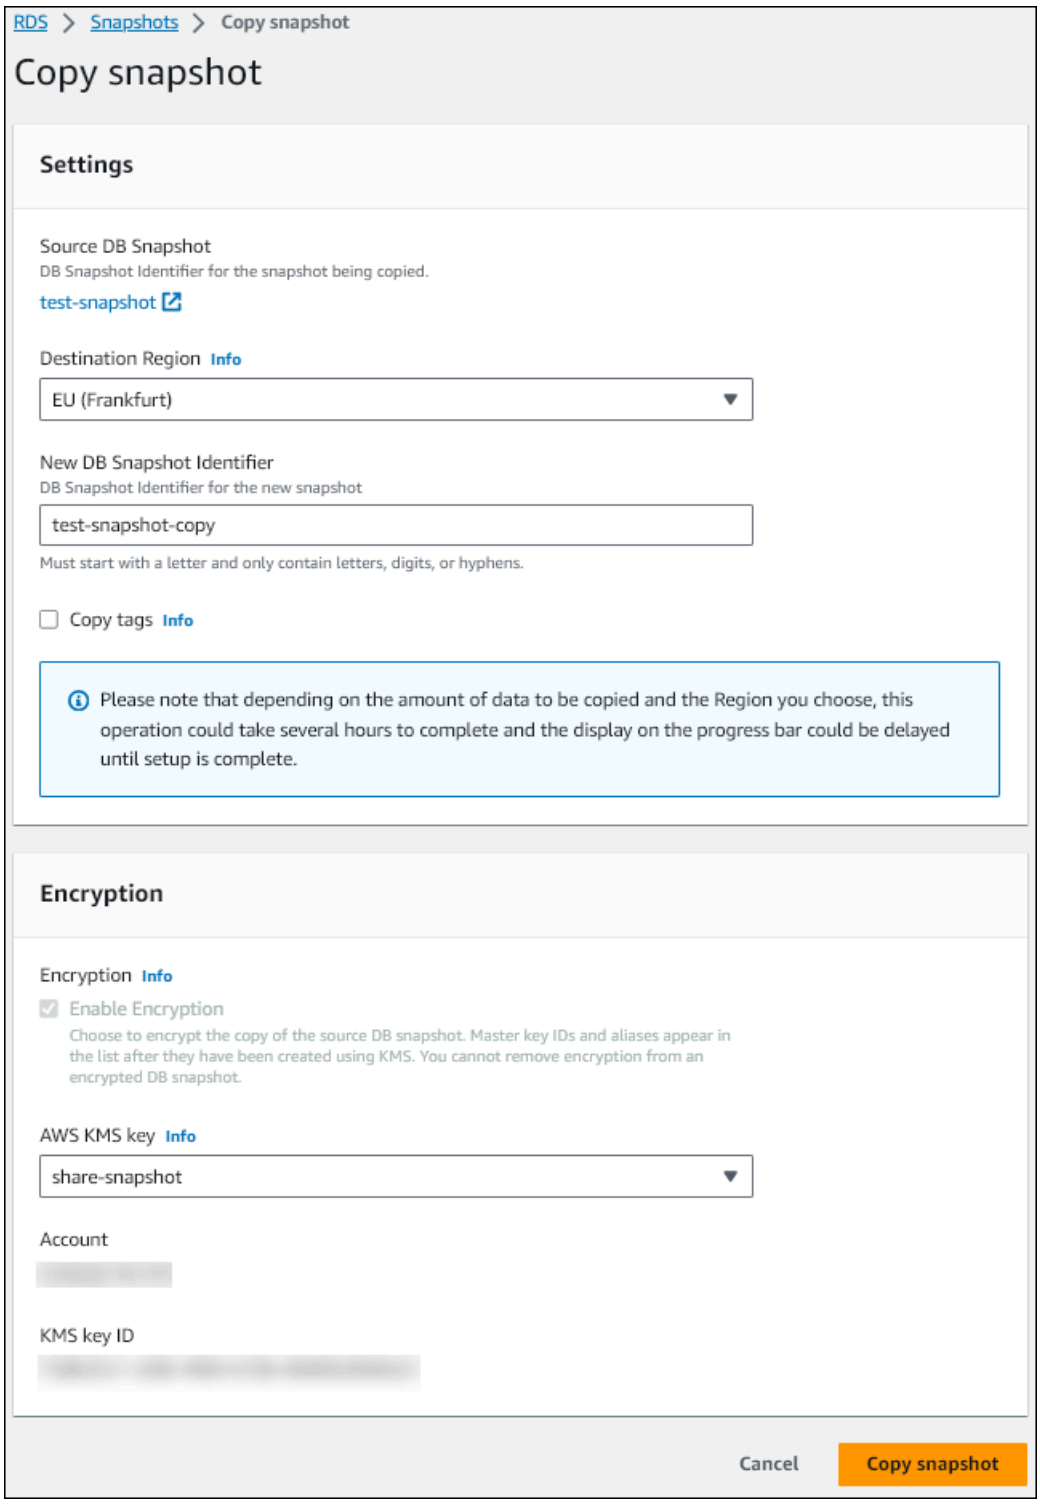
To copy and share the snapshot

1. Sign in to the AWS Management Console from the source AWS account.
2. Open the Amazon RDS console at https://console.aws.amazon.com/rds/
3. In the navigation pane, choose **Snapshots**.
4. Select the DB snapshot you want to copy.
5. For **Actions**, choose **Copy snapshot**.
6. On the **Copy snapshot** page:

   a. For **Destination Region**, choose the AWS Region where you created the customer managed key in the previous procedure.

   b. Enter the name of the DB snapshot copy in **New DB Snapshot Identifier**.

   c. For **AWS KMS key**, choose the customer managed key that you created.



d. Choose **Copy snapshot**.

7. When the snapshot copy is available, select it.
8. For **Actions**, choose **Share snapshot**.
9. On the **Snapshot permissions** page:

a. Enter the **AWS account ID** with which you're sharing the snapshot copy, then choose **Add**.

b. Choose **Save**.

The snapshot is shared.

Copy the shared snapshot in the target account

Now you can copy the shared snapshot in the target AWS account.

To copy the shared snapshot

1. Sign in to the AWS Management Console from the target AWS account.
2. Open the Amazon RDS console at https://console.aws.amazon.com/rds/
3. In the navigation pane, choose **Snapshots**.
4. Choose the **Shared with me** tab.
5. Select the shared snapshot.
6. For **Actions**, choose **Copy snapshot**.
7. Choose your settings for copying the snapshot as in the previous procedure, but use an AWS KMS key that belongs to the target account.

   Choose **Copy snapshot**.

Stopping snapshot sharing

To stop sharing a DB snapshot, you remove permission from the target AWS account.

Console

To stop sharing a manual DB snapshot with an AWS account

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Snapshots**.
3. Select the manual snapshot that you want to stop sharing.
4. Choose **Actions**, and then choose **Share snapshot**.

5. To remove permission for an AWS account, choose **Delete** for the AWS account identifier for that account from the list of authorized accounts.
6. Choose **Save** to save your changes.

CLI

To remove an AWS account identifier from the list, use the `--values-to-remove` parameter.

Example of stopping snapshot sharing

The following example prevents AWS account ID 444455556666 from restoring the snapshot.

For Linux, macOS, or Unix:

```
aws rds modify-db-snapshot-attribute \
--db-snapshot-identifier manual-snapshot1 \
--attribute-name restore \
--values-to-remove 444455556666
```

For Windows:

```
aws rds modify-db-snapshot-attribute ^
--db-snapshot-identifier manual-snapshot1 ^
--attribute-name restore ^
--values-to-remove 444455556666
```

RDS API

To remove sharing permission for an AWS account, use the `ModifyDBSnapshotAttribute` operation with `AttributeName` set to `restore` and the `ValuesToRemove` parameter. To mark a manual snapshot as private, remove the value `all` from the values list for the `restore` attribute.

Exporting DB snapshot data to Amazon S3

You can export DB snapshot data to an Amazon S3 bucket. The export process runs in the background and doesn't affect the performance of your active database.

When you export a DB snapshot, Amazon RDS extracts data from the snapshot and stores it in an Amazon S3 bucket. The data is stored in an Apache Parquet format that is compressed and consistent.

You can export all types of DB snapshots—including manual snapshots, automated system snapshots, and snapshots created by the AWS Backup service. By default, all data in the snapshot is exported. However, you can choose to export specific sets of databases, schemas, or tables.

After the data is exported, you can analyze the exported data directly through tools like Amazon Athena or Amazon Redshift Spectrum. For more information on using Athena to read Parquet data, see Parquet SerDe in the *Amazon Athena User Guide*. For more information on using Redshift Spectrum to read Parquet data, see COPY from columnar data formats in the *Amazon Redshift Database Developer Guide*.

Topics

Region and version availability

Feature availability and support varies across specific versions of each database engine and across AWS Regions. For more information on version and Region availability with exporting snapshots to S3, see Supported Regions and DB engines for exporting snapshots to S3 in Amazon RDS.

Limitations

Exporting DB snapshot data to Amazon S3 has the following limitations:

- You can't run multiple export tasks for the same DB snapshot simultaneously. This applies to both full and partial exports.
- Exporting snapshots from databases that use magnetic storage isn't supported.
- Exports to S3 don't support S3 prefixes containing a colon (:).
- The following characters in the S3 file path are converted to underscores (_) during export:

```
\ ` " (space)
```

- If a database, schema, or table has characters in its name other than the following, partial export isn't supported. However, you can export the entire DB snapshot.
  - Latin letters (A–Z)
  - Digits (0–9)
  - Dollar symbol ($)
  - Underscore (_)
- Spaces ( ) and certain characters aren't supported in database table column names. Tables with the following characters in column names are skipped during export:

```
, ; { } ( ) \n \t = (space)
```

- Tables with slashes (/) in their names are skipped during export.
- RDS for PostgreSQL temporary and unlogged tables are skipped during export.
- If the data contains a large object, such as a BLOB or CLOB, that is close to or greater than 500 MB, then the export fails.
- If a table contains a large row that is close to or greater than 2 GB, then the table is skipped during export.
- For partial exports, the `ExportOnly` list has a maximum size of 200 KB.

- We strongly recommend that you use a unique name for each export task. If you don't use a unique task name, you might receive the following error message:

  ExportTaskAlreadyExistsFault: An error occurred (ExportTaskAlreadyExists) when calling the StartExportTask operation: The export task with the ID *xxxxx* already exists.
- You can delete a snapshot while you're exporting its data to S3, but you're still charged for the storage costs for that snapshot until the export task has completed.
- You can't restore exported snapshot data from S3 to a new DB instance or import snapshot data from S3 into an existing DB instance.
- You can have up to five concurrent DB snapshot export tasks in progress per AWS account.
- To export a DB snapshot to a cross-account Amazon S3 bucket, you must use the AWS CLI or the RDS API.

Overview of exporting snapshot data

You use the following process to export DB snapshot data to an Amazon S3 bucket. For more details, see the following sections.

1. Identify the snapshot to export.

   Use an existing automated or manual snapshot, or create a manual snapshot of a DB instance or Multi-AZ DB cluster.
2. Set up access to the Amazon S3 bucket.

   A *bucket* is a container for Amazon S3 objects or files. To provide the information to access a bucket, take the following steps:

   a. Identify the S3 bucket where the snapshot is to be exported to. The S3 bucket must be in the same AWS Region as the snapshot. For more information, see Identifying the Amazon S3 bucket for export.

   b. Create an AWS Identity and Access Management (IAM) role that grants the snapshot export task access to the S3 bucket. For more information, see Providing access to an Amazon S3 bucket using an IAM role.
3. Create a symmetric encryption AWS KMS key for the server-side encryption. The KMS key is used by the snapshot export task to set up AWS KMS server-side encryption when writing the export data to S3.

The KMS key policy must include both the `kms:CreateGrant` and `kms:DescribeKey` permissions. For more information on using KMS keys in Amazon RDS, see AWS KMS key management.

If you have a deny statement in your KMS key policy, make sure to explicitly exclude the AWS service principal `export.rds.amazonaws.com`.

You can use a KMS key within your AWS account, or you can use a cross-account KMS key. For more information, see Using a cross-account AWS KMS key for encrypting Amazon S3 exports.

4. Export the snapshot to Amazon S3 using the console or the `start-export-task` CLI command. For more information, see Exporting a DB snapshot to an Amazon S3 bucket.
5. To access your exported data in the Amazon S3 bucket, see Uploading, downloading, and managing objects in the *Amazon Simple Storage Service User Guide*.

Setting up access to an Amazon S3 bucket

To export DB snapshot data to an Amazon S3 file, you first give the snapshot permission to access the Amazon S3 bucket. You then create an IAM role to allow the Amazon RDS service to write to the Amazon S3 bucket.

Topics

- Identifying the Amazon S3 bucket for export
- Providing access to an Amazon S3 bucket using an IAM role
- Using a cross-account Amazon S3 bucket
- Using a cross-account AWS KMS key for encrypting Amazon S3 exports

Identifying the Amazon S3 bucket for export

Identify the Amazon S3 bucket to export the DB snapshot to. Use an existing S3 bucket or create a new S3 bucket.

> **Note**
>
> The S3 bucket to export to must be in the same AWS Region as the snapshot.

For more information about working with Amazon S3 buckets, see the following in the *Amazon Simple Storage Service User Guide*:

- How do I view the properties for an S3 bucket?
- How do I enable default encryption for an Amazon S3 bucket?
- How do I create an S3 bucket?

Providing access to an Amazon S3 bucket using an IAM role

Before you export DB snapshot data to Amazon S3, give the snapshot export tasks write-access permission to the Amazon S3 bucket.

To grant this permission, create an IAM policy that provides access to the bucket, then create an IAM role and attach the policy to the role. You later assign the IAM role to your snapshot export task.

> **Important**
>
> If you plan to use the AWS Management Console to export your snapshot, you can choose to create the IAM policy and the role automatically when you export the snapshot. For instructions, see Exporting a DB snapshot to an Amazon S3 bucket.

To give DB snapshot tasks access to Amazon S3

1. Create an IAM policy. This policy provides the bucket and object permissions that allow your snapshot export task to access Amazon S3.

   In the policy, include the following required actions to allow the transfer of files from Amazon RDS to an S3 bucket:

   - `s3:PutObject*`
   - `s3:GetObject*`
   - `s3:ListBucket`
   - `s3:DeleteObject*`
   - `s3:GetBucketLocation`

In the policy, include the following resources to identify the S3 bucket and objects in the bucket. The following list of resources shows the Amazon Resource Name (ARN) format for accessing Amazon S3.

- `arn:aws:s3:::amzn-s3-demo-bucket`
- `arn:aws:s3:::amzn-s3-demo-bucket/*`

For more information on creating an IAM policy for Amazon RDS, see Creating and using an IAM policy for IAM database access. See also Tutorial: Create and attach your first customer managed policy in the *IAM User Guide*.

The following AWS CLI command creates an IAM policy named `ExportPolicy` with these options. It grants access to a bucket named *amzn-s3-demo-bucket*.

> **Note**
>
> After you create the policy, note the ARN of the policy. You need the ARN for a subsequent step when you attach the policy to an IAM role.

```
aws iam create-policy  --policy-name ExportPolicy --policy-document '{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "ExportPolicy",
            "Effect": "Allow",
            "Action": [
                "s3:PutObject*",
                "s3:ListBucket",
                "s3:GetObject*",
                "s3:DeleteObject*",
                "s3:GetBucketLocation"
            ],
            "Resource": [
                "arn:aws:s3:::amzn-s3-demo-bucket",
                "arn:aws:s3:::amzn-s3-demo-bucket/*"
            ]
        }
```

```
    ]
}'
```

2. Create an IAM role, so that Amazon RDS can assume this IAM role on your behalf to access your Amazon S3 buckets. For more information, see Creating a role to delegate permissions to an IAM user in the *IAM User Guide*.

   The following example shows using the AWS CLI command to create a role named `rds-s3-export-role`.

```
aws iam create-role  --role-name rds-s3-export-role  --assume-role-policy-document
 '{
    "Version": "2012-10-17",
    "Statement": [
      {
        "Effect": "Allow",
        "Principal": {
           "Service": "export.rds.amazonaws.com"
         },
        "Action": "sts:AssumeRole"
      }
    ]
  }'
```

3. Attach the IAM policy that you created to the IAM role that you created.

   The following AWS CLI command attaches the policy created earlier to the role named `rds-s3-export-role`. Replace *`your-policy-arn`* with the policy ARN that you noted in an earlier step.

```
aws iam attach-role-policy  --policy-arn your-policy-arn  --role-name rds-s3-
export-role
```

Using a cross-account Amazon S3 bucket

You can use Amazon S3 buckets across AWS accounts. To use a cross-account bucket, add a bucket policy to allow access to the IAM role that you're using for the S3 exports. For more information, see Example 2: Bucket owner granting cross-account bucket permissions.

Attach a bucket policy to your bucket, as shown in the following example.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws:iam::123456789012:role/Admin"
            },
            "Action": [
                "s3:PutObject*",
                "s3:ListBucket",
                "s3:GetObject*",
                "s3:DeleteObject*",
                "s3:GetBucketLocation"
            ],
            "Resource": [
                "arn:aws:s3:::amzn-s3-demo-destination-bucket",
                "arn:aws:s3:::amzn-s3-demo-destination-bucket/*"
            ]
        }
    ]
}
```

Using a cross-account AWS KMS key for encrypting Amazon S3 exports

You can use a cross-account AWS KMS key to encrypt Amazon S3 exports. First, you add a key policy to the local account, then you add IAM policies in the external account. For more information, see Allowing users in other accounts to use a KMS key.

To use a cross-account KMS key

1. Add a key policy to the local account.

   The following example gives `ExampleRole` and `ExampleUser` in the external account 444455556666 permissions in the local account 123456789012.

   ```
   {
       "Sid": "Allow an external account to use this KMS key",
       "Effect": "Allow",
       "Principal": {
           "AWS": [
               "arn:aws:iam::444455556666:role/ExampleRole",
   ```

```
            "arn:aws:iam::444455556666:user/ExampleUser"
        ]
    },
    "Action": [
        "kms:Encrypt",
        "kms:Decrypt",
        "kms:ReEncrypt*",
        "kms:GenerateDataKey*",
        "kms:CreateGrant",
        "kms:DescribeKey",
        "kms:RetireGrant"
    ],
    "Resource": "*"
}
```

2. Add IAM policies to the external account.

   The following example IAM policy allows the principal to use the KMS key in account 123456789012 for cryptographic operations. To give this permission to `ExampleRole` and `ExampleUser` in account 444455556666, attach the policy to them in that account.

```
{
    "Sid": "Allow use of KMS key in account 123456789012",
    "Effect": "Allow",
    "Action": [
        "kms:Encrypt",
        "kms:Decrypt",
        "kms:ReEncrypt*",
        "kms:GenerateDataKey*",
        "kms:CreateGrant",
        "kms:DescribeKey",
        "kms:RetireGrant"
    ],
    "Resource": "arn:aws:kms:us-
west-2:123456789012:key/1234abcd-12ab-34cd-56ef-1234567890ab"
}
```

Exporting a DB snapshot to an Amazon S3 bucket

You can have up to five concurrent DB snapshot export tasks in progress per AWS account.

> **Note**
>
> Exporting RDS snapshots can take a while depending on your database type and size. The export task first restores and scales the entire database before extracting the data to Amazon S3. The task's progress during this phase displays as **Starting**. When the task switches to exporting data to S3, progress displays as **In progress**.
> The time it takes for the export to complete depends on the data stored in the database. For example, tables with well-distributed numeric primary key or index columns export the fastest. Tables that don't contain a column suitable for partitioning and tables with only one index on a string-based column take longer. This longer export time occurs because the export uses a slower single-threaded process.

You can export a DB snapshot to Amazon S3 using the AWS Management Console, the AWS CLI, or the RDS API. To export a DB snapshot to a cross-account Amazon S3 bucket, use the AWS CLI or the RDS API.

If you use a Lambda function to export a snapshot, add the `kms:DescribeKey` action to the Lambda function policy. For more information, see AWS Lambda permissions.

Console

The **Export to Amazon S3** console option appears only for snapshots that can be exported to Amazon S3. A snapshot might not be available for export because of the following reasons:

- The DB engine isn't supported for S3 export.
- The DB engine version isn't supported for S3 export.
- S3 export isn't supported in the AWS Region where the snapshot was created.

To export a DB snapshot

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Snapshots**.
3. From the tabs, choose the type of snapshot that you want to export.
4. In the list of snapshots, choose the snapshot that you want to export.
5. For **Actions**, choose **Export to Amazon S3**.

The **Export to Amazon S3** window appears.

6. For **Export identifier**, enter a name to identify the export task. This value is also used for the name of the file created in the S3 bucket.
7. Choose the data to be exported:

   - Choose **All** to export all data in the snapshot.
   - Choose **Partial** to export specific parts of the snapshot. To identify which parts of the snapshot to export, enter one or more databases, schemas, or tables for **Identifiers**, separated by spaces.

     Use the following format:

     ```
     database[.schema][.table] database2[.schema2][.table2] ... databasen[.scheman]
     [.tablen]
     ```

     For example:

     ```
     mydatabase mydatabase2.myschema1 mydatabase2.myschema2.mytable1
      mydatabase2.myschema2.mytable2
     ```

8. For **S3 bucket**, choose the bucket to export to.

   To assign the exported data to a folder path in the S3 bucket, enter the optional path for **S3 prefix**.

9. For **IAM role**, either choose a role that grants you write access to your chosen S3 bucket, or create a new role.

   - If you created a role by following the steps in Providing access to an Amazon S3 bucket using an IAM role, choose that role.
   - If you didn't create a role that grants you write access to your chosen S3 bucket, then choose **Create a new role** to create the role automatically. Next, enter a name for the role in **IAM role name**.

10. For **AWS KMS key**, enter the ARN for the key to use for encrypting the exported data.
11. Choose **Export to Amazon S3**.

AWS CLI

To export a DB snapshot to Amazon S3 using the AWS CLI, use the start-export-task command with the following required options:

- `--export-task-identifier`
- `--source-arn`
- `--s3-bucket-name`
- `--iam-role-arn`
- `--kms-key-id`

In the following examples, the snapshot export task is named *my-snapshot-export*, which exports a snapshot to an S3 bucket named *amzn-s3-demo-bucket*.

Example

For Linux, macOS, or Unix:

```
aws rds start-export-task \
    --export-task-identifier my-snapshot-export \
    --source-arn arn:aws:rds:AWS_Region:123456789012:snapshot:snapshot-name \
    --s3-bucket-name amzn-s3-demo-bucket \
    --iam-role-arn iam-role \
    --kms-key-id my-key
```

For Windows:

```
aws rds start-export-task ^
    --export-task-identifier my-snapshot-export ^
    --source-arn arn:aws:rds:AWS_Region:123456789012:snapshot:snapshot-name ^
    --s3-bucket-name amzn-s3-demo-bucket ^
    --iam-role-arn iam-role ^
    --kms-key-id my-key
```

Sample output follows.

```
{
    "Status": "STARTING",
    "IamRoleArn": "iam-role",
```

```
    "ExportTime": "2019-08-12T01:23:53.109Z",
    "S3Bucket": "my-export-bucket",
    "PercentProgress": 0,
    "KmsKeyId": "my-key",
    "ExportTaskIdentifier": "my-snapshot-export",
    "TotalExtractedDataInGB": 0,
    "TaskStartTime": "2019-11-13T19:46:00.173Z",
    "SourceArn": "arn:aws:rds:AWS_Region:123456789012:snapshot:snapshot-name"
}
```

To provide a folder path in the S3 bucket for the snapshot export, include the `--s3-prefix` option in the start-export-task command.

RDS API

To export a DB snapshot to Amazon S3 using the Amazon RDS API, use the StartExportTask operation with the following required parameters:

- `ExportTaskIdentifier`
- `SourceArn`
- `S3BucketName`
- `IamRoleArn`
- `KmsKeyId`

Monitoring snapshot exports

You can monitor DB snapshot exports using the AWS Management Console, the AWS CLI, or the RDS API.

Console

To monitor DB snapshot exports

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Snapshots**.
3. To view the list of snapshot exports, choose the **Exports in Amazon S3** tab.
4. To view information about a specific snapshot export, choose the export task.

AWS CLI

To monitor DB snapshot exports using the AWS CLI, use the describe-export-tasks command.

The following example shows how to display current information about all of your snapshot exports.

Example

```
aws rds describe-export-tasks

{
    "ExportTasks": [
        {
            "Status": "CANCELED",
            "TaskEndTime": "2019-11-01T17:36:46.961Z",
            "S3Prefix": "something",
            "ExportTime": "2019-10-24T20:23:48.364Z",
            "S3Bucket": "amzn-s3-demo-bucket",
            "PercentProgress": 0,
            "KmsKeyId": "arn:aws:kms:AWS_Region:123456789012:key/K7MDENG/
bPxRfiCYEXAMPLEKEY",
            "ExportTaskIdentifier": "anewtest",
            "IamRoleArn": "arn:aws:iam::123456789012:role/export-to-s3",
            "TotalExtractedDataInGB": 0,
            "TaskStartTime": "2019-10-25T19:10:58.885Z",
            "SourceArn": "arn:aws:rds:AWS_Region:123456789012:snapshot:parameter-
groups-test"
        },
{
            "Status": "COMPLETE",
            "TaskEndTime": "2019-10-31T21:37:28.312Z",
            "WarningMessage": "{\"skippedTables\":[],\"skippedObjectives\":[],\"general
\":[{\"reason\":\"FAILED_TO_EXTRACT_TABLES_LIST_FOR_DATABASE\"}]}",
            "S3Prefix": "",
            "ExportTime": "2019-10-31T06:44:53.452Z",
            "S3Bucket": "amzn-s3-demo-bucket1",
            "PercentProgress": 100,
            "KmsKeyId": "arn:aws:kms:AWS_Region:123456789012:key/2Zp9Utk/
h3yCo8nvbEXAMPLEKEY",
            "ExportTaskIdentifier": "thursday-events-test",
            "IamRoleArn": "arn:aws:iam::123456789012:role/export-to-s3",
            "TotalExtractedDataInGB": 263,
            "TaskStartTime": "2019-10-31T20:58:06.998Z",
```

```
            "SourceArn":
 "arn:aws:rds:AWS_Region:123456789012:snapshot:rds:example-1-2019-10-31-06-44"
        },
        {
            "Status": "FAILED",
            "TaskEndTime": "2019-10-31T02:12:36.409Z",
            "FailureCause": "The S3 bucket edgcuc-export isn't located in the current
 AWS Region. Please, review your S3 bucket name and retry the export.",
            "S3Prefix": "",
            "ExportTime": "2019-10-30T06:45:04.526Z",
            "S3Bucket": "amzn-s3-demo-bucket2",
            "PercentProgress": 0,
            "KmsKeyId": "arn:aws:kms:AWS_Region:123456789012:key/2Zp9Utk/
h3yCo8nvbEXAMPLEKEY",
            "ExportTaskIdentifier": "wednesday-afternoon-test",
            "IamRoleArn": "arn:aws:iam::123456789012:role/export-to-s3",
            "TotalExtractedDataInGB": 0,
            "TaskStartTime": "2019-10-30T22:43:40.034Z",
            "SourceArn":
 "arn:aws:rds:AWS_Region:123456789012:snapshot:rds:example-1-2019-10-30-06-45"
        }
    ]
}
```

To display information about a specific snapshot export, include the `--export-task-identifier` option with the `describe-export-tasks` command. To filter the output, include the `--Filters` option. For more options, see the describe-export-tasks command.

RDS API

To display information about DB snapshot exports using the Amazon RDS API, use the DescribeExportTasks operation.

To track completion of the export workflow or to initiate another workflow, you can subscribe to Amazon Simple Notification Service topics. For more information on Amazon SNS, see Working with Amazon RDS event notification.

Canceling a snapshot export task

You can cancel a DB snapshot export task using the AWS Management Console, the AWS CLI, or the RDS API.

> **Note**
>
> Canceling a snapshot export task doesn't remove any data that was exported to Amazon S3. For information about how to delete the data using the console, see How do I delete objects from an S3 bucket? To delete the data using the CLI, use the delete-object command.

Console

To cancel a snapshot export task

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Snapshots**.
3. Choose the **Exports in Amazon S3** tab.
4. Choose the snapshot export task that you want to cancel.
5. Choose **Cancel**.
6. Choose **Cancel export task** on the confirmation page.

AWS CLI

To cancel a snapshot export task using the AWS CLI, use the cancel-export-task command. The command requires the `--export-task-identifier` option.

Example

```
aws rds cancel-export-task --export-task-identifier my_export
{
    "Status": "CANCELING",
    "S3Prefix": "",
    "ExportTime": "2019-08-12T01:23:53.109Z",
    "S3Bucket": "amzn-s3-demo-bucket",
    "PercentProgress": 0,
    "KmsKeyId": "arn:aws:kms:AWS_Region:123456789012:key/K7MDENG/bPxRfiCYEXAMPLEKEY",
    "ExportTaskIdentifier": "my_export",
    "IamRoleArn": "arn:aws:iam::123456789012:role/export-to-s3",
    "TotalExtractedDataInGB": 0,
```

```
    "TaskStartTime": "2019-11-13T19:46:00.173Z",
    "SourceArn": "arn:aws:rds:AWS_Region:123456789012:snapshot:export-example-1"
}
```

RDS API

To cancel a snapshot export task using the Amazon RDS API, use the CancelExportTask operation with the `ExportTaskIdentifier` parameter.

Failure messages for Amazon S3 export tasks

The following table describes the messages that are returned when Amazon S3 export tasks fail.

Failure message	Description
An unknown internal error occurred.	The task has failed because of an unknown error, exception, or failure.
An unknown internal error occurred writing the export task's metadata to the S3 bucket [bucket name].	The task has failed because of an unknown error, exception, or failure.
The RDS export failed to write the export task's metadata because it can't assume the IAM role [role ARN].	The export task assumes your IAM role to validate whether it is allowed to write metadata to your S3 bucket. If the task can't assume your IAM role, it fails.
The RDS export failed to write the export task's metadata to the S3 bucket [bucket name] using the IAM role [role ARN] with the KMS key [key ID]. Error code: [error code]	One or more permissions are missing, so the export task can't access the S3 bucket. This failure message is raised when receiving one of the following error codes: • `AWSSecurityTokenServiceException` with the error code `AccessDenied` • `AmazonS3Exception` with the error code `NoSuchBucket`, `AccessDenied`, `KMS.KMSInvalidStateException`, `403 Forbidden`, or `KMS.DisabledException`

Failure message	Description
	These error codes indicate settings are misconfigured for the IAM role, S3 bucket, or KMS key.
The IAM role [role ARN] isn't authorize d to call [S3 action] on the S3 bucket [bucket name]. Review your permissio ns and retry the export.	The IAM policy is misconfigured. Permission for the specific S3 action on the S3 bucket is missing, which causes the export task to fail.
KMS key check failed. Check the credentials on your KMS key and try again.	The KMS key credential check failed.
S3 credential check failed. Check the permissions on your S3 bucket and IAM policy.	The S3 credential check failed.
The S3 bucket [bucket name] isn't valid. Either it isn't located in the current AWS Region or it doesn't exist. Review your S3 bucket name and retry the export.	The S3 bucket is invalid.
The S3 bucket [bucket name] isn't located in the current AWS Region. Review your S3 bucket name and retry the export.	The S3 bucket is in the wrong AWS Region.

Troubleshooting PostgreSQL permissions errors

When exporting PostgreSQL databases to Amazon S3, you might see a `PERMISSIONS_DO_NOT_EXIST` error stating that certain tables were skipped. This error usually occurs when the superuser, which you specified when creating the database, doesn't have permissions to access those tables.

To fix this error, run the following command:

```
GRANT ALL PRIVILEGES ON ALL TABLES IN SCHEMA schema_name TO superuser_name
```

For more information on superuser privileges, see Master user account privileges.

File naming convention

Exported data for specific tables is stored in the format *base_prefix*/*files*, where the base prefix is the following:

```
export_identifier/database_name/schema_name.table_name/
```

For example:

```
export-1234567890123-459/rdststdb/rdststdb.DataInsert_7ADB5D19965123A2/
```

There are two conventions for how files are named.

- Current convention:

  ```
  batch_index/part-partition_index-random_uuid.format-based_extension
  ```

  The batch index is a sequence number that represents a batch of data read from the table. If we can't partition your table into small chunks to be exported in parallel, there will be multiple batch indexes. The same thing happens if your table is partitioned into multiple tables. There will be multiple batch indexes, one for each of the table partitions of your main table.

  If we can partition your table into small chunks to be read in parallel, there will be only the batch index 1 folder.

  Inside the batch index folder, there are one or more Parquet files that contain your table's data. The prefix of the Parquet filename is `part-`*partition_index*. If your table is partitioned, there will be multiple files starting with the partition index `00000`.

  There can be gaps in the partition index sequence. This happens because each partition is obtained from a ranged query in your table. If there is no data in the range of that partition, then that sequence number is skipped.

For example, suppose that the `id` column is the table's primary key, and its minimum and maximum values are `100` and `1000`. When we try to export this table with nine partitions, we read it with parallel queries such as the following:

```
SELECT * FROM table WHERE id <= 100 AND id < 200
SELECT * FROM table WHERE id <= 200 AND id < 300
```

This should generate nine files, from `part-00000-`*`random_uuid`*`.gz.parquet` to `part-00008-`*`random_uuid`*`.gz.parquet`. However, if there are no rows with IDs between `200` and `350`, one of the completed partitions is empty, and no file is created for it. In the previous example, `part-00001-`*`random_uuid`*`.gz.parquet` isn't created.

- Older convention:

```
part-partition_index-random_uuid.format-based_extension
```

This is the same as the current convention, but without the *`batch_index`* prefix, for example:

```
part-00000-c5a881bb-58ff-4ee6-1111-b41ecff340a3-c000.gz.parquet
part-00001-d7a881cc-88cc-5ab7-2222-c41ecab340a4-c000.gz.parquet
part-00002-f5a991ab-59aa-7fa6-3333-d41eccd340a7-c000.gz.parquet
```

The file naming convention is subject to change. Therefore, when reading target tables, we recommend that you read everything inside the base prefix for the table.

Data conversion when exporting to an Amazon S3 bucket

When you export a DB snapshot to an Amazon S3 bucket, Amazon RDS converts data to, exports data in, and stores data in the Parquet format. For more information about Parquet, see the Apache Parquet website.

Parquet stores all data as one of the following primitive types:

- BOOLEAN
- INT32
- INT64
- INT96

- FLOAT
- DOUBLE
- BYTE_ARRAY – A variable-length byte array, also known as binary
- FIXED_LEN_BYTE_ARRAY – A fixed-length byte array used when the values have a constant size

The Parquet data types are few to reduce the complexity of reading and writing the format. Parquet provides logical types for extending primitive types. A *logical type* is implemented as an annotation with the data in a `LogicalType` metadata field. The logical type annotation explains how to interpret the primitive type.

When the `STRING` logical type annotates a `BYTE_ARRAY` type, it indicates that the byte array should be interpreted as a UTF-8 encoded character string. After an export task completes, Amazon RDS notifies you if any string conversion occurred. The underlying data exported is always the same as the data from the source. However, due to the encoding difference in UTF-8, some characters might appear different from the source when read in tools such as Athena.

For more information, see Parquet logical type definitions in the Parquet documentation.

Topics

MySQL and MariaDB data type mapping to Parquet

The following table shows the mapping from MySQL and MariaDB data types to Parquet data types when data is converted and exported to Amazon S3.

Source data type	Parquet primitive type	Logical type annotation	Conversion notes
Numeric data types			
BIGINT	INT64		
BIGINT UNSIGNED	FIXED_LEN _BYTE_ARRAY(9)	DECIMAL(20,0)	Parquet supports only signed types, so the mapping requires

Source data type	Parquet primitive type	Logical type annotation	Conversion notes
			an additional byte (8 plus 1) to store the BIGINT_UNSIGNED type.
BIT	BYTE_ARRAY		
DECIMAL	INT32	DECIMAL(p,s)	If the source value is less than 2^{31}, it's stored as INT32.
	INT64	DECIMAL(p,s)	If the source value is 2^{31} or greater, but less than 2^{63}, it's stored as INT64.
	FIXED_LEN _BYTE_ARRAY(N)	DECIMAL(p,s)	If the source value is 2^{63} or greater, it's stored as FIXED_LEN _BYTE_ARRAY(N).
	BYTE_ARRAY	STRING	Parquet doesn't support Decimal precision greater than 38. The Decimal value is converted to a string in a BYTE_ARRAY type and encoded as UTF8.
DOUBLE	DOUBLE		
FLOAT	DOUBLE		
INT	INT32		

Source data type	Parquet primitive type	Logical type annotation	Conversion notes
INT UNSIGNED	INT64		
MEDIUMINT	INT32		
MEDIUMINT UNSIGNED	INT64		
NUMERIC	INT32	DECIMAL(p,s)	If the source value is less than 2^{31}, it's stored as INT32.
	INT64	DECIMAL(p,s)	If the source value is 2^{31} or greater, but less than 2^{63}, it's stored as INT64.
	FIXED_LEN_ARRAY(N)	DECIMAL(p,s)	If the source value is 2^{63} or greater, it's stored as FIXED_LEN_BYTE_ARRAY(N).
	BYTE_ARRAY	STRING	Parquet doesn't support Numeric precision greater than 38. This Numeric value is converted to a string in a BYTE_ARRAY type and encoded as UTF8.
SMALLINT	INT32		
SMALLINT UNSIGNED	INT32		

Source data type	Parquet primitive type	Logical type annotation	Conversion notes
TINYINT	INT32		
TINYINT UNSIGNED	INT32		
String data types			
BINARY	BYTE_ARRAY		
BLOB	BYTE_ARRAY		
CHAR	BYTE_ARRAY		
ENUM	BYTE_ARRAY	STRING	
LINESTRING	BYTE_ARRAY		
LONGBLOB	BYTE_ARRAY		
LONGTEXT	BYTE_ARRAY	STRING	
MEDIUMBLOB	BYTE_ARRAY		
MEDIUMTEXT	BYTE_ARRAY	STRING	
MULTILINESTRING	BYTE_ARRAY		
SET	BYTE_ARRAY	STRING	
TEXT	BYTE_ARRAY	STRING	
TINYBLOB	BYTE_ARRAY		
TINYTEXT	BYTE_ARRAY	STRING	
VARBINARY	BYTE_ARRAY		
VARCHAR	BYTE_ARRAY	STRING	
Date and time data types			

Source data type	Parquet primitive type	Logical type annotation	Conversion notes
DATE	BYTE_ARRAY	STRING	A date is converted to a string in a BYTE_ARRAY type and encoded as UTF8.
DATETIME	INT64	TIMESTAMP_MICROS	
TIME	BYTE_ARRAY	STRING	A TIME type is converted to a string in a BYTE_ARRAY and encoded as UTF8.
TIMESTAMP	INT64	TIMESTAMP_MICROS	
YEAR	INT32		
Geometric data types			
GEOMETRY	BYTE_ARRAY		
GEOMETRYCOLLECTION	BYTE_ARRAY		
MULTIPOINT	BYTE_ARRAY		
MULTIPOLYGON	BYTE_ARRAY		
POINT	BYTE_ARRAY		
POLYGON	BYTE_ARRAY		
JSON data type			
JSON	BYTE_ARRAY	STRING	

PostgreSQL data type mapping to Parquet

The following table shows the mapping from PostgreSQL data types to Parquet data types when data is converted and exported to Amazon S3.

PostgreSQL data type	Parquet primitive type	Logical type annotation	Mapping notes
Numeric data types			
BIGINT	INT64		
BIGSERIAL	INT64		
DECIMAL	BYTE_ARRAY	STRING	A DECIMAL type is converted to a string in a BYTE_ARRAY type and encoded as UTF8. This conversion is to avoid complications due to data precision and data values that are not a number (NaN).
DOUBLE PRECISION	DOUBLE		
INTEGER	INT32		
MONEY	BYTE_ARRAY	STRING	
REAL	FLOAT		
SERIAL	INT32		
SMALLINT	INT32	INT_16	
SMALLSERIAL	INT32	INT_16	

PostgreSQL data type	Parquet primitive type	Logical type annotation	Mapping notes
String and related data types			
ARRAY	BYTE_ARRAY	STRING	An array is converted to a string and encoded as BINARY (UTF8). This conversion is to avoid complicat ions due to data prec ision, data values that are not a number (NaN), and time data values.
BIT	BYTE_ARRAY	STRING	
BIT VARYING	BYTE_ARRAY	STRING	
BYTEA	BINARY		
CHAR	BYTE_ARRAY	STRING	
CHAR(N)	BYTE_ARRAY	STRING	
ENUM	BYTE_ARRAY	STRING	
NAME	BYTE_ARRAY	STRING	
TEXT	BYTE_ARRAY	STRING	
TEXT SEARCH	BYTE_ARRAY	STRING	
VARCHAR(N)	BYTE_ARRAY	STRING	
XML	BYTE_ARRAY	STRING	

PostgreSQL data type	Parquet primitive type	Logical type annotation	Mapping notes
Date and time data types			
DATE	BYTE_ARRAY	STRING	
INTERVAL	BYTE_ARRAY	STRING	
TIME	BYTE_ARRAY	STRING	
TIME WITH TIME ZONE	BYTE_ARRAY	STRING	
TIMESTAMP	BYTE_ARRAY	STRING	
TIMESTAMP WITH TIME ZONE	BYTE_ARRAY	STRING	
Geometric data types			
BOX	BYTE_ARRAY	STRING	
CIRCLE	BYTE_ARRAY	STRING	
LINE	BYTE_ARRAY	STRING	
LINESEGMENT	BYTE_ARRAY	STRING	
PATH	BYTE_ARRAY	STRING	
POINT	BYTE_ARRAY	STRING	
POLYGON	BYTE_ARRAY	STRING	
JSON data types			
JSON	BYTE_ARRAY	STRING	
JSONB	BYTE_ARRAY	STRING	
Other data types			

PostgreSQL data type	Parquet primitive type	Logical type annotation	Mapping notes
BOOLEAN	BOOLEAN		
CIDR	BYTE_ARRAY	STRING	Network data type
COMPOSITE	BYTE_ARRAY	STRING	
DOMAIN	BYTE_ARRAY	STRING	
INET	BYTE_ARRAY	STRING	Network data type
MACADDR	BYTE_ARRAY	STRING	
OBJECT IDENTIFIER	N/A		
PG_LSN	BYTE_ARRAY	STRING	
RANGE	BYTE_ARRAY	STRING	
UUID	BYTE_ARRAY	STRING	

Using AWS Backup to manage automated backups

AWS Backup is a fully managed backup service that makes it easy to centralize and automate the backup of data across AWS services in the cloud and on premises. You can manage backups of your Amazon RDS databases in AWS Backup.

> **Note**
>
> Backups managed by AWS Backup are considered manual DB snapshots, but don't count toward the DB snapshot quota for RDS. Backups that were created with AWS Backup have names ending in `awsbackup:backup-job-number`.

For more information about AWS Backup, see the *AWS Backup Developer Guide*.

To view backups managed by AWS Backup

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Snapshots**.
3. Choose the **Backup service** tab.

   Your AWS Backup backups are listed under **Backup service snapshots**.

Monitoring metrics in an Amazon RDS instance

In the following sections, you can find an overview of Amazon RDS monitoring and an explanation about how to access metrics. To learn how to monitor events, logs, and database activity streams, see Monitoring events, logs, and streams in an Amazon RDS DB instance.

Topics

Monitoring plan

Before you start monitoring Amazon RDS, create a monitoring plan. This plan should answer the following questions:

- What are your monitoring goals?
- Which resources will you monitor?
- How often will you monitor these resources?
- Which monitoring tools will you use?
- Who will perform the monitoring tasks?
- Whom should be notified when something goes wrong?

Performance baseline

To achieve your monitoring goals, you need to establish a baseline. To do this, measure performance under different load conditions at various times in your Amazon RDS environment. You can monitor metrics such as the following:

- Network throughput
- Client connections
- I/O for read, write, or metadata operations
- Burst credit balances for your DB instances

We recommend that you store historical performance data for Amazon RDS. Using the stored data, you can compare current performance against past trends. You can also distinguish normal performance patterns from anomalies, and devise techniques to address issues.

Performance guidelines

In general, acceptable values for performance metrics depend on what your application is doing relative to your baseline. Investigate consistent or trending variances from your baseline. The following metrics are often the source of performance issues:

- **High CPU or RAM consumption** – High values for CPU or RAM consumption might be appropriate, if they're in keeping with your goals for your application (like throughput or concurrency) and are expected.
- **Disk space consumption** – Investigate disk space consumption if space used is consistently at or above 85 percent of the total disk space. See if it is possible to delete data from the instance or archive data to a different system to free up space.
- **Network traffic** – For network traffic, talk with your system administrator to understand what expected throughput is for your domain network and internet connection. Investigate network traffic if throughput is consistently lower than expected.
- **Database connections** – If you see high numbers of user connections and also decreases in instance performance and response time, consider constraining database connections. The best number of user connections for your DB instance varies based on your instance class and the complexity of the operations being performed. To determine the number of database connections, associate your DB instance with a parameter group where the `User Connections`

parameter is set to a value other than 0 (unlimited). You can either use an existing parameter group or create a new one. For more information, see Parameter groups for Amazon RDS.

- **IOPS metrics** – The expected values for IOPS metrics depend on disk specification and server configuration, so use your baseline to know what is typical. Investigate if values are consistently different than your baseline. For best IOPS performance, make sure that your typical working set fits into memory to minimize read and write operations.

When performance falls outside your established baseline, you might need to make changes to optimize your database availability for your workload. For example, you might need to change the instance class of your DB instance. Or you might need to change the number of DB instances and read replicas that are available for clients.

Monitoring tools for Amazon RDS

Monitoring is an important part of maintaining the reliability, availability, and performance of Amazon RDS and your other AWS solutions. AWS provides various monitoring tools to watch Amazon RDS, report when something is wrong, and take automatic actions when appropriate.

Topics

Automated monitoring tools

We recommend that you automate monitoring tasks as much as possible.

Topics

Amazon RDS instance status and recommendations

You can use the following automated tools to watch Amazon RDS and report when something is wrong:

- **Amazon RDS instance status** — View details about the current status of your instance by using the Amazon RDS console, the AWS CLI, or the RDS API.
- **Amazon RDS recommendations** — Respond to automated recommendations for database resources, such as DB instances, read replicas, and DB parameter groups. For more information, see Recommendations from Amazon RDS.

Amazon CloudWatch metrics for Amazon RDS

Amazon RDS integrates with Amazon CloudWatch for additional monitoring capabilities.

- **Amazon CloudWatch** – This service monitors your AWS resources and the applications you run on AWS in real time. You can use the following Amazon CloudWatch features with Amazon RDS:
  - **Amazon CloudWatch metrics** – Amazon RDS automatically sends metrics to CloudWatch every minute for each active database. You don't get additional charges for Amazon RDS metrics in CloudWatch. For more information, see Monitoring Amazon RDS metrics with Amazon CloudWatch.
  - **Amazon CloudWatch alarms** – You can watch a single Amazon RDS metric over a specific time period. You can then perform one or more actions based on the value of the metric relative to a threshold that you set. For more information, see Monitoring Amazon RDS metrics with Amazon CloudWatch.

Amazon RDS Performance Insights and operating-system monitoring

You can use the following automated tools to monitor Amazon RDS performance:

- **Amazon RDS Performance Insights** – Assess the load on your database, and determine when and where to take action. For more information, see Monitoring DB load with Performance Insights on Amazon RDS.
- **Amazon RDS Enhanced Monitoring** – Look at metrics in real time for the operating system. For more information, see Monitoring OS metrics with Enhanced Monitoring.

Integrated services

The following AWS services are integrated with Amazon RDS:

- *Amazon EventBridge* is a serverless event bus service that makes it easy to connect your applications with data from a variety of sources. For more information, see Monitoring Amazon RDS events.
- *Amazon CloudWatch Logs* lets you monitor, store, and access your log files from Amazon RDS instances, CloudTrail, and other sources. For more information, see Monitoring Amazon RDS log files.
- *AWS CloudTrail* captures API calls and related events made by or on behalf of your AWS account and delivers the log files to an Amazon S3 bucket that you specify. For more information, see Monitoring Amazon RDS API calls in AWS CloudTrail.

- *Database Activity Streams* is an Amazon RDS feature that provides a near-real-time stream of the activity in your Oracle DB instance. For more information, see Monitoring Amazon RDS with Database Activity Streams.

Manual monitoring tools

You need to manually monitor those items that the CloudWatch alarms don't cover. The Amazon RDS, CloudWatch, AWS Trusted Advisor and other AWS console dashboards provide an at-a-glance view of the state of your AWS environment. We recommend that you also check the log files on your DB instance.

- From the Amazon RDS console, you can monitor the following items for your resources:
  - The number of connections to a DB instance
  - The amount of read and write operations to a DB instance
  - The amount of storage that a DB instance is currently using
  - The amount of memory and CPU being used for a DB instance
  - The amount of network traffic to and from a DB instance
- From the Trusted Advisor dashboard, you can review the following cost optimization, security, fault tolerance, and performance improvement checks:
  - Amazon RDS Idle DB Instances
  - Amazon RDS Security Group Access Risk
  - Amazon RDS Backups
  - Amazon RDS Multi-AZ

  For more information on these checks, see Trusted Advisor best practices (checks).
- CloudWatch home page shows:
  - Current alarms and status
  - Graphs of alarms and resources
  - Service health status

  In addition, you can use CloudWatch to do the following:
  - Create customized dashboards to monitor the services that you care about.
  - Graph metric data to troubleshoot issues and discover trends.
  - Search and browse all your AWS resource metrics.

- Create and edit alarms to be notified of problems.

Viewing instance status

Using the Amazon RDS console, you can quickly access the status of your DB instance.

Topics

Viewing Amazon RDS DB instance status

The status of a DB instance indicates the health of the DB instance. You can use the following procedures to view the DB instance status in the Amazon RDS console, the AWS CLI command, or the API operation.

> **Note**
>
> Amazon RDS also uses another status called *maintenance status*, which is shown in the **Maintenance** column of the Amazon RDS console. This value indicates the status of any maintenance patches that need to be applied to a DB instance. Maintenance status is independent of DB instance status. For more information about maintenance status, see Applying updates for a DB instance.

Find the possible status values for DB instances in the following table. This table also shows whether you will be billed for the DB instance and storage, billed only for storage, or not billed. For all DB instance statuses, you are always billed for backup usage.

DB instance status	Billed	Description
Available	Billed	The DB instance is healthy and available.
Backing-up	Billed	The DB instance is currently being backed up.
Configuring-enhanced-monitoring	Billed	Enhanced Monitoring is being enabled or disabled for this DB instance.
Configuring-iam-database-auth	Billed	AWS Identity and Access Management (IAM) database authentication is being enabled or disabled for this DB instance.
Configuring-log-exports	Billed	Publishing log files to Amazon CloudWatch Logs is being enabled or disabled for this DB instance.
Converting-to-vpc	Billed	The DB instance is being converted from a DB instance that is not in an Amazon Virtual Private Cloud (Amazon VPC) to a DB instance that is in an Amazon VPC.

DB instance status	Billed	Description
Creating	Not billed	The DB instance is being created. The DB instance is inaccessible while it is being created.
Delete-precheck	Not billed	Amazon RDS is validating that read replicas are healthy and are safe to delete.
Deleting	Not billed	The DB instance is being deleted.
Failed	Not billed	The DB instance has failed and Amazon RDS can't recover it. Perform a point-in-time restore to the latest restorable time of the DB instance to recover the data.
Inaccessible-encryption-credentials	Not billed	The AWS KMS key used to encrypt or decrypt the DB instance can't be accessed or recovered.
Inaccessible-encryption-credentials-recoverable	Billed for storage	The KMS key used to encrypt or decrypt the DB instance can't be accessed. However, if the KMS key is active, restarting the DB instance can recover it. For more information, see Encrypting a DB instance.
Incompatible-network	Not billed	Amazon RDS is attempting to perform a recovery action on a DB instance but can't do so because the VPC is in a state that prevents the action from being completed. This status can occur if, for example, all available IP addresses in a subnet are in use and Amazon RDS can't get an IP address for the DB instance.
Incompatible-option-group	Billed	Amazon RDS attempted to apply an option group change but can't do so, and Amazon RDS can't roll back to the previous option group state. For more information, check the **Recent Events** list for the DB instance. This status can occur if, for example, the option group contains an option such as TDE and the DB instance doesn't contain encrypted information.

DB instance status	Billed	Description
Incompatible-parameters	Billed	Amazon RDS can't start the DB instance because the parameters specified in the DB instance's DB parameter group aren't compatible with the DB instance. Revert the parameter changes or make them compatible with the DB instance to regain access to your DB instance. For more information about the incompatible parameters, check the **Recent Events** list for the DB instance.
Incompatible-restore	Not billed	Amazon RDS can't do a point-in-time restore. Common causes for this status include using temp tables, using MyISAM tables with MySQL, or using Aria tables with MariaDB.
Insufficient-capacity	Not billed	Amazon RDS can’t create your instance because sufficient capacity isn’t currently available. To create your DB instance in the same AZ with the same instance type, delete your DB instance, wait a few hours, and try to create again. Alternatively, create a new instance using a different instance class or AZ.
Maintenance	Billed	Amazon RDS is applying a maintenance update to the DB instance. This status is used for instance-level maintenance that RDS schedules well in advance.
Modifying	Billed	The DB instance is being modified because of a customer request to modify the DB instance.
Moving-to-vpc	Billed	The DB instance is being moved to a new Amazon Virtual Private Cloud (Amazon VPC).
Rebooting	Billed	The DB instance is being rebooted because of a customer request or an Amazon RDS process that requires the rebooting of the DB instance.
Resetting-master-credentials	Billed	The master credentials for the DB instance are being reset because of a customer request to reset them.

DB instance status	Billed	Description
Renaming	Billed	The DB instance is being renamed because of a customer request to rename it.
Restore-error	Billed	The DB instance encountered an error attempting to restore to a point-in-time or from a snapshot.
Starting	Billed for storage	The DB instance is starting.
Stopped	Billed for storage	The DB instance is stopped.
Stopping	Billed for storage	The DB instance is being stopped.
Storage-config-upgrade	Billed	The storage file system configuration of the DB instance is being upgraded. This status only applies to green databases within a blue/green deployment, or to DB instance read replicas.
Storage-full	Billed	The DB instance has reached its storage capacity allocation. This is a critical status, and we recommend that you fix this issue immediately. To do so, scale up your storage by modifying the DB instance. To avoid this situation, set Amazon CloudWatch alarms to warn you when storage space is getting low.
Storage-optimization	Billed	Amazon RDS is optimizing the storage of your DB instance. The storage optimization process is usually short, but can sometimes take up to and even beyond 24 hours. During storage optimization, the DB instance remains available. Storage optimization is a background process that doesn't affect the instance's availability.

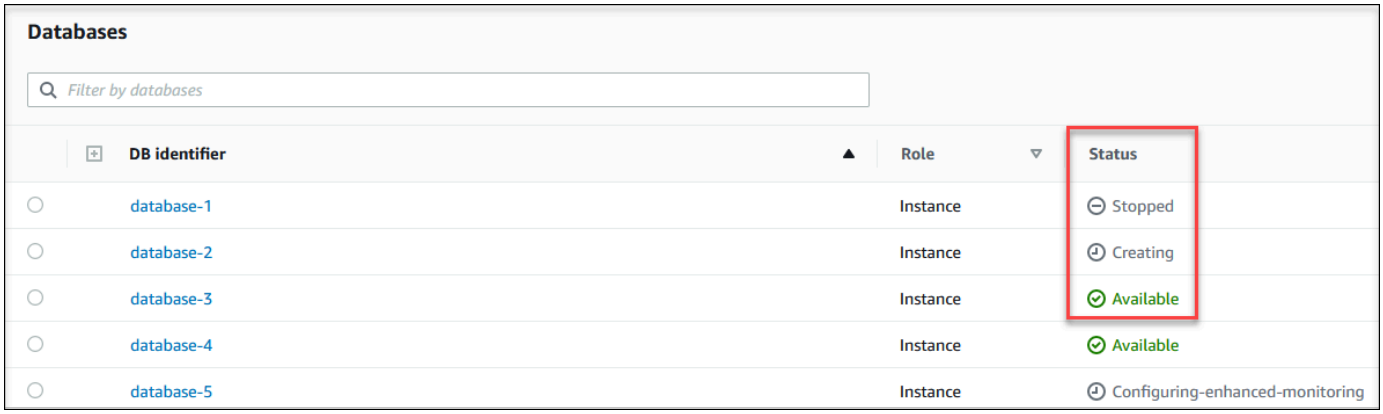
DB instance status	Billed	Description
Upgrading	Billed	The database engine version is being upgraded.

Console

To view the status of a DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.

   The **Databases page** appears with the list of DB instances. For each DB instance , the status value is displayed.



CLI

To view DB instance and its status information by using the AWS CLI, use the describe-db-instances command. For example, the following AWS CLI command lists all the DB instances information .

```
aws rds describe-db-instances
```

To view a specific DB instance and its status, call the describe-db-instances command with the following option:

- `DBInstanceIdentifier` – The name of the DB instance.

```
aws rds describe-db-instances --db-instance-identifier mydbinstance
```

To view just the status of all the DB instances, use the following query in AWS CLI.

```
aws rds describe-db-instances --query 'DBInstances[*].
[DBInstanceIdentifier,DBInstanceStatus]' --output table
```

API

To view the status of the DB instance using the Amazon RDS API, call the DescribeDBInstances operation.

Recommendations from Amazon RDS

Amazon RDS provides automated recommendations for database resources, such as DB instances, read replicas, and DB parameter groups. These recommendations provide best practice guidance by analyzing DB instance configuration, usage, and performance data.

Amazon RDS Performance Insights monitors specific metrics and automatically creates thresholds by analyzing what levels are considered potentially problematic for a specified resource. When new metric values cross a predefined threshold over a given period of time, Performance Insights generates a proactive recommendation. This recommendation helps to prevent future database performance impact. For example, the "Idle In Transaction" recommendation is generated for RDS for PostgreSQL instances when the sessions connected to the database are not performing active work, but can keep database resources blocked. To receive proactive recommendations, you must turn on Performance Insights with a paid tier retention period. For information about turning on Performance Insights, see Turning Performance Insights on and off for Amazon RDS. For information about pricing and data retention for Performance Insights see Pricing and data retention for Performance Insights.

DevOps Guru for RDS monitors certain metrics to detect when the metric's behavior becomes highly unusual or anomalous. These anomalies are reported as reactive insights with recommendations. For example, DevOps Guru for RDS might recommend you to consider increasing CPU capacity or investigate wait events that are contributing to DB load. DevOps Guru for RDS also provides threshold based proactive recommendations. For these recommendations, you must turn on DevOps Guru for RDS. For information about turning on DevOps Guru for RDS, see Turning on DevOps Guru and specifying resource coverage.

Recommendations will be in any of the following status: active, dismissed, pending, or resolved. Resolved recommendations are available for 365 days.

You can view or dismiss the recommendations. You can apply a configuration based active recommendation immediately, schedule it in the next maintenance window, or dismiss it. For threshold based proactive and machine learning based reactive recommendations, you need to review the suggested cause of the issue and then perform the recommended actions to fix the issue.

Recommendations are supported in the following AWS Regions:

- US East (Ohio)
- US East (N. Virginia)

- US West (N. California)
- US West (Oregon)
- Asia Pacific (Mumbai)
- Asia Pacific (Seoul)
- Asia Pacific (Singapore)
- Asia Pacific (Sydney)
- Asia Pacific (Tokyo)
- Canada (Central)
- Europe (Frankfurt)
- Europe (Ireland)
- Europe (London)
- Europe (Paris)
- South America (São Paulo)

Learn to view, apply, dismiss, and modify recommendations from Amazon RDS in the following sections.

Topics

Viewing Amazon RDS recommendations

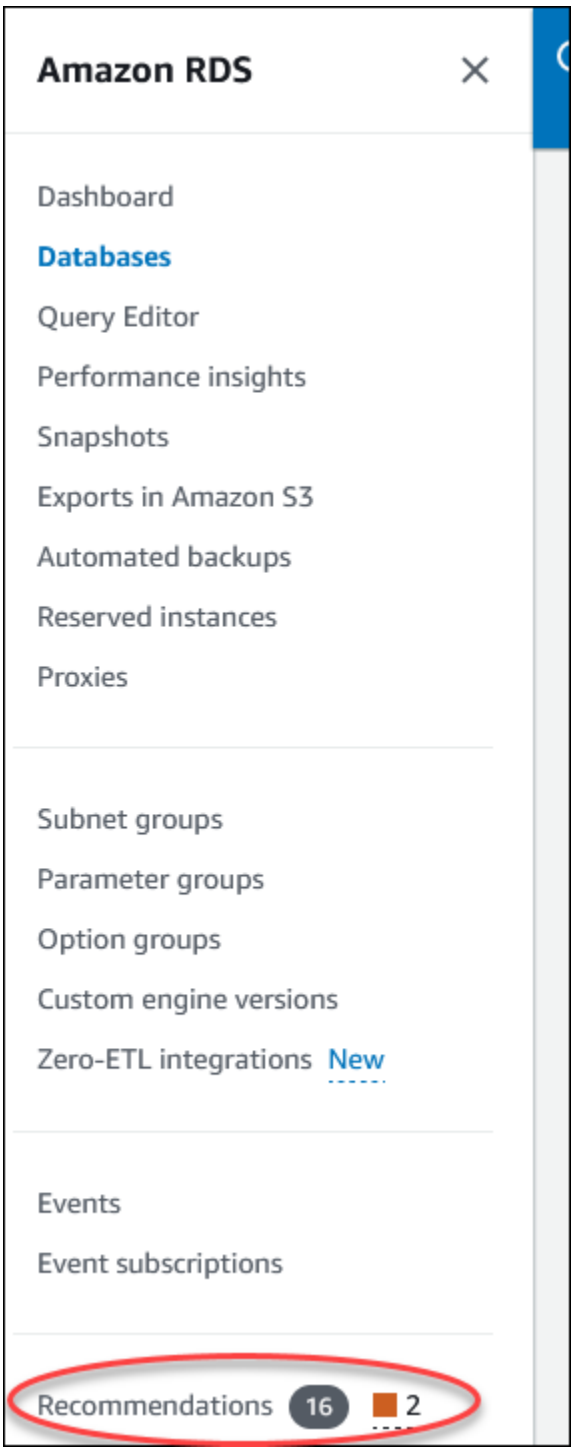
Using the Amazon RDS console, you can view Amazon RDS recommendations for your database resources.

Console

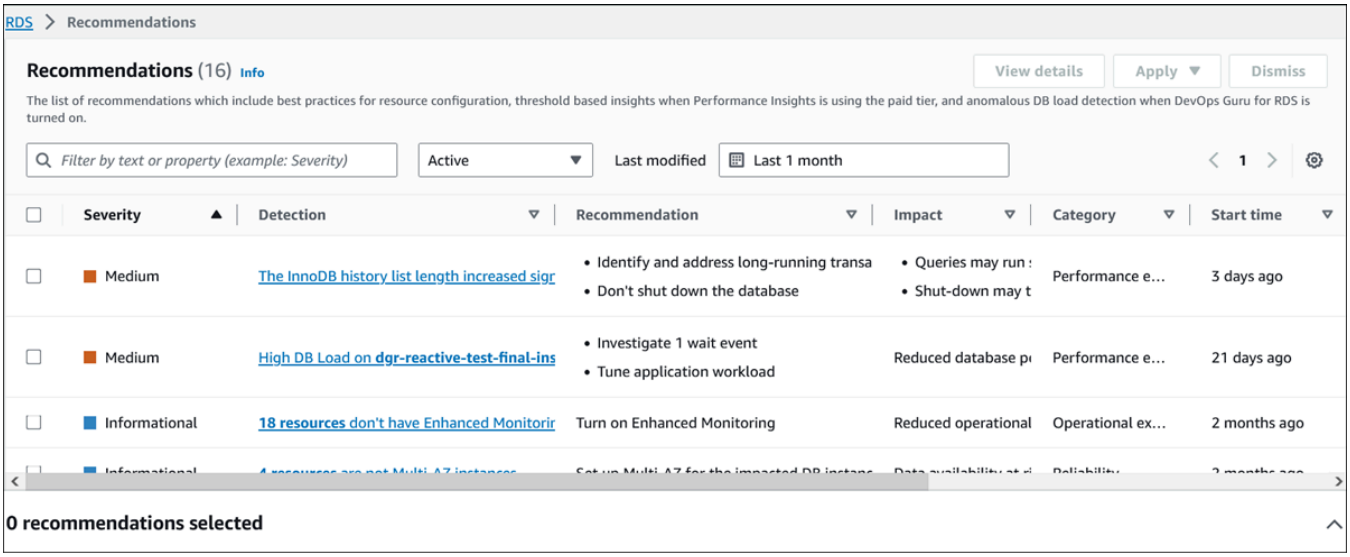
To view the Amazon RDS recommendations

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, do any of the following:

   - Choose **Recommendations**. The number of active recommendations for your resources and the number of recommendations with the highest severity generated in the last month are available next to **Recommendations**. To find the number of active recommendations for each severity, choose the number that shows the highest severity.

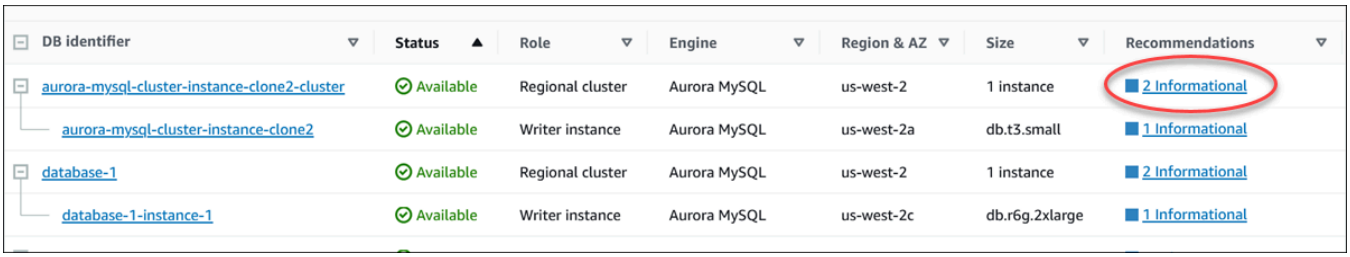


By default, the **Recommendations** page displays a list of new recommendations in the last month. Amazon RDS gives recommendations for all the resources in your account and sorts the recommendations by their severity.

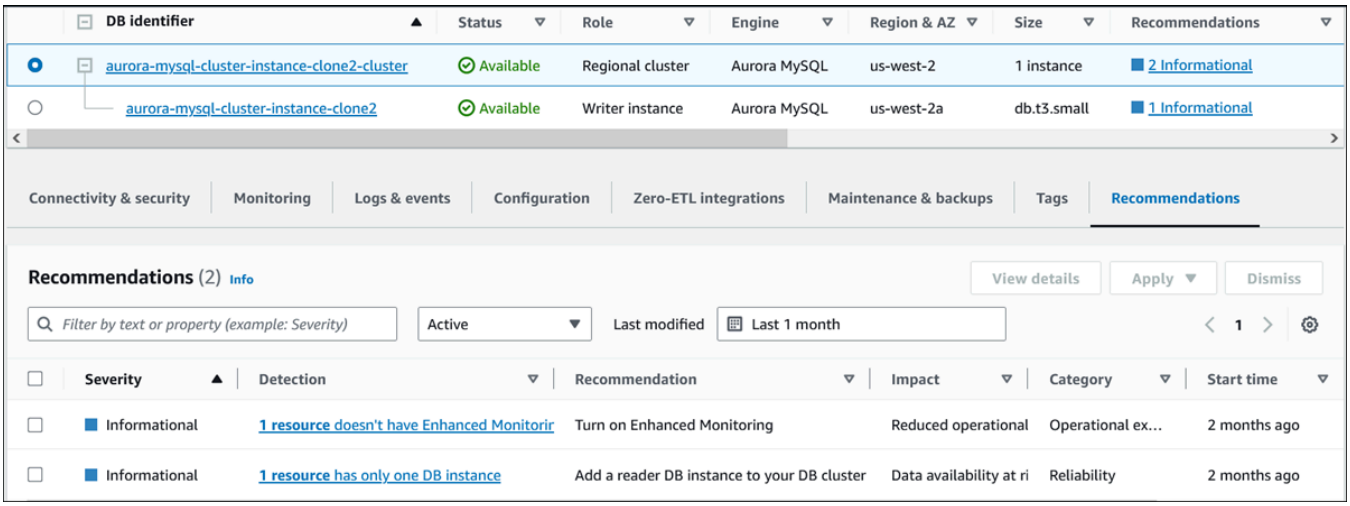


You can choose a recommendation to view a section at the bottom of the page which contains the affected resources and details of how the recommendation will be applied.

- In the **Databases** page, choose **Recommendations** for a resource.



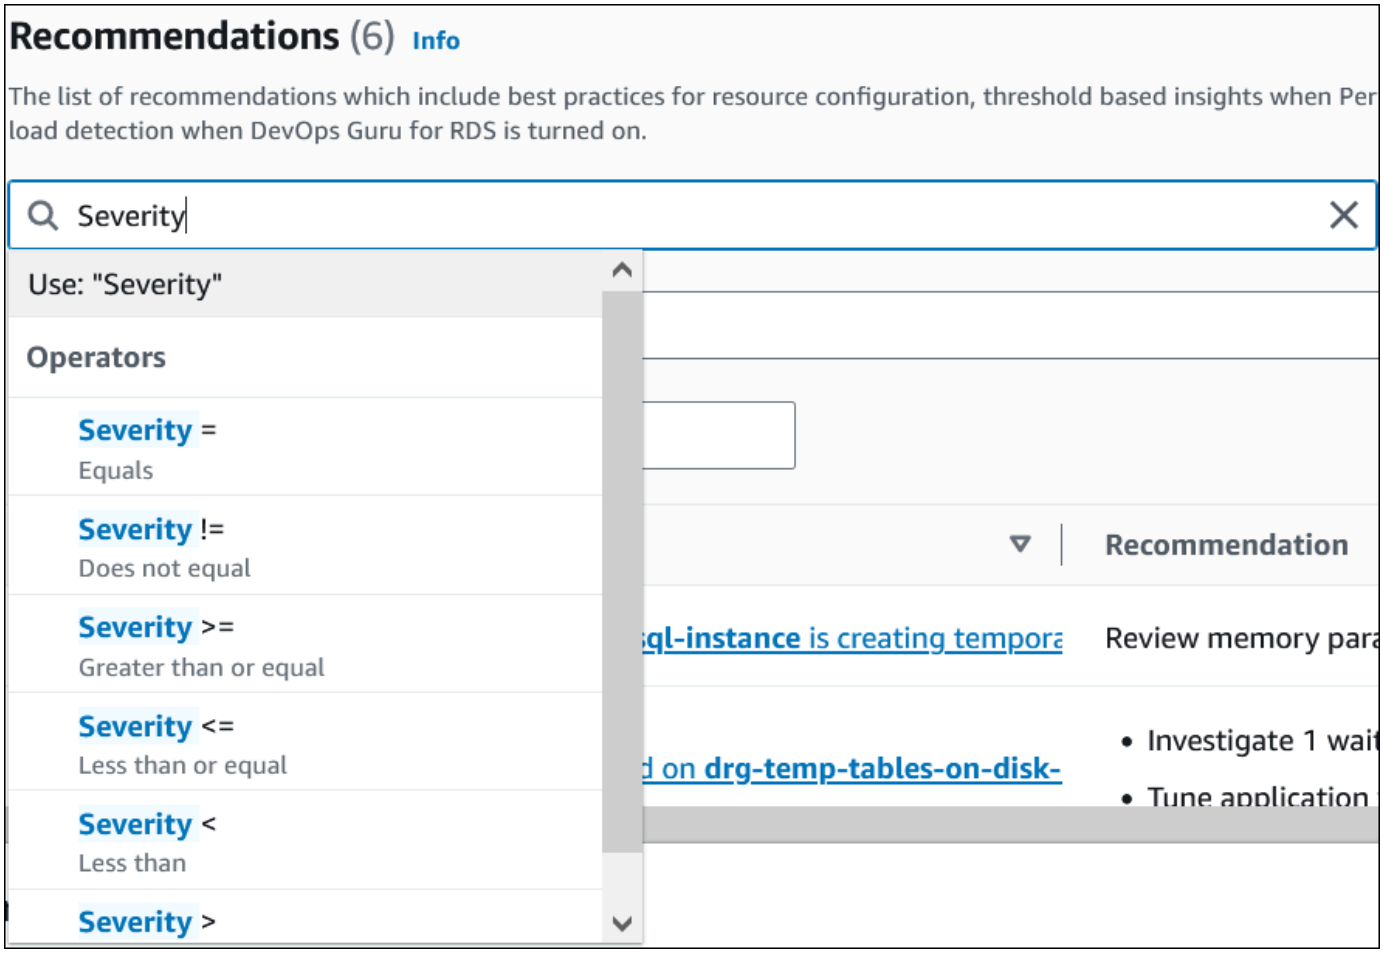
The **Recommendations** tab displays the recommendations and its details for the selected resource.



The following details are available for the recommendations:

- **Severity** – The implication level of the issue. The severity levels are **High**, **Medium**, **Low**, and **Informational**.
- **Detection** – The number of affected resources and a short description of the issue. Choose this link to view the recommendation and the analysis details.
- **Recommendation** – A short description of the recommended action to apply.
- **Impact** – A short description of the possible impact when the recommendation isn't applied.
- **Category** – The type of recommendation. The categories are **Performance efficiency**, **Security**, **Reliability**, **Cost optimization**, **Operational excellence**, and **Sustainability**.
- **Status** – The current status of the recommendation. The possible statuses are **All**, **Active**, **Dismissed**, **Resolved**, and **Pending**.
- **Start time** – The time when the issue began. For example, **18 hours ago**.
- **Last modified** – The time when the recommendation was last updated by the system because of a change in the **Severity**, or the time you responded to the recommendation. For example, **10 hours ago**.
- **End time** – The time when the issue ended. The time won't display for any continuing issues.
- **Resource identifier** – The name of one or more resources.

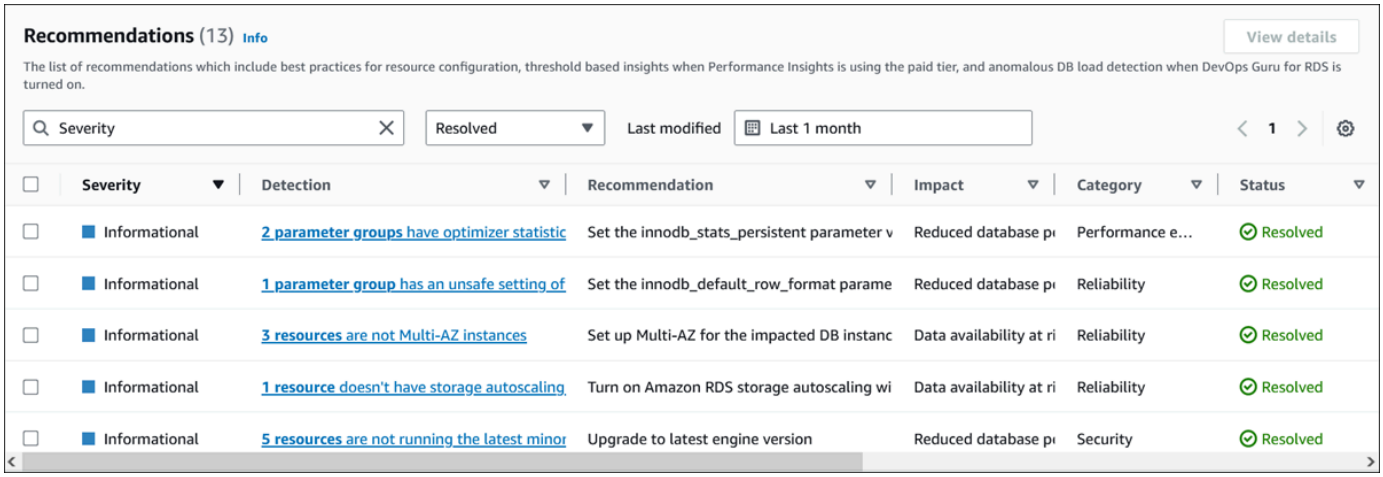
3. (Optional) Choose **Severity** or **Category** operators in the field to filter the list of recommendations.



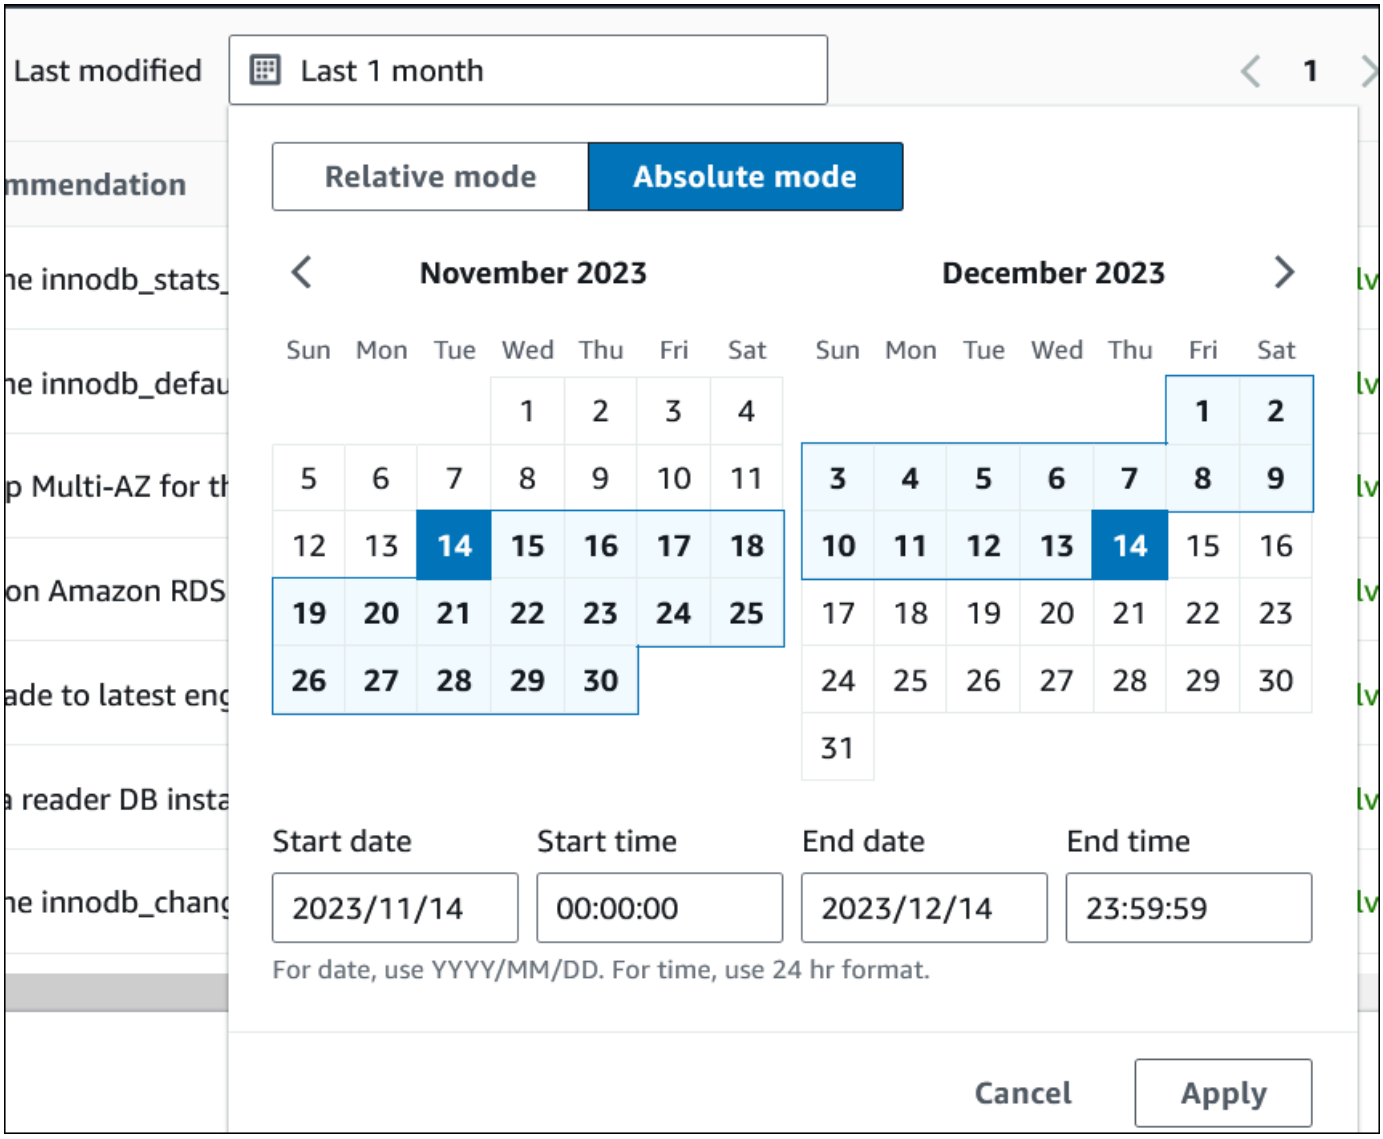
The recommendations for the selected operation appear.

4. (Optional) Choose any of the following recommendation status:

   - **Active** (default) – Shows the current recommendations that you can apply, schedule it for the next maintenance window, or dismiss.
   - **All** – Shows all the recommendations with the current status.
   - **Dismissed** – Shows the dismissed recommendations.
   - **Resolved** – Shows the recommendations that are resolved.
   - **Pending** – Shows the recommendations whose recommended actions are in progress or scheduled for the next maintenance window.



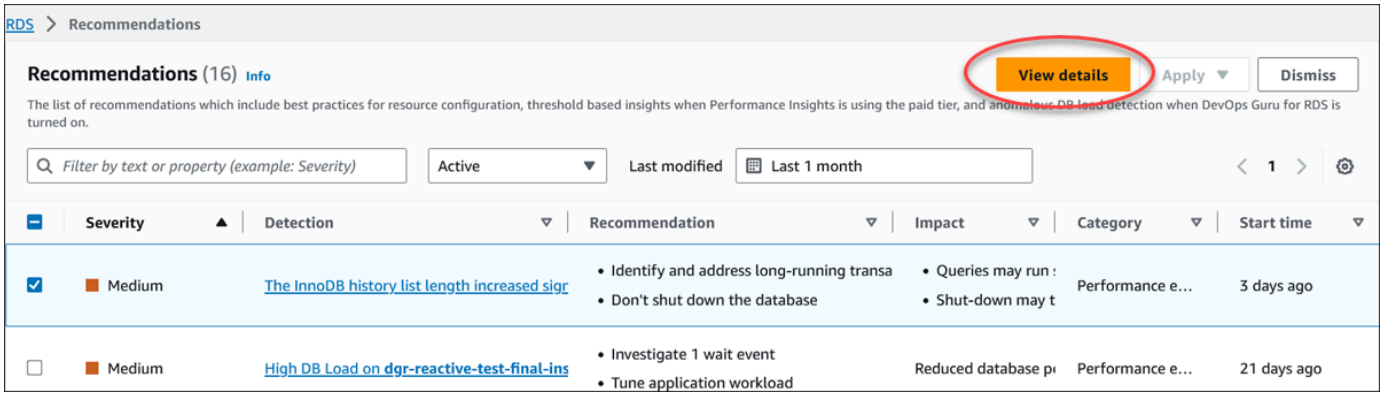
5. (Optional) Choose **Relative mode** or **Absolute mode** in **Last modified** to modify the time period. The **Recommendations** page displays the recommendations generated in the time period. The default time period is the last month. In the **Absolute mode**, you can choose the time period, or enter the time in **Start date** and **End date** fields.



The recommendations for the set time period display.

Note that you can see all recommendations for resources in your account by setting the range to **All**.

6. (Optional) Choose **Preferences** in the right to customize the details to display. You can choose a page size, wrap the lines of the text, and allow or hide the columns.
7. (Optional) Choose a recommendation and then choose **View details**.



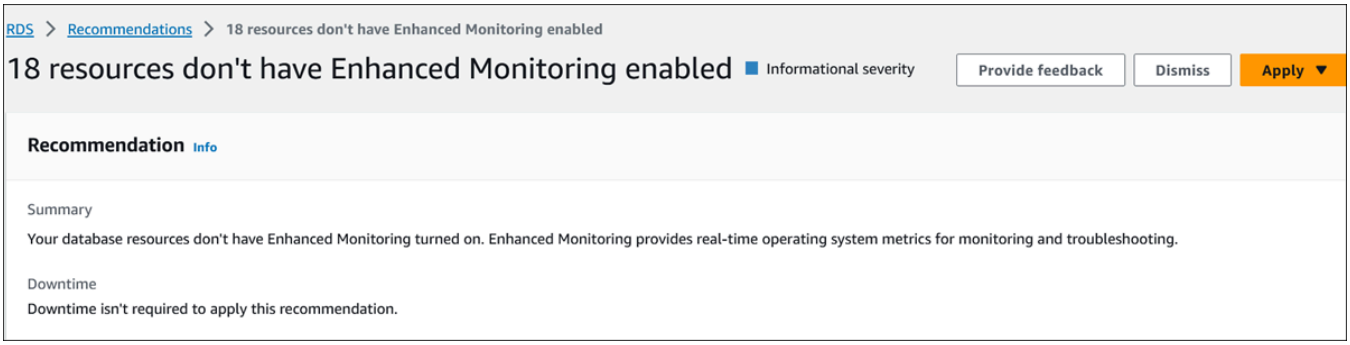
The recommendation details page appears. The title provides the total count of the resources with the issue detected and the severity.

For information about the components on the details page for an anomaly based reactive recommendation, see Viewing reactive anomalies in the *Amazon DevOps Guru User Guide*.

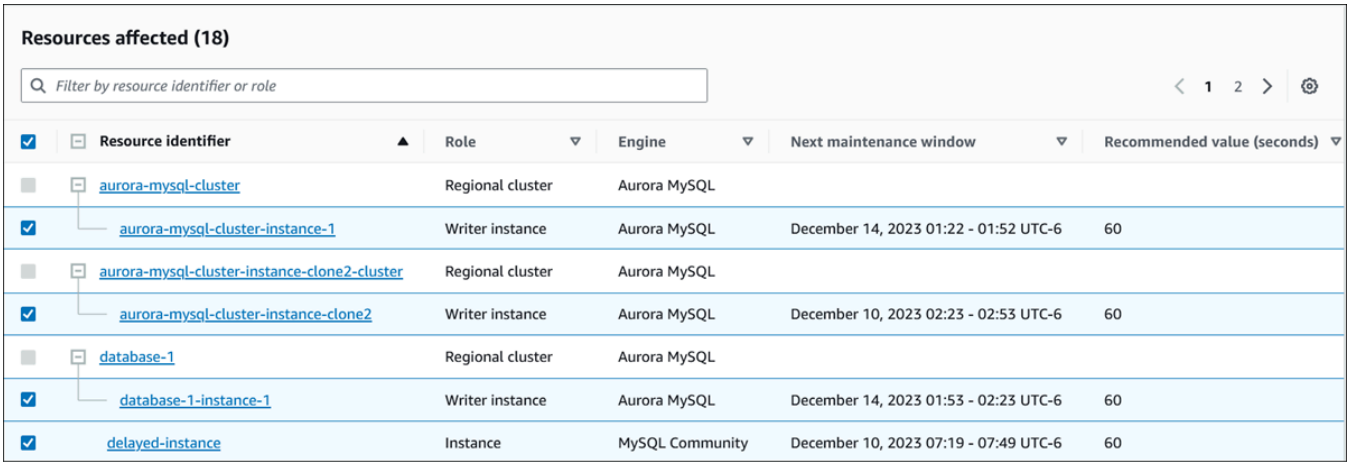
For information about the components on the details page for a threshold based proactive recommendation, see Viewing Performance Insights proactive recommendations.

The other automated recommendations display the following components on the recommendation details page:

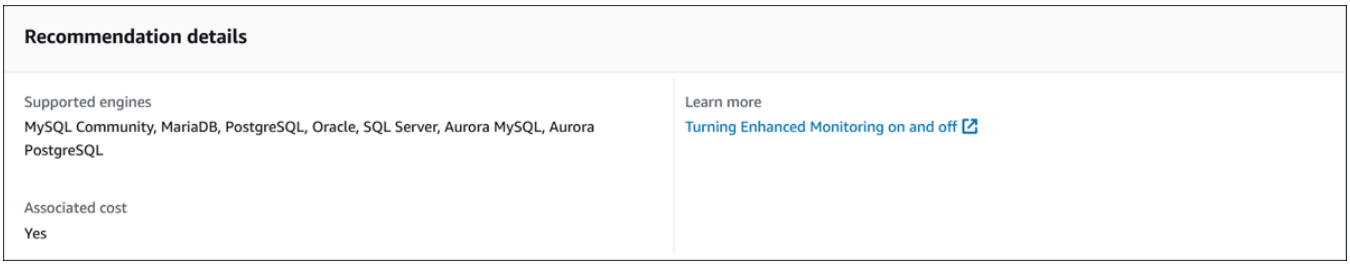
- **Recommendation** – A summary of the recommendation and whether downtime is required to apply the recommendation.



- **Resources affected** – Details of the affected resources.



- **Recommendation details** – Supported engine information, any required associated cost to apply the recommendation, and documentation link to learn more.



CLI

To view Amazon RDS recommendations of the DB instances, use the following command in AWS CLI.

```
aws rds describe-db-recommendations
```

RDS API

To view Amazon RDS recommendations using the Amazon RDS API, use the DescribeDBRecommendations operation.

Applying Amazon RDS recommendations

To apply Amazon RDS recommendations using the Amazon RDS console, select a configuration based recommendation or an affected resource in the details page. Then, choose to apply the recommendation immediately or schedule it for the next maintenance window. The resource might need to restart for the change to take effect. For a few DB parameter group recommendations, you might need to restart the resources.

The threshold based proactive or anomaly based reactive recommendations won't have the apply option and might need additional review.

Console

To apply a configuration based recommendation

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, perform any of the following:

   - Choose **Recommendations**.

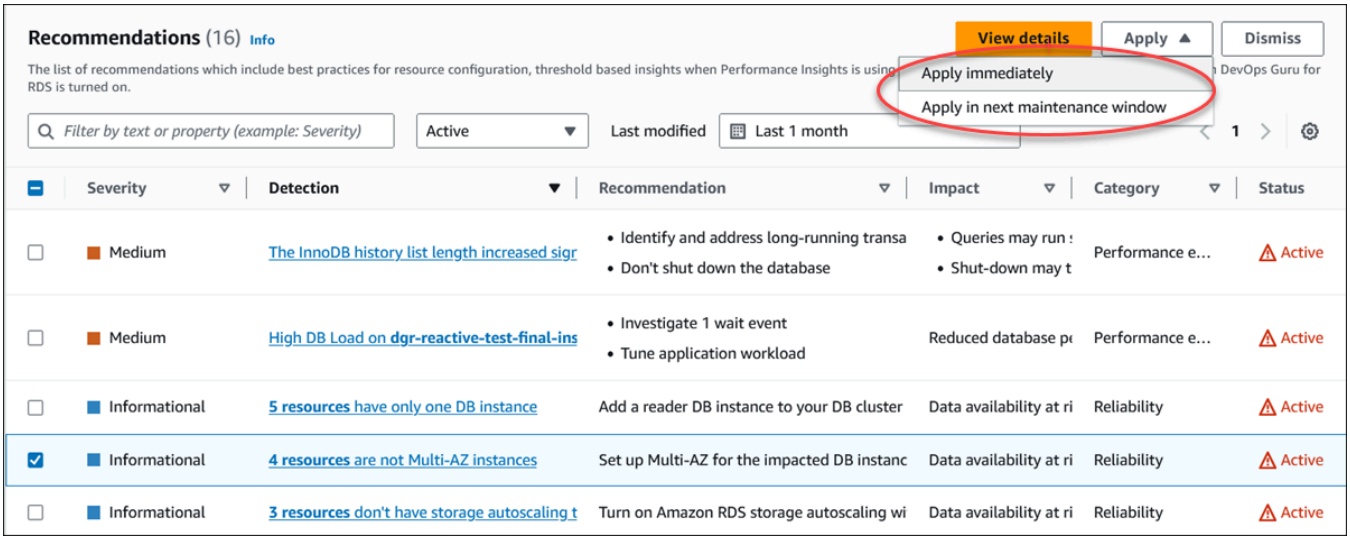
     The **Recommendations** page appears with the list of all recommendations.
   - Choose **Databases** and then choose **Recommendations** for a resource in the databases page.

     The details appear in the **Recommendations** tab for the selected recommendation.
   - Choose **Detection** for an active recommendation in the **Recommendations** page or the **Recommendations** tab in the **Databases** page.

     The recommendation details page appears.
3. Choose a recommendation, or one or more affected resources in the recommendation details page, and do any of the following:

   - Choose **Apply** and then choose **Apply immediately** to apply the recommendation immediately.
   - Choose **Apply** and then choose **Apply in next maintenance window** to schedule in the next maintenance window.

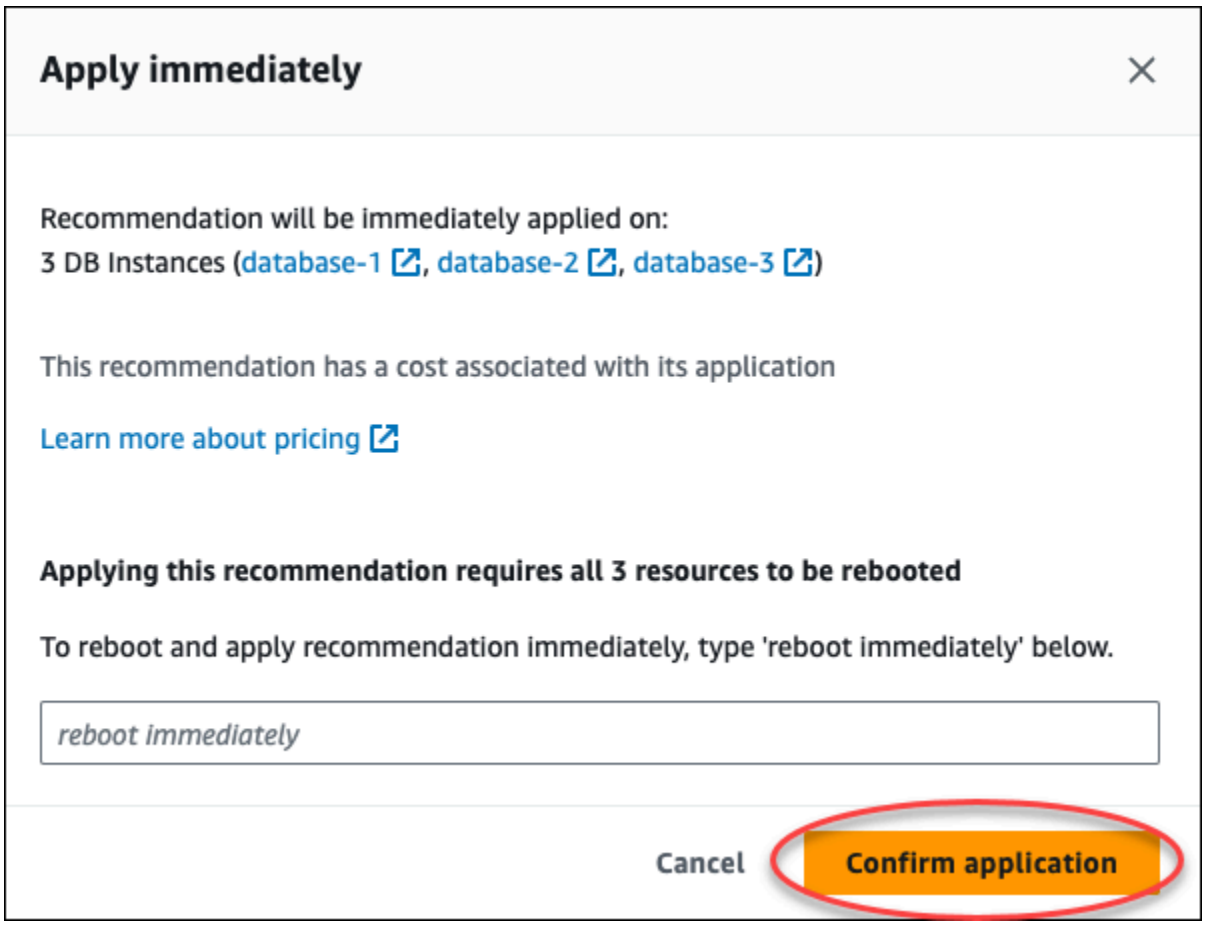
     The selected recommendation status is updated to pending until the next maintainance window.



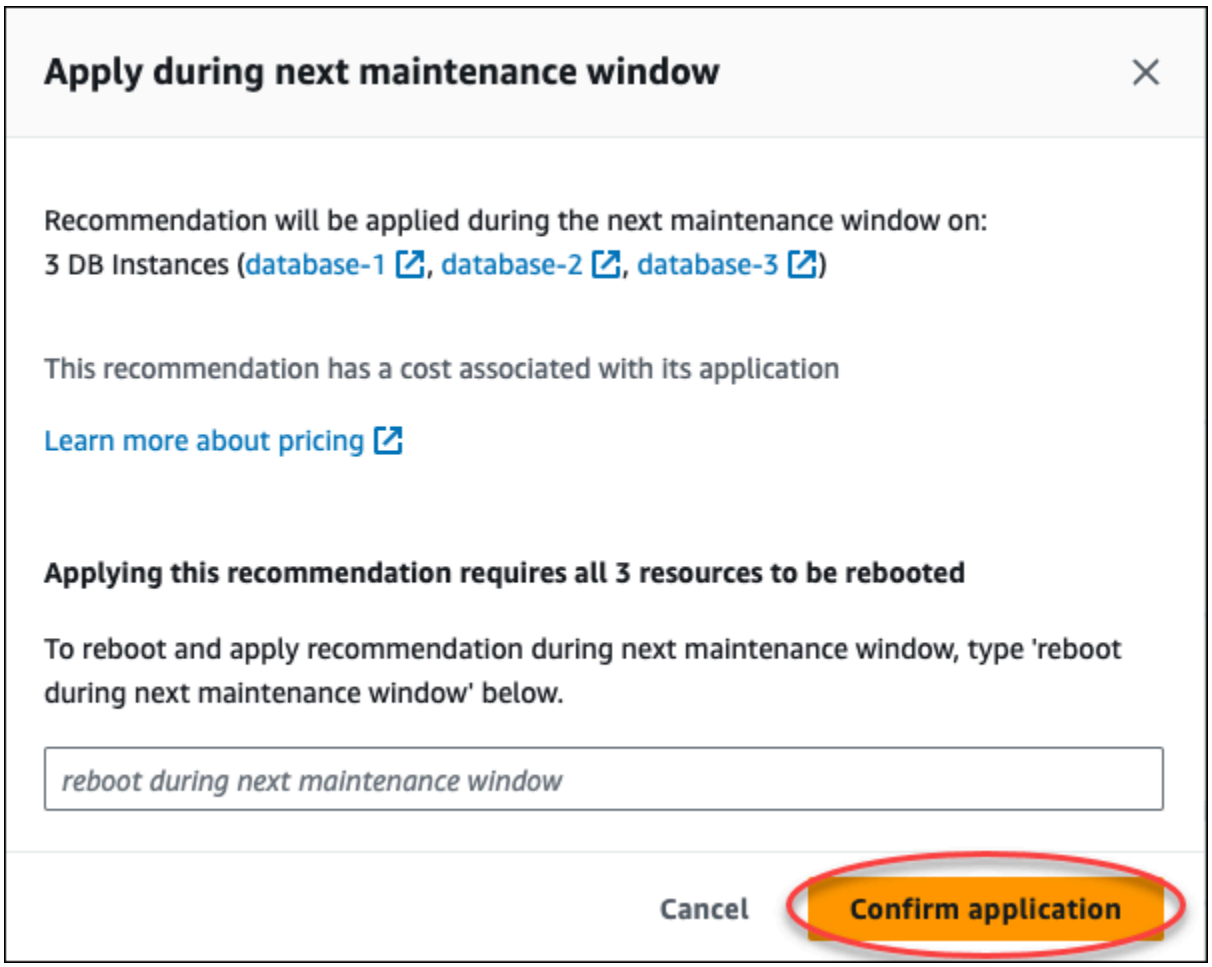
A confirmation window appears.

4. Choose **Confirm application** to apply the recommendation. This window confirms whether the resources need an automatic or manual restart for the changes to take effect.

   The following example shows the confirmation window to apply the recommendation immediately.



The following example shows the confirmation window to schedule applying the recommendation in the next maintenance window.



A banner displays a message when the recommendation applied is successful or has failed.

The following example shows the banner with the successful message.

The following example shows the banner with the failure message.

RDS API

To apply a configuration based RDS recommendation using the Amazon RDS API

1. Use the DescribeDBRecommendations operation. The `RecommendedActions` in the output can have one or more recommended actions.
2. Use the RecommendedAction object for each recommended action from step 1. The output contains `Operation` and `Parameters`.

   The following example shows the output with one recommended action.

