The events are represented in the stream as JSON objects. A JSON object contains a `DatabaseActivityMonitoringRecord`, which contains a `databaseActivityEventList` array. Predefined fields in the array include `class`, `clientApplication`, and `command`.

By default, an activity stream doesn't include engine-native audit fields. You can configure Amazon RDS for Oracle and SQL Server so that it includes these extra fields in the `engineNativeAuditFields` JSON object.

In Oracle Database, most events in the unified audit trail map to fields in the RDS data activity stream. For example, the `UNIFIED_AUDIT_TRAIL.SQL_TEXT` field in unified auditing maps to the `commandText` field in a database activity stream. However, Oracle Database audit fields such as `OS_USERNAME` don't map to predefined fields in a database activity stream.

In SQL Server, most of the event's fields that are recorded by the SQLAudit map to the fields in RDS database activity stream. For example, the `code` field from `sys.fn_get_audit_file` in the audit maps to the `commandText` field in a database activity stream. However, SQL Server database audit fields, such as `permission_bitmask`, don't map to predefined fields in a database activity stream.

For more information about databaseActivityEventList, see databaseActivityEventList JSON array for database activity streams.

DB parameter group override

Typically, you turn on unified auditing in RDS for Oracle by attaching a parameter group. However, Database Activity Streams require additional configuration. To improve your customer experience, Amazon RDS performs the following:

- If you activate an activity stream, RDS for Oracle ignores the auditing parameters in the parameter group.
- If you deactivate an activity stream, RDS for Oracle stops ignoring the auditing parameters.

The database activity stream for SQL Server is independent of any parameters you set in the SQL Audit option.

Asynchronous mode for database activity streams

Activity streams in Amazon RDS are always asynchronous. When a database session generates an activity stream event, the session returns to normal activities immediately. In the background, Amazon RDS makes the activity stream event into a durable record.

If an error occurs in the background task, Amazon RDS generates an event. This event indicates the beginning and end of any time windows where activity stream event records might have been lost. Asynchronous mode favors database performance over the accuracy of the activity stream.

Requirements and limitations for database activity streams

In RDS, database activity streams have the following requirements and limitations:

- Amazon Kinesis is required for database activity streams.
- AWS Key Management Service (AWS KMS) is required for database activity streams because they are always encrypted.
- Applying additional encryption to your Amazon Kinesis data stream is incompatible with database activity streams, which are already encrypted with your AWS KMS key.
- You create and manage audit policies yourself. Unlike Amazon Aurora, RDS for Oracle doesn't capture database activities by default.
- You create and manage audit policies or specifications yourself. Unlike Amazon Aurora, Amazon RDS doesn't capture database activities by default.
- In a Multi-AZ deployment, start the database activity stream only on the primary DB instance. The activity stream audits both the primary and standby DB instances automatically. No additional steps are required during a failover.
- Renaming a DB instance doesn't create a new Kinesis stream.
- CDBs aren't supported for RDS for Oracle.
- Read replicas aren't supported.

Region and version availability

Feature availability and support varies across specific versions of each database engine, and across AWS Regions. For more information on version and Region availability with database activity streams, see Supported Regions and DB engines for database activity streams in Amazon RDS.

Supported DB instance classes for database activity streams

For RDS for Oracle you can use database activity streams with the following DB instance classes:

- db.m4.*large
- db.m5.*large
- db.m5d.*large
- db.m6i.*large
- db.r4.*large
- db.r5.*large
- db.r5.*large.tpc*.mem*x
- db.r5b.*large
- db.r5b.*large.tpc*.mem*x
- db.r5d.*large
- db.r6i.*large
- db.x2idn.*large
- db.x2iedn.*large
- db.x2iezn.*large
- db.z1d.*large

For RDS for SQL Server you can use database activity streams with the following DB instance classes:

- db.m4.*large
- db.m5.*large
- db.m5d.*large
- db.m6i.*large
- db.r4.*large
- db.r5.*large
- db.r5b.*large
- db.r5d.*large
- db.r6i.*large
- db.x1e.*large

- db.z1d.*large

For more information about instance class types, see DB instance classes.

Configuring unified auditing for Oracle Database

When you configure unified auditing for use with database activity streams, the following situations are possible:

- Unified auditing isn't configured for your Oracle database.

  In this case, create new policies with the `CREATE AUDIT POLICY` command, then activate them with the `AUDIT POLICY` command. The following example creates and activates a policy to monitor users with specific privileges and roles.

  ```
  CREATE AUDIT POLICY table_pol
  PRIVILEGES CREATE ANY TABLE, DROP ANY TABLE
  ROLES emp_admin, sales_admin;

  AUDIT POLICY table_pol;
  ```

  For complete instructions, see Configuring Audit Policies in the Oracle Database documentation.
- Unified auditing is configured for your Oracle database.

  When you activate a database activity stream, RDS for Oracle automatically clears existing audit data. It also revokes audit trail privileges. RDS for Oracle can no longer do the following:

  - Purge unified audit trail records.
  - Add, delete, or modify the unified audit policy.
  - Update the last archived timestamp.

  > **Important**
  >
  > We strongly recommend that you back up your audit data before activating a database activity stream.

  For a description of the `UNIFIED_AUDIT_TRAIL` view, see UNIFIED_AUDIT_TRAIL. If you have an account with Oracle Support, see How To Purge The UNIFIED AUDIT TRAIL.

Configuring auditing policy for Microsoft SQL Server

A SQL Server database instance has the server audit RDS_DAS_AUDIT, which is managed by Amazon RDS. You can define the policies to record server events in the server audit specification RDS_DAS_SERVER_AUDIT_SPEC. You can create a database audit specification, such as RDS_DAS_DB_<name>, and define the policies to record database events. For the list of server and database level audit action groups, see SQL Server Audit Action Groups and Actions in the *Microsoft SQL Server documentation*.

The default server policy monitors only failed logins and changes to any database or server audit specifications for database activity streams.

Limitations for the audit and audit specifications include the following:

- You can't modify the server or database audit specifications when the database activity stream is in a *locked* state.
- You can't modify the server audit RDS_DAS_AUDIT specification.
- You can't modify the SQL Server audit RDS_DAS_CHANGES or its related server audit specification RDS_DAS_CHANGES_AUDIT_SPEC.
- When creating a database audit specification, you must use the format RDS_DAS_DB_<name> for example, RDS_DAS_DB_databaseActions.

> **Important**
>
> For smaller instance classes, we recommend that you don't audit all but only the data that is required. This helps to reduce the performance impact of Database Activity Streams on these instance classes.

The following sample code modifies the server audit specification RDS_DAS_SERVER_AUDIT_SPEC and audits any logout and successful login actions:

```
ALTER SERVER AUDIT SPECIFICATION [RDS_DAS_SERVER_AUDIT_SPEC]
      WITH (STATE=OFF);
ALTER SERVER AUDIT SPECIFICATION [RDS_DAS_SERVER_AUDIT_SPEC]
      ADD (LOGOUT_GROUP),
      ADD (SUCCESSFUL_LOGIN_GROUP)
      WITH (STATE = ON );
```

The following sample code creates a database audit specification RDS_DAS_DB_database_spec and attaches it to the server audit RDS_DAS_AUDIT:

```
USE testDB;
CREATE DATABASE AUDIT SPECIFICATION [RDS_DAS_DB_database_spec]
     FOR SERVER AUDIT [RDS_DAS_AUDIT]
     ADD ( INSERT, UPDATE, DELETE
          ON testTable BY testUser )
     WITH (STATE = ON);
```

After the audit specifications are configured, make sure that the specifications RDS_DAS_SERVER_AUDIT_SPEC and RDS_DAS_DB_<name> are set to a state of ON. Now they can send the audit data to your database activity stream.

Starting a database activity stream

When you start an activity stream for the DB instance, each database activity event that you configured in the audit policy generates an activity stream event. SQL commands such as CONNECT and SELECT generate access events. SQL commands such as CREATE and INSERT generate change events.

Important

Turning on an activity stream for an Oracle DB instance clears existing audit data. It also revokes audit trail privileges. When the stream is enabled, RDS for Oracle can no longer do the following:

- Purge unified audit trail records.
- Add, delete, or modify the unified audit policy.
- Update the last archived time stamp.

Console

To start a database activity stream

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.

3. Choose the Amazon RDS database instance on which you want to start an activity stream. In a Multi-AZ deployment, start the stream on only the primary instance. The activity stream audits both the primary and the standby instances.
4. For **Actions**, choose **Start activity stream**.

   The **Start database activity stream:** *name* window appears, where *name* is your RDS instance.
5. Enter the following settings:

   - For **AWS KMS key**, choose a key from the list of AWS KMS keys.

     Amazon RDS uses the KMS key to encrypt the key that in turn encrypts database activity. Choose a KMS key other than the default key. For more information about encryption keys and AWS KMS, see What is AWS Key Management Service? in the *AWS Key Management Service Developer Guide.*
   - For **Database activity events**, choose **Enable engine-native audit fields** to include the engine specific audit fields.
   - Choose **Immediately**.

     When you choose **Immediately**, the RDS instance restarts right away. If you choose **During the next maintenance window**, the RDS instance doesn't restart right away. In this case, the database activity stream doesn't start until the next maintenance window.
6. Choose **Start database activity stream**.

   The status for the the database shows that the activity stream is starting.

> **Note**
>
> If you get the error `You can't start a database activity stream in this configuration`, check Supported DB instance classes for database activity streams to see whether your RDS instance is using a supported instance class.

AWS CLI

To start database activity streams for a DB instance, configure the database using the start-activity-stream AWS CLI command.

- `--resource-arn` *arn* – Specifies the Amazon Resource Name (ARN) of the DB instance.

- `--kms-key-id` *key* – Specifies the KMS key identifier for encrypting messages in the database activity stream. The AWS KMS key identifier is the key ARN, key ID, alias ARN, or alias name for the AWS KMS key.
- `--engine-native-audit-fields-included` – Includes engine-specific auditing fields in the data stream. To exclude these fields, specify `--no-engine-native-audit-fields-included` (default).

The following example starts a database activity stream for a DB instance in asynchronous mode.

For Linux, macOS, or Unix:

```
aws rds start-activity-stream \
    --mode async \
    --kms-key-id my-kms-key-arn \
    --resource-arn my-instance-arn \
    --engine-native-audit-fields-included \
    --apply-immediately
```

For Windows:

```
aws rds start-activity-stream ^
    --mode async ^
    --kms-key-id my-kms-key-arn ^
    --resource-arn my-instance-arn ^
    --engine-native-audit-fields-included ^
    --apply-immediately
```

RDS API

To start database activity streams for a DB instance, configure the instance using the StartActivityStream operation.

Call the action with the parameters below:

- `Region`
- `KmsKeyId`
- `ResourceArn`
- `Mode`

- `EngineNativeAuditFieldsIncluded`

Modifying a database activity stream

You might want to customize your Amazon RDS audit policy when your activity stream is started. If you don't want to lose time and data by stopping your activity stream, you can change the *audit policy state* to either of the following settings:

Locked (default)

The audit policies in your database are read-only.

Unlocked

The audit policies in your database are read/write.

The basic steps are as follows:

1. Modify the audit policy state to unlocked.
2. Customize your audit policy.
3. Modify the audit policy state to locked.

Console

To modify the audit policy state of your activity stream

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.
3. For **Actions**, choose **Modify database activity stream**.

   The **Modify database activity stream: *name*** window appears, where *name* is your RDS instance.
4. Choose either of the following options:

   Locked

   When you lock your audit policy, it becomes read-only. You can't edit your audit policy unless you unlock the policy or stop the activity stream.

Unlocked

When you unlock your audit policy, it becomes read/write. You can edit your audit policy while the activity stream is started.

5. Choose **Modify DB activity stream**.

   The status for the Amazon RDS database shows **Configuring activity stream**.

6. (Optional) Choose the DB instance link. Then choose the **Configuration** tab.

   The **Audit policy status** field shows one of the following values:

   - **Locked**
   - **Unlocked**
   - **Locking policy**
   - **Unlocking policy**

AWS CLI

To modify the activity stream state for the database instance, use the modify-activity-stream AWS CLI command.

Option	Required?	Description
`--resource-arn` *my-instance-ARN*	Yes	The Amazon Resource Name (ARN) of your RDS database instance.
`--audit-policy-state`	No	The new state of the audit policy for the database activity stream on your instance: `locked` or `unlocked`.

The following example unlocks the audit policy for the activity stream started on *my-instance-ARN*.

For Linux, macOS, or Unix:

```
aws rds modify-activity-stream \
    --resource-arn my-instance-ARN \
```

```
    --audit-policy-state unlocked
```

For Windows:

```
aws rds modify-activity-stream ^
    --resource-arn my-instance-ARN ^
    --audit-policy-state unlocked
```

The following example describes the instance *my-instance*. The partial sample output shows that the audit policy is unlocked.

```
aws rds describe-db-instances --db-instance-identifier my-instance

{
    "DBInstances": [
        {
            ...
            "Engine": "oracle-ee",
            ...
            "ActivityStreamStatus": "started",
            "ActivityStreamKmsKeyId": "ab12345e-1111-2bc3-12a3-ab1cd12345e",
            "ActivityStreamKinesisStreamName": "aws-rds-das-db-
AB1CDEFG23GHIJK4LMNOPQRST",
            "ActivityStreamMode": "async",
            "ActivityStreamEngineNativeAuditFieldsIncluded": true,
            "ActivityStreamPolicyStatus": "unlocked",
            ...
        }
    ]
}
```

RDS API

To modify the policy state of your database activity stream, use the ModifyActivityStream operation.

Call the action with the parameters below:

- `AuditPolicyState`
- `ResourceArn`

Getting the status of a database activity stream

You can get the status of an activity stream for your Amazon RDS database instance using the console or AWS CLI.

Console

To get the status of a database activity stream

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**, and then choose the DB instance link.
3. Choose the **Configuration** tab, and check **Database activity stream** for status.

AWS CLI

You can get the activity stream configuration for a database instance as the response to a describe-db-instances CLI request.

The following example describes *my-instance*.

```
aws rds --region my-region describe-db-instances --db-instance-identifier my-db
```

The following example shows a JSON response. The following fields are shown:

- `ActivityStreamKinesisStreamName`
- `ActivityStreamKmsKeyId`
- `ActivityStreamStatus`
- `ActivityStreamMode`
- `ActivityStreamPolicyStatus`

```
{
    "DBInstances": [
        {
            ...
            "Engine": "oracle-ee",
            ...
```

```
            "ActivityStreamStatus": "starting",
            "ActivityStreamKmsKeyId": "ab12345e-1111-2bc3-12a3-ab1cd12345e",
            "ActivityStreamKinesisStreamName": "aws-rds-das-db-
AB1CDEFG23GHIJK4LMNOPQRST",
            "ActivityStreamMode": "async",
            "ActivityStreamEngineNativeAuditFieldsIncluded": true,
            "ActivityStreamPolicyStatus": locked",
            ...
        }
    ]
}
```

RDS API

You can get the activity stream configuration for a database as the response to a DescribeDBInstances operation.

Stopping a database activity stream

You can stop an activity stream using the console or AWS CLI.

If you delete your Amazon RDS database instance, the activity stream is stopped and the underlying Amazon Kinesis stream is deleted automatically.

Console

To turn off an activity stream

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.
3. Choose a database that you want to stop the database activity stream for.
4. For **Actions**, choose **Stop activity stream**. The **Database Activity Stream** window appears.
    a. Choose **Immediately**.

        When you choose **Immediately**, the RDS instance restarts right away. If you choose **During the next maintenance window**, the RDS instance doesn't restart right away. In this case, the database activity stream doesn't stop until the next maintenance window.

    b. Choose **Continue**.

AWS CLI

To stop database activity streams for your database, configure the DB instance using the AWS CLI command stop-activity-stream. Identify the AWS Region for the DB instance using the `--region` parameter. The `--apply-immediately` parameter is optional.

For Linux, macOS, or Unix:

```
aws rds --region MY_REGION \
    stop-activity-stream \
    --resource-arn MY_DB_ARN \
    --apply-immediately
```

For Windows:

```
aws rds --region MY_REGION ^
    stop-activity-stream ^
    --resource-arn MY_DB_ARN ^
    --apply-immediately
```

RDS API

To stop database activity streams for your database, configure the DB instance using the StopActivityStream operation. Identify the AWS Region for the DB instance using the `Region` parameter. The `ApplyImmediately` parameter is optional.

Monitoring database activity streams

Database activity streams monitor and report activities. The stream of activity is collected and transmitted to Amazon Kinesis. From Kinesis, you can monitor the activity stream, or other services and applications can consume the activity stream for further analysis. You can find the underlying Kinesis stream name by using the AWS CLI command `describe-db-instances` or the RDS API `DescribeDBInstances` operation.

Amazon RDS manages the Kinesis stream for you as follows:

- Amazon RDS creates the Kinesis stream automatically with a 24-hour retention period.
- Amazon RDS scales the Kinesis stream if necessary.
- If you stop the database activity stream or delete the DB instance, Amazon RDS deletes the Kinesis stream.

The following categories of activity are monitored and put in the activity stream audit log:

- **SQL commands** – All SQL commands are audited, and also prepared statements, built-in functions, and functions in PL/SQL. Calls to stored procedures are audited. Any SQL statements issued inside stored procedures or functions are also audited.
- **Other database information** – Activity monitored includes the full SQL statement, the row count of affected rows from DML commands, accessed objects, and the unique database name. Database activity streams also monitor the bind variables and stored procedure parameters.

  > **Important**
  >
  > The full SQL text of each statement is visible in the activity stream audit log, including any sensitive data. However, database user passwords are redacted if Oracle can determine them from the context, such as in the following SQL statement.
  >
  > ```
  > ALTER ROLE role-name WITH password
  > ```

- **Connection information** – Activity monitored includes session and network information, the server process ID, and exit codes.

If an activity stream has a failure while monitoring your DB instance, you are notified through RDS events.

In the following sections, you can access, audit, and process database activity streams.

Topics

- Accessing an activity stream from Amazon Kinesis
- Audit log contents and examples for database activity streams
- databaseActivityEventList JSON array for database activity streams
- Processing a database activity stream using the AWS SDK

Accessing an activity stream from Amazon Kinesis

When you enable an activity stream for a database, a Kinesis stream is created for you. From Kinesis, you can monitor your database activity in real time. To further analyze database activity, you can connect your Kinesis stream to consumer applications. You can also connect the stream to

compliance management applications such as IBM's Security Guardium or Imperva's SecureSphere Database Audit and Protection.

You can access your Kinesis stream either from the RDS console or the Kinesis console.

To access an activity stream from Kinesis using the RDS console

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.
3. Choose the Amazon RDS database instance on which you started an activity stream.
4. Choose **Configuration**.
5. Under **Database activity stream**, choose the link under **Kinesis stream**.
6. In the Kinesis console, choose **Monitoring** to begin observing the database activity.

To access an activity stream from Kinesis using the Kinesis console

1. Open the Kinesis console at https://console.aws.amazon.com/kinesis.
2. Choose your activity stream from the list of Kinesis streams.

   An activity stream's name includes the prefix `aws-rds-das-db-` followed by the resource ID of the database. The following is an example.

   ```
   aws-rds-das-db-NHVOV4PCLWHGF52NP
   ```

   To use the Amazon RDS console to find the resource ID for the database, choose your DB instance from the list of databases, and then choose the **Configuration** tab.

   To use the AWS CLI to find the full Kinesis stream name for an activity stream, use a describe-db-instances CLI request and note the value of `ActivityStreamKinesisStreamName` in the response.
3. Choose **Monitoring** to begin observing the database activity.

For more information about using Amazon Kinesis, see What Is Amazon Kinesis Data Streams?.

Audit log contents and examples for database activity streams

Monitored events are represented in the database activity stream as JSON strings. The structure consists of a JSON object containing a `DatabaseActivityMonitoringRecord`, which in turn contains a `databaseActivityEventList` array of activity events.

Topics

Examples of an audit log for an activity stream

Following are sample decrypted JSON audit logs of activity event records.

Example Activity event record of a CONNECT SQL statement

The following activity event record shows a login with the use of a `CONNECT` SQL statement (`command`) by a JDBC Thin Client (`clientApplication`) for your Oracle DB.

```
{
    "class": "Standard",
    "clientApplication": "JDBC Thin Client",

DatabaseActivityMonitoringRecords JSON object

The database activity event records are in a JSON object that contains the following information.

JSON Field	Data Type	Description
`type`	string	The type of JSON record. The value is `DatabaseActivityMonitoringRecords` .
`version`	string	The version of the database activity monitoring records. Oracle DB uses version 1.3 and SQL Server uses version 1.4. These engine versions introduce the `engineNativeAuditFields` JSON object.
databaseActivityEvents	string	A JSON object that contains the activity events.

JSON Field	Data Type	Description
key	string	An encryption key that you use to decrypt the databaseActivityEventList JSON array

databaseActivityEvents JSON Object

The `databaseActivityEvents` JSON object contains the following information.

Top-level fields in JSON record

Each event in the audit log is wrapped inside a record in JSON format. This record contains the following fields.

type

This field always has the value `DatabaseActivityMonitoringRecords`.

version

This field represents the version of the database activity stream data protocol or contract. It defines which fields are available.

databaseActivityEvents

An encrypted string representing one or more activity events. It's represented as a base64 byte array. When you decrypt the string, the result is a record in JSON format with fields as shown in the examples in this section.

key

The encrypted data key used to encrypt the `databaseActivityEvents` string. This is the same AWS KMS key that you provided when you started the database activity stream.

The following example shows the format of this record.

```
{
  "type":"DatabaseActivityMonitoringRecords",
  "version":"1.3",
```

```
  "databaseActivityEvents":"encrypted audit records",
  "key":"encrypted key"
}
```

```
        "type":"DatabaseActivityMonitoringRecords",
        "version":"1.4",
        "databaseActivityEvents":"encrypted audit records",
        "key":"encrypted key"
```

Take the following steps to decrypt the contents of the `databaseActivityEvents` field:

1. Decrypt the value in the `key` JSON field using the KMS key you provided when starting database activity stream. Doing so returns the data encryption key in clear text.
2. Base64-decode the value in the `databaseActivityEvents` JSON field to obtain the ciphertext, in binary format, of the audit payload.
3. Decrypt the binary ciphertext with the data encryption key that you decoded in the first step.
4. Decompress the decrypted payload.
   - The encrypted payload is in the `databaseActivityEvents` field.
   - The `databaseActivityEventList` field contains an array of audit records. The `type` fields in the array can be `record` or `heartbeat`.

The audit log activity event record is a JSON object that contains the following information.

JSON Field	Data Type	Description
`type`	string	The type of JSON record. The value is `DatabaseActivityMonitoringRecord` .
`instanceId`	string	The DB instance resource identifier. It corresponds to the DB instance attribute `DbiResourceId` .
databaseActivityEventList JSON array	string	An array of activity audit records or heartbeat messages.

databaseActivityEventList JSON array for database activity streams

The audit log payload is an encrypted `databaseActivityEventList` JSON array. The following table lists alphabetically the fields for each activity event in the decrypted `DatabaseActivityEventList` array of an audit log.

When unified auditing is enabled in Oracle Database, the audit records are populated in this new audit trail. The `UNIFIED_AUDIT_TRAIL` view displays audit records in tabular form by retrieving the audit records from the audit trail. When you start a database activity stream, a column in `UNIFIED_AUDIT_TRAIL` maps to a field in the `databaseActivityEventList` array.

> **Important**
>
> The event structure is subject to change. Amazon RDS might add new fields to activity events in the future. In applications that parse the JSON data, make sure that your code can ignore or take appropriate actions for unknown field names.

databaseActivityEventList fields for Amazon RDS for Oracle

The following are `databaseActivityEventList` fields for Amazon RDS for Oracle.

Field	Data Type	Source	Description
`class`	string	`AUDIT_TYPE` column in `UNIFIED_AUDIT_TRAIL`	The class of activity event. This corresponds to the `AUDIT_TYPE` column in the `UNIFIED_AUDIT_TRAIL` view. Valid values for Amazon RDS for Oracle are the following: • `Standard` • `FineGrainedAudit` • `XS` • `Database Vault`

Field	Data Type	Source	Description
			• Label Security • RMAN_AUDIT • Datapump • Direct path API For more informati on, see UNIFIED_A UDIT_TRAIL in the Oracle documentation.
clientApplication	string	CLIENT_PROGRAM_NAME in UNIFIED_AUDIT_TRAI L	The application the client used to connect as reported by the client. The client doesn't have to provide this informati on, so the value can be null. A sample value is JDBC Thin Client.
command	string	ACTION_NAME column in UNIFIED_AUDIT_TRAIL	Name of the action executed by the user. To understand the complete action, read both the command name and the AUDIT_TYPE value. A sample value is ALTER DATABASE.
commandText	string	SQL_TEXT column in UNIFIED_AUDIT_TRAIL	The SQL statement associated with the event. A sample value is ALTER DATABASE BEGIN BACKUP.

Field	Data Type	Source	Description
databaseName	string	NAME column in V$DATABASE	The name of the database.
dbid	numb	DBID column in UNIFIED_AUDIT_TRAIL	Numerical identifier for the database. A sample value is 1559204751 .
dbProtocol	string	N/A	The database protocol. In this beta, the value is oracle.
dbUserName	string	DBUSERNAME column in UNIFIED_AUDIT_TRAIL	Name of the database user whose actions were audited. A sample value is RDSADMIN.
endTime	string	N/A	This field isn't used for RDS for Oracle and is always null.

Field	Data Type	Source	Description
engineNativeAuditFields	objec	UNIFIED_AUDIT_TRAIL	By default, this object is empty. When you start the activity stream with the --engine-native-audit-fields-included option, this object includes the following columns and their values: ADDITIONAL_INFO APPLICATION_CONTEXTS AUDIT_OPTION AUTHENTICATION_TYPE CLIENT_IDENTIFIER CURRENT_USER DBLINK_INFO DBPROXY_USERNAME DIRECT_PATH_NUM_COLUMNS_LOADED DP_BOOLEAN_PARAMETERS1 DP_TEXT_PARAMETERS1 DV_ACTION_CODE DV_ACTION_NAME DV_ACTION_OBJECT_NAME DV_COMMENT DV_EXTENDED_ACTION_CODE DV_FACTOR_CONTEXT DV_GRANTEE DV_OBJECT_STATUS DV_RETURN_CODE

Field	Data Type	Source	Description
			DV_RULE_SET_NAME ENTRY_ID EXCLUDED_OBJECT EXCLUDED_SCHEMA EXCLUDED_USER EXECUTION_ID EXTERNAL_USERID FGA_POLICY_NAME GLOBAL_USERID INSTANCE_ID KSACL_SER VICE_NAME KSACL_SOURCE_LOCA TION KSACL_USER_NAME NEW_NAME NEW_SCHEMA OBJECT_EDITION OBJECT_PRIVILEGES OLS_GRANTEE OLS_LABEL_COM PONENT_NAME OLS_LABEL_COMPO NENT_TYPE OLS_MAX_READ_LABEL OLS_MAX_WRITE_LA BEL OLS_MIN_WRITE_ LABEL OLS_NEW_VALUE OLS_OLD_VALUE OLS_PARENT_ GROUP_NAME OLS_POLICY_NAME OLS_PRIVILEGES_GRA NTED OLS_PRIVILEGE S_USED OLS_PROGRAM _UNIT_NAME OLS_STRING_LABEL

Field	Data Type	Source	Description
			OS_USERNAME PROTOCOL_ACTIO N_NAME PROTOCOL_MESSAGE PROTOCOL_RET URN_CODE PROTOCOL_SESSION_I D PROTOCOL_USERHOST PROXY_SESSIONID RLS_INFO RMAN_DEVICE_TYPE RMAN_OBJECT_TYPE RMAN_OPERATION RMAN_SESSION_RECID RMAN_SESSION_STAMP ROLE SCN SYSTEM_PRIVILEGE SYSTEM_PRIVIL EGE_USED TARGET_USER TERMINAL UNIFIED_AUDIT_P OLICIES USERHOST XS_CALLBAC K_EVENT_TYPE XS_COOKIE XS_DATASEC_PO LICY_NAME XS_ENABLED_ROLE XS_ENTITY_TYPE XS_INACTIVITY _TIMEOUT XS_NS_ATTRIBUTE XS_NS_ATTRI BUTE_NEW_VAL XS_NS_ATTRIBUT E_OLD_VAL XS_NS_NAME

Field	Data Type	Source	Description
			XS_PACKAGE_NAME XS_PROCEDURE_NAME XS_PROXY_USER_NAME XS_SCHEMA_NAME XS_SESSIONID XS_TARGET_PRINC IPAL_NAME XS_USER_NAME For more informati on, see UNIFIED_A UDIT_TRAIL in the Oracle Database documenta tion.
errorMessage	string	N/A	This field isn't used for RDS for Oracle and is always null.
exitCode	numb	RETURN_CODE column in UNIFIED_AUDIT_TRAIL	Oracle Database error code generated by the action. If the action succeeded, the value is 0.
logTime	string	EVENT_TIMESTAMP_UT C column in UNIFIED_A UDIT_TRAIL	Timestamp of the creation of the audit trail entry. A sample value is 2020-11-27 06:56:14.981404 .
netProtocol	string	AUTHENTICATION_TYP E column in UNIFIED_A UDIT_TRAIL	The network communica tion protocol. A sample value is TCP.

Field	Data Type	Source	Description
objectName	string	OBJECT_NAME column in UNIFIED_AUDIT_TRAIL	The name of the object affected by the action. A sample value is employees .
objectType	string	OBJECT_SCHEMA column in UNIFIED_AUDIT_TRAIL	The schema name of object affected by the action. A sample value is hr.
paramList	list	SQL_BINDS column in UNIFIED_AUDIT_TRAIL	The list of bind variables , if any, associated with SQL_TEXT. A sample value is parameter _1,parameter_2 .
pid	numb	OS_PROCESS column in UNIFIED_AUDIT_TRAIL	Operating system process identifier of the Oracle database process. A sample value is 22396.
remoteHost	string	AUTHENTICATION_TYP E column in UNIFIED_A UDIT_TRAIL	Either the client IP address or name of the host from which the session was spawned. A sample value is 123.456.789.123 .
remotePort	string	AUTHENTICATION_TYP E column in UNIFIED_A UDIT_TRAIL	The client port number. A typical value in Oracle Database environments is 1521.

Field	Data Type	Source	Description
rowCount	numb	N/A	This field isn't used for RDS for Oracle and is always null.
serverHost	string	Database host	The IP address of the database server host. A sample value is 123.456.789.123 .
serverType	string	N/A	The database server type. The value is always ORACLE.
serverVersion	string	Database host	The Amazon RDS for Oracle version, Release Update (RU), and Release Update Revision (RUR). A sample value is 19.0.0.0.ru-2020-01.rur-2020-01.r1.EE.3 .
serviceName	string	Database host	The name of the service. A sample value is oracle-ee .
sessionId	numb	SESSIONID column in UNIFIED_AUDIT_TRAIL	The session identifier of the audit. An example is 1894327130 .
startTime	string	N/A	This field isn't used for RDS for Oracle and is always null.

Field	Data Type	Source	Description
statementId	numb	STATEMENT_ID column in UNIFIED_AUDIT_TRAIL	Numeric ID for each statement run. A statement can cause many actions. A sample value is 142197.
substatementId	N/A	N/A	This field isn't used for RDS for Oracle and is always null.
transactionId	string	TRANSACTION_ID column in UNIFIED_AUDIT_TRAIL	The identifier of the transaction in which the object is modified. A sample value is 02000800D5030000 .

databaseActivityEventList fields for Amazon RDS for SQL Server

The following are databaseActivityEventList fields for Amazon RDS for SQL Server.

Field	Data Type	Source	Description
class	string	sys.fn_get_audit_file.class_type mapped to sys.dm_audit_class_type_map.class_type_desc	The class of activity event. For more information, see SQL Server Audit (Database Engine) in the Microsoft documentation.
clientApplication	string	sys.fn_get_audit_file.application_name	The application that the client connects as reported by the client (SQL Server version 14 and higher). This field is null in SQL Server version 13.

Field	Data Type	Source	Description
command	string	sys.fn_get_audit_file.action_id mapped to sys.dm_audit_actions.name	The general category of the SQL statement. The value for this field depends on the value of the class.
commandText	string	sys.fn_get_audit_file.statement	This field indicates the SQL statement.
databaseName	string	sys.fn_get_audit_file.database_name	Name of the database.
dbProtocol	string	N/A	The database protocol. This value is SQLSERVER .
dbUserName	string	sys.fn_get_audit_file.server_principal_name	The database user for the client authentication.
endTime	string	N/A	This field isn't used by Amazon RDS for SQL Server and the value is null.
engineNativeAuditFields	object	Each field in sys.fn_get_audit_file that is not listed in this column.	By default, this object is empty. When you start the activity stream with the --engine-native-audit-fields-included option, this object includes other native engine audit fields, which are not returned by this JSON map.
errorMessage	string	N/A	This field isn't used by Amazon RDS for SQL Server and the value is null.

Field	Data Type	Source	Description
exitCode	integer	sys.fn_get_audit_file.succeeded	Indicates whether the action that started the event succeeded. This field can't be null. For all the events except login events, this field reports whether the permission check succeeded or failed, but not whether the operation succeeded or failed. Values include: • 0 – Fail • 1 – Success
logTime	string	sys.fn_get_audit_file.event_time	The event timestamp that is recorded by the SQL Server.
netProtocol	string	N/A	This field isn't used by Amazon RDS for SQL Server and the value is null.
objectName	string	sys.fn_get_audit_file.object_name	The name of the database object if the SQL statement is operating on an object.
objectType	string	sys.fn_get_audit_file.class_type mapped to sys.dm_audit_class_type_map.class_type_desc	The database object type if the SQL statement is operating on an object type.
paramList	string	N/A	This field isn't used by Amazon RDS for SQL Server and the value is null.

Field	Data Type	Source	Description
pid	integer	N/A	This field isn't used by Amazon RDS for SQL Server and the value is null.
remoteHost	string	sys.fn_get_audit_file.client_ip	The IP address or hostname of the client that issued the SQL statement (SQL Server version 14 and higher). This field is null in SQL Server version 13.
remotePort	integer	N/A	This field isn't used by Amazon RDS for SQL Server and the value is null.
rowCount	integer	sys.fn_get_audit_file.affected_rows	The number of table rows affected by the SQL statement (SQL Server version 14 and higher). This field is in SQL Server version 13.
serverHost	string	Database Host	The IP address of the host database server.
serverType	string	N/A	The database server type. The value is SQLSERVER .
serverVersion	string	Database Host	The database server version, for example, 15.00.4073.23.v1.R1 for SQL Server 2017.
serviceName	string	Database Host	The name of the service. An example value is sqlserver-ee.

Field	Data Type	Source	Description
sessionId	integer	sys.fn_get_audit_file.session_id	Unique identifier of the session.
startTime	string	N/A	This field isn't used by Amazon RDS for SQL Server and the value is null.
statementId	string	sys.fn_get_audit_file.sequence_group_id	A unique identifier for the client's SQL statement. The identifier is different for each event that is generated. A sample value is 0x38eaf415626718409 4bb82071aaab644 .
substatementId	integer	sys.fn_get_audit_file.sequence_number	An identifier to determine the sequence number for a statement. This identifier helps when large records are split into multiple records.
transactionId	integer	sys.fn_get_audit_file.transaction_id	An identifier of a transaction. If there aren't any active transactions, the value is zero.
type	string	Database activity stream generated	The type of event. The values are record or heartbeat .

Processing a database activity stream using the AWS SDK

You can programmatically process an activity stream by using the AWS SDK. The following are fully functioning Java and Python examples of using Database Activity Streams records for instance based enablement.

Java

IAM policy examples for database activity streams

Any user with appropriate AWS Identity and Access Management (IAM) role privileges for database activity streams can create, start, stop, and modify the activity stream settings for a DB instance. These actions are included in the audit log of the stream. For best compliance practices, we recommend that you don't provide these privileges to DBAs.

You set access to database activity streams using IAM policies. For more information about Amazon RDS authentication, see Identity and access management for Amazon RDS. For more information about creating IAM policies, see Creating and using an IAM policy for IAM database access.

Example Policy to allow configuring database activity streams

To give users fine-grained access to modify activity streams, use the service-specific operation context keys `rds:StartActivityStream` and `rds:StopActivityStream` in an IAM policy. The following IAM policy example allows a user or role to configure activity streams.

```
{
   "Version":"2012-10-17",
   "Statement":[
        {
            "Sid":"ConfigureActivityStreams",
            "Effect":"Allow",
            "Action": [
                "rds:StartActivityStream",
                "rds:StopActivityStream"
            ],
            "Resource":"*",
          }
     ]
}
```

Example Policy to allow starting database activity streams

The following IAM policy example allows a user or role to start activity streams.

```
{
    "Version":"2012-10-17",
    "Statement":[
        {
            "Sid":"AllowStartActivityStreams",
            "Effect":"Allow",
            "Action":"rds:StartActivityStream",
            "Resource":"*"
        }
    ]
}
```

Example Policy to allow stopping database activity streams

The following IAM policy example allows a user or role to stop activity streams.

```
{
    "Version":"2012-10-17",
    "Statement":[
        {
            "Sid":"AllowStopActivityStreams",
            "Effect":"Allow",
            "Action":"rds:StopActivityStream",
            "Resource":"*"
        }
     ]
}
```

Example Policy to deny starting database activity streams

The following IAM policy example prevents a user or role from starting activity streams.

```
{
    "Version":"2012-10-17",
    "Statement":[
        {
            "Sid":"DenyStartActivityStreams",
            "Effect":"Deny",
```

```
            "Action":"rds:StartActivityStream",
            "Resource":"*"
        }
     ]
}
```

Example Policy to deny stopping database activity streams

The following IAM policy example prevents a user or role from stopping activity streams.

```
{
    "Version":"2012-10-17",
    "Statement":[
        {
            "Sid":"DenyStopActivityStreams",
            "Effect":"Deny",
            "Action":"rds:StopActivityStream",
            "Resource":"*"
        }
    ]
}
```

Working with Amazon RDS Custom

Amazon RDS Custom automates database administration tasks and operations. RDS Custom makes it possible for you as a database administrator to access and customize your database environment and operating system. With RDS Custom, you can customize to meet the requirements of legacy, custom, and packaged applications.

For the latest webinars and blogs about RDS Custom, see Amazon RDS Custom resources.

Topics

Addressing the challenge of database customization

Amazon RDS Custom brings the benefits of Amazon RDS to a market that can't easily move to a fully managed service because of customizations that are required with third-party applications. Amazon RDS Custom saves administrative time, is durable, and scales with your business.

If you need the entire database and operating system to be fully managed by AWS, we recommend Amazon RDS. If you need administrative rights to the database and underlying operating system to make dependent applications available, Amazon RDS Custom is the better choice. If you want full management responsibility and simply need a managed compute service, the best option is self-managing your commercial databases on Amazon EC2.

To deliver a managed service experience, Amazon RDS doesn't let you access the underlying host. Amazon RDS also restricts access to some procedures and objects that require high-level privileges. However, for some applications, you might need to perform operations as a privileged operating system (OS) user.

For example, you might need to do the following:

- Install custom database and OS patches and packages.

- Configure specific database settings.
- Configure file systems to share files directly with their applications.

Previously, if you needed to customize your application, you had to deploy your database on-premises or on Amazon EC2. In this case, you bear most or all of the responsibility for database management, as summarized in the following table.

Feature	On-premises responsibility	Amazon EC2 responsibility	Amazon RDS responsibility
Application optimization	Customer	Customer	Customer
Scaling	Customer	Customer	AWS
High availability	Customer	Customer	AWS
Database backups	Customer	Customer	AWS
Database software patching	Customer	Customer	AWS
Database software install	Customer	Customer	AWS
OS patching	Customer	Customer	AWS
OS installation	Customer	Customer	AWS
Server maintenance	Customer	AWS	AWS
Hardware lifecycle	Customer	AWS	AWS
Power, network, and cooling	Customer	AWS	AWS

When you manage database software yourself, you gain more control, but you're also more prone to user errors. For example, when you make changes manually, you might accidentally

cause application downtime. You might spend hours checking every change to identify and fix an issue. Ideally, you want a managed database service that automates common DBA tasks, but also supports privileged access to the database and underlying operating system.

Management model and benefits for Amazon RDS Custom

Amazon RDS Custom is a managed database service for legacy, custom, and packaged applications that require access to the underlying operating system and database environment. RDS Custom automates setup, operation, and scaling of databases in the AWS Cloud while granting you access to the database and underlying operating system. With this access, you can configure settings, install patches, and enable native features to meet the dependent application's requirements. With RDS Custom, you can run your database workload using the AWS Management Console or the AWS CLI.

RDS Custom supports only the Oracle Database and Microsoft SQL Server DB engines.

Topics

Shared responsibility model in RDS Custom

With RDS Custom, you use the managed features of Amazon RDS, but you manage the host and customize the OS as you do in Amazon EC2. You take on additional database management responsibilities beyond what you do in Amazon RDS. The result is that you have more control over database and DB instance management than you do in Amazon RDS, while still benefiting from RDS automation.

Shared responsibility means the following:

1. You own part of the process when using an RDS Custom feature.

   For example, in RDS Custom for Oracle, you control which Oracle database patches to use and when to apply them to your DB instances.
2. You are responsible for making sure that any customizations to RDS Custom features work correctly.

To help protect against invalid customization, RDS Custom has automation software that runs outside of your DB instance. If your underlying Amazon EC2 instance becomes impaired, RDS Custom attempts to resolve these problems automatically by either rebooting or replacing the EC2 instance. The only user-visible change is a new IP address. For more information, see Amazon RDS Custom host replacement.

The following table details the shared responsibility model for different features of RDS Custom.

Feature	Amazon EC2 responsibility	Amazon RDS responsibility	RDS Custom for Oracle responsibility	RDS Custom for SQL Server responsibility
Application optimization	Customer	Customer	Customer	Customer
Scaling	Customer	AWS	Shared	Shared
High availability	Customer	AWS	Customer	AWS
Database backups	Customer	AWS	Shared	AWS
Database software patching	Customer	AWS	Shared	AWS for RPEV, Customer for CEV[1]
Database software install	Customer	AWS	Shared	AWS for RPEV, Customer for CEV[1]
OS patching	Customer	AWS	Customer	AWS for RPEV, Customer for CEV[1]
OS installation	Customer	AWS	Shared	AWS
Server maintenance	AWS	AWS	AWS	AWS

Feature	Amazon EC2 responsibility	Amazon RDS responsibility	RDS Custom for Oracle responsibility	RDS Custom for SQL Server responsibility
Hardware lifecycle	AWS	AWS	AWS	AWS
Power, network, and cooling	AWS	AWS	AWS	AWS

[1] A custom engine version (CEV) is a binary volume snapshot of a database version and Amazon Machine Image (AMI). An RDS provided engine version (RPEV) is the default Amazon Machine Image (AMI) and Microsoft SQL Server installation.

You can create an RDS Custom DB instance using Microsoft SQL Server. In this case:

- You can choose from two licensing models: License Included (LI) and Bring Your Own Media (BYOM).
- With LI, you don't need to purchase SQL Server licenses separately. AWS holds the license for the SQL Server database software.
- With BYOM, you provide and install your own Microsoft SQL Server binaries and licensing.

You can create an RDS Custom DB instance using Oracle Database. In this case, you do the following:

- Manage your own media.

  When using RDS Custom, you upload your own database installation files and patches. You create a custom engine version (CEV) from these files. Then you can create an RDS Custom DB instance by using this CEV.
- Manage your own licenses.

  You bring your own Oracle Database licenses and manage licenses by yourself.

Support perimeter and unsupported configurations in RDS Custom

RDS Custom provides a monitoring capability called the *support perimeter*. This feature ensures that your host and database environment are configured correctly. If you make a change that causes your DB instance to go outside the support perimeter, RDS Custom changes the instance status to `unsupported-configuration` until you manually fix the configuration problems. For more information, see RDS Custom support perimeter.

Key benefits of RDS Custom

With RDS Custom, you can do the following:

- Automate many of the same administrative tasks as Amazon RDS, including the following:
  - Lifecycle management of databases
  - Automated backups and point-in-time recovery (PITR)
  - Monitoring the health of RDS Custom DB instances and observing changes to the infrastructure, operating system, and database processes.
  - Notification or taking action to fix issues depending on disruption to the DB instance
- Install third-party applications.

  You can install software to run custom applications and agents. Because you have privileged access to the host, you can modify file systems to support legacy applications.
- Install custom patches.

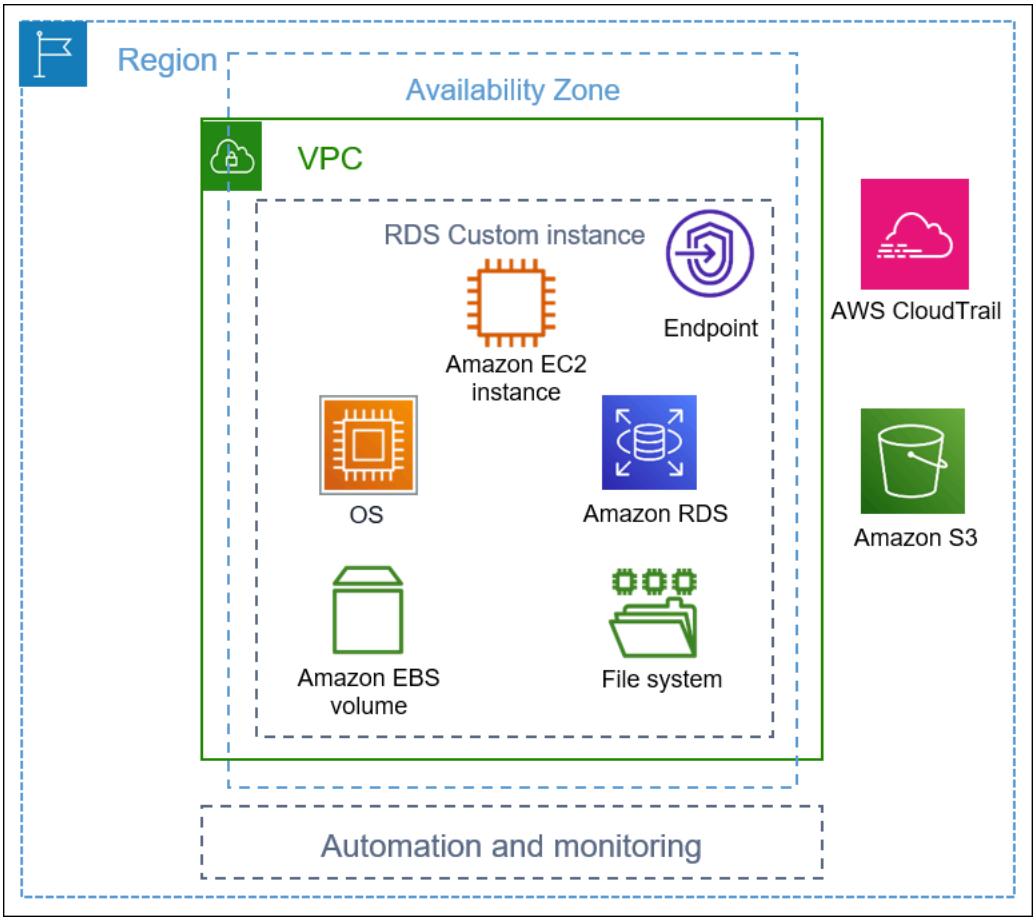
  You can apply custom database patches or modify OS packages on your RDS Custom DB instances.
- Stage an on-premises database before moving it to a fully managed service.

  If you manage your own on-premises database, you can stage the database to RDS Custom as-is. After you familiarize yourself with the cloud environment, you can migrate your database to a fully managed Amazon RDS DB instance.
- Create your own automation.

  You can create, schedule, and run custom automation scripts for reporting, management, or diagnostic tools.

Amazon RDS Custom architecture

Amazon RDS Custom architecture is based on Amazon RDS, with important differences. The following diagram shows the key components of the RDS Custom architecture.



Topics

- VPC
- RDS Custom automation and monitoring
- Amazon S3
- AWS CloudTrail

VPC

As in Amazon RDS, your RDS Custom DB instance resides in a virtual private cloud (VPC).

Your RDS Custom DB instance consists of the following main components:

- Amazon EC2 instance
- Instance endpoint
- Operating system installed on the Amazon EC2 instance
- Amazon EBS storage, which contains any additional file systems

RDS Custom automation and monitoring

RDS Custom has automation software that runs outside of the DB instance. This software communicates with agents on the DB instance and with other components within the overall RDS Custom environment.

The RDS Custom monitoring and recovery features offer similar functionality to Amazon RDS. By default, RDS Custom is in full automation mode. The automation software has the following primary responsibilities:

- Collect metrics and send notifications
- Perform automatic instance recovery

An important responsibility of RDS Custom automation is responding to problems with your Amazon EC2 instance. For various reasons, the host might become impaired or unreachable. RDS Custom resolves these problems by either rebooting or replacing the Amazon EC2 instance.

Topics

- Amazon RDS Custom host replacement
- RDS Custom support perimeter

Amazon RDS Custom host replacement

If the Amazon EC2 host becomes impaired, RDS Custom attempts to reboot it. If this effort fails, RDS Custom uses the same stop and start feature included in Amazon EC2. The only customer-visible change when a host is replaced is a new public IP address.

Topics

- Stopping and starting the host
- Effects of host replacement
- Best practices for Amazon EC2 hosts

Stopping and starting the host

RDS Custom automatically takes the following steps, with no user intervention required:

1. Stops the Amazon EC2 host.

   The EC2 instance performs a normal shutdown and stops running. Any Amazon EBS volumes remain attached to the instance, and their data persists. Any data stored in the instance store volumes (not supported on RDS Custom) or RAM of the host computer is gone.

   For more information, see Stop and start your instance in the *Amazon EC2 User Guide*.
2. Starts the Amazon EC2 host.

   The EC2 instance migrates to a new underlying host hardware. In some cases, the RDS Custom DB instance remains on the original host.

Effects of host replacement

In RDS Custom, you have full control over the root device volume and Amazon EBS storage volumes. The root volume can contain important data and configurations that you don't want to lose.

RDS Custom for Oracle retains all database and customer data after the operation, including root volume data. No user intervention is required. On RDS Custom for SQL Server, database data is retained, but any data on the C: drive, including operating system and customer data, is lost.

After the replacement process, the Amazon EC2 host has a new public IP address. The host retains the following:

- Instance ID
- Private IP addresses
- Elastic IP addresses
- Instance metadata
- Data storage volume data
- Root volume data (on RDS Custom for Oracle)

Best practices for Amazon EC2 hosts

The Amazon EC2 host replacement feature covers the majority of Amazon EC2 impairment scenarios. We recommend that you adhere to the following best practices:

- Before you change your configuration or the operating system, back up your data. If the root volume or operating system becomes corrupt, host replacement can't repair it. Your only options are restoring from a DB snapshot or point-in-time recovery.
- Don't manually stop or terminate the physical Amazon EC2 host. Both actions result in the instance being put outside the RDS Custom support perimeter.
- (RDS Custom for SQL Server) If you attach additional volumes to the Amazon EC2 host, configure them to remount upon restart. If the host is impaired, RDS Custom might stop and start the host automatically.

RDS Custom support perimeter

RDS Custom provides additional monitoring capability called the *support perimeter*. This additional monitoring ensures that your RDS Custom DB instance uses a supported AWS infrastructure, operating system, and database.

The support perimeter checks that your DB instance conforms to the requirements listed in Fixing unsupported configurations in RDS Custom for Oracle and Fixing unsupported configurations in

RDS Custom for SQL Server. If any of these requirements aren't met, RDS Custom considers your DB instance to be outside of the support perimeter.

Topics

- Unsupported configurations in RDS Custom
- Troubleshooting unsupported configurations

Unsupported configurations in RDS Custom

When your DB instance is outside the support perimeter, RDS Custom changes the DB instance status to `unsupported-configuration` and sends event notifications. After you fix the configuration problems, RDS Custom changes the DB instance status back to `available`.

While your DB instance is in the `unsupported-configuration` state, the following is true:

- Your database is reachable. An exception is when the DB instance is in the `unsupported-configuration` because the database is shutting down unexpectedly.
- You can't modify your DB instance.
- You can't take DB snapshots.
- Automatic backups aren't created.
- For RDS Custom for SQL Server DB instances only, RDS Custom doesn't replace the underlying Amazon EC2 instance if it becomes impaired. For more information about host replacement, see Amazon RDS Custom host replacement.
- You can delete your DB instance, but most other RDS Custom API operations aren't available.
- RDS Custom continues to support point-in-time recovery (PITR) by archiving redo log files and uploading them to Amazon S3. PITR in an `unsupported-configuration` state differs in the following ways:
  - PITR can take a long time to completely restore to a new RDS Custom DB instance. This situation occurs because you can't take either automated or manual snapshots while the instance is in the `unsupported-configuration` state.
  - PITR has to replay more redo logs starting from the most recent snapshot taken before the instance entered the `unsupported-configuration` state.
  - In some cases, the DB instance is in the `unsupported-configuration` state because you made a change that prevented the uploading of archived redo log files. Examples include

stopping the EC2 instance, stopping the RDS Custom agent, and detaching EBS volumes. In such cases, PITR can't restore the DB instance to the latest restorable time.

Troubleshooting unsupported configurations

RDS Custom provides troubleshooting guidance for the `unsupported-configuration` state. Although some guidance applies to both RDS Custom for Oracle and RDS Custom for SQL Server, other guidance depends on your DB engine. For engine-specific troubleshooting information, see the following topics:

- Fixing unsupported configurations in RDS Custom for Oracle
- Fixing unsupported configurations in RDS Custom for SQL Server

Amazon S3

If you use RDS Custom for Oracle, you upload installation media to a user-created Amazon S3 bucket. RDS Custom for Oracle uses the media in this bucket to create a custom engine version (CEV). A *CEV* is a binary volume snapshot of a database version and Amazon Machine Image (AMI). From the CEV, you can create an RDS Custom DB instance. For more information, see Working with custom engine versions for Amazon RDS Custom for Oracle.

For both RDS Custom for Oracle and RDS Custom for SQL Server, RDS Custom automatically creates an Amazon S3 bucket prefixed with the string `do-not-delete-rds-custom-`. RDS Custom uses the `do-not-delete-rds-custom-` S3 bucket to store the following types of files:

- AWS CloudTrail logs for the trail created by RDS Custom
- Support perimeter artifacts (see RDS Custom support perimeter)
- Database redo log files (RDS Custom for Oracle only)
- Transaction logs (RDS Custom for SQL Server only)
- Custom engine version artifacts (RDS Custom for Oracle only)

RDS Custom creates the `do-not-delete-rds-custom-` S3 bucket when you create either of the following resources:

- Your first CEV for RDS Custom for Oracle
- Your first DB instance for RDS Custom for SQL Server

RDS Custom creates one bucket for each combination of the following:

- AWS account ID
- Engine type (either RDS Custom for Oracle or RDS Custom for SQL Server)
- AWS Region

For example, if you create RDS Custom for Oracle CEVs in a single AWS Region, one `do-not-delete-rds-custom-` bucket exists. If you create multiple RDS Custom for SQL Server instances, and they reside in different AWS Regions, one `do-not-delete-rds-custom-` bucket exists in each AWS Region. If you create one RDS Custom for Oracle instance and two RDS Custom for SQL Server instances in a single AWS Region, two `do-not-delete-rds-custom-` buckets exist.

AWS CloudTrail

RDS Custom automatically creates an AWS CloudTrail trail whose name begins with `do-not-delete-rds-custom-`. The RDS Custom support perimeter relies on the events from CloudTrail to determine whether your actions affect RDS Custom automation. For more information, see Troubleshooting unsupported configurations.

RDS Custom creates the trail when you create your first DB instance. RDS Custom creates one trail for each combination of the following:

- AWS account ID
- Engine type (either RDS Custom for Oracle or RDS Custom for SQL Server)
- AWS Region

When you delete an RDS Custom DB instance, the CloudTrail for this instance isn't automatically removed. In this case, your AWS account continues to be billed for the undeleted CloudTrail. RDS Custom is not responsible for the deletion of this resource. To learn how to remove the CloudTrail manually, see Deleting a trail in the *AWS CloudTrail User Guide*.

Security in Amazon RDS Custom

Familiarize yourself with the security considerations for RDS Custom.

Topics

How RDS Custom securely manages tasks on your behalf

RDS Custom uses the following tools and techniques to securely run operations on your behalf:

AWSServiceRoleForRDSCustom service-linked role

A *service-linked role* is predefined by the service and includes all permissions that the service needs to call other AWS services on your behalf. For RDS Custom, `AWSServiceRoleForRDSCustom` is a service-linked role that is defined according to the principle of least privilege. RDS Custom uses the permissions in `AmazonRDSCustomServiceRolePolicy`, which is the policy attached to this role, to perform most provisioning and all off-host management tasks. For more information, see AmazonRDSCustomServiceRolePolicy.

When it performs tasks on the host, RDS Custom automation uses credentials from the service-linked role to run commands using AWS Systems Manager. You can audit the command history through the Systems Manager command history and AWS CloudTrail. Systems Manager connects to your RDS Custom DB instance using your networking setup. For more information, see Step 4: Configure IAM for RDS Custom for Oracle.

Temporary IAM credentials

When provisioning or deleting resources, RDS Custom sometimes uses temporary credentials derived from the credentials of the calling IAM principal. These IAM credentials are restricted by the IAM policies attached to that principal and expire after the operation is completed. To learn about the permissions required for IAM principals who use RDS Custom, see Step 5: Grant required permissions to your IAM user or role.

Amazon EC2 instance profile

An EC2 instance profile is a container for an IAM role that you can use to pass role information to an EC2 instance. An EC2 instance underlies an RDS Custom DB instance. You provide an instance profile when you create an RDS Custom DB instance. RDS Custom uses EC2 instance profile credentials when it performs host-based management tasks such as backups. For more information, see Create your IAM role and instance profile manually.

SSH key pair

When RDS Custom creates the EC2 instance that underlies a DB instance, it creates an SSH key pair on your behalf. The key uses the naming prefix `do-not-delete-rds-custom-ssh-privatekey-db-`. AWS Secrets Manager stores this SSH private key as a secret in your AWS account. Amazon RDS doesn't store, access, or use these credentials. For more information, see Amazon EC2 key pairs and Linux instances.

SSL certificates

RDS Custom DB instances don't support managed SSL certificates. If you want to deploy SSL, you can self-manage SSL certificates in your own wallet and create an SSL listener to secure the connections between the client database or for database replication. For more information, see Configuring Transport Layer Security Authentication in the Oracle Database documentation.

Securing your Amazon S3 bucket against the confused deputy problem

When you create an Amazon RDS Custom for Oracle custom engine version (CEV) or an RDS Custom for SQL Server DB instance, RDS Custom creates an Amazon S3 bucket. The S3 bucket stores files such as CEV artifacts, redo (transaction) logs, configuration items for the support perimeter, and AWS CloudTrail logs.

You can make these S3 buckets more secure by using the global condition context keys to prevent the *confused deputy problem*. For more information, see Preventing cross-service confused deputy problems.

The following RDS Custom for Oracle example shows the use of the `aws:SourceArn` and `aws:SourceAccount` global condition context keys in an S3 bucket policy. For RDS Custom for Oracle, make sure to include the Amazon Resource Names (ARNs) for the CEVs and the DB instances. For RDS Custom for SQL Server, make sure to include the ARN for the DB instances.

```
...
{
  "Sid": "AWSRDSCustomForOracleInstancesObjectLevelAccess",
  "Effect": "Allow",
  "Principal": {
     "Service": "custom.rds.amazonaws.com"
  },
  "Action": [
     "s3:GetObject",
     "s3:GetObjectVersion",
     "s3:DeleteObject",
     "s3:DeleteObjectVersion",
     "s3:GetObjectRetention",
     "s3:BypassGovernanceRetention"
  ],
  "Resource": "arn:aws:s3:::do-not-delete-rds-custom-123456789012-us-east-2-c8a6f7/
RDSCustomForOracle/Instances/*",
  "Condition": {
     "ArnLike": {
        "aws:SourceArn": [
            "arn:aws:rds:us-east-2:123456789012:db:*",
            "arn:aws:rds:us-east-2:123456789012:cev:*/*"
        ]
     },
     "StringEquals": {
        "aws:SourceAccount": "123456789012"
    }
  }
},
...
```

Rotating RDS Custom for Oracle credentials for compliance programs

Some compliance programs require database user credentials to change periodically, for example, every 90 days. RDS Custom for Oracle automatically rotates credentials for some predefined database users.

Topics

- Automatic rotation of credentials for predefined users
- Guidelines for rotating user credentials
- Rotating user credentials manually

Automatic rotation of credentials for predefined users

If your RDS Custom for Oracle DB instance is hosted in Amazon RDS, credentials for the following predefined Oracle users rotate every 30 days automatically. Credentials for the preceding users reside in AWS Secrets Manager.

Database user	Created by	Supported engine versions	Notes
SYS	Oracle	custom-oracle-ee custom-oracle-ee-cdb custom-oracle-se2 custom-oracle-se2-cdb	
SYSTEM	Oracle	custom-oracle-ee custom-oracle-ee-cdb custom-oracle-se2 custom-oracle-se2-cdb	
RDSADMIN	RDS	custom-oracle-ee custom-oracle-se2	
C##RDSADMIN	RDS	custom-oracle-ee-cdb custom-oracle-se2-cdb	User names with a C## prefix exist only in CDBs. For more information about CDBs, see Overview of Amazon RDS Custom for Oracle architecture.
RDS_DATAGUARD	RDS	custom-oracle-ee	This user exists only in read replicas, source databases for read replicas, and databases that you have physically

Database user	Created by	Supported engine versions	Notes
			migrated into RDS Custom using Oracle Data Guard.
C##RDS_DATAGUARD	RDS	custom-oracle-ee-cdb	This user exists only in read replicas, source databases for read replicas, and databases that you have physically migrated into RDS Custom using Oracle Data Guard. User names with a C## prefix exist only in CDBs. For more information about CDBs, see Overview of Amazon RDS Custom for Oracle architecture.

An exception to the automatic credential rotation is an RDS Custom for Oracle DB instance that you have manually configured as a standby database. RDS only rotates credentials for read replicas that you have created using the `create-db-instance-read-replica` CLI command or `CreateDBInstanceReadReplica` API.

Guidelines for rotating user credentials

To make sure that your credentials rotate according to your compliance program, note the following guidelines:

- If your DB instance rotates credentials automatically, don't manually change or delete a secret, password file, or password for users listed in Predefined Oracle users. Otherwise, RDS Custom might place your DB instance outside of the support perimeter, which suspends automatic rotation.
- The RDS master user is not predefined, so you are responsible for either changing the password manually or setting up automatic rotation in Secrets Manager. For more information, see Rotate AWS Secrets Manager secrets.

Rotating user credentials manually

For the following categories of databases, RDS doesn't automatically rotate the credentials for the users listed in Predefined Oracle users:

- A database that you configured manually to function as a standby database.
- An on-premises database.
- A DB instance that is outside of the support perimeter or in a state in which the RDS Custom automation can't run. In this case, RDS Custom also doesn't rotate keys.

If your database is in any of the preceding categories, you must rotate your user credentials manually.

To rotate user credentials manually for a DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In **Databases**, make sure that RDS isn't currently backing up your DB instance or performing operations such configuring high availability.
3. In the database details page, choose **Configuration** and note the Resource ID for the DB instance. Or you can use the AWS CLI command `describe-db-instances`.
4. Open the Secrets Manager console at https://console.aws.amazon.com/secretsmanager/.
5. In the search box, enter your DB Resource ID and find the secret in the following form:

   ```
   do-not-delete-rds-custom-db-resource-id-numeric-string
   ```

   This secret stores the password for `RDSADMIN`, `SYS`, and `SYSTEM`. The following sample key is for the DB instance with the DB resource ID `db-ABCDEFG12HIJKLNMNOPQRS3TUVWX`:

   ```
   do-not-delete-rds-custom-db-ABCDEFG12HIJKLNMNOPQRS3TUVWX-123456
   ```

   Important

   If your DB instance is a read replica and uses the `custom-oracle-ee-cdb` engine, two secrets exist with the suffix *db-resource-id-numeric-string*, one for the

master user and the other for RDSADMIN, SYS, and SYSTEM. To find the correct secret, run the following command on the host:

```
cat /opt/aws/rdscustomagent/config/database_metadata.json | python3 -c
 "import sys,json; print(json.load(sys.stdin)['dbMonitoringUserPassword'])"
```

The dbMonitoringUserPassword attribute indicates the secret for RDSADMIN, SYS, and SYSTEM.

6. If your DB instance exists in an Oracle Data Guard configuration, find the secret in the following form:

   ```
   do-not-delete-rds-custom-db-resource-id-numeric-string-dg
   ```

   This secret stores the password for RDS_DATAGUARD. The following sample key is for the DB instance with the DB resource ID db-ABCDEFG12HIJKLNMNOPQRS3TUVWX:

   ```
   do-not-delete-rds-custom-db-ABCDEFG12HIJKLNMNOPQRS3TUVWX-789012-dg
   ```

7. For all database users listed in Predefined Oracle users, update the passwords by following the instructions in Modify an AWS Secrets Manager secret.

8. If your database is a standalone database or a source database in an Oracle Data Guard configuration:

   a. Start your Oracle SQL client and log in as SYS.

   b. Run a SQL statement in the following form for each database user listed in Predefined Oracle users:

      ```
      ALTER USER user-name IDENTIFIED BY pwd-from-secrets-manager ACCOUNT UNLOCK;
      ```

      For example, if the new password for RDSADMIN stored in Secrets Manager is pwd-123, run the following statement:

      ```
      ALTER USER RDSADMIN IDENTIFIED BY pwd-123 ACCOUNT UNLOCK;
      ```

9. If your DB instance runs Oracle Database 12c Release 1 (12.1) and is managed by Oracle Data Guard, manually copy the password file (orapw) from the primary DB instance to each standby DB instance.

If your DB instance is hosted in Amazon RDS, the password file location is `/rdsdbdata/config/orapw`. For databases that aren't hosted in Amazon RDS, the default location is `$ORACLE_HOME/dbs/orapw$ORACLE_SID` on Linux and UNIX and `%ORACLE_HOME%\database\PWD%ORACLE_SID%.ora` on Windows.

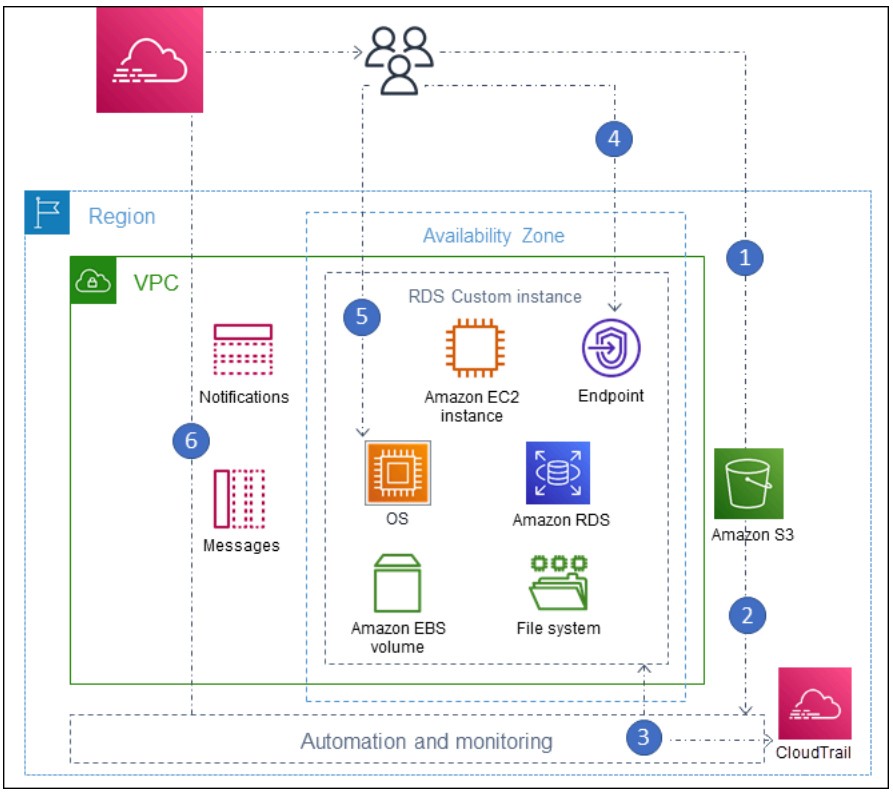
Working with RDS Custom for Oracle

Following, you can find instructions for creating, managing, and maintaining your RDS Custom for Oracle DB instances.

Topics

RDS Custom for Oracle workflow

The following diagram shows the typical workflow for RDS Custom for Oracle.



The steps are as follows:

1. Upload your database software to your Amazon S3 bucket.

   For more information, see Step 3: Upload your installation files to Amazon S3.

2. Create an RDS Custom for Oracle custom engine version (CEV) from your media.

   Choose either the CDB architecture or the traditional non-CDB architecture. For more information, see Creating a CEV.

3. Create an RDS Custom for Oracle DB instance from a CEV.

   For more information, see Creating an RDS Custom for Oracle DB instance.

4. Connect your application to the DB instance endpoint.

   For more information, see Connecting to your RDS Custom DB instance using SSH and Connecting to your RDS Custom DB instance using Session Manager.

5. (Optional) Access the host to customize your software.

6. Monitor notifications and messages generated by RDS Custom automation.

Database installation files

Your responsibility for media is a key difference between Amazon RDS and RDS Custom. Amazon RDS, which is a fully managed service, supplies the Amazon Machine Image (AMI) and database software. The Amazon RDS database software is preinstalled, so you need only choose a database engine and version, and create your database.

For RDS Custom, you supply your own media. When you create a custom engine version, RDS Custom installs the media that you provide. RDS Custom media contains your database installation files and patches. This service model is called *Bring Your Own Media (BYOM)*.

Custom engine versions for RDS Custom for Oracle

An *RDS Custom for Oracle custom engine version* (CEV) is a binary volume snapshot of a database version and AMI. By default, RDS Custom for Oracle uses the most recent AMI that Amazon EC2 makes available. You can also choose to reuse an existing AMI.

CEV manifest

After you download Oracle database installation files from Oracle, you upload them to an Amazon S3 bucket. When you create your CEV, you specify the file names in a JSON document called a *CEV manifest*. RDS Custom for Oracle uses the specified files and the AMI to create your CEV.

RDS Custom for Oracle provides JSON manifest templates with our recommended .zip files for each supported Oracle Database release. For example, the following template is for the 19.17.0.0.0 RU.

```
{
    "mediaImportTemplateVersion": "2020-08-14",
    "databaseInstallationFileNames": [
        "V982063-01.zip"
    ],
    "opatchFileNames": [
        "p6880880_190000_Linux-x86-64.zip"
    ],
    "psuRuPatchFileNames": [
        "p34419443_190000_Linux-x86-64.zip",
        "p34411846_190000_Linux-x86-64.zip"
    ],
    "otherPatchFileNames": [
        "p28852325_190000_Linux-x86-64.zip",
```

```
        "p29997937_190000_Linux-x86-64.zip",
        "p31335037_190000_Linux-x86-64.zip",
        "p32327201_190000_Linux-x86-64.zip",
        "p33613829_190000_Linux-x86-64.zip",
        "p34006614_190000_Linux-x86-64.zip",
        "p34533061_190000_Linux-x86-64.zip",
        "p34533150_190000_Generic.zip",
        "p28730253_190000_Linux-x86-64.zip",
        "p29213893_1917000DBRU_Generic.zip",
        "p33125873_1917000DBRU_Linux-x86-64.zip",
        "p34446152_1917000DBRU_Linux-x86-64.zip"
    ]
}
```

You can also specify installation parameters in the JSON manifest. For example, you can set nondefault values for the Oracle base, Oracle home, and the ID and name of the UNIX/Linux user and group. For more information, see JSON fields in the CEV manifest.

CEV naming format

Name your RDS Custom for Oracle CEV using a customer-specified string. The name format is the following, depending on your Oracle Database release:

- `19.`*`customized_string`*
- `18.`*`customized_string`*
- `12.2.`*`customized_string`*
- `12.1.`*`customized_string`*

You can use 1–50 alphanumeric characters, underscores, dashes, and periods. For example, you might name your CEV `19.my_cev1`.

Oracle multitenant architecture in RDS Custom for Oracle

The Oracle multitenant architecture enables an Oracle database to function as a container database (CDB). A CDB includes zero, one, or many customer-created pluggable databases (PDBs). A PDB is a portable collection of schemas and objects that appears to an application as a traditional non-CDB. Starting in Oracle Database 21c, all Oracle databases are CDBs.

When you create an RDS Custom for Oracle CEV, you specify the either the CDB or non-CDB architecture. You can create an RDS Custom for Oracle CDB only when the CEV that you used to

create it uses the Oracle multitenant architecture. For more information, see Working with custom engine versions for Amazon RDS Custom for Oracle.

Creating a DB instance for RDS Custom for Oracle

After you create your CEV, it's available for use. You can create multiple CEVs, and you can create multiple RDS Custom for Oracle DB instances from any CEV. You can also change the status of a CEV to make it available or inactive.

You can either create your RDS Custom for Oracle DB instance with the Oracle multitenant architecture (`custom-oracle-ee-cdb` or `custom-oracle-se2-cdb` engine type) or with the traditional non-CDB architecture (`custom-oracle-ee` or `custom-oracle-se2` engine type). When you create a container database (CDB), it contains one pluggable database (PDB) and one PDB seed. You can create additional PDBs manually using Oracle SQL.

To create your RDS Custom for Oracle DB instance, use the `create-db-instance` command. In this command, specify which CEV to use. The procedure is similar to creating an Amazon RDS DB instance. However, some parameters are different. For more information, see Configuring a DB instance for Amazon RDS Custom for Oracle.

Database connection

Like an Amazon RDS DB instance, an RDS Custom DB instance resides in a virtual private cloud (VPC). Your application connects to the Oracle database using an Oracle listener.

If your database is a CDB, you can use the listener `L_RDSCDB_001` to connect to the CDB root and to a PDB. If you plug a non-CDB into a CDB, make sure to set `USE_SID_AS_SERVICE_LISTENER = ON` so that migrated applications keep the same settings.

When you connect to a non-CDB, the master user is the user for the non-CDB. When you connect to a CDB, the master user is the user for the PDB. To connect to the CDB root, log in to the host, start a SQL client, and create an administrative user with SQL commands.

RDS Custom customization

You can access the RDS Custom host to install or customize software. To avoid conflicts between your changes and the RDS Custom automation, you can pause the automation for a specified period. During this period, RDS Custom doesn't perform monitoring or instance recovery. At the end of the period, RDS Custom resumes full automation. For more information, see Pausing and resuming your RDS Custom DB instance.

Database architecture for Amazon RDS Custom for Oracle

RDS Custom for Oracle supports both the Oracle multitenant and non-multitenant architecture.

Topics

Supported Oracle database architectures

The *Oracle multitenant architecture*, also called the *CDB architecture*, allows an Oracle database to function as a container database (CDB). A CDB includes pluggable databases (PDBs). A PDB is a collection of schemas and objects that appears to an application as a traditional Oracle database. For more information, see Introduction to the Multitenant Architecture in the *Oracle Multitenant Administrator's Guide*.

The CDB and non-CDB architectures are mutually exclusive. If an Oracle database isn't a CDB, it's a non-CDB and so can't contain PDBs. In RDS Custom for Oracle, only Oracle Database 19c supports the CDB architecture. Thus, if you create DB instances using previous Oracle database releases, you can create only non-CDBs. For more information, see Multitenant architecture considerations.

Supported engine types

When you create an Amazon RDS Custom for Oracle CEV or DB instance, choose either a CDB engine type or a non-CDB engine type:

- `custom-oracle-ee-cdb` and `custom-oracle-se2-cdb`

  These engine types specify the Oracle multitenant architecture. This option is available only for Oracle Database 19c. When you create an RDS for Oracle DB instance using the multitenant architecture, your CDB includes the following containers:

  - CDB root (`CDB$ROOT`)
  - PDB seed (`PDB$SEED`)
  - Initial PDB

  You can create more PDBs using the Oracle SQL command `CREATE PLUGGABLE DATABASE`. You can't use RDS APIs to create or delete PDBs.

- `custom-oracle-ee` and `custom-oracle-se2`

  These engine types specify the traditional non-CDB architecture. A non-CDB can't contain pluggable databases (PDBs).

For more information, see Multitenant architecture considerations.

Supported features in the Oracle multitenant architecture

An RDS Custom for Oracle CDB instance supports the following features:

- Backups
- Restoring and point-time-restore (PITR) from backups
- Read replicas
- Minor version upgrades

Feature availability and support for RDS Custom for Oracle

In this topic, you can find a summary of the RDS Custom for Oracle feature availability and support for quick reference.

Topics

AWS Region and database version support for RDS Custom for Oracle

Feature availability and support vary across specific versions of each database engine, and across AWS Regions. For more information on version and Region availability of RDS Custom for Oracle, see Supported Regions and DB engines for RDS Custom.

Database version support for RDS Custom for Oracle

RDS Custom for Oracle supports the following Oracle database versions:

- Oracle Database 19c
- Oracle Database 18c
- Oracle Database 12c Release 2 (12.2)
- Oracle Database 12c Release 1 (12.1)

Edition and licensing support for RDS Custom for Oracle

RDS Custom for Oracle supports Enterprise Edition (EE) and Standard Edition 2 (SE2) on the BYOL model.

Note the following limitations for Standard Edition 2:

- Oracle Data Guard isn't supported. Thus, you can't create Oracle read replicas.

- You can only use DB instance classes that have 16 or fewer vCPUs (up to 4xlarge).
- A CDB instance on Standard Edition 2 supports a maximum of 3 tenant databases.
- You can't migrate data between Enterprise Edition and Standard Edition 2.

DB instance class support for RDS Custom for Oracle

RDS Custom for Oracle supports the following DB instance classes. If you create a DB instance on Standard Edition 2, you can only use instance classes with 16 or fewer vCPUs (up to 4x large).

Type	Size
db.r6i	db.r6i.large |db.r6i.xlarge |db.r6i.2xlarge |db.r6i.4xlarge |db.r6i.8xlarge |db.r6i.12xlarge |db.r6i.16xlarge |db.r6i.24xlarge |db.r6i.32xlarge
db.r5b	db.r5b.large |db.r5b.xlarge |db.r5b.2xlarge |db.r5b.4xlarge |db.r5b.8xlarge |db.r5b.12xlarge |db.r5b.16xlarge |db.r5b.24xlarge
db.r5	db.r5.large |db.r5.xlarge |db.r5.2xlarge |db.r5.4xlarge | db.r5.8xlarge |db.r5.12xlarge |db.r5.16xlarge |db.r5.24xlarge
db.x2iec	db.x2iedn.xlarge |db.x2iedn.2xlarge |db.x2iedn.4xlarge | db.x2iedn.8xlarge |db.x2iedn.16xlarge |db.x2iedn.24xlarge | db.x2iedn.32xlarge
db.x2iez	db.x2iezn.2xlarge |db.x2iezn.4xlarge |db.x2iezn.6xlarge | db.x2iezn.8xlarge |db.x2iezn.12xlarge
db.m6i	db.m6i.large |db.m6i.xlarge |db.m6i.2xlarge |db.m6i.4xlarge |db.m6i.8xlarge |db.m6i.12xlarge |db.m6i.16xlarge |db.m6i.24xlarge |db.m6i.32xlarge
db.m5	db.m5.large |db.m5.xlarge |db.m5.2xlarge |db.m5.4xlarge | db.m5.8xlarge |db.m5.12xlarge |db.m5.16xlarge |db.m5.24xlarge
db.t3	db.t3.medium |db.t3.large |db.t3.xlarge |db.t3.2xlarge

Option group support for RDS Custom for Oracle

You can specify an option group when you create or modify an RDS Custom for Oracle DB instance. For more information, see Working with option groups in RDS Custom for Oracle.

RDS Custom for Oracle requirements and limitations

In this topic, you can find a summary of the Amazon RDS Custom for Oracle feature availability and requirements for quick reference.

Topics

General requirements for RDS Custom for Oracle

Make sure to meet the following requirements for Amazon RDS Custom for Oracle:

- You have access to My Oracle Support and Oracle Software Delivery Cloud to download the supported list of installation files and patches for RDS Custom for Oracle. If you use an unknown patch, custom engine version (CEV) creation fails. In this case, contact the RDS Custom support team and ask it to add the missing patch. For more information, see Step 2: Download your database installation files and patches from Oracle Software Delivery Cloud.
- You have access to Amazon S3. You need this service for the following reasons:
  - You upload your Oracle installation files to S3 buckets. You use the uploaded installation files to create your RDS Custom CEV.
  - RDS Custom for Oracle uses scripts downloaded from internally defined S3 buckets to perform actions on your DB instances. These scripts are necessary for onboarding and RDS Custom automation.
  - RDS Custom for Oracle uploads certain files to S3 buckets located in your customer account. These buckets use the following naming format: `do-not-delete-rds-custom-`*`account_id`*`-`*`region`*`-`*`six_character_alphanumeric_string`*. For example, you might have a bucket named `do-not-delete-rds-custom-123456789012-us-east-1-12a3b4`.

  For more information, see Step 3: Upload your installation files to Amazon S3 and Creating a CEV.

- You use the DB instance classes listed in DB instance class support for RDS Custom for Oracle to create your RDS Custom for Oracle DB instances.
- Your RDS Custom for Oracle DB instances run Oracle Linux 7 Update 9 or higher.
- You specify the gp2, gp3, or io1 solid state drives for Amazon EBS storage. The maximum storage size is 64 TiB.
- You have an AWS KMS key to create an RDS Custom for Oracle DB instance. For more information, see Step 1: Create or reuse a symmetric encryption AWS KMS key.
- You have the AWS Identity and Access Management (IAM) role and instance profile required for creating RDS Custom for Oracle DB instances. For more information, see Step 4: Configure IAM for RDS Custom for Oracle.
- The AWS Identity and Access Management (IAM) user that creates a CEV or RDS Custom DB instance has the required permissions for IAM, CloudTrail, and Amazon S3.

  For more information, see Step 5: Grant required permissions to your IAM user or role.
- You supply your own virtual private cloud (VPC) and security group configuration. For more information, see Step 6: Configure your VPC for RDS Custom for Oracle.
- You supply a networking configuration that RDS Custom for Oracle can use to access other AWS services. For specific requirements, see Step 4: Configure IAM for RDS Custom for Oracle.

General limitations for RDS Custom for Oracle

The following limitations apply to RDS Custom for Oracle:

- You can't modify the DB instance identifier of an existing RDS Custom for Oracle DB instance.
- You can specify the Oracle multitenant architecture for Oracle Database 19c only.
- You can't create multiple Oracle databases on a single RDS Custom for Oracle DB instance.
- You can’t stop your RDS Custom for Oracle DB instance or its underlying Amazon EC2 instance. Billing for an RDS Custom for Oracle DB instance can't be stopped.
- You can't use automatic shared memory management because RDS Custom for Oracle supports automatic memory management only. For more information, see Automatic Memory Management in the *Oracle Database Administrator’s Guide*.
- Make sure not to change the `DB_UNIQUE_NAME` for the primary DB instance. Changing the name causes any restore operation to become stuck.

For limitations specific to modifying an RDS Custom for Oracle DB instance, see Modifying your RDS Custom for Oracle DB instance. For replication limitations, see General limitations for RDS Custom for Oracle replication.

CEV and AMI limitations for RDS Custom for Oracle

The following limitations apply to RDS Custom for Oracle CEVs and AMIs:

- You can't provide your own AMI for use in an RDS Custom for Oracle CEV. You can specify either the default AMI or an AMI that has been previously used by an RDS Custom for Oracle CEV.

  > **Note**
  >
  > RDS Custom for Oracle releases a new default AMI when common vulnerabilities and exposures are discovered. No fixed schedule is available or guaranteed. RDS Custom for Oracle tends to publish a new default AMI every 30 days.

- You can't modify a CEV to use a different AMI.
- You can't create a CDB instance from a CEV that uses the `custom-oracle-ee` or `custom-oracle-se2` engine types. The CEV must use `custom-oracle-ee-cdb` or `custom-oracle-se2-cdb`.
- RDS Custom for Oracle doesn't currently allow you to upgrade the OS of your RDS Custom for Oracle DB instance with RDS API calls. As a workaround, you can update your OS manually with the following command: `sudo yum update --security`.

Unsupported settings for create and modify workflows

When you create or modify an RDS Custom for Oracle DB instance, you can't do the following:

- Change the number of CPU cores and threads per core on the DB instance class.
- Turn on storage autoscaling.
- Create a Multi-AZ deployment.

  > **Note**
  >
  > For an alternative HA solution, see the AWS blog article Build high availability for Amazon RDS Custom for Oracle using read replicas.

- Set backup retention to `0`.
- Configure Kerberos authentication.
- Specify your own DB parameter group or option group.
- Turn on Performance Insights.
- Turn on automatic minor version upgrade.

DB instance quotas for your AWS account

Make sure that the combined number of RDS Custom and Amazon RDS DB instances doesn't exceed your quota limit. For example, if your quota for Amazon RDS is 40 DB instances, you can have 20 RDS Custom for Oracle DB instances and 20 Amazon RDS DB instances.

Setting up your environment for Amazon RDS Custom for Oracle

Before you create an Amazon RDS Custom for Oracle DB instance, perform the following tasks.

Topics

Step 1: Create or reuse a symmetric encryption AWS KMS key

Customer managed keys are AWS KMS keys in your AWS account that you create, own, and manage. A customer managed symmetric encryption KMS key is required for RDS Custom. When you create an RDS Custom for Oracle DB instance, you supply the KMS key identifier. For more information, see Configuring a DB instance for Amazon RDS Custom for Oracle.

You have the following options:

- If you have an existing customer managed KMS key in your AWS account, you can use it with RDS Custom. No further action is necessary.
- If you already created a customer managed symmetric encryption KMS key for a different RDS Custom engine, you can reuse the same KMS key. No further action is necessary.
- If you don't have an existing customer managed symmetric encryption KMS key in your account, create a KMS key by following the instructions in Creating keys in the *AWS Key Management Service Developer Guide*.
- If you're creating a CEV or RDS Custom DB instance, and your KMS key is in a different AWS account, make sure to use the AWS CLI. You can't use the AWS console with cross-account KMS keys.

> **Important**
>
> RDS Custom doesn't support AWS managed KMS keys.

Make sure that your symmetric encryption key grants access to the `kms:Decrypt` and `kms:GenerateDataKey` operations to the AWS Identity and Access Management (IAM) role in your IAM instance profile. If you have a new symmetric encryption key in your account, no changes are required. Otherwise, make sure that your symmetric encryption key's policy grants access to these operations.

For more information, see Step 4: Configure IAM for RDS Custom for Oracle.

For more information about configuring IAM for RDS Custom for Oracle, see Step 4: Configure IAM for RDS Custom for Oracle.

Step 2: Download and install the AWS CLI

AWS provides you with a command-line interface to use RDS Custom features. You can use either version 1 or version 2 of the AWS CLI.

For information about downloading and installing the AWS CLI, see Installing or updating the latest version of the AWS CLI.

Skip this step if either of the following is true:

- You plan to access RDS Custom only from the AWS Management Console.
- You have already downloaded the AWS CLI for Amazon RDS or a different RDS Custom DB engine.

Step 3: Extract the CloudFormation templates for RDS Custom for Oracle

To simplify setup, we strongly recommend that you use AWS CloudFormation templates to create CloudFormation stacks. If you plan to configure IAM and your VPC manually, skip this step.

Topics

Step 3a: Download the CloudFormation template files

A *CloudFormation template* is a declaration of the AWS resources that make up a stack. The template is stored as a JSON file.

To download the CloudFormation template files

1. Open the context (right-click) menu for the link custom-oracle-iam.zip and choose **Save Link As**.
2. Save the file to your computer.
3. Repeat the previous steps for the link custom-vpc.zip.

   If you already configured your VPC for RDS Custom, skip this step.

Step 3b: Extract custom-oracle-iam.json

Open the `custom-oracle-iam.zip` file that you downloaded, and then extract the file `custom-oracle-iam.json`. The beginning of the file looks like the following.

```
{
  "AWSTemplateFormatVersion": "2010-09-09",
  "Parameters": {
    "EncryptionKey": {
      "Type": "String",
      "Default": "*",
      "Description": "KMS Key ARN for encryption of data managed by RDS Custom and by
 DB Instances."
    }
  },
  "Resources": {
    "RDSCustomInstanceServiceRole": {
      "Type": "AWS::IAM::Role",
      "Properties": {
        "RoleName": { "Fn::Sub": "AWSRDSCustomInstanceRole-${AWS::Region}" },
        "AssumeRolePolicyDocument": {
          "Version": "2012-10-17",
          "Statement": [
            {
              "Action": "sts:AssumeRole",
              "Effect": "Allow",
              "Principal": {
                "Service": "ec2.amazonaws.com"
              }
            }
          ]
        },...
```

Step 3c: Extract custom-vpc.json

> **Note**
>
> If you already configured an existing VPC for RDS Custom for Oracle, skip this step. For more information, see Configure your VPC manually for RDS Custom for Oracle.

Open the `custom-vpc.zip` file that you downloaded, and then extract the file `custom-vpc.json`. The beginning of the file looks like the following.

```
{
  "AWSTemplateFormatVersion": "2010-09-09",
  "Parameters": {
    "PrivateVpc": {
      "Type": "AWS::EC2::VPC::Id",
      "Description": "Private VPC Id to use for RDS Custom DB Instances"
    },
    "PrivateSubnets": {
      "Type": "List<AWS::EC2::Subnet::Id>",
      "Description": "Private Subnets to use for RDS Custom DB Instances"
    },
    "RouteTable": {
      "Type": "String",
      "Description": "Route Table that must be associated with the PrivateSubnets and
 used by S3 VPC Endpoint",
      "AllowedPattern": "rtb-[0-9a-z]+"
    }
  },
  "Resources": {
    "DBSubnetGroup": {
      "Type": "AWS::RDS::DBSubnetGroup",
      "Properties": {
        "DBSubnetGroupName": "rds-custom-private",
        "DBSubnetGroupDescription": "RDS Custom Private Network",
        "SubnetIds": {
          "Ref": "PrivateSubnets"
        }
      }
    },...
```

Step 4: Configure IAM for RDS Custom for Oracle

You use an IAM role or IAM user (known as an *IAM entity*) to create an RDS Custom DB instance using the console or AWS CLI. This IAM entity must have the necessary permissions for instance creation.

You can configure IAM using either CloudFormation or manual steps.

> **Important**
>
> We strongly recommend that you configure your RDS Custom for Oracle environment using AWS CloudFormation. This technique is the easiest and least error-prone.

Topics

- Configure IAM using CloudFormation
- Create your IAM role and instance profile manually

Configure IAM using CloudFormation

When you use the CloudFormation template for IAM, it creates the following required resources:

- An instance profile named `AWSRDSCustomInstanceProfile-`*`region`*
- A service role named `AWSRDSCustomInstanceRole-`*`region`*
- An access policy named `AWSRDSCustomIamRolePolicy` that is attached to the service role

To configure IAM using CloudFormation

1. Open the CloudFormation console at https://console.aws.amazon.com/cloudformation.
2. Start the Create Stack wizard, and choose **Create Stack**.
3. On the **Create stack** page, do the following:
   a. For **Prepare template**, choose **Template is ready**.
   b. For **Template source**, choose **Upload a template file**.
   c. For **Choose file**, navigate to, then choose **custom-oracle-iam.json**.
   d. Choose **Next**.

4. On the **Specify stack details** page, do the following:

   a. For **Stack name**, enter **`custom-oracle-iam`**.

   b. Choose **Next**.

5. On the **Configure stack options page**, choose **Next**.

6. On the **Review custom-oracle-iam** page, do the following:

   a. Select the **I acknowledge that AWS CloudFormation might create IAM resources with custom names** check box.

   b. Choose **Submit**.

   CloudFormation creates the IAM roles that RDS Custom for Oracle requires. In the left panel, when **custom-oracle-iam** shows **CREATE_COMPLETE**, proceed to the next step.

7. In the left panel, choose **custom-oracle-iam**. In the right panel, do the following:

   a. Choose **Stack info**. Your stack has an ID in the format **arn:aws:cloudformation:*region*:*account-no*:stack/custom-oracle-iam/*identifier***.

   b. Choose **Resources**. You should see the following:

      - An instance profile named **AWSRDSCustomInstanceProfile-*region***
      - A service role named **AWSRDSCustomInstanceRole-*region***

      When you create your RDS Custom DB instance, you need to supply the instance profile ID.

Create your IAM role and instance profile manually

Configuration is easiest when you use CloudFormation. However, you can also configure IAM manually. For manual setup, do the following:

- Step 1: Create the IAM role AWSRDSCustomInstanceRoleForRdsCustomInstance.
- Step 2: Add an access policy to AWSRDSCustomInstanceRoleForRdsCustomInstance.
- Step 2: Add an access policy to AWSRDSCustomInstanceRoleForRdsCustomInstance.
- Step 4: Add AWSRDSCustomInstanceRoleForRdsCustomInstance to AWSRDSCustomInstanceProfile.

Step 1: Create the IAM role AWSRDSCustomInstanceRoleForRdsCustomInstance

In this step, you create the role using the naming format `AWSRDSCustomInstanceRole-`*`region`*. Using the trust policy, Amazon EC2 can assume the role. The following example assumes that you have set the environment variable `$REGION` to the AWS Region in which you want to create your DB instance.

```
aws iam create-role \
  --role-name AWSRDSCustomInstanceRole-$REGION \
  --assume-role-policy-document '{
    "Version": "2012-10-17",
      "Statement": [
        {
          "Action": "sts:AssumeRole",
          "Effect": "Allow",
          "Principal": {
              "Service": "ec2.amazonaws.com"
          }
        }
      ]
    }'
```

Step 2: Add an access policy to AWSRDSCustomInstanceRoleForRdsCustomInstance

When you embed an inline policy in an IAM role, the inline policy is used as part of the role's access (permissions) policy. You create the `AWSRDSCustomIamRolePolicy` policy that permits Amazon EC2 to send and receive messages and perform various actions.

The following example creates the access policy named `AWSRDSCustomIamRolePolicy`, and adds it to the IAM role `AWSRDSCustomInstanceRole-`*`region`*. This example assumes that you have set the following environment variables:

`$REGION`

Set this variable to the AWS Region in which you plan to create your DB instance.

`$ACCOUNT_ID`

Set this variable to your AWS account number.

$KMS_KEY

Set this variable to the Amazon Resource Name (ARN) of the AWS KMS key that you want to use for your RDS Custom DB instances. To specify more than one KMS key, add it to the `Resources` section of statement ID (Sid) 11.

```
aws iam put-role-policy \
  --role-name AWSRDSCustomInstanceRole-$REGION \
  --policy-name AWSRDSCustomIamRolePolicy \
  --policy-document '{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "1",
            "Effect": "Allow",
            "Action": [
                "ssm:DescribeAssociation",
                "ssm:GetDeployablePatchSnapshotForInstance",
                "ssm:GetDocument",
                "ssm:DescribeDocument",
                "ssm:GetManifest",
                "ssm:GetParameter",
                "ssm:GetParameters",
                "ssm:ListAssociations",
                "ssm:ListInstanceAssociations",
                "ssm:PutInventory",
                "ssm:PutComplianceItems",
                "ssm:PutConfigurePackageResult",
                "ssm:UpdateAssociationStatus",
                "ssm:UpdateInstanceAssociationStatus",
                "ssm:UpdateInstanceInformation",
                "ssm:GetConnectionStatus",
                "ssm:DescribeInstanceInformation",
                "ssmmessages:CreateControlChannel",
                "ssmmessages:CreateDataChannel",
                "ssmmessages:OpenControlChannel",
                "ssmmessages:OpenDataChannel"
            ],
            "Resource": [
                "*"
            ]
        },
```

```
        {
            "Sid": "2",
            "Effect": "Allow",
            "Action": [
                "ec2messages:AcknowledgeMessage",
                "ec2messages:DeleteMessage",
                "ec2messages:FailMessage",
                "ec2messages:GetEndpoint",
                "ec2messages:GetMessages",
                "ec2messages:SendReply"
            ],
            "Resource": [
                "*"
            ]
        },
        {
            "Sid": "3",
            "Effect": "Allow",
            "Action": [
                "logs:PutRetentionPolicy",
                "logs:PutLogEvents",
                "logs:DescribeLogStreams",
                "logs:DescribeLogGroups",
                "logs:CreateLogStream",
                "logs:CreateLogGroup"
            ],
            "Resource": [
                "arn:aws:logs:'$REGION':'$ACCOUNT_ID':log-group:rds-custom-instance*"
            ]
        },
        {
            "Sid": "4",
            "Effect": "Allow",
            "Action": [
                "s3:putObject",
                "s3:getObject",
                "s3:getObjectVersion"
            ],
            "Resource": [
                "arn:aws:s3:::do-not-delete-rds-custom-*/*"
            ]
        },
        {
            "Sid": "5",
```

```
            "Effect": "Allow",
            "Action": [
                "cloudwatch:PutMetricData"
            ],
            "Resource": [
                "*"
            ],
            "Condition": {
                "StringEquals": {
                    "cloudwatch:namespace": [
                        "RDSCustomForOracle/Agent"
                    ]
                }
            }
        },
        {
            "Sid": "6",
            "Effect": "Allow",
            "Action": [
                "events:PutEvents"
            ],
            "Resource": [
                "*"
            ]
        },
        {
            "Sid": "7",
            "Effect": "Allow",
            "Action": [
                "secretsmanager:GetSecretValue",
                "secretsmanager:DescribeSecret"
            ],
            "Resource": [
                "arn:aws:secretsmanager:'$REGION':'$ACCOUNT_ID':secret:do-not-delete-
rds-custom-*"
            ]
        },
        {
           "Sid": "8",
           "Effect": "Allow",
           "Action": [
             "s3:ListBucketVersions"
           ],
           "Resource": [
```

```
            "arn:aws:s3:::do-not-delete-rds-custom-*"
          ]
        },
        {
           "Sid": "9",
           "Effect": "Allow",
           "Action": "ec2:CreateSnapshots",
           "Resource": [
               "arn:aws:ec2:*:*:instance/*",
               "arn:aws:ec2:*:*:volume/*"
           ],
           "Condition": {
               "StringEquals": {
                   "ec2:ResourceTag/AWSRDSCustom": "custom-oracle"
               }
           }
         },
         {
           "Sid": "10",
           "Effect": "Allow",
           "Action": "ec2:CreateSnapshots",
           "Resource": [
               "arn:aws:ec2:*::snapshot/*"
           ]
         },
         {
           "Sid": "11",
           "Effect": "Allow",
           "Action": [
             "kms:Decrypt",
             "kms:GenerateDataKey"
           ],
           "Resource": [
             "arn:aws:kms:'$REGION':'$ACCOUNT_ID':key/'$KMS_KEY'"
           ]
         },
         {
           "Sid": "12",
           "Effect": "Allow",
           "Action": "ec2:CreateTags",
           "Resource": "*",
           "Condition": {
               "StringLike": {
                   "ec2:CreateAction": [
```

```
                        "CreateSnapshots"
                    ]
                }
            }
        }
    ]
}'
```

Step 3: Create the RDS Custom instance profile AWSRDSCustomInstanceProfile

An instance profile is a container that includes a single IAM role. RDS Custom uses the instance profile to pass the role to the instance.

If you use the CLI to create a role, you create the role and instance profile as separate actions, with potentially different names. Create your IAM instance profile as follows, naming it using the format `AWSRDSCustomInstanceProfile-`*`region`*. The following example assumes that you have set the environment variable `$REGION` to the AWS Region in which you want to create your DB instance.

```
aws iam create-instance-profile \
    --instance-profile-name AWSRDSCustomInstanceProfile-$REGION
```

Step 4: Add AWSRDSCustomInstanceRoleForRdsCustomInstance to AWSRDSCustomInstanceProfile

Add your IAM role to the instance profile that you previously created. The following example assumes that you have set the environment variable `$REGION` to the AWS Region in which you want to create your DB instance.

```
aws iam add-role-to-instance-profile \
    --instance-profile-name AWSRDSCustomInstanceProfile-$REGION \
    --role-name AWSRDSCustomInstanceRole-$REGION
```

Step 5: Grant required permissions to your IAM user or role

Make sure that the IAM principal (user or role) that creates the CEV or RDS Custom DB instance has either of the following policies:

- The `AdministratorAccess` policy

- The `AmazonRDSFullAccess` policy with required permissions for Amazon S3 and AWS KMS, CEV creation, and DB instance creation

Topics

- IAM permissions required for Amazon S3 and AWS KMS
- IAM permissions required for creating a CEV
- IAM permissions required for creating a DB instance from a CEV

IAM permissions required for Amazon S3 and AWS KMS

To create CEVs or RDS Custom for Oracle DB instances, your IAM principal needs to access Amazon S3 and AWS KMS. The following sample JSON policy grants the required permissions.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "CreateS3Bucket",
            "Effect": "Allow",
            "Action": [
                "s3:CreateBucket",
                "s3:PutBucketPolicy",
                "s3:PutBucketObjectLockConfiguration",
                "s3:PutBucketVersioning"
            ],
            "Resource": "arn:aws:s3:::do-not-delete-rds-custom-*"
        },
        {
            "Sid": "CreateKmsGrant",
            "Effect": "Allow",
            "Action": [
                "kms:CreateGrant",
                "kms:DescribeKey"
            ],
            "Resource": "*"
        }
    ]
}
```

For more information about the `kms:CreateGrant` permission, see AWS KMS key management.

IAM permissions required for creating a CEV

To create a CEV, your IAM principal needs the following additional permissions:

```
s3:GetObjectAcl
s3:GetObject
s3:GetObjectTagging
s3:ListBucket
mediaimport:CreateDatabaseBinarySnapshot
```

The following sample JSON policy grants the additional permissions necessary to access bucket *my-custom-installation-files* and its contents.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AccessToS3MediaBucket",
            "Effect": "Allow",
            "Action": [
                "s3:GetObjectAcl",
                "s3:GetObject",
                "s3:GetObjectTagging",
                "s3:ListBucket"
            ],
            "Resource": [
                "arn:aws:s3:::my-custom-installation-files",
                "arn:aws:s3:::my-custom-installation-files/*"
            ]
        },
        {
            "Sid": "PermissionForByom",
            "Effect": "Allow",
            "Action": [
                "mediaimport:CreateDatabaseBinarySnapshot"
            ],
            "Resource": "*"
        }
    ]
}
```

You can grant similar permissions for Amazon S3 to caller accounts using an S3 bucket policy.

IAM permissions required for creating a DB instance from a CEV

To create an RDS Custom for Oracle DB instance from an existing CEV, the IAM principal needs the following additional permissions.

```
iam:SimulatePrincipalPolicy
cloudtrail:CreateTrail
cloudtrail:StartLogging
```

The following sample JSON policy grants the permissions necessary to validate an IAM role and log information to an AWS CloudTrail.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "ValidateIamRole",
            "Effect": "Allow",
            "Action": "iam:SimulatePrincipalPolicy",
            "Resource": "*"
        },
        {
            "Sid": "CreateCloudTrail",
            "Effect": "Allow",
            "Action": [
                "cloudtrail:CreateTrail",
                "cloudtrail:StartLogging"
            ],
            "Resource": "arn:aws:cloudtrail:*:*:trail/do-not-delete-rds-custom-*"
        }
    ]
}
```

Step 6: Configure your VPC for RDS Custom for Oracle

Your RDS Custom DB instance is in a virtual private cloud (VPC) based on the Amazon VPC service, just like an Amazon EC2 instance or Amazon RDS instance. You provide and configure your own VPC. Unlike RDS Custom for SQL Server, RDS Custom for Oracle doesn't create an access control list or security groups. You must attach you own security group, subnets, and route tables.

You can configure your virtual private cloud (VPC) using either CloudFormation or a manual process.

> **Important**
>
> We strongly recommend that you configure your RDS Custom for Oracle environment using AWS CloudFormation. This technique is the easiest and least error-prone.

Topics

- Configure your VPC using CloudFormation (recommended)
- Configure your VPC manually for RDS Custom for Oracle

Configure your VPC using CloudFormation (recommended)

If you've already configured your VPC for a different RDS Custom engine, and want to reuse the existing VPC, skip this step. This section assumes the following:

- You've already used CloudFormation to create your IAM instance profile and role.
- You know your route table ID.

  For a DB instance to be private, it must be in a private subnet. For a subnet to be private, it must not be associated with a route table that has a default internet gateway. For more information, see Configure route tables in the *Amazon VPC User Guide*.

When you use the CloudFormation template for your VPC, it creates the following resources:

- A private VPC
- A subnet group named `rds-custom-private`
- The following VPC endpoints, which your DB instance uses to communicate with dependent AWS services:
  - `com.amazonaws.region.ec2messages`
  - `com.amazonaws.region.events`
  - `com.amazonaws.region.logs`
  - `com.amazonaws.region.monitoring`
  - `com.amazonaws.region.s3`
  - `com.amazonaws.region.secretsmanager`
  - `com.amazonaws.region.ssm`

- `com.amazonaws.region.ssmmessages`

> **Note**
>
> For a complex networking setup with existing accounts, we recommend that you configure access to dependent services manually if access doesn't already exist. For more information, see Make sure your VPC can access dependent AWS services.

To configure your VPC using CloudFormation

1. Open the CloudFormation console at https://console.aws.amazon.com/cloudformation.
2. Start the Create Stack wizard, and choose **Create Stack** and then **With new resources (standard)**.
3. On the **Create stack** page, do the following:
   a. For **Prepare template**, choose **Template is ready**.
   b. For **Template source**, choose **Upload a template file**.
   c. For **Choose file**, navigate to, then choose `custom-vpc.json`.
   d. Choose **Next**.
4. On the **Specify stack details** page, do the following:
   a. For **Stack name**, enter **`custom-vpc`**.
   b. For **Parameters**, choose the private subnets to use for RDS Custom DB instances.
   c. Choose the private VPC ID to use for RDS Custom DB instances.
   d. Enter the route table associated with the private subnets.
   e. Choose **Next**.
5. On the **Configure stack options page**, choose **Next**.
6. On the **Review custom-vpc** page, choose **Submit**.

   CloudFormation configures your private VPC. In the left panel, when **custom-vpc** shows **CREATE_COMPLETE**, proceed to the next step.
7. (Optional) Review the details of your VPC. In the **Stacks** pane, choose **custom-vpc**. In the right pane, do the following:

a. Choose **Stack info**. Your stack has an ID in the format **arn:aws:cloudformation:*region*:*account-no*:stack/custom-vpc/*identifier***.

b. Choose **Resources**. You should see a subnet group named **rds-custom-private** and several VPC endpoints that use the naming format **vpce-*string***. Each endpoint corresponds to an AWS service that RDS Custom needs to communicate with. For more information, see Make sure your VPC can access dependent AWS services.

c. Choose **Parameters**. You should see the private subnets, private VPC, and the route table that you specified when you created the stack. When you create a DB instance, you need to supply the VPC ID and subnet group.

Configure your VPC manually for RDS Custom for Oracle

As an alternative to automating VPC creation with AWS CloudFormation, you can configure your VPC manually. This option might be best when you have a complex networking setup that uses existing resources.

Topics

- Make sure your VPC can access dependent AWS services
- Configure the instance metadata service

Make sure your VPC can access dependent AWS services

RDS Custom sends communication from your DB instance to other AWS services. Make sure the following services are accessible from the subnet in which you create your RDS Custom DB instances:

- Amazon CloudWatch
- Amazon CloudWatch Logs
- Amazon CloudWatch Events
- Amazon EC2
- Amazon EventBridge
- Amazon S3
- AWS Secrets Manager
- AWS Systems Manager

If creating Multi-AZ deployments

- Amazon Simple Queue Service

If RDS Custom can't communicate with the necessary services, it publishes the following events:

```
Database instance in incompatible-network. SSM Agent connection not available. Amazon
 RDS can't connect to the dependent AWS services.
```

```
Database instance in incompatible-network. Amazon RDS can't connect to dependent AWS
 services. Make sure port 443 (HTTPS) allows outbound connections, and try again.
 "Failed to connect to the following services: s3 events"
```

To avoid `incompatible-network` errors, make sure that VPC components involved in communication between your RDS Custom DB instance and AWS services satisfy the following requirements:

- The DB instance can make outbound connections on port 443 to other AWS services.
- The VPC allows incoming responses to requests originating from your RDS Custom DB instance.
- RDS Custom can correctly resolve the domain names of endpoints for each AWS service.

If you already configured a VPC for a different RDS Custom DB engine, you can reuse that VPC and skip this process.

Configure the instance metadata service

Make sure that your instance can do the following:

- Access the instance metadata service using Instance Metadata Service Version 2 (IMDSv2).
- Allow outbound communications through port 80 (HTTP) to the IMDS link IP address.
- Request instance metadata from `http://169.254.169.254`, the IMDSv2 link.

For more information, see Use IMDSv2 in the *Amazon EC2 User Guide*.

RDS Custom for Oracle automation uses IMDSv2 by default, by setting `HttpTokens=enabled` on the underlying Amazon EC2 instance. However, you can use IMDSv1 if you want. For more information, see Configure the instance metadata options in the *Amazon EC2 User Guide*.

Working with custom engine versions for Amazon RDS Custom for Oracle

A *custom engine version (CEV)* for Amazon RDS Custom for Oracle is a binary volume snapshot of a database engine and specific Amazon Machine Image (AMI). By default, RDS Custom for Oracle uses the latest available AMI managed by RDS Custom, but you can specify an AMI that was used in a previous CEV. You store your database installation files in Amazon S3. RDS Custom uses the installation files and the AMI to create your CEV for you.

Topics

Preparing to create a CEV

To create a CEV, access the installation files and patches that are stored in your Amazon S3 bucket for any of the following releases:

- Oracle Database 19c
- Oracle Database 18c
- Oracle Database 12c Release 2 (12.2)
- Oracle Database 12c Release 1 (12.1)

For example, you can use the April 2021 RU/RUR for Oracle Database 19c, or any valid combination of installation files and patches. For more information on the versions and Regions supported by RDS Custom for Oracle, see RDS Custom with RDS for Oracle.

Topics

- Step 4 (Optional): Share your installation media in S3 across AWS accounts
- Step 5: Prepare the CEV manifest
- Step 6 (Optional): Validate the CEV manifest
- Step 7: Add necessary IAM permissions

Step 1 (Optional): Download the manifest templates

A *CEV manifest* is a JSON document that includes the list of database installation .zip files for your CEV. To create a CEV, do the following:

1. Identify the Oracle database installation files that you want to include in your CEV.
2. Download the installation files.
3. Create a JSON manifest that lists the installation files.

RDS Custom for Oracle provides JSON manifest templates with our recommended .zip files for each supported Oracle Database release. For example, the following template is for the 19.17.0.0.0 RU.

```
{
    "mediaImportTemplateVersion": "2020-08-14",
    "databaseInstallationFileNames": [
        "V982063-01.zip"
    ],
    "opatchFileNames": [
        "p6880880_190000_Linux-x86-64.zip"
    ],
    "psuRuPatchFileNames": [
        "p34419443_190000_Linux-x86-64.zip",
        "p34411846_190000_Linux-x86-64.zip"
    ],
    "otherPatchFileNames": [
        "p28852325_190000_Linux-x86-64.zip",
        "p29997937_190000_Linux-x86-64.zip",
        "p31335037_190000_Linux-x86-64.zip",
        "p32327201_190000_Linux-x86-64.zip",
        "p33613829_190000_Linux-x86-64.zip",
        "p34006614_190000_Linux-x86-64.zip",
        "p34533061_190000_Linux-x86-64.zip",
        "p34533150_190000_Generic.zip",
```

```
        "p28730253_190000_Linux-x86-64.zip",
        "p29213893_1917000DBRU_Generic.zip",
        "p33125873_1917000DBRU_Linux-x86-64.zip",
        "p34446152_1917000DBRU_Linux-x86-64.zip"
    ]
}
```

Each template has an associated readme that includes instructions for downloading the patches, URLs for the .zip files, and file checksums. You can use these templates as they are or modify them with your own patches. To review the templates, download custom-oracle-manifest.zip to your local disk and then open it with a file archiving application. For more information, see Step 5: Prepare the CEV manifest.

Step 2: Download your database installation files and patches from Oracle Software Delivery Cloud

When you have identified the installation files that you want for your CEV, download them to your local system. The Oracle Database installation files and patches are hosted on Oracle Software Delivery Cloud. Each CEV requires a base release, such as Oracle Database 19c or Oracle Database 12c Release 2 (12.2), and an optional list of patches.

To download the database installation files for Oracle Database

1. Go to https://edelivery.oracle.com/ and sign in.
2. In the search box, enter **`Oracle Database Enterprise Edition`** or **`Oracle Database Standard Edition 2`** and choose **Search**.
3. Choose one of the following base releases:

Database version	Enterprise Edition	Standard Edition 2
Oracle Database 19c	**DLP: Oracle Database 19c Enterprise Edition 19.3.0.0.0 (Oracle Database Enterprise Edition)**	**DLP: Oracle Database 19c Standard Edition 2 19.3.0.0.0 (Oracle Database Standard Edition 2)**
Oracle Database 18c	**DLP: Oracle Database 18c Enterprise Edition 18.0.0.0.0 (Oracle Database Enterprise Edition)**	**DLP: Oracle Database Standard Edition 2 18.0.0.0.0 (Oracle Database Standard Edition 2)**

Database version	Enterprise Edition	Standard Edition 2
Oracle Database 12c Release 2 (12.2.0.1)	**DLP: Oracle Database 12c Enterprise Edition 12.2.0.1.0 (Oracle Database Enterprise Edition)**	**DLP: Oracle Database Standard Edition 2 12.2.0.1.0 (Oracle Database Standard Edition 2)**
Oracle Database 12c Release 1 (12.1.0.2)	**DLP: Oracle Database 12c Enterprise Edition 12.1.0.2.0 (Oracle Database Enterprise Edition)**	**DLP: Oracle Database Standard Edition 2 12.1.0.2.0 (Oracle Database Standard Edition 2)**

4. Choose **Continue**.
5. Clear the **Download Queue** check box.
6. Choose the option that corresponds to your base release:
   - **Oracle Database 19.3.0.0.0 - Long Term Release**.
   - **Oracle Database 18.0.0.0.0**
   - **Oracle Database 12.2.0.1.0**.
   - **Oracle Database 12.1.0.2.0**.
7. Choose **Linux x86-64** in **Platform/Languages**.
8. Choose **Continue**, and then sign the Oracle License Agreement.
9. Choose the .zip file that corresponds to your database release:

Database release and edition	Zip files	SHA-256 hash
19c EE and SE2	**V982063-01.zip**	`BA8329C757133DA313ED3B6D7F86C5AC42CD9970A28BF2E6233F3235233AA8D8`
18c EE and SE2	**V978967-01.zip**	`C96A4FD768787AF98272008833FE10B172691CF84E42816B138C12D4DE63AB96`

Database release and edition	Zip files	SHA-256 hash
12.2.0.1 EE and SE2	**V839960-01.zip**	96ED97D21F15C1AC0CCE3749DA6C3DAC7059BB60672D76B008103FC754D22DDE
12.1.0.2 EE	**V46095-01_1of2.zip** **V46095-01_2of2.zip**	31FDC2AF41687B4E547A3A18F796424D8C1AF36406D2160F65B0AF6A9CD47355 for V46095-01_1of2.zip 03DA14F5E875304B28F0F3BB02AF0EC33227885B99C9865DF70749D1E220ACCD for V46095-01_2of2.zip
12.1.0.2 SE2	**V77388-01_1of2.zip** **V77388-01_2of2.zip**	73873369753230F5A0921F95ACEADB591388CB06ED72A7F3AEA7BCBCEA2403BC for V77388-01_1of2.zip 2492E1BE1E3E3531DA83D0843C09C08E435AC8CEFD9A00C0DF56BE4F15CEEBF3 for V77388-01_2of2.zip

10. Download your desired Oracle patches from `updates.oracle.com` or `support.oracle.com` to your local system. You can find the URLs for the patches in the following locations:

    - The readme files in the .zip file that you downloaded in Step 1 (Optional): Download the manifest templates
    - The patches listed in each Release Update (RU) in Release notes for Amazon Relational Database Service (Amazon RDS) for Oracle

Step 3: Upload your installation files to Amazon S3

Upload your Oracle installation and patch files to Amazon S3 using the AWS CLI. The S3 bucket that contains your installation files must be in the same AWS Region as your CEV.

Examples in this section use the following placeholders:

- *install-or-patch-file.zip* – Oracle installation media file. For example, p32126828_190000_Linux-x86-64.zip is a patch.
- *amzn-s3-demo-destination-bucket* – Your Amazon S3 bucket designated for your uploaded installation files.
- *123456789012/cev1* – An optional prefix in your Amazon S3 bucket.
- *amzn-s3-demo-source-bucket* – An Amazon S3 bucket where you can optionally stage files.

Topics

Step 3a: Verify that your S3 bucket is in the correct AWS Region

Verify that your S3 bucket is in the AWS Region where you plan to run the `create-custom-db-engine-version` command.

```
aws s3api get-bucket-location --bucket amzn-s3-demo-destination-bucket
```

Step 3b: Make sure that your S3 bucket policy has the correct permissions

You can create a CEV from scratch or from a source CEV. If you plan to create new CEV from source CEVs, make sure that your S3 bucket policy has the correct permissions:

1. Identify the S3 bucket reserved by RDS Custom. The bucket name has the format `do-not-delete-rds-custom-account-region-string`. For example, the bucket might be named `do-not-delete-rds-custom-123456789012-us-east-1-abc123EXAMPLE`.
2. Make sure that the following permission is appended to your S3 bucket policy. Replace `do-not-delete-rds-custom-123456789012-us-east-1-abc123EXAMPLE` with the name of your bucket.

```
{
    "Sid": "AWSRDSCustomForOracleCustomEngineVersionGetObject",
```

```
    "Effect": "Allow",
    "Principal": {
        "Service": "custom.rds.amazonaws.com"
    },
    "Action": [
        "s3:GetObject",
        "s3:GetObjectTagging"
    ],
    "Resource": "arn:aws:s3:::do-not-delete-rds-custom-123456789012-us-
east-1-abc123EXAMPLE/CustomEngineVersions/*"
}, ...
```

Step 3c: Upload your files using the cp or sync commands

Choose either of the following options:

- Use `aws s3 cp` to upload a single .zip file.

  Upload each installation .zip file separately. Don't combine the .zip files into a single .zip file.
- Use `aws s3 sync` to upload a directory.

Example

The following example uploads *install-or-patch-file.zip* to the *123456789012/cev1* folder in the RDS Custom Amazon S3 bucket. Run a separate `aws s3` command for each .zip that you want to upload.

For Linux, macOS, or Unix:

```
aws s3 cp install-or-patch-file.zip \
    s3://amzn-s3-demo-destination-bucket/123456789012/cev1/
```

For Windows:

```
aws s3 cp install-or-patch-file.zip ^
    s3://amzn-s3-demo-destination-bucket/123456789012/cev1/
```

Example

The following example uploads the files in your local *cev1* folder to the *123456789012/cev1* folder in your Amazon S3 bucket.

For Linux, macOS, or Unix:

```
aws s3 sync cev1 \
    s3://amzn-s3-demo-destination-bucket/123456789012/cev1/
```

For Windows:

```
aws s3 sync cev1 ^
    s3://amzn-s3-demo-destination-bucket/123456789012/cev1/
```

Example

The following example uploads all files in *amzn-s3-demo-source-bucket* to the *123456789012/cev1* folder in your Amazon S3 bucket.

For Linux, macOS, or Unix:

```
aws s3 sync s3://amzn-s3-demo-source-bucket/ \
    s3://amzn-s3-demo-destination-bucket/123456789012/cev1/
```

For Windows:

```
aws s3 sync s3://amzn-s3-demo-source-bucket/ ^
    s3://amzn-s3-demo-destination-bucket/123456789012/cev1/
```

Step 3d: List the files in your S3 bucket

The following example uses the `s3 ls` command to list the files in your RDS Custom Amazon S3 bucket.

```
aws s3 ls \
    s3://amzn-s3-demo-destination-bucket/123456789012/cev1/
```

Step 4 (Optional): Share your installation media in S3 across AWS accounts

For the purposes of this section, the Amazon S3 bucket that contains your uploaded Oracle installation files is your *media bucket*. Your organization might use multiple AWS accounts in an AWS Region. If so, you might want to use one AWS account to populate your media bucket and a different AWS account to create CEVs. If you don't intend to share your media bucket, skip to the next section.

This section assumes the following:

- You can access the account that created your media bucket and a different account in which you intend to create CEVs.
- You intend to create CEVs in only one AWS Region. If you intend to use multiple Regions, create a media bucket in each Region.
- You're using the CLI. If you're using the Amazon S3 console, adapt the following steps.

To configure your media bucket for sharing across AWS accounts

1. Log in to the AWS account that contains the S3 bucket into which you uploaded your installation media.
2. Start with either a blank JSON policy template or an existing policy that you can adapt.

   The following command retrieves an existing policy and saves it as *`my-policy.json`*. In this example, the S3 bucket containing your installation files is named *`amzn-s3-demo-bucket`*.

   ```
   aws s3api get-bucket-policy \
       --bucket amzn-s3-demo-bucket \
       --query Policy \
       --output text > my-policy.json
   ```

3. Edit the media bucket permissions as follows:

   - In the `Resource` element of your template, specify the S3 bucket into which you uploaded your Oracle Database installation files.
   - In the `Principal` element, specify the ARNs for all AWS accounts that you intend to use to create CEVs. You can add the root, a user, or a role to the S3 bucket allow list. For more information, see IAM identifiers in the *AWS Identity and Access Management User Guide*.

```
{
    "Version": "2008-10-17",
    "Statement": [
        {
            "Sid": "GrantAccountsAccess",
            "Effect": "Allow",
            "Principal": {
                "AWS": [
                    "arn:aws:iam::account-1:root",
                    "arn:aws:iam::account-2:user/user-name-with-path",
                    "arn:aws:iam::account-3:role/role-name-with-path",
                    ...
                ]
            },
            "Action": [
                "s3:GetObject",
                "s3:GetObjectAcl",
                "s3:GetObjectTagging",
                "s3:ListBucket",
                "s3:GetBucketLocation"
            ],
            "Resource": [
                "arn:aws:s3:::amzn-s3-demo-bucket",
                "arn:aws:s3:::amzn-s3-demo-bucket/*"
            ]
        }
    ]
}
```

4. Attach the policy to your media bucket.

   In the following example, *amzn-s3-demo-bucket* is the name of the S3 bucket that contains your installation files, and *my-policy.json* is the name of your JSON file.

```
aws s3api put-bucket-policy \
    --bucket amzn-s3-demo-bucket \
    --policy file://my-policy.json
```

5. Log in to an AWS account in which you intend to create CEVs.
6. Verify that this account can access the media bucket in the AWS account that created it.

```
aws s3 ls --query "Buckets[].Name"
```

For more information, see aws s3 ls in the *AWS CLI Command Reference*.

7. Create a CEV by following the steps in Creating a CEV.

Step 5: Prepare the CEV manifest

A CEV manifest is a JSON document that includes the following:

- (Required) The list of installation .zip files that you uploaded to Amazon S3. RDS Custom applies the patches in the order in which they're listed in the manifest.
- (Optional) Installation parameters that set nondefault values for the Oracle base, Oracle home, and the ID and name of the UNIX/Linux user and group. Be aware that you can't modify the installation parameters for an existing CEV or an existing DB instance. You also can't upgrade from one CEV to another CEV when the installation parameters have different settings.

For sample CEV manifests, see the JSON templates that you downloaded in Step 1 (Optional): Download the manifest templates. You can also review the samples in CEV manifest examples.

Topics

- JSON fields in the CEV manifest
- Creating the CEV manifest
- CEV manifest examples

JSON fields in the CEV manifest

The following table describes the JSON fields in the manifest.

JSON field	Description
`MediaImportTemplateVersion`	Version of the CEV manifest. The date is in the format `YYYY-MM-DD` .
`databaseInstallationFileNames`	Ordered list of installation files for the database.

JSON field	Description
`opatchFileNames`	Ordered list of OPatch installers used for the Oracle DB engine. Only one value is valid. Values for `opatchFileNames` must start with `p6880880_` .
`psuRuPatchFileNames`	The PSU and RU patches for this database. **Important** If you include `psuRuPatchFileNames` , `opatchFileNames` is required. Values for `opatchFileNames` must start with `p6880880_` .
`OtherPatchFileNames`	The patches that aren't in the list of PSU and RU patches. RDS Custom applies these patches after applying the PSU and RU patches. **Important** If you include `OtherPatchFileNames` , `opatchFileNames` is required. Values for `opatchFileNames` must start with `p6880880_` .

JSON field	Description
`installationParameters`	Nondefault settings for the Oracle base, Oracle home, and the ID and name of the UNIX/Linux user and group. You can set the following parameters: **oracleBase** The directory under which your Oracle binaries are installed. It is the mount point of the binary volume that stores your files. The Oracle base directory can include multiple Oracle homes. For example, if `/home/oracle/oracle.19.0.0.0.ru-2020-04.rur-2020-04.r1.EE.1` is one of your Oracle home directories, then `/home/oracle` is the Oracle base directory. A user-specified Oracle base directory is not a symbolic link. If you don't specify the Oracle base, the default directory is `/rdsdbbin`. **oracleHome** The directory in which your Oracle database binaries are installed. For example, if you specify `/home/oracle/` as your Oracle base, then you might specify `/home/oracle/oracle.19.0.0.0.ru-2020-04.rur-2020-04.r1.EE.1/` as your Oracle home. A user-specified Oracle home directory is not a symbolic link. The Oracle home value is referenced by the `$ORACLE_HOME` environment variable. If you don't specify the Oracle home, the default naming format is `/rdsdbbin/oracle.` *major-engine-version* `.custom.r1.` *engine-edition* `.1`. **unixUname** The name of the UNIX user that owns the Oracle software. RDS Custom assumes this user when running local database commands. If you specify both `unixUid` and `unixUname`, RDS Custom creates the user if it doesn't exist, and then

JSON field	Description
	assigns the UID to the user if it's not the same as the initial UID. The default user name is `rdsdb`. **unixUid** The ID (UID) of the UNIX user that owns the Oracle software. If you specify both `unixUid` and `unixUname` , RDS Custom creates the user if it doesn't exist, and then assigns the UID to the user if it's not the same as the initial UID. The default UID is `61001`. This is the UID of the user `rdsdb`. **unixGroupName** The name of the UNIX group. The UNIX user that owns the Oracle software belongs to this group. The default group name is `rdsdb`. **unixGroupId** The ID of the UNIX group to which the UNIX user belongs. The default group ID is `1000`. This is the ID of the group `rdsdb`.

Each Oracle Database release has a different list of supported installation files. When you create your CEV manifest, make sure to specify only files that are supported by RDS Custom for Oracle. Otherwise, CEV creation fails with an error. All patches listed in Release notes for Amazon Relational Database Service (Amazon RDS) for Oracle are supported.

Creating the CEV manifest

To create a CEV manifest

1. List all installation files that you plan to apply, in the order that you want to apply them.
2. Correlate the installation files with the JSON fields described in JSON fields in the CEV manifest.

3. Do either of the following:

   - Create the CEV manifest as a JSON text file.
   - Edit the CEV manifest template when you create the CEV in the console. For more information, see Creating a CEV.

CEV manifest examples

The following examples show CEV manifest files for different Oracle Database releases. If you include a JSON field in your manifest, make sure that it isn't empty. For example, the following CEV manifest isn't valid because `otherPatchFileNames` is empty.

```
{
    "mediaImportTemplateVersion": "2020-08-14",
    "databaseInstallationFileNames": [
        "V982063-01.zip"
    ],
    "opatchFileNames": [

Example Sample CEV manifest for Oracle Database 12c Release 1 (12.1)

In the following example for the July 2021 PSU for Oracle Database 12c Release 1 (12.1), RDS Custom applies the patches in the order specified. Thus, RDS Custom applies p32768233, then

p32876425, then p18759211, and so on. The example sets new values for the UNIX user and group, and the Oracle home and Oracle base.

        "p29997937_180000_Linux-x86-64.zip",
        "p31335037_180000_Linux-x86-64.zip",
        "p31335142_180000_Generic.zip"
    ]
    "installationParameters": {
        "unixGroupName": "dba",
        "unixGroupId": 12345,
```

```
        "unixUname": "oracle",
        "unixUid": 12345,
        "oracleHome": "/home/oracle/18.0.0.0.ru-2020-10.rur-2020-10.r1",
        "oracleBase": "/home/oracle/"
    }
}
```

Example Sample CEV manifest for Oracle Database 19c

In the following example for Oracle Database 19c, RDS Custom applies p32126828, then p29213893, then p29782284, and so on. The example sets new values for the UNIX user and group, and the Oracle home and Oracle base.

```
{
    "mediaImportTemplateVersion": "2020-08-14",
    "databaseInstallationFileNames": [
        "V982063-01.zip"
    ],
    "opatchFileNames": [
        "p6880880_190000_Linux-x86-64.zip"
    ],
    "psuRuPatchFileNames": [
        "p32126828_190000_Linux-x86-64.zip"
    ],
    "otherPatchFileNames": [
        "p29213893_1910000DBRU_Generic.zip",
        "p29782284_1910000DBRU_Generic.zip",
        "p28730253_190000_Linux-x86-64.zip",
        "p29374604_1910000DBRU_Linux-x86-64.zip",
        "p28852325_190000_Linux-x86-64.zip",
        "p29997937_190000_Linux-x86-64.zip",
        "p31335037_190000_Linux-x86-64.zip",
        "p31335142_190000_Generic.zip"
    ],
    "installationParameters": {
        "unixGroupName": "dba",
        "unixGroupId": 12345,
        "unixUname": "oracle",
        "unixUid": 12345,
        "oracleHome": "/home/oracle/oracle.19.0.0.0.ru-2020-04.rur-2020-04.r1.EE.1",
        "oracleBase": "/home/oracle"
    }
}
```

Step 6 (Optional): Validate the CEV manifest

Optionally, verify that manifest is a valid JSON file by running the `json.tool` Python script. For example, if you change into the directory containing a CEV manifest named `manifest.json`, run the following command.

```
python -m json.tool < manifest.json
```

Step 7: Add necessary IAM permissions

Make sure that the IAM principal that creates the CEV has the necessary policies described in Step 5: Grant required permissions to your IAM user or role.

Creating a CEV

You can create a CEV using the AWS Management Console or the AWS CLI. Specify either the multitenant or non-multitenant architecture. For more information, see Multitenant architecture considerations.

Typically, creating a CEV takes about two hours. After the CEV is created, you can use it to create an RDS Custom DB instance. For more information, see Creating an RDS Custom for Oracle DB instance.

Note the following requirements and limitations for creating a CEV:

- The Amazon S3 bucket containing your installation files must be in the same AWS Region as your CEV. Otherwise, the creation process fails.
- The CEV name must be in the format *`major-engine-version.customized_string`*, as in `19.cdb_cev1`.
- The CEV name must contain 1–50 alphanumeric characters, underscores, dashes, or periods.
- The CEV name can't contain consecutive periods, as in `19..cdb_cev1`.

Console

To create a CEV

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.

2. In the navigation pane, choose **Custom engine versions**.

   The **Custom engine versions** page shows all CEVs that currently exist. If you haven't created any CEVs, the page is empty.

3. Choose **Create custom engine version**.

4. In **Engine options**, do the following:

   a. For **Engine type**, choose **Oracle**.

   b. For **Architecture settings**, optionally choose **Multitenant architecture** to create an Oracle multitenant CEV, which uses the DB engine `custom-oracle-ee-cdb` or `custom-oracle-se2-cdb`. You can create an RDS Custom for Oracle CDB with a Multitenant CEV only. If you don't choose this option, your CEV is a non-CDB, which uses the engine `custom-oracle-ee` or `custom-oracle-se2`.

   > **Note**
   >
   > The architecture that you choose is a permanent characteristic of your CEV. You can't modify your CEV to use a different architecture later.

   c. Choose either of the following options:

   - **Create new CEV** – Create a CEV from scratch. In this case, you must specify a JSON manifest specifying the database binaries.
   - **Create CEV from source** – In **Specify the CEV that you want to copy**, choose an existing CEV to use as the source CEV. In this case, you can specify a new Amazon Machine Image (AMI), but you can't specify different database binaries.

   d. For **Engine version**, choose the major engine version.

5. In **Version details**, do the following:

   a. Enter a valid name in **Custom engine version name**. For example, you might enter the name **`19.cdb_cev1`**.

   b. (Optional) Enter a description for your CEV.

6. In **Installation media**, do the following:

   a. (Optional) For **AMI ID**, either leave the field blank to use the latest service-provided AMI, or enter an AMI that you previously used to create a CEV. To obtain valid AMI IDs, use either of the following techniques:

- In the console, choose **Custom engine versions** in the left navigation pane, and choose the name of a CEV. The AMI ID used by the CEV appears in the **Configuration** tab.
- In the AWS CLI, use the `describe-db-engine-versions` command. Search the output for `ImageID`.

b. For **S3 location of manifest files**, enter the location of the Amazon S3 bucket that you specified in Step 3: Upload your installation files to Amazon S3. For example, enter **`s3://my-custom-installation-files/123456789012/cev1/`**.

> **Note**
>
> The AWS Region in which you create the CEV must be in the same Region as the S3 bucket.

c. (Create new CEV only) For **CEV manifest**, enter the JSON manifest that you created in Creating the CEV manifest.

7. In the **KMS key** section, select **Enter a key ARN** to list the available AWS KMS keys. Then select your KMS key from the list.

   An AWS KMS key is required for RDS Custom. For more information, see Step 1: Create or reuse a symmetric encryption AWS KMS key.
8. (Optional) Choose **Add new tag** to create a key-value pair for your CEV.
9. Choose **Create custom engine version**.

   If the JSON manifest is in an invalid format, the console displays **Error validating the CEV manifest**. Fix the problems, and try again.

The **Custom engine versions** page appears. Your CEV is shown with the status **Creating**. The process to create a CEV takes approximately two hours.

AWS CLI

To create a CEV by using the AWS CLI, run the create-custom-db-engine-version command.

The following options are required:

- `--engine` – Specify the engine type. For a CDB, specify either `custom-oracle-ee-cdb` or `custom-oracle-se2-cdb`. For a non-CDB, specify either `custom-oracle-ee` or `custom-`

`oracle-se2`. You can create CDBs only from a CEV created with `custom-oracle-ee-cdb` or `custom-oracle-se2-cdb`. You can create non-CDBs only from a CEV created with `custom-oracle-ee` or `custom-oracle-se2`.

- `--engine-version` – Specify the engine version. The format is *`major-engine-version.customized_string`*. The CEV name must contain 1–50 alphanumeric characters, underscores, dashes, or periods. The CEV name can't contain consecutive periods, as in `19..cdb_cev1`.
- `--kms-key-id` – Specify an AWS KMS key.
- `--manifest` – Specify either *`manifest_json_string`* or `--manifest file:`*`file_name`*. Newline characters aren't permitted in *`manifest_json_string`*. Make sure to escape double quotes (") in the JSON code by prefixing them with a backslash (\).

  The following example shows the *`manifest_json_string`* for 19c from Step 5: Prepare the CEV manifest. The example sets new values for the Oracle base, Oracle home, and the ID and name of the UNIX/Linux user and group. If you copy this string, remove all newline characters before you paste it into your command.

  ```
  "{\"mediaImportTemplateVersion\": \"2020-08-14\",
  \"databaseInstallationFileNames\": [\"V982063-01.zip\"],
  \"opatchFileNames\": [\"p6880880_190000_Linux-x86-64.zip\"],
  \"psuRuPatchFileNames\": [\"p32126828_190000_Linux-x86-64.zip\"],
  \"otherPatchFileNames\": [\"p29213893_1910000DBRU_Generic.zip\",
  \"p29782284_1910000DBRU_Generic.zip\",\"p28730253_190000_Linux-
  x86-64.zip\",\"p29374604_1910000DBRU_Linux-x86-64.zip\",
  \"p28852325_190000_Linux-x86-64.zip\",\"p29997937_190000_Linux-x86-64.zip
  \",\"p31335037_190000_Linux-x86-64.zip\",\"p31335142_190000_Generic.zip
  \"]\"installationParameters\":{ \"unixGroupName\":\"dba\",
  \ \"unixUname\":\"oracle\", \ \"oracleHome\":\"/home/oracle/
  oracle.19.0.0.0.ru-2020-04.rur-2020-04.r1.EE.1\", \ \"oracleBase\":\"/
  home/oracle/\"}}"
  ```

- `--database-installation-files-s3-bucket-name` – Specify the same bucket name that you specified in Step 3: Upload your installation files to Amazon S3. The AWS Region in which you run `create-custom-db-engine-version` must be the same Region as your Amazon S3 bucket.

You can also specify the following options:

- `--description` – Specify a description of your CEV.
- `--database-installation-files-s3-prefix` – Specify the folder name that you specified in Step 3: Upload your installation files to Amazon S3.
- `--image-id` – Specify an AMI ID that want to reuse. To find valid IDs, run the `describe-db-engine-versions` command, and then search the output for `ImageID`. By default, RDS Custom for Oracle uses the most recent available AMI.

The following example creates an Oracle multitenant CEV named `19.cdb_cev1`. The example reuses an existing AMI rather than use the latest available AMI. Make sure that the name of your CEV starts with the major engine version number.

Example

For Linux, macOS, or Unix:

```
aws rds create-custom-db-engine-version \
    --engine custom-oracle-se2-cdb \
    --engine-version 19.cdb_cev1 \
    --database-installation-files-s3-bucket-name us-east-1-123456789012-custom-
installation-files \
    --database-installation-files-s3-prefix 123456789012/cev1 \
    --kms-key-id my-kms-key \
    --description "test cev" \
    --manifest manifest_string \
    --image-id ami-012a345678901bcde
```

For Windows:

```
aws rds create-custom-db-engine-version ^
    --engine custom-oracle-se2-cdb ^
    --engine-version 19.cdb_cev1 ^
    --database-installation-files-s3-bucket-name us-east-1-123456789012-custom-
installation-files ^
    --database-installation-files-s3-prefix 123456789012/cev1 ^
    --kms-key-id my-kms-key ^
    --description "test cev" ^
    --manifest manifest_string ^
    --image-id ami-012a345678901bcde
```

Example

Get details about your CEV by using the `describe-db-engine-versions` command.

```
aws rds describe-db-engine-versions \
    --engine custom-oracle-se2-cdb \
    --include-all
```

The following partial sample output shows the engine, parameter groups, manifest, and other information.

```
{
    "DBEngineVersions": [
        {
            "Engine": "custom-oracle-se2-cdb",

```

Failure to create a CEV

If the process to create a CEV fails, RDS Custom issues `RDS-EVENT-0198` with the message `Creation failed for custom engine version` *`major-engine-version.cev_name`*, and includes details about the failure. For example, the event prints missing files.

You can't modify a failed CEV. You can only delete it, then try again to create a CEV after fixing the causes of the failure. For information about troubleshooting the reasons for CEV creation failure, see Troubleshooting custom engine version creation for RDS Custom for Oracle.

Modifying CEV status

You can modify a CEV using the AWS Management Console or the AWS CLI. You can modify the CEV description or its availability status. Your CEV has one of the following status values:

- `available` – You can use this CEV to create a new RDS Custom DB instance or upgrade a DB instance. This is the default status for a newly created CEV.
- `inactive` – You can't create or upgrade an RDS Custom instance with this CEV. You can't restore a DB snapshot to create a new RDS Custom DB instance with this CEV.

You can change the CEV from any supported status to any other supported status. You might change status to prevent the accidental use of a CEV or make a discontinued CEV eligible for use again. For example, you might change the status of your CEV from `available` to `inactive`, and from `inactive` back to `available`.

Console

To modify a CEV

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Custom engine versions**.
3. Choose a CEV whose description or status you want to modify.
4. For **Actions**, choose **Modify**.
5. Make any of the following changes:
   - For **CEV status settings**, choose a new availability status.
   - For **Version description**, enter a new description.

6. Choose **Modify CEV**.

   If the CEV is in use, the console displays **You can't modify the CEV status**. Fix the problems, and try again.

The **Custom engine versions** page appears.

AWS CLI

To modify a CEV by using the AWS CLI, run the modify-custom-db-engine-version command. You can find CEVs to modify by running the describe-db-engine-versions command.

The following options are required:

- `--engine` *`engine-type`*, where *`engine-type`* is `custom-oracle-ee`, `custom-oracle-se2`, `custom-oracle-ee-cdb`, or `custom-oracle-se2-cdb`
- `--engine-version` *`cev`*, where *`cev`* is the name of the custom engine version that you want to modify
- `--status` *`status`*, where *`status`* is the availability status that you want to assign to the CEV

The following example changes a CEV named `19.my_cev1` from its current status to `inactive`.

Example

For Linux, macOS, or Unix:

```
aws rds modify-custom-db-engine-version \
    --engine custom-oracle-se2 \
    --engine-version 19.my_cev1 \
    --status inactive
```

For Windows:

```
aws rds modify-custom-db-engine-version ^
    --engine custom-oracle-se2 ^
    --engine-version 19.my_cev1 ^
    --status inactive
```

Viewing CEV details

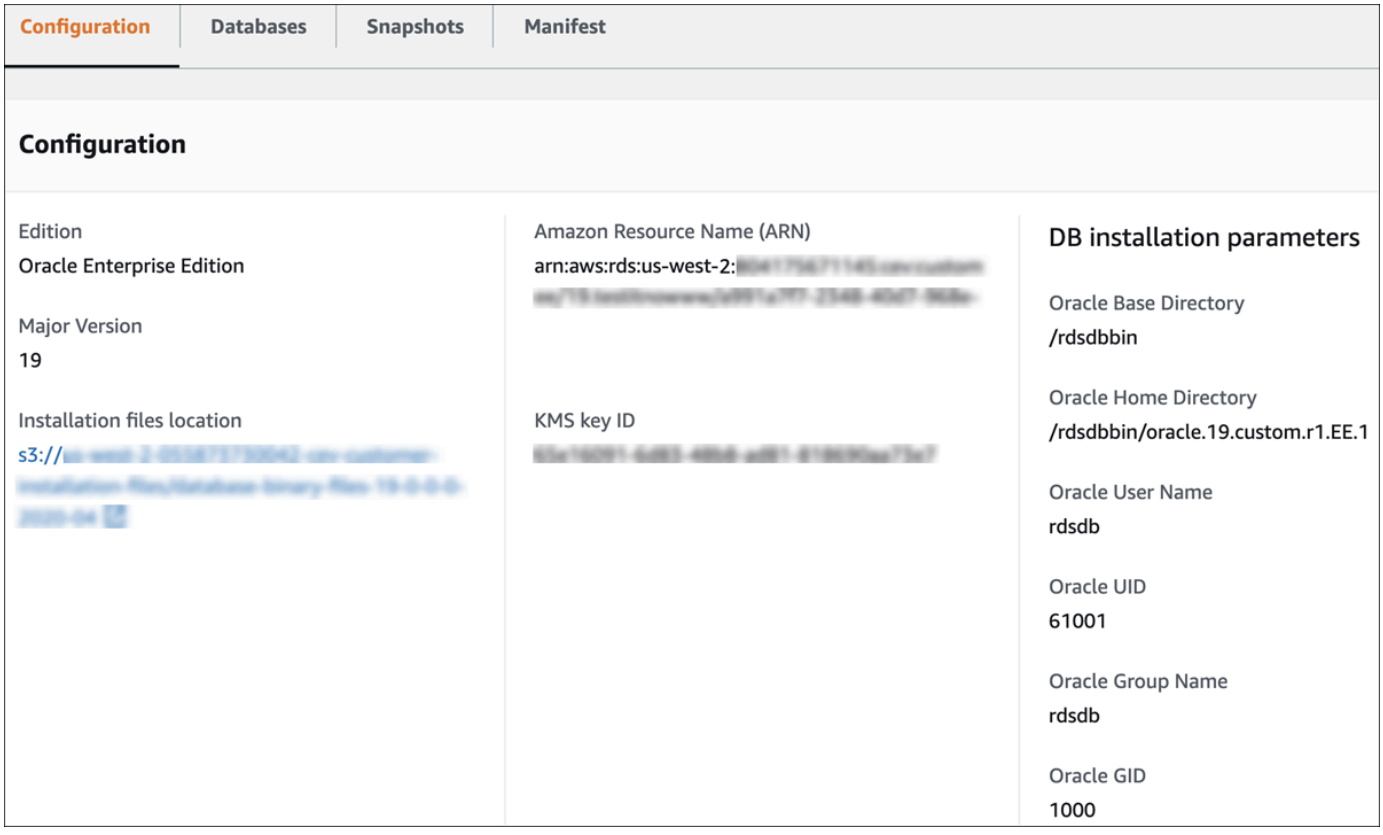
You can view details about your CEV manifest and the command used to create your CEV by using the AWS Management Console or the AWS CLI.

Console

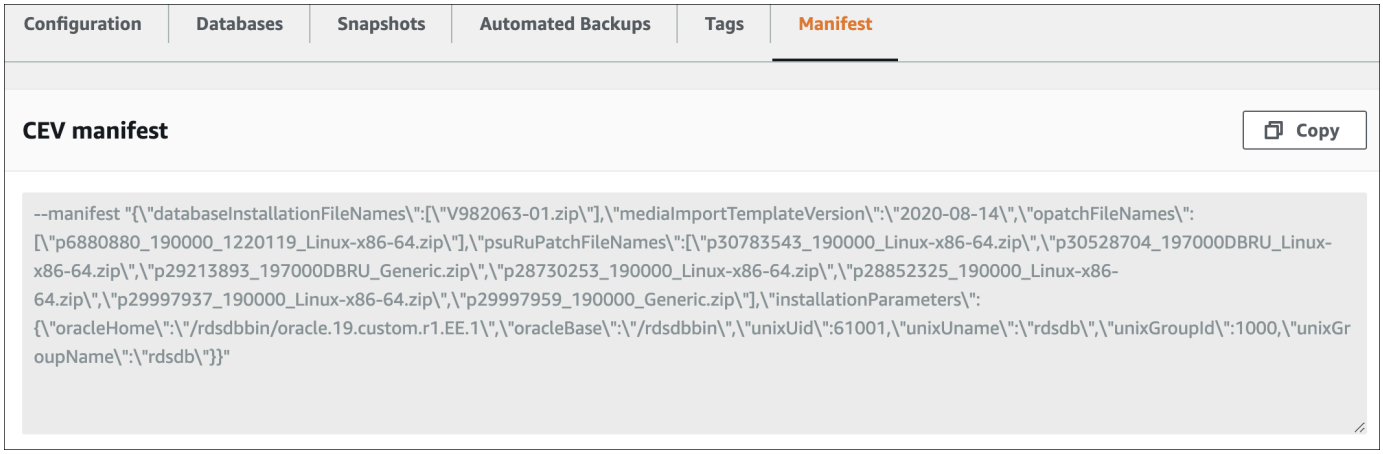
To view CEV details

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Custom engine versions**.

   The **Custom engine versions** page shows all CEVs that currently exist. If you haven't created any CEVs, the page is empty.
3. Choose the name of the CEV that you want to view.
4. Choose **Configuration** to view the installation parameters specified in your manifest.



5. Choose **Manifest** to view the installation parameters specified in the `--manifest` option of the `create-custom-db-engine-version` command. You can copy this text, replace values as needed, and use them in a new command.



AWS CLI

To view details about a CEV by using the AWS CLI, run the describe-db-engine-versions command.

The following options are required:

- `--engine` *`engine-type`*, where *`engine-type`* is `custom-oracle-ee`, `custom-oracle-se2`, `custom-oracle-ee-cdb`, or `custom-oracle-se2-cdb`
- `--engine-version` *`major-engine-version.customized_string`*

The following example creates a non-CDB CEV that uses Enterprise Edition. The CEV name `19.my_cev1` starts with the major engine version number, which is required.

Example

For Linux, macOS, or Unix:

```
aws rds describe-db-engine-versions \
    --engine custom-oracle-ee \
    --engine-version 19.my_cev1
```

For Windows:

```
aws rds describe-db-engine-versions ^
    --engine custom-oracle-ee ^
    --engine-version 19.my_cev1
```

The following partial sample output shows the engine, parameter groups, manifest, and other information.

```
"DBEngineVersions": [
    {
        "Engine": "custom-oracle-ee",
        "MajorEngineVersion": "19",
        "EngineVersion": "19.my_cev1",

        }
]
```

Deleting a CEV

You can delete a CEV using the AWS Management Console or the AWS CLI. Typically, deletion takes a few minutes.

To delete a CEV, it can't be in use by any of the following:

- An RDS Custom DB instance
- A snapshot of an RDS Custom DB instance
- An automated backup of your RDS Custom DB instance

Console

To delete a CEV

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Custom engine versions**.
3. Choose a CEV whose description or status you want to delete.
4. For **Actions**, choose **Delete**.

   The **Delete *cev_name*?** dialog box appears.
5. Enter **`delete me`**, and then choose **Delete**.

   In the **Custom engine versions** page, the banner shows that your CEV is being deleted.

AWS CLI

To delete a CEV by using the AWS CLI, run the delete-custom-db-engine-version command.

The following options are required:

- `--engine` *`engine-type`*, where *`engine-type`* is `custom-oracle-ee`, `custom-oracle-se2`, `custom-oracle-ee-cdb`, or `custom-oracle-se2-cdb`
- `--engine-version` *`cev`*, where *`cev`* is the name of the custom engine version to be deleted

The following example deletes a CEV named `19.my_cev1`.

Example

For Linux, macOS, or Unix:

```
aws rds delete-custom-db-engine-version \
```

```
    --engine custom-oracle-ee \
    --engine-version 19.my_cev1
```

For Windows:

```
aws rds delete-custom-db-engine-version ^
    --engine custom-oracle-ee ^
    --engine-version 19.my_cev1
```

Configuring a DB instance for Amazon RDS Custom for Oracle

You can create an RDS Custom DB instance, and then connect to it using Secure Shell (SSH) or AWS Systems Manager.

Topics

Multitenant architecture considerations

If you create an Amazon RDS Custom for Oracle DB instance with the Oracle multitenant architecture (`custom-oracle-ee-cdb` or `custom-oracle-se2-cdb` engine type), your database is a container database (CDB). If you don't specify the Oracle multitenant architecture, your database is a traditional non-CDB that uses the `custom-oracle-ee` or `custom-oracle-se2` engine type. A non-CDB can't contain pluggable databases (PDBs). For more information, see Database architecture for Amazon RDS Custom for Oracle.

When you create an RDS Custom for Oracle CDB instance, consider the following:

- You can create a multitenant database only from an Oracle Database 19c CEV.
- You can create a CDB instance only if the CEV uses the `custom-oracle-ee-cdb` or `custom-oracle-se2-cdb` engine type.
- If you create a CDB instance using Standard Edition 2, the CDB can contain a maximum of 3 PDBs.
- By default, your CDB is named RDSCDB, which is also the name of the Oracle System ID (Oracle SID). You can choose a different name.
- You CDB contains only one initial PDB. The PDB name defaults to `ORCL`. You can choose a different name for your initial PDB, but the Oracle SID and the PDB name can’t be the same.

- RDS Custom for Oracle doesn't supply APIs for PDBs. To create additional PDBs, use the Oracle SQL command `CREATE PLUGGABLE DATABASE`. RDS Custom for Oracle doesn't restrict the number of PDBs that you can create. In general, you are responsible for creating and managing PDBs, as in an on-premises deployment.
- You can't use RDS APIs to create, modify, and delete PDBs: you must use Oracle SQL statements. When you create a PDB using Oracle SQL, we recommend that you take a manual snapshot afterward in case you need to perform point-in-time recovery (PITR).
- You can't rename existing PDBs using Amazon RDS APIs. You also can't rename the CDB using the `modify-db-instance` command.
- The open mode for the CDB root is `READ WRITE` on the primary and `MOUNTED` on a mounted standby database. RDS Custom for Oracle attempts to open all PDBs when opening the CDB. If RDS Custom for Oracle can't open all PDBs, it issues the event `tenant database shutdown`.

Creating an RDS Custom for Oracle DB instance

Create an Amazon RDS Custom for Oracle DB instance using either the AWS Management Console or the AWS CLI. The procedure is similar to the procedure for creating an Amazon RDS DB instance. For more information, see Creating an Amazon RDS DB instance.

If you included installation parameters in your CEV manifest, then your DB instance uses the Oracle base, Oracle home, and the ID and name of the UNIX/Linux user and group that you specified. The `oratab` file, which is created by Oracle Database during installation, points to the real installation location rather than to a symbolic link. When RDS Custom for Oracle runs commands, it runs as the configured OS user rather than the default user `rdsdb`. For more information, see Step 5: Prepare the CEV manifest.

Before you attempt to create or connect to an RDS Custom DB instance, complete the tasks in Setting up your environment for Amazon RDS Custom for Oracle.

Console

To create an RDS Custom for Oracle DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.
3. Choose **Create database**.

4. In **Choose a database creation method**, select **Standard create**.
5. In the **Engine options** section, do the following:
   a. For **Engine type**, choose **Oracle**.
   b. For **Database management type**, choose **Amazon RDS Custom**.
   c. For **Architecture settings**, do one of the following:
      - Select **Multitenant architecture** to create a container database (CDB). At creation, your CDB contains one PDB seed and one initial PDB.

        > **Note**
        >
        > The **Multitenant architecture** setting is supported only for Oracle Database 19c.

      - Clear **Multitenant architecture** to create a non-CDB. A non-CDB can't contain PDBs.
   d. For **Edition**, choose **Oracle Enterprise Edition** or **Oracle Standard Edition 2**.
   e. For **Custom engine version**, choose an existing RDS Custom custom engine version (CEV). A CEV has the following format: *`major-engine-version`*`.`*`customized_string`*. An example identifier is `19.cdb_cev1`.

      If you chose **Multitenant architecture** in the previous step, you can only specify a CEV that uses the `custom-oracle-ee-cdb` or `custom-oracle-se2-cdb` engine type. The console filters out CEVs that were created with different engine types.
6. In **Templates**, choose **Production**.
7. In the **Settings** section, do the following:
   a. For **DB instance identifier**, enter a unique name for your DB instance.
   b. For **Master username**, enter a username. You can retrieve this value from the console later.

      When you connect to a non-CDB, the master user is the user for the non-CDB. When you connect to a CDB, the master user is the user for the PDB. To connect to the CDB root, log in to the host, start a SQL client, and create an administrative user with SQL commands.
   c. Clear **Auto generate a password**.
8. Choose a **DB instance class**.

   For supported classes, see DB instance class support for RDS Custom for Oracle.

9. In the **Storage** section, do the following:

    a. For **Storage type**, choose an SSD type: io1, gp2, or gp3. You have the following additional options:

    - For io1 or gp3, choose a rate for **Provisioned IOPS**. The default is 1000 for io1 and 12000 for gp3.
    - For gp3, choose a rate for **Storage throughput**. The default is 500 MiBps.

    b. For **Allocated storage**, choose a storage size. The default is 40 GiB.

10. For **Connectivity**, specify your **Virtual private cloud (VPC)**, **DB subnet group**, and **VPC security group (firewall)**.

11. For **RDS Custom security**, do the following:

    a. For **IAM instance profile**, choose the instance profile for your RDS Custom for Oracle DB instance.

    The IAM instance profile must begin with `AWSRDSCustom`, for example *`AWSRDSCustomInstanceProfileForRdsCustomInstance`*.

    b. For **Encryption**, choose **Enter a key ARN** to list the available AWS KMS keys. Then choose your key from the list.

    An AWS KMS key is required for RDS Custom. For more information, see Step 1: Create or reuse a symmetric encryption AWS KMS key.

12. For **Database options**, do the following:

    a. (Optional) For **System ID (SID)**, enter a value for the Oracle SID, which is also the name of your CDB. The SID is the name of the Oracle database instance that manages your database files. In this context, the term "Oracle database instance" refers exclusively to the system global area (SGA) and Oracle background processes. If you don't specify a SID, the value defaults to **RDSCDB**.

    b. (Optional) For **Initial database name**, enter a name. The default value is **ORCL**. In the multitenant architecture, the initial database name is the PDB name.

    > **Note**
    >
    > The SID and PDB name must be different.

c. For **Option group**, choose an option group or accept the default.

> **Note**
>
> The only supported option for RDS Custom for Oracle is `Timezone`. For more information, see Oracle time zone.

d. For **Backup retention period** choose a value. You can't choose **0 days**.

e. For the remaining sections, specify your preferred RDS Custom DB instance settings. For information about each setting, see Settings for DB instances. The following settings don't appear in the console and aren't supported:

- **Processor features**
- **Storage autoscaling**
- **Password and Kerberos authentication** option in **Database authentication** (only **Password authentication** is supported)
- **Performance Insights**
- **Log exports**
- **Enable auto minor version upgrade**
- **Deletion protection**

13. Choose **Create database**.

> **Important**
>
> When you create an RDS Custom for Oracle DB instance, you might receive the following error: The service-linked role is in the process of being created. Try again later. If you do, wait a few minutes and then try again to create the DB instance.

The **View credential details** button appears on the **Databases** page.

To view the master user name and password for the RDS Custom DB instance, choose **View credential details**.

To connect to the DB instance as the master user, use the user name and password that appear.

> **Important**
>
> You can't view the master user password again in the console. If you don't record it, you might have to change it. To change the master user password after the RDS Custom DB instance is available, log in to the database and run an `ALTER USER` command. You can't reset the password using the **Modify** option in the console.

14. Choose **Databases** to view the list of RDS Custom DB instances.
15. Choose the RDS Custom DB instance that you just created.

    On the RDS console, the details for the new RDS Custom DB instance appear:

    - The DB instance has a status of **creating** until the RDS Custom DB instance is created and ready for use. When the state changes to **available**, you can connect to the DB instance. Depending on the instance class and storage allocated, it can take several minutes for the new DB instance to be available.
    - **Role** has the value **Instance (RDS Custom)**.
    - **RDS Custom automation mode** has the value **Full automation**. This setting means that the DB instance provides automatic monitoring and instance recovery.

AWS CLI

You create an RDS Custom DB instance by using the create-db-instance AWS CLI command.

The following options are required:

- `--db-instance-identifier`
- `--db-instance-class` (for a list of supported instance classes, see DB instance class support for RDS Custom for Oracle)
- `--engine` *`engine-type`*, where *`engine-type`* is `custom-oracle-ee`, `custom-oracle-se2`, `custom-oracle-ee-cdb`, or `custom-oracle-se2-cdb`
- `--engine-version` *`cev`* (where *`cev`* is the name of the custom engine version that you specified in Creating a CEV)
- `--kms-key-id` *`my-kms-key`*
- `--backup-retention-period` *`days`* (where *`days`* is a value greater than `0`)
- `--no-auto-minor-version-upgrade`

- `--custom-iam-instance-profile AWSRDSCustomInstanceProfile-`*`us-east-1`* (where *`region`* is the AWS Region where you are creating your DB instance)

The following example creates an RDS Custom DB instance named `my-cfo-cdb-instance`. The database is a CDB with the nondefault name *`MYCDB`*. The nondefault PDB name is *`MYPDB`*. The backup retention period is three days.

Example

For Linux, macOS, or Unix:

```
aws rds create-db-instance \
    --engine custom-oracle-ee-cdb \
    --db-instance-identifier my-cfo-cdb-instance \
    --engine-version 19.cdb_cev1 \
    --db-name MYPDB \
    --db-system-id MYCDB \
    --allocated-storage 250 \
    --db-instance-class db.m5.xlarge \
    --db-subnet-group mydbsubnetgroup \
    --master-username myuser \
    --master-user-password mypassword \
    --backup-retention-period 3 \
    --port 8200 \
    --kms-key-id my-kms-key \
    --no-auto-minor-version-upgrade \
    --custom-iam-instance-profile AWSRDSCustomInstanceProfile-us-east-1
```

For Windows:

```
aws rds create-db-instance ^
    --engine custom-oracle-ee-cdb ^
    --db-instance-identifier my-cfo-cdb-instance ^
    --engine-version 19.cdb_cev1 ^
    --db-name MYPDB ^
    --db-system-id MYCDB ^
    --allocated-storage 250 ^
    --db-instance-class db.m5.xlarge ^
    --db-subnet-group mydbsubnetgroup ^
    --master-username myuser ^
    --master-user-password mypassword ^
    --backup-retention-period 3 ^
```

```
    --port 8200 ^
    --kms-key-id my-kms-key ^
    --no-auto-minor-version-upgrade ^
    --custom-iam-instance-profile AWSRDSCustomInstanceProfile-us-east-1
```

> **Note**
>
> Specify a password other than the prompt shown here as a security best practice.

Get details about your instance by using the `describe-db-instances` command.

Example

```
aws rds describe-db-instances --db-instance-identifier my-cfo-cdb-instance
```

The following partial output shows the engine, parameter groups, and other information.

```
        {
            "DBInstanceIdentifier": "my-cfo-cdb-instance",
            "DBInstanceClass": "db.m5.xlarge",
            "Engine": "custom-oracle-ee-cdb",
            "DBInstanceStatus": "available",
            "MasterUsername": "admin",
            "DBName": "MYPDB",
            "DBSystemID": "MYCDB",

            "BackupRetentionPeriod": 7,
            "DBSecurityGroups": [],
            "VpcSecurityGroups": [
                {
                    "VpcSecurityGroupId": "sg-0a1bcd2e",
                    "Status": "active"
                }
```

```
            ],
            "DBParameterGroups": [
                {
                    "DBParameterGroupName": "default.custom-oracle-ee-cdb-19",
                    "ParameterApplyStatus": "in-sync"
                }
            ],
...
```

RDS Custom service-linked role

A *service-linked role* gives Amazon RDS Custom access to resources in your AWS account. It makes using RDS Custom easier because you don't have to manually add the necessary permissions. RDS Custom defines the permissions of its service-linked roles, and unless defined otherwise, only RDS Custom can assume its roles. The defined permissions include the trust policy and the permissions policy, and that permissions policy can't be attached to any other IAM entity.

When you create an RDS Custom DB instance, both the Amazon RDS and RDS Custom service-linked roles are created (if they don't already exist) and used. For more information, see Using service-linked roles for Amazon RDS.

The first time that you create an RDS Custom for Oracle DB instance, you might receive the following error: The service-linked role is in the process of being created. Try again later. If you do, wait a few minutes and then try again to create the DB instance.

Connecting to your RDS Custom DB instance using Session Manager

After you create your RDS Custom DB instance, you can connect to it using AWS Systems Manager Session Manager. This is the preferred technique when your DB instance isn't publicly accessible.

Session Manager allows you to access Amazon EC2 instances through a browser-based shell or through the AWS CLI. For more information, see AWS Systems Manager Session Manager.

Console

To connect to your DB instance using Session Manager

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**, and then choose the RDS Custom DB instance to which you want to connect.

3. Choose **Configuration**.
4. Note the **Resource ID** for your DB instance. For example, the resource ID might be `db-ABCDEFGHIJKLMNOPQRS0123456`.
5. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
6. In the navigation pane, choose **Instances**.
7. Look for the name of your EC2 instance, and then click the instance ID associated with it. For example, the instance ID might be `i-abcdefghijklm01234`.
8. Choose **Connect**.
9. Choose **Session Manager**.
10. Choose **Connect**.

    A window opens for your session.

AWS CLI

You can connect to your RDS Custom DB instance using the AWS CLI. This technique requires the Session Manager plugin for the AWS CLI. To learn how to install the plugin, see Install the Session Manager plugin for the AWS CLI.

To find the DB resource ID of your RDS Custom DB instance, use `aws rds describe-db-instances`.

```
aws rds describe-db-instances \
    --query 'DBInstances[*].[DBInstanceIdentifier,DbiResourceId]' \
    --output text
```

The following sample output shows the resource ID for your RDS Custom instance. The prefix is `db-`.

```
db-ABCDEFGHIJKLMNOPQRS0123456
```

To find the EC2 instance ID of your DB instance, use `aws ec2 describe-instances`. The following example uses `db-ABCDEFGHIJKLMNOPQRS0123456` for the resource ID.

```
aws ec2 describe-instances \
    --filters "Name=tag:Name,Values=db-ABCDEFGHIJKLMNOPQRS0123456" \
    --output text \
```

```
    --query 'Reservations[*].Instances[*].InstanceId'
```

The following sample output shows the EC2 instance ID.

```
i-abcdefghijklm01234
```

Use the `aws ssm start-session` command, supplying the EC2 instance ID in the `--target` parameter.

```
aws ssm start-session --target "i-abcdefghijklm01234"
```

A successful connection looks like the following.

```
Starting session with SessionId: yourid-abcdefghijklm1234
[ssm-user@ip-123-45-67-89 bin]$
```

Connecting to your RDS Custom DB instance using SSH

The Secure Shell Protocol (SSH) is a network protocol that supports encrypted communication over an unsecured network. After you create your RDS Custom DB instance, you can connect to it using an ssh client. For more information, see Connecting to your Linux instance using SSH.

Your SSH connection technique depends on whether your DB instance is private, meaning that it doesn't accept connections from the public internet. In this case, you must use SSH tunneling to connect the ssh utility to your instance. This technique transports data with a dedicated data stream (tunnel) inside an existing SSH session. You can configure SSH tunneling using AWS Systems Manager.

> **Note**
>
> Various strategies are supported for accessing private instances. To learn how to connect an ssh client to private instances using bastion hosts, see Linux Bastion Hosts on AWS. To learn how to configure port forwarding, see Port Forwarding Using AWS Systems Manager Session Manager.

If your DB instance is in a public subnet and has the publicly available setting, then no SSH tunneling is required. You can connect with SSH just as would to a public Amazon EC2 instance.

To connect an ssh client to your DB instance, complete the following steps:

1. Step 1: Configure your DB instance to allow SSH connections
2. Step 2: Retrieve your SSH secret key and EC2 instance ID
3. Step 3: Connect to your EC2 instance using the ssh utility

Step 1: Configure your DB instance to allow SSH connections

To make sure that your DB instance can accept SSH connections, do the following:

- Make sure that your DB instance security group permits inbound connections on port 22 for TCP.

  To learn how to configure the security group for your DB instance, see Controlling access with security groups.
- If you don't plan to use SSH tunneling, make sure your DB instance resides in a public subnet and is publicly accessible.

  In the console, the relevant field is **Publicly accessible** on the **Connectivity & security** tab of the database details page. To check your settings in the CLI, run the following command:

  ```
  aws rds describe-db-instances \
  --query 'DBInstances[*].
  {DBInstanceIdentifier:DBInstanceIdentifier,PubliclyAccessible:PubliclyAccessible}' \
  --output table
  ```

  To change the accessibility settings for your DB instance, see Modifying an Amazon RDS DB instance.

Step 2: Retrieve your SSH secret key and EC2 instance ID

To connect to the DB instance using SSH, you need the SSH key pair associated with the instance. RDS Custom creates the SSH key pair on your behalf, naming it with the prefix `do-not-delete-rds-custom-ssh-privatekey-db-`. AWS Secrets Manager stores your SSH private key as a secret.

Retrieve your SSH secret key using either AWS Management Console or the AWS CLI. If your instance has a public DNS, and you don't intend to use SSH tunneling, then also retrieve the DNS name. You specify the DNS name for public connections.

Console

To retrieve the secret SSH key

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**, and then choose the RDS Custom DB instance to which you want to connect.
3. Choose **Configuration**.
4. Note the **Resource ID** value. For example, the DB instance resource ID might be `db-ABCDEFGHIJKLMNOPQRS0123456`.
5. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
6. In the navigation pane, choose **Instances**.
7. Find the name of your EC2 instance, and choose the instance ID associated with it. For example, the EC2 instance ID might be `i-abcdefghijklm01234`.
8. In **Details**, find **Key pair name**. The pair name includes the DB instance resource ID. For example, the pair name might be `do-not-delete-rds-custom-ssh-privatekey-db-ABCDEFGHIJKLMNOPQRS0123456-0d726c`.
9. If your EC2 instance is public, note the **Public IPv4 DNS**. For the example, the public Domain Name System (DNS) address might be `ec2-12-345-678-901.us-east-2.compute.amazonaws.com`.
10. Open the AWS Secrets Manager console at https://console.aws.amazon.com/secretsmanager/.
11. Choose the secret that has the same name as your key pair.
12. Choose **Retrieve secret value**.
13. Copy the SSH private key into a text file, and then save the file with the `.pem` extension. For example, save the file as `/tmp/do-not-delete-rds-custom-ssh-privatekey-db-ABCDEFGHIJKLMNOPQRS0123456-0d726c.pem`.

AWS CLI

To retrieve the SSH private key and save it in a .pem file, you can use the AWS CLI.

1. Find the DB resource ID of your RDS Custom DB instance using `aws rds describe-db-instances`.

```
aws rds describe-db-instances \
    --query 'DBInstances[*].[DBInstanceIdentifier,DbiResourceId]' \
    --output text
```

The following sample output shows the resource ID for your RDS Custom instance. The prefix is `db-`.

```
db-ABCDEFGHIJKLMNOPQRS0123456
```

2. Find the EC2 instance ID of your DB instance using `aws ec2 describe-instances`. The following example uses `db-ABCDEFGHIJKLMNOPQRS0123456` for the resource ID.

```
aws ec2 describe-instances \
    --filters "Name=tag:Name,Values=db-ABCDEFGHIJKLMNOPQRS0123456" \
    --output text \
    --query 'Reservations[*].Instances[*].InstanceId'
```

The following sample output shows the EC2 instance ID.

```
i-abcdefghijklm01234
```

3. To find the key name, specify the EC2 instance ID. The following example describes EC2 instance *i-0bdc4219e66944afa*.

```
aws ec2 describe-instances \
    --instance-ids i-0bdc4219e66944afa \
    --output text \
    --query 'Reservations[*].Instances[*].KeyName'
```

The following sample output shows the key name, which uses the prefix `do-not-delete-rds-custom-ssh-privatekey-`.

```
do-not-delete-rds-custom-ssh-privatekey-db-ABCDEFGHIJKLMNOPQRS0123456-0d726c
```

4. Save the private key in a .pem file named after the key using `aws secretsmanager`. The following example saves the file in your `/tmp` directory.

```
aws secretsmanager get-secret-value \
```

```
    --secret-id do-not-delete-rds-custom-ssh-privatekey-db-
ABCDEFGHIJKLMNOPQRS0123456-0d726c \
    --query SecretString \
    --output text >/tmp/do-not-delete-rds-custom-ssh-privatekey-db-
ABCDEFGHIJKLMNOPQRS0123456-0d726c.pem
```

Step 3: Connect to your EC2 instance using the ssh utility

Your connection technique depends on whether you are connecting to a private DB instance or connecting to a public instance. A private connection requires you to configure SSH tunneling through AWS Systems Manager.

To connect to an EC2 instance using the ssh utility

1. For private connections, modify your SSH configuration file to proxy commands to AWS Systems Manager Session Manager. For public connections, skip to Step 2.

   Add the following lines to `~/.ssh/config`. These lines proxy SSH commands for hosts whose names begin with `i-` or `mi-`.

   ```
   Host i-* mi-*
       ProxyCommand sh -c "aws ssm start-session --target %h --document-name AWS-
   StartSSHSession --parameters 'portNumber=%p'"
   ```

2. Change to the directory that contains your .pem file. Using `chmod`, set the permissions to `400`.

   ```
   cd /tmp
   chmod 400 do-not-delete-rds-custom-ssh-privatekey-db-
   ABCDEFGHIJKLMNOPQRS0123456-0d726c.pem
   ```

3. Run the ssh utility, specifying the .pem file and either the public DNS name (for public connections) or the EC2 instance ID (for private connections). Log in as user `ec2-user`.

   The following example connects to a public instance using the DNS name *ec2-12-345-678-901.us-east-2.compute.amazonaws.com*.

   ```
   ssh -i \
       "do-not-delete-rds-custom-ssh-privatekey-db-
   ABCDEFGHIJKLMNOPQRS0123456-0d726c.pem" \
       ec2-user@ec2-12-345-678-901.us-east-2.compute.amazonaws.com
   ```

The following example connects to a private instance using the EC2 instance ID *i-0bdc4219e66944afa*.

```
ssh -i \
    "do-not-delete-rds-custom-ssh-privatekey-db-
ABCDEFGHIJKLMNOPQRS0123456-0d726c.pem" \
    ec2-user@i-0bdc4219e66944afa
```

Logging in to your RDS Custom for Oracle database as SYS

After you create your RDS Custom DB instance, you can log in to your Oracle database as user SYS, which gives you SYSDBA privileges. You have the following login options:

- Get the SYS password from Secrets Manager, and specify this password in your SQL client.
- Use OS authentication to log in to your database. In this case, you don't need a password.

Finding the SYS password for your RDS Custom for Oracle database

Your can log in to your Oracle database as SYS or SYSTEM or by specifying the master user name in an API call. The password for SYS and SYSTEM is stored in Secrets Manager. The secret uses the naming format do-not-delete-rds-custom-*resource_id*-*uuid*. You can find the password using the AWS Management Console.

Console

To find the SYS password for your database in Secrets Manager

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the RDS console, complete the following steps:
    a. In the navigation pane, choose **Databases**.
    b. Choose the name of your RDS Custom for Oracle DB instance.
    c. Choose **Configuration**.
    d. Copy the value underneath **Resource ID**. For example, you resource ID might be **db-ABC12CDE3FGH4I5JKLMNO6PQR7**.
3. Open the Secrets Manager console at https://console.aws.amazon.com/secretsmanager/.

4. In the Secrets Manager console, complete the following steps:

   a. In the left navigation pane, choose **Secrets**.

   b. Filter the secrets by the resource ID that you copied in step 5.

   c. Choose the secret named **do-not-delete-rds-custom-*resource_id*-*uuid***, where *resource_id* is the resource ID that you copied in step 5. For example, if your resource ID is **db-ABC12CDE3FGH4I5JKLMNO6PQR7**, your secret will be named **do-not-delete-rds-custom-db-ABC12CDE3FGH4I5JKLMNO6PQR7**.

   d. In **Secret value**, choose **Retrieve secret value**.

   e. In **Key/value**, copy the value for **password**.

5. Install SQL*Plus on your DB instance and log in to your database as SYS. For more information, see Step 3: Connect your SQL client to an Oracle DB instance.

Logging in to your RDS Custom for Oracle database using OS authentication

The OS user `rdsdb` owns the Oracle database binaries. You can switch to the `rdsdb` user and log in to your RDS Custom for Oracle database without a password.

1. Connect to your DB instance with AWS Systems Manager. For more information, see Connecting to your RDS Custom DB instance using Session Manager.
2. In a web browser, go to https://www.oracle.com/database/technologies/instant-client/linux-x86-64-downloads.html.
3. For the latest database version that appears on the web page, copy the .rpm links (not the .zip links) for the Instant Client Basic Package and SQL*Plus Package. For example, the following links are for Oracle Database version 21.9:

   - https://download.oracle.com/otn_software/linux/instantclient/219000/oracle-instantclient-basic-21.9.0.0.0-1.el8.x86_64.rpm
   - https://download.oracle.com/otn_software/linux/instantclient/219000/oracle-instantclient-sqlplus-21.9.0.0.0-1.el8.x86_64.rpm

4. In your SSH session, run the `wget` command to the download the .rpm files from the links that you obtained in the previous step. The following example downloads the .rpm files for Oracle Database version 21.9:

```
wget https://download.oracle.com/otn_software/linux/instantclient/219000/oracle-
instantclient-basic-21.9.0.0.0-1.el8.x86_64.rpm
```

```
wget https://download.oracle.com/otn_software/linux/instantclient/219000/oracle-
instantclient-sqlplus-21.9.0.0.0-1.el8.x86_64.rpm
```

5. Install the packages by running the `yum` command as follows:

```
sudo yum install oracle-instantclient-*.rpm
```

6. Switch to the `rdsdb` user.

```
sudo su - rdsdb
```

7. Log in to your database using OS authentication.

```
$ sqlplus / as sysdba

SQL*Plus: Release 21.0.0.0.0 - Production on Wed Apr 12 20:11:08 2023
Version 21.9.0.0.0

Oracle Database 19c Enterprise Edition Release 19.0.0.0.0 - Production
Version 19.10.0.0.0
```

Installing additional software components on your RDS Custom for Oracle DB instance

In a newly created DB instance, your database environment includes Oracle binaries, a database, and a database listener. You might want to install additional software on the host operating system of the DB instance. For example, you might want to install Oracle Application Express (APEX), the Oracle Enterprise Manager (OEM) agent, or the Guardium S-TAP agent. For guidelines and high-level instructions, see the detailed AWS blog post Install additional software components on Amazon RDS Custom for Oracle.

Managing an Amazon RDS Custom for Oracle DB instance

Amazon RDS Custom supports a subset of the usual management tasks for Amazon RDS DB instances. Following, you can find instructions for the supported RDS Custom for Oracle management tasks using the AWS Management Console and the AWS CLI.

Topics

Working with container databases (CDBs) in RDS Custom for Oracle

You can either create your RDS Custom for Oracle DB instance with the Oracle multitenant architecture (`custom-oracle-ee-cdb` or `custom-oracle-se2-cdb` engine type) or with the traditional non-CDB architecture (`custom-oracle-ee` or `custom-oracle-se2` engine type). When you create a container database (CDB), it contains one pluggable database (PDB) and one PDB seed. You can create additional PDBs manually using Oracle SQL.

PDB and CDB names

When you create an RDS Custom for Oracle CDB instance, you specify a name for the initial PDB. By default, your initial PDB is named `ORCL`. You can choose a different name.

By default, your CDB is named `RDSCDB`. You can choose a different name. The CDB name is also the name of your Oracle system identifier (SID), which uniquely identifies the memory and processes that manage your CDB. For more information about the Oracle SID, see Oracle System Identifier (SID) in *Oracle Database Concepts*.

You can't rename existing PDBs using Amazon RDS APIs. You also can't rename the CDB using the `modify-db-instance` command.

PDB management

In the RDS Custom for Oracle shared responsibility model, you are responsible for managing PDBs and creating any additional PDBs. RDS Custom doesn't restrict the number of PDBs. You can manually create, modify, and delete PDBs by connecting to the CDB root and running a SQL statement. Create PDBs on an Amazon EBS data volume to prevent the DB instance from going outside the support perimeter.

To modify your CDBs or PDBs, complete the following steps:

1. Pause automation to prevent interference with RDS Custom actions.
2. Modify your CDB or PDBs.
3. Back up any modified PDBs.
4. Resume RDS Custom automation.

Automatic recovery of the CDB root

RDS Custom keeps the CDB root open in the same way as it keeps a non-CDB open. If the state of the CDB root changes, the monitoring and recovery automation attempts to recover the CDB root to the desired state. You receive RDS event notifications when the root CDB is shut down (`RDS-EVENT-0004`) or restarted (`RDS-EVENT-0006`), similar to the non-CDB architecture. RDS Custom attempts to open all PDBs in `READ WRITE` mode at DB instance startup. If some PDBs can't be opened, RDS Custom publishes the following event: `tenant database shutdown`.

Working with high availability features for RDS Custom for Oracle

To support replication between RDS Custom for Oracle DB instances, you can configure high availability (HA) with Oracle Data Guard. The primary DB instance automatically synchronizes data to the standby instances. This feature is supported only in Enterprise Edition.

You can configure your high availability environment in the following ways:

- Configure standby instances in different Availability Zones (AZs) to be resilient to AZ failures.
- Place your standby databases in mounted or read-only mode.
- Fail over or switch over from the primary database to a standby database with no data loss.
- Migrate data by configuring high availability for your on-premises instance, and then failing over or switching over to the RDS Custom standby database.

To learn how to configure high availability, see the whitepaper Build high availability for Amazon RDS Custom for Oracle using read replicas. You can perform the following tasks:

- Use a virtual private network (VPN) tunnel to encrypt data in transit for your high availability instances. Encryption in transit isn't configured automatically by RDS Custom.
- Configure Oracle Fast-Failover Observer (FSFO) to monitor your high availability instances.
- Allow the observer to perform automatic failover when necessary conditions are met.

Customizing your RDS Custom environment

RDS Custom for Oracle includes built-in features that allow you to customize your DB instance environment without pausing automation. For example, you can use RDS APIs to customize your environment as follows:

- Create and restore DB snapshots to create a clone environment.
- Create read replicas.
- Modify storage settings.
- Change the CEV to apply release updates

For some customizations, such as changing the character set, you can't use the RDS APIs. In these cases, you need to change the environment manually by accessing your Amazon EC2 instance as the root user or logging in to your Oracle database as SYSDBA.

To customize your instance manually, you must pause and resume RDS Custom automation. This pause ensures that your customizations don't interfere with RDS Custom automation. In this way, you avoid breaking the support perimeter, which places the instance in the `unsupported-configuration` state until you fix the underlying issues. Pausing and resuming are the only supported automation tasks when you modify an RDS Custom for Oracle DB instance.

General steps for customizing your RDS Custom environment

To customize your RDS Custom DB instance, complete the following steps:

1. Pause RDS Custom automation for a specified period using the console or CLI.
2. Identify your underlying Amazon EC2 instance.
3. Connect to your underlying Amazon EC2 instance using SSH keys or AWS Systems Manager.

4. Verify your current configuration settings at the database or operating system layer.

   You can validate your changes by comparing the initial configuration to the changed configuration. Depending on the type of customization, use OS tools or database queries.

5. Customize your RDS Custom for Oracle DB instance as needed.

6. Reboot your instance or database, if required.

   > **Note**
   >
   > In an on-premises Oracle CDB, you can preserve a specified open mode for PDBs using a built-in command or after a startup trigger. This mechanism brings PDBs to a specified state when the CDB restarts. When opening your CDB, RDS Custom automation discards any user-specified preserved states and attempts to open all PDBs. If RDS Custom can't open all PDBs, the following event is issued: `The following PDBs failed to open: list-of-PDBs`.

7. Verify your new configuration settings by comparing them with the previous settings.

8. Resume RDS Custom automation in either of the following ways:

   - Resume automation manually.
   - Wait for the pause period to end. In this case, RDS Custom resumes monitoring and instance recovery automatically.

9. Verify the RDS Custom automation framework

   If you followed the preceding steps correctly, RDS Custom starts an automated backup. The status of the instance in the console shows **Available**.

For best practices and step-by-step instructions, see the AWS blog posts Make configuration changes to an Amazon RDS Custom for Oracle instance: Part 1 and Recreate an Amazon RDS Custom for Oracle database: Part 2.

Pausing and resuming your RDS Custom DB instance

You can pause and resume automation for your DB instance using the console or CLI.

Console

To pause or resume RDS Custom automation

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**, and then choose the RDS Custom DB instance that you want to modify.
3. Choose **Modify**. The **Modify DB instance** page appears.
4. For **RDS Custom automation mode**, choose one of the following options:
   - **Paused** pauses the monitoring and instance recovery for the RDS Custom DB instance. Enter the pause duration that you want (in minutes) for **Automation mode duration**. The minimum value is 60 minutes (default). The maximum value is 1,440 minutes.
   - **Full automation** resumes automation.
5. Choose **Continue** to check the summary of modifications.

   A message indicates that RDS Custom will apply the changes immediately.
6. If your changes are correct, choose **Modify DB instance**. Or choose **Back** to edit your changes or **Cancel** to cancel your changes.

   On the RDS console, the details for the modification appear. If you paused automation, the **Status** of your RDS Custom DB instance indicates **Automation paused**.
7. (Optional) In the navigation pane, choose **Databases**, and then your RDS Custom DB instance.

   In the **Summary** pane, **RDS Custom automation mode** indicates the automation status. If automation is paused, the value is **Paused. Automation resumes in *num* minutes**.

AWS CLI

To pause or resume RDS Custom automation, use the `modify-db-instance` AWS CLI command. Identify the DB instance using the required parameter `--db-instance-identifier`. Control the automation mode with the following parameters:

- `--automation-mode` specifies the pause state of the DB instance. Valid values are `all-paused`, which pauses automation, and `full`, which resumes it.

- `--resume-full-automation-mode-minutes` specifies the duration of the pause. The default value is 60 minutes.

> **Note**
>
> Regardless of whether you specify `--no-apply-immediately` or `--apply-immediately`, RDS Custom applies modifications asynchronously as soon as possible.

In the command response, `ResumeFullAutomationModeTime` indicates the resume time as a UTC timestamp. When the automation mode is `all-paused`, you can use `modify-db-instance` to resume automation mode or extend the pause period. No other `modify-db-instance` options are supported.

The following example pauses automation for `my-custom-instance` for 90 minutes.

Example

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier my-custom-instance \
    --automation-mode all-paused \
    --resume-full-automation-mode-minutes 90
```

For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier my-custom-instance ^
    --automation-mode all-paused ^
    --resume-full-automation-mode-minutes 90
```

The following example extends the pause duration for an extra 30 minutes. The 30 minutes is added to the original time shown in `ResumeFullAutomationModeTime`.

Example

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
```

```
    --db-instance-identifier my-custom-instance \
    --automation-mode all-paused \
    --resume-full-automation-mode-minutes 30
```

For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier my-custom-instance ^
    --automation-mode all-paused ^
    --resume-full-automation-mode-minutes 30
```

The following example resumes full automation for `my-custom-instance`.

Example

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier my-custom-instance \
    --automation-mode full \
```

For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier my-custom-instance ^
    --automation-mode full
```

In the following partial sample output, the pending `AutomationMode` value is `full`.

```
{
    "DBInstance": {
        "PubliclyAccessible": true,
        "MasterUsername": "admin",
        "MonitoringInterval": 0,

Modifying your RDS Custom for Oracle DB instance

Modifying an RDS Custom for Oracle DB instance is similar to modifying an Amazon RDS DB instance. You can change settings such as the following:

- DB instance class
- Storage allocation and type
- Backup retention period
- Deletion protection
- Option group
- CEV (see Upgrading an RDS Custom for Oracle DB instance)
- Port

Topics

Requirements and limitations when modifying your DB instance storage

Consider the following requirements and limitations when you modify the storage for an RDS Custom for Oracle DB instance:

- The minimum allocated storage for RDS Custom for Oracle is 40 GiB, and the maximum is 64 TiB.
- As with Amazon RDS, you can't decrease the allocated storage. This is a limitation of Amazon EBS volumes.
- Storage autoscaling isn't supported for RDS Custom DB instances.

- Any storage volumes that you attach manually to your RDS Custom DB instance are outside the support perimeter.

  For more information, see RDS Custom support perimeter.
- Magnetic (standard) Amazon EBS storage isn't supported for RDS Custom. You can choose only the io1, gp2, or gp3 SSD storage types.

For more information about Amazon EBS storage, see Amazon RDS DB instance storage. For general information about storage modification, see Working with storage for Amazon RDS DB instances.

Requirements and limitations when modifying your DB instance class

Consider the following requirements and limitations when you modify the instance class for an RDS Custom for Oracle DB instance:

- Your DB instance must be in the `available` state.
- Your DB instance must have a minimum of 100 MiB of free space on the root volume, data volume, and binary volume.
- You can assign only a single elastic IP (EIP) to your RDS Custom for Oracle DB instance when using the default elastic network interface (ENI). If you attach multiple ENIs to your DB instance, the modify operation fails.
- All RDS Custom for Oracle tags must be present.
- If you use RDS Custom for Oracle replication, note the following requirements and limitations:
  - For primary DB instances and read replicas, you can change the instance class for only one DB instance at a time.
  - If your RDS Custom for Oracle DB instance has an on-premises primary or replica database, make sure to manually update private IP addresses on the on-premises DB instance after the modification completes. This action is necessary to preserve Oracle DataGuard functionality. RDS Custom for Oracle publishes an event when the modification succeeds.
  - You can't modify your RDS Custom for Oracle DB instance class when the primary or read replica DB instances have FSFO (Fast-Start Failover) configured.

How RDS Custom creates your DB instance when you modify the instance class

When you modify your instance class, RDS Custom creates your DB instance as follows:

- Creates the Amazon EC2 instance.
- Creates the root volume from the latest DB snapshot. RDS Custom for Oracle doesn't retain information added to the root volume after the latest DB snapshot.
- Creates Amazon CloudWatch alarms.
- Creates an Amazon EC2 SSH key pair if you have deleted the original key pair. Otherwise, RDS Custom for Oracle retains the original key pair.
- Creates new resources using the tags that are attached to your DB instance when you initiate the modification. RDS Custom doesn't transfer tags to the new resources when they are attached directly to underlying resources.
- Transfers the binary and data volumes with the most recent modifications to the new DB instance.
- Transfers the elastic IP address (EIP). If the DB instance is publicly accessible, then RDS Custom temporarily attaches a public IP address to the new DB instance before transferring the EIP. If the DB instance isn't publicly accessible, RDS Custom doesn't create public IP addresses.

Modifying your RDS Custom for Oracle DB instance

You can modify the DB instance class or storage using the console, AWS CLI, or RDS API.

Console

To modify an RDS Custom for Oracle DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.
3. Choose the DB instance that you want to modify.
4. Choose **Modify**.
5. (Optional) In **Instance configuration**, choose a value for **DB instance class**. For supported classes, see DB instance class support for RDS Custom for Oracle.
6. (Optional) In **Storage**, make the following changes as needed:

    a. Enter a new value for **Allocated storage**. It must be greater than the current value, and from 40 GiB–64 TiB.

    b. Change the value for **Storage type** to **General Purpose SSD (gp2)**, **General Purpose SSD (gp3)**, or **Provisioned IOPS (io1)**.

c. If you use **Provisioned IOPS (io1)** or **General Purpose SSD (gp3)**, you can change the **Provisioned IOPS** value.

7. (Optional) In **Additional configuration**, make the following changes as needed:
   - For **Option group**, choose a new option group. For more information, see Working with option groups in RDS Custom for Oracle.
8. Choose **Continue**.
9. Choose **Apply immediately** or **Apply during the next scheduled maintenance window**.
10. Choose **Modify DB instance**.

AWS CLI

To modify the storage for an RDS Custom for Oracle DB instance, use the modify-db-instance AWS CLI command. Set the following parameters as needed:

- `--db-instance-class` – A new instance class. For supported classes, see DB instance class support for RDS Custom for Oracle.
- `--allocated-storage` – Amount of storage to be allocated for the DB instance, in gibibytes. It must be greater than the current value, and from 40–65,536 GiB.
- `--storage-type` – The storage type: gp2, gp3, or io1.
- `--iops` – Provisioned IOPS for the DB instance, if using the io1 or gp3 storage types.
- `--apply-immediately` – Use `--apply-immediately` to apply the storage changes immediately.

  Or use `--no-apply-immediately` (the default) to apply the changes during the next maintenance window.

The following example changes the DB instance class of my-cfo-instance to db.m5.16xlarge. The command also changes the storage size to 1 TiB, storage type to io1, Provisioned IOPS to 3000, and option group to cfo-ee-19-mt.

Example

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier my-cfo-instance \
```

```
    --db-instance-class db.m5.16xlarge \
    --storage-type io1 \
    --iops 3000 \
    --allocated-storage 1024 \
    --option-group cfo-ee-19-mt \
    --apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier my-cfo-instance ^
    --db-instance-class db.m5.16xlarge ^
    --storage-type io1 ^
    --iops 3000 ^
    --allocated-storage 1024 ^
    --option-group cfo-ee-19-mt ^
    --apply-immediately
```

Changing the character set of an RDS Custom for Oracle DB instance

RDS Custom for Oracle defaults to the character set US7ASCII. You might want to specify different character sets to meet language or multibyte character requirements. When you use RDS Custom for Oracle, you can pause automation and then change the character set of your database manually.