```
   "RecommendedActions": [
       {
           "ActionId": "0b19ed15-840f-463c-a200-b10af1b552e3",
           "Title": "Turn on auto backup", // localized
           "Description": "Turn on auto backup for my-mysql-instance-1", //
localized
           "Operation": "ModifyDbInstance",
           "Parameters": [
               {
                   "Key": "DbInstanceIdentifier",
                   "Value": "my-mysql-instance-1"
               },
               {
                   "Key": "BackupRetentionPeriod",
                   "Value": "7"
               }
           ],
           "ApplyModes": ["immediately", "next-maintenance-window"],
           "Status": "applied"
       },
       ... // several others
   ],
```

3. Use the `operation` for each recommended action from the output in step 2 and input the `Parameters` values.
4. After the operation in step 2 is successful, use the ModifyDBRecommendation operation to modify the recommendation status.

Dismissing Amazon RDS recommendations

You can dismiss one or more Amazon RDS recommendations using the Amazon RDS console, AWS CLI, or Amazon RDS API.

Console

To dismiss one or more recommendations

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, perform any of the following:

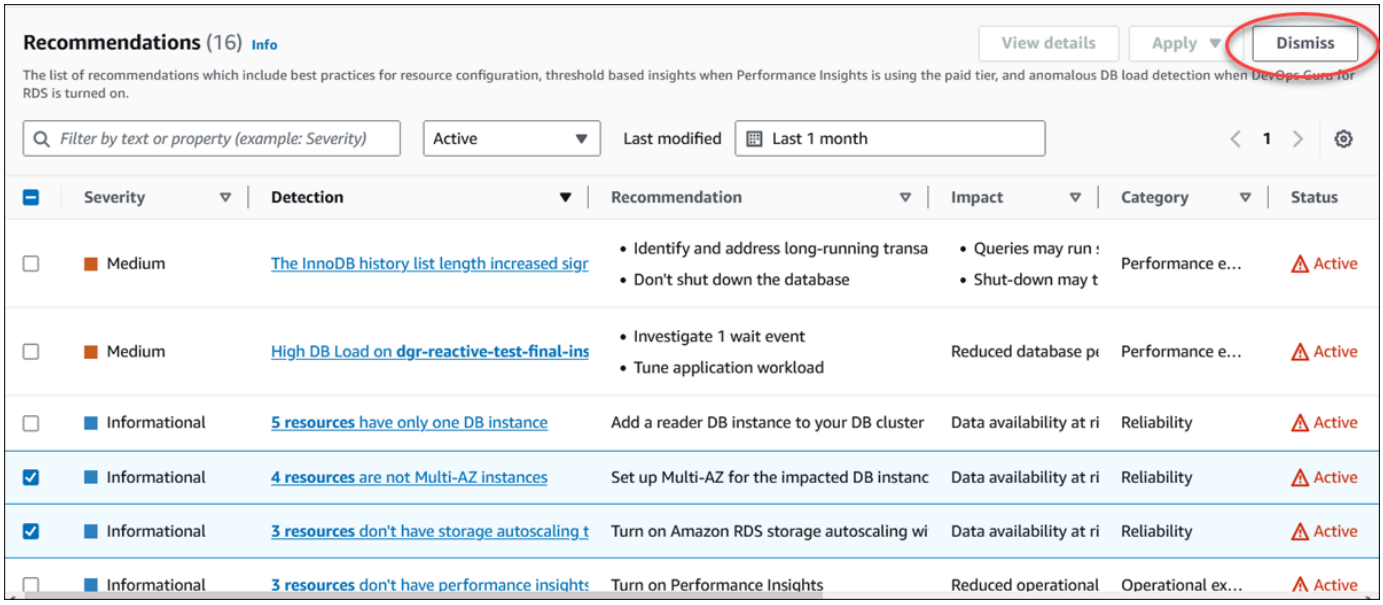
   - Choose **Recommendations**.

     The **Recommendations** page appears with the list of all recommendations.
   - Choose **Databases** and then choose **Recommendations** for a resource in the databases page.

     The details appear in the **Recommendations** tab for the selected recommendation.
   - Choose **Detection** for an active recommendation in the **Recommendations** page or the **Recommendations** tab in the **Databases** page.

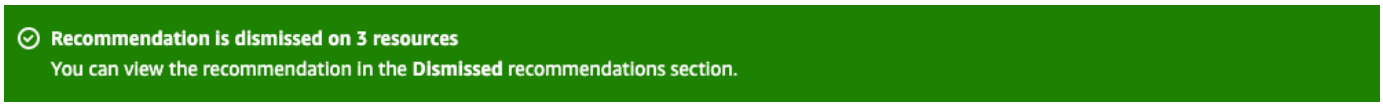
     The recommendation details page displays the list of affected resources.
3. Choose one or more recommendation, or one or more affected resources in the recommendation details page, and then choose **Dismiss**.

   The following example shows the **Recommendations** page with multiple active recommendations selected to dismiss.



A banner displays a message when the selected one or more recommendations are dismissed.

The following example shows the banner with the successful message.



The following example shows the banner with the failure message.

CLI

To dismiss a RDS recommendation using the AWS CLI

1. Run the command `aws rds describe-db-recommendations --filters "Name=status,Values=active"`.

   The output provides a list of recommendations in `active` status.
2. Find the `recommendationId` for the recommendation that you want to dismiss from step 1.
3. Run the command `>aws rds modify-db-recommendation --status dismissed --recommendationId <ID>` with the `recommendationId` from step 2 to dismiss the recommendation.

RDS API

To dismiss a RDS recommendation using the Amazon RDS API, use the ModifyDBRecommendation operation.

Modifying dismissed Amazon RDS recommendations to active recommendations

You can move one or more dismissed Amazon RDS recommendations to active recommendations using the Amazon RDS console, AWS CLI, or Amazon RDS API.

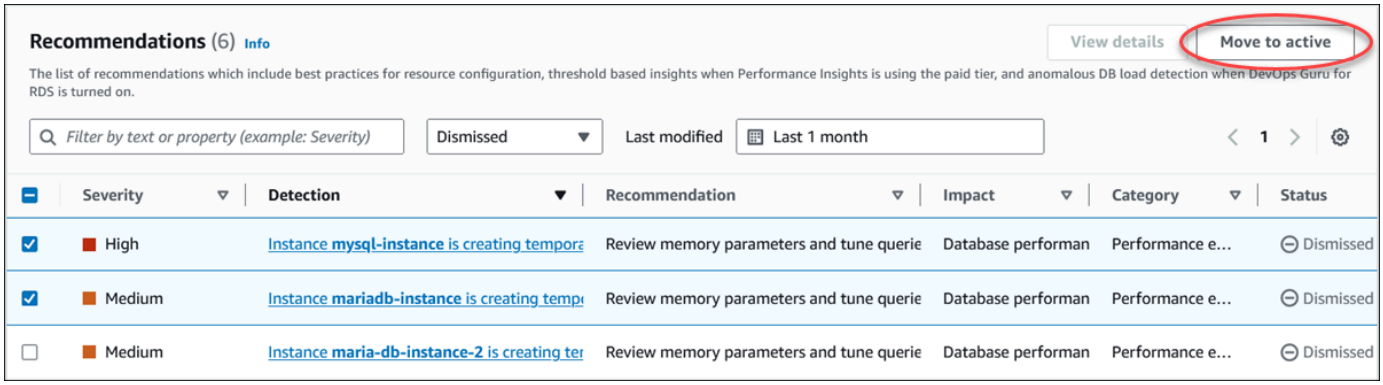
Console

To move one or more dismissed recommendations to active recommendations

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, perform any of the following:
   - Choose **Recommendations**.

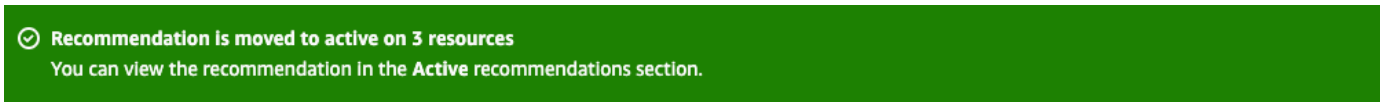
     The **Recommendations** page displays a list of recommendations sorted by the severity for all the resources in your account.
   - Choose **Databases** and then choose **Recommendations** for a resource in the databases page.

     The **Recommendations** tab displays the recommendations and its details for the selected resource.
3. Choose one or more dismissed recommendations from the list and then choose **Move to active**.



A banner displays a successful or failure message when the moving the selected recommendations from dismissed to active status.

The following example shows the banner with the successful message.



The following example shows the banner with the failure message.

CLI

To change a dismissed RDS recommendation to active recommendation using the AWS CLI

1. Run the command `aws rds describe-db-recommendations --filters "Name=status,Values=dismissed"`.

   The output provides a list of recommendations in `dismissed` status.
2. Find the `recommendationId` for the recommendation that you want to change the status from step 1.
3. Run the command `>aws rds modify-db-recommendation --status active --recommendationId <ID>` with the `recommendationId` from step 2 to change to active recommendation.

RDS API

To change a dismissed RDS recommendation to active recommendation using the Amazon RDS API, use the ModifyDBRecommendation operation.

Recommendations from Amazon RDS reference

Amazon RDS generates recommendations for a resource when the resource is created or modified. You can find examples of recommendations from Amazon RDS in the following table.

Type	Description	Recommendation	Downt requir	Additional informati on
Magnetic volume is in use	Your DB instances are using magnetic storage. Magnetic storage isn't recommended for most of the DB instances. Choose a different storage type: General Purpose (SSD) or Provisioned IOPS.	Choose a different storage type: General Purpose (SSD) or Provisioned IOPS.	Yes	Previous generatio n volumes in the Amazon EC2 documentation.
Resource Automated backups is turned off	Automated backups aren't turned on for your DB instances. Automated backups are recommend ed because they enable point-in-time recovery of your DB instances.	Turn on automated backups with a retention period of up to 14 days.	Yes	Enabling automated backups Demystifying Amazon RDS backup storage costs on the AWS Database Blog
Engine minor version upgrade is required	Your database resources aren't running the latest minor DB engine version. The latest minor version contains the latest security fixes and other improvements.	Upgrade to latest engine version.	Yes	Upgrading a DB instance engine version

Type	Description	Recommendation	Downt require	Additional informati on
Enhanced Monitoring is turned off	Your database resources don't have Enhanced Monitoring turned on. Enhanced Monitoring provides real-time operating system metrics for monitoring and troubleshooting.	Turn on Enhanced Monitoring.	No	Monitoring OS metrics with Enhanced Monitoring

Type	Description	Recommendation	Downt require	Additional informati on
Storage encryption is turned off	Amazon RDS supports encryptio n at rest for all the database engines by using the keys that you manage in AWS Key Management Service (AWS KMS). On an active DB instance with Amazon RDS encryption, the data stored at rest in the storage is encrypted, similar to automated backups, read replicas, and snapshots. If encryption isn't turned on while creating a DB instance, you will need to create and restore an encrypted copy of the decrypted snapshot of the DB instance before you turn on the encryptio n.	Turn on encryption of data at rest for your DB instance.	Yes	Security in Amazon RDS Copying a DB snapshot

Type	Description	Recommendation	Downt require	Additional informati on
Performan ce Insights is turned off	Performance Insights monitors your DB instance load to help you analyze and resolve database performance issues. We recommend that you turn on Performance Insights.	Turn on Performance Insights.	No	Monitoring DB load with Performance Insights on Amazon RDS
DB instances have storage autoscaling turned off	Storage autoscaling isn't turned on for your DB instance. When the database workload increases, RDS storage autoscali ng automatically scales the storage capacity with zero downtime.	Turn on Amazon RDS storage autoscali ng with a specified maximum storage threshold	No	Managing capacity automatically with Amazon RDS storage autoscaling
RDS resources major versions update is required	Databases with the current major version for the DB engine won't be supported. We recommend that you upgrade to the latest major version which includes new functionality and enhancements.	Upgrade to the latest major version for the DB engine.	Yes	Upgrading a DB instance engine version Using Amazon RDS Blue/Green Deployments for database updates

Type	Description	Recommendation	Downt require	Additional informati on
RDS resources instance class update is required	Your DB instance is running an earlier generation DB instance class. We have replaced DB instance classes from an earlier generatio n with DB instance classes with better cost, performance, or both. We recommend that you run your DB instance with a DB instance class from a newer generation.	Upgrade the DB instance class.	Yes	Supported DB engines for DB instance classes
RDS resources using end of support engine edition under license-i ncluded	We recommend that you upgrade the major version to the latest engine version supported by Amazon RDS to continue with the current license support. The engine version of your database won't be supported with the current license.	We recommend that you upgrade your database to the latest supported version in Amazon RDS to continue using the licensed model.	Yes	Oracle major version upgrades

Type	Description	Recommendation	Downt require	Additional informati on
DB instances not using Multi-AZ deployment	We recommend that you use Multi-AZ deployment. The Multi-AZ deploymen ts enhance the availability and durability of the DB instance.	Set up Multi-AZ for the impacted DB instances	No Downti doesn't occur during this change Howev there is a possibl perforr ce impact For more inform on, see Modify a DB instanc to be a Multi-AZ DB instanc deploy t	Pricing for Amazon RDS Multi-AZ

Type	Description	Recommendation	Downt require	Additional informati on
DB memory parameters are diverging from default	The memory parameters of the DB instances are significa ntly different from the default values. These settings can impact performance and cause errors. We recommend that you reset the custom memory parameters for the DB instance to their default values in the DB parameter group.	Reset the memory parameters to their default values.	No	Best practices for configuring performance parameters for Amazon RDS for MySQL on the AWS Database Blog
`InnoDB_Ch ange_Buff ering` parameter using less than optimum value	Change buffering allows a MySQL DB instance to defer a few writes, which are required to maintain secondary indexes. This feature was useful in environme nts with slow disks. The change buffering configuration improved the DB performance slightly but caused a delay in crash recovery and long shutdown times during upgrade.	Set `InnoDB_Ch ange_Buffering` parameter value to `NONE` in your DB parameter groups.	No	Best practices for configuring performance parameters for Amazon RDS for MySQL on the AWS Database Blog

Type	Description	Recommendation	Downt require	Additional informati on
Query cache parameter is turned on	When changes require that your query cache is purged, your DB instance will appear to stall. Most workloads don't benefit from a query cache. The query cache was removed from MySQL version 8.0. We recommend that you set the query_cache_type parameter to 0.	Set the `query_cac he_type` parameter value to `0` in your DB parameter groups.	Yes	Best practices for configuring performance parameters for Amazon RDS for MySQL on the AWS Database Blog
`log_outpu t` parameter is set to table	When `log_output` is set to `TABLE`, more storage is used than when `log_outpu t` is set to `FILE`. We recommend that you set the parameter to `FILE`, to avoid reaching the storage size limit.	Set the `log_outpu t` parameter value to `FILE` in your DB parameter groups.	No	MySQL database log files

Type	Description	Recommendation	Downt require	Additional informati on
Parameter groups not using huge pages	Large pages can increase database scalability, but your DB instance isn't using large pages. We recommend that you set the `use_large_pages` parameter value to `ONLY` in the DB parameter group for your DB instance.	Set the `use_large_pages` parameter value to `ONLY` in your DB parameter groups.	Yes	Turning on HugePages for an RDS for Oracle instance
`autovacuum` parameter is turned off	The autovacuum parameter is turned off for your DB instances. Turning autovacuum off increases the table and index bloat and impacts the performance. We recommend that you turn on autovacuum in your DB parameter groups.	Turn on the autovacuum parameter in your DB parameter groups.	No	Understanding autovacuum in Amazon RDS for PostgreSQL environments on the AWS Database Blog

Type	Description	Recommendation	Downt require	Additional informati on
synchrono us_commit parameter is turned off	When synchrono us_commit parameter is turned off, data can be lost in a database crash. The durability of the database is at risk. We recommend that you turn on the synchrono us_commit parameter.	Turn on synchrono us_commit parameter in your DB parameter groups.	Yes	Amazon Aurora PostgreSQL parameters: Replicati on, security, and logging on the AWS Database Blog
track_cou nts parameter is turned off	When the track_counts parameter is turned off, the database doesn't collect the database activity statistics. Autovacuu m requires these statistics to work correctly. We recommend that you set track_cou nts parameter to 1.	Set track_counts parameter to 1.	No	Run-time Statistics for PostgreSQL

Type	Description	Recommendation	Downt require	Additional informati on
enable_in dexonlysc an parameter is turned off	The query planner or optimizer can't use the index-only scan plan type when it is turned off. We recommend that you set the enable_in dexonlyscan parameter value to 1.	Set the enable_in dexonlyscan parameter value to 1.	No	Planner Method Configuration for PostgreSQL
enable_in dexscan parameter is turned off	The query planner or optimizer can't use the index scan plan type when it is turned off. We recommend that you set the enable_in dexscan value to 1.	Set the enable_in dexscan parameter value to 1.	No	Planner Method Configuration for PostgreSQL

Type	Description	Recommendation	Downt require	Additional informati on
innodb_fl ush_log_a t_trx parameter is turned off	The value of the innodb_fl ush_log_at_trx parameter of your DB instance isn't safe value. This parameter controls the persistence of commit operations to disk. We recommend that you set the innodb_fl ush_log_at_trx parameter to 1.	Set the innodb_fl ush_log_at_trx parameter value to 1.	No	Best practices for configuring performance parameters for Amazon RDS for MySQL on the AWS Database Blog
sync_binl og parameter is turned off	The synchronization of the binary log to disk isn't enforced before the transacti on commits are acknowledged in your DB instance. We recommend that you set the sync_binlog parameter value to 1.	Set the sync_binl og parameter value to 1.	No	Best practices for configuring replicati on parameters for Amazon RDS for MySQL on the AWS Database Blog

Type	Description	Recommendation	Downt require	Additional informati on
innodb_st ats_persi stent parameter is turned off	Your DB instance isn't configured to persist the InnoDB statistics to the disk. When the statistics aren't stored, they are recalculated each time the instance restarts and the table accessed. This leads to variations in the query execution plan. You can modify the value of this global parameter at the table level. We recommend that you set the innodb_st ats_persistent parameter value to ON.	Set the innodb_st ats_persistent parameter value to ON.	No	Best practices for configuring performance parameters for Amazon RDS for MySQL on the AWS Database Blog

Type	Description	Recommendation	Downt require	Additional informati on
innodb_op en_files parameter is low	The innodb_op en_files parameter controls the number of files InnoDB can open at one time. InnoDB opens all of the log and system tablespac e files when mysqld is running. Your DB instance has a low value for the maximum number of files InnoDB can open at one time. We recommend that you set the innodb_op en_files parameter to a minimum value of 65.	Set the innodb_op en_files parameter to a minimum value of 65.	Yes	InnoDB open files for MySQL

Type	Description	Recommendation	Downt require	Additional informati on
max_user_ connectio ns parameter is low	Your DB instance has a low value for the maximum number of simultaneous connections for each database account. We recommend setting the max_user_ connections parameter to a number greater than 5.	Increase the value of the max_user_ connections parameter to a number greater than 5.	Yes	Setting Account Resource Limits for MySQL
Read Replicas are open in writable mode	Your DB instance has a read replica in writable mode, which allows updates from clients. We recommend that you set the the read_only parameter to TrueIfReplica so that the read replicas isn't in writable mode.	Set the read_only parameter value to TrueIfReplica .	No	Best practices for configuring replicati on parameters for Amazon RDS for MySQL on the AWS Database Blog

Type	Description	Recommendation	Downt require	Additional informati on
innodb_de fault_row _format parameter setting is unsafe	Your DB instance encounters a known issue: A table created in a MySQL version lower than 8.0.26 with the row_forma t set to COMPACT or REDUNDANT will be inaccessible and unrecoverable when the index exceeds 767 bytes. We recommend that you set the innodb_de fault_row _format parameter value to DYNAMIC.	Set the innodb_de fault_row _format parameter value to DYNAMIC.	No	Changes in MySQL 8.0.26

Type	Description	Recommendation	Downt requir	Additional informati on
general_l ogging parameter is turned on	The general logging is turned on for your DB instance. This setting is useful while troubleshooting the database issues. However, turning on general logging increases the amount of I/O operations and allocated storage space, which might result in contentio n and performance degradation. Check your requireme nts for general logging usage. We recommend that you set the general_l ogging parameter value to 0.	Check your requireme nts for general logging usage. If it isn't mandatory , we recommend that you to set the general_logging parameter value to 0.	No	Overview of RDS for MySQL database logs

Type	Description	Recommendation	Downt require	Additional informati on
RDS instance under-pro visioned for system memory capacity	We recommend that you tune your queries to use lesser memory or use a DB instance type with higher allocated memory. When the instance is running low on memory, then the database performan ce is impacted.	Use a DB instance with higher memory capacity	Yes	Scaling Your Amazon RDS Instance Verticall y and Horizontally on the AWS Database Blog Amazon RDS instance types Amazon RDS pricing
RDS instance under-pro visioned for system CPU capacity	We recommend that you tune your queries to use less CPU or modify your DB instance to use a DB instance class with higher allocated vCPUs. Database performance might decline when a DB instance is running low on CPU.	Use a DB instance with higher CPU capacity	Yes	Scaling Your Amazon RDS Instance Verticall y and Horizontally on the AWS Database Blog Amazon RDS instance types Amazon RDS pricing

Type	Description	Recommendation	Downt require	Additional informati on
RDS resources are not utilizing connectio n pooling correctly	We recommend that you enable Amazon RDS Proxy to efficient ly pool and share existing database connections. If you are already using a proxy for your database, configure it correctly to improve connection pooling and load balancing across multiple DB instances. RDS Proxy can help reduce the risk of connectio n exhaustion and downtime while improving availability and scalability.	Enable RDS Proxy or modify your existing proxy configuration	No	Scaling Your Amazon RDS Instance Verticall y and Horizontally on the AWS Database Blog Using Amazon RDS Proxy Amazon RDS Proxy Pricing

Type	Description	Recommendation	Downt require	Additional informati on
RDS instances are creating excessive temporary objects	We recommend that you tune your workload to prevent creating excessive temporary objects, or switch to RDS instance classes supporting optimized reads. RDS Optimized Reads improves database performan ce for workloads involving a large number of temporary objects and/or large temporary objects. Evaluate your workload to determine if using an instance with RDS Optimized Reads benefits your database workload.	Use a DB instance type with RDS Optimized Reads	Yes	Amazon RDS instance types Improving query performance for RDS for MySQL with Amazon RDS Optimized Reads Improving query performance for RDS for MariaDB with Amazon RDS Optimized Reads Improving query performance for RDS for PostgreSQ L with Amazon RDS Optimized Reads

Type	Description	Recommendation	Downt require	Additional informati on
RDS instances are under-pro visioned for system IOPS capacity	We recommend tuning the database workload to reduce IOPS or scale up the DB instance to a type with a higher default IOPS limit. The current DB instance can't support the Provisioned IOPS, or the database workload has high IOPS utilization.	Use a DB instance type with higher default IOPS limits	Yes	Amazon RDS instance types Amazon RDS DB instance storage Database load
RDS instances have under-provisioned Amazon EBS volumes	We recommend tuning the database workload to reduce IOPS or increase the Provisioned IOPS for the database. When IOPS utilizati on approaches the Provisioned IOPS, database performan ce might decline.	Provision more IOPS for the DB instance	Yes	Amazon RDS instance types Amazon RDS DB instance storage Database load

Type	Description	Recommendation	Downt require	Additional informati on
RDS instances are under-pro visioned for throughput capacity	We recommend tuning the database workload to reduce throughput or increase the provision ed throughput for the database. When throughput utilization approache s the provisioned throughput, database performance might be impacted.	Provision more throughput for the DB instance	Yes	Amazon RDS instance types Amazon RDS DB instance storage Database load

Type	Description	Recommendation	Downt require	Additional informati on
RDS instances are under-pro visioned for EBS I/O	We recommend tuning the database workload to reduce I/O operations or modifying the DB instance to use Amazon RDS io2 Block Express volumes which are designed for database workloads that require high performance, high throughput, and low latency. With the current workload, the database might not be able to process I/O operations at the required rate which can lead to performance degradation.	Use Amazon RDS io2 Block Express volumes for the RDS instance	No	Amazon RDS DB instance storage Amazon CloudWatch metrics for Amazon RDS Provisioned IOPS SSD volumes in the Amazon EBS User Guide

Viewing metrics in the Amazon RDS console

Amazon RDS integrates with Amazon CloudWatch to display a variety of RDS DB instance metrics in the RDS console. For descriptions of these metrics, see Metrics reference for Amazon RDS.

For your DB instance, the following categories of metrics are monitored:

- **CloudWatch** – Shows the Amazon CloudWatch metrics for RDS that you can access in the RDS console. You can also access these metrics in the CloudWatch console. Each metric includes a graph that shows the metric monitored over a specific time span. For a list of CloudWatch metrics, see Amazon CloudWatch metrics for Amazon RDS.
- **Enhanced monitoring** – Shows a summary of operating-system metrics when your RDS DB instance has turned on Enhanced Monitoring. RDS delivers the metrics from Enhanced Monitoring to your Amazon CloudWatch Logs account. Each OS metric includes a graph showing the metric monitored over a specific time span. For an overview, see Monitoring OS metrics with Enhanced Monitoring. For a list of Enhanced Monitoring metrics, see OS metrics in Enhanced Monitoring.
- **OS Process list** – Shows details for each process running in your DB instance.
- **Performance Insights** – Opens the Amazon RDS Performance Insights dashboard for a DB instance. For an overview of Performance Insights, see Monitoring DB load with Performance Insights on Amazon RDS. For a list of Performance Insights metrics, see Amazon CloudWatch metrics for Amazon RDS Performance Insights.

Amazon RDS now provides a consolidated view of Performance Insights and CloudWatch metrics in the Performance Insights dashboard. Performance Insights must be turned on for your DB instance to use this view. You can choose the new monitoring view in the **Monitoring** tab or **Performance Insights** in the navigation pane. To view the instructions for choosing this view, see Viewing combined metrics with the Performance Insights dashboard.

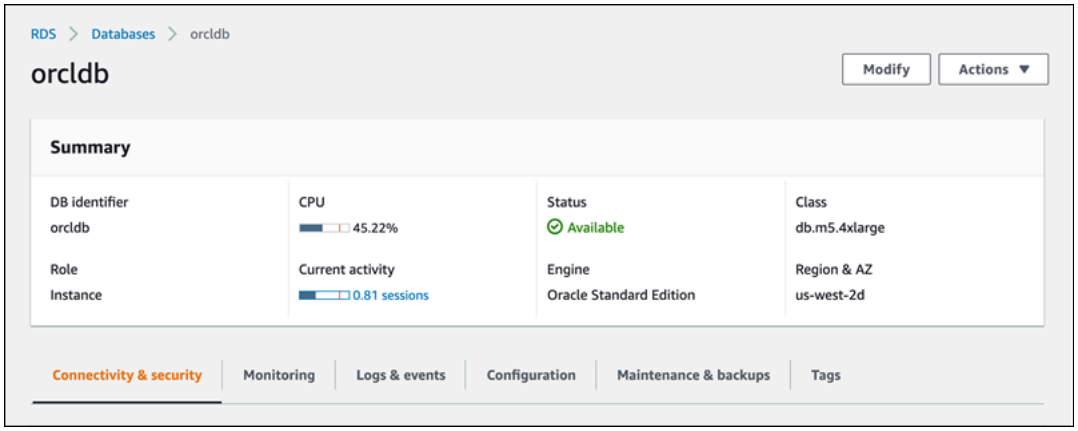
If you want to continue with the legacy monitoring view, continue with this procedure.

> **Note**
>
> The legacy monitoring view will be discontinued on December 15, 2023.

To view metrics for your DB instance in the legacy monitoring view:

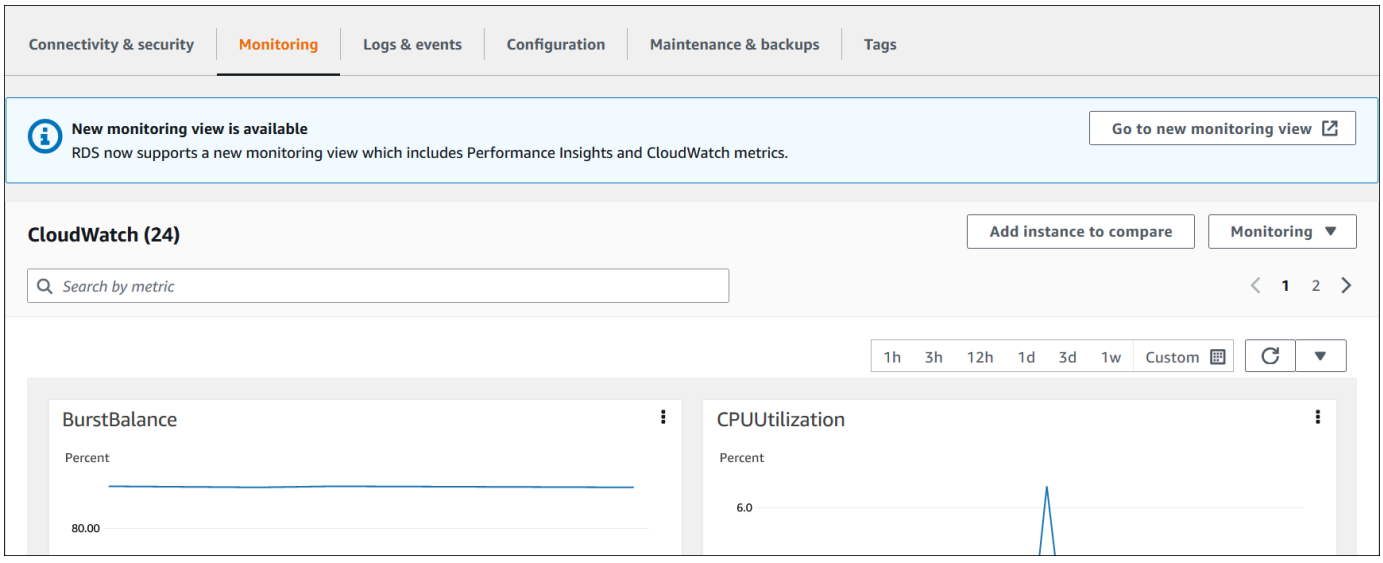
1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.
3. Choose the name of the DB instance that you want to monitor.

   The database page appears. The following example shows an Oracle database named `orclb`.

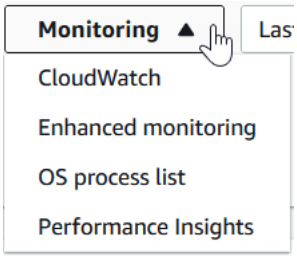


4. Scroll down and choose **Monitoring**.

   The monitoring section appears. By default, CloudWatch metrics are shown. For descriptions of these metrics, see Amazon CloudWatch metrics for Amazon RDS.



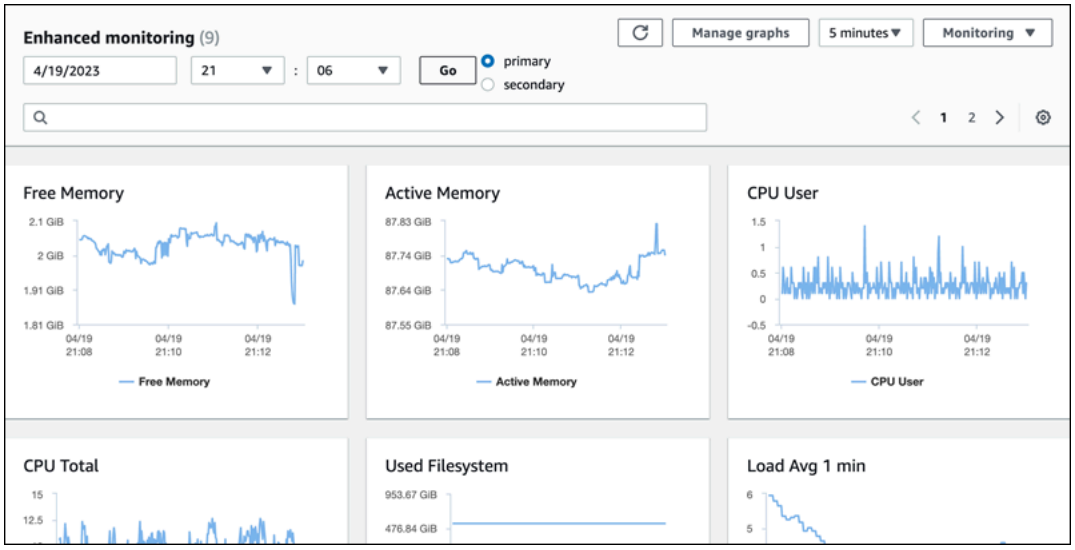
5. Choose **Monitoring** to see the metric categories.



6. Choose the category of metrics that you want to see.

   The following example shows Enhanced Monitoring metrics. For descriptions of these metrics, see [OS metrics in Enhanced Monitoring].

> **Note**
>
> Currently, viewing OS metrics for a Multi-AZ standby replica is not supported for MariaDB DB instances.



> **Tip**
>
> To choose the time range of the metrics represented by the graphs, you can use the time range list.
>
> To bring up a more detailed view, you can choose any graph. You can also apply metric-specific filters to the data.

Viewing combined metrics with the Performance Insights dashboard

Amazon RDS now provides a consolidated view of Performance Insights and CloudWatch metrics for your DB instance in the Performance Insights dashboard. You can use the preconfigured dashboard or create a custom dashboard. The preconfigured dashboard provides the most commonly used metrics to help diagnose performance issues for a database engine. Alternatively, you can create a custom dashboard with the metrics for a database engine that meet your analysis requirements. Then, use this dashboard for all the DB instances of that database engine type in your AWS account.

You can choose the new monitoring view in the **Monitoring** tab or **Performance Insights** in the navigation pane. When you navigate to the Performance Insights page, you see the options to choose between the new monitoring view and legacy view. The option you choose is saved as the default view.

Performance Insights must be turned on for your DB instance to view the combined metrics in the Performance Insights dashboard. For more information about turning on Performance Insights, see Turning Performance Insights on and off for Amazon RDS.

> **Note**
>
> We recommend that you choose the new monitoring view. You can continue to use the legacy monitoring view, but it was discontinued on December 15, 2023.

In the following sections, you can learn to display Performance Insights and CloudWatch metrics with the new and legacy monitoring views.

Topics

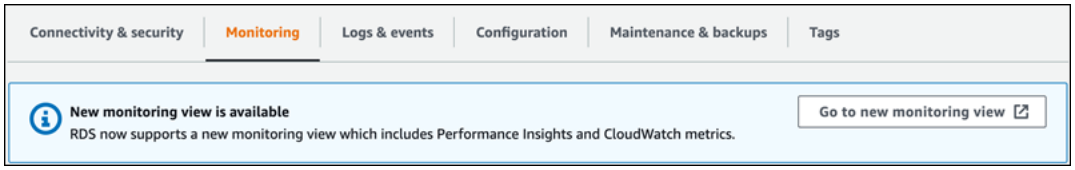
Choosing the new monitoring view from the Monitoring tab

From the Amazon RDS console, you can choose the new monitoring view to view Performance Insights and CloudWatch metrics for your DB instance.

To choose the new monitoring view in the Monitoring tab

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the left navigation pane, choose **Databases**.
3. Choose the DB instance that you want to monitor.
4. Scroll down and choose the **Monitoring** tab.

   A banner appears with the option to choose the new monitoring view. The following example shows the banner to choose the new monitoring view.



5. Choose **Go to new monitoring view** to open the Performance Insights dashboard with Performance Insights and CloudWatch metrics for your DB instance.
6. (Optional) If Performance Insights is turned off for your DB instance, a banner appears with the option to modify your DB cluster and turn on Performance Insights.

   The following example shows the banner to modify the DB cluster in the **Monitoring** tab .

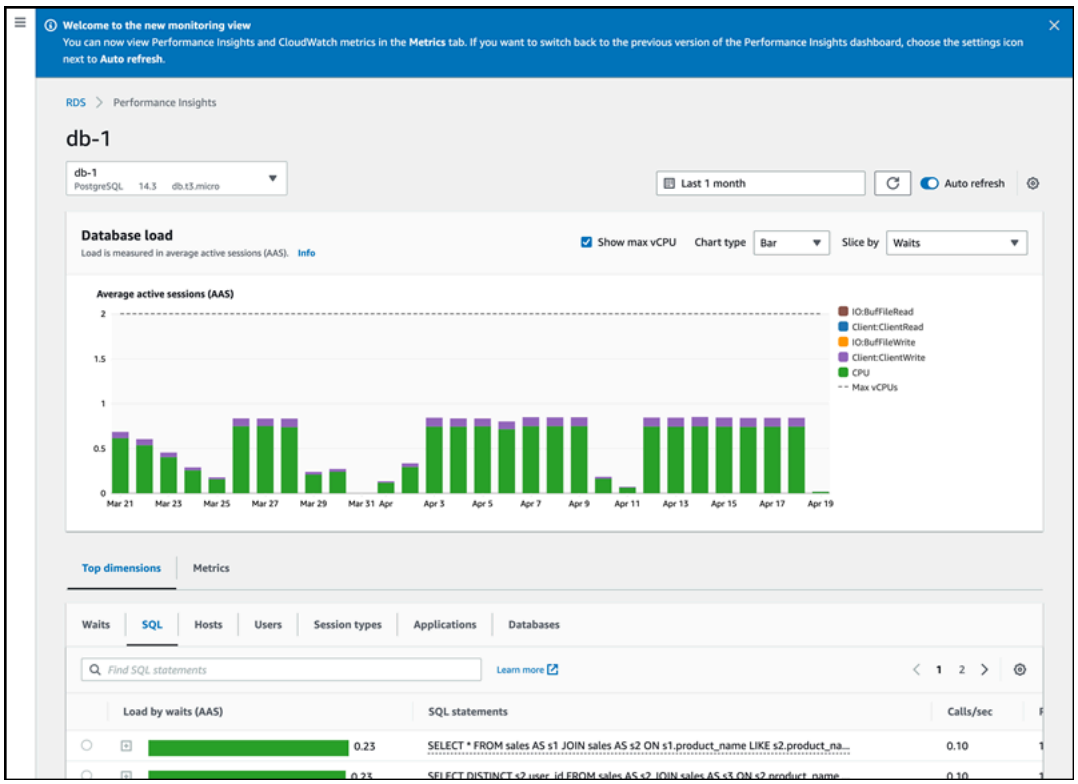
   Choose **Modify** to modify your DB cluster and turn on Performance Insights. For more information about turning on Performance Insights, see Turning Performance Insights on and off for Amazon RDS

Choosing the new monitoring view from the Performance Insights page

From the Amazon RDS console, you can choose the new monitoring view to view Performance Insights and CloudWatch metrics for your DB instance.

To choose the new monitoring view with Performance Insights in the navigation pane

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the left navigation pane, choose **Performance Insights**.
3. Choose a DB instance to view the Performance Insights dashboard that shows both Performance Insights and CloudWatch metrics for your DB instance.



Choosing the Performance Insights legacy view

You can choose the legacy monitoring view to view only the Performance Insights metrics for your DB instance.

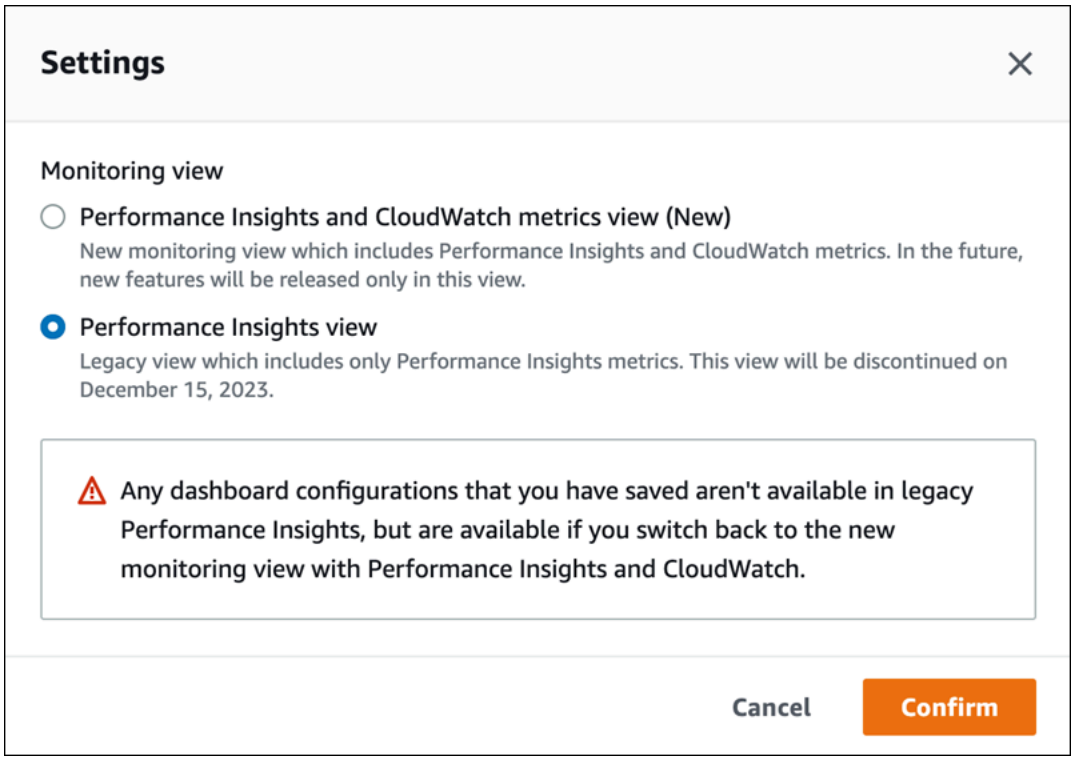
> **Note**
>
> This view was discontinued on December 15, 2023.

To choose the legacy monitoring view with Performance Insights in the navigation pane

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the left navigation pane, choose **Performance Insights**.
3. Choose a DB instance.
4. Choose the settings icon on the Performance Insights dashboard.

   You can now see the **Settings** window that shows the option to choose the legacy Performance Insights view.

   The following example shows the window with the option for the legacy monitoring view.



5. Select the **Performance Insights view** option and choose **Continue**.

   A warning message appears. Any dashboard configurations that you saved won't be available in this view.

6. Choose **Confirm** to continue to the legacy Performance Insights view.

   You can now view the Performance Insights dashboard that shows only Performance Insights metrics for the DB instance.

Creating a custom dashboard with Performance Insights

In the new monitoring view, you can create a custom dashboard with the metrics you need to meet your analysis requirements.

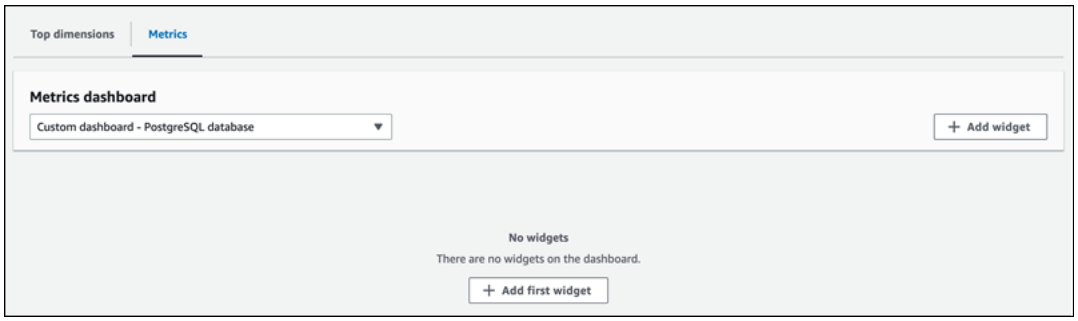
You can create a custom dashboard by selecting Performance Insights and CloudWatch metrics for your DB instance. You can use this custom dashboard for other DB instances of the same database engine type in your AWS account.

> **Note**
>
> The customized dashboard supports up to 50 metrics.

Use the widget settings menu to edit or delete the dashboard, and move or resize the widget window.

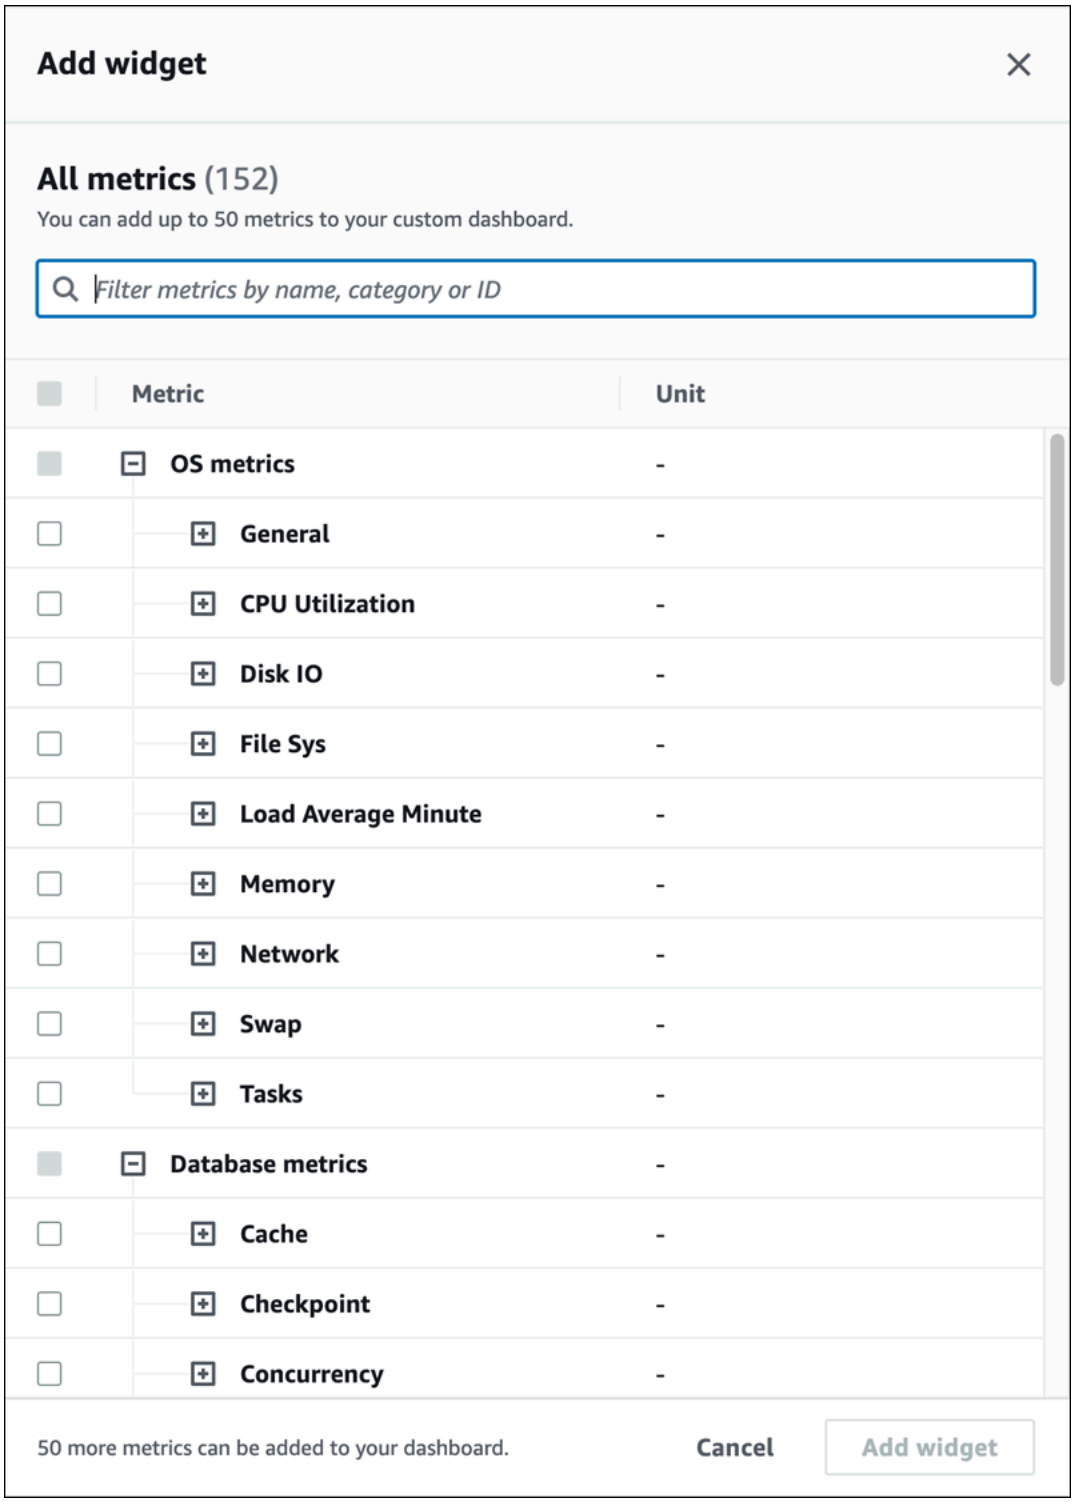
To create a custom dashboard with Performance Insights in the navigation pane

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the left navigation pane, choose **Performance Insights**.
3. Choose a DB instance.
4. Scroll down to the **Metrics tab** in the window.
5. Select the custom dashboard from the drop down list. The following example shows the custom dashboard creation.



6. Choose **Add widget** to open the **Add widget** window. You can open and view the available operating system (OS) metrics, database metrics, and CloudWatch metrics in the window.

   The following example shows the **Add widget** window with the metrics.



7. Select the metrics that you want to view in the dashboard and choose **Add widget**. You can use the search field to find a specific metric.

   The selected metrics appear on your dashboard.

8. (Optional) If you want to modify or delete your dashboard, choose the settings icon on the upper right of the widget, and then select one of the following actions in the menu.

   - **Edit** – Modify the metrics list in the window. Choose **Update widget** after you select the metrics for your dashboard.
   - **Delete** – Deletes the widget. Choose **Delete** in the confirmation window.

Choosing the preconfigured dashboard with Performance Insights

You can view the most commonly used metrics with the preconfigured dashboard. This dashboard helps diagnose performance issues with a database engine and reduce the average recovery time from hours to minutes.

> **Note**
>
> This dashboard can't be edited.

To choose the preconfigured dashboard with Performance Insights in the navigation pane

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the left navigation pane, choose **Performance Insights**.
3. Choose a DB instance.
4. Scroll down to the **Metrics tab** in the window
5. Select a preconfigured dashboard from the drop down list.

   You can view the metrics for the DB instance in the dashboard. The following example shows a preconfigured metrics dashboard.

Monitoring Amazon RDS metrics with Amazon CloudWatch

Amazon CloudWatch is a metrics repository. The repository collects and processes raw data from Amazon RDS into readable, near real-time metrics. For a complete list of Amazon RDS metrics sent to CloudWatch, see Metrics reference for Amazon RDS.

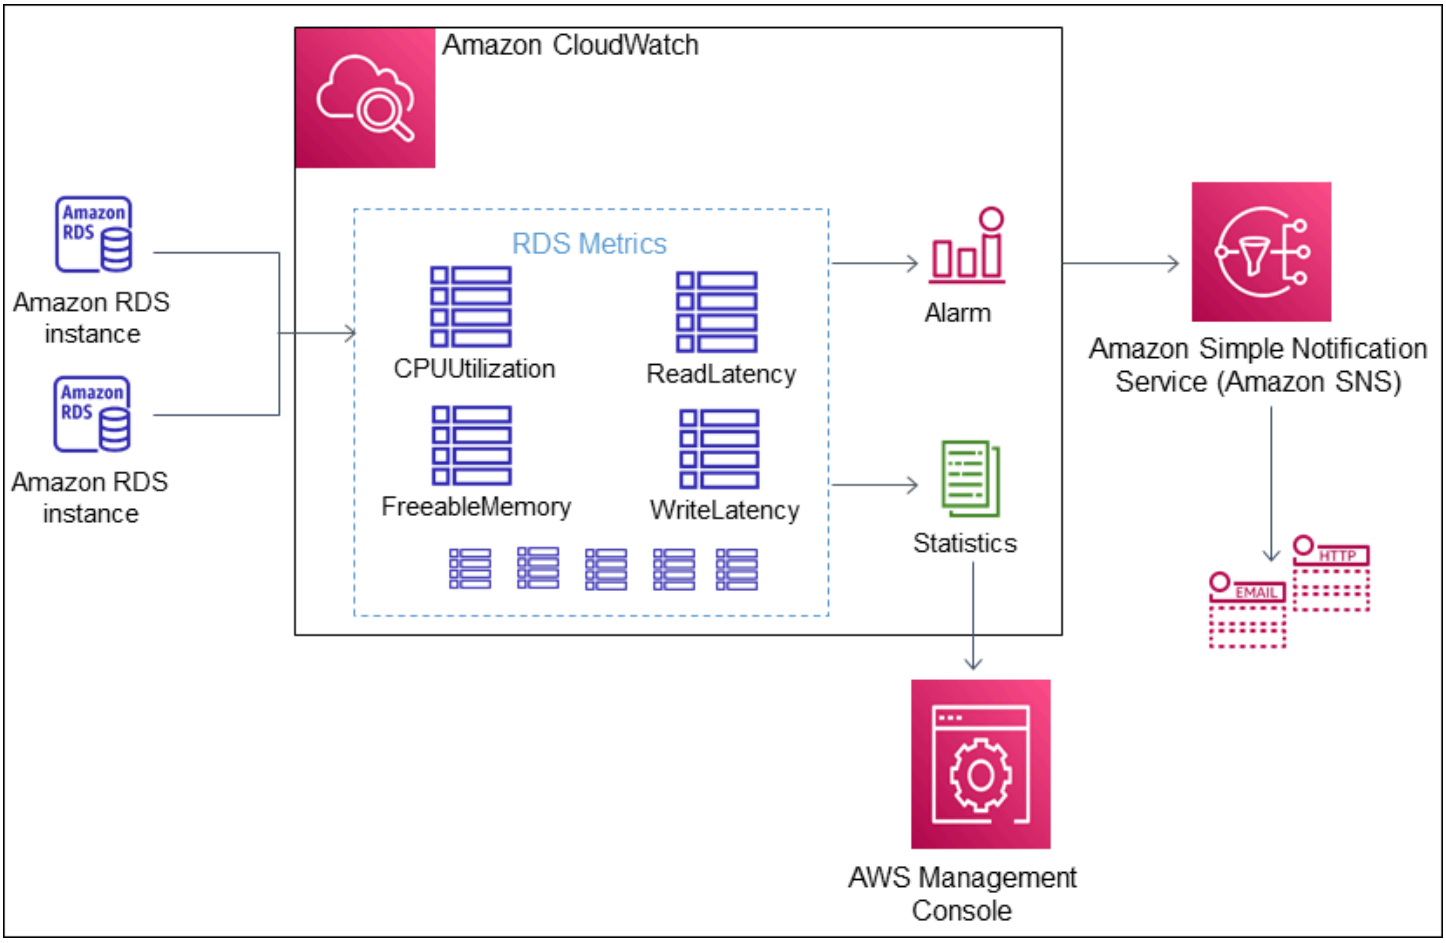
Topics

Overview of Amazon RDS and Amazon CloudWatch

By default, Amazon RDS automatically sends metric data to CloudWatch in 1-minute periods. For example, the `CPUUtilization` metric records the percentage of CPU utilization for a DB instance over time. Data points with a period of 60 seconds (1 minute) are available for 15 days. This means that you can access historical information and see how your web application or service is performing.

You can now export Performance Insights metrics dashboards from Amazon RDS to Amazon CloudWatch. You can export either the preconfigured or customized metrics dashboards as a new dashboard or add them to an existing CloudWatch dashboard. The exported dashboard is available to view in the CloudWatch console. For more information on how to export the Performance Insights metrics dashboards to CloudWatch, see Exporting Performance Insights metrics to CloudWatch.

As shown in the following diagram, you can set up alarms for your CloudWatch metrics. For example, you might create an alarm that signals when the CPU utilization for an instance is over 70%. You can configure Amazon Simple Notification Service to email you when the threshold is passed.



Amazon RDS publishes the following types of metrics to Amazon CloudWatch:

- Metrics for your RDS DB instances

  For a table of these metrics, see Amazon CloudWatch metrics for Amazon RDS.

- Performance Insights metrics

  For a table of these metrics, see Amazon CloudWatch metrics for Amazon RDS Performance Insights and Performance Insights counter metrics.

- Enhanced Monitoring metrics (published to Amazon CloudWatch Logs)

  For a table of these metrics, see OS metrics in Enhanced Monitoring.

- Usage metrics for the Amazon RDS service quotas in your AWS account

  For a table of these metrics, see Amazon CloudWatch usage metrics for Amazon RDS. For more information about Amazon RDS quotas, see Quotas and constraints for Amazon RDS.

For more information about CloudWatch, see What is Amazon CloudWatch? in the *Amazon CloudWatch User Guide*. For more information about CloudWatch metrics retention, see Metrics retention.

Viewing DB instance metrics in the CloudWatch console and AWS CLI

Following, you can find details about how to view metrics for your DB instance using CloudWatch. For information on monitoring metrics for your DB instance's operating system in real time using CloudWatch Logs, see Monitoring OS metrics with Enhanced Monitoring.

When you use Amazon RDS resources, Amazon RDS sends metrics and dimensions to Amazon CloudWatch every minute.

You can now export Performance Insights metrics dashboards from Amazon RDS to Amazon CloudWatch and view these metrics in the CloudWatch console. For more information on how to export the Performance Insights metrics dashboards to CloudWatch, see Exporting Performance Insights metrics to CloudWatch.

Use the following procedures to view the metrics for Amazon RDS in the CloudWatch console and CLI.

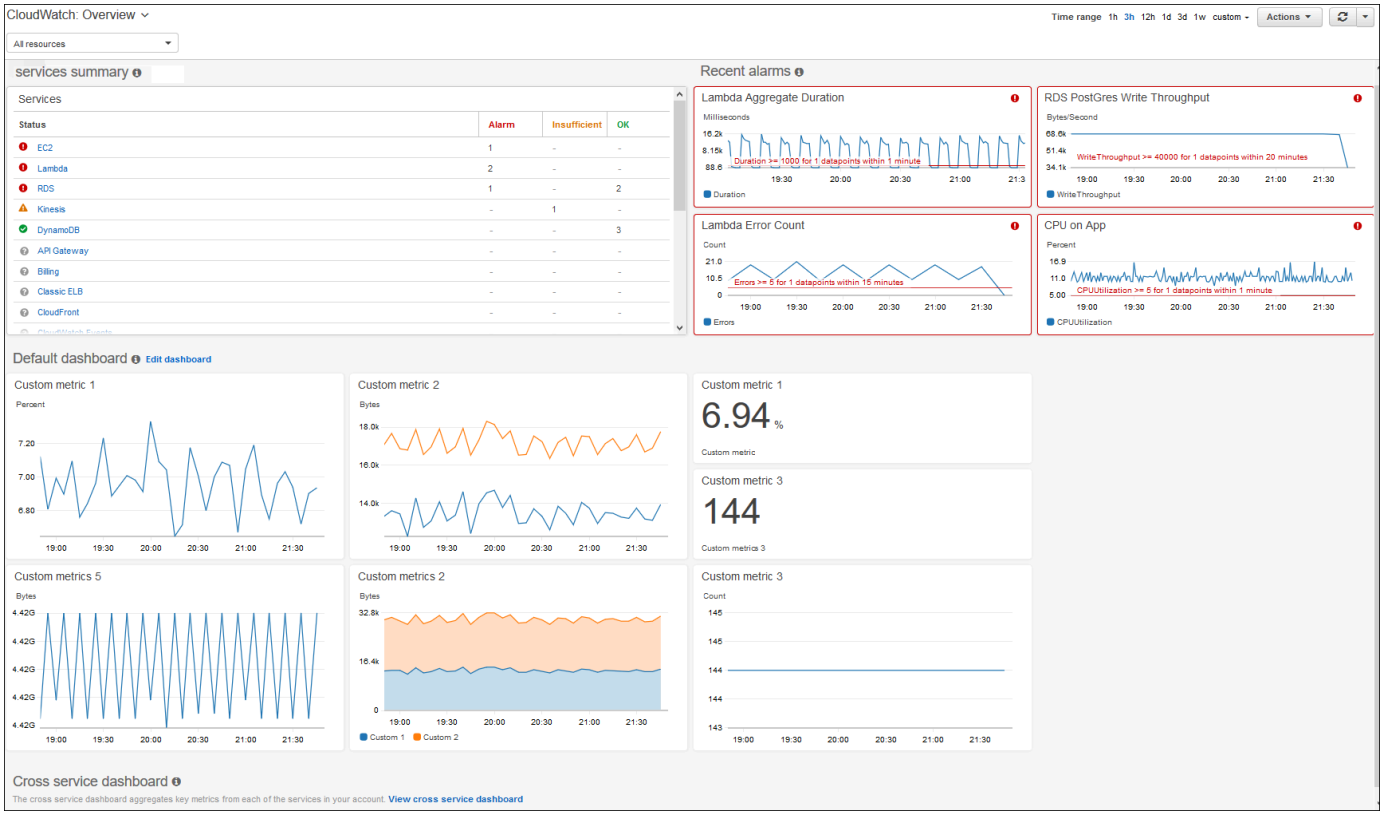
Console

To view metrics using the Amazon CloudWatch console

Metrics are grouped first by the service namespace, and then by the various dimension combinations within each namespace.

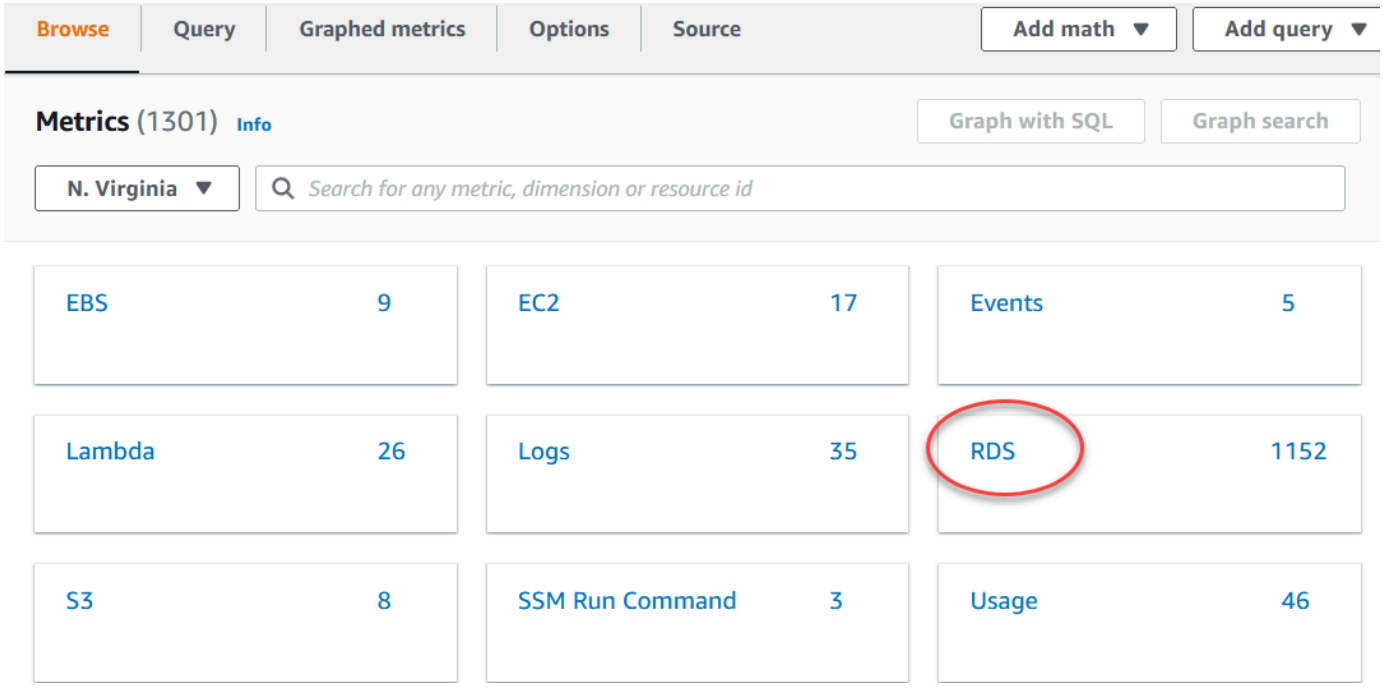
1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.

   The CloudWatch overview home page appears.



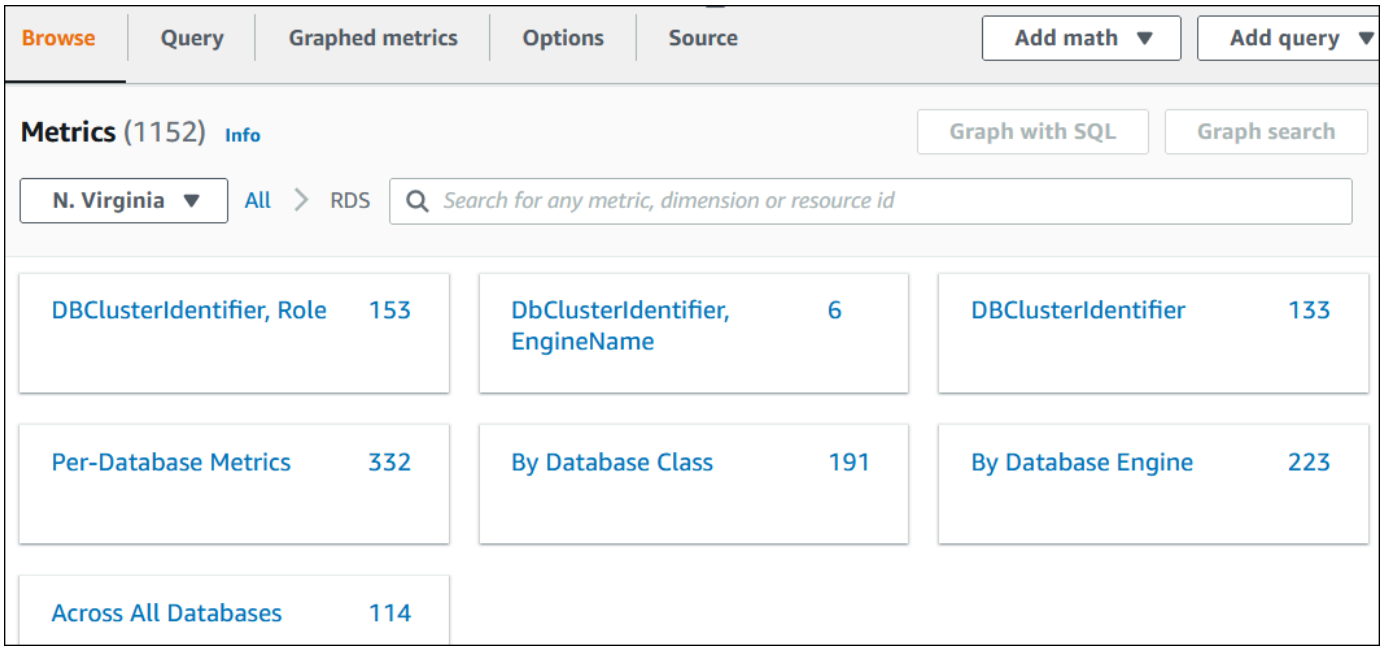
2. If necessary, change the AWS Region. From the navigation bar, choose the AWS Region where your AWS resources are. For more information, see [Regions and endpoints](#).

3. In the navigation pane, choose **Metrics** and then **All metrics**.

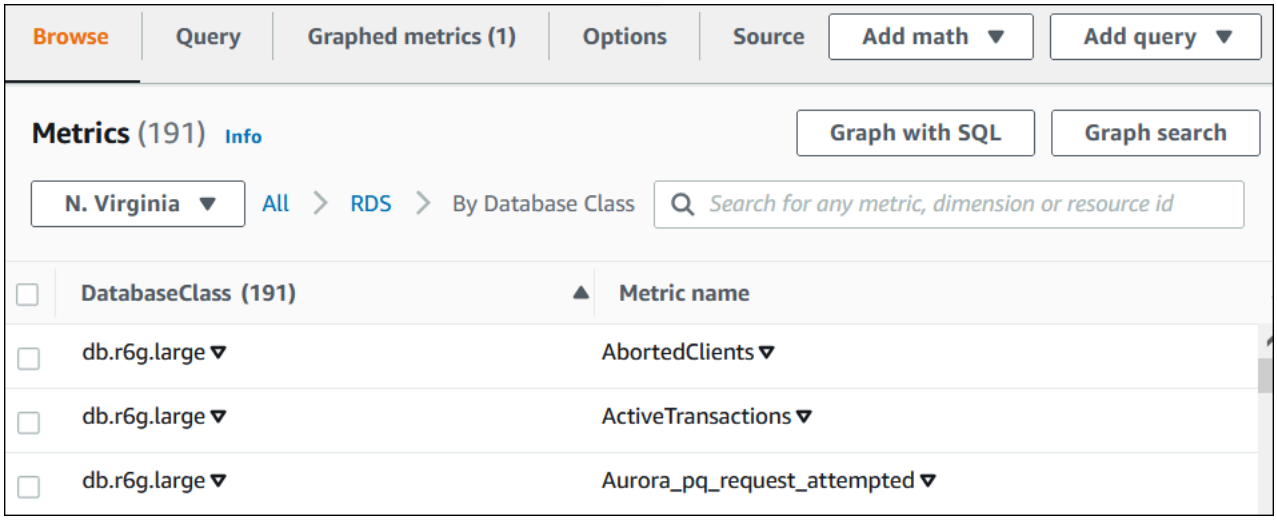


4. Scroll down and choose the **RDS** metric namespace.

The page displays the Amazon RDS dimensions. For descriptions of these dimensions, see Amazon CloudWatch dimensions for Amazon RDS.



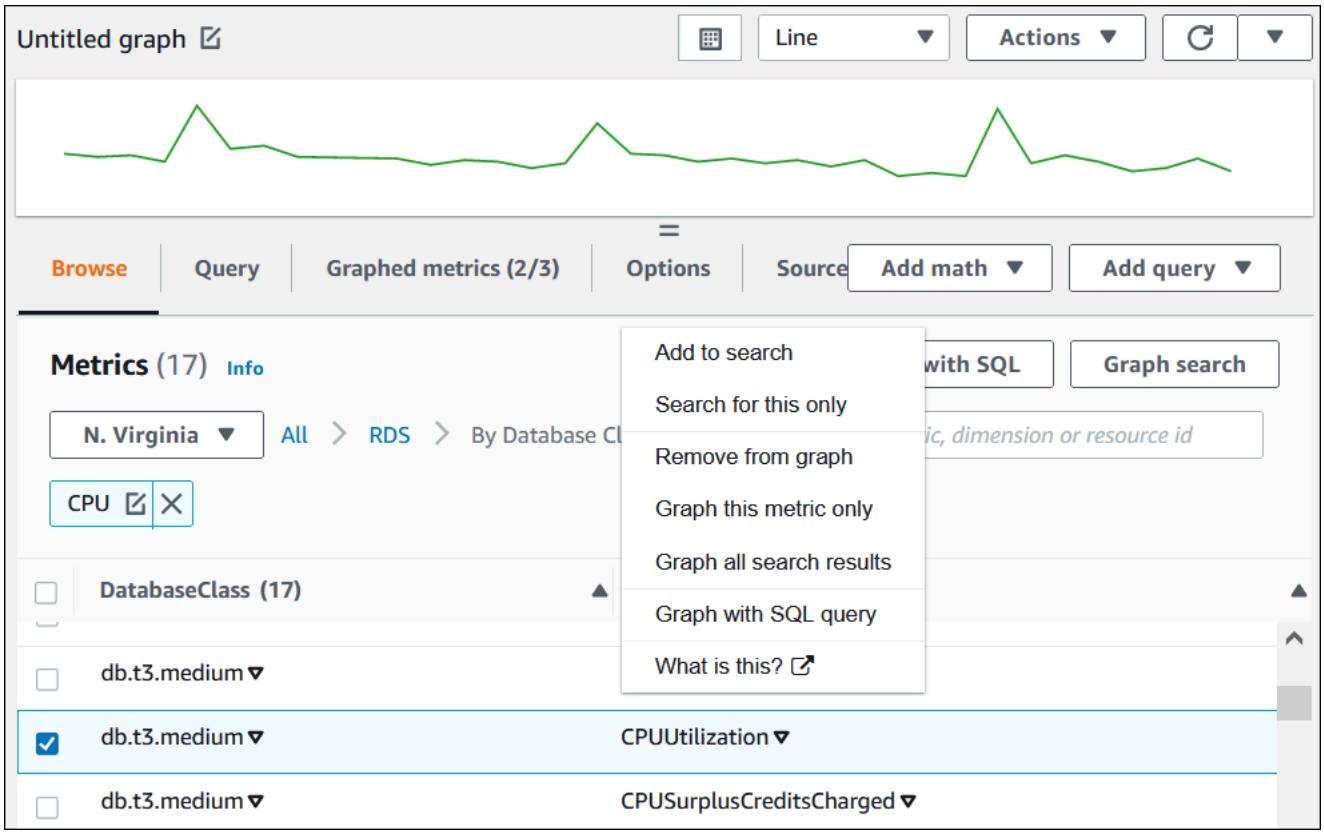
5. Choose a metric dimension, for example **By Database Class**.



6. Do any of the following actions:

- To sort the metrics, use the column heading.
- To graph a metric, select the check box next to the metric.
- To filter by resource, choose the resource ID, and then choose **Add to search**.
- To filter by metric, choose the metric name, and then choose **Add to search**.

The following example filters on the **db.t3.medium** class and graphs the **CPUUtilization** metric.



AWS CLI

To obtain metric information by using the AWS CLI, use the CloudWatch command `list-metrics`. In the following example, you list all metrics in the `AWS/RDS` namespace.

```
aws cloudwatch list-metrics --namespace AWS/RDS
```

To obtain metric data, use the command `get-metric-data`.

The following example gets `CPUUtilization` statistics for instance `my-instance` over the specific 24-hour period, with a 5-minute granularity.

Create a JSON file `CPU_metric.json` with the following contents.

```
{
   "StartTime" : "2023-12-25T00:00:00Z",
```

```
   "EndTime" : "2023-12-26T00:00:00Z",
   "MetricDataQueries" : [{
     "Id" : "cpu",
     "MetricStat" : {
    "Metric" : {
        "Namespace" : "AWS/RDS",
        "MetricName" : "CPUUtilization",
        "Dimensions" : [{ "Name" : "DBInstanceIdentifier" , "Value" : my-instance}]
    },
       "Period" : 360,
       "Stat" : "Minimum"
     }
   }]
}
```

Example

For Linux, macOS, or Unix:

```
aws cloudwatch get-metric-data \
    --cli-input-json file://CPU_metric.json
```

For Windows:

```
aws cloudwatch get-metric-data ^
     --cli-input-json file://CPU_metric.json
```

Sample output appears as follows:

```
{
    "MetricDataResults": [
        {
            "Id": "cpu",
            "Label": "CPUUtilization",
            "Timestamps": [
                "2023-12-15T23:48:00+00:00",
                "2023-12-15T23:42:00+00:00",
                "2023-12-15T23:30:00+00:00",
                "2023-12-15T23:24:00+00:00",
                ...
            ],
            "Values": [
```