Changing the character set of an RDS Custom for Oracle DB instance has the following requirements:

- You can only change the character on a newly provisioned RDS Custom instance that has an empty or starter database with no application data. For all other scenarios, change the character set using DMU (Database Migration Assistant for Unicode).
- You can only change to a character set supported by RDS for Oracle. For more information, see Supported DB character sets.

To change the character set of an RDS Custom for Oracle DB instance

1. Pause RDS Custom automation. For more information, see Pausing and resuming your RDS Custom DB instance.
2. Log in to your database as a user with SYSDBA privileges.

3. Restart the database in restricted mode, change the character set, and then restart the database in normal mode.

   Run the following script in your SQL client:

   ```
   SHUTDOWN IMMEDIATE;
   STARTUP RESTRICT;
   ALTER DATABASE CHARACTER SET INTERNAL_CONVERT AL32UTF8;
   SHUTDOWN IMMEDIATE;
   STARTUP;
   SELECT VALUE FROM NLS_DATABASE_PARAMETERS WHERE PARAMETER = 'NLS_CHARACTERSET';
   ```

   Verify that the output shows the correct character set:

   ```
   VALUE
   --------
   AL32UTF8
   ```

4. Resume RDS Custom automation. For more information, see Pausing and resuming your RDS Custom DB instance.

Setting the NLS_LANG value in RDS Custom for Oracle

A *locale* is a set of information addressing linguistic and cultural requirements that corresponds to a given language and country. To specify locale behavior for Oracle software, set the NLS_LANG environment variable on your client host. This variable sets the language, territory, and character set used by the client application in a database session.

For RDS Custom for Oracle, you can set only the language in the NLS_LANG variable: the territory and character use defaults. The language is used for Oracle database messages, collation, day names, and month names. Each supported language has a unique name, for example, American, French, or German. If language is not specified, the value defaults to American.

After you create your RDS Custom for Oracle database, you can set NLS_LANG on your client host to a language other than English. To see a list of languages supported by Oracle Database, log in to your RDS Custom for Oracle database and run the following query:

```
SELECT VALUE FROM V$NLS_VALID_VALUES WHERE PARAMETER='LANGUAGE' ORDER BY VALUE;
```

You can set NLS_LANG on the host command line. The following example sets the language to German for your client application using the Z shell on Linux.

```
export NLS_LANG=German
```

Your application reads the NLS_LANG value when it starts and then communicates it to the database when it connects.

For more information, see Choosing a Locale with the NLS_LANG Environment Variable in the *Oracle Database Globalization Support Guide*.

Support for Transparent Data Encryption

RDS Custom supports Transparent Data Encryption (TDE) for RDS Custom for Oracle DB instances.

However, you can't enable TDE using an option in a custom option group as you can in RDS for Oracle. You turn on TDE manually. For information about using Oracle Transparent Data Encryption, see Securing stored data using Transparent Data Encryption in the Oracle documentation.

Tagging RDS Custom for Oracle resources

You can tag RDS Custom resources as with Amazon RDS resources, but with some important differences:

- Don't create or modify the AWSRDSCustom tag that's required for RDS Custom automation. If you do, you might break the automation.
- The Name tag is added to RDS Custom resources with prefix value of do-not-delete-rds-custom. Any customer-passed value for the key is overwritten.
- Tags added to RDS Custom DB instances during creation are propagated to all other related RDS Custom resources.
- Tags aren't propagated when you add them to RDS Custom resources after DB instance creation.

For general information about resource tagging, see Tagging Amazon RDS resources.

Deleting an RDS Custom for Oracle DB instance

To delete an RDS Custom DB instance, do the following:

- Provide the name of the DB instance.

- Clear the option to take a final DB snapshot of the DB instance.
- Choose or clear the option to retain automated backups.

You can delete an RDS Custom DB instance using the console or the CLI. The time required to delete the DB instance can vary depending on the backup retention period (that is, how many backups to delete) and how much data is deleted.

Console

To delete an RDS Custom DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**, and then choose the RDS Custom DB instance that you want to delete. RDS Custom DB instances show the role **Instance (RDS Custom)**.
3. For **Actions**, choose **Delete**.
4. To retain automated backups, choose **Retain automated backups**.
5. Enter **`delete me`** in the box.
6. Choose **Delete**.

AWS CLI

You delete an RDS Custom DB instance by using the delete-db-instance AWS CLI command. Identify the DB instance using the required parameter `--db-instance-identifier`. The remaining parameters are the same as for an Amazon RDS DB instance, with the following exceptions:

- `--skip-final-snapshot` is required.
- `--no-skip-final-snapshot` isn't supported.
- `--final-db-snapshot-identifier` isn't supported.

The following example deletes the RDS Custom DB instance named `my-custom-instance`, and retains automated backups.

Example

For Linux, macOS, or Unix:

```
aws rds delete-db-instance \
    --db-instance-identifier my-custom-instance \
    --skip-final-snapshot \
    --no-delete-automated-backups
```

For Windows:

```
aws rds delete-db-instance ^
    --db-instance-identifier my-custom-instance ^
    --skip-final-snapshot ^
    --no-delete-automated-backups
```

Working with Oracle replicas for RDS Custom for Oracle

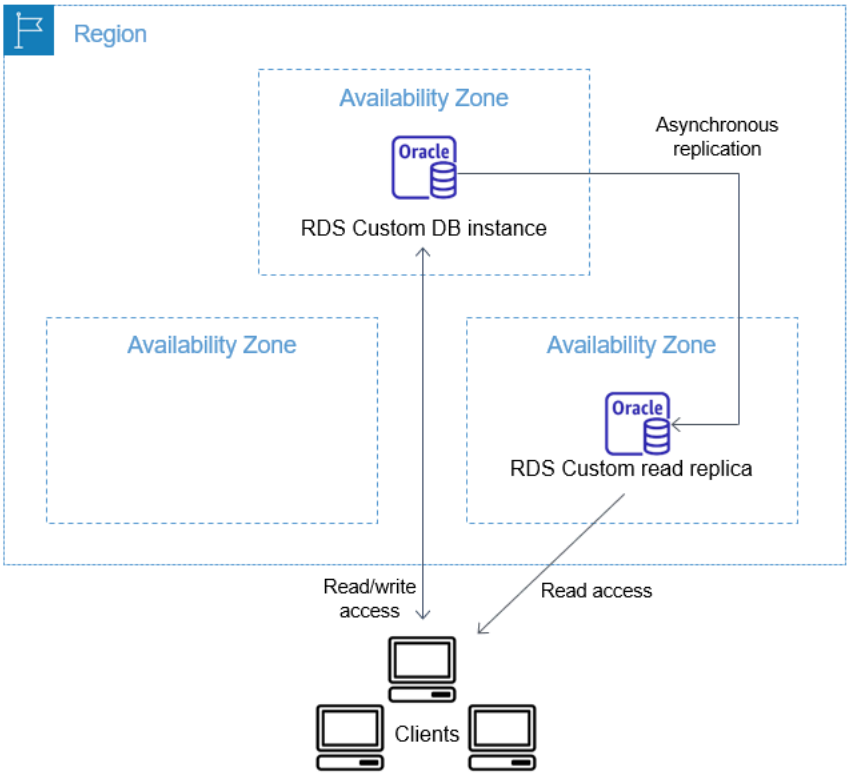
You can create Oracle replicas for RDS Custom for Oracle DB instances that run Oracle Enterprise Edition. Both container databases (CDBs) and non-CDBs are supported. Standard Edition 2 doesn't support Oracle Data Guard.

Creating an RDS Custom for Oracle replica is similar to creating an RDS for Oracle replica, but with important differences. For general information about creating and managing Oracle replicas, see Working with DB instance read replicas and Working with read replicas for Amazon RDS for Oracle.

Topics

Overview of RDS Custom for Oracle replication

The architecture of RDS Custom for Oracle replication is analogous to RDS for Oracle replication. A primary DB instance replicates asynchronously to one or more Oracle replicas.



Maximum number of replicas

As with RDS for Oracle, you can create up to five managed Oracle replicas of your RDS Custom for Oracle primary DB instance. You can also create your own manually configured (external) Oracle replicas. External replicas don't count toward your DB instance limit. They also lie outside the RDS Custom support perimeter. For more information about the support perimeter, see RDS Custom support perimeter.

Replica naming convention

Oracle replica names are based on the database unique name. The format is *DB_UNIQUE_NAME_X*, with letters appended sequentially. For example, if your database unique name is ORCL, the first two replicas are named ORCL_A and ORCL_B. The first six letters, A–F, are reserved for RDS Custom. RDS Custom copies database parameters from your primary DB instance to the replicas. For more information, see DB_UNIQUE_NAME in the Oracle documentation.

Replica backup retention

By default, RDS Custom Oracle replicas use the same backup retention period as your primary DB instance. You can modify the backup retention period to 1–35 days. RDS Custom supports backing up, restoring, and point-in-time recovery (PITR). For more information about backing up and restoring RDS Custom DB instances, see Backing up and restoring an Amazon RDS Custom for Oracle DB instance.

> **Note**
>
> While creating a Oracle replica, RDS Custom temporarily pauses the cleanup of redo log files. In this way, RDS Custom ensures that it can apply these logs to the new Oracle replica after it becomes available.

Replica promotion

You can promote managed Oracle replicas in RDS Custom for Oracle using the console, `promote-read-replica` AWS CLI command, or `PromoteReadReplica` API. If you delete your primary DB instance, and all replicas are healthy, RDS Custom for Oracle promotes your managed replicas to standalone instances automatically. If a replica has paused automation or is outside the support perimeter, you must fix the replica before RDS Custom can promote it automatically. You can only promote external Oracle replicas manually.

Guidelines and limitations for RDS Custom for Oracle replication

When you create RDS Custom for Oracle replicas, not all RDS Oracle replica options are supported.

Topics

General guidelines for RDS Custom for Oracle replication

When working with RDS Custom for Oracle, follow these guidelines:

- You can use RDS Custom for Oracle replication only in Oracle Enterprise Edition. Standard Edition 2 isn't supported.
- Don't modify the `RDS_DATAGUARD` user. This user is reserved for RDS Custom for Oracle automation. Modifying this user can result in undesired outcomes, such as an inability to create Oracle replicas for your RDS Custom for Oracle DB instance.
- Don't change the replication user password. It is required to administer the Oracle Data Guard configuration on the RDS Custom host. If you change the password, RDS Custom for Oracle might put your Oracle replica outside the support perimeter. For more information, see RDS Custom support perimeter.

  The password is stored in AWS Secrets Manager, tagged with the DB resource ID. Each Oracle replica has its own secret in Secrets Manager. The format for the secret is the following.

  ```
  do-not-delete-rds-custom-db-DB_resource_id-6-digit_UUID-dg
  ```

- Don't change the `DB_UNIQUE_NAME` for the primary DB instance. Changing the name causes any restore operation to become stuck.
- Don't specify the clause `STANDBYS=NONE` in a `CREATE PLUGGABLE DATABASE` command in an RDS Custom CDB. This way, if a failover occurs, your standby CDB contains all PDBs.

General limitations for RDS Custom for Oracle replication

RDS Custom for Oracle replicas have the following limitations:

- You can't create RDS Custom for Oracle replicas in read-only mode. However, you can manually change the mode of mounted replicas to read-only, and from read-only to mounted. For more information, see the documentation for the create-db-instance-read-replica AWS CLI command.
- You can't create cross-Region RDS Custom for Oracle replicas.
- You can't change the value of the Oracle Data Guard `CommunicationTimeout` parameter. This parameter is set to 15 seconds for RDS Custom for Oracle DB instances.

Networking requirements and limitations for RDS Custom for Oracle replication

Make sure that your network configuration supports RDS Custom for Oracle replicas. Consider the following:

- Make sure to enable port 1140 for both inbound and outbound communication within your virtual private cloud (VPC) for the primary DB instance and all of its replicas. This is required for Oracle Data Guard communication between read replicas.
- RDS Custom for Oracle validates the network while creating a Oracle replica. If the primary DB instance and the new replica can't connect over the network, RDS Custom for Oracle doesn't create the replica and places it in the `INCOMPATIBLE_NETWORK` state.
- For external Oracle replicas, such as those you create on Amazon EC2 or on-premises, use another port and listener for Oracle Data Guard replication. Trying to use port 1140 could cause conflicts with RDS Custom automation.
- The `/rdsdbdata/config/tnsnames.ora` file contains network service names mapped to listener protocol addresses. Note the following requirements and recommendations:
  - Entries in `tnsnames.ora` prefixed with `rds_custom_` are reserved for RDS Custom when handling Oracle replica operations.

    When creating manual entries in `tnsnames.ora`, don't use this prefix.
  - In some cases, you might want to switch over or fail over manually, or use failover technologies such as Fast-Start Failover (FSFO). If so, make sure to manually synchronize `tnsnames.ora` entries from the primary DB instance to all of the standby instances. This recommendation applies to both Oracle replicas managed by RDS Custom and to external Oracle replicas.

RDS Custom automation updates `tnsnames.ora` entries on only the primary DB instance. Make sure also to synchronize when you add or remove a Oracle replica.

If you don't synchronize the `tnsnames.ora` files and switch over or fail over manually, Oracle Data Guard on the primary DB instance might not be able to communicate with the Oracle replicas.

External replica limitations for RDS Custom for Oracle

RDS Custom for Oracle external replicas, which include on-premises replicas, have the following limitations:

- RDS Custom for Oracle doesn't detect instance role changes upon manual failover, such as FSFO, for external Oracle replicas.

  RDS Custom for Oracle does detect changes for managed replicas. The role change is noted in the event log. You can also see the new state by using the describe-db-instances AWS CLI command.
- RDS Custom for Oracle doesn't detect high replication lag for external Oracle replicas.

  RDS Custom for Oracle does detect lag for managed replicas. High replication lag produces the `Replication has stopped` event. You can also see the replication status by using the describe-db-instances AWS CLI command, but there might be a delay for it to be updated.
- RDS Custom for Oracle doesn't promote external Oracle replicas automatically if you delete your primary DB instance.

  The automatic promotion feature is available only for managed Oracle replicas. For information about promoting Oracle replicas manually, see the white paper Enabling high availability with Data Guard on Amazon RDS Custom for Oracle.

Replica promotion limitations for RDS Custom for Oracle

Promoting RDS Custom for Oracle managed Oracle replicas is the same as promoting RDS managed replicas, with some differences. Note the following limitations for RDS Custom for Oracle replicas:

- You can't promote a replica while RDS Custom for Oracle is backing it up.

- You can't change the backup retention period to `0` when you promote your Oracle replica.
- You can't promote your replica when it isn't in a healthy state.

  If you issue `delete-db-instance` on the primary DB instance, RDS Custom for Oracle validates that each managed Oracle replica is healthy and available for promotion. A replica might be ineligible for promotion because automation is paused or it is outside the support perimeter. In such cases, RDS Custom for Oracle publishes an event explaining the issue so that you can repair your Oracle replica manually.

Replica promotion guidelines for RDS Custom for Oracle

When promoting a replica, note the following guidelines:

- Don't initiate a failover while RDS Custom for Oracle is promoting your replica. Otherwise, the promotion workflow could become stuck.
- Don't switch over your primary DB instance while RDS Custom for Oracle is promoting your Oracle replica. Otherwise, the promotion workflow could become stuck.
- Don't shut down your primary DB instance while RDS Custom for Oracle is promoting your Oracle replica. Otherwise, the promotion workflow could become stuck.
- Don't try to restart replication with your newly promoted DB instance as a target. After RDS Custom for Oracle promotes your Oracle replica, it becomes a standalone DB instance and no longer has the replica role.

For more information, see Troubleshooting replica promotion for RDS Custom for Oracle.

Promoting an RDS Custom for Oracle replica to a standalone DB instance

Just as with RDS for Oracle, you can promote an RDS Custom for Oracle replica to a standalone DB instance. When you promote a Oracle replica, RDS Custom for Oracle reboots the DB instance before it becomes available. For more information about promoting Oracle replicas, see Promoting a read replica to be a standalone DB instance.

The following steps show the general process for promoting a Oracle replica to a DB instance:

1. Stop any transactions from being written to the primary DB instance.
2. Wait for RDS Custom for Oracle to apply all updates to your Oracle replica.

3. Promote your Oracle replica by choosing the **Promote** option on the Amazon RDS console, the AWS CLI command `promote-read-replica`, or the `PromoteReadReplica` Amazon RDS API operation.

Promoting a Oracle replica takes a few minutes to complete. During the process, RDS Custom for Oracle stops replication and reboots your replica. When the reboot completes, the Oracle replica is available as a standalone DB instance.

Console

To promote an RDS Custom for Oracle replica to a standalone DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the Amazon RDS console, choose **Databases**.

   The **Databases** pane appears. Each Oracle replica shows **Replica** in the **Role** column.
3. Choose the RDS Custom for Oracle replica that you want to promote.
4. For **Actions**, choose **Promote**.
5. On the **Promote Oracle replica** page, enter the backup retention period and the backup window for the newly promoted DB instance. You can't set this value to **0**.
6. When the settings are as you want them, choose **Promote Oracle replica**.

AWS CLI

To promote your RDS Custom for Oracle replica to a standalone DB instance, use the AWS CLI `promote-read-replica` command.

Example

For Linux, macOS, or Unix:

```
aws rds promote-read-replica \
--db-instance-identifier my-custom-read-replica \
--backup-retention-period 2 \
--preferred-backup-window 23:00-24:00
```

For Windows:

```
aws rds promote-read-replica ^
--db-instance-identifier my-custom-read-replica ^
--backup-retention-period 2 ^
--preferred-backup-window 23:00-24:00
```

RDS API

To promote your RDS Custom for Oracle replica to be a standalone DB instance, call the Amazon RDS API `PromoteReadReplica` operation with the required parameter `DBInstanceIdentifier`.

Backing up and restoring an Amazon RDS Custom for Oracle DB instance

Like Amazon RDS, RDS Custom creates and saves automated backups of your RDS Custom for Oracle DB instance during the backup window of your DB instance. You can also back up your DB instance manually.

The procedure is identical to taking a snapshot of an Amazon RDS DB instance. The first snapshot of an RDS Custom DB instance contains the data for the full DB instance. Subsequent snapshots are incremental.

Restore DB snapshots using either the AWS Management Console or the AWS CLI.

Topics

Creating an RDS Custom for Oracle snapshot

RDS Custom for Oracle creates a storage volume snapshot of your DB instance, backing up the entire DB instance and not just individual databases. When your DB instance contains a container database (CDB), the snapshot of the instance includes the root CDB and all PDBs.

When you create an RDS Custom for Oracle snapshot, specify which RDS Custom DB instance to back up. Give your snapshot a name so you can restore from it later.

When you create a snapshot, RDS Custom for Oracle creates an Amazon EBS snapshot for every volume attached to the DB instance. RDS Custom for Oracle uses the EBS snapshot of the root volume to register a new Amazon Machine Image (AMI). To make snapshots easy to associate with a specific DB instance, they're tagged with `DBSnapshotIdentifier`, `DbiResourceId`, and `VolumeType`.

Creating a DB snapshot results in a brief I/O suspension. This suspension can last from a few seconds to a few minutes, depending on the size and class of your DB instance. The snapshot creation time varies with the size of your database. Because the snapshot includes the entire

storage volume, the size of files, such as temporary files, also affects snapshot creation time. To learn more about creating snapshots, see Creating a DB snapshot for a Single-AZ DB instance.

Create an RDS Custom for Oracle snapshot using the console or the AWS CLI.

Console

To create an RDS Custom snapshot

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.
3. In the list of RDS Custom DB instances, choose the instance for which you want to take a snapshot.
4. For **Actions**, choose **Take snapshot**.

   The **Take DB snapshot** window appears.
5. For **Snapshot name**, enter the name of the snapshot.
6. Choose **Take snapshot**.

AWS CLI

You create a snapshot of an RDS Custom DB instance by using the create-db-snapshot AWS CLI command.

Specify the following options:

- `--db-instance-identifier` – Identifies which RDS Custom DB instance you are going to back up
- `--db-snapshot-identifier` – Names your RDS Custom snapshot so you can restore from it later

In this example, you create a DB snapshot called *`my-custom-snapshot`* for an RDS Custom DB instance called *`my-custom-instance`*.

Example

For Linux, macOS, or Unix:

```
aws rds create-db-snapshot \
    --db-instance-identifier my-custom-instance \
    --db-snapshot-identifier my-custom-snapshot
```

For Windows:

```
aws rds create-db-snapshot ^
    --db-instance-identifier my-custom-instance ^
    --db-snapshot-identifier my-custom-snapshot
```

Restoring from an RDS Custom for Oracle DB snapshot

When you restore an RDS Custom for Oracle DB instance, you provide the name of the DB snapshot and a name for the new instance. You can't restore from a snapshot to an existing RDS Custom DB instance. A new RDS Custom for Oracle DB instance is created when you restore.

The restore process differs in the following ways from restore in Amazon RDS:

- Before restoring a snapshot, RDS Custom for Oracle backs up existing configuration files. These files are available on the restored instance in the directory `/rdsdbdata/config/backup`. RDS Custom for Oracle restores the DB snapshot with default parameters and overwrites the previous database configuration files with existing ones. Thus, the restored instance doesn't preserve custom parameters and changes to database configuration files.
- The restored database has the same name as in the snapshot. You can't specify a different name. (For RDS Custom for Oracle, the default is `ORCL`.)

Console

To restore an RDS Custom DB instance from a DB snapshot

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Snapshots**.
3. Choose the DB snapshot that you want to restore from.
4. For **Actions**, choose **Restore snapshot**.
5. On the **Restore DB instance** page, for **DB instance identifier**, enter the name for your restored RDS Custom DB instance.

6. Choose **Restore DB instance**.

AWS CLI

You restore an RDS Custom DB snapshot by using the restore-db-instance-from-db-snapshot AWS CLI command.

If the snapshot you are restoring from is for a private DB instance, make sure to specify both the correct `db-subnet-group-name` and `no-publicly-accessible`. Otherwise, the DB instance defaults to publicly accessible. The following options are required:

- `db-snapshot-identifier` – Identifies the snapshot from which to restore
- `db-instance-identifier` – Specifies the name of the RDS Custom DB instance to create from the DB snapshot
- `custom-iam-instance-profile` – Specifies the instance profile associated with the underlying Amazon EC2 instance of an RDS Custom DB instance.

The following code restores the snapshot named `my-custom-snapshot` for `my-custom-instance`.

Example

For Linux, macOS, or Unix:

```
aws rds restore-db-instance-from-db-snapshot \
  --db-snapshot-identifier my-custom-snapshot \
  --db-instance-identifier my-custom-instance \
  --custom-iam-instance-profile AWSRDSCustomInstanceProfileForRdsCustomInstance \
  --no-publicly-accessible
```

For Windows:

```
aws rds restore-db-instance-from-db-snapshot ^
  --db-snapshot-identifier my-custom-snapshot ^
  --db-instance-identifier my-custom-instance ^
  --custom-iam-instance-profile AWSRDSCustomInstanceProfileForRdsCustomInstance ^
  --no-publicly-accessible
```

Restoring an RDS Custom for Oracle instance to a point in time

You can restore a DB instance to a specific point in time (PITR), creating a new DB instance. To support PITR, your DB instances must have backup retention set to a nonzero value.

The latest restorable time for an RDS Custom for Oracle DB instance depends on several factors, but is typically within 5 minutes of the current time. To see the latest restorable time for a DB instance, use the AWS CLI describe-db-instances command and look at the value returned in the `LatestRestorableTime` field for the DB instance. To see the latest restorable time for each DB instance in the Amazon RDS console, choose **Automated backups**.

You can restore to any point in time within your backup retention period. To see the earliest restorable time for each DB instance, choose **Automated backups** in the Amazon RDS console.

For general information about PITR, see Restoring a DB instance to a specified time.

Topics

- PITR considerations for RDS Custom for Oracle

PITR considerations for RDS Custom for Oracle

In RDS Custom for Oracle, PITR differs in the following important ways from PITR in Amazon RDS:

- The restored database has the same name as in the source DB instance. You can't specify a different name. The default is `ORCL`.
- `AWSRDSCustomIamRolePolicy` requires new permissions. For more information, see Step 2: Add an access policy to AWSRDSCustomInstanceRoleForRdsCustomInstance.
- All RDS Custom for Oracle DB instances must have backup retention set to a nonzero value.
- If you change the operating system or DB instance time zone, PITR might not work. For information about changing time zones, see Oracle time zone.
- If you set automation to `ALL_PAUSED`, RDS Custom pauses the upload of archived redo log files, including logs created before the latest restorable time (LRT). We recommend that you pause automation for a brief period.

  To illustrate, assume that your LRT is 10 minutes ago. You pause automation. During the pause, RDS Custom doesn't upload archived redo logs. If your DB instance crashes, you can only recover to a time before the LRT that existed when you paused. When you resume automation, RDS Custom resumes uploading logs. The LRT advances. Normal PITR rules apply.

- In RDS Custom, you can manually specify an arbitrary number of hours to retain archived redo logs before RDS Custom deletes them after upload. Specify the number of hours as follows:

  1. Create a text file named `/opt/aws/rdscustomagent/config/redo_logs_custom_configuration.json`.
  2. Add a JSON object in the following format: `{"archivedLogRetentionHours" : "num_of_hours"}`. The number must be an integer in the range 1–840.

- Assume that you plug a non-CDB into a container database (CDB) as a PDB and then attempt PITR. The operation succeeds only if you previously backed up the PDB. After you create or modify a PDB, we recommend that you always back it up.
- We recommend that you don't customize database initialization parameters. For example, modifying the following parameters affects PITR:
  - `CONTROL_FILE_RECORD_KEEP_TIME` affects the rules for uploading and deleting logs.
  - `LOG_ARCHIVE_DEST_n` doesn't support multiple destinations.
  - `ARCHIVE_LAG_TARGET` affects the latest restorable time. `ARCHIVE_LAG_TARGET` is set to `300` because the recovery point objective (RPO) is 5 minutes. To honor this objective, RDS switches the online redo log every 5 minutes and stores it in an Amazon S3 bucket. If the frequency of the log switch causes a performance issue for your RDS Custom for Oracle database, you can scale your DB instance and storage to one with higher IOPS and throughput. If necessary for your recovery plan, you can adjust the setting of the `ARCHIVE_LAG_TARGET` initialization parameter to a value from 60–7200.
- If you customize database initialization parameters, we strongly recommend that you customize only the following:
  - `COMPATIBLE`
  - `MAX_STRING_SIZE`
  - `DB_FILES`
  - `UNDO_TABLESPACE`
  - `ENABLE_PLUGGABLE_DATABASE`
  - `CONTROL_FILES`
  - `AUDIT_TRAIL`
  - `AUDIT_TRAIL_DEST`

  For all other initialization parameters, RDS Custom restores the default values. If you modify a parameter that isn't in the preceding list, it might have an adverse effect on PITR and lead to

unpredictable results. For example, `CONTROL_FILE_RECORD_KEEP_TIME` affects the rules for uploading and deleting logs.

You can restore an RDS Custom DB instance to a point in time using the AWS Management Console, the AWS CLI, or the RDS API.

Console

To restore an RDS Custom DB instance to a specified time

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Automated backups**.
3. Choose the RDS Custom DB instance that you want to restore.
4. For **Actions**, choose **Restore to point in time**.

   The **Restore to point in time** window appears.
5. Choose **Latest restorable time** to restore to the latest possible time, or choose **Custom** to choose a time.

   If you chose **Custom**, enter the date and time to which you want to restore the instance.

   Times are shown in your local time zone, which is indicated by an offset from Coordinated Universal Time (UTC). For example, UTC-5 is Eastern Standard Time/Central Daylight Time.
6. For **DB instance identifier**, enter the name of the target restored RDS Custom DB instance. The name must be unique.
7. Choose other options as needed, such as DB instance class.
8. Choose **Restore to point in time**.

AWS CLI

You restore a DB instance to a specified time by using the restore-db-instance-to-point-in-time AWS CLI command to create a new RDS Custom DB instance.

Use one of the following options to specify the backup to restore from:

- `--source-db-instance-identifier` *`mysourcedbinstance`*
- `--source-dbi-resource-id` *`dbinstanceresourceID`*

- `--source-db-instance-automated-backups-arn` *backupARN*

The `custom-iam-instance-profile` option is required.

The following example restores `my-custom-db-instance` to a new DB instance named `my-restored-custom-db-instance`, as of the specified time.

Example

For Linux, macOS, or Unix:

```
aws rds restore-db-instance-to-point-in-time \
    --source-db-instance-identifier my-custom-db-instance\
    --target-db-instance-identifier my-restored-custom-db-instance \
    --custom-iam-instance-profile AWSRDSCustomInstanceProfileForRdsCustomInstance \
    --restore-time 2022-10-14T23:45:00.000Z
```

For Windows:

```
aws rds restore-db-instance-to-point-in-time ^
    --source-db-instance-identifier my-custom-db-instance ^
    --target-db-instance-identifier my-restored-custom-db-instance ^
    --custom-iam-instance-profile AWSRDSCustomInstanceProfileForRdsCustomInstance ^
    --restore-time 2022-10-14T23:45:00.000Z
```

Deleting an RDS Custom for Oracle snapshot

You can delete DB snapshots managed by RDS Custom for Oracle when you no longer need them. The deletion procedure is the same for both Amazon RDS and RDS Custom DB instances.

The Amazon EBS snapshots for the binary and root volumes remain in your account for a longer time because they might be linked to some instances running in your account or to other RDS Custom for Oracle snapshots. These EBS snapshots are automatically deleted after they're no longer related to any existing RDS Custom for Oracle resources (DB instances or backups).

Console

To delete a snapshot of an RDS Custom DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.

2. In the navigation pane, choose **Snapshots**.
3. Choose the DB snapshot that you want to delete.
4. For **Actions**, choose **Delete snapshot**.
5. Choose **Delete** on the confirmation page.

AWS CLI

To delete an RDS Custom snapshot, use the AWS CLI command delete-db-snapshot.

The following option is required:

- `--db-snapshot-identifier` – The snapshot to be deleted

The following example deletes the `my-custom-snapshot` DB snapshot.

Example

For Linux, macOS, or Unix:

```
aws rds delete-db-snapshot \
  --db-snapshot-identifier my-custom-snapshot
```

For Windows:

```
aws rds delete-db-snapshot ^
  --db-snapshot-identifier my-custom-snapshot
```

Deleting RDS Custom for Oracle automated backups

You can delete retained automated backups for RDS Custom for Oracle when they are no longer needed. The procedure is the same as the procedure for deleting Amazon RDS backups.

Console

To delete a retained automated backup

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Automated backups**.

3. Choose **Retained**.
4. Choose the retained automated backup that you want to delete.
5. For **Actions**, choose **Delete**.
6. On the confirmation page, enter **`delete me`** and choose **Delete**.

AWS CLI

You can delete a retained automated backup by using the AWS CLI command [delete-db-instance-automated-backup](#).

The following option is used to delete a retained automated backup:

- `--dbi-resource-id` – The resource identifier for the source RDS Custom DB instance.

  You can find the resource identifier for the source DB instance of a retained automated backup by using the AWS CLI command [describe-db-instance-automated-backups](#).

The following example deletes the retained automated backup with source DB instance resource identifier `custom-db-123ABCEXAMPLE`.

Example

For Linux, macOS, or Unix:

```
aws rds delete-db-instance-automated-backup \
    --dbi-resource-id custom-db-123ABCEXAMPLE
```

For Windows:

```
aws rds delete-db-instance-automated-backup ^
    --dbi-resource-id custom-db-123ABCEXAMPLE
```

Working with option groups in RDS Custom for Oracle

RDS Custom uses option groups to enable and configure additional features. An *option group* specifies features, called options, that are available for an RDS Custom for Oracle DB instance. Options can have settings that specify how the option works. When you associate an RDS Custom for Oracle DB instance with an option group, the specified options and option settings are enabled for this instance. For general information about option groups in Amazon RDS, see Working with option groups.

Topics

Overview of option groups in RDS Custom for Oracle

To enable options for your Oracle database, add them to an option group, and then associate the option group with your DB instance. For more information, see Working with option groups.

Topics

Summary of RDS Custom for Oracle options

RDS Custom for Oracle supports the following options for a DB instance.

Option	Option ID	Description
Oracle time zone	`Timezone`	The time zone used by your RDS Custom for Oracle DB instance.

Basic steps for adding an option to an RDS Custom for Oracle DB instance

The general procedure for adding an option to your RDS Custom for Oracle DB instance is the following:

1. Create a new option group, or copy or modify an existing option group.
2. Add the option to the option group.
3. Associate the option group with your DB instance when you create or modify it.

Creating an option group for in RDS Custom for Oracle

You can create a new option group that derives its settings from the default option group. You then add one or more options to the new option group. Or, if you already have an existing option group, you can copy that option group with all of its options to a new option group. To learn how to copy an option group, see Copying an option group.

The default option groups for RDS Custom for Oracle are the following:

- `default:custom-oracle-ee`
- `default:custom-oracle-se2`
- `default:custom-oracle-ee-cdb`
- `default:custom-oracle-se2-cdb`

When you create an option group, the settings are derived from the default option group. After you have added the `TIME_ZONE` option, you can then associate the option group with your DB instance.

Console

One way of creating an option group is by using the AWS Management Console.

To create a new option group by using the console

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Option groups**.
3. Choose **Create group**.
4. In the **Create option group** window, do the following:

a. For **Name**, type a name for the option group that is unique within your AWS account. The name can contain only letters, digits, and hyphens.

b. For **Description**, type a brief description of the option group. The description is used for display purposes.

c. For **Engine**, choose any of the following RDS Custom for Oracle DB engines:

- **custom-oracle-ee**
- **custom-oracle-se2**
- **custom-oracle-ee-cdb**
- **custom-oracle-se2-cdb**

d. For **Major engine version**, choose a major engine version supported by RDS Custom for Oracle. For more information, see Supported Regions and DB engines for RDS Custom for Oracle.

5. To continue, choose **Create**. To cancel the operation instead, choose **Cancel**.

AWS CLI

To create an option group, use the AWS CLI `create-option-group` command with the following required parameters.

- `--option-group-name`
- `--engine-name`
- `--major-engine-version`
- `--option-group-description`

Example

The following example creates an option group named `testoptiongroup`, which is associated with the Oracle Enterprise Edition DB engine. The description is enclosed in quotation marks.

For Linux, macOS, or Unix:

```
aws rds create-option-group \
    --option-group-name testoptiongroup \
    --engine-name custom-oracle-ee-cdb \
    --major-engine-version 19 \
```

```
    --option-group-description "Test option group for a Custom Oracle CDB"
```

For Windows:

```
aws rds create-option-group ^
    --option-group-name testoptiongroup ^
    --engine-name custom-oracle-ee-cdb ^
    --major-engine-version 19 ^
    --option-group-description "Test option group for a Custom Oracle CDB"
```

RDS API

To create an option group, call the Amazon RDS API `CreateOptionGroup` operation.

Associating an option group with an RDS Custom for Oracle DB instance

You can associate your option group with a new or existing DB instance:

- For a new DB instance, apply the option group when you create the instance. For more information, see Creating an RDS Custom for Oracle DB instance.
- For an existing DB instance, apply the option group by modifying the instance and attaching the new option group. For more information, see Modifying your RDS Custom for Oracle DB instance.

Oracle time zone

To change the system time zone used by your RDS Custom for Oracle DB instance, use the time zone option. For example, you might change the time zone of a DB instance to be compatible with an on-premises environment, or a legacy application. The time zone option changes the time zone at the host level. Changing the time zone impacts all date columns and values, including `SYSDATE` and `SYSTIMESTAMP`.

Topics

- Time zone option settings in RDS Custom for Oracle
- Available time zones in RDS Custom for Oracle
- Considerations for setting the time zone in RDS Custom for Oracle
- Limitations for the time zone setting in RDS Custom for Oracle
- Adding the time zone option to an option group
- Removing the time zone option

Time zone option settings in RDS Custom for Oracle

Amazon RDS supports the following settings for the time zone option.

Option setting	Valid values	Description
TIME_ZONE	One of the available time zones. For the full list, see Available time zones in RDS Custom for Oracle.	The new time zone for your DB instance.

Available time zones in RDS Custom for Oracle

You can use the following values for the time zone option.

Zone	Time zone
Africa	Africa/Cairo, Africa/Casablanca, Africa/Harare, Africa/Lagos, Africa/Luanda, Africa/Monrovia, Africa/Nairobi, Africa/Tripoli, Africa/Windhoek
America	America/Araguaina, America/Argentina/Buenos_Aires, America/Asuncion, America/Bogota, America/Caracas, America/Chicago, America/Chihuahua, America/Cuiaba, America/Denver, America/Detroit, America/Fortaleza, America/Godthab, America/Guatemala, America/Halifax, America/Lima, America/Los_Angeles, America/Manaus, America/Matamoros, America/Mexico_City, America/Monterrey, America/Montevideo, America/New_York, America/Phoenix, America/Santiago, America/Sao_Paulo, America/Tijuana, America/Toronto
Asia	Asia/Amman, Asia/Ashgabat, Asia/Baghdad, Asia/Baku, Asia/Bangkok, Asia/Beirut, Asia/Calcutta, Asia/Damascus, Asia/Dhaka, Asia/Hong_Kong, Asia/Irkutsk, Asia/Jakarta, Asia/Jerusalem, Asia/Kabul, Asia/Karachi, Asia/Kathmandu, Asia/Kolkata, Asia/Krasnoyarsk, Asia/Magadan, Asia/Manila, Asia/Muscat, Asia/Novosibirsk, Asia/Rangoon, Asia/Riyadh, Asia/Seoul, Asia/Shanghai, Asia/Singapore, Asia/Taipei, Asia/Tehran, Asia/Tokyo, Asia/Ulaanbaatar, Asia/Vladivostok, Asia/Yakutsk, Asia/Yerevan
Atlantic	Atlantic/Azores, Atlantic/Cape_Verde

Zone	Time zone
Australia	Australia/Adelaide, Australia/Brisbane, Australia/Darwin, Australia/Eucla, Australia/Hobart, Australia/Lord_Howe, Australia/Perth, Australia/Sydney
Brazil	Brazil/DeNoronha, Brazil/East
Canada	Canada/Newfoundland, Canada/Saskatchewan
Etc	Etc/GMT-3
Europe	Europe/Amsterdam, Europe/Athens, Europe/Berlin, Europe/Dublin, Europe/Helsinki, Europe/Kaliningrad, Europe/London, Europe/Madrid, Europe/Moscow, Europe/Paris, Europe/Prague, Europe/Rome, Europe/Sarajevo
Pacific	Pacific/Apia, Pacific/Auckland, Pacific/Chatham, Pacific/Fiji, Pacific/Guam, Pacific/Honolulu, Pacific/Kiritimati, Pacific/Marquesas, Pacific/Samoa, Pacific/Tongatapu, Pacific/Wake
US	US/Alaska, US/Central, US/East-Indiana, US/Eastern, US/Pacific
UTC	UTC

Considerations for setting the time zone in RDS Custom for Oracle

If you choose to set the time zone for your DB instance, consider the following:

- When you add the time zone option, a brief outage occurs while your DB instance is automatically restarted.
- If you accidentally set the time zone incorrectly, you must recover your DB instance to its previous time zone setting. For this reason, we strongly suggest that you to use one of the following strategies before you add the time zone option to your instance:
  - If your RDS Custom for Oracle DB instance uses the default option group, take a snapshot of your DB instance. For more information, see Creating an RDS Custom for Oracle snapshot.
  - If your DB instance currently uses a nondefault option group, take a snapshot of your DB instance, and then create a new option group with the time zone option.
- We strongly recommend that you back up your DB instance manually after applying the `Timezone` option.

- We strongly recommend that you to test the time zone option on a test DB instance before you add it to a production DB instance. Adding the time zone option can cause problems with tables that use system date to add dates or times. We recommend that you analyze your data and applications to assess the impact of changing the time zone.

Limitations for the time zone setting in RDS Custom for Oracle

Note the following limitations:

- You can't change your timezone directly on your host without moving it outside the support perimeter. To change your database timezone, you must create an option group.
- Because the time zone option is a persistent option (but not a permanent option), you can't do the following:
  - Remove the option from an option group after you add the option.
  - Modify the time zone setting of the option to a different time zone.
- You can't associate multiple option groups with your RDS Custom for Oracle DB instance.
- You can't set the time zone for individual PDBs within a CDB.

Adding the time zone option to an option group

The default option groups for RDS Custom for Oracle are the following:

- `default:custom-oracle-ee`
- `default:custom-oracle-se2`
- `default:custom-oracle-ee-cdb`
- `default:custom-oracle-se2-cdb`

When you create an option group, the settings are derived from the default option group. For general information about option groups in Amazon RDS, see Working with option groups.

Console

To add the time zone option to an option group

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.

2. In the navigation pane, choose **Option groups**.
3. Choose the option group that you want to modify, and then choose **Add option**.
4. In the **Add option** window, do the following:
   a. Choose **Timezone**.
   b. In **Option settings**, choose a time zone.
   c. To enable the option on all associated RDS Custom for Oracle DB instances as soon as you add it, for **Apply Immediately**, choose **Yes**. If you choose **No** (the default), the option is enabled for each associated DB instances during its next maintenance window.
   d.

> **Important**
>
> If you add the time zone option to an existing option group that is already attached to one or more DB instances, a brief outage occurs while all the DB instances are automatically restarted.

5. When the settings are as you want them, choose **Add option**.
6. Back up the RDS Custom for Oracle DB instances whose time zones were updated. For more information, see Creating an RDS Custom for Oracle snapshot.

AWS CLI

The following example uses the AWS CLI add-option-to-option-group command to add the `Timezone` option and the `TIME_ZONE` option setting to an option group called `testoptiongroup`. The time zone is set to `America/Los_Angeles`.

For Linux, macOS, or Unix:

```
aws rds add-option-to-option-group \
    --option-group-name "testoptiongroup" \
    --options "OptionName=Timezone,OptionSettings=[{Name=TIME_ZONE,Value=America/
Los_Angeles}]" \
    --apply-immediately
```

For Windows:

```
aws rds add-option-to-option-group ^
    --option-group-name "testoptiongroup" ^
```

```
    --options "OptionName=Timezone,OptionSettings=[{Name=TIME_ZONE,Value=America/
Los_Angeles}]" ^
    --apply-immediately
```

Removing the time zone option

The time zone option is a persistent option, but not a permanent option. You can't remove the option from an option group after you add it. To disassociate the old option group from your DB instance:

1. Create a new option group with an updated `Timezone` option.
2. Associate the new option group with your DB instance when you modify the instance.

Migrating an on-premises database to RDS Custom for Oracle

Before you migrate an on-premises Oracle database to RDS Custom for Oracle, you need to consider the following factors:

- The amount of downtime the application can afford
- The size of the source database
- Network connectivity
- A requirement for a fallback plan
- The source and target Oracle database version and DB instance OS types
- Available replication tools, such as AWS Database Migration Service, Oracle GoldenGate, or third-party replication tools

Based on these factors, you can choose physical migration, logical migration, or a combination. If you choose physical migration, you can use the following techniques:

RMAN duplication

Active database duplication doesn't require a backup of your source database. It duplicates the live source database to the destination host by copying database files over the network to the auxiliary instance. The RMAN `DUPLICATE` command copies the required files as image copies or backup sets. To learn this technique, see the AWS blog post Physical migration of Oracle databases to Amazon RDS Custom using RMAN duplication.

Oracle Data Guard

In this technique, you back up a primary on-premises database and copy the backups to an Amazon S3 bucket. You then copy the backups to your RDS Custom for Oracle standby DB instance. After performing the necessary configuration, you manually switch over your primary database to your RDS Custom for Oracle standby database. To learn this technique, see the AWS blog post Physical migration of Oracle databases to Amazon RDS Custom using Data Guard.

For general information about logically importing data into RDS for Oracle, see Importing data into Oracle on Amazon RDS.

Upgrading a DB instance for Amazon RDS Custom for Oracle

You can upgrade an Amazon RDS Custom DB instance by modifying it to use a new custom engine version (CEV). For general information about upgrades, see Upgrading a DB instance engine version.

Topics

Overview of upgrades in RDS Custom for Oracle

With RDS Custom for Oracle, you can patch either your Oracle database or your DB instance operating system (OS) by creating new CEVs and then modifying your instance to use the new CEV.

Topics

CEV upgrade options

When you create a CEV for an upgrade, you have the following mutually exclusive options:

Database only

Reuse the Amazon Machine Image (AMI) currently in use by your DB instance, but specify different database binaries. RDS Custom allocates a new binary volume and then attaches it to the existing Amazon EC2 instance. RDS Custom replaces the entire database volume with a new volume that uses your target database version.

OS only

Reuse the database binaries currently in use by your DB instance, but specify a different AMI. RDS Custom allocates a new Amazon EC2 instance, and then attaches the existing binary volume to the new instance. The existing database volume is retained.

If you want to upgrade both the OS and database, you must upgrade the CEV twice. You can either upgrade the OS and then the database or upgrade the database and then the OS.

> **Warning**
>
> When you patch your OS, you lose your root volume data and any existing OS customization. Thus, we strongly recommend that you don't use the root volume for installations or for storing permanent data or files. We also recommend that you back up your data before the upgrade.

Patching without CEVs

We strongly recommend that you upgrade your RDS Custom for Oracle DB instance using CEVs. RDS Custom for Oracle automation synchronizes the patch metadata with the database binary on your DB instance.

In special circumstances, RDS Custom supports applying a "one-off" database patch directly to the underlying Amazon EC2 instance directly using the OPatch utility. A valid use case might be a database patch that you want to apply immediately, but the RDS Custom team is upgrading the CEV feature, causing a delay. To apply a database patch manually, perform the following steps:

1. Pause RDS Custom automation.
2. Apply your patch to the database binaries on the Amazon EC2 instance.
3. Resume RDS Custom automation.

A disadvantage of the preceding technique is that you must apply the database patch manually to every instance that you want to upgrade. In contrast, when you create a new CEV, you can create or upgrade multiple DB instances using the same CEV.

General steps for patching your DB instance with a CEV

Whether you patch the OS or your database, perform the following basic steps:

1. Create a CEV that contains either of the following, depending on whether you're patching the database or OS:
   - The Oracle Database RU that you want to apply to your DB instance
   - A different AMI–either the latest available or one that you specify–and an existing CEV to use as a source

   Follow the steps in Creating a CEV.
2. (Optional for database patching) Check available engine version upgrades by running `describe-db-engine-versions`.
3. Start the patching process by running `modify-db-instance`.

   The status of the instance being patched differs as follows:
   - While RDS is patching the database, the status of the DB instance changes to **Upgrading**.
   - While RDS is patching the OS, the status of the DB instance changes to **Modifying**.

   When the DB instance has the status **Available**, patching is complete.
4. Confirm that your DB instance uses the new CEV by running `describe-db-instances`.

Requirements for RDS Custom for Oracle upgrades

When upgrading your RDS Custom for Oracle DB instance to a target CEV, make sure you meet the following requirements:

- The target CEV to which you are upgrading must exist.
- You must upgrade either the OS or the database in a single operation. Upgrading both the OS and the database in a single API call isn't supported.
- The target CEV must use the installation parameter settings that are in the manifest of the current CEV. For example, you can't upgrade a database that uses the default Oracle home to a CEV that uses a nondefault Oracle home.
- For database upgrades, the target CEV must use a new minor database version, not a new major version. For example, you can't upgrade from an Oracle Database 12c CEV to an Oracle Database 19c CEV. But you can upgrade from version 21.0.0.0.ru-2023-04.rur-2023-04.r1 to version 21.0.0.0.ru-2023-07.rur-2023-07.r1.
- For OS upgrades, the target CEV must use a different AMI but have the same major version.

Considerations for RDS Custom for Oracle database upgrades

If you plan to upgrade your database, consider the following:

- When you upgrade the database binaries in your primary DB instance, RDS Custom for Oracle upgrades your read replicas automatically. When you upgrade the OS, you must upgrade the read replicas manually.
- When you upgrade a container database (CDB) to a new database version, RDS Custom for Oracle checks that all PDBs are open or could be opened. If these conditions aren't met, RDS Custom stops the check and returns the database to its original state without attempting the upgrade. If the conditions are met, RDS Custom patches the CDB root first, and then patches all other PDBs (including `PDB$SEED`) in parallel.

  After patching completes, RDS Custom attempts to open all PDBs. If any PDBs fail to open, you receive the following event: `The following PDBs failed to open: list-of-PDBs`. If RDS Custom fails to patch the CDB root or any PDBs, the instance is put into the `PATCH_DB_FAILED` state.
- You might want to perform a major database version upgrade and a conversion of non-CDB to CDB at the same time. In this case, we recommend that you proceed as follows:
  1. Create a new RDS Custom for Oracle DB instance that uses the Oracle multitenant architecture.
  2. Plug in a non-CDB into your CDB root, creating it as a PDB. Make sure that the non-CDB is the same major version as your CDB.
  3. Convert your PDB by running the `noncdb_to_pdb.sql` Oracle SQL script.
  4. Validate your CDB instance.
  5. Upgrade your CDB instance.

Considerations for RDS Custom for Oracle OS upgrades

When you plan an OS upgrade, consider the following:

- You can't provide your own AMI for use in an RDS Custom for Oracle CEV. You can specify either the default AMI or an AMI that has been previously used by an RDS Custom for Oracle CEV.

> **Note**
>
> RDS Custom for Oracle releases a new default AMI when common vulnerabilities and exposures are discovered. No fixed schedule is available or guaranteed. RDS Custom for Oracle tends to publish a new default AMI every 30 days.

- When you upgrade the OS in your primary DB instance, you must upgrade its associated read replicas manually.
- Reserve sufficient Amazon EC2 compute capacity for your instance type in your AZ before you begin patching the OS.

  When you create a Capacity Reservation, you specify the AZ, number of instances, and instance attributes (including instance type). For example, if your DB instance uses the underlying EC2 instance type r5.large, we recommend that you reserve EC2 capacity for r5.large in your AZ. During OS patching, RDS Custom creates one new host of type db.r5.large, which can become stuck if the AZ lacks EC2 capacity for this instance type. If you reserve EC2 capacity, you lower the risk of blocked patching caused by capacity constraints. For more information, see On-Demand Capacity Reservations in the *Amazon EC2 User Guide*.
- Back up your DB instance before you upgrade its OS. The upgrade removes your root volume data and any existing OS customizations.
- In the shared responsibility model, you're responsible for keeping your OS up to date. RDS Custom for Oracle doesn't mandate which patches you apply to your OS. If your RDS Custom for Oracle is functional, you can use the AMI associated with this CEV indefinitely.

Viewing valid CEV upgrade targets for RDS Custom for Oracle DB instances

You can see existing CEVs on the **Custom engine versions** page in the AWS Management Console.

You can also use the describe-db-engine-versions AWS CLI command to find valid CEVs to use when you upgrade your DB instances, as shown in the following example. This example assumes that you created a DB instance using the engine version `19.my_cev1`, and that the upgrade versions `19.my_cev2` and `19.my_cev` exist.

```
aws rds describe-db-engine-versions --engine custom-oracle-ee --engine-version
 19.my_cev1
```

The output resembles the following. The `ImageId` field shows the AMI ID.

```
{
    "DBEngineVersions": [
        {
            "Engine": "custom-oracle-ee",

                }
            ]
            ...
```

Upgrading an RDS Custom for Oracle DB instance

To upgrade your RDS Custom for Oracle DB instance, modify it to use a new CEV. This CEV can contain either new database binaries or a new AMI. If you want to upgrade the database and OS, you must perform two separate upgrades.

> **Note**
>
> If you upgrade the database, RDS Custom automatically upgrades read replicas after it upgrades the primary DB instance. If you upgrade the OS, you must upgrade the replicas manually.

Before you begin, review Requirements for RDS Custom for Oracle upgrades and Considerations for RDS Custom for Oracle database upgrades.

Console

To upgrade an RDS Custom for Oracle DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**, and then choose the RDS Custom for Oracle DB instance that you want to upgrade.
3. Choose **Modify**. The **Modify DB instance** page appears.
4. For **DB engine version**, choose a new CEV. Do the following:

   - If you are patching the database, make sure that the CEV specifies database binaries that are different from those used by your DB instance, and doesn't specify an AMI that is different from the AMI currently used by your DB instance.
   - If you are patching the OS, make sure that the CEV specifies an AMI that is different from the AMI currently used by your DB instance, and doesn't specify different database binaries.

   > **Warning**
   >
   > When you patch your OS, you lose your root volume data and any existing OS customization.

5. Choose **Continue** to check the summary of modifications.

   Choose **Apply immediately** to apply the changes immediately.
6. If your changes are correct, choose **Modify DB instance**. Or choose **Back** to edit your changes or **Cancel** to cancel your changes.

AWS CLI

The following examples show possible upgrade scenarios. The examples assume that you created an RDS Custom for Oracle DB instance with the following characteristics:

- DB instance named `my-custom-instance`
- CEV named `19.my_cev1`

- Oracle Database 19c using the non-CDB architecture
- Oracle Linux 7.9 using AMI `ami-1234`

The latest service-provided AMI is `ami-2345`. You can find AMIs by running the CLI command `describe-db-engine-versions`.

Topics

Upgrading the OS

In this example, you want to upgrade `ami-1234` to `ami-2345`, which is the latest service-provided AMI. Because this is an OS upgrade, the database binaries for `ami-1234` and `ami-2345` must be the same. You create a new CEV named `19.my_cev2` based on `19.my_cev1`.

Example

For Linux, macOS, or Unix:

```
aws rds create-custom-db-engine-version \
    --engine custom-oracle-ee \
    --engine-version 19.my_cev2 \
    --description "Non-CDB CEV based on ami-2345" \
    --kms-key-id key-name \
    --source-custom-db-engine-version-identifer arn:aws:rds:us-
west-2:123456789012:cev:custom-oracle-ee/19.my_cev1/12345678-ab12-1234-cde1-
abcde123456789 \
    --image-id ami-2345
```

For Windows:

```
aws rds create-custom-db-engine-version ^
    --engine custom-oracle-ee ^
    --engine-version 19.my_cev2 ^
    --description "Non-CDB CEV based on ami-2345" ^
    --kms-key-id key-name ^
    --source-custom-db-engine-version-identifer arn:aws:rds:us-
west-2:123456789012:cev:custom-oracle-ee/19.my_cev1/12345678-ab12-1234-cde1-
abcde123456789 ^
```

```
    --image-id ami-2345
```

To upgrade an RDS Custom DB instance, use the modify-db-instance AWS CLI command with the following parameters:

- `--db-instance-identifier` – Specify the RDS Custom for Oracle DB instance to be upgraded.
- `--engine-version` – Specify the CEV that has the new AMI.
- `--no-apply-immediately` | `--apply-immediately` – Specify whether to perform the upgrade immediately or wait until the scheduled maintenance window.

The following example upgrades `my-custom-instance` to version `19.my_cev2`. Only the OS is upgraded.

Example

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier my-custom-instance \
    --engine-version 19.my_cev2 \
    --apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier my-custom-instance ^
    --engine-version 19.my_cev2 ^
    --apply-immediately
```

Upgrading the database

In this example, you want to apply Oracle patch p35042068 to your RDS for Oracle DB instance. Because you upgraded your OS in Upgrading the OS, your DB instance is currently using `19.my_cev2`, which is based on `ami-2345`. You create a new CEV named `19.my_cev3` that also uses `ami-2345`, but you specify a new JSON manifest in the `$MANIFEST` environment variable. Thus, only the database binaries different in your new CEV and the CEV that your instance is currently using.

Example

For Linux, macOS, or Unix:

```
aws rds create-custom-db-engine-version \
    --engine custom-oracle-ee \
    --engine-version 19.my_cev3 \
    --description "Non-CDB CEV with p35042068 based on ami-2345" \
    --kms-key-id key-name \
    --image-id ami-2345 \
    --manifest $MANIFEST
```

For Windows:

```
aws rds create-custom-db-engine-version ^
    --engine custom-oracle-ee ^
    --engine-version 19.my_cev3 ^
    --description "Non-CDB CEV with p35042068 based on ami-2345" ^
    --kms-key-id key-name ^
    --image-id ami-2345 ^
    --manifest $MANIFEST
```

The following example upgrades `my-custom-instance` to engine version `19.my_cev3`. Only the database is upgraded.

Example

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier my-custom-instance \
    --engine-version 19.my_cev3 \
    --apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier my-custom-instance ^
    --engine-version 19.my_cev3 ^
    --apply-immediately
```

Viewing pending database upgrades for RDS Custom DB instances

You can see pending database upgrades for your Amazon RDS Custom DB instances by using the describe-db-instances or describe-pending-maintenance-actions AWS CLI command.

However, this approach doesn't work if you used the `--apply-immediately` option or if the upgrade is in progress.

The following `describe-db-instances` command shows pending database upgrades for `my-custom-instance`.

```
aws rds describe-db-instances --db-instance-identifier my-custom-instance
```

The output resembles the following.

```
{
    "DBInstances": [
        {
           "DBInstanceIdentifier": "my-custom-instance",
            "EngineVersion": "19.my_cev1",
            ...
            "PendingModifiedValues": {
                "EngineVersion": "19.my_cev3"
            ...
            }
        }
    ]
}
```

Troubleshooting an upgrade failure for an RDS Custom for Oracle DB instance

If an RDS Custom DB instance upgrade fails, an RDS event is generated and the DB instance status becomes `upgrade-failed`.

You can see this status by using the describe-db-instances AWS CLI command, as shown in the following example.

```
aws rds describe-db-instances --db-instance-identifier my-custom-instance
```

The output resembles the following.

```
{
    "DBInstances": [
        {
           "DBInstanceIdentifier": "my-custom-instance",
            "EngineVersion": "19.my_cev1",
            ...
            "PendingModifiedValues": {
                "EngineVersion": "19.my_cev3"
            ...
            }
            "DBInstanceStatus": "upgrade-failed"
        }
    ]
}
```

After an upgrade failure, all database actions are blocked except for modifying the DB instance to perform the following tasks:

- Retrying the same upgrade
- Pausing and resuming RDS Custom automation
- Point-in-time recovery (PITR)
- Deleting the DB instance

> **Note**
>
> If automation has been paused for the RDS Custom DB instance, you can't retry the upgrade until you resume automation.
> The same actions apply to an upgrade failure for an RDS-managed read replica as for the primary.

For more information, see Troubleshooting upgrades for RDS Custom for Oracle.

Troubleshooting DB issues for Amazon RDS Custom for Oracle

The shared responsibility model of RDS Custom provides OS shell–level access and database administrator access. RDS Custom runs resources in your account, unlike Amazon RDS, which runs resources in a system account. With greater access comes greater responsibility. In the following sections, you can learn how to troubleshoot issues with Amazon RDS Custom DB instances.

> **Note**
>
> This section explains how to troubleshoot RDS Custom for Oracle. For troubleshooting RDS Custom for SQL Server, see Troubleshooting DB issues for Amazon RDS Custom for SQL Server.

Topics

Viewing RDS Custom events

The procedure for viewing events is the same for RDS Custom and Amazon RDS DB instances. For more information, see Viewing Amazon RDS events.

To view RDS Custom event notification using the AWS CLI, use the `describe-events` command. RDS Custom introduces several new events. The event categories are the same as for Amazon RDS. For the list of events, see Amazon RDS event categories and event messages.

The following example retrieves details for the events that have occurred for the specified RDS Custom DB instance.

```
aws rds describe-events \
    --source-identifier my-custom-instance \
    --source-type db-instance
```

Subscribing to RDS Custom events

The procedure for subscribing to events is the same for RDS Custom and Amazon RDS DB instances. For more information, see Subscribing to Amazon RDS event notification.

To subscribe to RDS Custom event notification using the CLI, use the `create-event-subscription` command. Include the following required parameters:

- `--subscription-name`
- `--sns-topic-arn`

The following example creates a subscription for backup and recovery events for an RDS Custom DB instance in the current AWS account. Notifications are sent to an Amazon Simple Notification Service (Amazon SNS) topic, specified by `--sns-topic-arn`.

```
aws rds create-event-subscription \
    --subscription-name my-instance-events \
    --source-type db-instance \
    --event-categories '["backup","recovery"]' \
    --sns-topic-arn arn:aws:sns:us-east-1:123456789012:interesting-events
```

Troubleshooting custom engine version creation for RDS Custom for Oracle

When CEV creation fails, RDS Custom issues `RDS-EVENT-0198` with the message `Creation failed for custom engine version` *`major-engine-version.cev_name`*, and includes details about the failure. For example, the event prints missing files.

CEV creation might fail because of the following issues:

- The Amazon S3 bucket containing your installation files isn't in the same AWS Region as your CEV.
- When you request CEV creation in an AWS Region for the first time, RDS Custom creates an S3 bucket for storing RDS Custom resources (such as CEV artifacts, AWS CloudTrail logs, and transaction logs).

  CEV creation fails if RDS Custom can't create the S3 bucket. Either the caller doesn't have S3 permissions as described in Step 5: Grant required permissions to your IAM user or role, or the number of S3 buckets has reached the limit.

- The caller doesn't have permissions to get files from your S3 bucket that contains the installation media files. These permissions are described in Step 7: Add necessary IAM permissions.
- Your IAM policy has an `aws:SourceIp` condition. Make sure to follow the recommendations in AWS Denies access to AWS based on the source IP in the *AWS Identity and Access Management User Guide*. Also make sure that the caller has the S3 permissions described in Step 5: Grant required permissions to your IAM user or role.
- Installation media files listed in the CEV manifest aren't in your S3 bucket.
- The SHA-256 checksums of the installation files are unknown to RDS Custom.

  Confirm that the SHA-256 checksums of the provided files match the SHA-256 checksum on the Oracle website. If the checksums match, contact AWS Support and provide the failed CEV name, file name, and checksum.
- The OPatch version is incompatible with your patch files. You might get the following message: `OPatch is lower than minimum required version. Check that the version meets the requirements for all patches, and try again`. To apply an Oracle patch, you must use a compatible version of the OPatch utility. You can find the required version of the Opatch utility in the readme file for the patch. Download the most recent OPatch utility from My Oracle Support, and try creating your CEV again.
- The patches specified in the CEV manifest are in the wrong order.

You can view RDS events either on the RDS console (in the navigation pane, choose **Events**) or by using the `describe-events` AWS CLI command. The default duration is 60 minutes. If no events are returned, specify a longer duration, as shown in the following example.

```
aws rds describe-events --duration 360
```

Currently, the MediaImport service that imports files from Amazon S3 to create CEVs isn't integrated with AWS CloudTrail. Therefore, if you turn on data logging for Amazon RDS in CloudTrail, calls to the MediaImport service such as the `CreateCustomDbEngineVersion` event aren't logged.

However, you might see calls from the API gateway that accesses your Amazon S3 bucket. These calls come from the MediaImport service for the `CreateCustomDbEngineVersion` event.

Fixing unsupported configurations in RDS Custom for Oracle

In the shared responsibility model, it's your responsibility to fix configuration issues that put your RDS Custom for Oracle DB instance into the `unsupported-configuration` state. If the issue is with the AWS infrastructure, you can use the console or the AWS CLI to fix it. If the issue is with the operating system or the database configuration, you can log in to the host to fix it.

> **Note**
>
> This section explains how to fix unsupported configurations in RDS Custom for Oracle. For information about RDS Custom for SQL Server, see Fixing unsupported configurations in RDS Custom for SQL Server.

In the following table, you can find descriptions of the notifications and events that the support perimeter sends and how to fix them. These notifications and the support perimeter are subject to change. For background on the support perimeter, see RDS Custom support perimeter. For event descriptions, see Amazon RDS event categories and event messages.

Event ID	Configuration	RDS event message	Action
SP-00000	Manual unsupported configuration	The RDS Custom DB instance status is set to [Unsupported configuration] because of: *reason*.	To resolve this issue, create an AWS Support case.
AWS resources (infrastructure)			
SP-O100	Amazon Elastic Block Store (Amazon EBS) volumes	The following EBS volumes were added to EC2 instance *ec2_id*: *volume_id* . To resolve the issue, detach the	RDS Custom creates two types of EBS volume, besides the root volume created from the Amazon Machine Image (AMI), and associates them with the EC2 instance: • The binary volume where the database software binaries are located

Event ID	Configuration	RDS event message	Action

		specified volumes from the instance.	• The data volumes where database files are located
			
			When you create your DB instance, the storage configurations that you specify configure the data volumes.
			
			The support perimeter monitors the following:
			
			• The initial EBS volumes created with the DB instance are still associated with the instance.
			• The initial EBS volumes still have the same configurations as initially set: storage type, size, Provisioned IOPS, and storage throughput.
			• No additional EBS volumes are attached to the DB instance.
			
			Use the following CLI command to compare the volume type of the EBS volume details and the RDS Custom for Oracle DB instance details:
			
			`aws rds describe-db-instances \`
			`--db-instance-identifier db-instance-name | grep StorageType`

Event ID	Configuration	RDS event message	Action
SP-O100	Amazon Elastic Block Store (Amazon EBS) volumes	EBS volume *volume_id* has been detached from EC2 instance [*ec2_id*]. You can't detach the original volume from this instance. To resolve the issue, re-attach *volume_id* to *ec2_id*.	RDS Custom creates two types of EBS volume, besides the root volume created from the Amazon Machine Image (AMI), and associates them with the EC2 instance: • The binary volume where the database software binaries are located • The data volumes where database files are located When you create your DB instance, the storage configurations that you specify configure the data volumes. The support perimeter monitors the following: • The initial EBS volumes created with the DB instance are still associated with the instance. • The initial EBS volumes still have the same configurations as initially set: storage type, size, Provisioned IOPS, and storage throughput. • No additional EBS volumes are attached to the DB instance. Use the following CLI command to compare the volume type of the EBS volume details and the RDS Custom for Oracle DB instance details: `aws rds describe-db-instances \ --db-instance-identifier db-instance-name | grep StorageType`

Event ID	Configuration	RDS event message	Action
SP-O100	Amazon Elastic Block Store (Amazon EBS) volumes	The original EBS volume *volume_id* attached to EC2 instance *ec2_id* has been modified as follows: size [*X*] to [*Y*], type [*N*] to [*M*], or IOPS [*J*] to [*K*]. To resolve the issue, revert the modification.	RDS Custom creates two types of EBS volume, besides the root volume created from the Amazon Machine Image (AMI), and associates them with the EC2 instance: • The binary volume where the database software binaries are located • The data volumes where database files are located When you create your DB instance, the storage configurations that you specify configure the data volumes. The support perimeter monitors the following: • The initial EBS volumes created with the DB instance are still associated with the instance. • The initial EBS volumes still have the same configurations as initially set: storage type, size, Provisioned IOPS, and storage throughput. • No additional EBS volumes are attached to the DB instance. Use the following CLI command to compare the volume type of the EBS volume details and the RDS Custom for Oracle DB instance details: `aws rds describe-db-instances \ --db-instance-identifier db-instance-name | grep StorageType`

Event ID	Configuration	RDS event message	Action
SP-O1004	Amazon EC2 instance state	Automated recovery left EC2 instance [*ec2_id*] in an impaired state. To resolve the issue, see Troubleshooting instance recovery failures.	To check the status of a DB instance, use the console or run the following AWS CLI command: `aws rds describe-db-instances \ --db-instance-identifier *db-instance-name* |grep DBInstanceStatus`
SP-O1005	Amazon EC2 instance attributes	EC2 instance [*ec2_id*] was modified as follows: attribute [*att1*] changed from [*val-old*] to [*val-new*], attribute [*att2*] changed from [*val-old*] to [*val-new*]. To resolve the issue, revert to the original value.	

Event ID	Configuration	RDS event message	Action
SP-O1006	Amazon EC2 instance state	EC2 instance [*ec2_id*] was terminated or can't be found. To resolve the issue, delete the RDS Custom DB instance.	The support perimeter monitors EC2 instance state-change notifications. The EC2 instance must always be running. **To delete your DB instance** 1. To check the status of a DB instance, use the console or run the following AWS CLI command: `aws rds describe-db-instances \ --db-instance-identifier *db-instance-name* |grep DBInstanceStatus` 2. Delete your RDS Custom for Oracle DB instance.
SP-O1007	Amazon EC2 instance state	EC2 instance [*ec2_id*] was stopped. To resolve the issue, start the instance.	The support perimeter monitors EC2 instance state-change notifications. The EC2 instance must always be running. **To restart your DB instance** 1. To check the status of a DB instance, use the console or run the following AWS CLI command: `aws rds describe-db-instances \ --db-instance-identifier *db-instance-name* |grep DBInstanceStatus` 2. Start your DB instance. 3. Remount the binary and data volumes.
Operating system			

Event ID	Configuration	RDS event message	Action

SP-O200	RDS Custom agent status	The RDS Custom agent isn't running on EC2 instance [*ec2_id*]. Make sure the agent is running on [*ec2_id*].	On RDS Custom for Oracle, the DB instance goes outside the support perimeter if the RDS Custom agent stops. The agent publishes the `IamAlive` metric to Amazon CloudWatch every 30 seconds. An alarm is triggered if the metric hasn't been published for 30 seconds. The support perimeter also monitors the RDS Custom agent process state on the host every 30 minutes.
			
			To restart the RDS Custom agent
			
			1. Log in to your host and make sure that the RDS Custom agent is running.
			2. Run the following command to find the status of the agent.
			
			`service rdscustomagent status`
			
			3. Use the following command to start the agent.
			
			`service rdscustomagent start`
			
			When the RDS Custom agent is running again, the `IamAlive` metric is published to Amazon CloudWatch, and the alarm switches to the OK state. This switch notifies the support perimeter that the agent is running.

Event ID	Configuration	RDS event message	Action
SP-02002	AWS Systems Manager agent (SSM agent) status	The Systems Manager agent on EC2 instance [*ec2_id*] is unreachable. Make sure that you that have correctly configured the network, agent, and IAM permissions.	SSM Agent must always be running. The RDS Custom agent is responsible for making sure that the Systems Manager agent is running. If SSM Agent was terminated and then restarted, the RDS Custom agent publishes a metric to CloudWatch. The RDS Custom agent has an alarm on the metric set to trigger when there has been a restart in each of the previous three minutes. The support perimeter also monitors the process state of SSM Agent on the host every 30 minutes. For more information, see Troubleshooting SSM Agent.
SP-02003	AWS Systems Manager agent (SSM agent) status	The Systems Manager agent on EC2 instance [*ec2_id*] crashed multiple times. For more information, see the SSM Agent troubleshooting documentation.	For more information, see Troubleshooting SSM Agent.

Event ID	Configuration	RDS event message	Action
SP-O200	OS time zone	The time zone on EC2 instance [*ec2_id*] was changed. To resolve this issue, revert the timezone to the previous setting of [*previous-time-zone*]. Then use an RDS options group to change the time zone.	RDS automation detected that the time zone on the host was changed without the use of an option group. This host-level change can cause RDS automation failures, so the EC2 instance is placed in the `unsupported-configuration` state. **To fix the time zone setting** 1. Log in to your EC2 host and check the OS time zone as follows: `timedatectl` 2. Pause RDS Custom automation. For more information, see Pausing and resuming your RDS Custom DB instance. 3. Stop the DB instance. 4. Revert the time zone change on the operating system. 5. Start the DB instance. 6. Resume RDS Custom automation. Your DB instance becomes available within 30 minutes. To prevent moving out of perimeter in the future, modify your timezone through an options group. For more information, see Oracle time zone.

Event ID	Configuration	RDS event message	Action
SP-O200	sudo configurations	The sudo configurations on EC2 instance [*ec2_id*] lack necessary permissions. To resolve this issue, revert the recent changes to the sudo configurations.	The support perimeter monitors that certain OS users are allowed to run certain commands on the box. It monitors sudo configurations against the supported state. When the sudo configurations aren't supported, the RDS Custom tries to overwrite them back to the previous supported state. If that is successful, the following notification is sent: RDS Custom successfully overwrote your configuration. **To investigate changes to the sudo configurations** 1. Log in to your host. 2. Run the following command. `visudo -c -f /etc/sudoers.d/ individual_sudo_files` 3. Modify the sudo configurations as necessary. After the support perimeter determines that the sudo configurations are supported, your RDS Custom for Oracle DB instance becomes available within 30 minutes.

Event ID	Configuration	RDS event message	Action
SP-O200(	S3 bucket accessibility	RDS Custom automation can't download files from the S3 bucket on EC2 instance [*ec2_id*]. Check your networking configuration and make sure the instance allows connections to and from S3.	
Database			

Event ID	Configuration	RDS event message	Action
SP-O300	Database archive lag target	The ARCHIVE_LAG_TARGET parameter on EC2 instance [*ec2_id*] is out of the recommended range *value_range* . To resolve the issue, set the parameter to a value within value_range.	The support perimeter monitors the ARCHIVE_LAG_TARGET database parameter to verify that the latest restorable time of the DB instance is within reasonable bounds. **To change the lag target for archived redo logs** 1. Log in to your EC2 host 2. Connect to your RDS Custom for Oracle DB instance 3. Change the ARCHIVE_LAG_TARGET parameter to a value from 60–7200. For example, use the following SQL statement. `ALTER SYSTEM SET ARCHIVE_LAG_TARGET=300 SCOPE=BOTH;` Your DB instance becomes available within 30 minutes.

Event ID	Configuration	RDS event message	Action

SP-O300	Oracle Data Guard role	The database role [*role_name*] isn't supported for Oracle Data Guard on EC2 instance [*ec2_id*]. To resolve the issue, set the DATABASE_ROLE parameter to either PRIMARY or PHYSICAL STANDBY.	The support perimeter monitors the current database role every 15 seconds and sends a CloudWatch notification if the database role has changed. The Oracle Data Guard DATABASE_ROLE parameter must be either PRIMARY or PHYSICAL STANDBY.
			
			To restore your Oracle Data Guard database role to a supported value
			
			1. Check the Oracle Data Guard role by running the following statement:
			
			`SELECT DATABASE_ROLE FROM V$DATABASE;`
			
			2. If your DB instance is standalone, use either of the following statements to change it back to the PRIMARY role:
			
			`ALTER DATABASE COMMIT TO SWITCHOVER PRIMARY;`
			`ALTER DATABASE ACTIVATE STANDBY DATABASE;`
			
			If your DB instance is a replica, use the following statement to change it back to the PHYSICAL STANDBY role:
			
			`ALTER DATABASE CONVERT TO PHYSICAL STANDBY;`
			
			After the support perimeter determines that the database role is supported, your RDS Custom for Oracle DB instance becomes available within 15 seconds.

Event ID	Configuration	RDS event message	Action
SP-O300	Database health	The SMON process of the Oracle database is in a zombie state. To resolve the issue, manually recover the database on EC2 instance [*ec2_id*], open the database, and then immediately back it up. For more help, contact AWS Support.	The support perimeter monitors the DB instance state. It also monitors how many restarts occurred during the previous hour and day. You're notified when the instance is in a state where it still exists, but you can't interact with it. **To make the support perimeter evaluate your instance state** 1. Log in to your host and determine the database state. `ps -eo pid,state,command | grep smon` 2. If necessary, restart your DB instance. If the restart fails, proceed to the next step. 3. If necessary, restart your EC2 host. After your DB instance restarts, the RDS Custom agent detects that your DB instance is no longer in an unresponsive state. It then notifies the support perimeter to reevaluate your DB instance state.

Event ID	Configuration	RDS event message	Action

SP-O3004	Database log mode	The database log mode on EC2 instance [*ec2_id*] was changed to [*value_b*]. To resolve the issue, set the log mode to [*value_a*].	**To change your DB instance log mode to ARCHIVELOG**
			1. Log in to your EC2 host.
			2. Connect to your database and run the following statement:
			`SELECT LOG_MODE FROM V$DATABASE;`
			Or you can run the follow command in SQL*Plus:
			`ARCHIVE LOG LIST`
			3. Run the following SQL*Plus command to initiate a consistent shutdown.
			`SHUTDOWN IMMEDIATE`
			The RDS Custom agent automatically restarts your DB instance and sets the log mode to ARCHIVELOG . Your DB instance becomes available within 30 minutes.

SP-O3005	Oracle home path	The Oracle home on EC2 instance [*ec2_id*] was changed to *new_path*. To resolve the issue, revert the setting to *old_path*.	

Event ID	Configuration	RDS event message	Action

SP-O300(	Database unique name	The database unique name on EC2 instance [*ec2_id*] was changed to *new_value* . To resolve the issue, revert the name to *old_value* .	**To change the database unique name for your DB instance**
			1. Log in to your EC2 host.
			2. Connect to the database and run the following statement:
			`SELECT DB_UNIQUE_NAME FROM V$DATABASE;`
			3. Specify the original database unique name using the command `ALTER SYSTEM SET DB_UNIQUE_NAME` .
			4. Run the following SQL statement to initiate a consistent shutdown.
			`SHUTDOWN IMMEDIATE;`
			The RDS Custom agent automatically restarts your DB instance and sets the log mode to `ARCHIVELOG` . Your DB instance becomes available within 30 minutes.

Troubleshooting upgrades for RDS Custom for Oracle

Your upgrade of an RDS Custom for Oracle instance might fail. Following, you can find techniques that you can use during upgrades of RDS Custom DB for Oracle DB instances:

- Examine the upgrade output log files in the `/tmp` directory on your DB instance. The names of the logs depend on your DB engine version. For example, you might see logs that contain the strings `catupgrd` or `catup`.
- Examine the `alert.log` file located in the `/rdsdbdata/log/trace` directory.

- Run the following `grep` command in the `root` directory to track the upgrade OS process. This command shows where the log files are being written and determine the state of the upgrade process.

```
ps -aux | grep upg
```

The following shows sample output.

```
root     18884  0.0  0.0 235428  8172 ?        S<   17:03   0:00 /usr/bin/
sudo -u rdsdb /rdsdbbin/scripts/oracle-control ORCL op_apply_upgrade_sh RDS-
UPGRADE/2.upgrade.sh
rdsdb    18886  0.0  0.0 153968 12164 ?        S<   17:03   0:00 /usr/bin/perl -T -
w /rdsdbbin/scripts/oracle-control ORCL op_apply_upgrade_sh RDS-UPGRADE/2.upgrade.sh
rdsdb    18887  0.0  0.0 113196  3032 ?        S<   17:03   0:00 /bin/sh /rdsdbbin/
oracle/rdbms/admin/RDS-UPGRADE/2.upgrade.sh
rdsdb    18900  0.0  0.0 113196  1812 ?        S<   17:03   0:00 /bin/sh /rdsdbbin/
oracle/rdbms/admin/RDS-UPGRADE/2.upgrade.sh
rdsdb    18901  0.1  0.0 167652 20620 ?        S<   17:03   0:07 /rdsdbbin/oracle/
perl/bin/perl catctl.pl -n 4 -d /rdsdbbin/oracle/rdbms/admin -l /tmp catupgrd.sql
root     29944  0.0  0.0 112724  2316 pts/0    S+   18:43   0:00 grep --color=auto
 upg
```

- Run the following SQL query to verify the current state of the components to find the database version and the options installed on the DB instance.

```
SET LINESIZE 180
COLUMN COMP_ID FORMAT A15
COLUMN COMP_NAME FORMAT A40 TRUNC
COLUMN STATUS FORMAT A15 TRUNC
SELECT COMP_ID, COMP_NAME, VERSION, STATUS FROM DBA_REGISTRY ORDER BY 1;
```

The output resembles the following.

```
COMP_NAME                                STATUS               PROCEDURE
---------------------------------------- --------------------
 ------------------------------------------------
Oracle Database Catalog Views            VALID
 DBMS_REGISTRY_SYS.VALIDATE_CATALOG
Oracle Database Packages and Types       VALID
 DBMS_REGISTRY_SYS.VALIDATE_CATPROC
Oracle Text                              VALID                VALIDATE_CONTEXT
```

```
Oracle XML Database                    VALID                DBMS_REGXDB.VALIDATEXDB

4 rows selected.
```

- Run the following SQL query to check for invalid objects that might interfere with the upgrade process.

```
SET PAGES 1000 LINES 2000
COL OBJECT FOR A40
SELECT SUBSTR(OWNER,1,12) OWNER,
       SUBSTR(OBJECT_NAME,1,30) OBJECT,
       SUBSTR(OBJECT_TYPE,1,30) TYPE, STATUS,
       CREATED
FROM   DBA_OBJECTS
WHERE  STATUS <>'VALID'
AND    OWNER IN ('SYS','SYSTEM','RDSADMIN','XDB');
```

Troubleshooting replica promotion for RDS Custom for Oracle

You can promote managed Oracle replicas in RDS Custom for Oracle using the console, `promote-read-replica` AWS CLI command, or `PromoteReadReplica` API. If you delete your primary DB instance, and all replicas are healthy, RDS Custom for Oracle promotes your managed replicas to standalone instances automatically. If a replica has paused automation or is outside the support perimeter, you must fix the replica before RDS Custom can promote it automatically. For more information, see Replica promotion limitations for RDS Custom for Oracle.

The replica promotion workflow might become stuck in the following situation:

- The primary DB instance is in the state `STORAGE_FULL`.
- The primary database can't archive all of its online redo logs.
- A gap exists between the archived redo log files on your Oracle replica and the primary database.

To respond to the stuck workflow

1. Synchronize the redo log gap on your Oracle replica DB instance.
2. Force the promotion of your read replica to the latest applied redo log. Run the following commands in SQL*Plus:

```
ALTER DATABASE ACTIVATE STANDBY DATABASE;
```

```
SHUTDOWN IMMEDIATE
STARTUP
```

3. Contact AWS Support and ask them to move your DB instance to `available` status.

Known issues and limitations for Amazon RDS Custom for Oracle

When working with RDS Custom for Oracle, note the following issues and limitations for DB instances.

Topics

Known issues

Note the following issues for RDS Custom for Oracle:

- Some RDS APIs can be blocked when a database instance is on an older AMI. To resolve this issue, patch your DB instance to the latest AMI using OS patching. For more information, see CEV upgrade options.
- You must configure the `crontab` file after scale compute, OS upgrades, and other workflows where RDS Custom replaces the root volume. We highly recommend that you keep a backup of `crontab`.
- You must declare the following initialization parameters in `/rdsdbdata/config/oracle_pfile`:
  - `MEMORY_MAX_TARGET`
  - `MEMORY_TARGET`
  - `PGA_AGGREGATE_TARGET`
  - `PROCESSES`
  - `SGA_TARGET`
  - `USE_LARGE_PAGES`

  If the preceding parameters aren't declared in `/rdsdbdata/config/oracle_pfile`, read replica creation and scale compute might fail.

Limitations

RDS Custom for Oracle has the following limitations:

- You can't delete the symbolic links for configuration files such as the server parameter file, audit files, `listener.ora`, `tnsnames.ora`, or `sqlnet.ora`. You also can't modify the directory structure for these files. RDS Custom automation expects these files to exist in a specific directory structure.

  To create a server parameter file from an initialization parameter file, use the following syntax.

  ```
  CREATE SPFILE='/rdsdbdata/admin/$ORACLE_SID/pfile/spfile$ORACLE_SID.ora'
      FROM PFILE='/rdsdbdata/config/oracle_pfile';
  ```

- You can't change the master username for your RDS Custom for Oracle DB instance by using the `ModifyDBInstance` API.
- Control file multiplexing isn't currently supported because of a read replica issue. Before you create a read replica, make sure to specify only one filename in the `CONTROL_FILES` initialization parameter on the source database.
- Comments aren't supported in a server parameter file or initialization parameter file.
- You can't make more than 20 snapshot copies at the same time in the same Region.

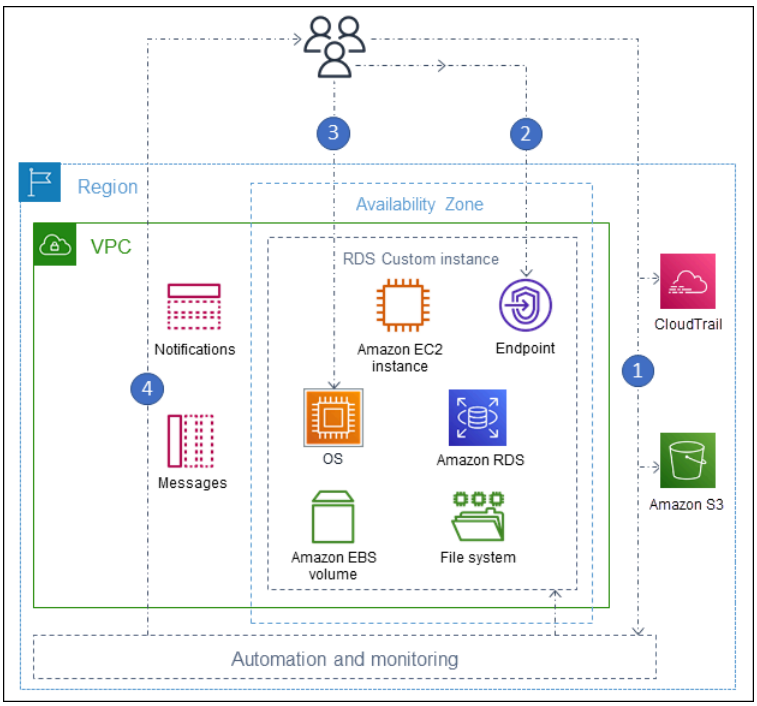
Working with RDS Custom for SQL Server

Following, you can find instructions for creating, managing, and maintaining your RDS Custom for SQL Server DB instances.

Topics

RDS Custom for SQL Server workflow

The following diagram shows the typical workflow for RDS Custom for SQL Server.



The steps are as follows:

1. Create an RDS Custom for SQL Server DB instance from an engine version offered by RDS Custom.

   For more information, see Creating an RDS Custom for SQL Server DB instance.
2. Connect your application to the RDS Custom DB instance endpoint.

   For more information, see Connecting to your RDS Custom DB instance using AWS Systems Manager and Connecting to your RDS Custom DB instance using RDP.
3. (Optional) Access the host to customize your software.
4. Monitor notifications and messages generated by RDS Custom automation.

Creating a DB instance for RDS Custom

You create your RDS Custom DB instance using the `create-db-instance` command. The procedure is similar to creating an Amazon RDS instance. However, some of the parameters are different. For more information, see Creating and connecting to a DB instance for Amazon RDS Custom for SQL Server.

Database connection

Like an Amazon RDS DB instance, your RDS Custom for SQL Server DB instance resides in a VPC. Your application connects to the RDS Custom instance using a client such as SQL Server Management Suite (SSMS), just as in RDS for SQL Server.

RDS Custom customization

You can access the RDS Custom host to install or customize software. To avoid conflicts between your changes and the RDS Custom automation, you can pause the automation for a specified period. During this period, RDS Custom doesn't perform monitoring or instance recovery. At the end of the period, RDS Custom resumes full automation. For more information, see Pausing and resuming RDS Custom automation.

Requirements and limitations for Amazon RDS Custom for SQL Server

Following, you can find a summary of the Amazon RDS Custom for SQL Server requirements and limitations for quick reference. Requirements and limitations also appear in the relevant sections.

Topics

Region and version availability

Feature availability and support varies across specific versions of each database engine, and across AWS Regions. For more information on version and Region availability of Amazon RDS with Amazon RDS Custom for SQL Server, see Supported Regions and DB engines for RDS Custom for SQL Server.

General requirements for RDS Custom for SQL Server

Make sure to follow these requirements for Amazon RDS Custom for SQL Server:

- Use the instance classes shown in DB instance class support for RDS Custom for SQL Server. The only storage types supported are solid state drives (SSD) of types gp2, gp3, io1, and io2 Block Express. The maximum storage limit is 16 TiB.
- Make sure that you have a symmetric encryption AWS KMS key to create an RDS Custom DB instance. For more information, see Make sure that you have a symmetric encryption AWS KMS key.
- Make sure that you create an AWS Identity and Access Management (IAM) role and instance profile. For more information, see Creating your IAM role and instance profile manually and Automated instance profile creation using the AWS Management Console.

- Make sure to supply a networking configuration that RDS Custom can use to access other AWS services. For specific requirements, see Step 2: Configure networking, instance profile, and encryption.
- The combined number of RDS Custom and Amazon RDS DB instances can't exceed your quota limit. For example, if your quota is 40 DB instances, you can have 20 RDS Custom for SQL Server DB instances and 20 Amazon RDS DB instances.
- RDS Custom automatically creates an AWS CloudTrail trail whose name begins with `do-not-delete-rds-custom-`. The RDS Custom support perimeter relies on the events from CloudTrail to determine whether your actions affect RDS Custom automation. RDS Custom creates the trail when you create your first DB instance. To use an already existing CloudTrail, contact AWS Support. For more information, see AWS CloudTrail.
- You can't use RDS Proxy with RDS Custom for SQL Server.

DB instance class support for RDS Custom for SQL Server

Check if the DB instance class is supported in your Region by using the describe-orderable-db-instance-options command.

RDS Custom for SQL Server supports the DB instance classes shown in the following table:

SQL Server edition	RDS Custom support
Enterprise Edition	db.r5.xlarge–db.r5.24xlarge db.r5b.xlarge–db.r5b.24xlarge db.m5.xlarge–db.m5.24xlarge db.r6i.xlarge–db.r6i.32xlarge db.m6i.xlarge–db.m6i.32xlarge db.x2iedn.xlarge–db.x2iedn.32xlarge
Standard Edition	db.r5.large–db.r5.24xlarge

SQL Server edition	RDS Custom support
	db.r5b.large–db.r5b.8xlarge db.m5.large–db.m5.24xlarge db.r6i.large–db.r6i.8xlarge db.m6i.large–db.m6i.8xlarge db.x2iedn.xlarge–db.x2iedn.8xlarge
Developer Edition	db.r5.xlarge–db.r5.24xlarge db.r5b.xlarge–db.r5b.24xlarge db.m5.xlarge–db.m5.24xlarge db.r6i.xlarge–db.r6i.32xlarge db.m6i.xlarge–db.m6i.32xlarge db.x2iedn.xlarge–db.x2iedn.32xlarge
Web Edition	db.r5.large–db.r5.4xlarge db.m5.large–db.m5.4xlarge db.r6i.large–db.r6i.4xlarge db.m6i.large–db.m6i.4xlarge db.r5b.large–db.r5b.4xlarge

The following recommendations apply to db.x2iedn class types:

- At creation, local storage is a raw and unallocated device. Before using a DB instance with this instance class, you must mount and format the local storage. Afterward, configure `tempdb` on

it to ensure optimal performance. For more information, see Optimize tempdb performance in Amazon RDS Custom for SQL Server using local instance storage.

- Local storage reverts to its raw and unallocated state when you run DB instance operations such as scale compute, instance replacement, snapshot restore, or point-in-time recovery (PITR). In these situations, you must remount, reformat, and reconfigure the drive and `tempdb` to restore functionality.
- For Multi-AZ instances, we recommend that you perform the configuration on a standby DB instance. This way, if a failover occurs, the system continues to operate without issues because the configuration is already in place on the standby instance.

Limitations for RDS Custom for SQL Server

The following limitations apply to RDS Custom for SQL Server:

- You can't create read replicas in Amazon RDS for RDS Custom for SQL Server DB instances. However, you can configure high availability automatically with a Multi-AZ deployment. For more information, see Managing a Multi-AZ deployment for RDS Custom for SQL Server.
- You can't modify the DB instance identifier of an existing RDS Custom for SQL Server DB instance.
- For an RDS Custom for SQL Server DB instance that wasn't created with a custom engine version (CEV), changes to the Microsoft Windows operating system aren't guaranteed to persist. For example, you lose these changes when you initiate a snapshot or point-in-time restore operation. If the RDS Custom for SQL Server DB instance was created with a CEV, then those changes are persisted.
- Not all options are supported. For example, when you create an RDS Custom for SQL Server DB instance, you can't do the following:
  - Change the number of CPU cores and threads per core on the DB instance class.
  - Turn on storage autoscaling.
  - Configure Kerberos authentication using the AWS Management Console. However, you can configure Windows Authentication manually and use Kerberos.
  - Specify your own DB parameter group, option group, or character set.
  - Turn on Performance Insights.
  - Turn on automatic minor version upgrade.
- The maximum DB instance storage is 16 TiB.

Collation and character support for RDS Custom for SQL Server DB instances

RDS Custom for SQL Server supports a wide range of server collations, both in traditional and UTF-8 encoding, for the SQL_Latin, Japanese, German, and Arabic locales. The default server collation is `SQL_Latin1_General_CP1_CI_AS`, however, you can select another supported collation to use. You can select a collation using the same procedure that RDS for SQL Server uses. For more information, see Collations and character sets for Microsoft SQL Server.

The following requirements and limitations apply when working with server collations on RDS Custom for SQL Server:

- You can set the server collation when you create an RDS Custom for SQL Server DB instance. You can't modify the server-level collation after the DB instance is created.
- You can't modify the server level collation when restoring from a DB snapshot or during a point in time recovery (PITR).
- When you create a DB instance from an RDS Custom for SQL Server CEV, the DB instance doesn't inherit the server collation from the CEV. Instead, the default server collation of `SQL_Latin1_General_CP1_CI_AS` is used. If you've configured a non-default server collation on a RDS Custom for SQL Server CEV and want to use that same server collation on a new DB instance, be sure to select that same collation when you create the DB instance from the CEV.

  > **Note**
  >
  > If the collation you select while creating the DB instance is different from the collation of the CEV, the Microsoft SQL Server system databases on the new RDS Custom for SQL Server DB instance will be rebuilt to use the updated collation. The rebuild process is only performed on the new RDS Custom for SQL Server DB instance and has no impact on the CEV itself. Any previous modifications that you made to the system databases on the CEV will not be retained on the new RDS Custom for SQL Server DB instance once the system databases are rebuilt. Examples of some modifications include user-defined objects in the `master` database, scheduled jobs in the `msdb` database, or changes to default database settings in the `model` database on your CEV. You can manually recreate your modifications once the new RDS Custom for SQL Server DB instance is created.

- When you create a DB instance from an RDS Custom for SQL Server custom engine version (CEV) and select a different collation from that of the CEV, ensure that your golden image (AMI)

used for CEV creation meets the following requirements so the Microsoft SQL Server system databases on the new DB instance can be rebuilt:

- For SQL Server 2022, ensure the `setup.exe` file is located in the following path: `C:\Program Files\Microsoft SQL Server\160\Setup Bootstrap\SQL2022\setup.exe`
- For SQL Server 2019, ensure the `setup.exe` file is located in the following path: `C:\Program Files\Microsoft SQL Server\150\Setup Bootstrap\SQL2019\setup.exe`
- Copies of the data and log templates for the `master`, `model`, and `msdb` databases must exist in their default locations. For more information, see Rebuild system databases in the Microsoft public documentation.
- Ensure your SQL Server Database Engine uses `NT Service\MSSQLSERVER` or `NT AUTHORITY\NETWORK SERVICE` as the service account. Any other account will not have the required permissions on the `C:\` drive when configuring a non-default server collation for the DB instance.

- If the server collation selected for a new DB instance is the same as that configured on your CEV, the Microsoft SQL Server system databases on the new RDS Custom for SQL Server DB instance do not undergo the rebuild process. Any previous modifications that you made to the system databases on the CEV will automatically persist to the new RDS Custom for SQL Server DB instance.

You can set your collation to one of the values listed in the following table.

Arabic_100_BIN	Arabic-100, binary sort
Arabic_100_BIN2	Arabic-100, binary code point comparison sort
Arabic_100_CI_AI	Arabic-100, case-insensitive, accent-insensitive, kanatype-insensitive, width-insensitive

Local time zone for RDS Custom for SQL Server DB instances

The time zone of an RDS Custom for SQL Server DB instance is set by default. The current default is Coordinated Universal Time (UTC). You can set the time zone of your DB instance to a local time zone instead, to match the time zone of your applications.

You set the time zone when you first create your DB instance. You can create your DB instance by using the AWS Management Console, the Amazon RDS API CreateDBInstance action, or the AWS CLI create-db-instance command.

If your DB instance is part of a Multi-AZ deployment, then when you fail over, your time zone remains the local time zone that you set.

When you request a point-in-time restore, you specify the time to restore to. The time is shown in your local time zone. For more information, see Restoring a DB instance to a specified time.

The following are limitations to setting the local time zone on your DB instance:

- You can configure the time zone for a DB instance during instance creation, but you can't modify the time zone of an existing RDS Custom for SQL Server DB instance.
- If the time zone is modified for an existing RDS Custom for SQL Server DB instance, RDS Custom changes the DB instance status to `unsupported-configuration`, and sends event notifications.
- You can't restore a snapshot from a DB instance in one time zone to a DB instance in a different time zone.
- We strongly recommend that you don't restore a backup file from one time zone to a different time zone. If you restore a backup file from one time zone to a different time zone, you must audit your queries and applications for the effects of the time zone change. For more information, see Importing and exporting SQL Server databases using native backup and restore.

Supported time zones

You can set your local time zone to one of the values listed in the following table.

Time zone	Standard time offset	Description	Notes
Afghanistan Standard Time	(UTC+04:30)	Kabul	This time zone doesn't observe

Time zone	Standard time offset	Description	Notes
			daylight saving time.
Alaskan Standard Time	(UTC–09:00)	Alaska	
Aleutian Standard Time	(UTC–10:00)	Aleutian Islands	
Altai Standard Time	(UTC+07:00)	Barnaul, Gorno-Altaysk	
Arab Standard Time	(UTC+03:00)	Kuwait, Riyadh	This time zone doesn't observe daylight saving time.
Arabian Standard Time	(UTC+04:00)	Abu Dhabi, Muscat	
Arabic Standard Time	(UTC+03:00)	Baghdad	This time zone doesn't observe daylight saving time.
Argentina Standard Time	(UTC–03:00)	City of Buenos Aires	This time zone doesn't observe daylight saving time.
Astrakhan Standard Time	(UTC+04:00)	Astrakhan, Ulyanovsk	
Atlantic Standard Time	(UTC–04:00)	Atlantic Time (Canada)	

Time zone	Standard time offset	Description	Notes
AUS Central Standard Time	(UTC+09:30)	Darwin	This time zone doesn't observe daylight saving time.
Aus Central W. Standard Time	(UTC+08:45)	Eucla	
AUS Eastern Standard Time	(UTC+10:00)	Canberra, Melbourne, Sydney	
Azerbaijan Standard Time	(UTC+04:00)	Baku	
Azores Standard Time	(UTC–01:00)	Azores	
Bahia Standard Time	(UTC–03:00)	Salvador	
Bangladesh Standard Time	(UTC+06:00)	Dhaka	This time zone doesn't observe daylight saving time.
Belarus Standard Time	(UTC+03:00)	Minsk	This time zone doesn't observe daylight saving time.
Bougainville Standard Time	(UTC+11:00)	Bougainville Island	
Canada Central Standard Time	(UTC–06:00)	Saskatchewan	This time zone doesn't observe daylight saving time.

Using a Service Master Key with RDS Custom for SQL Server

RDS Custom for SQL Server supports using a Service Master Key (SMK). RDS Custom retains the same SMK throughout the lifespan of your RDS Custom for SQL Server DB instance. By retaining the same SMK, your DB instance can use objects that are encrypted with the SMK, such as linked

server passwords and credentials. If you use a Multi-AZ deployment, RDS Custom also synchronizes and maintains the SMK between primary and secondary DB instances.

Topics

Region and version availability

Using an SMK is supported in all Regions where RDS Custom for SQL Server is available, for all SQL Server versions available on RDS Custom. For more information on version and Region availability of Amazon RDS with RDS Custom for SQL Server, see Supported Regions and DB engines for RDS Custom for SQL Server.

Supported features

When using a SMK with RDS Custom for SQL Server, the following features are supported:

- Transparent Data Encryption (TDE)
- Column-level encryption
- Database Mail
- Linked Servers
- SQL Server Integration Services (SSIS)

Using TDE

An SMK enables the ability to configure Transparent Data Encryption (TDE), which encrypts data before it is written to storage, and automatically decrypts data when the data is read from storage. Unlike RDS for SQL Server, configuring TDE on an RDS Custom for SQL Server DB instance doesn't require using option groups. Instead, once you've created a certificate and database encryption key, you can run the following command to turn on TDE at the database level:

```
ALTER DATABASE [myDatabase] SET ENCRYPTION ON;
```

For more information on using TDE with RDS for SQL Server, see Support for Transparent Data Encryption in SQL Server.

For detailed information on TDE in Microsoft SQL Server, see Transparent data encryption in the Microsoft documentation.

Configuring features

For detailed steps on configuring features that use a SMK with RDS Custom for SQL Server, you can use the following posts in the Amazon RDS database blog:

- Linked servers: Configuring linked servers on RDS Custom for SQL Server.
- SSIS: Migrate SSIS packages to RDS Custom for SQL Server.
- TDE: Secure your data using TDE on RDS Custom for SQL Server.

Requirements and limitations

When using an SMK with an RDS Custom for SQL Server DB instance, keep in mind the following requirements and limitations:

- If you re-generate the SMK on your DB instance, you should immediately perform a manual DB snapshot. We recommend avoiding re-generating the SMK if possible.
- You must maintain backups of the server certificates and database master key passwords. If you don't maintain backups of these, it may result in data loss.
- If you configure SSIS, you should use an SSM document to join the RDS Custom for SQL Server DB instance to the domain in case of a scale compute or host replacement.
- When TDE or column-encryption is enabled, database backups are automatically encrypted. When you perform a snapshot restore or point in time recovery, the SMK from the source DB instance will be restored to decrypt data for the restore, and a new SMK will be generated to re-encrypt data on the restored instance.

For more information on Service Master Keys in Microsoft SQL Server, see SQL Server and Database Encryption Keys in the Microsoft documentation.

Setting up your environment for Amazon RDS Custom for SQL Server

Before you create and manage a DB instance for Amazon RDS Custom for SQL Server DB instance, make sure to perform the following tasks.

Contents

> **Note**
>
> For a step-by-step tutorial on how to set up prerequisites and launch Amazon RDS Custom for SQL Server, see Get started with Amazon RDS Custom for SQL Server using an

CloudFormation template (Network setup) and Explore the prerequisites required to create an Amazon RDS Custom for SQL Server instance.

Prerequisites for setting up RDS Custom for SQL Server

Before creating an RDS Custom for SQL Server DB instance, make sure that your environment meets the requirements described in this topic. You can also use the CloudFormation template to set up the prerequisites within your AWS account. For more information, see Configuring with AWS CloudFormation

RDS Custom for SQL Server requires that you configure the following prerequisites:

- Configure the AWS Identity and Access Management (IAM) permissions required for instance creation. This is the AWS Identity and Access Management (IAM) user or role needed to make a `create-db-instance` request to RDS.
- Configure prerequisite resources required by RDS Custom for SQL Server DB instance:
  - Configure the AWS KMS key required for encryption of RDS Custom instance. RDS Custom requires a customer managed key at the time of instance creation for encryption. The KMS key ARN, ID, alias ARN, or alias name is passed as `kms-key-id` parameter in the request to create the RDS Custom DB instance.
  - Configure the permissions required inside RDS Custom for SQL Server DB instance. RDS Custom attaches an instance profile to DB instance at creation and uses it for automation within the DB instance. The instance profile name is set to `custom-iam-instance-profile` in the RDS Custom create request. You can create an instance profile from the AWS Management Console or manually create your instance profile. For more information, see Automated instance profile creation using the AWS Management Console and Creating your IAM role and instance profile manually.
  - Configure the networking setup as per the requirements of RDS Custom for SQL Server. RDS Custom instances reside in the subnets (configured with DB subnet group) that you provide at instance creation. These subnets must allow RDS Custom instances to communicate with services required for RDS automation.

Note

For the requirements mentioned above, make sure there aren't any service control policies (SCPs) restricting account level permissions.

If the account that you're using is part of an AWS Organization, it might have service control policies (SCPs) restricting account level permissions. Make sure that the SCPs don't restrict the permissions on users and roles that you create using the following procedures. For more information about SCPs, see Service control policies (SCPs) in the *AWS Organizations User Guide*. Use the describe-organization AWS CLI command to check whether your account is part of an AWS Organization.
For more information about AWS Organizations, see What is AWS Organizations in the *AWS Organizations User Guide*.

For general requirements that apply to RDS Custom for SQL Server, see General requirements for RDS Custom for SQL Server.

Automated instance profile creation using the AWS Management Console

RDS Custom requires you to create and configure an instance profile to launch any RDS Custom for SQL Server DB instance. Use the AWS Management Console to create and attach a new instance profile in a single step. This option is available under RDS Custom security section in the **Create database**, **Restore snapshot**, and **Restore to point in time** console pages. Choose **Create a new instance profile** to provide an instance profile name suffix. The AWS Management Console creates a new instance profile that has the permissions required for RDS Custom automation tasks. To automatically create new instance profiles, your logged-in AWS Management Console user must have `iam:CreateInstanceProfile`, `iam:AddRoleToInstanceProfile`, `iam:CreateRole`, and `iam:AttachRolePolicy` permissions.

Note

This option is only available in the AWS Management Console. If you are using the CLI or SDK, use the RDS Custom provided CloudFormation template or manually create an instance profile. For more information, see Creating your IAM role and instance profile manually.

Step 1: Grant required permissions to your IAM principal

Make sure that you have sufficient access to create an RDS Custom instance. The IAM role or IAM user (referred to as the *IAM principal*) for creating an RDS Custom for SQL Server DB instance using the console or CLI must have either of the following policies for successful DB instance creation:

- The `AdministratorAccess` policy
- The `AmazonRDSFullAccess` policy with the following additional permissions:

```
iam:SimulatePrincipalPolicy
cloudtrail:CreateTrail
cloudtrail:StartLogging
s3:CreateBucket
s3:PutBucketPolicy
s3:PutBucketObjectLockConfiguration
s3:PutBucketVersioning
kms:CreateGrant
kms:DescribeKey
kms:Decrypt
kms:ReEncryptFrom
kms:ReEncryptTo
kms:GenerateDataKeyWithoutPlaintext
kms:GenerateDataKey
ec2:DescribeImages
ec2:RunInstances
ec2:CreateTags
```

RDS Custom uses these permissions during instance creation. These permissions configure resources in your account that are required for RDS Custom operations.

For more information about the `kms:CreateGrant` permission, see AWS KMS key management.

The following sample JSON policy grants the required permissions.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "ValidateIamRole",
            "Effect": "Allow",
            "Action": "iam:SimulatePrincipalPolicy",
            "Resource": "*"
        },
        {
            "Sid": "CreateCloudTrail",
            "Effect": "Allow",
            "Action": [
```

```
                "cloudtrail:CreateTrail",
                "cloudtrail:StartLogging"
            ],
            "Resource": "arn:aws:cloudtrail:*:*:trail/do-not-delete-rds-custom-*"
        },
        {
            "Sid": "CreateS3Bucket",
            "Effect": "Allow",
            "Action": [
                "s3:CreateBucket",
                "s3:PutBucketPolicy",
                "s3:PutBucketObjectLockConfiguration",
                "s3:PutBucketVersioning"
            ],
            "Resource": "arn:aws:s3:::do-not-delete-rds-custom-*"
        },
        {
            "Sid": "CreateKmsGrant",
            "Effect": "Allow",
            "Action": [
                "kms:CreateGrant",
                "kms:DescribeKey"
            ],
            "Resource": "*"
        }
    ]
}
```

The IAM principal requires the following additional permissions to work with custom engine versions (CEVs):

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "ConfigureKmsKeyEncryptionPermission",
            "Effect": "Allow",
            "Action": [
                "kms:CreateGrant",
                "kms:DescribeKey",
                "kms:Decrypt",
                "kms:ReEncryptFrom",
                "kms:ReEncryptTo",
```

```
                "kms:GenerateDataKeyWithoutPlaintext",
                "kms:GenerateDataKey"
            ],
            "Resource": "arn:aws:kms:region:account_id:key/key_id"
        },
        {
            "Sid": "CreateEc2Instance",
            "Effect": "Allow",
            "Action": [
                "ec2:DescribeImages",
                "ec2:RunInstances",
                "ec2:CreateTags"
            ],
            "Resource": "*"
        }
    ]
}
```

Replace *account_id* with the ID of the account that you are using to create your instance. Replace *region* with the AWS Region you are using to create your instance. Replace *key_id* with your customer managed key ID. You can add multiple keys as required.

For more information about the resource-level permissions that are required to launch an EC2 instance, see Launch instances (RunInstances).

Also, the IAM principal requires the `iam:PassRole` permission on the IAM role. That must be attached to the instance profile passed in the `custom-iam-instance-profile` parameter in the request to create the RDS Custom DB instance. The instance profile and its attached role are created later in Step 2: Configure networking, instance profile, and encryption.

> **Note**
>
> Make sure that the previously listed permissions aren't restricted by service control policies (SCPs), permission boundaries, or session policies associated with the IAM principal.

Step 2: Configure networking, instance profile, and encryption

You can configure your IAM instance profile role, virtual private cloud (VPC), and AWS KMS symmetric encryption key by using either of the following processes:

- Configuring with AWS CloudFormation (recommended)
- Configuring manually

> **Note**
>
> If your account is part of any AWS Organizations, make sure that the permissions required by the instance profile role aren't restricted by service control policies (SCPs).
> The networking configurations in this topic work best with DB instances that aren't publicly accessible. You can't connect directly to such DB instances from outside the VPC.

Configuring with AWS CloudFormation

To simplify setup, you can use an AWS CloudFormation template file to create a CloudFormation stack. A CloudFormation template creates all the networking, instance profiles, and encryption resources according the requirements of RDS Custom.

To learn how to create stacks, see Creating a stack on the AWS CloudFormation console in the *AWS CloudFormation User Guide*.

For a tutorial on how to launch Amazon RDS Custom for SQL Server using an AWS CloudFormation template, see Get started with Amazon RDS Custom for SQL Server using an AWS CloudFormation template in the *AWS Database Blog* .

Topics

- Parameters required by CloudFormation
- Download AWS CloudFormation template file
- Configuring resources using CloudFormation

Parameters required by CloudFormation

The following parameters are required to configure RDS Custom prerequisite resources with CloudFormation:

Parameter group	Parameter name	Default Value	Description
Availability Configuration	Select an availability configuration for prerequisites setup	Multi-AZ	Specify whether to setup prerequisites in Single-AZ or Multi-AZ configuration for RDS Custom instances . You should use Multi-AZ configuration if you require at least one Multi-AZ DB instance in this configuration
Network Configuration	IPv4 CIDR block for VPC	10.0.0.0/16	Specify an IPv4 CIDR block (or IP address range) for your VPC. This VPC is configured to create and work with RDS Custom DB instance.
	IPv4 CIDR block for 1 of 2 private subnets	10.0.128.0/20	Specify an IPv4 CIDR block (or IP address range) for your first private subnet. This is one of the two subnets in which the RDS Custom DB instance can be created. This is a private subnet with no access to internet.
	IPv4 CIDR block for 2 of 2 private subnets	10.0.144.0/20	Specify an IPv4 CIDR block (or IP address range) for

Parameter group	Parameter name	Default Value	Description
			your second private subnet. This is one of the two subnets in which the RDS Custom DB instance can be created. This is a private subnet with no access to internet.
	IPv4 CIDR block for public subnet	10.0.0.0/20	Specify an IPv4 CIDR block (or IP address range) for your public subnet. This is one of the subnet in which the EC2 instance can connect with RDS Custom DB instance can be created. This is a public subnet with access to internet.
RDP Access Configuration	IPv4 CIDR block of your source	-	Specify an IPv4 CIDR block (or IP address range) of your source. This is the IP range from where you make RDP connection to EC2 instance in the public subnet. If not set, RDP connection to EC2 instance is not configured.

Parameter group	Parameter name	Default Value	Description
	Setup RDP access to RDS Custom for SQL Server instance	No	Specify whether to enable the RDP connection from the EC2 instance to the RDS Custom for SQL Server instance. By default, RDP connection from the EC2 instance to the DB instance is not configured.

Resources created by CloudFormation

Successfully creating the CloudFormation stack using default settings creates the following resources in your AWS account:

- Symmetric encryption KMS key for encryption of data managed by RDS Custom.
- The instance profile is is associated to an IAM role with `AmazonRDSCustomInstanceProfileRolePolicy` to provide permissions required by RDS Custom. For more information, see AmazonRDSCustomServiceRolePolicy in the *AWS Managed Policy Reference Guide*.
- VPC with the CIDR range specified as the CloudFormation parameter. The default value is `10.0.0.0/16`.
- Two private subnets with the CIDR range specified in the parameters, and two different Availability Zones in the AWS Region. The default values for the subnet CIDRs are `10.0.128.0/20` and `10.0.144.0/20`.
- One public subnet with the CIDR range specified in the parameters. The default value for the subnet CIDR is 10.0.0.0/20. The EC2 instance resides in this subnet and can be used to connect to the RDS Custom instance.
- DHCP option set for the VPC with domain name resolution to an Amazon Domain Name System (DNS) server.
- Route table to associate with two private subnets and no access to the internet.

- Route table to associate with public subnet and has access to the internet.
- Internet gateway associated with the VPC to allow internet access to public subnet.
- Network access control list (ACL) to associate with two private subnets and access restricted to HTTPS and DB port within VPC.
- VPC security group to be associated with the RDS Custom instance. Access is restricted for outbound HTTPS to AWS service endpoints that are required by RDS Custom and inbound DB port from EC2 instance security group.
- VPC security group to be associated with the EC2 instance in public subnet. Access is restricted for outbound DB port to RDS Custom instance security group.
- VPC security group to be associated with VPC endpoints that are created for AWS service endpoints that are required by RDS Custom.
- DB subnet group in which RDS Custom instances are created. Two private subnets created by this template are added to the DB subnet group.
- VPC endpoints for each of the AWS service endpoints that are required by RDS Custom.

Setting availability configuration to multi-az will create following resources in addition to above list:

- Network ACL rules allowing communication between private subnets.
- Inbound and outbound access to Multi-AZ port within VPC security group associated with the RDS Custom instance.
- VPC endpoints to AWS service endpoint(s) that are required for Multi-AZ communication.

In addition, setting RDP access configuration creates the following resources:

- Configuring RDP access to public subnet from your source IP address:
  - Network ACL rules that allow RDP connection from your source IP to public subnet.
  - Ingress access to RDP port from your source IP to VPC security group associated with the EC2 instance.
- Configuring RDP access from EC2 instance in public subnet to RDS Custom Instance in private subnets:
  - Network ACL rules allowing RDP connection from public subnet to private subnets.
  - Inbound access to RDP port from VPC security group associated with the EC2 instance to VPC security group associated with the RDS Custom Instance.

Use the following procedures to create the CloudFormation stack for RDS Custom for SQL Server.

Download AWS CloudFormation template file

To download the template file

1. Open the context (right-click) menu for the link custom-sqlserver-onboard.zip and choose **Save Link As**.
2. Save and extract the file to your computer.

Configuring resources using CloudFormation

To configure resources using CloudFormation

1. Open the CloudFormation console at https://console.aws.amazon.com/cloudformation.
2. To start the Create Stack wizard, choose **Create Stack**.

   The **Create stack** page appears.
3. For **Prerequisite - Prepare template**, choose **Template is ready**.
4. For **Specify template**, do the following:

   a. For **Template source**, choose **Upload a template file**.

   b. For **Choose file**, navigate to and then choose the correct file.
5. Choose **Next**.

   The **Specify stack details** page appears.
6. For **Stack name**, enter **`rds-custom-sqlserver`**.
7. For **Parameters**, do the following:

   a. To keep the default options, choose **Next**.

   b. To change options, choose the appropriate availability configuration, networking configuration, and RDP access configuration, and then choose **Next**.

      Read the description of each parameter carefully before changing parameters.

> **Note**
>
> If you choose to create at least one Multi-AZ instance in this CloudFormation stack, make sure that the CloudFormation stack parameter **Select an availability configuration for prerequisites setup** is set to `Multi-AZ`. If you create the CloudFormation stack as Single-AZ, update the CloudFormation stack to Multi-AZ configuration before creating the first Multi-AZ instance.

8. On the **Configure stack options page**, choose **Next.**
9. On the **Review rds-custom-sqlserver** page, do the following:
    a. For **Capabilities**, select the **I acknowledge that AWS CloudFormation might create IAM resources with custom names** check box.
    b. Choose **Create stack**.

> **Note**
>
> Do not update the resources created from this AWS CloudFormation stack directly from the resource pages. This prevents you from applying future updates to these resources by using a AWS CloudFormation template.

CloudFormation creates the resources that RDS Custom for SQL Server requires. If the stack creation fails, read through the **Events** tab to see which resource creation failed and its status reason.

The **Outputs** tab for this CloudFormation stack in the console should have information about all resources to be passed as parameters for creating an RDS Custom for SQL Server DB instance. Make sure to use the VPC security group and DB subnet group created by CloudFormation for RDS Custom DB instances. By default, RDS tries to attach the default VPC security group, which might not have the access that you need.

If you used CloudFormation to create resources, you can skip Configuring manually.

Updating the CloudFormation stack

You can also update some of the configuration on the CloudFormation stack after creation. The configurations that can be updated are:

- Availability Configuration for RDS Custom for SQL Server
  - **Select an availability configuration for prerequisites setup**: Update this parameter to switch between Single-AZ and Multi-AZ configuration. If you are using this CloudFormation stack for at least one Multi-AZ instance, you must update the stack to choose Multi-AZ configuration.
- RDP Access Configuration for RDS Custom for SQL Server
  - IPv4 CIDR block of your source: You can update the IPv4 CIDR block (or IP address range) of your source by updating this parameter. Setting this parameter to blank removes RDP access configuration from your source CIDR block to public subnet.
  - Setup RDP access to RDS Custom for SQL Server: Enable or disable the RDP connection from the EC2 instance to the RDS Custom for SQL Server instance.

Deleting the CloudFormation stack

You can delete the CloudFormation stack after deleting all the RDS Custom instances that uses resources from the stack. RDS Custom doesn't keep track of the CloudFormation stack, hence it doesn't block deletion of the stack when there are DB instances that uses stack resources. Make sure that there are no RDS Custom DB instances that uses the stack resources when deleting the stack.

> **Note**
>
> When you delete a CloudFormation stack, all of the resources created by the stack are deleted except the KMS key. The KMS key goes into a pending-deletion state and is deleted after 30 days. To keep the KMS key, perform a CancelKeyDeletion operation during the 30-day grace period.

Configuring manually

If you choose to configure resources manually, perform the following tasks.

> **Note**
>
> To simplify setup, you can use the AWS CloudFormation template file to create a CloudFormation stack rather than a manual configuration. For more information, see Configuring with AWS CloudFormation.
> You can also use the AWS CLI to complete this section. If so, download and install the latest CLI.

Topics

- Make sure that you have a symmetric encryption AWS KMS key
- Creating your IAM role and instance profile manually
- Configuring your VPC manually

Make sure that you have a symmetric encryption AWS KMS key

A symmetric encryption AWS KMS key is required for RDS Custom. When you create an RDS Custom for SQL Server DB instance, make sure to supply the KMS key identifier as parameter `kms-key-id`. For more information, see Creating and connecting to a DB instance for Amazon RDS Custom for SQL Server.

You have the following options:

- If you have an existing customer managed KMS key in your AWS account, you can use it with RDS Custom. No further action is necessary.
- If you already created a customer managed symmetric encryption KMS key for a different RDS Custom engine, you can reuse the same KMS key. No further action is necessary.
- If you don't have an existing customer managed symmetric encryption KMS key in your account, create a KMS key by following the instructions in Creating keys in the *AWS Key Management Service Developer Guide*.
- If you're creating a CEV or RDS Custom DB instance, and your KMS key is in a different AWS account, make sure to use the AWS CLI. You can't use the AWS console with cross-account KMS keys.

> **Important**
>
> RDS Custom doesn't support AWS managed KMS keys.

Make sure that your symmetric encryption key grants access to the `kms:Decrypt` and `kms:GenerateDataKey` operations to the AWS Identity and Access Management (IAM) role in your IAM instance profile. If you have a new symmetric encryption key in your account, no changes are required. Otherwise, make sure that your symmetric encryption key's policy grants access to these operations.

For more information, see Step 4: Configure IAM for RDS Custom for Oracle.

Creating your IAM role and instance profile manually

You can manually create an instance profile and use it to launch RDS Custom instances. If you plan to create the instance in the AWS Management Console, skip this section. The AWS Management Console allows you to create and attach an instance profile to your RDS Custom DB instances. For more information, see Automated instance profile creation using the AWS Management Console.

When you manually create an instance profile, pass the instance profile name as the `custom-iam-instance-profile` parameter to your `create-db-instance` CLI command. RDS Custom uses the role associated with this instance profile to run automation to manage the instance.

To create the IAM instance profile and IAM roles for RDS Custom for SQL Server

1. Create the IAM role named `AWSRDSCustomSQLServerInstanceRole` with a trust policy that lets Amazon EC2 assume this role.
2. Add the AWS Managed Policy `AmazonRDSCustomInstanceProfileRolePolicy` to `AWSRDSCustomSQLServerInstanceRole`.
3. Create an IAM instance profile for RDS Custom for SQL Server that is named `AWSRDSCustomSQLServerInstanceProfile`.
4. Add `AWSRDSCustomSQLServerInstanceRole` to the instance profile.

Create the AWSRDSCustomSQLServerInstanceRole IAM role

The following example creates the `AWSRDSCustomSQLServerInstanceRole` role. The trust policy lets Amazon EC2 assume the role.

```
aws iam create-role \
    --role-name AWSRDSCustomSQLServerInstanceRole \
    --assume-role-policy-document '{
        "Version": "2012-10-17",
          "Statement": [
            {
              "Action": "sts:AssumeRole",
              "Effect": "Allow",
              "Principal": {
                  "Service": "ec2.amazonaws.com"
              }
            }
          ]
        }'
```

Add an access policy to AWSRDSCustomSQLServerInstanceRole

To provide the required permissions, attach the AWS managed policy `AmazonRDSCustomInstanceProfileRolePolicy` to `AWSRDSCustomSQLServerInstanceRole`. `AmazonRDSCustomInstanceProfileRolePolicy` allows RDS Custom instances to send and receive messages, and perform various automation actions.

> **Note**
>
> Make sure that the permissions in the access policy aren't restricted by SCPs or permission boundaries associated with the instance profile role.

The following example attaches AWS managed policy `AWSRDSCustomSQLServerIamRolePolicy` to the `AWSRDSCustomSQLServerInstanceRole` role.

```
aws iam attach-role-policy \
    --role-name AWSRDSCustomSQLServerInstanceRole \
    --policy-arn arn:aws:iam::aws:policy/AmazonRDSCustomInstanceProfileRolePolicy
```

Create your RDS Custom for SQL Server instance profile

An instance profile is a container that includes a single IAM role. RDS Custom uses the instance profile to pass the role to the instance.

If you use the AWS Management Console to create a role for Amazon EC2, the console automatically creates an instance profile and gives it the same name as the role when the role is created. Create your instance profile as follows, naming it `AWSRDSCustomSQLServerInstanceProfile`.

```
aws iam create-instance-profile \
    --instance-profile-name AWSRDSCustomSQLServerInstanceProfile
```

Add AWSRDSCustomSQLServerInstanceRole to your RDS Custom for SQL Server instance profile

Add the `AWSRDSCustomInstanceRoleForRdsCustomInstance` role to the previously created `AWSRDSCustomSQLServerInstanceProfile` profile.

```
aws iam add-role-to-instance-profile \
    --instance-profile-name AWSRDSCustomSQLServerInstanceProfile \
    --role-name AWSRDSCustomSQLServerInstanceRole
```

Configuring your VPC manually

Your RDS Custom DB instance is in a virtual private cloud (VPC) based on the Amazon VPC service, just like an Amazon EC2 instance or Amazon RDS instance. You provide and configure your own VPC. Thus, you have full control over your instance networking setup.

RDS Custom sends communication from your DB instance to other AWS services. Make sure the following services are accessible from the subnet in which you create your RDS Custom DB instances:

- Amazon CloudWatch
- Amazon CloudWatch Logs
- Amazon CloudWatch Events
- Amazon EC2
- Amazon EventBridge
- Amazon S3
- AWS Secrets Manager
- AWS Systems Manager

If creating Multi-AZ deployments

- Amazon Simple Queue Service

If RDS Custom can't communicate with the necessary services, it publishes the following events:

```
Database instance in incompatible-network. SSM Agent connection not available. Amazon
 RDS can't connect to the dependent AWS services.
```

```
Database instance in incompatible-network. Amazon RDS can't connect to dependent AWS
 services. Make sure port 443 (HTTPS) allows outbound connections, and try again.
 "Failed to connect to the following services: s3 events"
```

To avoid `incompatible-network` errors, make sure that VPC components involved in communication between your RDS Custom DB instance and AWS services satisfy the following requirements:

- The DB instance can make outbound connections on port 443 to other AWS services.
- The VPC allows incoming responses to requests originating from your RDS Custom DB instance.
- RDS Custom can correctly resolve the domain names of endpoints for each AWS service.

If you already configured a VPC for a different RDS Custom DB engine, you can reuse that VPC and skip this process.

Topics

- Configure your VPC security group
- Configure endpoints for dependent AWS services
- Configure the instance metadata service

Configure your VPC security group

A *security group* acts as a virtual firewall for a VPC instance, controlling both inbound and outbound traffic. An RDS Custom DB instance has a security group attached to its network interface that protects the instance. Make sure that your security group permits traffic between RDS Custom and other AWS services through HTTPS. You pass this security group as the `vpc-security-group-ids` parameter in the instance creation request.

To configure your security group for RDS Custom

1. Sign in to the AWS Management Console and open the Amazon VPC console at https://console.aws.amazon.com/vpc.
2. Allow RDS Custom to use the default security group, or create your own security group.

   For detailed instructions, see Provide access to your DB instance in your VPC by creating a security group.
3. Make sure that your security group permits outbound connections on port 443. RDS Custom needs this port to communicate with dependent AWS services.
4. If you have a private VPC and use VPC endpoints, make sure that the security group associated with the DB instance allows outbound connections on port 443 to VPC endpoints. Also make sure that the security group associated with the VPC endpoint allows inbound connections on port 443 from the DB instance.

   If incoming connections aren't allowed, the RDS Custom instance can't connect to the AWS Systems Manager and Amazon EC2 endpoints. For more information, see Create a Virtual Private Cloud endpoint in the *AWS Systems Manager User Guide*.
5. For RDS Custom for SQL Server Multi-AZ instances, make sure that the security group associated with the DB instance allows inbound and outbound connections on port 1120 to this security group itself. This is required for peer host connection on a Multi-AZ RDS Custom for SQL Server DB instance.

For more information about security groups, see Security groups for your VPC in the *Amazon VPC Developer Guide*.

Configure endpoints for dependent AWS services

We recommend that you add endpoints for every service to your VPC using the following instructions. However, you can use any solution that lets your VPC communicate with AWS service endpoints. For example, you can use Network Address Translation (NAT) or AWS Direct Connect.

To configure endpoints for AWS services with which RDS Custom works

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. On the navigation bar, use the Region selector to choose the AWS Region.
3. In the navigation pane, choose **Endpoints**. In the main pane, choose **Create Endpoint**.

4. For **Service category**, choose **AWS services**.
5. For **Service Name**, choose the endpoint shown in the table.
6. For **VPC**, choose your VPC.
7. For **Subnets**, choose a subnet from each Availability Zone to include.

   The VPC endpoint can span multiple Availability Zones. AWS creates an elastic network interface for the VPC endpoint in each subnet that you choose. Each network interface has a Domain Name System (DNS) host name and a private IP address.
8. For **Security group**, choose or create a security group.

   You can use security groups to control access to your endpoint, much as you use a firewall. Make sure that the security group allows inbound connections on port 443 from the DB instances. For more information about security groups, see Security groups for your VPC in the *Amazon VPC User Guide*.
9. Optionally, you can attach a policy to the VPC endpoint. Endpoint policies can control access to the AWS service to which you are connecting. The default policy allows all requests to pass through the endpoint. If you're using a custom policy, make sure that requests from the DB instance are allowed in the policy.
10. Choose **Create endpoint**.

The following table explains how to find the list of endpoints that your VPC needs for outbound communications.

Service	Endpoint format	Notes and links
AWS Systems Manager	Use the following endpoint formats: • `ssm.region.amazonaws.com` • `ssmmessages. region.amazonaws.com`	For the list of endpoints in each Region, see AWS Systems Manager endpoints and quotas in the *Amazon Web Services General Reference*.
AWS Secrets Manager	Use the endpoint format `secretsmanager. region.amazonaws.com .`	For the list of endpoints in each Region, see AWS Secrets Manager endpoints and quotas in the *Amazon Web Services General Reference*.

Service	Endpoint format	Notes and links
Amazon CloudWatch	Use the following endpoint formats: • For CloudWatch metrics, use `monitoring.` *`region`*`.amazonaws.com` • For CloudWatch Events, use `events.`*`region`*`.amazonaws.com` • For CloudWatch Logs, use `logs.`*`region`*`.amazonaws.com`	For the list of endpoints in every Region, see: • Amazon CloudWatch endpoints and quotas in the *Amazon Web Services General Reference* • Amazon CloudWatch Logs endpoints and quotas in the *Amazon Web Services General Reference* • Amazon CloudWatch Events endpoints and quotas in the *Amazon Web Services General Reference*
Amazon EC2	Use the following endpoint formats: • `ec2.`*`region`*`.amazonaws.com` • `ec2messages.` *`region`*`.amazonaws.com`	For the list of endpoints in each Region, see Amazon Elastic Compute Cloud endpoints and quotas in the *Amazon Web Services General Reference*.

Service	Endpoint format	Notes and links
Amazon S3	Use the endpoint format `s3.region.amazonaws.com` .	For the list of endpoints in each Region, see Amazon Simple Storage Service endpoints and quotas in the *Amazon Web Services General Reference*. To learn more about gateway endpoints for Amazon S3, see Endpoints for Amazon S3 in the *Amazon VPC Developer Guide*. To learn how to create an access point, see Creating access points in the *Amazon VPC Developer Guide*. To learn how to create a gateway endpoints for Amazon S3, see Gateway VPC endpoints.
Amazon Simple Queue Service	Use the endpoint format `sqs.region.amazonaws.com`	For the list of endpoints in each Region, see Amazon Simple Queue Service endpoints and quotas.

Configure the instance metadata service

Make sure that your instance can do the following:

- Access the instance metadata service using Instance Metadata Service Version 2 (IMDSv2).
- Allow outbound communications through port 80 (HTTP) to the IMDS link IP address.
- Request instance metadata from `http://169.254.169.254`, the IMDSv2 link.

For more information, see Use IMDSv2 in the *Amazon EC2 User Guide*.

Cross-instance restriction

When you create an instance profile by following the steps above, it uses the AWS managed policy `AmazonRDSCustomInstanceProfileRolePolicy` to provide the required permissions to RDS Custom which allows instance management and monitoring automation. The managed policy ensures that the permissions allow access to only those resources which RDS Custom requires to run automation. We recommend using the managed policy to support new features and address security requirements which are automatically applied to existing instance profiles without manual intervention. For more information, see AWS managed policy: AmazonRDSCustomInstanceProfileRolePolicy.

The `AmazonRDSCustomInstanceProfileRolePolicy` managed policy restricts the instance profile to have cross-account access but it might allow access to some RDS Custom managed resources across RDS Custom instances within the same account. Based on your requirement, you can use permission boundaries to further restrict cross-instance access. Permission boundaries define the maximum permissions that the identity-based policies can grant to an entity, but doesn't grant permissions by themselves. For more information, see Evaluating effective permissions with boundaries.

For example, the following policy restricts instance profile role to access a specific AWS KMS key and limits access to RDS Custom managed resources across instances which are using different AWS KMS keys.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "DenyOtherKmsKeyAccess",
            "Effect": "Deny",
            "Action": "kms:*",
            "NotResource": "arn:aws:kms:region:acct_id:key/KMS_key_ID"
        },
        {
            "Sid": "NoBoundarySetByDefault",
            "Effect": "Allow",
            "Action": "*",
            "Resource": "*"
        }
    ]
}
```

Note

Make sure the permissions boundary does not block any permissions that `AmazonRDSCustomInstanceProfileRolePolicy` grants to RDS Custom.

Bring Your Own Media with RDS Custom for SQL Server

RDS Custom for SQL Server supports two licensing models: License Included (LI) and Bring Your Own Media (BYOM).

With BYOM, you can do the following:

1. Provide and install your own Microsoft SQL Server binaries with supported cumulative updates (CU) on an AWS EC2 Windows AMI.
2. Save the AMI as a golden image, which is a template that you can use to create a custom engine version (CEV).
3. Create a CEV from your golden image.
4. Create new RDS Custom for SQL Server DB instances by using your CEV.

Amazon RDS then manages your DB instances for you.

> **Note**
>
> If you also have a License Included (LI) RDS Custom for SQL Server DB instance, you can't use the SQL Server software from this DB instance with BYOM. You must bring your own SQL Server binaries to BYOM.

Requirements for BYOM for RDS Custom for SQL Server

The same general requirements for custom engine versions with RDS Custom for SQL Server also apply to BYOM. For more information, see Requirements for RDS Custom for SQL Server CEVs.

When using BYOM, make you sure that you meet the following additional requirements:

- Use one of the following supported editions: SQL Server 2022 or 2019 Enterprise, Standard, or Developer edition.
- Grant the SQL Server sysadmin (SA) server role privilege to `NT AUTHORITY\SYSTEM`.
- Keep the Windows Server OS configured with UTC time.

  Amazon EC2 Windows instances are set to the UTC time zone by default. For more information about viewing and changing the time for a Windows instance, see Set the time for a Windows instance.

- Open TCP port 1433 and UDP port 1434 to allow SSM connections.

Limitations of BYOM for RDS Custom for SQL Server

The same general limitations for RDS Custom for SQL Server also apply to BYOM. For more information, see Requirements and limitations for Amazon RDS Custom for SQL Server.

With BYOM, the following additional limitations apply:

- Only the default SQL Server instance (MSSQLSERVER) is supported. Named SQL Server instances aren't supported. RDS Custom for SQL Server detects and monitors only the default SQL Server instance.
- Only a single installation of SQL Server is supported on each AMI. Multiple installations of different SQL Server versions aren't supported.
- SQL Server Web edition isn't supported with BYOM.
- Evaluation versions of SQL Server editions aren't supported with BYOM. When you install SQL Server, don't select the checkbox for using an evaluation version.
- Feature availability and support varies across specific versions of each database engine, and across AWS Regions. For more information, see Region availability for RDS Custom for SQL Server CEVs and Version support for RDS Custom for SQL Server CEVs.

Creating an RDS Custom for SQL Server DB instance with BYOM

To prepare and create an RDS Custom for SQL Server DB instance with BYOM, see Preparing a CEV using Bring Your Own Media (BYOM).

Working with custom engine versions for RDS Custom for SQL Server

A *custom engine version (CEV)* for RDS Custom for SQL Server is an Amazon Machine Image (AMI) that includes Microsoft SQL Server.

The basic steps of the CEV workflow are as follows:

1. Choose an AWS EC2 Windows AMI to use as a base image for a CEV. You have the option to use pre-installed Microsoft SQL Server, or bring your own media to install SQL Server yourself.
2. Install other software on the operating system (OS) and customize the configuration of the OS and SQL Server to meet your enterprise needs.
3. Save the AMI as a golden image
4. Create a custom engine version (CEV) from your golden image.
5. Create new RDS Custom for SQL Server DB instances by using your CEV.

Amazon RDS then manages these DB instances for you.

A CEV allows you to maintain your preferred baseline configuration of the OS and database. Using a CEV ensures that the host configuration, such as any third-party agent installation or other OS customizations, are persisted on RDS Custom for SQL Server DB instances. With a CEV, you can quickly deploy fleets of RDS Custom for SQL Server DB instances with the same configuration.

Topics

Preparing to create a CEV for RDS Custom for SQL Server

You can create a CEV using an Amazon Machine Image (AMI) that contains pre-installed, License Included (LI) Microsoft SQL Server, or with an AMI on which you install your own SQL Server installation media (BYOM).

Contents

Preparing a CEV using Bring Your Own Media (BYOM)

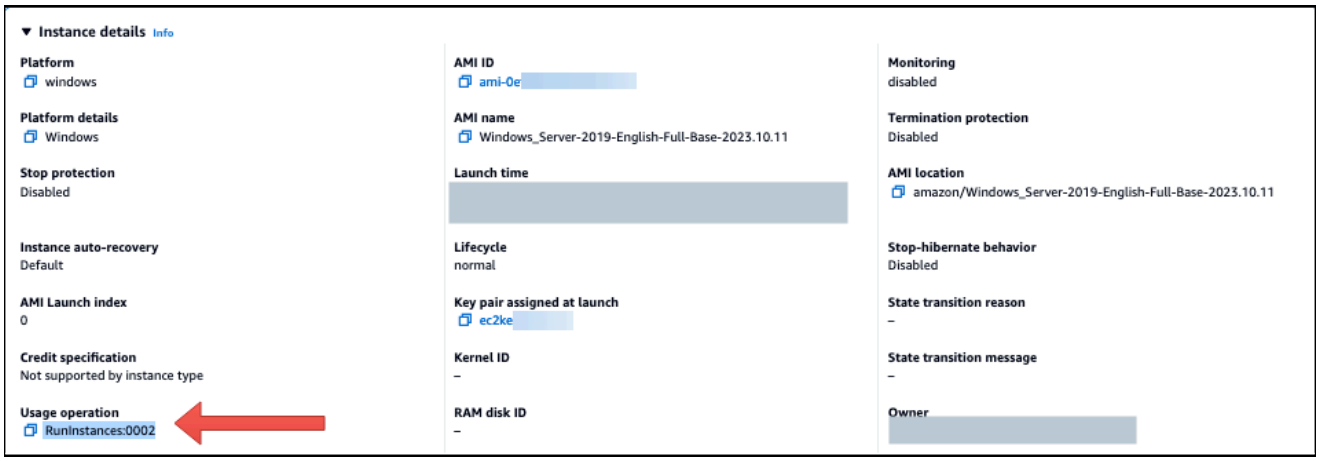
The following steps use an AMI with **Windows Server 2019 Base** as an example.

To create a CEV using BYOM

1. On the Amazon EC2 console, choose **Launch Instance**.
2. For **Name**, enter the name of the instance.
3. Under Quick Start, choose **Windows**.
4. Choose **Microsoft Windows Server 2019 Base**.
5. Choose an appropriate instance type, key pair, network and storage settings, and launch the instance.
6. After launching or creating the EC2 instance, ensure the correct Windows AMI was selected from Step 4:

    a. Select the EC2 instance in the Amazon EC2 console.

    b. In the **Details** section, check the **Usage operation** and ensure that it is set to **RunInstances:0002**.



7. Log in to the EC2 instance and copy your SQL Server installation media to it.

   > **Note**
   >
   > If you're building a CEV using SQL Server Developer edition, you may need to obtain the installation media using your Microsoft Visual Studio subscription.

8. Install SQL Server. Make sure that you do the following:

   a. Review Requirements for BYOM for RDS Custom for SQL Server and Version support for RDS Custom for SQL Server CEVs.

   b. Set the instance root directory to the default `C:\Program Files\Microsoft SQL Server\`. Don't change this directory.

   c. Set the SQL Server Database Engine Account Name to either `NT Service\MSSQLSERVER` or `NT AUTHORITY\NETWORK SERVICE`.

   d. Set the SQL Server Startup mode to **Manual**.

   e. Choose SQL Server Authentication mode as **Mixed**.

   f. Leave the current settings for the default Data directories and TempDB locations.

9. Grant the SQL Server sysadmin (SA) server role privilege to `NT AUTHORITY\SYSTEM`:

```
USE [master]
GO
EXEC master..sp_addsrvrolemember @loginame = N'NT AUTHORITY\SYSTEM' , @rolename =
 N'sysadmin'
GO
```

10. Install additional software or customize the OS and database configuration to meet your requirements.

11. Run Sysprep on the EC2 instance. For more information, see Create an Amazon EC2 AMI using Windows Sysprep.

12. Save the AMI that contains your installed SQL Server version, other software, and customizations. This will be your golden image.

13. Create a new CEV by providing the AMI ID of the image that you created. For detailed steps, see Creating a CEV for RDS Custom for SQL Server.

14. Create a new RDS Custom for SQL Server DB instance using the CEV. For detailed steps, see Create an RDS Custom for SQL Server DB instance from a CEV.

Preparing a CEV using pre-installed SQL Server (LI)

The following steps to create a CEV using pre-installed Microsoft SQL Server (LI) use an AMI with **SQL Server CU20** Release number `2023.05.10` as an example. When you create a CEV, choose an AMI with the most recent release number. This ensures that you are using a supported version of Windows Server and SQL Server with the latest Cumulative Update (CU).

To create a CEV using pre-installed Microsoft SQL Server (LI)

1. Choose the latest available AWS EC2 Windows Amazon Machine Image (AMI) with License Included (LI) Microsoft Windows Server and SQL Server.

   a. Search for **CU20** within the Windows AMI version history.

   b. Note the Release number. For SQL Server 2019 CU20, the release number is `2023.05.10`.

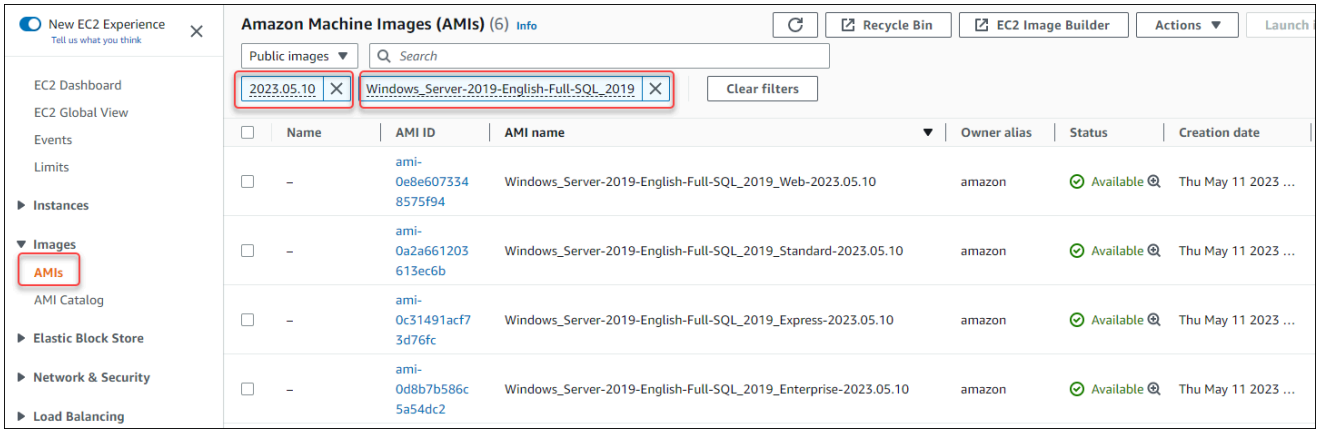
   c. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.

   d. In the left navigation panel of the Amazon EC2 console choose **Images**, then **AMIs**.

   e. Choose **Public images**.

   f. Enter `2023.05.10` into the search box. A list of AMIs appears.

   g. Enter `Windows_Server-2019-English-Full-SQL_2019` into the search box to filter the results. The following results should appear.



h. Choose the AMI with the SQL Server edition that you want to use.

2. Create or launch an EC2 instance from your chosen AMI.
3. Log in to the EC2 instance and install additional software or customize the OS and database configuration to meet your requirements.
4. Run Sysprep on the EC2 instance. For more information prepping an AMI using Sysprep, see Create a standardized Amazon Machine Image (AMI) using Sysprep.
5. Save the AMI that contains your installed SQL Server version, other software, and customizations. This will be your golden image.
6. Create a new CEV by providing the AMI ID of the image that you created. For detailed steps on creating a CEV, see Creating a CEV for RDS Custom for SQL Server.
7. Create a new RDS Custom for SQL Server DB instance using the CEV. For detailed steps, see Create an RDS Custom for SQL Server DB instance from a CEV.

Region availability for RDS Custom for SQL Server CEVs

Custom engine version (CEV) support for RDS Custom for SQL Server is available in the following AWS Regions:

- US East (Ohio)
- US East (N. Virginia)
- US West (Oregon)
- Asia Pacific (Mumbai)
- Asia Pacific (Seoul)
- Asia Pacific (Singapore)

- Asia Pacific (Sydney)
- Asia Pacific (Tokyo)
- Canada (Central)
- Europe (Frankfurt)
- Europe (Ireland)
- Europe (London)
- Europe (Stockholm)
- South America (São Paulo)

Version support for RDS Custom for SQL Server CEVs

CEV creation for RDS Custom for SQL Server is supported for the following AWS EC2 Windows AMIs:

- For CEVs using pre-installed media, AWS EC2 Windows AMIs with License Included (LI) Microsoft Windows Server 2019 (OS) and SQL Server 2022 or 2019
- For CEVs using bring your own media (BYOM), AWS EC2 Windows AMIs with Microsoft Windows Server 2019 (OS)

CEV creation for RDS Custom for SQL Server is supported for the following operating system (OS) and database editions:

- For CEVs using pre-installed media:
  - SQL Server 2022 with CU9, for Enterprise, Standard, and Web editions
  - SQL Server 2019 with CU17, CU18, CU20, and CU24, for Enterprise, Standard, and Web editions
- For CEVs using bring your own media (BYOM):
  - SQL Server 2022 with CU9, for Enterprise, Standard, and Developer editions
  - SQL Server 2019 with CU17, CU18, CU20, and CU24, for Enterprise, Standard, and Developer editions
- For CEVs using pre-installed media or bring your own media (BYOM), Windows Server 2019 is the only supported OS.

For more information, see AWS Windows AMI version history.

Requirements for RDS Custom for SQL Server CEVs

The following requirements apply to creating a CEV for RDS Custom for SQL Server:

- The AMI used to create a CEV must be based on an OS and database configuration supported by RDS Custom for SQL Server. For more information on supported configurations, see Requirements and limitations for Amazon RDS Custom for SQL Server.
- The CEV must have a unique name. You can't create a CEV with the same name as an existing CEV.
- You must name the CEV using a naming pattern of SQL Server *major version + minor version + customized string*. The *major version + minor version* must match the SQL Server version provided with the AMI. For example, you can name an AMI with SQL Server 2019 CU17 as **15.00.4249.2.my_cevtest**.
- You must prepare an AMI using Sysprep. For more information about prepping an AMI using Sysprep, see Create a standardized Amazon Machine Image (AMI) using Sysprep.
- You are responsible for maintaining the life cycle of the AMI. An RDS Custom for SQL Server DB instance created from a CEV doesn't store a copy of the AMI. It maintains a pointer to the AMI that you used to create the CEV. The AMI must exist for an RDS Custom for SQL Server DB instance to remain operable.

Limitations for RDS Custom for SQL Server CEVs

The following limitations apply to custom engine versions with RDS Custom for SQL Server:

- You can't delete a CEV if there are resources, such as DB instances or DB snapshots, associated with it.
- To create an RDS Custom for SQL Server DB instance, a CEV must have a status of `pending-validation`, `available`, `failed`, or `validating`. You can't create an RDS Custom for SQL Server DB instance using a CEV if the CEV status is `incompatible-image-configuration`.
- To modify a RDS Custom for SQL Server DB instance to use a new CEV, the CEV must have a status of `available`.
- You can't create an AMI or CEV from an existing RDS Custom for SQL Server DB instance.
- You can't modify an existing CEV to use a different AMI. However, you can modify an RDS Custom for SQL Server DB instance to use a different CEV. For more information, see Modifying an RDS Custom for SQL Server DB instance.

- Encrypting an AMI or CEV with a customer-managed KMS key different than the KMS key provided during DB instance creation is not supported.
- Cross-Region copy of CEVs isn't supported.
- Cross-account copy of CEVs isn't supported.
- You can't restore or recover a CEV after you delete it. However, you can create a new CEV from the same AMI.
- A RDS Custom for SQL Server DB instance stores your SQL Server database files in the *D:*\drive. The AMI associated with a CEV should store the Microsoft SQL Server system database files in the *C:*\ drive.
- An RDS Custom for SQL Server DB instance retains your configuration changes made to SQL Server. Any configuration changes to the OS on a running RDS Custom for SQL Server DB instance created from a CEV aren't retained. If you need to make a permanent configuration change to the OS and have it retained as your new baseline configuration, create a new CEV and modify the DB instance to use the new CEV.

  Important

  Modifying an RDS Custom for SQL Server DB instance to use a new CEV is an offline operation. You can perform the modification immediately or schedule it to occur during a weekly maintenance window.

- When you modify a CEV, Amazon RDS doesn't push those modifications to any associated RDS Custom for SQL Server DB instances. You must modify each RDS Custom for SQL Server DB instance to use the new or updated CEV. For more information, see Modifying an RDS Custom for SQL Server DB instance.
- **Important**

  If an AMI used by a CEV is deleted, any modifications that may require host replacement, for example, scale compute, will fail. The RDS Custom for SQL Server DB instance will then be placed outside of the RDS support perimeter. We recommend that you avoid deleting any AMI that's associated to a CEV.

Creating a CEV for RDS Custom for SQL Server

You can create a custom engine version (CEV) using the AWS Management Console or the AWS CLI. You can then use the CEV to create an RDS Custom for SQL Server DB instance.

Make sure that the Amazon Machine Image (AMI) is in the same AWS account and Region as your CEV. Otherwise, the process to create a CEV fails.

For more information, see Creating and connecting to a DB instance for Amazon RDS Custom for SQL Server.

> **Important**
>
> The steps to create a CEV are the same for AMIs created with pre-installed SQL Server and those created using bring your own media (BYOM).

Console

To create a CEV

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Custom engine versions**.

   The **Custom engine versions** page shows all CEVs that currently exist. If you haven't created any CEVs, the table is empty.
3. Choose **Create custom engine version**.
4. For **Engine type**, choose **Microsoft SQL Server**.
5. For **Edition**, choose the DB engine edition that you want to use.
6. For **Major version**, choose the major engine version that's installed on your AMI.
7. In **Version details**, enter a valid name in **Custom engine version name**.

   The name format is *major-engine-version*.*minor-engine-version*.*customized_string*. You can use 1–50 alphanumeric characters, underscores, dashes, and periods. For example, you might enter the name **15.00.4249.2.my_cevtest**.

   Optionally, enter a description for your CEV.

8. For **Installation Media**, browse to or enter the AMI ID that you'd like to create the CEV from.
9. In the **Tags** section, add any tags to identify the CEV.
10. Choose **Create custom engine version**.

The **Custom engine versions** page appears. Your CEV is shown with the status **pending-validation**

AWS CLI

To create a CEV by using the AWS CLI, run the create-custom-db-engine-version command.

The following options are required:

- `--engine`
- `--engine-version`
- `--image-id`

You can also specify the following options:

- `--description`
- `--region`
- `--tags`

The following example creates a CEV named `15.00.4249.2.my_cevtest`. Make sure that the name of your CEV begins with the major engine version number.

Example

For Linux, macOS, or Unix:

```
aws rds create-custom-db-engine-version \
    --engine custom-sqlserver-ee \
    --engine-version 15.00.4249.2.my_cevtest \
    --image-id ami-0r93cx31t5r596482 \
    --description "Custom SQL Server EE 15.00.4249.2 cev test"
```

The following partial output shows the engine, parameter groups, and other information.

```
"DBEngineVersions": [
    {
    "Engine": "custom-sqlserver-ee",
    "MajorEngineVersion": "15.00",
    "EngineVersion": "15.00.4249.2.my_cevtest",
    "DBEngineDescription": "Microsoft SQL Server Enterprise Edition for RDS Custom for
 SQL Server",
    "DBEngineVersionArn": "arn:aws:rds:us-east-1:<my-account-id>:cev:custom-sqlserver-
ee/15.00.4249.2.my_cevtest/a1234a1-123c-12rd-bre1-1234567890",
    "DBEngineVersionDescription": "Custom SQL Server EE 15.00.4249.2 cev test",

    "Image": [
        "ImageId": "ami-0r93cx31t5r596482",
        "Status": "pending-validation"
     ],
    "CreateTime": "2022-11-20T19:30:01.831000+00:00",
    "SupportsLogExportsToCloudwatchLogs": false,
    "SupportsReadReplica": false,
    "Status": "pending-validation",
    "SupportsParallelQuery": false,
    "SupportsGlobalDatabases": false,
    "TagList": []
    }
]
```

If the process to create a CEV fails, RDS Custom for SQL Server issues `RDS-EVENT-0198` with the message `Creation failed for custom engine version` *`major-engine-version.cev_name`*. The message includes details about the failure, for example, the event prints missing files. To find troubleshooting ideas for CEV creation issues, see Troubleshooting CEV errors for RDS Custom for SQL Server.

Create an RDS Custom for SQL Server DB instance from a CEV

After you successfully create a CEV, the **CEV status** shows `pending-validation`. You can now create a new RDS Custom for SQL Server DB instance using the CEV. To create a new RDS Custom for SQL Server DB instance from a CEV, see Creating an RDS Custom for SQL Server DB instance.

Lifecycle of a CEV

The CEV lifecycle includes the following statuses.

CEV status	Description	Troubleshooting suggestions
`pending-validation`	A CEV was created and is pending the validation of the associated AMI. A CEV will remain in `pending-validation` until an RDS Custom for SQL Server DB instance is created from it.	If there are no existing tasks, create a new RDS Custom for SQL Server DB instance from the CEV. When creating the RDS Custom for SQL Server DB instance, the system attempts to validate the associated AMI for a CEV.
`validating`	A creation task for the RDS Custom for SQL Server DB instance based on a new CEV is in progress. When creating the RDS Custom for SQL Server DB instance, the system attempts to validate the associated AMI of a CEV.	Wait for the creation task of the existing RDS Custom for SQL Server DB instance to complete. You can use the RDS EVENTS console to review detailed event messages for troubleshooting.
`available`	The CEV was successfully validated. A CEV will enter the	The CEV doesn't require any additional validation. It can be used to create additional RDS Custom for SQL Server DB instances or modify existing ones.

CEV status	Description	Troubleshooting suggestions
	`available` status once an RDS Custom for SQL Server DB instance has been successfu lly created from it.	
`inactive`	The CEV has been modified to an inactive state.	You can't create or upgrade an RDS Custom DB instance with this CEV. Also, you can't restore a DB snapshot to create a new RDS Custom DB instance with this CEV. For information about how to change the state to `ACTIVE`, see Modifying a CEV for RDS Custom for SQL Server.
`failed`	The create DB instance step failed for this CEV before it could validate the AMI. Alternatively, the underlying AMI used by the CEV isn't in an available state.	Troubleshoot the root cause for why the system couldn't create the DB instance. View the detailed error message and try to create a new DB instance again. Ensure that the underlying AMI used by the CEV is in an available state.

CEV status	Description	Troubleshooting suggestions
`incompatible-image-configuration`	There was an error validating the AMI.	View the technical details of the error. You can't attempt to validate the AMI with this CEV again. Review the following: recommendations: • Ensure your CEV is named using the required naming pattern of SQL Server *major version + minor version + customized string*. • Ensure the SQL Server version in the CEV name matches the version provided with the AMI. • Ensure the OS build version meets the minimum required build version. • Ensure the OS major version meets the minimum required major version. Create a new CEV using the correct information. If needed, create a new EC2 instance using a supported AMI and run the Sysprep process on it.

Modifying a CEV for RDS Custom for SQL Server

You can modify a CEV using the AWS Management Console or the AWS CLI. You can modify the CEV description or its availability status. Your CEV has one of the following status values:

- `available` – You can use this CEV to create a new RDS Custom DB instance or upgrade a DB instance. This is the default status for a newly created CEV.
- `inactive` – You can't create or upgrade an RDS Custom DB instance with this CEV. You can't restore a DB snapshot to create a new RDS Custom DB instance with this CEV.

You can change the CEV status from `available` to `inactive` or from `inactive` to `available`. You might change the status to `INACTIVE` to prevent the accidental use of a CEV or to make a discontinued CEV eligible for use again.

Console

To modify a CEV

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Custom engine versions**.
3. Choose a CEV whose description or status you want to modify.
4. For **Actions**, choose **Modify**.
5. Make any of the following changes:
   - For **CEV status settings**, choose a new availability status.
   - For **Version description**, enter a new description.
6. Choose **Modify CEV**.

   If the CEV is in use, the console displays **You can't modify the CEV status**. Fix the problems, then try again.

The **Custom engine versions** page appears.

AWS CLI

To modify a CEV by using the AWS CLI, run the modify-custom-db-engine-version command. You can find CEVs to modify by running the describe-db-engine-versions command.

The following options are required:

- `--engine`
- `--engine-version` *`cev`*, where *`cev`* is the name of the custom engine version that you want to modify
- `--status` *`status`*, where *`status`* is the availability status that you want to assign to the CEV

The following example changes a CEV named `15.00.4249.2.my_cevtest` from its current status to `inactive`.

Example

For Linux, macOS, or Unix:

```
aws rds modify-custom-db-engine-version \
    --engine custom-sqlserver-ee \
    --engine-version 15.00.4249.2.my_cevtest \
    --status inactive
```

For Windows:

```
aws rds modify-custom-db-engine-version ^
    --engine custom-sqlserver-ee ^
    --engine-version 15.00.4249.2.my_cevtest ^
    --status inactive
```

Modifying an RDS Custom for SQL Server DB instance to use a new CEV

You can modify an existing RDS Custom for SQL Server DB instance to use a different CEV. The changes that you can make include:

- Changing the CEV
- Changing the DB instance class
- Changing the backup retention period and backup window
- Changing the maintenance window

Console

To modify an RDS Custom for SQL Server DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.
3. Choose the DB instance that you want to modify.
4. Choose **Modify**.
5. Make the following changes as needed:

    a. For **DB engine version**, choose a different CEV.

b. Change the value for **DB instance class**. For supported classes, see DB instance class support for RDS Custom for SQL Server.

c. Change the value for **Backup retention period**.

d. For **Backup window**, set values for the **Start time** and **Duration**.

e. For **DB instance maintenance window**, set values for the **Start day**, **Start time**, and **Duration**.

6. Choose **Continue**.
7. Choose **Apply immediately** or **Apply during the next scheduled maintenance window**.
8. Choose **Modify DB instance**.

> **Note**
>
> When modifying a DB instance from one CEV to an another CEV, for example, when upgrading a minor version, the SQL Server system databases, including their data and configurations, are persisted from the current RDS Custom for SQL Server DB instance.

AWS CLI

To modify a DB instance to use a different CEV by using the AWS CLI, run the modify-db-instance command.

The following options are required:

- `--db-instance-identifier`
- `--engine-version` *`cev`*, where *`cev`* is the name of the custom engine version that you want the DB instance to change to.

The following example modifies a DB instance named `my-cev-db-instance` to use a CEV named `15.00.4249.2.my_cevtest_new` and applies the change immediately.

Example

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
```

```
    --db-instance-identifier my-cev-db-instance \
    --engine-version 15.00.4249.2.my_cevtest_new \
    --apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier my-cev-db-instance ^
    --engine-version 15.00.4249.2.my_cevtest_new ^
    --apply-immediately
```

Viewing CEV details for Amazon RDS Custom for SQL Server

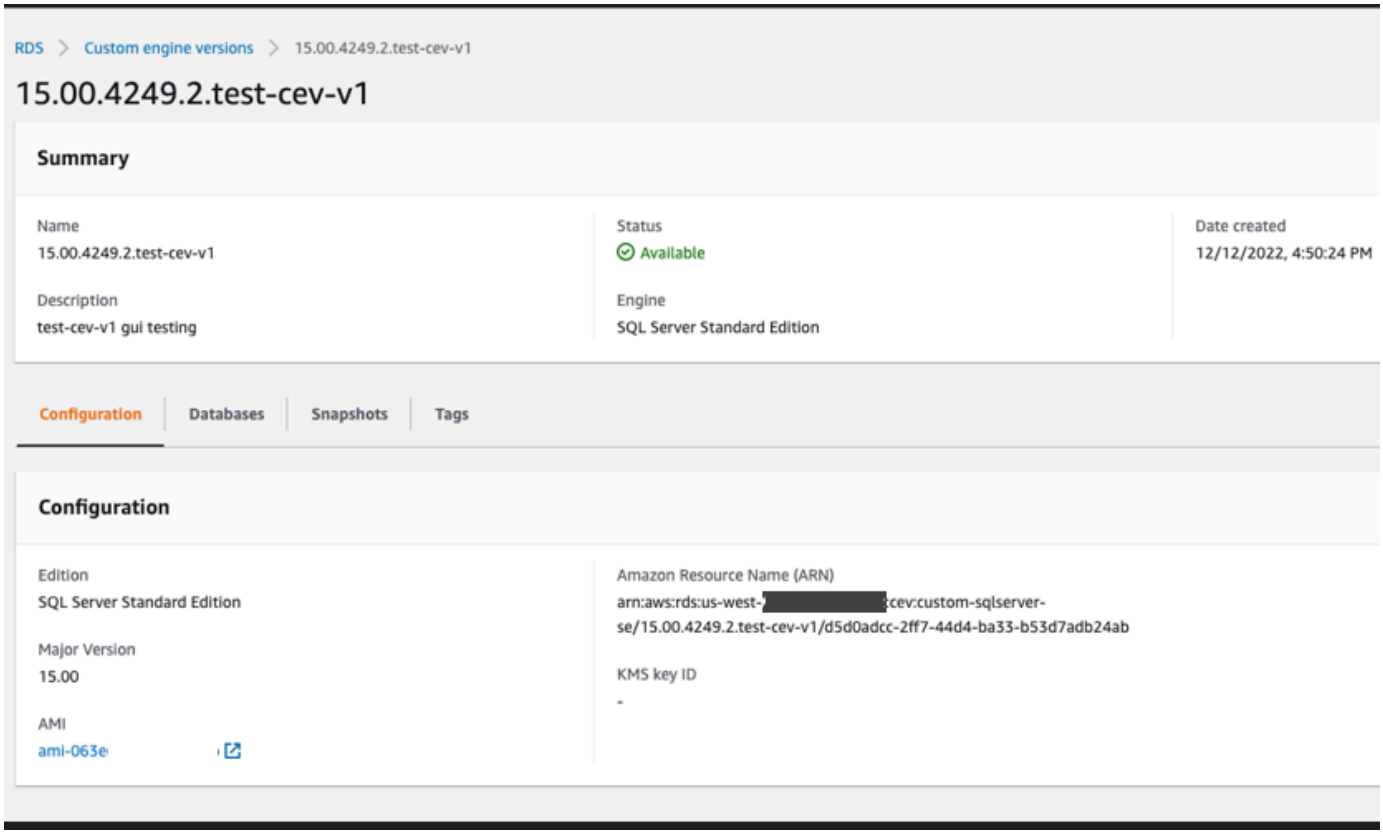
You can view details about your CEV by using the AWS Management Console or the AWS CLI.

Console

To view CEV details

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Custom engine versions**.

   The **Custom engine versions** page shows all CEVs that currently exist. If you haven't created any CEVs, the page is empty.
3. Choose the name of the CEV that you want to view.
4. Choose **Configuration** to view the details.



AWS CLI

To view details about a CEV by using the AWS CLI, run the describe-db-engine-versions command.

You can also specify the following options:

- `--include-all`, to view all CEVs with any lifecycle state. Without the `--include-all` option, only the CEVs in an `available` lifecycle state will be returned.

```
aws rds describe-db-engine-versions --engine custom-sqlserver-ee --engine-version
 15.00.4249.2.my_cevtest --include-all
{
    "DBEngineVersions": [
        {
            "Engine": "custom-sqlserver-ee",
            "MajorEngineVersion": "15.00",
            "EngineVersion": "15.00.4249.2.my_cevtest",
            "DBParameterGroupFamily": "custom-sqlserver-ee-15.0",
            "DBEngineDescription": "Microsoft SQL Server Enterprise Edition for custom
 RDS",
```

```
            "DBEngineVersionArn": "arn:aws:rds:us-east-1:{my-account-id}:cev:custom-
sqlserver-ee/15.00.4249.2.my_cevtest/a1234a1-123c-12rd-bre1-1234567890",
            "DBEngineVersionDescription": "Custom SQL Server EE 15.00.4249.2 cev test",
            "Image": {
                "ImageId": "ami-0r93cx31t5r596482",
                "Status": "pending-validation"
            },
            "DBEngineMediaType": "AWS Provided",
            "CreateTime": "2022-11-20T19:30:01.831000+00:00",
            "ValidUpgradeTarget": [],
            "SupportsLogExportsToCloudwatchLogs": false,
            "SupportsReadReplica": false,
            "SupportedFeatureNames": [],
            "Status": "pending-validation",
            "SupportsParallelQuery": false,
            "SupportsGlobalDatabases": false,
            "TagList": [],
            "SupportsBabelfish": false
        }
    ]
}
```

You can use filters to view CEVs with a certain lifecycle status. For example, to view CEVs that have a lifecycle status of either `pending-validation`, `available`, or `failed`:

```
aws rds describe-db-engine-versions engine custom-sqlserver-ee
                region us-west-2 include-all query 'DBEngineVersions[?Status ==
 pending-validation ||
                Status == available || Status == failed]'
```

Deleting a CEV for RDS Custom for SQL Server

You can delete a CEV using the AWS Management Console or the AWS CLI. Typically, this task takes a few minutes.

Before deleting a CEV, make sure it isn't being used by any of the following:

- An RDS Custom DB instance
- A snapshot of an RDS Custom DB instance
- An automated backup of your RDS Custom DB instance

Console

To delete a CEV

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Custom engine versions**.
3. Choose a CEV whose description or status you want to delete.
4. For **Actions**, choose **Delete**.

   The **Delete *cev_name*?** dialog box appears.
5. Enter **`delete me`**, and then choose **Delete**.

   In the **Custom engine versions** page, the banner shows that your CEV is being deleted.

AWS CLI

To delete a CEV by using the AWS CLI, run the delete-custom-db-engine-version command.

The following options are required:

- `--engine custom-sqlserver-ee`
- `--engine-version` *`cev`*, where *`cev`* is the name of the custom engine version to be deleted

The following example deletes a CEV named `15.00.4249.2.my_cevtest`.

Example

For Linux, macOS, or Unix:

```
aws rds delete-custom-db-engine-version \
    --engine custom-sqlserver-ee \
    --engine-version 15.00.4249.2.my_cevtest
```

For Windows:

```
aws rds delete-custom-db-engine-version ^
    --engine custom-sqlserver-ee ^
    --engine-version 15.00.4249.2.my_cevtest
```

Creating and connecting to a DB instance for Amazon RDS Custom for SQL Server

You can create an RDS Custom DB instance, and then connect to it using AWS Systems Manager or Remote Desktop Protocol (RDP).

Important

Before you can create or connect to an RDS Custom for SQL Server DB instance, make sure to complete the tasks in Setting up your environment for Amazon RDS Custom for SQL Server.

You can tag RDS Custom DB instances when you create them, but don't create or modify the `AWSRDSCustom` tag that's required for RDS Custom automation. For more information, see Tagging RDS Custom for SQL Server resources.

The first time that you create an RDS Custom for SQL Server DB instance, you might receive the following error: The service-linked role is in the process of being created. Try again later. If you do, wait a few minutes and then try again to create the DB instance.

Topics

Creating an RDS Custom for SQL Server DB instance

Create an Amazon RDS Custom for SQL Server DB instance using either the AWS Management Console or the AWS CLI. The procedure is similar to the procedure for creating an Amazon RDS DB instance.

For more information, see Creating an Amazon RDS DB instance.

Console

To create an RDS Custom for SQL Server DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.
3. Choose **Create database**.
4. Choose **Standard create** for the database creation method.
5. For **Engine options**, choose **Microsoft SQL Server** for the engine type.
6. For **Database management type**, choose **Amazon RDS Custom**.
7. In the **Edition** section, choose the DB engine edition that you want to use.
8. (Optional) If you intend to create the DB instance from a CEV, check the **Use custom engine version (CEV)** check box. Select your CEV in the drop-down list.
9. For **Database version**, keep the default value version.
10. For **Templates**, choose **Production**.
11. In the **Settings** section, enter a unique name for the **DB instance identifier**.
12. To enter your master password, do the following:

    a. In the **Settings** section, open **Credential Settings**.

    b. Clear the **Auto generate a password** check box.

    c. Change the **Master username** value and enter the same password in **Master password** and **Confirm password**.

    By default, the new RDS Custom DB instance uses an automatically generated password for the master user.
13. In the **DB instance size** section, choose a value for **DB instance class**.

    For supported classes, see DB instance class support for RDS Custom for SQL Server.
14. Choose **Storage** settings.
15. For **RDS Custom security**, do the following:

    a. For **IAM instance profile**, you have two options to choose the instance profile for your RDS Custom for SQL Server DB instance.

1. Choose **Create a new instance profile** and provide an instance profile name suffix. For more information, see Automated instance profile creation using the AWS Management Console.
2. Choose an existing instance profile. From the ddropdown list, choose instance profile that begins with `AWSRDSCustom`.

b. For **Encryption**, choose **Enter a key ARN** to list the available AWS KMS keys. Then choose your key from the list.

An AWS KMS key is required for RDS Custom. For more information, see Make sure that you have a symmetric encryption AWS KMS key.

16. For the remaining sections, specify your preferred RDS Custom DB instance settings. For information about each setting, see Settings for DB instances. The following settings don't appear in the console and aren't supported:

- **Processor features**
- **Storage autoscaling**
- **Availability & durability**
- **Password and Kerberos authentication** option in **Database authentication** (only **Password authentication** is supported)
- **Database options** group in **Additional configuration**
- **Performance Insights**
- **Log exports**
- **Enable auto minor version upgrade**
- **Deletion protection**

Backup retention period is supported, but you can't choose **0 days**.

17. Choose **Create database**.

The **View credential details** button appears on the **Databases** page.

To view the master user name and password for the RDS Custom DB instance, choose **View credential details**.

To connect to the DB instance as the master user, use the user name and password that appear.

> **Important**
>
> You can't view the master user password again. If you don't record it, you might have to change it. To change the master user password after the RDS Custom DB instance is available, modify the DB instance. For more information about modifying a DB instance, see Managing an Amazon RDS Custom for SQL Server DB instance.

18. Choose **Databases** to view the list of RDS Custom DB instances.
19. Choose the RDS Custom DB instance that you just created.

    On the RDS console, the details for the new RDS Custom DB instance appear:

    - The DB instance has a status of **creating** until the RDS Custom DB instance is created and ready for use. When the state changes to **available**, you can connect to the DB instance. Depending on the instance class and storage allocated, it can take several minutes for the new DB instance to be available.
    - **Role** has the value **Instance (RDS Custom)**.
    - **RDS Custom automation mode** has the value **Full automation**. This setting means that the DB instance provides automatic monitoring and instance recovery.

AWS CLI

You create an RDS Custom DB instance by using the create-db-instance AWS CLI command.

The following options are required:

- `--db-instance-identifier`
- `--db-instance-class` (for a list of supported instance classes, see DB instance class support for RDS Custom for SQL Server)
- `--engine` (`custom-sqlserver-ee`, `custom-sqlserver-se`, or `custom-sqlserver-web`)
- `--kms-key-id`
- `--custom-iam-instance-profile`

The following example creates an RDS Custom for SQL Server DB instance named `my-custom-instance`. The backup retention period is 3 days.

> **Note**
>
> To create a DB instance from a custom engine version (CEV), supply an existing CEV name to the `--engine-version` parameter. For example, `--engine-version 15.00.4249.2.my_cevtest`

Example

For Linux, macOS, or Unix:

```
aws rds create-db-instance \
    --engine custom-sqlserver-ee \
    --engine-version 15.00.4073.23.v1 \
    --db-instance-identifier my-custom-instance \
    --db-instance-class db.m5.xlarge \
    --allocated-storage 20 \
    --db-subnet-group mydbsubnetgroup \
    --master-username myuser \
    --master-user-password mypassword \
    --backup-retention-period 3 \
    --no-multi-az \
    --port 8200 \
    --kms-key-id mykmskey \
    --custom-iam-instance-profile AWSRDSCustomInstanceProfileForRdsCustomInstance
```

For Windows:

```
aws rds create-db-instance ^
    --engine custom-sqlserver-ee ^
    --engine-version 15.00.4073.23.v1 ^
    --db-instance-identifier my-custom-instance ^
    --db-instance-class db.m5.xlarge ^
    --allocated-storage 20 ^
    --db-subnet-group mydbsubnetgroup ^
    --master-username myuser ^
    --master-user-password mypassword ^
    --backup-retention-period 3 ^
    --no-multi-az ^
    --port 8200 ^
    --kms-key-id mykmskey ^
```

```
    --custom-iam-instance-profile AWSRDSCustomInstanceProfileForRdsCustomInstance
```

> **Note**
>
> Specify a password other than the prompt shown here as a security best practice.

Get details about your instance by using the `describe-db-instances` command.

```
aws rds describe-db-instances --db-instance-identifier my-custom-instance
```

The following partial output shows the engine, parameter groups, and other information.

```
{
    "DBInstances": [
        {
            "PendingModifiedValues": {},
            "Engine": "custom-sqlserver-ee",
            "MultiAZ": false,
            "DBSecurityGroups": [],
            "DBParameterGroups": [
                {
                    "DBParameterGroupName": "default.custom-sqlserver-ee-15",
                    "ParameterApplyStatus": "in-sync"
                }
            ],
            "AutomationMode": "full",
            "DBInstanceIdentifier": "my-custom-instance",
            "TagList": []
        }
    ]
}
```

RDS Custom service-linked role

A *service-linked role* gives Amazon RDS Custom access to resources in your AWS account. It makes using RDS Custom easier because you don't have to manually add the necessary permissions. RDS Custom defines the permissions of its service-linked roles, and unless defined otherwise, only RDS Custom can assume its roles. The defined permissions include the trust policy and the permissions policy, and that permissions policy can't be attached to any other IAM entity.

When you create an RDS Custom DB instance, both the Amazon RDS and RDS Custom service-linked roles are created (if they don't already exist) and used. For more information, see Using service-linked roles for Amazon RDS.

The first time that you create an RDS Custom for SQL Server DB instance, you might receive the following error: The service-linked role is in the process of being created. Try again later. If you do, wait a few minutes and then try again to create the DB instance.

Connecting to your RDS Custom DB instance using AWS Systems Manager

After you create your RDS Custom DB instance, you can connect to it using AWS Systems Manager Session Manager. Session Manager is a Systems Manager capability that you can use to manage Amazon EC2 instances through a browser-based shell or through the AWS CLI. For more information, see AWS Systems Manager Session Manager.

Console

To connect to your DB instance using Session Manager

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**, and then choose the RDS Custom DB instance to which you want to connect.
3. Choose **Configuration**.
4. Note the **Resource ID** value for your DB instance. For example, the resource ID might be `db-ABCDEFGHIJKLMNOPQRS0123456`.
5. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
6. In the navigation pane, choose **Instances**.
7. Look for the name of your EC2 instance, and then choose the instance ID associated with it. For example, the instance ID might be `i-abcdefghijklm01234`.
8. Choose **Connect**.
9. Choose **Session Manager**.
10. Choose **Connect**.

    A window opens for your session.

AWS CLI

You can connect to your RDS Custom DB instance using the AWS CLI. This technique requires the Session Manager plugin for the AWS CLI. To learn how to install the plugin, see Install the Session Manager plugin for the AWS CLI.

To find the DB resource ID of your RDS Custom DB instance, use `describe-db-instances`.

```
aws rds describe-db-instances \
    --query 'DBInstances[*].[DBInstanceIdentifier,DbiResourceId]' \
    --output text
```

The following sample output shows the resource ID for your RDS Custom instance. The prefix is `db-`.

```
db-ABCDEFGHIJKLMNOPQRS0123456
```

To find the EC2 instance ID of your DB instance, use `aws ec2 describe-instances`. The following example uses `db-ABCDEFGHIJKLMNOPQRS0123456` for the resource ID.

```
aws ec2 describe-instances \
    --filters "Name=tag:Name,Values=db-ABCDEFGHIJKLMNOPQRS0123456" \
    --output text \
    --query 'Reservations[*].Instances[*].InstanceId'
```

The following sample output shows the EC2 instance ID.

```
i-abcdefghijklm01234
```

Use the `aws ssm start-session` command, supplying the EC2 instance ID in the `--target` parameter.

```
aws ssm start-session --target "i-abcdefghijklm01234"
```

A successful connection looks like the following.

```
Starting session with SessionId: yourid-abcdefghijklm1234
[ssm-user@ip-123-45-67-89 bin]$
```

Connecting to your RDS Custom DB instance using RDP

After you create your RDS Custom DB instance, you can connect to this instance using an RDP client. The procedure is the same as for connecting to an Amazon EC2 instance. For more information, see Connect to your Windows instance.

To connect to the DB instance, you need the key pair associated with the instance. RDS Custom creates the key pair for you. The pair name uses the prefix `do-not-delete-rds-custom-`*`DBInstanceIdentifier`*. AWS Secrets Manager stores your private key as a secret.

Complete the task in the following steps:

1. Configure your DB instance to allow RDP connections.
2. Retrieve your secret key.
3. Connect to your EC2 instance using the RDP utility.

Configure your DB instance to allow RDP connections

To allow RDP connections, configure your VPC security group and set a firewall rule on the host.

Configure your VPC security group

Make sure that the VPC security group associated with your DB instance permits inbound connections on port 3389 for Transmission Control Protocol (TCP). To learn how to configure your VPC security group, see Configure your VPC security group.

Set the firewall rule on the host

To permit inbound connections on port 3389 for TCP, set a firewall rule on the host. The following examples show how to do this.

We recommend that you use the specific `-Profile` value: `Public`, `Private`, or `Domain`. Using `Any` refers to all three values. You can also specify a combination of values separated by a comma. For more information about setting firewall rules, see Set-NetFirewallRule in the Microsoft documentation.

To use Systems Manager Session Manager to set a firewall rule

1. Connect to Session Manager as shown in Connecting to your RDS Custom DB instance using AWS Systems Manager.
2. Run the following command.

```
Set-NetFirewallRule -DisplayName "Remote Desktop - User Mode (TCP-In)" -Direction
 Inbound -LocalAddress Any -Profile Any
```

To use Systems Manager CLI commands to set a firewall rule

1. Use the following command to open RDP on the host.

```
OPEN_RDP_COMMAND_ID=$(aws ssm send-command --region $AWS_REGION \
    --instance-ids $RDS_CUSTOM_INSTANCE_EC2_ID \
    --document-name "AWS-RunPowerShellScript" \
    --parameters '{"commands":["Set-NetFirewallRule -DisplayName \"Remote Desktop -
 User Mode (TCP-In)\" -Direction Inbound -LocalAddress Any -Profile Any"]}' \
    --comment "Open RDP port" | jq -r ".Command.CommandId")
```

2. Use the command ID returned in the output to get the status of the previous command. To use the following query to return the command ID, make sure that you have the jq plug-in installed.

```
aws ssm list-commands \
    --region $AWS_REGION \
    --command-id $OPEN_RDP_COMMAND_ID
```

Retrieve your secret key

Retrieve your secret key using either AWS Management Console or the AWS CLI.

Console

To retrieve the secret key

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**, and then choose the RDS Custom DB instance to which you want to connect.
3. Choose the **Configuration** tab.
4. Note the **DB instance ID** for your DB instance, for example, *my-custom-instance*.
5. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.

6. In the navigation pane, choose **Instances**.
7. Look for the name of your EC2 instance, and then choose the instance ID associated with it.

   In this example, the instance ID is `i-abcdefghijklm01234`.
8. In **Details**, find **Key pair name**. The pair name includes the DB identifier. In this example, the pair name is `do-not-delete-rds-custom-`*`my-custom-instance`*`-`*`0d726c`*.
9. In the instance summary, find **Public IPv4 DNS**. For the example, the public DNS might be `ec2-12-345-678-901.us-east-2.compute.amazonaws.com`.
10. Open the AWS Secrets Manager console at https://console.aws.amazon.com/secretsmanager/.
11. Choose the secret that has the same name as your key pair.
12. Choose **Retrieve secret value**.

AWS CLI

To retrieve the private key

1. Get the list of your RDS Custom DB instances by calling the `aws rds describe-db-instances` command.

   ```
   aws rds describe-db-instances \
       --query 'DBInstances[*].[DBInstanceIdentifier,DbiResourceId]' \
       --output text
   ```
2. Choose the DB instance identifier from the sample output, for example `do-not-delete-rds-custom-`*`my-custom-instance`*.
3. Find the EC2 instance ID of your DB instance by calling the `aws ec2 describe-instances` command. The following example uses the EC2 instance name to describe the DB instance.

   ```
   aws ec2 describe-instances \
       --filters "Name=tag:Name,Values=do-not-delete-rds-custom-my-custom-instance" \
       --output text \
       --query 'Reservations[*].Instances[*].InstanceId'
   ```

   The following sample output shows the EC2 instance ID.

   ```
   i-abcdefghijklm01234
   ```

4. Find the key name by specifying the EC2 instance ID, as shown in the following example.

```
aws ec2 describe-instances \
    --instance-ids i-abcdefghijklm01234 \
    --output text \
    --query 'Reservations[*].Instances[*].KeyName'
```

The following sample output shows the key name, which uses the prefix `do-not-delete-rds-custom-`*`DBInstanceIdentifier`*.

```
do-not-delete-rds-custom-my-custom-instance-0d726c
```

Connect to your EC2 instance using the RDP utility

Follow the procedure in Connect to your Windows instance using RDP in the *Amazon EC2 User Guide*. This procedure assumes that you created a .pem file that contains your private key.

Managing an Amazon RDS Custom for SQL Server DB instance

Amazon RDS Custom for SQL Server supports a subset of the usual management tasks for Amazon RDS DB instances. Following, you can find instructions for the supported RDS Custom for SQL Server management tasks using the AWS Management Console and the AWS CLI.

Topics

Pausing and resuming RDS Custom automation

RDS Custom automatically provides monitoring and instance recovery for an RDS Custom for SQL Server DB instance. If you need to customize the instance, do the following:

1. Pause RDS Custom automation for a specified period. The pause ensures that your customizations don't interfere with RDS Custom automation.
2. Customize the RDS Custom for SQL Server DB instance as needed.
3. Do either of the following:
   - Resume automation manually.
   - Wait for the pause period to end. In this case, RDS Custom resumes monitoring and instance recovery automatically.

> **Important**
>
> Pausing and resuming automation are the only supported automation tasks when modifying an RDS Custom for SQL Server DB instance.

Console

To pause or resume RDS Custom automation

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**, and then choose the RDS Custom DB instance that you want to modify.
3. Choose **Modify**. The **Modify DB instance** page appears.
4. For **RDS Custom automation mode**, choose one of the following options:
   - **Paused** pauses the monitoring and instance recovery for the RDS Custom DB instance. Enter the pause duration that you want (in minutes) for **Automation mode duration**. The minimum value is 60 minutes (default). The maximum value is 1,440 minutes.
   - **Full automation** resumes automation.
5. Choose **Continue** to check the summary of modifications.

   A message indicates that RDS Custom will apply the changes immediately.
6. If your changes are correct, choose **Modify DB instance**. Or choose **Back** to edit your changes or **Cancel** to cancel your changes.

   On the RDS console, the details for the modification appear. If you paused automation, the **Status** of your RDS Custom DB instance indicates **Automation paused**.
7. (Optional) In the navigation pane, choose **Databases**, and then your RDS Custom DB instance.

   In the **Summary** pane, **RDS Custom automation mode** indicates the automation status. If automation is paused, the value is **Paused. Automation resumes in *num* minutes**.

AWS CLI

To pause or resume RDS Custom automation, use the `modify-db-instance` AWS CLI command. Identify the DB instance using the required parameter `--db-instance-identifier`. Control the automation mode with the following parameters:

- `--automation-mode` specifies the pause state of the DB instance. Valid values are `all-paused`, which pauses automation, and `full`, which resumes it.

- `--resume-full-automation-mode-minutes` specifies the duration of the pause. The default value is 60 minutes.

> **Note**
>
> Regardless of whether you specify `--no-apply-immediately` or `--apply-immediately`, RDS Custom applies modifications asynchronously as soon as possible.

In the command response, `ResumeFullAutomationModeTime` indicates the resume time as a UTC timestamp. When the automation mode is `all-paused`, you can use `modify-db-instance` to resume automation mode or extend the pause period. No other `modify-db-instance` options are supported.

The following example pauses automation for `my-custom-instance` for 90 minutes.

Example

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier my-custom-instance \
    --automation-mode all-paused \
    --resume-full-automation-mode-minutes 90
```

For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier my-custom-instance ^
    --automation-mode all-paused ^
    --resume-full-automation-mode-minutes 90
```

The following example extends the pause duration for an extra 30 minutes. The 30 minutes is added to the original time shown in `ResumeFullAutomationModeTime`.

Example

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
```

```
    --db-instance-identifier my-custom-instance \
    --automation-mode all-paused \
    --resume-full-automation-mode-minutes 30
```

For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier my-custom-instance ^
    --automation-mode all-paused ^
    --resume-full-automation-mode-minutes 30
```

The following example resumes full automation for `my-custom-instance`.