```
                13.299778337027714,
                13.677507543049558,
                14.24976250395827,
                13.02521708695145,
                ...
            ],
            "StatusCode": "Complete"
        }
    ],
    "Messages": []
}
```

For more information, see Getting statistics for a metric in the *Amazon CloudWatch User Guide*.

Exporting Performance Insights metrics to CloudWatch

Performance Insights lets you export the preconfigured or custom metrics dashboard for your DB instance to Amazon CloudWatch. You can export the metrics dashboard as a new dashboard or add it to an existing CloudWatch dashboard. When you choose to add the dashboard to an existing CloudWatch dashboard, you can create a header label so that the metrics appear in a separate section in the CloudWatch dashboard.

You can view the exported metrics dashboard in the CloudWatch console. If you add new metrics to a Performance Insights metrics dashboard after you export it, you must export this dashboard again to view the new metrics in the CloudWatch console.

You can also select a metric widget in the Performance Insights dashboard and view the metrics data in the CloudWatch console.

For more information about viewing the metrics in the CloudWatch console, see Viewing DB instance metrics in the CloudWatch console and AWS CLI.

In the following sections, export Performance Insights metrics to CloudWatch as a new or existing dashboard and view Performance Insights metrics in CloudWatch.

Topics

- Exporting Performance Insights metrics as a new dashboard to CloudWatch
- Adding Performance Insights metrics to an existing CloudWatch dashboard
- Viewing a Performance Insights metric widget in CloudWatch

Exporting Performance Insights metrics as a new dashboard to CloudWatch

Choose a preconfigured or custom metrics dashboard from the Performance Insights dashboard and export it as a new dashboard to CloudWatch. You can view the exported dashboard in the CloudWatch console.

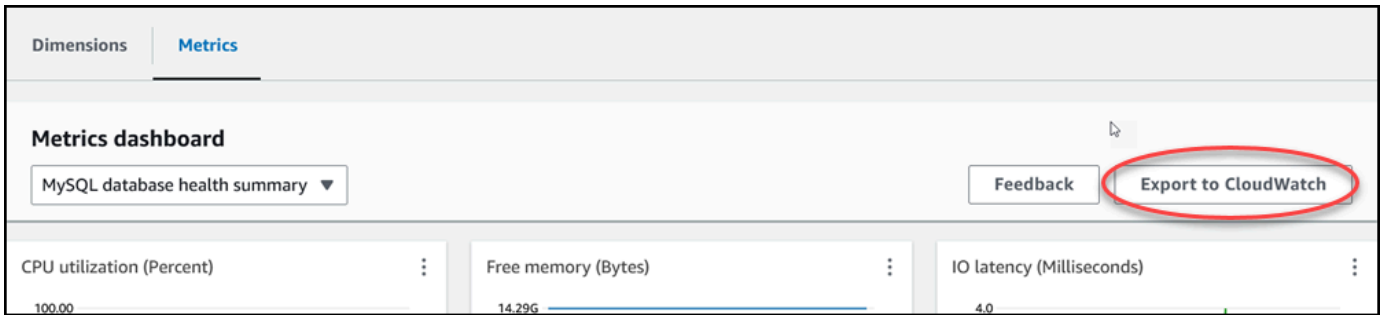
To export a Performance Insights metric dashboard as a new dashboard to CloudWatch

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the left navigation pane, choose **Performance Insights**.
3. Choose a DB instance.

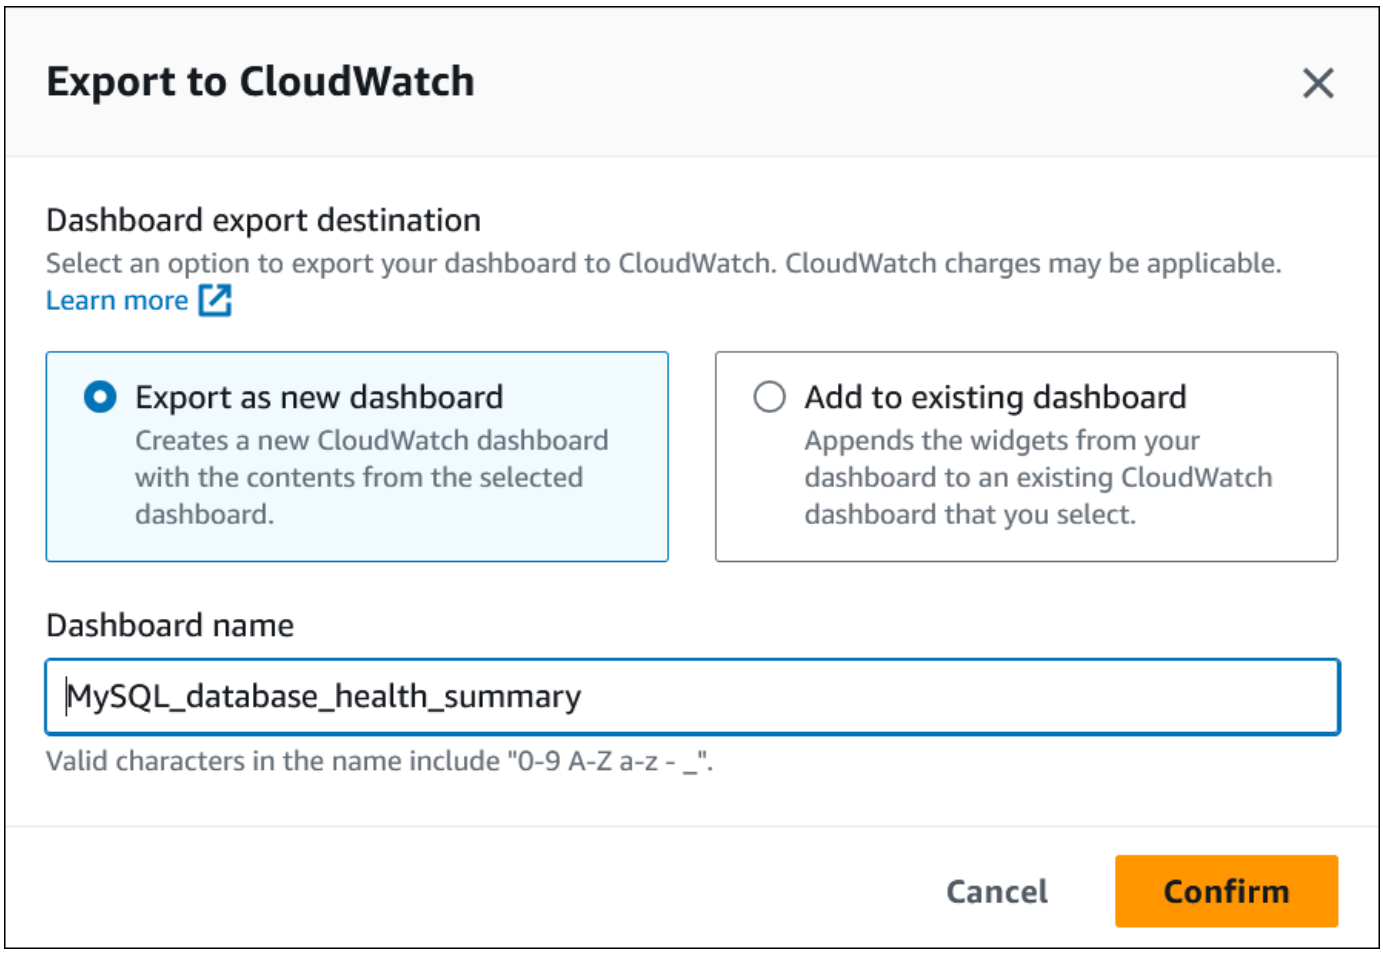
   The Performance Insights dashboard appears for the DB instance.
4. Scroll down and choose **Metrics**.

   By default, the preconfigured dashboard with Performance Insights metrics appears.
5. Choose a preconfigured or custom dashboard and then choose **Export to CloudWatch**.

   The **Export to CloudWatch** window appears.

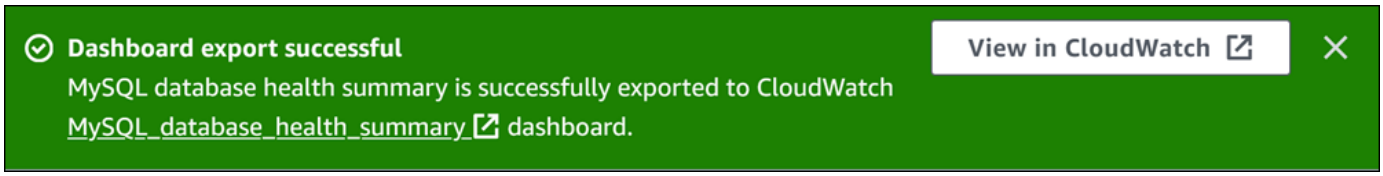


6. Choose **Export as new dashboard**.



7. Enter a name for the new dashboard in the **Dashboard name** field and choose **Confirm**.

   A banner displays a message after the dashboard export is successful.



8. Choose the link or **View in CloudWatch** in the banner to view the metrics dashboard in the CloudWatch console.

Adding Performance Insights metrics to an existing CloudWatch dashboard

Add a preconfigured or custom metrics dashboard to an existing CloudWatch dashboard. You can add a label to the metrics dashboard to appear in a separate section in the CloudWatch dashboard.

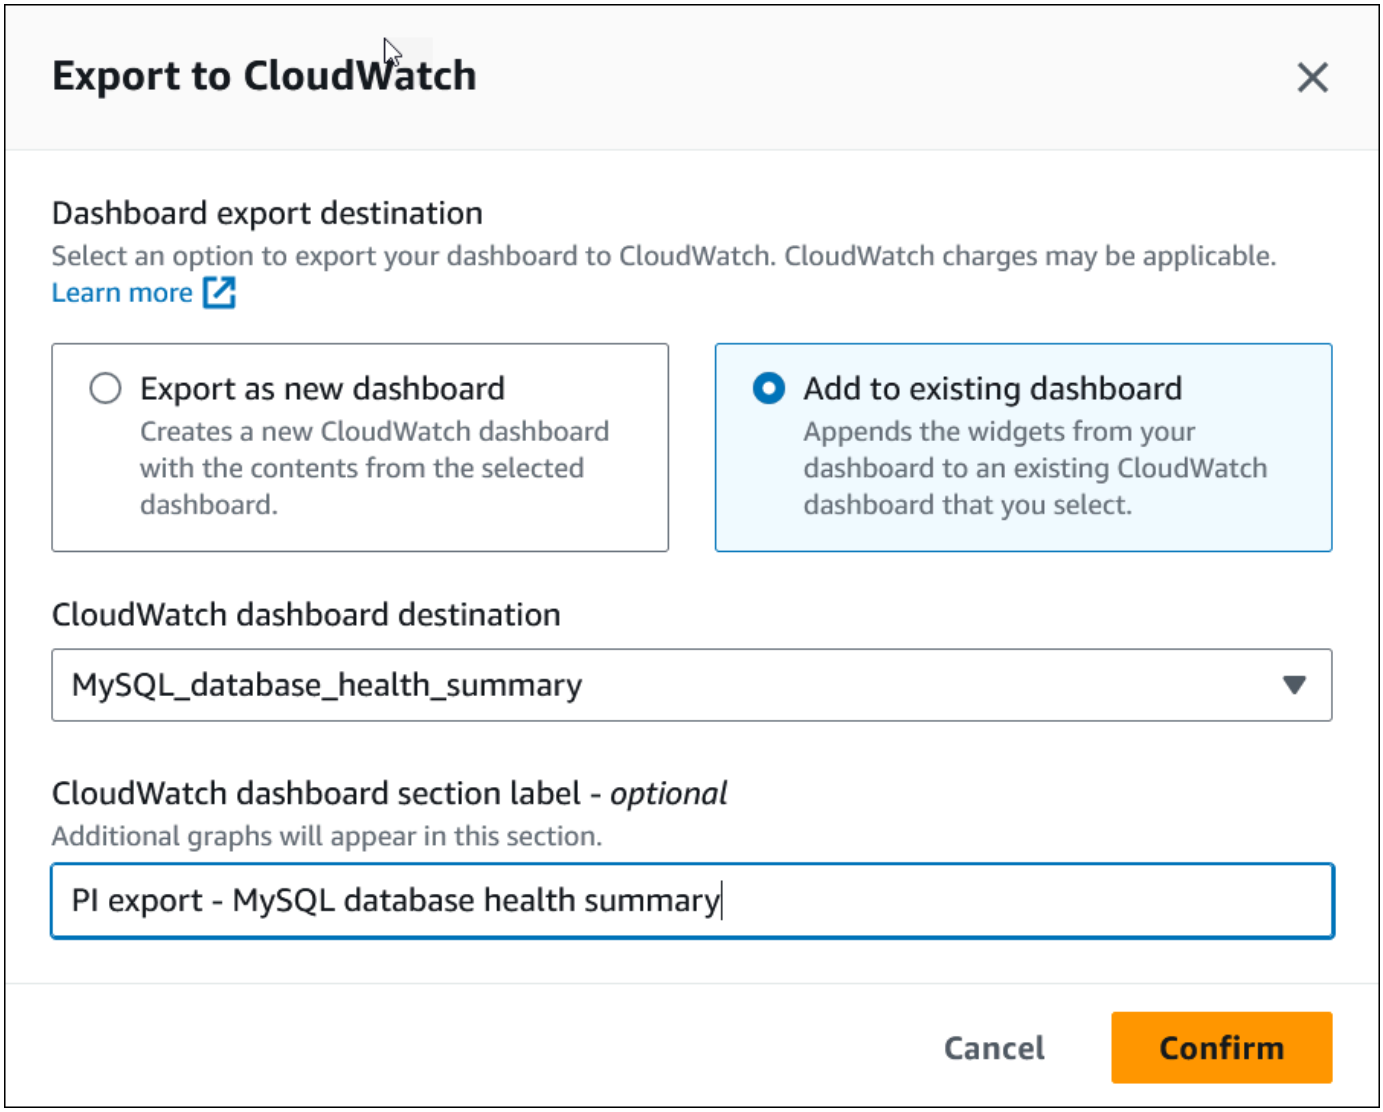
To export the metrics to an existing CloudWatch dashboard

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the left navigation pane, choose **Performance Insights**.
3. Choose a DB instance.

   The Performance Insights dashboard appears for the DB instance.
4. Scroll down and choose **Metrics**.

   By default, the preconfigured dashboard with Performance Insights metrics appears.
5. Choose the preconfigured or custom dashboard and then choose **Export to CloudWatch**.

   The **Export to CloudWatch** window appears.
6. Choose **Add to existing dashboard**.



7. Specify the dashboard destination and label, and then choose **Confirm**.

   - **CloudWatch dashboard destination** - Choose an existing CloudWatch dashboard.
   - **CloudWatch dashboard section label - optional** - Enter a name for the Performance Insights metrics to appear in this section in the CloudWatch dashboard.

   A banner displays a message after the dashboard export is successful.

8. Choose the link or **View in CloudWatch** in the banner to view the metrics dashboard in the CloudWatch console.

Viewing a Performance Insights metric widget in CloudWatch

Select a Performance Insights metric widget in the Amazon RDS Performance Insights dashboard and view the metric data in the CloudWatch console.

To export a metric widget and view the metrics data in the CloudWatch console

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the left navigation pane, choose **Performance Insights**.
3. Choose a DB instance.

   The Performance Insights dashboard appears for the DB instance.
4. Scroll down to **Metrics**.

   By default, the preconfigured dashboard with Performance Insights metrics appears.
5. Choose a metric widget and then choose **View in CloudWatch** in the menu.

   The metric data appears in the CloudWatch console.

Creating CloudWatch alarms to monitor Amazon RDS

You can create a CloudWatch alarm that sends an Amazon SNS message when the alarm changes state. An alarm watches a single metric over a time period that you specify. The alarm can also perform one or more actions based on the value of the metric relative to a given threshold over a number of time periods. The action is a notification sent to an Amazon SNS topic or Amazon EC2 Auto Scaling policy.

Alarms invoke actions for sustained state changes only. CloudWatch alarms don't invoke actions simply because they are in a particular state. The state must have changed and have been maintained for a specified number of time periods.

You can use the **DB_PERF_INSIGHTS** metric math function in the CloudWatch console to query Amazon RDS for Performance Insights counter metrics. The **DB_PERF_INSIGHTS** function also includes the DBLoad metric at sub-minute intervals. You can set CloudWatch alarms on these metrics.

For more details on how to create an alarm, see Create an alarm on Performance Insights counter metrics from an AWS database.

To set an alarm using the AWS CLI

- Call `put-metric-alarm`. For more information, see *AWS CLI Command Reference*.

To set an alarm using the CloudWatch API

- Call `PutMetricAlarm`. For more information, see *Amazon CloudWatch API Reference*

For more information about setting up Amazon SNS topics and creating alarms, see Using Amazon CloudWatch alarms.

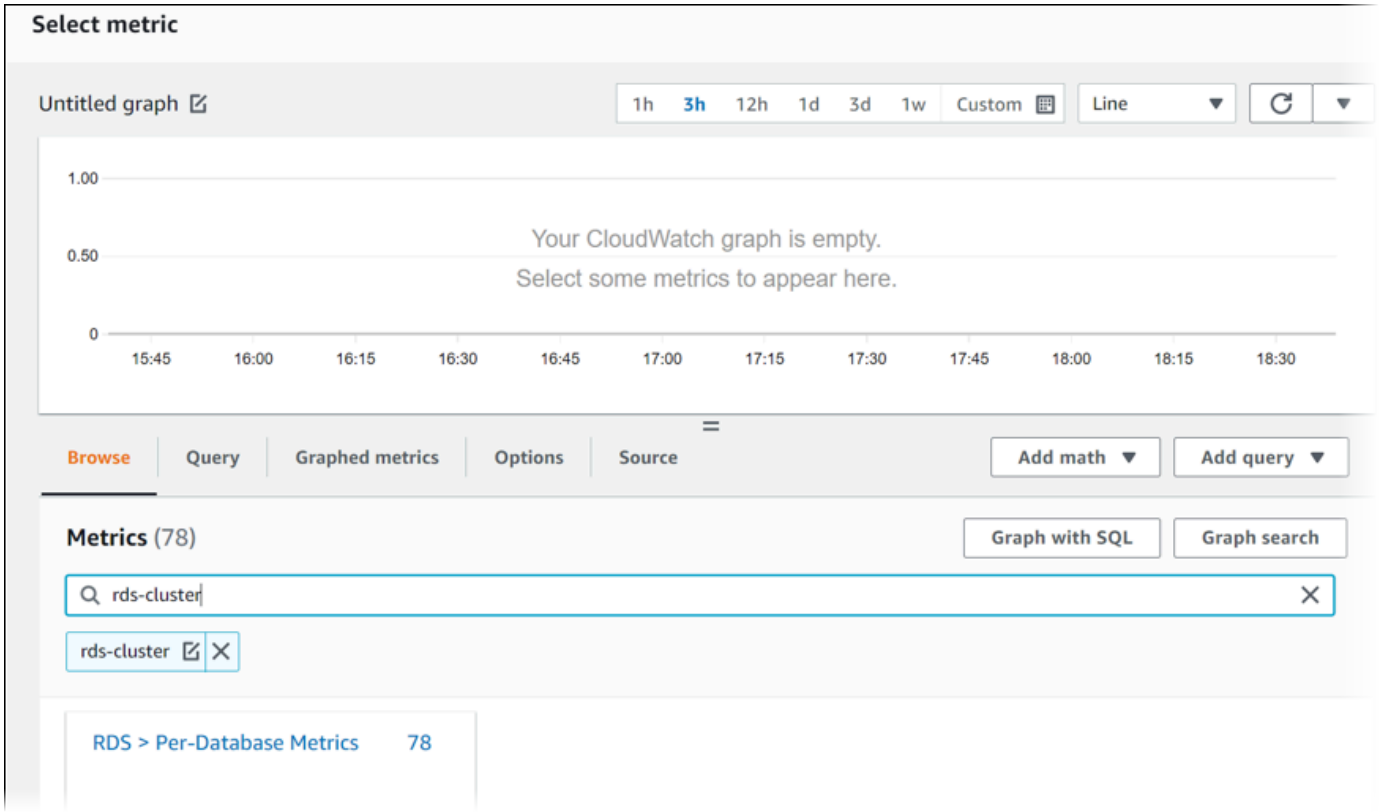
Tutorial: Creating an Amazon CloudWatch alarm for Multi-AZ DB cluster replica lag

You can create an Amazon CloudWatch alarm that sends an Amazon SNS message when replica lag for a Multi-AZ DB cluster has exceeded a threshold. An alarm watches the `ReplicaLag` metric over a time period that you specify. The action is a notification sent to an Amazon SNS topic or Amazon EC2 Auto Scaling policy.

To set a CloudWatch alarm for Multi-AZ DB cluster replica lag

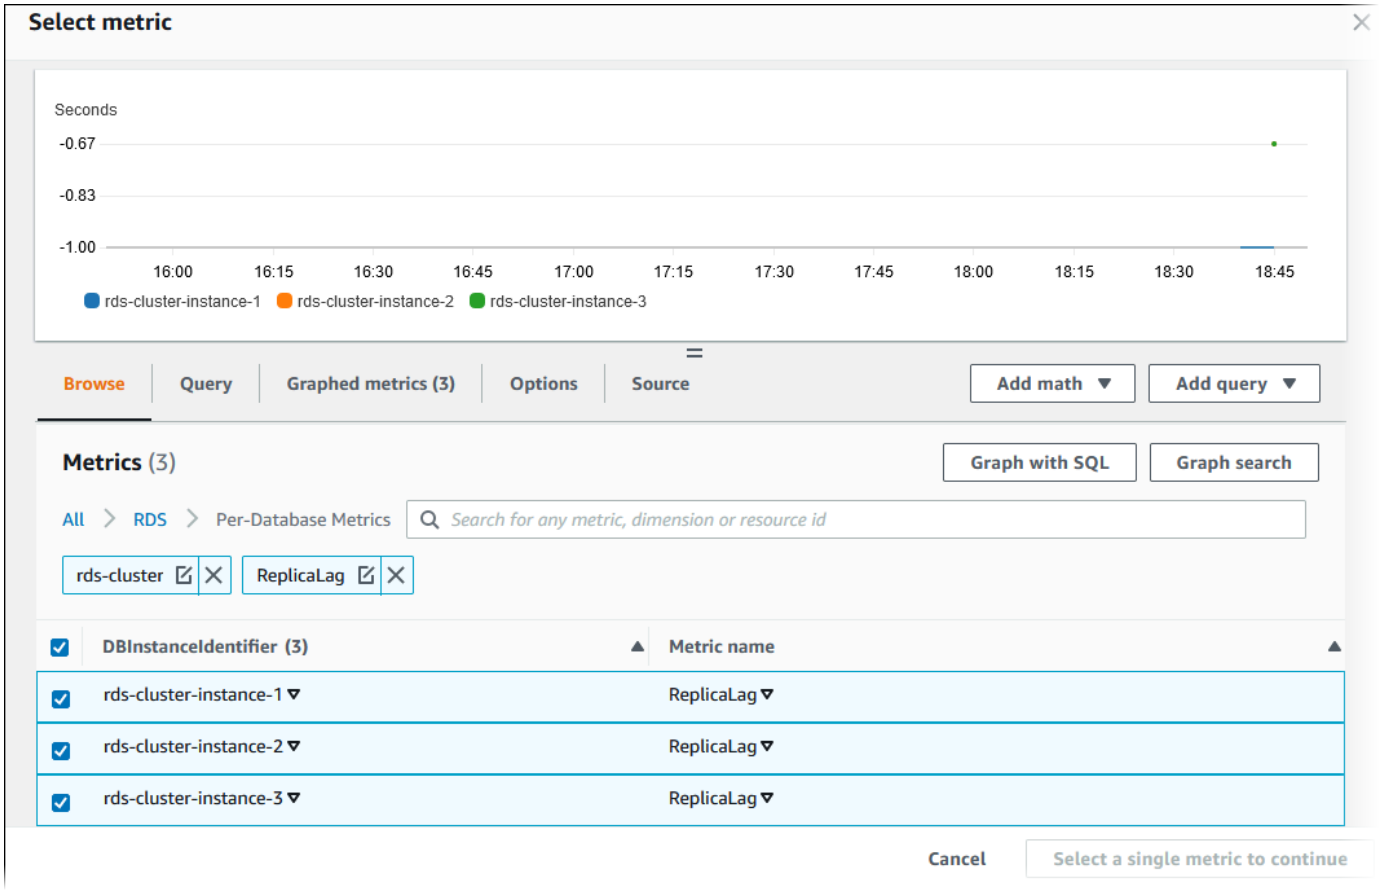
1. Sign in to the AWS Management Console and open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Alarms**, **All alarms**.
3. Choose **Create alarm**.
4. On the **Specify metric and conditions** page, choose **Select metric**.
5. In the search box, enter the name of your Multi-AZ DB cluster and press Enter.

   The following image shows the **Select metric** page with a Multi-AZ DB cluster named `rds-cluster` entered.



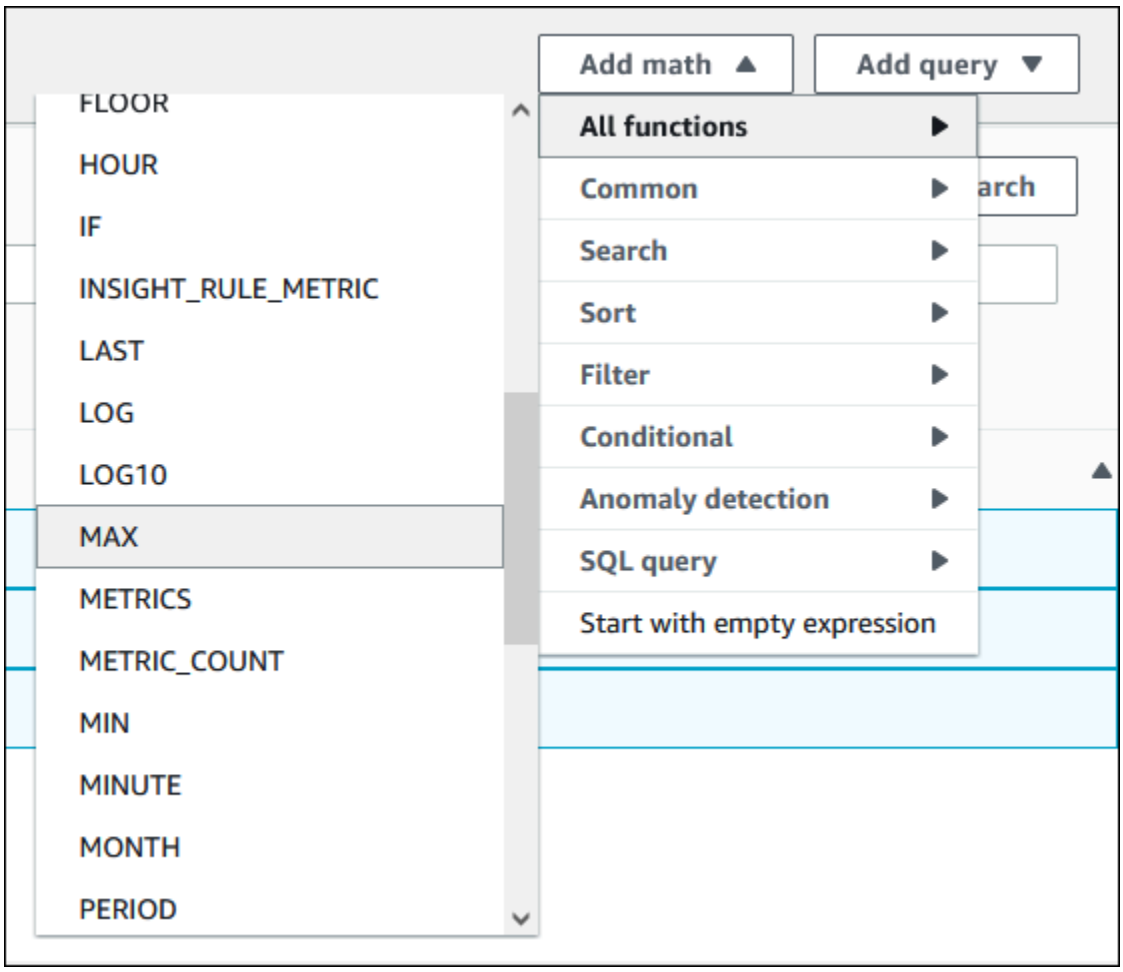
6. Choose **RDS**, **Per-Database Metrics**.
7. In the search box, enter **`ReplicaLag`** and press Enter, then select each DB instance in the DB cluster.

   The following image shows the **Select metric** page with the DB instances selected for the **ReplicaLag** metric.



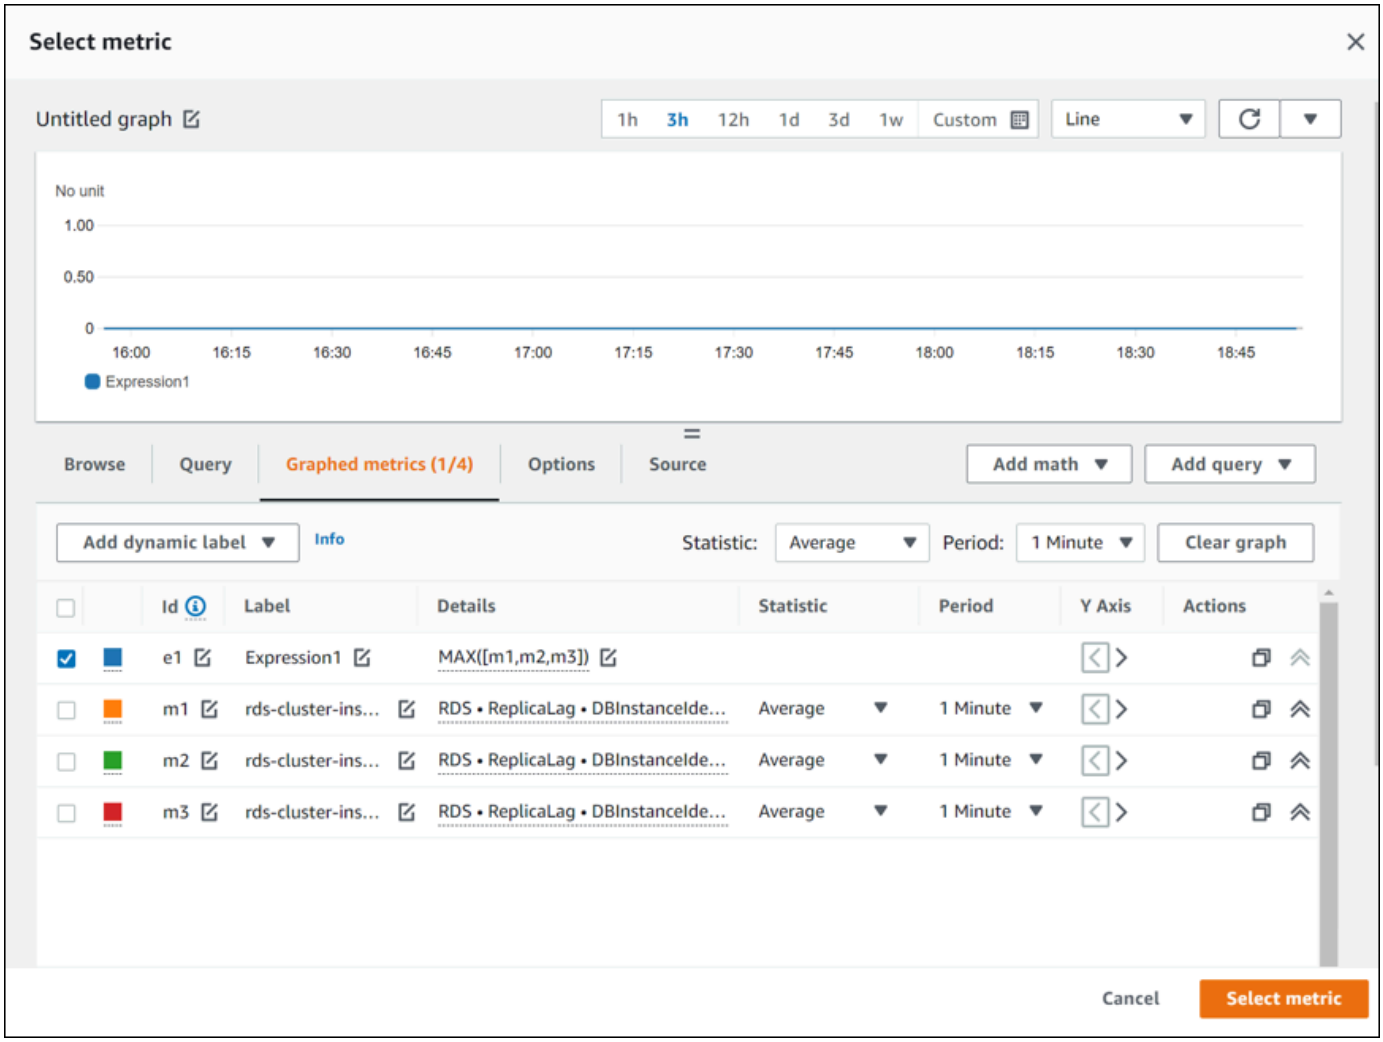
This alarm considers the replica lag for all three of the DB instances in the Multi-AZ DB cluster. The alarm responds when any DB instance exceeds the threshold. It uses a math expression that returns the maximum value of the three metrics. Start by sorting by metric name, and then choose all three **ReplicaLag** metrics.

8. From **Add math**, choose **All functions**, **MAX**.



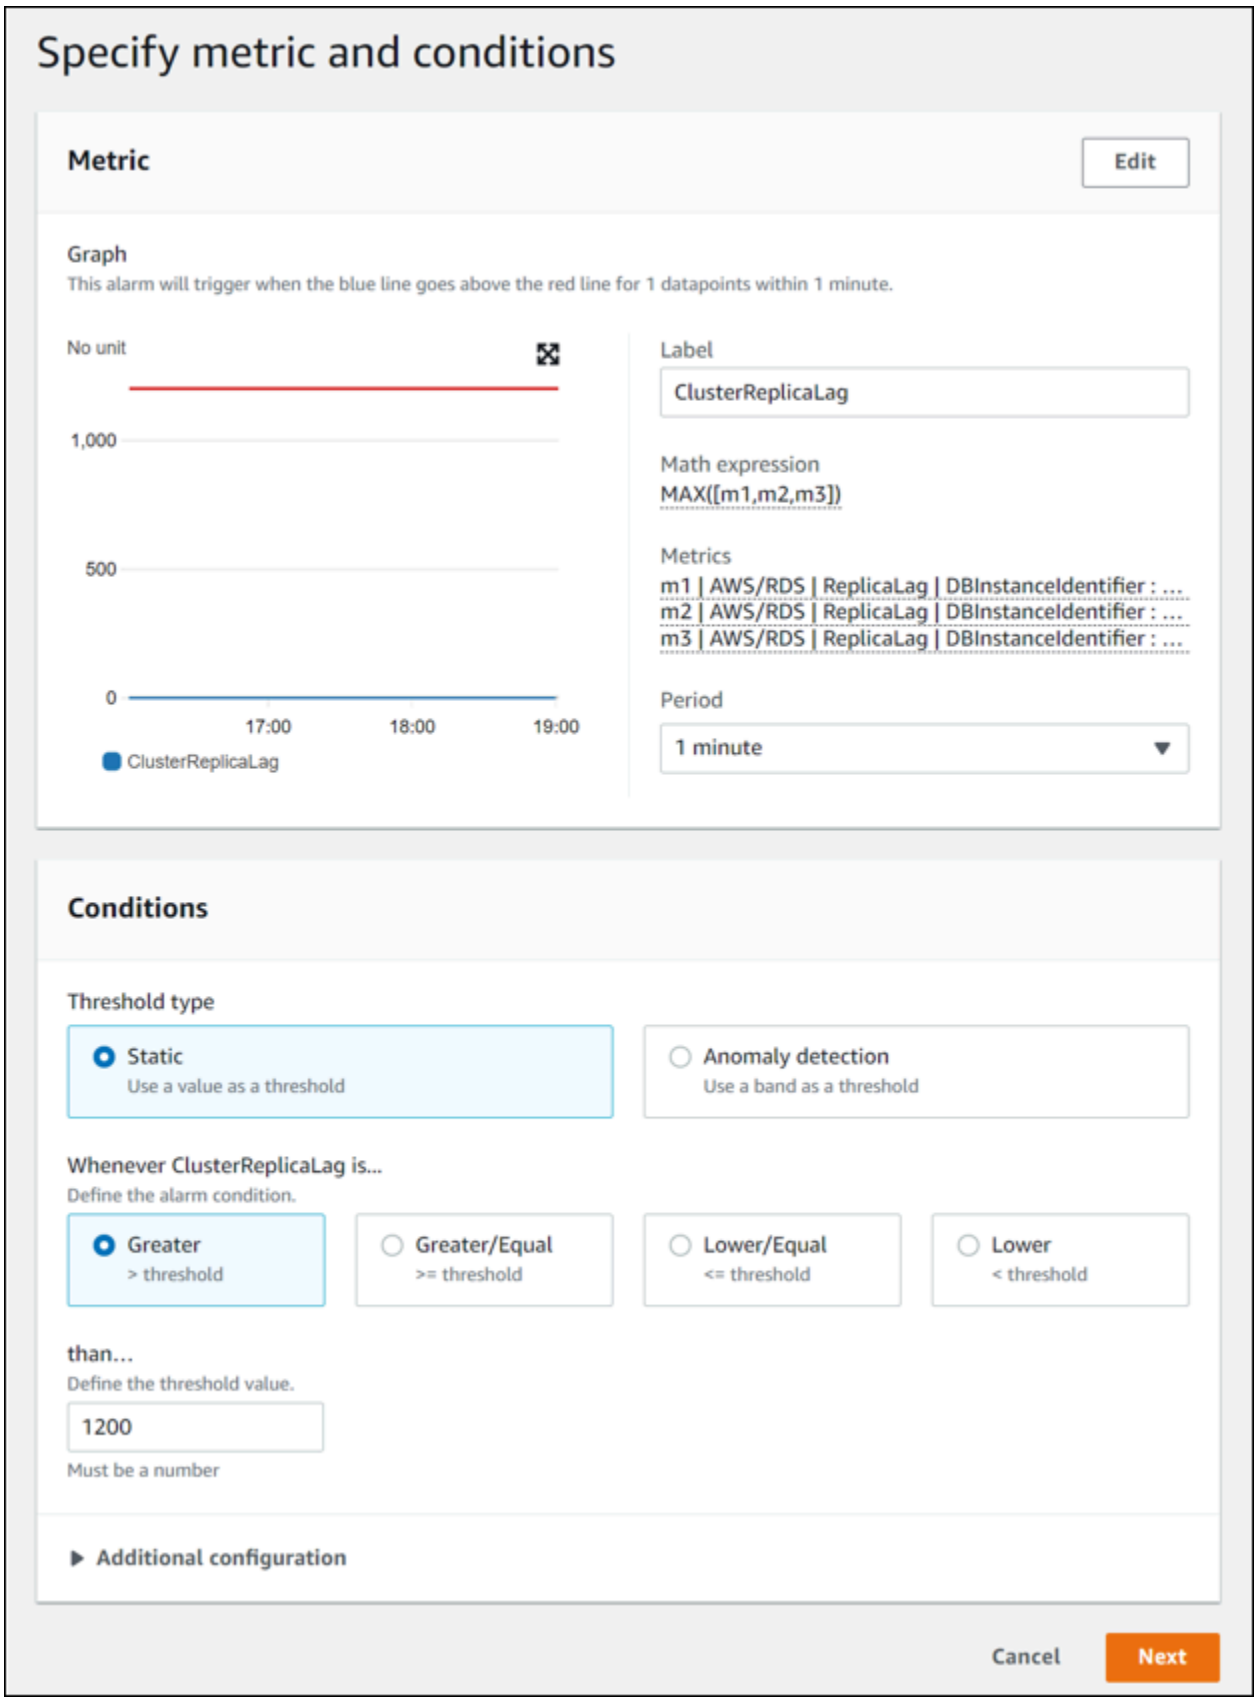
9. Choose the **Graphed metrics** tab, and edit the details for **Expression1** to **`MAX([m1,m2,m3])`**.
10. For all three **ReplicaLag** metrics, change the **Period** to **1 minute**.
11. Clear selection from all metrics except for **Expression1**.

    The **Select metric** page should look similar to the following image.



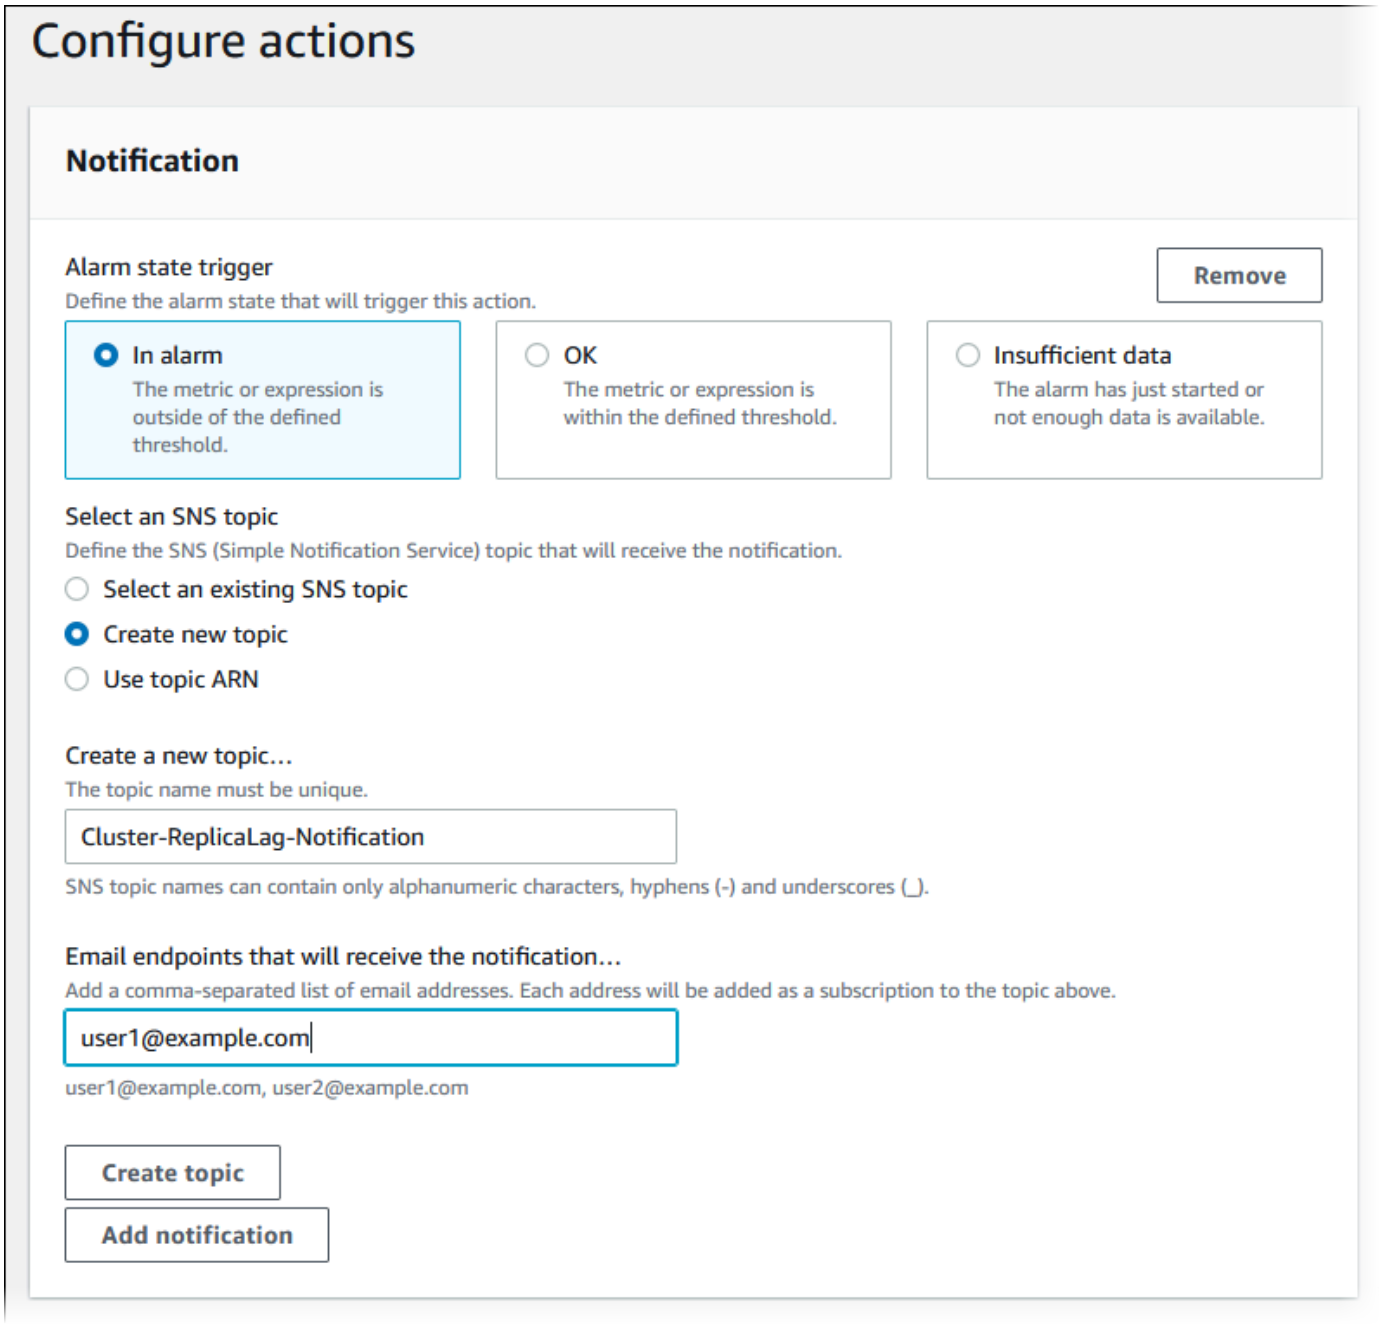
12. Choose **Select metric**.
13. On the **Specify metric and conditions** page, change the label to a meaningful name, such as **`ClusterReplicaLag`**, and enter a number of seconds in **Define the threshold value**. For this tutorial, enter **`1200`** seconds (20 minutes). You can adjust this value for your workload requirements.

    The **Specify metric and conditions** page should look similar to the following image.

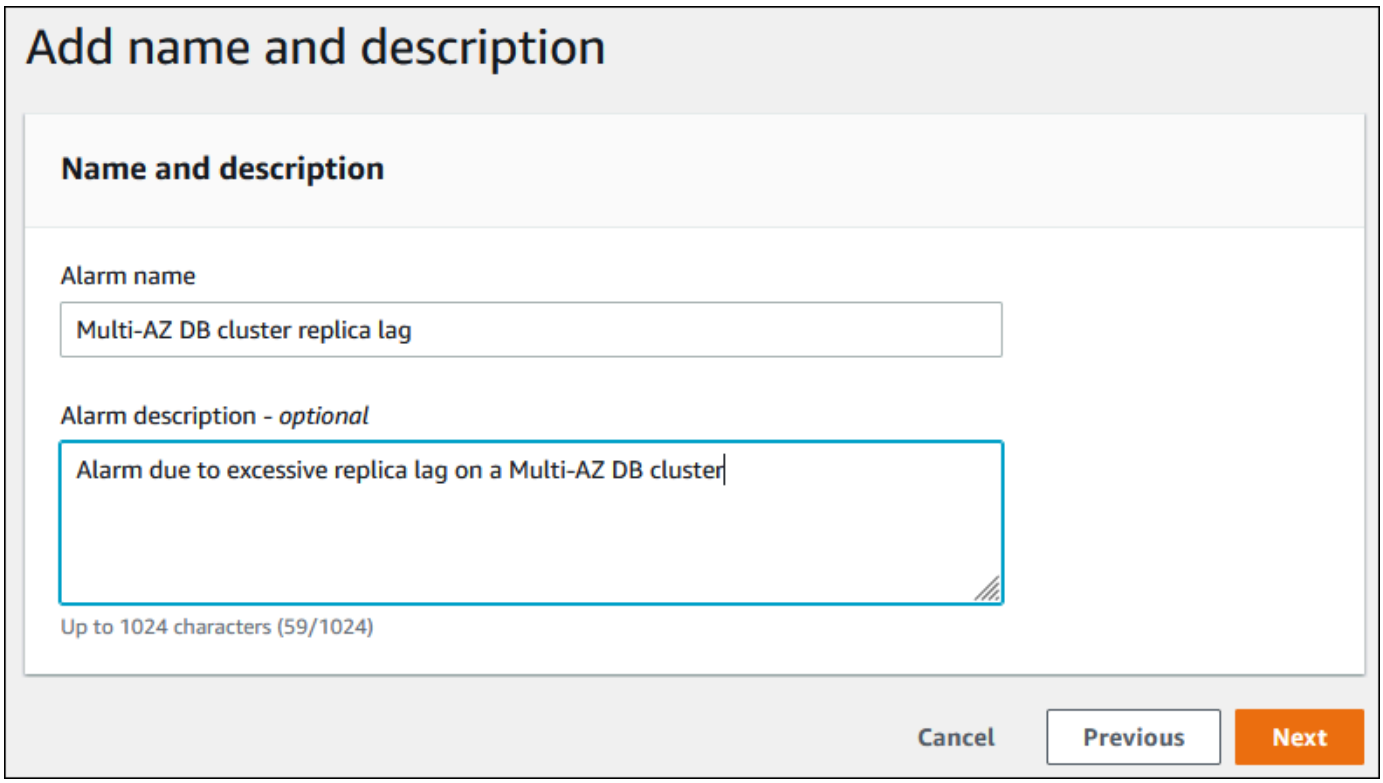


14. Choose **Next**, and the **Configure actions** page appears.

15. Keep **In alarm** selected, choose **Create new topic**, and enter the topic name and a valid email address.



16. Choose **Create topic**, and then choose **Next**.
17. On the **Add name and description** page, enter the **Alarm name** and **Alarm description**, and then choose **Next**.



18. Preview the alarm that you're about to create on the **Preview and create** page, and then choose **Create alarm**.

Monitoring DB load with Performance Insights on Amazon RDS

Performance Insights expands on existing Amazon RDS monitoring features to illustrate and help you analyze your database performance. With the Performance Insights dashboard, you can visualize the database load on your Amazon RDS DB instance load and filter the load by waits, SQL statements, hosts, or users. For information about using Performance Insights with Amazon DocumentDB, see *Amazon DocumentDB Developer Guide*.

Topics

Overview of Performance Insights on Amazon RDS

By default, RDS enables Performance Insights in the console create wizard for all Amazon RDS engines. If you have more than one database on a DB instance, Performance Insights aggregates performance data.

You can find an overview of Performance Insights for Amazon RDS in the following video.

Using Performance Insights to Analyze Performance of Amazon Aurora PostgreSQL

> **Important**
>
> The following topics describe using Amazon RDS Performance Insights with non-Aurora DB engines. For information about using Amazon RDS Performance Insights with Amazon Aurora, see Using Amazon RDS Performance Insights in the *Amazon Aurora User Guide*.

Topics

Database load

Database load (DB load) measures the level of session activity in your database. `DBLoad` is the key metric in Performance Insights, and Performance Insights collects DB load every second.

Topics

Active sessions

A *database session* represents an application's dialogue with a relational database. An *active session* is a connection that has submitted work to the DB engine and is waiting for a response.

A session is active when it's either running on CPU or waiting for a resource to become available so that it can proceed. For example, an active session might wait for a page (or block) to be read into memory, and then consume CPU while it reads data from the page.

Average active sessions

The *average active sessions (AAS)* is the unit for the `DBLoad` metric in Performance Insights. It measures how many sessions are concurrently active on the database.

Every second, Performance Insights samples the number of sessions concurrently running a query. For each active session, Performance Insights collects the following data:

- SQL statement
- Session state (running on CPU or waiting)

- Host
- User running the SQL

Performance Insights calculates the AAS by dividing the total number of sessions by the number of samples for a specific time period. For example, the following table shows 5 consecutive samples of a running query taken at 1-second intervals.

Sample	Number of sessions running query	AAS	Calculation
1	2	2	2 total sessions / 1 sample
2	0	1	2 total sessions / 2 samples
3	4	2	6 total sessions / 3 samples
4	0	1.5	6 total sessions / 4 samples
5	4	2	10 total sessions / 5 samples

In the preceding example, the DB load for the time interval was 2 AAS. This measurement means that, on average, 2 sessions were active at any given time during the interval when the 5 samples were taken.

Average active executions

The *average active executions (AAE)* per second is related to AAS. To calculate the AAE, Performance Insights divides the total execution time of a query by the time interval. The following table shows the AAE calculation for the same query in the preceding table.

Elapsed time (sec)	Total execution time (sec)	AAE	Calculation
60	120	2	120 execution seconds/60 elapsed seconds

Elapsed time (sec)	Total execution time (sec)	AAE	Calculation
120	120	1	120 execution seconds/120 elapsed seconds
180	380	2.11	380 execution seconds/180 elapsed seconds
240	380	1.58	380 execution seconds/240 elapsed seconds
300	600	2	600 execution seconds/300 elapsed seconds

In most cases, the AAS and AAE for a query are approximately the same. However, because the inputs to the calculations are different data sources, the calculations often vary slightly.

Dimensions

The `db.load` metric is different from the other time-series metrics because you can break it into subcomponents called *dimensions*. You can think of dimensions as "slice by" categories for the different characteristics of the `DBLoad` metric.

When you are diagnosing performance issues, the following dimensions are often the most useful:

Topics

- Wait events
- Top SQL
- Plans

For a complete list of dimensions for the Amazon RDS engines, see DB load sliced by dimensions.

Wait events

A *wait event* causes a SQL statement to wait for a specific event to happen before it can continue running. Wait events are an important dimension, or category, for DB load because they indicate where work is impeded.

Every active session is either running on the CPU or waiting. For example, sessions consume CPU when they search memory for a buffer, perform a calculation, or run procedural code. When sessions aren't consuming CPU, they might be waiting for a memory buffer to become free, a data file to be read, or a log to be written to. The more time that a session waits for resources, the less time it runs on the CPU.

When you tune a database, you often try to find out the resources that sessions are waiting for. For example, two or three wait events might account for 90 percent of DB load. This measure means that, on average, active sessions are spending most of their time waiting for a small number of resources. If you can find out the cause of these waits, you can attempt a solution.

Wait events vary by DB engine:

- For information about all MariaDB and MySQL wait events, see Wait Event Summary Tables in the MySQL documentation.
- For information about all PostgreSQL wait events, see The Statistics Collector > Wait Event tables in the PostgreSQL documentation.
- For information about all Oracle wait events, see Descriptions of Wait Events in the Oracle documentation.
- For information about all SQL Server wait events, see Types of Waits in the SQL Server documentation.

> **Note**
>
> For Oracle, background processes sometimes do work without an associated SQL statement. In these cases, Performance Insights reports the type of background process concatenated with a colon and the wait class associated with that background process. Types of background process include `LGWR`, `ARC0`, `PMON`, and so on.
> For example, when the archiver is performing I/O, the Performance Insights report for it is similar to `ARC1:System I/O`. Occasionally, the background process type is also missing, and Performance Insights only reports the wait class, for example `:System I/O`.

Top SQL

Where wait events show bottlenecks, top SQL shows which queries are contributing the most to DB load. For example, many queries might be currently running on the database, but a single query might consume 99 percent of the DB load. In this case, the high load might indicate a problem with the query.

By default, the Performance Insights console displays top SQL queries that are contributing to the database load. The console also shows relevant statistics for each statement. To diagnose performance problems for a specific statement, you can examine its execution plan.

Plans

An *execution plan*, also called simply a *plan*, is a sequence of steps that access data. For example, a plan for joining tables `t1` and `t2` might loop through all rows in `t1` and compare each row to a row in `t2`. In a relational database, an *optimizer* is built-in code that determines the most efficient plan for a SQL query.

For DB instances, Performance Insights collects execution plans automatically. To diagnose SQL performance problems, examine the captured plans for high-resource SQL queries. The plans show how the database has parsed and run queries.

To learn how to analyze DB load using plans, see:

- Oracle: Analyzing Oracle execution plans using the Performance Insights dashboard
- SQL Server: Analyzing SQL Server execution plans using the Performance Insights dashboard

Plan capture

Every five minutes, Performance Insights identifies the most resource-intensive queries and captures their plans. Thus, you don't need to manually collect and manage a huge number of plans. Instead, you can use the **Top SQL** tab to focus on the plans for the most problematic queries.

> **Note**
>
> Performance Insights doesn't capture plans for queries whose text exceeds the maximum collectable query text limit. For more information, see Accessing more SQL text in the Performance Insights dashboard.

The retention period for execution plans is the same as for your Performance Insights data. The retention setting in the free tier is **Default (7 days)**. To retain your performance data for longer, specify 1–24 months. For more information about retention periods, see Pricing and data retention for Performance Insights.

Digest queries

The **Top SQL** tab shows digest queries by default. A digest query doesn't itself have a plan, but all queries that use literal values have plans. For example, a digest query might include the text `WHERE `email`=?`. The digest might contain two queries, one with the text `WHERE email=user1@example.com` and another with `WHERE email=user2@example.com`. Each of these literal queries might include multiple plans.

When you select a digest query, the console shows all plans for child statements of the selected digest. Thus, you don't need to look through all the child statements to find the plan. You might see plans that aren't in the displayed list of top 10 child statements. The console shows plans for all child queries for which plans have been collected, regardless of whether the queries are in the top 10.

Maximum CPU

In the dashboard, the **Database load** chart collects, aggregates, and displays session information. To see whether active sessions are exceeding the maximum CPU, look at their relationship to the **Max vCPU** line. Performance Insights determines the **Max vCPU** value by the number of vCPU (virtual CPU) cores for your DB instance.

One process can run on a vCPU at a time. If the number of processes exceeds the number of vCPUs, the processes start queuing. When queuing increases, database performance decreases. If the DB load is often above the **Max vCPU** line, and the primary wait state is CPU, the CPU is overloaded. In this case, you might want to throttle connections to the instance, tune any SQL queries with a high CPU load, or consider a larger instance class. High and consistent instances of any wait state indicate that there might be bottlenecks or resource contention issues to resolve. This can be true even if the DB load doesn't cross the **Max vCPU** line.

Amazon RDS DB engine, Region, and instance class support for Performance Insights

The following table provides Amazon RDS DB engines that support Performance Insights.

Note

For Amazon Aurora, see Amazon Aurora DB engine support for Performance Insights in *Amazon Aurora User Guide*.

Amazon RDS DB engine	Supported engine versions and Regions	Instance class restrictions
Amazon RDS for MariaDB	For more information on version and Region availability of Performance Insights with RDS for MariaDB, see Supported Regions and DB engines for Performance Insights in Amazon RDS.	Performance Insights isn't supported for the following instance classes: • db.t2.micro • db.t2.small • db.t3.micro • db.t3.small • db.t4g.micro • db.t4g.small
RDS for MySQL	For more information on version and Region availability of Performance Insights with RDS for MySQL, see Supported Regions and DB engines for Performance Insights in Amazon RDS.	Performance Insights isn't supported for the following instance classes: • db.t2.micro • db.t2.small • db.t3.micro • db.t3.small •

Amazon RDS DB engine	Supported engine versions and Regions	Instance class restrictions
		• db.t4g.micro • db.t4g.small
Amazon RDS for Microsoft SQL Server	For more information on version and Region availability of Performance Insights with RDS for SQL Server, see Supported Regions and DB engines for Performance Insights in Amazon RDS.	N/A
Amazon RDS for PostgreSQL	For more information on version and Region availability of Performance Insights with RDS for PostgreSQL, see Supported Regions and DB engines for Performance Insights in Amazon RDS.	N/A
Amazon RDS for Oracle	For more information on version and Region availability of Performance Insights with RDS for Oracle, see Supported Regions and DB engines for Performance Insights in Amazon RDS.	N/A

Amazon RDS DB engine, Region, and instance class support for Performance Insights features

The following table provides Amazon RDS DB engines that support Performance Insights features.

Feature	Pricing tier	Supported regions	Supported DB engines	Supported instance classes
SQL statistics for Performance Insights	All	All	All	All
Analyzing Oracle execution plans using the Performance Insights dashboard	All	All	RDS for Oracle	All
Analyzing database performance for a period of time	Paid tier only	• US East (Ohio) • US East (N. Virginia) • US West (N. California) • US West (Oregon) • Asia Pacific (Mumbai) • Asia Pacific (Seoul) • Asia Pacific (Singapore) • Asia Pacific (Sydney) • Asia Pacific (Tokyo) • Canada (Central) • Europe (Frankfurt)	RDS for PostgreSQL	All

Feature	Pricing tier	Supported regions	Supported DB engines	Supported instance classes
		• Europe (Ireland) • Europe (London) • Europe (Paris) • Europe (Stockholm)		

Feature	Pricing tier	Supported regions	Supported DB engines	Supported instance classes
Viewing Performance Insights proactive recommendations	Paid tier only	• US East (Ohio) • US East (N. Virginia) • US West (N. Pricing and data retention for Performance Insights

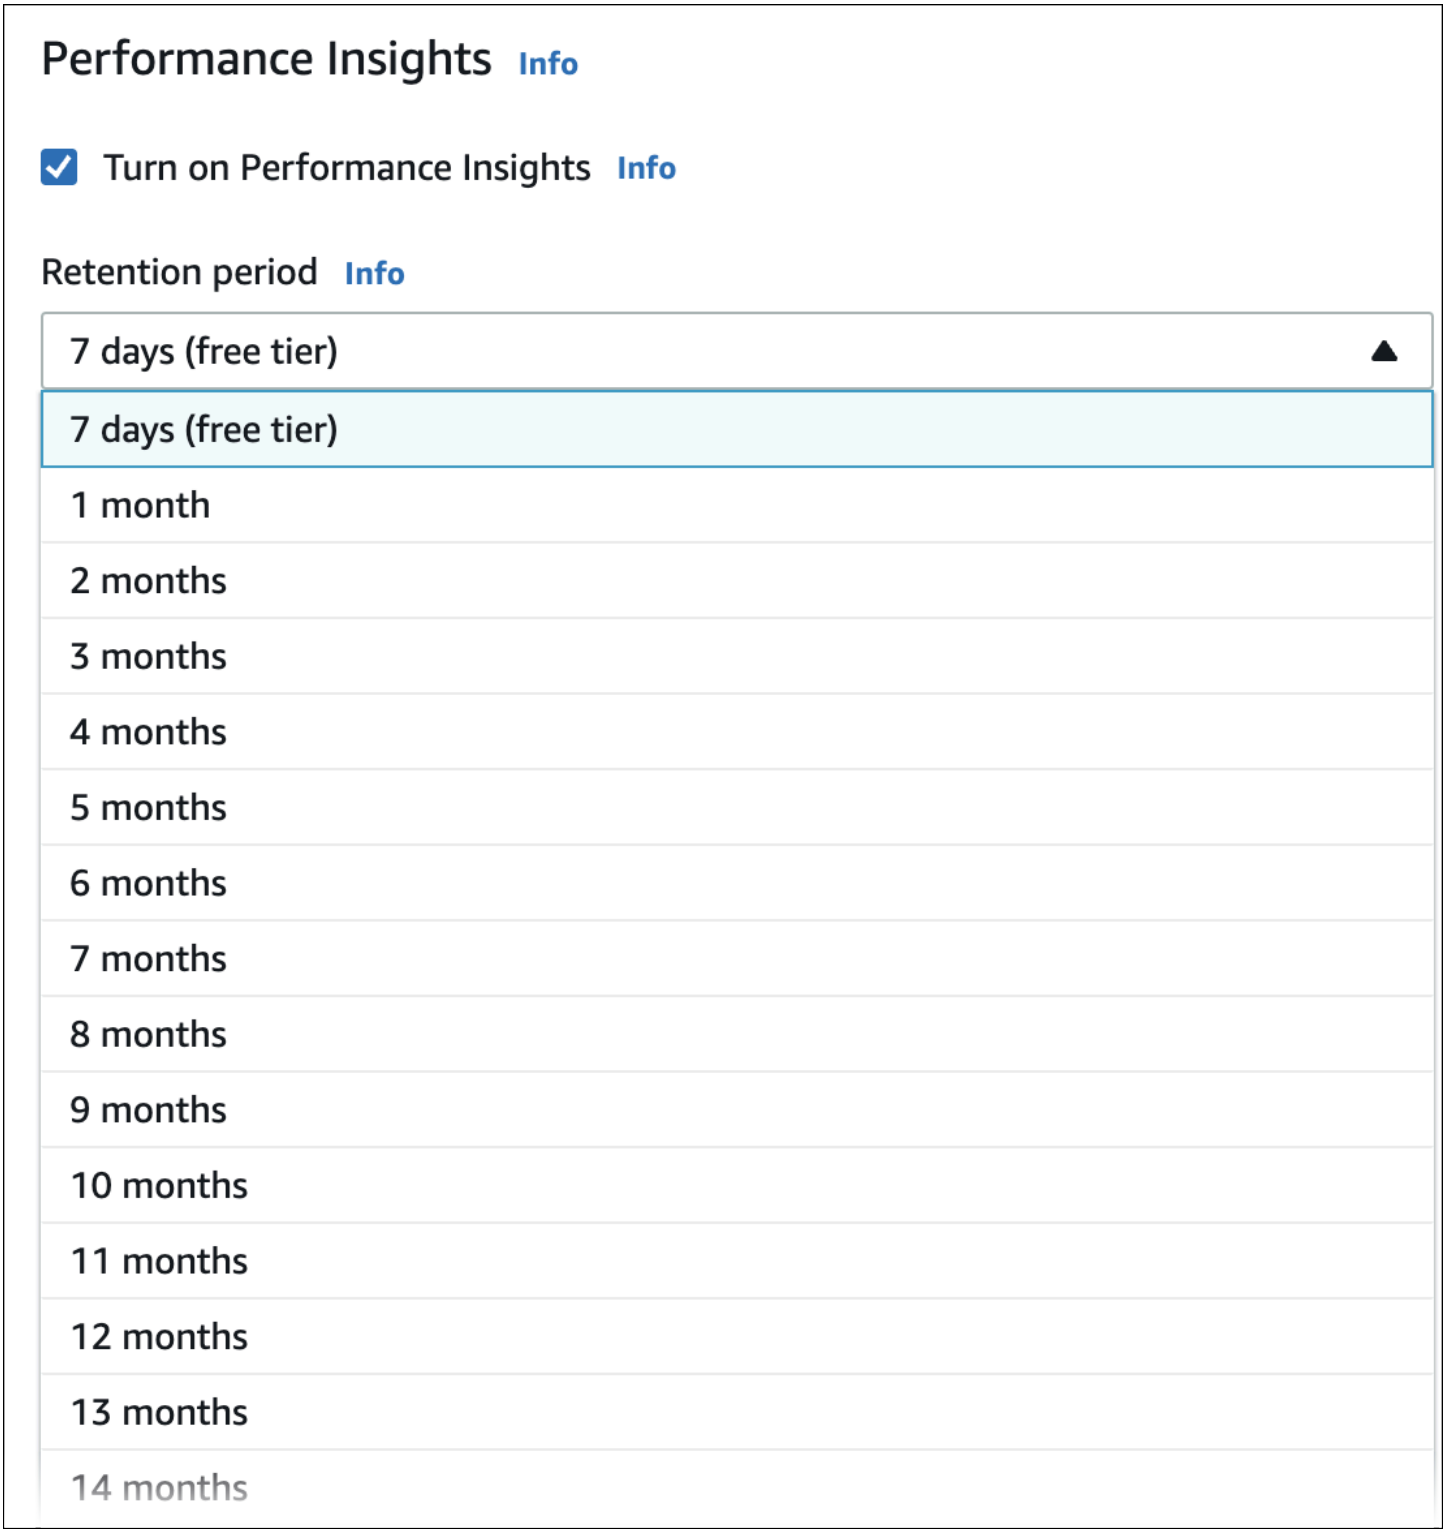
By default, Performance Insights offers a free tier that includes 7 days of performance data history and 1 million API requests per month. You can also purchase longer retention periods. For complete pricing information, see Performance Insights Pricing.

In the RDS console, you can choose any of the following retention periods for your Performance Insights data:

- **Default (7 days)**
- ***n* months**, where ***n*** is a number from 1–24



To learn how to set a retention period using the AWS CLI, see AWS CLI.

Turning Performance Insights on and off for Amazon RDS

You can turn on Performance Insights for your DB instance or Multi-AZ DB cluster when you create it. If needed, you can turn it off later. Turning Performance Insights on and off doesn't cause downtime, a reboot, or a failover.

> **Note**
>
> Performance Schema is an optional performance tool used by Amazon RDS for MariaDB or MySQL. If you turn Performance Schema on or off, you need to reboot. If you turn Performance Insights on or off, however, you don't need to reboot. For more information, see Overview of the Performance Schema for Performance Insights on Amazon RDS for MariaDB or MySQL.

The Performance Insights agent consumes limited CPU and memory on the DB host. When the DB load is high, the agent limits the performance impact by collecting data less frequently.

Console

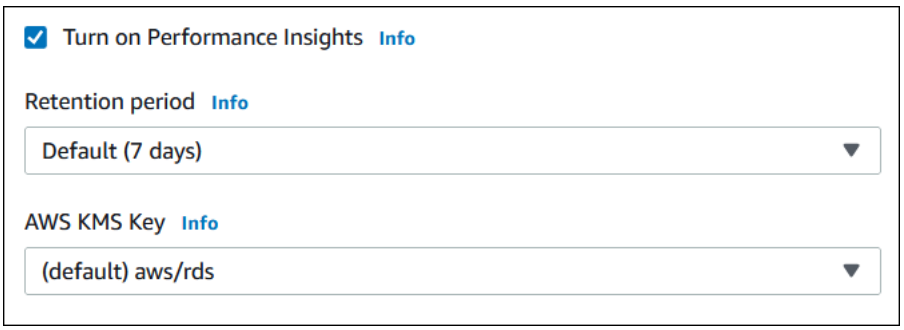
In the console, you can turn Performance Insights on or off when you create or modify a DB instance or Multi-AZ DB cluster.

Turning Performance Insights on or off when creating a DB instance or Multi-AZ DB cluster

When you create a new DB instance or Multi-AZ DB cluster, turn on Performance Insights by choosing **Enable Performance Insights** in the **Performance Insights** section. Or choose **Disable Performance Insights**. For more information, see the following topics:

- To create a DB instance, follow the instructions for your DB engine in Creating an Amazon RDS DB instance.
- To create a Multi-AZ DB cluster, follow the instructions for your DB engine in Creating a Multi-AZ DB cluster.

The following screenshot shows the **Performance Insights** section.



If you choose **Enable Performance Insights**, you have the following options:

- **Retention** – The amount of time to retain Performance Insights data. The retention setting in the free tier is **Default (7 days)**. To retain your performance data for longer, specify 1–24 months. For more information about retention periods, see Pricing and data retention for Performance Insights.
- **AWS KMS key** – Specify your AWS KMS key. Performance Insights encrypts all potentially sensitive data using your KMS key. Data is encrypted in flight and at rest. For more information, see Changing an AWS KMS policy for Performance Insights.

Turning Performance Insights on or off when modifying a DB instance or Multi-AZ DB cluster

In the console, you can modify a DB instance or Multi-AZ DB cluster to turn Performance Insights on or off.

To turn Performance Insights on or off for a DB instance or Multi-AZ DB cluster using the console

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Choose **Databases**.
3. Choose a DB instance or Multi-AZ DB cluster, and choose **Modify**.
4. In the **Performance Insights** section, choose either **Enable Performance Insights** or **Disable Performance Insights**.

   If you choose **Enable Performance Insights**, you have the following options:

   - **Retention** – The amount of time to retain Performance Insights data. The retention setting in the free tier is **Default (7 days)**. To retain your performance data for longer, specify 1–24

months. For more information about retention periods, see Pricing and data retention for Performance Insights.

- **AWS KMS key** – Specify your KMS key. Performance Insights encrypts all potentially sensitive data using your KMS key. Data is encrypted in flight and at rest. For more information, see Encrypting Amazon RDS resources.

5. Choose **Continue**.
6. For **Scheduling of Modifications**, choose Apply immediately. If you choose Apply during the next scheduled maintenance window, your instance ignores this setting and turns on Performance Insights immediately.
7. Choose **Modify instance**.

AWS CLI

When you use the create-db-instance AWS CLI command, turn on Performance Insights by specifying `--enable-performance-insights`. Or turn off Performance Insights by specifying `--no-enable-performance-insights`.

You can also specify these values using the following AWS CLI commands:

- create-db-instance-read-replica
- modify-db-instance
- restore-db-instance-from-s3
- create-db-cluster (Multi-AZ DB cluster)
- modify-db-cluster (Multi-AZ DB cluster)

The following procedure describes how to turn Performance Insights on or off for an existing DB instance using the AWS CLI.

To turn Performance Insights on or off for a DB instance using the AWS CLI

- Call the modify-db-instance AWS CLI command and supply the following values:
  - `--db-instance-identifier` – The name of the DB instance.
  - `--enable-performance-insights` to turn on or `--no-enable-performance-insights` to turn off

The following example turns on Performance Insights for `sample-db-instance`.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier sample-db-instance \
    --enable-performance-insights
```

For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier sample-db-instance ^
    --enable-performance-insights
```

When you turn on Performance Insights in the CLI, you can optionally specify the number of days to retain Performance Insights data with the `--performance-insights-retention-period` option. You can specify 7, *month* * 31 (where *month* is a number from 1–23), or 731. For example, if you want to retain your performance data for 3 months, specify 93, which is 3 * 31. The default is 7 days. For more information about retention periods, see Pricing and data retention for Performance Insights.

The following example turns on Performance Insights for `sample-db-instance` and specifies that Performance Insights data is retained for 93 days (3 months).

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier sample-db-instance \
    --enable-performance-insights \
    --performance-insights-retention-period 93
```

For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier sample-db-instance ^
    --enable-performance-insights ^
    --performance-insights-retention-period 93
```

If you specify a retention period such as 94 days, which isn't a valid value, RDS issues an error.

```
An error occurred (InvalidParameterValue) when calling the CreateDBInstance operation:
Invalid Performance Insights retention period. Valid values are: [7, 31, 62, 93, 124,
 155, 186, 217,
248, 279, 310, 341, 372, 403, 434, 465, 496, 527, 558, 589, 620, 651, 682, 713, 731]
```

RDS API

When you create a new DB instance using the CreateDBInstance operation Amazon RDS API operation, turn on Performance Insights by setting `EnablePerformanceInsights` to `True`. To turn off Performance Insights, set `EnablePerformanceInsights` to `False`.

You can also specify the `EnablePerformanceInsights` value using the following API operations:

- ModifyDBInstance
- CreateDBInstanceReadReplica
- RestoreDBInstanceFromS3
- CreateDBCluster (Multi-AZ DB cluster)
- ModifyDBCluster (Multi-AZ DB cluster)

When you turn on Performance Insights, you can optionally specify the amount of time, in days, to retain Performance Insights data with the `PerformanceInsightsRetentionPeriod` parameter. You can specify 7, *`month`* * 31 (where *`month`* is a number from 1–23), or 731. For example, if you want to retain your performance data for 3 months, specify 93, which is 3 * 31. The default is 7 days. For more information about retention periods, see Pricing and data retention for Performance Insights.

Overview of the Performance Schema for Performance Insights on Amazon RDS for MariaDB or MySQL

The Performance Schema is an optional feature for monitoring Amazon RDS for MariaDB or MySQL runtime performance at a low level of detail. The Performance Schema is designed to have minimal impact on database performance. Performance Insights is a separate feature that you can use with or without the Performance Schema.

Topics

- Overview of the Performance Schema

Overview of the Performance Schema

The Performance Schema monitors events in MariaDB and MySQL databases. An *event* is a database server action that consumes time and has been instrumented so that timing information can be collected. Examples of events include the following:

- Function calls
- Waits for the operating system
- Stages of SQL execution
- Groups of SQL statements

The `PERFORMANCE_SCHEMA` storage engine is a mechanism for implementing the Performance Schema feature. This engine collects event data using instrumentation in the database source code. The engine stores events in memory-only tables in the `performance_schema` database. You can query `performance_schema` just as you can query any other tables. For more information, see MySQL Performance Schema in the *MySQL Reference Manual*.

Performance Insights and the Performance Schema

Performance Insights and the Performance Schema are separate features, but they are connected. The behavior of Performance Insights for Amazon RDS for MariaDB or MySQL depends on whether the Performance Schema is turned on, and if so, whether Performance Insights manages the Performance Schema automatically. The following table describes the behavior.

Performance Schema turned on	Performance Insights management mode	Performance Insights behavior
Yes	Automatic	•

Performance Schema turned on	Performance Insights management mode	Performance Insights behavior
		Collects detailed, low-level monitoring information • Collects active session metrics every second • Displays DB load categorized by detailed wait events, which you can use to identify bottlenecks
Yes	Manual	• Collects wait events and per-SQL metrics • Collects active session metrics every five seconds instead of every second • Reports user states such as inserting and sending, which don't help you identify bottlenecks
No	N/A	• Doesn't collect wait events, per-SQL metrics, or other detailed, low-level monitoring information • Collects active session metrics every five seconds instead of every second • Reports user states such as inserting and sending, which don't help you identify bottlenecks

Automatic management of the Performance Schema by Performance Insights

When you create an Amazon RDS for MariaDB or MySQL DB instance with Performance Insights turned on, the Performance Schema is also turned on. In this case, Performance Insights automatically manages your Performance Schema parameters. This is the recommended configuration.

When Performance Insights manages the Performance Schema automatically, the **Source** of `performance_schema` is `System default`.

> **Note**
>
> Automatic management of the Performance Schema isn't supported for the t4g.medium instance class.

If you change the `performance_schema` parameter value manually, and then later want to change to automatic management, see Turn on the Performance Schema for Amazon RDS for MariaDB or MySQL.

> **Important**
>
> When Performance Insights turns on the Performance Schema, it doesn't change the parameter group values. However, the values are changed on the DB instances that are running. The only way to see the changed values is to run the `SHOW GLOBAL VARIABLES` command.

Effect of a reboot on the Performance Schema

Performance Insights and the Performance Schema differ in their requirements for DB instance reboots:

Performance Schema

To turn this feature on or off, you must reboot the DB instance.

Performance Insights

To turn this feature on or off, you don't need to reboot the DB instance.

If the Performance Schema isn't currently turned on, and you turn on Performance Insights without rebooting the DB instance, the Performance Schema won't be turned on.

Determining whether Performance Insights is managing the Performance Schema

To find out whether Performance Insights is currently managing the Performance Schema for major engine versions 5.7 and 8.0, review the following table.

Setting of performance_schema parameter	Setting of the Source column	Performance Insights is managing the Performance Schema?
`0`	`System default`	Yes
`0` or `1`	`Modified`	No

In the following procedure, you determine whether Performance Insights is managing the Performance Schema automatically.

To determine whether Performance Insights is managing the Performance Schema automatically

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Choose **Parameter groups**.
3. Select the name of the parameter group for your DB instance.
4. Enter **`performance_schema`** in the search bar.
5. Check whether **Source** is the system default and **Value** is **0**. If so, Performance Insights is managing the Performance Schema automatically.

   In the example shown here, Performance Insights isn't managing the Performance Schema automatically.

Turn on the Performance Schema for Amazon RDS for MariaDB or MySQL

Assume that Performance Insights is turned on for your DB instance or Multi-AZ DB cluster but isn't currently managing the Performance Schema. If you want to allow Performance Insights to manage the Performance Schema automatically, complete the following steps.

To configure the Performance Schema for automatic management

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Choose **Parameter groups**.
3. Select the name of the parameter group for your DB instance or Multi-AZ DB cluster.
4. Choose **Edit**.
5. Enter **`perf`** in the search bar.
6. Select the `performance_schema` parameter.
7. Choose **Set to default value**.
8. Confirm by choosing **Set values to default**.
9. Choose **Save Changes**.
10. Reboot the DB instance or Multi-AZ DB cluster.

> **Important**
>
> Whenever you turn the Performance Schema on or off, make sure to reboot the DB instance or Multi-AZ DB cluster.

For more information about modifying instance parameters, see Modifying parameters in a DB parameter group in Amazon RDS. For more information about the dashboard, see Analyzing metrics with the Performance Insights dashboard. For more information about the MySQL performance schema, see MySQL 8.0 Reference Manual.

Configuring access policies for Performance Insights

To access Performance Insights, a principal must have the appropriate permissions from AWS Identity and Access Management (IAM). You can grant access in the following ways:

- Attach the `AmazonRDSPerformanceInsightsReadOnly` managed policy to a permission set or role to access all read-only operations of the Performance Insights API.
- Attach the `AmazonRDSPerformanceInsightsFullAccess` managed policy to a permission set or role to access all operations of the Performance Insights API.
- Create a custom IAM policy and attach it to a permission set or role.

If you specified a customer managed key when you turned on Performance Insights, make sure that users in your account have the `kms:Decrypt` and `kms:GenerateDataKey` permissions on the AWS KMS key.

In the following sections, attach an AWS managed policy to an IAM principal, create a custom IAM policy, change an AWS KMS policy, and grant fine-grained access for Performance Insights.

Topics

Attaching the AmazonRDSPerformanceInsightsReadOnly policy to an IAM principal

`AmazonRDSPerformanceInsightsReadOnly` is an AWS managed policy that grants access to all read-only operations of the Amazon RDS Performance Insights API.

If you attach `AmazonRDSPerformanceInsightsReadOnly` to a permission set or role, the recipient can use Performance Insights with other console features.

For more information, see AWS managed policy: AmazonRDSPerformanceInsightsReadOnly.

Attaching the AmazonRDSPerformanceInsightsFullAccess policy to an IAM principal

`AmazonRDSPerformanceInsightsFullAccess` is an AWS managed policy that grants access to all operations of the Amazon RDS Performance Insights API.

If you attach `AmazonRDSPerformanceInsightsFullAccess` to a permission set or role, the recipient can use Performance Insights with other console features.

For more information, see AWS managed policy: AmazonRDSPerformanceInsightsFullAccess.

Creating a custom IAM policy for Performance Insights

For users who don't have either the `AmazonRDSPerformanceInsightsReadOnly` or `AmazonRDSPerformanceInsightsFullAccess` policy, you can grant access to Performance Insights by creating or modifying a user-managed IAM policy. When you attach the policy to an IAM permission set or role, the recipient can use Performance Insights.

To create a custom policy

1. Open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation pane, choose **Policies**.
3. Choose **Create policy**.
4. On the **Create Policy** page, choose the **JSON** option.
5. Copy and paste the text provided in the *JSON policy document* section in the *AWS Managed Policy Reference Guide* for AmazonRDSPerformanceInsightsReadOnly or AmazonRDSPerformanceInsightsFullAccess policy.
6. Choose **Review policy**.
7. Provide a name for the policy and optionally a description, and then choose **Create policy**.

You can now attach the policy to a permission set or role. The following procedure assumes that you already have a user available for this purpose.

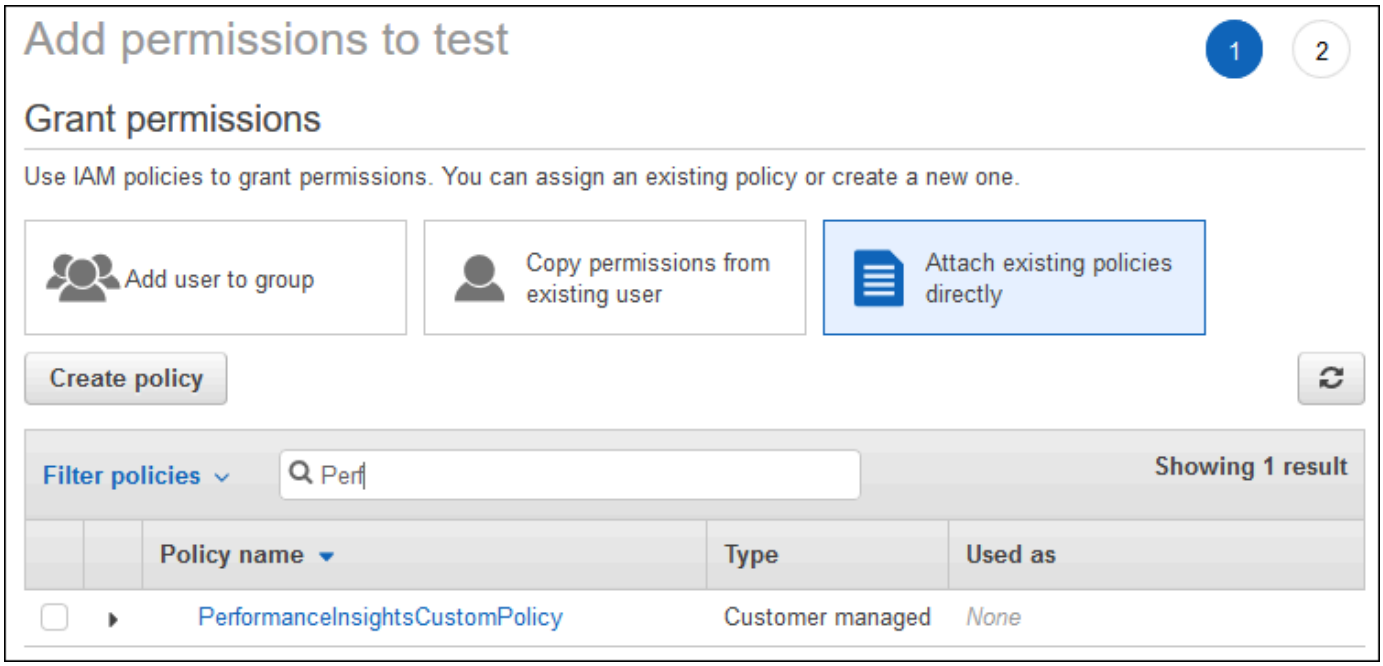
To attach the policy to a user

1. Open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation pane, choose **Users**.
3. Choose an existing user from the list.

> **Important**
>
> To use Performance Insights, make sure that you have access to Amazon RDS in addition to the custom policy. For example, the

`AmazonRDSPerformanceInsightsReadOnly` predefined policy provides read-only access to Amazon RDS. For more information, see Managing access using policies.

4. On the **Summary** page, choose **Add permissions**.
5. Choose **Attach existing policies directly**. For **Search**, type the first few characters of your policy name, as shown in the following image.



6. Choose your policy, and then choose **Next: Review**.
7. Choose **Add permissions**.

Changing an AWS KMS policy for Performance Insights

Performance Insights uses an AWS KMS key to encrypt sensitive data. When you enable Performance Insights through the API or the console, you can do either of the following:

- Choose the default AWS managed key.

  Amazon RDS uses the AWS managed key for your new DB instance. Amazon RDS creates an AWS managed key for your AWS account. Your AWS account has a different AWS managed key for Amazon RDS for each AWS Region.
- Choose a customer managed key.

  If you specify a customer managed key, users in your account that call the Performance Insights API need the `kms:Decrypt` and `kms:GenerateDataKey` permissions on the KMS key. You can

configure these permissions through IAM policies. However, we recommend that you manage these permissions through your KMS key policy. For more information, see Key policies in AWS KMS in the *AWS Key Management Service Developer Guide*.

Example

The following example shows how to add statements to your KMS key policy. These statements allow access to Performance Insights. Depending on how you use the KMS key, you might want to change some restrictions. Before adding statements to your policy, remove all comments.

```
{
"Version" : "2012-10-17",
 "Id" : "your-policy",
 "Statement" : [ {
    //This represents a statement that currently exists in your policy.
 }
 ....,
 //Starting here, add new statement to your policy for Performance Insights.
 //We recommend that you add one new statement for every RDS instance
{
    "Sid" : "Allow viewing RDS Performance Insights",
    "Effect": "Allow",
    "Principal": {
        "AWS": [
            //One or more principals allowed to access Performance Insights
            "arn:aws:iam::444455556666:role/Role1"
        ]
    },
    "Action": [
        "kms:Decrypt",
        "kms:GenerateDataKey"
    ],
    "Resource": "*",
    "Condition" : {
        "StringEquals" : {
            //Restrict access to only RDS APIs (including Performance Insights).
            //Replace region with your AWS Region.
            //For example, specify us-west-2.
            "kms:ViaService" : "rds.region.amazonaws.com"
        },
        "ForAnyValue:StringEquals": {
            //Restrict access to only data encrypted by Performance Insights.
```

```
            "kms:EncryptionContext:aws:pi:service": "rds",
            "kms:EncryptionContext:service": "pi",

            //Restrict access to a specific RDS instance.
            //The value is a DbiResourceId.
           "kms:EncryptionContext:aws:rds:db-id": "db-AAAAABBBBBCCCCDDDDDEEEEE"
        }
    }
}
```

How Performance Insights uses AWS KMS customer managed key

Performance Insights uses customer managed keys to encrypt sensitive data. When you turn on Performance Insights, you can provide an AWS KMS key through the API. Performance Insights creates KMS permissions on this key. It uses the key and performs the necessary operations to process sensitive data. Sensitive data includes fields such as user, database, application, and SQL query text. Performance Insights ensures that the data remains encrypted both at rest and in-flight.

How Performance Insights IAM works with AWS KMS

IAM gives permissions to specific APIs. Performance Insights has the following public APIs, which you can restrict using IAM policies:

- `DescribeDimensionKeys`
- `GetDimensionKeyDetails`
- `GetResourceMetadata`
- `GetResourceMetrics`
- `ListAvailableResourceDimensions`
- `ListAvailableResourceMetrics`

You can use the following API requests to get sensitive data.

- `DescribeDimensionKeys`
- `GetDimensionKeyDetails`
- `GetResourceMetrics`

When you use the API to get sensitive data, Performance Insights leverages the caller's credentials. This check ensures that access to sensitive data is limited to those with access to the KMS key.

When calling these APIs, you need permissions to call the API through the IAM policy and permissions to invoke the `kms:decrypt` action through the AWS KMS key policy.

The `GetResourceMetrics` API can return both sensitive and non-sensitive data. The request parameters determine whether the response should include sensitive data. The API returns sensitive data when the request includes a sensitive dimension in either the filter or group-by parameters.

For more information about the dimensions that you can use with the `GetResourceMetrics` API, see DimensionGroup.

Example Examples

The following example requests the sensitive data for the `db.user` group:

```
POST / HTTP/1.1
Host: <Hostname>
Accept-Encoding: identity
X-Amz-Target: PerformanceInsightsv20180227.GetResourceMetrics
Content-Type: application/x-amz-json-1.1
User-Agent: <UserAgentString>
X-Amz-Date: <Date>
Authorization: AWS4-HMAC-SHA256 Credential=<Credential>, SignedHeaders=<Headers>,
 Signature=<Signature>
Content-Length: <PayloadSizeBytes>
{
  "ServiceType": "RDS",
  "Identifier": "db-ABC1DEFGHIJKL2MNOPQRSTUV3W",
  "MetricQueries": [
    {
      "Metric": "db.load.avg",
      "GroupBy": {
        "Group": "db.user",
        "Limit": 2
      }
    }
  ],
  "StartTime": 1693872000,
```

```
  "EndTime": 1694044800,
  "PeriodInSeconds": 86400
}
```

Example

The following example requests the non-sensitive data for the `db.load.avg` metric:

```
POST / HTTP/1.1
Host: <Hostname>
Accept-Encoding: identity
X-Amz-Target: PerformanceInsightsv20180227.GetResourceMetrics
Content-Type: application/x-amz-json-1.1
User-Agent: <UserAgentString>
X-Amz-Date: <Date>
Authorization: AWS4-HMAC-SHA256 Credential=<Credential>, SignedHeaders=<Headers>,
 Signature=<Signature>
Content-Length: <PayloadSizeBytes>
{
    "ServiceType": "RDS",
    "Identifier": "db-ABC1DEFGHIJKL2MNOPQRSTUV3W",
    "MetricQueries": [
        {
            "Metric": "db.load.avg"
        }
    ],
    "StartTime": 1693872000,
    "EndTime": 1694044800,
    "PeriodInSeconds": 86400
}
```

Granting fine-grained access for Performance Insights

Fine-grained access control offers additional ways of controlling access to Performance Insights. This access control can allow or deny access to individual dimensions for `GetResourceMetrics`, `DescribeDimensionKeys`, and `GetDimensionKeyDetails` Performance Insights actions. To use fine-grained access, specify dimensions in the IAM policy by using condition keys. The evaluation of the access follows the IAM policy evaluation logic. For more information, see Policy evaluation logic in the *IAM User Guide*. If the IAM policy statement doesn't specify any dimension,

then the statement controls access to all the dimensions for the specified action. For the list of available dimensions, see DimensionGroup.

To find out the dimensions that your credentials are authorized to access, use the `AuthorizedActions` parameter in `ListAvailableResourceDimensions` and specify the action. The allowed values for `AuthorizedActions` are as follows:

- `GetResourceMetrics`
- `DescribeDimensionKeys`
- `GetDimensionKeyDetails`

For example, if you specify `GetResourceMetrics` to the `AuthorizedActions` parameter, `ListAvailableResourceDimensions` returns the list of dimensions that the `GetResourceMetrics` action is authorized to access. If you specify multiple actions in the `AuthorizedActions` parameter, then `ListAvailableResourceDimensions` returns an intersection of dimensions that those actions are authorized to access.

Example

The following example provides access to the specified dimensions for `GetResourceMetrics` and `DescribeDimensionKeys` actions.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AllowToDiscoverDimensions",
            "Effect": "Allow",
            "Action": [
                "pi:ListAvailableResourceDimensions"
            ],
            "Resource": [
                "arn:aws:pi:us-east-1:123456789012:metrics/rds/db-
ABC1DEFGHIJKL2MNOPQRSTUV3W"
            ]
        },
        {
            "Sid": "SingleAllow",
            "Effect": "Allow",
            "Action": [
```

```
                "pi:GetResourceMetrics",
                "pi:DescribeDimensionKeys"
            ],
            "Resource": [
                "arn:aws:pi:us-east-1:123456789012:metrics/rds/db-
ABC1DEFGHIJKL2MNOPQRSTUV3W"
            ],
            "Condition": {
                "ForAllValues:StringEquals": {
                    // only these dimensions are allowed. Dimensions not included in
                    // a policy with "Allow" effect will be denied
                    "pi:Dimensions": [
                        "db.sql_tokenized.id",
                        "db.sql_tokenized.statement"
                    ]
                }
            }
        }

    ]
}
```

The following is the response for the requested dimension:

```
 // ListAvailableResourceDimensions API
// Request
{
    "ServiceType": "RDS",
    "Identifier": "db-ABC1DEFGHIJKL2MNOPQRSTUV3W",
    "Metrics": [ "db.load" ],
    "AuthorizedActions": ["DescribeDimensionKeys"]
}

// Response
{
    "MetricDimensions": [ {
        "Metric": "db.load",
        "Groups": [
            {
                "Group": "db.sql_tokenized",
```

```
                "Dimensions": [
                    { "Identifier": "db.sql_tokenized.id" },
                  //  { "Identifier": "db.sql_tokenized.db_id" }, // not included
 because not allows in the IAM Policy
                    { "Identifier": "db.sql_tokenized.statement" }
                ]
            }

        ] }
    ]
}
```

The following example specifies one allow and two deny access for the dimensions.

```
{
    "Version": "2012-10-17",
    "Statement": [
          {
            "Sid": "AllowToDiscoverDimensions",
            "Effect": "Allow",
            "Action": [
                "pi:ListAvailableResourceDimensions"
            ],
            "Resource": [
                "arn:aws:pi:us-east-1:123456789012:metrics/rds/db-
ABC1DEFGHIJKL2MNOPQRSTUV3W"
            ]
          },

          {
            "Sid": "O01AllowAllWithoutSpecifyingDimensions",

```

Analyzing metrics with the Performance Insights dashboard

The Performance Insights dashboard contains database performance information to help you analyze and troubleshoot performance issues. On the main dashboard page, you can view information about the database load. You can "slice" DB load by dimensions such as wait events or SQL.

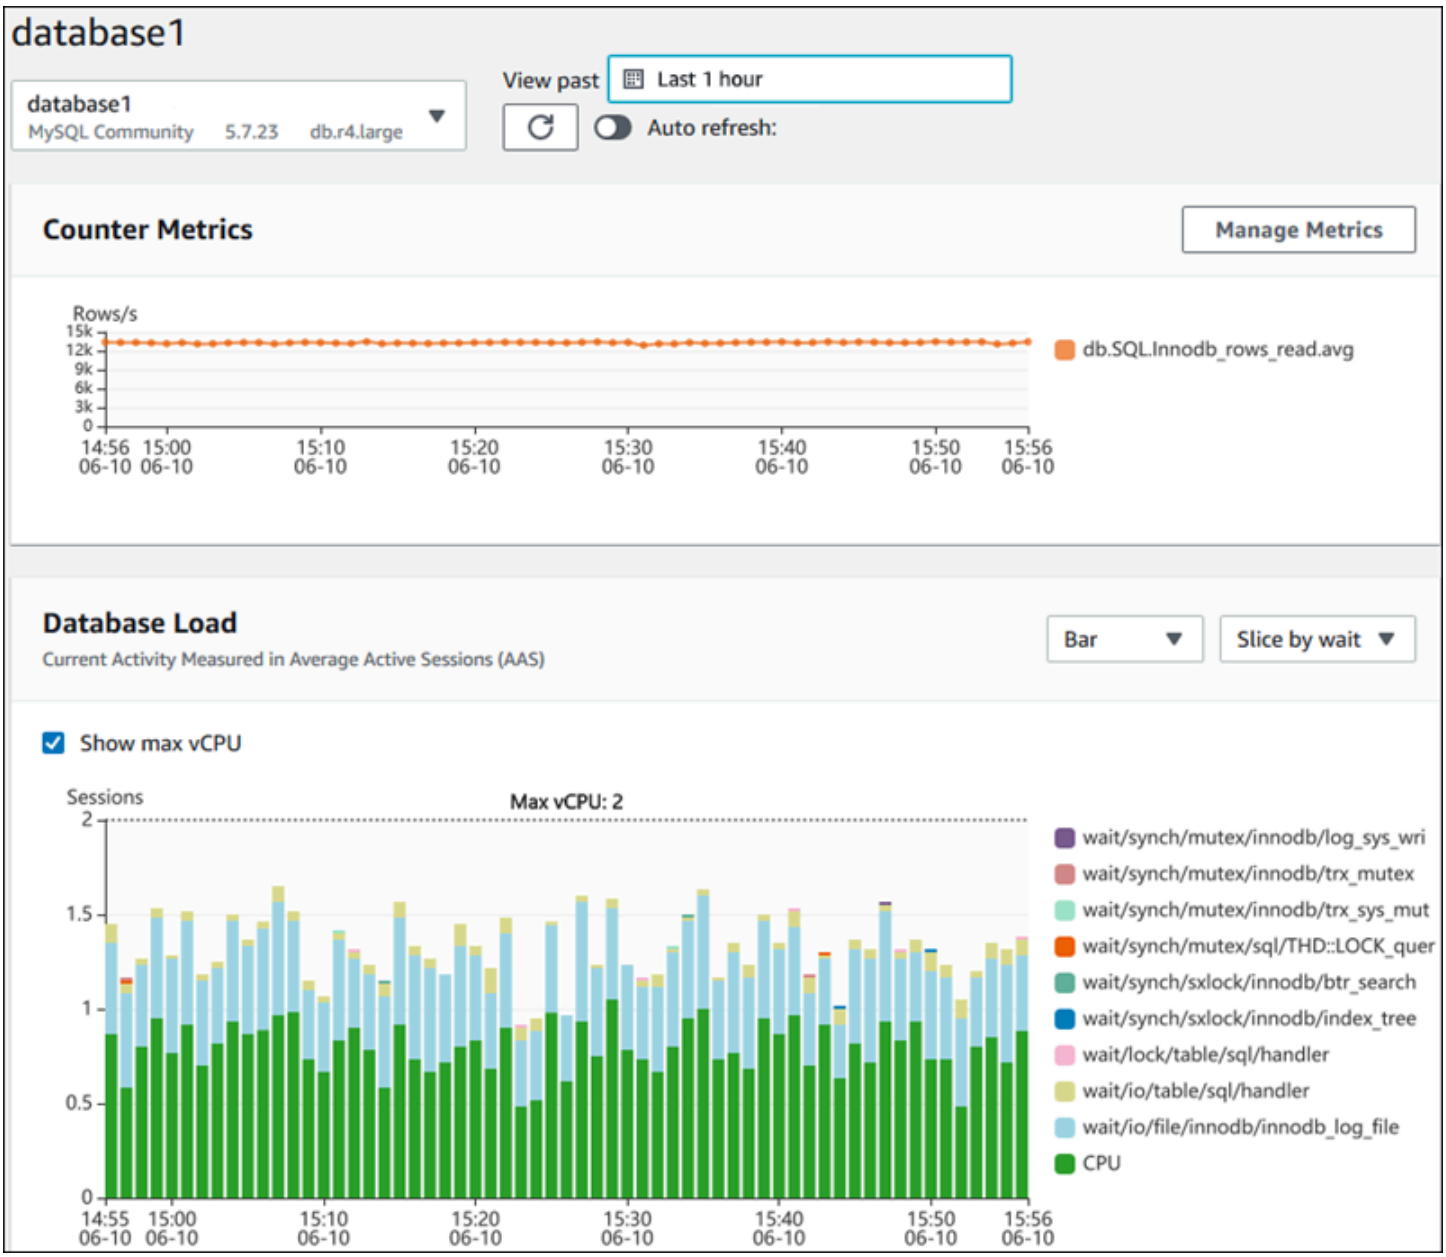
Performance Insights dashboard

- Overview of the Performance Insights dashboard

- Accessing the Performance Insights dashboard
- Analyzing DB load by wait events
- Analyzing database performance for a period of time
- Analyzing queries with the Top SQL tab in Performance Insights
- Analyzing top Oracle PDB load
- Analyzing execution plans using the Performance Insights dashboard

Overview of the Performance Insights dashboard

The dashboard is the easiest way to interact with Performance Insights. The following example shows the dashboard for a MySQL DB instance.

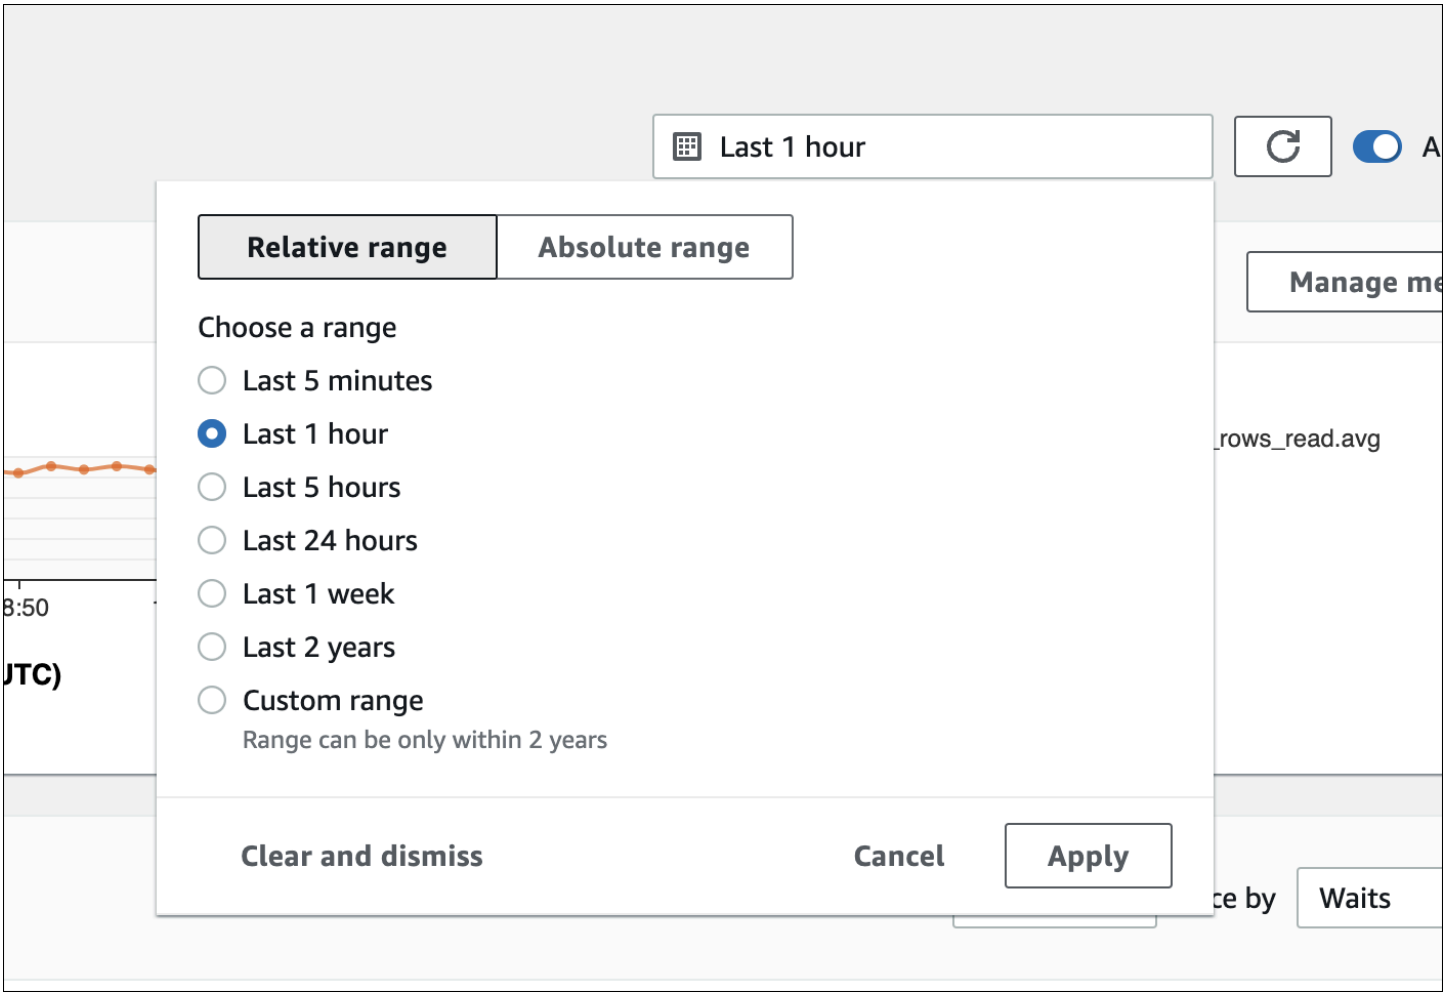


Topics

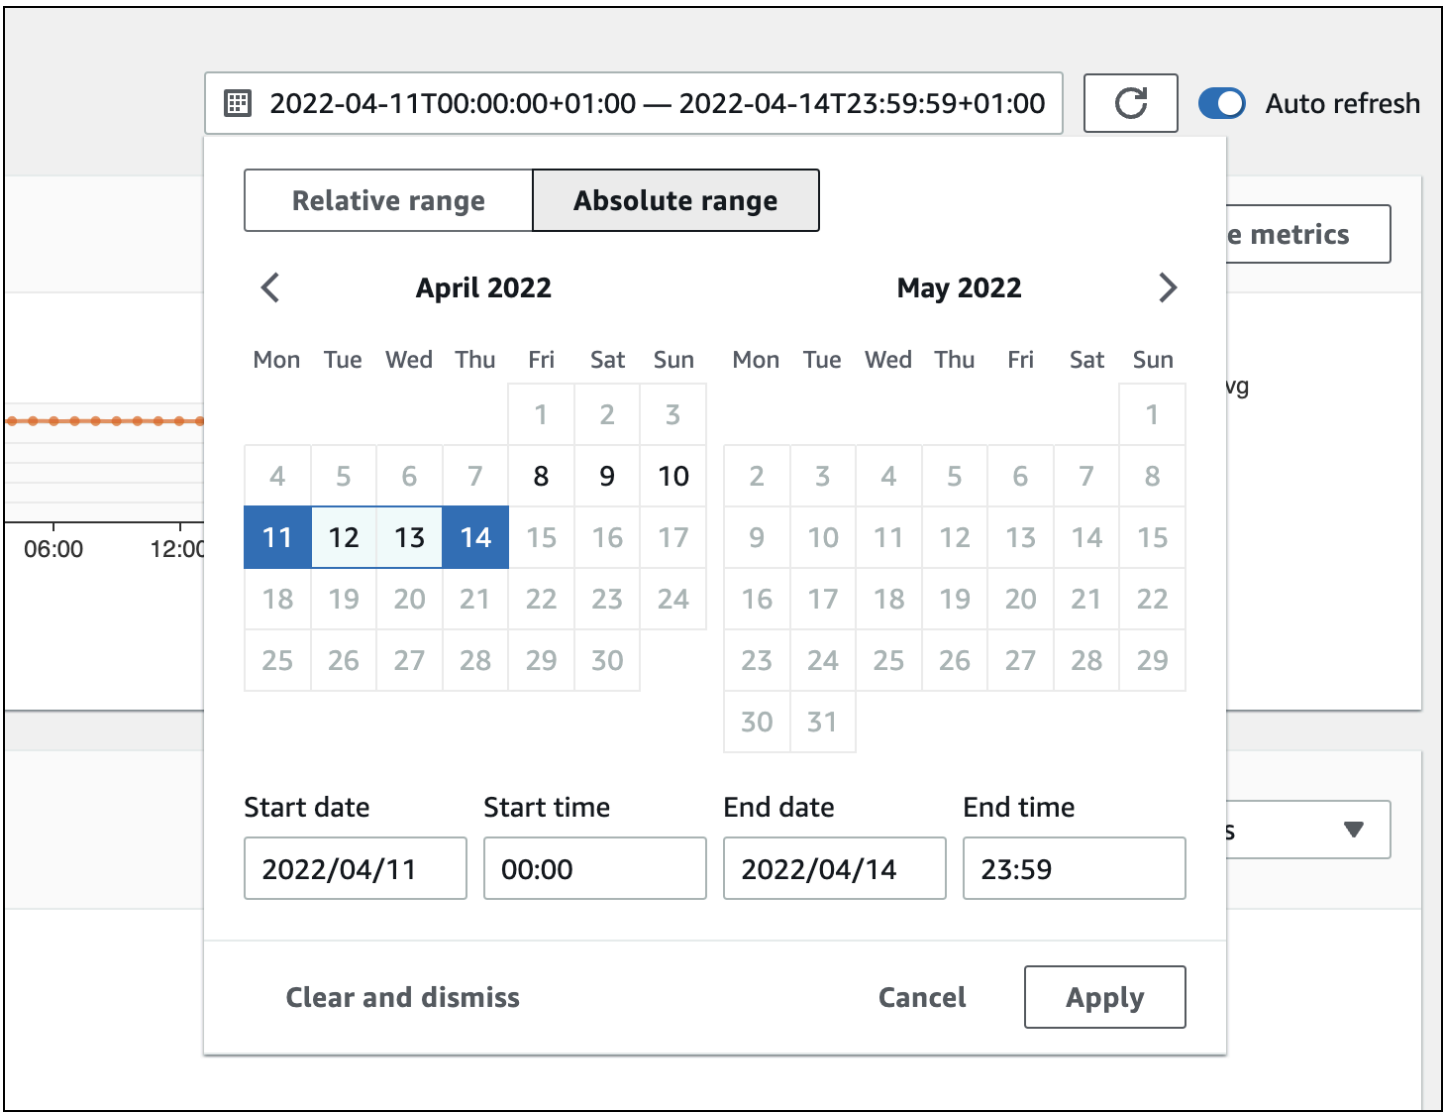
- Time range filter
- Counter metrics chart
- Database load chart
- Top dimensions table

Time range filter

By default, the Performance Insights dashboard shows DB load for the last hour. You can adjust this range to be as short as 5 minutes or as long as 2 years. You can also select a custom relative range.



You can select an absolute range with a beginning and ending date and time. The following example shows the time range beginning at midnight on 4/11/22 and ending at 11:59 PM on 4/14/22.



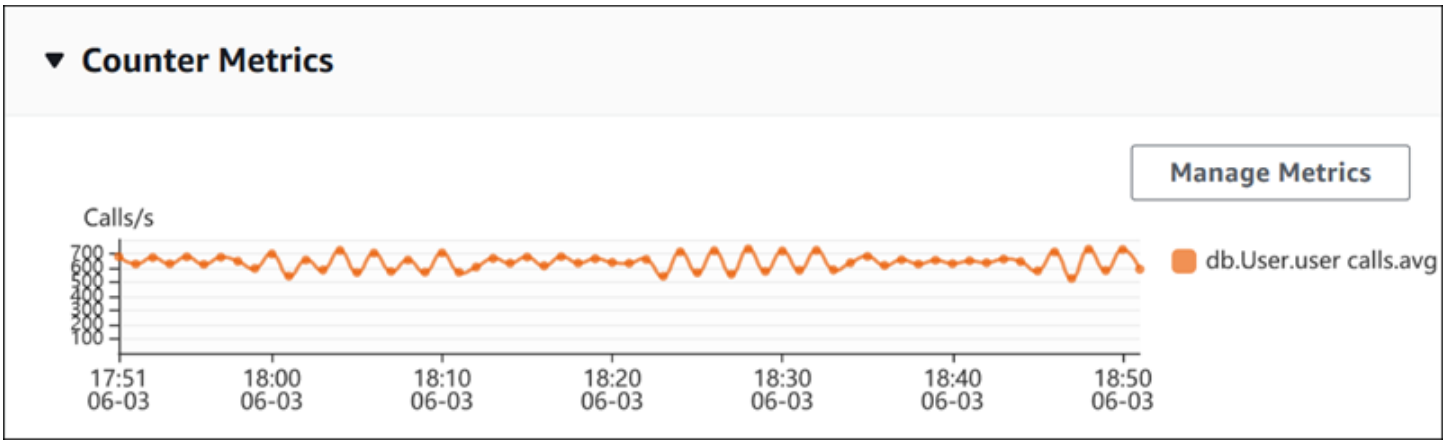
Counter metrics chart

With counter metrics, you can customize the Performance Insights dashboard to include up to 10 additional graphs. These graphs show a selection of dozens of operating system and database performance metrics. You can correlate this information with DB load to help identify and analyze performance problems.

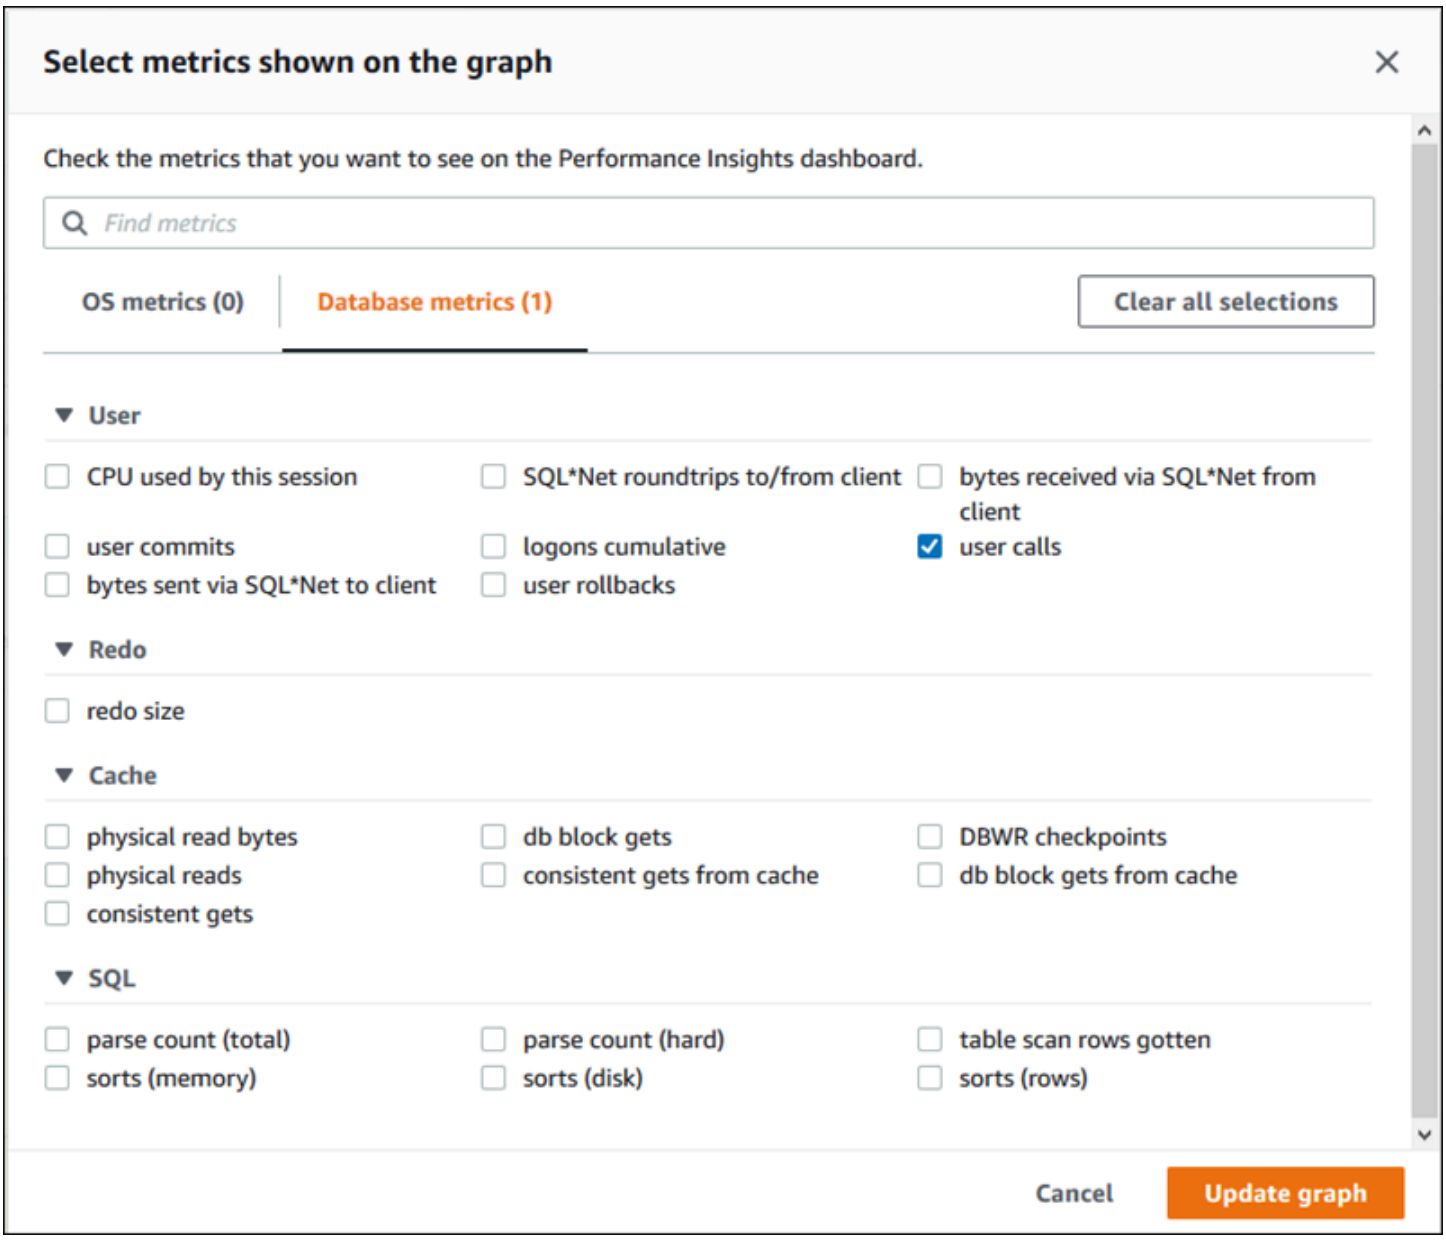
The **Counter metrics** chart displays data for performance counters. The default metrics depend on the DB engine:

- MySQL and MariaDB – `db.SQL.Innodb_rows_read.avg`
- Oracle – `db.User.user calls.avg`
- Microsoft SQL Server – `db.Databases.Active Transactions(_Total).avg`

- PostgreSQL – `db.Transactions.xact_commit.avg`



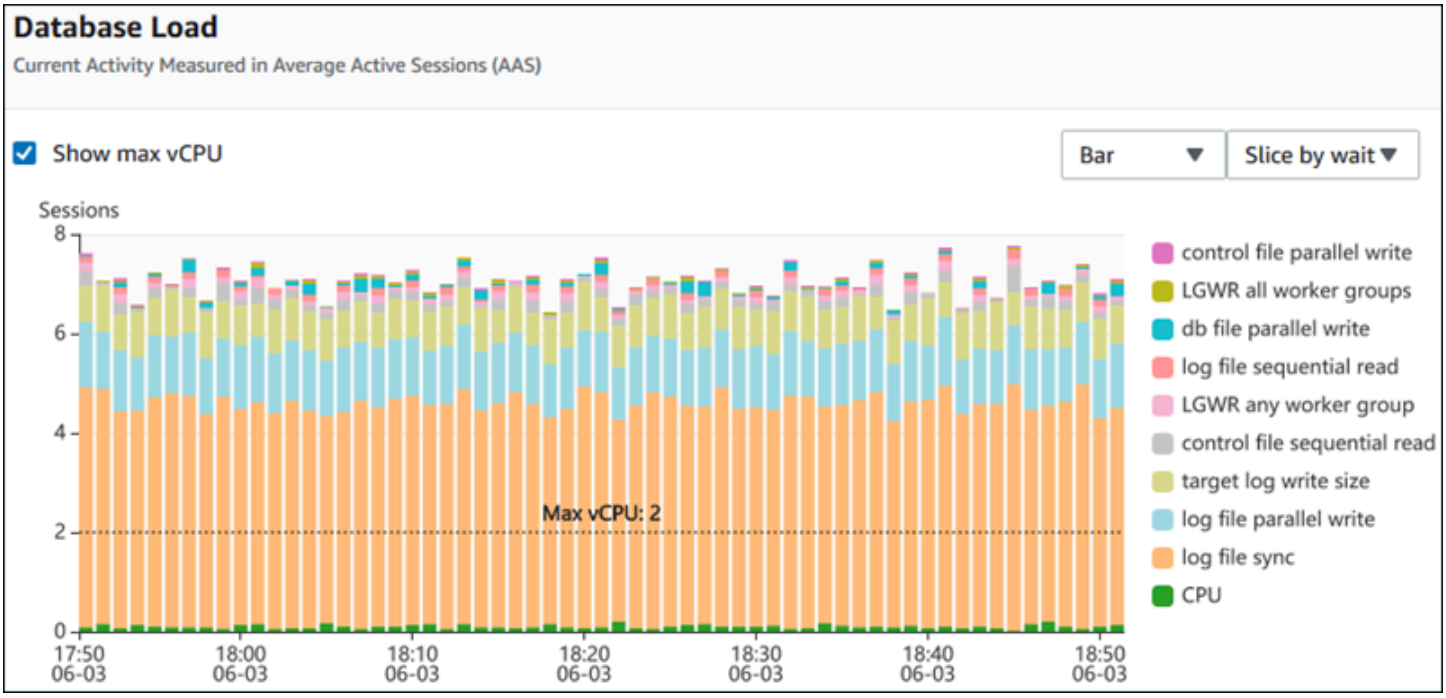
To change the performance counters, choose **Manage Metrics**. You can select multiple **OS metrics** or **Database metrics**, as shown in the following screenshot. To see details for any metric, hover over the metric name.



For descriptions of the counter metrics that you can add for each DB engine, see Performance Insights counter metrics.

Database load chart

The **Database load** chart shows how the database activity compares to DB instance capacity as represented by the **Max vCPU** line. By default, the stacked line chart represents DB load as average active sessions per unit of time. The DB load is sliced (grouped) by wait states.

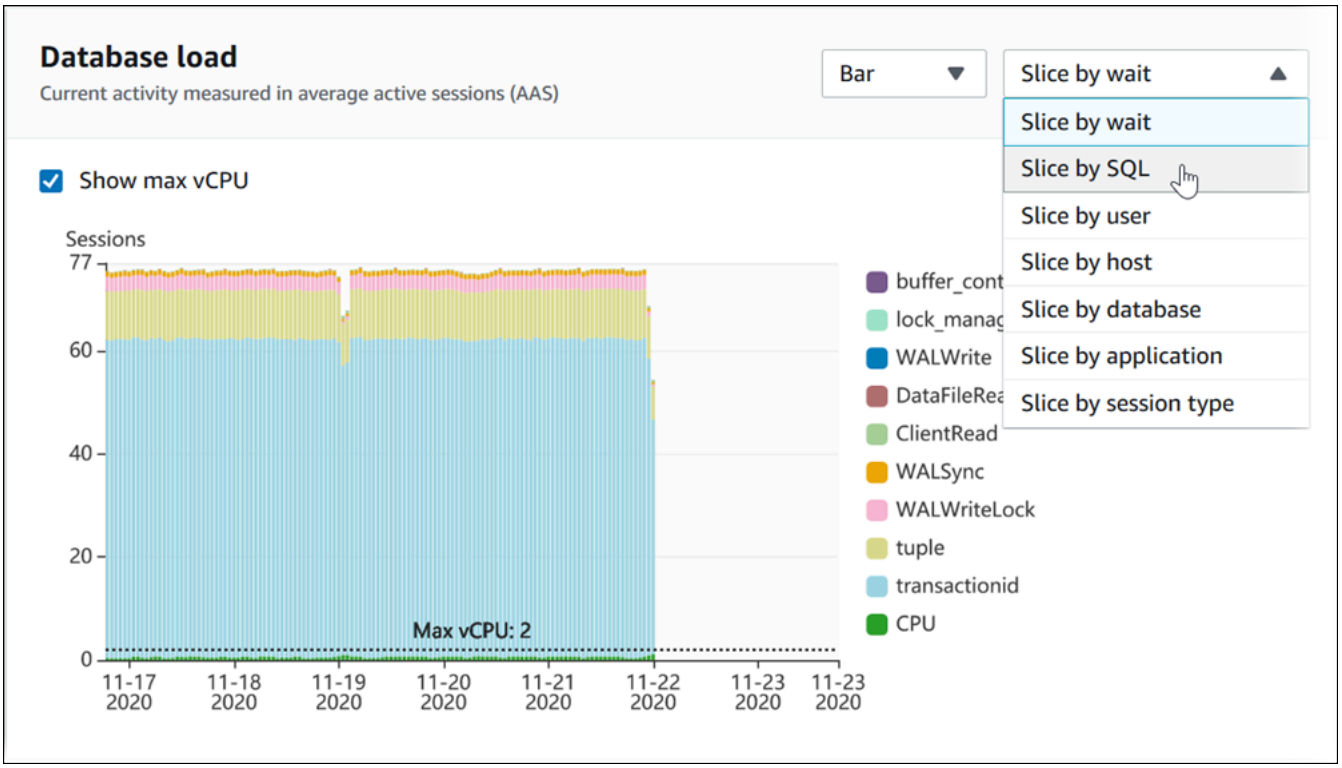


DB load sliced by dimensions

You can choose to display load as active sessions grouped by any supported dimensions. The following table shows which dimensions are supported for the different engines.

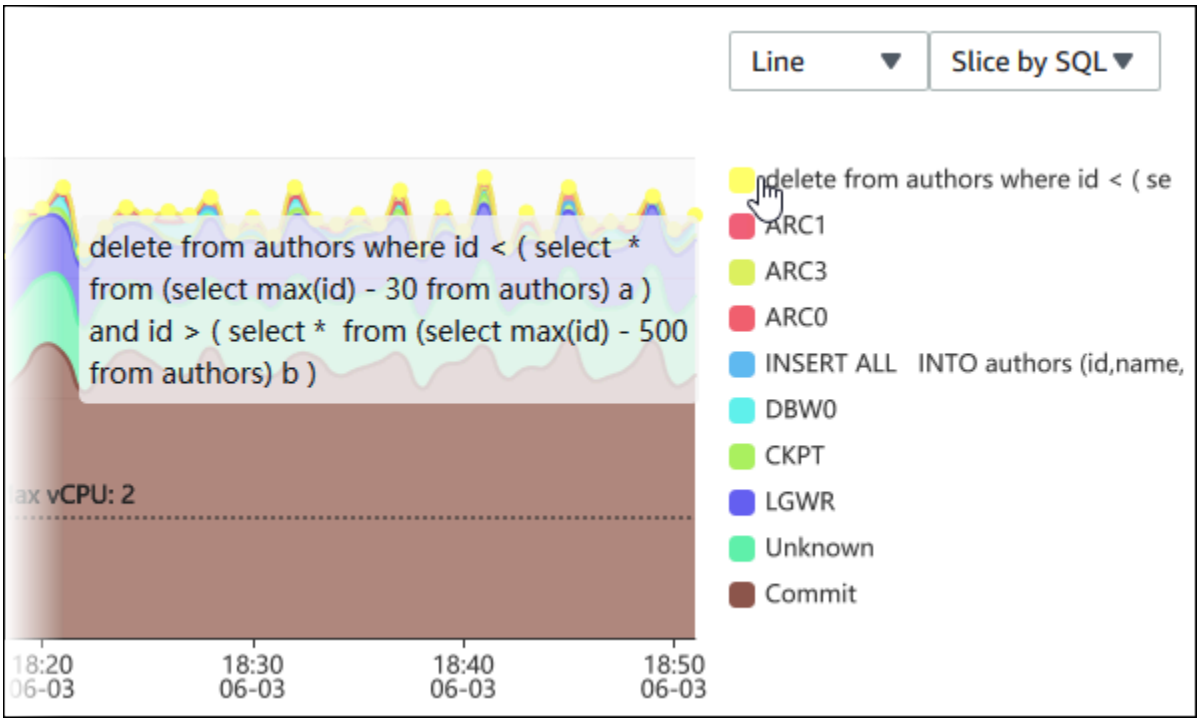
Dimension	Oracle	SQL Server	PostgreSQL	MySQL
Host	Yes	Yes	Yes	Yes
SQL	Yes	Yes	Yes	Yes
User	Yes	Yes	Yes	Yes
Waits	Yes	Yes	Yes	Yes
Plans	Yes	No	No	No
Application	No	No	Yes	No
Database	No	No	Yes	Yes
Session type	No	No	Yes	No

The following image shows the dimensions for a PostgreSQL DB instance.

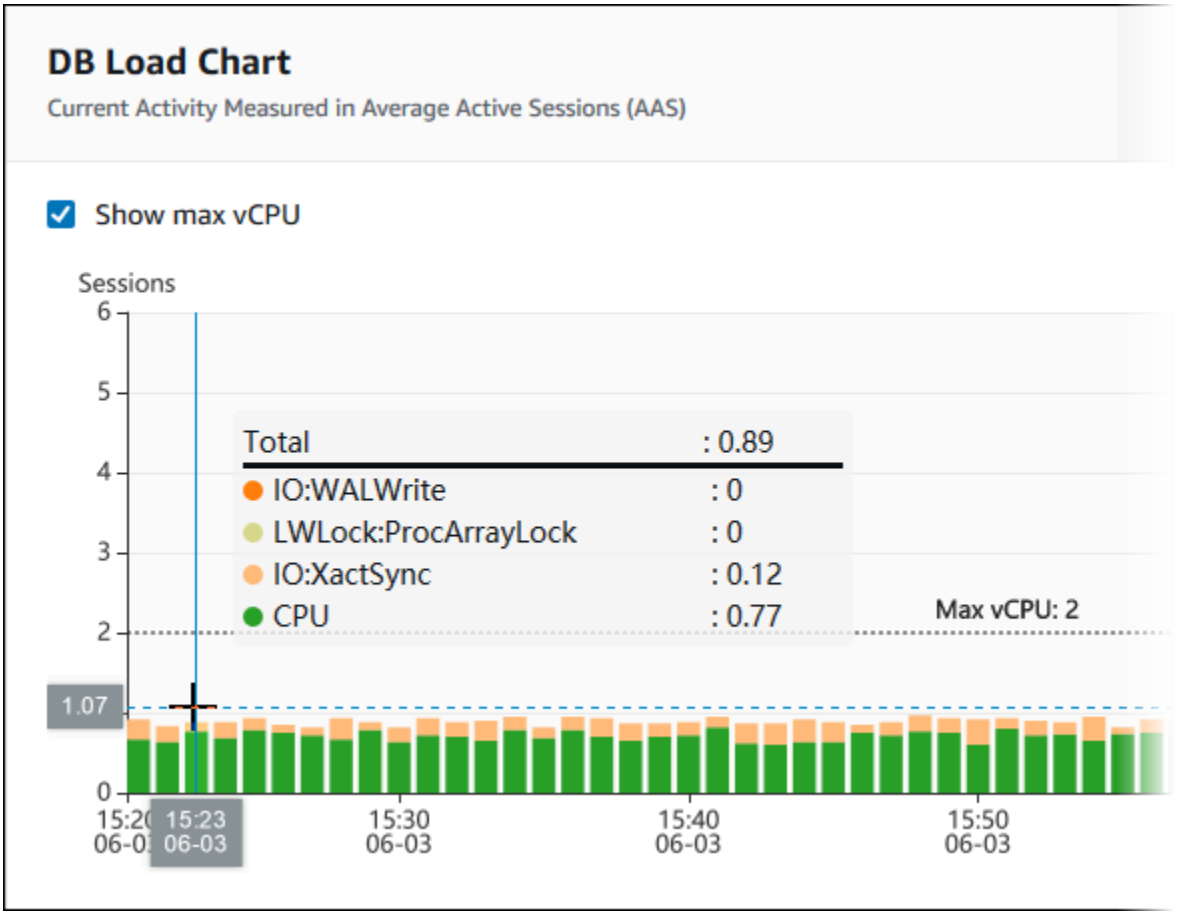


DB load details for a dimension item

To see details about a DB load item within a dimension, hover over the item name. The following image shows details for a SQL statement.

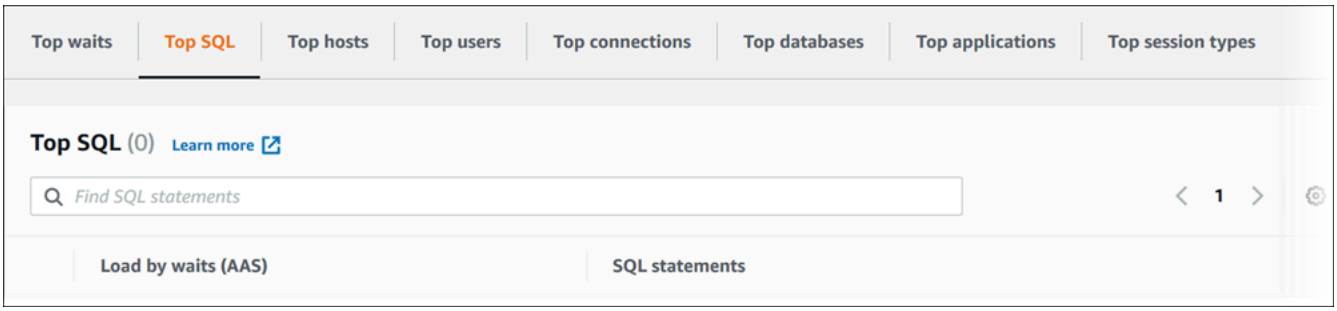


To see details for any item for the selected time period in the legend, hover over that item.



Top dimensions table

The Top dimensions table slices DB load by different dimensions. A dimension is a category or "slice by" for different characteristics of DB load. If the dimension is SQL, **Top SQL** shows the SQL statements that contribute the most to DB load.



Choose any of the following dimension tabs.

Tab	Description	Supported engines
Top SQL	The SQL statements that are currently running	All
Top waits	The event for which the database backend is waiting	All
Top hosts	The host name of the connected client	All
Top users	The user logged in to the database	All
Top databases	The name of the database to which the client is connected	PostgreSQL, MySQL, MariaDB, and SQL Server only
Top applications	The name of the application that is connected to the database	PostgreSQL and SQL Server only
Top session types	The type of the current session	PostgreSQL only

To learn how to analyze queries by using the **Top SQL** tab, see Overview of the Top SQL tab.

Accessing the Performance Insights dashboard

Amazon RDS provides a consolidated view of Performance Insights and CloudWatch metrics in the Performance Insights dashboard.

To access the Performance Insights dashboard, use the following procedure.

To view the Performance Insights dashboard in the AWS Management Console

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the left navigation pane, choose **Performance Insights**.
3. Choose a DB instance.

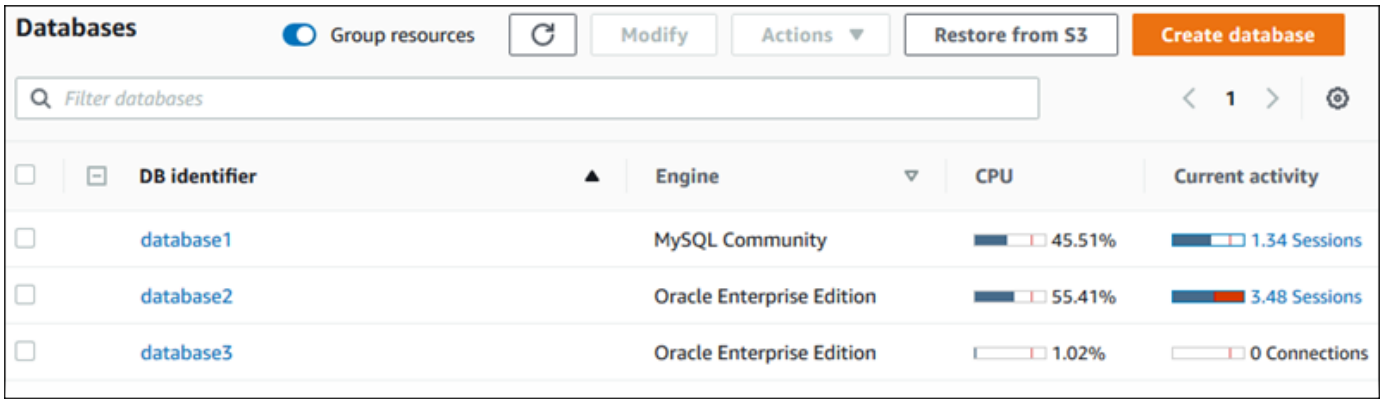
4. Choose the default monitoring view in the displayed window.

   - Select the **Performance Insights and CloudWatch metrics view (New)** option and choose **Continue** to view Performance Insights and CloudWatch metrics.
   - Select the **Performance Insights view** option and choose **Continue** for the legacy monitoring view. Then, continue with this procedure.

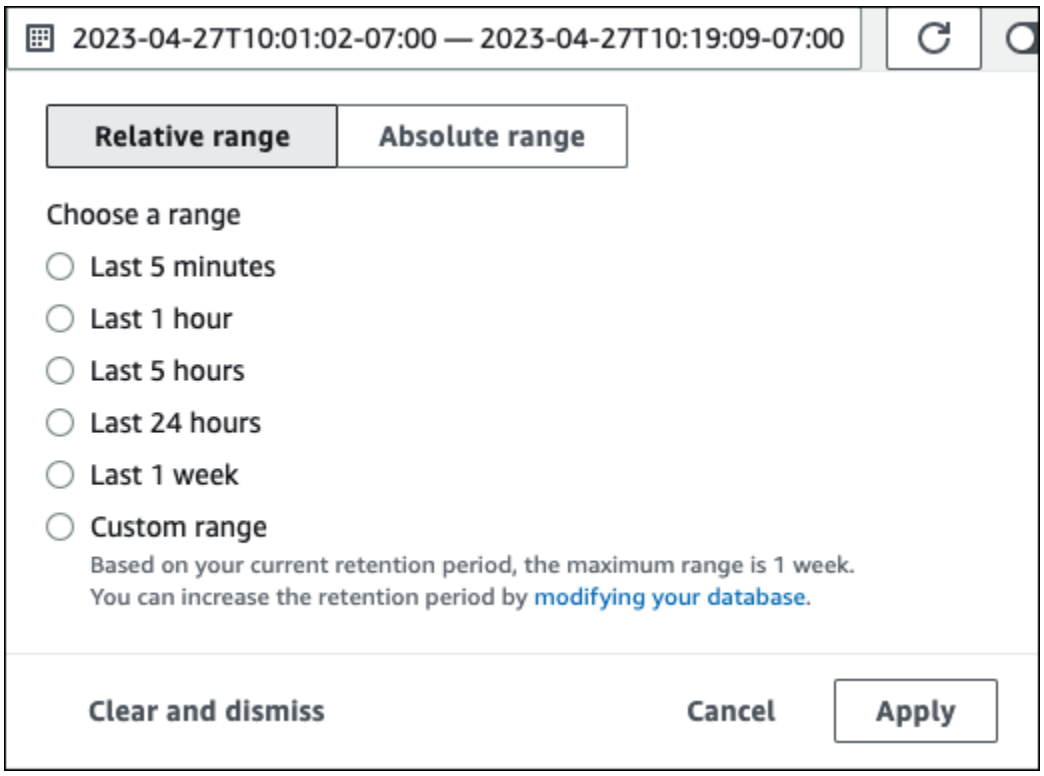
   > **Note**
   >
   > This view will be discontinued on December 15, 2023.

   The Performance Insights dashboard appears for the DB instance.

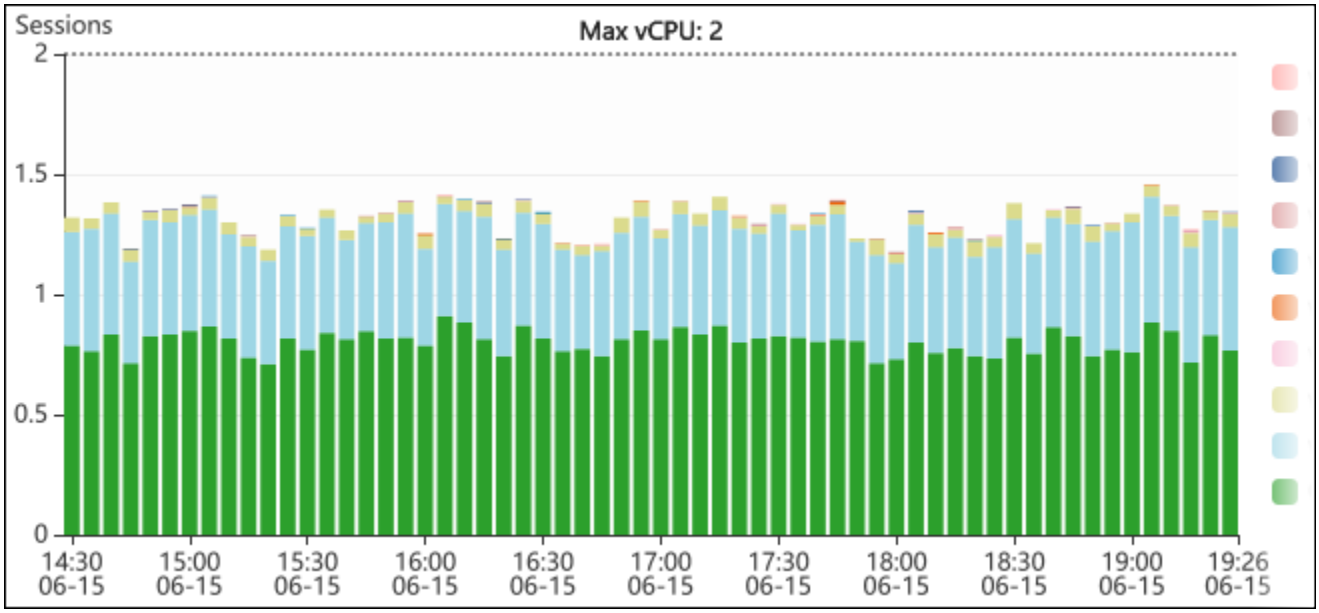
   For DB instances with Performance Insights turned on, you can also access the dashboard by choosing the **Sessions** item in the list of DB instances. Under **Current activity**, the **Sessions** item shows the database load in average active sessions over the last five minutes. The bar graphically shows the load. When the bar is empty, the DB instance is idle. As the load increases, the bar fills with blue. When the load passes the number of virtual CPUs (vCPUs) on the DB instance class, the bar turns red, indicating a potential bottleneck.



5. (Optional) Choose the date or time range in the upper right and specify a different relative or absolute time interval. You can now specify a time period, and generate a database performance analysis report. The report provides the identified insights and recommendations. For more information, see Creating a performance analysis report in Performance Insights.

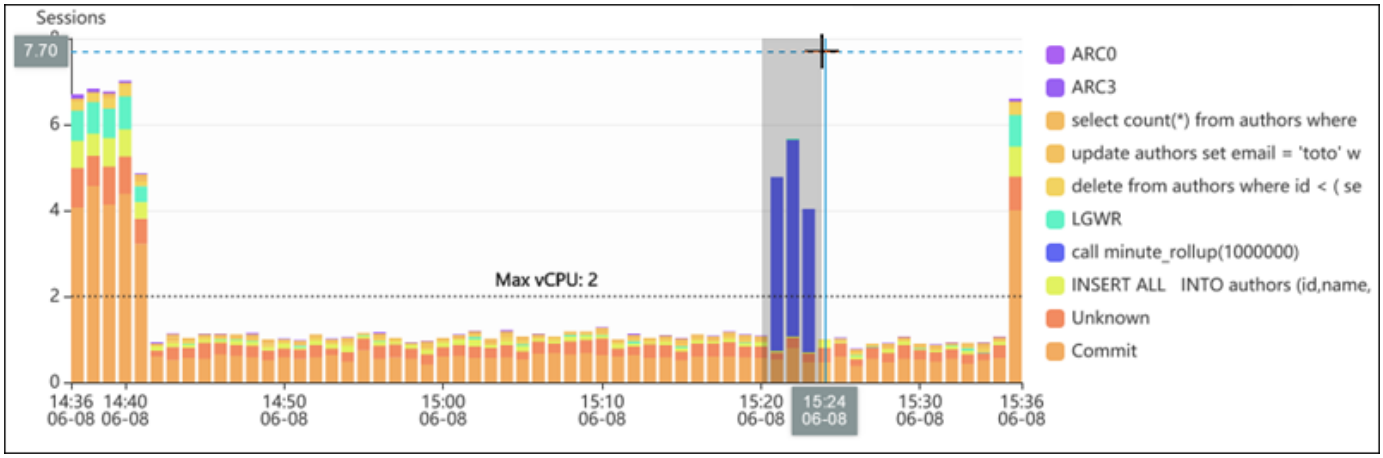


In the following screenshot, the DB load interval is 5 hours.

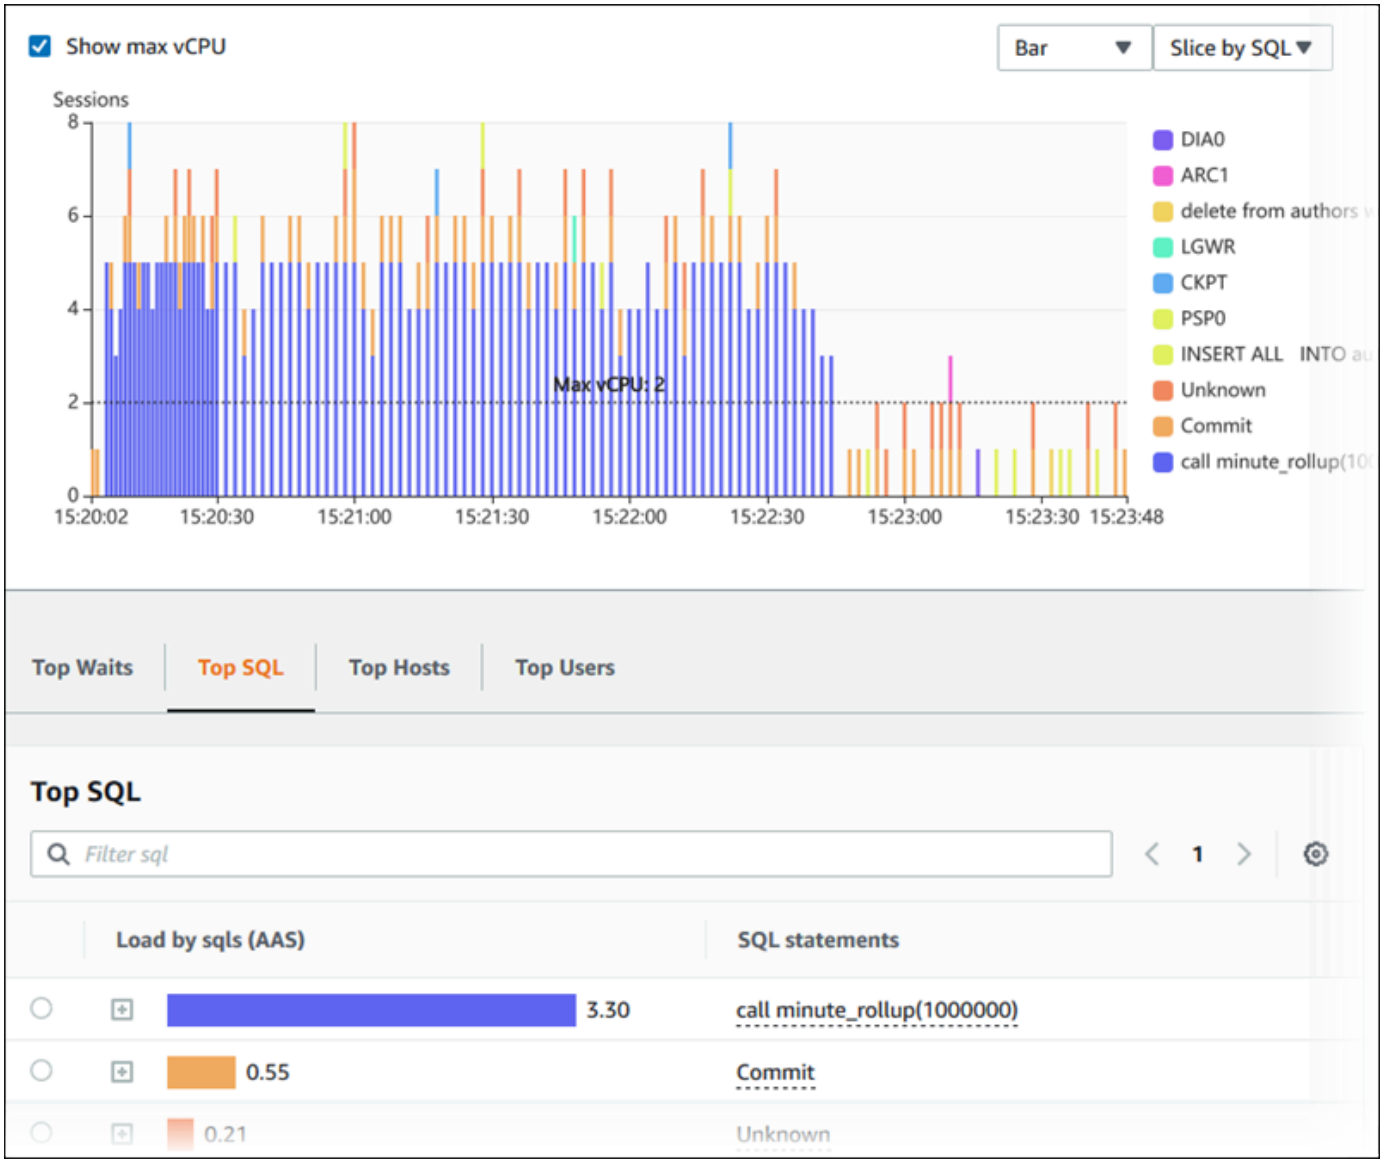


6. (Optional) To zoom in on a portion of the DB load chart, choose the start time and drag to the end of the time period you want.

   The selected area is highlighted in the DB load chart.



When you release the mouse, the DB load chart zooms in on the selected AWS Region, and the **Top *dimensions*** table is recalculated.



7. (Optional) To refresh your data automatically, select **Auto refresh**.

The Performance Insights dashboard automatically refreshes with new data. The refresh rate depends on the amount of data displayed:

- 5 minutes refreshes every 10 seconds.
- 1 hour refreshes every 5 minutes.
- 5 hours refreshes every 5 minutes.
- 24 hours refreshes every 30 minutes.
- 1 week refreshes every day.

- 1 month refreshes every day.

Analyzing DB load by wait events

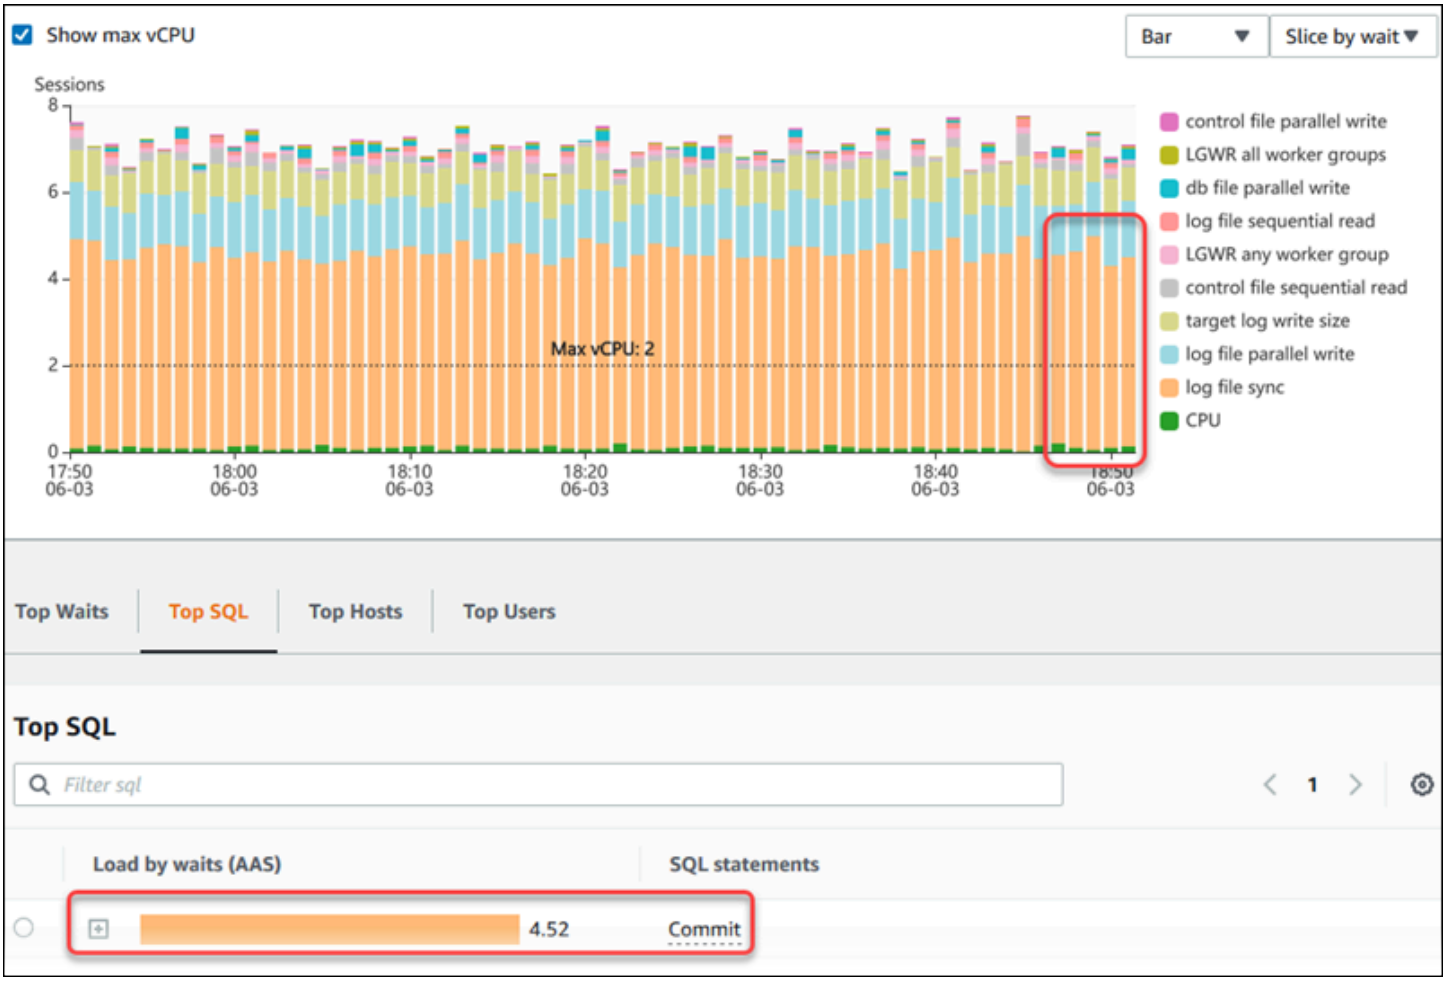
If the **Database load** chart shows a bottleneck, you can find out where the load is coming from. To do so, look at the top load items table below the **Database load** chart. Choose a particular item, like a SQL query or a user, to drill down into that item and see details about it.

DB load grouped by waits and top SQL queries is the default Performance Insights dashboard view. This combination typically provides the most insight into performance issues. DB load grouped by waits shows if there are any resource or concurrency bottlenecks in the database. In this case, the **SQL** tab of the top load items table shows which queries are driving that load.

Your typical workflow for diagnosing performance issues is as follows:

1. Review the **Database load** chart and see if there are any incidents of database load exceeding the **Max CPU** line.
2. If there is, look at the **Database load** chart and identify which wait state or states are primarily responsible.
3. Identify the digest queries causing the load by seeing which of the queries the **SQL** tab on the top load items table are contributing most to those wait states. You can identify these by the **DB Load by Wait** column.
4. Choose one of these digest queries in the **SQL** tab to expand it and see the child queries that it is composed of.

For example, in the dashboard following, **log file sync** waits account for most of the DB load. The **LGWR all worker groups** wait is also high. The **Top SQL** chart shows what is causing the **log file sync** waits: frequent `COMMIT` statements. In this case, committing less frequently will reduce DB load.



Analyzing database performance for a period of time

Analyze database performance with on-demand analysis by creating a performance analysis report for a period of time. View performance analysis reports to find performance issues, such as resource bottlenecks or changes in a query in your DB instance. The Performance Insights dashboard allows you to select a time period and create a performance analysis report. You can also add one or more tags to the report.

To use this feature, you must be using the paid tier retention period. For more information, see Pricing and data retention for Performance Insights

The report is available in the **Performance analysis reports - new** tab to select and view. The report contains the insights, related metrics, and recommendations to resolve the performance issue. The report is available to view for the duration of Performance Insights retention period.

The report is deleted if the start time of the report analysis period is outside of the retention period. You can also delete the report before the retention period ends.

To detect the performance issues and generate the analysis report for your DB instance, you must turn on Performance Insights. For more information about turning on Performance Insights, see Turning Performance Insights on and off for Amazon RDS.

For the region, DB engine, and instance class support information for this feature, see Amazon RDS DB engine, Region, and instance class support for Performance Insights features

In the following sections, you can create, view, add tags, and delete a performance analysis report.

Topics

- Creating a performance analysis report in Performance Insights
- Viewing a performance analysis report in Performance Insights
- Adding tags to a performance analysis report in Performance Insights
- Deleting a performance analysis report in Performance Insights

Creating a performance analysis report in Performance Insights

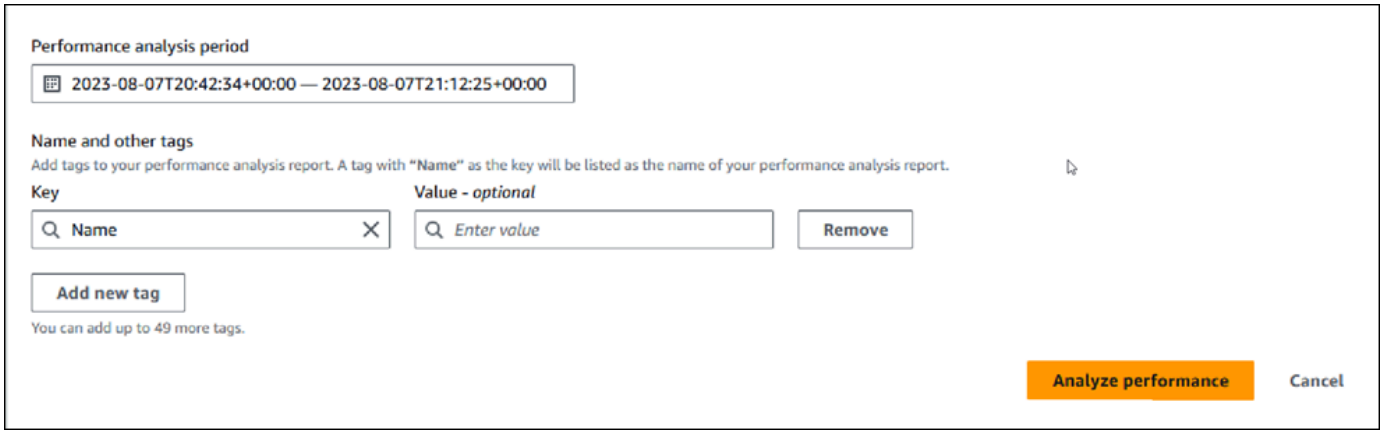
You can create a performance analysis report for a specific period in the Performance Insights dashboard. You can select a time period and add one or more tags to the analysis report.

The analysis period can range from 5 minutes to 6 days. There must be at least 24 hours of performance data before the analysis start time.

To create a performance analysis report for a time period

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the left navigation pane, choose **Performance Insights**.
3. Choose a DB instance.
4. Choose **Analyze performance** in **Database load** section on the Performance Insights dashboard.

   The fields to set the time period and add one or more tags to the performance analysis report are displayed.

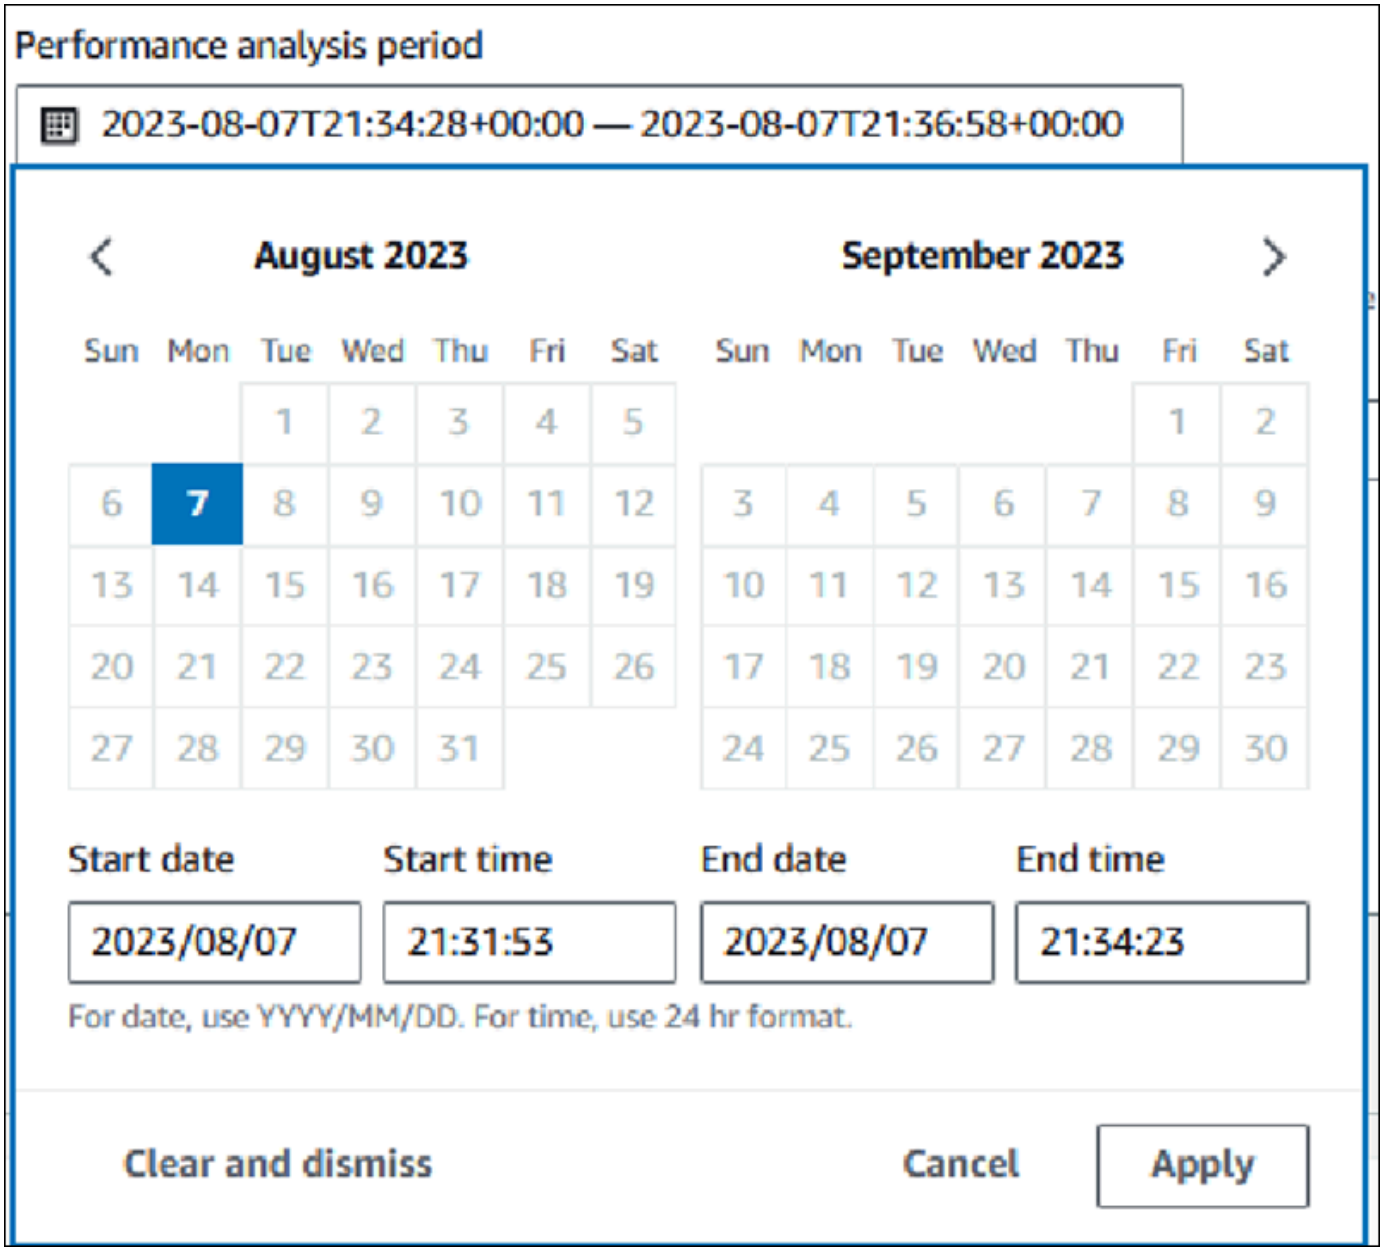


5. Choose the time period. If you set a time period in the **Relative range** or **Absolute range** in the upper right, you can only enter or select the analysis report date and time within this time period. If you select the analysis period outside of this time period, an error message displays.

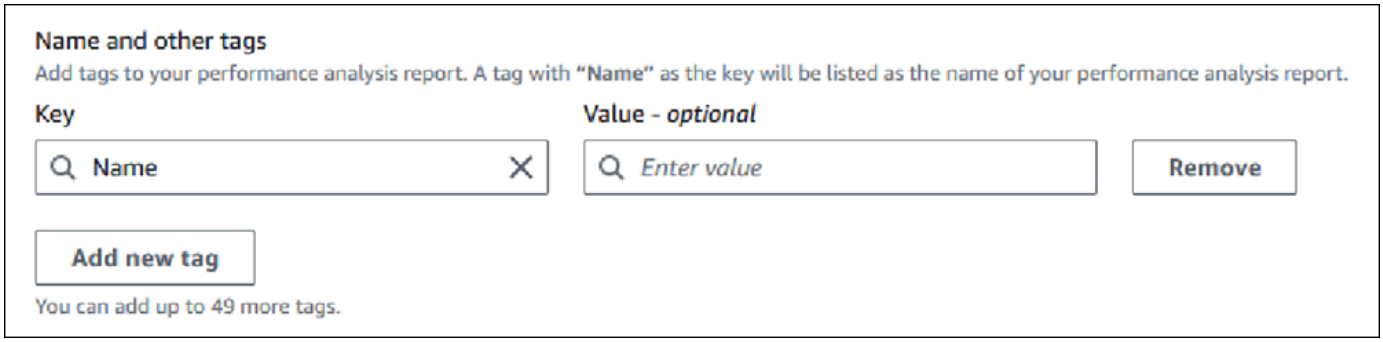
   To set the time period, you can do any of the following:

   - Press and drag any of the sliders on the DB load chart.

     The **Performance analysis period** box displays the selected time period and DB load chart highlights the selected time period.
   - Choose the **Start date**, **Start time**, **End date**, and **End time** in the **Performance analysis period** box.



6. (Optional) Enter **Key** and **Value-*optional*** to add a tag for the report.



7. Choose **Analyze performance**.

   A banner displays a message whether the report generation is successful or failed. The message also provides the link to view the report.

   The following example shows the banner with the report creation successful message.

   The report is available to view in **Performance analysis reports - new** tab.

You can create a performance analysis report using the AWS CLI. For an example on how to create a report using AWS CLI, see Creating a performance analysis report for a time period.

Viewing a performance analysis report in Performance Insights

The **Performance analysis reports - new** tab lists all the reports that are created for the DB instance. The following are displayed for each report:

- **ID**: Unique identifier of the report.
- **Name**: Tag key added to the report.
- **Report creation time**: Time you created the report.
- **Analysis start time**: Start time of the analysis in the report.
- **Analysis end time**: End time of the analysis in the report.

To view a performance analysis report

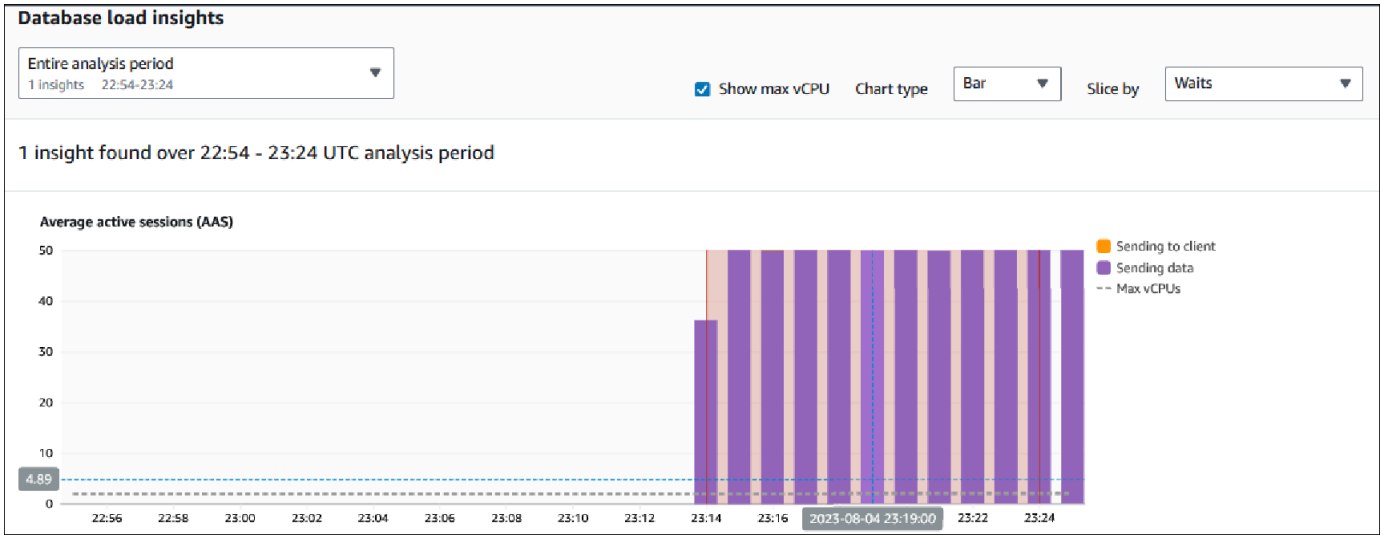
1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the left navigation pane, choose **Performance Insights**.
3. Choose a DB instance for which you want to view the analysis report.
4. Scroll down and choose **Performance analysis reports - new** tab in the Performance Insights dashboard.

   All the analysis reports for the different time periods are displayed.
5. Choose **ID** of the report you want to view.

The DB load chart displays the entire analysis period by default if more than one insight is identified. If the report has identified one insight then the DB load chart displays the insight by default.

The dashboard also lists the tags for the report in the **Tags** section.

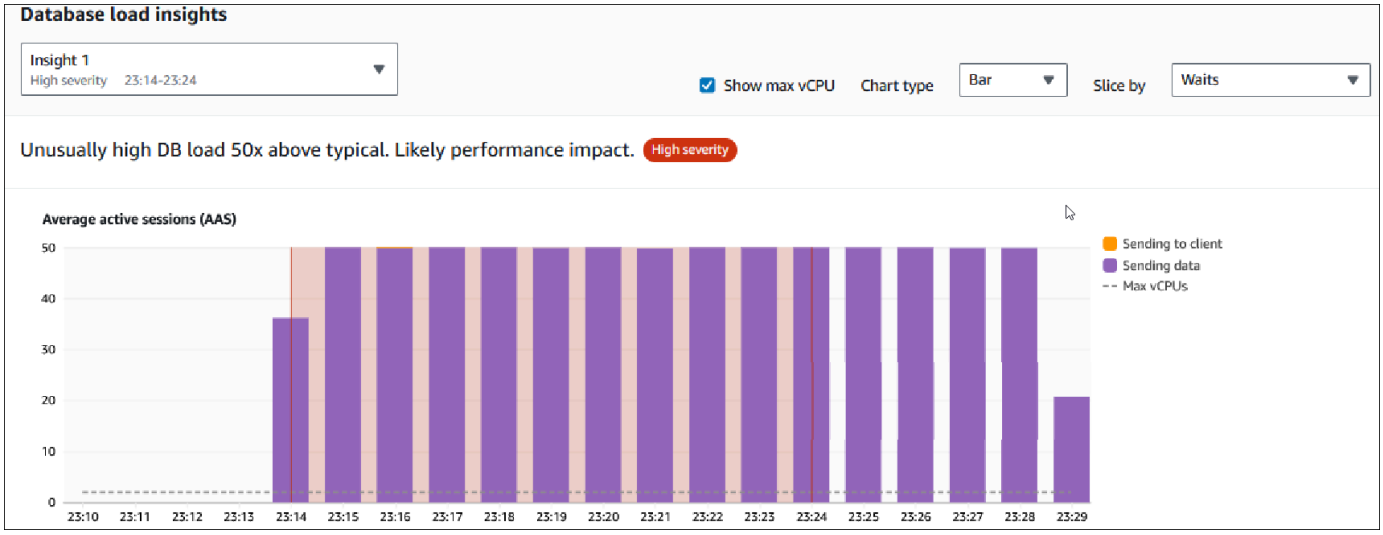
The following example shows the entire analysis period for the report.

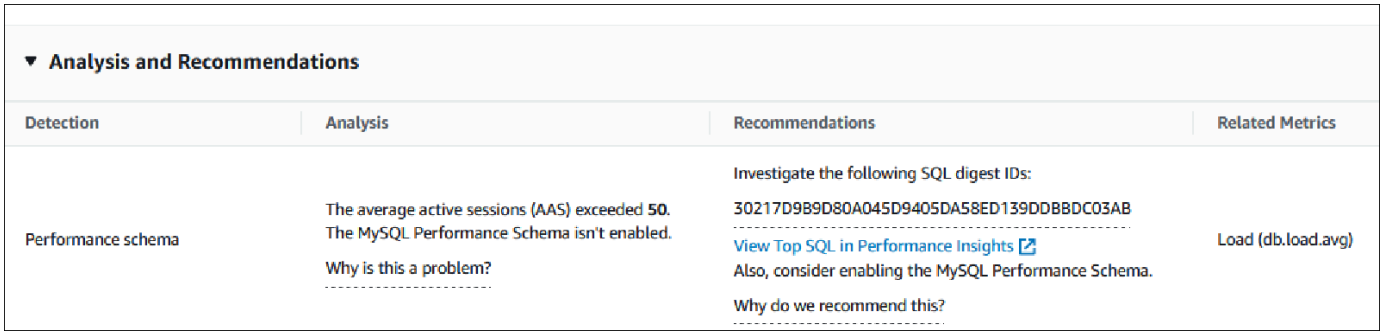


6. Choose the insight in the **Database load insights** list you want to view if more than one insight is identified in the report.

   The dashboard displays the insight message, DB load chart highlighting the time period of the insight, analysis and recommendations, and the list of report tags.

   The following example shows the DB load insight in the report.





Adding tags to a performance analysis report in Performance Insights

You can add a tag when you create or view a report. You can add up to 50 tags for a report.

You need permissions to add the tags. For more information about the access policies for Performance Insights, see Configuring access policies for Performance Insights

To add one or more tags while creating a report, see step 6 in the procedure Creating a performance analysis report in Performance Insights.

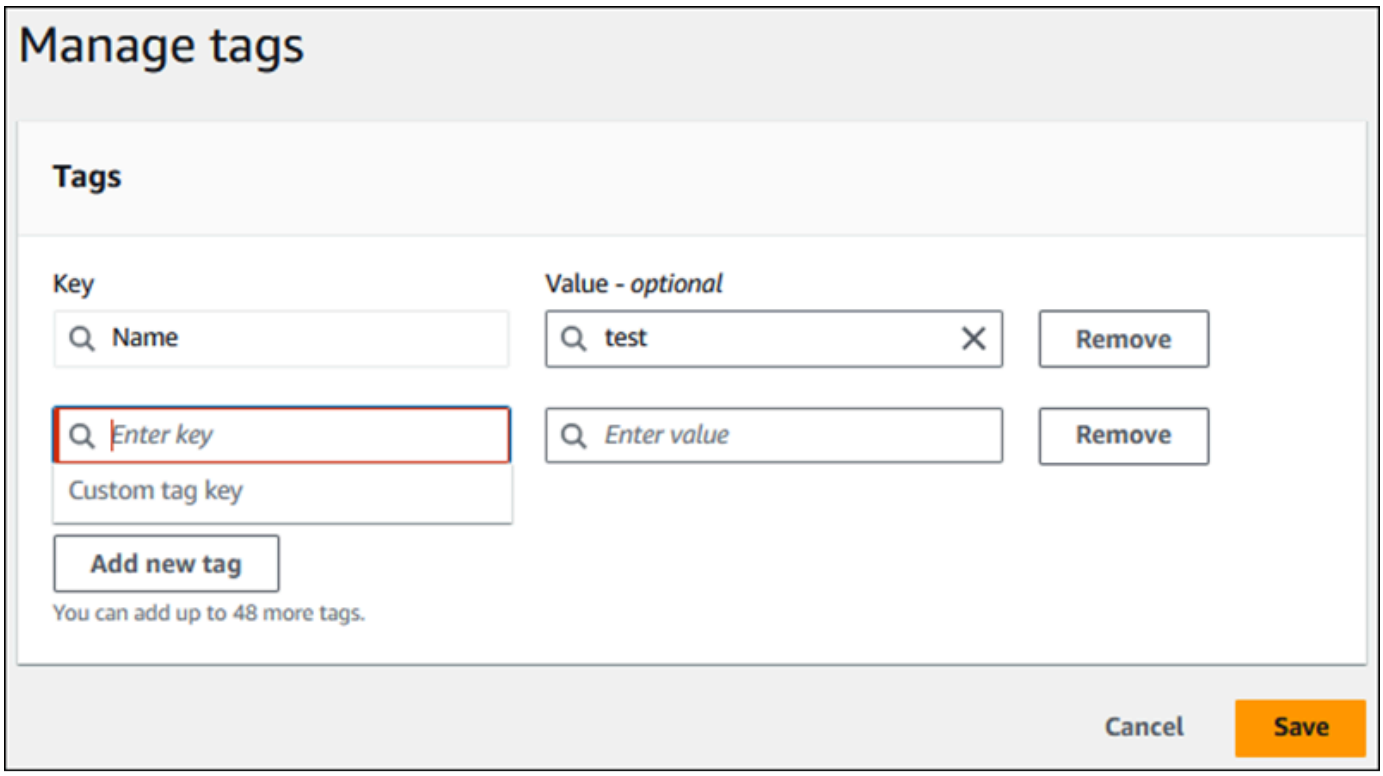
To add one or more tags when viewing a report

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the left navigation pane, choose **Performance Insights**.
3. Choose a DB instance.

   The Performance Insights dashboard appears for the DB instance.
4. Scroll down and choose **Performance analysis reports - new** tab.
5. Choose the report for which you want to add the tags.

   The dashboard displays the report.
6. Scroll down to **Tags** and choose **Manage tags**.
7. Choose **Add new tag**.
8. Enter the **Key** and **Value - *optional***, and choose **Add new tag**.

   The following example provides the option to add a new tag for the selected report.



A new tag is created for the report.

The list of tags for the report is displayed in the **Tags** section on the dashboard. If you want to remove a tag from the report, choose **Remove** next to the tag.

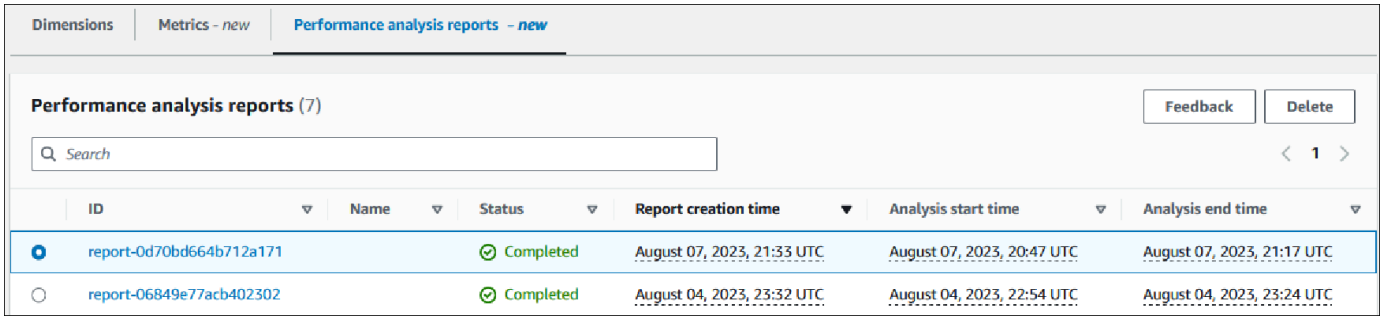
Deleting a performance analysis report in Performance Insights

You can delete a report from the list of reports displayed in the **Performance analysis reports** tab or while viewing a report.

To delete a report

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the left navigation pane, choose **Performance Insights**.
3. Choose a DB instance.

   The Performance Insights dashboard appears for the DB instance.
4. Scroll down and choose **Performance analysis reports - new** tab.
5. Select the report you want to delete and choose **Delete** in the upper right.



A confirmation window is displayed. The report is deleted after you choose confirm.

6. (Optional) Choose **ID** of the report you want to delete.

   In the report page, choose **Delete** in the upper right.

   A confirmation window is displayed. The report is deleted after you choose confirm.

Analyzing queries with the Top SQL tab in Performance Insights

In the Amazon RDS Performance Insights dashboard, you can find information about running and recent queries in the **Top SQL** tab in the **Top dimensions** table. You can use this information to tune your queries.

Topics

- Overview of the Top SQL tab
- Accessing more SQL text in the Performance Insights dashboard
- Viewing SQL statistics in the Performance Insights dashboard

Overview of the Top SQL tab

By default, the **Top SQL** tab shows the 25 queries that are contributing the most to DB load. To help tune your queries, you can analyze information such as the query text and SQL statistics. You can also choose the statistics that you want to appear in the **Top SQL** tab.

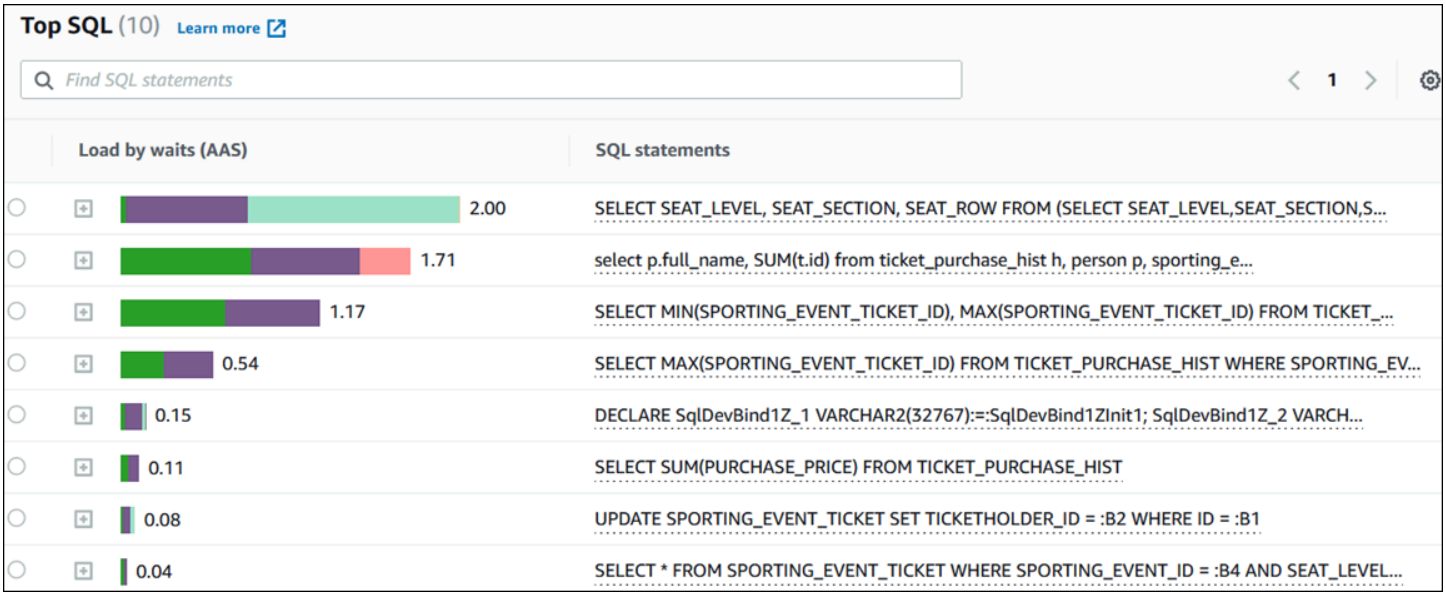
Topics

- SQL text
- SQL statistics
- Load by waits (AAS)

- View SQL information
- Choose statistics preferences

SQL text

By default, each row in the **Top SQL** table shows 500 bytes of text for each statement.

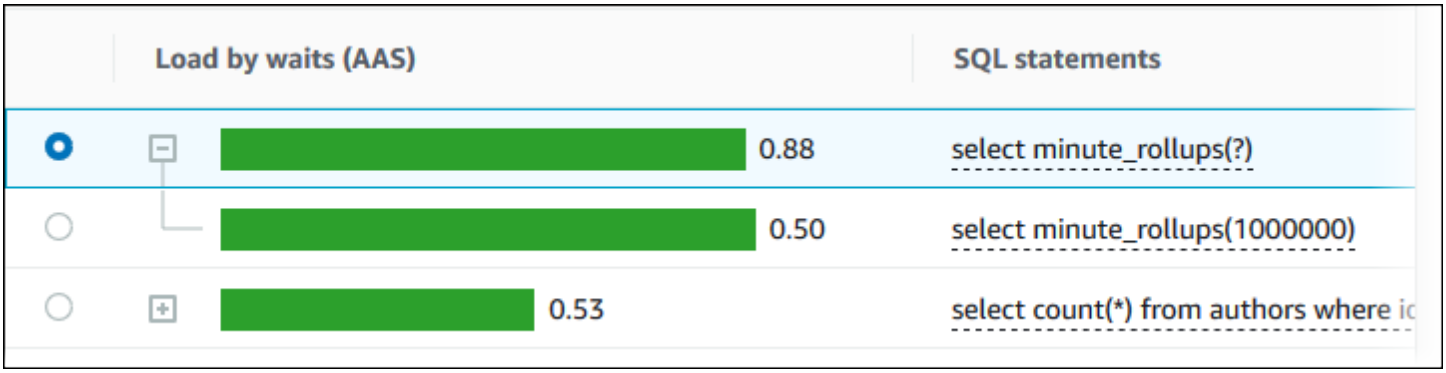


To learn how to see more than the default 500 bytes of SQL text, see Accessing more SQL text in the Performance Insights dashboard.

A *SQL digest* is a composite of multiple actual queries that are structurally similar but might have different literal values. The digest replaces hardcoded values with a question mark. For example, a digest might be `SELECT * FROM emp WHERE lname= ?`. This digest might include the following child queries:

```
SELECT * FROM emp WHERE lname = 'Sanchez'
SELECT * FROM emp WHERE lname = 'Olagappan'
SELECT * FROM emp WHERE lname = 'Wu'
```

To see the literal SQL statements in a digest, select the query, and then choose the plus symbol (+). In the following example, the selected query is a digest.



Note

A SQL digest groups similar SQL statements, but doesn't redact sensitive information.

Performance Insights can show Oracle SQL text as **Unknown**. The text has this status in the following situations:

- An Oracle database user other than SYS is active but not currently executing SQL. For example, when a parallel query completes, the query coordinator waits for helper processes to send their session statistics. For the duration of the wait, the query text shows **Unknown**.
- For an RDS for Oracle instance on Standard Edition 2, Oracle Resource Manager limits the number of parallel threads. The background process doing this work causes the query text to show as **Unknown**.

SQL statistics

SQL statistics are performance-related metrics about SQL queries. For example, Performance Insights might show executions per second or rows processed per second. Performance Insights collects statistics for only the most common queries. Typically, these match the top queries by load shown in the Performance Insights dashboard.

Every line in the **Top SQL** table shows relevant statistics for the SQL statement or digest, as shown in the following example.

Performance Insights can report `0.00` and `-` (unknown) for SQL statistics. This situation occurs under the following conditions:

- Only one sample exists. For example, Performance Insights calculates rates of change for RDS PostgreSQL queries based on multiple samples from the `pg_stat_statements` view. When a workload runs for a short time, Performance Insights might collect only one sample, which means that it can't calculate a rate of change. The unknown value is represented with a dash (`-`).
- Two samples have the same values. Performance Insights can't calculate a rate of change because no change has occurred, so it reports the rate as `0.00`.
- An RDS PostgreSQL statement lacks a valid identifier. PostgreSQL creates a identifier for a statement only after parsing and analysis. Thus, a statement can exist in the PostgreSQL internal in-memory structures with no identifier. Because Performance Insights samples internal in-memory structures once per second, low-latency queries might appear for only a single sample. If the query identifier isn't available for this sample, Performance Insights can't associate this statement with its statistics. The unknown value is represented with a dash (`-`).

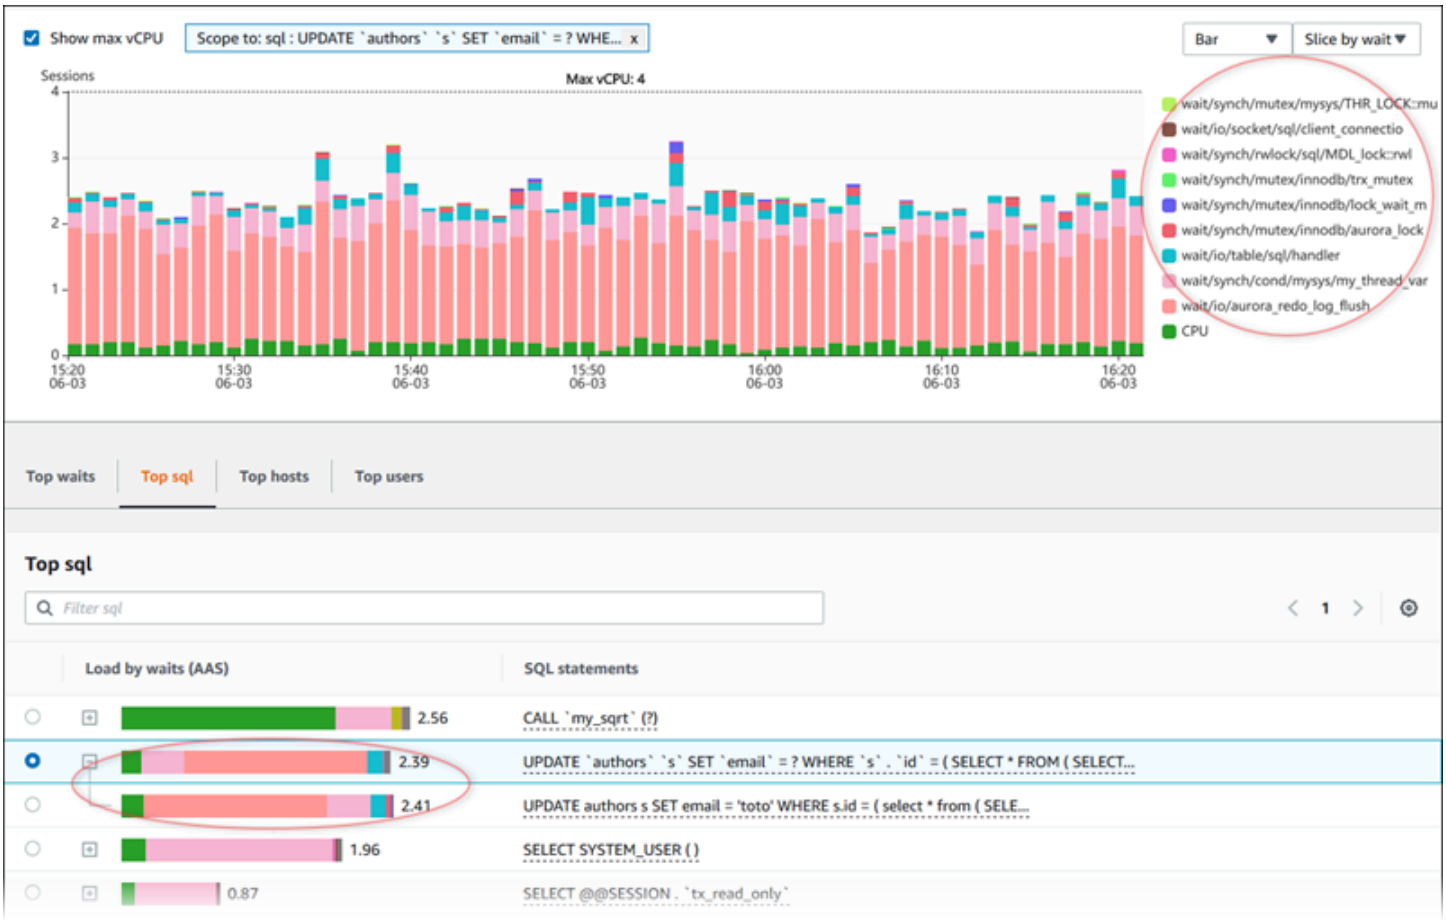
For a description of the SQL statistics for the Amazon RDS engines, see SQL statistics for Performance Insights.

Load by waits (AAS)

In **Top SQL**, the **Load by waits (AAS)** column illustrates the percentage of the database load associated with each top load item. This column reflects the load for that item by whatever grouping is currently selected in the **DB Load Chart**. For more information about Average active sessions (AAS), see Average active sessions.

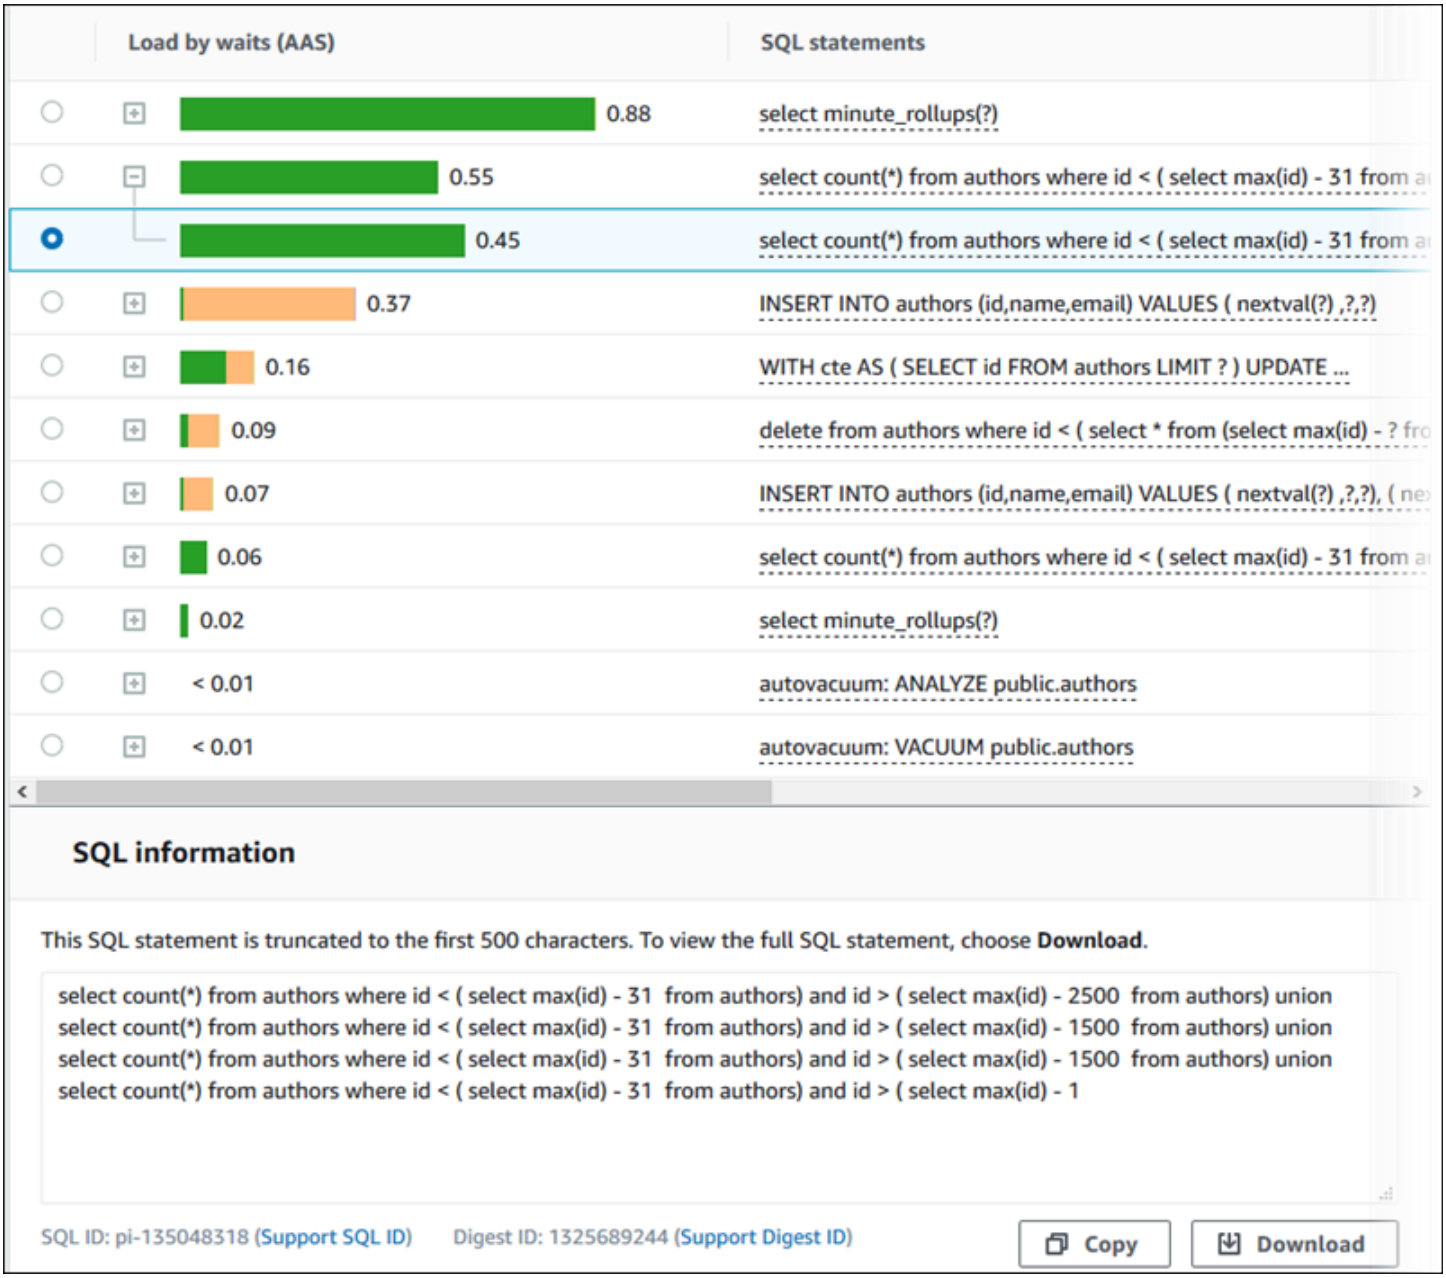
For example, you might group the **DB load** chart by wait states. You examine SQL queries in the top load items table. In this case, the **DB Load by Waits** bar is sized, segmented, and color-coded to

show how much of a given wait state that query is contributing to. It also shows which wait states are affecting the selected query.



View SQL information

In the **Top SQL** table, you can open a statement to view its information. The information appears in the bottom pane.

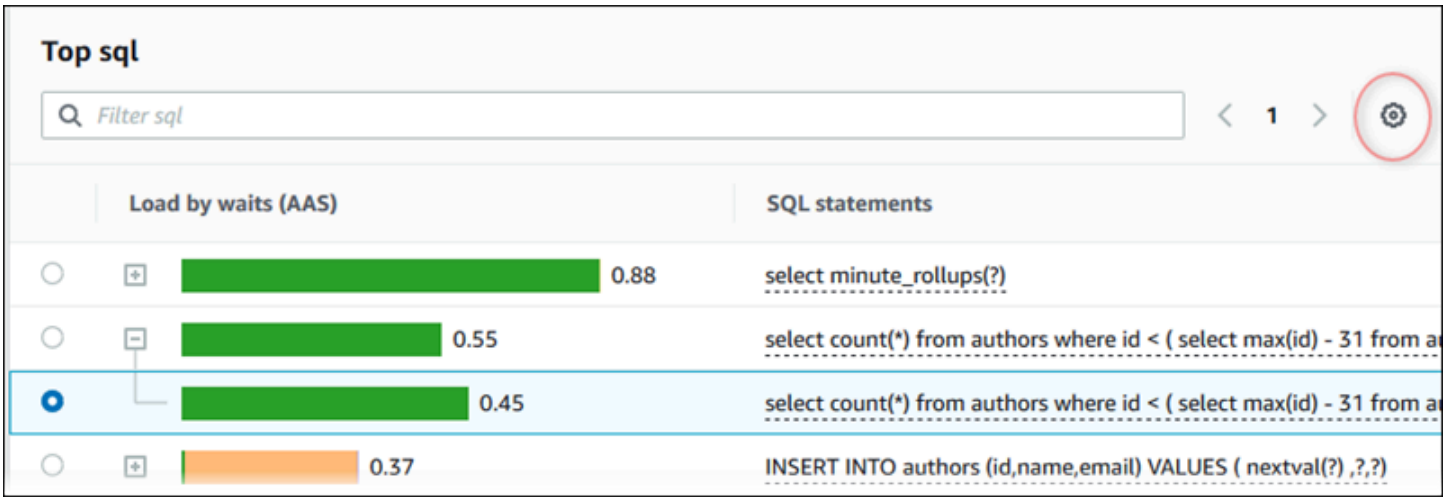


The following types of identifiers (IDs) that are associated with SQL statements:

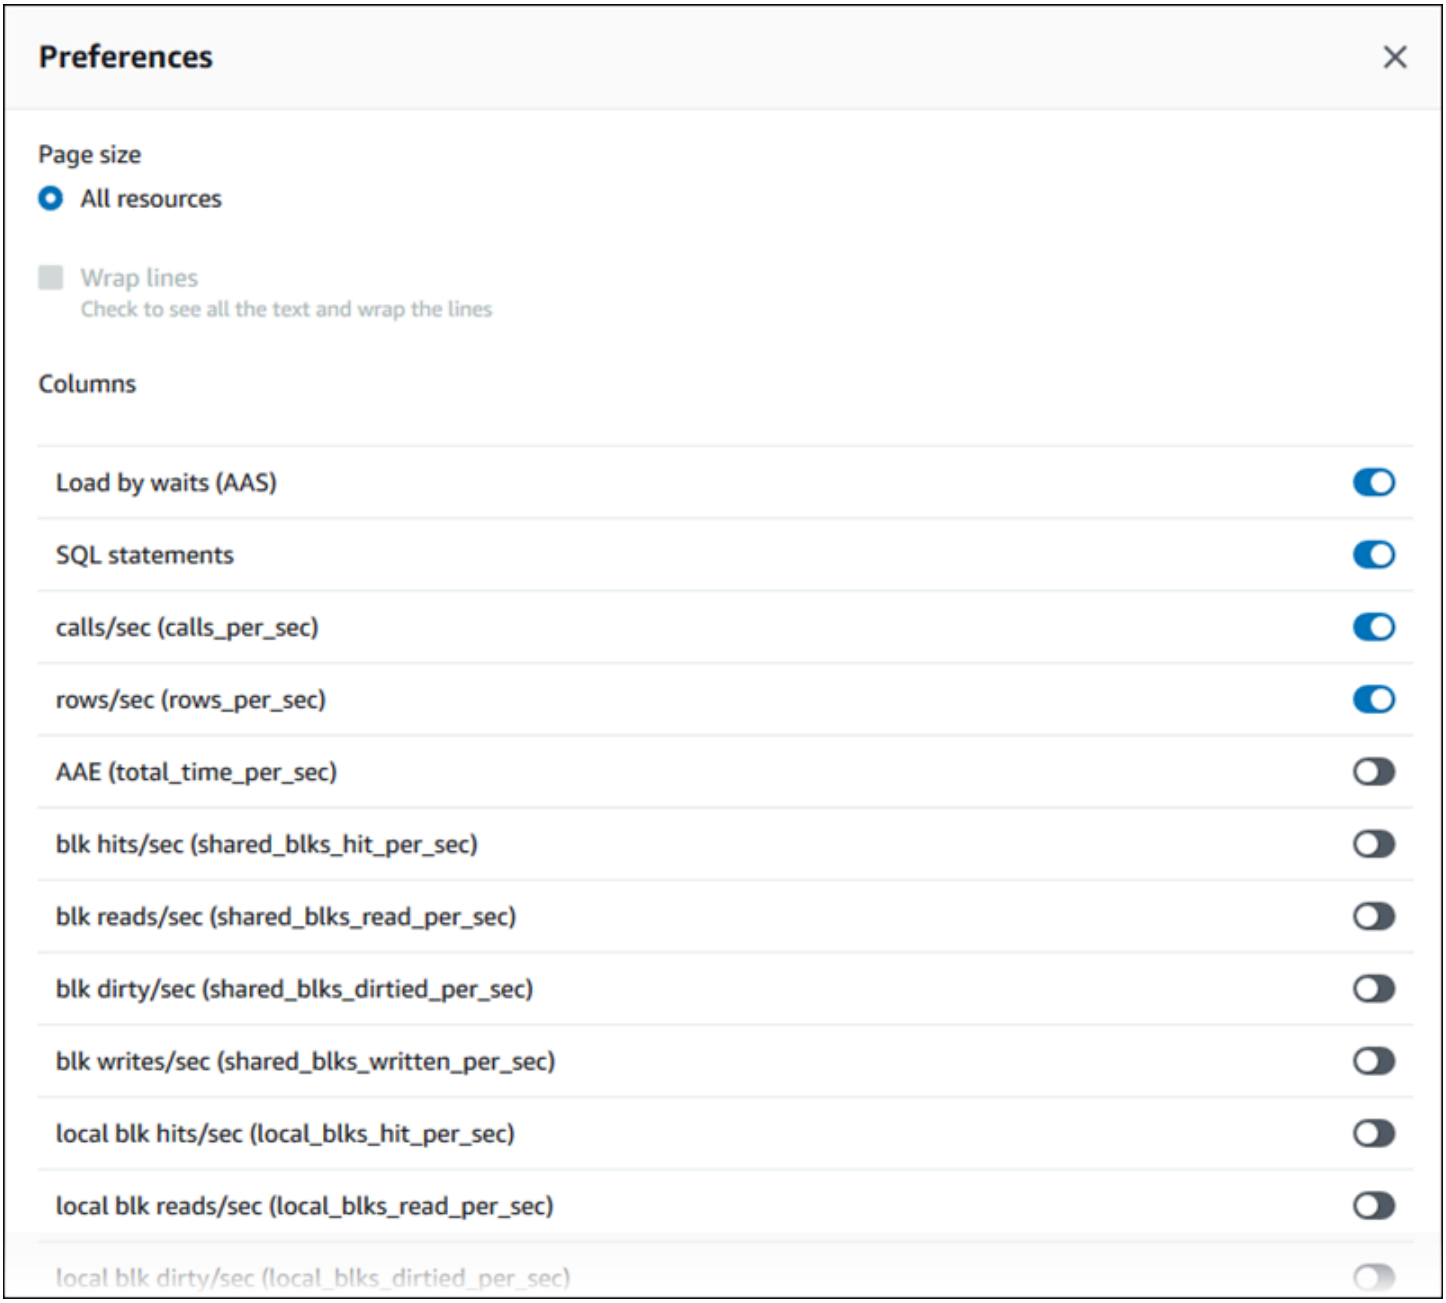
- **Support SQL ID** – A hash value of the SQL ID. This value is only for referencing a SQL ID when you are working with AWS Support. AWS Support doesn't have access to your actual SQL IDs and SQL text.
- **Support Digest ID** – A hash value of the digest ID. This value is only for referencing a digest ID when you are working with AWS Support. AWS Support doesn't have access to your actual digest IDs and SQL text.

Choose statistics preferences

You can control the statistics displayed in the **Top SQL** tab by choosing the **Preferences** icon.



When you choose the **Preferences** icon, the **Preferences** window opens. The following screenshot is an example of the **Preferences** window.



To enable the statistics that you want to appear in the **Top SQL** tab, use your mouse to scroll to the bottom of the window, and then choose **Continue**.

For more information about per-second or per-call statistics for the Amazon RDS engines, see the engine specific SQL statistics section in SQL statistics for Performance Insights

Accessing more SQL text in the Performance Insights dashboard

By default, each row in the **Top SQL** table shows 500 bytes of SQL text for each SQL statement.

When a SQL statement exceeds 500 bytes, you can view more text in the **SQL text** section below the **Top SQL** table. In this case, the maximum length for the text displayed in **SQL text** is 4 KB. This limit is introduced by the console and is subject to the limits set by the database engine. To save the text shown in **SQL text**, choose **Download**.

Topics

- Text size limits for Amazon RDS engines
- Setting the SQL text limit for Amazon RDS for PostgreSQL DB instances
- Viewing and downloading SQL text in the Performance Insights dashboard

Text size limits for Amazon RDS engines

When you download SQL text, the database engine determines its maximum length. You can download SQL text up to the following per-engine limits.

DB engine	Maximum length of downloaded text
Amazon RDS for MySQL and MariaDB	1,024 bytes
Amazon RDS for Microsoft SQL Server	4,096 characters
Amazon RDS for Oracle	1,000 bytes

The **SQL text** section of the Performance Insights console displays up to the maximum that the engine returns. For example, if MySQL returns at most 1 KB to Performance Insights, it can only collect and show 1 KB, even if the original query is larger. Thus, when you view the query in **SQL text** or download it, Performance Insights returns the same number of bytes.

If you use the AWS CLI or API, Performance Insights doesn't have the 4 KB limit enforced by the console. `DescribeDimensionKeys` and `GetResourceMetrics` return at most 500 bytes.

> **Note**
>
> `GetDimensionKeyDetails` returns the full query, but the size is subject to the engine limit.

Setting the SQL text limit for Amazon RDS for PostgreSQL DB instances

Amazon RDS for PostgreSQL handles text differently. You can set the text size limit with the DB instance parameter `track_activity_query_size`. This parameter has the following characteristics:

Default text size

On Amazon RDS for PostgreSQL version 9.6, the default setting for the `track_activity_query_size` parameter is 1,024 bytes. On Amazon RDS for PostgreSQL version 10 or higher, the default is 4,096 bytes.

Maximum text size

The limit for `track_activity_query_size` is 102,400 bytes for Amazon RDS for PostgreSQL version 12 and lower. The maximum is 1 MB for version 13 and higher.

If the engine returns 1 MB to Performance Insights, the console displays only the first 4 KB. If you download the query, you get the full 1 MB. In this case, viewing and downloading return different numbers of bytes. For more information about the `track_activity_query_size` DB instance parameter, see Run-time Statistics in the PostgreSQL documentation.

To increase the SQL text size, increase the `track_activity_query_size` limit. To modify the parameter, change the parameter setting in the parameter group that is associated with the Amazon RDS for PostgreSQL DB instance.

To change the setting when the instance uses the default parameter group

1. Create a new DB instance parameter group for the appropriate DB engine and DB engine version.
2. Set the parameter in the new parameter group.
3. Associate the new parameter group with the DB instance.

For information about setting a DB instance parameter, see Modifying parameters in a DB parameter group in Amazon RDS.

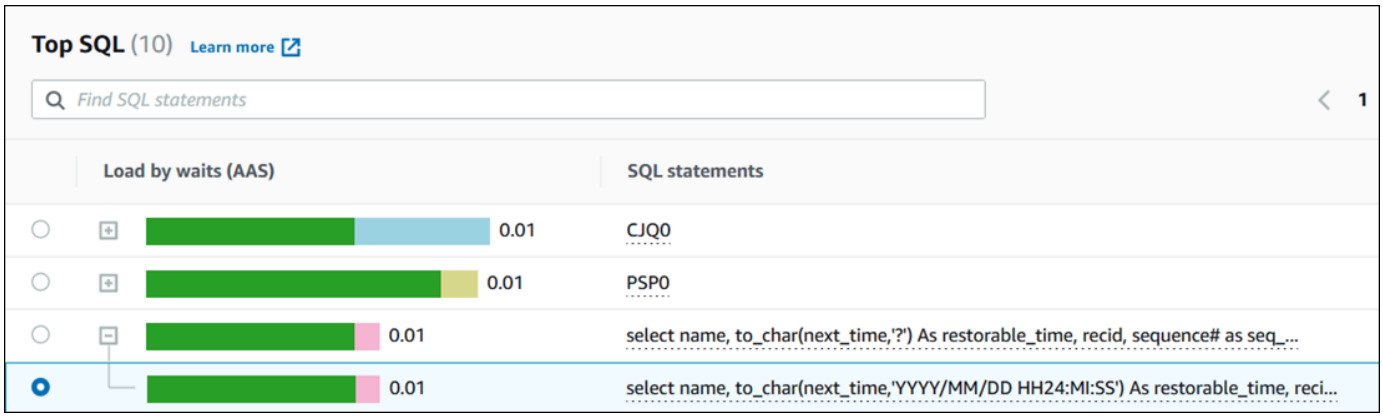
Viewing and downloading SQL text in the Performance Insights dashboard

In the Performance Insights dashboard, you can view or download SQL text.

To view more SQL text in the Performance Insights dashboard

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Performance Insights**.
3. Choose a DB instance.
4. Scroll down to the **Top SQL** tab in the Performance Insights dashboard.
5. Choose the plus sign to expand a SQL digest and choose one of the digest's child queries.

   SQL statements with text larger than 500 bytes look similar to the following image.



6. Scroll down to the **SQL text** tab.

   The Performance Insights dashboard can display up to 4,096 bytes for each SQL statement.

7. (Optional) Choose **Copy** to copy the displayed SQL statement, or choose **Download** to download the SQL statement to view the SQL text up to the DB engine limit.

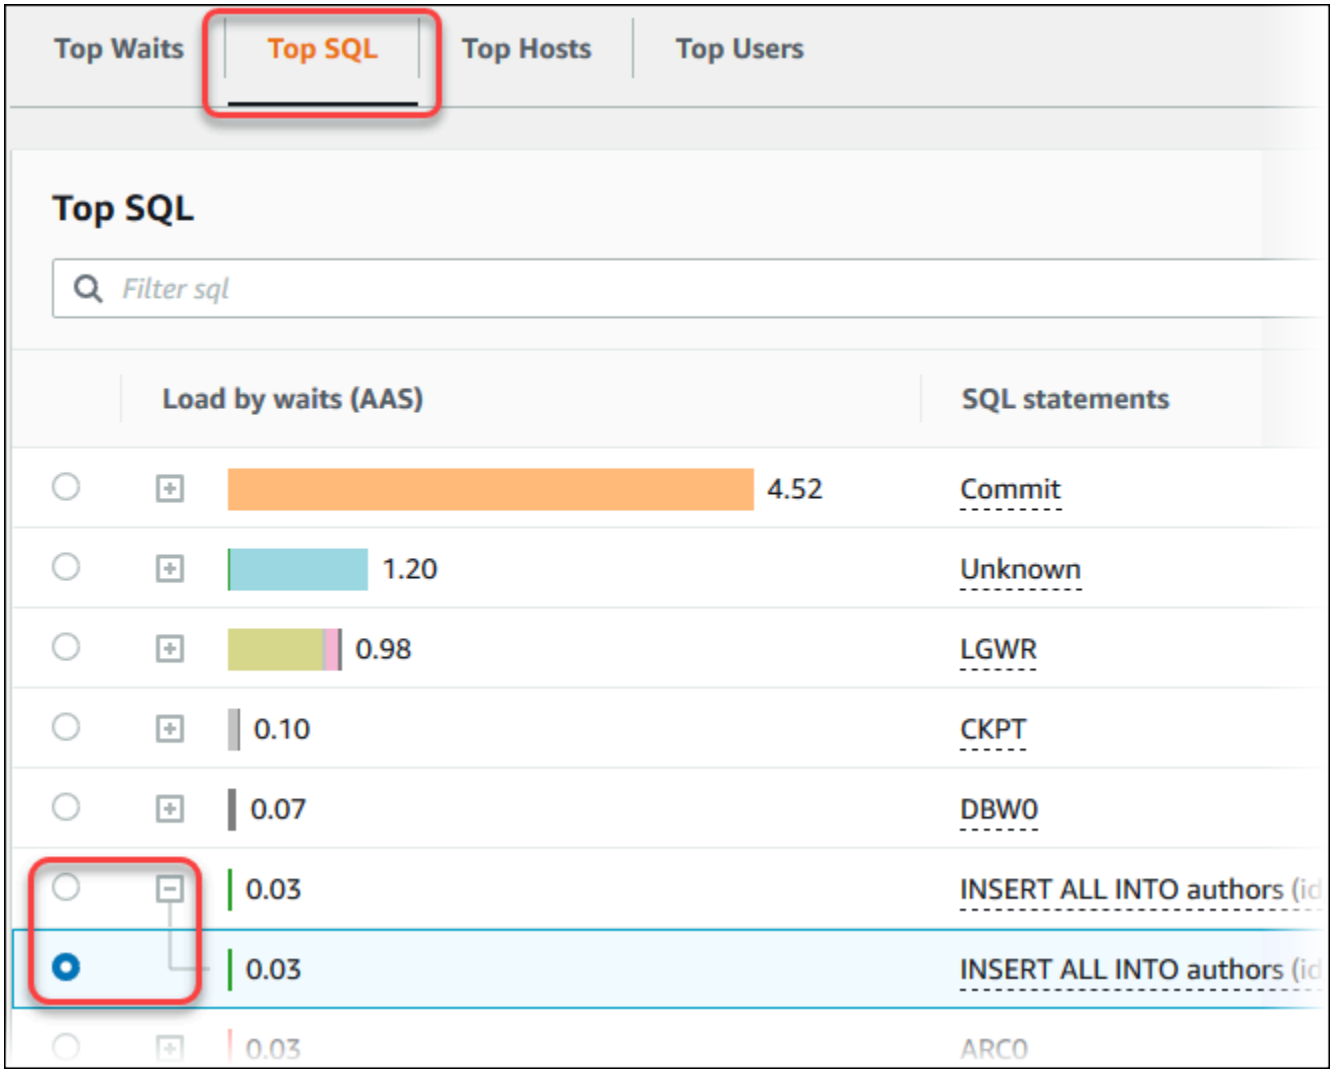
> **Note**
>
> To copy or download the SQL statement, disable pop-up blockers.

Viewing SQL statistics in the Performance Insights dashboard

In the Performance Insights dashboard, SQL statistics are available in the **Top SQL** tab of the **Database load** chart.

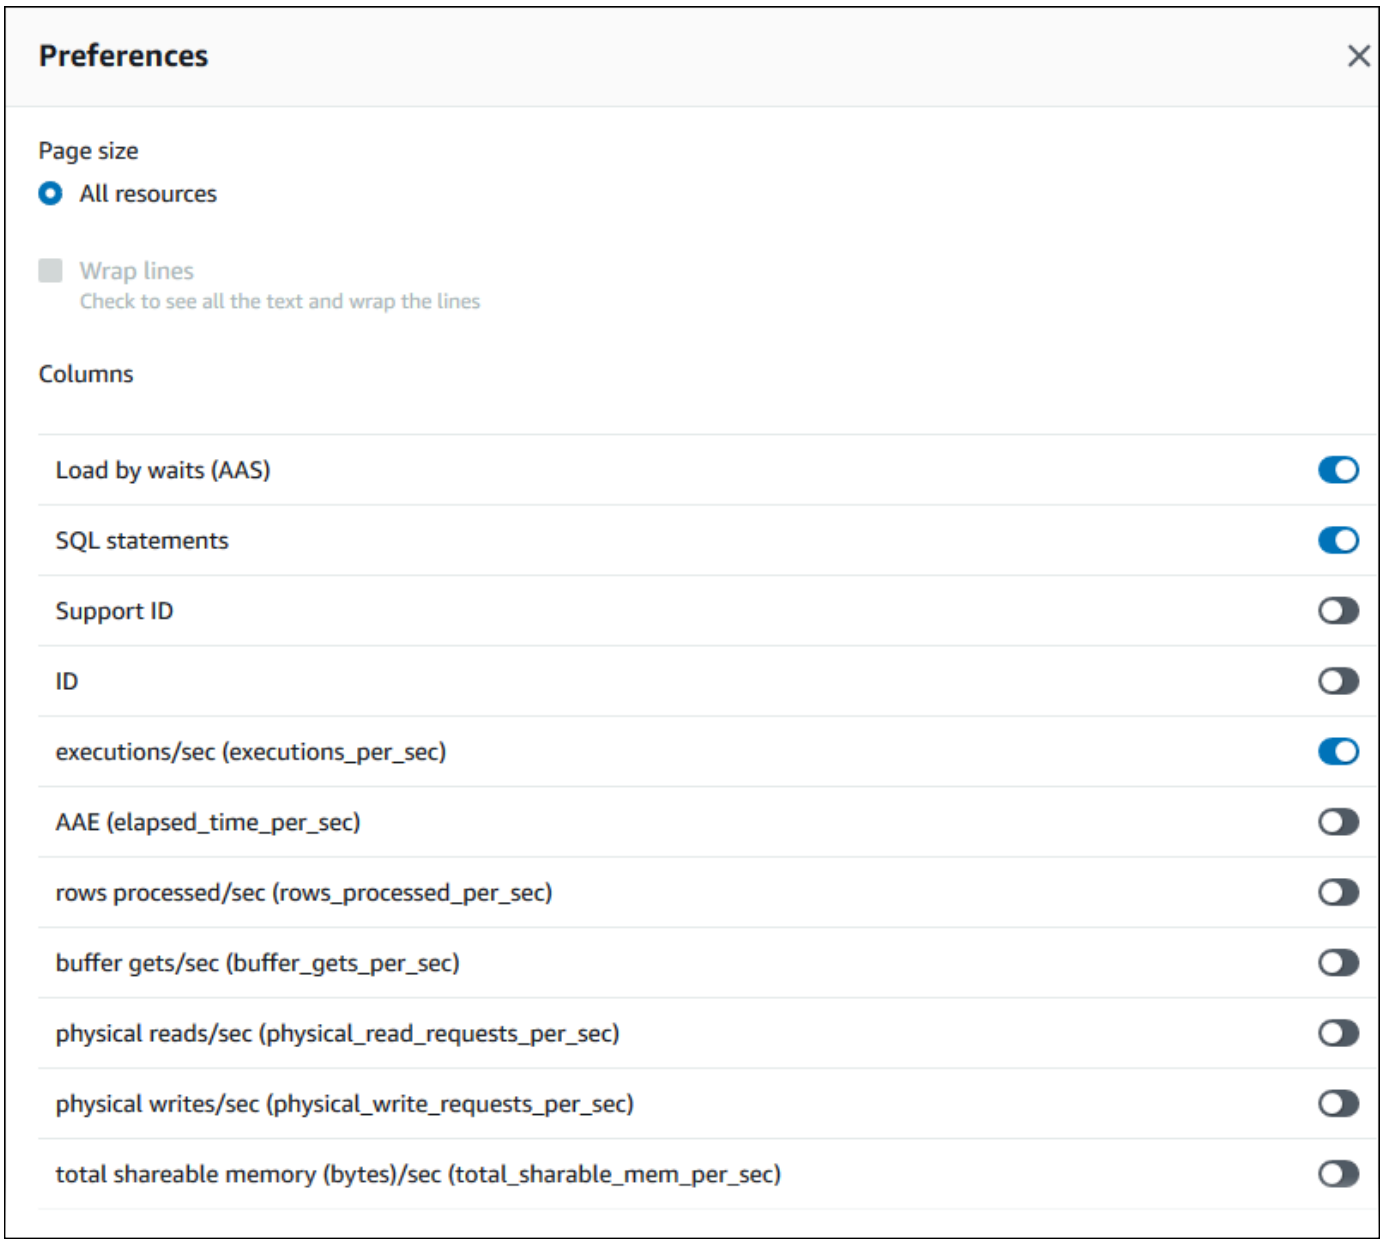
To view SQL statistics

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the left navigation pane, choose **Performance Insights**.
3. At the top of the page, choose the database whose SQL statistics you want to see.
4. Scroll to the bottom of the page and choose the **Top SQL** tab.
5. Choose an individual statement or digest query.