Example

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier my-custom-instance \
    --automation-mode full \
```

For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier my-custom-instance ^
    --automation-mode full
```

In the following partial sample output, the pending `AutomationMode` value is `full`.

```
{
    "DBInstance": {
        "PubliclyAccessible": true,

Modifying an RDS Custom for SQL Server DB instance

Modifying an RDS Custom for SQL Server DB instance is similar to doing this for Amazon RDS, but the changes that you can make are limited to the following:

- Changing the DB instance class
- Changing the backup retention period and backup window
- Changing the maintenance window
- Upgrading the DB engine version when a new version becomes available
- Changing the allocated storage, provisioned IOPS, and storage type
- Allowing and removing Multi-AZ deployments

The following limitations apply to modifying an RDS Custom for SQL Server DB instance:

- Custom DB option and parameter groups aren't supported.
- Any storage volumes that you attach manually to your RDS Custom DB instance are outside the support perimeter.

  For more information, see RDS Custom support perimeter.

Console

To modify an RDS Custom for SQL Server DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.
3. Choose the DB instance that you want to modify.
4. Choose **Modify**.
5. Make the following changes as needed:

a. For **DB engine version**, choose the new version.

b. Change the value for **DB instance class**. For supported classes, see DB instance class support for RDS Custom for SQL Server

c. Change the value for **Backup retention period**.

d. For **Backup window**, set values for the **Start time** and **Duration**.

e. For **DB instance maintenance window**, set values for the **Start day**, **Start time**, and **Duration**.

6. Choose **Continue**.
7. Choose **Apply immediately** or **Apply during the next scheduled maintenance window**.
8. Choose **Modify DB instance**.

AWS CLI

To modify an RDS Custom for SQL Server DB instance, use the modify-db-instance AWS CLI command. Set the following parameters as needed:

- `--db-instance-class` – For supported classes, see DB instance class support for RDS Custom for SQL Server
- `--engine-version` – The version number of the database engine to which you're upgrading.
- `--backup-retention-period` – How long to retain automated backups, from 0–35 days.
- `--preferred-backup-window` – The daily time range during which automated backups are created.
- `--preferred-maintenance-window` – The weekly time range (in UTC) during which system maintenance can occur.
- `--apply-immediately` – Use `--apply-immediately` to apply the storage changes immediately.

  Or use `--no-apply-immediately` (the default) to apply the changes during the next maintenance window.

Modifying the storage for an RDS Custom for SQL Server DB instance

Modifying storage for an RDS Custom for SQL Server DB instance is similar to modifying storage for an Amazon RDS DB instance, but you can only do the following:

- Increase the allocated storage size.
- Change the storage type. You can use available storage types such as General Purpose or Provisioned IOPS. Provisioned IOPS is supported for the gp3, io1, and io2 Block Express storage types.
- Change the provisioned IOPS, if you're using the volume types that support Provisioned IOPS.

The following limitations apply to modifying the storage for an RDS Custom for SQL Server DB instance:

- The minimum allocated storage size for RDS Custom for SQL Server is 20 GiB, and the maximum supported storage size is 16 TiB.
- As with Amazon RDS, you can't decrease the allocated storage. This is a limitation of Amazon Elastic Block Store (Amazon EBS) volumes. For more information, see Working with storage for Amazon RDS DB instances
- Storage autoscaling isn't supported for RDS Custom for SQL Server DB instances.
- Any storage volumes that you manually attach to your RDS Custom DB instance are not considered for storage scaling. Only the RDS-provided default data volumes, i.e., the D drive, are considered for storage scaling.

  For more information, see RDS Custom support perimeter.
- Scaling storage usually doesn't cause any outage or performance degradation of the DB instance. After you modify the storage size for a DB instance, the status of the DB instance is **storage-optimization**.
- Storage optimization can take several hours. You can't make further storage modifications for either six (6) hours or until storage optimization has completed on the instance, whichever is longer. For more information, see Working with storage for Amazon RDS DB instances

For more information about storage, see Amazon RDS DB instance storage.

For general information about storage modification, see Working with storage for Amazon RDS DB instances.

Console

To modify the storage for an RDS Custom for SQL Server DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.
3. Choose the DB instance that you want to modify.
4. Choose **Modify**.
5. Make the following changes as needed:
    a. Enter a new value for **Allocated storage**. It must be greater than the current value, and from 20 GiB–16 TiB.
    b. Change the value for **Storage type**. You can choose from the available General Purpose or Provisioned IOPS storage types. Provisioned IOPS is supported for the gp3, io1, and io2 Block Express storage types.
    c. If you're specifying a storage type that supports Provisioned IOPS, you can define the **Provisioned IOPS** value.
6. Choose **Continue**.
7. Choose **Apply immediately** or **Apply during the next scheduled maintenance window**.
8. Choose **Modify DB instance**.

AWS CLI

To modify the storage for an RDS Custom for SQL Server DB instance, use the modify-db-instance AWS CLI command. Set the following parameters as needed:

- `--allocated-storage` – Amount of storage to be allocated for the DB instance, in gibibytes. It must be greater than the current value, and from 20–16,384 GiB.
- `--storage-type` – The storage type, for example, gp2, gp3, io1, or io2.
- `--iops` – Provisioned IOPS for the DB instance. You can specify this only for storage types that support Provisioned IOPS (gp3, io1, and io2).
- `--apply-immediately` – Use `--apply-immediately` to apply the storage changes immediately.

Or use `--no-apply-immediately` (the default) to apply the changes during the next maintenance window.

The following example changes the storage size of my-custom-instance to 200 GiB, storage type to io1, and Provisioned IOPS to 3000.

Example

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier my-custom-instance \
    --storage-type io1 \
    --iops 3000 \
    --allocated-storage 200 \
    --apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier my-custom-instance ^
    --storage-type io1 ^
    --iops 3000 ^
    --allocated-storage 200 ^
    --apply-immediately
```

Tagging RDS Custom for SQL Server resources

You can tag RDS Custom resources as with Amazon RDS resources, but with some important differences:

- Don't create or modify the `AWSRDSCustom` tag that's required for RDS Custom automation. If you do, you might break the automation.
- The `Name` tag is added to RDS Custom resources with prefix value of `do-not-delete-rds-custom`. Any customer-passed value for the key is overwritten.
- Tags added to RDS Custom DB instances during creation are propagated to all other related RDS Custom resources.
- Tags aren't propagated when you add them to RDS Custom resources after DB instance creation.

For general information about resource tagging, see Tagging Amazon RDS resources.

Deleting an RDS Custom for SQL Server DB instance

To delete an RDS Custom for SQL Server DB instance, do the following:

- Provide the name of the DB instance.
- Choose or clear the option to take a final DB snapshot of the DB instance.
- Choose or clear the option to retain automated backups.

You can delete an RDS Custom for SQL Server DB instance using the console or the CLI. The time required to delete the DB instance can vary depending on the backup retention period (that is, how many backups to delete), how much data is deleted, and whether a final snapshot is taken.

Warning

Deleting a RDS Custom for SQL Server DB instance will permanently delete the EC2 instance and the associated Amazon EBS volumes. You shouldn't terminate or delete these resources at any time, otherwise, the deletion and the final snapshot creation may fail.

Note

You can't create a final DB snapshot of your DB instance if it has a status of `creating`, `failed`, `incompatible-create`, `incompatible-restore`, or `incompatible-network`. For more information, see Viewing Amazon RDS DB instance status.

Important

When you choose to take a final snapshot, we recommend that you avoid writing data to your DB instance while the DB instance deletion is in progress. Once the DB instance deletion is initiated, data changes are not guaranteed to be captured by the final snapshot.

Console

To delete an RDS Custom DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**, and then choose the RDS Custom for SQL Server DB instance that you want to delete. RDS Custom for SQL Server DB instances show the role **Instance (RDS Custom for SQL Server)**.
3. For **Actions**, choose **Delete**.
4. To take a final snapshot, choose **Create final snapshot**, and provide a name for the **Final snapshot name**.
5. To retain automated backups, choose **Retain automated backups**.
6. Enter **`delete me`** in the box.
7. Choose **Delete**.

AWS CLI

You delete an RDS Custom for SQL Server DB instance by using the delete-db-instance AWS CLI command. Identify the DB instance using the required parameter `--db-instance-identifier`. The remaining parameters are the same as for an Amazon RDS DB instance.

The following example deletes the RDS Custom for SQL Server DB instance named `my-custom-instance`, takes a final snapshot, and retains automated backups.

Example

For Linux, macOS, or Unix:

```
aws rds delete-db-instance \
    --db-instance-identifier my-custom-instance \
    --no-skip-final-snapshot \
    --final-db-snapshot-identifier my-custom-instance-final-snapshot \
    --no-delete-automated-backups
```

For Windows:

```
aws rds delete-db-instance ^
```

```
    --db-instance-identifier my-custom-instance ^
    --no-skip-final-snapshot ^
    --final-db-snapshot-identifier my-custom-instance-final-snapshot ^
    --no-delete-automated-backups
```

To take a final snapshot, the `--final-db-snapshot-identifier` option is required and must be specified.

To skip the final snapshot, specify the `--skip-final-snapshot` option instead of the `--no-skip-final-snapshot` and `--final-db-snapshot-identifier` options in the command.

To delete automated backups, specify the `--delete-automated-backups` option instead of the `--no-delete-automated-backups` option in the command.

Starting and stopping an RDS Custom for SQL Server DB instance

You can start and stop your RDS Custom for SQL Server DB instance. The same general requirements and limitations for RDS for SQL Server DB instances apply to stopping and starting your RDS Custom for SQL Server DB instances. For more information, see Stopping an Amazon RDS DB instance temporarily.

The following considerations also apply to starting and stopping your RDS Custom for SQL Server DB instance:

- Modifying an EC2 instance attribute of an RDS Custom for SQL Server DB instance while the DB instance is `STOPPED` isn't supported.
- You can stop and start an RDS Custom for SQL Server DB instance only if it's configured for a single Availability Zone. You can't stop an RDS Custom for SQL Server DB instance in a Multi-AZ configuration.
- A `SYSTEM` snapshot will be created when you stop an RDS Custom for SQL Server DB instance. The snapshot will be automatically deleted when you start the RDS Custom for SQL Server DB instance again.
- If you delete your EC2 instance while your RDS Custom for SQL Server DB instance is stopped, the `C:` drive will be replaced when you start the RDS Custom for SQL Server DB instance again.
- The `C:\` drive, hostname, and your custom configurations are persisted when you stop an RDS Custom for SQL Server DB instance, as long as you don't modify the instance type.
- The following actions will result in RDS Custom placing the DB instance outside the support perimeter, and you're still charged for DB instance hours:

- Starting the underlying EC2 instance while Amazon RDS is stopped. To resolve, you can call the `start-db-instance` Amazon RDS API, or stop the EC2 so the RDS Custom instance returns to `STOPPED`.
- Stopping underlying EC2 instance when the RDS Custom for SQL Server DB instance is `ACTIVE`.

For more details about stopping and starting DB instances, see Stopping an Amazon RDS DB instance temporarily, and Starting an Amazon RDS DB instance that was previously stopped.

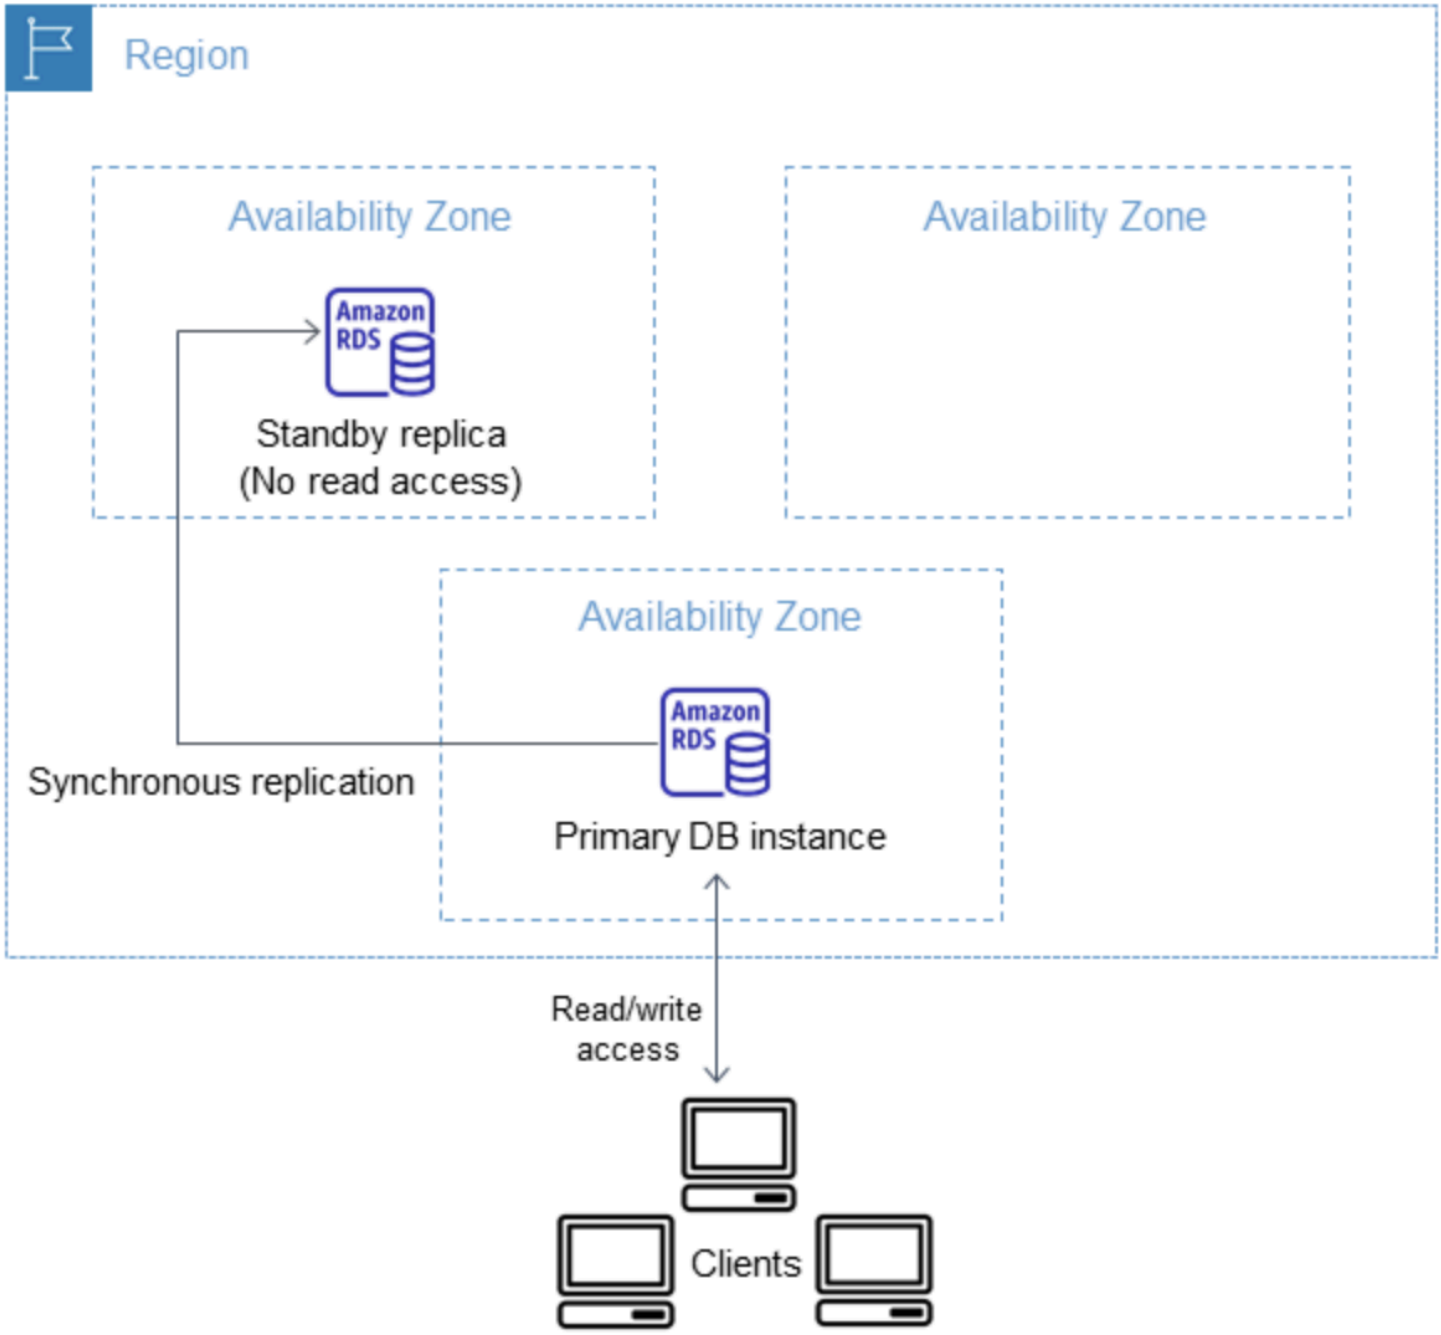
Managing a Multi-AZ deployment for RDS Custom for SQL Server

In a Multi-AZ DB instance deployment for RDS Custom for SQL Server, Amazon RDS automatically provisions and maintains a synchronous standby replica in a different Availability Zone (AZ). The primary DB instance is synchronously replicated across Availability Zones to a standby replica to provide data redundancy.

Important

A Multi-AZ deployment for RDS Custom for SQL Server is different than Multi-AZ for RDS for SQL Server. Unlike Multi-AZ for RDS for SQL Server, you must set up prerequisites for RDS Custom for SQL Server before creating your Multi-AZ DB instance because RDS Custom runs inside your own account, which requires permissions.
If you don't complete the prerequisites, your Multi-AZ DB instance might fail to run, or automatically revert to a Single-AZ DB instance. For more information about prerequisites, see Prerequisites for a Multi-AZ deployment with RDS Custom for SQL Server.

Running a DB instance with high availability can enhance availability during planned system maintenance. In the event of planned database maintenance or unplanned service disruption, Amazon RDS automatically fails over to the up-to-date secondary DB instance. This functionality lets database operations resume quickly without manual intervention. The primary and standby instances use the same endpoint, whose physical network address transitions to the secondary replica as part of the failover process. You don't have to reconfigure your application when a failover occurs.



You can create an RDS Custom for SQL Server Multi-AZ deployment by specifying Multi-AZ when creating an RDS Custom DB instance. You can use the console to convert existing RDS Custom for SQL Server DB instances to Multi-AZ deployments by modifying the DB instance and specifying the Multi-AZ option. You can also specify a Multi-AZ DB instance deployment with the AWS CLI or Amazon RDS API.

The RDS console shows the Availability Zone of the standby replica (the secondary AZ). You can also use the `describe-db-instances` CLI command or the `DescribeDBInstances` API operation to find the secondary AZ.

RDS Custom for SQL Server DB instances with Multi-AZ deployment can have increased write and commit latency compared to a Single-AZ deployment. This increase can happen because of the synchronous data replication between DB instances. You might have a change in latency if your deployment fails over to the standby replica, although AWS is engineered with low-latency network connectivity between Availability Zones.

> **Note**
>
> For production workloads, we recommend that you use a DB instance class with Provisioned IOPS (input/output operations per second) for fast, consistent performance. For more information about DB instance classes, see Requirements and limitations for Amazon RDS Custom for SQL Server.

Topics

Region and version availability

Multi-AZ deployments for RDS Custom for SQL Server are supported for the following SQL Server editions:

- SQL Server 2022 and 2019: Enterprise, Standard, Web, and Developer Edition

> **Note**
>
> Multi-AZ deployments for RDS Custom for SQL Server aren't supported on SQL Server 2019 CU8 (15.00.4073.23) or lower versions.

Multi-AZ deployments for RDS Custom for SQL Server are available in all Regions where RDS Custom for SQL Server is available. For more information on Region availability of Multi-AZ deployments for RDS Custom for SQL Server, see Supported Regions and DB engines for RDS Custom for SQL Server.

Limitations for a Multi-AZ deployment with RDS Custom for SQL Server

Multi-AZ deployments with RDS Custom for SQL Server have the following limitations:

- Cross-Region Multi-AZ deployments aren't supported.
- You can’t configure the secondary DB instance to accept database read activity.
- When you use a Custom Engine Version (CEV) with a Multi-AZ deployment, your secondary DB instance will also use the same CEV. The secondary DB instance can't use a different CEV.

Prerequisites for a Multi-AZ deployment with RDS Custom for SQL Server

If you have an existing RDS Custom for SQL Server Single-AZ deployment, the following additional prerequisites are required before modifying it to a Multi-AZ deployment. You can choose to complete the prerequisites manually or with the provided CloudFormation template. The latest CloudFormation template contains the prerequisites for both Single-AZ and Multi-AZ deployments.

> **Important**
>
> To simplify setup, we recommend that you use the latest AWS CloudFormation template file provided in the network setup instructions to create the prerequisites. For more information, see Configuring with AWS CloudFormation.

> **Note**
>
> When you modify an existing RDS Custom for SQL Server Single-AZ deployment to a Multi-AZ deployment, you must complete these prerequisites. If you don't complete the

prerequisites, the Multi-AZ setup will fail. To complete the prerequisites, follow the steps in Modifying an RDS Custom for SQL Server Single-AZ deployment to a Multi-AZ deployment.

- Update the RDS security group inbound and outbound rules to allow port 1120.
- Add a rule in your private network Access Control List (ACL) that allows TCP ports `0-65535` for the DB instance VPC.
- Create new Amazon SQS VPC endpoints that allow the RDS Custom for SQL Server DB instance to communicate with SQS.
- Update the SQS permissions in the instance profile role.

Creating an RDS Custom for SQL Server Multi-AZ deployment

To create an RDS Custom for SQL Server Multi-AZ deployment, follow the steps in Creating and connecting to a DB instance for Amazon RDS Custom for SQL Server.

Important

To simplify setup, we recommend that you use the latest AWS CloudFormation template file provided in the network setup instructions. For more information, see Configuring with AWS CloudFormation.

Creating a Multi-AZ deployment takes a few minutes to complete.

Modifying an RDS Custom for SQL Server Single-AZ deployment to a Multi-AZ deployment

You can modify an existing RDS Custom for SQL Server DB instance from a Single-AZ deployment to a Multi-AZ deployment. When you modify the DB instance,Amazon RDS performs several actions:

- Takes a snapshot of the primary DB instance.
- Creates new volumes for the standby replica from the snapshot. These volumes initialize in the background, and maximum volume performance is achieved after the data is fully initialized.
- Turns on synchronous block-level replication between the primary and secondary DB instances.

> **Important**
>
> We recommend that you avoid modifying your RDS Custom for SQL Server DB instance from a Single-AZ to a Multi-AZ deployment on a production DB instance during periods of peak activity.

AWS uses a snapshot to create the standby instance to avoid downtime when you convert from Single-AZ to Multi-AZ, but performance might be impacted during and after converting to Multi-AZ. This impact can be significant for workloads that are sensitive to write latency. While this capability allows large volumes to quickly be restored from snapshots, it can cause increase in the latency of I/O operations because of the synchronous replication. This latency can impact your database performance.

Topics

- Configuring prerequisites to modify a Single-AZ to a Multi-AZ deployment using CloudFormation
- Configuring prerequisites to modify a Single-AZ to a Multi-AZ deployment manually
- Modify using the RDS console, AWS CLI, or RDS API.

Configuring prerequisites to modify a Single-AZ to a Multi-AZ deployment using CloudFormation

To use a Multi-AZ deployment, you must ensure you've applied the latest CloudFormation template with prerequisites, or manually configure the latest prerequisites. If you've already applied the latest CloudFormation prerequisite template, you can skip these steps.

To configure the RDS Custom for SQL Server Multi-AZ deployment prerequisites using CloudFormation

1. Open the CloudFormation console at https://console.aws.amazon.com/cloudformation.
2. To start the Create Stack wizard, select the existing stack you used to create a Single-AZ deployment and choose **Update**.

   The **Update stack** page appears.
3. For **Prerequisite - Prepare template**, choose **Replace current template**.
4. For **Specify template**, do the following:

a. Download the latest AWS CloudFormation template file. Open the context (right-click) menu for the link custom-sqlserver-onboard.zip and choose **Save Link As**.

b. Save and extract the `custom-sqlserver-onboard.json` file to your computer.

c. For **Template source**, choose **Upload a template file**.

d. For **Choose file**, navigate to and then choose `custom-sqlserver-onboard.json`.

5. Choose **Next**.

   The **Specify stack details** page appears.

6. To keep the default options, choose **Next**.

   The **Advanced Options** page appears.

7. To keep the default options, choose **Next**.

8. To keep the default options, choose **Next**.

9. On the **Review Changes** page, do the following:

   a. For **Capabilities**, select the **I acknowledge that AWS CloudFormation might create IAM resources with custom names** check box.

   b. Choose **Submit**.

10. Verify the update is successful. The status of a successful operation shows `UPDATE_COMPLETE`.

If the update fails, any new configuration specified in the update process will be rolled back. The existing resource will still be usable. For example, if you add network ACL rules numbered 18 and 19, but there were existing rules with same numbers, the update would return the following error: `Resource handler returned message: "The network acl entry identified by 18 already exists.` In this scenario you can modify the existing ACL rules to use a number lower than 18, then retry the update.

Configuring prerequisites to modify a Single-AZ to a Multi-AZ deployment manually

> **Important**
>
> To simplify setup, we recommend that you use the latest AWS CloudFormation template file provided in the network setup instructions. For more information, see Configuring prerequisites to modify a Single-AZ to a Multi-AZ deployment using CloudFormation.

If you choose to configure the prerequisites manually, perform the following tasks.

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. Choose **Endpoint**. The **Create Endpoint** page appears.
3. For **Service Category**, choose **AWS services**.
4. In **Services**, search for *SQS*
5. In **VPC**, choose the VPC where your RDS Custom for SQL Server DB instance is deployed.
6. In **Subnets**, choose the subnets where your RDS Custom for SQL Server DB instance is deployed.
7. In **Security Groups**, choose the *-vpc-endpoint-sg* group.
8. For **Policy**, choose **Custom**
9. In your custom policy, replace the *AWS partition*, *Region*, *accountId*,and *IAM-Instance-role* with your own values.

```
                {
        "Version": "2012-10-17",
        "Statement": [
            {
                "Condition": {
                    "StringLike": {
                        "aws:ResourceTag/AWSRDSCustom": "custom-sqlserver"
                    }
                },
                "Action": [
                    "SQS:SendMessage",
                    "SQS:ReceiveMessage",
                    "SQS:DeleteMessage",
                    "SQS:GetQueueUrl"
                ],
                "Resource": "arn:${AWS::Partition}:sqs:${AWS::Region}:
${AWS::AccountId}:do-not-delete-rds-custom-*",
                "Effect": "Allow",
                "Principal": {
                    "AWS": "arn:${AWS::Partition}:iam::${AWS::AccountId}:role/{IAM-
Instance-role}"
                }
            }
        ]
```

```
    }
```

10. Update the **Instance profile** with permission to access Amazon SQS. Replace the *AWS partition*, *Region*, and *accountId* with your own values.

```
                        {
    "Sid": "SendMessageToSQSQueue",
    "Effect": "Allow",
    "Action": [
      "SQS:SendMessage",
      "SQS:ReceiveMessage",
      "SQS:DeleteMessage",
      "SQS:GetQueueUrl"

    ],
    "Resource": [
      {
        "Fn::Sub": "arn:${AWS::Partition}:sqs:${AWS::Region}:${AWS::AccountId}:do-
not-delete-rds-custom-*"
      }
    ],
    "Condition": {
      "StringLike": {
        "aws:ResourceTag/AWSRDSCustom": "custom-sqlserver"
      }
    }
  }
                        >
```

11. Update the Amazon RDS security group inbound and outbound rules to allow port 1120.

    a. In **Security Groups**, choose the *-rds-custom-instance-sg* group.

    b. For **Inbound Rules**, create a **Custom TCP** rule to allow port *1120* from the source *-rds-custom-instance-sg* group.

    c. For **Outbound Rules**, create a **Custom TCP** rule to allow port *1120* to the destination *-rds-custom-instance-sg* group.

12. Add a rule in your private network Access Control List (ACL) that allows TCP ports `0-65535` for the source subnet of the DB instance.

> **Note**
>
> When creating an **Inbound Rule** and **Outbound Rule**, take note of the highest existing **Rule number**. The new rules you create must have a **Rule number** lower than 100 and not match any existing **Rule number**.

a. In **Network ACLs**, choose the *-private-network-acl* group.

b. For **Inbound Rules**, create an **All TCP** rule to allow TCP ports `0-65535` with a source from *privatesubnet1* and *privatesubnet2*.

c. For **Outbound Rules**, create an **All TCP** rule to allow TCP ports `0-65535` to destination *privatesubnet1* and *privatesubnet2*.

Modify using the RDS console, AWS CLI, or RDS API.

After you've completed the prerequisites, you can modify an RDS Custom for SQL Server DB instance from a Single-AZ to Multi-AZ deployment using the RDS console, AWS CLI, or RDS API.

Console

To modify an existing RDS Custom for SQL Server Single-AZ to Multi-AZ deployment

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the Amazon RDS console, choose **Databases**.

   The **Databases** pane appears.
3. Choose the RDS Custom for SQL Server DB instance that you want to modify.
4. For **Actions**, choose **Convert to Multi-AZ deployment**.
5. On the **Confirmation** page, choose **Apply immediately** to apply the changes immediately. Choosing this option doesn't cause downtime, but there is a possible performance impact. Alternatively, you can choose to apply the update during the next maintenance window. For more information, see Schedule modifications setting.
6. On the **Confirmation** page, choose **Convert to Multi-AZ**.

AWS CLI

To convert to a Multi-AZ DB instance deployment by using the AWS CLI, call the modify-db-instance command and set the `--multi-az` option. Specify the DB instance identifier and the values for other options that you want to modify. For information about each option, see Settings for DB instances.

Example

The following code modifies `mycustomdbinstance` by including the `--multi-az` option. The changes are applied during the next maintenance window by using `--no-apply-immediately`. Use `--apply-immediately` to apply the changes immediately. For more information, see Schedule modifications setting.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier mycustomdbinstance \
    --multi-az \
    --no-apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier mycustomdbinstance ^
    --multi-az  \ ^
    --no-apply-immediately
```

RDS API

To convert to a Multi-AZ DB instance deployment with the RDS API, call the ModifyDBInstance operation and set the `MultiAZ` parameter to true.

Modifying an RDS Custom for SQL Server Multi-AZ deployment to a Single-AZ deployment

You can modify an existing RDS Custom for SQL Server DB instance from a Multi-AZ to a Single-AZ deployment.

Console

To modify an RDS Custom for SQL Server DB instance from a Multi-AZ to Single-AZ deployment.

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the Amazon RDS console, choose **Databases**.

   The **Databases** pane appears.
3. Choose the RDS Custom for SQL Server DB instance that you want to modify.
4. For **Multi-AZ deployment**, choose **No**.
5. On the **Confirmation** page, choose **Apply immediately** to apply the changes immediately. Choosing this option doesn't cause downtime, but there is a possible performance impact. Alternatively, you can choose to apply the update during the next maintenance window. For more information, see Schedule modifications setting.
6. On the **Confirmation** page, choose **Modify DB Instance**.

AWS CLI

To modify a Multi-AZ deployment to a Single-AZ deployment by using the AWS CLI, call the modify-db-instance command and include the `--no-multi-az` option. Specify the DB instance identifier and the values for other options that you want to modify. For information about each option, see Settings for DB instances.

Example

The following code modifies `mycustomdbinstance` by including the `--no-multi-az` option. The changes are applied during the next maintenance window by using `--no-apply-immediately`. Use `--apply-immediately` to apply the changes immediately. For more information, see Schedule modifications setting.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier mycustomdbinstance \
    --no-multi-az  \
    --no-apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier mycustomdbinstance ^
    --no-multi-az \ ^
    --no-apply-immediately
```

RDS API

To modify a Multi-AZ deployment to a Single-AZ deployment by using the RDS API, call the ModifyDBInstance operation and set the `MultiAZ` parameter to `false`.

Failover process for an RDS Custom for SQL Server Multi-AZ deployment

If a planned or unplanned outage of your DB instance results from an infrastructure defect, Amazon RDS automatically switches to a standby replica in another Availability Zone if you have turned on Multi-AZ. The time that it takes for the failover to complete depends on the database activity and other conditions at the time that the primary DB instance became unavailable. Failover times are typically 60 – 120 seconds. However, large transactions or a lengthy recovery process can increase failover time. When the failover is complete, it can take additional time for the RDS console to show the new Availability Zone.

> **Note**
>
> You can force a failover manually when you reboot a DB instance with failover. For more information on rebooting a DB instance, see Rebooting a DB instance

Amazon RDS handles failovers automatically so you can resume database operations as quickly as possible without administrative intervention. The primary DB instance switches over automatically to the standby replica if any of the conditions described in the following table occurs. You can view these failover reasons in the RDS event log.

Failover reason	Description
`The operating system for the RDS Custom for SQL Server Multi-AZ DB instance`	A failover was triggered during the maintenance window for an OS patch or a security update. For more information, see Maintaining a DB instance.

Failover reason	Description
is being patched in an offline operation	
The primary host of the RDS Custom for SQL Server Multi-AZ DB instance is unhealthy.	The Multi-AZ DB instance deployment detected an impaired primary DB instance and failed over.
The primary host of the RDS Custom for SQL Server Multi-AZ DB instance is unreachable due to loss of network connectivity.	RDS monitoring detected a network reachability failure to the primary DB instance and triggered a failover.
The RDS Custom for SQL Server Multi-AZ DB instance was modified by the customer.	A DB instance modification triggered a failover. For more informati on, see Modifying an RDS Custom for SQL Server DB instance.
The storage volume of the primary host of the RDS Custom for SQL Server Multi-AZ DB instance experienced a failure.	The Multi-AZ DB instance deployment detected a storage issue on the primary DB instance and failed over.

Failover reason	Description
`The user requested a failover of the RDS Custom for SQL Server Multi-AZ DB instance.`	The RDS Custom for SQL Server Multi-AZ DB instance was rebooted with failover. For more information, see Rebooting a DB instance.
`The RDS Custom for SQL Server Multi-AZ primary DB instance is busy or unresponsive.`	The primary DB instance is unresponsive. We recommend that you try the following steps: • Examine the event logs and CloudWatch logs for excessive CPU, memory, or swap space usage. For more information, see Working with Amazon RDS event notification. • Create a rule that triggers on an Amazon RDS event. For more information, see Creating a rule that triggers on an Amazon RDS event. • Evaluate your workload to determine whether you're using the appropriate DB instance class. For more information, see DB instance classes.

To determine if your Multi-AZ DB instance has failed over, you can do the following:

- Set up DB event subscriptions to notify you by email or SMS that a failover has been initiated. For more information about events, see Working with Amazon RDS event notification.
- View your DB events by using the RDS console or API operations.
- View the current state of your RDS Custom for SQL Server Multi-AZ DB instance deployment by using the RDS console, CLI, or API operations.

Time to live (TTL) settings with applications using an RDS Custom for SQL Server Multi-AZ deployment

The failover mechanism automatically changes the Domain Name System (DNS) record of the DB instance to point to the standby DB instance. As a result, you need to re-establish any existing connections to your DB instance. Ensure that any DNS cache time-to-live (TTL) configuration value

is low, and validate that your application will not cache DNS for an extended time. A high TTL value might prevent your application from quickly reconnecting to the DB instance after failover.

Backing up and restoring an Amazon RDS Custom for SQL Server DB instance

Like Amazon RDS, RDS Custom creates and saves automated backups of your RDS Custom for SQL Server DB instance when backup retention is enabled. You can also back up your DB instance manually. The automated backups are comprised of snapshot backups and transaction log backups. Snapshot backups are taken for the entire storage volume of DB instance during your specified backup window. Transaction log backups are taken for the PITR-eligible databases on a regular interval period. RDS Custom saves the automated backups of your DB instance according to your specified backup retention period. You can use automated backups to recover your DB instance to a point in time within the backup retention period.

You can also take snapshot backups manually. You can create a new DB instance from these snapshot backups at any time. For more information about manually creating a DB snapshot, see Creating an RDS Custom for SQL Server snapshot.

Although snapshot backups serve operationally as full backups, you are billed only for incremental storage use. The first snapshot of an RDS Custom DB instance contains the data for the full DB instance. Subsequent snapshots of the same database are incremental, which means that only the data that has changed after your most recent snapshot is saved.

Topics

Creating an RDS Custom for SQL Server snapshot

RDS Custom for SQL Server creates a storage volume snapshot of your DB instance, backing up the entire DB instance and not just individual databases. When you create a snapshot, specify which RDS Custom for SQL Server DB instance to back up. Give your snapshot a name so you can restore from it later.

When you create a snapshot, RDS Custom for SQL Server creates an Amazon EBS snapshot for volume (`D:`), which is the database volume attached to the DB instance. To make snapshots

easy to associate with a specific DB instance, they're tagged with `DBSnapshotIdentifier`, `DbiResourceId`, and `VolumeType`.

Creating a DB snapshot results in a brief I/O suspension. This suspension can last from a few seconds to a few minutes, depending on the size and class of your DB instance. The snapshot creation time varies with the total count and size of your databases. To learn more about the number of databases eligible for a point in time restore (PITR) operation, see Number of databases eligible for PITR per instance class type.

Because the snapshot includes the entire storage volume, the size of files, such as temporary files, also affects snapshot creation time. To learn more about creating snapshots, see Creating a DB snapshot for a Single-AZ DB instance.

Create an RDS Custom for SQL Server snapshot using the console or the AWS CLI.

Console

To create an RDS Custom snapshot

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.
3. In the list of RDS Custom DB instances, choose the instance for which you want to take a snapshot.
4. For **Actions**, choose **Take snapshot**.

   The **Take DB snapshot** window appears.
5. For **Snapshot name**, enter the name of the snapshot.
6. Choose **Take snapshot**.

AWS CLI

You create a snapshot of an RDS Custom DB instance by using the create-db-snapshot AWS CLI command.

Specify the following options:

- `--db-instance-identifier` – Identifies which RDS Custom DB instance you are going to back up

- `--db-snapshot-identifier` – Names your RDS Custom snapshot so you can restore from it later

In this example, you create a DB snapshot called *my-custom-snapshot* for an RDS Custom DB instance called *my-custom-instance*.

Example

For Linux, macOS, or Unix:

```
aws rds create-db-snapshot \
    --db-instance-identifier my-custom-instance \
    --db-snapshot-identifier my-custom-snapshot
```

For Windows:

```
aws rds create-db-snapshot ^
    --db-instance-identifier my-custom-instance ^
    --db-snapshot-identifier my-custom-snapshot
```

Restoring from an RDS Custom for SQL Server DB snapshot

When you restore an RDS Custom for SQL Server DB instance, you provide the name of the DB snapshot and a name for the new instance. You can't restore from a snapshot to an existing RDS Custom DB instance. A new RDS Custom for SQL Server DB instance is created when you restore.

Restoring from a snapshot will restore the storage volume to the point in time at which the snapshot was taken. This will include all the databases and any other files that were present on the `(D:)` volume.

Console

To restore an RDS Custom DB instance from a DB snapshot

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Snapshots**.
3. Choose the DB snapshot that you want to restore from.
4. For **Actions**, choose **Restore snapshot**.

5. On the **Restore DB instance** page, for **DB instance identifier**, enter the name for your restored RDS Custom DB instance.
6. Choose **Restore DB instance**.

AWS CLI

You restore an RDS Custom DB snapshot by using the restore-db-instance-from-db-snapshot AWS CLI command.

If the snapshot you are restoring from is for a private DB instance, make sure to specify both the correct `db-subnet-group-name` and `no-publicly-accessible`. Otherwise, the DB instance defaults to publicly accessible. The following options are required:

- `db-snapshot-identifier` – Identifies the snapshot from which to restore
- `db-instance-identifier` – Specifies the name of the RDS Custom DB instance to create from the DB snapshot
- `custom-iam-instance-profile` – Specifies the instance profile associated with the underlying Amazon EC2 instance of an RDS Custom DB instance.

The following code restores the snapshot named `my-custom-snapshot` for `my-custom-instance`.

Example

For Linux, macOS, or Unix:

```
aws rds restore-db-instance-from-db-snapshot \
  --db-snapshot-identifier my-custom-snapshot \
  --db-instance-identifier my-custom-instance \
  --custom-iam-instance-profile AWSRDSCustomInstanceProfileForRdsCustomInstance \
  --no-publicly-accessible
```

For Windows:

```
aws rds restore-db-instance-from-db-snapshot ^
  --db-snapshot-identifier my-custom-snapshot ^
  --db-instance-identifier my-custom-instance ^
  --custom-iam-instance-profile AWSRDSCustomInstanceProfileForRdsCustomInstance ^
```

```
  --no-publicly-accessible
```

Restoring an RDS Custom for SQL Server instance to a point in time

You can restore a DB instance to a specific point in time (PITR), creating a new DB instance. To support PITR, your DB instances must have backup retention enabled.

The latest restorable time for an RDS Custom for SQL Server DB instance depends on several factors, but is typically within 5 minutes of the current time. To see the latest restorable time for a DB instance, use the AWS CLI describe-db-instances command and look at the value returned in the `LatestRestorableTime` field for the DB instance. To see the latest restorable time for each DB instance in the Amazon RDS console, choose **Automated backups**.

You can restore to any point in time within your backup retention period. To see the earliest restorable time for each DB instance, choose **Automated backups** in the Amazon RDS console.

For general information about PITR, see Restoring a DB instance to a specified time.

Topics

- PITR considerations for RDS Custom for SQL Server
- Number of databases eligible for PITR per instance class type
- Making databases ineligible for PITR
- Transaction logs in Amazon S3
- PITR Restore using the AWS Management Console, the AWS CLI, or the RDS API.

PITR considerations for RDS Custom for SQL Server

In RDS Custom for SQL Server, PITR differs in the following important ways from PITR in Amazon RDS:

- PITR only restores the databases in the DB instance. It doesn't restore the operating system or files on the C: drive.
- For an RDS Custom for SQL Server DB instance, a database is backed up automatically and is eligible for PITR only under the following conditions:
  - The database is online.
  - Its recovery model is set to FULL.
  - It's writable.

  - It has its physical files on the D: drive.
  - It's not listed in the `rds_pitr_blocked_databases` table. For more information, see Making databases ineligible for PITR.
- The databases eligible for PITR are determined by the order of their database ID. RDS Custom for SQL Server allows up to 5,000 databases per DB instance. However, the maximum number of databases restored by a PITR operation for an RDS Custom for SQL Server DB instance is dependent on the instance class type. For more information, see Number of databases eligible for PITR per instance class type.

  Other databases that aren't part of PITR can be restored from DB snapshots, including the automated snapshot backups used for PITR.
- Adding a new database, renaming a database, or restoring a database that is eligible for PITR initiates a snapshot of the DB instance.
- The maximum number of databases eligible for PITR changes when the database instance goes through a scale compute operation, depending on the target instance class type. If the instance is scaled up, allowing more databases on the instance to be eligible for PITR, a new snapshot is taken.
- Restored databases have the same name as in the source DB instance. You can't specify a different name.
- `AWSRDSCustomSQLServerIamRolePolicy` requires access to other AWS services. For more information, see Add an access policy to AWSRDSCustomSQLServerInstanceRole.
- Time zone changes aren't supported for RDS Custom for SQL Server. If you change the operating system or DB instance time zone, PITR (and other automation) doesn't work.

Number of databases eligible for PITR per instance class type

The following table shows the maximum number of databases eligible for PITR based on instance class type.

Instance class type	Maximum number of PITR eligible databases				
db.*.large	100				

Instance class type	Maximum number of PITR eligible databases
db.*.xlarge to db.*.2xlarge	150
db.*.4xlarge to db.*.8xlarge	300
db.*.12xlarge to db.*.16xlarge	600
db.*.24xlarge, db.*32xlarge	1000

* *Represents different instance class types.*

The maximum number of databases eligible for PITR on a DB instance depends on the instance class type. The number ranges from 100 on the smallest to 1000 on the largest instance class types supported by RDS Custom for SQL Server. SQL server system databases (`master, model, msdb, tempdb`), aren't included in this limit. When a DB instance is scaled up or down, depending on the target instance class type, RDS Custom will automatically update the number of database eligible for PITR. RDS Custom for SQL Server will send `RDS-EVENT-0352` when the maximum number of databases eligible for PITR changes on a DB instance. For more information, see Custom engine version events.

Note

PITR support for greater than 100 databases is only available on DB instances created after August 26, 2023. For instances created before August 26, 2023, the maximum number of databases eligible for PITR is 100, regardless of the instance class. To enable PITR support for more than 100 databases on DB instances created before August 26, 2023, you can perform the following action:

- Upgrade the DB engine version to 15.00.4322.2.v1 or higher

During a PITR operation, RDS Custom will restore all of the databases that were part of PITR on source DB instance at restore time. Once the target DB instance has completed restore operations, if backup retention is enabled, the DB instance will start backing up based on the maximum number of databases eligible for PITR on target DB instance.

For example, if your DB instance runs on a `db.*.xlarge` that has 200 databases:

1. RDS Custom for SQL Server will choose the first 150 databases, ordered by their database ID, for PITR backup.
2. You modify the instance to scale up to db.*.4xlarge.
3. Once the scale compute operation is completed, RDS Custom for SQL Server will choose the first 300 databases, ordered by their database ID, for PITR backup. Each one of the 200 databases that satisfy the PITR requirement conditions will now be eligible for PITR.
4. You now modify the instance to scale down back to db.*.xlarge.
5. Once the scale compute operation is completed, RDS Custom for SQL Server will again select the first 150 databases, ordered by their database ID, for PITR backup.

Making databases ineligible for PITR

You can choose to exclude individual databases from PITR. To do this, put their `database_id` values into a `rds_pitr_blocked_databases` table. Use the following SQL script to create the table.

To create the rds_pitr_blocked_databases table

- Run the following SQL script.

```
create table msdb..rds_pitr_blocked_databases
(
database_id INT NOT NULL,
database_name SYSNAME NOT NULL,
db_entry_updated_date datetime NOT NULL DEFAULT GETDATE(),
db_entry_updated_by SYSNAME NOT NULL DEFAULT CURRENT_USER,
PRIMARY KEY (database_id)
```

```
);
```

For the list of eligible and ineligible databases, see the `RI.End` file in the `RDSCustomForSQLServer/Instances/`*`DB_instance_resource_ID`*`/TransactionLogMetadata` directory in the Amazon S3 bucket `do-not-delete-rds-custom-`*`$ACCOUNT_ID`*`-`*`$REGION`*`-`*`unique_identifier`*. For more information about the `RI.End` file, see Transaction logs in Amazon S3.

You can also determine the list of eligible databases for PITR using the following SQL script. Set the `@limit` variable to the maximum number of databases on eligible for PITR for the instance class. For more information, see Number of databases eligible for PITR per instance class type.

To determine the list of eligible databases for PITR on a DB instance class

- Run the following SQL script.

```
DECLARE @Limit INT;
SET @Limit = (insert-database-instance-limit-here);

USE msdb;
IF (EXISTS (SELECT * FROM INFORMATION_SCHEMA.TABLES WHERE TABLE_SCHEMA = 'dbo' AND
 TABLE_NAME = 'rds_pitr_blocked_databases'))
    WITH TABLE0 AS (
        SELECT hdrs.database_id as DatabaseId, sdb.name as DatabaseName,
 'ALWAYS_ON_NOT_WRITABLE_REPLICA' as Reason, NULL as DatabaseNameOnPitrTable
        FROM sys.dm_hadr_database_replica_states hdrs
        INNER JOIN sys.databases sdb ON sdb.database_id = hdrs.database_id
        WHERE (hdrs.is_local = 1 AND hdrs.is_primary_replica = 0)
        OR (sys.fn_hadr_is_primary_replica (sdb.name) = 1 AND DATABASEPROPERTYEX
 (sdb.name, 'Updateability') = 'READ_ONLY')
    ),
    TABLE1 as (
            SELECT dbs.database_id as DatabaseId, sysdbs.name as DatabaseName,
 'OPTOUT' as Reason,
            CASE WHEN dbs.database_name = sysdbs.name THEN NULL ELSE
 dbs.database_name END AS DatabaseNameOnPitrTable
            FROM msdb.dbo.rds_pitr_blocked_databases dbs
            INNER JOIN sys.databases sysdbs ON dbs.database_id = sysdbs.database_id
            WHERE sysdbs.database_id > 4
            ),
    TABLE2 as (
```

```
            SELECT
            db.name AS DatabaseName,
            db.create_date AS CreateDate,
            db.state_desc AS DatabaseState,
            db.database_id AS DatabaseId,
            rs.database_guid AS DatabaseGuid,
            rs.last_log_backup_lsn AS LastLogBackupLSN,
            rs.recovery_fork_guid RecoveryForkGuid,
            rs.first_recovery_fork_guid AS FirstRecoveryForkGuid,
            db.recovery_model_desc AS RecoveryModel,
            db.is_auto_close_on AS IsAutoClose,
            db.is_read_only as IsReadOnly,
            NEWID() as FileName,
            CASE WHEN(db.state_desc = 'ONLINE'
                    AND db.recovery_model_desc != 'SIMPLE'
                    AND((db.is_auto_close_on = 0 and db.collation_name IS NOT NULL)
 OR db.is_auto_close_on = 1))
                    AND db.is_read_only != 1
                    AND db.user_access = 0
                    AND db.source_database_id IS NULL
                    AND db.is_in_standby != 1
                    THEN 1 ELSE 0 END AS IsPartOfSnapshot,
            CASE WHEN db.source_database_id IS NULL THEN 0 ELSE 1 END AS
 IsDatabaseSnapshot
            FROM sys.databases db
            INNER JOIN sys.database_recovery_status rs
            ON db.database_id = rs.database_id
            WHERE DB_NAME(db.database_id) NOT IN('tempdb') AND
            db.database_id NOT IN (SELECT DISTINCT DatabaseId FROM TABLE1) AND
            db.database_id NOT IN (SELECT DISTINCT DatabaseId FROM TABLE0)
        ),
        TABLE3 as(
            Select @Limit+count(DatabaseName) as TotalNumberOfDatabases from TABLE2
 where TABLE2.IsPartOfSnapshot=1 and DatabaseName in ('master','model','msdb')
        )
        SELECT TOP(SELECT TotalNumberOfDatabases from TABLE3)
 DatabaseName,CreateDate,DatabaseState,DatabaseId from TABLE2 where
 TABLE2.IsPartOfSnapshot=1
        ORDER BY TABLE2.DatabaseID ASC
ELSE
    WITH TABLE0 AS (
        SELECT hdrs.database_id as DatabaseId, sdb.name as DatabaseName,
 'ALWAYS_ON_NOT_WRITABLE_REPLICA' as Reason, NULL as DatabaseNameOnPitrTable
        FROM sys.dm_hadr_database_replica_states hdrs

>
> The databases that are only symbolic links are also excluded from databases eligible for PITR operations. The above query doesn't filter based on this criteria.

Transaction logs in Amazon S3

The backup retention period determines whether transaction logs for RDS Custom for SQL Server DB instances are automatically extracted and uploaded to Amazon S3. A nonzero value means that automatic backups are created, and that the RDS Custom agent uploads the transaction logs to S3 every 5 minutes.

Transaction log files on S3 are encrypted at rest using the AWS KMS key that you provided when you created your DB instance. For more information, see Protecting data using server-side encryption in the *Amazon Simple Storage Service User Guide*.

The transaction logs for each database are uploaded to an S3 bucket named `do-not-delete-rds-custom-`*`$ACCOUNT_ID`*`-`*`$REGION`*`-`*`unique_identifier`*. The `RDSCustomForSQLServer/Instances/`*`DB_instance_resource_ID`* directory in the S3 bucket contains two subdirectories:

- `TransactionLogs` – Contains the transaction logs for each database and their respective metadata.

  The transaction log file name follows the pattern *`yyyyMMddHHmm`*`.`*`database_id`*`.`*`timestamp`*, for example:

  ```
  202110202230.11.1634769287
  ```

  The same file name with the suffix `_metadata` contains information about the transaction log such as log sequence numbers, database name, and `RdsChunkCount`. `RdsChunkCount` determines how many physical files represent a single transaction log file. You might see files with suffixes `_0001`, `_0002`, and so on, which mean the physical chunks of a transaction log file. If you want to use a chunked transaction log file, make sure to merge the chunks after downloading them.

Consider a scenario where you have the following files:

- `202110202230.11.1634769287`
- `202110202230.11.1634769287_0001`
- `202110202230.11.1634769287_0002`
- `202110202230.11.1634769287_metadata`

The `RdsChunkCount` is 3. The order for merging the files is the following: `202110202230.11.1634769287`, `202110202230.11.1634769287_0001`, `202110202230.11.1634769287_0002`.

- `TransactionLogMetadata` – Contains metadata information about each iteration of transaction log extraction.

  The `RI.End` file contains information for all databases that had their transaction logs extracted, and all databases that exist but didn't have their transaction logs extracted. The `RI.End` file name follows the pattern *`yyyyMMddHHmm`*`.RI.End.`*`timestamp`*, for example:

  ```
  202110202230.RI.End.1634769281
  ```

PITR Restore using the AWS Management Console, the AWS CLI, or the RDS API.

You can restore an RDS Custom for SQL Server DB instance to a point in time using the AWS Management Console, the AWS CLI, or the RDS API.

Console

To restore an RDS Custom DB instance to a specified time

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Automated backups**.
3. Choose the RDS Custom DB instance that you want to restore.
4. For **Actions**, choose **Restore to point in time**.

   The **Restore to point in time** window appears.
5. Choose **Latest restorable time** to restore to the latest possible time, or choose **Custom** to choose a time.

If you chose **Custom**, enter the date and time to which you want to restore the instance.

Times are shown in your local time zone, which is indicated by an offset from Coordinated Universal Time (UTC). For example, UTC-5 is Eastern Standard Time/Central Daylight Time.

6. For **DB instance identifier**, enter the name of the target restored RDS Custom DB instance. The name must be unique.
7. Choose other options as needed, such as DB instance class.
8. Choose **Restore to point in time**.

AWS CLI

You restore a DB instance to a specified time by using the restore-db-instance-to-point-in-time AWS CLI command to create a new RDS Custom DB instance.

Use one of the following options to specify the backup to restore from:

- `--source-db-instance-identifier` *`mysourcedbinstance`*
- `--source-dbi-resource-id` *`dbinstanceresourceID`*
- `--source-db-instance-automated-backups-arn` *`backupARN`*

The `custom-iam-instance-profile` option is required.

The following example restores `my-custom-db-instance` to a new DB instance named `my-restored-custom-db-instance`, as of the specified time.

Example

For Linux, macOS, or Unix:

```
aws rds restore-db-instance-to-point-in-time \
    --source-db-instance-identifier my-custom-db-instance\
    --target-db-instance-identifier my-restored-custom-db-instance \
    --custom-iam-instance-profile AWSRDSCustomInstanceProfileForRdsCustomInstance \
    --restore-time 2022-10-14T23:45:00.000Z
```

For Windows:

```
aws rds restore-db-instance-to-point-in-time ^
```

```
    --source-db-instance-identifier my-custom-db-instance ^
    --target-db-instance-identifier my-restored-custom-db-instance ^
    --custom-iam-instance-profile AWSRDSCustomInstanceProfileForRdsCustomInstance ^
    --restore-time 2022-10-14T23:45:00.000Z
```

Deleting an RDS Custom for SQL Server snapshot

You can delete DB snapshots managed by RDS Custom for SQL Server when you no longer need them. The deletion procedure is the same for both Amazon RDS and RDS Custom DB instances.

The Amazon EBS snapshots for the binary and root volumes remain in your account for a longer time because they might be linked to some instances running in your account or to other RDS Custom for SQL Server snapshots. These EBS snapshots are automatically deleted after they're no longer related to any existing RDS Custom for SQL Server resources (DB instances or backups).

Console

To delete a snapshot of an RDS Custom DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Snapshots**.
3. Choose the DB snapshot that you want to delete.
4. For **Actions**, choose **Delete snapshot**.
5. Choose **Delete** on the confirmation page.

AWS CLI

To delete an RDS Custom snapshot, use the AWS CLI command delete-db-snapshot.

The following option is required:

- `--db-snapshot-identifier` – The snapshot to be deleted

The following example deletes the `my-custom-snapshot` DB snapshot.

Example

For Linux, macOS, or Unix:

```
aws rds delete-db-snapshot \
  --db-snapshot-identifier my-custom-snapshot
```

For Windows:

```
aws rds delete-db-snapshot ^
  --db-snapshot-identifier my-custom-snapshot
```

Deleting RDS Custom for SQL Server automated backups

You can delete retained automated backups for RDS Custom for SQL Server when they are no longer needed. The procedure is the same as the procedure for deleting Amazon RDS backups.

Console

To delete a retained automated backup

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Automated backups**.
3. Choose **Retained**.
4. Choose the retained automated backup that you want to delete.
5. For **Actions**, choose **Delete**.
6. On the confirmation page, enter **`delete me`** and choose **Delete**.

AWS CLI

You can delete a retained automated backup by using the AWS CLI command delete-db-instance-automated-backup.

The following option is used to delete a retained automated backup:

- `--dbi-resource-id` – The resource identifier for the source RDS Custom DB instance.

  You can find the resource identifier for the source DB instance of a retained automated backup by using the AWS CLI command describe-db-instance-automated-backups.

The following example deletes the retained automated backup with source DB instance resource identifier `custom-db-123ABCEXAMPLE`.

Example

For Linux, macOS, or Unix:

```
aws rds delete-db-instance-automated-backup \
    --dbi-resource-id custom-db-123ABCEXAMPLE
```

For Windows:

```
aws rds delete-db-instance-automated-backup ^
    --dbi-resource-id custom-db-123ABCEXAMPLE
```

Copying an Amazon RDS Custom for SQL Server DB snapshot

With RDS Custom for SQL Server, you can copy automated backups and manual DB snapshots. After copying a snapshot, the copy you create is a manual snapshot. You can make multiple copies of an automated backup or manual snapshot but each copy must have a unique identifier.

You can only copy a snapshot within the same AWS account across different AWS Regions where RDS Custom for SQL Server is available. The following operations are currently not supported:

- Copying DB snapshots within the same AWS Region.
- Copying DB snapshots across AWS accounts.

RDS Custom for SQL Server supports incremental snapshot copying. For more information, see Incremental snapshot copying.

Topics

Limitations

The following limitations apply to copying a DB snapshot for RDS Custom for SQL Server:

- If you delete a source snapshot before the target snapshot becomes available, the snapshot copy might fail. Verify that the target snapshot has a status of `AVAILABLE` before you delete the source snapshot.
- You cannot specify an option group name or copy an options group in your DB snapshot copy request.
- If you delete any dependent AWS resources of the source DB snapshot before or during the copy process, your copy snapshot request could fail asynchronously.
  - If you delete the Service Master Key (SMK) backup file for your source DB instance stored in the RDS Custom managed S3 bucket in your account, the DB snapshot copy succeeds

asynchronously. However, SQL Server features dependent on SMK such as TDE enabled databases run into issues. For more information, see Troubleshooting PENDING_RECOVERY state for TDE enabled databases in RDS Custom for SQL Server.

- Copying DB snapshots within the same AWS Region is currently not supported.
- Copying DB snapshots across AWS accounts is currently not supported.

The limitations of copying a DB snapshot for Amazon RDS also apply to RDS Custom for SQL Server. For more information, see Limitations.

Handling encryption

All RDS Custom for SQL Server DB instances and DB snapshots are encrypted with KMS keys. You can only copy an encrypted snapshot to an encrypted snapshot, therefore you must specify a KMS key valid in the destination AWS Region for your DB snapshot copy request.

The source snapshot remains encrypted throughout the copy process. Amazon RDS uses envelope encryption to protect data during the copy operation with the specified destination AWS Region KMS key. For more information, see Envelope encryption in the *AWS Key Management Service Developer Guide*.

Cross-Region copying

You can copy DB snapshots across AWS Regions. However, there are certain constraints and considerations for cross-Region snapshot copying.

Authorizing RDS to communicate across AWS Regions for snapshot copying

After a cross-Region DB snapshot copy request is processed successfully, RDS starts the copy. An authorization request for RDS to access the source snapshot is created. This authorization request links the source DB snapshot to the target DB snapshot. This allows RDS to copy only to the specified target snapshot.

RDS verifies the authorization by using the `rds:CrossRegionCommunication` permission in the service-linked IAM role. If the copy is authorized, RDS can communicate with the source Region and complete the copy operation.

RDS doesn't have access to DB snapshots that weren't authorized previously by a CopyDBSnapshot request. The authorization is revoked after the copy completes.

RDS uses the service-linked role to verify the authorization in the source Region. The copy fails if you delete the service-linked role during the copy process.

For more information, see Using service-linked roles in the *AWS Identity and Access Management User Guide*.

Using AWS Security Token Service credentials

Session tokens from the global AWS Security Token Service (AWS STS) endpoint are valid only in AWS Regions that are enabled by default (commercial Regions). If you use credentials from the `assumeRole` API operation in AWS STS, use the regional endpoint if the source Region is an opt-in Region. Otherwise, the request fails. Your credentials must be valid in both Regions, which is true for opt-in Regions only when you use the regional AWS STS endpoint.

To use the global endpoint, make sure that it's enabled for both Regions in the operations. Set the global endpoint to `Valid` in all AWS Regions in the AWS STS account settings.

For more information, see Managing AWS STS in an AWS Region in the *AWS Identity and Access Management User Guide*.

Snapshots of DB instances created with Custom Engine Versions (CEV)

For a DB snapshot of a DB instance using a Custom Engine Version (CEV), RDS associates the CEV with the DB snapshot. To copy a source DB snapshot associated with a CEV across AWS Regions, RDS copies the CEV along with the source DB snapshot to the destination region.

If you are copying multiple DB snapshots associated with the same CEV to the same destination region, the first copy request copies the associated CEV. The copy process of the following requests finds the initially copied CEV and associates it with the following DB snapshot copies. The existing CEV copy must be in `AVAILABLE` state to be associated with the DB snapshot copies.

To copy a DB snapshot associated with a CEV, the requester's IAM policy must have the permissions to authorize both the DB snapshot copying and the associated CEV copying. The following permissions are needed in your requester's IAM policy to allow the associated CEV copying:

- `rds:CopyCustomDBEngineVersion` - Your requester IAM principal needs to have the permission to copy the source CEV to the target region along with the source DB snapshot. The snapshot copy request fails due to authorization errors if your requester IAM principal is not authorized to copy the source CEV.
- `ec2:CreateTags` - The underlying EC2 AMI of the source CEV is copied to the target region as a part of the CEV copy. RDS Custom attempts to tag the AMI with the `AWSRDSCustom` tag before

copying the AMI. Make sure your requester IAM principal has the permission to create the tag against the AMI underlying the source CEV in the source region.

For more information about CEV copying permissions, see Grant required permissions to your IAM principal.

Grant required permissions to your IAM principal

Make sure that you have sufficient access to copy a RDS Custom for SQL Server DB snapshot. The IAM role or user (referred to as the IAM principal) for copying a DB snapshot using the console or CLI must have either of the following policies for successful DB instance creation:

- The `AdministratorAccess` policy or,
- The `AmazonRDSFullAccess` policy with the following additional permissions:

```
s3:CreateBucket
s3:GetBucketPolicy
s3:PutBucketPolicy
kms:CreateGrant
kms:DescribeKey
ec2:CreateTags
```

RDS Custom uses these permissions during snapshot copying across AWS Regions. These permissions configure resources in your account that are required for RDS Custom operations. For more information about the `kms:CreateGrant` permission, see AWS KMS key management.

The following sample JSON policy grants the required permissions in addition to `AmazonRDSFullAccess` policy.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "CreateS3BucketAndReadWriteBucketPolicy",
            "Effect": "Allow",
            "Action": [
                "s3:CreateBucket",
                "s3:PutBucketPolicy",
                "s3:GetBucketPolicy"
```

```
            ],
            "Resource": "arn:aws:s3:::do-not-delete-rds-custom-*"
        },
        {
            "Sid": "CreateKmsGrant",
            "Effect": "Allow",
            "Action": [
                "kms:CreateGrant",
                "kms:DescribeKey"
            ],
            "Resource": "*"
        },
        {
            "Sid": "CreateEc2Tags",
            "Effect": "Allow",
            "Action": [
                "ec2:CreateTags"
            ],
            "Resource": "*"
        }
    ]
}
```

Note

Make sure that the listed permissions aren't restricted by service control policies (SCPs), permission boundaries, or session policies associated with the IAM principal.

If you use conditions with context keys in the requester's IAM policy, certain conditions can cause the request to fail. For more information about common pitfalls due to IAM policy conditions, see Requesting a cross-Region DB snapshot copy.

Copying a DB snapshot

Use the following procedures to copy a DB snapshot. For each AWS account, you can copy up to 20 DB snapshots at a time from one AWS Region to another. If you copy a DB snapshot to another AWS Region, you create a manual DB snapshot that is retained in that AWS Region. Copying a DB snapshot out of the source AWS Region incurs Amazon RDS data transfer charges. For more information about data transfer pricing, see Amazon RDS pricing.

After the DB snapshot copy has been created in the new AWS Region, the DB snapshot copy behaves the same as all other DB snapshots in that AWS Region.

You can copy a DB snapshot using the AWS Management Console, AWS CLI, or the Amazon RDS API.

Console

The following procedure copies a RDS Custom for SQL Server DB snapshot by using the AWS Management Console.

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Snapshots**.
3. Select the RDS Custom for SQL Server DB snapshot that you want to copy.
4. In the **Actions** dropwdown , choose **Copy snapshot**.

RDS > Snapshots > Copy snapshot

Copy snapshot

Settings

Source DB snapshot
DB snapshot identifier for the snapshot being copied.
db1-snapshot

New DB snapshot identifier
DB snapshot identifier for the new snapshot.
copied-db1-snapshot
Must start with a letter and only contain letters, digits, or hyphens.

Destination Region Info
Choose a Region

Resource tags Info
Copy tags from the source DB snapshot

Depending on the amount of data to be copied and the Region you choose, this operation can take several hours to complete. The display on the progress bar might be delayed until setup is complete.

Encryption

Encryption Info
Enable Encryption
Choose to encrypt the copy of the source DB snapshot. Master key IDs and aliases appear in the list after they have been created using KMS. You cannot remove encryption from an encrypted DB snapshot.

AWS KMS key Info
Enter a key ARN

Amazon Resource Name (ARN)
Example: arn:aws:kms:<region>:<accountID>:key/<key-id>

Account

KMS key ID

Cancel Copy snapshot

5. To copy the DB snapshot to a different AWS Region, set **Destination Region** to the required value.

   > **Note**
   >
   > The destination AWS Region must have the same database engine version available as the source AWS Region.

6. For **New DB snapshot identifier**, enter a unique name for the DB snapshot. You can make multiple copies of an automated backup or manual snapshot but each copy must have a unique identifier.
7. (Optional) Select **Copy Tags** to copy tags and values from the snapshot to the copy of the snapshot.
8. For **Encryption**, specify the KMS key identifier to use to encrypt the DB snapshot copy.

   > **Note**
   >
   > RDS Custom for SQL Server encrypts all DB snapshots. You can't create an unencrypted DB snapshot.

9. Choose **Copy snapshot**.

RDS Custom for SQL Server creates a DB snapshot copy of your DB instance in the AWS Region of your selection.

AWS CLI

You can copy a RDS Custom for SQL Server DB snapshot by using the AWS CLI command copy-db-snapshot. If you are copying the snapshot to a new AWS Region, run the command in the new AWS Region. The following options are used to copy a DB snapshot. Not all options are required for all scenarios.

- `--source-db-snapshot-identifier` - The identifier for the source DB snapshot.
  - If the source snapshot is in a different AWS Region than the copy, specify a valid DB snapshot ARN. For example, `arn:aws:rds:us-west-2:123456789012:snapshot:instance1-snapshot-12345678`.
- `--target-db-snapshot-identifier` - The identifier for the new copy of the DB snapshot.

- `--kms-key-id` -The KMS key identifier for an encrypted DB snapshot. The KMS key identifier is the Amazon Resource Name (ARN), key identifier, or key alias for the KMS key.
  - If you copy an encrypted snapshot to a different AWS Region, then you must specify a KMS key for the destination AWS Region. KMS keys are specific to the AWS Region that they are created in and you cannot use encryption keys from one AWS Region in another AWS Region unless a multi-Region key is used. For more information on multi-Region KMS keys, see Using multi-Region keys in AWS KMS.
- `--copy-tags` - Include the tags and values from the source snapshot to the copy of the snapshot.

The following options are not supported for copying an RDS Custom for SQL Server DB snapshot:

- `--copy-option-group`
- `--option-group-name`
- `--pre-signed-url`
- `--target-custom-availability-zone`

The following code example copies an encrypted DB snapshot from the US West (Oregon) Region to the US East (N. Virginia) Region. Run the command in the destination (us-east-1) Region.

For Linux, macOS, or Unix:

```
aws rds copy-db-snapshot \
     --region us-east-1 \
    --source-db-snapshot-identifier arn:aws:rds:us-
west-2:123456789012:snapshot:instance1-snapshot-12345678 \
    --target-db-snapshot-identifier mydbsnapshotcopy \
    --kms-key-id a1b2c3d4-1234-5678-wxyz-a1b2c3d4d5e6
```

For Windows:

```
aws rds copy-db-snapshot ^
     --region us-east-1 ^
    --source-db-snapshot-identifier arn:aws:rds:us-
west-2:123456789012:snapshot:instance1-snapshot-12345678 ^
```

```
    --target-db-snapshot-identifier mydbsnapshotcopy ^
    --kms-key-id a1b2c3d4-1234-5678-wxyz-a1b2c3d4d5e6
```

RDS API

You can copy a RDS Custom for SQL Server DB snapshot by using the Amazon RDS API operation CopyDBSnapshot. If you are copying the snapshot to a new AWS Region, perform the action in the new AWS Region. The following parameters are used to copy a DB snapshot. Not all parameters are required:

- `SourceDBSnapshotIdentifier` - The identifier for the source DB snapshot.
  - If the source snapshot is in a different AWS Region than the copy, specify a valid DB snapshot ARN. For example, `arn:aws:rds:us-west-2:123456789012:snapshot:instance1-snapshot-12345678`.
- `TargetDBSnapshotIdentifier` - The identifier for the new copy of the DB snapshot.
- `KmsKeyId` - The KMS key identifier for an encrypted DB snapshot. The KMS key identifier is the Amazon Resource Name (ARN), key identifier, or key alias for the KMS key.
  - If you copy an encrypted snapshot to a different AWS Region, then you must specify a KMS key for the destination AWS Region. KMS keys are specific to the AWS Region that they are created in and you cannot use encryption keys from one AWS Region in another AWS Region unless a multi-Region key is used. For more information on multi-Region KMS keys, see Using multi-Region keys in AWS KMS.
- `CopyTags` - Set this parameter to `true` to copy tags and values from the source snapshot to the copy of the snapshot. The default is `false`.

The following options are not supported copying a RDS Custom for SQL Server DB snapshot:

- `CopyOptionGroup`
- `OptionGroupName`
- `PreSignedUrl`
- `TargetCustomAvailabilityZone`

The following code creates a copy of a snapshot, with the new name `mydbsnapshotcopy`, in the US East (N. Virginia) Region.

```
https://rds.us-east-1.amazonaws.com/
```

```
    ?Action=CopyDBSnapshot
    &KmsKeyId=a1b2c3d4-1234-5678-wxyz-a1b2c3d4d5e6
    &SourceDBSnapshotIdentifier=arn%3Aaws%3Ards%3Aus-
west-2%3A123456789012%3Asnapshot%3Ainstance1-snapshot-12345678
    &TargetDBSnapshotIdentifier=mydbsnapshotcopy
    &Version=2014-10-31
    &X-Amz-Algorithm=AWS4-HMAC-SHA256
    &X-Amz-Credential=AKIADQKE4SARGYLE/20161117/us-east-1/rds/aws4_request
    &X-Amz-Date=20161117T221704Z
    &X-Amz-SignedHeaders=content-type;host;user-agent;x-amz-content-sha256;x-amz-
date
    &X-Amz-

```

Migrating an on-premises database to Amazon RDS Custom for SQL Server

You can use the following process to migrate an on-premises Microsoft SQL Server database to Amazon RDS Custom for SQL Server using native backup and restore:

1. Take a full backup of the database on the on-premises DB instance.
2. Upload the backup file to Amazon S3.
3. Download the backup file from S3 to your RDS Custom for SQL Server DB instance.
4. Restore a database using the downloaded backup file on the RDS Custom for SQL Server DB instance.

This process explains the migration of a database from on-premises to RDS Custom for SQL Server, using native full backup and restore. To reduce the cutover time during the migration process, you might also consider using differential or log backups.

For general information about native backup and restore for RDS for SQL Server, see Importing and exporting SQL Server databases using native backup and restore.

Topics

Prerequisites

Perform the following tasks before migrating the database:

1. Configure Remote Desktop Connection (RDP) for your RDS Custom for SQL Server DB instance. For more information, see Connecting to your RDS Custom DB instance using RDP.
2. Configure access to Amazon S3 so you can upload and download the database backup file. For more information, see Integrating an Amazon RDS for SQL Server DB instance with Amazon S3.

Backing up the on-premises database

You use SQL Server native backup to take a full backup of the database on the on-premises DB instance.

The following example shows a backup of a database called `mydatabase`, with the `COMPRESSION` option specified to reduce the backup file size.

To back up the on-premises database

1. Using SQL Server Management Studio (SSMS), connect to the on-premises SQL Server instance.
2. Run the following T-SQL command.

```
backup database mydatabase to
disk ='C:\Program Files\Microsoft SQL Server\MSSQL13.MSSQLSERVER\MSSQL\Backup\mydb-full-compressed.bak'
with compression;
```

Uploading the backup file to Amazon S3

You use the AWS Management Console to upload the backup file `mydb-full-compressed.bak` to Amazon S3.

To upload the backup file to S3

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. For **Buckets**, choose the name of the bucket to which you want to upload your backup file.
3. Choose **Upload**.
4. In the **Upload** window, do one of the following:

   - Drag and drop `mydb-full-compressed.bak` to the **Upload** window.
   - Choose **Add file**, choose `mydb-full-compressed.bak`, and then choose **Open**.

   Amazon S3 uploads your backup file as an S3 object. When the upload completes, you can see a success message on the **Upload: status** page.

Downloading the backup file from Amazon S3

You use the console to download the backup file from S3 to the RDS Custom for SQL Server DB instance.

To download the backup file from S3

1. Using RDP, connect to your RDS Custom for SQL Server DB instance.
2. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
3. In the **Buckets** list, choose the name of the bucket that contains your backup file.
4. Choose the backup file `mydb-full-compressed.bak`.
5. For **Actions**, choose **Download as**.
6. Open the context (right-click) menu for the link provided, then choose **Save As**.
7. Save `mydb-full-compressed.bak` to the `D:\rdsdbdata\BACKUP` directory.

Restoring the backup file to the RDS Custom for SQL Server DB instance

You use SQL Server native restore to restore the backup file to your RDS Custom for SQL Server DB instance.

In this example, the `MOVE` option is specified because the data and log file directories are different from the on-premises DB instance.

To restore the backup file

1. Using SSMS, connect to your RDS Custom for SQL Server DB instance.
2. Run the following T-SQL command.

```
restore database mydatabase from disk='D:\rdsdbdata\BACKUP\mydb-full-
compressed.bak'
with move 'mydatabase' to 'D:\rdsdbdata\DATA\mydatabase.mdf',
move 'mydatabase_log' to 'D:\rdsdbdata\DATA\mydatabase_log.ldf';
```

Upgrading a DB instance for Amazon RDS Custom for SQL Server

You can upgrade an Amazon RDS Custom for SQL Server DB instance by modifying it to use a new DB engine version, the same as you do for Amazon RDS.

The same limitations for upgrading an RDS Custom for SQL Server DB instance apply as for modifying an RDS Custom for SQL Server DB instance in general. For more information, see Modifying an RDS Custom for SQL Server DB instance.

For general information about upgrading DB instances, see Upgrading a DB instance engine version.

If you upgrade an RDS Custom for SQL Server DB instance in a Multi-AZ deployment, then Amazon RDS performs rolling upgrades, so you have an outage only for the duration of a failover. For more information, see Multi-AZ and in-memory optimization considerations.

Major version upgrades

Amazon RDS Custom for SQL Server currently supports the following major version upgrades.

Current version	Supported upgrade versions
SQL Server 2019	SQL Server 2022

You can use an AWS CLI query, such as the following example, to find the available upgrades for a particular database engine version.

Example

For Linux, macOS, or Unix:

```
aws rds describe-db-engine-versions \
    --engine sqlserver-se \
    --engine-version 15.00.4322.2.v1 \
    --query "DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}" \
    --output table
```

For Windows:

```
aws rds describe-db-engine-versions ^
```

```
    --engine sqlserver-se ^
    --engine-version 15.00.4322.2.v1 ^
    --query "DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}" ^
    --output table
```

Database compatibility level

You can use Microsoft SQL Server database compatibility levels to adjust some database behaviors to mimic previous versions of SQL Server. For more information, see Compatibility level in the Microsoft documentation.

When you upgrade your DB instance, all existing databases remain at their original compatibility level. For example, if you upgrade from SQL Server 2019 to SQL Server 2022, all existing databases have a compatibility level of 150. Any new database created after the upgrade have compatibility level 160.

You can change the compatibility level of a database by using the ALTER DATABASE command. For example, to change a database named `customeracct` to be compatible with SQL Server 2022, issue the following command:

```
ALTER DATABASE customeracct SET COMPATIBILITY_LEVEL = 160
```

Troubleshooting DB issues for Amazon RDS Custom for SQL Server

The shared responsibility model of RDS Custom provides OS shell–level access and database administrator access. RDS Custom runs resources in your account, unlike Amazon RDS, which runs resources in a system account. With greater access comes greater responsibility. In the following sections, you can learn how to troubleshoot issues with Amazon RDS Custom for SQL Server DB instances.

> **Note**
>
> This section explains how to troubleshoot RDS Custom for SQL Server. For troubleshooting RDS Custom for Oracle, see Troubleshooting DB issues for Amazon RDS Custom for Oracle.

Topics

Viewing RDS Custom events

The procedure for viewing events is the same for RDS Custom and Amazon RDS DB instances. For more information, see Viewing Amazon RDS events.

To view RDS Custom event notification using the AWS CLI, use the `describe-events` command. RDS Custom introduces several new events. The event categories are the same as for Amazon RDS. For the list of events, see Amazon RDS event categories and event messages.

The following example retrieves details for the events that have occurred for the specified RDS Custom DB instance.

```
aws rds describe-events \
    --source-identifier my-custom-instance \
```

```
    --source-type db-instance
```

Subscribing to RDS Custom events

The procedure for subscribing to events is the same for RDS Custom and Amazon RDS DB instances. For more information, see Subscribing to Amazon RDS event notification.

To subscribe to RDS Custom event notification using the CLI, use the `create-event-subscription` command. Include the following required parameters:

- `--subscription-name`
- `--sns-topic-arn`

The following example creates a subscription for backup and recovery events for an RDS Custom DB instance in the current AWS account. Notifications are sent to an Amazon Simple Notification Service (Amazon SNS) topic, specified by `--sns-topic-arn`.

```
aws rds create-event-subscription \
    --subscription-name my-instance-events \
    --source-type db-instance \
    --event-categories '["backup","recovery"]' \
    --sns-topic-arn arn:aws:sns:us-east-1:123456789012:interesting-events
```

Troubleshooting CEV errors for RDS Custom for SQL Server

When you try to create a CEV, it might fail. In this case, RDS Custom issues the `RDS-EVENT-0198` event message. For more information on viewing RDS events, see Amazon RDS event categories and event messages.

Use the following information to help you address possible causes.

Message	Troubleshooting suggestions		
`Custom Engine Version creation expected a Sysprep'd AMI. Retry creation using a Sysprep'd AMI.`	Run Sysprep on the EC2 instance that you created from the AMI. For more information about prepping an AMI using Sysprep, see Create a standardized Amazon Machine Image (AMI) using Sysprep.		

Message	Troubleshooting suggestions
EC2 Image permissions for image (AMI_ID) weren't found for customer (Customer_ID). Verify customer (Customer_ID) has valid permissions on the EC2 Image.	Verify that your account and profile used for creation has the required permissions on create EC2 Instance and Describe Images for the selected AMI.
Failed to rebuild databases with server collation (collation name) due to missing setup.exe file for SQL Server.	Verify that the setup file is available at C:\Program Files\Microsoft SQL Server\nnn\Setup Bootstrap\SQLnnnn\setup.exe .
Image (AMI_ID) doesn't exist in your account (ACCOUNT_ID). Verify (ACCOUNT_ID) is the owner of the EC2 image.	Ensure the AMI exists in the same customer account.
Image id (AMI_ID) isn't valid. Specify a valid image id, and try again.	The name of the AMI is incorrect . Ensure the correct AMI ID is provided.

Message	Troubleshooting suggestions
`Image (AMI_ID) operating system platform isn't supported. Specify a valid image, and try again.`	Choose a supported AMI that has Windows Server with SQL Server Enterprise, Standard, or Web edition. Choose an AMI with one of the following usage operation codes from the EC2 Marketplace: • RunInstances:0102 - Windows with SQL Server Enterprise • RunInstances:0006 - Windows with SQL Server Standard • RunInstances:0202 - Windows with SQL Server Web
`SQL Server Web Edition isn't supported for creating a Custom Engine Version using Bring Your Own Media. Specify a valid image, and try again.`	Use an AMI that contains a supported edition of SQL Server. For more information, see Version support for RDS Custom for SQL Server CEVs.
`The custom engine version can't be the same as the OEV engine version. Specify a valid CEV, and try again.`	Classic RDS Custom for SQL Server engine versions aren't supported . For example, version **15.00.4073.23.v1**. Use a supported version number.
`The custom engine version isn't in an active state. Specify a valid CEV, and try again.`	The CEV must be in an `AVAILABLE` state to complete the operation. Modify the CEV from `INACTIVE` to `AVAILABLE` .

Message	Troubleshooting suggestions
`The custom engine version isn't valid for an upgrade. Specify a valid CEV with an engine version greater or equal to (X), and try again.`	The target CEV is not valid. Check the requirements for a valid upgrade path.
`The custom engine version isn't valid. Names can include only lowercase letters (a-z), dashes (-), underscores (_), and periods (.). Specify a valid CEV, and try again.`	Follow the required CEV naming convention. For more information, see Requirements for RDS Custom for SQL Server CEVs.
`The custom engine version isn't valid. Specify valid database engine version, and try again. Example: 15.00.4073.23-cev123.`	An unsupported DB engine version was provided. Use a supported DB engine version.
`The expected architecture is (X) for image (AMI_ID), but architecture (Y) was found.`	Use an AMI built on the **x86_64** architecture.
`The expected owner of image (AMI_ID) is customer account ID (ACCOUNT_ID), but owner (ACCOUNT_ID) was found.`	Create the EC2 instance from the AMI that you have permission for. Run Sysprep on the EC2 instance to create and save a base image.
`The expected platform is (X) for image (AMI_ID), but platform (Y) was found.`	Use an AMI built with the Windows platform.

Message	Troubleshooting suggestions
`The expected root device type is (X) for image %s, but root device type (Y) was found.`	Create the AMI with the EBS device type.
`The expected SQL Server edition is (X), but (Y) was found.`	Choose a supported AMI that has Windows Server with SQL Server Enterprise, Standard, or Web edition. Choose an AMI with one of the following usage operation codes from the EC2 Marketplace: • RunInstances:0102 - Windows with SQL Server Enterprise • RunInstances:0006 - Windows with SQL Server Standard • RunInstances:0202 - Windows with SQL Server Web
`The expected state is (X) for image (AMI_ID), but the following state was found: (Y).`	Ensure the AMI is in a state of `AVAILABLE` .
`The provided Windows OS name (X) isn't valid. Make sure the OS is one of the following: (Y).`	Use a supported Windows OS.
`Unable to find bootstrap log file in path.`	Verify that the log file is available at `C:\Program Files\Microsoft SQL Server\nnn\Setup Bootstrap\Log\Summary.txt` .

Message	Troubleshooting suggestions
`RDS expected a Windows build version greater than or equal to (X), but found version (Y)..`	Use an AMI with a minimum OS build version of **14393**.
`RDS expected a Windows major version greater than or equal to (X), but found version (Y)..`	Use an AMI with a minimum OS major version of **10.0** or higher.

Fixing unsupported configurations in RDS Custom for SQL Server

Because of the shared responsibility model, it's your responsibility to fix configuration issues that put your RDS Custom for SQL Server DB instance into the `unsupported-configuration` state. If the issue is with the AWS infrastructure, you can use the console or the AWS CLI to fix it. If the issue is with the operating system or the database configuration, you can log in to the host to fix it.

> **Note**
>
> This section explains how to fix unsupported configurations in RDS Custom for SQL Server. For information about RDS Custom for Oracle, see Fixing unsupported configurations in RDS Custom for Oracle.

In the following table, you can find descriptions of the notifications and events that the support perimeter sends and how to fix them. These notifications and the support perimeter are subject to change. For background on the support perimeter, see RDS Custom support perimeter. For event descriptions, see Amazon RDS event categories and event messages.

Event Code	Configuration area	RDS event message	Validation process
`SP-S0000`	Manual Unsupported Configuration	The RDS Custom DB instance status is set to [Unsuppor	To resolve this issue, create a support case.

Event Code	Configuration area	RDS event message	Validation process
		ted configuration] because of: X.	
AWS Resource (infrastructure)			
SP-S1001	EC2 Instance State	The RDS Custom DB instance status is set to [Unsupported configuration] because of: The underlying EC2 instance %s has been stopped without stopping the RDS instance. You can resolve this by starting the underlying EC2 instance and ensuring that the binary and data volumes are attached. If your intention is to stop the RDS instance, make sure that underlying EC2 instance is in the AVAILABLE state first and then use the RDS console or CLI to stop the RDS instance.	To check the status of a DB instance, use the console or run the following AWS CLI command: `aws rds describe-db-instances \ --db-instance-identifier db-instance-name |grep DBInstanceStatus`

Event Code	Configuration area	RDS event message	Validation process

SP-S1002	EC2 Instance State	The RDS Custom DB instance status is set to [Unsupported configuration] because of: The RDS DB instance status is set to STOPPED but the underlying EC2 instance %s has been started. You can resolve this by stopping the underlying EC2 instance. If your intention is to start the RDS instance, use the console or CLI.	Use the following AWS CLI command to check the status of a DB instance:
			`aws rds describe-db-instances \ --db-instance-identifier db-instance-name |grep DBInstanceStatus`
			You can also check the status of the EC2 instance using the EC2 console.
			To start a DB instance, use the console or run the following AWS CLI command:
			`aws rds start-db-instance \ --db-instance-identifier db-instance-name`

Event Code	Configuration area	RDS event message	Validation process
SP-S1003	EC2 Instance Class	The RDS Custom DB instance status is set to [Unsupported configuration] because of: There is a mismatch between the expected and configured DB instance class of the EC2 host. You can resolve this by modifying the DB instance class to its original class type.	Use the following CLI command to check the expected DB instance class: `aws rds describe-db-instances \ --db-instance-identifier db-instance-name |grep DBInstanceClass`
SP-S1004	EBS Storage Volume Not Accessible	The RDS Custom DB instance status is set to [Unsupported configuration] because of: The original EBS storage volume %s that was associated with the EC2 instance is currently not accessible.	

Event Code	Configuration area	RDS event message	Validation process
SP-S1005	EBS Storage Volume Detached	The RDS Custom DB instance status is set to [Unsupported configuration] because of: The original EBS storage volume "volume-id" isn't attached. You can resolve this by attaching the EBS volume associated to the EC2 instance.	After re-attaching the EBS volume, use the following CLI commands to check if the EBS volume 'volume-id' is properly attached to the RDS instance: `aws ec2 describe-volumes \ --volume-ids volume-id |grep InstanceId`

SP-S1006	EBS Storage Volume Size	The RDS Custom DB instance status is set to [Unsupported configuration] because of: There is a mismatch between the expected and configured settings of EBS storage volume "volume-id". The volume size has been changed manually at EC2 level from its original value(s) of [%s]. To resolve this issue, create a support case.	Use the following CLI command to compare the volume size of the EBS volume 'volume-id' details and the RDS instance details:
			`aws rds describe-db-instances \ --db-instance-identifier db-instance-name |grep AllocatedStorage`
			Use the following CLI command to view the actual allocated volume size:
			`aws ec2 describe-volumes \ --volume-ids |grep Size`

Event Code	Configuration area	RDS event message	Validation process

SP-S1007	EBS Storage Volume Configuration	The RDS Custom DB instance status is set to [Unsupported configuration] because of: There is a mismatch between the expected and configured settings of EBS storage volume "volume-id". You can resolve this by modifying the EBS storage volume configuration [IOPS, Throughput, Volume type] to its original value(s) of [IOPS: %s, Throughput: %s, Volume type: %s] at the EC2 level. For future storage modifications, use the RDS console or CLI. The volume size has also been changed manually at EC2 level from its original value(s) of [%s]. To resolve this issue, create a support case.	Use the following CLI command to compare the volume type of the EBS volume 'volume-id' details and the RDS instance details. Make sure that the values at the EBS level matches the values at the RDS level:
			`aws rds describe-db-instances \ --db-instance-identifier db-instance-name |grep StorageType`
			To get the expected value for Storage Throughput at the RDS level:
			`aws rds describe-db-instances \ --db-instance-identifier db-instance-name |grep StorageThroughput`
			To get the expected value for Volume IOPS at the RDS level:
			`aws rds describe-db-instances \ --db-instance-identifier db-instance-name |grep Iops`
			To get the current Storage Type at the EC2 Level:

Event Code	Configuration area	RDS event message	Validation process

			`aws ec2 describe-volumes \ --volume-ids |grep VolumeTyp e`
			
			To get the current value for Storage Throughput at the EC2 Level:
			
			`aws ec2 describe-volumes \ --volume-ids |grep Throughpu t`
			
			To get the current value for Volume IOPS at the EC2 Level:
			
			`aws ec2 describe-volumes \ --volume-ids |grep Iops`

Event Code	Configuration area	RDS event message	Validation process

SP-S1008	EBS Storage Volume Size and Configuration	The RDS Custom DB instance status is set to [Unsupported configuration] because of: There is a mismatch between the expected and configured settings of EBS storage volume "volume-id". You can resolve this by modifying the EBS storage volume configuration [IOPS, Throughput, Volume type] to its original value(s) of [IOPS: %s, Throughput: %s, Volume type: %s] at the EC2 level. For future storage modifications, use the RDS console or CLI. The volume size has also been changed manually at EC2 level from its original value(s) of [%s]. To resolve this issue, create a support case.	Use the following CLI command to compare the volume type of the EBS volume 'volume-id' details and the RDS instance details. Make sure that the values at the EBS level matches the values at the RDS level:
			`aws rds describe-db-instances \ --db-instance-identifier *db-instance-name* |grep StorageType`
			To get the expected value for Storage Throughput at the RDS level:
			`aws rds describe-db-instances \ --db-instance-identifier *db-instance-name* |grep StorageThroughput`
			To get the expected value for Volume IOPS at the RDS level:
			`aws rds describe-db-instances \ --db-instance-identifier *db-instance-name* |grep Iops`
			To get the current Storage Type at the EC2 Level:

Event Code	Configuration area	RDS event message	Validation process

			`aws ec2 describe-volumes \ --volume-ids |grep VolumeTyp e`
			
			To get the current value for Storage Throughput at the EC2 Level:
			
			`aws ec2 describe-volumes \ --volume-ids |grep Throughpu t`
			
			To get the current value for Volume IOPS at the EC2 Level:
			
			`aws ec2 describe-volumes \ --volume-ids |grep Iops`
			
			To get the expected Allocated Volume Size:
			
			`aws rds describe-db-instan ces \ --db-instance-identifier *db-instance-name* |grep Allocated Storage`
			
			To get the actual Allocated Volume Size:
			
			`aws ec2 describe-volumes \ --volume-ids |grep Size`

Event Code	Configuration area	RDS event message	Validation process
SP-S1009	SQS Permissions	The RDS Custom DB instance status is set to [Unsupported configuration] because of: Amazon Simple Queue Service (SQS) permissions are missing for the IAM instance profile. You can resolve this by making sure the IAM profile associated with the host has the following permissions: ["SQS:SendMessage","SQS:ReceiveMessage","SQS:DeleteMessage","SQS:GetQueueUrl"].	

Event Code	Configuration area	RDS event message	Validation process
SP-S1010	SQS VPC Endpoint	The RDS Custom DB instance status is set to [Unsupported configuration] because of: A VPC endpoint policy is blocking the Amazon Simple Queue Service (SQS) operations. You can resolve this by modifying your VPC endpoint policy to allow the required SQS actions.	
Operating System			

Event Code	Configuration area	RDS event message	Validation process
SP-S2001	SQL Service Status	The RDS Custom DB instance status is set to [Unsupported configuration] because of: The SQL Server service isn't started. You can resolve this by restarting the SQL Server service on the host. If this DB instance is a Multi-AZ DB instance and restart fails, then stop and start the host to initiate a failover.	

Event Code	Configuration area	RDS event message	Validation process
SP-S2002	RDS Custom Agent Status	The RDS Custom DB instance status is set to [Unsupported configuration] because of: The RDS Custom Agent service isn't installed or couldn't be started. You can resolve this by reviewing the Windows Event Log to determine why the service won't start, and take appropriate steps to fix the issue. For additional assistance, create a support case.	

Event Code	Configuration area	RDS event message	Validation process
SP-S1009	SQS Permissions	The RDS Custom DB instance status is set to [Unsupported configuration] because of: Amazon Simple Queue Service (SQS) permissions are missing for the IAM instance profile. You can resolve this by making sure the IAM profile associated with the host has the following permissions: ["SQS:SendMessage","SQS:ReceiveMessage","SQS:DeleteMessage","SQS:GetQueueUrl"].	

Event Code	Configuration area	RDS event message	Validation process
SP-S1010	SQS VPC Endpoint	The RDS Custom DB instance status is set to [Unsupported configuration] because of: A VPC endpoint policy is blocking the Amazon Simple Queue Service (SQS) operations. You can resolve this by modifying your VPC endpoint policy to allow the required SQS actions.	
Operating System			

Event Code	Configuration area	RDS event message	Validation process
SP-S2001	SQL Service Status	The RDS Custom DB instance status is set to [Unsupported configuration] because of: The SQL Server service isn't started. You can resolve this by restarting the SQL Server service on the host. If this DB instance is a Multi-AZ DB instance and restart fails, then stop and start the host to initiate a failover.	

Event Code	Configuration area	RDS event message	Validation process

SP-S2002	RDS Custom Agent Status	The RDS Custom DB instance status is set to [Unsupported configuration] because of: The RDS Custom Agent service isn't installed or couldn't be started. You can resolve this by reviewing the Windows Event Log to determine why the service won't start, and take appropriate steps to fix the issue. For additional assistance, create a support case.	Log in to the host and make sure that the RDS Custom agent is running.
			
			You can use the following commands to view the agent status.
			
			`$name = "RDSCustomAgent"`
			`$service = Get-Service $name`
			`Write-Host $service.Status`
			
			If the status isn't Running, you can start the service with the following command:
			
			`Start-Service $name`
			
			If the agent can't start, check the Windows Events to see why it can't start. The agent requires a Windows user to start the service. Ensure a Windows user exists and has privileges to run the service.

Event Code	Configuration area	RDS event message	Validation process
SP-S2003	SSM Agent Status	The RDS Custom DB instance status is set to [Unsupported configuration] because of: The Amazon SSM Agent service is unreachable. You can troubleshoot this by checking the service status with the `Get-Service AmazonSSMAgent` PowerShell command, or starting the service with `Start-Service AmazonSSMAgent`. Ensure that HTTPS (port 443) outbound traffic to the **ssm**, **ssmmessages**, and **ec2messages** regional endpoints is allowed.	For more information, see Troubleshooting SSM Agent. To troubleshoot SSM endpoints, see Unable to connect to SSM endpoints and Use ssm-cli to troubleshoot managed node availability.

Event Code	Configuration area	RDS event message	Validation process
SP-S2004	RDS Custom Agent Login	SP-S2004 The RDS Custom DB instance status is set to [Unsupported configuration] because of: An unexpected issue occurred with the SQL login "$HOSTNAME/RDSAgent" . To resolve this issue, create a support case.	

Event Code	Configuration area	RDS event message	Validation process
SP-S2005	Timezone	The RDS Custom DB instance status is set to [Unsupported configuration] because of: The timezone on the Amazon EC2 Instance [%s] was changed. You can resolve this by modifying the time zone back to the setting specified during instance creation. If you would like to create an instance with a specific timezone, see the RDS Custom documentation.	Run the `Get-Timezone` PowerShell command to confirm the timezone. For more information, see Local time zone for RDS Custom for SQL Server DB instances.

Event Code	Configuration area	RDS event message	Validation process
SP-S2006	High Availability Software Solution Version	The RDS Custom DB instance status is set to [Unsupported configuration] because of: The high availability software solution of the current instance is different from the expected version. To resolve this issue, create a support case.	

Event Code	Configuration area	RDS event message	Validation process
SP-S2007	High Availability Software Solution Configuration	The RDS Custom DB instance status is set to [Unsupported configuration] because of: The configuration settings of the high availability software solution have been modified to unexpected values on the instance %s. To fix this issue, reboot the EC2 instance. When you reboot the EC2 instance, it automatically updates the settings to the required configuration for the high availability software solution.	
Database			

Event Code	Configuration area	RDS event message	Validation process
SP-S3001	SQL Server Shared Memory Protocol	The RDS Custom DB instance status is set to [Unsupported configuration] because of: The SQL Server shared memory protocol is disabled. You can resolve this by enabling the shared memory protocol in SQL Server Configuration Manager.	You can validate this by checking: **SQL Server Configuration Manager > SQL Server Network Configuration > Protocols for MSSQLSERVER> Shared Memory** as Enabled. After you enable the protocol, restart the SQL Server process.
SP-S3002	Service Master Key	The RDS Custom DB instance status is set to [Unsupported configuration] because of: RDS Automation is unable to take the backup of Service Master Key (SMK) as part of the new SMK generation. To resolve this issue, create a support case.	

Event Code	Configuration area	RDS event message	Validation process
SP-S3003	Service Master Key	The RDS Custom DB instance status is set to [Unsupported configuration] because of: The metadata related to the Service Master Key (SMK) is missing or incomplete. To resolve this issue, create a support case.	

Event Code	Configuration area	RDS event message	Validation process

SP-S3004	DB Engine Version and Edition	There is a mismatch between the expected and installed SQL Server version and edition. Modifying the SQL Server edition is not supported on RDS Custom for SQL Server. Also, manually changing the SQL Server version on the RDS Custom EC2 instance is not supported. To resolve this issue, create a support case.	Run the following query to get the SQL version:
			`select @@version`
			Run the following AWS CLI command to get the RDS SQL engine version and edition:
			`aws rds describe-db-instances \ --db-instance-identifier db-instance-name |grep EngineVersion`
			`aws rds describe-db-instances \ --db-instance-identifier db-instance-name |grep Engine`
			For more information, see Modifying an RDS Custom for SQL Server DB instance and Upgrading a DB instance engine version.

Event Code	Configuration area	RDS event message	Validation process

SP-S3005	DB Engine Edition	The current SQL Server edition doesn't match the expected SQL Server edition [%s]. Modifying the SQL Server edition is not supported on RDS Custom for SQL Server. To resolve this issue, create a support case.	Run the following query to get the SQL edition:
			Example
			`select @@version`
			Run the following AWS CLI command to get the RDS SQL engine edition:
			`aws rds describe-db-instances \ --db-instance-identifier db-instance-name |grep Engine`

Event Code	Configuration area	RDS event message	Validation process

SP-S3006	DB Engine Version	The current SQL Server version doesn't match the expected SQL Server version [%s]. You can't manually change the SQL Server version on the RDS Custom EC2 instance. To resolve this issue, create a support case. For any future modifications to SQL Server version, you can modify the instance from the AWS RDS console or through the modify-db-instance CLI command.	Run the following query to get the SQL version:
			Example
			`select @@version`
			Run the following AWS CLI command to get the RDS SQL engine version:
			`aws rds describe-db-instances \ --db-instance-identifier db-instance-name |grep EngineVersion`
			For more information, see Modifying an RDS Custom for SQL Server DB instance and Upgrading a DB instance engine version.

Event Code	Configuration area	RDS event message	Validation process

SP-S3007	Database file location	The RDS Custom DB instance status is set to [Unsupported configuration] because of: Database files are configured outside of the D:\ drive. You can resolve this by making sure that all database files, including ROW, LOG, FILESTREAM, etc... are stored on the D:\ drive.	Run the following query to list the location of database files that aren't in the default path:
			`USE master;`
			`SELECT physical_name as files_not_in_default_path`
			`FROM sys.master_files`
			`WHERE SUBSTRING(physical_name,1,3)!='D:\';`

Troubleshooting `Storage-Full` in RDS Custom for SQL Server

RDS Custom monitors the available space on both the root (C:) and data (D:) volumes of an RDS Custom for SQL Server DB instance. RDS Custom moves the instance state to the `Storage-Full` status when either volume has less than 500 MiB disk space available. To scale the instance storage, see Modifying the storage for an RDS Custom for SQL Server DB instance.

> **Note**
>
> Instances in `Storage-Full` can take up to 30 minutes to resolve after scaling storage.

Troubleshooting PENDING_RECOVERY state for TDE enabled databases in RDS Custom for SQL Server

SQL Server databases with transparent data encryption (TDE) enabled might remain in `PENDING_RECOVERY` state if the automatic decryption runs into issues. This typically occurs after

a DB instance restore if the source DB instance Service Master Key (SMK) backup file stored in the RDS Custom managed S3 bucket in your account has been deleted prior to the restore completion.

To enable the automatic decryption and bring the TDE enabled databases online, you need to open the Database Master Key (DMK) with its password and ecrypt the DMK using the SMK.

Use the following SQL Server commands for reference:

```
-- Identify PENDING_RECOVERY TDE databases
USE MASTER;
GO
SELECT name, is_encrypted, state_desc FROM sys.databases;
GO

-- Open DMK using password
OPEN MASTER KEY DECRYPTION BY PASSWORD = '<password>';
GO

-- Encrypt DMK using SMK
ALTER MASTER KEY ADD ENCRYPTION BY SERVICE MASTER KEY;
GO

-- Close SMK
CLOSE MASTER KEY;
GO

-- Bring the TDE databases online
ALTER DATABASE <database_name> SET ONLINE;
GO

-- Verify TDE databases are now in ONLINE state
SELECT name, is_encrypted, state_desc FROM sys.databases;
GO
```

Working with Amazon RDS on AWS Outposts

Amazon RDS on AWS Outposts extends RDS for SQL Server, RDS for MySQL, and RDS for PostgreSQL databases to AWS Outposts environments. AWS Outposts uses the same hardware as in public AWS Regions to bring AWS services, infrastructure, and operation models on-premises. With RDS on Outposts, you can provision managed DB instances close to the business applications that must run on-premises. For more information about AWS Outposts, see AWS Outposts.

You use the same AWS Management Console, AWS CLI, and RDS API to provision and manage on-premises RDS on Outposts DB instances as you do for RDS DB instances running in the AWS Cloud. RDS on Outposts automates tasks, such as database provisioning, operating system and database patching, backup, and long-term archival in Amazon S3.

RDS on Outposts supports automated backups of DB instances. Network connectivity between your Outpost and your AWS Region is required to back up and restore DB instances. All DB snapshots and transaction logs from an Outpost are stored in your AWS Region. From your AWS Region, you can restore a DB instance from a DB snapshot to a different Outpost. For more information, see Introduction to backups.

RDS on Outposts supports automated maintenance and upgrades of DB instances. For more information, see Maintaining a DB instance.

RDS on Outposts uses encryption at rest for DB instances and DB snapshots using your AWS KMS key. For more information about encryption at rest, see Encrypting Amazon RDS resources.

By default, EC2 instances in Outposts subnets can use the Amazon Route 53 DNS Service to resolve domain names to IP addresses. You might encounter longer DNS resolution times with Route 53, depending on the path latency between your Outpost and the AWS Region. In such cases, you can use the DNS servers installed locally in your on-premises environment. For more information, see DNS in the *AWS Outposts User Guide*.

When network connectivity to the AWS Region isn't available, your DB instance continues to run locally. You can continue to access DB instances using DNS name resolution by configuring a local DNS server as a secondary server. However, you can't create new DB instances or modify existing DB instances. Automatic backups don't occur when there is no connectivity. If there is a DB instance failure, the DB instance isn't automatically replaced until connectivity is restored. We recommend restoring network connectivity as soon as possible.

Topics

Prerequisites for Amazon RDS on AWS Outposts

The following are prerequisites for using Amazon RDS on AWS Outposts:

- Install AWS Outposts in your on-premises data center. For more information about AWS Outposts, see AWS Outposts.
- Make sure that you have at least one subnet available for RDS on Outposts. You can use the same subnet for other workloads.
- Make sure that you have a reliable network connection between your Outpost and an AWS Region.

Amazon RDS on AWS Outposts support for Amazon RDS features

The following table describes the Amazon RDS features supported by Amazon RDS on AWS Outposts.

Feature	Supported	Notes	More information

DB instance provisioning	Yes	You can only create DB instances for RDS for SQL Server, RDS for MySQL, and RDS for PostgreSQL DB engines. The following versions are supported:
		• Microsoft SQL Server:
		  • 15.00.4043.16.v1 and higher 2019 versions
		  • 14.00.3294.2.v1 and higher 2017 versions
		  • 13.00.5820.21.v1 and higher 2016 versions
		• MySQL version 8.0.28 and higher MySQL 8.0 versions
		• All PostgreSQL 16 & 15 & 14 & 13 versions, and PostgreSQL version 12.5 and higher PostgreSQL 12 versions
			Creating DB instances for Amazon RDS on AWS Outposts

Connect to a Microsoft SQL Server DB instance with Microsoft	Yes	Some TLS versions and encryption ciphers might not be secure. To turn them off, follow the instructions in Configuri	Connecting to a DB instance running the Microsoft SQL Server database engine

Feature	Supported	Notes	More information
SQL Server Management Studio		ng security protocols and ciphers.	
Modifying the master user password	Yes	—	Modifying an Amazon RDS DB instance
Renaming a DB instance	Yes	—	Modifying an Amazon RDS DB instance
Rebooting a DB instance	Yes	—	Rebooting a DB instance
Stopping a DB instance	Yes	—	Stopping an Amazon RDS DB instance temporarily
Starting a DB instance	Yes	—	Starting an Amazon RDS DB instance that was previously stopped
Multi-AZ deployments	Yes	Multi-AZ deployments are supported on MySQL and PostgreSQL DB instances. Multi-AZ deployments do not support Direct VPC Routing (DVR).	Creating DB instances for Amazon RDS on AWS Outposts Configuring and managing a Multi-AZ deployment
DB parameter groups	Yes	—	Parameter groups for Amazon RDS

Feature	Supported	Notes	More information
Read replicas	Yes	Read replicas are supported for MySQL and PostgreSQL DB instances. Read replicas do not support Direct VPC Routing (DVR).	Creating read replicas for Amazon RDS on AWS Outposts
Encryption at rest	Yes	RDS on Outposts doesn't support unencrypted DB instances.	Encrypting Amazon RDS resources
AWS Identity and Access Management (IAM) database authentication	No	—	IAM database authentication for MariaDB, MySQL, and PostgreSQL
Associating an IAM role with a DB instance	No	—	add-role-to-db-instance AWS CLI command AddRoleToDBInstance RDS API operation
Kerberos authentication	No	—	Kerberos authentication
Tagging Amazon RDS resources	Yes	—	Tagging Amazon RDS resources
Option groups	Yes	—	Working with option groups
Modifying the maintenance window	Yes	—	Maintaining a DB instance

Feature	Supported	Notes	More information
Automatic minor version upgrade	Yes	—	Automatically upgrading the minor engine version
Modifying the backup window	Yes	—	Introduction to backups Modifying an Amazon RDS DB instance
Changing the DB instance class	Yes	—	Modifying an Amazon RDS DB instance
Changing the allocated storage	Yes	—	Modifying an Amazon RDS DB instance
Storage autoscaling	Yes	—	Managing capacity automatically with Amazon RDS storage autoscaling

Feature	Supported	Notes	More information
Manual and automatic DB instance snapshots	Yes	You can store automated backups and manual snapshots in your AWS Region. Or you can store them locally on your Outpost. Local backups are supported on MySQL and PostgreSQL DB instances. To store backups on your Outpost, make sure that you have Amazon S3 on Outposts configured. Local backups are not supported for Multi-AZ instance deployments.	Creating DB instances for Amazon RDS on AWS Outposts Amazon S3 on Outposts Creating a DB snapshot for a Single-AZ DB instance
Restoring from a DB snapshot	Yes	You can store automated backups and manual snapshots for the restored DB instance in the parent AWS Region or locally on your Outpost.	Considerations for restoring DB instances on Amazon RDS on AWS Outposts Restoring to a DB instance
Restoring a DB instance from Amazon S3	No	—	Restoring a backup into a MySQL DB instance
Exporting snapshot data to Amazon S3	No	—	Exporting DB snapshot data to Amazon S3

Feature	Supported	Notes	More information
Point-in-time recovery	Yes	You can store automated backups and manual snapshots for the restored DB instance in the parent AWS Region or locally on your Outpost, with one exception.	Considerations for restoring DB instances on Amazon RDS on AWS Outposts Restoring a DB instance to a specified time
Enhanced monitoring	No	—	Monitoring OS metrics with Enhanced Monitoring
Amazon CloudWatch monitoring	Yes	You can view the same set of metrics that are available for your databases in the AWS Region.	Monitoring Amazon RDS metrics with Amazon CloudWatch
Publishing database engine logs to CloudWatch Logs	Yes	—	Publishing database logs to Amazon CloudWatch Logs
Event notification	Yes	—	Working with Amazon RDS event notification
Amazon RDS Performance Insights	No	—	Monitoring DB load with Performance Insights on Amazon RDS

Feature	Supported	Notes	More information
Viewing or downloading database logs	No	RDS on Outposts doesn't support viewing database logs using the console or describing database logs using the AWS CLI or RDS API. RDS on Outposts doesn't support downloading database logs using the console or downloading database logs using the AWS CLI or RDS API.	Monitoring Amazon RDS log files
Amazon RDS Proxy	No	—	Using Amazon RDS Proxy
Stored procedures for Amazon RDS for MySQL	Yes	—	RDS for MySQL stored procedure reference
Replication with external databases for RDS for MySQL	No	—	Configuring binary log file position replication with an external source instance
Native backup and restore for Amazon RDS for Microsoft SQL Server	Yes	—	Importing and exporting SQL Server databases using native backup and restore

Supported DB instance classes for Amazon RDS on AWS Outposts

Amazon RDS on AWS Outposts supports the following DB instance classes:

- General purpose DB instance classes
  - db.m5.24xlarge
  - db.m5.16xlarge
  - db.m5.12xlarge
  - db.m5.8xlarge
  - db.m5.4xlarge
  - db.m5.2xlarge
  - db.m5.xlarge
  - db.m5.large
- Memory optimized DB instance classes
  - db.r5.24xlarge
  - db.r5.16xlarge
  - db.r5.12xlarge
  - db.r5.8xlarge
  - db.r5.4xlarge
  - db.r5.2xlarge
  - db.r5.xlarge
  - db.r5.large

Depending on how you've configured your Outpost, you might not have all of these classes available. For example, if you haven't purchased the db.r5 classes for your Outpost, you can't use them with RDS on Outposts.

Only general purpose SSD storage is supported for RDS on Outposts DB instances. For more information about DB instance classes, see DB instance classes.

Amazon RDS manages maintenance and recovery for your DB instances and requires active capacity on the Outpost to do so. We recommend that you configure N+1 EC2 instances for each

DB instance class in your production environments. RDS on Outposts can use the extra capacity of these EC2 instances for maintenance and repair operations. For example, if your production environments have 3 db.m5.large and 5 db.r5.xlarge DB instance classes, then we recommend that they have at least 4 m5.large EC2 instances and 6 r5.xlarge EC2 instances. For more information, see Resilience in AWS Outposts in the *AWS Outposts User Guide*.

Customer-owned IP addresses for Amazon RDS on AWS Outposts

Amazon RDS on AWS Outposts uses information that you provide about your on-premises network to create an address pool. This pool is known as a *customer-owned IP address pool* (CoIP pool). *Customer-owned IP addresses* (CoIPs) provide local or external connectivity to resources in your Outpost subnets through your on-premises network. For more information about CoIPs, see Customer-owned IP addresses in the *AWS Outposts User Guide*.

Each RDS on Outposts DB instance has a private IP address for traffic inside its virtual private cloud (VPC). This private IP address isn't publicly accessible. You can use the **Public** option to set whether the DB instance also has a public IP address in addition to the private IP address. Using the public IP address for connections routes them through the internet and can result in high latencies in some cases.

Instead of using these private and public IP addresses, RDS on Outposts supports using CoIPs for DB instances through their subnets. When you use a CoIP for an RDS on Outposts DB instance, you connect to the DB instance with the DB instance endpoint. RDS on Outposts then automatically uses the CoIP for all connections from both inside and outside of the VPC.

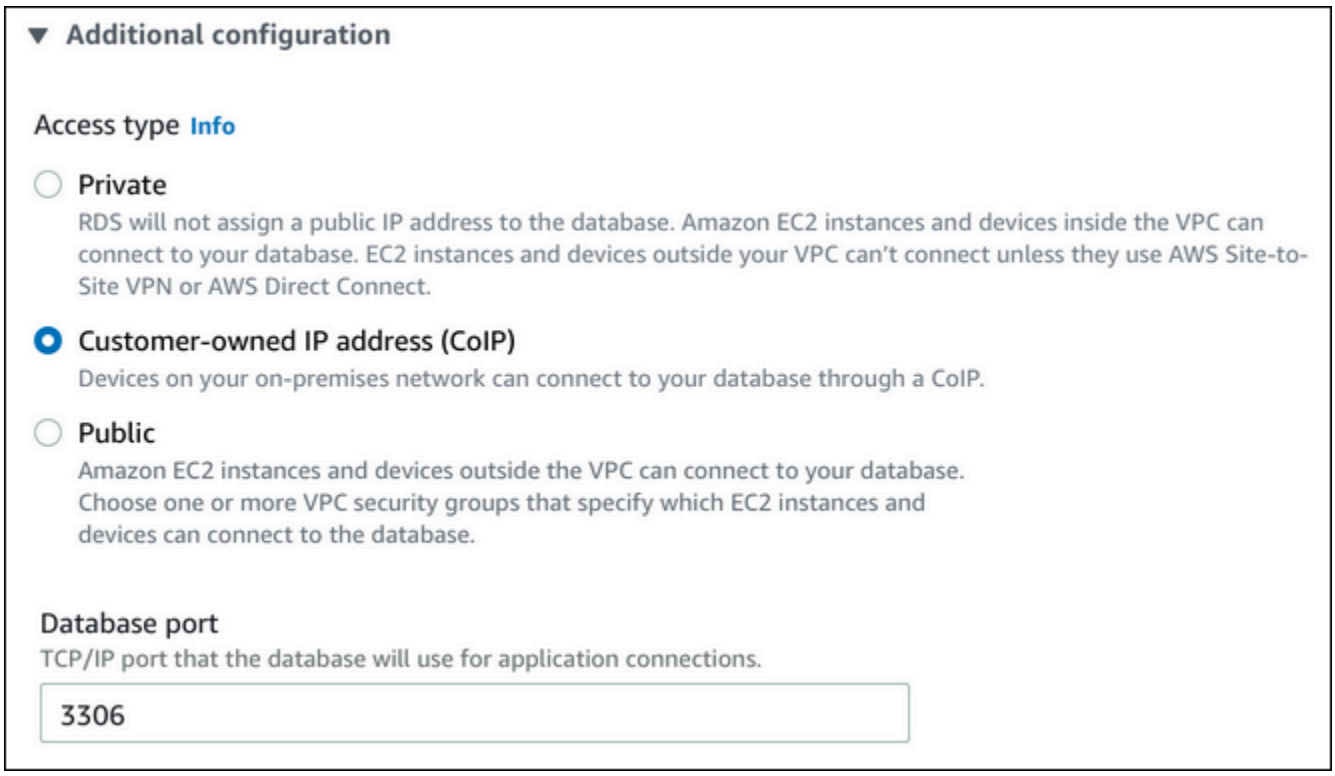
CoIPs can provide the following benefits for RDS on Outposts DB instances:

- Lower connection latency
- Enhanced security

Using CoIPs

You can turn CoIPs on or off for an RDS on Outposts DB instance using the AWS Management Console, the AWS CLI, or the RDS API:

- With the AWS Management Console, choose the **Customer-owned IP address (CoIP)** setting in **Access type** to use CoIPs. Choose one of the other settings to turn them off.



- With the AWS CLI, use the `--enable-customer-owned-ip | --no-enable-customer-owned-ip` option.
- With the RDS API, use the `EnableCustomerOwnedIp` parameter.

You can turn CoIPs on or off when you perform any of the following actions:

- Create a DB instance

  For more information, see Creating DB instances for Amazon RDS on AWS Outposts.
- Modify a DB instance

  For more information, see Modifying an Amazon RDS DB instance.
- Create a read replica

  For more information, see Creating read replicas for Amazon RDS on AWS Outposts.
- Restore a DB instance from a snapshot

  For more information, see Restoring to a DB instance.
- Restore a DB instance to a specified time

For more information, see Restoring a DB instance to a specified time.

> **Note**
>
> In some cases, you might turn on CoIPs for a DB instance but Amazon RDS isn't able to allocate a CoIP for the DB instance. In such cases, the DB instance status is changed to **incompatible-network**. For more information about the DB instance status, see Viewing Amazon RDS DB instance status.

Limitations

The following limitations apply to CoIP support for RDS on Outposts DB instances:

- When using a CoIP for a DB instance, make sure that public accessibility is turned off for that DB instance.
- Make sure that the inbound rules for your VPC security groups include the CoIP address range (CIDR block). For more information about setting up security groups, see Provide access to your DB instance in your VPC by creating a security group.
- You can't assign a CoIP from a CoIP pool to a DB instance. When you use a CoIP for a DB instance, Amazon RDS automatically assigns a CoIP from a CoIP pool to the DB instance.
- You must use the AWS account that owns the Outpost resources (owner) or share the following resources with other AWS accounts (consumers) in the same organization:
  - The Outpost
  - The local gateway (LGW) route table for the DB instance's VPC
  - The CoIP pool or pools for the LGW route table

  For more information, see Working with shared AWS Outposts resources in the *AWS Outposts User Guide*.

Working with Multi-AZ deployments for Amazon RDS on AWS Outposts

For Multi-AZ deployments, Amazon RDS creates a primary DB instance on one AWS Outpost. RDS synchronously replicates the data to a standby DB instance on a different Outpost.

Multi-AZ deployments on AWS Outposts operate like Multi-AZ deployments in AWS Regions, but with the following differences:

- They require a local connection between two or more Outposts.
- They require customer-owned IP (CoIP) pools. For more information, see Customer-owned IP addresses for Amazon RDS on AWS Outposts.
- Replication runs on your local network.

Multi-AZ on AWS Outposts is available for all supported versions of MySQL and PostgreSQL on RDS on Outposts. Local backups aren't supported for Multi-AZ deployments. For more information, see Creating DB instances for Amazon RDS on AWS Outposts.

Working with the shared responsibility model

Although AWS uses commercially reasonable efforts to provide DB instances configured for high availability, the availability uses a shared responsibility model. The ability of RDS on Outposts to fail over and repair DB instances requires each of your Outposts to be connected to its AWS Region.

RDS on Outposts also requires connectivity between the Outpost that is hosting the primary DB instance and the Outpost that is hosting the standby DB instance for synchronous replication. Any impact to this connection can prevent RDS on Outposts from performing a failover.

You might see elevated latencies for a standard DB instance deployment as a result of the synchronous data replication. The bandwidth and latency of the connection between the Outpost hosting the primary DB instance and the Outpost hosting the standby DB instance directly affect latencies. For more information, see Prerequisites.

Improving availability

We recommend the following actions to improve availability:

- Allocate enough additional capacity for your mission-critical applications to allow recovery and failover if there is an underlying host issue. This applies to all Outposts that contain subnets in your DB subnet group. For more information, see Resilience in AWS Outposts.
- Provide redundant network connectivity for your Outposts.
- Use more than two Outposts. Having more than two Outposts allows Amazon RDS to recover a DB instance. RDS does this recovery by moving the DB instance to another Outpost if the current Outpost experiences a failure.
- Provide dual power sources and redundant network connectivity for your Outpost.

We recommend the following for your local networks:

- The round trip time (RTT) latency between the Outpost hosting your primary DB instance and the Outpost hosting your standby DB instance directly affects write latency. Keep the RTT latency between the AWS Outposts in the low single-digit milliseconds. We recommend not more than 5 milliseconds, but your requirements might vary.

  You can find the net impact to network latency in the Amazon CloudWatch metrics for `WriteLatency`. For more information, see Amazon CloudWatch metrics for Amazon RDS.
- The availability of the connection between the Outposts affects the overall availability of your DB instances. Have redundant network connectivity between the Outposts.

Prerequisites

Multi-AZ deployments on RDS on Outposts have the following prerequisites:

- Have at least two Outposts, connected over local connections and attached to different Availability Zones in an AWS Region.
- Make sure that your DB subnet groups contain the following:
  - At least two subnets in at least two Availability Zones in a given AWS Region.
  - Subnets only in Outposts.
  - At least two subnets in at least two Outposts within the same virtual private cloud (VPC).
- Associate your DB instance's VPC with all of your local gateway route tables. This association is necessary because replication runs over your local network using your Outposts' local gateways.

For example, suppose that your VPC contains subnet-A in Outpost-A and subnet-B in Outpost-B. Outpost-A uses LocalGateway-A (LGW-A), and Outpost-B uses LocalGateway-B (LGW-B). LGW-A has RouteTable-A, and LGW-B has RouteTable-B. You want to use both RouteTable-A and RouteTable-B for replication traffic. To do this, associate your VPC with both RouteTable-A and RouteTable-B.

For more information about how to create an association, see the Amazon EC2 create-local-gateway-route-table-vpc-association AWS CLI command.

- Make sure that your Outposts use customer-owned IP (CoIP) routing. Each route table must also each have at least one address pool. Amazon RDS allocates an additional IP address each for the primary and standby DB instances for data synchronization.
- Make sure that the AWS account that owns the RDS DB instances owns the local gateway route tables and CoIP pools. Or make sure it's part of a Resource Access Manager share with access to the local gateway route tables and CoIP pools.
- Make sure that the IP addresses in your CoIP pools can be routed from one Outpost local gateway to the others.
- Make sure that the VPC's CIDR blocks (for example, 10.0.0.0/4) and your CoIP pool CIDR blocks don't contain IP addresses from Class E (240.0.0.0/4). RDS uses these IP addresses internally.
- Make sure that you correctly set up outbound and related inbound traffic.

  RDS on Outposts establishes a virtual private network (VPN) connection between the primary and standby DB instances. For this to work correctly, your local network must allow outbound and related inbound traffic for Internet Security Association and Key Management Protocol (ISAKMP). It does so using User Datagram Protocol (UDP) port 500 and IP Security (IPsec) Network Address Translation Traversal (NAT-T) using UDP port 4500.

For more information on CoIPs, see Customer-owned IP addresses for Amazon RDS on AWS Outposts in this guide, and Customer-owned IP addresses in the *AWS Outposts User Guide*.

Working with API operations for Amazon EC2 permissions

Regardless of whether you use CoIPs for your DB instance on AWS Outposts, RDS requires access to your CoIP pool resources. RDS can call the following EC2 permissions API operations for CoIPs on your behalf for Multi-AZ deployments:

- `CreateCoipPoolPermission` – When you create a Multi-AZ DB instance on RDS on Outposts

- `DeleteCoipPoolPermission` – When you delete a Multi-AZ DB instance on RDS on Outposts

These API operations grant to, or remove from, internal RDS accounts the permission to allocate elastic IP addresses from the CoIP pool specified by the permission. You can view these IP addresses using the `DescribeCoipPoolUsage` API operation. For more information on CoIPs, see Customer-owned IP addresses for Amazon RDS on AWS Outposts and Customer-owned IP addresses in the *AWS Outposts User Guide*.

RDS can also call the following EC2 permission API operations for local gateway route tables on your behalf for Multi-AZ deployments:

- `CreateLocalGatewayRouteTablePermission` – When you create a Multi-AZ DB instance on RDS on Outposts
- `DeleteLocalGatewayRouteTablePermission` – When you delete a Multi-AZ DB instance on RDS on Outposts

These API operations grant to, or remove from, internal RDS accounts the permission to associate internal RDS VPCs with your local gateway route tables. You can view these route table–VPC associations using the `DescribeLocalGatewayRouteTableVpcAssociations` API operations.

Creating DB instances for Amazon RDS on AWS Outposts

Creating an Amazon RDS on AWS Outposts DB instance is similar to creating an Amazon RDS DB instance in the AWS Cloud. However, make sure that you specify a DB subnet group that is associated with your Outpost.

A virtual private cloud (VPC) based on the Amazon VPC service can span all of the Availability Zones in an AWS Region. You can extend any VPC in the AWS Region to your Outpost by adding an Outpost subnet. To add an Outpost subnet to a VPC, specify the Amazon Resource Name (ARN) of the Outpost when you create the subnet.

Before you create an RDS on Outposts DB instance, you can create a DB subnet group that includes one subnet that is associated with your Outpost. When you create an RDS on Outposts DB instance, specify this DB subnet group. You can also choose to create a new DB subnet group when you create your DB instance.

For information about configuring AWS Outposts, see the AWS Outposts User Guide.

Console

Creating a DB subnet group

Create a DB subnet group with one subnet that is associated with your Outpost.

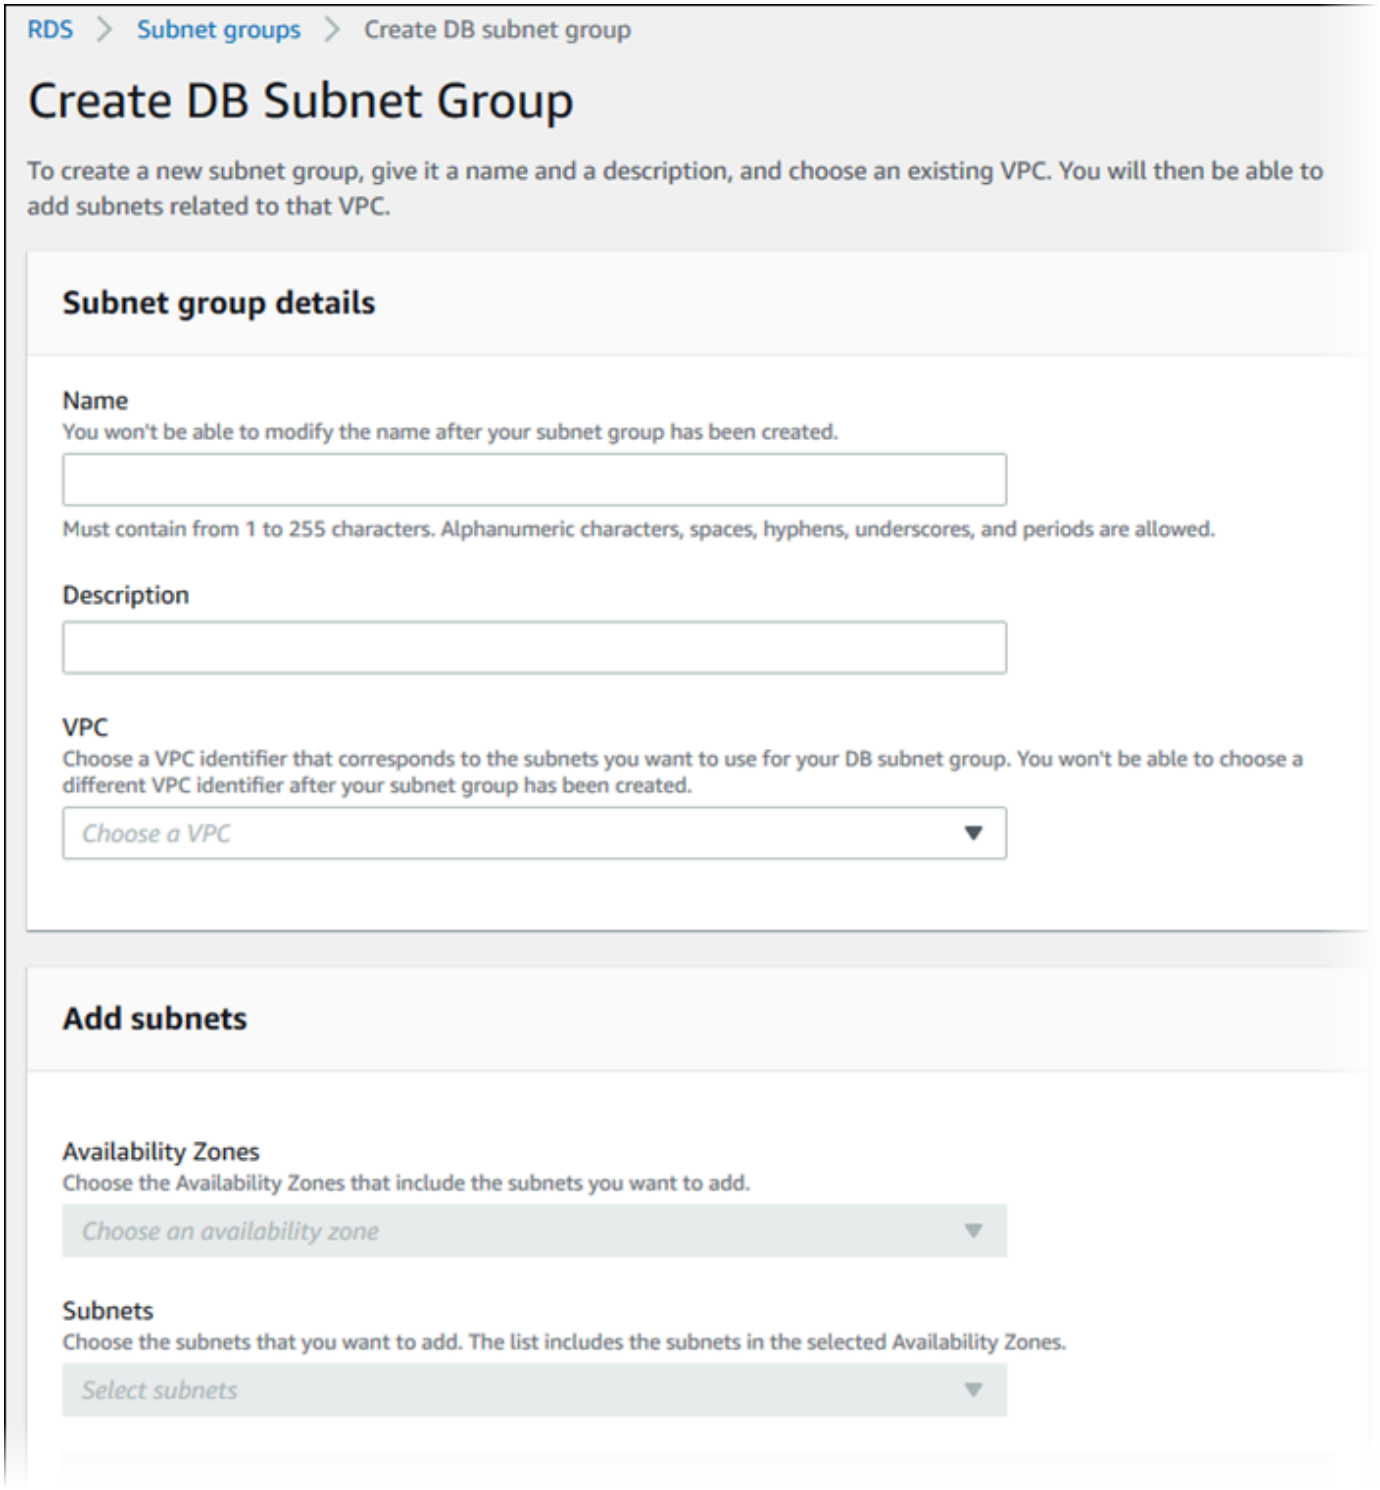
You can also create a new DB subnet group for the Outpost when you create your DB instance. If you want to do so, then skip this procedure.

> **Note**
>
> To create a DB subnet group for the AWS Cloud, specify at least two subnets.

To create a DB subnet group for your Outpost

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the upper-right corner of the Amazon RDS console, choose the AWS Region where you want to create the DB subnet group.
3. Choose **Subnet groups**, and then choose **Create DB Subnet Group**.

The **Create DB subnet group** page appears.



4. For **Name**, choose the name of the DB subnet group.
5. For **Description**, choose a description for the DB subnet group.
6. For **VPC**, choose the VPC that you're creating the DB subnet group for.

7. For **Availability Zones**, choose the Availability Zone for your Outpost.
8. For **Subnets**, choose the subnet for use by RDS on Outposts.
9. Choose **Create** to create the DB subnet group.

Creating the RDS on Outposts DB instance

Create the DB instance, and choose the Outpost for your DB instance.

To create an RDS on Outposts DB instance using the console

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the upper-right corner of the Amazon RDS console, choose the AWS Region where the Outpost on which you want to create the DB instance is attached.
3. In the navigation pane, choose **Databases**.
4. Choose **Create database**.

   The AWS Management Console detects available Outposts that you have configured and presents the **On-premises** option in the **Database location** section.

   > **Note**
   >
   > If you haven't configured any Outposts, either the **Database location** section doesn't appear or the **RDS on Outposts** option isn't available in the **Choose an on-premises creation method** section.

5. For **Database location**, choose **On-premises**.
6. For **On-premises creation method**, choose **RDS on Outposts**.
7. Specify your settings for **Outposts Connectivity**. These settings are for the Outpost that uses the VPC that has the DB subnet group for your DB instance. Your VPC must be based on the Amazon VPC service.

   a. For **Virtual Private Cloud (VPC)**, choose the VPC that contains the DB subnet group for your DB instance.

   b. For **VPC security group**, choose the Amazon VPC security group for your DB instance.

   c. For **DB subnet group**, choose the DB subnet group for your DB instance.

You can choose an existing DB subnet group that's associated with the Outpost—for example, if you performed the procedure in Creating a DB subnet group.

You can also create a new DB subnet group for the Outpost.

8. For **Multi-AZ deployment**, choose **Create a standby instance (recommended for production usage)** to create a standby DB instance in another Outpost.

> **Note**
>
> This option isn't available for Microsoft SQL Server.
> If you choose to create a Multi-AZ deployment, you can't store backups on your Outpost.

9. Under **Backup**, do the following:

   a. For **Backup target**, choose one of the following:

   - **AWS Cloud** to store automated backups and manual snapshots in the parent AWS Region.
   - **Outposts (on-premises)** to create local backups.

   > **Note**
   >
   > To store backups on your Outpost, your Outpost must have Amazon S3 capability. For more information, see Amazon S3 on Outposts.
   > Local backups aren't supported for Multi-AZ deployments or read replicas.

   b. Choose **Enable automated backups** to create point-in-time snapshots of your DB instance.

   If you turn on automated backups, then you can choose values for **Backup retention period** and **Backup window**, or leave the default values.

10. Specify other DB instance settings as needed.

    For information about each setting when creating a DB instance, see Settings for DB instances.

11. Choose **Create database**.

The **Databases** page appears. A banner tells you that your DB instance is being created, and displays the **View credential details** button.

Viewing DB instance details

After you create your DB instance, you can view credentials and other details for it.

To view DB instance details

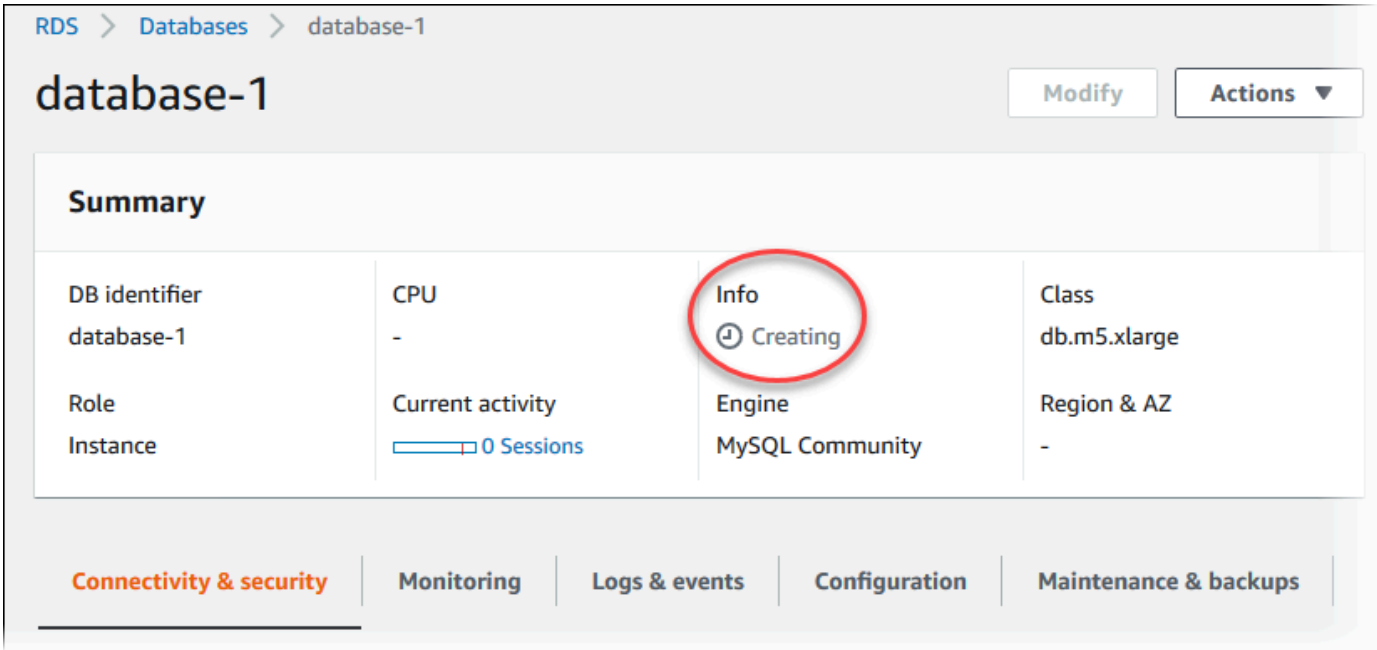
1. To view the master user name and password for the DB instance, choose **View credential details** on the **Databases** page.

   You can connect to the DB instance as the master user by using these credentials.

   > **Important**
   >
   > You can't view the master user password again. If you don't record it, you might have to change it. To change the master user password after the DB instance is available, modify the DB instance. For more information about modifying a DB instance, see Modifying an Amazon RDS DB instance.

2. Choose the name of the new DB instance on the **Databases** page.

   On the RDS console, the details for the new DB instance appear. The DB instance has a status of **Creating** until the DB instance is created and ready for use. When the state changes to **Available**, you can connect to the DB instance. Depending on the DB instance class and storage allocated, it can take several minutes for the new DB instance to be available.



After the DB instance is available, you can manage it the same way that you manage RDS DB instances in the AWS Cloud.

AWS CLI

Before you create a new DB instance in an Outpost with the AWS CLI, first create a DB subnet group for use by RDS on Outposts.

To create a DB subnet group for your Outpost

- Use the create-db-subnet-group command. For `--subnet-ids`, specify the subnet group in the Outpost for use by RDS on Outposts.

  For Linux, macOS, or Unix:

```
aws rds create-db-subnet-group \
    --db-subnet-group-name myoutpostdbsubnetgr \
    --db-subnet-group-description "DB subnet group for RDS on Outposts" \
    --subnet-ids subnet-abc123
```

  For Windows:

```
aws rds create-db-subnet-group ^
    --db-subnet-group-name myoutpostdbsubnetgr ^
```

```
    --db-subnet-group-description "DB subnet group for RDS on Outposts" ^
    --subnet-ids subnet-abc123
```

To create an RDS on Outposts DB instance using the AWS CLI

- Use the create-db-instance command. Specify an Availability Zone for the Outpost, an Amazon VPC security group associated with the Outpost, and the DB subnet group you created for the Outpost. You can include the following options:
  - `--db-instance-identifier`
  - `--db-instance-class`
  - `--engine` – The database engine. Use one of the following values:
    - MySQL – Specify `mysql`.
    - PostgreSQL – Specify `postgres`.
    - Microsoft SQL Server – Specify `sqlserver-ee`, `sqlserver-se`, or `sqlserver-web`.
  - `--availability-zone`
  - `--vpc-security-group-ids`
  - `--db-subnet-group-name`
  - `--allocated-storage`
  - `--max-allocated-storage`
  - `--master-username`
  - `--master-user-password`
  - `--multi-az | --no-multi-az` – (Optional) Whether to create a standby DB instance in a different Availability Zone. The default is `--no-multi-az`.

    The `--multi-az` option isn't available for SQL Server.
  - `--backup-retention-period`
  - `--backup-target` – (Optional) Where to store automated backups and manual snapshots. Use one of the following values:
    - `outposts` – Store them locally on your Outpost.
    - `region` – Store them in the parent AWS Region. This is the default value.

If you use the `--multi-az` option, you can't use `outposts` for `--backup-target`. In addition, the DB instance can't have read replicas if you use `outposts` for `--backup-target`.

- `--storage-encrypted`
- `--kms-key-id`

Example

The following example creates a MySQL DB instance named `myoutpostdbinstance` with backups stored on your Outpost.

For Linux, macOS, or Unix:

```
aws rds create-db-instance \
    --db-instance-identifier myoutpostdbinstance \
    --engine-version 8.0.17 \
    --db-instance-class db.m5.large \
    --engine mysql \
    --availability-zone us-east-1d \
    --vpc-security-group-ids outpost-sg \
    --db-subnet-group-name myoutpostdbsubnetgr \
    --allocated-storage 100 \
    --max-allocated-storage 1000 \
    --master-username masterawsuser \
    --manage-master-user-password \
    --backup-retention-period 3 \
    --backup-target outposts \
    --storage-encrypted \
    --kms-key-id mykey
```

For Windows:

```
aws rds create-db-instance ^
    --db-instance-identifier myoutpostdbinstance ^
    --engine-version 8.0.17 ^
    --db-instance-class db.m5.large ^
    --engine mysql ^
    --availability-zone us-east-1d ^
    --vpc-security-group-ids outpost-sg ^
    --db-subnet-group-name myoutpostdbsubnetgr ^
```

```
    --allocated-storage 100 ^
    --max-allocated-storage 1000 ^
    --master-username masterawsuser ^
    --manage-master-user-password ^
    --backup-retention-period 3 ^
    --backup-target outposts ^
    --storage-encrypted ^
    --kms-key-id mykey
```

For information about each setting when creating a DB instance, see Settings for DB instances.

RDS API

To create a new DB instance in an Outpost with the RDS API, first create a DB subnet group for use by RDS on Outposts by calling the CreateDBSubnetGroup operation. For `SubnetIds`, specify the subnet group in the Outpost for use by RDS on Outposts.

Next, call the CreateDBInstance operation with the following parameters. Specify an Availability Zone for the Outpost, an Amazon VPC security group associated with the Outpost, and the DB subnet group you created for the Outpost.

- `AllocatedStorage`
- `AvailabilityZone`
- `BackupRetentionPeriod`
- `BackupTarget`

  If you are creating a Multi-AZ DB instance deployment, you can't use `outposts` for `BackupTarget`. In addition, the DB instance can't have read replicas if you use `outposts` for `BackupTarget`.
- `DBInstanceClass`
- `DBInstanceIdentifier`
- `VpcSecurityGroupIds`
- `DBSubnetGroupName`
- `Engine`
- `EngineVersion`
- `MasterUsername`
- `MasterUserPassword`

- `MaxAllocatedStorage` (optional)
- `MultiAZ` (optional)
- `StorageEncrypted`
- `KmsKeyID`

For information about each setting when creating a DB instance, see Settings for DB instances.

Creating read replicas for Amazon RDS on AWS Outposts

Amazon RDS on AWS Outposts uses the MySQL and PostgreSQL DB engines' built-in replication functionality to create a read replica from a source DB instance. The source DB instance becomes the primary DB instance. Updates made to the primary DB instance are asynchronously copied to the read replica. You can reduce the load on your primary DB instance by routing read queries from your applications to the read replica. Using read replicas, you can elastically scale out beyond the capacity constraints of a single DB instance for read-heavy database workloads.

When you create a read replica from an RDS on Outposts DB instance, the read replica uses a customer-owned IP address (CoIP). For more information, see Customer-owned IP addresses for Amazon RDS on AWS Outposts.

Read replicas on RDS on Outposts have the following limitations:

- You can't create read replicas for RDS for SQL Server on RDS on Outposts DB instances.
- Cross-Region read replicas aren't supported on RDS on Outposts.
- Cascading read replicas aren't supported on RDS on Outposts.
- The source RDS on Outposts DB instance can't have local backups. The backup target for the source DB instance must be your AWS Region.
- Read replicas require customer-owned IP (CoIP) pools. For more information, see Customer-owned IP addresses for Amazon RDS on AWS Outposts.
- Read replicas on RDS on Outposts can only be created in the same virtual private cloud (VPC) as the source DB instance.
- Read replicas on RDS on Outposts can be located on the same Outpost or another Outpost in the same VPC as the source DB instance.
- You can't create read replicas for DB instances encrypted with AWS KMS External Key Store (XKS).

You can create a read replica from an RDS on Outposts DB instance using the AWS Management Console, AWS CLI, or RDS API. For more information on read replicas, see Working with DB instance read replicas.

Console

To create a read replica from a source DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.
3. Choose the DB instance that you want to use as the source for a read replica.
4. For **Actions**, choose **Create read replica**.
5. For **DB instance identifier**, enter a name for the read replica.
6. Specify your settings for **Outposts Connectivity**. These settings are for the Outpost that uses the virtual private cloud (VPC) that has the DB subnet group for your DB instance. Your VPC must be based on the Amazon VPC service.
7. Choose your **DB instance class**. We recommend that you use the same or larger DB instance class and storage type as the source DB instance for the read replica.
8. For **Multi-AZ deployment**, choose **Create a standby instance (recommended for production usage)** to create a standby DB instance in a different Availability Zone.

   Creating your read replica as a Multi-AZ DB instance is independent of whether the source database is a Multi-AZ DB instance.
9. (Optional) Under **Connectivity**, set values for **Subnet Group** and **Availability Zone**.

   If you specify values for both **Subnet Group** and **Availability Zone**, the read replica is created on an Outpost that is associated with the Availability Zone in the DB subnet group.

   If you specify a value for **Subnet Group** and **No preference** for **Availability Zone**, the read replica is created on a random Outpost in the DB subnet group.
10. For **AWS KMS key**, choose the AWS KMS key identifier of the KMS key.

    The read replica must be encrypted.
11. Choose other options as needed.
12. Choose **Create read replica**.

After the read replica is created, you can see it on the **Databases** page in the RDS console. It shows **Replica** in the **Role** column.

AWS CLI

To create a read replica from a source MySQL or PostgreSQL DB instance, use the AWS CLI command create-db-instance-read-replica.

You can control where the read replica is created by specifying the `--db-subnet-group-name` and `--availability-zone` options:

- If you specify both the `--db-subnet-group-name` and `--availability-zone` options, the read replica is created on an Outpost that is associated with the Availability Zone in the DB subnet group.
- If you specify the `--db-subnet-group-name` option and don't specify the `--availability-zone` option, the read replica is created on a random Outpost in the DB subnet group.
- If you don't specify either option, the read replica is created on the same Outpost as the source RDS on Outposts DB instance.

The following example creates a replica and specifies the location of the read replica by including `--db-subnet-group-name` and `--availability-zone` options.

Example

For Linux, macOS, or Unix:

```
aws rds create-db-instance-read-replica \
    --db-instance-identifier myreadreplica \
    --source-db-instance-identifier mydbinstance \
    --availability-zone us-west-2a
```

For Windows:

```
aws rds create-db-instance-read-replica ^
    --db-instance-identifier myreadreplica ^
    --source-db-instance-identifier mydbinstance ^
    --availability-zone us-west-2a
```

RDS API

To create a read replica from a source MySQL or PostgreSQL DB instance, call the Amazon RDS API CreateDBInstanceReadReplica operation with the following required parameters:

- `DBInstanceIdentifier`
- `SourceDBInstanceIdentifier`

You can control where the read replica is created by specifying the `DBSubnetGroupName` and `AvailabilityZone` parameters:

- If you specify both the `DBSubnetGroupName` and `AvailabilityZone` parameters, the read replica is created on an Outpost that is associated with the Availability Zone in the DB subnet group.
- If you specify the `DBSubnetGroupName` parameter and don't specify the `AvailabilityZone` parameter, the read replica is created on a random Outpost in the DB subnet group.
- If you don't specify either parameter, the read replica is created on the same Outpost as the source RDS on Outposts DB instance.

Considerations for restoring DB instances on Amazon RDS on AWS Outposts

When you restore a DB instance in Amazon RDS on AWS Outposts, you can generally choose the storage location for automated backups and manual snapshots of the restored DB instance.

- When restoring from a manual DB snapshot, you can store backups either in the parent AWS Region or locally on your Outpost.
- When restoring from an automated backup (point-in-time recovery), you have fewer choices:
  - If restoring from the parent AWS Region, you can store backups either in the AWS Region or on your Outpost.
  - If restoring from your Outpost, you can store backups only on your Outpost.

Using Amazon RDS Proxy

By using Amazon RDS Proxy, you can allow your applications to pool and share database connections to improve their ability to scale. RDS Proxy makes applications more resilient to database failures by automatically connecting to a standby DB instance while preserving application connections. By using RDS Proxy, you can also enforce AWS Identity and Access Management (IAM) authentication for databases, and securely store credentials in AWS Secrets Manager.

Using RDS Proxy, you can handle unpredictable surges in database traffic. Otherwise, these surges might cause issues due to oversubscribing connections or new connections being created at a fast rate. RDS Proxy establishes a database connection pool and reuses connections in this pool. This approach avoids the memory and CPU overhead of opening a new database connection each time. To protect a database against oversubscription, you can control the number of database connections that are created.

RDS Proxy queues or throttles application connections that can't be served immediately from the connection pool. Although latencies might increase, your application can continue to scale without abruptly failing or overwhelming the database. If connection requests exceed the limits you specify, RDS Proxy rejects application connections (that is, it sheds load). At the same time, it maintains predictable performance for the load that RDS can serve with the available capacity.

You can reduce the overhead to process credentials and establish a secure connection for each new connection. RDS Proxy can handle some of that work on behalf of the database.

RDS Proxy is fully compatible with the engine versions that it supports. You can enable RDS Proxy for most applications with no code changes.

Topics

- Working with RDS Proxy events
- Troubleshooting for RDS Proxy
- Using RDS Proxy with AWS CloudFormation

Region and version availability

Feature availability and support varies across specific versions of each database engine, and across AWS Regions. For more information on version and Region availability of Amazon RDS with RDS Proxy, see Supported Regions and DB engines for Amazon RDS Proxy.

Quotas and limitations for RDS Proxy

The following quotas and limitations apply to RDS Proxy:

- Each AWS account ID is limited to 20 proxies. If your application requires more proxies, request an increase via the **Service Quotas** page within the AWS Management Console. In the **Service Quotas** page, select **Amazon Relational Database Service (Amazon RDS)** and locate **Proxies** to request a quota increase. AWS can automatically increase your quota or pending review of your request by AWS Support.
- Each proxy can have up to 200 associated Secrets Manager secrets. Thus, each proxy can connect to with up to 200 different user accounts at any given time.
- Each proxy has a default endpoint. You can also add up to 20 proxy endpoints for each proxy. You can create, view, modify, and delete these endpoints.
- For RDS DB instances in replication configurations, you can associate a proxy only with the writer DB instance, not a read replica.
- Your RDS Proxy must be in the same virtual private cloud (VPC) as the database. The proxy can't be publicly accessible, although the database can be. For example, if you're prototyping your database on a local host, you can't connect to your proxy unless you set up the necessary network requirements to allow connection to the proxy. This is because your local host is outside of the proxy's VPC.
- You can't use RDS Proxy with a VPC that has its tenancy set to `dedicated`.
- If you use RDS Proxy with an RDS DB instance that has IAM authentication enabled, check user authentication. Users who connect through a proxy must authenticate through sign-in

credentials. For details about Secrets Manager and IAM support in RDS Proxy, see Setting up database credentials in AWS Secrets Manager for RDS Proxy and Setting up AWS Identity and Access Management (IAM) policies for RDS Proxy.

- You can't use RDS Proxy with custom DNS when using SSL hostname validation.
- Each proxy can be associated with a single target DB instance . However, you can associate multiple proxies with the same DB instance .
- Any statement with a text size greater than 16 KB causes the proxy to pin the session to the current connection.
- Certain Regions have Availability-Zone (AZ) restrictions to consider while creating your proxy. US East (N. Virginia) Region does not support RDS Proxy in the `use1-az3` Availability Zone. US West (N. California) Region does not support RDS Proxy in the `usw1-az2` Availability Zone. When selecting subnets while creating your proxy, make sure that you don't select subnets in the Availability Zones mentioned above.
- Currently, RDS Proxy doesn't support any global condition context keys.

  For more information about global condition context keys, see AWS global condition context keys in the *IAM User Guide*.
- You can't use RDS Proxy with RDS Custom for SQL Server.

For additional limitations for each DB engine, see the following sections:

- Additional limitations for RDS for MariaDB
- Additional limitations for RDS for Microsoft SQL Server
- Additional limitations for RDS for MySQL
- Additional limitations for RDS for PostgreSQL

Additional limitations for RDS for MariaDB

The following additional limitations apply to RDS Proxy with RDS for MariaDB databases:

- Currently, all proxies listen on port 3306 for MariaDB. The proxies still connect to your database using the port that you specified in the database settings.
- You can't use RDS Proxy with self-managed MariaDB databases in Amazon EC2 instances.
- You can't use RDS Proxy with an RDS for MariaDB DB instance that has the `read_only` parameter in its DB parameter group set to 1.

- RDS Proxy doesn't support MariaDB compressed mode. For example, it doesn't support the compression used by the `--compress` or `-C` options of the `mysql` command.
- Some SQL statements and functions can change the connection state without causing pinning. For the most current pinning behavior, see Avoiding pinning an RDS Proxy.
- RDS Proxy doesn't support the MariaDB `auth_ed25519` plugin.
- RDS Proxy doesn't support Transport Layer Security (TLS) version 1.3 for MariaDB databases.
- Database connections processing a `GET DIAGNOSTIC` command might return inaccurate information when RDS Proxy reuses the same database connection to run another query. This can happen when RDS Proxy multiplexes database connections. For more information, see Overview of RDS Proxy concepts.

> **Important**
>
> For proxies associated with MariaDB databases, don't set the configuration parameter `sql_auto_is_null` to `true` or a nonzero value in the initialization query. Doing so might cause incorrect application behavior.

Additional limitations for RDS for Microsoft SQL Server

The following additional limitations apply to RDS Proxy with RDS for Microsoft SQL Server databases:

- The number of Secrets Manager secrets that you need to create for a proxy depends on the collation that your DB instance uses. For example, suppose that your DB instance uses case-sensitive collation. If your application accepts both "Admin" and "admin," then your proxy needs two separate secrets. For more information about collation in SQL Server, see the Microsoft SQL Server documentation.
- RDS Proxy doesn't support connections that use Active Directory.
- You can't use IAM authentication with clients that don't support token properties. For more information, see Considerations for connecting to a proxy with Microsoft SQL Server.
- The results of `@@IDENTITY`, `@@ROWCOUNT`, and `SCOPE_IDENTITY` aren't always accurate. As a work-around, retrieve their values in the same session statement to ensure that they return the correct information.

- If the connection uses multiple active result sets (MARS), RDS Proxy doesn't run the initialization queries. For information about MARS, see the Microsoft SQL Server documentation.
- Currently, RDS Proxy does not support RDS for SQL Server DB instances that run on major version *SQL Server 2022*.
- RDS Proxy does not support RDS for SQL Server DB instances that run on major version *SQL Server 2014*.
- RDS Proxy does not support client applications that can't handle multiple response messages in one TLS record.

Additional limitations for RDS for MySQL

The following additional limitations apply to RDS Proxy with RDS for MySQL databases:

- RDS Proxy doesn't support the MySQL `sha256_password` and `caching_sha2_password` authentication plugins. These plugins implement SHA-256 hashing for user account passwords.
- Currently, all proxies listen on port 3306 for MySQL. The proxies still connect to your database using the port that you specified in the database settings.
- You can't use RDS Proxy with self-managed MySQL databases in EC2 instances.
- You can't use RDS Proxy with an RDS for MySQL DB instance that has the `read_only` parameter in its DB parameter group set to 1.
- RDS Proxy doesn't support MySQL compressed mode. For example, it doesn't support the compression used by the `--compress` or `-C` options of the `mysql` command.
- Database connections processing a `GET DIAGNOSTIC` command might return inaccurate information when RDS Proxy reuses the same database connection to run another query. This can happen when RDS Proxy multiplexes database connections.
- Some SQL statements and functions such as `SET LOCAL` can change the connection state without causing pinning. For the most current pinning behavior, see Avoiding pinning an RDS Proxy.
- Using the `ROW_COUNT()` function in a multi-statement query is not supported.
- RDS Proxy does not support client applications that can't handle multiple response messages in one TLS record.

Important

For proxies associated with MySQL databases, don't set the configuration parameter `sql_auto_is_null` to `true` or a nonzero value in the initialization query. Doing so might cause incorrect application behavior.

Additional limitations for RDS for PostgreSQL

The following additional limitations apply to RDS Proxy with RDS for PostgreSQL databases:

- RDS Proxy doesn't support session pinning filters for PostgreSQL.
- Currently, all proxies listen on port 5432 for PostgreSQL.
- For PostgreSQL, RDS Proxy doesn't currently support canceling a query from a client by issuing a `CancelRequest`. This is the case, for example, when you cancel a long-running query in an interactive psql session by using Ctrl+C.
- The results of the PostgreSQL function lastval aren't always accurate. As a work-around, use the INSERT statement with the `RETURNING` clause.
- RDS Proxy currently doesn't support streaming replication mode.
- With RDS for PostgreSQL 16, modifications to the `scram_iterations` value exclusively impact the authentication process between the proxy and the database. Specifically, if you configure `ClientPasswordAuthType` to `scram-sha-256`, any customizations made to the `scram_iterations` value doesn't influence client-to-proxy password authentication. Instead, the iteration value for client-to-proxy password authentication is fixed at 4096.

Important

For existing proxies with PostgreSQL databases, if you modify the database authentication to use `SCRAM` only, the proxy becomes unavailable for up to 60 seconds. To avoid the issue, do one of the following:

- Ensure that the database allows both `SCRAM` and `MD5` authentication.
- To use only `SCRAM` authentication, create a new proxy, migrate your application traffic to the new proxy, then delete the proxy previously associated with the database.

Planning where to use RDS Proxy

You can determine which of your DB instances, clusters, and applications might benefit the most from using RDS Proxy. To do so, consider these factors:

- Any DB instance that encounters "too many connections" errors is a good candidate for associating with a proxy. This is often characterized by a high value of the `ConnectionAttempts` CloudWatch metric. The proxy enables applications to open many client connections, while the proxy manages a smaller number of long-lived connections to the DB instance .
- For DB instances that use smaller AWS instance classes, such as T2 or T3, using a proxy can help avoid out-of-memory conditions. It can also help reduce the CPU overhead for establishing connections. These conditions can occur when dealing with large numbers of connections.
- You can monitor certain Amazon CloudWatch metrics to determine whether a DB instance is approaching certain types of limit. These limits are for the number of connections and the memory associated with connection management. You can also monitor certain CloudWatch metrics to determine whether a DB instance is handling many short-lived connections. Opening and closing such connections can impose performance overhead on your database. For information about the metrics to monitor, see Monitoring RDS Proxy metrics with Amazon CloudWatch.
- AWS Lambda functions can also be good candidates for using a proxy. These functions make frequent short database connections that benefit from connection pooling offered by RDS Proxy. You can take advantage of any IAM authentication you already have for Lambda functions, instead of managing database credentials in your Lambda application code.
- Applications that typically open and close large numbers of database connections and don't have built-in connection pooling mechanisms are good candidates for using a proxy.
- Applications that keep a large number of connections open for long periods are typically good candidates for using a proxy. Applications in industries such as software as a service (SaaS) or ecommerce often minimize the latency for database requests by leaving connections open. With RDS Proxy, an application can keep more connections open than it can when connecting directly to the DB instance.
- You might not have adopted IAM authentication and Secrets Manager due to the complexity of setting up such authentication for all DB instances. If so, you can leave the existing authentication methods in place and delegate the authentication to a proxy. The proxy can enforce the authentication policies for client connections for particular applications. You can

take advantage of any IAM authentication you already have for Lambda functions, instead of managing database credentials in your Lambda application code.

- RDS Proxy can help make applications more resilient and transparent to database failures. RDS Proxy bypasses Domain Name System (DNS) caches to reduce failover times by up to 66% for Amazon RDS Multi-AZ DB instances. RDS Proxy also automatically routes traffic to a new database instance while preserving application connections. This makes failovers more transparent for applications.

RDS Proxy concepts and terminology

You can simplify connection management for your Amazon RDS DB instances by using RDS Proxy.

RDS Proxy handles the network traffic between the client application and the database. It does so in an active way first by understanding the database protocol. It then adjusts its behavior based on the SQL operations from your application and the result sets from the database.

RDS Proxy reduces the memory and CPU overhead for connection management on your database. The database needs less memory and CPU resources when applications open many simultaneous connections. It also doesn't require logic in your applications to close and reopen connections that stay idle for a long time. Similarly, it requires less application logic to reestablish connections in case of a database problem.

The infrastructure for RDS Proxy is highly available and deployed over multiple Availability Zones (AZs). The computation, memory, and storage for RDS Proxy are independent of your RDS DB instance. This separation helps lower overhead on your database servers, so that they can devote their resources to serving database workloads. The RDS Proxy compute resources are serverless, automatically scaling based on your database workload.

Topics

Overview of RDS Proxy concepts

RDS Proxy handles the infrastructure to perform connection pooling and the other features described in the sections that follow. You see the proxies represented in the RDS console on the **Proxies** page.

Each proxy handles connections to a single RDS DB instance. The proxy automatically determines the current writer instance for RDS Multi-AZ DB instance or cluster.

The connections that a proxy keeps open and available for your database applications to use make up the *connection pool*.

By default, RDS Proxy can reuse a connection after each transaction in your session. This transaction-level reuse is called *multiplexing*. When RDS Proxy temporarily removes a connection from the connection pool to reuse it, that operation is called *borrowing* the connection. When it's safe to do so, RDS Proxy returns that connection to the connection pool.

In some cases, RDS Proxy can't be sure that it's safe to reuse a database connection outside of the current session. In these cases, it keeps the session on the same connection until the session ends. This fallback behavior is called *pinning*.

A proxy has a default endpoint. You connect to this endpoint when you work with an Amazon RDS DB instance. You do so instead of connecting to the read/write endpoint that connects directly to the instance . For RDS DB clusters, you can also create additional read/write and read-only endpoints. For more information, see Overview of proxy endpoints.

For example, you can still connect to the cluster endpoint for read/write connections without connection pooling. You can still connect to the reader endpoint for load-balanced read-only connections. You can still connect to the instance endpoints for diagnosis and troubleshooting of specific DB instances within a cluster. If you use other AWS services such as AWS Lambda to connect to RDS databases, change their connection settings to use the proxy endpoint. For example, you specify the proxy endpoint to allow Lambda functions to access your database while taking advantage of RDS Proxy functionality.

Each proxy contains a target group. This *target group* embodies the RDS DB instance that the proxy can connect to. The RDS DB instance associated with a proxy are called the *targets* of that proxy. For convenience, when you create a proxy through the console, RDS Proxy also creates the corresponding target group and registers the associated targets automatically.

An *engine family* is a related set of database engines that use the same DB protocol. You choose the engine family for each proxy that you create.

Connection pooling

Each proxy performs connection pooling for the writer instance of its associated RDS database . *Connection pooling* is an optimization that reduces the overhead associated with opening and closing connections and with keeping many connections open simultaneously. This overhead includes memory needed to handle each new connection. It also involves CPU overhead to close each connection and open a new one. Examples include Transport Layer Security/Secure Sockets Layer (TLS/SSL) handshaking, authentication, negotiating capabilities, and so on. Connection pooling simplifies your application logic. You don't need to write application code to minimize the number of simultaneous open connections.

Each proxy also performs connection multiplexing, also known as connection reuse. With *multiplexing*, RDS Proxy performs all the operations for a transaction using one underlying database connection. RDS then can use a different connection for the next transaction. You can open many simultaneous connections to the proxy, and the proxy keeps a smaller number of connections open to the DB instance or cluster. Doing so further minimizes the memory overhead for connections on the database server. This technique also reduces the chance of "too many connections" errors.

RDS Proxy security

RDS Proxy uses the existing RDS security mechanisms such as TLS/SSL and AWS Identity and Access Management (IAM). For general information about those security features, see Security in Amazon RDS. Also, make sure to familiarize yourself with how RDS work with authentication, authorization, and other areas of security.

RDS Proxy can act as an additional layer of security between client applications and the underlying database. For example, you can connect to the proxy using TLS 1.3, even if the underlying DB instance supports an older version of TLS. You can connect to the proxy using an IAM role. This is so even if the proxy connects to the database using the native user and password authentication method. By using this technique, you can enforce strong authentication requirements for database applications without a costly migration effort for the DB instances themselves.

You store the database credentials used by RDS Proxy in AWS Secrets Manager. Each database user for the RDS DB instance accessed by a proxy must have a corresponding secret in Secrets Manager. You can also set up IAM authentication for users of RDS Proxy. By doing so, you can enforce IAM

authentication for database access even if the databases use native password authentication. We recommend using these security features instead of embedding database credentials in your application code.

Using TLS/SSL with RDS Proxy

You can connect to RDS Proxy using the TLS/SSL protocol.

> **Note**
>
> RDS Proxy uses certificates from the AWS Certificate Manager (ACM). If you are using RDS Proxy, you don't need to download Amazon RDS certificates or update applications that use RDS Proxy connections.

To enforce TLS for all connections between the proxy and your database, you can specify a setting **Require Transport Layer Security** when you create or modify a proxy in the AWS Management Console.

RDS Proxy can also ensure that your session uses TLS/SSL between your client and the RDS Proxy endpoint. To have RDS Proxy do so, specify the requirement on the client side. SSL session variables are not set for SSL connections to a database using RDS Proxy.

- For RDS for MySQL, specify the requirement on the client side with the `--ssl-mode` parameter when you run the `mysql` command.
- For Amazon RDS PostgreSQL, specify `sslmode=require` as part of the `conninfo` string when you run the `psql` command.

RDS Proxy supports TLS protocol version 1.0, 1.1, 1.2, and 1.3. You can connect to the proxy using a higher version of TLS than you use in the underlying database.

By default, client programs establish an encrypted connection with RDS Proxy, with further control available through the `--ssl-mode` option. From the client side, RDS Proxy supports all SSL modes.

For the client, the SSL modes are the following:

PREFERRED

SSL is the first choice, but it isn't required.

DISABLED

No SSL is allowed.

REQUIRED

Enforce SSL.

VERIFY_CA

Enforce SSL and verify the certificate authority (CA).

VERIFY_IDENTITY

Enforce SSL and verify the CA and CA hostname.

When using a client with `--ssl-mode VERIFY_CA` or `VERIFY_IDENTITY`, specify the `--ssl-ca` option pointing to a CA in `.pem` format. For the `.pem` file to use, download all root CA PEMs from Amazon Trust Services and place them into a single `.pem` file.

RDS Proxy uses wildcard certificates, which apply to both a domain and its subdomains. If you use the `mysql` client to connect with SSL mode `VERIFY_IDENTITY`, currently you must use the MySQL 8.0-compatible `mysql` command.

Failover

Failover is a high-availability feature that replaces a database instance with another one when the original instance becomes unavailable. A failover might happen because of a problem with a database instance. It might also be part of normal maintenance procedures, such as during a database upgrade. Failover applies to RDS DB instances in a Multi-AZ configuration.

Connecting through a proxy makes your applications more resilient to database failovers. When the original DB instance becomes unavailable, RDS Proxy connects to the standby database without dropping idle application connections. This helps speed up and simplify the failover process. This is less disruptive to your application than a typical reboot or database problem.

Without RDS Proxy, a failover involves a brief outage. During the outage, you can't perform write operations on the database in failover. Any existing database connections are disrupted, and your application must reopen them. The database becomes available for new connections and write operations when a read-only DB instance is promoted in place of one that's unavailable.

During DB failovers, RDS Proxy continues to accept connections at the same IP address and automatically directs connections to the new primary DB instance. Clients connecting through RDS Proxy are not susceptible to the following:

- Domain Name System (DNS) propagation delays on failover.
- Local DNS caching.
- Connection timeouts.
- Uncertainty about which DB instance is the current writer.
- Waiting for a query response from a former writer that became unavailable without closing connections.

For applications that maintain their own connection pool, going through RDS Proxy means that most connections stay alive during failovers or other disruptions. Only connections that are in the middle of a transaction or SQL statement are canceled. RDS Proxy immediately accepts new connections. When the database writer is unavailable, RDS Proxy queues up incoming requests.

For applications that don't maintain their own connection pools, RDS Proxy offers faster connection rates and more open connections. It offloads the expensive overhead of frequent reconnects from the database. It does so by reusing database connections maintained in the RDS Proxy connection pool. This approach is particularly important for TLS connections, where setup costs are significant.

Transactions

All the statements within a single transaction always use the same underlying database connection. The connection becomes available for use by a different session when the transaction ends. Using the transaction as the unit of granularity has the following consequences:

- Connection reuse can happen after each individual statement when the RDS for MySQL `autocommit` setting is turned on.
- Conversely, when the `autocommit` setting is turned off, the first statement you issue in a session begins a new transaction. For example, suppose that you enter a sequence of `SELECT`, `INSERT`, `UPDATE`, and other data manipulation language (DML) statements. In this case, connection reuse doesn't happen until you issue a `COMMIT`, `ROLLBACK`, or otherwise end the transaction.
- Entering a data definition language (DDL) statement causes the transaction to end after that statement completes.

RDS Proxy detects when a transaction ends through the network protocol used by the database client application. Transaction detection doesn't rely on keywords such as `COMMIT` or `ROLLBACK` appearing in the text of the SQL statement.

In some cases, RDS Proxy might detect a database request that makes it impractical to move your session to a different connection. In these cases, it turns off multiplexing for that connection the remainder of your session. The same rule applies if RDS Proxy can't be certain that multiplexing is practical for the session. This operation is called *pinning*. For ways to detect and minimize pinning, see Avoiding pinning an RDS Proxy.

Getting started with RDS Proxy

Use the information in the following pages to set up and manage Using Amazon RDS Proxy and set related security options. The security options control who can access each proxy and how each proxy connects to DB instances.

If you're new to RDS Proxy, we recommend following the pages in the order that we present them.

Topics

- Setting up network prerequisites for RDS Proxy
- Setting up database credentials in AWS Secrets Manager for RDS Proxy
- Setting up AWS Identity and Access Management (IAM) policies for RDS Proxy
- Creating an RDS Proxy
- Viewing an RDS Proxy
- Connecting to a database through RDS Proxy

Setting up network prerequisites for RDS Proxy

Using RDS Proxy requires you to have a common virtual private cloud (VPC) between your RDS DB instance and RDS Proxy. This VPC should have a minimum of two subnets that are in different Availability Zones. Your account can either own these subnets or share them with other accounts. For information about VPC sharing, see Work with shared VPCs.

Your client application resources such as Amazon EC2, Lambda, or Amazon ECS can be in the same VPC as the proxy. Or they can be in a separate VPC from the proxy. If you successfully connected to any RDS DB instances , you already have the required network resources.

Topics

Getting information about your subnets

To create a proxy, you must provide the subnets and the VPC that the proxy operates within. The following Linux example shows AWS CLI commands that examine the VPCs and subnets owned by your AWS account. In particular, you pass subnet IDs as parameters when you create a proxy using the CLI.

```
aws ec2 describe-vpcs
aws ec2 describe-internet-gateways
aws ec2 describe-subnets --query '*[].[VpcId,SubnetId]' --output text | sort
```

The following Linux example shows AWS CLI commands to determine the subnet IDs corresponding to a specific RDS DB instance. Find the VPC ID for the DB instance. Examine the VPC to find its subnets. The following Linux example shows how.

```
$ #From the DB instance, trace through the DBSubnetGroup and Subnets to find the subnet
 IDs.
$ aws rds describe-db-instances --db-instance-identifier my_instance_id --query '*[].
[DBSubnetGroup]|[0]|[0]|[Subnets]|[0]|[*].SubnetIdentifier' --output text
```

```
subnet_id_1
subnet_id_2
subnet_id_3
...
```

```
$ #From the DB instance, find the VPC.
$ aws rds describe-db-instances --db-instance-identifier my_instance_id --query '*[].
[DBSubnetGroup]|[0]|[0].VpcId' --output text
```

```
my_vpc_id
```

```
$ aws ec2 describe-subnets --filters Name=vpc-id,Values=my_vpc_id --query '*[].
[SubnetId]' --output text
```

```
subnet_id_1
subnet_id_2
subnet_id_3
subnet_id_4
subnet_id_5
subnet_id_6
```

Planning for IP address capacity

An RDS Proxy automatically adjusts its capacity as needed based on the size and number of DB instances registered with it. Certain operations might also require additional proxy capacity such as increasing the size of a registered database or internal RDS Proxy maintenance operations. During these operations, your proxy might need more IP addresses to provision the extra capacity. These additional addresses allow your proxy to scale without affecting your workload. A lack of free IP addresses in your subnets prevents a proxy from scaling up. This can lead to higher query latencies or client connection failures. RDS notifies you through event `RDS-EVENT-0243` when there aren't enough free IP addresses in your subnets. For information about this event, see Working with RDS Proxy events.

Following are the recommended minimum numbers of IP addresses to leave free in your subnets for your proxy based on DB instance class sizes.

DB instance class	Minimum free IP addresses
db.*.xlarge or smaller	10
db.*.2xlarge	15
db.*.4xlarge	25
db.*.8xlarge	45
db.*.12xlarge	60
db.*.16xlarge	75
db.*.24xlarge	110

These recommended numbers of IP addresses are estimates for a proxy with only the default endpoint. A proxy with additional endpoints or read replicas might need more free IP addresses. For each additional endpoint, we recommend that you reserve three more IP addresses. For each read replica, we recommend that you reserve additional IP addresses as specified in the table based on that read replica's size.

> **Note**
>
> RDS Proxy doesn't support more than 215 IP addresses in a VPC.

Setting up database credentials in AWS Secrets Manager for RDS Proxy

For each proxy that you create, you first use the Secrets Manager service to store sets of user name and password credentials. You create a separate Secrets Manager secret for each database user account that the proxy connects to on the RDS DB instance.

In Secrets Manager console, you create these secrets with values for the `username` and `password` fields. Doing so allows the proxy to connect to the corresponding database users on a RDS DB instance that you associate with the proxy. To do this, you can use the setting **Credentials for other database**, **Credentials for RDS database**, or **Other type of secrets**. Fill in the appropriate values for the **User name** and **Password** fields, and values for any other required fields. The proxy ignores other fields such as **Host** and **Port** if they're present in the secret. Those details are automatically supplied by the proxy.

You can also choose **Other type of secrets**. In this case, you create the secret with keys named `username` and `password`.

To connect through the proxy as a specific database user, make sure that the password associated with a secret matches the database password for that user. If there's a mismatch, you can update the associated secret in Secrets Manager. In this case, you can still connect to other accounts where the secret credentials and the database passwords do match.

> **Note**
>
> For RDS for SQL Server, RDS Proxy needs a secret in Secrets Manager that is case sensitive to application code irrespective of the DB instance collation settings. For example, if your application can use both usernames "Admin" or "admin", then configure the proxy with

secrets for both "Admin" and "admin". RDS Proxy does not accommodate username case-insensitivity in the authentication process between the client and proxy.
For more information about collation in SQL Server, see the Microsoft SQL Server documentation.

When you create a proxy through the AWS CLI or RDS API, you specify the Amazon Resource Names (ARNs) of the corresponding secrets. You do so for all the DB user accounts that the proxy can access. In the AWS Management Console, you choose the secrets by their descriptive names.

For instructions about creating secrets in Secrets Manager, see the Creating a secret page in the Secrets Manager documentation. Use one of the following techniques:

- Use Secrets Manager in the console.
- To use the CLI to create a Secrets Manager secret for use with RDS Proxy, use a command such as the following.

```
aws secretsmanager create-secret
  --name "secret_name"
  --description "secret_description"
  --region region_name
  --secret-string '{"username":"db_user","password":"db_user_password"}'
```

- You can also create a custom key to encrypt your Secrets Manager secret. The following command creates an example key.

```
PREFIX=my_identifier
aws kms create-key --description "$PREFIX-test-key" --policy '{
  "Id":"$PREFIX-kms-policy",
  "Version":"2012-10-17",
  "Statement":
    [
      {
        "Sid":"Enable IAM User Permissions",
        "Effect":"Allow",
        "Principal":{"AWS":"arn:aws:iam::account_id:root"},
        "Action":"kms:*","Resource":"*"
      },
      {
        "Sid":"Allow access for Key Administrators",
        "Effect":"Allow",
```

```
        "Principal":
          {
            "AWS":
              ["$USER_ARN","arn:aws:iam:account_id::role/Admin"]
          },
        "Action":
          [
            "kms:Create*",
            "kms:Describe*",
            "kms:Enable*",
            "kms:List*",
            "kms:Put*",
            "kms:Update*",
            "kms:Revoke*",
            "kms:Disable*",
            "kms:Get*",
            "kms:Delete*",
            "kms:TagResource",
            "kms:UntagResource",
            "kms:ScheduleKeyDeletion",
            "kms:CancelKeyDeletion"
          ],
        "Resource":"*"
      },
      {
        "Sid":"Allow use of the key",
        "Effect":"Allow",
        "Principal":{"AWS":"$ROLE_ARN"},
        "Action":["kms:Decrypt","kms:DescribeKey"],
        "Resource":"*"
      }
    ]
}'
```

For example, the following commands create Secrets Manager secrets for two database users:

```
aws secretsmanager create-secret \
  --name secret_name_1 --description "db admin user" \
  --secret-string '{"username":"admin","password":"choose_your_own_password"}'

aws secretsmanager create-secret \
  --name secret_name_2 --description "application user" \
```

```
  --secret-string '{"username":"app-user","password":"choose_your_own_password"}'
```

To create these secrets encrypted with your custom AWS KMS key, use the following commands:

```
aws secretsmanager create-secret \
  --name secret_name_1 --description "db admin user" \
  --secret-string '{"username":"admin","password":"choose_your_own_password"}'
  --kms-key-id arn:aws:kms:us-east-2:account_id:key/key_id

aws secretsmanager create-secret \
  --name secret_name_2 --description "application user" \
  --secret-string '{"username":"app-user","password":"choose_your_own_password"}'
  --kms-key-id arn:aws:kms:us-east-2:account_id:key/key_id
```

To see the secrets owned by your AWS account, use a command such as the following.

```
aws secretsmanager list-secrets
```

When you create a proxy using the CLI, you pass the Amazon Resource Names (ARNs) of one or more secrets to the `--auth` parameter. The following Linux example shows how to prepare a report with only the name and ARN of each secret owned by your AWS account. This example uses the `--output table` parameter that is available in AWS CLI version 2. If you are using AWS CLI version 1, use `--output text` instead.

```
aws secretsmanager list-secrets --query '*[].[Name,ARN]' --output table
```

To verify that you stored the correct credentials and in the right format in a secret, use a command such as the following. Substitute the short name or the ARN of the secret for *your_secret_name*.

```
aws secretsmanager get-secret-value --secret-id your_secret_name
```

The output should include a line displaying a JSON-encoded value like the following.

```
"SecretString": "{\"username\":\"your_username\",\"password\":\"your_password\"}",
```

Setting up AWS Identity and Access Management (IAM) policies for RDS Proxy

After you create the secrets in Secrets Manager, you create an IAM policy that can access those secrets. For general information about using IAM, see Identity and access management for Amazon RDS.

> **Tip**
>
> The following procedure applies if you use the IAM console. If you use the AWS Management Console for RDS, RDS can create the IAM policy for you automatically. In that case, you can skip the following procedure.

To create an IAM policy that accesses your Secrets Manager secrets for use with your proxy

1. Sign in to the IAM console. Follow the **Create role** process, as described in Creating IAM roles, choosing Creating a role to delegate permissions to an AWS service.

   Choose **AWS service** for the **Trusted entity type**. Under **Use case**, select **RDS** from **Use cases for other AWS services** dropdown. Select **RDS - Add Role to Database**.

2. For the new role, perform the **Add inline policy** step. Use the same general procedures as in Editing IAM policies. Paste the following JSON into the JSON text box. Substitute your own account ID. Substitute your AWS Region for `us-east-2`. Substitute the Amazon Resource Names (ARNs) for the secrets that you created, see Specifying KMS keys in IAM policy statements. For the `kms:Decrypt` action, substitute the ARN of the default AWS KMS key or your own KMS key. Which one you use depends on which one you used to encrypt the Secrets Manager secrets.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "VisualEditor0",
            "Effect": "Allow",
            "Action": "secretsmanager:GetSecretValue",
            "Resource": [
                "arn:aws:secretsmanager:us-east-2:account_id:secret:secret_name_1",
                "arn:aws:secretsmanager:us-east-2:account_id:secret:secret_name_2"
```

```
            ]
        },
        {
            "Sid": "VisualEditor1",
            "Effect": "Allow",
            "Action": "kms:Decrypt",
            "Resource": "arn:aws:kms:us-east-2:account_id:key/key_id",
            "Condition": {
                "StringEquals": {
                    "kms:ViaService": "secretsmanager.us-east-2.amazonaws.com"
                }
            }
        }
    ]
}
```

3. Edit the trust policy for this IAM role. Paste the following JSON into the JSON text box.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "",
      "Effect": "Allow",
      "Principal": {
        "Service": "rds.amazonaws.com"
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
```

The following commands perform the same operation through the AWS CLI.

```
PREFIX=my_identifier
USER_ARN=$(aws sts get-caller-identity --query "Arn" --output text)

aws iam create-role --role-name my_role_name \
  --assume-role-policy-document '{"Version":"2012-10-17","Statement":
[{"Effect":"Allow","Principal":{"Service":
["rds.amazonaws.com"]},"Action":"sts:AssumeRole"}]}'
```

```
ROLE_ARN=arn:aws:iam::account_id:role/my_role_name

aws iam put-role-policy --role-name my_role_name \
  --policy-name $PREFIX-secret-reader-policy --policy-document '{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "VisualEditor0",
            "Effect": "Allow",
            "Action": "secretsmanager:GetSecretValue",
            "Resource": [
                "arn:aws:secretsmanager:us-east-2:account_id:secret:secret_name_1",
                "arn:aws:secretsmanager:us-east-2:account_id:secret:secret_name_2"
            ]
        },
        {
            "Sid": "VisualEditor1",
            "Effect": "Allow",
            "Action": "kms:Decrypt",
            "Resource": "arn:aws:kms:us-east-2:account_id:key/key_id",
            "Condition": {
                "StringEquals": {
                    "kms:ViaService": "secretsmanager.us-east-2.amazonaws.com"
                }
            }
        }
    ]
}
```

Creating an RDS Proxy

To manage connections for a specified set of DB instances, you can create a proxy. You can associate a proxy with an RDS for MariaDB, RDS for Microsoft SQL Server, RDS for MySQL, or RDS for PostgreSQL DB instance.

AWS Management Console

To create a proxy

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Proxies**.

3. Choose **Create proxy**.
4. Choose all the settings for your proxy.

   For **Proxy configuration**, provide information for the following:

   - **Engine family**. This setting determines which database network protocol the proxy recognizes when it interprets network traffic to and from the database. For RDS for MariaDB or RDS for MySQL, choose **MariaDB and MySQL**. For RDS for PostgreSQL, choose **PostgreSQL**. For RDS for SQL Server, choose **SQL Server**.
   - **Proxy identifier**. Specify a name of that is unique within your AWS account ID and current AWS Region.
   - **Idle client connection timeout**. Choose a time period that a client connection can be idle before the proxy closes it. The default is 1,800 seconds (30 minutes). A client connection is considered idle when the application doesn't submit a new request within the specified time after the previous request completed. The underlying database connection stays open and is returned to the connection pool. Thus, it's available to be reused for new client connections.

     To have the proxy proactively remove stale connections, lower the idle client connection timeout. When the workload is spiking, to save the cost of establishing connections, increase the idle client connection timeout."

   For **Target group configuration**, provide information for the following:

   - **Database**. Choose one RDS DB instance to access through this proxy. The list only includes DB instances and clusters with compatible database engines, engine versions, and other settings. If the list is empty, create a new DB instance or cluster that's compatible with RDS Proxy. To do so, follow the procedure in Creating an Amazon RDS DB instance. Then try creating the proxy again.
   - **Connection pool maximum connections**. Specify a value from 1 through 100. This setting represents the percentage of the `max_connections` value that RDS Proxy can use for its connections. If you only intend to use one proxy with this DB instance or cluster, you can set this value to 100. For details about how RDS Proxy uses this setting, see MaxConnectionsPercent.
   - **Session pinning filters**. (Optional) This option allows you to force RDS Proxy to not pin for certain types of detected session states. This circumvents the default safety measures for

multiplexing database connections across client connections. Currently, the setting isn't supported for PostgreSQL. The only choice is `EXCLUDE_VARIABLE_SETS`.

Enabling this setting can cause session variables of one connection to impact other connections. This can cause errors or correctness issues if your queries depend on session variable values set outside of the current transaction. Consider using this option after verifying it is safe for your applications to share database connections across client connections.

The following patterns can be considered safe:

- `SET` statements where there is no change to the effective session variable value, i.e., there is no change to the session variable.
- You change the session variable value and execute a statement in the same transaction.

For more information, see Avoiding pinning an RDS Proxy.

- **Connection borrow timeout**. In some cases, you might expect the proxy to sometimes use all available database connections. In such cases, you can specify how long the proxy waits for a database connection to become available before returning a timeout error. You can specify a period up to a maximum of five minutes. This setting only applies when the proxy has the maximum number of connections open and all connections are already in use.
- **Initialization query**. (Optional) You can specify one or more SQL statements for the proxy to run when opening each new database connection. The setting is typically used with `SET` statements to make sure that each connection has identical settings, such as time zone and character sets. For multiple statements, use semicolons as the separator. You can also include multiple variables in a single `SET` statement, such as `SET x=1, y=2`.

For **Authentication**, provide information for the following:

- **IAM role**. Choose an IAM role that has permission to access the Secrets Manager secrets that you chose earlier. Or, you can create a new IAM role from the AWS Management Console.
- **Secrets Manager secrets**. Choose at least one Secrets Manager secret that contains database user credentials that allow the proxy to access the RDS DB instance.
- **Client authentication type**. Choose the type of authentication the proxy uses for connections from clients. Your choice applies to all Secrets Manager secrets that you associate with this proxy. If you need to specify a different client authentication type for each secret, then create your proxy by using the AWS CLI or the API instead.

- **IAM authentication**. Choose whether to require, allow, or disallow IAM authentication for connections to your proxy. The allow option is only valid for proxies for RDS for SQL Server. Your choice applies to all Secrets Manager secrets that you associate with this proxy. If you need to specify a different IAM authentication for each secret, create your proxy by using the AWS CLI or the API instead.

For **Connectivity**, provide information for the following:

- **Require Transport Layer Security**. Choose this setting if you want the proxy to enforce TLS/SSL for all client connections. For an encrypted or unencrypted connection to a proxy, the proxy uses the same encryption setting when it makes a connection to the underlying database.
- **Subnets**. This field is prepopulated with all the subnets associated with your VPC. You can remove any subnets that you don't need for this proxy. You must leave at least two subnets.

Provide additional connectivity configuration:

- **VPC security group**. Choose an existing VPC security group. Or, you can create a new security group from the AWS Management Console. You must configure the **Inbound rules** to allow your applications to access the proxy. You must also configure the **Outbound rules** to allow traffic from your DB targets.

> **Note**
>
> This security group must allow connections from the proxy to the database. The same security group is used for ingress from your applications to the proxy, and for egress from the proxy to the database. For example, suppose that you use the same security group for your database and your proxy. In this case, make sure that you specify that resources in that security group can communicate with other resources in the same security group.
> When using a shared VPC, you can't use the default security group for the VPC, or one that belongs to another account. Choose a security group that belongs to your account. If one doesn't exist, create one. For more information about this limitation, see Work with shared VPCs.

RDS deploys a proxy over multiple Availability Zones to ensure high availability. To enable cross-AZ communication for such a proxy, the network access control list (ACL) for your proxy subnet must allow engine port specific egress and all ports to ingress. For more information about network ACLs, see Control traffic to subnets using network ACLs. If the network ACL for your proxy and target are identical, you must add a **TCP** protocol ingress rule where the **Source** is set to the VPC CIDR. You must also add an engine port specific **TCP** protocol egress rule where the **Destination** is set to the VPC CIDR.

(Optional) Provide advanced configuration:

- **Enable enhanced logging**. You can enable this setting to troubleshoot proxy compatibility or performance issues.

  When this setting is enabled, RDS Proxy includes detailed information about proxy performance in its logs. This information helps you to debug issues involving SQL behavior or the performance and scalability of the proxy connections. Thus, only enable this setting for debugging and when you have security measures in place to safeguard any sensitive information that appears in the logs.

  To minimize overhead associated with your proxy, RDS Proxy automatically turns this setting off 24 hours after you enable it. Enable it temporarily to troubleshoot a specific issue.

5. Choose **Create Proxy**.

AWS CLI

To create a proxy by using the AWS CLI, call the create-db-proxy command with the following required parameters:

- `--db-proxy-name`
- `--engine-family`
- `--role-arn`
- `--auth`
- `--vpc-subnet-ids`

The `--engine-family` value is case-sensitive.

Example

For Linux, macOS, or Unix:

```
aws rds create-db-proxy \
    --db-proxy-name proxy_name \
    --engine-family { MYSQL | POSTGRESQL | SQLSERVER } \
    --auth ProxyAuthenticationConfig_JSON_string \
    --role-arn iam_role \
    --vpc-subnet-ids space_separated_list \
    [--vpc-security-group-ids space_separated_list] \
    [--require-tls | --no-require-tls] \
    [--idle-client-timeout value] \
    [--debug-logging | --no-debug-logging] \
    [--tags comma_separated_list]
```

For Windows:

```
aws rds create-db-proxy ^
    --db-proxy-name proxy_name ^
    --engine-family { MYSQL | POSTGRESQL | SQLSERVER } ^
    --auth ProxyAuthenticationConfig_JSON_string ^
    --role-arn iam_role ^
    --vpc-subnet-ids space_separated_list ^
    [--vpc-security-group-ids space_separated_list] ^
    [--require-tls | --no-require-tls] ^
    [--idle-client-timeout value] ^
    [--debug-logging | --no-debug-logging] ^
    [--tags comma_separated_list]
```

The following is an example of the JSON value for the `--auth` option. This example applies a different client authentication type to each secret.

```
[
  {
    "Description": "proxy description 1",
    "AuthScheme": "SECRETS",
    "SecretArn": "arn:aws:secretsmanager:us-
west-2:123456789123:secret/1234abcd-12ab-34cd-56ef-1234567890ab",
    "IAMAuth": "DISABLED",
    "ClientPasswordAuthType": "POSTGRES_SCRAM_SHA_256"
  },
```

```
  {
    "Description": "proxy description 2",
    "AuthScheme": "SECRETS",
    "SecretArn": "arn:aws:secretsmanager:us-
west-2:111122223333:secret/1234abcd-12ab-34cd-56ef-1234567890cd",
    "IAMAuth": "DISABLED",
    "ClientPasswordAuthType": "POSTGRES_MD5"

  },

  {
    "Description": "proxy description 3",
    "AuthScheme": "SECRETS",
    "SecretArn": "arn:aws:secretsmanager:us-
west-2:111122221111:secret/1234abcd-12ab-34cd-56ef-1234567890ef",
    "IAMAuth": "REQUIRED"
  }

]
```

Tip

If you don't already know the subnet IDs to use for the `--vpc-subnet-ids` parameter, see Setting up network prerequisites for RDS Proxy for examples of how to find them.