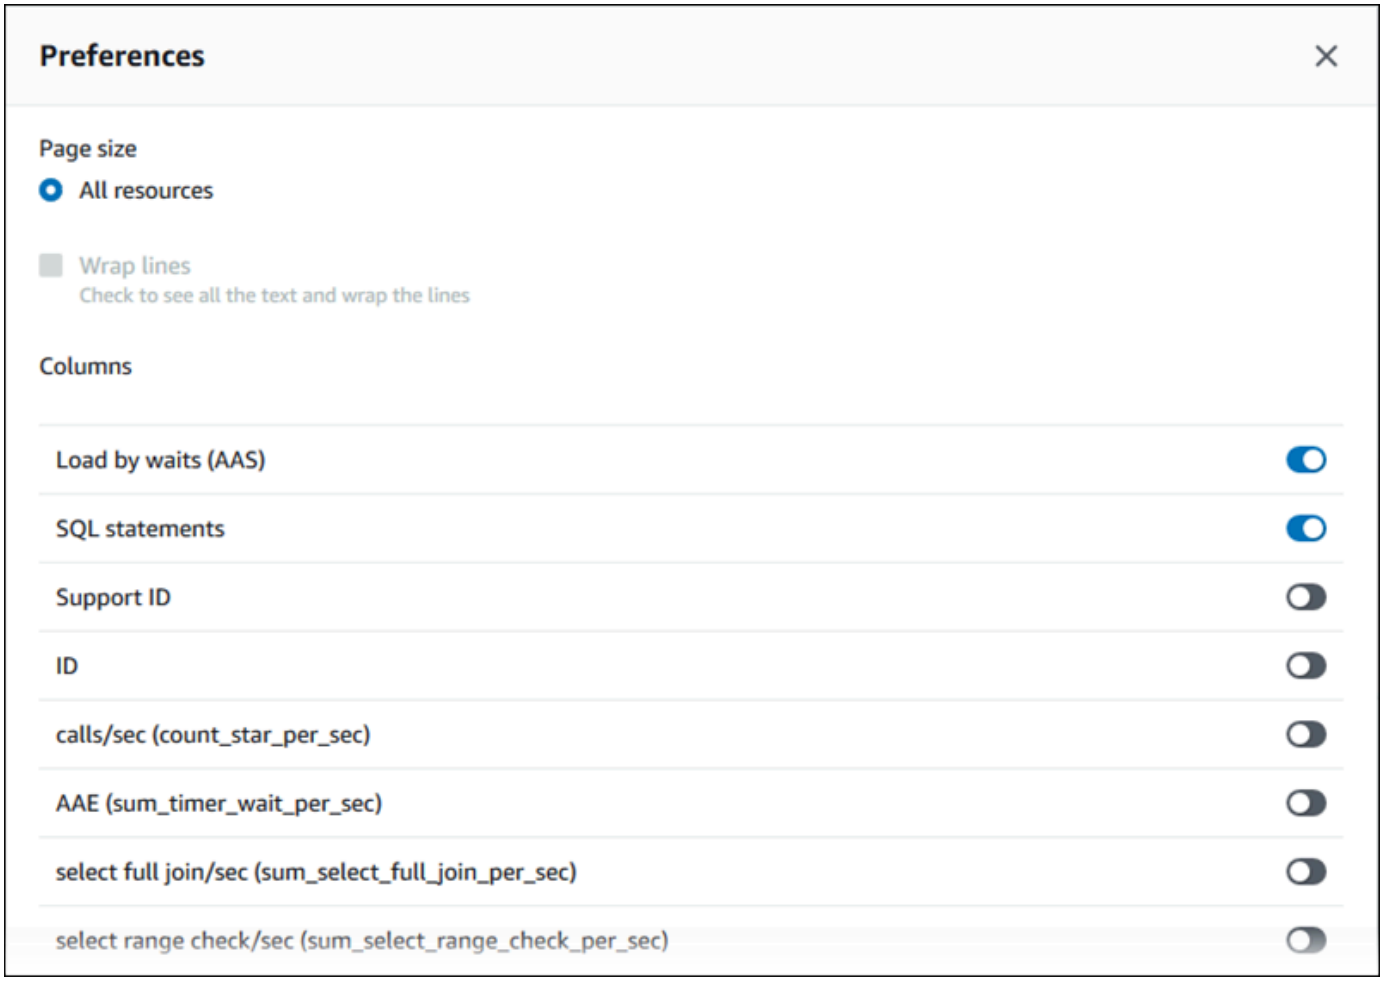


6. Choose which statistics to display by choosing the gear icon in the upper-right corner of the chart. For descriptions of the SQL statistics for the Amazon RDS engines, see SQL statistics for Performance Insights.

   The following example shows the statistics preferences for Oracle DB instances.



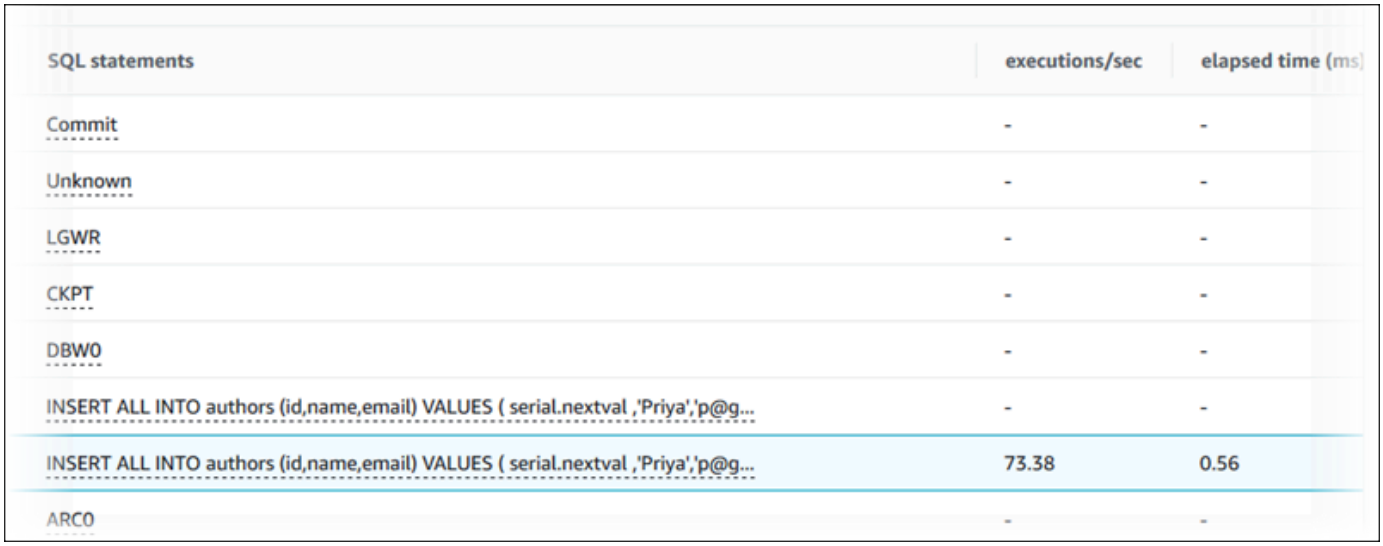
The following example shows the preferences for MariaDB and MySQL DB instances.



7. Choose Save to save your preferences.

   The **Top SQL** table refreshes.

   The following example shows statistics for an Oracle SQL query.



SQL statements	executions/sec	elapsed time (ms)
Commit	-	-
Unknown	-	-
LGWR	-	-
CKPT	-	-
DBW0	-	-
INSERT ALL INTO authors (id,name,email) VALUES (serial.nextval ,'Priya','p@g...	-	-
INSERT ALL INTO authors (id,name,email) VALUES (serial.nextval ,'Priya','p@g...	73.38	0.56
ARC0	-	-

Analyzing top Oracle PDB load

When analyzing the load on an Oracle container DB (CDB), you might want to identify which pluggable databases (PDBs) contribute the most to DB load. You might also want to compare the performance of individual PDBs that are running similar queries to fine tune performance. For more information about Oracle CDBs, see RDS for Oracle database architecture.

In the Amazon RDS Performance Insights dashboard, you can find information about pluggable databases (PDBs) under **Top PDB** tab in the **Dimensions** tab.

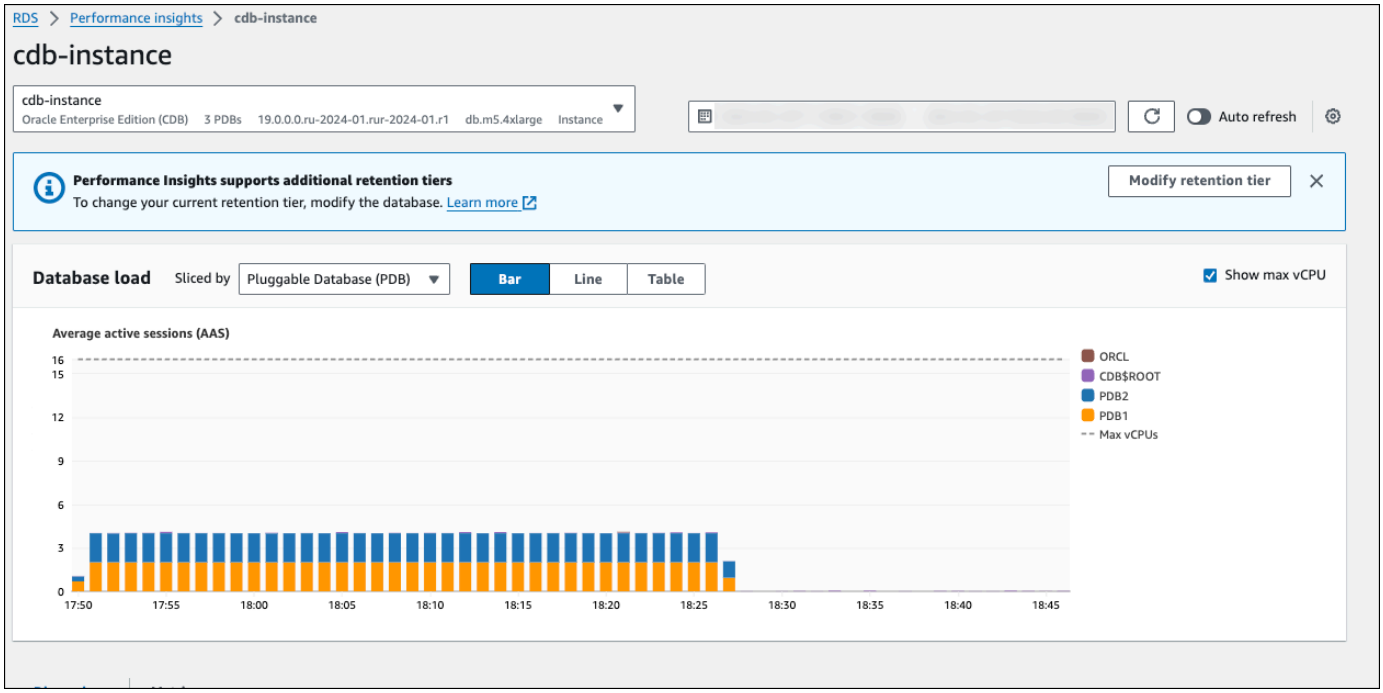
For the region, DB engine, and instance class support information for this feature, see Amazon RDS DB engine, Region, and instance class support for Performance Insights features.

To analyze Top PDB load in an Oracle CDB

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the left navigation pane, select **Performance Insights**.
3. Choose an Oracle CDB instance.

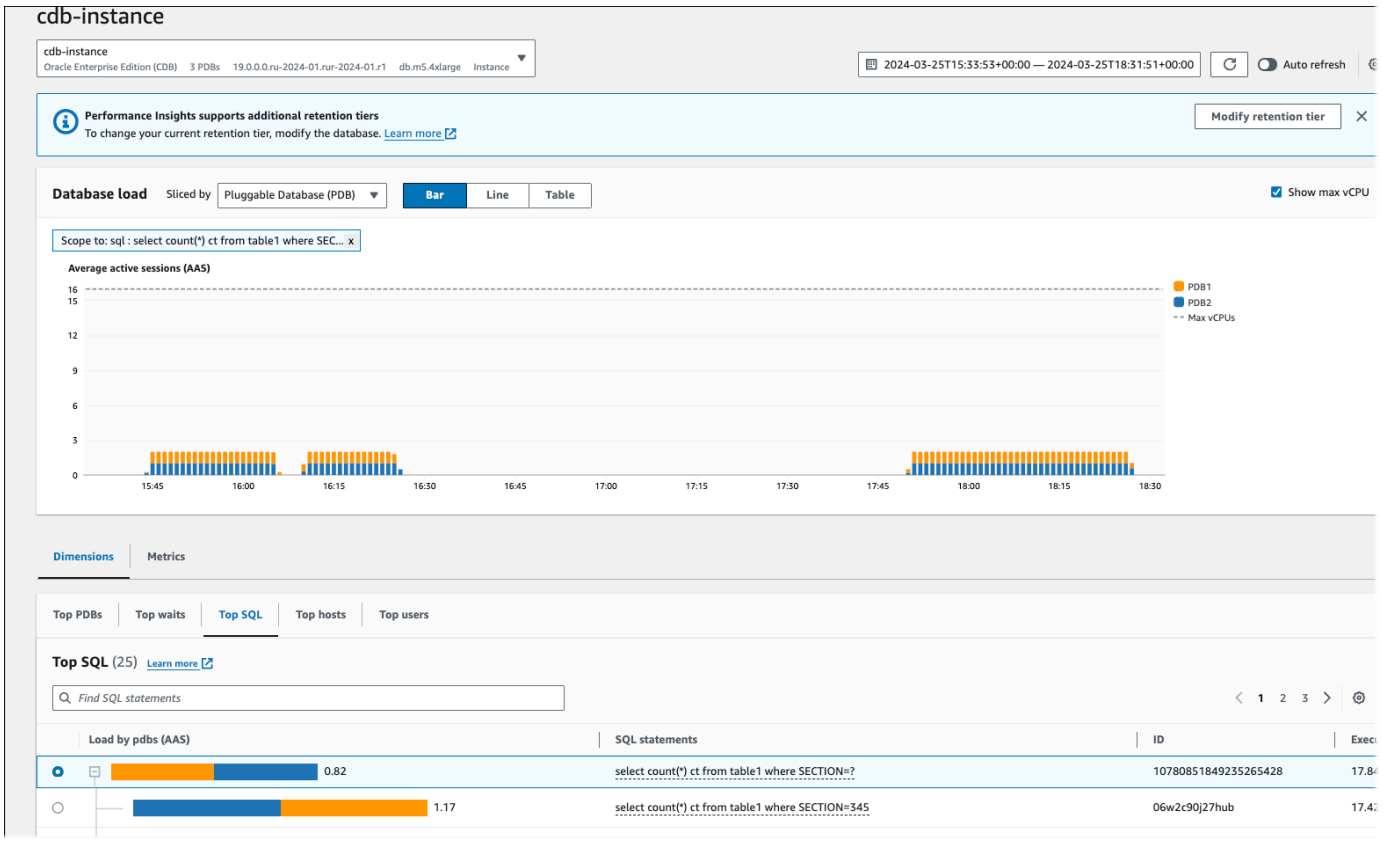
   The Performance Insights dashboard appears for the DB instance.
4. In the **Database load (DB load)** section, choose **Pluggable database (PDB)** next to Slice by.

   The Average active sessions chart shows the PDB with the highest load. The PDB identifiers appear to the right of the color-coded squares. Each identifier uniquely identifies a PDB.

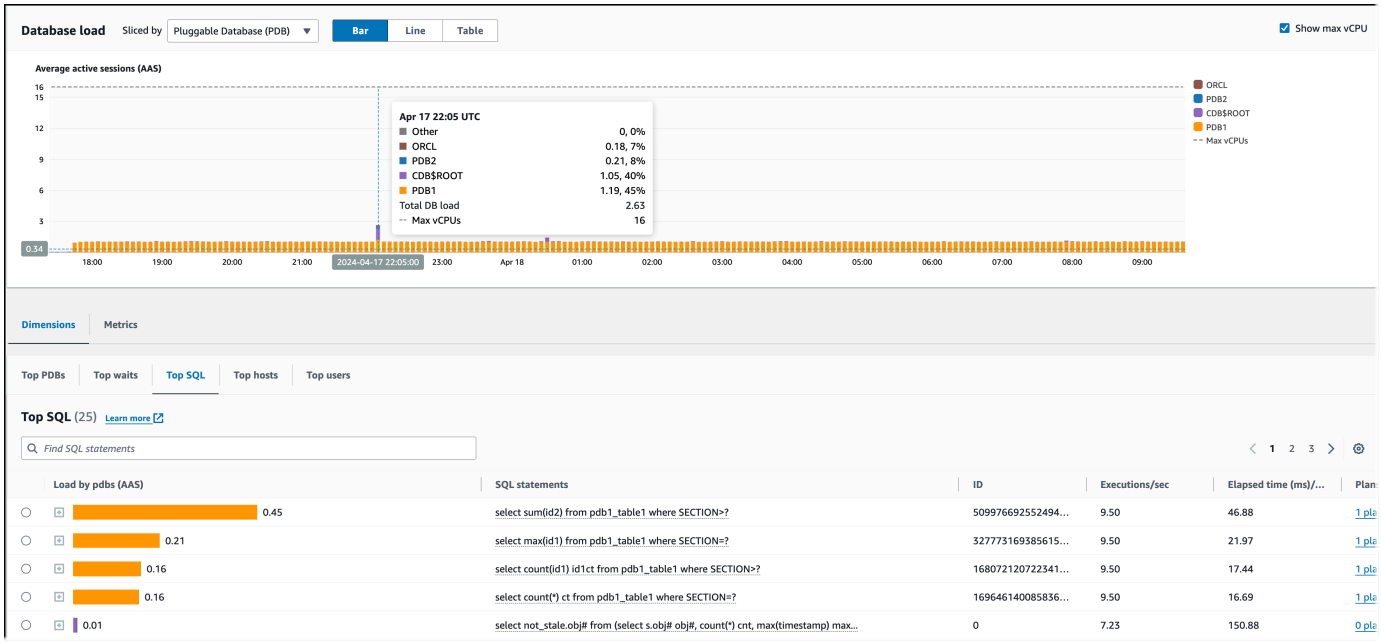


5. Scroll down to the **Top SQL** tab.

   In the following example, you can see the same SQL query and the load it drives to multiple PDBs.



In the following example, a single PDB is handling higher load than other PDBs in the CDB.



For more information about Oracle CDBs, see CDBs and PDBs.

Analyzing execution plans using the Performance Insights dashboard

In the Amazon RDS Performance Insights dashboard, you can find information about execution plans for Oracle and SQL Server DB instances. You can use this information to know which plans contribute the most to DB load.

Analyzing execution plans

- Overview of analyzing execution plans
- Analyzing Oracle execution plans using the Performance Insights dashboard
- Analyzing SQL Server execution plans using the Performance Insights dashboard

Overview of analyzing execution plans

You can use the Amazon RDS Performance Insights dashboard to know which plans contribute the most to DB load for Oracle and SQL Server DB instances.

For example, the top SQL statements at a given time might be using the plans shown in the following table.

Top SQL	Plan
SELECT SUM(amount_sold) FROM sales WHERE prod_id = 10	Plan A
SELECT SUM(amount_sold) FROM sales WHERE prod_id = 521	Plan B
SELECT SUM(s_total) FROM sales WHERE region = 10	Plan A
SELECT * FROM emp WHERE emp_id = 1000	Plan C
SELECT SUM(amount_sold) FROM sales WHERE prod_id = 72	Plan A

With the plan feature of Performance Insights, you can do the following:

- Find out which plans are used by the top SQL queries.

  For example, you might find out that most of the DB load is generated by queries using plan A and plan B, with only a small percentage using plan C.
- Compare different plans for the same query.

  In the preceding example, three queries are identical except for the product ID. Two queries use plan A, but one query uses plan B. To see the difference in the two plans, you can use Performance Insights.
- Find out when a query switched to a new plan.

  You might see that a query used plan A and then switched to plan B at a certain time. Was there a change in the database at this point? For example, if a table is empty, the optimizer might choose a full table scan. If the table is loaded with a million rows, the optimizer might switch to an index range scan.
- Drill down to the specific steps of a plan with the highest cost.

  For example, the for a long-running query might show a missing a join condition in an equi-join. This missing condition forces a Cartesian join, which joins all rows of two tables.

You can perform the preceding tasks by using the plan capture feature of Performance Insights. Just as you can slice queries by wait events and top SQL, you can slice them by the plan dimension.

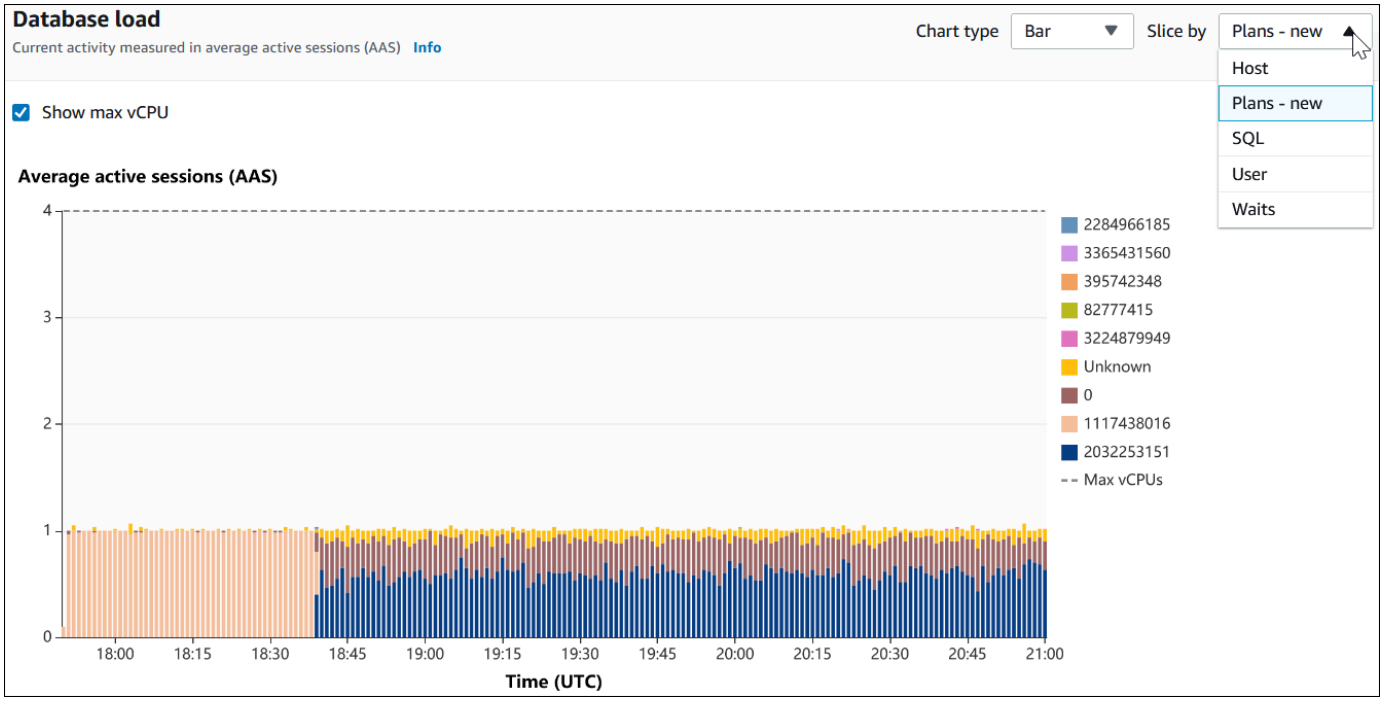
Analyzing Oracle execution plans using the Performance Insights dashboard

When analyzing DB load on an Oracle Database, you might want to know which plans are contributing the most to DB load. You can determine which plans are contributing the most to DB load by using the plan capture feature of Performance Insights.

To analyze Oracle execution plans using the console

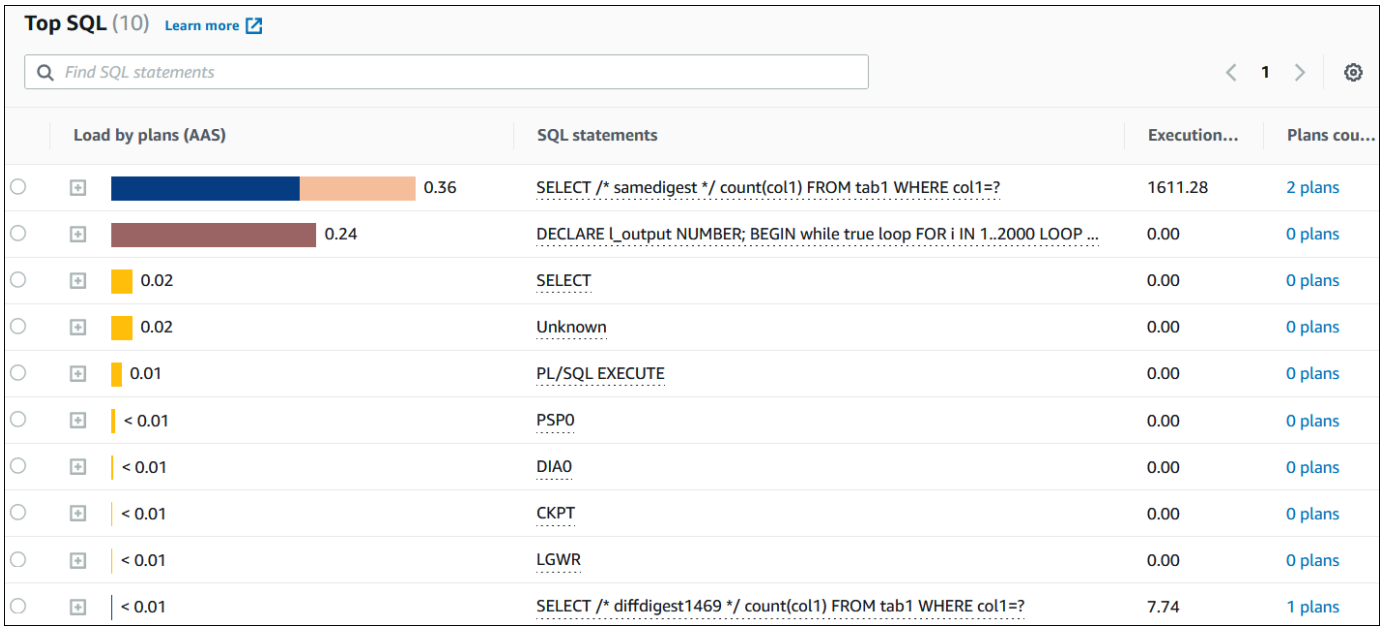
1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Performance Insights**.
3. Choose an Oracle DB instance. The Performance Insights dashboard is displayed for that DB instance.
4. In the **Database load (DB load)** section, choose **Plans** next to **Slice by**.

   The Average active sessions chart shows the plans used by your top SQL statements. The plan hash values appear to the right of the color-coded squares. Each hash value uniquely identifies a plan.



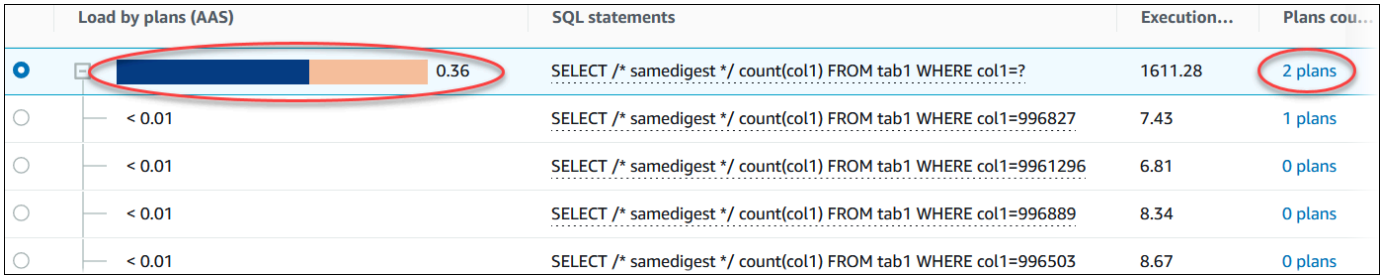
5. Scroll down to the **Top SQL** tab.

In the following example, the top SQL digest has two plans. You can tell that it's a digest by the question mark in the statement.



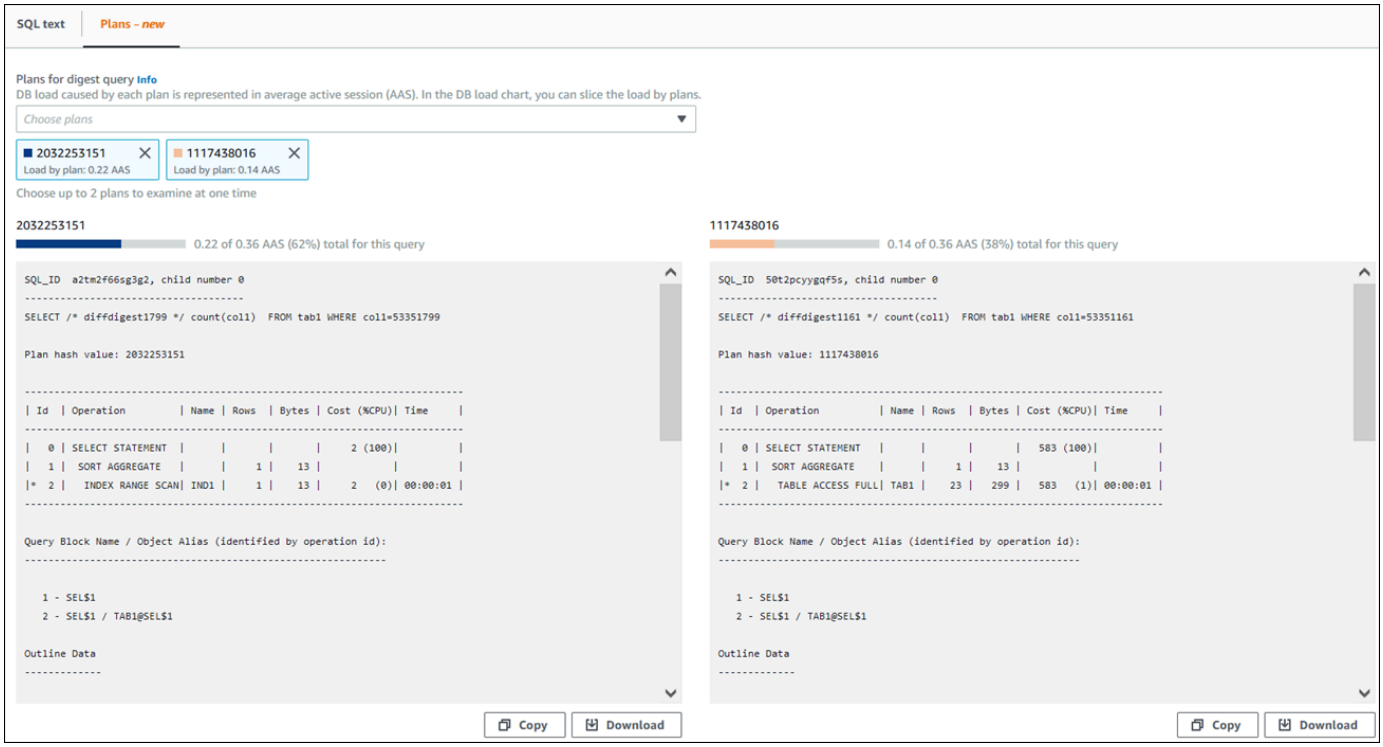
6. Choose the digest to expand it into its component statements.

   In the following example, the SELECT statement is a digest query. The component queries in the digest use two different plans. The colors of the plans correspond to the database load chart. The total number of plans in the digest is shown in the second column.

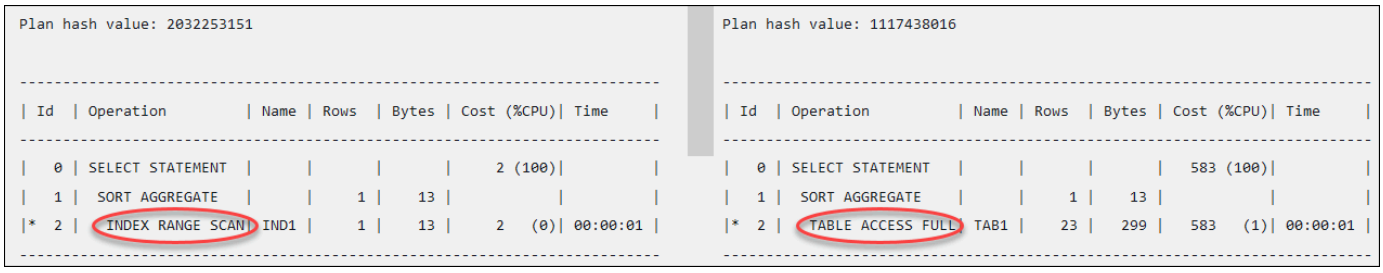


7. Scroll down and choose two **Plans** to compare from **Plans for digest query** list.

   You can view either one or two plans for a query at a time. The following screenshot compares the two plans in the digest, with hash 2032253151 and hash 1117438016. In the following example, 62% of the average active sessions running this digest query are using the plan on the left, whereas 38% are using the plan on the right.



In this example, the plans differ in an important way. Step 2 in plan 2032253151 uses an index scan, whereas plan 1117438016 uses a full table scan. For a table with a large number of rows, a query of a single row is almost always faster with an index scan.



8. (Optional) Choose **Copy** to copy the plan to the clipboard, or **Download** to save the plan to your hard drive.

Analyzing SQL Server execution plans using the Performance Insights dashboard

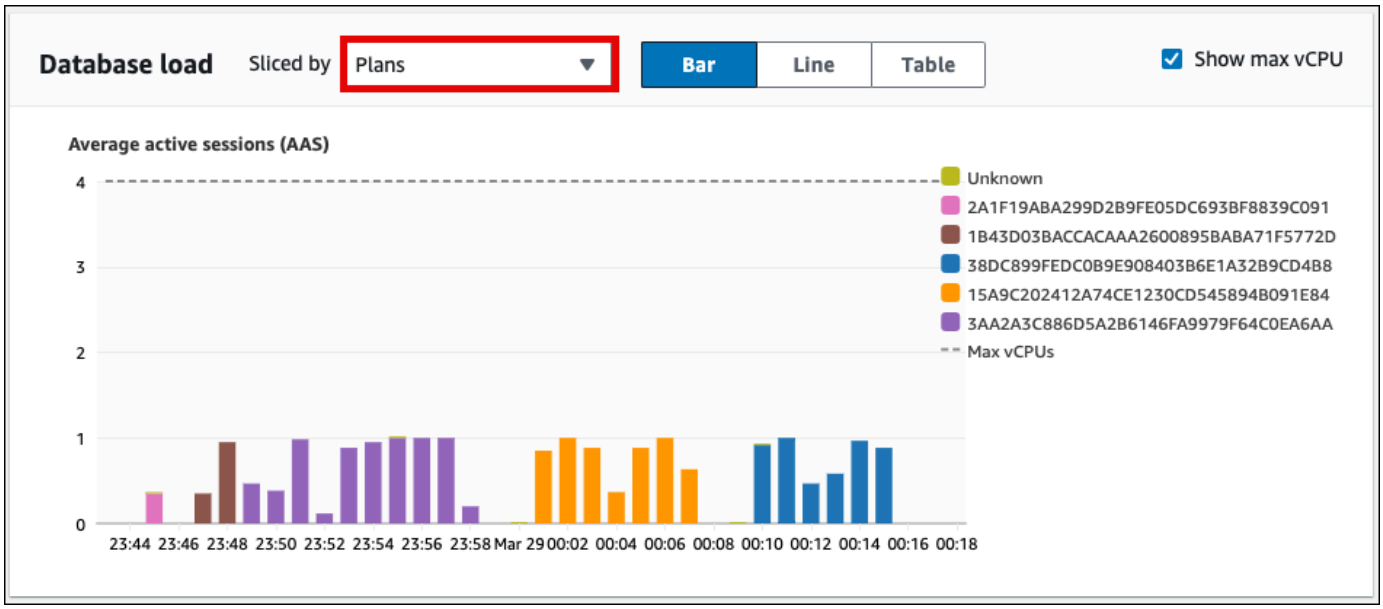
When analyzing DB load on a SQL Server Database, you might want to know which plans are contributing the most to DB load. You can determine which plans are contributing the most to DB load by using the plan capture feature of Performance Insights.

To analyze SQL Server execution plans using the console

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.

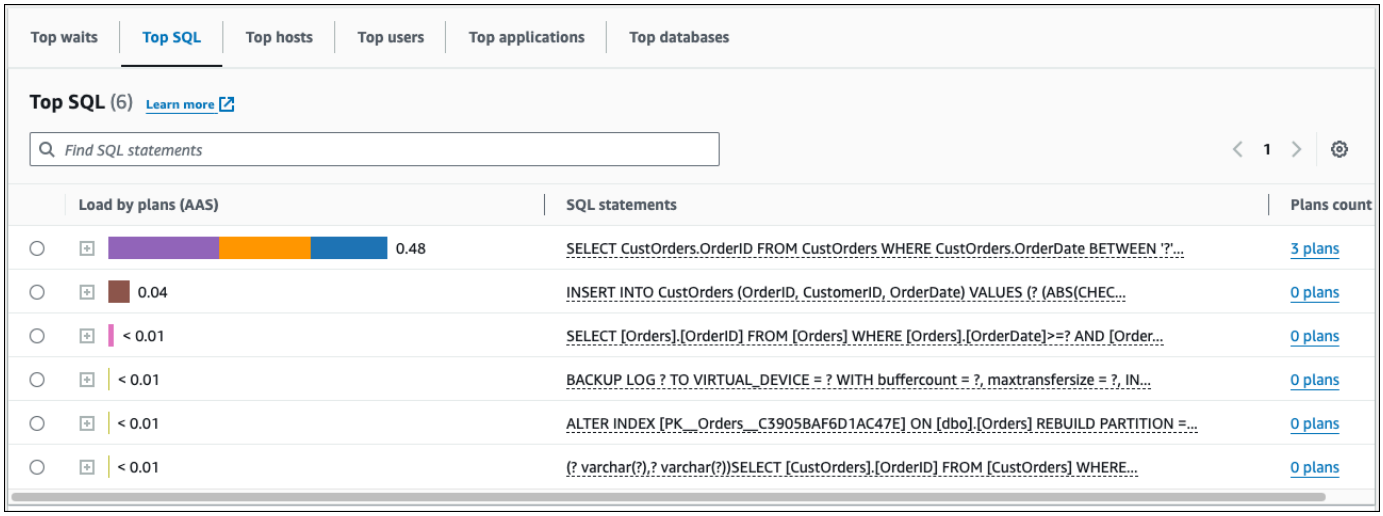
2. In the navigation pane, choose **Performance Insights**.
3. Choose a SQL Server DB instance. The Performance Insights dashboard is displayed for that DB instance.
4. In the **Database load (DB load)** section, choose **Plans** next to **Slice by**.

   The Average active sessions chart shows the plans used by your top SQL statements. The plan hash values appear to the right of the color-coded squares. Each hash value uniquely identifies a plan.



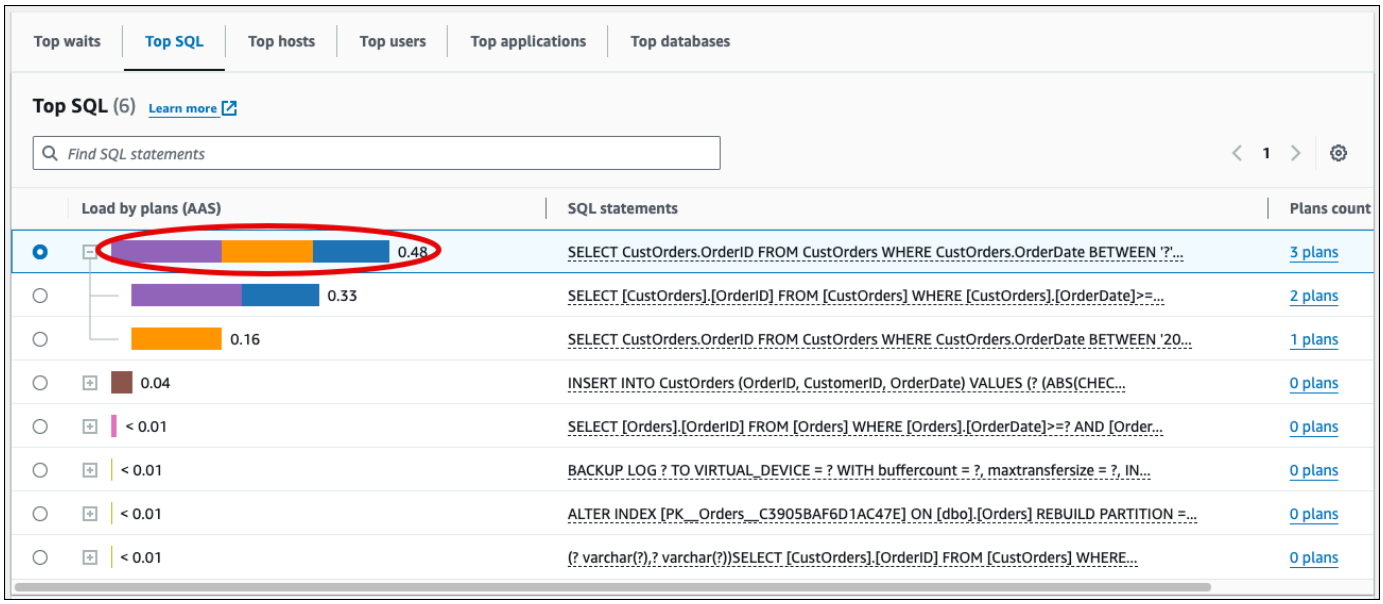
5. Scroll down to the **Top SQL** tab.

   In the following example, the top SQL digest has three plans. The presence of a question mark in the SQL statement indicates that the statement is a digest. To view the full SQL statement, choose a value in the **SQL statements** column.



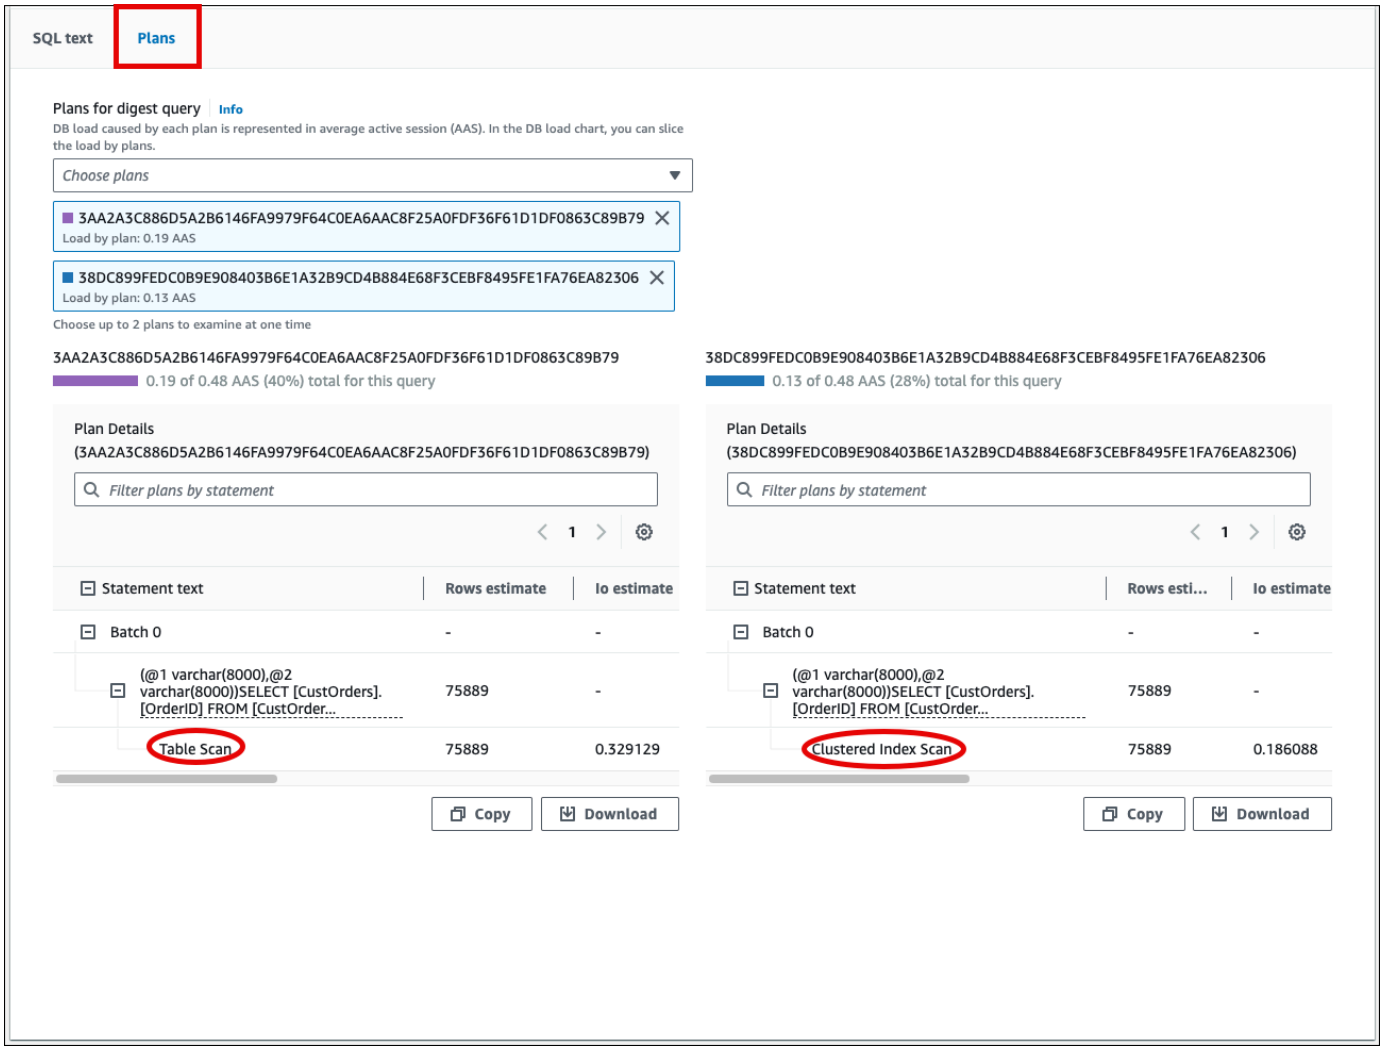
6. Choose the digest to expand it into its component statements.

   In the following example, the SELECT statement is a digest query. The component queries in the digest use three different execution plans. The colors assigned to the plans correspond to the database load chart.



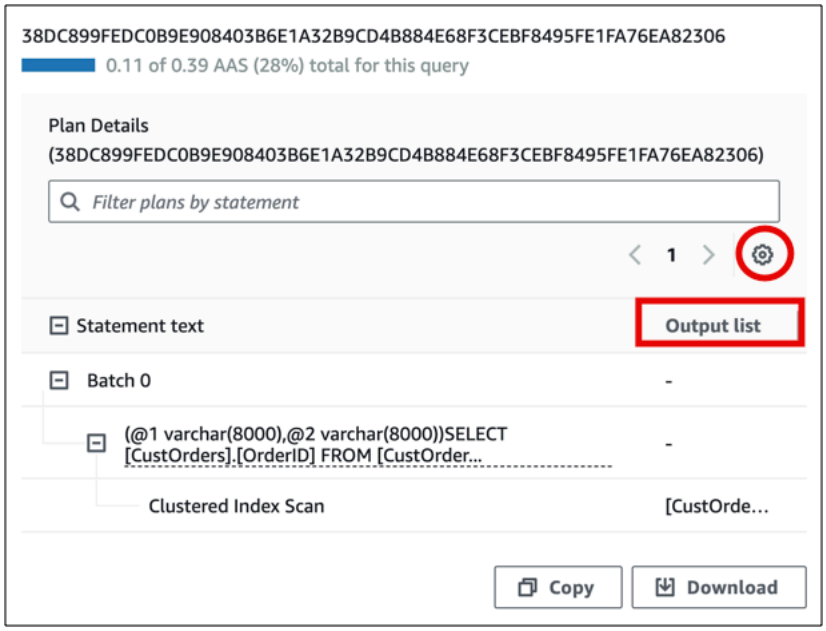
7. Scroll down and choose two **Plans** to compare from **Plans for digest query** list.

   You can view either one or two plans for a query at a time. The following screenshot compares two plans in the digest. In the following example, 40% of the average active sessions running this digest query are using the plan on the left, whereas 28% are using the plan on the right.



In the previous example, the plans differ in an important way. Step 2 in the plan on the left uses an table scan, whereas the plan on the right uses a clustered index scan. For a table with a large number of rows, a query retrieving a single row is almost always faster with a clustered index scan.

8. (Optional) Choose the **Settings** icon on the Plan Details table to customize the visibility and order of columns. The following screenshot shows the Plan Details table with the **Output list** column as the second column.



9. (Optional) Choose **Copy** to copy the plan to the clipboard, or **Download** to save the plan to your hard drive.

> **Note**
>
> Performance Insights displays estimated execution plans using a hierarchical tree table. The table includes the partial execution information for each statement. For more information about the columns in the Plan Details table, see SET SHOWPLAN_ALL in the SQL Server documentation. To display the full execution information for an estimated execution plan, choose **Download** to download the plan and then upload the plan to SQL Server Management Studio. For more information about displaying an estimated execution plan using SQL Server Management Studio, see Display an Estimated Execution Plan in the SQL Server documentation.

Viewing Performance Insights proactive recommendations

Amazon RDS Performance Insights monitors specific metrics and automatically creates thresholds by analyzing what levels might be potentially problematic for a specified resource. When the new metric values cross a predefined threshold over a given period of time, Performance Insights generates a proactive recommendation. This recommendation helps to prevent future database performance impact. To receive these proactive recommendations, you must turn on Performance Insights with a paid tier retention period.

For more information about turning on Performance Insights, see Turning Performance Insights on and off for Amazon RDS. For information about pricing and data retention for Performance Insights, see Pricing and data retention for Performance Insights.

To find out the regions, DB engines, and instance classes supported for the proactive recommendations, see Amazon RDS DB engine, Region, and instance class support for Performance Insights features.

You can view the detailed analysis and recommended investigations of proactive recommendations in the recommendation details page.

For more information about recommendations, see Recommendations from Amazon RDS.

To view the detailed analysis of a proactive recommendation

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, do any of the following:

   - Choose **Recommendations**.

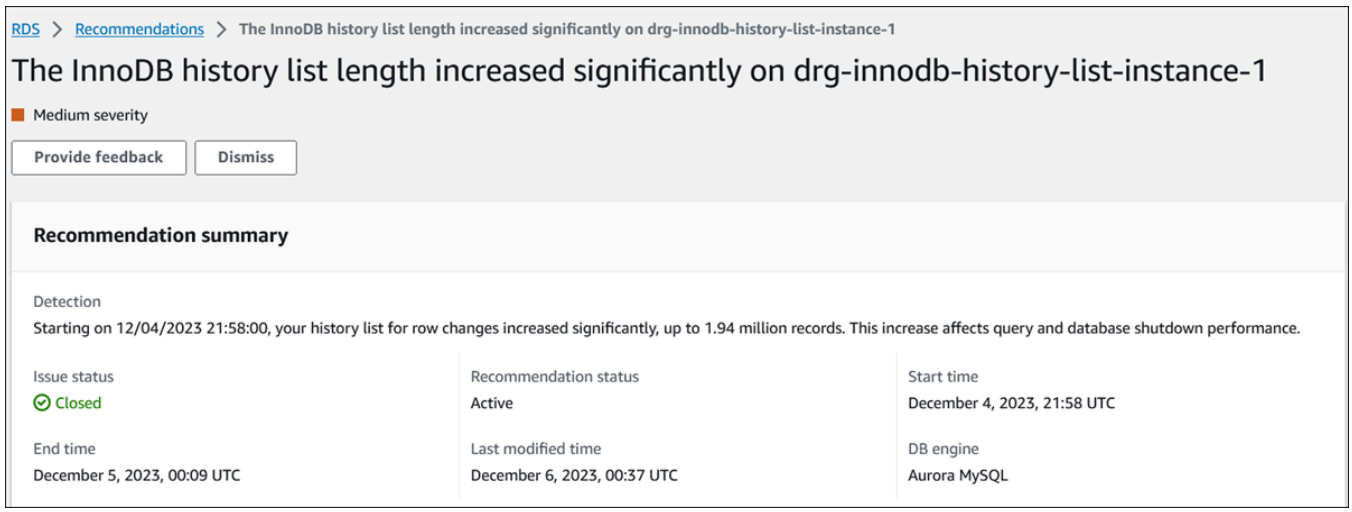
     The **Recommendations** page displays a list of recommendations sorted by the severity for all the resources in your account.
   - Choose **Databases** and then choose **Recommendations** for a resource in the databases page.

     The **Recommendations** tab displays the recommendations and its details for the selected resource.
3. Find a proactive recommendation and choose **View details**.

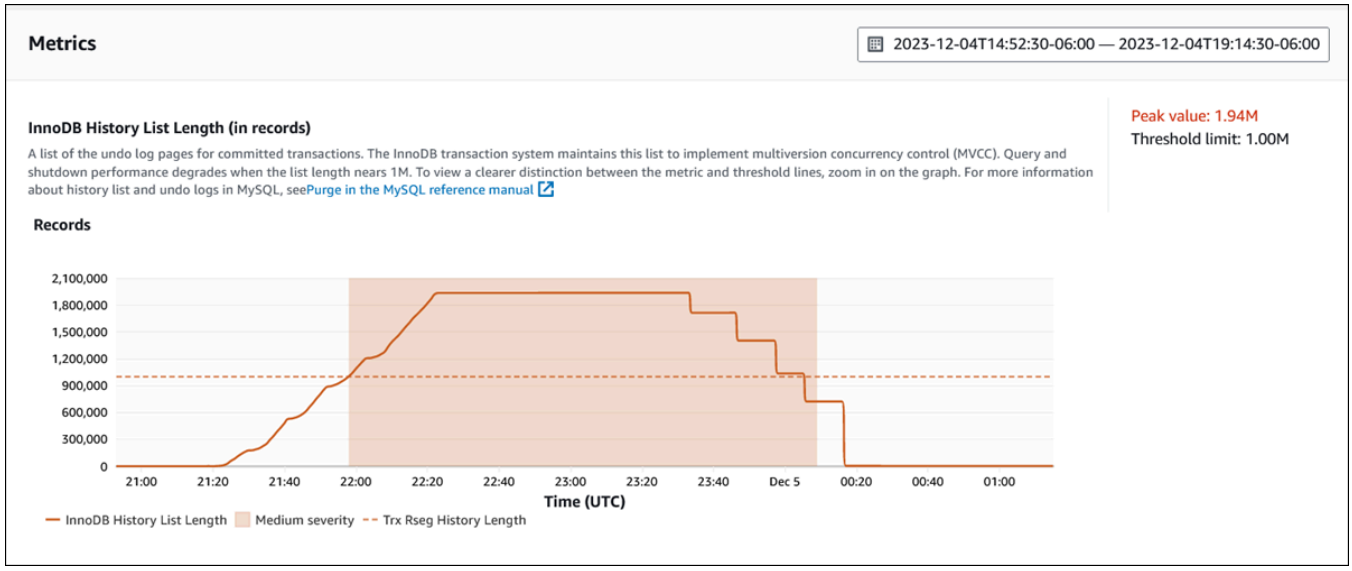
   The recommendation details page appears. The title provides the name of the affected resource with the issue detected and the severity.

   The following are the components on the recommendation details page:

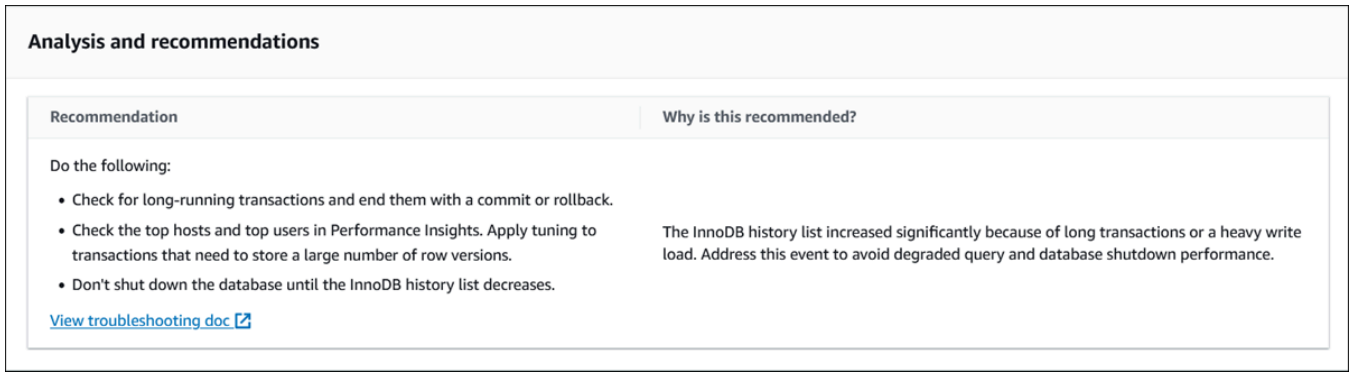
   - **Recommendation summary** – The detected issue, recommendation and issue status, issue start and end time, recommendation modified time, and the engine type.



- **Metrics** – The graphs of the detected issue. Each graph displays a threshold determined by the resource's baseline behavior and data of the metric reported from the issue start time.



- **Analysis and recommendations** – The recommendation and the reason for the suggested recommendation.



You can review the cause of the issue and then perform the suggested recommended actions to fix the issue, or choose **Dismiss** in the upper right to dismiss the recommendation.

Retrieving metrics with the Performance Insights API for Amazon RDS

When Performance Insights is turned on, the API provides visibility into instance performance. Amazon CloudWatch Logs provides the authoritative source for vended monitoring metrics for AWS services.

Performance Insights offers a domain-specific view of database load measured as average active sessions (AAS). This metric appears to API consumers as a two-dimensional time-series dataset. The time dimension of the data provides DB load data for each time point in the queried time range. Each time point decomposes overall load in relation to the requested dimensions, such as SQL, `Wait-event`, `User`, or `Host`, measured at that time point.

Amazon RDS Performance Insights monitors your Amazon RDS DB instance so that you can analyze and troubleshoot database performance. One way to view Performance Insights data is in the AWS Management Console. Performance Insights also provides a public API so that you can query your own data. You can use the API to do the following:

- Offload data into a database
- Add Performance Insights data to existing monitoring dashboards
- Build monitoring tools

To use the Performance Insights API, enable Performance Insights on one of your Amazon RDS DB instances. For information about enabling Performance Insights, see Turning Performance Insights on and off for Amazon RDS. For more information about the Performance Insights API, see the Amazon RDS Performance Insights API Reference.

The Performance Insights API provides the following operations.

Performance Insights action	AWS CLI command	Description
`CreatePerformanceAnalysisReport`	`aws pi create-performance-analysis-report`	Creates a performance analysis report for a specific time period for the DB

Performance Insights action	AWS CLI command	Description
		instance. The result is `AnalysisReportId` which is the unique identifier of the report.
DeletePerformanceAnalysisReport	aws pi delete-performance-analysis-report	Deletes a performance analysis report.
DescribeDimensionKeys	aws pi describe-dimension-keys	Retrieves the top N dimension keys for a metric for a specific time period.
GetDimensionKeyDetails	aws pi get-dimension-key-details	Retrieves the attributes of the specified dimension group for a DB instance or data source. For example, if you specify a SQL ID, and if the dimension details are available, `GetDimensionKeyDetails` retrieves the full text of the dimension `db.sql.statement` associated with this ID. This operation is useful because `GetResourceMetrics` and `DescribeDimensionKeys` don't support retrieval of large SQL statement text.
GetPerformanceAnalysisReport	aws pi get-performance-analysis-report	Retrieves the report including the insights for the report. The result includes the report status, report ID, report time details, insights, and recommendations.

Performance Insights action	AWS CLI command	Description
GetResourceMetadata	aws pi get-resource-metadata	Retrieve the metadata for different features. For example, the metadata might indicate that a feature is turned on or off on a specific DB instance.
GetResourceMetrics	aws pi get-resource-metrics	Retrieves Performance Insights metrics for a set of data sources over a time period. You can provide specific dimension groups and dimensions, and provide aggregation and filtering criteria for each group.
ListAvailableResourceDimensions	aws pi list-available-resource-dimensions	Retrieve the dimensions that can be queried for each specified metric type on a specified instance.
ListAvailableResourceMetrics	aws pi list-available-resource-metrics	Retrieve all available metrics of the specified metric types that can be queried for a specified DB instance.
ListPerformanceAnalysisReports	aws pi list-performance-analysis-reports	Retrieves all the analysis reports available for the DB instance. The reports are listed based on the start time of each report.
ListTagsForResource	aws pi list-tags-for-resource	Lists all the metadata tags added to the resource. The list includes the name and value of the tag.

Performance Insights action	AWS CLI command	Description
TagResource	aws pi tag-resource	Adds metadata tags to the Amazon RDS resource. The tag includes a name and a value.
UntagResource	aws pi untag-resource	Removes the metadata tag from the resource.

For more information about retrieving time-series metrics and AWS CLI examples for Performance Insights, see the following topics.

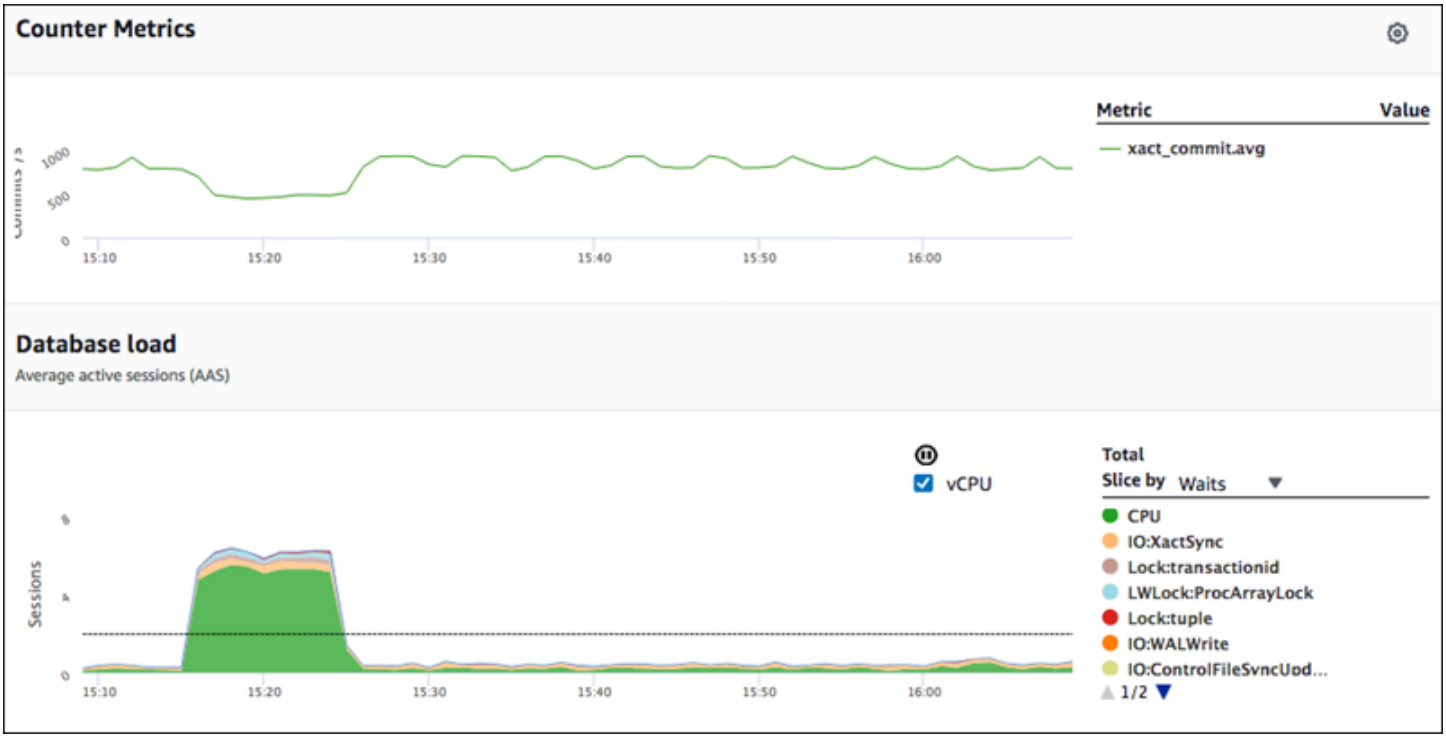
Topics

- Retrieving time-series metrics for Performance Insights
- AWS CLI examples for Performance Insights

Retrieving time-series metrics for Performance Insights

The `GetResourceMetrics` operation retrieves one or more time-series metrics from the Performance Insights data. `GetResourceMetrics` requires a metric and time period, and returns a response with a list of data points.

For example, the AWS Management Console uses `GetResourceMetrics` to populate the **Counter Metrics** chart and the **Database Load** chart, as seen in the following image.



All metrics returned by `GetResourceMetrics` are standard time-series metrics, with the exception of `db.load`. This metric is displayed in the **Database Load** chart. The `db.load` metric is different from the other time-series metrics because you can break it into subcomponents called *dimensions*. In the previous image, `db.load` is broken down and grouped by the waits states that make up the `db.load`.

> **Note**
>
> `GetResourceMetrics` can also return the `db.sampleload` metric, but the `db.load` metric is appropriate in most cases.

For information about the counter metrics returned by `GetResourceMetrics`, see Performance Insights counter metrics.

The following calculations are supported for the metrics:

- Average – The average value for the metric over a period of time. Append `.avg` to the metric name.
- Minimum – The minimum value for the metric over a period of time. Append `.min` to the metric name.

- Maximum – The maximum value for the metric over a period of time. Append `.max` to the metric name.
- Sum – The sum of the metric values over a period of time. Append `.sum` to the metric name.
- Sample count – The number of times the metric was collected over a period of time. Append `.sample_count` to the metric name.

For example, assume that a metric is collected for 300 seconds (5 minutes), and that the metric is collected one time each minute. The values for each minute are 1, 2, 3, 4, and 5. In this case, the following calculations are returned:

- Average – 3
- Minimum – 1
- Maximum – 5
- Sum – 15
- Sample count – 5

For information about using the `get-resource-metrics` AWS CLI command, see `get-resource-metrics`.

For the `--metric-queries` option, specify one or more queries that you want to get results for. Each query consists of a mandatory `Metric` and optional `GroupBy` and `Filter` parameters. The following is an example of a `--metric-queries` option specification.

```
{
   "Metric": "string",
   "GroupBy": {
     "Group": "string",
     "Dimensions": ["string", ...],
     "Limit": integer
   },
   "Filter": {"string": "string"
     ...}
```

AWS CLI examples for Performance Insights

In the following sections, learn more about the AWS Command Line Interface (AWS CLI) for Performance Insights and use AWS CLI examples.

Topics

Built-in help for the AWS CLI for Performance Insights

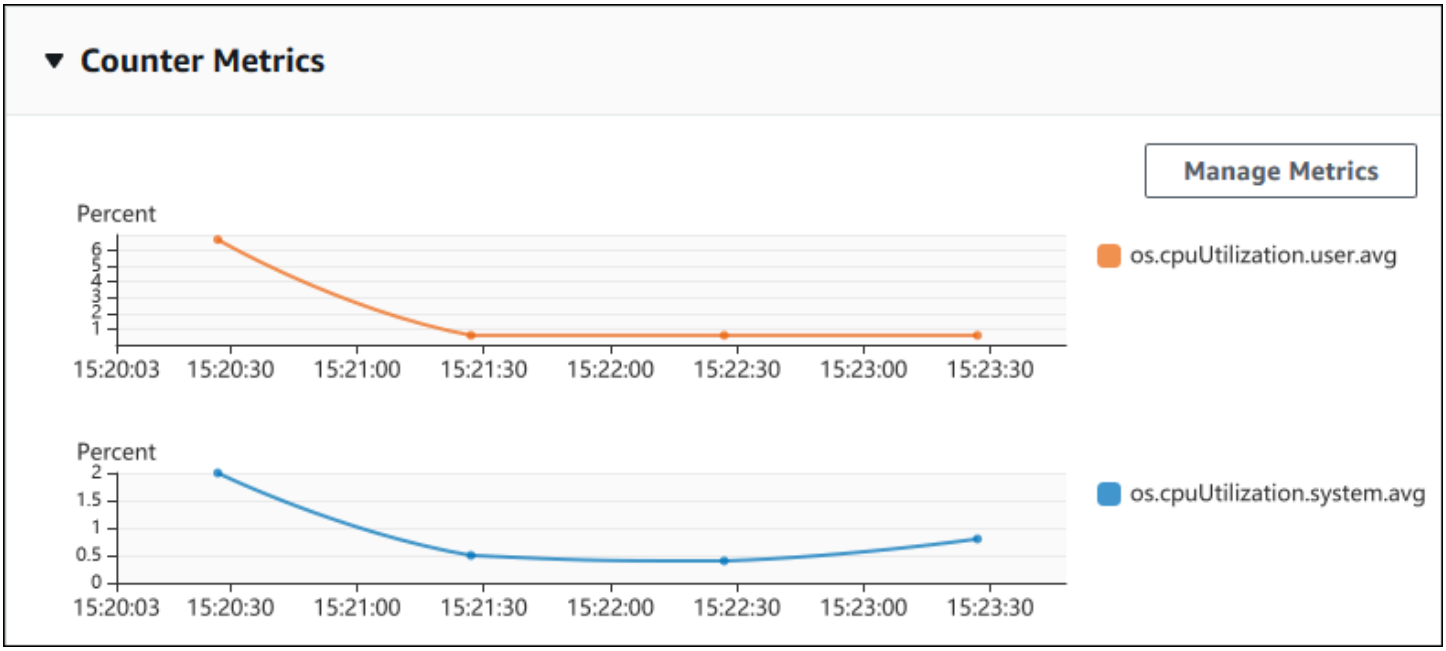
You can view Performance Insights data using the AWS CLI. You can view help for the AWS CLI commands for Performance Insights by entering the following on the command line.

```
aws pi help
```

If you don't have the AWS CLI installed, see Installing the AWS CLI in the *AWS CLI User Guide* for information about installing it.

Retrieving counter metrics

The following screenshot shows two counter metrics charts in the AWS Management Console.



The following example shows how to gather the same data that the AWS Management Console uses to generate the two counter metric charts.

For Linux, macOS, or Unix:

```
aws pi get-resource-metrics \
   --service-type RDS \
   --identifier db-ID \
   --start-time 2018-10-30T00:00:00Z \
   --end-time   2018-10-30T01:00:00Z \
   --period-in-seconds 60 \
   --metric-queries '[{"Metric": "os.cpuUtilization.user.avg"  },
                      {"Metric": "os.cpuUtilization.idle.avg"}]'
```

For Windows:

```
aws pi get-resource-metrics ^
   --service-type RDS ^
   --identifier db-ID ^
   --start-time 2018-10-30T00:00:00Z ^
   --end-time   2018-10-30T01:00:00Z ^
   --period-in-seconds 60 ^
   --metric-queries '[{"Metric": "os.cpuUtilization.user.avg"  },
                      {"Metric": "os.cpuUtilization.idle.avg"}]'
```

You can also make a command easier to read by specifying a file for the `--metrics-query` option. The following example uses a file called query.json for the option. The file has the following contents.

```
[
    {
        "Metric": "os.cpuUtilization.user.avg"
    },
    {
        "Metric": "os.cpuUtilization.idle.avg"
    }
]
```

Run the following command to use the file.

For Linux, macOS, or Unix:

```
aws pi get-resource-metrics \
   --service-type RDS \
   --identifier db-ID \
   --start-time 2018-10-30T00:00:00Z \
   --end-time   2018-10-30T01:00:00Z \
   --period-in-seconds 60 \
   --metric-queries file://query.json
```

For Windows:

```
aws pi get-resource-metrics ^
   --service-type RDS ^
   --identifier db-ID ^
   --start-time 2018-10-30T00:00:00Z ^
   --end-time   2018-10-30T01:00:00Z ^
   --period-in-seconds 60 ^
   --metric-queries file://query.json
```

The preceding example specifies the following values for the options:

- `--service-type` – RDS for Amazon RDS
- `--identifier` – The resource ID for the DB instance
- `--start-time` and `--end-time` – The ISO 8601 `DateTime` values for the period to query, with multiple supported formats

It queries for a one-hour time range:

- `--period-in-seconds` – `60` for a per-minute query
- `--metric-queries` – An array of two queries, each just for one metric.

  The metric name uses dots to classify the metric in a useful category, with the final element being a function. In the example, the function is `avg` for each query. As with Amazon CloudWatch, the supported functions are `min`, `max`, `total`, and `avg`.

The response looks similar to the following.

```
{
    "Identifier": "db-XXX",
    "AlignedStartTime": 1540857600.0,
    "AlignedEndTime": 1540861200.0,
    "MetricList": [
        { //A list of key/datapoints
            "Key": {
                "Metric": "os.cpuUtilization.user.avg" //Metric1
            },
            "DataPoints": [
                //Each list of datapoints has the same timestamps and same number of
 items
                {
                    "Timestamp": 1540857660.0, //Minute1
                    "Value": 4.0
                },
                {
                    "Timestamp": 1540857720.0, //Minute2
                    "Value": 4.0
                },
                {
                    "Timestamp": 1540857780.0, //Minute 3
                    "Value": 10.0
                }
                //... 60 datapoints for the os.cpuUtilization.user.avg metric
            ]
        },
        {
            "Key": {
                "Metric": "os.cpuUtilization.idle.avg" //Metric2
            },
```

```
            "DataPoints": [
                {
                    "Timestamp": 1540857660.0, //Minute1
                    "Value": 12.0
                },
                {
                    "Timestamp": 1540857720.0, //Minute2
                    "Value": 13.5
                },
                //... 60 datapoints for the os.cpuUtilization.idle.avg metric
            ]
        }
    ] //end of MetricList
} //end of response
```

The response has an `Identifier`, `AlignedStartTime`, and `AlignedEndTime`. B the `--period-in-seconds` value was `60`, the start and end times have been aligned to the minute. If the `--period-in-seconds` was `3600`, the start and end times would have been aligned to the hour.

The `MetricList` in the response has a number of entries, each with a `Key` and a `DataPoints` entry. Each `DataPoint` has a `Timestamp` and a `Value`. Each `Datapoints` list has 60 data points because the queries are for per-minute data over an hour, with `Timestamp1/Minute1`, `Timestamp2/Minute2`, and so on, up to `Timestamp60/Minute60`.

Because the query is for two different counter metrics, there are two elements in the response `MetricList`.

Retrieving the DB load average for top wait events

The following example is the same query that the AWS Management Console uses to generate a stacked area line graph. This example retrieves the `db.load.avg` for the last hour with load divided according to the top seven wait events. The command is the same as the command in Retrieving counter metrics. However, the query.json file has the following contents.

```
[
    {
        "Metric": "db.load.avg",
        "GroupBy": { "Group": "db.wait_event", "Limit": 7 }
    }
]
```

Run the following command.

For Linux, macOS, or Unix:

```
aws pi get-resource-metrics \
   --service-type RDS \
   --identifier db-ID \
   --start-time 2018-10-30T00:00:00Z \
   --end-time   2018-10-30T01:00:00Z \
   --period-in-seconds 60 \
   --metric-queries file://query.json
```

For Windows:

```
aws pi get-resource-metrics ^
   --service-type RDS ^
   --identifier db-ID ^
   --start-time 2018-10-30T00:00:00Z ^
   --end-time   2018-10-30T01:00:00Z ^
   --period-in-seconds 60 ^
   --metric-queries file://query.json
```

The example specifies the metric of `db.load.avg` and a `GroupBy` of the top seven wait events. For details about valid values for this example, see DimensionGroup in the *Performance Insights API Reference.*

The response looks similar to the following.

```
{
    "Identifier": "db-XXX",
    "AlignedStartTime": 1540857600.0,
    "AlignedEndTime": 1540861200.0,
    "MetricList": [
        { //A list of key/datapoints
            "Key": {
                //A Metric with no dimensions. This is the total db.load.avg
                "Metric": "db.load.avg"
            },
            "DataPoints": [
                //Each list of datapoints has the same timestamps and same number of
 items
                {

                    "Value": 0.26666666666666666
                }
                //... 60 datapoints for the total db.load.avg key
            ]
        },
        {
            "Key": {
                //Another key. This is db.load.avg broken down by CPU
                "Metric": "db.load.avg",
                "Dimensions": {
                    "db.wait_event.name": "CPU",
                    "db.wait_event.type": "CPU"
                }
            },
            "DataPoints": [
                {
                    "Timestamp": 1540857660.0, //Minute1
                    "Value": 0.35
                },
                {
                    "Timestamp": 1540857720.0, //Minute2
                    "Value": 0.15
                },
                //... 60 datapoints for the CPU key
            ]
        },
        //... In total we have 8 key/datapoints entries, 1) total, 2-8) Top Wait Events
    ] //end of MetricList
} //end of response
```

In this response, there are eight entries in the `MetricList`. There is one entry for the total `db.load.avg`, and seven entries each for the `db.load.avg` divided according to one of the top seven wait events. Unlike in the first example, because there was a grouping dimension, there must be one key for each grouping of the metric. There can't be only one key for each metric, as in the basic counter metric use case.

Retrieving the DB load average for top SQL

The following example groups `db.wait_events` by the top 10 SQL statements. There are two different groups for SQL statements:

- `db.sql` – The full SQL statement, such as `select * from customers where customer_id = 123`
- `db.sql_tokenized` – The tokenized SQL statement, such as `select * from customers where customer_id = ?`

When analyzing database performance, it can be useful to consider SQL statements that only differ by their parameters as one logic item. So, you can use `db.sql_tokenized` when querying. However, especially when you're interested in explain plans, sometimes it's more useful to examine full SQL statements with parameters, and query grouping by `db.sql`. There is a parent-child relationship between tokenized and full SQL, with multiple full SQL (children) grouped under the same tokenized SQL (parent).

The command in this example is the similar to the command in Retrieving the DB load average for top wait events. However, the query.json file has the following contents.

```
[
    {
        "Metric": "db.load.avg",
        "GroupBy": { "Group": "db.sql_tokenized", "Limit": 10 }
    }
]
```

The following example uses `db.sql_tokenized`.

For Linux, macOS, or Unix:

```
aws pi get-resource-metrics \
   --service-type RDS \
   --identifier db-ID \
   --start-time 2018-10-29T00:00:00Z \
   --end-time   2018-10-30T00:00:00Z \
   --period-in-seconds 3600 \
   --metric-queries file://query.json
```

For Windows:

```
aws pi get-resource-metrics ^
   --service-type RDS ^
   --identifier db-ID ^
   --start-time 2018-10-29T00:00:00Z ^
   --end-time   2018-10-30T00:00:00Z  ^
   --period-in-seconds 3600 ^
   --metric-queries file://query.json
```

This example queries over 24 hours, with a one hour period-in-seconds.

The example specifies the metric of `db.load.avg` and a `GroupBy` of the top seven wait events. For details about valid values for this example, see DimensionGroup in the *Performance Insights API Reference.*

The response looks similar to the following.

```
{
    "AlignedStartTime": 1540771200.0,
    "AlignedEndTime": 1540857600.0,
    "Identifier": "db-XXX",

    "MetricList": [ //11 entries in the MetricList
        {
            "Key": { //First key is total
                "Metric": "db.load.avg"
            }
            "DataPoints": [ //Each DataPoints list has 24 per-hour Timestamps and a
 value
                {
                    "Value": 1.6964980544747081,
                    "Timestamp": 1540774800.0
                },
                //... 24 datapoints
            ]
        },
        {
            "Key": { //Next key is the top tokenized SQL
                "Dimensions": {
                    "db.sql_tokenized.statement": "INSERT INTO authors (id,name,email)
 VALUES\n( nextval(?)  ,?,?)",
                    "db.sql_tokenized.db_id": "pi-2372568224",
                    "db.sql_tokenized.id": "AKIAIOSFODNN7EXAMPLE"
                },
```

```
                "Metric": "db.load.avg"
            },
            "DataPoints": [ //... 24 datapoints
            ]
        },
        // In total 11 entries, 10 Keys of top tokenized SQL, 1 total key
    ] //End of MetricList
} //End of response
```

This response has 11 entries in the `MetricList` (1 total, 10 top tokenized SQL), with each entry having 24 per-hour `DataPoints`.

For tokenized SQL, there are three entries in each dimensions list:

- `db.sql_tokenized.statement` – The tokenized SQL statement.
- `db.sql_tokenized.db_id` – Either the native database ID used to refer to the SQL, or a synthetic ID that Performance Insights generates for you if the native database ID isn't available. This example returns the `pi-2372568224` synthetic ID.
- `db.sql_tokenized.id` – The ID of the query inside Performance Insights.

  In the AWS Management Console, this ID is called the Support ID. It's named this because the ID is data that AWS Support can examine to help you troubleshoot an issue with your database. AWS takes the security and privacy of your data extremely seriously, and almost all data is stored encrypted with your AWS KMS key. Therefore, nobody inside AWS can look at this data. In the example preceding, both the `tokenized.statement` and the `tokenized.db_id` are stored encrypted. If you have an issue with your database, AWS Support can help you by referencing the Support ID.

When querying, it might be convenient to specify a `Group` in `GroupBy`. However, for finer-grained control over the data that's returned, specify the list of dimensions. For example, if all that is needed is the `db.sql_tokenized.statement`, then a `Dimensions` attribute can be added to the query.json file.

```
[
    {
        "Metric": "db.load.avg",
        "GroupBy": {
            "Group": "db.sql_tokenized",
            "Dimensions":["db.sql_tokenized.statement"],
```

```
            "Limit": 10
        }
    }
]
```

Retrieving the DB load average filtered by SQL

The preceding image shows that a particular query is selected, and the top average active sessions stacked area line graph is scoped to that query. Although the query is still for the top seven overall wait events, the value of the response is filtered. The filter causes it to take into account only sessions that are a match for the particular filter.

The corresponding API query in this example is similar to the command in [Retrieving the DB load average for top SQL](). However, the query.json file has the following contents.

```
[
 {
        "Metric": "db.load.avg",
        "GroupBy": { "Group": "db.wait_event", "Limit": 5  },
        "Filter": { "db.sql_tokenized.id": "AKIAIOSFODNN7EXAMPLE" }
    }
]
```

For Linux, macOS, or Unix:

```
aws pi get-resource-metrics \
   --service-type RDS \
   --identifier db-ID \
   --start-time 2018-10-30T00:00:00Z \
   --end-time   2018-10-30T01:00:00Z \
   --period-in-seconds 60 \
   --metric-queries file://query.json
```

For Windows:

```
aws pi get-resource-metrics ^
   --service-type RDS ^
   --identifier db-ID ^
   --start-time 2018-10-30T00:00:00Z ^
   --end-time   2018-10-30T01:00:00Z ^
   --period-in-seconds 60 ^
   --metric-queries file://query.json
```

The response looks similar to the following.

```
{
    "Identifier": "db-XXX",
    "AlignedStartTime": 1556215200.0,
    "MetricList": [
        {
            "Key": {
                "Metric": "db.load.avg"
            },
            "DataPoints": [
                {

                },
                {
                    "Timestamp": 1556222400.0,
                    "Value": 0.05805134189031505
                }
            ]
        },
        {
            "Key": {
                "Metric": "db.load.avg",
                "Dimensions": {
                    "db.wait_event.type": "synch",
                    "db.wait_event.name": "wait/synch/mutex/innodb/lock_wait_mutex"
                }
            },
            "DataPoints": [
                {
                    "Timestamp": 1556218800.0,
                    "Value": 0.017573696145124718
                },
```

```
                {
                    "Timestamp": 1556222400.0,
                    "Value": 0.002333722287047841
                }
            ]
        }
    ],
    "AlignedEndTime": 1556222400.0
} //end of response
```

In this response, all values are filtered according to the contribution of tokenized SQL AKIAIOSFODNN7EXAMPLE specified in the query.json file. The keys also might follow a different order than a query without a filter, because it's the top five wait events that affected the filtered SQL.

Retrieving the full text of a SQL statement

The following example retrieves the full text of a SQL statement for DB instance `db-10BCD2EFGHIJ3KL4M5NO6PQRS5`. The `--group` is `db.sql`, and the `--group-identifier` is `db.sql.id`. In this example, *`my-sql-id`* represents a SQL ID retrieved by invoking `pi get-resource-metrics` or `pi describe-dimension-keys`.

Run the following command.

For Linux, macOS, or Unix:

```
aws pi get-dimension-key-details \
   --service-type RDS \
   --identifier db-10BCD2EFGHIJ3KL4M5NO6PQRS5 \
   --group db.sql \
   --group-identifier my-sql-id \
   --requested-dimensions statement
```

For Windows:

```
aws pi get-dimension-key-details ^
   --service-type RDS ^
   --identifier db-10BCD2EFGHIJ3KL4M5NO6PQRS5 ^
   --group db.sql ^
   --group-identifier my-sql-id ^
   --requested-dimensions statement
```

In this example, the dimensions details are available. Thus, Performance Insights retrieves the full text of the SQL statement, without truncating it.

```
{
    "Dimensions":[
    {
        "Value": "SELECT e.last_name, d.department_name FROM employees e, departments d
 WHERE e.department_id=d.department_id",
        "Dimension": "db.sql.statement",
        "Status": "AVAILABLE"
    },
    ...
    ]
}
```

Creating a performance analysis report for a time period

The following example creates a performance analysis report with the `1682969503` start time and `1682979503` end time for the `db-loadtest-0` database.

```
aws pi create-performance-analysis-report \
        --service-type RDS \
        --identifier db-loadtest-0 \
        --start-time 1682969503 \
        --end-time 1682979503 \
        --region us-west-2
```

The response is the unique identifier `report-0234d3ed98e28fb17` for the report.

```
{
   "AnalysisReportId": "report-0234d3ed98e28fb17"
}
```

Retrieving a performance analysis report

The following example retrieves the analysis report details for the `report-0d99cc91c4422ee61` report.

```
aws pi get-performance-analysis-report \
--service-type RDS \
--identifier db-loadtest-0 \
--analysis-report-id report-0d99cc91c4422ee61 \
```

```
--region us-west-2
```

The response provides the report status, ID, time details, and insights.

```
        {
    "AnalysisReport": {
        "Status": "Succeeded",
        "ServiceType": "RDS",
        "Identifier": "db-loadtest-0",
        "StartTime": 1680583486.584,
        "AnalysisReportId": "report-0d99cc91c4422ee61",
        "EndTime": 1680587086.584,
        "CreateTime": 1680587087.139,
        "Insights": [
           ... (Condensed for space)
        ]
    }
}
```

Listing all the performance analysis reports for the DB instance

The following example lists all the available performance analysis reports for the `db-loadtest-0` database.

```
aws pi list-performance-analysis-reports \
--service-type RDS \
--identifier db-loadtest-0 \
--region us-west-2
```

The response lists all the reports with the report ID, status, and time period details.

```
{
    "AnalysisReports": [
        {
            "Status": "Succeeded",
            "EndTime": 1680587086.584,
            "CreationTime": 1680587087.139,
            "StartTime": 1680583486.584,
            "AnalysisReportId": "report-0d99cc91c4422ee61"
        },
        {
```

```
            "Status": "Succeeded",
            "EndTime": 1681491137.914,
            "CreationTime": 1681491145.973,
            "StartTime": 1681487537.914,
            "AnalysisReportId": "report-002633115cc002233"
        },
        {
            "Status": "Succeeded",
            "EndTime": 1681493499.849,
            "CreationTime": 1681493507.762,
            "StartTime": 1681489899.849,
            "AnalysisReportId": "report-043b1e006b47246f9"
        },
        {
            "Status": "InProgress",
            "EndTime": 1682979503.0,
            "CreationTime": 1682979618.994,
            "StartTime": 1682969503.0,
            "AnalysisReportId": "report-01ad15f9b88bcbd56"
        }
    ]
}
```

Deleting a performance analysis report

The following example deletes the analysis report for the `db-loadtest-0` database.

```
aws pi delete-performance-analysis-report \
--service-type RDS \
--identifier db-loadtest-0 \
--analysis-report-id report-0d99cc91c4422ee61 \
--region us-west-2
```

Adding tag to a performance analysis report

The following example adds a tag with a key `name` and value `test-tag` to the `report-01ad15f9b88bcbd56` report.

```
aws pi tag-resource \
--service-type RDS \
--resource-arn arn:aws:pi:us-west-2:356798100956:perf-reports/RDS/db-loadtest-0/
report-01ad15f9b88bcbd56 \
--tags Key=name,Value=test-tag \
```

```
--region us-west-2
```

Listing all the tags for a performance analysis report

The following example lists all the tags for the `report-01ad15f9b88bcbd56` report.

```
aws pi list-tags-for-resource \
--service-type RDS \
--resource-arn arn:aws:pi:us-west-2:356798100956:perf-reports/RDS/db-loadtest-0/
report-01ad15f9b88bcbd56 \
--region us-west-2
```

The response lists the value and key for all the tags added to the report:

```
{
    "Tags": [
        {
            "Value": "test-tag",
            "Key": "name"
        }
    ]
}
```

Deleting tags from a performance analysis report

The following example deletes the `name` tag from the `report-01ad15f9b88bcbd56` report.

```
aws pi untag-resource \
--service-type RDS \
--resource-arn arn:aws:pi:us-west-2:356798100956:perf-reports/RDS/db-loadtest-0/
report-01ad15f9b88bcbd56 \
--tag-keys name \
--region us-west-2
```

After the tag is deleted, calling the `list-tags-for-resource` API doesn't list this tag.

Logging Performance Insights calls using AWS CloudTrail

Performance Insights runs with AWS CloudTrail, a service that provides a record of actions taken by a user, role, or an AWS service in Performance Insights. CloudTrail captures all API calls for Performance Insights as events. This capture includes calls from the Amazon RDS console and from code calls to the Performance Insights API operations.

If you create a trail, you can enable continuous delivery of CloudTrail events to an Amazon S3 bucket, including events for Performance Insights. If you don't configure a trail, you can still view the most recent events in the CloudTrail console in **Event history**. Using the data collected by CloudTrail, you can determine certain information. This information includes the request that was made to Performance Insights, the IP address the request was made from, who made the request, and when it was made. It also includes additional details.

To learn more about CloudTrail, see the AWS CloudTrail User Guide.

Working with Performance Insights information in CloudTrail

CloudTrail is enabled on your AWS account when you create the account. When activity occurs in Performance Insights, that activity is recorded in a CloudTrail event along with other AWS service events in the CloudTrail console in **Event history**. You can view, search, and download recent events in your AWS account. For more information, see Viewing Events with CloudTrail Event History in *AWS CloudTrail User Guide.*

For an ongoing record of events in your AWS account, including events for Performance Insights, create a trail. A *trail* enables CloudTrail to deliver log files to an Amazon S3 bucket. By default, when you create a trail in the console, the trail applies to all AWS Regions. The trail logs events from all AWS Regions in the AWS partition and delivers the log files to the Amazon S3 bucket that you specify. Additionally, you can configure other AWS services to further analyze and act upon the event data collected in CloudTrail logs. For more information, see the following topics in *AWS CloudTrail User Guide:*

- Overview for Creating a Trail
- CloudTrail Supported Services and Integrations
- Configuring Amazon SNS Notifications for CloudTrail
- Receiving CloudTrail Log Files from Multiple Regions and Receiving CloudTrail Log Files from Multiple Accounts

All Performance Insights operations are logged by CloudTrail and are documented in the Performance Insights API Reference. For example, calls to the `DescribeDimensionKeys` and `GetResourceMetrics` operations generate entries in the CloudTrail log files.

Every event or log entry contains information about who generated the request. The identity information helps you determine the following:

- Whether the request was made with root or IAM user credentials.
- Whether the request was made with temporary security credentials for a role or federated user.
- Whether the request was made by another AWS service.

For more information, see the CloudTrail userIdentity Element.

Performance Insights log file entries

A *trail* is a configuration that enables delivery of events as log files to an Amazon S3 bucket that you specify. CloudTrail log files contain one or more log entries. An *event* represents a single request from any source. Each event includes information about the requested operation, the date and time of the operation, request parameters, and so on. CloudTrail log files aren't an ordered stack trace of the public API calls, so they don't appear in any specific order.

The following example shows a CloudTrail log entry that demonstrates the `GetResourceMetrics` operation.

```
{
    "eventVersion": "1.05",
    "userIdentity": {
        "type": "IAMUser",
         "principalId": "AKIAIOSFODNN7EXAMPLE",
        "arn": "arn:aws:iam::123456789012:user/johndoe",
        "accountId": "123456789012",
        "accessKeyId": "AKIAI44QH8DHBEXAMPLE",
        "userName": "johndoe"
    },
    "eventTime": "2019-12-18T19:28:46Z",
    "eventSource": "pi.amazonaws.com",
    "eventName": "GetResourceMetrics",
    "awsRegion": "us-east-1",
    "sourceIPAddress": "72.21.198.67",
    "userAgent": "aws-cli/1.16.240 Python/3.7.4 Darwin/18.7.0 botocore/1.12.230",
    "requestParameters": {
        "identifier": "db-YTDU5J5V66X7CXSCVDFD2V3SZM",
        "metricQueries": [
            {
                "metric": "os.cpuUtilization.user.avg"
            },
            {
                "metric": "os.cpuUtilization.idle.avg"
```

```
            }
        ],
        "startTime": "Dec 18, 2019 5:28:46 PM",
        "periodInSeconds": 60,
        "endTime": "Dec 18, 2019 7:28:46 PM",
        "serviceType": "RDS"
    },
    "responseElements": null,
    "requestID": "9ffbe15c-96b5-4fe6-bed9-9fccff1a0525",
    "eventID": "08908de0-2431-4e2e-ba7b-f5424f908433",
    "eventType": "AwsApiCall",
    "recipientAccountId": "123456789012"
}
```

Performance Insights API and interface VPC endpoints (AWS PrivateLink)

You can use AWS PrivateLink to create a private connection between your VPC and Amazon RDS Performance Insights. You can access Performance Insights as if it were in your VPC, without the use of an internet gateway, NAT device, VPN connection, or AWS Direct Connect connection. Instances in your VPC don't need public IP addresses to access Performance Insights.

You establish this private connection by creating an *interface endpoint*, powered by AWS PrivateLink. We create an endpoint network interface in each subnet that you enable for the interface endpoint. These are requester-managed network interfaces that serve as the entry point for traffic destined for Performance Insights.

For more information, see Access AWS services through AWS PrivateLink in the *AWS PrivateLink Guide*.

Considerations for Performance Insights

Before you set up an interface endpoint for Performance Insights, review Considerations in the *AWS PrivateLink Guide*.

Performance Insights supports making calls to all of its API actions through the interface endpoint.

By default, full access to Performance Insights is allowed through the interface endpoint. To control traffic to Performance Insights through the interface endpoint, associate a security group with the endpoint network interfaces.

Availability

Performance Insights API currently supports VPC endpoints in AWS Regions that support Performance Insights. For information about Performance Insights availability, see Supported Regions and DB engines for Performance Insights in Amazon RDS .

Create an interface endpoint for Performance Insights

You can create an interface endpoint for Performance Insights using either the Amazon VPC console or the AWS Command Line Interface (AWS CLI). For more information, see Create an interface endpoint in the *AWS PrivateLink Guide*.

Create an interface endpoint for Performance Insights using the following service name:

If you enable private DNS for the interface endpoint, you can make API requests to Performance Insights using its default Regional DNS name. For example, `pi.us-east-1.amazonaws.com`.

Creating a VPC endpoint policy for Performance Insights API

An endpoint policy is an IAM resource that you can attach to an interface endpoint. The default endpoint policy allows full access to Performance Insights through the interface endpoint. To control the access allowed to Performance Insights from your VPC, attach a custom endpoint policy to the interface endpoint.

An endpoint policy specifies the following information:

- The principals that can perform actions (AWS accounts, IAM users, and IAM roles).
- The actions that can be performed.
- The resources on which the actions can be performed.

For more information, see Control access to services using endpoint policies in the *AWS PrivateLink Guide*.

Example: VPC endpoint policy for Performance Insights actions

The following is an example of a custom endpoint policy. When you attach this policy to your interface endpoint, it grants access to the listed Performance Insights actions for all principals on all resources.

```
{
   "Statement":[
      {
         "Principal":"*",
         "Effect":"Allow",
         "Action":[
            "rds:CreatePerformanceAnalysisReport",
            "rds:DeletePerformanceAnalysisReport",
            "rds:GetPerformanceAnalysisReport"
         ],
         "Resource":"*"
      }
   ]
}
```

Example: VPC endpoint policy that denies all access from a specified AWS account

The following VPC endpoint policy denies AWS account 123456789012 all access to resources using the endpoint. The policy allows all actions from other accounts.

```
{
  "Statement": [
    {
      "Action": "*",
      "Effect": "Allow",
      "Resource": "*",
      "Principal": "*"
    },
    {
      "Action": "*",
      "Effect": "Deny",
      "Resource": "*",
      "Principal": { "AWS": [ "123456789012" ] }
     }
   ]
}
```

IP addressing for Performance Insights

IP addresses enable resources in your VPC to communicate with each other, and with resources over the internet. Performance Insights supports both IPv4 and IPv6 addressing protocols. By default, Performance Insights and Amazon VPC use the IPv4 addressing protocol. You can't turn off

this behavior. When you create a VPC, make sure to specify an IPv4 CIDR block (a range of private IPv4 addresses).

You can optionally assign an IPv6 CIDR block to your VPC and subnets, and assign IPv6 addresses from that block to RDS resources in your subnet. Support for the IPv6 protocol expands the number of supported IP addresses. By using the IPv6 protocol, you ensure that you have sufficient available addresses for the future growth of the internet. New and existing RDS resources can use IPv4 and IPv6 addresses within your VPC. Configuring, securing, and translating network traffic between the two protocols used in different parts of an application can cause operational overhead. You can standardize on the IPv6 protocol for Amazon RDS resources to simplify your network configuration. For more information about service endpoints and quotas, see Amazon Relational Database Service endpoints and quotas.

For more information about Amazon RDS IP addressing, see Amazon RDS IP addressing.

Analyzing performance anomalies with Amazon DevOps Guru for Amazon RDS

Amazon DevOps Guru is a fully managed operations service that helps developers and operators improve the performance and availability of their applications. DevOps Guru offloads the tasks associated with identifying operational issues so that you can quickly implement recommendations to improve your application. For more information, see What is Amazon DevOps Guru? in the *Amazon DevOps Guru User Guide*.

DevOps Guru detects, analyzes, and makes recommendations for existing operational issues for all Amazon RDS DB engines. DevOps Guru for RDS extends this capability by applying machine learning to Performance Insights metrics for RDS for PostgreSQL databases. These monitoring features allow DevOps Guru for RDS to detect and diagnose performance bottlenecks and recommend specific corrective actions. DevOps Guru for RDS can also detect problematic conditions in your RDS for PostgreSQL database before they occur.

You can now view these recommendations in RDS console. For more information, see Recommendations from Amazon RDS.

The following video is an overview of DevOps Guru for RDS.

For a deep dive on this subject, see Amazon DevOps Guru for RDS under the hood.

Topics

Benefits of DevOps Guru for RDS

If you're responsible for RDS for PostgreSQL database, you might not know that an event or regression that is affecting that database is occurring. When you learn about the issue, you might not know why it's occurring or what to do about it. Rather than turning to a database administrator (DBA) for help or relying on third-party tools, you can follow recommendations from DevOps Guru for RDS.

You gain the following advantages from the detailed analysis of DevOps Guru for RDS:

Fast diagnosis

DevOps Guru for RDS continuously monitors and analyzes database telemetry. Performance Insights, Enhanced Monitoring, and Amazon CloudWatch collect telemetry data for your database instance. DevOps Guru for RDS uses statistical and machine learning techniques to mine this data and detect anomalies. To learn more about telemetry data, see Monitoring DB load with Performance Insights on Amazon RDS and Monitoring OS metrics with Enhanced Monitoring in the *Amazon RDS User Guide*.

Fast resolution

Each anomaly identifies the performance issue and suggests avenues of investigation or corrective actions. For example, DevOps Guru for RDS might recommend that you investigate specific wait events. Or it might recommend that you tune your application pool settings to limit the number of database connections. Based on these recommendations, you can resolve performance issues more quickly than by troubleshooting manually.

Proactive insights

DevOps Guru for RDS uses metrics from your resources to detect potentially problematic behavior before it becomes a bigger problem. For example, it can detect when your database is using an increasing number of on-disk temporary tables, which could start to impact performance. DevOps Guru then provides recommendations to help you address issues before they become bigger problems.

Deep knowledge of Amazon engineers and machine learning

To detect performance issues and help you resolve bottlenecks, DevOps Guru for RDS relies on machine learning (ML) and advanced mathematical formulas. Amazon database engineers contributed to the development of the DevOps Guru for RDS findings, which encapsulate many years of managing hundreds of thousands of databases. By drawing on this collective knowledge, DevOps Guru for RDS can teach you best practices.