Note

The security group must allow access to the database the proxy connects to. The same security group is used for ingress from your applications to the proxy, and for egress from the proxy to the database. For example, suppose that you use the same security group for your database and your proxy. In this case, make sure that you specify that resources in that security group can communicate with other resources in the same security group.
When using a shared VPC, you can't use the default security group for the VPC, or one that belongs to another account. Choose a security group that belongs to your account. If one doesn't exist, create one. For more information about this limitation, see Work with shared VPCs.

To create the right associations for the proxy, you also use the register-db-proxy-targets command. Specify the target group name `default`. RDS Proxy automatically creates a target group with this name when you create each proxy.

```
aws rds register-db-proxy-targets
    --db-proxy-name value
    [--target-group-name target_group_name]
    [--db-instance-identifiers space_separated_list]  # rds db instances, or
    [--db-cluster-identifiers cluster_id]        # rds db cluster (all instances)
```

RDS API

To create an RDS proxy, call the Amazon RDS API operation CreateDBProxy. You pass a parameter with the AuthConfig data structure.

RDS Proxy automatically creates a target group named `default` when you create each proxy. You associate an RDS DB instance with the target group by calling the function RegisterDBProxyTargets.

Viewing an RDS Proxy

After you create one or more RDS proxies, you can view them all. Doing so makes it possible to examine their configuration details and choose which ones to modify, delete, and so on.

In order for database applications to use a proxy, you must provide the proxy endpoint in the connection string.

AWS Management Console

To view your proxy

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the upper-right corner of the AWS Management Console, choose the AWS Region in which you created the RDS Proxy.
3. In the navigation pane, choose **Proxies**.
4. Choose the name of an RDS proxy to display its details.
5. On the details page, the **Target groups** section shows how the proxy is associated with a specific RDS DB instance. You can follow the link to the **default** target group page to see more details about the association between the proxy and the database. This page is where you

see settings that you specified when creating the proxy. These include maximum connection percentage, connection borrow timeout, engine family, and session pinning filters.

CLI

To view your proxy using the CLI, use the describe-db-proxies command. By default, it displays all proxies owned by your AWS account. To see details for a single proxy, specify its name with the `--db-proxy-name` parameter.

```
aws rds describe-db-proxies [--db-proxy-name proxy_name]
```

To view the other information associated with the proxy, use the following commands.

```
aws rds describe-db-proxy-target-groups  --db-proxy-name proxy_name

aws rds describe-db-proxy-targets --db-proxy-name proxy_name
```

Use the following sequence of commands to see more detail about the things that are associated with the proxy:

1. To get a list of proxies, run describe-db-proxies.
2. To show connection parameters such as the maximum percentage of connections that the proxy can use, run describe-db-proxy-target-groups `--db-proxy-name`. Use the name of the proxy as the parameter value.
3. To see the details of the RDS DB instance associated with the returned target group, run describe-db-proxy-targets.

RDS API

To view your proxies using the RDS API, use the DescribeDBProxies operation. It returns values of the DBProxy data type.

To see details of the connection settings for the proxy, use the proxy identifiers from this return value with the DescribeDBProxyTargetGroups operation. It returns values of the DBProxyTargetGroup data type.

To see the RDS instance or Aurora DB cluster associated with the proxy, use the DescribeDBProxyTargets operation. It returns values of the DBProxyTarget data type.

Connecting to a database through RDS Proxy

The way to connect to an RDS DB instance through a proxy or by connecting to the database is generally the same. For more information, see Overview of proxy endpoints.

Topics

Connecting to a proxy using native authentication

Use the following steps to connect to a proxy using native authentication:

1. Find the proxy endpoint. In the AWS Management Console, you can find the endpoint on the details page for the corresponding proxy. With the AWS CLI, you can use the describe-db-proxies command. The following example shows how.

```
# Add --output text to get output as a simple tab-separated list.
$ aws rds describe-db-proxies --query '*[*].
{DBProxyName:DBProxyName,Endpoint:Endpoint}'
[
    [
        {
            "Endpoint": "the-proxy.proxy-demo.us-east-1.rds.amazonaws.com",
            "DBProxyName": "the-proxy"
        },
        {
            "Endpoint": "the-proxy-other-secret.proxy-demo.us-
east-1.rds.amazonaws.com",
            "DBProxyName": "the-proxy-other-secret"
        },
        {
            "Endpoint": "the-proxy-rds-secret.proxy-demo.us-
east-1.rds.amazonaws.com",
            "DBProxyName": "the-proxy-rds-secret"
        },
        {
            "Endpoint": "the-proxy-t3.proxy-demo.us-east-1.rds.amazonaws.com",
```

```
            "DBProxyName": "the-proxy-t3"
        }
    ]
]
```

2. Specify the endpoint as the host parameter in the connection string for your client application. For example, specify the proxy endpoint as the value for the `mysql -h` option or `psql -h` option.
3. Supply the same database user name and password as you usually do.

Connecting to a proxy using IAM authentication

When you use IAM authentication with RDS Proxy, set up your database users to authenticate with regular user names and passwords. The IAM authentication applies to RDS Proxy retrieving the user name and password credentials from Secrets Manager. The connection from RDS Proxy to the underlying database doesn't go through IAM.

To connect to RDS Proxy using IAM authentication, use the same general connection procedure as for IAM authentication with an RDS DB instance. For general information about using IAM, see Security in Amazon RDS.

The major differences in IAM usage for RDS Proxy include the following:

- You don't configure each individual database user with an authorization plugin. The database users still have regular user names and passwords within the database. You set up Secrets Manager secrets containing these user names and passwords, and authorize RDS Proxy to retrieve the credentials from Secrets Manager.

  The IAM authentication applies to the connection between your client program and the proxy. The proxy then authenticates to the database using the user name and password credentials retrieved from Secrets Manager.
- Instead of the instance, cluster, or reader endpoint, you specify the proxy endpoint. For details about the proxy endpoint, see Connecting to your DB instance using IAM authentication.
- In the direct database IAM authentication case, you selectively choose database users and configure them to be identified with a special authentication plugin. You can then connect to those users using IAM authentication.

  In the proxy use case, you provide the proxy with Secrets that contain some user's user name and password (native authentication). You then connect to the proxy using IAM authentication. Here,

you do this by generating an authentication token with the proxy endpoint, not the database endpoint. You also use a user name that matches one of the user names for the secrets that you provided.

- Make sure that you use Transport Layer Security (TLS)/Secure Sockets Layer (SSL) when connecting to a proxy using IAM authentication.

You can grant a specific user access to the proxy by modifying the IAM policy. An example follows.

```
"Resource": "arn:aws:rds-db:us-east-2:1234567890:dbuser:prx-ABCDEFGHIJKL01234/db_user"
```

Considerations for connecting to a proxy with Microsoft SQL Server

For connecting to a proxy using IAM authentication, you don't use the password field. Instead, you provide the appropriate token property for each type of database driver in the token field. For example, use the `accessToken` property for JDBC, or the `sql_copt_ss_access_token` property for ODBC. Or use the `AccessToken` property for the .NET SqlClient driver. You can't use IAM authentication with clients that don't support token properties.

Under some conditions, a proxy can't share a database connection and instead pins the connection from your client application to the proxy to a dedicated database connection. For more information about these conditions, see Avoiding pinning an RDS Proxy.

Considerations for connecting to a proxy with PostgreSQL

For PostgreSQL, when a client starts a connection to a PostgreSQL database, it sends a startup message. This message includes pairs of parameter name and value strings. For details, see the `StartupMessage` in PostgreSQL message formats in the PostgreSQL documentation.

When connecting through an RDS proxy, the startup message can include the following currently recognized parameters:

- `user`
- `database`

The startup message can also include the following additional runtime parameters:

- `application_name`

- client_encoding
- DateStyle
- TimeZone
- extra_float_digits
- search_path

For more information about PostgreSQL messaging, see the Frontend/Backend protocol in the PostgreSQL documentation.

For PostgreSQL, if you use JDBC, we recommend the following to avoid pinning:

- Set the JDBC connection parameter `assumeMinServerVersion` to at least `9.0` to avoid pinning. This prevents the JDBC driver from performing an extra round trip during connection startup when it runs `SET extra_float_digits = 3`.
- Set the JDBC connection parameter `ApplicationName` to *`any/your-application-name`* to avoid pinning. Doing this prevents the JDBC driver from performing an extra round trip during connection startup when it runs `SET application_name = "PostgreSQL JDBC Driver"`. Note the JDBC parameter is `ApplicationName` but the PostgreSQL `StartupMessage` parameter is `application_name`.

For more information, see Avoiding pinning an RDS Proxy. For more information about connecting using JDBC, see Connecting to the database in the PostgreSQL documentation.

Managing an RDS Proxy

This section provides information on how to manage RDS Proxy operation and configuration. These procedures help your application make the most efficient use of database connections and achieve maximum connection reuse. The more that you can take advantage of connection reuse, the more CPU and memory overhead that you can save. This in turn reduces latency for your application and enables the database to devote more of its resources to processing application requests.

- Avoiding pinning an RDS Proxy
- Deleting an RDS Proxy

Modifying RDS Proxy

You can change specific settings associated with a proxy after you create the proxy. You do so by modifying the proxy itself, its associated target group, or both. Each proxy has an associated target group.

AWS Management Console

> **Important**
>
> The values in the **Client authentication type** and **IAM authentication** fields apply to all Secrets Manager secrets that are associated with this proxy. To specify different values for each secret, modify your proxy by using the AWS CLI or the API instead.

To modify the settings for a proxy

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Proxies**.
3. In the list of proxies, choose the proxy whose settings you want to modify or go to its details page.
4. For **Actions**, choose **Modify**.
5. Enter or choose the properties to modify. You can modify the following:
   - **Proxy identifier** – Rename the proxy by entering a new identifier.
   - **Idle client connection timeout** – Enter a time period for the idle client connection timeout.
   - **IAM role** – Change the IAM role used to retrieve the secrets from Secrets Manager.
   - **Secrets Manager secrets** – Add or remove Secrets Manager secrets. These secrets correspond to database user names and passwords.
   - **Client authentication type** – (PostgreSQL only) Change the type of authentication for client connections to the proxy.

- **IAM authentication** – Require or disallow IAM authentication for connections to the proxy.
- **Require Transport Layer Security** – Turn the requirement for Transport layer Security (TLS) on or off.
- **VPC security group** – Add or remove VPC security groups for the proxy to use.
- **Enable enhanced logging** – Enable or disable enhanced logging.

6. Choose **Modify**.

If you didn't find the settings listed that you want to change, use the following procedure to update the target group for the proxy. The *target group* associated with a proxy controls the settings related to the physical database connections. Each proxy has one associated target group named `default`, which is created automatically along with the proxy.

You can only modify the target group from the proxy details page, not from the list on the **Proxies** page.

To modify the settings for a proxy target group

1. On the **Proxies** page, go to the details page for a proxy.
2. For **Target groups**, choose the `default` link. Currently, all proxies have a single target group named `default`.
3. On the details page for the **default** target group, choose **Modify**.
4. Choose new settings for the properties that you can modify:

   - **Database** – Choose a different RDS DB instance or cluster.
   - **Connection pool maximum connections** – Adjust what percentage of the maximum available connections the proxy can use.
   - **Session pinning filters** – (Optional) Choose a session pinning filter. This circumvents the default safety measures for multiplexing database connections across client connections. Currently, the setting isn't supported for PostgreSQL. The only choice is `EXCLUDE_VARIABLE_SETS`.

     Enabling this setting can cause session variables of one connection to impact other connections. This can cause errors or correctness issues if your queries depend on session variable values set outside of the current transaction. Consider using this option after verifying it is safe for your applications to share database connections across client connections.

The following patterns can be considered safe:

- SET statements where there is no change to the effective session variable value, i.e., there is no change to the session variable.
- You change the session variable value and execute a statement in the same transaction.

For more information, see Avoiding pinning an RDS Proxy.

- **Connection borrow timeout** – Adjust the connection borrow timeout interval. This setting applies when the maximum number of connections is already being used for the proxy. The setting determines how long the proxy waits for a connection to become available before returning a timeout error.
- **Initialization query** – (Optional) Add an initialization query, or modify the current one. You can specify one or more SQL statements for the proxy to run when opening each new database connection. The setting is typically used with SET statements to make sure that each connection has identical settings such as time zone and character set. For multiple statements, use semicolons as the separator. You can also include multiple variables in a single SET statement, such as `SET x=1, y=2`.

You can't change certain properties, such as the target group identifier and the database engine.

5. Choose **Modify target group**.

AWS CLI

To modify a proxy using the AWS CLI, use the commands modify-db-proxy, modify-db-proxy-target-group, deregister-db-proxy-targets, and register-db-proxy-targets.

With the `modify-db-proxy` command, you can change properties such as the following:

- The set of Secrets Manager secrets used by the proxy.
- Whether TLS is required.
- The idle client timeout.
- Whether to log additional information from SQL statements for debugging.
- The IAM role used to retrieve Secrets Manager secrets.
- The security groups used by the proxy.

The following example shows how to rename an existing proxy.

```
aws rds modify-db-proxy --db-proxy-name the-proxy --new-db-proxy-name the_new_name
```

To modify connection-related settings or rename the target group, use the `modify-db-proxy-target-group` command. Currently, all proxies have a single target group named `default`. When working with this target group, you specify the name of the proxy and `default` for the name of the target group.

The following example shows how to first check the `MaxIdleConnectionsPercent` setting for a proxy and then change it, using the target group.

```
aws rds describe-db-proxy-target-groups --db-proxy-name the-proxy

{
    "TargetGroups": [
        {
            "Status": "available",
            "UpdatedDate": "2019-11-30T16:49:30.342Z",
            "ConnectionPoolConfig": {
                "MaxIdleConnectionsPercent": 50,
                "ConnectionBorrowTimeout": 120,
                "MaxConnectionsPercent": 100,
                "SessionPinningFilters": []
            },
            "TargetGroupName": "default",
            "CreatedDate": "2019-11-30T16:49:27.940Z",
            "DBProxyName": "the-proxy",
            "IsDefault": true
        }
    ]
}

aws rds modify-db-proxy-target-group --db-proxy-name the-proxy --target-group-name
 default --connection-pool-config '
{ "MaxIdleConnectionsPercent": 75 }'

{
    "DBProxyTargetGroup": {
        "Status": "available",
        "UpdatedDate": "2019-12-02T04:09:50.420Z",
        "ConnectionPoolConfig": {
```

```
            "MaxIdleConnectionsPercent": 75,
            "ConnectionBorrowTimeout": 120,
            "MaxConnectionsPercent": 100,
            "SessionPinningFilters": []
        },
        "TargetGroupName": "default",
        "CreatedDate": "2019-11-30T16:49:27.940Z",
        "DBProxyName": "the-proxy",
        "IsDefault": true
    }
}
```

With the `deregister-db-proxy-targets` and `register-db-proxy-targets` commands, you change which RDS DB instances the proxy is associated with through its target group. Currently, each proxy can connect to one RDS DB instance. The target group tracks the connection details for all the RDS DB instances in a Multi-AZ configuration.

The following example starts with a proxy that is associated with an Aurora MySQL cluster named `cluster-56-2020-02-25-1399`. The example shows how to change the proxy so that it can connect to a different cluster named `provisioned-cluster`.

When you work with an RDS DB instance, you specify the `--db-instance-identifier` option.

The following example modifies an Aurora MySQL proxy. An Aurora PostgreSQL proxy has port 5432.

```
aws rds describe-db-proxy-targets --db-proxy-name the-proxy

{
    "Targets": [
        {
            "Endpoint": "instance-9814.demo.us-east-1.rds.amazonaws.com",
            "Type": "RDS_INSTANCE",
            "Port": 3306,
            "RdsResourceId": "instance-9814"
        },
        {
            "Endpoint": "instance-8898.demo.us-east-1.rds.amazonaws.com",
            "Type": "RDS_INSTANCE",
            "Port": 3306,
            "RdsResourceId": "instance-8898"
        },
        {
```

```
            "Endpoint": "instance-1018.demo.us-east-1.rds.amazonaws.com",
            "Type": "RDS_INSTANCE",
            "Port": 3306,
            "RdsResourceId": "instance-1018"
        },
        {
            "Type": "TRACKED_CLUSTER",
            "Port": 0,
            "RdsResourceId": "cluster-56-2020-02-25-1399"
        },
        {
            "Endpoint": "instance-4330.demo.us-east-1.rds.amazonaws.com",
            "Type": "RDS_INSTANCE",
            "Port": 3306,
            "RdsResourceId": "instance-4330"
        }
    ]
}

aws rds deregister-db-proxy-targets --db-proxy-name the-proxy --db-cluster-identifier
 cluster-56-2020-02-25-1399

aws rds describe-db-proxy-targets --db-proxy-name the-proxy

{
    "Targets": []
}

aws rds register-db-proxy-targets --db-proxy-name the-proxy --db-cluster-identifier
 provisioned-cluster

{
    "DBProxyTargets": [
        {
            "Type": "TRACKED_CLUSTER",
            "Port": 0,
            "RdsResourceId": "provisioned-cluster"
        },
        {
            "Endpoint": "gkldje.demo.us-east-1.rds.amazonaws.com",
            "Type": "RDS_INSTANCE",
            "Port": 3306,
            "RdsResourceId": "gkldje"
        },
```

```
        {
            "Endpoint": "provisioned-1.demo.us-east-1.rds.amazonaws.com",
            "Type": "RDS_INSTANCE",
            "Port": 3306,
            "RdsResourceId": "provisioned-1"
        }
    ]
}
```

RDS API

To modify a proxy using the RDS API, you use the operations ModifyDBProxy, ModifyDBProxyTargetGroup, DeregisterDBProxyTargets, and RegisterDBProxyTargets operations.

With `ModifyDBProxy`, you can change properties such as the following:

- The set of Secrets Manager secrets used by the proxy.
- Whether TLS is required.
- The idle client timeout.
- Whether to log additional information from SQL statements for debugging.
- The IAM role used to retrieve Secrets Manager secrets.
- The security groups used by the proxy.

With `ModifyDBProxyTargetGroup`, you can modify connection-related settings or rename the target group. Currently, all proxies have a single target group named `default`. When working with this target group, you specify the name of the proxy and `default` for the name of the target group.

With `DeregisterDBProxyTargets` and `RegisterDBProxyTargets`, you change which RDS DB instance the proxy is associated with through its target group. Currently, each proxy can connect to one RDS DB instance . The target group tracks the connection details for the RDS DB instances in a Multi-AZ configuration .

Adding a new database user when using RDS Proxy

In some cases, you might add a new database user to an RDS DB instance or cluster that's associated with a proxy. If so, add or repurpose a Secrets Manager secret to store the credentials for that user. To do this, run through the following steps:

1. Create a new Secrets Manager secret, using the procedure described in Setting up database credentials in AWS Secrets Manager for RDS Proxy.
2. Update the IAM role to give RDS Proxy access to the new Secrets Manager secret. To do so, update the resources section of the IAM role policy.
3. Modify the RDS Proxy to add the new Secrets Manager secret under **Secrets Manager secrets**.
4. If the new user takes the place of an existing one, update the credentials stored in the proxy's Secrets Manager secret for the existing user.

Adding a new database user to a PostgreSQL database when using RDS Proxy

When adding a new user to your PostgreSQL database, if you have run the following command:

```
REVOKE CONNECT ON DATABASE postgres FROM PUBLIC;
```

Grant the `rdsproxyadmin` user the `CONNECT` privilege so the user can monitor connections on the target database.

```
GRANT CONNECT ON DATABASE postgres TO rdsproxyadmin;
```

You can also allow other target database users to perform health checks by changing `rdsproxyadmin` to the database user in the command above.

Changing the password for a database user when using RDS Proxy

In some cases, you might change the password for a database user in an RDS DB instance that's associated with a proxy. If so, update the corresponding Secrets Manager secret with the new password.

RDS Proxy connection considerations

Configuring connection settings

To adjust RDS Proxy's connection pooling, you can modify the following settings:

- IdleClientTimeout
- MaxConnectionsPercent

- MaxIdleConnectionsPercent
- ConnectionBorrowTimeout

IdleClientTimeout

You can specify how long a client connection can be idle before the proxy closes it. The default is 1,800 seconds (30 minutes).

A client connection is considered *idle* when the application doesn't submit a new request within the specified time after the previous request completed. The underlying database connection stays open and is returned to the connection pool. Thus, it's available to be reused for new client connections. If you want the proxy to proactively remove stale connections, then lowering the idle client connection timeout. If your workload establishes frequent connections with the proxy, then raising the idle client connection timeout to save the cost of establishing connections.

This setting is represented by the **Idle client connection timeout** field in the RDS console and the `IdleClientTimeout` setting in the AWS CLI and the API. To learn how to change the value of the **Idle client connection timeout** field in the RDS console, see AWS Management Console. To learn how to change the value of the `IdleClientTimeout` setting, see the CLI command modify-db-proxy or the API operation ModifyDBProxy.

MaxConnectionsPercent

You can limit the number of connections that an RDS Proxy can establish with the target database. You specify the limit as a percentage of the maximum connections available for your database. This setting is represented by the **Connection pool maximum connections** field in the RDS console and the `MaxConnectionsPercent` setting in the AWS CLI and the API.

The `MaxConnectionsPercent` value is expressed as a percentage of the `max_connections` setting for the RDS DB instance used by the target group. The proxy doesn't create all of these connections in advance. This setting allows the proxy to establish these connections as the workload needs them.

For example, for a registered database target with `max_connections` set to 1000, and `MaxConnectionsPercent` set to 95, RDS Proxy sets 950 connections as the upper limit for concurrent connections to that database target.

A common side-effect of your workload reaching the maximum number of allowed database connections is an increase in overall query latency, along with an increase in

the DatabaseConnectionsBorrowLatency metric. You can monitor currently used and total allowed database connections by comparing the DatabaseConnections and MaxDatabaseConnectionsAllowed metrics.

When setting this parameter, note the following best practices:

- Allow sufficient connection headroom for changes in workload pattern. It is recommended to set the parameter at least 30% above your maximum recent monitored usage. As RDS Proxy redistributes database connection quotas across multiple nodes, internal capacity changes might require at least 30% headroom for additional connections to avoid increased borrow latencies.
- RDS Proxy reserves a certain number of connections for active monitoring to support fast failover, traffic routing and internal operations. The MaxDatabaseConnectionsAllowed metric does not include these reserved connections. It represents the number of connections available to serve the workload, and can be lower than the value derived from the MaxConnectionsPercent setting.

  Minimal recommended MaxConnectionsPercent values

  - db.t3.small: 30
  - db.t3.medium or above: 20

To learn how to change the value of the **Connection pool maximum connections** field in the RDS console, see AWS Management Console. To learn how to change the value of the MaxConnectionsPercent setting, see the CLI command modify-db-proxy-target-group or the API operation ModifyDBProxyTargetGroup.

For information on database connection limits, see Maximum number of database connections.

MaxIdleConnectionsPercent

You can control the number of idle database connections that RDS Proxy can keep in the connection pool. By default, RDS Proxy considers a database connection in its pool to be *idle* when there's been no activity on the connection for five minutes.

The MaxIdleConnectionsPercent value is expressed as a percentage of the max_connections setting for the RDS DB instance target group. The default value is 50 percent of MaxConnectionsPercent, and the upper limit is the value of MaxConnectionsPercent. For example, if MaxConnectionsPercent, is 80, then the default value of MaxIdleConnectionsPercent is 40. If the value of MaxConnectionsPercent isn't

specified, then for RDS for SQL Server, `MaxIdleConnectionsPercent` is 5, and for all other engines, the default is 50.

With a high value, the proxy leaves a high percentage of idle database connections open. With a low value, the proxy closes a high percentage of idle database connections. If your workloads are unpredictable, consider setting a high value for `MaxIdleConnectionsPercent`. Doing so means that RDS Proxy can accommodate surges in activity without opening a lot of new database connections.

This setting is represented by the `MaxIdleConnectionsPercent` setting of `DBProxyTargetGroup` in the AWS CLI and the API. To learn how to change the value of the `MaxIdleConnectionsPercent` setting, see the CLI command modify-db-proxy-target-group or the API operation ModifyDBProxyTargetGroup.

For information on database connection limits, see Maximum number of database connections.

ConnectionBorrowTimeout

You can choose how long RDS Proxy waits for a database connection in the connection pool to become available for use before returning a timeout error. The default is 120 seconds. This setting applies when the number of connections is at the maximum, and so no connections are available in the connection pool. It also applies when no appropriate database instance is available to handle the request, such as when a failover operation is in process. Using this setting, you can set the best wait period for your application without changing the query timeout in your application code.

This setting is represented by the **Connection borrow timeout** field in the RDS console or the `ConnectionBorrowTimeout` setting of `DBProxyTargetGroup` in the AWS CLI or API. To learn how to change the value of the **Connection borrow timeout** field in the RDS console, see AWS Management Console. To learn how to change the value of the `ConnectionBorrowTimeout` setting, see the CLI command modify-db-proxy-target-group or the API operation ModifyDBProxyTargetGroup.

Client and database connections

Connections from your application to RDS Proxy are known as client connections. Connections from a proxy to the database are database connections. When using RDS Proxy, client connections terminate at the proxy while database connections are managed within RDS Proxy.

Application-side connection pooling can provide the benefit of reducing recurring connection establishment between your application and RDS Proxy.

Consider the following configuration aspects before implementing an application-side connection pool:

- Client connection max life: RDS Proxy enforces a maximum life of client connections of 24 hours. This value is not configurable. Configure your pool with a maximum connection life less than 24 hours to avoid unexpected client connection drops.
- Client connection idle timeout: RDS Proxy enforces a maximum idle time for client connections. Configure your pool with an idle connection timeout of a value lower than your client connection idle timeout setting for RDS Proxy to avoid unexpected connection drops.

The maximum number of client connections configured in your application-side connection pool does not have to be limited to the **max_connections** setting for RDS Proxy.

Client connection pooling results in a longer client connection life. If your connections experience pinning, then pooling client connections might reduce multiplexing efficiency. Client connections that are pinned but idle in the application-side connection pool continue to hold on to a database connection and prevent the database connection to be reused by other client connections. Review your proxy logs to check whether your connections experience pinning.

> **Note**
>
> RDS Proxy closes database connections some time after 24 hours when they are no longer in use. The proxy performs this action regardless of the value of the maximum idle connections setting.

Avoiding pinning an RDS Proxy

Multiplexing is more efficient when database requests don't rely on state information from previous requests. In that case, RDS Proxy can reuse a connection at the conclusion of each transaction. Examples of such state information include most variables and configuration parameters that you can change through SET or SELECT statements. SQL transactions on a client connection can multiplex between underlying database connections by default.

Your connections to the proxy can enter a state known as *pinning*. When a connection is pinned, each later transaction uses the same underlying database connection until the session ends. Other client connections also can't reuse that database connection until the session ends. The session ends when the client connection is dropped.

RDS Proxy automatically pins a client connection to a specific DB connection when it detects a session state change that isn't appropriate for other sessions. Pinning reduces the effectiveness of connection reuse. If all or almost all of your connections experience pinning, consider modifying your application code or workload to reduce the conditions that cause the pinning.

For example, your application changes a session variable or configuration parameter. In this case, later statements can rely on the new variable or parameter to be in effect. Thus, when RDS Proxy processes requests to change session variables or configuration settings, it pins that session to the DB connection. That way, the session state remains in effect for all later transactions in the same session.

For some database engines, this rule doesn't apply to all parameters that you can set. RDS Proxy tracks certain statements and variables. Thus, RDS Proxy doesn't pin the session when you modify them. In this case, RDS Proxy only reuses the connection for other sessions that have the same values for those settings. For details about what RDS Proxy tracks for a database engine, see the following:

- What RDS Proxy tracks for RDS for SQL Server databases
- What RDS Proxy tracks for RDS for MariaDB and RDS for MySQL databases

What RDS Proxy tracks for RDS for SQL Server databases

Following are the SQL Server statements that RDS Proxy tracks:

- `USE`
- `SET ANSI_NULLS`
- `SET ANSI_PADDING`
- `SET ANSI_WARNINGS`
- `SET ARITHABORT`
- `SET CONCAT_NULL_YIELDS_NULL`
- `SET CURSOR_CLOSE_ON_COMMIT`
- `SET DATEFIRST`
- `SET DATEFORMAT`
- `SET LANGUAGE`
- `SET LOCK_TIMEOUT`

- SET NUMERIC_ROUNDABORT
- SET QUOTED_IDENTIFIER
- SET TEXTSIZE
- SET TRANSACTION ISOLATION LEVEL

What RDS Proxy tracks for RDS for MariaDB and RDS for MySQL databases

Following are the MariaDB and MySQL statements that RDS Proxy tracks:

- DROP DATABASE
- DROP SCHEMA
- USE

Following are the MySQL and MariaDB variables that RDS Proxy tracks:

- AUTOCOMMIT
- AUTO_INCREMENT_INCREMENT
- CHARACTER SET (or CHAR SET)
- CHARACTER_SET_CLIENT
- CHARACTER_SET_DATABASE
- CHARACTER_SET_FILESYSTEM
- CHARACTER_SET_CONNECTION
- CHARACTER_SET_RESULTS
- CHARACTER_SET_SERVER
- COLLATION_CONNECTION
- COLLATION_DATABASE
- COLLATION_SERVER
- INTERACTIVE_TIMEOUT
- NAMES
- NET_WRITE_TIMEOUT
- QUERY_CACHE_TYPE
- SESSION_TRACK_SCHEMA

- SQL_MODE
- TIME_ZONE
- TRANSACTION_ISOLATION (or TX_ISOLATION)
- TRANSACTION_READ_ONLY (or TX_READ_ONLY)
- WAIT_TIMEOUT

Minimizing pinning

Performance tuning for RDS Proxy involves trying to maximize transaction-level connection reuse (multiplexing) by minimizing pinning.

You can minimize pinning by doing the following:

- Avoid unnecessary database requests that might cause pinning.
- Set variables and configuration settings consistently across all connections. That way, later sessions are more likely to reuse connections that have those particular settings.

  However, for PostgreSQL setting a variable leads to session pinning.
- For a MySQL engine family database, apply a session pinning filter to the proxy. You can exempt certain kinds of operations from pinning the session if you know that doing so doesn't affect the correct operation of your application.
- See how frequently pinning occurs by monitoring the Amazon CloudWatch metric DatabaseConnectionsCurrentlySessionPinned. For information about this and other CloudWatch metrics, see Monitoring RDS Proxy metrics with Amazon CloudWatch.
- If you use SET statements to perform identical initialization for each client connection, you can do so while preserving transaction-level multiplexing. In this case, you move the statements that set up the initial session state into the initialization query used by a proxy. This property is a string containing one or more SQL statements, separated by semicolons.

  For example, you can define an initialization query for a proxy that sets certain configuration parameters. Then, RDS Proxy applies those settings whenever it sets up a new connection for that proxy. You can remove the corresponding SET statements from your application code, so that they don't interfere with transaction-level multiplexing.

  For metrics about how often pinning occurs for a proxy, see Monitoring RDS Proxy metrics with Amazon CloudWatch.

Conditions that cause pinning for all engine families

The proxy pins the session to the current connection in the following situations where multiplexing might cause unexpected behavior:

- Any statement with a text size greater than 16 KB causes the proxy to pin the session.

Conditions that cause pinning for RDS for Microsoft SQL Server

For RDS for SQL Server, the following interactions also cause pinning:

- Using multiple active result sets (MARS). For information about MARS, see the SQL Server documentation.
- Using distributed transaction coordinator (DTC) communication.
- Creating temporary tables, transactions, cursors, or prepared statements.
- Using the following `SET` statements:
  - `SET ANSI_DEFAULTS`
  - `SET ANSI_NULL_DFLT`
  - `SET ARITHIGNORE`
  - `SET DEADLOCK_PRIORITY`
  - `SET FIPS_FLAGGER`
  - `SET FMTONLY`
  - `SET FORCEPLAN`
  - `SET IDENTITY_INSERT`
  - `SET NOCOUNT`
  - `SET NOEXEC`
  - `SET OFFSETS`
  - `SET PARSEONLY`
  - `SET QUERY_GOVERNOR_COST_LIMIT`
  - `SET REMOTE_PROC_TRANSACTIONS`
  - `SET ROWCOUNT`
  - `SET SHOWPLAN_ALL`, `SHOWPLAN_TEXT`, and `SHOWPLAN_XML`
  - `SET STATISTICS`

- `SET XACT_ABORT`

Conditions that cause pinning for RDS for MariaDB and RDS for MySQL

For MariaDB and MySQL, the following interactions also cause pinning:

- Explicit table lock statements `LOCK TABLE`, `LOCK TABLES`, or `FLUSH TABLES WITH READ LOCK` cause the proxy to pin the session.
- Creating named locks by using `GET_LOCK` causes the proxy to pin the session.
- Setting a user variable or a system variable (with some exceptions) causes the proxy to pin the session. If this situation reduces your connection reuse too much, then choose for `SET` operations to not cause pinning. For information about how to do so by setting the session pinning filters property, see Creating an RDS Proxy and Modifying RDS Proxy.
- Creating a temporary table causes the proxy to pin the session. That way, the contents of the temporary table are preserved throughout the session regardless of transaction boundaries.
- Calling the functions `ROW_COUNT`, `FOUND_ROWS`, and `LAST_INSERT_ID` sometimes causes pinning.
- Prepared statements cause the proxy to pin the session. This rule applies whether the prepared statement uses SQL text or the binary protocol.
- RDS Proxy does not pin connections when you use SET LOCAL.
- Calling stored procedures and stored functions doesn't cause pinning. RDS Proxy doesn't detect any session state changes resulting from such calls. Make sure that your application doesn't change session state inside stored routines if you rely on that session state to persist across transactions. For example, RDS Proxy isn't currently compatible with a stored procedure that creates a temporary table that persists across all transactions.

If you have expert knowledge about your application behavior, you can skip the pinning behavior for certain application statements. To do so, choose the **Session pinning filters** option when creating the proxy. Currently, you can opt out of session pinning for setting session variables and configuration settings.

Conditions that cause pinning for RDS for PostgreSQL

For PostgreSQL, the following interactions also cause pinning:

- Using `SET` commands.

- Using PREPARE, DISCARD, DEALLOCATE, or EXECUTE commands to manage prepared statements.
- Creating temporary sequences, tables, or views.
- Declaring cursors.
- Discarding the session state.
- Listening on a notification channel.
- Loading a library module such as auto_explain.
- Manipulating sequences using functions such as nextval and setval.
- Interacting with locks using functions such as pg_advisory_lock and pg_try_advisory_lock.

> **Note**
>
> RDS Proxy does not pin on transaction level advisory locks, specifically pg_advisory_xact_lock, pg_advisory_xact_lock_shared, pg_try_advisory_xact_lock, and pg_try_advisory_xact_lock_shared.

- Setting a parameter, or resetting a parameter to its default. Specifically, using SET and set_config commands to assign default values to session variables.
- Calling stored procedures and stored functions doesn't cause pinning. RDS Proxy doesn't detect any session state changes resulting from such calls. Make sure that your application doesn't change session state inside stored routines if you rely on that session state to persist across transactions. For example, RDS Proxy isn't currently compatible with a stored procedure that creates a temporary table that persists across all transactions.

Deleting an RDS Proxy

You can delete a proxy when you no longer need it. Or, you might delete a proxy if you take the DB instance or cluster associated with it out of service.

AWS Management Console

To delete a proxy

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.

2. In the navigation pane, choose **Proxies**.
3. Choose the proxy to delete from the list.
4. Choose **Delete Proxy**.

AWS CLI

To delete a DB proxy, use the AWS CLI command delete-db-proxy. To remove related associations, also use the deregister-db-proxy-targets command.

```
aws rds delete-db-proxy --name proxy_name
```

```
aws rds deregister-db-proxy-targets
    --db-proxy-name proxy_name
    [--target-group-name target_group_name]
    [--target-ids comma_separated_list]       # or
    [--db-instance-identifiers instance_id]       # or
    [--db-cluster-identifiers cluster_id]
```

RDS API

To delete a DB proxy, call the Amazon RDS API function DeleteDBProxy. To delete related items and associations, you also call the functions DeleteDBProxyTargetGroup and DeregisterDBProxyTargets.

Working with Amazon RDS Proxy endpoints

Learn about endpoints for RDS Proxy and how to use them. By using proxy endpoints, you can take advantage of the following capabilities:

- You can use multiple endpoints with a proxy to monitor and troubleshoot connections from different applications independently.
- You can use a cross-VPC endpoint to allow access to databases in one VPC from resources such as Amazon EC2 instances in a different VPC.

Topics

- Overview of proxy endpoints

Overview of proxy endpoints

Working with RDS Proxy endpoints involves the same kinds of procedures as with RDS instance endpoints. If you aren't familiar with RDS endpoints, find more information in Connecting to a DB instance running the MySQL database engine and Connecting to a DB instance running the PostgreSQL database engine.

For a proxy endpoint that you create, you can also associate the endpoint with a different virtual private cloud (VPC) than the proxy itself uses. By doing so, you can connect to the proxy from a different VPC, for example a VPC used by a different application within your organization.

For information about limits associated with proxy endpoints, see Limitations for proxy endpoints.

In the RDS Proxy logs, each entry is prefixed with the name of the associated proxy endpoint. This name can be the name you specified for a user-defined endpoint. Or, it can be the special name `default` for the default endpoint of a proxy that performs read/write requests.

Each proxy endpoint has its own set of CloudWatch metrics. You can monitor the metrics for all endpoints of a proxy. You can also monitor metrics for a specific endpoint, or for all the read/write or read-only endpoints of a proxy. For more information, see Monitoring RDS Proxy metrics with Amazon CloudWatch.

A proxy endpoint uses the same authentication mechanism as its associated proxy. RDS Proxy automatically sets up permissions and authorizations for the user-defined endpoint, consistent with the properties of the associated proxy.

Limitations for proxy endpoints

RDS Proxy endpoints have the following limitations:

- Each proxy has a default endpoint that you can modify but not create or delete.
- The maximum number of user-defined endpoints for a proxy is 20. Thus, a proxy can have up to 21 endpoints: the default endpoint, plus 20 that you create.
- When you associate additional endpoints with a proxy, RDS Proxy automatically determines which DB instances in your cluster to use for each endpoint.

Proxy endpoints for Multi-AZ DB cluster

By default, the endpoint that you connect to when you use RDS Proxy with a Multi-AZ DB cluster has read/write capability. As a result, this endpoint sends all requests to the writer instance of the cluster. All of those connections count against the `max_connections` value for the writer instance. If your proxy is associated with a Multi-AZ DB cluster, then you can create additional read/write or read-only endpoints for that proxy.

You can use a read-only endpoint with your proxy for read-only queries. You do this the same way that you use the reader endpoint for a Multi-AZ DB cluster. Doing so helps you to take advantage of the read scalability of a Multi-AZ DB cluster with one or more reader DB instances. You can run more simultaneous queries and make more simultaneous connections by using a read-only endpoint and adding more reader DB instances to your Multi-AZ DB cluster as needed. These reader endpoints help to improve the read scalability of your query-intensive applications. Reader endpoints also help to improve the availability of your connections if a reader DB instance in your cluster becomes unavailable.

Reader endpoints for Multi-AZ DB clusters

With RDS Proxy, you can create and use reader endpoints. However, these endpoints only work for proxies associated with Multi-AZ DB clusters. If you use the RDS CLI or API, you might see the `TargetRole` attribute with a value of `READ_ONLY`. You can take advantage of such proxies by changing the target of a proxy from an RDS DB instance to a Multi-AZ DB cluster.

You can create and connect to read-only endpoints called *reader endpoints* when you use RDS Proxy with Multi-AZ DB clusters.

How reader endpoints help application availability

In some cases, a reader instance in your cluster might become unavailable. If that occurs, connections that use a reader endpoint of a DB proxy can recover more quickly than ones that use the Multi-AZ DB cluster reader endpoint. RDS Proxy routes connections to only the available

reader instance in the cluster. There isn't a delay due to DNS caching when an instance becomes unavailable.

If the connection is multiplexed, RDS Proxy directs subsequent queries to a different reader instance without any interruption to your application. If a reader instance is in an unavailable state, all client connections to that instance endpoint are closed.

If the connection is pinned, the next query on the connection returns an error. However, your application can immediately reconnect to the same proxy endpoint. RDS Proxy routes the connection to a different reader DB instance that's in `available` state. When you manually reconnect, RDS Proxy doesn't check the replication lag between the old and new reader instance.

If your Multi-AZ DB cluster doesn't have any available reader instances, RDS Proxy attempts to connect to a reader endpoint when it becomes available. If no reader instance becomes available within the connection borrow timeout period, the connection attempt fails. If a reader instance does become available, the connection attempt succeeds.

How reader endpoints help query scalability

Reader endpoints for a proxy help with Multi-AZ DB cluster query scalability in the following ways:

- Where practical, RDS Proxy uses the same reader DB instance for all the queries issue using a particular reader endpoint connection. That way, a set of related queries on the same tables can take advantage of caching, plan optimization, and so on, on a particular DB instance.
- If a reader DB instance becomes unavailable, the effect on your application depends on whether the session is multiplexed or pinned. If the session is multiplexed, RDS Proxy routes any subsequent queries to a different reader DB instance without any action on your part. If the session is pinned, your application gets an error and must reconnect. You can reconnect to the reader endpoint immediately and RDS Proxy routes the connection to an available reader DB instance. For more information about multiplexing and pinning for proxy sessions, see Overview of RDS Proxy concepts.

Accessing RDS databases across VPCs

By default, the components of your RDS technology stack are all in the same Amazon VPC. For example, suppose that an application running on an Amazon EC2 instance connects to an Amazon RDS DB instance. In this case, the application server and database must both be within the same VPC.

With RDS Proxy, you can set up access to an Amazon RDS DB instance in one VPC from resources in another VPC, such as EC2 instances. For example, your organization might have multiple applications that access the same database resources. Each application might be in its own VPC.

To enable cross-VPC access, you create a new endpoint for the proxy. The proxy itself resides in the same VPC as the Amazon RDS DB instance. However, the cross-VPC endpoint resides in the other VPC, along with the other resources such as the EC2 instances. The cross-VPC endpoint is associated with subnets and security groups from the same VPC as the EC2 and other resources. These associations let you connect to the endpoint from the applications that otherwise can't access the database due to the VPC restrictions.

The following steps explain how to create and access a cross-VPC endpoint through RDS Proxy:

1. Create two VPCs, or choose two VPCs that you already use for RDS work. Each VPC should have its own associated network resources such as an internet gateway, route tables, subnets, and security groups. If you only have one VPC, you can consult Getting started with Amazon RDS for the steps to set up another VPC to use RDS successfully. You can also examine your existing VPC in the Amazon EC2 console to see the kinds of resources to connect together.
2. Create a DB proxy associated with the Amazon RDS DB instance that you want to connect to. Follow the procedure in Creating an RDS Proxy.
3. On the **Details** page for your proxy in the RDS console, under the **Proxy endpoints** section, choose **Create endpoint**. Follow the procedure in Creating a proxy endpoint.
4. Choose whether to make the cross-VPC endpoint read/write or read-only.
5. Instead of accepting the default of the same VPC as the Amazon RDS DB instance, choose a different VPC. This VPC must be in the same AWS Region as the VPC where the proxy resides.
6. Now instead of accepting the defaults for subnets and security groups from the same VPC as the Amazon RDS DB instance, make new selections. Make these based on the subnets and security groups from the VPC that you chose.
7. You don't need to change any of the settings for the Secrets Manager secrets. The same credentials work for all endpoints for your proxy, regardless of which VPC each endpoint is in.
8. Wait for the new endpoint to reach the **Available** state.
9. Make a note of the full endpoint name. This is the value ending in `*Region_name*.rds.amazonaws.com` that you supply as part of the connection string for your database application.

10 Access the new endpoint from a resource in the same VPC as the endpoint. A simple way to test this process is to create a new EC2 instance in this VPC. Then, log into the EC2 instance and run the `mysql` or `psql` commands to connect by using the endpoint value in your connection string.

Creating a proxy endpoint

To create a proxy endpoint, follow these instructions:

Console

To create a proxy endpoint

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Proxies**.
3. Click the name of the proxy that you want to create a new endpoint for.

   The details page for that proxy appears.
4. In the **Proxy endpoints** section, choose **Create proxy endpoint**.

   The **Create proxy endpoint** window appears.
5. For **Proxy endpoint name**, enter a descriptive name of your choice.
6. For **Target role**, choose whether to make the endpoint read/write or read-only.

   Connections that use read/write endpoints can perform any kind of operations, such as data definition language (DDL) statements, data manipulation language (DML) statements, and queries. These endpoints always connect to the primary instance of the RDS DB cluster. You can use read/write endpoints for general database operations when you only use a single endpoint in your application. You can also use read/write endpoints for administrative operations, online transaction processing (OLTP) applications, and extract-transform-load (ETL) jobs.

   Connections that use a read-only endpoint can only perform queries. RDS Proxy can use one of the reader instances for each connection to the endpoint. That way, a query-intensive application can take advantage of a Multi-AZ DB cluster's clustering capability. These read-only connections don't impose any overhead on the primary instance of the cluster. That way, your reporting and analysis queries don't slow down the write operations of your OLTP applications.

7. For **Virtual Private Cloud (VPC)**, choose the default to access the endpoint from the same EC2 instances or other resources that normally use to access the proxy or its associated database. To set up cross-VPC access for this proxy, choose a VPC other than the default. For more information about cross-VPC access, see Accessing RDS databases across VPCs.
8. For **Subnets**, RDS Proxy fills in the same subnets as the associated proxy by default. To restrict access to the endpoint to only a portion of the VPC's address range being able to connect to it, remove one or more subnets.
9. For **VPC security group**, you can choose an existing security group or create a new one. RDS Proxy fills in the same security group or groups as the associated proxy by default. If the inbound and outbound rules for the proxy are appropriate for this endpoint, then keep the default choice.

   If you choose to create a new security group, specify a name for the security group on this page. Then edit the security group settings from the EC2 console later.
10. Choose **Create proxy endpoint**.

AWS CLI

To create a proxy endpoint, use the AWS CLI create-db-proxy-endpoint command.

Include the following required parameters:

- `--db-proxy-name` *`value`*
- `--db-proxy-endpoint-name` *`value`*
- `--vpc-subnet-ids` *`list_of_ids`*. Separate the subnet IDs with spaces. You don't specify the ID of the VPC itself.

You can also include the following optional parameters:

- `--target-role { READ_WRITE | READ_ONLY }`. This parameter defaults to `READ_WRITE`. When the proxy is associated with a Multi-AZ DB cluster that only contains a writer DB instance, you can't specify `READ_ONLY`. For more information about the intended use of read-only endpoints with Multi-AZ DB clusters, see Reader endpoints for Multi-AZ DB clusters.
- `--vpc-security-group-ids` *`value`*. Separate the security group IDs with spaces. If you omit this parameter, RDS Proxy uses the default security group for the VPC. RDS Proxy determines the VPC based on the subnet IDs that you specify for the `--vpc-subnet-ids` parameter.

Example

The following example creates a proxy endpoint named `my-endpoint`.

For Linux, macOS, or Unix:

```
aws rds create-db-proxy-endpoint \
  --db-proxy-name my-proxy \
  --db-proxy-endpoint-name my-endpoint \
  --vpc-subnet-ids subnet_id subnet_id subnet_id ... \
  --target-role READ_ONLY \
  --vpc-security-group-ids security_group_id ]
```

For Windows:

```
aws rds create-db-proxy-endpoint ^
  --db-proxy-name my-proxy ^
  --db-proxy-endpoint-name my-endpoint ^
  --vpc-subnet-ids subnet_id_1 subnet_id_2 subnet_id_3 ... ^
  --target-role READ_ONLY ^
  --vpc-security-group-ids security_group_id
```

RDS API

To create a proxy endpoint, use the RDS API CreateDBProxyEndpoint action.

Viewing proxy endpoints

To view existing proxy endpoints, follow these instructions:

Console

To view the details for a proxy endpoint

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Proxies**.
3. In the list, choose the proxy whose endpoint you want to view. Click the proxy name to view its details page.
4. In the **Proxy endpoints** section, choose the endpoint that you want to view. Click its name to view the details page.

5. Examine the parameters whose values you're interested in. You can check properties such as the following:
   - Whether the endpoint is read/write or read-only.
   - The endpoint address that you use in a database connection string.
   - The VPC, subnets, and security groups associated with the endpoint.

AWS CLI

To view one or more proxy endpoints, use the AWS CLI describe-db-proxy-endpoints command.

You can include the following optional parameters:

- `--db-proxy-endpoint-name`
- `--db-proxy-name`

The following example describes the `my-endpoint` proxy endpoint.

Example

For Linux, macOS, or Unix:

```
aws rds describe-db-proxy-endpoints \
  --db-proxy-endpoint-name my-endpoint
```

For Windows:

```
aws rds describe-db-proxy-endpoints ^
  --db-proxy-endpoint-name my-endpoint
```

RDS API

To describe one or more proxy endpoints, use the RDS API DescribeDBProxyEndpoints operation.

Modifying a proxy endpoint

To modify your proxy endpoints, follow these instructions:

Console

To modify one or more proxy endpoints

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Proxies**.
3. In the list, choose the proxy whose endpoint you want to modify. Click the proxy name to view its
4. In the **Proxy endpoints** section, choose the endpoint that you want to modify. You can select it in the list, or click its name to view the details page.
5. On the proxy details page, under the **Proxy endpoints** section, choose **Edit**. Or, on the proxy endpoint details page, for **Actions**, choose **Edit**.
6. Change the values of the parameters that you want to modify.
7. Choose **Save changes**.

AWS CLI

To modify a proxy endpoint, use the AWS CLI modify-db-proxy-endpoint command with the following required parameters:

- `--db-proxy-endpoint-name`

Specify changes to the endpoint properties by using one or more of the following parameters:

- `--new-db-proxy-endpoint-name`
- `--vpc-security-group-ids`. Separate the security group IDs with spaces.

The following example renames the `my-endpoint` proxy endpoint to `new-endpoint-name`.

Example

For Linux, macOS, or Unix:

```
aws rds modify-db-proxy-endpoint \
  --db-proxy-endpoint-name my-endpoint \
  --new-db-proxy-endpoint-name new-endpoint-name
```

For Windows:

```
aws rds modify-db-proxy-endpoint ^
  --db-proxy-endpoint-name my-endpoint ^
  --new-db-proxy-endpoint-name new-endpoint-name
```

RDS API

To modify a proxy endpoint, use the RDS API ModifyDBProxyEndpoint operation.

Deleting a proxy endpoint

To delete an endpoint for your proxy, follow these instructions:

> **Note**
>
> You can't delete the default proxy endpoint that RDS Proxy automatically creates for each proxy.
> When you delete a proxy, RDS Proxy automatically deletes all the associated endpoints.

Console

To delete a proxy endpoint using the AWS Management Console

1. In the navigation pane, choose **Proxies**.
2. In the list, choose the proxy whose endpoint you want to endpoint. Click the proxy name to view its details page.
3. In the **Proxy endpoints** section, choose the endpoint that you want to delete. You can select one or more endpoints in the list, or click the name of a single endpoint to view the details page.
4. On the proxy details page, under the **Proxy endpoints** section, choose **Delete**. Or, on the proxy endpoint details page, for **Actions**, choose **Delete**.

AWS CLI

To delete a proxy endpoint, run the delete-db-proxy-endpoint command with the following required parameters:

- `--db-proxy-endpoint-name`

The following command deletes the proxy endpoint named `my-endpoint`.

For Linux, macOS, or Unix:

```
aws rds delete-db-proxy-endpoint \
  --db-proxy-endpoint-name my-endpoint
```

For Windows:

```
aws rds delete-db-proxy-endpoint ^
  --db-proxy-endpoint-name my-endpoint
```

RDS API

To delete a proxy endpoint with the RDS API, run the DeleteDBProxyEndpoint operation. Specify the name of the proxy endpoint for the `DBProxyEndpointName` parameter.

Monitoring RDS Proxy metrics with Amazon CloudWatch

You can monitor RDS Proxy by using Amazon CloudWatch. CloudWatch collects and processes raw data from the proxies into readable, near-real-time metrics. To find these metrics in the CloudWatch console, choose **Metrics**, then choose **RDS**, and choose **Per-Proxy Metrics**. For more information, see Using Amazon CloudWatch metrics in the Amazon CloudWatch User Guide.

> **Note**
>
> RDS publishes these metrics for each underlying Amazon EC2 instance associated with a proxy. A single proxy might be served by more than one EC2 instance. Use CloudWatch statistics to aggregate the values for a proxy across all the associated instances.
> Some of these metrics might not be visible until after the first successful connection by a proxy.

In the RDS Proxy logs, each entry is prefixed with the name of the associated proxy endpoint. This name can be the name you specified for a user-defined endpoint, or the special name `default` for the default endpoint of a proxy that performs read/write requests.

All RDS Proxy metrics are in the group `proxy`.

Each proxy endpoint has its own CloudWatch metrics. You can monitor the usage of each proxy endpoint independently. For more information about proxy endpoints, see Working with Amazon RDS Proxy endpoints.

You can aggregate the values for each metric using one of the following dimension sets. For example, by using the `ProxyName` dimension set, you can analyze all the traffic for a particular proxy. By using the other dimension sets, you can split the metrics in different ways. You can split the metrics based on the different endpoints or target databases of each proxy, or the read/write and read-only traffic to each database.

- Dimension set 1: `ProxyName`
- Dimension set 2: `ProxyName`, `EndpointName`
- Dimension set 3: `ProxyName`, `TargetGroup`, `Target`
- Dimension set 4: `ProxyName`, `TargetGroup`, `TargetRole`

Metric	Description	Valid period	CloudWatch dimension set
`AvailabilityPercentage`	The percentage of time for which the target group was available in the role indicated by the dimension. This metric is reported every minute. The most useful statistic for this metric is `Average`.	1 minute	Dimension set 4
`ClientConnections`	The current number of client connections. This metric is reported every minute. The most	1 minute	Dimension set 1, Dimension set 2

Metric	Description	Valid period	CloudWatch dimension set
	useful statistic for this metric is Sum.		
ClientConnectionsClosed	The number of client connections closed. The most useful statistic for this metric is Sum.	1 minute and above	Dimension set 1, Dimension set 2
ClientConnectionsNoTLS	The current number of client connections without Transport Layer Security (TLS). This metric is reported every minute. The most useful statistic for this metric is Sum.	1 minute and above	Dimension set 1, Dimension set 2
ClientConnectionsReceived	The number of client connection requests received. The most useful statistic for this metric is Sum.	1 minute and above	Dimension set 1, Dimension set 2
ClientConnectionsSetupFailedAuth	The number of client connection attempts that failed due to misconfigured authentication or TLS. The most useful statistic for this metric is Sum.	1 minute and above	Dimension set 1, Dimension set 2

Metric	Description	Valid period	CloudWatch dimension set
ClientConnectionsSetupSucceeded	The number of client connections successfully established with any authentication mechanism with or without TLS. The most useful statistic for this metric is Sum.	1 minute and above	Dimension set 1, Dimension set 2
ClientConnectionsTLS	The current number of client connections with TLS. This metric is reported every minute. The most useful statistic for this metric is Sum.	1 minute and above	Dimension set 1, Dimension set 2
DatabaseConnectionRequests	The number of requests to create a database connection. The most useful statistic for this metric is Sum.	1 minute and above	Dimension set 1, Dimension set 3, Dimension set 4
DatabaseConnectionRequestsWithTLS	The number of requests to create a database connection with TLS. The most useful statistic for this metric is Sum.	1 minute and above	Dimension set 1, Dimension set 3, Dimension set 4

Metric	Description	Valid period	CloudWatch dimension set
DatabaseConnections	The current number of database connections. This metric is reported every minute. The most useful statistic for this metric is Sum.	1 minute	Dimension set 1, Dimension set 3, Dimension set 4
DatabaseConnectionsBorrowLatency	The time in microseconds that it takes for the proxy being monitored to get a database connection. The most useful statistic for this metric is Average.	1 minute and above	Dimension set 1, Dimension set 2
DatabaseConnectionsCurrentlyBorrowed	The current number of database connections in the borrow state. This metric is reported every minute. The most useful statistic for this metric is Sum.	1 minute	Dimension set 1, Dimension set 3, Dimension set 4
DatabaseConnectionsCurrentlyInTransaction	The current number of database connections in a transaction. This metric is reported every minute. The most useful statistic for this metric is Sum.	1 minute	Dimension set 1, Dimension set 3, Dimension set 4

Metric	Description	Valid period	CloudWatch dimension set
DatabaseConnectionsCurrentlySessionPinned	The current number of database connections currently pinned because of operations in client requests that change session state. This metric is reported every minute. The most useful statistic for this metric is Sum.	1 minute	Dimension set 1, Dimension set 3, Dimension set 4
DatabaseConnectionsSetupFailed	The number of database connection requests that failed. The most useful statistic for this metric is Sum.	1 minute and above	Dimension set 1, Dimension set 3, Dimension set 4
DatabaseConnectionsSetupSucceeded	The number of database connections successfully established with or without TLS. The most useful statistic for this metric is Sum.	1 minute and above	Dimension set 1, Dimension set 3, Dimension set 4

Metric	Description	Valid period	CloudWatch dimension set
DatabaseConnectionsWithTLS	The current number of database connections with TLS. This metric is reported every minute. The most useful statistic for this metric is Sum.	1 minute	Dimension set 1, Dimension set 3, Dimension set 4
MaxDatabaseConnectionsAllowed	The maximum number of database connections allowed. This metric is reported every minute. The most useful statistic for this metric is Sum.	1 minute	Dimension set 1, Dimension set 3, Dimension set 4
QueryDatabaseResponseLatency	The time in microseconds that the database took to respond to the query. The most useful statistic for this metric is Average.	1 minute and above	Dimension set 1, Dimension set 2, Dimension set 3, Dimension set 4
QueryRequests	The number of queries received. A query including multiple statements is counted as one query. The most useful statistic for this metric is Sum.	1 minute and above	Dimension set 1, Dimension set 2

Metric	Description	Valid period	CloudWatch dimension set
QueryRequestsNoTLS	The number of queries received from non-TLS connections. A query including multiple statements is counted as one query. The most useful statistic for this metric is Sum.	1 minute and above	Dimension set 1, Dimension set 2
QueryRequestsTLS	The number of queries received from TLS connections. A query including multiple statements is counted as one query. The most useful statistic for this metric is Sum.	1 minute and above	Dimension set 1, Dimension set 2
QueryResponseLatency	The time in microseconds between getting a query request and the proxy responding to it. The most useful statistic for this metric is Average.	1 minute and above	Dimension set 1, Dimension set 2

You can find logs of RDS Proxy activity under CloudWatch in the AWS Management Console. Each proxy has an entry in the **Log groups** page.

Important

These logs are intended for human consumption for troubleshooting purposes and not for programmatic access. The format and content of the logs is subject to change.
In particular, older logs don't contain any prefixes indicating the endpoint for each request. In newer logs, each entry is prefixed with the name of the associated proxy endpoint. This name can be the name that you specified for a user-defined endpoint, or the special name `default` for requests using the default endpoint of a proxy.

Working with RDS Proxy events

An *event* indicates a change in an environment such as an AWS environment or a service or application from a software as a service (SaaS) partner. Or, it can be one of your own custom applications or services. For example, Amazon RDS generates an event when you create or modify an RDS Proxy. Amazon RDS delivers events to Amazon EventBridge in near-real time. Following, you can find a list of RDS Proxy events that you can subscribe to and an example of an RDS Proxy event.

For more information about working with events, see the following:

- For instructions on how to view events by using the AWS Management Console, AWS CLI, or RDS API, see Viewing Amazon RDS events.
- To learn how to configure Amazon RDS to send events to EventBridge, see Creating a rule that triggers on an Amazon RDS event.

RDS Proxy events

The following table shows the event category and a list of events when an RDS Proxy is the source type.

Category	RDS event ID	Message	Notes
configuration change	RDS-EVENT-0204	RDS modified DB proxy *name*.	None

Category	RDS event ID	Message	Notes
configuration change	RDS-EVENT-0207	RDS modified the end point of the DB proxy *name*.	None
configuration change	RDS-EVENT-0213	RDS detected the addition of the DB instance and automatically added it to the target group of the DB proxy *name*.	None
configuration change	RDS-EVENT-0213	RDS detected creation of DB instance *name* and automatically added it to target group *name* of DB proxy *name*.	None
configuration change	RDS-EVENT-0214	RDS detected deletion of DB instance *name* and automatically removed it from target group *name* of DB proxy *name*.	None
configuration change	RDS-EVENT-0215	RDS detected deletion of DB cluster *name* and automatically removed it from target group *name* of DB proxy *name*.	None
creation	RDS-EVENT-0203	RDS created DB proxy *name*.	None
creation	RDS-EVENT-0206	RDS created endpoint *name* for DB proxy *name*.	None
deletion	RDS-EVENT-0205	RDS deleted DB proxy *name*.	None

Category	RDS event ID	Message	Notes
deletion	RDS-EVENT-0208	RDS deleted endpoint *name* for DB proxy *name*.	None
failure	RDS-EVENT-0243	RDS failed to provision capacity for proxy *name* because there aren't enough IP addresses available in your subnets: *name*. To fix the issue, make sure that your subnets have the minimum number of unused IP addresses as recommend ed in the RDS Proxy documentation.	To determine the recommended number for your instance class, see Planning for IP address capacity.
failure	RDS-EVENT-0275	RDS throttled some connections to DB proxy *name*. The number of simultaneous connection requests from the client to the proxy has exceeded the limit.	None

The following is an example of an RDS Proxy event in JSON format. The event shows that RDS modified the endpoint named `my-endpoint` of the RDS Proxy named `my-rds-proxy`. The event ID is RDS-EVENT-0207.

```

```

Troubleshooting for RDS Proxy

Following, you can find troubleshooting ideas for some common RDS Proxy issues and information on CloudWatch logs for RDS Proxy.

In the RDS Proxy logs, each entry is prefixed with the name of the associated proxy endpoint. This name can be the name that you specified for a user-defined endpoint. Or, it can be the special name `default` for the default endpoint of a proxy that performs read/write requests. For more information about proxy endpoints, see Working with Amazon RDS Proxy endpoints.

Topics

- Verifying connectivity for a proxy
- Common issues and solutions

Verifying connectivity for a proxy

You can use the following commands to verify that all components such as the proxy, database, and compute instances in the connection can communicate with the each other.

Examine the proxy itself using the describe-db-proxies command. Also examine the associated target group using the describe-db-proxy-target-groups command. Check that the details of the targets match the RDS DB instance that you intend to associate with the proxy. Use commands such as the following.

```
aws rds describe-db-proxies --db-proxy-name $DB_PROXY_NAME
aws rds describe-db-proxy-target-groups --db-proxy-name $DB_PROXY_NAME
```

To confirm that the proxy can connect to the underlying database, examine the targets specified in the target groups using the describe-db-proxy-targets command. Use a command such as the following.

```
aws rds describe-db-proxy-targets --db-proxy-name $DB_PROXY_NAME
```

The output of the describe-db-proxy-targets command includes a `TargetHealth` field. You can examine the fields `State`, `Reason`, and `Description` inside `TargetHealth` to check if the proxy can communicate with the underlying DB instance.

- A `State` value of `AVAILABLE` indicates that the proxy can connect to the DB instance.
- A `State` value of `UNAVAILABLE` indicates a temporary or permanent connection problem. In this case, examine the `Reason` and `Description` fields. For example, if `Reason` has a value of `PENDING_PROXY_CAPACITY`, try connecting again after the proxy finishes its scaling operation. If `Reason` has a value of `UNREACHABLE`, `CONNECTION_FAILED`, or `AUTH_FAILURE`, use the explanation from the `Description` field to help you diagnose the issue.
- The `State` field might have a value of `REGISTERING` for a brief time before changing to `AVAILABLE` or `UNAVAILABLE`.

If the following Netcat command (`nc`) is successful, you can access the proxy endpoint from the EC2 instance or other system where you're logged in. This command reports failure if you're not in the same VPC as the proxy and the associated database. You might be able to log directly in to the database without being in the same VPC. However, you can't log into the proxy unless you're in the same VPC.

```
nc -zx MySQL_proxy_endpoint 3306

nc -zx PostgreSQL_proxy_endpoint 5432
```

You can use the following commands to make sure that your EC2 instance has the required properties. In particular, the VPC for the EC2 instance must be the same as the VPC for the that the proxy connects to.

```
aws ec2 describe-instances --instance-ids your_ec2_instance_id
```

Examine the Secrets Manager secrets used for the proxy.

```
aws secretsmanager list-secrets
aws secretsmanager get-secret-value --secret-id your_secret_id
```

Make sure that the `SecretString` field displayed by `get-secret-value` is encoded as a JSON string that includes the `username` and `password` fields. The following example shows the format of the `SecretString` field.

```
{
  "ARN": "some_arn",
  "Name": "some_name",
  "VersionId": "some_version_id",
  "SecretString": '{"username":"some_username","password":"some_password"}',
  "VersionStages": [ "some_stage" ],
  "CreatedDate": some_timestamp
}
```

Common issues and solutions

This section describes some common issues and potential solutions when using RDS Proxy.

After running the `aws rds describe-db-proxy-targets` CLI command, if the `TargetHealth` description states `Proxy does not have any registered credentials`, verify the following:

- There are credentials registered for the user to access the proxy.
- The IAM role to access the Secrets Manager secret used by the proxy is valid.

You might encounter the following RDS events while creating or connecting to a DB proxy.

Category	RDS event ID	Description
failure	RDS-EVENT-0243	RDS couldn't provision capacity for the proxy because there aren't enough IP addresses available in your subnets. To fix the issue, make sure that your subnets

Category	RDS event ID	Description
		have the minimum number of unused IP addresses. To determine the recommend ed number for your instance class, see Planning for IP address capacity.
failure	RDS-EVENT-0275	RDS throttled some connectio ns to DB proxy *name*. The number of simultaneous connection requests from the client to the proxy has exceeded the limit.

You might encounter the following issues while creating a new proxy or connecting to a proxy.

Error	Causes or workarounds
`403: The security token included in the request is invalid`	Select an existing IAM role instead of choosing to create a new one.

You might encounter the following issues while connecting to a MySQL proxy.

Error	Causes or workarounds
`ERROR 1040 (HY000): Connections rate limit exceeded (`*`limit_value`*` )`	The rate of connection requests from the client to the proxy has exceeded the limit.

Error	Causes or workarounds
`ERROR 1040 (HY000): IAM authentication rate limit exceeded`	The number of simultaneous requests with IAM authentication from the client to the proxy has exceeded the limit.
`ERROR 1040 (HY000): Number simultaneous connections exceeded (limit_value )`	The number of simultaneous connection requests from the client to the proxy exceeded the limit.
`ERROR 1045 (28000): Access denied for user 'DB_USER'@'%' (using password: YES)`	The Secrets Manager secret used by the proxy doesn't match the user name and password of an existing database user. Either update the credentials in the Secrets Manager secret, or make sure the database user exists and has the same password as in the secret.
`ERROR 1105 (HY000): Unknown error`	An unknown error occurred.
`ERROR 1231 (42000): Variable ''character_set_client'' can't be set to the value of value`	The value set for the `character_set_client` parameter is not valid. For example, the value `ucs2` is not valid because it can crash the MySQL server.

Error	Causes or workarounds
`ERROR 3159 (HY000): This RDS Proxy requires TLS connections.`	You enabled the setting **Require Transport Layer Security** in the proxy but your connection included the parameter `ssl-mode=DISABLED` in the MySQL client. Do either of the following: • Disable the setting **Require Transport Layer Security** for the proxy. • Connect to the database using the minimum setting of `ssl-mode=REQUIRED` in the MySQL client.
`ERROR 2026 (HY000): SSL connection error: Internal Server` *`Error`*	The TLS handshake to the proxy failed. Some possible reasons include the following: • SSL is required but the server doesn't support it. • An internal server error occurred. • A bad handshake occurred.
`ERROR 9501 (HY000): Timed-out waiting to acquire database connection`	The proxy timed-out waiting to acquire a database connection. Some possible reasons include the following: • The proxy is unable to establish a database connection because the maximum connections have been reached • The proxy is unable to establish a database connection because the database is unavailable.

You might encounter the following issues while connecting to a PostgreSQL proxy.

Error	Cause	Solution
`IAM authentication is allowed only with SSL connections.`	The user tried to connect to the database using IAM authentication with the setting `sslmode=disable` in the PostgreSQL client.	The user needs to connect to the database using the minimum setting of `sslmode=require` in the PostgreSQL client. For more information, see the

Error	Cause	Solution
		PostgreSQL SSL support documentation.
`This RDS Proxy requires TLS connections.`	The user enabled the option **Require Transport Layer Security** but tried to connect with `sslmode=disable` in the PostgreSQL client.	To fix this error, do one of the following: • Disable the proxy's **Require Transport Layer Security** option. • Connect to the database using the minimum setting of `sslmode=allow` in the PostgreSQL client.
`IAM authentication failed for user` *`user_name`* `. Check the IAM token for this user and try again.`	This error might be due to the following reasons: • The client supplied the incorrect IAM user name. • The client supplied an incorrect IAM authorization token for the user. • The client is using an IAM policy that does not have the necessary permissions. • The client supplied an expired IAM authorization token for the user.	To fix this error, do the following: 1. Confirm that the provided IAM user exists. 2. Confirm that the IAM authorization token belongs to the provided IAM user. 3. Confirm that the IAM policy has adequate permissions for RDS. 4. Check the validity of the IAM authorization token used.

Error	Cause	Solution
`This RDS proxy has no credentials for the role role_name . Check the credentials for this role and try again.`	There is no Secrets Manager secret for this role.	Add a Secrets Manager secret for this role. For more information, see Setting up AWS Identity and Access Management (IAM) policies for RDS Proxy.
`RDS supports only IAM, MD5, or SCRAM authentication.`	The database client being used to connect to the proxy is using an authentication mechanism not currently supported by the proxy.	If you're not using IAM authentication, use the MD5 or SCRAM password authentication.
`A user name is missing from the connection startup packet. Provide a user name for this connection.`	The database client being used to connect to the proxy isn't sending a user name when trying to establish a connection.	Make sure to define a user name when setting up a connection to the proxy using the PostgreSQL client of your choice.
`Feature not supported: RDS Proxy supports only version 3.0 of the PostgreSQL messaging protocol.`	The PostgreSQL client used to connect to the proxy uses a protocol older than 3.0.	Use a newer PostgreSQL client that supports the 3.0 messaging protocol. If you're using the PostgreSQL `psql` CLI, use a version greater than or equal to 7.4.
`Feature not supported: RDS Proxy currently doesn't support streaming replication mode.`	The PostgreSQL client used to connect to the proxy is trying to use the streaming replication mode, which isn't currently supported by RDS Proxy.	Turn off the streaming replication mode in the PostgreSQL client being used to connect.

Error	Cause	Solution
`Feature not supported : RDS Proxy currently doesn't support the option` *option_name* .	Through the startup message, the PostgreSQL client used to connect to the proxy is requesting an option that isn't currently supported by RDS Proxy.	Turn off the option being shown as not supported from the message above in the PostgreSQL client being used to connect.
`The IAM authentication failed because of too many competing requests.`	The number of simultaneous requests with IAM authentication from the client to the proxy has exceeded the limit.	Reduce the rate in which connections using IAM authentication from a PostgreSQL client are established.
`The maximum number of client connections to the proxy exceeded` *number_value* .	The number of simultaneous connection requests from the client to the proxy exceeded the limit.	Reduce the number of active connections from PostgreSQL clients to this RDS proxy.
`Rate of connection to proxy exceeded` *number_value* .	The rate of connection requests from the client to the proxy has exceeded the limit.	Reduce the rate in which connections from a PostgreSQL client are established.
`The password that was provided for the role` *role_name* `is wrong.`	The password for this role doesn't match the Secrets Manager secret.	Check the secret for this role in Secrets Manager to see if the password is the same as what's being used in your PostgreSQL client.
`The IAM authentication failed for the role` *role_name* `. Check the IAM token for this role and try again.`	There is a problem with the IAM token used for IAM authentication.	Generate a new authentication token and use it in a new connection.

Error	Cause	Solution
`IAM is allowed only with SSL connections.`	A client tried to connect using IAM authentication, but SSL wasn't enabled.	Enable SSL in the PostgreSQL client.
`Unknown error.`	An unknown error occurred.	Reach out to AWS Support to investigate the issue.
`Timed-out waiting to acquire database connection.`	The proxy timed-out waiting to acquire a database connection. Some possible reasons include the following: • The proxy can't establish a database connection because the maximum connections have been reached. • The proxy can't establish a database connection because the database is unavailable.	Possible solutions are the following: • Check the target of the status to see if it's unavailable. • Check if there are long-running transactions and/or queries being executed. They can use database connections from the connection pool for a long time.

Error	Cause	Solution
`Request returned an error: database_error .`	The database connection established from the proxy returned an error.	The solution depends on the specific database error. One example is: `Request returned an error: database "your-database-name" does not exist`. This means that the specified database name doesn't exist on the database server. Or it means that the user name used as a database name (if a database name isn't specified) doesn't exist on the server.

Using RDS Proxy with AWS CloudFormation

You can use RDS Proxy with AWS CloudFormation. This helps you to create groups of related resources. Such a group can include a proxy that can connect to a newly created Amazon RDS DB instance. RDS Proxy support in AWS CloudFormation involves two new registry types: `DBProxy` and `DBProxyTargetGroup`.

The following listing shows a sample AWS CloudFormation template for RDS Proxy.

```
Resources:
 DBProxy:
   Type: AWS::RDS::DBProxy
   Properties:
     DBProxyName: CanaryProxy
     EngineFamily: MYSQL
     RoleArn:
      Fn::ImportValue: SecretReaderRoleArn
     Auth:
       - {AuthScheme: SECRETS, SecretArn: !ImportValue ProxySecret, IAMAuth: DISABLED}
     VpcSubnetIds:
       Fn::Split: [",", "Fn::ImportValue": SubnetIds]
```

```
ProxyTargetGroup:
  Type: AWS::RDS::DBProxyTargetGroup
  Properties:
    DBProxyName: CanaryProxy
    TargetGroupName: default
    DBInstanceIdentifiers:
      - Fn::ImportValue: DBInstanceName
  DependsOn: DBProxy
```

For more information about the resources in this sample, see DBProxy and DBProxyTargetGroup.

For more information about resources that you can create using AWS CloudFormation, see RDS resource type reference.

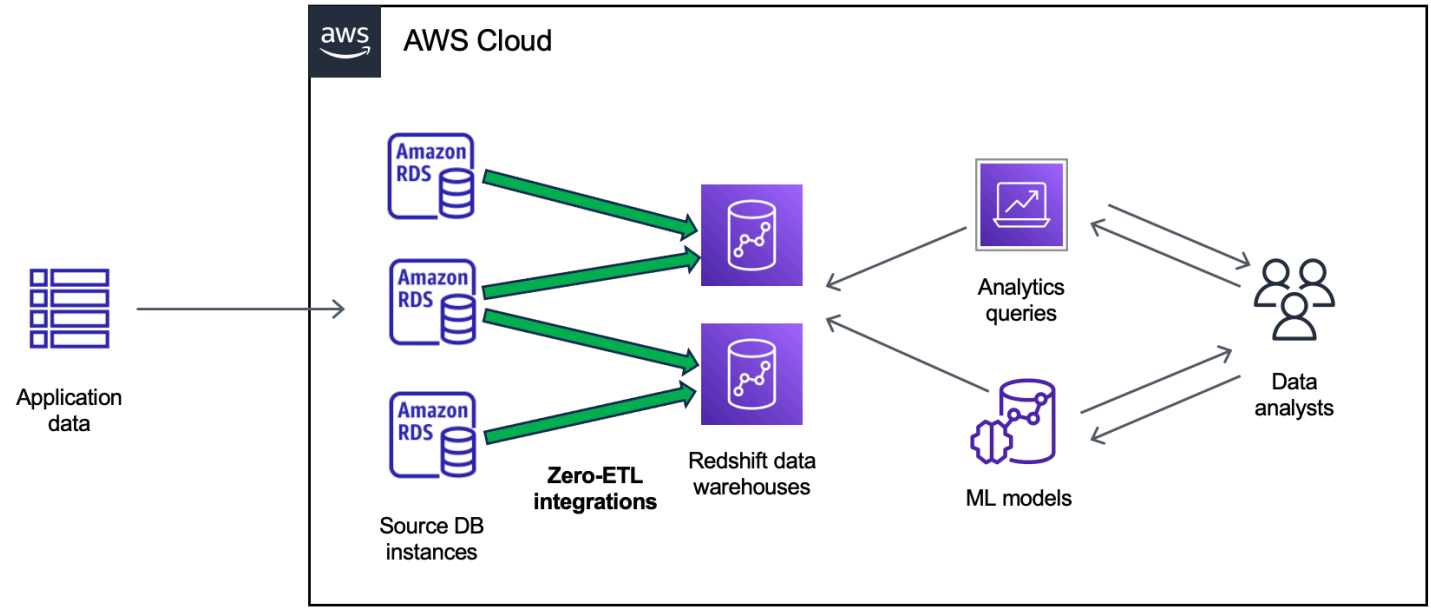
Working with Amazon RDS zero-ETL integrations with Amazon Redshift

An Amazon RDS zero-ETL integration with Amazon Redshift enables near real-time analytics and machine learning (ML) using Amazon Redshift on petabytes of transactional data from RDS. It's a fully managed solution for making transactional data available in Amazon Redshift after it is written to an RDS database. *Extract, transform,* and *load* (ETL) is the process of combining data from multiple sources into a large, central data warehouse.

A zero-ETL integration makes the data in your RDS database available in Amazon Redshift in near real-time. Once that data is in Amazon Redshift, you can power your analytics, ML, and AI workloads using the built-in capabilities of Amazon Redshift, such as machine learning, materialized views, data sharing, federated access to multiple data stores and data lakes, and integrations with Amazon SageMaker, Amazon QuickSight, and other AWS services.

To create a zero-ETL integration, you specify an RDS database as the *source*, and an Amazon Redshift data warehouse as the *target*. The integration replicates data from the source database into the target data warehouse.

The following diagram illustrates this functionality:



The integration monitors the health of the data pipeline and recovers from issues when possible. You can create integrations from multiple RDS databases into a single Amazon Redshift namespace, enabling you to derive insights across multiple applications.

Topics

Benefits

RDS zero-ETL integrations with Amazon Redshift have the following benefits:

- Help you derive holistic insights from multiple data sources.
- Eliminate the need to build and maintain complex data pipelines that perform extract, transform, and load (ETL) operations. Zero-ETL integrations remove the challenges that come with building and managing pipelines by provisioning and managing them for you.
- Reduce operational burden and cost, and let you focus on improving your applications.
- Let you leverage Amazon Redshift's analytics and ML capabilities to derive insights from transactional and other data, to respond effectively to critical, time-sensitive events.

Key concepts

As you get started with zero-ETL integrations, consider the following concepts:

Integration

A fully managed data pipeline that automatically replicates transactional data and schemas from an RDS database to an Amazon Redshift data warehouse.

Source database

The RDS database where data is replicated from. You can specify a Single-AZ or Multi-AZ DB instance, or a Multi-AZ DB cluster.

Target data warehouse

The Amazon Redshift data warehouse where the data is replicated to. There are two types of data warehouse: a provisioned cluster data warehouse and a serverless data warehouse. A provisioned cluster data warehouse is a collection of computing resources called nodes, which are organized into a group called a *cluster*. A serverless data warehouse is comprised of a workgroup that stores compute resources, and a namespace that houses the database objects and users. Both data warehouses run an Amazon Redshift engine and contain one or more databases.

Multiple source databases can write to the same target.

For more information, see Data warehouse system architecture in the *Amazon Redshift Developer Guide*.

Limitations

The following limitations apply to RDS zero-ETL integrations with Amazon Redshift.

Topics

- General limitations
- RDS for MySQL limitations
- Amazon Redshift limitations

General limitations

- The source database must be in the same Region as the target Amazon Redshift data warehouse.
- You can't rename a database if it has existing integrations.

- You can't create multiple integrations between the same source and target databases.
- You can't delete a database that has existing integrations. You must delete all associated integrations first.
- If you stop the source database, the last few transactions might not be replicated to the target data warehouse until you resume the database.
- You can’t delete an integration if the source database is stopped.
- If your database is the source of a blue/green deployment, the blue and green environments can't have existing zero-ETL integrations during switchover. You must delete the integration first and switch over, then recreate it.
- You can't create an integration for a source database that has another integration being actively created.
- When you initially create an integration, or when a table is being resynchronized, data seeding from the source to the target can take 20-25 minutes or more depending on the size of the source database. This delay can lead to increased replica lag.
- Some data types aren't supported. For more information, see the section called “Data type differences”.
- XA transaction aren't supported.
- Object identifiers (including database name, table name, column names, and others) can contain only alphanumeric characters, numbers, $, and _ (underscore).
- System tables, temporary tables, and views aren't replicated to Amazon Redshift.

RDS for MySQL limitations

- Your source database must be running a supported version of RDS for MySQL. For a list of supported versions, see the section called “Zero-ETL integrations ”.
- Zero-ETL integrations rely on MySQL binary logging (binlog) to capture ongoing data changes. Don't use binlog-based data filtering, as it can cause data inconsistencies between the source and target databases.
- Zero-ETL integrations are supported only for databases configured to use the InnoDB storage engine.
- Foreign key references with predefined table updates aren't supported. Specifically, `ON DELETE` and `ON UPDATE` rules aren't supported with `CASCADE`, `SET NULL`, and `SET DEFAULT` actions. Attempting to create or update a table with such references to another table will put the table into a failed state.

- `ALTER TABLE` partition operations cause your table to resynchronize in order to reload data from RDS to Amazon Redshift. The table will be unavailable for querying while it's resynchronizing. For more information, see the section called “One or more of my Amazon Redshift tables requires a resync”.

Amazon Redshift limitations

For a list of Amazon Redshift limitations related to zero-ETL integrations, see Considerations in the *Amazon Redshift Management Guide*.

Quotas

Your account has the following quotas related to RDS zero-ETL integrations with Amazon Redshift. Each quota is per-Region unless otherwise specified.

Name	Default	Description
Integrations	100	The total number of integrations within an AWS account.
Integrations per target data warehouse	50	The number of integrations sending data to a single target Amazon Redshift data warehouse.
Integrations per source instance	5	The number of integrations sending data from a single source DB instance.

In addition, Amazon Redshift places certain limits on the number of tables allowed in each DB instance or cluster node. For more information, see Quotas and limits in Amazon Redshift in the *Amazon Redshift Management Guide*.

Supported Regions

RDS zero-ETL integrations with Amazon Redshift are available in a subset of AWS Regions. For a list of supported Regions, see the section called “Zero-ETL integrations ”.

Getting started with Amazon RDS zero-ETL integrations with Amazon Redshift

Before you create a zero-ETL integration with Amazon Redshift, configure your RDS database and your Amazon Redshift data warehouse with the required parameters and permissions. During setup, you'll complete the following steps:

1. Create a custom DB parameter group.
2. Create a source database.
3. Create a target Amazon Redshift data warehouse.

After you complete these tasks, continue to the section called “Creating zero-ETL integrations”.

> **Tip**
>
> You can have RDS complete these setup steps for you while you're creating the integration, rather than performing them manually. To immediately start creating an integration, see the section called “Creating zero-ETL integrations”.

Step 1: Create a custom DB parameter group

Amazon RDS zero-ETL integrations with Amazon Redshift require specific values for the DB parameters that control binary logging (binlog). To configure binary logging, you must first create a custom DB parameter group, and then associate it with the source database.

Create a custom DB parameter group with the following settings. For instructions to create a parameter group, see the section called “DB parameter groups”.

- `binlog_format=ROW`
- `binlog_row_image=full`

In addition, make sure that the `binlog_row_value_options` parameter is *not* set to `PARTIAL_JSON`.

Step 2: Select or create a source database

After you create a custom DB parameter group, choose or create an RDS for MySQL database. This database will be the source of data replication to Amazon Redshift. For instructions to create a Single-AZ or Multi-AZ DB instance, see the section called "Creating a DB instance".

The database must be running a supported DB engine version. For a list of supported versions, see the section called "Zero-ETL integrations ".

For instructions to create a Single-AZ or Multi-AZ DB instance, see the section called "Creating a DB instance". For instructions to create a Multi-AZ DB cluster, see the section called "Creating a Multi-AZ DB cluster".

When you create the database, under **Additional configuration**, change the default **DB parameter group** to the custom parameter group that you created in the previous step.

> **Note**
>
> If you associate the parameter group with the database *after* the database is already created, you must reboot the database to apply the changes before you can create a zero-ETL integration. For instructions, see the section called "Rebooting a DB instance" or the section called "Rebooting a Multi-AZ DB cluster".

In addition, make sure that automated backups are enabled on the database. For more information, see the section called "Enabling automated backups".

Step 3: Create a target Amazon Redshift data warehouse

After you create your source database, you must create and configure a target data warehouse in Amazon Redshift. The data warehouse must meet the following requirements:

- Using an RA3 node type with at least two nodes, or Redshift Serverless.
- Encrypted (if using a provisioned cluster). For more information, see Amazon Redshift database encryption.

For instructions to create a data warehouse, see Creating a cluster for provisioned clusters, or Creating a workgroup with a namespace for Redshift Serverless.

Enable case sensitivity on the data warehouse

For the integration to be successful, the case sensitivity parameter (`enable_case_sensitive_identifier`) must be enabled for the data warehouse. By default, case sensitivity is disabled on all provisioned clusters and Redshift Serverless workgroups.

To enable case sensitivity, perform the following steps depending on your data warehouse type:

- **Provisioned cluster** – To enable case sensitivity on a provisioned cluster, create a custom parameter group with the `enable_case_sensitive_identifier` parameter enabled. Then, associate the parameter group with the cluster. For instructions, see Managing parameter groups using the console or Configuring parameter values using the AWS CLI.

  > **Note**
  >
  > Remember to reboot the cluster after you associate the custom parameter group with it.

- **Serverless workgroup** – To enable case sensitivity on a Redshift Serverless workgroup, you must use the AWS CLI. The Amazon Redshift console doesn't currently support modifying Redshift Serverless parameter values. Send the following update-workgroup request:

  ```
  aws redshift-serverless update-workgroup \
    --workgroup-name target-workgroup \
    --config-parameters
   parameterKey=enable_case_sensitive_identifier,parameterValue=true
  ```

  You don't need to reboot a workgroup after you modify its parameter values.

Configure authorization for the data warehouse

After you create a data warehouse, you must configure the source RDS database as an authorized integration source. For instructions, see Configure authorization for your Amazon Redshift data warehouse.

Set up an integration using the AWS SDKs

Rather than setting up each resource manually, you can run the following Python script to automatically set up the required resources for you. The code example uses the AWS SDK for Python (Boto3) to create a source RDS for MySQL DB instance and target Amazon Redshift data

warehouse, each with the required parameter values. It then waits for the databases to be available before creating a zero-ETL integration between them. You can comment out different functions depending on which resources you need to set up.

To install the required dependencies, run the following commands:

```
pip install boto3
pip install time
```

Within the script, optionally modify the names of the source, target, and parameter groups. The final function creates an integration named `my-integration` after the resources are set up.

Python code example

```
import boto3
import time

# Build the client using the default credential configuration.
# You can use the CLI and run 'aws configure' to set access key, secret
# key, and default Region.

rds = boto3.client('rds')
redshift = boto3.client('redshift')
sts = boto3.client('sts')

source_db_name = 'my-source-db' # A name for the source database
source_param_group_name = 'my-source-param-group' # A name for the source parameter
 group
target_cluster_name = 'my-target-cluster' # A name for the target cluster
target_param_group_name = 'my-target-param-group' # A name for the target parameter
 group

def create_source_db(*args):
    """Creates a source RDS for MySQL DB instance"""

    response = rds.create_db_parameter_group(
        DBParameterGroupName=source_param_group_name,
        DBParameterGroupFamily='mysql8.0',
        Description='RDS for MySQL zero-ETL integrations'
    )
    print('Created source parameter group: ' + response['DBParameterGroup']
['DBParameterGroupName'])
```

```
    response = rds.modify_db_parameter_group(
        DBParameterGroupName=source_param_group_name,
        Parameters=[
            {
                'ParameterName': 'binlog_format',
                'ParameterValue': 'ROW',
                'ApplyMethod': 'pending-reboot'
            },
            {
                'ParameterName': 'binlog_row_image',
                'ParameterValue': 'full',
                'ApplyMethod': 'pending-reboot'
            }
        ]
    )
    print('Modified source parameter group: ' + response['DBParameterGroupName'])

    response = rds.create_db_instance(
        DBInstanceIdentifier=source_db_name,
        DBParameterGroupName=source_param_group_name,
        Engine='mysql',
        EngineVersion='8.0.32',
        DBName='mydb',
        DBInstanceClass='db.m5.large',
        AllocatedStorage=15,
        MasterUsername='username',
        MasterUserPassword='Password01**'
    )
    print('Creating source database: ' + response['DBInstance']
['DBInstanceIdentifier'])
    source_arn = (response['DBInstance']['DBInstanceArn'])
    create_target_cluster(target_cluster_name, source_arn, target_param_group_name)
    return(response)

def wait_for_db_availability(*args):
    """Waits for both databases to be available"""

    print('Waiting for source and target to be available...')

    response = rds.describe_db_instances(
        DBInstanceIdentifier=source_db_name
    )
    source_status = response['DBInstances'][0]['DBInstanceStatus']
    source_arn = response['DBInstances'][0]['DBInstanceArn']

    response = redshift.describe_clusters(
        ClusterIdentifier=target_cluster_name
    )
    target_status = response['Clusters'][0]['ClusterStatus']
    target_arn = response['Clusters'][0]['ClusterNamespaceArn']

    # Every 60 seconds, check whether the databases are available
    if source_status != 'available' or target_status != 'available':
        time.sleep(60)
        response = wait_for_db_availability(
            source_db_name, target_cluster_name)
    else:
        print('Databases available. Ready to create zero-ETL integration.')
        create_integration(source_arn, target_arn)
        return

def create_integration(source_arn, target_arn):
```

```
    """Creates a zero-ETL integration using the source and target databases"""

    response = rds.create_integration(
        SourceArn=source_arn,
        TargetArn=target_arn,
        IntegrationName='my-integration'
    )
    print('Creating integration: ' + response['IntegrationName'])

def main():
    """main function"""
    create_source_db(source_db_name, source_param_group_name)
    wait_for_db_availability(source_db_name, target_cluster_name)

if __name__ == "__main__":
    main()
```

Next steps

With a source RDS database and an Amazon Redshift target data warehouse, you can now create a zero-ETL integration and replicate data. For instructions, see the section called “Creating zero-ETL integrations”.

Creating Amazon RDS zero-ETL integrations with Amazon Redshift

When you create an Amazon RDS zero-ETL integration, you specify the source RDS database and the target Amazon Redshift data warehouse. You can also customize encryption settings and add tags. Amazon RDS creates an integration between the source database and its target. Once the integration is active, any data that you insert into the source database will be replicated into the configured Amazon Redshift target.

Topics

Prerequisites

Before you create a zero-ETL integration, you must create a source database and a target Amazon Redshift data warehouse. You also must allow replication into the data warehouse by adding the database as an authorized integration source.

For instructions to complete each of these steps, see the section called "Getting started with zero-ETL integrations".

Required permissions

Certain IAM permissions are required to create a zero-ETL integration. At minimum, you need permissions to perform the following actions:

- Create zero-ETL integrations for the source RDS database.
- View and delete all zero-ETL integrations.
- Create inbound integrations into the target data warehouse. You don't need this permission if the same account owns the Amazon Redshift data warehouse and this account is an authorized principal for that data warehouse. For information about adding authorized principals, see Configure authorization for your Amazon Redshift data warehouse.

The following sample policy demonstrates the least privilege permissions required to create and manage integrations. You might not need these exact permissions if your user or role has broader permissions, such as an `AdministratorAccess` managed policy.

> **Note**
>
> Redshift Amazon Resource Names (ARNs) have the following format. Note the use of a forward slash (`/`) rather than a colon (`:`) before the serverless namespace UUID.
>
> - Provisioned cluster – `arn:aws:redshift:{region}:{account-id}:namespace:namespace-uuid`
> - Serverless – `arn:aws:redshift-serverless:{region}:{account-id}:namespace/namespace-uuid`

Sample policy

```
{
    "Version": "2012-10-17",
    "Statement": [{
        "Effect": "Allow",
        "Action": [
            "rds:CreateIntegration"
        ],
        "Resource": [
            "arn:aws:rds:{region}:{account-id}:db:source-db",
            "arn:aws:rds:{region}:{account-id}:integration:*"
        ]
    },
    {
        "Effect": "Allow",
        "Action": [
            "rds:DescribeIntegrations"
        ],
        "Resource": ["*"]
    },
    {
        "Effect": "Allow",
        "Action": [
            "rds:DeleteIntegration",
            "rds:ModifyIntegration"
        ],
        "Resource": [
            "arn:aws:rds:{region}:{account-id}:integration:*"
        ]
    },
    {
        "Effect": "Allow",
        "Action": [
            "redshift:CreateInboundIntegration"
        ],
        "Resource": [
            "arn:aws:redshift:{region}:{account-id}:namespace:namespace-uuid"
        ]
    }]
}
```

Choosing a target data warehouse in a different account

If you plan to specify a target Amazon Redshift data warehouse that's in another AWS account, you must create a role that allows users in the current account to access resources in the target account. For more information, see Providing access to an IAM user in another AWS account that you own.

The role must have the following permissions, which allow the user to view available Amazon Redshift provisioned clusters and Redshift Serverless namespaces in the target account.