How DevOps Guru for RDS works

DevOps Guru for RDS collects data about your RDS for PostgreSQL databases from Amazon RDS Performance Insights. The most important metric is DBLoad. DevOps Guru for RDS consumes the Performance Insights metrics, analyzes them with machine learning, and publishes insights to the dashboard.

An *insight* is a collection of related anomalies that were detected by DevOps Guru.

In DevOps Guru for RDS, an *anomaly* is a pattern that deviates from what is considered normal performance for your RDS for PostgreSQL database.

Proactive insights

A *proactive insight* lets you know about problematic behavior before it occurs. It contains anomalies with recommendations and related metrics to help you address issues in your RDS for PostgreSQL databases before become bigger problems. These insights are published in the DevOps Guru dashboard.

For example, DevOps Guru might detect that your RDS for PostgreSQL database is creating many on-disk temporary tables. If not addressed, this trend might lead to performance issues. Each proactive insight includes recommendations for corrective behavior and links to relevant topics in Tuning RDS for PostgreSQL with Amazon DevOps Guru proactive insights. For more information, see Working with insights in DevOps Guru in the *Amazon DevOps Guru User Guide*.

Reactive insights

A *reactive insight* identifies anomalous behavior as it occurs. If DevOps Guru for RDS finds performance issues in your RDS for PostgreSQL DB instances, it publishes a reactive insight in the DevOps Guru dashboard. For more information, see Working with insights in DevOps Guru in the *Amazon DevOps Guru User Guide*.

Causal anomalies

A *causal anomaly* is a top-level anomaly within a reactive insight. **Database load (DB load)** is the causal anomaly for DevOps Guru for RDS.

An anomaly measures performance impact by assigning a severity level of **High**, **Medium**, or **Low**. To learn more, see Key concepts for DevOps Guru for RDS in the *Amazon DevOps Guru User Guide*.

If DevOps Guru detects a current anomaly on your DB instance, you're alerted in the **Databases** page of the RDS console. The console also alerts you to anomalies that occurred in the past 24 hours. To go to the anomaly page from the RDS console, choose the link in the alert message. The RDS console also alerts you in the page for your RDS for PostgreSQL DB instance.

Contextual anomalies

A *contextual anomaly* is a finding within **Database load (DB load)** that is related to a reactive insight. Each contextual anomaly describes a specific RDS for PostgreSQL performance issue that

requires investigation. For example, DevOps Guru for RDS might recommend that you consider increasing CPU capacity or investigate wait events that are contributing to DB load.

> **Important**
>
> We recommend that you test any changes on a test instance before modifying a production instance. In this way, you understand the impact of the change.

To learn more, see Analyzing anomalies in Amazon RDS in the *Amazon DevOps Guru User Guide*.

Setting up DevOps Guru for RDS

To allow DevOps Guru for Amazon RDS to publish insights for a RDS for PostgreSQL database, complete the following tasks.

Topics

- Configuring IAM access policies for DevOps Guru for RDS
- Turning on Performance Insights for your RDS for PostgreSQL DB instances
- Turning on DevOps Guru and specifying resource coverage

Configuring IAM access policies for DevOps Guru for RDS

To view alerts from DevOps Guru in the RDS console, your AWS Identity and Access Management (IAM) user or role must have either of the following policies:

- The AWS managed policy `AmazonDevOpsGuruConsoleFullAccess`
- The AWS managed policy `AmazonDevOpsGuruConsoleReadOnlyAccess` and either of the following policies:
  - The AWS managed policy `AmazonRDSFullAccess`
  - A customer managed policy that includes `pi:GetResourceMetrics` and `pi:DescribeDimensionKeys`

For more information, see Configuring access policies for Performance Insights.

Turning on Performance Insights for your RDS for PostgreSQL DB instances

DevOps Guru for RDS relies on Performance Insights for its data. Without Performance Insights, DevOps Guru publishes anomalies, but doesn't include the detailed analysis and recommendations.

When you create or modify a RDS for PostgreSQL DB instance, you can turn on Performance Insights. For more information, see Turning Performance Insights on and off for Amazon RDS.

Turning on DevOps Guru and specifying resource coverage

You can turn on DevOps Guru to have it monitor your RDS for PostgreSQL databases in either of the following ways.

Topics

- Turning on DevOps Guru in the RDS console
- Adding RDS for PostgreSQL resources in the DevOps Guru console
- Adding RDS for PostgreSQL resources using AWS CloudFormation

Turning on DevOps Guru in the RDS console

You can take multiple paths in the Amazon RDS console to turn on DevOps Guru.

Topics

- Turning on DevOps Guru when you create an RDS for PostgreSQL database
- Turning on DevOps Guru from the notification banner
- Responding to a permissions error when you turn on DevOps Guru

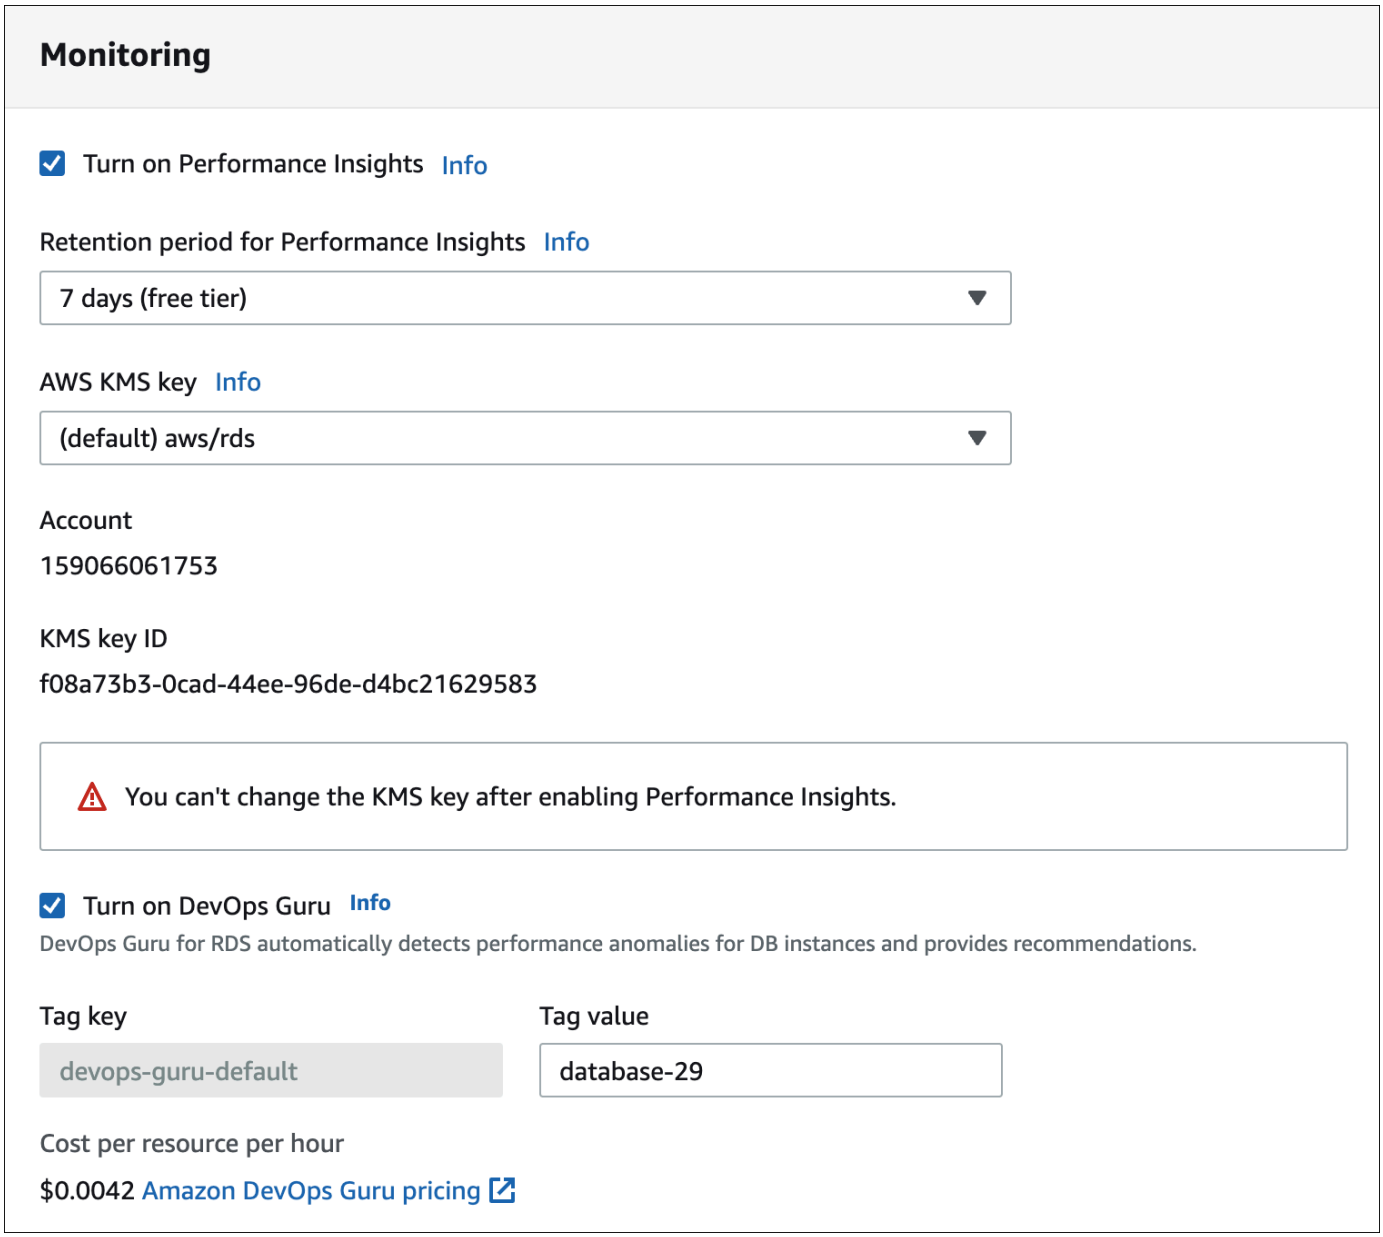
Turning on DevOps Guru when you create an RDS for PostgreSQL database

The creation workflow includes a setting that turns on DevOps Guru coverage for your database. This setting is turned on by default when you choose the **Production** template.

To turn on DevOps Guru when you create an RDS for PostgreSQL database

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Follow the steps in Creating a DB instance, up to but not including the step where you choose monitoring settings.

3. In **Monitoring**, choose **Turn on Performance Insights**. For DevOps Guru for RDS to provide detailed analysis of performance anomalies, Performance Insights must be turned on.
4. Choose **Turn on DevOps Guru**.



5. Create a tag for your database so that DevOps Guru can monitor it. Do the following:
   - In the text field for **Tag key**, enter a name that begins with **`Devops-Guru-`**.
   - In the text field for **Tag value**, enter any value. For example, if you enter **`rds-database-1`** for the name of your RDS for PostgreSQL database, you can also enter **`rds-database-1`** as the tag value.

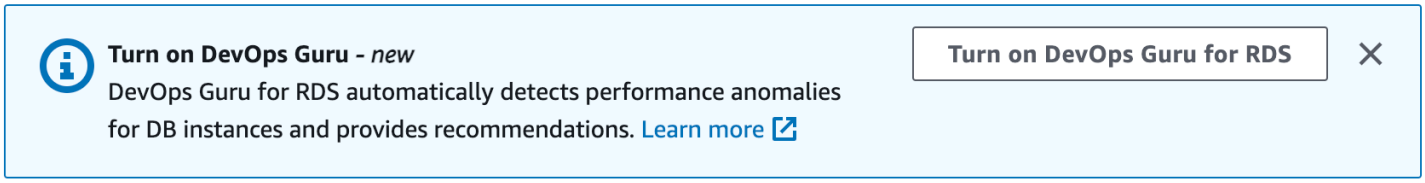
For more information about tags, see "Use tags to identify resources in your DevOps Guru applications" in the *Amazon DevOps Guru User Guide*.

6. Complete the remaining steps in Creating a DB instance.

Turning on DevOps Guru from the notification banner

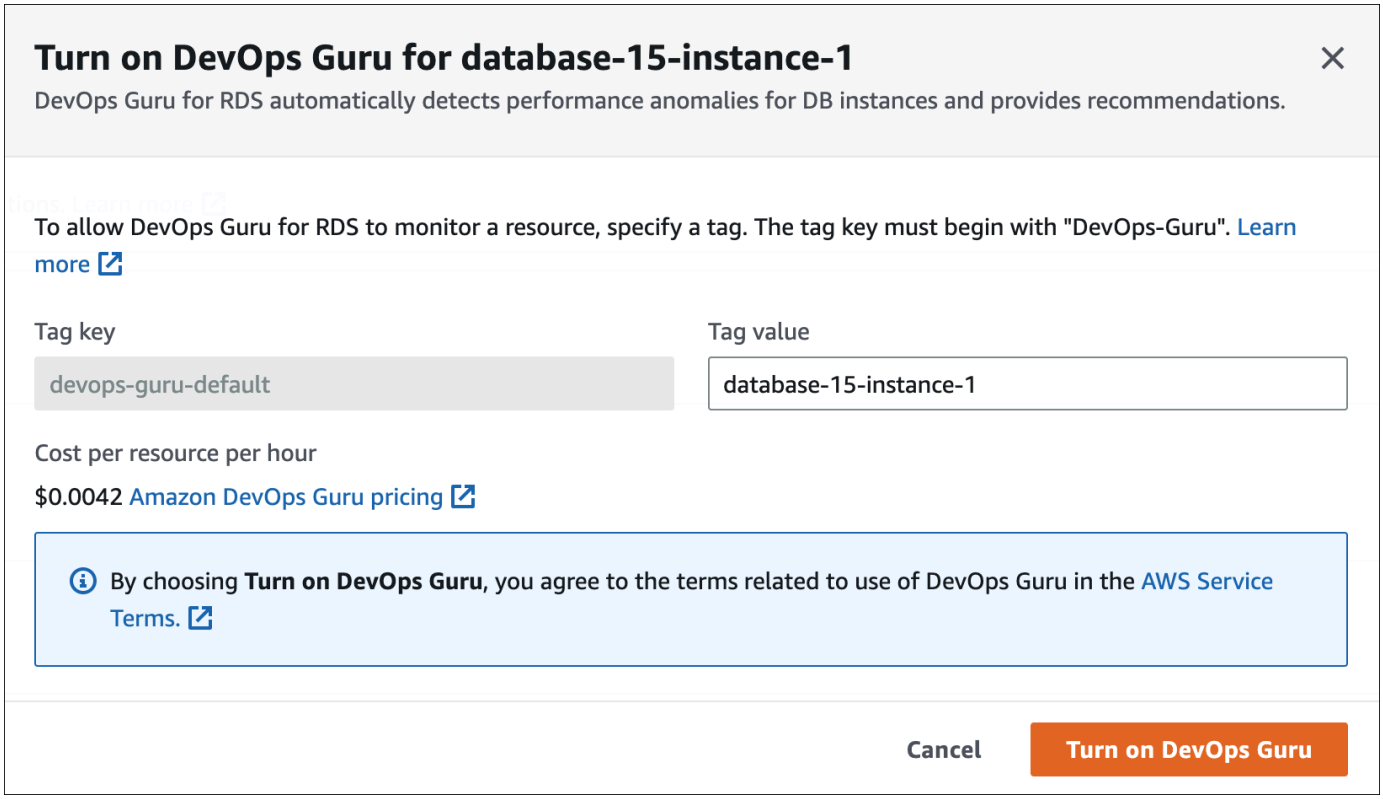
If your resources aren't covered by DevOps Guru, Amazon RDS notifies you with a banner in the following locations:

- The **Monitoring** tab of a DB cluster instance
- The Performance Insights dashboard



To turn on DevOps Guru for your RDS for PostgreSQL database

1. In the banner, choose **Turn on DevOps Guru for RDS**.
2. Enter a tag key name and value. For more information about tags, see "Use tags to identify resources in your DevOps Guru applications" in the *Amazon DevOps Guru User Guide*.



3. Choose **Turn on DevOps Guru**.

Responding to a permissions error when you turn on DevOps Guru

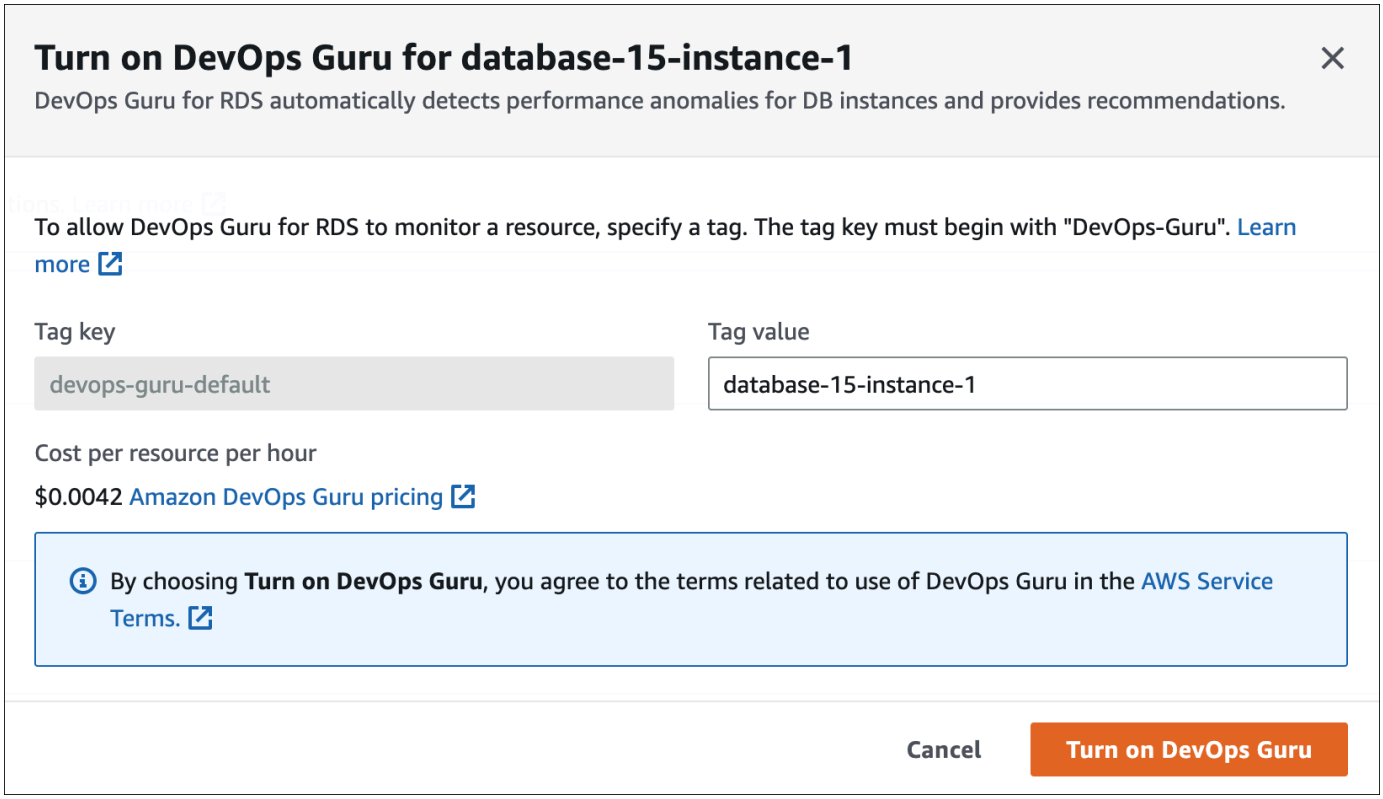
If you turn on DevOps Guru from the RDS console when you create a database, RDS might display the following banner about missing permissions.

To respond to a permissions error

1. Grant your IAM user or role the user managed role `AmazonDevOpsGuruConsoleFullAccess`. For more information, see Configuring IAM access policies for DevOps Guru for RDS.
2. Open the RDS console.
3. In the navigation pane, choose **Performance Insights**.
4. Choose a DB instance in the cluster that you just created.
5. Choose the switch to turn on **DevOps Guru for RDS**.

DevOps Guru for RDS

6. Choose a tag value. For more information, see "Use tags to identify resources in your DevOps Guru applications" in the *Amazon DevOps Guru User Guide*.



7. Choose **Turn on DevOps Guru**.

Adding RDS for PostgreSQL resources in the DevOps Guru console

You can specify your DevOps Guru resource coverage on the DevOps Guru console. Follow the step described in Specify your DevOps Guru resource coverage in the *Amazon DevOps Guru User Guide*. When you edit your analyzed resources, choose one of the following options:

- Choose **All account resources** to analyze all supported resources, including the RDS for PostgreSQL databases, in your AWS account and Region.
- Choose **CloudFormation stacks** to analyze the RDS for PostgreSQL databases that are in stacks you choose. For more information, see Use AWS CloudFormation stacks to identify resources in your DevOps Guru applications in the *Amazon DevOps Guru User Guide*.
- Choose **Tags** to analyze the RDS for PostgreSQL databases that you have tagged. For more information, see Use tags to identify resources in your DevOps Guru applications in the *Amazon DevOps Guru User Guide*.

For more information, see Enable DevOps Guru in the *Amazon DevOps Guru User Guide*.

Adding RDS for PostgreSQL resources using AWS CloudFormation

You can use tags to add coverage for your RDS for PostgreSQL resources to your CloudFormation templates. The following procedure assumes that you have a CloudFormation template both for your RDS for PostgreSQL DB instance and DevOps Guru stack.

To specify an RDS for PostgreSQL DB instance using a CloudFormation tag

1. In the CloudFormation template for your DB instance, define a tag using a key/value pair.

   The following example assigns the value `my-db-instance1` to `Devops-guru-cfn-default` for an RDS for PostgreSQL DB instance.

   ```
   MyDBInstance1:
     Type: "AWS::RDS::DBInstance"
     Properties:
       DBInstanceIdentifier: my-db-instance1
       Tags:
         - Key: Devops-guru-cfn-default
           Value: devopsguru-my-db-instance1
   ```

2. In the CloudFormation template for your DevOps Guru stack, specify the same tag in your resource collection filter.

   The following example configures DevOps Guru to provide coverage for the resource with the tag value `my-db-instance1`.

   ```
   DevOpsGuruResourceCollection:
     Type: AWS::DevOpsGuru::ResourceCollection
     Properties:
       ResourceCollectionFilter:
         Tags:
           - AppBoundaryKey: "Devops-guru-cfn-default"
             TagValues:
             - "devopsguru-my-db-instance1"
   ```

   The following example provides coverage for all resources within the application boundary `Devops-guru-cfn-default`.

   ```
   DevOpsGuruResourceCollection:
   ```

```
  Type: AWS::DevOpsGuru::ResourceCollection
  Properties:
    ResourceCollectionFilter:
      Tags:
        - AppBoundaryKey: "Devops-guru-cfn-default"
          TagValues:
          - "*"
```

For more information, see AWS::DevOpsGuru::ResourceCollection and AWS::RDS::DBInstance in the *AWS CloudFormation User Guide*.

Monitoring OS metrics with Enhanced Monitoring

With Enhanced Monitoring, you can monitor the operating system of your DB instance in real time. When you want to see how different processes or threads use the CPU, Enhanced Monitoring metrics are useful.

Topics

Overview of Enhanced Monitoring

Amazon RDS provides metrics in real time for the operating system (OS) that your DB instance runs on. You can view all the system metrics and process information for your RDS DB instances on the console. You can manage which metrics you want to monitor for each instance and customize the dashboard according to your requirements. For descriptions of the Enhanced Monitoring metrics, see OS metrics in Enhanced Monitoring.

RDS delivers the metrics from Enhanced Monitoring into your Amazon CloudWatch Logs account. You can create metrics filters in CloudWatch from CloudWatch Logs and display the graphs on the CloudWatch dashboard. You can consume the Enhanced Monitoring JSON output from CloudWatch Logs in a monitoring system of your choice. For more information, see Enhanced Monitoring in the Amazon RDS FAQs.

Topics

Enhanced Monitoring availability

Enhanced Monitoring is available for the following database engines:

- Db2
- MariaDB
- Microsoft SQL Server
- MySQL
- Oracle
- PostgreSQL

Enhanced Monitoring is available for all DB instance classes except for the db.m1.small instance class.

Differences between CloudWatch and Enhanced Monitoring metrics

A *hypervisor* creates and runs virtual machines (VMs). Using a hypervisor, an instance can support multiple guest VMs by virtually sharing memory and CPU. CloudWatch gathers metrics about CPU utilization from the hypervisor for a DB instance. In contrast, Enhanced Monitoring gathers its metrics from an agent on the DB instance.

You might find differences between the CloudWatch and Enhanced Monitoring measurements, because the hypervisor layer performs a small amount of work. The differences can be greater if your DB instances use smaller instance classes. In this scenario, more virtual machines (VMs) are probably managed by the hypervisor layer on a single physical instance.

For descriptions of the Enhanced Monitoring metrics, see OS metrics in Enhanced Monitoring. For more information about CloudWatch metrics, see the *Amazon CloudWatch User Guide*.

Retention of Enhanced Monitoring metrics

By default, Enhanced Monitoring metrics are stored for 30 days in the CloudWatch Logs. This retention period is different from typical CloudWatch metrics.

To modify the amount of time the metrics are stored in the CloudWatch Logs, change the retention for the `RDSOSMetrics` log group in the CloudWatch console. For more information, see Change log data retention in CloudWatch logs in the *Amazon CloudWatch Logs User Guide*.

Cost of Enhanced Monitoring

Enhanced Monitoring metrics are stored in the CloudWatch Logs instead of in CloudWatch metrics. The cost of Enhanced Monitoring depends on the following factors:

- You are charged for Enhanced Monitoring only if you exceed the free tier provided by Amazon CloudWatch Logs. Charges are based on CloudWatch Logs data transfer and storage rates.
- The amount of information transferred for an RDS instance is directly proportional to the defined granularity for the Enhanced Monitoring feature. A smaller monitoring interval results in more frequent reporting of OS metrics and increases your monitoring cost. To manage costs, set different granularities for different instances in your accounts.
- Usage costs for Enhanced Monitoring are applied for each DB instance that Enhanced Monitoring is enabled for. Monitoring a large number of DB instances is more expensive than monitoring only a few.
- DB instances that support a more compute-intensive workload have more OS process activity to report and higher costs for Enhanced Monitoring.

For more information about pricing, see Amazon CloudWatch pricing.

Setting up and enabling Enhanced Monitoring

To use Enhanced Monitoring, you must create an IAM role, and then enable Enhanced Monitoring.

Topics

- Creating an IAM role for Enhanced Monitoring
- Turning Enhanced Monitoring on and off
- Protecting against the confused deputy problem

Creating an IAM role for Enhanced Monitoring

Enhanced Monitoring requires permission to act on your behalf to send OS metric information to CloudWatch Logs. You grant Enhanced Monitoring permissions using an AWS Identity and Access Management (IAM) role. You can either create this role when you enable Enhanced Monitoring or create it beforehand.

Topics

- Creating the IAM role when you enable Enhanced Monitoring
- Creating the IAM role before you enable Enhanced Monitoring

Creating the IAM role when you enable Enhanced Monitoring

When you enable Enhanced Monitoring in the RDS console, Amazon RDS can create the required IAM role for you. The role is named `rds-monitoring-role`. RDS uses this role for the specified DB instance, read replica, or Multi-AZ DB cluster.

To create the IAM role when enabling Enhanced Monitoring

1. Follow the steps in Turning Enhanced Monitoring on and off.
2. Set **Monitoring Role** to **Default** in the step where you choose a role.

Creating the IAM role before you enable Enhanced Monitoring

You can create the required role before you enable Enhanced Monitoring. When you enable Enhanced Monitoring, specify your new role's name. You must create this required role if you enable Enhanced Monitoring using the AWS CLI or the RDS API.

The user that enables Enhanced Monitoring must be granted the `PassRole` permission. For more information, see Example 2 in Granting a user permissions to pass a role to an AWS service in the *IAM User Guide*.

To create an IAM role for Amazon RDS enhanced monitoring

1. Open the IAM console at https://console.aws.amazon.com.
2. In the navigation pane, choose **Roles**.
3. Choose **Create role**.
4. Choose the **AWS service** tab, and then choose **RDS** from the list of services.
5. Choose **RDS - Enhanced Monitoring**, and then choose **Next**.
6. Ensure that the **Permissions policies** shows **AmazonRDSEnhancedMonitoringRole**, and then choose **Next**.
7. For **Role name**, enter a name for your role. For example, enter **`emaccess`**.

   The trusted entity for your role is the AWS service **monitoring.rds.amazonaws.com**.
8. Choose **Create role**.

Turning Enhanced Monitoring on and off

You can turn Enhanced Monitoring on and off using the AWS Management Console, AWS CLI, or RDS API. You choose the RDS DB instances on which you want to turn on Enhanced Monitoring. You can set different granularities for metric collection on each DB instance.

Console

You can turn on Enhanced Monitoring when you create a DB instance, Multi-AZ DB cluster, or read replica, or when you modify a DB instance or Multi-AZ DB cluster. If you modify a DB instance to turn on Enhanced Monitoring, you don't need to reboot your DB instance for the change to take effect.

You can turn on Enhanced Monitoring in the RDS console when you do one of the following actions in the **Databases** page:

- **Create a DB instance or Multi-AZ DB cluster** – Choose **Create database**.
- **Create a read replica** – Choose **Actions**, then **Create read replica**.
- **Modify a DB instance or Multi-AZ DB cluster** – Choose **Modify**.

To turn Enhanced Monitoring on or off in the RDS console

1. Scroll to **Additional configuration**.
2. In **Monitoring**, choose **Enable Enhanced Monitoring** for your DB instance or read replica. To turn Enhanced Monitoring off, choose **Disable Enhanced Monitoring**.
3. Set the **Monitoring Role** property to the IAM role that you created to permit Amazon RDS to communicate with Amazon CloudWatch Logs for you, or choose **Default** to have RDS create a role for you named `rds-monitoring-role`.
4. Set the **Granularity** property to the interval, in seconds, between points when metrics are collected for your DB instance or read replica. The **Granularity** property can be set to one of the following values: `1`, `5`, `10`, `15`, `30`, or `60`.

   The fastest that the RDS console refreshes is every 5 seconds. If you set the granularity to 1 second in the RDS console, you still see updated metrics only every 5 seconds. You can retrieve 1-second metric updates by using CloudWatch Logs.

AWS CLI

To turn on Enhanced Monitoring using the AWS CLI, in the following commands, set the `--monitoring-interval` option to a value other than `0` and set the `--monitoring-role-arn` option to the role you created in Creating an IAM role for Enhanced Monitoring.

- create-db-instance
- create-db-instance-read-replica
- modify-db-instance
- create-db-cluster (Multi-AZ DB cluster)
- modify-db-cluster (Multi-AZ DB cluster)

The `--monitoring-interval` option specifies the interval, in seconds, between points when Enhanced Monitoring metrics are collected. Valid values for the option are `0`, `1`, `5`, `10`, `15`, `30`, and `60`.

To turn off Enhanced Monitoring using the AWS CLI, set the `--monitoring-interval` option to `0` in these commands.

Example

The following example turns on Enhanced Monitoring for a DB instance:

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier mydbinstance \
    --monitoring-interval 30 \
    --monitoring-role-arn arn:aws:iam::123456789012:role/emaccess
```

For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier mydbinstance ^
    --monitoring-interval 30 ^
    --monitoring-role-arn arn:aws:iam::123456789012:role/emaccess
```

Example

The following example turns on Enhanced Monitoring for a Multi-AZ DB cluster:

For Linux, macOS, or Unix:

```
aws rds modify-db-cluster \
    --db-cluster-identifier mydbcluster \
    --monitoring-interval 30 \
    --monitoring-role-arn arn:aws:iam::123456789012:role/emaccess
```

For Windows:

```
aws rds modify-db-cluster ^
    --db-cluster-identifier mydbcluster ^
    --monitoring-interval 30 ^
    --monitoring-role-arn arn:aws:iam::123456789012:role/emaccess
```

RDS API

To turn on Enhanced Monitoring using the RDS API, set the `MonitoringInterval` parameter to a value other than `0` and set the `MonitoringRoleArn` parameter to the role you created in Creating an IAM role for Enhanced Monitoring. Set these parameters in the following actions:

- CreateDBInstance
- CreateDBInstanceReadReplica
- ModifyDBInstance
- CreateDBCluster (Multi-AZ DB cluster)
- ModifyDBCluster (Multi-AZ DB cluster)

The `MonitoringInterval` parameter specifies the interval, in seconds, between points when Enhanced Monitoring metrics are collected. Valid values are `0`, `1`, `5`, `10`, `15`, `30`, and `60`.

To turn off Enhanced Monitoring using the RDS API, set `MonitoringInterval` to `0`.

Protecting against the confused deputy problem

The confused deputy problem is a security issue where an entity that doesn't have permission to perform an action can coerce a more-privileged entity to perform the action. In AWS, cross-service impersonation can result in the confused deputy problem. Cross-service impersonation can occur when one service (the *calling service*) calls another service (the *called service*). The calling service can be manipulated to use its permissions to act on another customer's resources in a way it should

not otherwise have permission to access. To prevent this, AWS provides tools that help you protect your data for all services with service principals that have been given access to resources in your account. For more information, see The confused deputy problem.

To limit the permissions to the resource that Amazon RDS can give another service, we recommend using the `aws:SourceArn` and `aws:SourceAccount` global condition context keys in a trust policy for your Enhanced Monitoring role. If you use both global condition context keys, they must use the same account ID.

The most effective way to protect against the confused deputy problem is to use the `aws:SourceArn` global condition context key with the full ARN of the resource. For Amazon RDS, set `aws:SourceArn` to `arn:aws:rds:`*`Region`*`:`*`my-account-id`*`:db:`*`dbname`*.

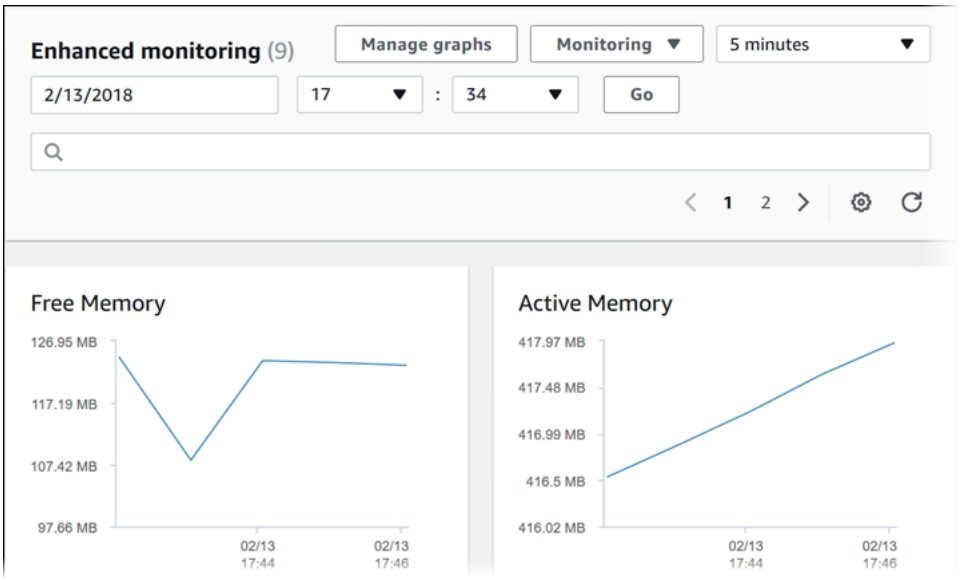
The following example uses the `aws:SourceArn` and `aws:SourceAccount` global condition context keys in a trust policy to prevent the confused deputy problem.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": "monitoring.rds.amazonaws.com"
      },
      "Action": "sts:AssumeRole",
      "Condition": {
        "StringLike": {
          "aws:SourceArn": "arn:aws:rds:Region:my-account-id:db:dbname"
        },
        "StringEquals": {
          "aws:SourceAccount": "my-account-id"
        }
      }
    }
  ]
}
```

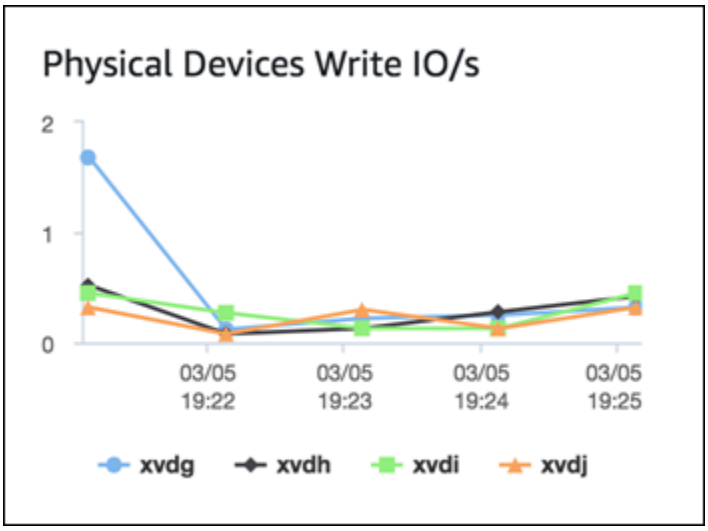
Viewing OS metrics in the RDS console

You can view OS metrics reported by Enhanced Monitoring in the RDS console by choosing **Enhanced monitoring** for **Monitoring**.

The following example shows the Enhanced Monitoring page. For descriptions of the Enhanced Monitoring metrics, see OS metrics in Enhanced Monitoring.



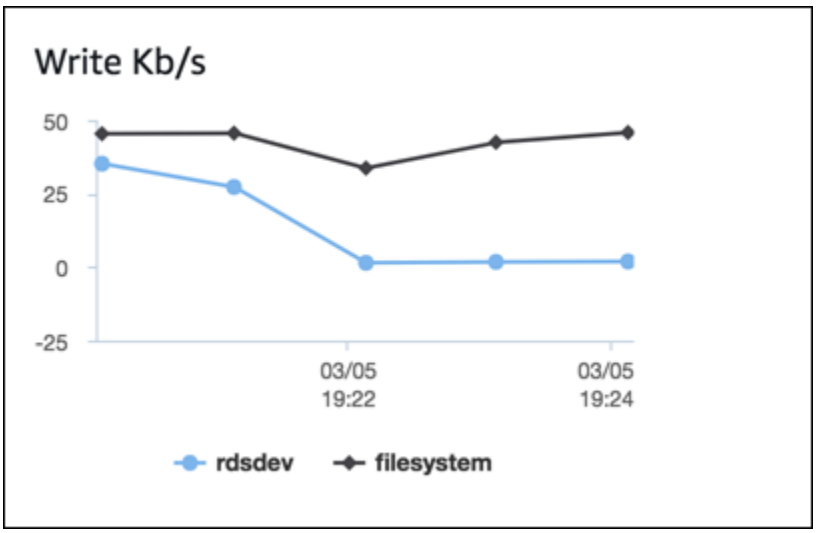
Some DB instances use more than one disk for the DB instance's data storage volume. On those DB instances, the **Physical Devices** graphs show metrics for each one of the disks. For example, the following graph shows metrics for four disks.



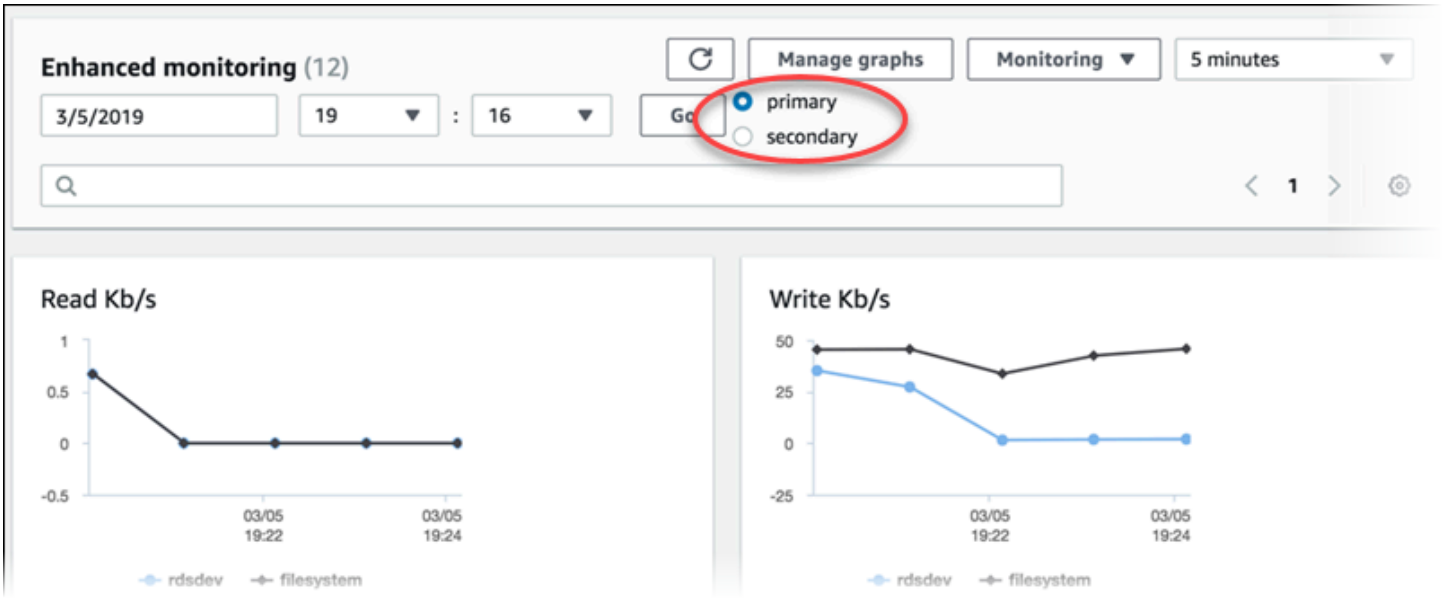
> **Note**
>
> Currently, **Physical Devices** graphs are not available for Microsoft SQL Server DB instances.

When you are viewing aggregated **Disk I/O** and **File system** graphs, the **rdsdev** device relates to the `/rdsdbdata` file system, where all database files and logs are stored. The **filesystem** device

relates to the / file system (also known as root), where files related to the operating system are stored.



If the DB instance is a Multi-AZ deployment, you can view the OS metrics for the primary DB instance and its Multi-AZ standby replica. In the **Enhanced monitoring** view, choose **primary** to view the OS metrics for the primary DB instance, or choose **secondary** to view the OS metrics for the standby replica.

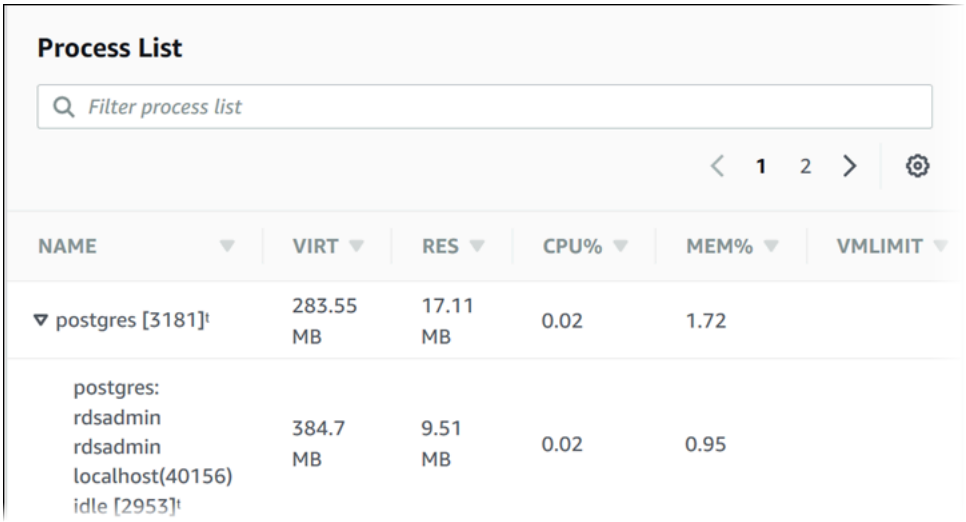


For more information about Multi-AZ deployments, see [Configuring and managing a Multi-AZ deployment].

> **Note**
>
> Currently, viewing OS metrics for a Multi-AZ standby replica is not supported for MariaDB DB instances.

If you want to see details for the processes running on your DB instance, choose **OS process list** for **Monitoring**.

The **Process List** view is shown following.



The Enhanced Monitoring metrics shown in the **Process list** view are organized as follows:

- **RDS child processes** – Shows a summary of the RDS processes that support the DB instance, for example `mysqld` for MySQL DB instances. Process threads appear nested beneath the parent process. Process threads show CPU utilization only as other metrics are the same for all threads for the process. The console displays a maximum of 100 processes and threads. The results are a combination of the top CPU consuming and memory consuming processes and threads. If there are more than 50 processes and more than 50 threads, the console displays the top 50 consumers in each category. This display helps you identify which processes are having the greatest impact on performance.
- **RDS processes** – Shows a summary of the resources used by the RDS management agent, diagnostics monitoring processes, and other AWS processes that are required to support RDS DB instances.
- **OS processes** – Shows a summary of the kernel and system processes, which generally have minimal impact on performance.

The items listed for each process are:

- **VIRT** – Displays the virtual size of the process.
- **RES** – Displays the actual physical memory being used by the process.
- **CPU%** – Displays the percentage of the total CPU bandwidth being used by the process.
- **MEM%** – Displays the percentage of the total memory being used by the process.

The monitoring data that is shown in the RDS console is retrieved from Amazon CloudWatch Logs. You can also retrieve the metrics for a DB instance as a log stream from CloudWatch Logs. For more information, see Viewing OS metrics using CloudWatch Logs.

Enhanced Monitoring metrics are not returned during the following:

- A failover of the DB instance.
- Changing the instance class of the DB instance (scale compute).

Enhanced Monitoring metrics are returned during a reboot of a DB instance because only the database engine is rebooted. Metrics for the operating system are still reported.

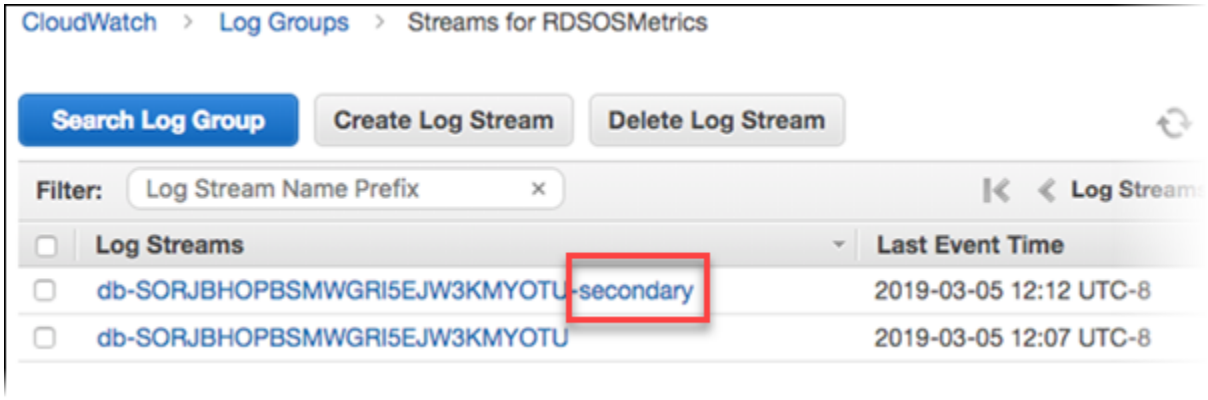
Viewing OS metrics using CloudWatch Logs

After you have enabled Enhanced Monitoring for your DB instance or Multi-AZ DB cluster, you can view the metrics for it using CloudWatch Logs, with each log stream representing a single DB instance or DB cluster being monitored. The log stream identifier is the resource identifier (`DbiResourceId`) for the DB instance or DB cluster.

To view Enhanced Monitoring log data

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. If necessary, choose the AWS Region that your DB instance or Multi-AZ DB cluster is in. For more information, see Regions and endpoints in the *Amazon Web Services General Reference*.
3. Choose **Logs** in the navigation pane.
4. Choose **RDSOSMetrics** from the list of log groups.

   In a Multi-AZ DB instance deployment, log files with `-secondary` appended to the name are for the Multi-AZ standby replica.



5. Choose the log stream that you want to view from the list of log streams.

Metrics reference for Amazon RDS

In this reference, you can find descriptions of Amazon RDS metrics for Amazon CloudWatch, Performance Insights, and Enhanced Monitoring.

Topics

Amazon CloudWatch metrics for Amazon RDS

Amazon RDS publishes metrics to Amazon CloudWatch in the `AWS/RDS` and `AWS/Usage` namespaces.

Topics

Amazon CloudWatch instance-level metrics for Amazon RDS

The `AWS/RDS` namespace in Amazon CloudWatch includes the following instance-level metrics.

> **Note**
>
> The Amazon RDS console might display metrics in units that are different from the units sent to Amazon CloudWatch. For example, the Amazon RDS console might display a metric in megabytes (MB), while the metric is sent to Amazon CloudWatch in bytes.

Metric	Description	Applies to	Units
`BinLogDiskUsage`	The amount of disk space occupied by binary logs. If automatic backups are enabled for MySQL and MariaDB instances, including read replicas, binary logs are created.	MariaDB MySQL	Bytes
`BurstBalance`	The percent of General Purpose SSD (gp2) burst-bucket I/O credits available.	All	Percent
`CheckpointLag`	The amount of time since the most recent checkpoint.		Seconds
`ConnectionAttempts`	The number of attempts to connect to an instance, whether successful or not.	MySQL	Count
`CPUUtilization`	The percentage of CPU utilization.	All	Percentage
`CPUCreditUsage`	The number of CPU credits spent by the instance for CPU utilization. One CPU credit equals one vCPU running at 100 percent utilization for one minute or an equivalent combination of vCPUs, utilization, and time. For example, you might have one vCPU running at 50 percent utilization for two minutes or two vCPUs running at 25 percent utilization for two minutes. This metric applies only to `db.t2`, `db.t3`, and `db.t4g` instances. **Note** We recommend using the T DB instance classes only		Credits (vCPU-minutes)

Metric	Description	Applies to	Units
	for development and test servers, or other non-production servers. For more details on the T instance classes, see DB instance class types CPU credit metrics are available at a five-minute frequency only. If you specify a period greater than five minutes, use the `Sum` statistic instead of the `Average` statistic.		

Metric	Description	Applies to	Units
`CPUCreditBalance`	The number of earned CPU credits that an instance has accrued since it was launched or started. For T2 Standard, the `CPUCreditBalance` also includes the number of launch credits that have been accrued. Credits are accrued in the credit balance after they are earned, and removed from the credit balance when they are spent. The credit balance has a maximum limit, determined by the instance size. After the limit is reached, any new credits that are earned are discarded. For T2 Standard, launch credits don't count towards the limit. The credits in the `CPUCreditBalance` are available for the instance to spend to burst beyond its baseline CPU utilization. When an instance is running, credits in the `CPUCreditBalance` don't expire. When the instance stops, the `CPUCreditBalance` does not persist, and all accrued credits are lost. CPU credit metrics are available at a five-minute frequency only. This metric applies only to `db.t2`, `db.t3`, and `db.t4g` instances.		Credits (vCPU-minutes)

Metric	Description	Applies to	Units
	Note We recommend using the T DB instance classes only for development and test servers, or other non-production servers. For more details on the T instance classes, see DB instance class types Launch credits work the same way in Amazon RDS as they do in Amazon EC2. For more information, see Launch credits in the *Amazon Elastic Compute Cloud User Guide for Linux Instances*.		
`CPUSurplusCreditBalance`	The number of surplus credits that have been spent by an unlimited instance when its `CPUCreditBalance` value is zero. The `CPUSurplusCreditBalance` value is paid down by earned CPU credits. If the number of surplus credits exceeds the maximum number of credits that the instance can earn in a 24-hour period, the spent surplus credits above the maximum incur an additional charge. CPU credit metrics are available at a 5-minute frequency only.	All	Credits (vCPU-minutes)

Metric	Description	Applies to	Units
`CPUSurplusCreditsCharged`	The number of spent surplus credits that are not paid down by earned CPU credits, and which thus incur an additional charge. Spent surplus credits are charged when any of the following occurs: • The spent surplus credits exceed the maximum number of credits that the instance can earn in a 24-hour period. Spent surplus credits above the maximum are charged at the end of the hour. • The instance is stopped or terminated. • The instance is switched from `unlimited` to `standard`. CPU credit metrics are available at a 5-minute frequency only.	All	Credits (vCPU-minutes)

Metric	Description	Applies to	Units
`DatabaseConnections`	The number of client network connections to the database instance. The number of database sessions can be higher than the metric value because the metric value doesn't include the following: • Sessions that no longer have a network connection but which the database hasn't cleaned up • Sessions created by the database engine for its own purposes • Sessions created by the database engine's parallel execution capabilities • Sessions created by the database engine job scheduler • Amazon RDS connections	All	Count
`DiskQueueDepth`	The number of outstanding I/Os (read/write requests) waiting to access the disk.	All	Count
`DiskQueueDepthLogVolume`	The number of outstanding I/Os (read/write requests) waiting to access the log volume disk.	All	Count

Metric	Description	Applies to	Units
EBSByteBalance%	The percentage of throughput credits remaining in the burst bucket of your RDS database. This metric is available for basic monitoring only. The metric value is based on the throughput of all volumes, including the root volume, rather than on only those volumes containing database files. To find the instance sizes that support this metric, see the instance sizes with an asterisk (*) in the EBS optimized by default table in *Amazon EC2 User Guide*. The Sum statistic is not applicable to this metric.	All	Percentage

Metric	Description	Applies to	Units
EBSIOBalance%	The percentage of I/O credits remaining in the burst bucket of your RDS database. This metric is available for basic monitoring only. The metric value is based on the IOPS of all volumes, including the root volume, rather than on only those volumes containing database files. To find the instance sizes that support this metric, see Amazon EBS–optimized instance types in *Amazon EC2 User Guide*. The Sum statistic isn't applicable to this metric. This metric is different from BurstBalance . To learn how to use this metric, see Improving application performance and reducing costs with Amazon EBS-Optimized Instance burst capability.	All	Percentage
FailedSQLServerAgentJobsCount	The number of failed Microsoft SQL Server Agent jobs during the last minute.	Microsoft SQL Server	Count per minute
FreeableMemory	The amount of available random access memory. For MariaDB, MySQL, Oracle, and PostgreSQL DB instances, this metric reports the value of the MemAvailable field of /proc/meminfo .	All	Bytes

Metric	Description	Applies to	Units
FreeLocalStorage	The amount of available local storage space. This metric only applies to DB instance classes with NVMe SSD instance store volumes. For information about Amazon EC2 instances with NVMe SSD instance store volumes, see Instance store volumes. The equivalent RDS DB instance classes have the same instance store volumes. For example, the db.m6gd and db.r6gd DB instance classes have NVMe SSD instance store volumes.		Bytes
FreeLocalStoragePercent	The percentage of available local storage space. This metric only applies to DB instance classes with NVMe SSD instance store volumes. For information about Amazon EC2 instances with NVMe SSD instance store volumes, see Instance store volumes. The equivalent RDS DB instance classes have the same instance store volumes. For example, the db.m6gd and db.r6gd DB instance classes have NVMe SSD instance store volumes.		Percentage
FreeStorageSpace	The amount of available storage space.	All	Bytes
FreeStorageSpaceLogVolume	The amount of available storage space on the log volume.	All	Bytes

Metric	Description	Applies to	Units
MaximumUsedTransactionIDs	The maximum transaction IDs that have been used.	PostgreSQL	Count
NetworkReceiveThroughput	The incoming (receive) network traffic on the DB instance, including both customer database traffic and Amazon RDS traffic used for monitoring and replication.	All	Bytes per second
NetworkTransmitThroughput	The outgoing (transmit) network traffic on the DB instance, including both customer database traffic and Amazon RDS traffic used for monitoring and replication.	All	Bytes per second
OldestReplicationSlotLag	The lagging size of the replica lagging the most in terms of write-ahead log (WAL) data received.	PostgreSQL	Bytes
ReadIOPS	The average number of disk read I/O operations per second.	All	Count per second

Metric	Description	Applies to	Units
`ReadIOPSLocalStorage`	The average number of disk read I/O operations to local storage per second. This metric only applies to DB instance classes with NVMe SSD instance store volumes. For information about Amazon EC2 instances with NVMe SSD instance store volumes, see Instance store volumes. The equivalent RDS DB instance classes have the same instance store volumes. For example, the db.m6gd and db.r6gd DB instance classes have NVMe SSD instance store volumes.		Count per second
`ReadIOPSLogVolume`	The average number of disk read I/O operations per second for the log volume.	All	Count per second
`ReadLatency`	The average amount of time taken per disk I/O operation.	All	Seconds
`ReadLatencyLocalStorage`	The average amount of time taken per disk I/O operation for local storage. This metric only applies to DB instance classes with NVMe SSD instance store volumes. For information about Amazon EC2 instances with NVMe SSD instance store volumes, see Instance store volumes. The equivalent RDS DB instance classes have the same instance store volumes. For example, the db.m6gd and db.r6gd DB instance classes have NVMe SSD instance store volumes.		Seconds

Metric	Description	Applies to	Units
ReadLatencyLogVolume	The average amount of time taken per disk I/O operation for the log volume.	All	Seconds
ReadThroughput	The average number of bytes read from disk per second.	All	Bytes per second
ReadThroughputLocalStorage	The average number of bytes read from disk per second for local storage. This metric only applies to DB instance classes with NVMe SSD instance store volumes. For information about Amazon EC2 instances with NVMe SSD instance store volumes, see Instance store volumes. The equivalent RDS DB instance classes have the same instance store volumes. For example, the db.m6gd and db.r6gd DB instance classes have NVMe SSD instance store volumes.		Bytes per second
ReadThroughputLogVolume	The average number of bytes read from disk per second for the log volume.	All	Bytes per second

Metric	Description	Applies to	Units
ReplicaLag	For read replica configurations, the amount of time a read replica DB instance lags behind the source DB instance. Applies to MariaDB, Microsoft SQL Server, MySQL, Oracle, and PostgreSQL read replicas. For Multi-AZ DB clusters, the differenc e in time between the latest transacti on on the writer DB instance and the latest applied transaction on a reader DB instance.		Seconds
ReplicationChannelLag	For multi-source replica configura tions, the amount of time a particula r channel on the multi-source replica lags behind the source DB instance. For more information, see the section called “Monitoring multi-source replication channels”.	MySQL	Seconds
ReplicationSlotDiskUsage	The disk space used by replication slot files.	PostgreSQL	Bytes
SwapUsage	The amount of swap space used on the DB instance.	MariaDB MySQL Oracle PostgreSQL	Bytes
TransactionLogsDiskUsage	The disk space used by transaction logs.	PostgreSQL	Bytes

Metric	Description	Applies to	Units
`TransactionLogsGeneration`	The size of transaction logs generated per second.	PostgreSQL	Bytes per second
`WriteIOPS`	The average number of disk write I/O operations per second.	All	Count per second
`WriteIOPSLocalStorage`	The average number of disk write I/O operations per second on local storage. This metric only applies to DB instance classes with NVMe SSD instance store volumes. For information about Amazon EC2 instances with NVMe SSD instance store volumes, see Instance store volumes. The equivalent RDS DB instance classes have the same instance store volumes. For example, the db.m6gd and db.r6gd DB instance classes have NVMe SSD instance store volumes.		Count per second
`WriteIOPSLogVolume`	The average number of disk write I/O operations per second for the log volume.	All	Count per second
`WriteLatency`	The average amount of time taken per disk I/O operation.	All	Seconds

Metric	Description	Applies to	Units
`WriteLatencyLocalStorage`	The average amount of time taken per disk I/O operation on local storage. This metric only applies to DB instance classes with NVMe SSD instance store volumes. For information about Amazon EC2 instances with NVMe SSD instance store volumes, see Instance store volumes. The equivalent RDS DB instance classes have the same instance store volumes. For example, the db.m6gd and db.r6gd DB instance classes have NVMe SSD instance store volumes.		Seconds
`WriteLatencyLogVolume`	The average amount of time taken per disk I/O operation for the log volume.	All	Seconds
`WriteThroughput`	The average number of bytes written to disk per second.	All	Bytes per second
`WriteThroughputLogVolume`	The average number of bytes written to disk per second for the log volume.	All	Bytes per second

Metric	Description	Applies to	Units
`WriteThroughputLocalStorage`	The average number of bytes written to disk per second for local storage. This metric only applies to DB instance classes with NVMe SSD instance store volumes. For information about Amazon EC2 instances with NVMe SSD instance store volumes, see Instance store volumes. The equivalent RDS DB instance classes have the same instance store volumes. For example, the db.m6gd and db.r6gd DB instance classes have NVMe SSD instance store volumes.		Bytes per second

Amazon CloudWatch usage metrics for Amazon RDS

The `AWS/Usage` namespace in Amazon CloudWatch includes account-level usage metrics for your Amazon RDS service quotas. CloudWatch collects usage metrics automatically for all AWS Regions.

For more information, see CloudWatch usage metrics in the *Amazon CloudWatch User Guide*. For more information about quotas, see Quotas and constraints for Amazon RDS and Requesting a quota increase in the *Service Quotas User Guide*.

Metric	Description	Units*
`AllocatedStorage`	The total storage for all DB instances. The sum excludes temporary migration instances.	Gigabytes
`DBClusterParameterGroups`	The number of DB cluster parameter groups in your AWS account. The count excludes default parameter groups.	Count
`DBClusters`	The number of Amazon Aurora DB clusters in your AWS account.	Count
`DBInstances`	The number of DB instances in your AWS account.	Count

Metric	Description	Units*
DBParameterGroups	The number of DB parameter groups in your AWS account. The count excludes the default DB parameter groups.	Count
DBSecurityGroups	The number of security groups in your AWS account. The count excludes the default security group and the default VPC security group.	Count
DBSubnetGroups	The number of DB subnet groups in your AWS account. The count excludes the default subnet group.	Count
ManualClusterSnapshots	The number of manually created DB cluster snapshots in your AWS account. The count excludes invalid snapshots.	Count
ManualSnapshots	The number of manually created DB snapshots in your AWS account. The count excludes invalid snapshots.	Count
OptionGroups	The number of option groups in your AWS account. The count excludes the default option groups.	Count
ReservedDBInstances	The number of reserved DB instances in your AWS account. The count excludes retired or declined instances.	Count

Note

Amazon RDS doesn't publish units for usage metrics to CloudWatch. The units only appear in the documentation.

Amazon CloudWatch dimensions for Amazon RDS

You can filter Amazon RDS metrics data by using any dimension in the following table.

Dimension	Filters the requested data for . . .
DBInstanceIdentifier	A specific DB instance.

Dimension	Filters the requested data for . . .
`DatabaseClass`	All instances in a database class. For example, you can aggregate metrics for all instances that belong to the database class `db.r5.large` .
`EngineName`	The identified engine name only. For example, you can aggregate metrics for all instances that have the engine name `postgres`.
`SourceRegion`	The specified Region only. For example, you can aggregate metrics for all DB instances in the `us-east-1` Region.

Amazon CloudWatch metrics for Amazon RDS Performance Insights

Performance Insights automatically publishes some metrics to Amazon CloudWatch. The same data can be queried from Performance Insights, but having the metrics in CloudWatch makes it easy to add CloudWatch alarms. It also makes it easy to add the metrics to existing CloudWatch Dashboards.

Metric	Description
DBLoad	The number of active sessions for the database. Typically, you want the data for the average number of active sessions. In Performance Insights, this data is queried as `db.load.avg` .
DBLoadCPU	The number of active sessions where the wait event type is CPU. In Performance Insights, this data is queried as `db.load.avg` , filtered by the wait event type CPU.
DBLoadNonCPU	The number of active sessions where the wait event type is not CPU.

Metric	Description
DBLoadRelativeToNumVCPUs	The ratio of the DB load to the number of virtual CPUs for the database.

> **Note**
>
> These metrics are published to CloudWatch only if there is load on the DB instance.

You can examine these metrics using the CloudWatch console, the AWS CLI, or the CloudWatch API. You can also examine other Performance Insights counter metrics using a special metric math function. For more information, see Querying other Performance Insights counter metrics in CloudWatch.

For example, you can get the statistics for the DBLoad metric by running the get-metric-statistics command.

```
aws cloudwatch get-metric-statistics \
    --region us-west-2 \
    --namespace AWS/RDS \
    --metric-name DBLoad  \
    --period 60 \
    --statistics Average \
    --start-time 1532035185 \
    --end-time 1532036185 \
    --dimensions Name=DBInstanceIdentifier,Value=db-loadtest-0
```

This example generates output similar to the following.

```
{
  "Datapoints": [
  {
  "Timestamp": "2021-07-19T21:30:00Z",
  "Unit": "None",
  "Average": 2.1
  },
  {
  "Timestamp": "2021-07-19T21:34:00Z",
```

```
"Unit": "None",
"Average": 1.7
},
{
"Timestamp": "2021-07-19T21:35:00Z",
"Unit": "None",
"Average": 2.8
},
{
"Timestamp": "2021-07-19T21:31:00Z",
"Unit": "None",
"Average": 1.5
},
{
"Timestamp": "2021-07-19T21:32:00Z",
"Unit": "None",
"Average": 1.8
},
{
"Timestamp": "2021-07-19T21:29:00Z",
"Unit": "None",
"Average": 3.0
},
{
"Timestamp": "2021-07-19T21:33:00Z",
"Unit": "None",
"Average": 2.4
}
],
"Label": "DBLoad"
}
```

For more information about CloudWatch, see What is Amazon CloudWatch? in the *Amazon CloudWatch User Guide*.

Querying other Performance Insights counter metrics in CloudWatch

You can query, alarm, and graphs on RDS Performance Insights metrics from CloudWatch. You can access information about your DB instance by using the `DB_PERF_INSIGHTS` metric math function for CloudWatch. This function allows you to use the Performance Insights metrics that are not directly reported to CloudWatch to create a new time series.

You can use the new Metric Math function by clicking on the **Add Math** drop-down menu in the **Select metric** screen in the CloudWatch console. You can use it to create alarms and graphs on Performance Insights metrics or on combinations of CloudWatch and Performance Insights metrics, including high-resolution alarms for sub-minute metrics. You can also use the function programmatically by including the Metric Math expression in a `get-metric-data` request. For more information, see Metric math syntax and functions and Create an alarm on Performance Insights counter metrics from an AWS database.

Performance Insights counter metrics

Counter metrics are operating system and database performance metrics in the Performance Insights dashboard. To help identify and analyze performance problems, you can correlate counter metrics with DB load. You can add a statistic function to the metric to get the metric values. For example, the supported functions for `os.memory.active` metric are `.avg`, `.min`, `.max`, `.sum`, and `.sample_count`.

The counter metrics are collected one time each minute. The OS metrics collection depends on whether Enhanced Monitoring is turned on or off. If Enhanced Monitoring is turned off, the OS metrics are collected one time each minute. If Enhanced Monitoring is turned on, the OS metrics are collected for the selected time period. For more information about turning Enhanced Monitoring on or off, see Turning Enhanced Monitoring on and off.

Topics

- Performance Insights operating system counters
- Performance Insights counters for Amazon RDS for MariaDB and MySQL
- Performance Insights counters for Amazon RDS for Microsoft SQL Server
- Performance Insights counters for Amazon RDS for Oracle
- Performance Insights counters for Amazon RDS for PostgreSQL

Performance Insights operating system counters

The following operating system counters, which are prefixed with `os`, are available with Performance Insights for all RDS engines except RDS for SQL Server .

You can use `ListAvailableResourceMetrics` API for the list of available counter metrics for your DB instance. For more information, see ListAvailableResourceMetrics in the Amazon RDS Performance Insights API Reference guide.

Counter	Type	Metric	Description
Active	Memory	os.memory.active	The amount of assigned memory, in kilobytes.
Buffers	Memory	os.memory.buffers	The amount of memory used for buffering I/O requests prior to writing to the storage device, in kilobytes.
Cached	Memory	os.memory.cached	The amount of memory used for caching file system–based I/O, in kilobytes.
DB Cache	Memory	os.memory.db.cache	The amount of memory used for page cache by database process including tmpfs (shmem), in bytes.
DB Resident Set Size	Memory	os.memory.db.residentSetSize	The amount of memory used for anonymous and swap cache by database process not including tmpfs (shmem), in bytes.
DB Swap	Memory	os.memory.db.swap	The amount of memory used for

Counter	Type	Metric	Description
			swap by database process, in bytes.
Dirty	Memory	os.memory.dirty	The amount of memory pages in RAM that have been modified but not written to their related data block in storage, in kilobytes.
Free	Memory	os.memory.free	The amount of unassigned memory, in kilobytes.
Huge Pages Free	Memory	os.memory.hugePagesFree	The number of free huge pages. Huge pages are a feature of the Linux kernel.
Huge Pages Rsvd	Memory	os.memory.hugePagesRsvd	The number of committed huge pages.
Huge Pages Size	Memory	os.memory.hugePagesSize	The size for each huge pages unit, in kilobytes.
Huge Pages Surp	Memory	os.memory.hugePagesSurp	The number of available surplus huge pages over the total.
Huge Pages Total	Memory	os.memory.hugePagesTotal	The total number of huge pages.

Counter	Type	Metric	Description
Inactive	Memory	os.memory.inactive	The amount of least-frequently used memory pages, in kilobytes.
Mapped	Memory	os.memory.mapped	The total amount of file-system contents that is memory mapped inside a process address space, in kilobytes.s
Out of Memory Kill Count	Memory	os.memory .outOfMemoryKillCount	The number of OOM kills that happened over the last collection interval.
Page Tables	Memory	os.memory.pageTables	The amount of memory used by page tables, in kilobytes.
Slab	Memory	os.memory.slab	The amount of reusable kernel data structures, in kilobytes.
Total	Memory	os.memory.total	The total amount of memory, in kilobytes.
Writeback	Memory	os.memory.writeback	The amount of dirty pages in RAM that are still being written to the backing storage, in kilobytes.

Counter	Type	Metric	Description
Guest	Cpu Utilization	os.cpuUtilization.guest	The percentage of CPU in use by guest programs.
Idle	Cpu Utilization	os.cpuUtilization.idle	The percentage of CPU that is idle.
Irq	Cpu Utilization	os.cpuUtilization.irq	The percentage of CPU in use by software interrupts.
Nice	Cpu Utilization	os.cpuUtilization.nice	The percentage of CPU in use by programs running at lowest priority.
Steal	Cpu Utilization	os.cpuUtilization.steal	The percentage of CPU in use by other virtual machines.
System	Cpu Utilization	os.cpuUtilization.system	The percentage of CPU in use by the kernel.
Total	Cpu Utilization	os.cpuUtilization.total	The total percentage of the CPU in use. This value includes the nice value.
User	Cpu Utilization	os.cpuUtilization.user	The percentage of CPU in use by user programs.
Wait	Cpu Utilization	os.cpuUtilization.wait	The percentage of CPU unused while waiting for I/O access.

Counter	Type	Metric	Description
Read IOs PS	Disk IO	os.diskIO.<devicename>.readIOsPS	The number of read operations per second.
Write IOs PS	Disk IO	os.diskIO.<devicename>.writeIOsPS	The number of write operations per second.
Avg Queue Len	Disk IO	os.diskIO.<devicename>.avgQueueLen	The number of requests waiting in the I/O device's queue.
Avg Req Sz	Disk IO	os.diskIO.<devicename>.avgReqSz	The number of requests waiting in the I/O device's queue.
Await	Disk IO	os.diskIO.<devicename>.await	The number of milliseconds required to respond to requests, including queue time and service time.
Read IOs PS	Disk IO	os.diskIO.<devicename>.readIOsPS	The number of read operations per second.
Read KB	Disk IO	os.diskIO.<devicename>.readKb	The total number of kilobytes read.
Read KB PS	Disk IO	os.diskIO.<devicename>.readKbPS	The number of kilobytes read per second.

Counter	Type	Metric	Description
Rrqm PS	Disk IO	os.diskIO.<devicename>.rrqmPS	The number of merged read requests queued per second.
TPS	Disk IO	os.diskIO.<devicename>.tps	The number of I/O transactions per second.
Util	Disk IO	os.diskIO.<devicename>.util	The percentage of CPU time during which requests were issued.
Write KB	Disk IO	os.diskIO.<devicename>.writeKb	The total number of kilobytes written.
Write KB PS	Disk IO	os.diskIO.<devicename>.writeKbPS	The number of kilobytes written per second.
Wrqm PS	Disk IO	os.diskIO.<devicename>.wrqmPS	The number of merged write requests queued per second.
Blocked	Tasks	os.tasks.blocked	The number of tasks that are blocked.
Running	Tasks	os.tasks.running	The number of tasks that are running.
Sleeping	Tasks	os.tasks.sleeping	The number of tasks that are sleeping.
Stopped	Tasks	os.tasks.stopped	The number of tasks that are stopped.

Counter	Type	Metric	Description
Total	Tasks	os.tasks.total	The total number of tasks.
Zombie	Tasks	os.tasks.zombie	The number of child tasks that are inactive with an active parent task.
One	Load Average Minute	os.loadAverageMinute.one	The number of processes requesting CPU time over the last minute.
Fifteen	Load Average Minute	os.loadAverageMinute.fifteen	The number of processes requesting CPU time over the last 15 minutes.
Five	Load Average Minute	os.loadAverageMinute.five	The number of processes requesting CPU time over the last 5 minutes.
Cached	Swap	os.swap.cached	The amount of swap memory, in kilobytes, used as cache memory.
Free	Swap	os.swap.free	The amount of swap memory free, in kilobytes.
In	Swap	os.swap.in	The amount of memory, in kilobytes, swapped in from disk.

Counter	Type	Metric	Description
Out	Swap	os.swap.out	The amount of memory, in kilobytes, swapped out to disk.
Total	Swap	os.swap.total	The total amount of swap memory available in kilobytes.
Max Files	File Sys	os.fileSys.maxFiles	The maximum number of files that can be created for the file system.
Used Files	File Sys	os.fileSys.usedFiles	The number of files in the file system.
Used File Percent	File Sys	os.fileSys.usedFilePercent	The percentage of available files in use.
Used Percent	File Sys	os.fileSys.usedPercent	The percentage of the file-system disk space in use.
Used	File Sys	os.fileSys.used	The amount of disk space used by files in the file system, in kilobytes.
Total	File Sys	os.fileSys.total	The total number of disk space available for the file system, in kilobytes.
Rx	Network	os.network.rx	The number of bytes received per second.

Counter	Type	Metric	Description
Tx	Network	os.network.tx	The number of bytes uploaded per second.
Acu Utilization	General	os.general.acuUtilization	The percentage of current capacity out of the maximum configured capacity.
Max Configured Acu	General	os.general.maxConfiguredAcu	The maximum capacity configured by the user, in ACUs.
Min Configured Acu	General	os.general.minConfiguredAcu	The minimum capacity configured by the user, in ACUs.
Num VCPUs	General	os.general.numVCPUs	The number of virtual CPUs for the DB instance.
Serverless Database Capacity	General	os.general.serverlessDatabaseCapacity	The current capacity of the instance, in ACUs.

Performance Insights counters for Amazon RDS for MariaDB and MySQL

The following database counters are available with Performance Insights for Amazon RDS for MariaDB and MySQL.

Topics

- Native counters for RDS for MariaDB and RDS for MySQL
- Non-native counters for Amazon RDS for MariaDB and MySQL

Native counters for RDS for MariaDB and RDS for MySQL

Native metrics are defined by the database engine and not by Amazon RDS. For definitions of these native metrics, see Server status variables in the MySQL documentation.

Counter	Type	Unit	Metric
Com_analyze	SQL	Queries per second	db.SQL.Com_analyze
Com_optimize	SQL	Queries per second	db.SQL.Com_optimize
Com_select	SQL	Queries per second	db.SQL.Com_select
Connections	SQL	The number of connection attempts per minute (successful or not) to the MySQL server	db.Users.Connections
Innodb_rows_deleted	SQL	Rows per second	db.SQL.Innodb_rows_deleted
Innodb_rows_inserted	SQL	Rows per second	db.SQL.Innodb_rows_inserted
Innodb_rows_read	SQL	Rows per second	db.SQL.Innodb_rows_read
Innodb_rows_updated	SQL	Rows per second	db.SQL.Innodb_rows_updated
Select_full_join	SQL	Queries per second	db.SQL.Select_full_join

Counter	Type	Unit	Metric
Select_full_range_join	SQL	Queries per second	db.SQL.Select_full_range_join
Select_range	SQL	Queries per second	db.SQL.Select_range
Select_range_check	SQL	Queries per second	db.SQL.Select_range_check
Select_scan	SQL	Queries per second	db.SQL.Select_scan
Slow_queries	SQL	Queries per second	db.SQL.Slow_queries
Sort_merge_passes	SQL	Queries per second	db.SQL.Sort_merge_passes
Sort_range	SQL	Queries per second	db.SQL.Sort_range
Sort_rows	SQL	Queries per second	db.SQL.Sort_rows
Sort_scan	SQL	Queries per second	db.SQL.Sort_scan
Questions	SQL	Queries per second	db.SQL.Questions
Innodb_row_lock_time	Locks	Milliseconds (average)	db.Locks.Innodb_row_lock_time
Table_locks_immediate	Locks	Requests per second	db.Locks.Table_locks_immediate
Table_locks_waited	Locks	Requests per second	db.Locks.Table_locks_waited

Counter	Type	Unit	Metric
Aborted_clients	Users	Connections	db.Users.Aborted_clients
Aborted_connects	Users	Connections	db.Users.Aborted_connects
max_connections	Users	Connections	db.User.max_connections
Threads_created	Users	Connections	db.Users.Threads_created
Threads_running	Users	Connections	db.Users.Threads_running
Innodb_data_writes	I/O	Operations per second	db.IO.Innodb_data_writes
Innodb_dblwr_writes	I/O	Operations per second	db.IO.Innodb_dblwr_writes
Innodb_log_write_requests	I/O	Operations per second	db.IO.Innodb_log_write_requests
Innodb_log_writes	I/O	Operations per second	db.IO.Innodb_log_writes
Innodb_pages_written	I/O	Pages per second	db.IO.Innodb_pages_written
Created_tmp_disk_tables	Temp	Tables per second	db.Temp.Created_tmp_disk_tables
Created_tmp_tables	Temp	Tables per second	db.Temp.Created_tmp_tables
Innodb_buffer_pool_pages_data	Cache	Pages	db.Cache.Innodb_buffer_pool_pages_data
Innodb_buffer_pool_pages_total	Cache	Pages	db.Cache.Innodb_buffer_pool_pages_total

Counter	Type	Unit	Metric
Innodb_buffer_pool_read_requests	Cache	Pages per second	db.Cache.Innodb_buffer_pool_read_requests
Innodb_buffer_pool_reads	Cache	Pages per second	db.Cache.Innodb_buffer_pool_reads
Opened_tables	Cache	Tables	db.Cache.Opened_tables
Opened_table_definitions	Cache	Tables	db.Cache.Opened_table_definitions
Qcache_hits	Cache	Queries	db.Cache.Qcache_hits

Non-native counters for Amazon RDS for MariaDB and MySQL

Non-native counter metrics are counters defined by Amazon RDS. A non-native metric can be a metric that you get with a specific query. A non-native metric also can be a derived metric, where two or more native counters are used in calculations for ratios, hit rates, or latencies.

Counter	Type	Metric	Description	Definition
innodb_buffer_pool_hits	Cache	db.Cache.innoDB_buffer_pool_hits	The number of reads that InnoDB could satisfy from the buffer pool.	`innodb_buffer_pool_read_requests - innodb_buffer_pool_reads`
innodb_buffer_pool_hit_rate	Cache	db.Cache.innoDB_buffer_pool_hit_rate	The percentage of reads that InnoDB could	`100 * innodb_buffer_pool_read_requests / (innodb_buffer_poo`

Counter	Type	Metric	Description	Definition
			satisfy from the buffer pool.	`l_read_requests + innodb_buffer_pool_reads)`

Counter	Type	Metric	Description	Definition
innodb_buffer_pool_usage	Cache	db.Cache.innoDB_buffer_pool_usage	The percentage of the InnoDB buffer pool that contains data (pages). **Note** When using compressed tables, this value can vary. For more information, see the information about `Innodb_buffer_pages_ta`	`Innodb_buffer_pool_pages_data / Innodb_buffer_pool_pages_total * 100.0`

Counter	Type	Metric	Description	Definition
			and Innodb ffer_p _pages tal in Server - status variable in the MySQL docume tion.	
query_cache_hit_rate	Cache	db.Cache.query_cac he_hit_rate	MySQL result set cache (query cache) hit ratio.	Qcache_hits / (QCache_hits + Com_select) * 100

Counter	Type	Metric	Description	Definition
innodb_datafile_writes_to_disk	I/O	db.IO.innoDB_datafile_writes_to_disk	The number of InnoDB data file writes to disk, excluding double write and redo logging write operations.	`Innodb_data_writes - Innodb_log_writes - Innodb_dblwr_writes`
innodb_rows_changed	SQL	db.SQL.innodb_rows_changed	The total InnoDB row operations.	`db.SQL.Innodb_rows_inserted + db.SQL.Innodb_rows_deleted + db.SQL.Innodb_rows_updated`
active_transactions	Transactions	db.Transactions.active_transactions	The total active transactions.	`SELECT COUNT(1) AS active_transactions FROM INFORMATION_SCHEMA.INNODB_TRX`

Counter	Type	Metric	Description	Definition
trx_rseg_history_len	Transactions	db.Transactions.trx_rseg_history_len	A list of the undo log pages for committed transactions that is maintained by the InnoDB transaction system to implement multi-version concurrency control. For more information about undo log records details, see https://dev.mysql.com/doc/refman/8.0/en/innodb-multi-versioning.html in the MySQL documentation.	`SELECT COUNT AS trx_rseg_history_len FROM INFORMATION_SCHEMA.INNODB_METRICS WHERE NAME='trx_rseg_history_len'`

Counter	Type	Metric	Description	Definition
innodb_deadlocks	Locks	db.Locks.innodb_deadlocks	The total number of deadlocks.	`SELECT COUNT AS innodb_deadlocks FROM INFORMATION_SCHEMA.INNODB_METRICS WHERE NAME='lock_deadlocks'`
innodb_lock_timeouts	Locks	db.Locks.innodb_lock_timeouts	The total number of locks that timed out.	`SELECT COUNT AS innodb_lock_timeouts FROM INFORMATION_SCHEMA.INNODB_METRICS WHERE NAME='lock_timeouts'`
innodb_row_lock_waits	Locks	db.Locks.innodb_row_lock_waits	The total number of row locks that resulted in a wait.	`SELECT COUNT AS innodb_row_lock_waits FROM INFORMATION_SCHEMA.INNODB_METRICS WHERE NAME='lock_row_lock_waits'`

Performance Insights counters for Amazon RDS for Microsoft SQL Server

The following database counters are available with Performance Insights for RDS for Microsoft SQL Server.

Native counters for RDS for Microsoft SQL Server

Native metrics are defined by the database engine and not by Amazon RDS. You can find definitions for these native metrics in Use SQL Server Objects in the Microsoft SQL Server documentation.

Counter	Type	Unit	Metric
Forwarded Records	Access Methods	Records per second	db.Access Methods.Forwarded Records
Page Splits	Access Methods	Splits per second	db.Access Methods.Page Splits
Buffer cache hit ratio	Buffer Manager	Ratio	db.Buffer Manager.Buffer cache hit ratio
Page life expectancy	Buffer Manager	Expectancy in seconds	db.Buffer Manager.Page life expectancy
Page lookups	Buffer Manager	Lookups per second	db.Buffer Manager.Page lookups
Page reads	Buffer Manager	Reads per second	db.Buffer Manager.Page reads
Page writes	Buffer Manager	Writes per second	db.Buffer Manager.Page writes
Active Transactions	Databases	Transactions	db.Databases.Active Transactions (_Total)
Log Bytes Flushed	Databases	Bytes flushed per second	db.Databases.Log Bytes Flushed (_Total)
Log Flush Waits	Databases	Waits per second	db.Databases.Log Flush Waits (_Total)
Log Flushes	Databases	Flushes per second	db.Databases.Log Flushes (_Total)

Counter	Type	Unit	Metric
Write Transactions	Databases	Transactions per second	db.Databases.Write Transactions (_Total)
Processes blocked	General Statistics	Processes blocked	db.General Statistics.Processes blocked
User Connections	General Statistics	Connections	db.General Statistics.User Connections
Latch Waits	Latches	Waits per second	db.Latches.Latch Waits
Number of Deadlocks	Locks	Deadlocks per second	db.Locks.Number of Deadlocks (_Total)
Memory Grants Pending	Memory Manager	Memory grants	db.Memory Manager.Memory Grants Pending
Batch Requests	SQL Statistics	Requests per second	db.SQL Statistics.Batch Requests
SQL Compilations	SQL Statistics	Compilations per second	db.SQL Statistics.SQL Compilations
SQL Re-Compilations	SQL Statistics	Re-compilations per second	db.SQL Statistics.SQL Re-Compilations

Performance Insights counters for Amazon RDS for Oracle

The following database counters are available with Performance Insights for RDS for Oracle.

Native counters for RDS for Oracle

Native metrics are defined by the database engine and not by Amazon RDS. You can find definitions for these native metrics in Statistics Descriptions in the Oracle documentation.

Note

For the `CPU used by this session` counter metric, the unit has been transformed from the native centiseconds to active sessions to make the value easier to use. For example, CPU send in the DB Load chart represents the demand for CPU. The counter metric `CPU used by this session` represents the amount of CPU used by Oracle sessions. You can compare CPU send to the `CPU used by this session` counter metric. When demand for CPU is higher than CPU used, sessions are waiting for CPU time.

Counter	Type	Unit	Metric
CPU used by this session	User	Active sessions	db.User.CPU used by this session
SQL*Net roundtrips to/from client	User	Roundtrips per second	db.User.SQL*Net roundtrips to/from client
Bytes received via SQL*Net from client	User	Bytes per second	db.User.bytes received via SQL*Net from client
User commits	User	Commits per second	db.User.user commits
Logons cumulative	User	Logons per second	db.User.logons cumulative
User calls	User	Calls per second	db.User.user calls
Bytes sent via SQL*Net to client	User	Bytes per second	db.User.bytes sent via SQL*Net to client
User rollbacks	User	Rollbacks per second	db.User.user rollbacks
Redo size	Redo	Bytes per second	db.Redo.redo size
Parse count (total)	SQL	Parses per second	db.SQL.parse count (total)

Counter	Type	Unit	Metric
Parse count (hard)	SQL	Parses per second	db.SQL.parse count (hard)
Table scan rows gotten	SQL	Rows per second	db.SQL.table scan rows gotten
Sorts (memory)	SQL	Sorts per second	db.SQL.sorts (memory)
Sorts (disk)	SQL	Sorts per second	db.SQL.sorts (disk)
Sorts (rows)	SQL	Sorts per second	db.SQL.sorts (rows)
Physical read bytes	Cache	Bytes per second	db.Cache.physical read bytes
DB block gets	Cache	Blocks per second	db.Cache.db block gets
DBWR checkpoints	Cache	Checkpoints per minute	db.Cache.DBWR checkpoints
Physical reads	Cache	Reads per second	db.Cache.physical reads
Consistent gets from cache	Cache	Gets per second	db.Cache.consistent gets from cache
DB block gets from cache	Cache	Gets per second	db.Cache.db block gets from cache
Consistent gets	Cache	Gets per second	db.Cache.consistent gets

Performance Insights counters for Amazon RDS for PostgreSQL

The following database counters are available with Performance Insights for Amazon RDS for PostgreSQL.

Topics

Native counters for Amazon RDS for PostgreSQL

Native metrics are defined by the database engine and not by Amazon RDS. You can find definitions for these native metrics in Viewing Statistics in the PostgreSQL documentation.

Counter	Type	Unit	Metric
blks_hit	Cache	Blocks per second	db.Cache.blks_hit
buffers_alloc	Cache	Blocks per second	db.Cache.buffers_alloc
buffers_checkpoint	Checkpoint	Blocks per second	db.Checkpoint.buffers_checkpoint
checkpoint_sync_time	Checkpoint	Milliseconds per checkpoint	db.Checkpoint.checkpoint_sync_time
checkpoint_write_time	Checkpoint	Milliseconds per checkpoint	db.Checkpoint.checkpoint_write_time
checkpoints_req	Checkpoint	Checkpoints per minute	db.Checkpoint.checkpoints_req
checkpoints_timed	Checkpoint	Checkpoints per minute	db.Checkpoint.checkpoints_timed
maxwritten_clean	Checkpoint	Bgwriter clean stops per minute	db.Checkpoint.maxwritten_clean

Counter	Type	Unit	Metric
deadlocks	Concurrency	Deadlocks per minute	db.Concurrency.deadlocks
blk_read_time	I/O	Milliseconds	db.IO.blk_read_time
blks_read	I/O	Blocks per second	db.IO.blks_read
buffers_backend	I/O	Blocks per second	db.IO.buffers_backend
buffers_backend_fsync	I/O	Blocks per second	db.IO.buffers_backend_fsync
buffers_clean	I/O	Blocks per second	db.IO.buffers_clean
tup_deleted	SQL	Tuples per second	db.SQL.tup_deleted
tup_fetched	SQL	Tuples per second	db.SQL.tup_fetched
tup_inserted	SQL	Tuples per second	db.SQL.tup_inserted
tup_returned	SQL	Tuples per second	db.SQL.tup_returned
tup_updated	SQL	Tuples per second	db.SQL.tup_updated
temp_bytes	Temp	Bytes per second	db.Temp.temp_bytes
temp_files	Temp	Files per minute	db.Temp.temp_files
xact_commit	Transactions	Commits per second	db.Transactions.xact_commit
xact_rollback	Transactions	Rollbacks per second	db.Transactions.xact_rollback
numbackends	User	Connections	db.User.numbackends
archived_count	Write-ahead log (WAL)	Files per minute	db.WAL.archived_count

Non-native counters for Amazon RDS for PostgreSQL

Non-native counter metrics are counters defined by Amazon RDS. A non-native metric can be a metric that you get with a specific query. A non-native metric also can be a derived metric, where two or more native counters are used in calculations for ratios, hit rates, or latencies.

Counter	Type	Metric	Description	Definition
checkpoint_sync_latency	Checkpoint	db.Checkpoint.checkpoint_sync_latency	The total amount of time that has been spent in the portion of checkpoint processing where files are synchronized to disk.	`checkpoint_sync_time / (checkpoints_timed + checkpoints_req)`
checkpoint_write_latency	Checkpoint	db.Checkpoint.checkpoint_write_latency	The total amount of time that has been spent in the portion of checkpoint processing where files are written to disk.	`checkpoint_write_time / (checkpoints_timed + checkpoints_req)`
read_latency	I/O	db.IO.read_latency	The time spent reading data file blocks by backends in this instance.	`blk_read_time / blks_read`
idle_in_transaction_aborted_count	State	db.state.idle_in_transaction_aborted_count	The number of sessions in the `idle in transaction (aborted)` state.	–

Counter	Type	Metric	Description	Definition
idle_in_transaction_count	State	db.state.idle_in_transaction_count	The number of sessions in the `idle in transaction` state.	–
idle_in_transaction_max_time	State	db.state.idle_in_transaction_max_time	The duration of the longest running transaction in the `idle in transaction` state, in seconds.	–
active_transactions	Transactions	db.Transactions.active_transactions	The number of active transactions.	–
blocked_transactions	Transactions	db.Transactions.blocked_transactions	The number of blocked transactions.	–
max_used_xact_ids	Transactions	db.Transactions.max_used_xact_ids	The number of transactions that haven't been vacuumed.	–
max_connections	Users	db.User.max_connections	The maximum number of connections allowed for a DB instance as configured in `max_connections` parameter.	–

Counter	Type	Metric	Description	Definition
archive_failed_count	WAL	db.WAL.archive_failed_count	The number of failed attempts for archiving WAL files, in files per minute.	–

SQL statistics for Performance Insights

SQL statistics are performance-related metrics about SQL queries that are collected by Performance Insights. Performance Insights gathers statistics for each second that a query is running and for each SQL call. The SQL statistics are an average for the selected time range.

A SQL digest is a composite of all queries having a given pattern but not necessarily having the same literal values. The digest replaces literal values with a question mark. For example, `SELECT * FROM emp WHERE lname= ?`. This digest might consist of the following child queries:

```
SELECT * FROM emp WHERE lname = 'Sanchez'
SELECT * FROM emp WHERE lname = 'Olagappan'
SELECT * FROM emp WHERE lname = 'Wu'
```

All engines support SQL statistics for digest queries.

For the region, DB engine, and instance class support information for this feature, see Amazon RDS DB engine, Region, and instance class support for Performance Insights features

Topics

- SQL statistics for MariaDB and MySQL

- SQL statistics for SQL Server
- SQL statistics for RDS PostgreSQL

SQL statistics for MariaDB and MySQL

MariaDB and MySQL collect SQL statistics only at the digest level. No statistics are shown at the statement level.

Topics

Digest statistics for MariaDB and MySQL

Performance Insights collects SQL digest statistics from the `events_statements_summary_by_digest` table. The `events_statements_summary_by_digest` table is managed by your database.

The digest table doesn't have an eviction policy. When the table is full, the AWS Management Console shows the following message:

```
Performance Insights is unable to collect SQL Digest statistics on new queries because
 the table events_statements_summary_by_digest is full.
Please truncate events_statements_summary_by_digest table to clear the issue. Check the
 User Guide for more details.
```

In this situation, MariaDB and MySQL don't track SQL queries. To address this issue, Performance Insights automatically truncates the digest table when both of the following conditions are met:

- The table is full.
- Performance Insights manages the Performance Schema automatically.

  For automatic management, the `performance_schema` parameter must be set to `0` and the **Source** must not be set to `user`. If Performance Insights isn't managing the Performance Schema automatically, see Overview of the Performance Schema for Performance Insights on Amazon RDS for MariaDB or MySQL.

In the AWS CLI, check the source of a parameter value by running the describe-db-parameters command.

Per-second statistics for MariaDB and MySQL

The following SQL statistics are available for MariaDB and MySQL DB instances.

Metric	Unit
db.sql_tokenized.stats.count_star_per_sec	Calls per second
db.sql_tokenized.stats.sum_timer_wait_per_sec	Average active executions per second (AAE)
db.sql_tokenized.stats.sum_select_full_join_per_sec	Select full join per second
db.sql_tokenized.stats.sum_select_range_check_per_sec	Select range check per second
db.sql_tokenized.stats.sum_select_scan_per_sec	Select scan per second
db.sql_tokenized.stats.sum_sort_merge_passes_per_sec	Sort merge passes per second
db.sql_tokenized.stats.sum_sort_scan_per_sec	Sort scans per second
db.sql_tokenized.stats.sum_sort_range_per_sec	Sort ranges per second
db.sql_tokenized.stats.sum_sort_rows_per_sec	Sort rows per second
db.sql_tokenized.stats.sum_rows_affected_per_sec	Rows affected per second
db.sql_tokenized.stats.sum_rows_examined_per_sec	Rows examined per second
db.sql_tokenized.stats.sum_rows_sent_per_sec	Rows sent per second
db.sql_tokenized.stats.sum_created_tmp_disk_tables_per_sec	Created temporary disk tables per second

Metric	Unit
db.sql_tokenized.stats.sum_created_tmp_tables_per_sec	Created temporary tables per second
db.sql_tokenized.stats.sum_lock_time_per_sec	Lock time per second (in ms)

Per-call statistics for MariaDB and MySQL

The following metrics provide per call statistics for a SQL statement.

Metric	Unit
db.sql_tokenized.stats.sum_timer_wait_per_call	Average latency per call (in ms)
db.sql_tokenized.stats.sum_select_full_join_per_call	Select full joins per call
db.sql_tokenized.stats.sum_select_range_check_per_call	Select range check per call
db.sql_tokenized.stats.sum_select_scan_per_call	Select scans per call
db.sql_tokenized.stats.sum_sort_merge_passes_per_call	Sort merge passes per call
db.sql_tokenized.stats.sum_sort_scan_per_call	Sort scans per call
db.sql_tokenized.stats.sum_sort_range_per_call	Sort ranges per call
db.sql_tokenized.stats.sum_sort_rows_per_call	Sort rows per call
db.sql_tokenized.stats.sum_rows_affected_per_call	Rows affected per call

Metric	Unit
db.sql_tokenized.stats.sum_rows_examined_per_call	Rows examined per call
db.sql_tokenized.stats.sum_rows_sent_per_call	Rows sent per call
db.sql_tokenized.stats.sum_created_tmp_disk_tables_per_call	Created temporary disk tables per call
db.sql_tokenized.stats.sum_created_tmp_tables_per_call	Created temporary tables per call
db.sql_tokenized.stats.sum_lock_time_per_call	Lock time per call (in ms)

SQL statistics for Oracle

Amazon RDS for Oracle collects SQL statistics both at the statement and digest level. At the statement level, the ID column represents the value of `V$SQL.SQL_ID`. At the digest level, the ID column shows the value of `V$SQL.FORCE_MATCHING_SIGNATURE`.

If the ID is `0` at the digest level, Oracle Database has determined that this statement is not suitable for reuse. In this case, the child SQL statements could belong to different digests. However, the statements are grouped together under the `digest_text` for the first SQL statement collected.

Topics

- Per-second statistics for Oracle
- Per-call statistics for Oracle

Per-second statistics for Oracle

The following metrics provide per-second statistics for an Oracle SQL query.

Metric	Unit
db.sql.stats.executions_per_sec	Number of executions per second

Metric	Unit
db.sql.stats.elapsed_time_per_sec	Average active executions (AAE)
db.sql.stats.rows_processed_per_sec	Rows processed per second
db.sql.stats.buffer_gets_per_sec	Buffer gets per second
db.sql.stats.physical_read_requests_per_sec	Physical reads per second
db.sql.stats.physical_write_requests_per_sec	Physical writes per second
db.sql.stats.total_sharable_mem_per_sec	Total shareable memory per second (in bytes)
db.sql.stats.cpu_time_per_sec	CPU time per second (in ms)

The following metrics provide per-call statistics for an Oracle SQL digest query.

Metric	Unit
db.sql_tokenized.stats.executions_per_sec	Number of executions per second
db.sql_tokenized.stats.elapsed_time_per_sec	Average active executions (AAE)
db.sql_tokenized.stats.rows_processe d_per_sec	Rows processed per second
db.sql_tokenized.stats.buffer_gets_per_sec	Buffer gets per second
db.sql_tokenized.stats.physical_read_requests _per_sec	Physical reads per second
db.sql_tokenized.stats.physical_write_request s_per_sec	Physical writes per second
db.sql_tokenized.stats.total_sharabl e_mem_per_sec	Total shareable memory per second (in bytes)
db.sql_tokenized.stats.cpu_time_per_sec	CPU time per second (in ms)

Per-call statistics for Oracle

The following metrics provide per-call statistics for an Oracle SQL statement.

Metric	Unit
db.sql.stats.elapsed_time_per_exec	Elapsed time per executions (in ms)
db.sql.stats.rows_processed_per_exec	Rows processed per execution
db.sql.stats.buffer_gets_per_exec	Buffer gets per execution
db.sql.stats.physical_read_requests_per_exec	Physical reads per execution
db.sql.stats.physical_write_requests_per_exec	Physical writes per execution
db.sql.stats.total_sharable_mem_per_exec	Total shareable memory per execution (in bytes)
db.sql.stats.cpu_time_per_exec	CPU time per execution (in ms)

The following metrics provide per-call statistics for an Oracle SQL digest query.

Metric	Unit
db.sql_tokenized.stats.elapsed_time_per_exec	Elapsed time per executions (in ms)
db.sql_tokenized.stats.rows_processed_per_exec	Rows processed per execution
db.sql_tokenized.stats.buffer_gets_per_exec	Buffer gets per execution
db.sql_tokenized.stats.physical_read_requests_per_exec	Physical reads per execution
db.sql_tokenized.stats.physical_write_requests_per_exec	Physical writes per execution
db.sql_tokenized.stats.total_sharable_mem_per_exec	Total shareable memory per execution (in bytes)

Metric	Unit
db.sql_tokenized.stats.cpu_time_per_exec	CPU time per execution (in ms)

SQL statistics for SQL Server

Amazon RDS for SQL Server collects SQL statistics both at the statement and digest level. At the statement level, the ID column represents the value of `sql_handle`. At the digest level, the ID column shows the value of `query_hash`.

SQL Server returns NULL values for `query_hash` for a few statements. For example, ALTER INDEX, CHECKPOINT, UPDATE STATISTICS, COMMIT TRANSACTION, FETCH NEXT FROM Cursor, and a few INSERT statements, SELECT @<variable>, conditional statements, and executable stored procedures. In this case, the `sql_handle` value is displayed as the ID at the digest level for that statement.

Topics

- Per-second statistics for SQL Server
- Per-call statistics for SQL Server

Per-second statistics for SQL Server

The following metrics provide per-second statistics for a SQL Server SQL query.

Metric	Unit
db.sql.stats.execution_count_per_sec	Number of executions per second
db.sql.stats.total_elapsed_time_per_sec	Total elapsed time per second
db.sql.stats.total_rows_per_sec	Total rows processed per second
db.sql.stats.total_logical_reads_per_sec	Total logical reads per second
db.sql.stats.total_logical_writes_per_sec	Total logical writes per second
db.sql.stats.total_physical_reads_per_sec	Total physical reads per second

Metric	Unit
db.sql.stats.total_worker_time_per_sec	Total CPU time (in ms)

The following metrics provide per-second statistics for a SQL Server SQL digest query.

Metric	Unit
db.sql_tokenized.stats.execution_count_per_sec	Number of execution per second
db.sql_tokenized.stats.total_elapsed_time_per_sec	Total elapsed time per second
db.sql_tokenized.stats.total_rows_per_sec	Total rows processed per second
db.sql_tokenized.stats.total_logical_reads_per_sec	Total logical reads per second
db.sql_tokenized.stats.total_logical_writes_per_sec	Total logical writes per second
db.sql_tokenized.stats.total_physical_reads_per_sec	Total physical reads per second
db.sql_tokenized.stats.total_worker_time_per_sec	Total CPU time (in ms)

Per-call statistics for SQL Server

The following metrics provide per-call statistics for a SQL Server SQL statement.

Metric	Unit
db.sql.stats.total_elapsed_time_per_call	Total elapsed time per execution
db.sql.stats.total_rows_per_call	Total rows processed per execution

Metric	Unit
db.sql.stats.total_logical_reads_per_call	Total logical reads per execution
db.sql.stats.total_logical_writes_per_call	Total logical writes per execution
db.sql.stats.total_physical_reads_per_call	Total physical reads per execution
db.sql.stats.total_worker_time_per_call	Total CPU time per execution (in ms)

The following metrics provide per-call statistics for a SQL Server SQL digest query.

Metric	Unit
db.sql_tokenized.stats.total_elapsed_time_per_call	Total elapsed time per execution
db.sql_tokenized.stats.total_rows_per_call	Total rows processed per execution
db.sql_tokenized.stats.total_logical_reads_per_call	Total logical reads per execution
db.sql_tokenized.stats.total_logical_writes_per_call	Total logical writes per execution
db.sql_tokenized.stats.total_physical_reads_per_call	Total physical reads per execution
db.sql_tokenized.stats.total_worker_time_per_call	Total CPU time per execution (in ms)

SQL statistics for RDS PostgreSQL

For each SQL call and for each second that a query runs, Performance Insights collects SQL statistics. RDS for PostgreSQL collect SQL statistics only at the digest–level. No statistics are shown at the statement-level.

Following, you can find information about digest-level statistics for RDS for PostgreSQL.

Topics

Digest statistics for RDS PostgreSQL

To view SQL digest statistics, RDS PostgreSQL must load the `pg_stat_statements` library. For PostgreSQL DB instances that are compatible with PostgreSQL 11 or later, the database loads this library by default. For PostgreSQL DB instances that are compatible with PostgreSQL 10 or earlier, enable this library manually. To enable it manually, add `pg_stat_statements` to `shared_preload_libraries` in the DB parameter group associated with the DB instance. Then reboot your DB instance. For more information, see Parameter groups for Amazon RDS.

> **Note**
>
> Performance Insights can only collect statistics for queries in `pg_stat_activity` that aren't truncated. By default, PostgreSQL databases truncate queries longer than 1,024 bytes. To increase the query size, change the `track_activity_query_size` parameter in the DB parameter group associated with your DB instance. When you change this parameter, a DB instance reboot is required.

Per-second digest statistics for RDS PostgreSQL

The following SQL digest statistics are available for PostgreSQL DB instances.

Metric	Unit
db.sql_tokenized.stats.calls_per_sec	Calls per second
db.sql_tokenized.stats.rows_per_sec	Rows per second
db.sql_tokenized.stats.total_time_per_sec	Average active executions per second (AAE)
db.sql_tokenized.stats.shared_blks_hit_per_sec	Block hits per second

Metric	Unit
db.sql_tokenized.stats.shared_blks_read_per_sec	Block reads per second
db.sql_tokenized.stats.shared_blks_dirtied_per_sec	Blocks dirtied per second
db.sql_tokenized.stats.shared_blks_written_per_sec	Block writes per second
db.sql_tokenized.stats.local_blks_hit_per_sec	Local block hits per second
db.sql_tokenized.stats.local_blks_read_per_sec	Local block reads per second
db.sql_tokenized.stats.local_blks_dirtied_per_sec	Local block dirty per second
db.sql_tokenized.stats.local_blks_written_per_sec	Local block writes per second
db.sql_tokenized.stats.temp_blks_written_per_sec	Temporary writes per second
db.sql_tokenized.stats.temp_blks_read_per_sec	Temporary reads per second
db.sql_tokenized.stats.blk_read_time_per_sec	Average concurrent reads per second
db.sql_tokenized.stats.blk_write_time_per_sec	Average concurrent writes per second

Per-call digest statistics for RDS PostgreSQL

The following metrics provide per call statistics for a SQL statement.

Metric	Unit
db.sql_tokenized.stats.rows_per_call	Rows per call

Metric	Unit
db.sql_tokenized.stats.avg_latency_per_call	Average latency per call (in ms)
db.sql_tokenized.stats.shared_blks_hit_per_call	Block hits per call
db.sql_tokenized.stats.shared_blks_read_per_call	Block reads per call
db.sql_tokenized.stats.shared_blks_written_per_call	Block writes per call
db.sql_tokenized.stats.shared_blks_dirtied_per_call	Blocks dirtied per call
db.sql_tokenized.stats.local_blks_hit_per_call	Local block hits per call
db.sql_tokenized.stats.local_blks_read_per_call	Local block reads per call
db.sql_tokenized.stats.local_blks_dirtied_per_call	Local block dirty per call
db.sql_tokenized.stats.local_blks_written_per_call	Local block writes per call
db.sql_tokenized.stats.temp_blks_written_per_call	Temporary block writes per call
db.sql_tokenized.stats.temp_blks_read_per_call	Temporary block reads per call
db.sql_tokenized.stats.blk_read_time_per_call	Read time per call (in ms)
db.sql_tokenized.stats.blk_write_time_per_call	Write time per call (in ms)

For more information about these metrics, see pg_stat_statements in the PostgreSQL documentation.

OS metrics in Enhanced Monitoring

Amazon RDS provides metrics in real time for the operating system (OS) that your DB instance runs on. RDS delivers the metrics from Enhanced Monitoring to your Amazon CloudWatch Logs account. The following tables list the OS metrics available using Amazon CloudWatch Logs.

Topics

OS metrics for Db2, MariaDB, MySQL, Oracle, and PostgreSQL

Group	Metric	Console name	Description
General	engine	Not applicable	The database engine for the DB instance.
	instanceID	Not applicable	The DB instance identifier.
	instanceResourceID	Not applicable	An immutable identifier for the DB instance that is unique to an AWS Region, also used as the log stream identifier.
	numVCPUs	Not applicable	The number of virtual CPUs for the DB instance.
	timestamp	Not applicable	The time at which the metrics were taken.
	uptime	Not applicable	The amount of time that the DB instance has been active.
	version	Not applicable	The version of the OS metrics' stream JSON format.

Group	Metric	Console name	Description
cpuUtilization	guest	**CPU Guest**	The percentage of CPU in use by guest programs.
	idle	**CPU Idle**	The percentage of CPU that is idle.
	irq	**CPU IRQ**	The percentage of CPU in use by software interrupts.
	nice	**CPU Nice**	The percentage of CPU in use by programs running at lowest priority.
	steal	**CPU Steal**	The percentage of CPU in use by other virtual machines.
	system	**CPU System**	The percentage of CPU in use by the kernel.
	total	**CPU Total**	The total percentage of the CPU in use. This value includes the nice value.
	user	**CPU User**	The percentage of CPU in use by user programs.
	wait	**CPU Wait**	The percentage of CPU unused while waiting for I/O access.
diskIO	avgQueueLen	**Avg Queue Size**	The number of requests waiting in the I/O device's queue.
	avgReqSz	**Ave Request Size**	The average request size, in kilobytes.
	await	**Disk I/O Await**	The number of milliseconds required to respond to requests, including queue time and service time.
	device	Not applicable	The identifier of the disk device in use.

Group	Metric	Console name	Description
	readIOsPS	**Read IO/s**	The number of read operations per second.
	readKb	**Read Total**	The total number of kilobytes read.
	readKbPS	**Read Kb/s**	The number of kilobytes read per second.
	readLatency	**Read Latency**	The elapsed time between the submission of a read I/O request and its completion, in milliseconds. This metric is only available for Amazon Aurora.
	readThroughput	**Read Throughput**	The amount of network throughput used by requests to the DB cluster, in bytes per second. This metric is only available for Amazon Aurora.
	rrqmPS	**Rrqms**	The number of merged read requests queued per second.
	tps	**TPS**	The number of I/O transactions per second.
	util	**Disk I/O Util**	The percentage of CPU time during which requests were issued.
	writeIOsPS	**Write IO/s**	The number of write operations per second.
	writeKb	**Write Total**	The total number of kilobytes written.
	writeKbPS	**Write Kb/s**	The number of kilobytes written per second.

Group	Metric	Console name	Description
	writeLatency	**Write Latency**	The average elapsed time between the submission of a write I/O request and its completion, in milliseconds. This metric is only available for Amazon Aurora.
	writeThroughput	**Write Throughput**	The amount of network throughput used by responses from the DB cluster, in bytes per second. This metric is only available for Amazon Aurora.
	wrqmPS	**Wrqms**	The number of merged write requests queued per second.
physicalDeviceIO	avgQueueLen	**Physical Devices Avg Queue Size**	The number of requests waiting in the I/O device's queue.
	avgReqSz	**Physical Devices Ave Request Size**	The average request size, in kilobytes.
	await	**Physical Devices Disk I/O Await**	The number of milliseconds required to respond to requests, including queue time and service time.
	device	Not applicable	The identifier of the disk device in use.
	readIOsPS	**Physical Devices Read IO/s**	The number of read operations per second.

Group	Metric	Console name	Description
	readKb	**Physical Devices Read Total**	The total number of kilobytes read.
	readKbPS	**Physical Devices Read Kb/s**	The number of kilobytes read per second.
	rrqmPS	**Physical Devices Rrqms**	The number of merged read requests queued per second.
	tps	**Physical Devices TPS**	The number of I/O transactions per second.
	util	**Physical Devices Disk I/O Util**	The percentage of CPU time during which requests were issued.
	writeIOsPS	**Physical Devices Write IO/s**	The number of write operations per second.
	writeKb	**Physical Devices Write Total**	The total number of kilobytes written.
	writeKbPS	**Physical Devices Write Kb/s**	The number of kilobytes written per second.

Group	Metric	Console name	Description
	wrqmPS	**Physical Devices Wrqms**	The number of merged write requests queued per second.
fileSys	maxFiles	**Max Inodes**	The maximum number of files that can be created for the file system.
	mountPoint	Not applicable	The path to the file system.
	name	Not applicable	The name of the file system.
	total	**Total Filesystem**	The total number of disk space available for the file system, in kilobytes.
	used	**Used Filesystem**	The amount of disk space used by files in the file system, in kilobytes.
	usedFilePercent	**Used Inodes**	The percentage of available files in use.
	usedFiles	**Used%**	The number of files in the file system.
	usedPercent	**Used Filesystem**	The percentage of the file-system disk space in use.
loadAverageMinute	fifteen	**Load Avg 15 min**	The number of processes requesting CPU time over the last 15 minutes.
	five	**Load Avg 5 min**	The number of processes requesting CPU time over the last 5 minutes.
	one	**Load Avg 1 min**	The number of processes requesting CPU time over the last minute.

Group	Metric	Console name	Description
memory	active	**Active Memory**	The amount of assigned memory, in kilobytes.
	buffers	**Buffered Memory**	The amount of memory used for buffering I/O requests prior to writing to the storage device, in kilobytes.
	cached	**Cached Memory**	The amount of memory used for caching file system–based I/O.
	dirty	**Dirty Memory**	The amount of memory pages in RAM that have been modified but not written to their related data block in storage, in kilobytes.
	free	**Free Memory**	The amount of unassigned memory, in kilobytes.
	hugePages Free	**Huge Pages Free**	The number of free huge pages. Huge pages are a feature of the Linux kernel.
	hugePages Rsvd	**Huge Pages Rsvd**	The number of committed huge pages.
	hugePages Size	**Huge Pages Size**	The size for each huge pages unit, in kilobytes.
	hugePages Surp	**Huge Pages Surp**	The number of available surplus huge pages over the total.
	hugePages Total	**Huge Pages Total**	The total number of huge pages.

Group	Metric	Console name	Description
	inactive	**Inactive Memory**	The amount of least-frequently used memory pages, in kilobytes.
	mapped	**Mapped Memory**	The total amount of file-system contents that is memory mapped inside a process address space, in kilobytes.
	pageTables	**Page Tables**	The amount of memory used by page tables, in kilobytes.
	slab	**Slab Memory**	The amount of reusable kernel data structures, in kilobytes.
	total	**Total Memory**	The total amount of memory, in kilobytes.
	writeback	**Writeback Memory**	The amount of dirty pages in RAM that are still being written to the backing storage, in kilobytes.
network	interface	Not applicable	The identifier for the network interface being used for the DB instance.
	rx	**RX**	The number of bytes received per second.
	tx	**TX**	The number of bytes uploaded per second.
processList	cpuUsedPc	**CPU %**	The percentage of CPU used by the process.
	id	Not applicable	The identifier of the process.
	memoryUsedPc	**MEM%**	The percentage of memory used by the process.
	name	Not applicable	The name of the process.

Group	Metric	Console name	Description
	parentID	Not applicable	The process identifier for the parent process of the process.
	rss	**RES**	The amount of RAM allocated to the process, in kilobytes.
	tgid	Not applicable	The thread group identifier, which is a number representing the process ID to which a thread belongs. This identifier is used to group threads from the same process.
	vss	**VIRT**	The amount of virtual memory allocated to the process, in kilobytes.
swap	swap	**Swap**	The amount of swap memory available, in kilobytes.
	swap in	**Swaps in**	The amount of memory, in kilobytes, swapped in from disk.
	swap out	**Swaps out**	The amount of memory, in kilobytes, swapped out to disk.
	free	**Free Swap**	The amount of swap memory free, in kilobytes.
	committed	**Committed Swap**	The amount of swap memory, in kilobytes, used as cache memory.
tasks	blocked	**Tasks Blocked**	The number of tasks that are blocked.
	running	**Tasks Running**	The number of tasks that are running.
	sleeping	**Tasks Sleeping**	The number of tasks that are sleeping.

Group	Metric	Console name	Description
	stopped	**Tasks Stopped**	The number of tasks that are stopped.
	total	**Tasks Total**	The total number of tasks.
	zombie	**Tasks Zombie**	The number of child tasks that are inactive with an active parent task.

OS metrics for Microsoft SQL Server

Group	Metric	Console name	Description
General	engine	Not applicable	The database engine for the DB instance.
	instanceID	Not applicable	The DB instance identifier.
	instanceResourceID	Not applicable	An immutable identifier for the DB instance that is unique to an AWS Region, also used as the log stream identifier.
	numVCPUs	Not applicable	The number of virtual CPUs for the DB instance.
	timestamp	Not applicable	The time at which the metrics were taken.
	uptime	Not applicable	The amount of time that the DB instance has been active.
	version	Not applicable	The version of the OS metrics' stream JSON format.

Group	Metric	Console name	Description
cpuUtilization	idle	**CPU Idle**	The percentage of CPU that is idle.
	kern	**CPU Kernel**	The percentage of CPU in use by the kernel.
	user	**CPU User**	The percentage of CPU in use by user programs.
disks	name	Not applicable	The identifier for the disk.
	totalKb	**Total Disk Space**	The total space of the disk, in kilobytes.
	usedKb	**Used Disk Space**	The amount of space used on the disk, in kilobytes.
	usedPc	**Used Disk Space %**	The percentage of space used on the disk.
	availKb	**Available Disk Space**	The space available on the disk, in kilobytes.
	availPc	**Available Disk Space %**	The percentage of space available on the disk.
	rdCountPS	**Reads/s**	The number of read operations per second
	rdBytesPS	**Read Kb/s**	The number of bytes read per second.
	wrCountPS	**Write IO/s**	The number of write operations per second.
	wrBytesPS	**Write Kb/s**	The amount of bytes written per second.

Group	Metric	Console name	Description
memory	commitTotKb	**Commit Total**	The amount of pagefile-backed virtual address space in use, that is, the current commit charge. This value is composed of main memory (RAM) and disk (pagefiles).
	commitLimitKb	**Maximum Commit**	The maximum possible value for the commitTotKb metric. This value is the sum of the current pagefile size plus the physical memory available for pageable contents, excluding RAM that is assigned to nonpageable areas.
	commitPeakKb	**Commit Peak**	The largest value of the commitTotKb metric since the operating system was last started.
	kernTotKb	**Total Kernel Memory**	The sum of the memory in the paged and nonpaged kernel pools, in kilobytes.
	kernPagedKb	**Paged Kernel Memory**	The amount of memory in the paged kernel pool, in kilobytes.
	kernNonpagedKb	**Nonpaged Kerenel Memory**	The amount of memory in the nonpaged kernel pool, in kilobytes.
	pageSize	**Page Size**	The size of a page, in bytes.
	physTotKb	**Total Memory**	The amount of physical memory, in kilobytes.
	physAvailKb	**Available Memory**	The amount of available physical memory, in kilobytes.

Group	Metric	Console name	Description
	sqlServerTotKb	**SQL Server Total Memory**	The amount of memory committed to SQL Server, in kilobytes.
	sysCacheKb	**System Cache**	The amount of system cache memory, in kilobytes.
network	interface	Not applicable	The identifier for the network interface being used for the DB instance.
	rdBytesPS	**Network Read Kb/s**	The number of bytes received per second.
	wrBytesPS	**Network Write Kb/s**	The number of bytes sent per second.
processList	cpuUsedPc	**Used %**	The percentage of CPU used by the process.
	memUsedPc	**MEM%**	The percentage of total memory used by the process.
	name	Not applicable	The name of the process.
	pid	Not applicable	The identifier of the process. This value is not present for processes that are owned by Amazon RDS.
	ppid	Not applicable	The process identifier for the parent of this process. This value is only present for child processes.
	tid	Not applicable	The thread identifier. This value is only present for threads. The owning process can be identified by using the pid value.

Group	Metric	Console name	Description
	workingSetKb	Not applicable	The amount of memory in the private working set plus the amount of memory that is in use by the process and can be shared with other processes, in kilobytes.
	workingSetPrivKb	Not applicable	The amount of memory that is in use by a process, but can't be shared with other processes, in kilobytes.
	workingSetShareableKb	Not applicable	The amount of memory that is in use by a process and can be shared with other processes, in kilobytes.
	virtKb	Not applicable	The amount of virtual address space the process is using, in kilobytes. Use of virtual address space doesn't necessarily imply corresponding use of either disk or main memory pages.
system	handles	**Handles**	The number of handles that the system is using.
	processes	**Processes**	The number of processes running on the system.
	threads	**Threads**	The number of threads running on the system.

Monitoring events, logs, and streams in an Amazon RDS DB instance

When you monitor your Amazon RDS databases and your other AWS solutions, your goal is to maintain the following:

- Reliability
- Availability
- Performance
- Security

Monitoring metrics in an Amazon RDS instance explains how to monitor your instance using metrics. A complete solution must also monitor database events, log files, and activity streams. AWS provides you with the following monitoring tools:

- *Amazon EventBridge* is a serverless event bus service that makes it easy to connect your applications with data from a variety of sources. EventBridge delivers a stream of real-time data from your own applications, Software-as-a-Service (SaaS) applications, and AWS services. EventBridge routes that data to targets such as AWS Lambda. This way, you can monitor events that happen in services and build event-driven architectures. For more information, see the Amazon EventBridge User Guide.
- *Amazon CloudWatch Logs* provides a way to monitor, store, and access your log files from Amazon RDS instances, AWS CloudTrail, and other sources. Amazon CloudWatch Logs can monitor information in the log files and notify you when certain thresholds are met. You can also archive your log data in highly durable storage. For more information, see the Amazon CloudWatch Logs User Guide.
- *AWS CloudTrail* captures API calls and related events made by or on behalf of your AWS account. CloudTrail delivers the log files to an Amazon S3 bucket that you specify. You can identify which users and accounts called AWS, the source IP address from which the calls were made, and when the calls occurred. For more information, see the AWS CloudTrail User Guide.
- *Database Activity Streams* is an Amazon RDS feature that provides a near real-time stream of the activity in your DB instance. Amazon RDS pushes activities to an Amazon Kinesis data stream. The Kinesis stream is created automatically. From Kinesis, you can configure AWS services such as Amazon Data Firehose and AWS Lambda to consume the stream and store the data.

Topics

Viewing logs, events, and streams in the Amazon RDS console

Amazon RDS integrates with AWS services to show information about logs, events, and database activity streams in the RDS console.

The **Logs & events** tab for your RDS DB instance shows the following information:

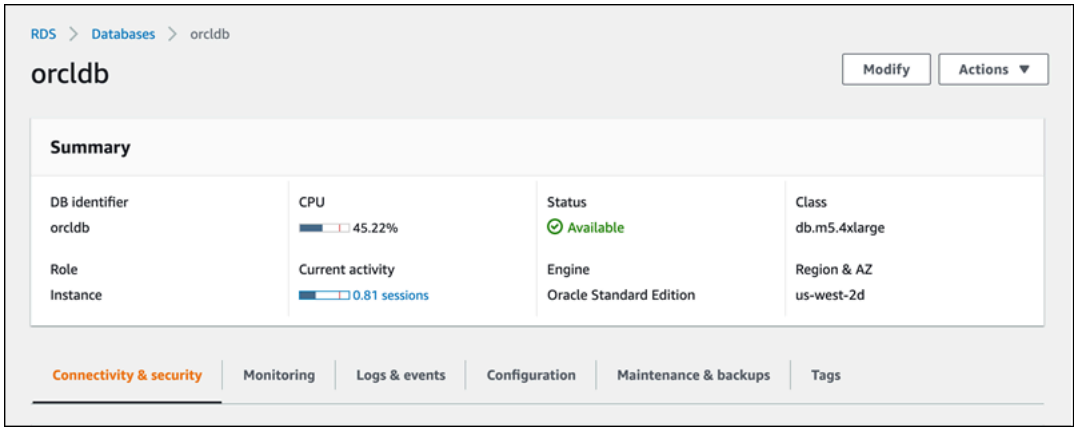
- **Amazon CloudWatch alarms** – Shows any metric alarms that you have configured for the DB instance. If you haven't configured alarms, you can create them in the RDS console. For more information, see Monitoring Amazon RDS metrics with Amazon CloudWatch.
- **Recent events** – Shows a summary of events (environment changes) for your RDS DB instance . For more information, see Viewing Amazon RDS events.
- **Logs** – Shows database log files generated by a DB instance. For more information, see Monitoring Amazon RDS log files.

The **Configuration** tab displays information about database activity streams.

To view logs, events, and streams for your DB instance in the RDS console

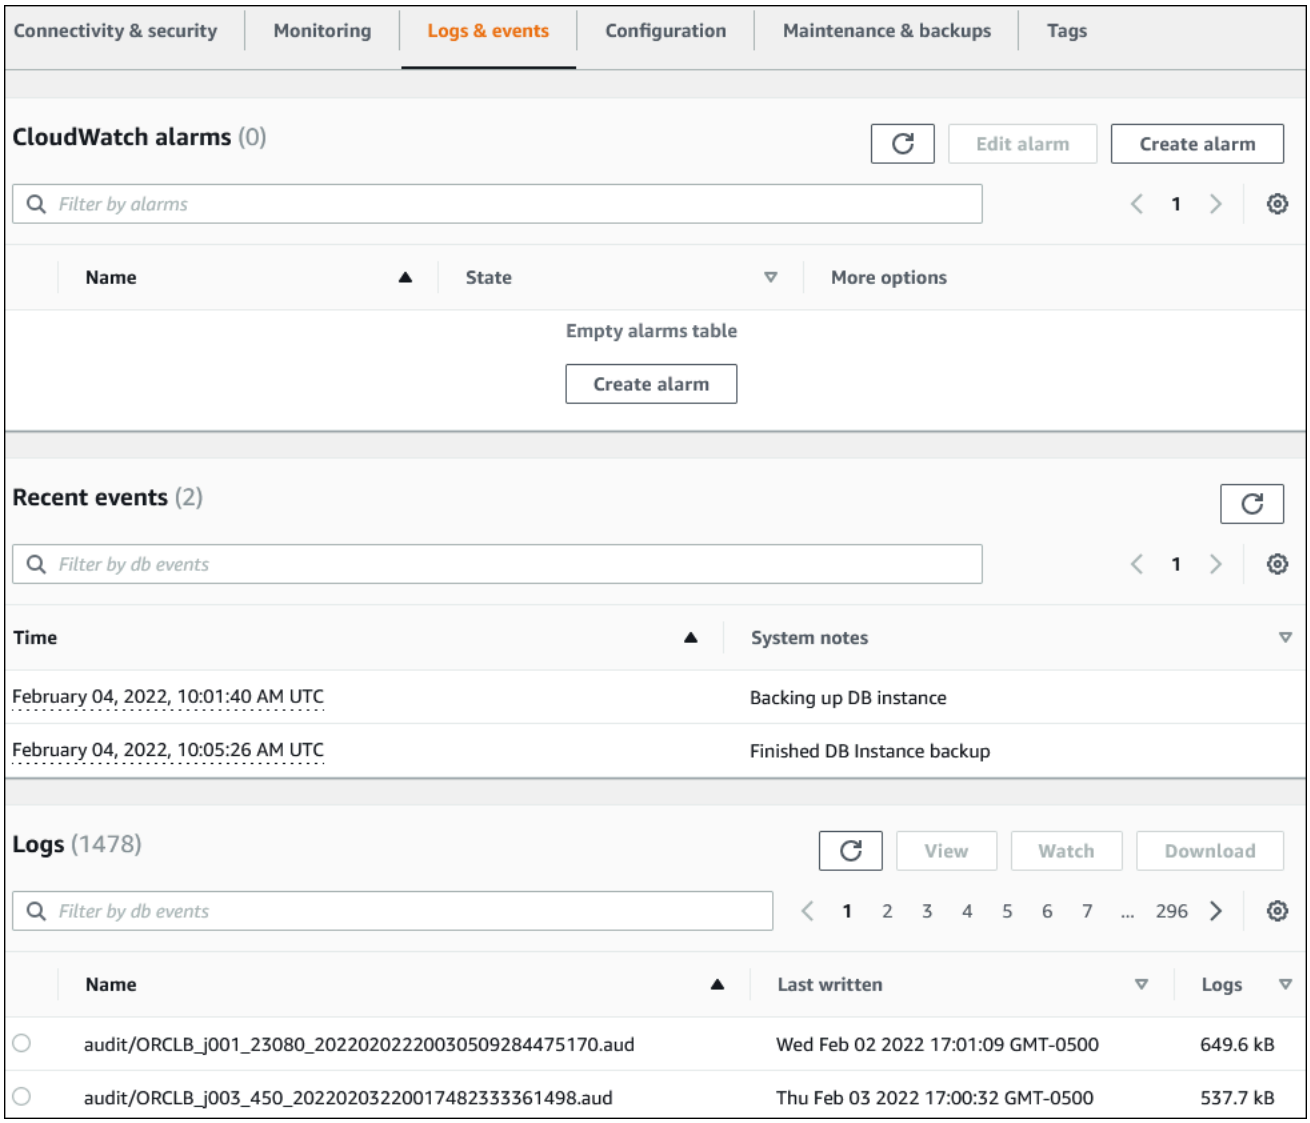
1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.
3. Choose the name of the DB instance that you want to monitor.

   The database page appears. The following example shows an Oracle database named `orclb`.



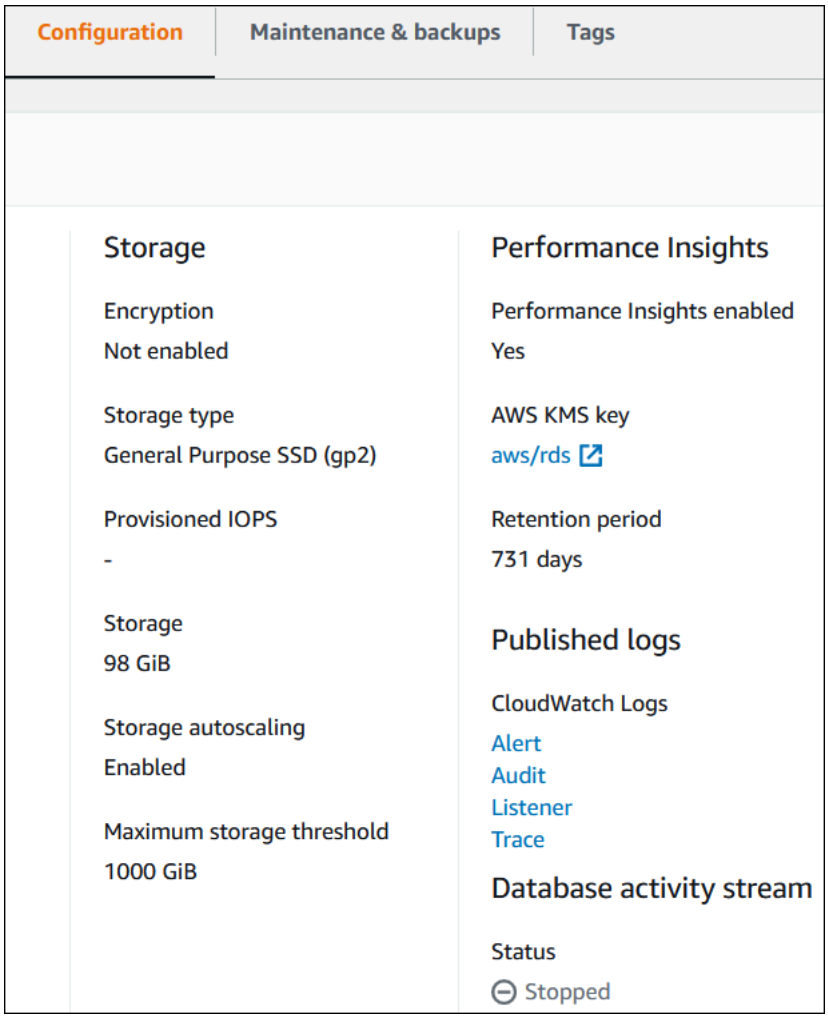
4. Choose **Logs & events**.

   The Logs & events section appears.



5. Choose **Configuration**.

   The following example shows the status of the database activity streams for your DB instance.



Monitoring Amazon RDS events

An *event* indicates a change in an environment. This can be an AWS environment, an SaaS partner service or application, or a custom application or service. For descriptions of the RDS events, see Amazon RDS event categories and event messages.

Topics

Overview of events for Amazon RDS

An *RDS event* indicates a change in the Amazon RDS environment. For example, Amazon RDS generates an event when the state of a DB instance changes from pending to running. Amazon RDS delivers events to EventBridge in near-real time.

> **Note**
>
> Amazon RDS emits events on a best effort basis. We recommend that you avoid writing programs that depend on the order or existence of notification events, because they might be out of sequence or missing.

Amazon RDS records events that relate to the following resources:

- DB instances

  For a list of DB instance events, see DB instance events.
- DB parameter groups

  For a list of DB parameter group events, see DB parameter group events.
- DB security groups

  For a list of DB security group events, see DB security group events.

- DB snapshots

  For a list of DB snapshot events, see DB snapshot events.
- RDS Proxy events

  For a list of RDS Proxy events, see RDS Proxy events.
- Blue/green deployment events

  For a list of blue/green deployment events, see Blue/green deployment events.

This information includes the following:

- The date and time of the event
- The source name and source type of the event
- A message associated with the event
- Event notifications include tags from when the message was sent and may not reflect tags at the time when the event occurred

Viewing Amazon RDS events

You can retrieve the following event information for your Amazon RDS resources:

- Resource name
- Resource type
- Time of the event
- Message summary of the event

You can access events in the following parts of the AWS Management Console:

- The **Events** tab, which shows events from the past 24 hours.
- The **Recent events** table in the **Logs & events** section in the **Databases** tab, which can show events for up to the past 2 weeks.

You can also retrieve events by using the describe-events AWS CLI command, or the DescribeEvents RDS API operation. If you use the AWS CLI or the RDS API to view events, you can retrieve events for up to the past 14 days.

> **Note**
>
> If you need to store events for longer periods of time, you can send Amazon RDS events to EventBridge. For more information, see Creating a rule that triggers on an Amazon RDS event

For descriptions of the Amazon RDS events, see Amazon RDS event categories and event messages.

To access detailed information about events using AWS CloudTrail, including request parameters, see CloudTrail events.

Console

To view all Amazon RDS events for the past 24 hours

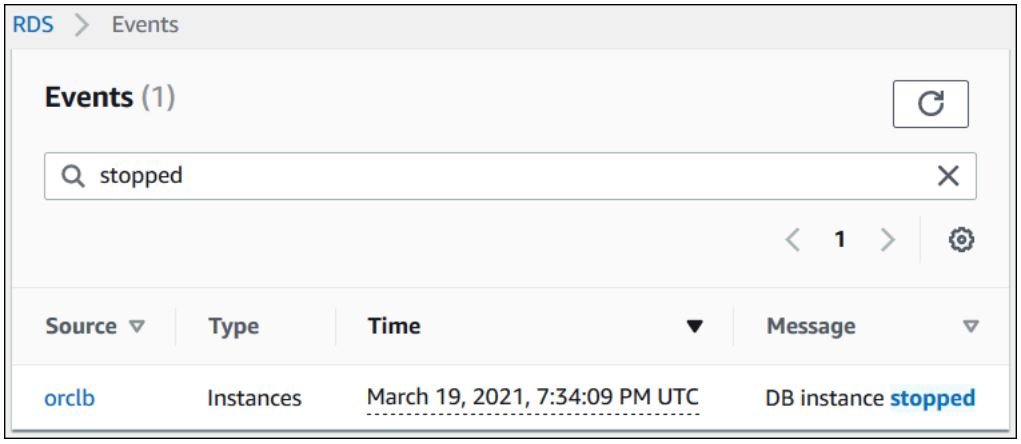
1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.

2. In the navigation pane, choose **Events**.

   The available events appear in a list.

3. (Optional) Enter a search term to filter your results.

   The following example shows a list of events filtered by the characters **`stopped`**.



AWS CLI

To view all events generated in the last hour, call describe-events with no parameters.

```
aws rds describe-events
```

The following sample output shows that a DB instance has been stopped.

```
{
    "Events": [
        {
            "EventCategories": [
                "notification"
            ],
            "SourceType": "db-instance",
            "SourceArn": "arn:aws:rds:us-east-1:123456789012:db:testinst",
            "Date": "2022-04-22T21:31:00.681Z",
            "Message": "DB instance stopped",
            "SourceIdentifier": "testinst"
        }
    ]
}
```

To view all Amazon RDS events for the past 10080 minutes (7 days), call the describe-events AWS CLI command and set the `--duration` parameter to `10080`.

```
aws rds describe-events --duration 10080
```

The following example shows the events in the specified time range for DB instance *test-instance*.

```
aws rds describe-events \
    --source-identifier test-instance \
    --source-type db-instance \
    --start-time 2022-03-13T22:00Z \
    --end-time 2022-03-13T23:59Z
```

The following sample output shows the status of a backup.

```
{
    "Events": [
        {
            "SourceType": "db-instance",
            "SourceIdentifier": "test-instance",
            "EventCategories": [
                "backup"
            ],
            "Message": "Backing up DB instance",
            "Date": "2022-03-13T23:09:23.983Z",
            "SourceArn": "arn:aws:rds:us-east-1:123456789012:db:test-instance"
        },
        {
            "SourceType": "db-instance",
            "SourceIdentifier": "test-instance",
            "EventCategories": [
                "backup"
            ],
            "Message": "Finished DB Instance backup",
            "Date": "2022-03-13T23:15:13.049Z",
            "SourceArn": "arn:aws:rds:us-east-1:123456789012:db:test-instance"
        }
    ]
}
```

API

You can view all Amazon RDS instance events for the past 14 days by calling the DescribeEvents RDS API operation and setting the `Duration` parameter to `20160`.

Working with Amazon RDS event notification

Amazon RDS uses the Amazon Simple Notification Service (Amazon SNS) to provide notification when an Amazon RDS event occurs. These notifications can be in any notification form supported by Amazon SNS for an AWS Region, such as an email, a text message, or a call to an HTTP endpoint.

Topics

Overview of Amazon RDS event notification

Amazon RDS groups events into categories that you can subscribe to so that you can be notified when an event in that category occurs.

Topics

RDS resources eligible for event subscription

You can subscribe to an event category for the following resources:

- DB instance
- DB snapshot
- DB parameter group
- DB security group
- RDS Proxy
- Custom engine version

For example, if you subscribe to the backup category for a given DB instance, you're notified whenever a backup-related event occurs that affects the DB instance. If you subscribe to a configuration change category for a DB instance, you're notified when the DB instance is changed. You also receive notification when an event notification subscription changes.

You might want to create several different subscriptions. For example, you might create one subscription that receives all event notifications for all DB instances and another subscription that includes only critical events for a subset of the DB instances. For the second subscription, specify one or more DB instances in the filter.

Basic process for subscribing to Amazon RDS event notifications

The process for subscribing to Amazon RDS event notification is as follows:

1. You create an Amazon RDS event notification subscription by using the Amazon RDS console, AWS CLI, or API.

   Amazon RDS uses the ARN of an Amazon SNS topic to identify each subscription. The Amazon RDS console creates the ARN for you when you create the subscription. Create the ARN by using the Amazon SNS console, the AWS CLI, or the Amazon SNS API.
2. Amazon RDS sends an approval email or SMS message to the addresses you submitted with your subscription.
3. You confirm your subscription by choosing the link in the notification you received.
4. The Amazon RDS console updates the **My Event Subscriptions** section with the status of your subscription.
5. Amazon RDS begins sending the notifications to the addresses that you provided when you created the subscription.

To learn about identity and access management when using Amazon SNS, see Identity and access management in Amazon SNS in the *Amazon Simple Notification Service Developer Guide*.

You can use AWS Lambda to process event notifications from a DB instance. For more information, see Using AWS Lambda with Amazon RDS in the *AWS Lambda Developer Guide*.

Delivery of RDS event notifications

Amazon RDS sends notifications to the addresses that you provide when you create the subscription. The notification can include message attributes which provide structured metadata about the message. For more information about message attributes, see Amazon RDS event categories and event messages.

Event notifications might take up to five minutes to be delivered.

> **Important**
>
> Amazon RDS doesn't guarantee the order of events sent in an event stream. The event order is subject to change.

When Amazon SNS sends a notification to a subscribed HTTP or HTTPS endpoint, the POST message sent to the endpoint has a message body that contains a JSON document. For more information, see Amazon SNS message and JSON formats in the *Amazon Simple Notification Service Developer Guide*.

You can configure SNS to notify you with text messages. For more information, see Mobile text messaging (SMS) in the *Amazon Simple Notification Service Developer Guide*.

To turn off notifications without deleting a subscription, choose **No** for **Enabled** in the Amazon RDS console. Or you can set the `Enabled` parameter to `false` using the AWS CLI or Amazon RDS API.

Billing for Amazon RDS event notifications

Billing for Amazon RDS event notification is through Amazon SNS. Amazon SNS fees apply when using event notification. For more information about Amazon SNS billing, see Amazon Simple Notification Service pricing.

Examples of Amazon RDS events using Amazon EventBridge

The following examples illustrate different types of Amazon RDS events in JSON format. For a tutorial that shows you how to capture and view events in JSON format, see Tutorial: Log DB instance state changes using Amazon EventBridge.

Topics

- Example of a DB instance event
- Example of a DB parameter group event
- Example of a DB snapshot event

Example of a DB instance event

The following is an example of a DB instance event in JSON format. The event shows that RDS performed a multi-AZ failover for the instance named `my-db-instance`. The event ID is RDS-EVENT-0049.

```
{
  "version": "0",
  "id": "68f6e973-1a0c-d37b-f2f2-94a7f62ffd4e",
  "detail-type": "RDS DB Instance Event",
  "source": "aws.rds",
  "account": "123456789012",
  "time": "2018-09-27T22:36:43Z",
  "region": "us-east-1",
  "resources": [
    "arn:aws:rds:us-east-1:123456789012:db:my-db-instance"
  ],
  "detail": {
    "EventCategories": [
      "failover"
    ],
    "SourceType": "DB_INSTANCE",
    "SourceArn": "arn:aws:rds:us-east-1:123456789012:db:my-db-instance",
    "Date": "2018-09-27T22:36:43.292Z",
    "Message": "A Multi-AZ failover has completed.",
    "SourceIdentifier": "my-db-instance",
    "EventID": "RDS-EVENT-0049"
  }
}
```

Example of a DB parameter group event

The following is an example of a DB parameter group event in JSON format. The event shows that the parameter `time_zone` was updated in parameter group `my-db-param-group`. The event ID is RDS-EVENT-0037.

```
{
  "version": "0",
  "id": "844e2571-85d4-695f-b930-0153b71dcb42",
  "detail-type": "RDS DB Parameter Group Event",
  "source": "aws.rds",
  "account": "123456789012",
  "time": "2018-10-06T12:26:13Z",
  "region": "us-east-1",
  "resources": [
    "arn:aws:rds:us-east-1:123456789012:pg:my-db-param-group"
  ],
  "detail": {
    "EventCategories": [
      "configuration change"
    ],
    "SourceType": "DB_PARAM",
    "SourceArn": "arn:aws:rds:us-east-1:123456789012:pg:my-db-param-group",
    "Date": "2018-10-06T12:26:13.882Z",
    "Message": "Updated parameter time_zone to UTC with apply method immediate",
    "SourceIdentifier": "my-db-param-group",
    "EventID": "RDS-EVENT-0037"
  }
}
```

Example of a DB snapshot event

The following is an example of a DB snapshot event in JSON format. The event shows the deletion of the snapshot named `my-db-snapshot`. The event ID is RDS-EVENT-0041.

```
{
  "version": "0",
  "id": "844e2571-85d4-695f-b930-0153b71dcb42",
  "detail-type": "RDS DB Snapshot Event",
  "source": "aws.rds",
  "account": "123456789012",
  "time": "2018-10-06T12:26:13Z",
  "region": "us-east-1",
```

```
  "resources": [
    "arn:aws:rds:us-east-1:123456789012:snapshot:rds:my-db-snapshot"
  ],
  "detail": {
    "EventCategories": [
      "deletion"
    ],
    "SourceType": "SNAPSHOT",
    "SourceArn": "arn:aws:rds:us-east-1:123456789012:snapshot:rds:my-db-snapshot",
    "Date": "2018-10-06T12:26:13.882Z",
    "Message": "Deleted manual snapshot",
    "SourceIdentifier": "my-db-snapshot",
    "EventID": "RDS-EVENT-0041"
  }
}
```

Granting permissions to publish notifications to an Amazon SNS topic

To grant Amazon RDS permissions to publish notifications to an Amazon Simple Notification Service (Amazon SNS) topic, attach an AWS Identity and Access Management (IAM) policy to the destination topic. For more information about permissions, see Example cases for Amazon Simple Notification Service access control in the *Amazon Simple Notification Service Developer Guide*.

By default, an Amazon SNS topic has a policy allowing all Amazon RDS resources within the same account to publish notifications to it. You can attach a custom policy to allow cross-account notifications, or to restrict access to certain resources.

The following is an example of an IAM policy that you attach to the destination Amazon SNS topic. It restricts the topic to DB instances with names that match the specified prefix. To use this policy, specify the following values:

- `Resource` – The Amazon Resource Name (ARN) for your Amazon SNS topic
- `SourceARN` – Your RDS resource ARN
- `SourceAccount` – Your AWS account ID

To see a list of resource types and their ARNs, see Resources Defined by Amazon RDS in the *Service Authorization Reference*.

```
{
  "Version": "2008-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": "events.rds.amazonaws.com"
      },
      "Action": [
        "sns:Publish"
      ],
      "Resource": "arn:aws:sns:us-east-1:123456789012:topic_name",
      "Condition": {
        "ArnLike": {
          "aws:SourceArn": "arn:aws:rds:us-east-1:123456789012:db:prefix-*"
        },
        "StringEquals": {
          "aws:SourceAccount": "123456789012"
```

```
          }
        }
      }
    ]
}
```

Subscribing to Amazon RDS event notification

The simplest way to create a subscription is with the RDS console. If you choose to create event notification subscriptions using the CLI or API, you must create an Amazon Simple Notification Service topic and subscribe to that topic with the Amazon SNS console or Amazon SNS API. You will also need to retain the Amazon Resource Name (ARN) of the topic because it is used when submitting CLI commands or API operations. For information on creating an SNS topic and subscribing to it, see Getting started with Amazon SNS in the *Amazon Simple Notification Service Developer Guide*.

You can specify the type of source you want to be notified of and the Amazon RDS source that triggers the event:

Source type

The type of source. For example, **Source type** might be **Instances**. You must choose a source type.

`Resources` **to include**

The Amazon RDS resources that are generating the events. For example, you might choose **Select specific instances** and then **myDBInstance1**.

The following table explains the result when you specify or don't specify ***`Resources`*** **to include**.

Resources to include	Description	Example
Specified	RDS notifies you about all events for the specified resource only.	If your **Source type** is **Instances** and your resource is **myDBInstance1**, RDS notifies you about all events for myDBInstance1 only.
Not specified	RDS notifies you about the events for the specified source type for all your Amazon RDS resources.	If your **Source type** is **Instances**, RDS notifies you about all instance-related events in your account.

An Amazon SNS topic subscriber receives every message published to the topic by default. To receive only a subset of the messages, the subscriber must assign a filter policy to the topic subscription. For more information about SNS message filtering, see Amazon SNS message filtering in the *Amazon Simple Notification Service Developer Guide*

Console

To subscribe to RDS event notification

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In navigation pane, choose **Event subscriptions**.
3. In the **Event subscriptions** pane, choose **Create event subscription**.
4. Enter your subscription details as follows:

   a. For **Name**, enter a name for the event notification subscription.

   b. For **Send notifications to**, do one of the following:

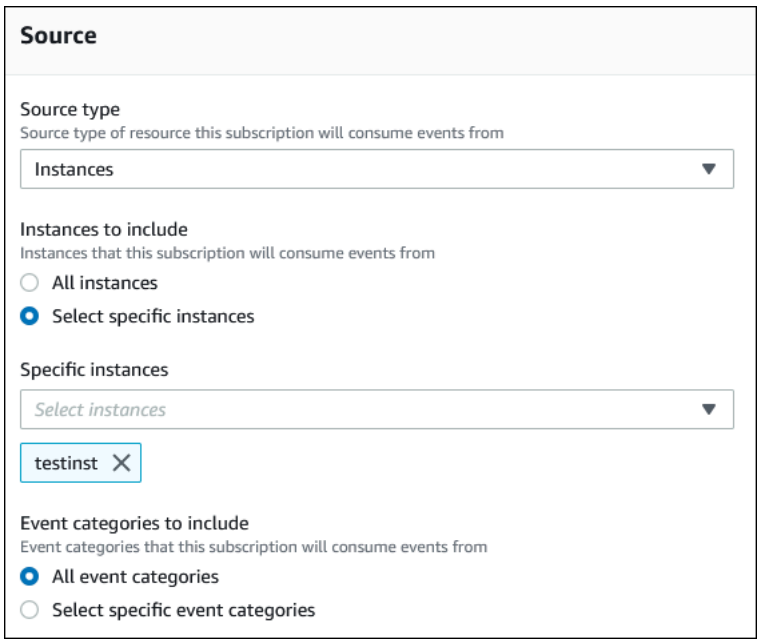
   - Choose **New email topic**. Enter a name for your email topic and a list of recipients. We recommend that you configure the events subscriptions to the same email address as your primary account contact. The recommendations, service events, and personal health messages are sent using different channels. The subscriptions to the same email address ensures that all the messages are consolidated in one location.
   - Choose **Amazon Resource Name (ARN)**. Then choose existing Amazon SNS ARN for an Amazon SNS topic.

     If you want to use a topic that has been enabled for server-side encryption (SSE), grant Amazon RDS the necessary permissions to access the AWS KMS key. For more information, see Enable compatibility between event sources from AWS services and encrypted topics in the *Amazon Simple Notification Service Developer Guide*.

   c. For **Source type**, choose a source type. For example, choose **Instances** or **Parameter groups**.

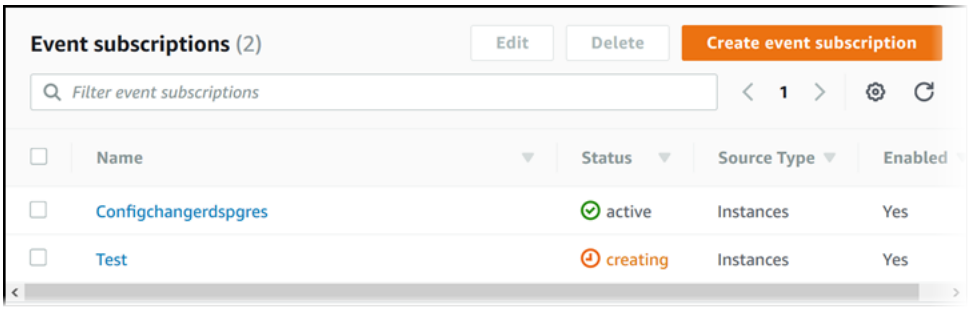
   d. Choose the event categories and resources that you want to receive event notifications for.

   The following example configures event notifications for the DB instance named `testinst`.



e. Choose **Create**.

The Amazon RDS console indicates that the subscription is being created.



AWS CLI

To subscribe to RDS event notification, use the AWS CLI `create-event-subscription` command. Include the following required parameters:

- `--subscription-name`
- `--sns-topic-arn`

Example

For Linux, macOS, or Unix:

```
aws rds create-event-subscription \
```

```
    --subscription-name myeventsubscription \
    --sns-topic-arn arn:aws:sns:us-east-1:123456789012:myawsuser-RDS \
    --enabled
```

For Windows:

```
aws rds create-event-subscription ^
    --subscription-name myeventsubscription ^
    --sns-topic-arn arn:aws:sns:us-east-1:123456789012:myawsuser-RDS ^
    --enabled
```

API

To subscribe to Amazon RDS event notification, call the Amazon RDS API function `CreateEventSubscription`. Include the following required parameters:

- `SubscriptionName`
- `SnsTopicArn`

Amazon RDS event notification tags and attributes

When Amazon RDS sends an event notification to Amazon Simple Notification Service (SNS) or Amazon EventBridge, the notification contains message attributes and event tags. RDS sends the message attributes separately along with the message, while the event tags are in the body of the message. Use the message attributes and the Amazon RDS tags to add metadata to your resources. You can modify these tags with your own notations about the DB instances. For more information about tagging Amazon RDS resources, see Tagging Amazon RDS resources.

By default, the Amazon SNS and Amazon EventBridge receives every message sent to them. SNS and EventBridge can filter the message and send the notifications to the preferred communication mode, such as an email, a text message, or a call to an HTTP endpoint.

> **Note**
>
> The notification sent in an email or a text message will not have event tags.

The following table shows the message attributes for RDS events sent to the topic subscriber.

Amazon RDS event attribute	Description
EventID	Identifier for the RDS event message, for example, RDS-EVENT-0006.
Resource	The ARN identifier for the resource emitting the event, for example, `arn:aws:rds:ap-southeast-2:123456789012:db:database-1` .

The RDS tags provide data about the resource that was affected by the service event. RDS adds the current state of the tags in the message body when the notification is sent to SNS or EventBridge.

For more information about filtering message attributes for SNS, see Amazon SNS message filtering in the *Amazon Simple Notification Service Developer Guide*.

For more information about filtering event tags for EventBridge, see Content filtering in Amazon EventBridge event patterns in the *Amazon EventBridge User Guide*.

For more information about filtering payload-based tags for SNS, see https://aws.amazon.com/blogs/compute/introducing-payload-based-message-filtering-for-amazon-sns/

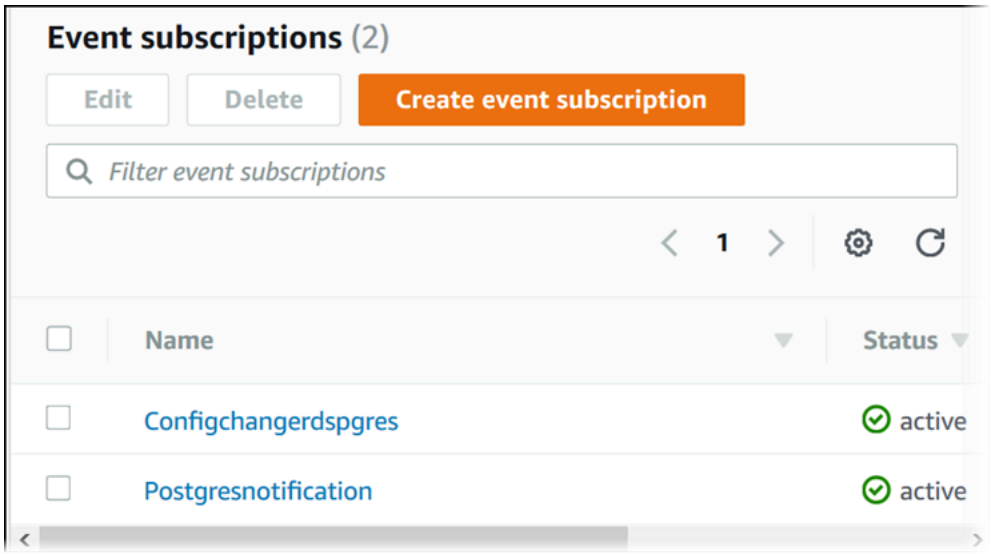
Listing Amazon RDS event notification subscriptions

You can list your current Amazon RDS event notification subscriptions.

Console

To list your current Amazon RDS event notification subscriptions

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Event subscriptions**. The **Event subscriptions** pane shows all your event notification subscriptions.



AWS CLI

To list your current Amazon RDS event notification subscriptions, use the AWS CLI `describe-event-subscriptions` command.

Example

The following example describes all event subscriptions.

```
aws rds describe-event-subscriptions
```

The following example describes the `myfirsteventsubscription`.

```
aws rds describe-event-subscriptions --subscription-name myfirsteventsubscription
```

API

To list your current Amazon RDS event notification subscriptions, call the Amazon RDS API `DescribeEventSubscriptions` action.

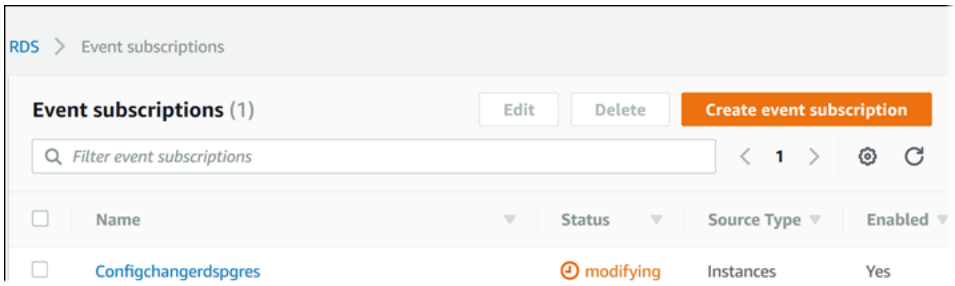
Modifying an Amazon RDS event notification subscription

After you have created a subscription, you can change the subscription name, source identifier, categories, or topic ARN.

Console

To modify an Amazon RDS event notification subscription

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Event subscriptions**.
3. In the **Event subscriptions** pane, choose the subscription that you want to modify and choose **Edit**.
4. Make your changes to the subscription in either the **Target** or **Source** section.
5. Choose **Edit**. The Amazon RDS console indicates that the subscription is being modified.



AWS CLI

To modify an Amazon RDS event notification subscription, use the AWS CLI `modify-event-subscription` command. Include the following required parameter:

- `--subscription-name`

Example

The following code enables `myeventsubscription`.

For Linux, macOS, or Unix:

```
aws rds modify-event-subscription \
```

```
    --subscription-name myeventsubscription \
    --enabled
```

For Windows:

```
aws rds modify-event-subscription ^
    --subscription-name myeventsubscription ^
    --enabled
```

API

To modify an Amazon RDS event, call the Amazon RDS API operation `ModifyEventSubscription`. Include the following required parameter:

- `SubscriptionName`

Adding a source identifier to an Amazon RDS event notification subscription

You can add a source identifier (the Amazon RDS source generating the event) to an existing subscription.

Console

You can easily add or remove source identifiers using the Amazon RDS console by selecting or deselecting them when modifying a subscription. For more information, see Modifying an Amazon RDS event notification subscription.

AWS CLI

To add a source identifier to an Amazon RDS event notification subscription, use the AWS CLI `add-source-identifier-to-subscription` command. Include the following required parameters:

- `--subscription-name`
- `--source-identifier`

Example

The following example adds the source identifier `mysqldb` to the `myrdseventsubscription` subscription.

For Linux, macOS, or Unix:

```
aws rds add-source-identifier-to-subscription \
    --subscription-name myrdseventsubscription \
    --source-identifier mysqldb
```

For Windows:

```
aws rds add-source-identifier-to-subscription ^
    --subscription-name myrdseventsubscription ^
    --source-identifier mysqldb
```

API

To add a source identifier to an Amazon RDS event notification subscription, call the Amazon RDS API `AddSourceIdentifierToSubscription`. Include the following required parameters:

- `SubscriptionName`
- `SourceIdentifier`

Removing a source identifier from an Amazon RDS event notification subscription

You can remove a source identifier (the Amazon RDS source generating the event) from a subscription if you no longer want to be notified of events for that source.

Console

You can easily add or remove source identifiers using the Amazon RDS console by selecting or deselecting them when modifying a subscription. For more information, see Modifying an Amazon RDS event notification subscription.

AWS CLI

To remove a source identifier from an Amazon RDS event notification subscription, use the AWS CLI `remove-source-identifier-from-subscription` command. Include the following required parameters:

- `--subscription-name`
- `--source-identifier`

Example

The following example removes the source identifier `mysqldb` from the `myrdseventsubscription` subscription.

For Linux, macOS, or Unix:

```
aws rds remove-source-identifier-from-subscription \
    --subscription-name myrdseventsubscription \
    --source-identifier mysqldb
```

For Windows:

```
aws rds remove-source-identifier-from-subscription ^
    --subscription-name myrdseventsubscription ^
    --source-identifier mysqldb
```

API

To remove a source identifier from an Amazon RDS event notification subscription, use the Amazon RDS API `RemoveSourceIdentifierFromSubscription` command. Include the following required parameters:

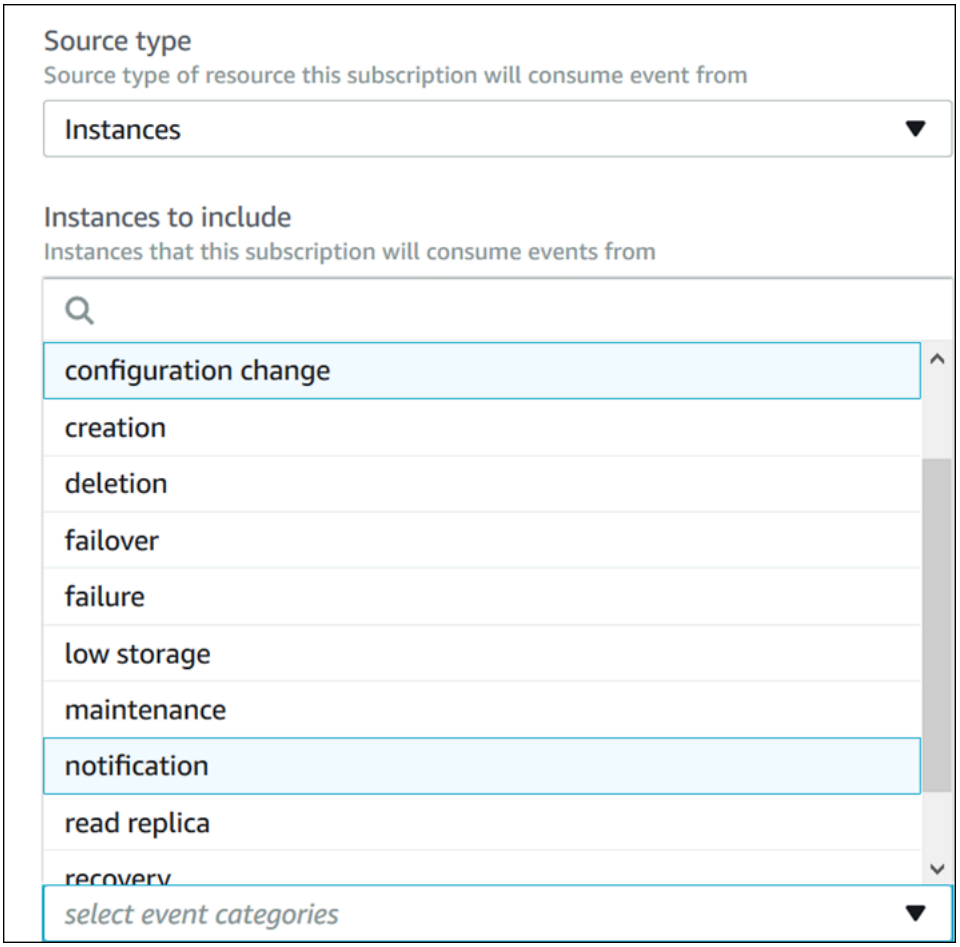
- `SubscriptionName`
- `SourceIdentifier`

Listing the Amazon RDS event notification categories

All events for a resource type are grouped into categories. To view the list of categories available, use the following procedures.

Console

When you create or modify an event notification subscription, the event categories are displayed in the Amazon RDS console. For more information, see Modifying an Amazon RDS event notification subscription.



AWS CLI

To list the Amazon RDS event notification categories, use the AWS CLI `describe-event-categories` command. This command has no required parameters.

Example

```
aws rds describe-event-categories
```

API

To list the Amazon RDS event notification categories, use the Amazon RDS API `DescribeEventCategories` command. This command has no required parameters.

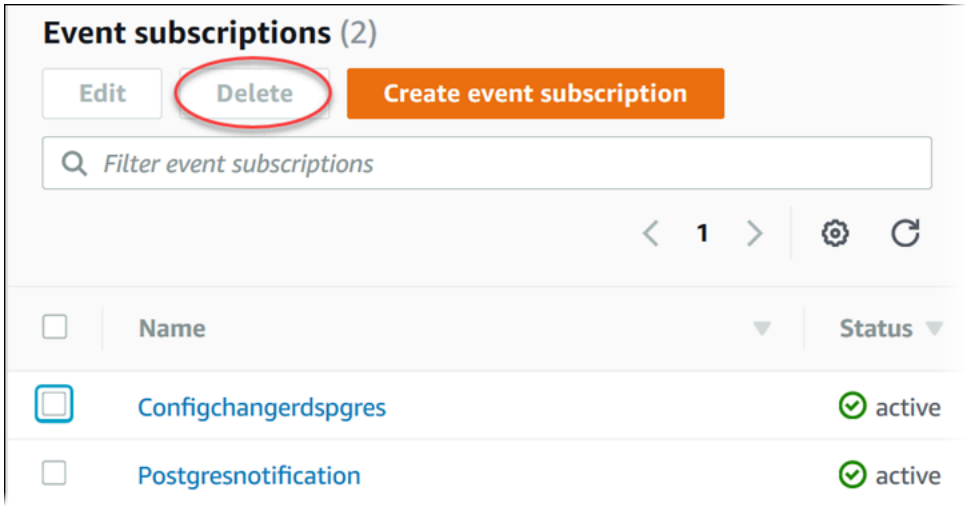
Deleting an Amazon RDS event notification subscription

You can delete a subscription when you no longer need it. All subscribers to the topic will no longer receive event notifications specified by the subscription.

Console

To delete an Amazon RDS event notification subscription

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **DB Event Subscriptions**.
3. In the **My DB Event Subscriptions** pane, choose the subscription that you want to delete.
4. Choose **Delete**.
5. The Amazon RDS console indicates that the subscription is being deleted.



AWS CLI

To delete an Amazon RDS event notification subscription, use the AWS CLI `delete-event-subscription` command. Include the following required parameter:

- `--subscription-name`

Example

The following example deletes the subscription `myrdssubscription`.

```
aws rds delete-event-subscription --subscription-name myrdssubscription
```

API

To delete an Amazon RDS event notification subscription, use the RDS API `DeleteEventSubscription` command. Include the following required parameter:

- `SubscriptionName`

Creating a rule that triggers on an Amazon RDS event

Using Amazon EventBridge, you can automate AWS services and respond to system events such as application availability issues or resource changes.

Topics

Creating rules to send Amazon RDS events to Amazon EventBridge

You can write simple rules to indicate which Amazon RDS events interest you and which automated actions to take when an event matches a rule. You can set a variety of targets, such as an AWS Lambda function or an Amazon SNS topic, which receive events in JSON format. For example, you can configure Amazon RDS to send events to Amazon EventBridge whenever a DB instance is created or deleted. For more information, see the Amazon CloudWatch Events User Guide and the Amazon EventBridge User Guide.

To create a rule that triggers on an RDS event:

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. Under **Events** in the navigation pane, choose **Rules**.
3. Choose **Create rule**.
4. For **Event Source**, do the following:
    a. Choose **Event Pattern**.
    b. For **Service Name**, choose **Relational Database Service (RDS)**.
    c. For **Event Type**, choose the type of Amazon RDS resource that triggers the event. For example, if a DB instance triggers the event, choose **RDS DB Instance Event**.
5. For **Targets**, choose **Add Target** and choose the AWS service that is to act when an event of the selected type is detected.
6. In the other fields in this section, enter information specific to this target type, if any is needed.
7. For many target types, EventBridge needs permissions to send events to the target. In these cases, EventBridge can create the IAM role needed for your event to run:

- To create an IAM role automatically, choose **Create a new role for this specific resource**.
- To use an IAM role that you created before, choose **Use existing role**.

8. Optionally, repeat steps 5-7 to add another target for this rule.
9. Choose **Configure details**. For **Rule definition**, type a name and description for the rule.

   The rule name must be unique within this Region.
10. Choose **Create rule**.

For more information, see Creating an EventBridge Rule That Triggers on an Event in the *Amazon CloudWatch User Guide*.

Tutorial: Log DB instance state changes using Amazon EventBridge

In this tutorial, you create an AWS Lambda function that logs the state changes for an Amazon RDS instance. You then create a rule that runs the function whenever there is a state change of an existing RDS DB instance. The tutorial assumes that you have a small running test instance that you can shut down temporarily.

> **Important**
>
> Don't perform this tutorial on a running production DB instance.

Topics

- Step 1: Create an AWS Lambda function
- Step 2: Create a rule
- Step 3: Test the rule

Step 1: Create an AWS Lambda function

Create a Lambda function to log the state change events. You specify this function when you create your rule.

To create a Lambda function

1. Open the AWS Lambda console at https://console.aws.amazon.com/lambda/.

2. If you're new to Lambda, you see a welcome page. Choose **Get Started Now**. Otherwise, choose **Create function**.
3. Choose **Author from scratch**.
4. On the **Create function** page, do the following:

   a. Enter a name and description for the Lambda function. For example, name the function **`RDSInstanceStateChange`**.

   b. In **Runtime**, select **Node.js 16x**.

   c. For **Architecture**, choose **x86_64**.

   d. For **Execution role**, do either of the following:

      - Choose **Create a new role with basic Lambda permissions**.
      - For **Existing role**, choose **Use an existing role**. Choose the role that you want to use.

   e. Choose **Create function**.
5. On the **RDSInstanceStateChange** page, do the following:

   a. In **Code source**, select **index.js**.

   b. In the **index.js** pane, delete the existing code.

   c. Enter the following code:

```
console.log('Loading function');

exports.handler = async (event, context) => {
    console.log('Received event:', JSON.stringify(event));
};
```

   d. Choose **Deploy**.

Step 2: Create a rule

Create a rule to run your Lambda function whenever you launch an Amazon RDS instance.

To create the EventBridge rule

1. Open the Amazon EventBridge console at https://console.aws.amazon.com/events/.
2. In the navigation pane, choose **Rules**.
3. Choose **Create rule**.

4. Enter a name and description for the rule. For example, enter **`RDSInstanceStateChangeRule`**.
5. Choose **Rule with an event pattern**, and then choose **Next**.
6. For **Event source**, choose **AWS events or EventBridge partner events**.
7. Scroll down to the **Event pattern** section.
8. For **Event source**, choose **AWS services**.
9. For **AWS service**, choose **Relational Database Service (RDS)**.
10. For **Event type**, choose **RDS DB Instance Event**.
11. Leave the default event pattern. Then choose **Next**.
12. For **Target types**, choose **AWS service**.
13. For **Select a target**, choose **Lambda function**.
14. For **Function**, choose the Lambda function that you created. Then choose **Next**.
15. In **Configure tags**, choose **Next**.
16. Review the steps in your rule. Then choose **Create rule**.

Step 3: Test the rule

To test your rule, shut down an RDS DB instance. After waiting a few minutes for the instance to shut down, verify that your Lambda function was invoked.

To test your rule by stopping a DB instance

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Stop an RDS DB instance.
3. Open the Amazon EventBridge console at https://console.aws.amazon.com/events/.
4. In the navigation pane, choose **Rules**, choose the name of the rule that you created.
5. In **Rule details**, choose **Monitoring**.

   You are redirected to the Amazon CloudWatch console. If you are not redirected, click **View the metrics in CloudWatch**.
6. In **All metrics**, choose the name of the rule that you created.

   The graph should indicate that the rule was invoked.
7. In the navigation pane, choose **Log groups**.

8. Choose the name of the log group for your Lambda function (**/aws/lambda/*function-name***).
9. Choose the name of the log stream to view the data provided by the function for the instance that you launched. You should see a received event similar to the following:

```
{
    "version": "0",
    "id": "12a345b6-78c9-01d2-34e5-123f4ghi5j6k",
    "detail-type": "RDS DB Instance Event",
    "source": "aws.rds",
    "account": "111111111111",
    "time": "2021-03-19T19:34:09Z",
    "region": "us-east-1",
    "resources": [
        "arn:aws:rds:us-east-1:111111111111:db:testdb"
    ],
    "detail": {
        "EventCategories": [
            "notification"
        ],
        "SourceType": "DB_INSTANCE",
        "SourceArn": "arn:aws:rds:us-east-1:111111111111:db:testdb",
        "Date": "2021-03-19T19:34:09.293Z",
        "Message": "DB instance stopped",
        "SourceIdentifier": "testdb",
        "EventID": "RDS-EVENT-0087"
    }
}
```

   For more examples of RDS events in JSON format, see Overview of events for Amazon RDS.
10. (Optional) When you're finished, you can open the Amazon RDS console and start the instance that you stopped.

Amazon RDS event categories and event messages

Amazon RDS generates a significant number of events in categories that you can subscribe to using the Amazon RDS Console, AWS CLI, or the API.

Topics

DB cluster events

The following table shows the event category and a list of events when a DB cluster is the source type.

For more information about Multi-AZ DB cluster deployments, see Multi-AZ DB cluster deployments.

Category	RDS event ID	Message	Notes
configuration change	RDS-EVENT-0016	Reset master credentials.	None
creation	RDS-EVENT-0170	DB cluster created.	None
failover	RDS-EVENT-0069	Cluster failover failed, check the health of your cluster instances and try again.	None

Category	RDS event ID	Message	Notes
failover	RDS-EVENT-0070	Promoting previous primary again: *name*.	None
failover	RDS-EVENT-0071	Completed failover to DB instance: *name*.	None
failover	RDS-EVENT-0072	Started same AZ failover to DB instance: *name*.	None
failover	RDS-EVENT-0073	Started cross AZ failover to DB instance: *name*.	None
failure	RDS-EVENT-0354	You can't create the DB cluster because of incompatible resources. *message*.	The *message* includes details about the failure.
failure	RDS-EVENT-0355	The DB cluster can't be created because of insufficient resource limits. *message*.	The *message* includes details about the failure.
global failover	RDS-EVENT-0181	Global switchover to DB cluster *name* in Region *name* started.	This event is for a switchover operation (previously called "managed planned failover"). The process can be delayed because other operation s are running on the DB cluster.

Category	RDS event ID	Message	Notes
global failover	RDS-EVENT-0182	Old primary DB cluster *name* in Region *name* successfully shut down.	This event is for a switchover operation (previously called "managed planned failover"). The old primary instance in the global database isn't accepting writes. All volumes are synchronized.
global failover	RDS-EVENT-0183	Waiting for data synchronization across global cluster members. Current lags behind primary DB cluster: *reason*.	This event is for a switchover operation (previously called "managed planned failover"). A replication lag is occurring during the synchronization phase of the global database failover.
global failover	RDS-EVENT-0184	New primary DB cluster *name* in Region *name* was successfully promoted.	This event is for a switchover operation (previously called "managed planned failover"). The volume topology of the global database is reestablished with the new primary volume.

Category	RDS event ID	Message	Notes
global failover	RDS-EVENT-0185	Global switchover to DB cluster *name* in Region *name* finished.	This event is for a switchover operation (previously called "managed planned failover"). The global database switchover is finished on the primary DB cluster. Replicas might take long to come online after the failover completes.
global failover	RDS-EVENT-0186	Global switchover to DB cluster *name* in Region *name* is cancelled.	This event is for a switchover operation (previously called "managed planned failover").
global failover	RDS-EVENT-0187	Global switchover to DB cluster *name* in Region *name* failed.	This event is for a switchover operation (previously called "managed planned failover").
global failover	RDS-EVENT-0238	Global failover to DB cluster *name* in Region *name* completed.	None
global failover	RDS-EVENT-0239	Global failover to DB cluster *name* in Region *name* failed.	None

Category	RDS event ID	Message	Notes
global failover	RDS-EVENT-0240	Started resynchronizing members of DB cluster *name* in Region *name* after global failover.	None
global failover	RDS-EVENT-0241	Finished resynchronizing members of DB cluster *name* in Region *name* after global failover.	None
maintenance	RDS-EVENT-0156	The DB cluster has a DB engine minor version upgrade available.	None
maintenance	RDS-EVENT-0176	Database cluster engine major version has been upgraded.	None
maintenance	RDS-EVENT-0177	Database cluster upgrade is in progress.	None
maintenance	RDS-EVENT-0286	Database cluster engine version upgrade started.	None
maintenance	RDS-EVENT-0287	Operating system upgrade requirement detected.	None
maintenance	RDS-EVENT-0288	Cluster operating system upgrade starting.	None
maintenance	RDS-EVENT-0289	Cluster operating system upgrade completed.	None
notification	RDS-EVENT-0172	Renamed cluster from *name* to *name*.	None

DB instance events

The following table shows the event category and a list of events when a DB instance is the source type.

Category	RDS event ID	Message	Notes
availability	RDS-EVENT-0004	DB instance shutdown.	None
availability	RDS-EVENT-0006	DB instance restarted.	None
availability	RDS-EVENT-0022	Error restarting mysql: *message*.	An error has occurred while restarting MySQL.
availability	RDS-EVENT-0221	DB instance has reached the storage-full threshold , and the database has been shut down. You can increase the allocated storage to address this issue.	None
availability	RDS-EVENT-0222	Free storage capacity for DB instance *name* is low at *percentage* of the allocated storage [Allocated storage: *amount*, Free storage: *amount*]. The database will be shut down to prevent corruption if free storage is lower than *amount*. You can increase the allocated storage to address this issue.	For more information, see Amazon RDS DB instance storage.

Category	RDS event ID	Message	Notes
availability	RDS-EVENT-0330	The free storage capacity of the dedicated transacti on log volume is too low for DB instance *name*. The log volume free storage is *percentage* of the allocated storage. [Allocated storage: *amount*, Free storage: *amount*] The database will be shut down to prevent corruption if the free storage is lower than *amount*. You can disable the dedicated transaction log volume to resolve this issue.	For more information, see Dedicated log volume (DLV).
availability	RDS-EVENT-0331	The free storage capacity of the dedicated transacti on log volume is too low for DB instance *name*. The log volume free storage is *percentage* of the provisioned storage. [Provisioned Storage: *amount*, Free Storage: *amount*] You can disable the dedicated transaction log volume to resolve this issue.	For more information, see Dedicated log volume (DLV).

Category	RDS event ID	Message	Notes
availability	RDS-EVENT-0396	Amazon RDS has scheduled a reboot for this read replica in this instance's next maintenance window after internal user password rotation.	None
backup	RDS-EVENT-0001	Backing up DB instance.	None
backup	RDS-EVENT-0002	Finished DB instance backup.	None
backup	RDS-EVENT-0086	We are unable to associate the option group *name* with the database instance *name*. Confirm that option group *name* is supported on your DB instance class and configuration. If so, verify all option group settings and retry.	For more information see Working with option groups.
configuration change	RDS-EVENT-0011	Updated to use DBParameterGroup *name*.	None
configuration change	RDS-EVENT-0012	Applying modification to database instance class.	None
configuration change	RDS-EVENT-0014	Finished applying modification to DB instance class.	None
configuration change	RDS-EVENT-0016	Reset master credentials.	None

Category	RDS event ID	Message	Notes
configuration change	RDS-EVENT-0017	Finished applying modification to allocated storage.	None
configuration change	RDS-EVENT-0018	Applying modification to allocated storage.	None
configuration change	RDS-EVENT-0024	Applying modification to convert to a Multi-AZ DB instance.	None
configuration change	RDS-EVENT-0025	Finished applying modification to convert to a Multi-AZ DB instance.	None
configuration change	RDS-EVENT-0028	Disabled automated backups.	None
configuration change	RDS-EVENT-0029	Finished applying modification to convert to a standard (Single-AZ) DB instance.	None
configuration change	RDS-EVENT-0030	Applying modification to convert to a standard (Single-AZ) DB instance.	None
configuration change	RDS-EVENT-0032	Enabled automated backups.	None
configuration change	RDS-EVENT-0033	There are *number* users matching the master username; only resetting the one not tied to a specific host.	None

Category	RDS event ID	Message	Notes
configuration change	RDS-EVENT-0067	Unable to reset your password. Error informati on: *message*.	None
configuration change	RDS-EVENT-0078	Monitoring Interval changed to *number*.	The Enhanced Monitorin g configuration has been changed.
configuration change	RDS-EVENT-0092	Finished updating DB parameter group.	None
configuration change	RDS-EVENT-0217	Applying autoscaling-initiated modification to allocated storage.	None
configuration change	RDS-EVENT-0218	Finished applying autoscali ng-initiated modification to allocated storage.	None
configuration change	RDS-EVENT-0295	Storage configuration upgrade started.	None
configuration change	RDS-EVENT-0296	Storage configuration upgrade completed.	None
configuration change	RDS-EVENT-0332	The dedicated log volume is disabled.	For more information, see Dedicated log volume (DLV).
configuration change	RDS-EVENT-0333	Disabling the dedicated log volume has started.	For more information, see Dedicated log volume (DLV).
configuration change	RDS-EVENT-0334	Enabling the dedicated log volume has started.	For more information, see Dedicated log volume (DLV).

Category	RDS event ID	Message	Notes
configuration change	RDS-EVENT-0335	The dedicated log volume is enabled.	For more information, see Dedicated log volume (DLV).
configuration change	RDS-EVENT-0383	*engine version* doesn't support the memcached plugin. RDS will continue upgrading your DB instance and remove this plugin.	Starting with MySQL 8.3.0, the memcached plugin isn't supported. For more information, see Changes in MySQL 8.3.0 (2024-01-16, Innovation Release).
creation	RDS-EVENT-0005	DB instance created.	None
deletion	RDS-EVENT-0003	DB instance deleted.	None
failover	RDS-EVENT-0013	Multi-AZ instance failover started.	A Multi-AZ failover that resulted in the promotion of a standby DB instance has started.
failover	RDS-EVENT-0015	Multi-AZ failover to standby complete - DNS propagation may take a few minutes.	A Multi-AZ failover that resulted in the promotion of a standby DB instance is complete. It may take several minutes for the DNS to transfer to the new primary DB instance.
failover	RDS-EVENT-0034	Abandoning user requested failover since a failover recently occurred on the database instance.	Amazon RDS isn't attempting a requested failover because a failover recently occurred on the DB instance.
failover	RDS-EVENT-0049	Multi-AZ instance failover completed.	None

Category	RDS event ID	Message	Notes
failover	RDS-EVENT-0050	Multi-AZ instance activation started.	A Multi-AZ activation has started after a successful DB instance recovery.
failover	RDS-EVENT-0051	Multi-AZ instance activation completed.	A Multi-AZ activation is complete. Your database should be accessible now.
failover	RDS-EVENT-0065	Recovered from partial failover.	None
failure	RDS-EVENT-0031	DB instance put into *name* state. RDS recommends that you initiate a point-in-time-restore.	The DB instance has failed due to an incompatible configuration or an underlying storage issue. Begin a point-in-time-restore for the DB instance.
failure	RDS-EVENT-0035	Database instance put into *state*. *message*.	The DB instance has invalid parameters. For example, if the DB instance could not start because a memory-related parameter is set too high for this instance class, your action would be to modify the memory parameter and reboot the DB instance.
failure	RDS-EVENT-0036	Database instance in *state*. *message*.	The DB instance is in an incompatible network. Some of the specified subnet IDs are invalid or do not exist.

Category	RDS event ID	Message	Notes
failure	RDS-EVENT-0058	The Statspack installation failed. *message*.	Error while creating Oracle Statspack user account PERFSTAT. Drop the account before you add the STATSPACK option.
failure	RDS-EVENT-0079	Amazon RDS has been unable to create credentials for enhanced monitoring and this feature has been disabled. This is likely due to the rds-monitoring-role not being present and configured correctly in your account. Please refer to the troubleshooting section in the Amazon RDS documentation for further details.	Enhanced Monitoring can't be enabled without the Enhanced Monitoring IAM role. For information about creating the IAM role, see To create an IAM role for Amazon RDS enhanced monitoring.
failure	RDS-EVENT-0080	Amazon RDS has been unable to configure enhanced monitoring on your instance: *name* and this feature has been disabled. This is likely due to the rds-monitoring-role not being present and configured correctly in your account. Please refer to the troubleshooting section in the Amazon RDS documentation for further details.	Enhanced Monitoring was disabled because an error occurred during the configuration change. It is likely that the Enhanced Monitoring IAM role is configured incorrectly. For information about creating the enhanced monitoring IAM role, see To create an IAM role for Amazon RDS enhanced monitoring.

Category	RDS event ID	Message	Notes
failure	RDS-EVENT-0081	Amazon RDS has been unable to create credentials for *name* option. This is due to the *name* IAM role not being configured correctly in your account. Please refer to the troubleshooting section in the Amazon RDS documentation for further details.	The IAM role that you use to access your Amazon S3 bucket for SQL Server native backup and restore is configured incorrectly. For more information, see Setting up for native backup and restore.
failure	RDS-EVENT-0165	The RDS Custom DB instance is outside the support perimeter.	It's your responsibility to fix configuration issues that put your RDS Custom DB instance into the `unsupported-configuration` state. If the issue is with the AWS infrastructure, you can use the console or the AWS CLI to fix it. If the issue is with the operating system or the database configuration, you can log in to the host to fix it. For more information, see RDS Custom support perimeter.

Category	RDS event ID	Message	Notes
failure	RDS-EVENT-0188	The DB instance is in a state that can't be upgraded. *message*	Amazon RDS was unable to upgrade a MySQL DB instance from version 5.7 to version 8.0 because of incompatibilities related to the data dictionary. The DB instance was rolled back to MySQL version 5.7. For more information, see Rollback after failure to upgrade from MySQL 5.7 to 8.0.
failure	RDS-EVENT-0219	DB instance is in an invalid state. No actions are necessary. Autoscaling will retry later.	None
failure	RDS-EVENT-0220	DB instance is in the cooling-off period for a previous scale storage operation. We're optimizin g your DB instance. This takes at least 6 hours. No actions are necessary. Autoscaling will retry after the cooling-off period.	None
failure	RDS-EVENT-0223	Storage autoscaling is unable to scale the storage for the reason: *reason*.	None

Category	RDS event ID	Message	Notes
failure	RDS-EVENT-0224	Storage autoscaling has triggered a pending scale storage task that will reach or exceed the maximum storage threshold. Increase the maximum storage threshold.	None
failure	RDS-EVENT-0237	DB instance has a storage type that's currently unavailable in the Availabil ity Zone. Autoscaling will retry later.	None
failure	RDS-EVENT-0254	Underlying storage quota for this customer account has exceeded the limit. Please increase the allowed storage quota to let the scaling go through on the instance.	None
failure	RDS-EVENT-0278	The DB instance creation failed. *message*	The *message* includes details about the failure.
failure	RDS-EVENT-0279	The promotion of the RDS Custom read replica failed. *message*	The *message* includes details about the failure.
failure	RDS-EVENT-0280	RDS Custom couldn't upgrade the DB instance because the pre-check failed. *message*	The *message* includes details about the failure.

Category	RDS event ID	Message	Notes
failure	RDS-EVENT-0281	RDS Custom couldn't modify the DB instance because the pre-check failed. *message*	The *message* includes details about the failure.
failure	RDS-EVENT-0282	RDS Custom couldn't modify the DB instance because the Elastic IP permissions aren't correct. Please confirm the Elastic IP address is tagged with `AWSRDSCustom` .	None
failure	RDS-EVENT-0283	RDS Custom couldn't modify the DB instance because the Elastic IP limit has been reached in your account. Release unused Elastic IPs or request a quota increase for your Elastic IP address limit.	None
failure	RDS-EVENT-0284	RDS Custom couldn't convert the instance to high availability because the pre-check failed. *message*	The *message* includes details about the failure.
failure	RDS-EVENT-0285	RDS Custom couldn't create a final snapshot for the DB instance because *message*.	The *message* includes details about the failure.
failure	RDS-EVENT-0306	Storage configuration upgrade failed. Please retry the upgrade.	None

Category	RDS event ID	Message	Notes
failure	RDS-EVENT-0315	Unable to move incompatible-network database, *name*, to the available status: *message*	The database networking configuration is invalid. The database could not be moved from incompatible-network to available.
failure	RDS-EVENT-0328	Failed to join a host to a domain. Domain membership status for instance *instancename* has been set to Failed.	None
failure	RDS-EVENT-0329	Failed to join a host to your domain. During the domain join process, Microsoft Windows returned the error code *message*. Verify your network and permission configurations and issue a `modify-db-instance` request to re-attempt the domain join.	When using a self-managed Active Directory, see Troubleshooting self-managed Active Directory.
failure	RDS-EVENT-0353	The DB instance can't be created because of insufficient resource limits. *message*.	The *message* includes details about the failure.

Category	RDS event ID	Message	Notes
failure	RDS-EVENT-0356	RDS was unable to configure the Kerberos endpoint in your domain. This might prevent Kerberos authentication for your DB instance. Verify the network configuration between your DB instance and domain controllers.	None
low storage	RDS-EVENT-0007	Allocated storage has been exhausted. Allocate additional storage to resolve.	The allocated storage for the DB instance has been consumed. To resolve this issue, allocate additional storage for the DB instance. For more information, see the RDS FAQ. You can monitor the storage space for a DB instance using the **Free Storage Space** metric.
low storage	RDS-EVENT-0089	The free storage capacity for DB instance: *name* is low at *percentage* of the provisioned storage [Provisioned Storage: *size*, Free Storage: *size*]. You may want to increase the provisioned storage to address this issue.	The DB instance has consumed more than 90% of its allocated storage. You can monitor the storage space for a DB instance using the **Free Storage Space** metric.

Category	RDS event ID	Message	Notes
low storage	RDS-EVENT-0227	Your Aurora cluster's storage is dangerously low with only *amount* terabytes remaining. Please take measures to reduce the storage load on your cluster.	The Aurora storage subsystem is running low on space.
maintenance	RDS-EVENT-0026	Applying off-line patches to DB instance.	Offline maintenance of the DB instance is taking place. The DB instance is currently unavailable.
maintenance	RDS-EVENT-0027	Finished applying off-line patches to DB instance.	Offline maintenance of the DB instance is complete. The DB instance is now available.
maintenance	RDS-EVENT-0047	Database instance patched.	None
maintenance	RDS-EVENT-0155	The DB instance has a DB engine minor version upgrade available.	None
maintenance	RDS-EVENT-0178	Database instance upgrade is in progress.	None
maintenance	RDS-EVENT-0264	The pre-check started for the DB engine version upgrade.	None
maintenance	RDS-EVENT-0265	The pre-check finished for the DB engine version upgrade.	None

Category	RDS event ID	Message	Notes
maintenance	RDS-EVENT-0266	The downtime started for the DB instance.	None
maintenance	RDS-EVENT-0267	The engine version upgrade started.	None
maintenance	RDS-EVENT-0268	The engine version upgrade finished.	None
maintenance	RDS-EVENT-0269	The post-upgrade tasks are in progress.	None
maintenance	RDS-EVENT-0270	The DB engine version upgrade failed. The engine version upgrade rollback succeeded.	None
maintenance, failure	RDS-EVENT-0195	*message*	The update of the Oracle time zone file failed. For more information, see Oracle time zone file autoupgrade.
maintenance, notification	RDS-EVENT-0191	A new version of the time zone file is available for update.	If you update your RDS for Oracle DB engine, Amazon RDS generates this event if you haven't chosen a time zone file upgrade and the database doesn't use the latest DST time zone file available on the instance. For more information, see Oracle time zone file autoupgrade.

Category	RDS event ID	Message	Notes
maintenance, notification	RDS-EVENT-0192	The update of your time zone file has started.	The upgrade of your Oracle time zone file has begun. For more informati on, see Oracle time zone file autoupgrade.
maintenance, notification	RDS-EVENT-0193	No update is available for the current time zone file version.	Your Oracle DB instance is using latest time zone file version, and either of the following statements is true: • You recently added the `TIMEZONE_FILE_AUTOUPGRADE` option. • Your Oracle DB engine is being upgraded. For more information, see Oracle time zone file autoupgrade.
maintenance, notification	RDS-EVENT-0194	The update of your time zone file has finished.	The update of your Oracle time zone file has completed. For more information, see Oracle time zone file autoupgra de.
notification	RDS-EVENT-0044	*message*	This is an operator-issued notification. For more information, see the event message.

Category	RDS event ID	Message	Notes
notification	RDS-EVENT-0048	Delaying database engine upgrade since this instance has read replicas that need to be upgraded first.	Patching of the DB instance has been delayed.
notification	RDS-EVENT-0054	*message*	The MySQL storage engine you are using is not InnoDB, which is the recommended MySQL storage engine for Amazon RDS. For information about MySQL storage engines, see Supported storage engines for RDS for MySQL.
notification	RDS-EVENT-0055	*message*	The number of tables you have for your DB instance exceeds the recommended best practices for Amazon RDS. Reduce the number of tables on your DB instance. For information about recommended best practices, see Amazon RDS basic operational guidelines.

Category	RDS event ID	Message	Notes
notification	RDS-EVENT-0056	*message*	The number of databases you have for your DB instance exceeds the recommended best practices for Amazon RDS. Reduce the number of databases on your DB instance. For information about recommended best practices, see Amazon RDS basic operational guidelines.
notification	RDS-EVENT-0064	The TDE encryption key was rotated successfully.	For information about recommended best practices, see Amazon RDS basic operational guidelines.
notification	RDS-EVENT-0084	Unable to convert the DB instance to Multi-AZ: *message*.	You attempted to convert a DB instance to Multi-AZ, but it contains in-memory file groups that are not supported for Multi-AZ. For more information, see Multi-AZ deployments for Amazon RDS for Microsoft SQL Server.
notification	RDS-EVENT-0087	DB instance stopped.	None
notification	RDS-EVENT-0088	DB instance started.	None

Category	RDS event ID	Message	Notes
notification	RDS-EVENT-0154	DB instance is being started due to it exceeding the maximum allowed time being stopped.	None
notification	RDS-EVENT-0157	Unable to modify the DB instance class. *`message`*.	RDS can't modify the DB instance class because the target instance class can't support the number of databases that exist on the source DB instance. The error message appears as: "The instance has *N* databases, but after conversion it would only support *N*". For more information, see Limitations for Microsoft SQL Server DB instances.
notification	RDS-EVENT-0158	Database instance is in a state that cannot be upgraded: *`message`*.	None
notification	RDS-EVENT-0167	*`message`*	The RDS Custom support perimeter configuration has changed.

Category	RDS event ID	Message	Notes
notification	RDS-EVENT-0189	The gp2 burst balance credits for the RDS database instance are low. To resolve this issue, reduce IOPS usage or modify your storage settings to enable higher performance.	The gp2 burst balance credits for the RDS database instance are low. To resolve this issue, reduce IOPS usage or modify your storage settings to enable higher performance. For more information, see I/O credits and burst performance in the *Amazon Elastic Compute Cloud User Guide*.
notification	RDS-EVENT-0225	Allocated storage size *amount* GB is approaching the maximum storage threshold *amount* GB. Increase the maximum storage threshold.	This event is invoked when the allocated storage reaches 80% of the maximum storage threshold. To avoid the event, increase the maximum storage threshold.

Category	RDS event ID	Message	Notes
notification	RDS-EVENT-0231	Your DB instance's storage modification encounter ed an internal error. The modification request is pending and will be retried later.	An error has occurred in the read replicati on process. For more information, see the event message. In addition, see the troubleshooting section for read replicas for your DB engine. • Troubleshooting a MariaDB read replica problem • Troubleshooting a SQL Server read replica problem • Troubleshooting a MySQL read replica problem • Troubleshooting RDS for Oracle replicas

Category	RDS event ID	Message	Notes
notification	RDS-EVENT-0253	The database is using the doublewrite buffer. *message*. For more information see the RDS Optimized Writes for *name* documentation.	RDS Optimized Writes is incompatible with the instance storage configuration. For more information, see Improving write performance with RDS Optimized Writes for MySQL and Improving write performance with Amazon RDS Optimized Writes for MariaDB. You can perform storage configuration upgrade to enable Optimized Writes by Creating a blue/green deployment.
notification	RDS-EVENT-0297	The storage configuration for DB instance *name* supports a maximum size of 16384 GiB. Perform a storage configuration upgrade to support storage sizes greater than 16384 GiB.	You cannot increase the allocated storage size of the DB instance beyond 16384 GiB. To overcome this limitation, perform a storage configuration upgrade. For more information, see Upgrading the storage file system for a DB instance.

Category	RDS event ID	Message	Notes
notification	RDS-EVENT-0298	The storage configuration for DB instance *name* supports a maximum table size of 2048 GiB. Perform a storage configuration upgrade to support table sizes greater than 2048 GiB.	RDS MySQL and MariaDB instances with this limitation cannot have a table size exceeding 2048 GiB. To overcome this limitation, perform a storage configuration upgrade. For more information, see Upgrading the storage file system for a DB instance.
notification	RDS-EVENT-0327	Amazon RDS could not find the secret *SECRET ARN*. *message.*	None
read replica	RDS-EVENT-0045	Replication has stopped.	Replication on your DB instance has been stopped due to insufficient storage. Scale storage or reduce the maximum size of your redo logs to let replication continue. To accommodate redo logs of size *amount* MiB you need at least *amount* MiB free storage.

Category	RDS event ID	Message	Notes
read replica	RDS-EVENT-0046	Replication for the Read Replica resumed.	This message appears when you first create a read replica, or as a monitoring message confirming that replication is functioning properly. If this message follows an `RDS-EVENT-0045` notification, then replication has resumed following an error or after replication was stopped.
read replica	RDS-EVENT-0057	Replication streaming has been terminated.	None
read replica	RDS-EVENT-0062	Replication for the Read Replica has been manually stopped.	None
read replica	RDS-EVENT-0063	Replication from Non RDS instance has been reset.	None
read replica	RDS-EVENT-0202	Read replica creation failed.	None
read replica	RDS-EVENT-0357	Replication channel *name* started.	For information about replication channels, see the section called "Configuring multi-source replication".

Category	RDS event ID	Message	Notes
read replica	RDS-EVENT-0358	Replication channel *name* stopped.	For information about replication channels, see the section called "Configuring multi-source replication".
read replica	RDS-EVENT-0359	Replication channel *name* was manually stopped.	For information about replication channels, see the section called "Configuring multi-source replication".
read replica	RDS-EVENT-0360	Replication channel *name* was reset.	For information about replication channels, see the section called "Configuring multi-source replication".
recovery	RDS-EVENT-0020	Recovery of the DB instance has started. Recovery time will vary with the amount of data to be recovered.	None
recovery	RDS-EVENT-0021	Recovery of the DB instance is complete.	None
recovery	RDS-EVENT-0023	Emergent Snapshot Request: *message*.	A manual backup has been requested but Amazon RDS is currently in the process of creating a DB snapshot. Submit the request again after Amazon RDS has completed the DB snapshot.

Category	RDS event ID	Message	Notes
recovery	RDS-EVENT-0052	Multi-AZ instance recovery started.	Recovery time will vary with the amount of data to be recovered.
recovery	RDS-EVENT-0053	Multi-AZ instance recovery completed. Pending failover or activation.	None
recovery	RDS-EVENT-0066	Instance will be degraded while mirroring is reestablished: *message*.	The SQL Server DB instance is re-establishing its mirror. Performance will be degraded until the mirror is reestablished. A database was found with non-FULL recovery model. The recovery model was changed back to FULL and mirroring recovery was started. (<dbname>: <recovery model found>[,...])"
recovery	RDS-EVENT-0166	*message*	The RDS Custom DB instance is inside the support perimeter.
recovery	RDS-EVENT-0361	Recovery of standby DB instance has started.	The standby DB instance is rebuilt during the recovery process. Database performance is impacted during the recovery process.

Category	RDS event ID	Message	Notes
recovery	RDS-EVENT-0362	Recovery of standby DB instance has completed.	The standby DB instance is rebuilt during the recovery process. Database performance is impacted during the recovery process.
restoration	RDS-EVENT-0019	Restored from DB instance *name* to *name*.	The DB instance has been restored from a point-in-time backup.
security	RDS-EVENT-0068	Decrypting hsm partition password to update instance.	RDS is decrypting the AWS CloudHSM partition password to make updates to the DB instance. For more information see Oracle Database Transparent Data Encryption (TDE) with AWS CloudHSM in the *AWS CloudHSM User Guide*.
security patching	RDS-EVENT-0230	A system update is available for your DB instance. For information about applying updates, see 'Maintaining a DB instance' in the RDS User Guide.	A new Operating System update is available. A new, minor version, operating system update is available for your DB instance. For information about applying updates, see Operating system updates in Amazon RDS.

DB parameter group events

The following table shows the event category and a list of events when a DB parameter group is the source type.

Category	RDS event ID	Message	Notes
configuration change	RDS-EVENT-0037	Updated parameter *name* to *value* with apply method *method*.	None

DB security group events

The following table shows the event category and a list of events when a DB security group is the source type.

> **Note**
>
> DB security groups are resources for EC2-Classic. EC2-Classic was retired on August 15, 2022. If you haven't migrated from EC2-Classic to a VPC, we recommend that you migrate as soon as possible. For more information, see Migrate from EC2-Classic to a VPC in the *Amazon EC2 User Guide* and the blog EC2-Classic Networking is Retiring – Here's How to Prepare.

Category	RDS event ID	Message	Notes
configuration change	RDS-EVENT-0038	Applied change to security group.	None
failure	RDS-EVENT-0039	Revoking authorization as *user*.	The security group owned by *user* doesn't exist. The authorization for the security group has been revoked because it is invalid.

DB snapshot events

The following table shows the event category and a list of events when a DB snapshot is the source type.

Category	RDS event ID	Message	Notes
creation	RDS-EVENT-0040	Creating manual snapshot.	None
creation	RDS-EVENT-0042	Manual snapshot created.	None
creation	RDS-EVENT-0090	Creating automated snapshot.	None
creation	RDS-EVENT-0091	Automated snapshot created.	None
deletion	RDS-EVENT-0041	Deleted user snapshot.	None
notification	RDS-EVENT-0059	Started copy of snapshot*name* from region *name*.	This is a cross-Region snapshot copy.
notification	RDS-EVENT-0060	Finished copy of snapshot *name* from region *name* in *number* minutes.	This is a cross-Region snapshot copy.
notification	RDS-EVENT-0061	Canceled snapshot copy request of *name* from region *name*.	This is a cross-Region snapshot copy.
notification	RDS-EVENT-0159	The snapshot export task failed.	None
notification	RDS-EVENT-0160	The snapshot export task was canceled.	None
notification	RDS-EVENT-0161	The snapshot export task completed.	None

Category	RDS event ID	Message	Notes
notification	RDS-EVENT-0196	Started copy of snapshot *name* in region *name*.	This is a local snapshot copy.
notification	RDS-EVENT-0197	Finished copy of snapshot *name* in region *name*.	This is a local snapshot copy.
notification	RDS-EVENT-0190	Canceled snapshot copy request of *name* in region *name*.	This is a local snapshot copy.
restoration	RDS-EVENT-0043	Restored from snapshot *name*.	A DB instance is being restored from a DB snapshot.

DB cluster snapshot events

The following table shows the event category and a list of events when a DB cluster snapshot is the source type.

Category	RDS event ID	Message	Notes
backup	RDS-EVENT-0074	Creating manual cluster snapshot.	None
backup	RDS-EVENT-0075	Manual cluster snapshot created.	None
backup	RDS-EVENT-0168	Creating automated cluster snapshot.	None
backup	RDS-EVENT-0169	Automated cluster snapshot created.	None

RDS Proxy events

The following table shows the event category and a list of events when an RDS Proxy is the source type.

Category	RDS event ID	Message	Notes
configuration change	RDS-EVENT-0204	RDS modified DB proxy *name*.	None
configuration change	RDS-EVENT-0207	RDS modified the end point of the DB proxy *name*.	None
configuration change	RDS-EVENT-0213	RDS detected the addition of the DB instance and automatically added it to the target group of the DB proxy *name*.	None
configuration change	RDS-EVENT-0213	RDS detected creation of DB instance *name* and automatically added it to target group *name* of DB proxy *name*.	None
configuration change	RDS-EVENT-0214	RDS detected deletion of DB instance *name* and automatically removed it from target group *name* of DB proxy *name*.	None
configuration change	RDS-EVENT-0215	RDS detected deletion of DB cluster *name* and automatically removed it from target group *name* of DB proxy *name*.	None

Category	RDS event ID	Message	Notes
creation	RDS-EVENT-0203	RDS created DB proxy *name*.	None
creation	RDS-EVENT-0206	RDS created endpoint *name* for DB proxy *name*.	None
deletion	RDS-EVENT-0205	RDS deleted DB proxy *name*.	None
deletion	RDS-EVENT-0208	RDS deleted endpoint *name* for DB proxy *name*.	None
failure	RDS-EVENT-0243	RDS failed to provision capacity for proxy *name* because there aren't enough IP addresses available in your subnets: *name*. To fix the issue, make sure that your subnets have the minimum number of unused IP addresses as recommend ed in the RDS Proxy documentation.	To determine the recommended number for your instance class, see Planning for IP address capacity.
failure	RDS-EVENT-0275	RDS throttled some connections to DB proxy *name*. The number of simultaneous connection requests from the client to the proxy has exceeded the limit.	None

Blue/green deployment events

The following table shows the event category and a list of events when a blue/green deployment is the source type.

For more information about blue/green deployments, see Using Amazon RDS Blue/Green Deployments for database updates.

Category	Amazon RDS event ID	Message	Notes
creation	RDS-EVENT-0244	Blue/green deployment tasks completed. You can make more modifications to the green environment databases or switch over the deployment.	None
failure	RDS-EVENT-0245	Creation of blue/green deployment failed because the (source/target) DB (instance/cluster) wasn't found.	None
deletion	RDS-EVENT-0246	Blue/green deployment deleted.	None
notification	RDS-EVENT-0247	Switchover from *blue* to *green* started.	None
notification	RDS-EVENT-0248	Switchover completed on blue/green deployment.	None
failure	RDS-EVENT-0249	Switchover canceled on blue/green deployment.	None
notification	RDS-EVENT-0250	Switchover from primary/read replica *blue* to *green* started.	None

Category	Amazon RDS event ID	Message	Notes
notification	RDS-EVENT-0251	Switchover from primary/read replica *blue* to *green* completed. Renamed *blue* to *blue-old* and *green* to *blue*.	None
failure	RDS-EVENT-0252	Switchover from primary/read replica *blue* to *green* was canceled due to *reason*.	None
notification	RDS-EVENT-0307	Sequence sync for switchover of *blue* to *green* has initiated. Switchover when using sequences may lead to extended downtime.	None
notification	RDS-EVENT-0308	Sequence sync for switchover of *blue* to *green* has completed.	None
failure	RDS-EVENT-0310	Sequence sync for switchover of *blue* to *green* was cancelled because sequences failed to sync.	None

Custom engine version events

The following table shows the event category and a list of events when a custom engine version is the source type.

Category	Amazon RDS event ID	Message	Notes
creation	RDS-EVENT-0316	Preparing to create custom engine version *name*. The entire creation process may take up to four hours to complete.	None
creation	RDS-EVENT-0317	Creating custom engine version *name*.	None
creation	RDS-EVENT-0318	Validating custom engine version *name*.	None
creation	RDS-EVENT-0319	Custom engine version *name* has been created successfully.	None
creation	RDS-EVENT-0320	RDS can't create custom engine version *name* because of an internal issue. We are addressin g the problem and will contact you if necessary . For further assistance, contact AWS Premium Support/.	None
failure	RDS-EVENT-0198	Creation failed for custom engine version *name*. *message*	The *message* includes details about the failure, such as missing files.
failure	RDS-EVENT-0277	Failure during deletion of custom engine version *name*. *message*	The *message* includes details about the failure.

Category	Amazon RDS event ID	Message	Notes
restoring	RDS-EVENT-0352	The maximum database count supported for point-in-time restore has changed.	The *message* includes details about the event.

Monitoring Amazon RDS log files

Every RDS database engine generates logs that you can access for auditing and troubleshooting. The type of logs depends on your database engine.

You can access database logs for DB instances using the AWS Management Console, the AWS Command Line Interface (AWS CLI), or the Amazon RDS API. You can't view, watch, or download transaction logs.

Topics

Viewing and listing database log files

You can view database log files for your Amazon RDS DB engine by using the AWS Management Console. You can list what log files are available for download or monitoring by using the AWS CLI or Amazon RDS API.

> **Note**
>
> If you can't view the list of log files for an existing RDS for Oracle DB instance, reboot the instance to view the list.

Console

To view a database log file

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.
3. Choose the name of the DB instance that has the log file that you want to view.
4. Choose the **Logs & events** tab.
5. Scroll down to the **Logs** section.
6. (Optional) Enter a search term to filter your results.
7. Choose the log that you want to view, and then choose **View**.

AWS CLI

To list the available database log files for a DB instance, use the AWS CLI `describe-db-log-files` command.

The following example returns a list of log files for a DB instance named `my-db-instance`.

Example

```
aws rds describe-db-log-files --db-instance-identifier my-db-instance
```

RDS API

To list the available database log files for a DB instance, use the Amazon RDS API `DescribeDBLogFiles` action.

Downloading a database log file

You can use the AWS Management Console, AWS CLI, or API to download a database log file.

Console

To download a database log file

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.
3. Choose the name of the DB instance that has the log file that you want to view.

4. Choose the **Logs & events** tab.
5. Scroll down to the **Logs** section.
6. In the **Logs** section, choose the button next to the log that you want to download, and then choose **Download**.
7. Open the context (right-click) menu for the link provided, and then choose **Save Link As**. Enter the location where you want the log file to be saved, and then choose **Save**.

AWS CLI

To download a database log file, use the AWS CLI command `download-db-log-file-portion`. By default, this command downloads only the latest portion of a log file. However, you can download an entire file by specifying the parameter `--starting-token 0`.

The following example shows how to download the entire contents of a log file called *log/ERROR.4* and store it in a local file called *errorlog.txt*.

Example

For Linux, macOS, or Unix:

```
aws rds download-db-log-file-portion \
    --db-instance-identifier myexampledb \
    --starting-token 0 --output text \
    --log-file-name log/ERROR.4 > errorlog.txt
```

For Windows:

```
aws rds download-db-log-file-portion ^
    --db-instance-identifier myexampledb ^
    --starting-token 0 --output text ^
    --log-file-name log/ERROR.4 > errorlog.txt
```

RDS API

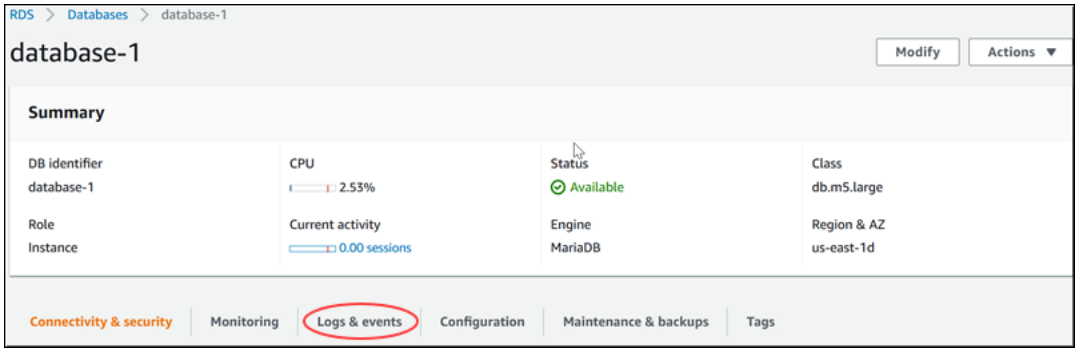
To download a database log file, use the Amazon RDS API `DownloadDBLogFilePortion` action.

Watching a database log file

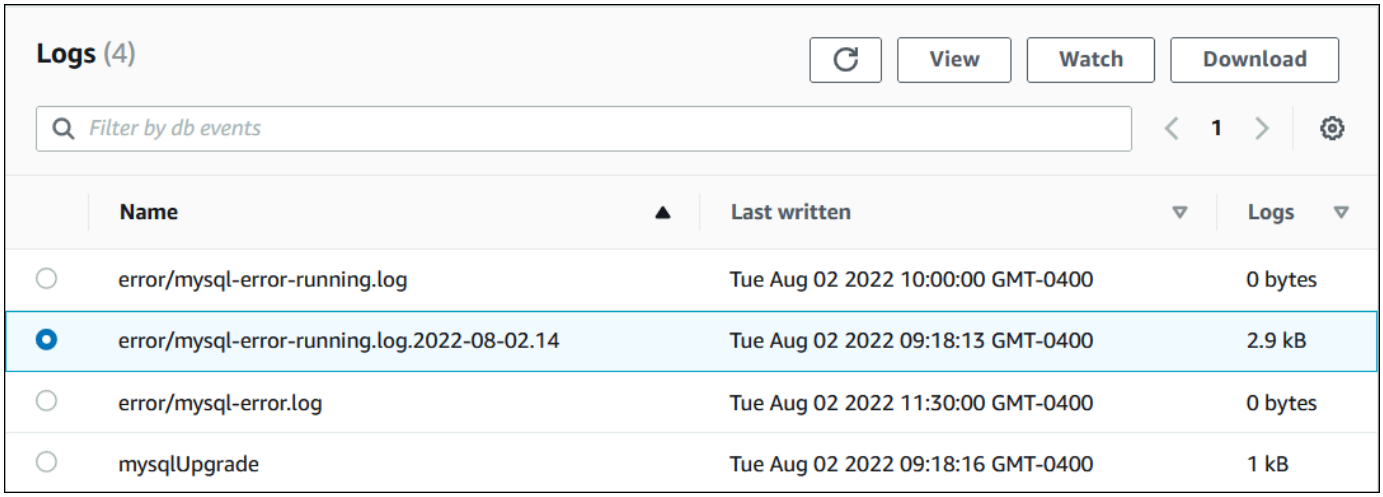
Watching a database log file is equivalent to tailing the file on a UNIX or Linux system. You can watch a log file by using the AWS Management Console. RDS refreshes the tail of the log every 5 seconds.

To watch a database log file

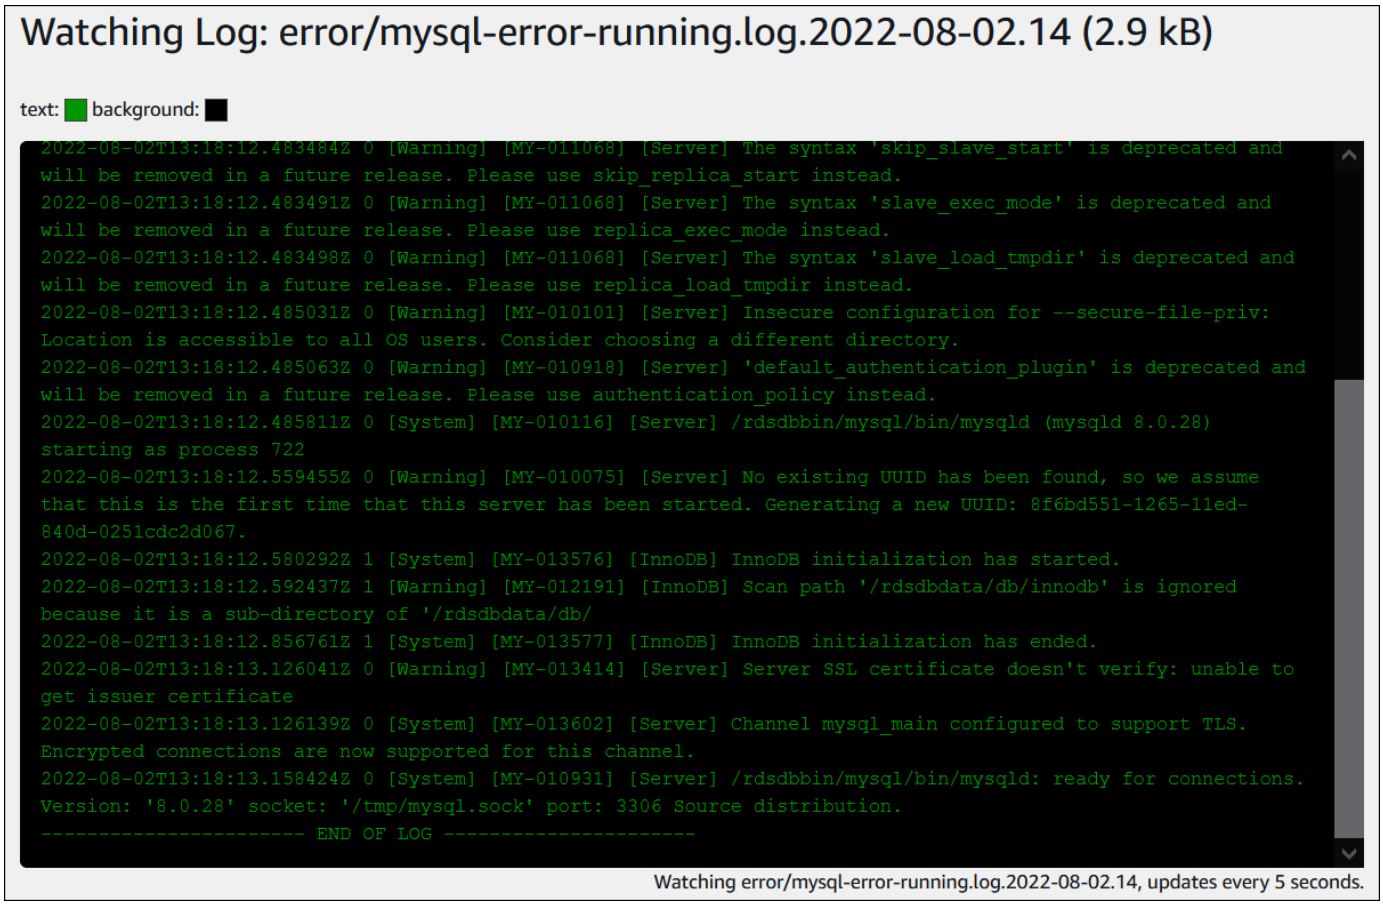
1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.
3. Choose the name of the DB instance that has the log file that you want to view.
4. Choose the **Logs & events** tab.



5. In the **Logs** section, choose a log file, and then choose **Watch**.



RDS shows the tail of the log, as in the following MySQL example.



Publishing database logs to Amazon CloudWatch Logs

In an on-premises database, the database logs reside on the file system. Amazon RDS doesn't provide host access to the database logs on the file system of your DB instance. For this reason,

Amazon RDS lets you export database logs to Amazon CloudWatch Logs. With CloudWatch Logs, you can perform real-time analysis of the log data. You can also store the data in highly durable storage and manage the data with the CloudWatch Logs Agent.

Topics

Overview of RDS integration with CloudWatch Logs

In CloudWatch Logs, a *log stream* is a sequence of log events that share the same source. Each separate source of logs in CloudWatch Logs makes up a separate log stream. A *log group* is a group of log streams that share the same retention, monitoring, and access control settings.

Amazon RDS continuously streams your DB instance log records to a log group. For example, you have a log group `/aws/rds/instance/`*`instance_name`*`/`*`log_type`* for each type of log that you publish. This log group is in the same AWS Region as the database instance that generates the log.

AWS retains log data published to CloudWatch Logs for an indefinite time period unless you specify a retention period. For more information, see Change log data retention in CloudWatch Logs.

Deciding which logs to publish to CloudWatch Logs

Each RDS database engine supports its own set of logs. To learn about the options for your database engine, review the following topics:

- the section called “Publishing MariaDB logs to Amazon CloudWatch Logs”
- the section called “Publishing MySQL logs to Amazon CloudWatch Logs”
- the section called “Publishing Oracle logs to Amazon CloudWatch Logs”
- the section called “Publishing PostgreSQL logs to Amazon CloudWatch Logs”
- the section called “Publishing SQL Server logs to Amazon CloudWatch Logs”

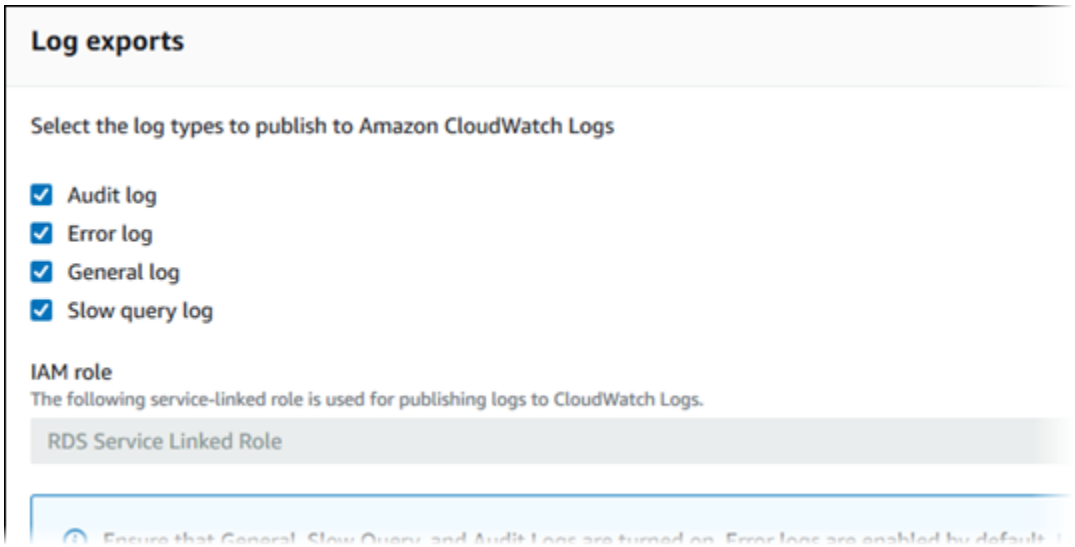
Specifying the logs to publish to CloudWatch Logs

You specify which logs to publish in the console. Make sure that you have a service-linked role in AWS Identity and Access Management (IAM). For more information about service-linked roles, see Using service-linked roles for Amazon RDS.

To specify the logs to publish

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.
3. Do either of the following:
   - Choose **Create database**.
   - Choose a database from the list, and then choose **Modify**.
4. In **Logs exports**, choose which logs to publish.

   The following example specifies the audit log, error logs, general log, and slow query log.



Searching and filtering your logs in CloudWatch Logs

You can search for log entries that meet a specified criteria using the CloudWatch Logs console. You can access the logs either through the RDS console, which leads you to the CloudWatch Logs console, or from the CloudWatch Logs console directly.

To search your RDS logs using the RDS console

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.
3. Choose a DB instance.
4. Choose **Configuration**.
5. Under **Published logs**, choose the database log that you want to view.

To search your RDS logs using the CloudWatch Logs console

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Log groups**.
3. In the filter box, enter **`/aws/rds`**.
4. For **Log Groups**, choose the name of the log group containing the log stream to search.
5. For **Log Streams**, choose the name of the log stream to search.
6. Under **Log events**, enter the filter syntax to use.

For more information, see Searching and filtering log data in the *Amazon CloudWatch Logs User Guide*. For a blog tutorial explaining how to monitor RDS logs, see Build proactive database monitoring for Amazon RDS with Amazon CloudWatch Logs, AWS Lambda, and Amazon SNS.

Reading log file contents using REST

Amazon RDS provides a REST endpoint that allows access to DB instance log files. This is useful if you need to write an application to stream Amazon RDS log file contents.

The syntax is:

```
GET /v13/downloadCompleteLogFile/DBInstanceIdentifier/LogFileName HTTP/1.1
Content-type: application/json
host: rds.region.amazonaws.com
```

The following parameters are required:

- *`DBInstanceIdentifier`*—the name of the DB instance that contains the log file you want to download.

- *LogFileName*—the name of the log file to be downloaded.

The response contains the contents of the requested log file, as a stream.

The following example downloads the log file named *log/ERROR.6* for the DB instance named *sample-sql* in the *us-west-2* region.

```
GET /v13/downloadCompleteLogFile/sample-sql/log/ERROR.6 HTTP/1.1
host: rds.us-west-2.amazonaws.com
X-Amz-Security-Token: AQoDYXdzEIH//////////
wEa0AIXLhngC5zp9CyB1R6abwKrXHVR5efnAVN3XvR7IwqKYalFSn6UyJuEFTft9nObglx4QJ+GXV9cpACkETq=
X-Amz-Date: 20140903T233749Z
X-Amz-Algorithm: AWS4-HMAC-SHA256
X-Amz-Credential: AKIADQKE4SARGYLE/20140903/us-west-2/rds/aws4_request
X-Amz-SignedHeaders: host
X-Amz-Content-SHA256: e3b0c44298fc1c229afbf4c8996fb92427ae41e4649b934de495991b7852b855
X-Amz-Expires: 86400
X-Amz-Signature: 353a4f14b3f250142d9afc34f9f9948154d46ce7d4ec091d0cdabbcf8b40c558
```

If you specify a nonexistent DB instance, the response consists of the following error:

- DBInstanceNotFound—*DBInstanceIdentifier* does not refer to an existing DB instance. (HTTP status code: 404)

MariaDB database log files

You can monitor the MariaDB error log, slow query log, and the general log. The MariaDB error log is generated by default; you can generate the slow query and general logs by setting parameters in your DB parameter group. Amazon RDS rotates all of the MariaDB log files; the intervals for each type are given following.

You can monitor the MariaDB logs directly through the Amazon RDS console, Amazon RDS API, Amazon RDS CLI, or AWS SDKs. You can also access MariaDB logs by directing the logs to a database table in the main database and querying that table. You can use the mysqlbinlog utility to download a binary log.

For more information about viewing, downloading, and watching file-based database logs, see Monitoring Amazon RDS log files.

Topics

Accessing MariaDB error logs

The MariaDB error log is written to the `<host-name>.err` file. You can view this file by using the Amazon RDS console, You can also retrieve the log using the Amazon RDS API, Amazon RDS CLI, or AWS SDKs. The `<host-name>.err` file is flushed every 5 minutes, and its contents are appended to `mysql-error-running.log`. The `mysql-error-running.log` file is then rotated every hour and the hourly files generated during the last 24 hours are retained. Each log file has the hour it was generated (in UTC) appended to its name. The log files also have a timestamp that helps you determine when the log entries were written.

MariaDB writes to the error log only on startup, shutdown, and when it encounters errors. A DB instance can go hours or days without new entries being written to the error log. If you see no recent entries, it's because the server did not encounter an error that resulted in a log entry.

Accessing the MariaDB slow query and general logs

You can write the MariaDB slow query log and general log to a file or database table by setting parameters in your DB parameter group. For information about creating and modifying a DB parameter group, see Parameter groups for Amazon RDS. You must set these parameters before you can view the slow query log or general log in the Amazon RDS console or by using the Amazon RDS API, AWS CLI, or AWS SDKs.

You can control MariaDB logging by using the parameters in this list:

- `slow_query_log` or `log_slow_query`: To create the slow query log, set to 1. The default is 0.
- `general_log`: To create the general log, set to 1. The default is 0.
- `long_query_time` or `log_slow_query_time`: To prevent fast-running queries from being logged in the slow query log, specify a value for the shortest query run time to be logged, in seconds. The default is 10 seconds; the minimum is 0. If log_output = FILE, you can specify a floating point value that goes to microsecond resolution. If log_output = TABLE, you must specify an integer value with second resolution. Only queries whose run time exceeds the `long_query_time` or `log_slow_query_time` value are logged. For example, setting `long_query_time` or `log_slow_query_time` to 0.1 prevents any query that runs for less than 100 milliseconds from being logged.
- `log_queries_not_using_indexes`: To log all queries that do not use an index to the slow query log, set this parameter to 1. The default is 0. Queries that do not use an index are logged even if their run time is less than the value of the `long_query_time` parameter.
- `log_output` *`option`*: You can specify one of the following options for the `log_output` parameter:
  - **TABLE** (default)– Write general queries to the `mysql.general_log` table, and slow queries to the `mysql.slow_log` table.
  - **FILE**– Write both general and slow query logs to the file system. Log files are rotated hourly.
  - **NONE**– Disable logging.

When logging is enabled, Amazon RDS rotates table logs or deletes log files at regular intervals. This measure is a precaution to reduce the possibility of a large log file either blocking database use or affecting performance. FILE and TABLE logging approach rotation and deletion as follows:

- When FILE logging is enabled, log files are examined every hour and log files older than 24 hours are deleted. In some cases, the remaining combined log file size after the deletion might exceed the threshold of 2 percent of a DB instance's allocated space. In these cases, the largest log files are deleted until the log file size no longer exceeds the threshold.
- When TABLE logging is enabled, in some cases log tables are rotated every 24 hours. This rotation occurs if the space used by the table logs is more than 20 percent of the allocated storage space. It also occurs if the size of all logs combined is greater than 10 GB. If the amount of space used for a DB instance is greater than 90 percent of the DB instance's allocated storage space, the thresholds for log rotation are reduced. Log tables are then rotated if the space used by the table logs is more than 10 percent of the allocated storage space. They're also rotated if the size of all logs combined is greater than 5 GB.

  When log tables are rotated, the current log table is copied to a backup log table and the entries in the current log table are removed. If the backup log table already exists, then it is deleted before the current log table is copied to the backup. You can query the backup log table if needed. The backup log table for the `mysql.general_log` table is named `mysql.general_log_backup`. The backup log table for the `mysql.slow_log` table is named `mysql.slow_log_backup`.

  You can rotate the `mysql.general_log` table by calling the `mysql.rds_rotate_general_log` procedure. You can rotate the `mysql.slow_log` table by calling the `mysql.rds_rotate_slow_log` procedure.

  Table logs are rotated during a database version upgrade.

Amazon RDS records both TABLE and FILE log rotation in an Amazon RDS event and sends you a notification.

To work with the logs from the Amazon RDS console, Amazon RDS API, Amazon RDS CLI, or AWS SDKs, set the `log_output` parameter to FILE. Like the MariaDB error log, these log files are rotated hourly. The log files that were generated during the previous 24 hours are retained.

For more information about the slow query and general logs, go to the following topics in the MariaDB documentation:

- Slow query log
- General query log

Publishing MariaDB logs to Amazon CloudWatch Logs

You can configure your MariaDB DB instance to publish log data to a log group in Amazon CloudWatch Logs. With CloudWatch Logs, you can perform real-time analysis of the log data, and use CloudWatch to create alarms and view metrics. You can use CloudWatch Logs to store your log records in highly durable storage.

Amazon RDS publishes each MariaDB database log as a separate database stream in the log group. For example, suppose that you configure the export function to include the slow query log. Then slow query data is stored in a slow query log stream in the `/aws/rds/instance/my_instance/slowquery` log group.

The error log is enabled by default. The following table summarizes the requirements for the other MariaDB logs.

Log	Requirement
Audit log	The DB instance must use a custom option group with the `MARIADB_AUDIT_PLUGIN` option.
General log	The DB instance must use a custom parameter group with the parameter setting `general_log = 1` to enable the general log.
Slow query log	The DB instance must use a custom parameter group with the parameter setting `slow_query_log = 1` or `log_slow_query = 1` to enable the slow query log.
Log output	The DB instance must use a custom parameter group with the parameter setting `log_output = FILE` to write logs to the file system and publish them to CloudWatch Logs.

Console

To publish MariaDB logs to CloudWatch Logs from the console

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**, and then choose the DB instance that you want to modify.
3. Choose **Modify**.
4. In the **Log exports** section, choose the logs that you want to start publishing to CloudWatch Logs.
5. Choose **Continue**, and then choose **Modify DB Instance** on the summary page.

AWS CLI

You can publish a MariaDB logs with the AWS CLI. You can call the `modify-db-instance` command with the following parameters:

- `--db-instance-identifier`
- `--cloudwatch-logs-export-configuration`

> **Note**
>
> A change to the `--cloudwatch-logs-export-configuration` option is always applied to the DB instance immediately. Therefore, the `--apply-immediately` and `--no-apply-immediately` options have no effect.

You can also publish MariaDB logs by calling the following AWS CLI commands:

- `create-db-instance`
- `restore-db-instance-from-db-snapshot`
- `restore-db-instance-from-s3`
- `restore-db-instance-to-point-in-time`

Run one of these AWS CLI commands with the following options:

- `--db-instance-identifier`
- `--enable-cloudwatch-logs-exports`
- `--db-instance-class`
- `--engine`

Other options might be required depending on the AWS CLI command you run.

Example

The following example modifies an existing MariaDB DB instance to publish log files to CloudWatch Logs. The `--cloudwatch-logs-export-configuration` value is a JSON object. The key for this object is `EnableLogTypes`, and its value is an array of strings with any combination of `audit`, `error`, `general`, and `slowquery`.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier mydbinstance \
    --cloudwatch-logs-export-configuration '{"EnableLogTypes":
["audit","error","general","slowquery"]}'
```

For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier mydbinstance ^
    --cloudwatch-logs-export-configuration '{"EnableLogTypes":
["audit","error","general","slowquery"]}'
```

Example

The following command creates a MariaDB DB instance and publishes log files to CloudWatch Logs. The `--enable-cloudwatch-logs-exports` value is a JSON array of strings. The strings can be any combination of `audit`, `error`, `general`, and `slowquery`.

For Linux, macOS, or Unix:

```
aws rds create-db-instance \
```

```
    --db-instance-identifier mydbinstance \
    --enable-cloudwatch-logs-exports '["audit","error","general","slowquery"]' \
    --db-instance-class db.m4.large \
    --engine mariadb
```

For Windows:

```
aws rds create-db-instance ^
    --db-instance-identifier mydbinstance ^
    --enable-cloudwatch-logs-exports '["audit","error","general","slowquery"]' ^
    --db-instance-class db.m4.large ^
    --engine mariadb
```

RDS API

You can publish MariaDB logs with the RDS API. You can call the `ModifyDBInstance` operation with the following parameters:

- `DBInstanceIdentifier`
- `CloudwatchLogsExportConfiguration`

> **Note**
>
> A change to the `CloudwatchLogsExportConfiguration` parameter is always applied to the DB instance immediately. Therefore, the `ApplyImmediately` parameter has no effect.

You can also publish MariaDB logs by calling the following RDS API operations:

- `CreateDBInstance`
- `RestoreDBInstanceFromDBSnapshot`
- `RestoreDBInstanceFromS3`
- `RestoreDBInstanceToPointInTime`

Run one of these RDS API operations with the following parameters:

- `DBInstanceIdentifier`
- `EnableCloudwatchLogsExports`
- `Engine`
- `DBInstanceClass`

Other parameters might be required depending on the AWS CLI command you run.

Log file size

The MariaDB slow query log, error log, and the general log file sizes are constrained to no more than 2 percent of the allocated storage space for a DB instance. To maintain this threshold, logs are automatically rotated every hour and log files older than 24 hours are removed. If the combined log file size exceeds the threshold after removing old log files, then the largest log files are deleted until the log file size no longer exceeds the threshold.

Managing table-based MariaDB logs

You can direct the general and slow query logs to tables on the DB instance. To do so, create a DB parameter group and set the `log_output` server parameter to `TABLE`. General queries are then logged to the `mysql.general_log` table, and slow queries are logged to the `mysql.slow_log` table. You can query the tables to access the log information. Enabling this logging increases the amount of data written to the database, which can degrade performance.

Both the general log and the slow query logs are disabled by default. To enable logging to tables, you must also set the following server parameters to `1`:

- `general_log`
- `slow_query_log` or `log_slow_query`

Log tables keep growing until the respective logging activities are turned off by resetting the appropriate parameter to `0`. A large amount of data often accumulates over time, which can use up a considerable percentage of your allocated storage space. Amazon RDS does not allow you to truncate the log tables, but you can move their contents. Rotating a table saves its contents to a backup table and then creates a new empty log table. You can manually rotate the log tables with the following command line procedures, where the command prompt is indicated by `PROMPT>`:

```
PROMPT> CALL mysql.rds_rotate_slow_log;
```

```
PROMPT> CALL mysql.rds_rotate_general_log;
```

To completely remove the old data and reclaim the disk space, call the appropriate procedure twice in succession.

Binary logging format

MariaDB on Amazon RDS supports the *row-based*, *statement-based*, and *mixed* binary logging formats. The default binary logging format is *mixed*. For details on the different MariaDB binary log formats, see Binary log formats in the MariaDB documentation.

If you plan to use replication, the binary logging format is important. This is because it determines the record of data changes that is recorded in the source and sent to the replication targets. For information about the advantages and disadvantages of different binary logging formats for replication, see Advantages and disadvantages of statement-based and row-based replication in the MySQL documentation.

> **Important**
>
> Setting the binary logging format to row-based can result in very large binary log files. Large binary log files reduce the amount of storage available for a DB instance. They also can increase the amount of time to perform a restore operation of a DB instance. Statement-based replication can cause inconsistencies between the source DB instance and a read replica. For more information, see Unsafe statements for statement-based replication in the MariaDB documentation.

To set the MariaDB binary logging format

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Parameter groups**.
3. Choose the parameter group that is used by the DB instance that you want to modify.

   You can't modify a default parameter group. If the DB instance is using a default parameter group, create a new parameter group and associate it with the DB instance.

   For more information on DB parameter groups, see Parameter groups for Amazon RDS.
4. For **Parameter group actions**, choose **Edit**.

5. Set the `binlog_format` parameter to the binary logging format of your choice (**ROW**, **STATEMENT**, or **MIXED**).
6. Choose **Save changes** to save the updates to the DB parameter group.

Accessing MariaDB binary logs

You can use the mysqlbinlog utility to download binary logs in text format from MariaDB DB instances. The binary log is downloaded to your local computer. For more information about using the mysqlbinlog utility, go to Using mysqlbinlog in the MariaDB documentation.

To run the mysqlbinlog utility against an Amazon RDS instance, use the following options:

- Specify the `--read-from-remote-server` option.
- `--host`: Specify the DNS name from the endpoint of the instance.
- `--port`: Specify the port used by the instance.
- `--user`: Specify a MariaDB user that has been granted the replication slave permission.
- `--password`: Specify the password for the user, or omit a password value so the utility prompts you for a password.
- `--result-file`: Specify the local file that receives the output.
- Specify the names of one or more binary log files. To get a list of the available logs, use the SQL command SHOW BINARY LOGS.

For more information about mysqlbinlog options, go to mysqlbinlog options in the MariaDB documentation.

The following is an example:

For Linux, macOS, or Unix:

```
mysqlbinlog \
    --read-from-remote-server \
    --host=mariadbinstance1.1234abcd.region.rds.amazonaws.com \
    --port=3306  \
    --user ReplUser \
    --password <password> \
    --result-file=/tmp/binlog.txt
```

For Windows:

```
mysqlbinlog ^
    --read-from-remote-server ^
    --host=mariadbinstance1.1234abcd.region.rds.amazonaws.com ^
    --port=3306  ^
    --user ReplUser ^
    --password <password> ^
    --result-file=/tmp/binlog.txt
```

Amazon RDS normally purges a binary log as soon as possible. However, the binary log must still be available on the instance to be accessed by mysqlbinlog. To specify the number of hours for RDS to retain binary logs, use the `mysql.rds_set_configuration` stored procedure. Specify a period with enough time for you to download the logs. After you set the retention period, monitor storage usage for the DB instance to ensure that the retained binary logs don't take up too much storage.

The following example sets the retention period to 1 day.

```
call mysql.rds_set_configuration('binlog retention hours', 24);
```

To display the current setting, use the `mysql.rds_show_configuration` stored procedure.

```
call mysql.rds_show_configuration;
```

Binary log annotation

In a MariaDB DB instance, you can use the `Annotate_rows` event to annotate a row event with a copy of the SQL query that caused the row event. This approach provides similar functionality to enabling the `binlog_rows_query_log_events` parameter on an RDS for MySQL DB instance.

You can enable binary log annotations globally by creating a custom parameter group and setting the `binlog_annotate_row_events` parameter to **1**. You can also enable annotations at the session level, by calling `SET SESSION binlog_annotate_row_events = 1`. Use the `replicate_annotate_row_events` to replicate binary log annotations to the replica instance if binary logging is enabled on it. No special privileges are required to use these settings.

The following is an example of a row-based transaction in MariaDB. The use of row-based logging is triggered by setting the transaction isolation level to read-committed.

```
CREATE DATABASE IF NOT EXISTS test;
USE test;
CREATE TABLE square(x INT PRIMARY KEY, y INT NOT NULL) ENGINE = InnoDB;
SET SESSION TRANSACTION ISOLATION LEVEL READ COMMITTED;
BEGIN
INSERT INTO square(x, y) VALUES(5, 5 * 5);
COMMIT;
```

Without annotations, the binary log entries for the transaction look like the following:

```
BEGIN
/*!*/;
# at 1163
# at 1209
#150922  7:55:57 server id 1855786460  end_log_pos 1209         Table_map:
 `test`.`square` mapped to number 76
#150922  7:55:57 server id 1855786460  end_log_pos 1247         Write_rows: table id 76
 flags: STMT_END_F
### INSERT INTO `test`.`square`
### SET
###   @1=5
###   @2=25
# at 1247
#150922  7:56:01 server id 1855786460  end_log_pos 1274         Xid = 62
COMMIT/*!*/;
```

The following statement enables session-level annotations for this same transaction, and disables them after committing the transaction:

```
CREATE DATABASE IF NOT EXISTS test;
USE test;
CREATE TABLE square(x INT PRIMARY KEY, y INT NOT NULL) ENGINE = InnoDB;
SET SESSION TRANSACTION ISOLATION LEVEL READ COMMITTED;
SET SESSION binlog_annotate_row_events = 1;
BEGIN;
INSERT INTO square(x, y) VALUES(5, 5 * 5);
COMMIT;
SET SESSION binlog_annotate_row_events = 0;
```

With annotations, the binary log entries for the transaction look like the following:

```
BEGIN
```

```
/*!*/;
# at 423
# at 483
# at 529
#150922  8:04:24 server id 1855786460  end_log_pos 483  Annotate_rows:
#Q> INSERT INTO square(x, y) VALUES(5, 5 * 5)
#150922  8:04:24 server id 1855786460  end_log_pos 529  Table_map: `test`.`square`
 mapped to number 76
#150922  8:04:24 server id 1855786460  end_log_pos 567  Write_rows: table id 76 flags:
 STMT_END_F
### INSERT INTO `test`.`square`
### SET
###   @1=5
###   @2=25
# at 567
#150922  8:04:26 server id 1855786460  end_log_pos 594  Xid = 88
COMMIT/*!*/;
```

Microsoft SQL Server database log files

You can access Microsoft SQL Server error logs, agent logs, trace files, and dump files by using the Amazon RDS console, AWS CLI, or RDS API. For more information about viewing, downloading, and watching file-based database logs, see Monitoring Amazon RDS log files.

Topics

Retention schedule

Log files are rotated each day and whenever your DB instance is restarted. The following is the retention schedule for Microsoft SQL Server logs on Amazon RDS.

Log type	Retention schedule
Error logs	A maximum of 30 error logs are retained. Amazon RDS might delete error logs older than 7 days.
Agent logs	A maximum of 10 agent logs are retained. Amazon RDS might delete agent logs older than 7 days.
Trace files	Trace files are retained according to the trace file retention period of your DB instance. The default trace file retention period is 7 days. To modify the trace file retention period for your DB instance, see Setting the retention period for trace and dump files.
Dump files	Dump files are retained according to the dump file retention period of your DB instance. The default dump file retention period is 7 days. To modify the dump file retention period for your DB instance, see Setting the retention period for trace and dump files.

Viewing the SQL Server error log by using the rds_read_error_log procedure

You can use the Amazon RDS stored procedure `rds_read_error_log` to view error logs and agent logs. For more information, see Viewing error and agent logs.

Publishing SQL Server logs to Amazon CloudWatch Logs

With Amazon RDS for SQL Server, you can publish error and agent log events directly to Amazon CloudWatch Logs. Analyze the log data with CloudWatch Logs, then use CloudWatch to create alarms and view metrics.

With CloudWatch Logs, you can do the following:

- Store logs in highly durable storage space with a retention period that you define.
- Search and filter log data.
- Share log data between accounts.
- Export logs to Amazon S3.
- Stream data to Amazon OpenSearch Service.
- Process log data in real time with Amazon Kinesis Data Streams. For more information, see Working with Amazon CloudWatch Logs in the *Amazon Managed Service for Apache Flink for SQL Applications Developer Guide*.

Amazon RDS publishes each SQL Server database log as a separate database stream in the log group. For example, if you publish the agent logs and error logs, error data is stored in an error log stream in the `/aws/rds/instance/my_instance/error` log group, and agent log data is stored in the `/aws/rds/instance/my_instance/agent` log group.

For Multi-AZ DB instances, Amazon RDS publishes the database log as two separate streams in the log group. For example, if you publish the error logs, the error data is stored in the error log streams `/aws/rds/instance/my_instance.node1/error` and `/aws/rds/instance/my_instance.node2/error` respectively. The log streams don't change during a failover and the error log stream of each node can contain error logs from primary or secondary instance. With Multi-AZ, a log stream is automatically created for `/aws/rds/instance/my_instance/rds-events` to store event data such as DB instance failovers.

> **Note**
>
> Publishing SQL Server logs to CloudWatch Logs isn't enabled by default. Publishing trace and dump files isn't supported. Publishing SQL Server logs to CloudWatch Logs is supported in all regions, except for Asia Pacific (Hong Kong).

Console

To publish SQL Server DB logs to CloudWatch Logs from the AWS Management Console

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**, and then choose the DB instance that you want to modify.
3. Choose **Modify**.
4. In the **Log exports** section, choose the logs that you want to start publishing to CloudWatch Logs.

   You can choose **Agent log**, **Error log**, or both.
5. Choose **Continue**, and then choose **Modify DB Instance** on the summary page.

AWS CLI

To publish SQL Server logs, you can use the `modify-db-instance` command with the following parameters:

- `--db-instance-identifier`
- `--cloudwatch-logs-export-configuration`

> **Note**
>
> A change to the `--cloudwatch-logs-export-configuration` option is always applied to the DB instance immediately. Therefore, the `--apply-immediately` and `--no-apply-immediately` options have no effect.

You can also publish SQL Server logs using the following commands:

- create-db-instance
- restore-db-instance-from-db-snapshot
- restore-db-instance-to-point-in-time

Example

The following example creates an SQL Server DB instance with CloudWatch Logs publishing enabled. The `--enable-cloudwatch-logs-exports` value is a JSON array of strings that can include `error`, `agent`, or both.

For Linux, macOS, or Unix:

```
aws rds create-db-instance \
    --db-instance-identifier mydbinstance \
    --enable-cloudwatch-logs-exports '["error","agent"]' \
    --db-instance-class db.m4.large \
    --engine sqlserver-se
```

For Windows:

```
aws rds create-db-instance ^
    --db-instance-identifier mydbinstance ^
    --enable-cloudwatch-logs-exports "[\"error\",\"agent\"]" ^
    --db-instance-class db.m4.large ^
    --engine sqlserver-se
```

Note

When using the Windows command prompt, you must escape double quotes (") in JSON code by prefixing them with a backslash (\).

Example

The following example modifies an existing SQL Server DB instance to publish log files to CloudWatch Logs. The `--cloudwatch-logs-export-configuration` value is a JSON object. The key for this object is `EnableLogTypes`, and its value is an array of strings that can include `error`, `agent`, or both.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier mydbinstance \
    --cloudwatch-logs-export-configuration '{"EnableLogTypes":["error","agent"]}'
```

For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier mydbinstance ^
    --cloudwatch-logs-export-configuration "{\"EnableLogTypes\":[\"error\",\"agent\"]}"
```

> **Note**
>
> When using the Windows command prompt, you must escape double quotes (") in JSON code by prefixing them with a backslash (\).

Example

The following example modifies an existing SQL Server DB instance to disable publishing agent log files to CloudWatch Logs. The `--cloudwatch-logs-export-configuration` value is a JSON object. The key for this object is `DisableLogTypes`, and its value is an array of strings that can include `error`, `agent`, or both.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier mydbinstance \
    --cloudwatch-logs-export-configuration '{"DisableLogTypes":["agent"]}'
```

For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier mydbinstance ^
    --cloudwatch-logs-export-configuration "{\"DisableLogTypes\":[\"agent\"]}"
```

> **Note**
>
> When using the Windows command prompt, you must escape double quotes (") in JSON code by prefixing them with a backslash (\).

MySQL database log files

You can monitor the MySQL logs directly through the Amazon RDS console, Amazon RDS API, AWS CLI, or AWS SDKs. You can also access MySQL logs by directing the logs to a database table in the main database and querying that table. You can use the mysqlbinlog utility to download a binary log.

For more information about viewing, downloading, and watching file-based database logs, see Monitoring Amazon RDS log files.

Topics

Overview of RDS for MySQL database logs

You can monitor the following types of RDS for MySQL log files:

- Error log
- Slow query log
- General log
- Audit log

The RDS for MySQL error log is generated by default. You can generate the slow query and general logs by setting parameters in your DB parameter group.

Topics

- Size limits on redo logs

RDS for MySQL error logs

RDS for MySQL writes errors in the `mysql-error.log` file. Each log file has the hour it was generated (in UTC) appended to its name. The log files also have a timestamp that helps you determine when the log entries were written.

RDS for MySQL writes to the error log only on startup, shutdown, and when it encounters errors. A DB instance can go hours or days without new entries being written to the error log. If you see no recent entries, it's because the server didn't encounter an error that would result in a log entry.

By design, the error logs are filtered so that only unexpected events such as errors are shown. However, the error logs also contain some additional database information, for example query progress, which isn't shown. Therefore, even without any actual errors the size of the error logs might increase because of ongoing database activities. And while you might see a certain size in bytes or kilobytes for the error logs in the AWS Management Console, they might have 0 bytes when you download them.

RDS for MySQL writes `mysql-error.log` to disk every 5 minutes. It appends the contents of the log to `mysql-error-running.log`.

RDS for MySQL rotates the `mysql-error-running.log` file every hour. It retains the logs generated during the last two weeks.

> **Note**
>
> The log retention period is different between Amazon RDS and Aurora.

RDS for MySQL slow query and general logs

You can write the RDS for MySQL slow query log and the general log to a file or a database table. To do so, set parameters in your DB parameter group. For information about creating and modifying a DB parameter group, see Parameter groups for Amazon RDS. You must set these parameters before you can view the slow query log or general log in the Amazon RDS console or by using the Amazon RDS API, Amazon RDS CLI, or AWS SDKs.

You can control RDS for MySQL logging by using the parameters in this list:

- `slow_query_log`: To create the slow query log, set to 1. The default is 0.
- `general_log`: To create the general log, set to 1. The default is 0.
- `long_query_time`: To prevent fast-running queries from being logged in the slow query log, specify a value for the shortest query runtime to be logged, in seconds. The default is 10 seconds; the minimum is 0. If log_output = FILE, you can specify a floating point value that goes to microsecond resolution. If log_output = TABLE, you must specify an integer value with second resolution. Only queries whose runtime exceeds the `long_query_time` value are logged. For example, setting `long_query_time` to 0.1 prevents any query that runs for less than 100 milliseconds from being logged.
- `log_queries_not_using_indexes`: To log all queries that do not use an index to the slow query log, set to 1. Queries that don't use an index are logged even if their runtime is less than the value of the `long_query_time` parameter. The default is 0.
- `log_output` *`option`*: You can specify one of the following options for the `log_output` parameter.
  - **TABLE** (default) – Write general queries to the `mysql.general_log` table, and slow queries to the `mysql.slow_log` table.
  - **FILE** – Write both general and slow query logs to the file system.
  - **NONE** – Disable logging.

For more information about the slow query and general logs, go to the following topics in the MySQL documentation:

- The slow query log
- The general query log

MySQL audit log

To access the audit log, the DB instance must use a custom option group with the `MARIADB_AUDIT_PLUGIN` option. For more information, see MariaDB Audit Plugin support for MySQL.

Log rotation and retention for RDS for MySQL

When logging is enabled, Amazon RDS rotates table logs or deletes log files at regular intervals. This measure is a precaution to reduce the possibility of a large log file either blocking database use or affecting performance. RDS for MySQL handles rotation and deletion as follows:

- The MySQL slow query log, error log, and the general log file sizes are constrained to no more than 2 percent of the allocated storage space for a DB instance. To maintain this threshold, logs are automatically rotated every hour. MySQL removes log files more than two weeks old. If the combined log file size exceeds the threshold after removing old log files, then the oldest log files are deleted until the log file size no longer exceeds the threshold.
- When `FILE` logging is enabled, log files are examined every hour and log files more than two weeks old are deleted. In some cases, the remaining combined log file size after the deletion might exceed the threshold of 2 percent of a DB instance's allocated space. In these cases, the oldest log files are deleted until the log file size no longer exceeds the threshold.
- When `TABLE` logging is enabled, in some cases log tables are rotated every 24 hours. This rotation occurs if the space used by the table logs is more than 20 percent of the allocated storage space. It also occurs if the size of all logs combined is greater than 10 GB. If the amount of space used for a DB instance is greater than 90 percent of the DB instance's allocated storage space, then the thresholds for log rotation are reduced. Log tables are then rotated if the space used by the table logs is more than 10 percent of the allocated storage space. They're also rotated if the size of all logs combined is greater than 5 GB. You can subscribe to the `low_free_storage` event to be notified when log tables are rotated to free up space. For more information, see Working with Amazon RDS event notification.

  When log tables are rotated, the current log table is first copied to a backup log table. Then the entries in the current log table are removed. If the backup log table already exists, then it is deleted before the current log table is copied to the backup. You can query the backup log table if needed. The backup log table for the `mysql.general_log` table is named `mysql.general_log_backup`. The backup log table for the `mysql.slow_log` table is named `mysql.slow_log_backup`.

  You can rotate the `mysql.general_log` table by calling the `mysql.rds_rotate_general_log` procedure. You can rotate the `mysql.slow_log` table by calling the `mysql.rds_rotate_slow_log` procedure.

  Table logs are rotated during a database version upgrade.

To work with the logs from the Amazon RDS console, Amazon RDS API, Amazon RDS CLI, or AWS SDKs, set the `log_output` parameter to FILE. Like the MySQL error log, these log files are rotated hourly. The log files that were generated during the previous two weeks are retained. Note that the retention period is different between Amazon RDS and Aurora.

Size limits on redo logs

For RDS for MySQL version 8.0.32 and lower, the default value of this parameter is 256 MB. This amount is derived by multiplying the default value of the `innodb_log_file_size` parameter (128 MB) by the default value of the `innodb_log_files_in_group` parameter (2). For more information, see Best practices for configuring parameters for Amazon RDS for MySQL, part 1: Parameters related to performance.

Starting with RDS for MySQL version 8.0.33, Amazon RDS uses the `innodb_redo_log_capacity` parameter instead of the `innodb_log_file_size` parameter. The Amazon RDS default value of the `innodb_redo_log_capacity` parameter is 2 GB. For more information, see Changes in MySQL 8.0.30 in the MySQL documentation.

Publishing MySQL logs to Amazon CloudWatch Logs

You can configure your MySQL DB instance to publish log data to a log group in Amazon CloudWatch Logs. With CloudWatch Logs, you can perform real-time analysis of the log data, and use CloudWatch to create alarms and view metrics. You can use CloudWatch Logs to store your log records in highly durable storage.

Amazon RDS publishes each MySQL database log as a separate database stream in the log group. For example, if you configure the export function to include the slow query log, slow query data is stored in a slow query log stream in the `/aws/rds/instance/my_instance/slowquery` log group.

The error log is enabled by default. The following table summarizes the requirements for the other MySQL logs.

Log	Requirement
Audit log	The DB instance must use a custom option group with the `MARIADB_AUDIT_PLUGIN` option.
General log	The DB instance must use a custom parameter group with the parameter setting `general_log = 1` to enable the general log.

Log	Requirement
Slow query log	The DB instance must use a custom parameter group with the parameter setting `slow_query_log = 1` to enable the slow query log.
Log output	The DB instance must use a custom parameter group with the parameter setting `log_output = FILE` to write logs to the file system and publish them to CloudWatch Logs.

Console

To publish MySQL logs to CloudWatch Logs using the console

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**, and then choose the DB instance that you want to modify.
3. Choose **Modify**.
4. In the **Log exports** section, choose the logs that you want to start publishing to CloudWatch Logs.
5. Choose **Continue**, and then choose **Modify DB Instance** on the summary page.

AWS CLI

You can publish MySQL logs with the AWS CLI. You can call the `modify-db-instance` command with the following parameters:

- `--db-instance-identifier`
- `--cloudwatch-logs-export-configuration`

> **Note**
>
> A change to the `--cloudwatch-logs-export-configuration` option is always applied to the DB instance immediately. Therefore, the `--apply-immediately` and `--no-apply-immediately` options have no effect.

You can also publish MySQL logs by calling the following AWS CLI commands:

- `create-db-instance`
- `restore-db-instance-from-db-snapshot`
- `restore-db-instance-from-s3`
- `restore-db-instance-to-point-in-time`

Run one of these AWS CLI commands with the following options:

- `--db-instance-identifier`
- `--enable-cloudwatch-logs-exports`
- `--db-instance-class`
- `--engine`

Other options might be required depending on the AWS CLI command you run.

Example

The following example modifies an existing MySQL DB instance to publish log files to CloudWatch Logs. The `--cloudwatch-logs-export-configuration` value is a JSON object. The key for this object is `EnableLogTypes`, and its value is an array of strings with any combination of `audit`, `error`, `general`, and `slowquery`.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier mydbinstance \
    --cloudwatch-logs-export-configuration '{"EnableLogTypes":
["audit","error","general","slowquery"]}'
```

For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier mydbinstance ^
    --cloudwatch-logs-export-configuration '{"EnableLogTypes":
["audit","error","general","slowquery"]}'
```

Example

The following example creates a MySQL DB instance and publishes log files to CloudWatch Logs. The `--enable-cloudwatch-logs-exports` value is a JSON array of strings. The strings can be any combination of `audit`, `error`, `general`, and `slowquery`.

For Linux, macOS, or Unix:

```
aws rds create-db-instance \
    --db-instance-identifier mydbinstance \
    --enable-cloudwatch-logs-exports '["audit","error","general","slowquery"]' \
    --db-instance-class db.m4.large \
    --engine MySQL
```

For Windows:

```
aws rds create-db-instance ^
    --db-instance-identifier mydbinstance ^
    --enable-cloudwatch-logs-exports '["audit","error","general","slowquery"]' ^
    --db-instance-class db.m4.large ^
    --engine MySQL
```

RDS API

You can publish MySQL logs with the RDS API. You can call the `ModifyDBInstance` action with the following parameters:

- `DBInstanceIdentifier`
- `CloudwatchLogsExportConfiguration`

> **Note**
>
> A change to the `CloudwatchLogsExportConfiguration` parameter is always applied to the DB instance immediately. Therefore, the `ApplyImmediately` parameter has no effect.

You can also publish MySQL logs by calling the following RDS API operations:

- `CreateDBInstance`
- `RestoreDBInstanceFromDBSnapshot`
- `RestoreDBInstanceFromS3`
- `RestoreDBInstanceToPointInTime`

Run one of these RDS API operations with the following parameters:

- `DBInstanceIdentifier`
- `EnableCloudwatchLogsExports`
- `Engine`
- `DBInstanceClass`

Other parameters might be required depending on the AWS CLI command you run.

Sending MySQL log output to tables

You can direct the general and slow query logs to tables on the DB instance by creating a DB parameter group and setting the `log_output` server parameter to `TABLE`. General queries are then logged to the `mysql.general_log` table, and slow queries are logged to the `mysql.slow_log` table. You can query the tables to access the log information. Enabling this logging increases the amount of data written to the database, which can degrade performance.

Both the general log and the slow query logs are disabled by default. In order to enable logging to tables, you must also set the `general_log` and `slow_query_log` server parameters to `1`.

Log tables keep growing until the respective logging activities are turned off by resetting the appropriate parameter to `0`. A large amount of data often accumulates over time, which can use up a considerable percentage of your allocated storage space. Amazon RDS doesn't allow you to

truncate the log tables, but you can move their contents. Rotating a table saves its contents to a backup table and then creates a new empty log table. You can manually rotate the log tables with the following command line procedures, where the command prompt is indicated by PROMPT>:

```
PROMPT> CALL mysql.rds_rotate_slow_log;
PROMPT> CALL mysql.rds_rotate_general_log;
```

To completely remove the old data and reclaim the disk space, call the appropriate procedure twice in succession.

Configuring RDS for MySQL binary logging

The *binary log* is a set of log files that contain information about data modifications made to an MySQL server instance. The binary log contains information such as the following:

- Events that describe database changes such as table creation or row modifications
- Information about the duration of each statement that updated data
- Events for statements that could have updated data but didn't

The binary log records statements that are sent during replication. It is also required for some recovery operations. For more information, see The Binary Log and Binary Log Overview in the MySQL documentation.

The automated backups feature determines whether binary logging is turned on or off for MySQL. You have the following options:

Turn binary logging on

Set the backup retention period to a positive nonzero value.

Turn binary logging off

Set the backup retention period to zero.

For more information, see Enabling automated backups.

MySQL on Amazon RDS supports the *row-based*, *statement-based*, and *mixed* binary logging formats. We recommend mixed unless you need a specific binlog format. For details on the different MySQL binary log formats, see Binary logging formats in the MySQL documentation.

If you plan to use replication, the binary logging format is important because it determines the record of data changes that is recorded in the source and sent to the replication targets. For information about the advantages and disadvantages of different binary logging formats for replication, see Advantages and disadvantages of statement-based and row-based replication in the MySQL documentation.

> **Important**
>
> Setting the binary logging format to row-based can result in very large binary log files. Large binary log files reduce the amount of storage available for a DB instance and can increase the amount of time to perform a restore operation of a DB instance.
> Statement-based replication can cause inconsistencies between the source DB instance and a read replica. For more information, see Determination of safe and unsafe statements in binary logging in the MySQL documentation.
> Enabling binary logging increases the number of write disk I/O operations to the DB instance. You can monitor IOPS usage with the `WriteIOPS` CloudWatch metric.

To set the MySQL binary logging format

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Parameter groups**.
3. Choose the DB parameter group, associated with the DB instance, that you want to modify.

   You can't modify a default parameter group. If the DB instance is using a default parameter group, create a new parameter group and associate it with the DB instance.

   For more information on parameter groups, see Parameter groups for Amazon RDS.
4. From **Actions**, choose **Edit**.
5. Set the `binlog_format` parameter to the binary logging format of your choice (`ROW`, `STATEMENT`, or `MIXED`).

   You can turn off binary logging by setting the backup retention period of a DB instance to zero, but this disables daily automated backups. Disabling automated backups turns off or disables the `log_bin` session variable. This disables binary logging on the RDS for MySQL DB instance, which in turn resets the `binlog_format` session variable to the default value of `ROW` in the database. We recommend that you don't disable backups. For more information about the **Backup retention period** setting, see Settings for DB instances.

6. Choose **Save changes** to save the updates to the DB parameter group.

Because the `binlog_format` parameter is dynamic in RDS for MySQL, you don't need to reboot the DB instance for the changes to apply. (Note that in Aurora MySQL, this parameter is static. For more information, see Configuring Aurora MySQL binary logging.)

> **Important**
>
> Changing a DB parameter group affects all DB instances that use that parameter group. If you want to specify different binary logging formats for different MySQL DB instances in an AWS Region, the DB instances must use different DB parameter groups. These parameter groups identify different logging formats. Assign the appropriate DB parameter group to the each DB instance.

Accessing MySQL binary logs

You can use the mysqlbinlog utility to download or stream binary logs from RDS for MySQL DB instances. The binary log is downloaded to your local computer, where you can perform actions such as replaying the log using the mysql utility. For more information about using the mysqlbinlog utility, see Using mysqlbinlog to back up binary log files in the MySQL documentation.

To run the mysqlbinlog utility against an Amazon RDS instance, use the following options:

- `--read-from-remote-server` – Required.
- `--host` – The DNS name from the endpoint of the instance.
- `--port` – The port used by the instance.
- `--user` – A MySQL user that has been granted the `REPLICATION SLAVE` permission.
- `--password` – The password for the MySQL user, or omit a password value so that the utility prompts you for a password.
- `--raw` – Download the file in binary format.
- `--result-file` – The local file to receive the raw output.
- `--stop-never` – Stream the binary log files.
- `--verbose` – When you use the `ROW` binlog format, include this option to see the row events as pseudo-SQL statements. For more information on the `--verbose` option, see mysqlbinlog row event display in the MySQL documentation.

- Specify the names of one or more binary log files. To get a list of the available logs, use the SQL command `SHOW BINARY LOGS`.

For more information about mysqlbinlog options, see mysqlbinlog — Utility for processing binary log files in the MySQL documentation.

The following examples show how to use the mysqlbinlog utility.

For Linux, macOS, or Unix:

```
mysqlbinlog \
    --read-from-remote-server \
    --host=MySQLInstance1.cg034hpkmmjt.region.rds.amazonaws.com \
    --port=3306  \
    --user ReplUser \
    --password \
    --raw \
    --verbose \
    --result-file=/tmp/ \
    binlog.00098
```

For Windows:

```
mysqlbinlog ^
    --read-from-remote-server ^
    --host=MySQLInstance1.cg034hpkmmjt.region.rds.amazonaws.com ^
    --port=3306  ^
    --user ReplUser ^
    --password ^
    --raw ^
    --verbose ^
    --result-file=/tmp/ ^
    binlog.00098
```

Amazon RDS normally purges a binary log as soon as possible, but the binary log must still be available on the instance to be accessed by mysqlbinlog. To specify the number of hours for RDS to retain binary logs, use the mysql.rds_set_configuration stored procedure and specify a period with enough time for you to download the logs. After you set the retention period, monitor storage usage for the DB instance to ensure that the retained binary logs don't take up too much storage.

The following example sets the retention period to 1 day.

```
call mysql.rds_set_configuration('binlog retention hours', 24);
```

To display the current setting, use the mysql.rds_show_configuration stored procedure.

```
call mysql.rds_show_configuration;
```

Oracle database log files

You can access Oracle alert logs, audit files, and trace files by using the Amazon RDS console or API. For more information about viewing, downloading, and watching file-based database logs, see Monitoring Amazon RDS log files.

The Oracle audit files provided are the standard Oracle auditing files. Amazon RDS supports the Oracle fine-grained auditing (FGA) feature. However, log access doesn't provide access to FGA events that are stored in the `SYS.FGA_LOG$` table and that are accessible through the `DBA_FGA_AUDIT_TRAIL` view.

The `DescribeDBLogFiles` API operation that lists the Oracle log files that are available for a DB instance ignores the `MaxRecords` parameter and returns up to 1,000 records. The call returns `LastWritten` as a POSIX date in milliseconds.

Topics

- Retention schedule
- Working with Oracle trace files
- Publishing Oracle logs to Amazon CloudWatch Logs
- Accessing alert logs and listener logs

Retention schedule

The Oracle database engine might rotate log files if they get very large. To retain audit or trace files, download them. If you store the files locally, you reduce your Amazon RDS storage costs and make more space available for your data.

The following table shows the retention schedule for Oracle alert logs, audit files, and trace files on Amazon RDS.

Log type	Retention schedule
Alert logs	The text alert log is rotated daily with 30-day retention managed by Amazon RDS. The XML alert log is retained for at least seven days. You can access this log by using the `ALERTLOG` view.
Audit files	The default retention period for audit files is seven days. Amazon RDS might delete audit files older than seven days.

Log type	Retention schedule
Trace files	The default retention period for trace files is seven days. Amazon RDS might delete trace files older than seven days.
Listener logs	The default retention period for the listener logs is seven days. Amazon RDS might delete listener logs older than seven days.

> **Note**
>
> Audit files and trace files share the same retention configuration.

Working with Oracle trace files

Following, you can find descriptions of Amazon RDS procedures to create, refresh, access, and delete trace files.

Topics

- Listing files
- Generating trace files and tracing a session
- Retrieving trace files
- Purging trace files

Listing files

You can use either of two procedures to allow access to any file in the `background_dump_dest` path. The first procedure refreshes a view containing a listing of all files currently in `background_dump_dest`.

```
EXEC rdsadmin.manage_tracefiles.refresh_tracefile_listing;
```

After the view is refreshed, query the following view to access the results.

```
SELECT * FROM rdsadmin.tracefile_listing;
```

An alternative to the previous process is to use `FROM table` to stream nonrelational data in a table-like format to list database directory contents.

```
SELECT * FROM TABLE(rdsadmin.rds_file_util.listdir('BDUMP'));
```

The following query shows the text of a log file.

```
SELECT text FROM
 TABLE(rdsadmin.rds_file_util.read_text_file('BDUMP','alert_dbname.log.date'));
```

On a read replica, get the name of the BDUMP directory by querying `V$DATABASE.DB_UNIQUE_NAME`. If the unique name is `DATABASE_B`, then the BDUMP directory is `BDUMP_B`. The following example queries the BDUMP name on a replica and then uses this name to query the contents of `alert_DATABASE.log.2020-06-23`.

```
SELECT 'BDUMP' || (SELECT regexp_replace(DB_UNIQUE_NAME,'.*(_[A-Z])', '\1') FROM V
$DATABASE) AS BDUMP_VARIABLE FROM DUAL;

BDUMP_VARIABLE
--------------
BDUMP_B

SELECT TEXT FROM
 table(rdsadmin.rds_file_util.read_text_file('BDUMP_B','alert_DATABASE.log.2020-06-23'));
```

Generating trace files and tracing a session

Because there are no restrictions on `ALTER SESSION`, many standard methods to generate trace files in Oracle remain available to an Amazon RDS DB instance. The following procedures are provided for trace files that require greater access.

Oracle method	Amazon RDS method
`oradebug hanganalyze 3`	`EXEC rdsadmin.manage_tracefiles.hanganalyze;`
`oradebug dump systemstate 266`	`EXEC rdsadmin.manage_tracefiles.dump_systemstate;`

You can use many standard methods to trace individual sessions connected to an Oracle DB instance in Amazon RDS. To enable tracing for a session, you can run subprograms in PL/SQL packages supplied by Oracle, such as `DBMS_SESSION` and `DBMS_MONITOR`. For more information, see Enabling tracing for a session in the Oracle documentation.

Retrieving trace files

You can retrieve any trace file in `background_dump_dest` using a standard SQL query on an Amazon RDS–managed external table. To use this method, you must execute the procedure to set the location for this table to the specific trace file.

For example, you can use the `rdsadmin.tracefile_listing` view mentioned preceding to list all of the trace files on the system. You can then set the `tracefile_table` view to point to the intended trace file using the following procedure.

```
EXEC
 rdsadmin.manage_tracefiles.set_tracefile_table_location('CUST01_ora_3260_SYSTEMSTATE.trc');
```

The following example creates an external table in the current schema with the location set to the file provided. You can retrieve the contents into a local file using a SQL query.

```
SPOOL /tmp/tracefile.txt
SELECT * FROM tracefile_table;
SPOOL OFF;
```

Purging trace files

Trace files can accumulate and consume disk space. Amazon RDS purges trace files by default and log files that are older than seven days. You can view and set the trace file retention period using the `show_configuration` procedure. You should run the command `SET SERVEROUTPUT ON` so that you can view the configuration results.

The following example shows the current trace file retention period, and then sets a new trace file retention period.

```
# Show the current tracefile retention
SQL> EXEC rdsadmin.rdsadmin_util.show_configuration;
NAME:tracefile retention
VALUE:10080
```

```
DESCRIPTION:tracefile expiration specifies the duration in minutes before tracefiles in
 bdump are automatically deleted.

# Set the tracefile retention to 24 hours:
SQL> EXEC rdsadmin.rdsadmin_util.set_configuration('tracefile retention',1440);
SQL> commit;

#show the new tracefile retention
SQL> EXEC rdsadmin.rdsadmin_util.show_configuration;
NAME:tracefile retention
VALUE:1440
DESCRIPTION:tracefile expiration specifies the duration in minutes before tracefiles in
 bdump are automatically deleted.
```

In addition to the periodic purge process, you can manually remove files from the `background_dump_dest`. The following example shows how to purge all files older than five minutes.

```
EXEC rdsadmin.manage_tracefiles.purge_tracefiles(5);
```

You can also purge all files that match a specific pattern (if you do, don't include the file extension, such as .trc). The following example shows how to purge all files that start with `SCHPOC1_ora_5935`.

```
EXEC rdsadmin.manage_tracefiles.purge_tracefiles('SCHPOC1_ora_5935');
```

Publishing Oracle logs to Amazon CloudWatch Logs

You can configure your RDS for Oracle DB instance to publish log data to a log group in Amazon CloudWatch Logs. With CloudWatch Logs, you can analyze the log data, and use CloudWatch to create alarms and view metrics. You can use CloudWatch Logs to store your log records in highly durable storage.

Amazon RDS publishes each Oracle database log as a separate database stream in the log group. For example, if you configure the export function to include the audit log, audit data is stored in an audit log stream in the `/aws/rds/instance/my_instance/audit` log group. The following table summarizes the requirements for RDS for Oracle to publish logs to Amazon CloudWatch Logs.

Log name	Requirement	Default
Alert log	None. You can't disable this log.	Enabled
Trace log	Set the `trace_enabled` parameter to TRUE or leave it set at the default.	TRUE
Audit log	Set the `audit_trail` parameter to any of the following allowed values: `{ none | os | db [, extended] | xml [, extended] }`	none
Listener log	None. You can't disable this log.	Enabled
Oracle Management Agent log	None. You can't disable this log.	Enabled

This Oracle Management Agent log consists of the log groups shown in the following table.

Log name	CloudWatch log group
emctl.log	oemagent-emctl
emdctlj.log	oemagent-emdctlj
gcagent.log	oemagent-gcagent
gcagent_errors.log	oemagent-gcagent-errors
emagent.nohup	oemagent-emagent-nohup
secure.log	oemagent-secure

For more information, see Locating Management Agent Log and Trace Files in the Oracle documentation.

Console

To publish Oracle DB logs to CloudWatch Logs from the AWS Management Console

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**, and then choose the DB instance that you want to modify.
3. Choose **Modify**.
4. In the **Log exports** section, choose the logs that you want to start publishing to CloudWatch Logs.
5. Choose **Continue**, and then choose **Modify DB Instance** on the summary page.

AWS CLI

To publish Oracle logs, you can use the `modify-db-instance` command with the following parameters:

- `--db-instance-identifier`
- `--cloudwatch-logs-export-configuration`

> **Note**
>
> A change to the `--cloudwatch-logs-export-configuration` option is always applied to the DB instance immediately. Therefore, the `--apply-immediately` and `--no-apply-immediately` options have no effect.

You can also publish Oracle logs using the following commands:

- `create-db-instance`
- `restore-db-instance-from-db-snapshot`
- `restore-db-instance-from-s3`
- `restore-db-instance-to-point-in-time`

Example

The following example creates an Oracle DB instance with CloudWatch Logs publishing enabled. The `--cloudwatch-logs-export-configuration` value is a JSON array of strings. The strings can be any combination of `alert`, `audit`, `listener`, and `trace`.

For Linux, macOS, or Unix:

```
aws rds create-db-instance \
    --db-instance-identifier mydbinstance \
    --cloudwatch-logs-export-configuration
 '["trace","audit","alert","listener","oemagent"]' \
    --db-instance-class db.m5.large \
    --allocated-storage 20 \
    --engine oracle-ee \
    --engine-version 19.0.0.0.ru-2024-04.rur-2024-04.r1 \
    --license-model bring-your-own-license \
    --master-username myadmin \
    --manage-master-user-password
```

For Windows:

```
aws rds create-db-instance ^
    --db-instance-identifier mydbinstance ^
    --cloudwatch-logs-export-configuration trace alert audit listener oemagent ^
    --db-instance-class db.m5.large ^
    --allocated-storage 20 ^
    --engine oracle-ee ^
    --engine-version 19.0.0.0.ru-2024-04.rur-2024-04.r1 ^
    --license-model bring-your-own-license ^
    --master-username myadmin ^
    --manage-master-user-password
```

Example

The following example modifies an existing Oracle DB instance to publish log files to CloudWatch Logs. The `--cloudwatch-logs-export-configuration` value is a JSON object. The key for this object is `EnableLogTypes`, and its value is an array of strings with any combination of `alert`, `audit`, `listener`, and `trace`.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier mydbinstance \
    --cloudwatch-logs-export-configuration '{"EnableLogTypes":
["trace","alert","audit","listener","oemagent"]}'
```

For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier mydbinstance ^
    --cloudwatch-logs-export-configuration EnableLogTypes=\"trace\",\"alert\",\"audit
\",\"listener\",\"oemagent\"
```

Example

The following example modifies an existing Oracle DB instance to disable publishing audit and listener log files to CloudWatch Logs. The `--cloudwatch-logs-export-configuration` value is a JSON object. The key for this object is `DisableLogTypes`, and its value is an array of strings with any combination of `alert`, `audit`, `listener`, and `trace`.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier mydbinstance \
    --cloudwatch-logs-export-configuration '{"DisableLogTypes":["audit","listener"]}'
```

For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier mydbinstance ^
    --cloudwatch-logs-export-configuration DisableLogTypes=\"audit\",\"listener\"
```

RDS API

You can publish Oracle DB logs with the RDS API. You can call the `ModifyDBInstance` action with the following parameters:

- `DBInstanceIdentifier`
- `CloudwatchLogsExportConfiguration`

> **Note**
>
> A change to the `CloudwatchLogsExportConfiguration` parameter is always applied to the DB instance immediately. Therefore, the `ApplyImmediately` parameter has no effect.

You can also publish Oracle logs by calling the following RDS API operations:

- `CreateDBInstance`
- `RestoreDBInstanceFromDBSnapshot`
- `RestoreDBInstanceFromS3`
- `RestoreDBInstanceToPointInTime`

Run one of these RDS API operations with the following parameters:

- `DBInstanceIdentifier`
- `EnableCloudwatchLogsExports`
- `Engine`
- `DBInstanceClass`

Other parameters might be required depending on the RDS operation that you run.

Accessing alert logs and listener logs

You can view the alert log using the Amazon RDS console. You can also use the following SQL statement.

```
SELECT message_text FROM alertlog;
```

Access the listener log using Amazon CloudWatch Logs.

> **Note**
>
> Oracle rotates the alert and listener logs when they exceed 10 MB, at which point they are unavailable from Amazon RDS views.

RDS for PostgreSQL database log files

RDS for PostgreSQL logs database activities to the default PostgreSQL log file. For an on-premises PostgreSQL DB instance, these messages are stored locally in `log/postgresql.log`. For an RDS for PostgreSQL DB instance, the log file is available on the Amazon RDS instance. Also, you must use the Amazon RDS Console to view or download its contents. The default logging level captures login failures, fatal server errors, deadlocks, and query failures.

For more information about how you can view, download, and watch file-based database logs, see Monitoring Amazon RDS log files. To learn more about PostgreSQL logs, see Working with Amazon RDS and Aurora PostgreSQL logs: Part 1 and Working with Amazon RDS and Aurora PostgreSQL logs: Part 2.

In addition to the standard PostgreSQL logs discussed in this topic, RDS for PostgreSQL also supports the PostgreSQL Audit extension (`pgAudit`). Most regulated industries and government agencies need to maintain an audit log or audit trail of changes made to data to comply with legal requirements. For information about installing and using pgAudit, see Using pgAudit to log database activity.

Topics

- Parameters for logging in Aurora PostgreSQL
- Turning on query logging for your RDS for PostgreSQL DB instance
- Publishing PostgreSQL logs to Amazon CloudWatch Logs

Parameters for logging in Aurora PostgreSQL

You can customize the logging behavior for your RDS for PostgreSQL DB instance by modifying various parameters. In the following table you can find the parameters that affect how long the logs are stored, when to rotate the log, and whether to output the log as a CSV (comma-separated value) format. You can also find the text output sent to STDERR, among other settings. To change settings for the parameters that are modifiable, use a custom DB parameter group for your RDS for PostgreSQL instance. For more information, see DB parameter groups for Amazon RDS DB instances. As noted in the table, the `log_line_prefix` can't be changed.

Parameter	Default	Description
log_destination	stderr	Sets the output format for the log. The default is `stderr` but you can also specify comma-separated value (CSV) by adding `csvlog` to the setting. For more information, see Setting the log destination (`stderr`, `csvlog`)
log_filename	postgresql.log.%Y-%m-%d-%H	Specifies the pattern for the log file name. In addition to the default, this parameter supports `postgresql.log.%Y-%m-%d` for the filename pattern.
log_line_prefix	%t:%r:%u@%d:[%p]:	Defines the prefix for each log line that gets written to `stderr`, to note the time (%t), remote host (%r), user (%u), database (%d), and process ID (%p). You can't modify this parameter.
log_rotation_age	60	Minutes after which log file is automatically rotated. You can change this value within the range of 1 and 1440 minutes. For more information, see Setting log file rotation.
log_rotation_size	–	The size (kB) at which the log is automatic ally rotated. By default, this parameter isn't used because logs are rotated based on the `log_rotation_age` parameter. To learn more, see Setting log file rotation.
rds.log_retention_period	4320	PostgreSQL logs that are older than the specified number of minutes are deleted. The default value of 4320 minutes deletes log files after 3 days. For more information, see Setting the log retention period.

To identify application issues, you can look for query failures, login failures, deadlocks, and fatal server errors in the log. For example, suppose that you converted a legacy application from Oracle to Amazon RDS PostgreSQL, but not all queries converted correctly. These incorrectly formatted queries generate error messages that you can find in the logs to help identify problems. For more information about logging queries, see Turning on query logging for your RDS for PostgreSQL DB instance.

In the following topics, you can find information about how to set various parameters that control the basic details for your PostgreSQL logs.

Topics

- Setting the log retention period
- Setting log file rotation
- Setting the log destination (stderr, csvlog)
- Understanding the log_line_prefix parameter

Setting the log retention period

The `rds.log_retention_period` parameter specifies how long your RDS for PostgreSQL DB instance keeps its log files. The default setting is 3 days (4,320 minutes), but you can set this value to anywhere from 1 day (1,440 minutes) to 7 days (10,080 minutes). Be sure that your RDS for PostgreSQL DB instance has sufficient storage to hold the log files for the period of time.

We recommend that you have your logs routinely published to Amazon CloudWatch Logs so that you can view and analyze system data long after the logs have been removed from your RDS for PostgreSQL DB instance. For more information, see Publishing PostgreSQL logs to Amazon CloudWatch Logs.

Setting log file rotation

Amazon RDS creates new log files every hour by default. The timing is controlled by the `log_rotation_age` parameter. This parameter has a default value of 60 (minutes), but you can set it to anywhere from 1 minute to 24 hours (1,440 minutes). When it's time for rotation, a new distinct log file is created. The file is named according to the pattern specified by the `log_filename` parameter.

Log files can also be rotated according to their size, as specified in the `log_rotation_size` parameter. This parameter specifies that the log should be rotated when it reaches the specified

size (in kilobytes). For an RDS for PostgreSQL DB instance, `log_rotation_size` is unset, that is, there is no value specified. However, you can set the parameter from 0-2097151 kB (kilobytes).

The log file names are based on the file name pattern specified in the `log_filename` parameter. The available settings for this parameter are as follows:

- `postgresql.log.%Y-%m-%d` – Default format for the log file name. Includes the year, month, and date in the name of the log file.
- `postgresql.log.%Y-%m-%d-%H` – Includes the hour in the log file name format.

For more information, see `log_rotation_age` and `log_rotation_size` in the PostgreSQL documentation.

Setting the log destination (`stderr`, `csvlog`)

By default, Amazon RDS PostgreSQL generates logs in standard error (stderr) format. This format is the default setting for the `log_destination` parameter. Each message is prefixed using the pattern specified in the `log_line_prefix` parameter. For more information, see Understanding the log_line_prefix parameter.

RDS for PostgreSQL can also generate the logs in `csvlog` format. The `csvlog` is useful for analyzing the log data as comma-separated values (CSV) data. For example, suppose that you use the `log_fdw` extension to work with your logs as foreign tables. The foreign table created on `stderr` log files contains a single column with log event data. By adding `csvlog` to the `log_destination` parameter, you get the log file in the CSV format with demarcations for the multiple columns of the foreign table. You can now sort and analyze your logs more easily. To learn how to use the `log_fdw` with `csvlog`, see Using the log_fdw extension to access the DB log using SQL.

If you specify `csvlog` for this parameter, be aware that both `stderr` and `csvlog` files are generated. Be sure to monitor the storage consumed by the logs, taking into account the `rds.log_retention_period` and other settings that affect log storage and turnover. Using `stderr` and `csvlog` more than doubles the storage consumed by the logs.

If you add `csvlog` to `log_destination` and you want to revert to the `stderr` alone, you need to reset the parameter. To do so, open the Amazon RDS Console and then open the custom DB parameter group for your instance. Choose the `log_destination` parameter, choose **Edit parameter**, and then choose **Reset**.

For more information about configuring logging, see Working with Amazon RDS and Aurora PostgreSQL logs: Part 1.

Understanding the log_line_prefix parameter

The `stderr` log format prefixes each log message with the details specified by the `log_line_prefix` parameter, as follows.

```
%t:%r:%u@%d:[%p]:t
```

You can't change this setting. Each log entry sent to `stderr` includes the following information.

- `%t` – Time of log entry
- `%r` – Remote host address
- `%u@%d` – User name @ database name
- `[%p]` – Process ID if available

Turning on query logging for your RDS for PostgreSQL DB instance

You can collect more detailed information about your database activities, including queries, queries waiting for locks, checkpoints, and many other details by setting some of the parameters listed in the following table. This topic focuses on logging queries.

Parameter	Default	Description
log_connections	–	Logs each successful connection.
log_disconnections	–	Logs the end of each session and its duration.
log_checkpoints	1	Logs each checkpoint.
log_lock_waits	–	Logs long lock waits. By default, this parameter isn't set.
log_min_duration_sample	–	(ms) Sets the minimum execution time above which a sample of statements is logged. Sample size is set using the `log_statement_sample_rate` parameter.

Parameter	Default	Description
log_min_duration_statement	–	Any SQL statement that runs atleast for the specified amount of time or longer gets logged. By default, this parameter isn't set. Turning on this parameter can help you find unoptimized queries.
log_statement	–	Sets the type of statements logged. By default, this parameter isn't set, but you can change it to `all`, `ddl`, or `mod` to specify the types of SQL statements that you want logged. If you specify anything other than none for this parameter, you should also take additional steps to prevent the exposure of passwords in the log files. For more information, see Mitigating risk of password exposure when using query logging.
log_statement_sample_rate	–	The percentage of statements exceeding the time specified in `log_min_duration_sample` to be logged, expressed as a floating point value between 0.0 and 1.0.
log_statement_stats	–	Writes cumulative performance statistics to the server log.

Using logging to find slow performing queries

You can log SQL statements and queries to help find slow performing queries. You turn on this capability by modifying the settings in the `log_statement` and `log_min_duration` parameters as outlined in this section. Before turning on query logging for your RDS for PostgreSQL DB instance, you should be aware of possible password exposure in the logs and how to mitigate the risks. For more information, see Mitigating risk of password exposure when using query logging.

Following, you can find reference information about the `log_statement` and `log_min_duration` parameters.

log_statement

This parameter specifies the type of SQL statements that should get sent to the log. The default value is none. If you change this parameter to `all`, `ddl`, or `mod`, be sure to apply recommended actions to mitigate the risk of exposing passwords in the logs. For more information, see Mitigating risk of password exposure when using query logging.

all

Logs all statements. This setting is recommended for debugging purposes.

ddl

Logs all data definition language (DDL) statements, such as CREATE, ALTER, DROP, and so on.

mod

Logs all DDL statements and data manipulation language (DML) statements, such as INSERT, UPDATE, and DELETE, which modify the data.

none

No SQL statements get logged. We recommend this setting to avoid the risk of exposing passwords in the logs.

log_min_duration_statement

Any SQL statement that runs atleast for the specified amount of time or longer gets logged. By default, this parameter isn't set. Turning on this parameter can help you find unoptimized queries.

–1–2147483647

The number of milliseconds (ms) of runtime over which a statement gets logged.

To set up query logging

These steps assume that your RDS for PostgreSQL DB instance uses a custom DB parameter group.

1. Set the `log_statement` parameter to `all`. The following example shows the information that is written to the `postgresql.log` file with this parameter setting.

```
2022-10-05 22:05:52 UTC:52.95.4.1(11335):postgres@labdb:[3639]:LOG: statement:
 SELECT feedback, s.sentiment,s.confidence
```

```
FROM support,aws_comprehend.detect_sentiment(feedback, 'en') s
ORDER BY s.confidence DESC;
2022-10-05 22:05:52 UTC:52.95.4.1(11335):postgres@labdb:[3639]:LOG: QUERY
 STATISTICS
2022-10-05 22:05:52 UTC:52.95.4.1(11335):postgres@labdb:[3639]:DETAIL: ! system
 usage stats:
! 0.017355 s user, 0.000000 s system, 0.168593 s elapsed
! [0.025146 s user, 0.000000 s system total]
! 36644 kB max resident size
! 0/8 [0/8] filesystem blocks in/out
! 0/733 [0/1364] page faults/reclaims, 0 [0] swaps

2022-10-05 22:05:56 UTC:52.95.4.1(11335):postgres@labdb:[3639]:STATEMENT: ORDER BY
 s.confidence DESC;
----------------------- END OF LOG ----------------------
```

2. Set the `log_min_duration_statement` parameter. The following example shows the information that is written to the `postgresql.log` file when the parameter is set to 1.

   Queries that exceed the duration specified in the `log_min_duration_statement` parameter are logged. The following shows an example. You can view the log file for your RDS for PostgreSQL DB instance in the Amazon RDS Console.

```
2022-10-05 19:05:19 UTC:52.95.4.1(6461):postgres@labdb:[6144]:LOG: statement: DROP
 table comments;

 estimate=131028 kB
----------------------- END OF LOG ----------------------
```

Mitigating risk of password exposure when using query logging

We recommend that you keep `log_statement` set to none to avoid exposing passwords. If you set `log_statement` to `all`, `ddl`, or mod, we recommend that you take one or more of the following steps.

- For the client, encrypt sensitive information. For more information, see Encryption Options in the PostgreSQL documentation. Use the ENCRYPTED (and UNENCRYPTED) options of the CREATE and ALTER statements. For more information, see CREATE USER in the PostgreSQL documentation.
- For your RDS for PostgreSQL DB instance, set up and use the PostgreSQL Auditing (pgAudit) extension. This extension redacts sensitive information in CREATE and ALTER statements sent to the log. For more information, see Using pgAudit to log database activity.
- Restrict access to the CloudWatch logs.
- Use stronger authentication mechanisms such as IAM.

Publishing PostgreSQL logs to Amazon CloudWatch Logs

To store your PostgreSQL log records in highly durable storage, you can use Amazon CloudWatch Logs. With CloudWatch Logs, you can also perform real-time analysis of log data and use CloudWatch to view metrics and create alarms. For example, if you set `log_statement` to `ddl`, you can set up an alarm to alert you whenever a DDL statement is executed. You can choose to have your PostgreSQL logs uploaded to CloudWatch Logs during the process of creating your RDS for PostgreSQL DB instance. If you chose not to upload logs at that time, you can later modify your instance to start uploading logs from that point forward. In other words, existing logs aren't uploaded. Only new logs are uploaded as they're created on your modified RDS for PostgreSQL DB instance.

All currently available RDS for PostgreSQL versions support publishing log files to CloudWatch Logs. For more information, see Amazon RDS for PostgreSQL updates in the *Amazon RDS for PostgreSQL Release Notes.*.

To work with CloudWatch Logs, configure your RDS for PostgreSQL DB instance to publish log data to a log group.

You can publish the following log types to CloudWatch Logs for RDS for PostgreSQL:

- Postgresql log

- Upgrade log

After you complete the configuration, Amazon RDS publishes the log events to log streams within a CloudWatch log group. For example, the PostgreSQL log data is stored within the log group `/aws/rds/instance/my_instance/postgresql`. To view your logs, open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.

Console

To publish PostgreSQL logs to CloudWatch Logs using the console

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.
3. Choose the DB instance that you want to modify, and then choose **Modify**.
4. In the **Log exports** section, choose the logs that you want to start publishing to CloudWatch Logs.

   The **Log exports** section is available only for PostgreSQL versions that support publishing to CloudWatch Logs.
5. Choose **Continue**, and then choose **Modify DB Instance** on the summary page.

AWS CLI

You can publish PostgreSQL logs with the AWS CLI. You can call the `modify-db-instance` command with the following parameters.

- `--db-instance-identifier`
- `--cloudwatch-logs-export-configuration`

> **Note**
>
> A change to the `--cloudwatch-logs-export-configuration` option is always applied to the DB instance immediately. Therefore, the `--apply-immediately` and `--no-apply-immediately` options have no effect.

You can also publish PostgreSQL logs by calling the following CLI commands:

- create-db-instance
- restore-db-instance-from-db-snapshot
- restore-db-instance-to-point-in-time

Run one of these CLI commands with the following options:

- `--db-instance-identifier`
- `--enable-cloudwatch-logs-exports`
- `--db-instance-class`
- `--engine`

Other options might be required depending on the CLI command you run.

Example Modify an instance to publish logs to CloudWatch Logs

The following example modifies an existing PostgreSQL DB instance to publish log files to CloudWatch Logs. The `--cloudwatch-logs-export-configuration` value is a JSON object. The key for this object is `EnableLogTypes`, and its value is an array of strings with any combination of `postgresql` and `upgrade`.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier mydbinstance \
    --cloudwatch-logs-export-configuration '{"EnableLogTypes":["postgresql",
 "upgrade"]}'
```

For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier mydbinstance ^
    --cloudwatch-logs-export-configuration '{"EnableLogTypes":
["postgresql","upgrade"]}'
```

Example Create an instance to publish logs to CloudWatch Logs

The following example creates a PostgreSQL DB instance and publishes log files to CloudWatch Logs. The `--enable-cloudwatch-logs-exports` value is a JSON array of strings. The strings can be any combination of `postgresql` and `upgrade`.

For Linux, macOS, or Unix:

```
aws rds create-db-instance \
    --db-instance-identifier mydbinstance \
    --enable-cloudwatch-logs-exports '["postgresql","upgrade"]' \
    --db-instance-class db.m4.large \
    --engine postgres
```

For Windows:

```
aws rds create-db-instance ^
    --db-instance-identifier mydbinstance ^
    --enable-cloudwatch-logs-exports '["postgresql","upgrade"]' ^
    --db-instance-class db.m4.large ^
    --engine postgres
```

RDS API

You can publish PostgreSQL logs with the RDS API. You can call the `ModifyDBInstance` action with the following parameters:

- `DBInstanceIdentifier`
- `CloudwatchLogsExportConfiguration`

> **Note**
>
> A change to the `CloudwatchLogsExportConfiguration` parameter is always applied to the DB instance immediately. Therefore, the `ApplyImmediately` parameter has no effect.

You can also publish PostgreSQL logs by calling the following RDS API operations:

- CreateDBInstance
- RestoreDBInstanceFromDBSnapshot
- RestoreDBInstanceToPointInTime

Run one of these RDS API operations with the following parameters:

- DBInstanceIdentifier
- EnableCloudwatchLogsExports
- Engine
- DBInstanceClass

Other parameters might be required depending on the operation that you run.

Monitoring Amazon RDS API calls in AWS CloudTrail

AWS CloudTrail is an AWS service that helps you audit your AWS account. AWS CloudTrail is turned on for your AWS account when you create it. For more information about CloudTrail, see the AWS CloudTrail User Guide.

Topics

CloudTrail integration with Amazon RDS

All Amazon RDS actions are logged by CloudTrail. CloudTrail provides a record of actions taken by a user, role, or an AWS service in Amazon RDS.

CloudTrail events

CloudTrail captures API calls for Amazon RDS as events. An *event* represents a single request from any source and includes information about the requested action, the date and time of the action, request parameters, and so on. Events include calls from the Amazon RDS console and from code calls to the Amazon RDS API operations.

Amazon RDS activity is recorded in a CloudTrail event in **Event history**. You can use the CloudTrail console to view the last 90 days of recorded API activity and events in an AWS Region. For more information, see Viewing events with CloudTrail event history.

CloudTrail trails

For an ongoing record of events in your AWS account, including events for Amazon RDS, create a *trail*. A trail is a configuration that enables delivery of events to a specified Amazon S3 bucket. CloudTrail typically delivers log files within 15 minutes of account activity.

> **Note**
>
> If you don't configure a trail, you can still view the most recent events in the CloudTrail console in **Event history**.

You can create two types of trails for an AWS account: a trail that applies to all Regions, or a trail that applies to one Region. By default, when you create a trail in the console, the trail applies to all Regions.

Additionally, you can configure other AWS services to further analyze and act upon the event data collected in CloudTrail logs. For more information, see:

- Overview for creating a trail
- CloudTrail supported services and integrations
- Configuring Amazon SNS notifications for CloudTrail
- Receiving CloudTrail log files from multiple Regions and Receiving CloudTrail log files from multiple accounts

Amazon RDS log file entries

CloudTrail log files contain one or more log entries. CloudTrail log files are not an ordered stack trace of the public API calls, so they do not appear in any specific order.

The following example shows a CloudTrail log entry that demonstrates the `CreateDBInstance` action.

```
{
    "eventVersion": "1.04",
    "userIdentity": {
        "type": "IAMUser",

    "dbiResourceId": "db-ETDZIIXHEWY5N7GXVC4SH7H5IA",
    "dBSecurityGroups": [],
    "pendingModifiedValues": {
        "masterUserPassword": "****",
        "pendingCloudwatchLogsExports": {
            "logTypesToEnable": [
                "audit",
                "error",
```

```
                    "general",
                    "slowquery"
                ]
            }
        },
        "dBInstanceStatus": "creating",
        "publiclyAccessible": true,
        "domainMemberships": [],
        "copyTagsToSnapshot": false,
        "dBInstanceIdentifier": "test-instance",
        "licenseModel": "general-public-license",
        "iAMDatabaseAuthenticationEnabled": false,
        "performanceInsightsEnabled": false,
        "vpcSecurityGroups": [
            {
                "status": "active",
                "vpcSecurityGroupId": "sg-f839b688"
            }
        ]
    },
    "requestID": "daf2e3f5-96a3-4df7-a026-863f96db793e",
    "eventID": "797163d3-5726-441d-80a7-6eeb7464acd4",
    "eventType": "AwsApiCall",
    "recipientAccountId": "123456789012"
}
```

As shown in the `userIdentity` element in the preceding example, every event or log entry contains information about who generated the request. The identity information helps you determine the following:

- Whether the request was made with root or IAM user credentials.
- Whether the request was made with temporary security credentials for a role or federated user.
- Whether the request was made by another AWS service.

For more information about the `userIdentity`, see the CloudTrail userIdentity element. For more information about `CreateDBInstance` and other Amazon RDS actions, see the Amazon RDS API Reference.

Monitoring Amazon RDS with Database Activity Streams

By using Database Activity Streams, you can monitor near real-time streams of database activity.

Topics

Overview of Database Activity Streams

As an Amazon RDS database administrator, you need to safeguard your database and meet compliance and regulatory requirements. One strategy is to integrate database activity streams with your monitoring tools. In this way, you monitor and set alarms for auditing activity in your database.

Security threats are both external and internal. To protect against internal threats, you can control administrator access to data streams by configuring the Database Activity Streams feature. Amazon RDS DBAs don't have access to the collection, transmission, storage, and processing of the streams.

Contents

- Requirements and limitations for database activity streams
- Region and version availability
- Supported DB instance classes for database activity streams

How database activity streams work

Amazon RDS pushes activities to an Amazon Kinesis data stream in near real time. The Kinesis stream is created automatically. From Kinesis, you can configure AWS services such as Amazon Data Firehose and AWS Lambda to consume the stream and store the data.

> **Important**
>
> Use of the database activity streams feature in Amazon RDS is free, but Amazon Kinesis charges for a data stream. For more information, see Amazon Kinesis Data Streams pricing.

You can configure applications for compliance management to consume database activity streams. These applications can use the stream to generate alerts and audit activity on your database.

Amazon RDS supports database activity streams in Multi-AZ deployments. In this case, database activity streams audit both the primary and standby instances.

Auditing in Oracle Database and Microsoft SQL Server Database

Auditing is the monitoring and recording of configured database actions. Amazon RDS doesn't capture database activity by default. You create and manage audit policies in your database yourself.

Topics

- Unified auditing in Oracle Database
- Auditing in Microsoft SQL Server
- Non-native audit fields for Oracle Database and SQL Server
- DB parameter group override

Unified auditing in Oracle Database

In an Oracle database, a *unified audit policy* is a named group of audit settings that you can use to audit an aspect of user behavior. A policy can be as simple as auditing the activities of a single user. You can also create complex audit policies that use conditions.

An Oracle database writes audit records, including SYS audit records, to the *unified audit trail*. For example, if an error occurs during an `INSERT` statement, standard auditing indicates the error number and the SQL that was run. The audit trail resides in a read-only table in the `AUDSYS` schema. To access these records, query the `UNIFIED_AUDIT_TRAIL` data dictionary view.

Typically, you configure database activity streams as follows:

1. Create an Oracle Database audit policy by using the `CREATE AUDIT POLICY` command.

   The Oracle Database generates audit records.
2. Activate the audit policy by using the `AUDIT POLICY` command.
3. Configure database activity streams.

   Only activities that match the Oracle Database audit policies are captured and sent to the Amazon Kinesis data stream. When database activity streams are enabled, an Oracle database administrator can't alter the audit policy or remove audit logs.

To learn more about unified audit policies, see About Auditing Activities with Unified Audit Policies and AUDIT in the *Oracle Database Security Guide*.

Auditing in Microsoft SQL Server

Database Activity Stream uses SQLAudit feature to audit the SQL Server database.

RDS for SQL Server instance contains the following:

- Server audit – The SQL server audit collects a single instance of server or database-level actions, and a group of actions to monitor. The server-level audits `RDS_DAS_AUDIT` and `RDS_DAS_AUDIT_CHANGES` are managed by RDS.
- Server audit specification – The server audit specification records the server-level events. You can modify the `RDS_DAS_SERVER_AUDIT_SPEC` specification. This specification is linked to the server audit `RDS_DAS_AUDIT`. The `RDS_DAS_CHANGES_AUDIT_SPEC` specification is managed by RDS.

- Database audit specification – The database audit specification records the database-level events. You can create a database audit specification RDS_DAS_DB_<name> and link it to RDS_DAS_AUDIT server audit.

You can configure database activity streams by using the console or CLI. Typically, you configure database activity streams as follows:

1. (Optional) Create a database audit specification with the CREATE DATABASE AUDIT SPECIFICATION command and link it to RDS_DAS_AUDIT server audit.
2. (Optional) Modify the server audit specification with the ALTER SERVER AUDIT SPECIFICATION command and define the policies.
3. Activate the database and server audit policies. For example:

   ```
   ALTER DATABASE AUDIT SPECIFICATION [<Your database specification>] WITH (STATE=ON)

   ALTER SERVER AUDIT SPECIFICATION [RDS_DAS_SERVER_AUDIT_SPEC] WITH (STATE=ON)
   ```
4. Configure database activity streams.

   Only activities that match the server and database audit policies are captured and sent to the Amazon Kinesis data stream. When database activity streams are enabled and the policies are locked, a database administrator can't alter the audit policy or remove audit logs.

   > **Important**
   >
   > If the database audit specification for a specific database is enabled and the policy is in a locked state, then the database can't be dropped.

For more information about SQL Server auditing, see SQL Server Audit Components in the *Microsoft SQL Server documentation*.

Non-native audit fields for Oracle Database and SQL Server

When you start a database activity stream, every database event generates a corresponding activity stream event. For example, a database user might run `SELECT` and `INSERT` statements. The database audits these events and sends them to an Amazon Kinesis data stream.