Required permissions and trust policy

```
{
   "Version":"2012-10-17",
   "Statement":[
      {
         "Effect":"Allow",
         "Action":[
            "redshift:DescribeClusters",
            "redshift-serverless:ListNamespaces"
         ],
         "Resource":[
            "*"
         ]
      }
   ]
}
```

The role must have the following trust policy, which specifies the target account ID.

```
{
   "Version":"2012-10-17",
   "Statement":[
      {
         "Effect":"Allow",
         "Principal":{
            "AWS": "arn:aws:iam::{external-account-id}:root"
         },
         "Action":"sts:AssumeRole"
      }
   ]
}
```

For instructions to create the role, see Creating a role using custom trust policies.

Creating zero-ETL integrations

You can create a zero-ETL integration using the AWS Management Console, the AWS CLI, or the RDS API.

By default, RDS for MySQL immediately purges binary log files. Because zero-ETL integrations rely on binary logs to replicate data from the source to the target, the retention period for the source database must be at least one hour. As soon as you create an integration, Amazon RDS checks the binary log file retention period for the selected source database. If the current value is 0 hours, Amazon RDS automatically changes it to 1 hour. Otherwise, the value remains the same.

RDS console

To create a zero-ETL integration

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the left navigation pane, choose **Zero-ETL integrations**.
3. Choose **Create zero-ETL integration**.
4. For **Integration identifier**, enter a name for the integration. The name can have up to 63 alphanumeric characters and can include hyphens.
5. Choose **Next**.
6. For **Source**, select the RDS database where the data will originate from.

   > **Note**
   >
   > RDS notifies you if the DB parameters aren't configured correctly. If you receive this message, you can either choose **Fix it for me**, or configure them manually. For instructions to fix them manually, see the section called “Step 1: Create a custom DB parameter group”.
   > Modifying DB parameters requires a reboot. Before you can create the integration, the reboot must be complete and the new parameter values must be successfully applied to the database.

7. Once your source database is successfully configured, choose **Next**.

8. For **Target**, do the following:

    1. (Optional) To use a different AWS account for the Amazon Redshift target, choose **Specify a different account**. Then, enter the ARN of an IAM role with permissions to display your data warehouses. For instructions to create the IAM role, see the section called "Choosing a target data warehouse in a different account".
    2. For **Amazon Redshift data warehouse**, select the target for replicated data from the source database. You can choose a provisioned Amazon Redshift *cluster* or a Redshift Serverless *namespace* as the target.

    > **Note**
    >
    > RDS notifies you if the resource policy or case sensitivity settings for the specified data warehouse aren't configured correctly. If you receive this message, you can either choose **Fix it for me**, or configure them manually. For instructions to fix them manually, see Turn on case sensitivity for your data warehouse and Configure authorization for your data warehouse in the *Amazon Redshift Management Guide*.
    > Modifying case sensitivity for a *provisioned* Redshift cluster requires a reboot. Before you can create the integration, the reboot must be complete and the new parameter value must be successfully applied to the cluster.
    > If your selected source and target are in different AWS accounts, then Amazon RDS cannot fix these settings for you. You must navigate to the other account and fix them manually in Amazon Redshift.

9. Once your target data warehouse is configured correctly, choose **Next**.
10. (Optional) For **Tags**, add one or more tags to the integration. For more information, see the section called "Tagging RDS resources".
11. For **Encryption**, specify how you want your integration to be encrypted. By default, RDS encrypts all integrations with an AWS owned key. To choose a customer managed key instead, enable **Customize encryption settings** and choose a KMS key to use for encryption. For more information, see the section called "Encrypting Amazon RDS resources".

    Optionally, add an encryption context. For more information, see Encryption context in the *AWS Key Management Service Developer Guide*.

> **Note**
>
> Amazon RDS adds the following encryption context pairs in addition to any that you add:
>
> - `aws:redshift:integration:arn` - `IntegrationArn`
> - `aws:servicename:id` - `Redshift`
>
> This reduces the overall number of pairs that you can add from 8 to 6, and contributes to the overall character limit of the grant constraint. For more information, see Using grant constraints in the *AWS Key Management Service Developer Guide*.

12. Choose **Next**.
13. Review your integration settings and choose **Create zero-ETL integration**.

    If creation fails, see the section called "I can't create a zero-ETL integration" for troubleshooting steps.

The integration has a status of `Creating` while it's being created, and the target Amazon Redshift data warehouse has a status of `Modifying`. During this time, you can't query the data warehouse or make any configuration changes on it.

When the integration is successfully created, the status of the integration and the target Amazon Redshift data warehouse both change to `Active`.

AWS CLI

To create a zero-ETL integration using the AWS CLI, use the create-integration command with the following options:

- `--integration-name` – Specify a name for the integration.
- `--source-arn` – Specify the ARN of the RDS database that will be the source for the integration.
- `--target-arn` – Specify the ARN of the Amazon Redshift data warehouse that will be the target for the integration.

Example

For Linux, macOS, or Unix:

```
aws rds create-integration \
    --integration-name my-integration \
    --source-arn arn:aws:rds:{region}:{account-id}:my-db \
    --target-arn arn:aws:redshift:{region}:{account-id}:namespace:namespace-uuid
```

For Windows:

```
aws rds create-integration ^
    --integration-name my-integration ^
    --source-arn arn:aws:rds:{region}:{account-id}:my-db ^
    --target-arn arn:aws:redshift:{region}:{account-id}:namespace:namespace-uuid
```

RDS API

To create a zero-ETL integration by using the Amazon RDS API, use the `CreateIntegration` operation with the following parameters:

- `IntegrationName` – Specify a name for the integration.
- `SourceArn` – Specify the ARN of the RDS database that will be the source for the integration.
- `TargetArn` – Specify the ARN of the Amazon Redshift data warehouse that will be the target for the integration.

Encrypting integrations with a customer managed key

If you specify a custom KMS key rather than an AWS owned key when you create an integration, the key policy must provide the Amazon Redshift service principal access to the `CreateGrant` action. In addition, it must allow the requestor account or role to perform to the `DescribeKey` and `CreateGrant` actions.

The following sample key policy statements demonstrate the permissions required in your policy document. Some examples include context keys to further reduce the scope of permissions.

Sample key policy statements

The following policy statement allows the requestor account or role to retrieve information about a KMS key.

```
{
   "Effect":"Allow",
   "Principal":{
      "AWS":"arn:aws:iam::{account-ID}:role/{role-name}"
   },
   "Action":"kms:DescribeKey",
   "Resource":"*"
}
```

The following policy statement allows the requestor account or role to add a grant to a KMS key. The `kms:ViaService` condition key limits use of the KMS key to requests from Amazon RDS.

```
{
   "Effect":"Allow",
   "Principal":{
      "AWS":"arn:aws:iam::{account-ID}:role/{role-name}"
   },
   "Action":"kms:CreateGrant",
   "Resource":"*",
   "Condition":{
      "StringEquals":{
         "kms:EncryptionContext:{context-key}":"{context-value}",
         "kms:ViaService":"rds.{region}.amazonaws.com"
      },
      "ForAllValues:StringEquals":{
         "kms:GrantOperations":[
            "Decrypt",
            "GenerateDataKey",
            "CreateGrant"
         ]
      }
   }
}
```

The following policy statement allows the Amazon Redshift service principal to add a grant to a KMS key.

```
{
   "Effect":"Allow",
   "Principal":{
      "Service":"redshift.amazonaws.com"
   },
```

```
    "Action":"kms:CreateGrant",
    "Resource":"*",
    "Condition":{
       "StringEquals":{
          "kms:EncryptionContext:{context-key}":"{context-value}",
          "aws:SourceAccount":"{account-ID}"
       },
       "ForAllValues:StringEquals":{
          "kms:GrantOperations":[
             "Decrypt",
             "GenerateDataKey",
             "CreateGrant"
          ]
       },
       "ArnLike":{
          "aws:SourceArn":"arn:aws:*:{region}:{account-ID}:integration:*"
       }
    }
}
```

For more information, see Creating a key policy in the *AWS Key Management Service Developer Guide*.

Next steps

After you successfully create a zero-ETL integration, you must create a destination database within your target Amazon Redshift cluster or workgroup. Then, you can start adding data to the source RDS database and querying it in Amazon Redshift. For instructions, see Creating destination databases in Amazon Redshift.

Data filtering for Amazon RDS zero-ETL integrations with Amazon Redshift

You can use data filtering for Amazon RDS zero-ETL integrations to define the scope of replication from the source Amazon RDS database to the target Amazon Redshift data warehouse. Rather than replicating *all* data to the target, you can define one or more filters that selectively include or exclude certain tables from being replicated. Only filtering at the database and table level is available for zero-ETL integrations. You can't filter by columns or rows.

Data filtering can be useful when you want to:

- Join certain tables from two or more different source databases and you don't need complete data from either database.
- Save costs by performing analytics using only a subset of tables rather than an entire fleet of databases.
- Filter out sensitive information—such as phone numbers, addresses, or credit card details—from certain tables.

You can add data filters to a zero-ETL integration using the AWS Management Console, the AWS Command Line Interface (AWS CLI), or the Amazon RDS API.

If the integration has a provisioned Amazon Redshift cluster as its target, the cluster must be on patch 180 or higher.

Topics

Format of a data filter

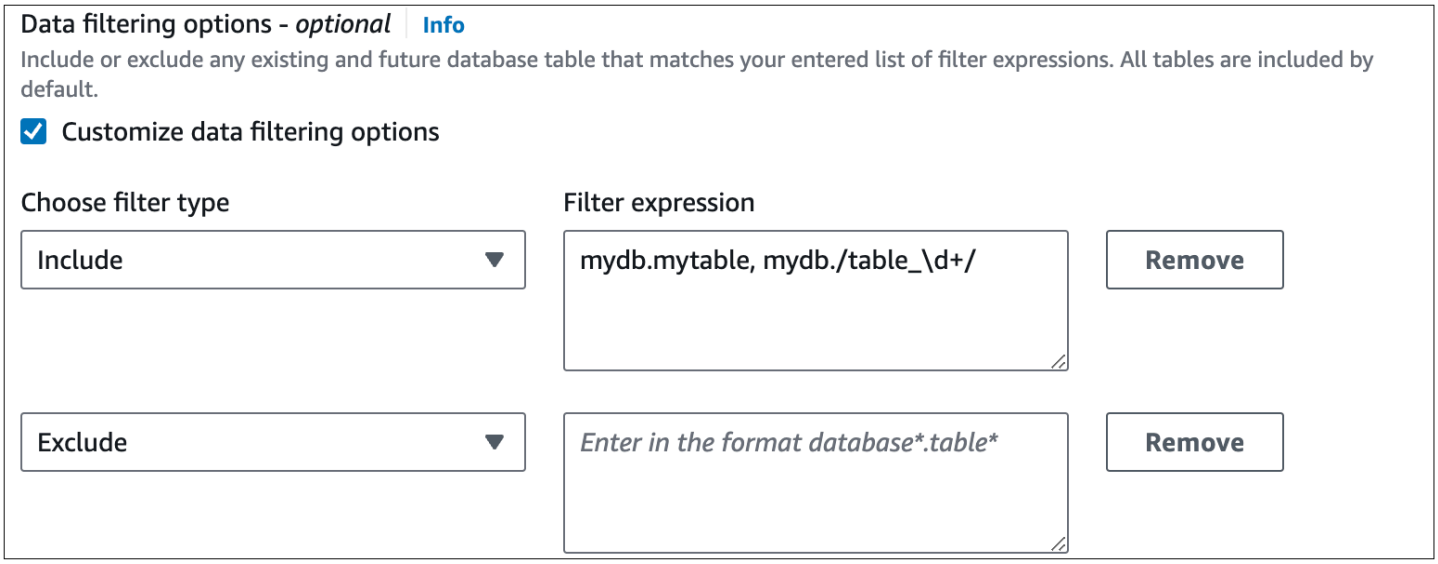
You can define multiple filters for a single integration. Each filter either includes or excludes any existing and future database tables that match one of the patterns in the filter expression. Amazon RDS zero-ETL integrations use Maxwell filter syntax for data filtering.

Each filter has the following elements:

Element	Description
Filter type	An `Include` filter type *includes* all tables that match one of the patterns in the filter expression. An `Exclude` filter type *excludes* all tables that match one of the patterns.

Element	Description
Filter expression	A comma-separated list of patterns. Expressions must use Maxwell filter syntax.
Pattern	A filter pattern in the format *database*.*table*. You can specify literal database and table names (such as `mydb.mytable` , or use wildcards (*). You can also define regular expressions in the database and table name. Amazon RDS supports filtering only at the database and table level. You can't include column-level filters (`database.table.column`) or denylists A single integration can have a maximum of 99 total patterns. In the console, you can contain patterns within a single filter expression, or spread them out among multiple expressions. A single pattern can't exceed 256 characters in length.

The following image shows the structure of data filters in the console:



Important

Do not include personally identifying, confidential, or sensitive information in your filter patterns.

Data filters in the AWS CLI

When using the AWS CLI to add a data filter, the syntax differs slightly compared to the console. Each individual pattern must be associated with its own filter type (`Include` or `Exclude`). You can't group multiple patterns with a single filter type.

For example, in the console you can group the following comma-separated patterns within a single `Include` statement:

```
mydb.mytable, mydb./table_\d+/
```

However, when using the AWS CLI, the same data filter must be in the following format:

```
'include: mydb.mytable, include: mydb./table_\d+/'
```

Filter logic

If you don't specify any data filters in your integration, Amazon RDS assumes a default filter of `include:*.*` and replicates all tables to the target data warehouse. However, if you specify

at least one filter, the logic starts with an assumed `exclude:*.*`, meaning that all tables are automatically *excluded* from replication. This allows you to directly define which tables and databases to include.

For example, if you define the following filter:

```
'include: db.table1, include: db.table2'
```

Amazon RDS evaluates the filter as follows:

```
'exclude:*.*, include: db.table1, include: db.table2'
```

Therefore, only `table1` and `table2` from the database named db are replicated to the target data warehouse.

Filter precedence

Amazon RDS evaluates data filters in the order in which they're specified. In the AWS Management Console, this means that Amazon RDS evaluates filter expressions from left to right and from top to bottom. If you specify a certain pattern for the first filter, then a second filter or even an individual pattern specified immediately after it can override it.

For example, your first filter might be `Include books.stephenking`, which includes a single table named `stephenking` from within the `books` database. However, if you add a second filter of `Exclude books.*`, it overrides the `Include` filter defined before it. Thus, no tables from the `books` index are replicated to Amazon Redshift.

If you specify at least one filter, the logic starts with an assumed `exclude:*.*`, meaning that all tables are automatically *excluded* from replication. Therefore, as a general best practice, define your filters from most broad to least broad. For example, use one or more `Include` statements to define all of the data that you want to replicate. Then, begin adding `Exclude` filters to selectively exclude certain tables from being replicated.

The same principle applies to filters that you define using the AWS CLI. Amazon RDS evaluates these filter patterns in the order that they're specified, so a pattern might override one specified before it.

Examples

The following examples demonstrate how data filtering works for zero-ETL integrations:

- Include all databases and all tables:

```
'include: *.*'
```

- Include all tables within the `books` database:

```
'include: books.*'
```

- Exclude any tables named `mystery`:

```
'include: *.*, exclude: *.mystery'
```

- Include two specific tables within the `books` database:

```
'include: books.stephen_king, include: books.carolyn_keene'
```

- Include all tables in the `books` database, except for those containing the substring `mystery`:

```
'include: books.*, exclude: books./.*mystery.*/'
```

- Include all tables in the `books` database, except those starting with `mystery`:

```
'include: books.*, exclude: books./mystery.*/'
```

- Include all tables in the `books` database, except those ending with `mystery`:

```
'include: books.*, exclude: books./.*mystery/'
```

- Include all tables in the `books` database that start with `table_`, except for the one named `table_stephen_king`. For example, `table_movies` or `table_books` would be replicated, but not `table_stephen_king`.

```
'include: books./table_.*/, exclude: books.table_stephen_king'
```

Adding data filters to an integration

You can configure data filtering using the AWS Management Console, the AWS CLI, or the Amazon RDS API.

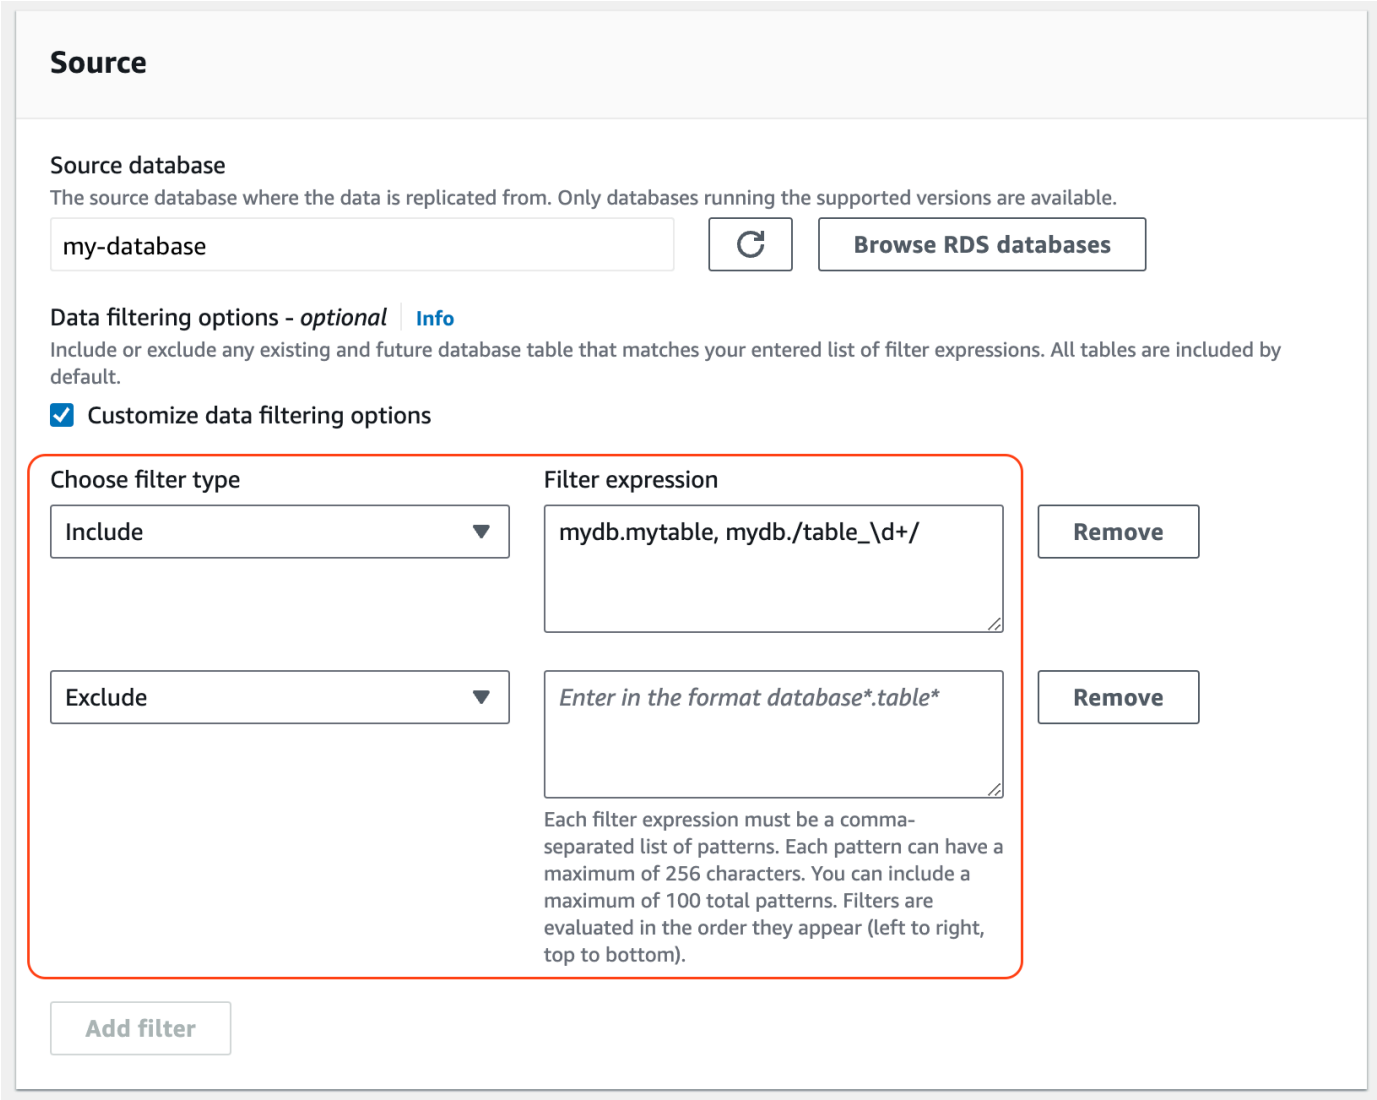
> **Important**
>
> If you add a filter after creating an integration, then Amazon RDS reevaluates the filter as if it always existed. It removes any data that is currently in the target Amazon Redshift data warehouse that doesn't match the new filtering criteria. This action causes all affected tables to resynchronize.

RDS console

To add data filters to a zero-ETL integration

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Zero-ETL integrations**. Select the integration that you want to add data filters to, and then choose **Modify**.
3. Under **Source**, add one or more `Include` and `Exclude` statements.

   The following image shows an example of data filters for an integration:



4. When all the changes are as you want them, choose **Continue** and **Save changes**.

AWS CLI

To add data filters to a zero-ETL integration using the AWS CLI, call the [modify-integration](#) command. In addition to the integration identifier, specify the `--data-filter` parameter with a comma-separated list of `Include` and `Exclude` Maxwell filters.

Example

The following example adds filter patterns to `my-integration`.

For Linux, macOS, or Unix:

```
aws rds modify-integration \
```

```
    --integration-identifier my-integration \
    --data-filter 'include: foodb.*, exclude: foodb.tbl, exclude: foodb./table_\d+/'
```

For Windows:

```
aws rds modify-integration ^
    --integration-identifier my-integration ^
    --data-filter 'include: foodb.*, exclude: foodb.tbl, exclude: foodb./table_\d+/'
```

RDS API

To modify a zero-ETL integration using the RDS API, call the ModifyIntegration operation. Specify the integration identifier and provide a comma-separated list of filter patterns.

Removing data filters from an integration

When you remove a data filter from an integration, Amazon RDS reevaluates the remaining filters as if the removed filter never existed. Amazon RDS then replicates any data that previously didn't match the filtering criteria (but now does) into the target Amazon Redshift data warehouse.

Removing one or more data filters causes all affected tables to resynchronize.

Adding data to a source RDS database and querying it in Amazon Redshift

To finish creating a zero-ETL integration that replicates data from Amazon RDS into Amazon Redshift, you must create a destination database in Amazon Redshift.

First, connect to your Amazon Redshift cluster or workgroup and create a database with a reference to your integration identifier. Then, you can add data to your source RDS database and see it replicated in Amazon Redshift.

Topics

- Creating a destination database in Amazon Redshift
- Adding data to the source database
- Querying your Amazon RDS data in Amazon Redshift
- Data type differences between RDS and Amazon Redshift databases

Creating a destination database in Amazon Redshift

Before you can start replicating data into Amazon Redshift, after you create an integration, you must create a destination database in your target data warehouse. This destination database must include a reference to the integration identifier. You can use the Amazon Redshift console or the Query editor v2 to create the database.

For instructions to create a destination database, see Create a destination database in Amazon Redshift.

Adding data to the source database

After you configure your integration, you can add some data to the RDS database that you want to replicate into your Amazon Redshift data warehouse.

> **Note**
>
> There are differences between data types in Amazon RDS and Amazon Redshift. For a table of data type mappings, see the section called "Data type differences".

First, connect to the source database using the MySQL client of your choice. For instructions, see the section called "Connecting to a DB instance running MySQL".

Then, create a table and insert a row of sample data.

> **Important**
>
> Make sure that the table has a primary key. Otherwise, it can't be replicated to the target data warehouse.

The following example uses the MySQL Workbench utility.

```
CREATE DATABASE my_db;

USE my_db;

CREATE TABLE books_table (ID int NOT NULL, Title VARCHAR(50) NOT NULL, Author
 VARCHAR(50) NOT NULL,
```

```
Copyright INT NOT NULL, Genre VARCHAR(50) NOT NULL, PRIMARY KEY (ID));

INSERT INTO books_table VALUES (1, 'The Shining', 'Stephen King', 1977, 'Supernatural
 fiction');
```

Querying your Amazon RDS data in Amazon Redshift

After you add data to the RDS database, it's replicated into Amazon Redshift and is ready to be queried.

To query the replicated data

1. Navigate to the Amazon Redshift console and choose **Query editor v2** from the left navigation pane.
2. Connect to your cluster or workgroup and choose your destination database (which you created from the integration) from the dropdown menu (**destination_database** in this example). For instructions to create a destination database, see Create a destination database in Amazon Redshift.
3. Use a SELECT statement to query your data. In this example, you can run the following command to select all data from the table that you created in the source RDS database:

   ```
   SELECT * from my_db."books_table";
   ```

   
   - *my_db* is the RDS database schema name.
   - *books_table* is the RDS table name.

You can also query the data using the a command line client. For example:

```
destination_database=# select * from my_db."books_table";
```

```
 ID |       Title |        Author |   Copyright |                  Genre |  txn_seq |
 txn_id
----+-------------+---------------+-------------+------------------------+----------
+--------+
  1 | The Shining |  Stephen King |        1977 |   Supernatural fiction |        2 |
 12192
```

> **Note**
>
> For case-sensitivity, use double quotes (" ") for schema, table, and column names. For more information, see enable_case_sensitive_identifier.

Data type differences between RDS and Amazon Redshift databases

The following table shows the mapping of an RDS for MySQL data type to a corresponding Amazon Redshift data type. *Amazon RDS currently supports only these data types for zero-ETL integrations.*

If a table in your source database includes an unsupported data type, the table goes out of sync and isn't consumable by the Amazon Redshift target. Streaming from the source to the target continues, but the table with the unsupported data type isn't available. To fix the table and make it available in Amazon Redshift, you must manually revert the breaking change and then refresh the integration by running `ALTER DATABASE...INTEGRATION REFRESH`.

RDS for MySQL

RDS for MySQL data type	Amazon Redshift data type	Description	Limitations
INT	INTEGER	Signed four-byte integer	
SMALLINT	SMALLINT	Signed two-byte integer	
TINYINT	SMALLINT	Signed two-byte integer	

RDS for MySQL data type	Amazon Redshift data type	Description	Limitations
MEDIUMINT	INTEGER	Signed four-byte integer	
BIGINT	BIGINT	Signed eight-byte integer	
INT UNSIGNED	BIGINT	Signed eight-byte integer	
TINYINT UNSIGNED	SMALLINT	Signed two-byte integer	
MEDIUMINT UNSIGNED	INTEGER	Signed four-byte integer	
BIGINT UNSIGNED	DECIMAL(20,0)	Exact numeric of selectable precision	
DECIMAL(p,s) = NUMERIC(p,s)	DECIMAL(p,s)	Exact numeric of selectable precision	Precision greater than 38 and scale greater than 37 not supported
DECIMAL(p,s) UNSIGNED = NUMERIC(p,s) UNSIGNED	DECIMAL(p,s)	Exact numeric of selectable precision	Precision greater than 38 and scale greater than 37 not supported
FLOAT4/REAL	REAL	Single precision floating-point number	

RDS for MySQL data type	Amazon Redshift data type	Description	Limitations
FLOAT4/REAL UNSIGNED	REAL	Single precision floating-point number	
DOUBLE/REAL/FLOAT8	DOUBLE PRECISION	Double precision floating-point number	
DOUBLE/REAL/FLOAT8 UNSIGNED	DOUBLE PRECISION	Double precision floating-point number	
BIT(n)	VARBYTE(8)	Variable-length binary value	
BINARY(n)	VARBYTE(n)	Variable-length binary value	
VARBINARY(n)	VARBYTE(n)	Variable-length binary value	
CHAR(n)	VARCHAR(n)	Variable-length string value	
VARCHAR(n)	VARCHAR(n)	Variable-length string value	
TEXT	VARCHAR(65535)	Variable-length string value up to 65535 bytes	
TINYTEXT	VARCHAR(255)	Variable-length string value up to 255 bytes	

RDS for MySQL data type	Amazon Redshift data type	Description	Limitations
MEDIUMTEXT	VARCHAR(65535)	Variable-length string value up to 65535 bytes	
LONGTEXT	VARCHAR(65535)	Variable-length string value up to 65535 bytes	
ENUM	VARCHAR(1020)	Variable-length string value up to 1020 bytes	
SET	VARCHAR(1020)	Variable-length string value up to 1020 bytes	
DATE	DATE	Calendar date (year, month, day)	
DATETIME	TIMESTAMP	Date and time (without time zone)	
TIMESTAMP(p)	TIMESTAMP	Date and time (without time zone)	
TIME	VARCHAR(18)	Variable-length string value up to 18 bytes	
YEAR	VARCHAR(4)	Variable-length string value up to 4 bytes	

RDS for MySQL data type	Amazon Redshift data type	Description	Limitations
JSON	SUPER	Semistructured data or documents as values	

Viewing and monitoring Amazon RDS zero-ETL integrations with Amazon Redshift

You can view the details of an Amazon RDS zero-ETL integration to see its configuration information and current status. You can also monitor the status of your integration by querying specific system views in Amazon Redshift. In addition, Amazon Redshift publishes certain integration-related metrics to Amazon CloudWatch, which you can view within the Amazon Redshift console.

Topics

Viewing integrations

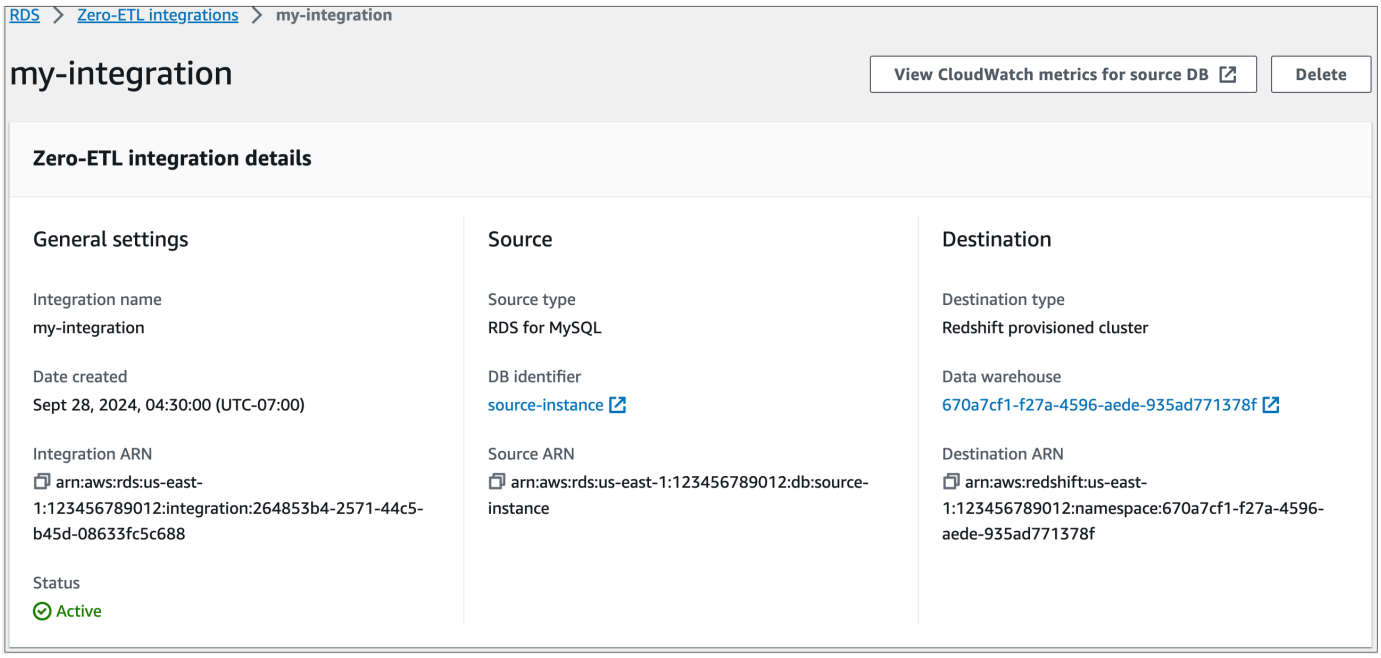
You can view Amazon RDS zero-ETL integrations with Amazon Redshift using the AWS Management Console, the AWS CLI, or the RDS API.

Console

To view the details of a zero-ETL integration

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. From the left navigation pane, choose **Zero-ETL integrations**.

3. Select an integration to view more details about it, such as its source database and target data warehouse.



An integration can have the following statuses:

- `Creating` – The integration is being created.
- `Active` – The integration is sending transactional data to the target data warehouse.
- `Syncing` – The integration has encountered a recoverable error and is reseeding data. Affected tables aren't available for querying in Amazon Redshift until they finish resyncing.
- `Needs attention` – The integration encountered an event or error that requires manual intervention to resolve it. To fix the issue, follow the instructions in the error message on the integration details page.
- `Failed` – The integration encountered an unrecoverable event or error that can't be fixed. You must delete and recreate the integration.
- `Deleting` – The integration is being deleted.

AWS CLI

To view all zero-ETL integrations in the current account using the AWS CLI, use the describe-integrations command and specify the `--integration-identifier` option.

Example

For Linux, macOS, or Unix:

```
aws rds describe-integrations \
    --integration-identifier ee605691-6c47-48e8-8622-83f99b1af374
```

For Windows:

```
aws rds describe-integrations ^
    --integration-identifier ee605691-6c47-48e8-8622-83f99b1af374
```

RDS API

To view zero-ETL integration using the Amazon RDS API, use the `DescribeIntegrations` operation with the `IntegrationIdentifier` parameter.

Monitoring integrations using system tables

Amazon Redshift has system tables and views that contain information about how the system is functioning. You can query these system tables and views the same way that you would query any other database table. For more information about system tables and views in Amazon Redshift, see System tables reference in the *Amazon Redshift Database Developer Guide*.

You can query the following system views and tables to get information about your zero-ETL integrations with Amazon Redshift:

- SVV_INTEGRATION – Provides configuration details for your integrations.
- SVV_INTEGRATION_TABLE_STATE – Describes the state of each table within an integration.
- SYS_INTEGRATION_TABLE_STATE_CHANGE – Displays table state change logs for an integration.
- SYS_INTEGRATION_ACTIVITY – Provides information about completed integration runs.

All integration-related Amazon CloudWatch metrics originate from Amazon Redshift. For more information, see Monitoring zero-ETL integrations in the *Amazon Redshift Management Guide*. Currently, Amazon RDS doesn't publish any integration metrics to CloudWatch.

Monitoring integrations with Amazon EventBridge

Amazon Redshift sends integration-related events to Amazon EventBridge. For a list of events and their corresponding event IDs, see Zero-ETL integration event notifications with Amazon EventBridge in the *Amazon Redshift Management Guide*.

Modifying Amazon RDS zero-ETL integrations with Amazon Redshift

You can modify only the name, description, and data filtering options for a zero-ETL integration with Amazon Redshift. You can't modify the AWS KMS key used to encrypt the integration, or the source or target databases.

If you add a data filter to an existing integration, Amazon RDS reevaluates the filter as if it always existed. It removes any data that is currently in the target Amazon Redshift data warehouse that doesn't match the new filtering criteria. If you *remove* a data filter from an integration, it replicates any data that previously didn't match the filtering criteria (but now does) into the target data warehouse. For more information, see the section called “Data filtering for zero-ETL integrations”.

You can modify a zero-ETL integration using the AWS Management Console, the AWS CLI, or the Amazon RDS API.

RDS console

To modify a zero-ETL integration

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Zero-ETL integrations**, and then choose the integration that you want to modify.
3. Choose **Modify** and make modifications to any available settings.
4. When all the changes are as you want them, choose **Modify**.

AWS CLI

To modify a zero-ETL integration using the AWS CLI, call the modify-integration command. Along with the `--integration-identifier`, specify any of the following options:

- `--integration-name` – Specify a new name for the integration.
- `--description` – Specify a new description for the integration.
- `--data-filter` – Specify data filtering options for the integration. For more information, see the section called "Data filtering for zero-ETL integrations".

Example

The following request modifies an existing integration.

For Linux, macOS, or Unix:

```
aws rds modify-integration \
    --integration-identifier ee605691-6c47-48e8-8622-83f99b1af374 \
    --integration-name my-renamed-integration
```

For Windows:

```
aws rds modify-integration ^
    --integration-identifier ee605691-6c47-48e8-8622-83f99b1af374 ^
    --integration-name my-renamed-integration
```

RDS API

To modify a zero-ETL integration using the RDS API, call the ModifyIntegration operation. Specify the integration identifier, and the parameters that you want to modify.

Deleting Amazon RDS zero-ETL integrations with Amazon Redshift

When you delete a zero-ETL integration, Amazon RDS removes it from the source database. Your transactional data isn't deleted from Amazon RDS or Amazon Redshift, but Amazon RDS doesn't send new data to Amazon Redshift.

You can only delete an integration when it has a status of `Active`, `Failed`, `Syncing`, or `Needs attention`.

You can delete zero-ETL integrations using the AWS Management Console, the AWS CLI, or the RDS API.

Console

To delete a zero-ETL integration

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. From the left navigation pane, choose **Zero-ETL integrations**.
3. Select the zero-ETL integration that you want to delete.
4. Choose **Actions**, **Delete**, and confirm deletion.

AWS CLI

To delete a zero-ETL integration, use the delete-integration command and specify the `--integration-identifier` option.

Example

For Linux, macOS, or Unix:

```
aws rds delete-integration \
    --integration-identifier ee605691-6c47-48e8-8622-83f99b1af374
```

For Windows:

```
aws rds delete-integration ^
    --integration-identifier ee605691-6c47-48e8-8622-83f99b1af374
```

RDS API

To delete a zero-ETL integration using the Amazon RDS API, use the `DeleteIntegration` operation with the `IntegrationIdentifier` parameter.

Troubleshooting Amazon RDS zero-ETL integrations with Amazon Redshift

You can check the state of a zero-ETL integration by querying the SVV_INTEGRATION system table in Amazon Redshift. If the `state` column has a value of `ErrorState`, it means something's wrong. For more information, see the section called “Monitoring using system tables”.

Use the following information to troubleshoot common issues with Amazon RDS zero-ETL integrations with Amazon Redshift.

Topics

I can't create a zero-ETL integration

If you can't create a zero-ETL integration, make sure that the following are correct for your source database:

- Your source database must be running a supported DB engine version. For a list of supported versions, see the section called “Zero-ETL integrations ”.
- You correctly configured DB parameters. If the required parameters are set incorrectly or not associated with the database, creation fails. See the section called “Step 1: Create a custom DB parameter group”.

In addition, make sure the following are correct for your target data warehouse:

- Case sensitivity is enabled. See Turn on case sensitivity for your data warehouse.
- You added the correct authorized principal and integration source. See Configure authorization for your Amazon Redshift data warehouse.
- The data warehouse is encrypted (if it's a provisioned cluster). See Amazon Redshift database encryption.

My integration is stuck in a state of `Syncing`

Your integration might consistently show a status of `Syncing` if you change the value of one of the required DB parameters.

To fix this issue, check the values of the parameters in the parameter group associated with the source database, and make sure that they match the required values. For more information, see the section called “Step 1: Create a custom DB parameter group”.

If you modify any parameters, make sure to reboot the database to apply the changes.

My tables aren't replicating to Amazon Redshift

If you don't see one or more tables reflected in Amazon Redshift, you can run the following command to resynchronize them:

```
ALTER DATABASE dbname INTEGRATION REFRESH TABLES table1, table2;
```

For more information, see ALTER DATABASE in the Amazon Redshift SQL reference.

Your data might not be replicating because one or more of your source tables doesn't have a primary key. The monitoring dashboard in Amazon Redshift displays the status of these tables as `Failed`, and the status of the overall zero-ETL integration changes to `Needs attention`. To resolve this issue, you can identify an existing key in your table that can become a primary key, or you can add a synthetic primary key. For detailed solutions, see Handle tables without primary keys while creating Amazon Aurora MySQL or Amazon RDS for MySQL zero-ETL integrations with Amazon Redshift.

One or more of my Amazon Redshift tables requires a resync

Running certain commands on your source database might require your tables to be resynchronized. In these cases, the SVV_INTEGRATION_TABLE_STATE system view shows a `table_state` of `ResyncRequired`, which means that the integration must completely reload data for that specific table from MySQL to Amazon Redshift.

When the table starts to resynchronize, it enters a state of `Syncing`. You don't need to take any manual action to resynchronize a table. While table data is resynchronizing, you can't access it in Amazon Redshift.

The following are some example operations that can put a table into a `ResyncRequired` state, and possible alternatives to consider.

Operation	Example	Alternative
Adding a column into a specific position	`ALTER TABLE table_name ADD COLUMN column_name INTEGER NOT NULL first;`	Amazon Redshift doesn't support

Operation	Example	Alternative
		adding columns into specific positions using `first` or `after` keywords. If the order of columns in the target table isn't critical, add the column to the end of the table using a simpler command: `ALTER TABLE table_name ADD COLUMN column_name column_type ;`

Operation	Example	Alternative
Adding a timestamp column with the default `CURRENT_TIMESTAMP`	`ALTER TABLE table_name ADD COLUMN column_name TIMESTAMP NOT NULL DEFAULT CURRENT_TIMESTAMP;`	The `CURRENT_TIMESTAMP` value for existing table rows is calculated by RDS for MySQL and can't be simulated in Amazon Redshift without full table data resynchronization. If possible, switch the default value to a literal constant like `2023-01-01 00:00:15` to avoid latency in table availability.

Operation	Example	Alternative
Performing multiple column operations within a single command	`ALTER TABLE table_name ADD COLUMN column_1, RENAME COLUMN column_2 TO column_3;`	Consider splitting the command into two separate operations, ADD and RENAME, which won't require resynchronization.

Amazon RDS for Db2

Amazon RDS supports DB instances that run the following editions of IBM Db2:

- Db2 Standard Edition
- Db2 Advanced Edition

Amazon RDS supports DB instances that run the following versions of Db2:

- Db2 11.5

For more information about minor version support, see Db2 on Amazon RDS versions.

Before creating a DB instance, complete the steps in the Setting up your Amazon RDS environment section of this user guide. When you create a DB instance using your master user, the user gets `DBADM` authority, with some limitations. Use this user for administrative tasks such as creating additional database accounts. You can't use `SYSADM`, `SYSCTRL`, `SYSMAINT` instance-level authority, or `SECADM` database-level authority.

You can create the following:

- DB instances
- DB snapshots
- Point-in-time restores
- Automated storage backups
- Manual storage backups

You can use DB instances running Db2 inside a virtual private cloud (VPC). You can also add features to your Amazon RDS for Db2 DB instance by enabling various options. Amazon RDS supports Multi-AZ deployments for RDS for Db2 as a high availability, failover solution.

Important

To deliver a managed service experience, Amazon RDS doesn't provide shell access to DB instances. It also restricts access to certain system procedures and tables that need elevated

privileges. You can access your database using standard SQL clients such as IBM Db2 CLP. However, you can't access the host directly by using Telnet or Secure Shell (SSH).

Topics

Overview of Db2 on Amazon RDS

You can read the following sections to get an overview of Db2 on Amazon RDS.

Topics

- EBCDIC collation for Db2 databases on Amazon RDS
- Local time zone for Amazon RDS for Db2 DB instances

Amazon RDS for Db2 features

Amazon RDS for Db2 supports most of the features and capabilities of the IBM Db2 database. Some features might have limited support or restricted privileges. For more information about the Db2 database features for specific Db2 versions, see the IBM Db2 documentation.

You can filter new Amazon RDS features on the What's New with Database? page. For **Products**, choose **Amazon RDS**. Then, you can search by using keywords such as **`Db2 2023`**.

> **Note**
>
> The following lists aren't exhaustive.

Topics

- Supported features in RDS for Db2
- Unsupported features in RDS for Db2

Supported features in RDS for Db2

RDS for Db2 supports features that include features that are native to IBM Db2 and features that are core to Amazon RDS.

Features native to IBM Db2

RDS for Db2 supports the following Db2 database features:

- Creation of a standard database that uses a customer-defined code set, collation, page size, and territory. Use the Amazon RDS rdsadmin.create_database stored procedure.
- Addition, deletion, or modification of local users and groups. Use the Amazon RDS stored procedures for Granting and revoking privileges.
- Creation of roles with the Amazon RDS rdsadmin.create_role stored procedure.
- Support for standard row-organized tables.

- Support for analytic workload for column-organized tables.
- Ability to define Db2-compatibility features such as Oracle and MySQL.
- Support for Java-based external stored procedures.
- Support for data encryption in transit by using SSL/TLS.
- Monitoring the status of a database (`ALIVE`, `DOWN`, `STORAGE_FULL`, `UNKNOWN`, and `STANDBY_CONNECTABLE`).
- Restoration of a customer-provided offline or online Linux (LE) database. Use Amazon RDS stored procedures for Managing databases.
- Application of customer-provided Db2 archive logs to keep the database synchronized with self-managed Db2 databases. Use Amazon RDS stored procedures for Managing databases.
- Support for Db2 instance-level and database-level auditing.
- Support for homogeneous federation.
- Ability to load a table from data files in Amazon Simple Storage Service (Amazon S3).
- Authorizations granted to users, groups or roles, such as `CONNECT`, `SYSMON`, `ACCESSCTRL`, `DATAACCESS`, `SQLADM`, `WLMADM`, `EXPLAIN`, `LOAD`, or `IMPLICIT_SCHEMA`

Features core to Amazon RDS

RDS for Db2 supports the following core Amazon RDS features:

- Custom parameter groups to assign to DB instances.
- Creation, modification, and deletion of DB instances.
- Restoration of a self-managed Db2 offline or online Linux (LE) database backup.

> **Note**
>
> To be able to restore your backup, don't provide a name for your database when you create a DB instance. For more information, see Creating an Amazon RDS DB instance.

- Support of gp3, io2, and io1 storage types.
- Use of AWS Managed Microsoft AD for Kerberos authentication, and LDAP group authorization for RDS for Db2.
- Modification of security groups, ports, instance types, storage, backup retention periods, and other settings for existing Db2 instances.

- Deletion protection for DB instances.
- Cross-Region point-in-time recovery (PITR).
- Use of AWS Key Management Service (AWS KMS) for storage encryption and encryption at rest.
- Multi-AZ DB instances with one standby for high availability.
- Reboots of DB instances.
- Updates to master passwords.
- Restoration of DB instances to a specific time.
- Backup and restoration of DB instances by using storage-level backups.
- Start and stop of DB instances.
- Maintenance of DB instances.

Unsupported features in RDS for Db2

RDS for Db2 doesn't support the following Db2 database features:

- `SYSADM`, `SECADM`, and `SYSMAINT` access for the master user.
- External stored procedures written in C, C++, or Cobol.
- Multiple Db2 DB instances on a single host.
- Multiple Db2 databases on a single RDS for Db2 DB instance.
- External GSS-API plugins for authentication.
- External third-party plugins to back up or restore Db2 databases.
- Multi-node massively parallel processing (MPP), such as IBM Db2 Warehouse.
- IBM Db2 pureScale.
- High Availability Disaster Recovery (HADR).
- Native database encryption.
- Heterogeneous federation to Informix, Sybase, and Teradata. For more information, see the section called “Federation”.
- Cross-Region point-in-time-recovery (PITR) for encrypted backups.
- Creation of non-fenced routines and migration of existing non-fenced routines by backing up and restoring data. For more information, see Non-fenced routines.
- Creation of new non-automatic storage tablespaces. For more information, see Non-automatic storage tablespaces during migration.

- External tables.

Db2 on Amazon RDS versions

For Db2, version numbers take the form of *major.minor.build.revision*, for example, 11.5.9.0.sb00000000.r1. Our version implementation matches that of Db2.

major

The major version number is both the integer and the first fractional part of the version number, for example, 11.5. A version change is considered major if the major version number changes—for example, going from version 11.5 to 12.1.

minor

The minor version number is both the third and fourth parts of the version number, for example, 9.0 in 11.5.9.0. The third part indicates the Db2 modpack, for example, 9 in 9.0. The fourth part indicates the Db2 fixpack, for example, 0 in 9.0. A version change is considered minor if either the Db2 modpack or the Db2 fixpack changes—for example, going from version 11.5.9.0 to 11.5.9.1, or from 11.5.9.0 to 11.5.10.0, with exceptions to provide catalog table updates. (Amazon RDS takes care of these exceptions.)

build

The build number is the fifth part of the version number, for example, sb00000000 in 11.5.9.0.sb00000000. A build number where the number portion is all zeroes indicates a standard build. A build number where the number portion isn't all zeroes indicates a special build. A build number changes if there is a security fix or special build of an existing Db2 version. A build number change also indicates that Amazon RDS automatically applied a new minor version.

revision

The revision number is the sixth part of the version number, for example, r1 in 11.5.9.0.sb00000000.r1. A revision is an Amazon RDS revision to an existing Db2 release. A revision number change indicates that Amazon RDS automatically applied a new minor version.

Topics

Supported Db2 minor versions on Amazon RDS

The following table shows the minor versions of Db2 11.5 that Amazon RDS currently supports.

> **Note**
>
> Dates with only a month and a year are approximate and are updated with an exact date when it's known.

Db2 engine version	IBM release date	RDS release date	
11.5.9.0	15 November 2023	27 November 2023	

You can specify any currently supported Db2 version when creating a new DB instance. You can specify the major version (such as Db2 11.5) and any supported minor version for the specified major version. If no version is specified, Amazon RDS defaults to a supported version, typically the most recent version. If a major version is specified but a minor version is not, Amazon RDS defaults to a recent release of the major version that you have specified. To see a list of supported versions, as well as defaults for newly created DB instances, use the describe-db-engine-versions AWS Command Line Interface (AWS CLI) command.

For example, to list the supported engine versions for Amazon RDS for Db2, run the following AWS CLI command. Replace *region* with your AWS Region.

For Linux, macOS, or Unix:

```
aws rds describe-db-engine-versions \
    --filters Name=engine,Values=db2-ae,db2-se \
    --query "DBEngineVersions[].{Engine:Engine, EngineVersion:EngineVersion,
 DBParameterGroupFamily:DBParameterGroupFamily}" \
    --region region
```

For Windows:

```
aws rds describe-db-engine-versions ^
    --filters Name=engine,Values=db2-ae,db2-se ^
    --query "DBEngineVersions[].{Engine:Engine, EngineVersion:EngineVersion,
 DBParameterGroupFamily:DBParameterGroupFamily}" ^
```

```
    --region region
```

This command produces output similar to the following example:

```
[
    {
    "Engine": "db2-ae",
    "EngineVersion": "11.5.9.0.sb00000000.r1",
    "DBParameterGroupFamily": "db2-ae-11.5"
    },
    {
    "Engine": "db2-se",
    "EngineVersion": "11.5.9.0.sb00000000.r1",
    "DBParameterGroupFamily": "db2-se-11.5"
    }
]
```

The default Db2 version might vary by AWS Region. To create a DB instance with a specific minor version, specify the minor version during DB instance creation. You can determine the default version for an AWS Region for `db2-ae` and `db2-se` database engines by running the `describe-db-engine-versions` command. The following example returns the default version for `db2-ae` in US East (N. Virginia).

For Linux, macOS, or Unix:

```
aws rds describe-db-engine-versions \
    --default-only --engine db2-ae \
    --query "DBEngineVersions[].{Engine:Engine, EngineVersion:EngineVersion,
 DBParameterGroupFamily:DBParameterGroupFamily}" \
    --region us-east-1
```

For Windows:

```
aws rds describe-db-engine-versions ^
    --default-only --engine db2-ae ^
    --query "DBEngineVersions[].{Engine:Engine, EngineVersion:EngineVersion,
 DBParameterGroupFamily:DBParameterGroupFamily}" ^
    --region us-east-1
```

This command produces output similar to the following example:

```
[
    {
    "Engine": "db2-ae",
    "EngineVersion": "11.5.9.0.sb00000000.r1",
    "DBParameterGroupFamily": "db2-ae-11.5"
    }
]
```

With Amazon RDS, you control when to upgrade your Db2 instance to a new major version supported by Amazon RDS. You can maintain compatibility with specific Db2 versions, test new versions with your application before deploying in production, and perform major version upgrades at times that best fit your schedule.

When automatic minor version upgrade is enabled, Amazon RDS automatically upgrades your DB instances to new Db2 minor versions as they are supported by Amazon RDS. This patching occurs during your scheduled maintenance window. You can modify a DB instance to enable or disable automatic minor version upgrades.

Except for Db2 versions 11.5.9.1 and 11.5.10.0, automatic upgrades to new Db2 minor version includes automatic upgrades to new builds and revisions. For 11.5.9.1 and 11.5.10.0, manually upgrade minor versions.

If you opt out of automatically scheduled upgrades, you can manually upgrade to a supported minor version release by following the same procedure as you would for a major version update. For information, see Upgrading a DB instance engine version.

Supported Db2 major versions on Amazon RDS

RDS for Db2 major versions are available under standard support at least until IBM end of support (base) for the corresponding IBM version. The following table shows the dates that you can use to plan your testing and upgrade cycles. If Amazon extends support for an RDS for Db2 version for longer than originally stated, we plan to update this table to reflect the later date.

You can use the following dates to plan your testing and upgrade cycles.

> **Note**
>
> Dates with only a month and a year are approximate and are updated with an exact date when it's known.

Db2 major version	IBM release date	RDS release date	IBM end of support (base)	IBM end of support (extended)	
Db2 11.5	27 June 2019	27 November 2023	30 September 2025	4 years after end of support	

Amazon RDS for Db2 licensing options

Amazon RDS for Db2 has two licensing options: Bring Your Own License (BYOL) and Db2 license through AWS Marketplace.

Topics

- Bring Your Own License for Db2
- Db2 license through AWS Marketplace
- Switching between Db2 licenses

Bring Your Own License for Db2

In the BYOL model, you use your existing Db2 database licenses to deploy databases on Amazon RDS. Verify that you have the appropriate Db2 database license for the DB instance class and Db2 database edition that you want to run. You must also follow IBM policies for licensing IBM database software in the cloud computing environment.

> **Note**
>
> Multi-AZ DB instances are cold standbys because the Db2 database is installed but not running. Standbys aren't readable, running, or serving requests. For more information, see IBM Db2 licensing information on the IBM website.

In this model, you continue to use your active IBM support account, and you contact IBM directly for Db2 database service requests. If you have an AWS Support account with case support, you can contact AWS Support for Amazon RDS issues. Amazon Web Services and IBM have a multi-vendor support process for cases that require assistance from both organizations.

Amazon RDS supports the BYOL model for Db2 Standard Edition and Db2 Advanced Edition.

Topics

IBM IDs for Bring Your Own License for Db2

In the BYOL model, you need your IBM Customer ID and your IBM Site ID to create, modify, or restore RDS for Db2 DB instances. You must create a custom parameter group with your IBM Customer ID and your IBM Site ID *before* you create an RDS for Db2 DB instance. For more information, see Adding IBM IDs to a parameter group for RDS for Db2 DB instances. You can run multiple RDS for Db2 DB instances with different IBM Customer IDs and IBM Site IDs in the same AWS account or AWS Region.

> **Important**
>
> If you're an existing IBM Db2 customer, you can find your IBM Customer ID and your IBM Site ID on your Proof of Entitlement certificate from IBM.
> If you're a new IBM Db2 customer, you must first purchase a Db2 software license from IBM. After you purchase a Db2 software license, you will receive a Proof of Entitlement from IBM, which lists your IBM Customer ID and your IBM Site ID.
> If we can't verify your license by your IBM Customer ID and your IBM Site ID, we might terminate any DB instances running with these unverified licenses.

Adding IBM IDs to a parameter group for RDS for Db2 DB instances

Because you can't modify default parameter groups, you must create a custom parameter group and then modify it to include the values for your IBM Customer ID and your IBM Site ID. For information about parameter groups, see DB parameter groups for Amazon RDS DB instances.

> **Important**
>
> You must create a custom parameter group with your IBM Customer ID and your IBM Site ID *before* you create an RDS for Db2 DB instance.

Use the parameter settings in the following table.

Parameter	Value
rds.ibm_customer_id	<your IBM Customer ID>
rds.ibm_site_id	<your IBM Site ID>
ApplyMethod	immediate ,pending-reboot

These parameters are dynamic, which means that any changes to them take effect immediately and that you don't need to reboot the DB instance. If you don't want the changes to take effect immediately, you can set ApplyMethod to pending-reboot and schedule these changes to be made during a maintenance window.

You can create and modify a custom parameter group by using the AWS Management Console, the AWS CLI, or the Amazon RDS API.

Console

To add your IBM Customer ID and your IBM Site ID to a parameter group

1. Create a new DB parameter group. For more information about creating a DB parameter group, see Creating a DB parameter group in Amazon RDS.
2. Modify the parameter group that you created. For more information about modifying a parameter group, see Modifying parameters in a DB parameter group in Amazon RDS.

AWS CLI

To add your IBM Customer ID and your IBM Site ID to a parameter group

1. Create a custom parameter group by running the create-db-parameter-group command.

   Include the following required options:

   - --db-parameter-group-name – A name for the parameter group that you are creating.
   - --db-parameter-group-family – The Db2 engine edition and major version. Valid values: db2-se-11.5, db2-ae-11.5.

- `--description` – A description for this parameter group.

For more information about creating a DB parameter group, see Creating a DB parameter group in Amazon RDS.

2. Modify the parameters in the custom parameter group that you created by running the modify-db-parameter-group command.

   Include the following required options:

   - `--db-parameter-group-name` – The name of the parameter group that you created.
   - `--parameters` – An array of parameter names, values, and the application methods for the parameter update.

   For more information about modifying a parameter group, see Modifying parameters in a DB parameter group in Amazon RDS.

RDS API

To add your IBM Customer ID and your IBM Site ID to a parameter group

1. Create a custom DB parameter group by using the Amazon RDS API CreateDBParameterGroup operation.

   Include the following required parameters:

   - `DBParameterGroupName`
   - `DBParameterGroupFamily`
   - `Description`

   For more information about creating a DB parameter group, see Creating a DB parameter group in Amazon RDS.

2. Modify the parameters in the custom parameter group that you created by using the RDS API ModifyDBParameterGroup operation.

   Include the following required parameters:

   - `DBParameterGroupName`

- `Parameters`

  For more information about modifying a parameter group, see Modifying parameters in a DB parameter group in Amazon RDS.

Now you are ready to create a DB instance and attach the custom parameter group to the DB instance. For more information, see Creating an Amazon RDS DB instance and Associating a DB parameter group with a DB instance in Amazon RDS.

Integrating with AWS License Manager

To aid in monitoring RDS for Db2 license usage in the BYOL model, AWS License Manager integrates with RDS for Db2. License Manager supports tracking of RDS for Db2 engine editions based on virtual CPUs (vCPUs). You can also use License Manager with AWS Organizations to manage all of your organizational accounts centrally.

The following table shows available values for the Engine Edition product information filter for RDS for Db2.

Value	Description
`db2-se`	Db2 Standard Edition
`db2-ae`	Db2 Advanced Edition

Topics

- Terminology
- Creating a self-managed license in AWS License Manager
- Settings for creating self-managed licenses by using the AWS License Manager CLI and API

Terminology

This page uses the following terminology when discussing the Amazon RDS integration with AWS License Manager.

Self-managed license

Self-managed license is a term used in AWS License Manager. The Amazon RDS console refers to the license as an AWS License Manager configuration. A self-managed license contains licensing rules based on the terms of your enterprise agreements. The rules that you create determine how AWS processes commands that consume licenses. While creating a self-managed license, work closely with your organization's compliance team to review your enterprise agreements. For more information, see Self-managed licenses in License Manager.

Creating a self-managed license in AWS License Manager

To track license usage of your RDS for Db2 DB instances, you must create a self-managed license. In this case, RDS for Db2 resources that match the product information filter are automatically associated with the self-managed license. Discovery of RDS for Db2 DB instances can take up to 24 hours.

> **Note**
>
> If you create an RDS for Db2 DB instance by using the AWS Management Console, you will create a self-managed license by entering a name for the license. Then Amazon RDS associates the DB instance with this license. (In the Amazon RDS console, this license is referred to as an AWS License Manager configuration.) If you want to create an RDS for Db2 DB instance by using the AWS License Manager CLI or AWS License Manager API, you must first create a self-managed license with the following steps. The same situation applies to restoring an RDS for Db2 DB instance to a point in time or from a snapshot.

Console

To create a self-managed license to track the license usage of your RDS for Db2 DB instances

1. Go to https://console.aws.amazon.com/license-manager/.
2. Create a self-managed license.

   For instructions, see Create a self-managed license in the *AWS License Manager User Guide*.

   Add a rule for an **RDS Product Information Filter** in the **Product Information** panel.

   For more information, see ProductInformation in the *AWS License Manager API Reference*.

AWS License Manager CLI

> **Note**
>
> This procedure uses an AWS License Manager CLI command.

To create a self-managed license by using the AWS CLI, call the AWS License Manager create-license-configuration command. Use the `--cli-input-json` or `--cli-input-yaml` parameters to pass the parameters to the command.

For more information about the parameters, see the section called "Settings for creating self-managed licenses by using the AWS License Manager CLI and API".

The following code creates a self-managed license for Db2 Standard Edition.

```
aws license-manager create-license-configuration --cli-input-json file://rds-db2-
se.json
```

The following JSON is the content of the `rds-db2-se.json` file used in the previous command.

```
{
    "Name": "rds-db2-se",
    "Description": "RDS Db2 Standard Edition",
    "LicenseCountingType": "vCPU",
    "LicenseCountHardLimit": false,
    "ProductInformationList": [
        {
            "ResourceType": "RDS",
            "ProductInformationFilterList": [
                {
                    "ProductInformationFilterName": "Engine Edition",
                    "ProductInformationFilterValue": ["db2-se"],
                    "ProductInformationFilterComparator": "EQUALS"
                }
            ]
        }
    ]
}
```

For more information about product information, see Automated discovery of resource inventory in the *AWS License Manager User Guide*.

For more information about the `--cli-input` parameter, see Generating AWS CLI skeleton and input parameters from a JSON or YAML input file in the *AWS CLI User Guide*.

AWS License Manager API

> **Note**
>
> This procedure uses an AWS License Manager API command.

To create a self-managed license, use the `CreateLicenseConfiguration` AWS License Manager API operation with the following required parameters:

- `Name`
- `LicenseCountingType`
- `ProductInformationList`
- `ResourceType`
- `ProductInformationFilterList`
- `ProductInformationFilterName`
- `ProductInformationFilterValue`
- `ProductInformationFilterComparator`

For more information about the parameters, see the section called "Settings for creating self-managed licenses by using the AWS License Manager CLI and API".

Settings for creating self-managed licenses by using the AWS License Manager CLI and API

In the following table, you can find details about the settings for creating self-managed licenses by using the AWS License Manager CLI and API. For more information, see create-license-configuration in the *AWS CLI Command Reference* and `CreateLicenseConfiguration` in the *AWS License Manager API Reference*.

Parameter name	Data type	Required	Description
Name	string	Yes	The name of the license configuration.

Parameter name	Data type	Required	Description
Description	string	No	The description of the license configuration.
LicenseCountingType	string	Yes	The dimension used to track the license inventory. Valid value: vCPU.
LicenseCountHardLimit	boolean	No	Indicates whether hard or soft license enforcement is used. Exceeding a hard limit blocks the launch of new instances.
ProductInformationList	array of objects	Yes	A list of product information for a license configuration.
ResourceType	string	Yes	The resource type. Valid value: RDS.
ProductInformationFilterList	array of objects	Yes	A list of product information filters for a license configuration.
ProductInformationFilterName	string	Yes	The name of the type of filter being declared. Valid value: `Engine Edition`.

Parameter name	Data type	Required	Description
ProductInformation FilterValue	array of strings	Yes	The value to filter on. You must only specify one value. Valid values: `db2-se` or `db2-ae`.
ProductInformation FilterComparator	string	Yes	The logical operator for `ProductInformation FilterName`. Valid value: `EQUALS`.

Db2 license through AWS Marketplace

In the Db2 license through AWS Marketplace model, you pay an hourly rate to subscribe to Db2 licenses. This model helps you get started quickly with RDS for Db2 without needing to purchase licenses.

To use Db2 license through AWS Marketplace, you need an active AWS Marketplace subscription for the particular IBM Db2 edition that you want to use. If you don't already have one, subscribe to AWS Marketplace for that IBM Db2 edition.

Amazon RDS supports Db2 license through AWS Marketplace for IBM Db2 Standard Edition and IBM Db2 Advanced Edition.

Topics

- Terminology
- Payments and billing
- Subscribing to Db2 Marketplace listings and registering with IBM
- Obtaining a private offer

Terminology

This page uses the following terminology when discussing the Amazon RDS integration with AWS Marketplace.

SaaS subscription

In AWS Marketplace, software-as-a-service (SaaS) products such as the pay-as-you-go license model adopt a usage-based subscription model. IBM, the software seller for Db2, tracks your usage and you pay only for what you use.

Public offer

Public offers allow you to purchase AWS Marketplace products directly from the AWS Management Console.

Private offer

Private offers are a purchasing program that allow sellers and buyers to negotiate custom prices and end user licensing agreement (EULA) terms for purchases in AWS Marketplace.

Db2 Marketplace fees

Fees charged for the Db2 software license usage by IBM. These service fees are metered through AWS Marketplace and appear on your AWS bill under the AWS Marketplace section.

Amazon RDS fees

Fees that AWS charges for the RDS for Db2 services, which excludes licenses when using AWS Marketplace for Db2 licenses. Fees are metered through the Amazon RDS service being used and appear on your AWS bill.

Payments and billing

RDS for Db2 integrates with AWS Marketplace to offer hourly, pay-as-you-go licenses for Db2. The Db2 Marketplace fees cover the license costs of the Db2 software, and the Amazon RDS fees cover the costs of your RDS for Db2 DB instance usage. For information about pricing, see Amazon RDS for Db2 pricing.

To stop these fees, you must delete any RDS for Db2 DB instances. In addition, you can remove your subscriptions to AWS Marketplace for Db2 licenses. If you remove your subscriptions without deleting your DB instances, Amazon RDS will continue to bill you for the use of the DB instances. For more information, see the section called “Deleting a DB instance”.

You can view bills and manage payments for your RDS for Db2 DB instances that use Db2 license through AWS Marketplace in the AWS Billing console. Your bills includes two charges: one for your usage of Db2 license through AWS Marketplace and one for your usage of Amazon RDS. For

more information about billing, see Viewing your bill in the *AWS Billing and Cost Management User Guide*.

Subscribing to Db2 Marketplace listings and registering with IBM

To use Db2 license through AWS Marketplace, you must use the AWS Management Console to complete the following two tasks. You can't complete these tasks through the AWS CLI or the RDS API.

> **Note**
>
> If you want to create your DB instances by using the AWS CLI or the RDS API, you must complete these two tasks first.

Topics

- Task 1: Subscribe to Db2 in AWS Marketplace
- Task 2: Register your subscription with IBM

Task 1: Subscribe to Db2 in AWS Marketplace

To use Db2 license with AWS Marketplace, you need to have an active AWS Marketplace subscription for Db2. Because subscriptions are associated with a specific IBM Db2 edition, you need to subscribe to Db2 in AWS Marketplace for each edition of Db2 that you want to use: IBM Db2 Advanced Edition, IBM Db2 Standard Edition. For information about AWS Marketplace subscriptions, see Saas usage-based subscriptions in the *AWS Marketplace Buyer Guide*.

We recommend that you subscribe to Db2 in AWS Marketplace *before* you start to create a DB instance.

Task 2: Register your subscription with IBM

After you subscribe to Db2 in AWS Marketplace, complete the registration of your IBM order from the AWS Marketplace page for the type of Db2 subscription that you chose. On the AWS Marketplace page, choose **View purchase options**, and then choose **Set up your account**. You can register either with your existing IBM account or by creating a free IBM account.

Obtaining a private offer

You can request an AWS Marketplace private offer for Db2 from IBM. For more information, see Private offers in the *AWS Marketplace Buyer Guide*.

> **Note**
>
> If you are an AWS Organizations user and received a private offer that was issued to your payer and member accounts, follow the procedure below to subscribe to Db2 directly on each account in your organization.

To obtain a Db2 private offer

1. After a private offer has been issued, sign in to the AWS Marketplace Console.
2. Open the email with a Db2 private offer link.
3. Follow the link to directly access the private offer.

   > **Note**
   >
   > Following this link before logging in to the correct account will result in a **Page note found** (404) error.

4. Review the terms and conditions.
5. Choose **Accept terms**.

   > **Note**
   >
   > If an AWS Marketplace private offer is not accepted, the Db2 service fees from AWS Marketplace will continue to be billed at the public hourly rate.

6. To verify the offer details, select **Show details** in the product listing.

After you've completed the procedure, you can create your DB instance by following the steps in the section called “Creating a DB instance”. In the AWS Management Console, under **License**, make sure that you choose **Through AWS Marketplace**.

Switching between Db2 licenses

You can switch between Db2 licenses in RDS for Db2. For example, you can start with Bring Your Own License, and then switch to Db2 license through AWS Marketplace.

> **Important**
>
> If you want to switch to Db2 license through AWS Marketplace, make sure that you have an active AWS Marketplace subscription for the IBM Db2 edition that you want to use. If you don't, first subscribe to Db2 in AWS Marketplace for that Db2 edition, and then complete the restore procedure.

Console

To switch between Db2 licenses

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Automated backups**.

   The automated backups are displayed on the **Current Region** tab.
3. Choose the DB instance that you want to restore.
4. For **Actions**, choose **Restore to point in time**.

   The **Restore to point in time** window appears.
5. Choose **Latest restorable time** to restore to the latest possible time, or choose **Custom** to choose a time.

   If you chose **Custom**, enter the date and time you want to restore the instance to.

   > **Note**
   >
   > Times are shown in your local time zone, which is indicated by an offset from Coordinated Universal Time (UTC). For example, UTC-5 is Eastern Standard Time/Central Daylight Time.
6. For **DB engine**, choose the Db2 license you want to use.

7. For **DB instance identifier**, enter the name of the target restored DB instance. The name must be unique.
8. Choose other options as needed, such as DB instance class, storage, and whether you want to use storage autoscaling.

   For information about each setting, see Settings for DB instances.
9. Choose **Restore to point in time**.

For more information, see Restoring a DB instance to a specified time.

AWS CLI

To switch between Db2 licenses, use the AWS CLI command restore-db-instance-to-point-in-time. The following example restores the latest point-in-time version, sets the DB engine to IBM Db2 Advanced Edition, and sets the license model to Db2 license through AWS Marketplace.

You can specify other settings. For information about each setting, see Settings for DB instances.

Example

For Linux, macOS, or Unix:

```
aws rds restore-db-instance-to-point-in-time \
    --source-db-instance-identifier my_source_db_instance \
    --target-db-instance-identifier my_target_db_instance \
    --use-latest-restorable-time \
    --engine db2-ae \
    --license-model marketplace-license
```

For Windows:

```
aws rds restore-db-instance-to-point-in-time ^
    --source-db-instance-identifier my_source_db_instance ^
    --target-db-instance-identifier my_target_db_instance ^
    --use-latest-restorable-time ^
    --engine db2-ae ^
    --license-model marketplace-license
```

For more information, see Restoring a DB instance to a specified time.

RDS API

To switch between Db2 licenses, call the Amazon RDS API `RestoreDBInstanceToPointInTime` operation with the following parameters:

- `SourceDBInstanceIdentifier`
- `TargetDBInstanceIdentifier`
- `RestoreTime`
- `Engine`
- `LicenseModel`

For more information, see Restoring a DB instance to a specified time.

Amazon RDS for Db2 instance classes

The computation and memory capacity of a DB instance is determined by its instance class. The DB instance class you need depends on your processing power and memory requirements.

Supported RDS for Db2 instance classes

The supported Amazon RDS for Db2 instance classes are a subset of the Amazon RDS DB instance classes. For the complete list of Amazon RDS instance classes, see DB instance classes.

Topics

- Supported RDS for Db2 instance classes for Db2 Standard Edition
- Supported RDS for Db2 instance classes for Db2 Advanced Edition

Supported RDS for Db2 instance classes for Db2 Standard Edition

The following table lists all instance classes supported for the Db2 Standard Edition of Db2 database version 11.5.9.0. These instance classes are available for both Bring Your Own License (BYOL) and Db2 license through AWS Marketplace.

Instance class type	Instance class
General purpose instance classes with 3rd generation Intel Xeon Scalable processors, SSD storage, and network optimization	db.m6idn.large–db.m6idn.8xlarge
General purpose instance classes powered by 3rd generation Intel Xeon Scalable processors	db.m6in.large–db.m6in.8xlarge
General purpose instance classes	db.m6i.large–db.m6i.8xlarge
Memory optimized instance classes with local NVMe-based SSDs, powered by 3rd generation Intel Xeon Scalable processors	db.x2iedn.xlarge
Memory optimized instance classes powered by 3rd generation Intel Xeon Scalable processors	db.r6idn.large–db.r6idn.4xlarge db.r6in.large–db.r6in.4xlarge
Memory optimized instance classes	db.r6i.large–db.r6i.4xlarge
Burstable performance instance classes	db.t3.small–db.t3.2xlarge

Supported RDS for Db2 instance classes for Db2 Advanced Edition

The following table lists all instance classes supported for the Db2 Advanced Edition of Db2 database version 11.5.9.0. These instance classes are available for both Bring Your Own License (BYOL) and Db2 license through AWS Marketplace.

Instance class type	Instance class
General purpose instance classes with 3rd generation Intel Xeon Scalable processors, SSD storage, and network optimization	db.m6idn.12xlarge–db.m6idn.32xlarge
General purpose instance classes powered by 3rd generation Intel Xeon Scalable processors	db.m6in.12xlarge–db.m6in.32xlarge

Instance class type	Instance class
General purpose instance classes	db.m6i.12xlarge–db.m6i.32xlarge
Memory optimized instance classes with local NVMe-based SSDs, powered by 3rd generation Intel Xeon Scalable processors	db.x2iedn.2xlarge–db.x2iedn.32xlarge
Memory optimized instance classes powered by 3rd generation Intel Xeon Scalable processors	db.r6idn.8xlarge–db.r6idn.32xlarge db.r6in.8xlarge–db.r6in.32xlarge
Memory optimized instance classes	db.r6i.8xlarge–db.r6i.32xlarge

Amazon RDS for Db2 default roles

RDS for Db2 adds the following six roles and grants them to the `master_user_role` with the `ADMIN` option. When the database is provisioned, RDS for Db2 grants `master_user_role` to the master user. The master user can in turn grant these roles to other users, groups, or roles with native `GRANT` statements by connecting to the database.

- **DBA** – RDS for Db2 creates this empty role with `DATAACCESS` authorization. The master user can add more authorizations or privileges to this role, and then grant the role to other users, groups, or roles.
- **DBA_RESTRICTED** – RDS for Db2 creates this empty role. The master user can add privileges to this role, and then grant the role to other users, groups, or roles.
- **DEVELOPER** – RDS for Db2 creates this empty role with `DATAACCESS` authorization. The master user can add more authorizations or privileges to this role, and then grant the role to other users, groups, or roles.
- **ROLE_NULLID_PACKAGES** – RDS for Db2 grants `EXECUTE` privileges to this role on `ALL NULLID` packages that were bound by Db2 when `CREATE DATABASE` was run.
- **ROLE_PROCEDURES** – RDS for Db2 grants `EXECUTE` privileges to this role on all `SYSIBM` procedures.

- **ROLE_TABLESPACES** – RDS for Db2 grants USAGE privileges on tablespaces created by the `CREATE DATABASE` command.

Amazon RDS for Db2 parameters

Amazon RDS for Db2 uses three types of parameters: database manager configuration parameters, registry variables, and database configuration parameters. You can manage the first two types through parameter groups and the last type through the rdsadmin.update_db_param stored procedure.

By default, an RDS for Db2 DB instance uses a DB parameter group that is specific to a Db2 database and DB instance. This parameter group contains parameters for the IBM Db2 database engine, specifically the database manager configuration parameters and registry variables. For information about working with parameter groups, see Parameter groups for Amazon RDS.

RDS for Db2 database configuration parameters are set to the default values of the storage engine that you have selected. For more information about Db2 parameters, see the Db2 database configuration parameters in the IBM Db2 documentation.

Topics

- Viewing the parameters in parameter groups
- Viewing all parameters with Db2 commands
- Modifying the parameters in parameter groups
- Modifying the database configuration parameters with Db2 commands

Viewing the parameters in parameter groups

The database manager configuration parameters and the registry variables are set in parameter groups. You can view the database manager configuration parameters and the registry variables for a specific Db2 version by using the AWS Management Console, the AWS CLI, or the RDS API.

Console

To view the parameter values for a DB parameter group

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.

2. In the navigation pane, choose **Parameter groups**.

   The DB parameter groups appear in a list.
3. Choose the name of the parameter group to see its list of parameters.

AWS CLI

You can view the database manager configuration parameters and the registry variables for a Db2 version by running the describe-engine-default-parameters AWS CLI command. Specify one of the following values for the `--db-parameter-group-family` option:

- `db2-ae-11.5`
- `db2-se-11.5`

For example, to view the parameters for Db2 Standard Edition 11.5, run the following command:

```
aws rds describe-engine-default-parameters --db-parameter-group-family db2-se-11.5
```

This command produces output similar to the following example:

```
{
    "EngineDefaults": {
        "Parameters": [
            {
                "ParameterName": "agent_stack_sz",
                "ParameterValue": "1024",
                "Description": "You can use this parameter to determine the amount of
 memory that is allocated by Db2 for each agent thread stack.",
                "Source": "engine-default",
                "ApplyType": "static",
                "DataType": "integer",
                "AllowedValues": "256-32768",
                "IsModifiable": false
            },
            {
                "ParameterName": "agentpri",
                "ParameterValue": "-1",
                "Description": "This parameter controls the priority given to all
 agents and to other database manager instance processes and threads by the operating
```

```
 system scheduler. This priority determines how CPU time is allocated to the database
 manager processes, agents, and threads relative to other processes and threads running
 on the machine.",
                "Source": "engine-default",
                "ApplyType": "static",
                "DataType": "integer",
                "AllowedValues": "1-99",
                "IsModifiable": false
            },
            ...
        ]
    }
}
```

To list only the modifiable parameters for Db2 Standard Edition 11.5, run the following command:

For Linux, macOS, or Unix:

```
aws rds describe-engine-default-parameters \
    --db-parameter-group-family db2-se-11.5 \
    --query 'EngineDefaults.Parameters[?IsModifiable==`true`].
{ParameterName:ParameterName, DefaultValue:ParameterValue}'
```

For Windows:

```
aws rds describe-engine-default-parameters ^
    --db-parameter-group-family db2-se-11.5 ^
    --query 'EngineDefaults.Parameters[?IsModifiable==`true`].
{ParameterName:ParameterName, DefaultValue:ParameterValue}'
```

RDS API

To view the parameter values for a DB parameter group, use the RDS API `DescribeDBParameters` command with the following required parameter.

- `DBParameterGroupName`

Viewing all parameters with Db2 commands

You can view the settings for database manager configuration parameters, database configuration parameters, and registry variables by using Db2 commands.

To view the settings

1. Connect to your Db2 database. In the following example, replace *database_name*, *master_username*, and *master_password* with your information.

```
db2 "connect to database_name user master_username using master_password"
```

2. Find the supported Db2 version.

```
db2 "select service_level, fixpack_num from table(sysproc.env_get_inst_info()) as
 instanceinfo"
```

3. View the parameters for a specific Db2 version.

   - View database manager configuration parameters by running the following command:

```
db2 "select cast(substr(name,1,24) as varchar(24)) as name, case
    when value_flags = 'NONE' then '' else value_flags end flags,
    cast(substr(value,1,64) as varchar(64)) as current_value
    from sysibmadm.dbmcfg
    order by name asc with UR"
```

   - View all of your database configuration parameters by running the following command:

```
db2 "select cast(substr(name,1,24) as varchar(24)) as name, case
    when value_flags = 'NONE' then '' else value_flags end flags,
    cast(substr(value,1,64) as varchar(64)) as current_value
    from table(db_get_cfg(null)) order by name asc, member asc with UR"
```

   - View the currently set registry variables by running the following command:

```
db2 "select cast(substr(reg_var_name,1,50) as varchar(50)) as reg_var_name,
    cast(substr(reg_var_value,1,50) as varchar(50)) as reg_var_value,
    level from table(env_get_reg_variables(null))
    order by reg_var_name,member with UR"
```

Modifying the parameters in parameter groups

You can modify the database manager configuration parameters and the registry variables in custom parameter groups by using the AWS Management Console, the AWS CLI, or the RDS API. For more information, see DB parameter groups for Amazon RDS DB instances.

Console

To modify database manager configuration parameters and registry variables

1. Create a custom parameter group. For more information about creating a DB parameter group, see Creating a DB parameter group in Amazon RDS.
2. Modify the parameters in that custom parameter group. For more information about modifying a parameter group, see Modifying parameters in a DB parameter group in Amazon RDS.

AWS CLI

To modify database manager configuration parameters and registry variables

1. Create a custom parameter group by running the create-db-parameter-group command.

   Include the following required options:

   - `--db-parameter-group-name` – A name for the parameter group that you are creating.
   - `--db-parameter-group-family` – The Db2 engine edition and major version. Valid values: `db2-se-11.5`, `db2-ae-11.5`.
   - `--description` – A description for this parameter group.

   For more information about creating a DB parameter group, see Creating a DB parameter group in Amazon RDS.
2. Modify the parameters in the custom parameter group that you created by running the modify-db-parameter-group command.

   Include the following required options:

   - `--db-parameter-group-name` – The name of the parameter group that you created.
   - `--parameters` – An array of parameter names, values, and the application methods for the parameter update.

   For more information about modifying a parameter group, see Modifying parameters in a DB parameter group in Amazon RDS.

RDS API

To modify database manager configuration parameters and registry variables

1. Create a custom DB parameter group by using the CreateDBParameterGroup operation.

   Include the following required parameters:

   - `DBParameterGroupName`
   - `DBParameterGroupFamily`
   - `Description`

   For more information about creating a DB parameter group, see Creating a DB parameter group in Amazon RDS.
2. Modify the parameters in the custom parameter group that you created by using the ModifyDBParameterGroup operation.

   Include the following required parameters:

   - `DBParameterGroupName`
   - `Parameters`

   For more information about modifying a parameter group, see Modifying parameters in a DB parameter group in Amazon RDS.

Modifying the database configuration parameters with Db2 commands

You can modify the database configuration parameters with Db2 commands.

To modify the database configuration parameters

1. Connect to the `rdsadmin` database. In the following example, replace *`master_username`* and *`master_password`* with your information.

   ```
   db2 "connect to rdsadmin user master_username using master_password"
   ```
2. Change the database configuration parameters by calling the `rdsadmin.update_db_param` stored procedure. For more information, see rdsadmin.update_db_param.

```
db2 "call rdsadmin.update_db_param(
    'database_name',
    'parameter_to_modify',
    'changed_value')"
```

EBCDIC collation for Db2 databases on Amazon RDS

Amazon RDS for Db2 supports EBCDIC collation for Db2 databases. You can only specify an EBCDIC collation sequence for a database when you create the database by using the Amazon RDS the section called “rdsadmin.create_database” stored procedure.

When you create an RDS for Db2 DB instance by using the AWS Management Console, AWS CLI, or RDS API, you can specify a database name. If you specify a database name, Amazon RDS creates a database with the default collation of SYSTEM. If you need to create a database with EBCDIC collation, don't specify a database name when you create a DB instance.

The collation for a database in RDS for Db2 is set at the time of creation and is immutable. If you specified a database name when you created a DB instance and you want a database with EBCDIC collation, delete the DB instance and create a new one.

To create a Db2 database with EBCDIC collation

1. Create an RDS for Db2 DB instance without specifying a database name by using the AWS Management Console, AWS CLI, or RDS API. For more information, see Creating a DB instance.
2. Create a Db2 database and set the collation option to an EBCDIC value by calling the `rdsadmin.create_database` stored procedure. For more information, see rdsadmin.create_database.

> **Important**
>
> After you create a database using the stored procedure, you can't change the collation sequence. If you want a database to use a different collation sequence, drop the database by calling the the section called “rdsadmin.drop_database” stored procedure. Then, create a database with the required collation sequence.

Local time zone for Amazon RDS for Db2 DB instances

The time zone of an Amazon RDS DB instance running Db2 is set by default. The default is Coordinated Universal Time (UTC). To match the time zone of your applications, you can set the time zone of your DB instance to a local time zone instead.

You set the time zone when you first create your DB instance. You can create your DB instance by using the AWS Management Console, the RDS API, or the AWS CLI. For more information, see Creating a DB instance.

If your DB instance is part of a Multi-AZ deployment, then when it fails over, its time zone remains the local time zone that you set.

You can restore your DB instance to a point in time that you specify. The time appears in your local time zone. For more information, see Restoring a DB instance to a specified time.

Setting the local time zone on your DB instance has the following limitations:

- You can't modify the time zone of an existing Amazon RDS for Db2 DB instance.
- You can't restore a snapshot from a DB instance in one time zone to a DB instance in a different time zone.
- We strongly recommend that you don't restore a backup file from one time zone to a different time zone. If you restore a backup file from one time zone to another, then you must audit your queries and applications for the effects of the time zone change.

Available time zones

You can use the following values for the time zone setting.

Zone	Time zone
Africa	Africa/Cairo, Africa/Casablanca, Africa/Harare, Africa/Lagos, Africa/Luanda, Africa/Monrovia, Africa/Nairobi, Africa/Tripoli, Africa/Windhoek
America	America/Araguaina, America/Argentina/Buenos_Aires, America/Asuncion, America/Bogota, America/Caracas, America/Chicago, America/Chihuahua, America/Cuiaba, America/Denver, America/Detroit, America/Fortaleza, America/Godthab, America/Guatemala, America/Halifax, America/Lima,

Zone	Time zone
	America/Los_Angeles, America/Manaus, America/Matamoros, America/Mexico_City, America/Monterrey, America/Montevideo, America/New_York, America/Phoenix, America/Santiago, America/Sao_Paulo, America/Tijuana, America/Toronto
Asia	Asia/Amman, Asia/Ashgabat, Asia/Baghdad, Asia/Baku, Asia/Bangkok, Asia/Beirut, Asia/Calcutta, Asia/Damascus, Asia/Dhaka, Asia/Hong_Kong, Asia/Irkutsk, Asia/Jakarta, Asia/Jerusalem, Asia/Kabul, Asia/Karachi, Asia/Kathmandu, Asia/Kolkata, Asia/Krasnoyarsk, Asia/Magadan, Asia/Manila, Asia/Muscat, Asia/Novosibirsk, Asia/Rangoon, Asia/Riyadh, Asia/Seoul, Asia/Shanghai, Asia/Singapore, Asia/Taipei, Asia/Tehran, Asia/Tokyo, Asia/Ulaanbaatar, Asia/Vladivostok, Asia/Yakutsk, Asia/Yerevan
Atlantic	Atlantic/Azores, Atlantic/Cape_Verde
Australia	Australia/Adelaide, Australia/Brisbane, Australia/Darwin, Australia/Eucla, Australia/Hobart, Australia/Lord_Howe, Australia/Perth, Australia/Sydney
Brazil	Brazil/DeNoronha, Brazil/East
Canada	Canada/Newfoundland, Canada/Saskatchewan
Etc	Etc/GMT-3
Europe	Europe/Amsterdam, Europe/Athens, Europe/Berlin, Europe/Dublin, Europe/Helsinki, Europe/Kaliningrad, Europe/London, Europe/Madrid, Europe/Moscow, Europe/Paris, Europe/Prague, Europe/Rome, Europe/Sarajevo, Europe/Stockholm
Pacific	Pacific/Apia, Pacific/Auckland, Pacific/Chatham, Pacific/Fiji, Pacific/Guam, Pacific/Honolulu, Pacific/Kiritimati, Pacific/Marquesas, Pacific/Samoa, Pacific/Tongatapu, Pacific/Wake
US	US/Alaska, US/Central, US/East-Indiana, US/Eastern, US/Pacific
UTC	UTC

Prerequisites for creating an Amazon RDS for Db2 DB instance

The following items are prerequisites before creating a DB instance.

Topics

Administrator account

When you create a DB instance, you must designate an administrator account for the instance. Amazon RDS grants ACCESSCTRL authority to this local database administrator account.

The administrator account has the following characteristics, capabilities, and limitations:

- Is a local user and not an AWS account.
- Doesn't have Db2 instance-level authorities such as SYSADM, SYSMAINT, or SYSCTRL.
- Can't stop or start a Db2 instance.
- Can't drop a Db2 database if you specified the name when you created the DB instance.
- Has full access to the Db2 database including catalog tables and views.
- Can create local users and groups by using Amazon RDS stored procedures.
- Can grant and revoke authorities and privileges.

The administrator account can perform the following tasks:

- Create, modify, or delete DB instances.
- Create DB snapshots.
- Initiate point-in-time restores.
- Create automated backups of DB snapshots.
- Create manual backups of DB snapshots.
- Use other Amazon RDS features.

Additional considerations

Before creating a DB instance, consider the following items:

- Each Amazon RDS for Db2 DB instance can host a single Db2 database.
- Initial database name
  - If you don't provide a database name when you create a DB instance, Amazon RDS doesn't create a database.
  - Don't provide a database name under the following circumstances:
    - You want to use Amazon RDS stored procedures to create or drop a database.
    - You want to create a database that uses an EBCDIC collation sequence. For more information, see EBCDIC collation for Db2 databases on Amazon RDS.
    - You want to restore backups from Amazon S3.
    - You are migrating from AIX or Windows. For more information, see One-time migration from AIX or Windows to Linux environments.
- In the Bring Your Own License (BYOL) model, you must first create a custom parameter group that contains your IBM Customer ID and your IBM Site ID. For more information, see Bring Your Own License for Db2.
- In the Db2 license through AWS Marketplace model, you need an active AWS Marketplace subscription for the particular IBM Db2 edition that you want to use. If you don't already have one, subscribe to Db2 in AWS Marketplace for the IBM Db2 edition that you want to use. For more information, see Db2 license through AWS Marketplace.

Connecting to your Amazon RDS for Db2 DB instance

After Amazon RDS provisions your Amazon RDS for Db2 DB instance, you can use any standard SQL client application to connect to the DB instance. Because Amazon RDS is a managed service, you can't sign in as SYSADM, SYSCTRL, SECADM, or SYSMAINT.

You can connect to a DB instance that is running the IBM Db2 database engine by using IBM Db2 CLP, IBM CLPPlus, DBeaver, or IBM Db2 Data Management Console.

Topics

Finding the endpoint of your Amazon RDS for Db2 DB instance

Each Amazon RDS DB instance has an endpoint, and each endpoint has the DNS name and port number for the DB instance. To connect to your Amazon RDS for Db2 DB instance with a SQL client application, you need the DNS name and port number for your DB instance.

You can find the endpoint for a DB instance by using the AWS Management Console or the AWS CLI.

Console

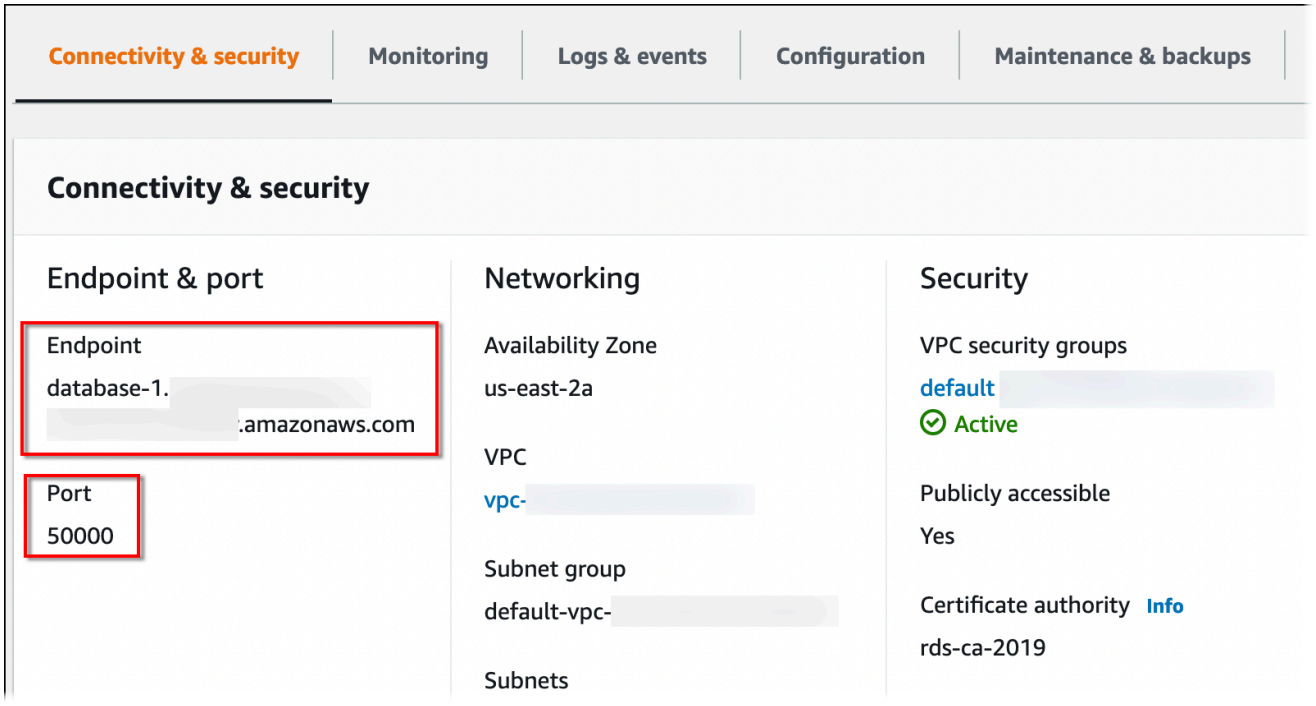
To find the endpoint of an RDS for Db2 DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the upper-right corner of the console, choose the AWS Region of your DB instance.
3. Find the DNS name and port number for your RDS for Db2 DB Instance.

    a. Choose **Databases** to display a list of your DB instances.

b. Choose the RDS for Db2 DB instance name to display the instance details.

c. On the **Connectivity & security** tab, copy the endpoint. Also, note the port number. You need both the endpoint and the port number to connect to the DB instance.



AWS CLI

To find the endpoint of an RDS for Db2 DB instance, run the describe-db-instances command. In the following example, replace *database-1* with the name of your DB instance.

For Linux, macOS, or Unix:

```
aws rds describe-db-instances \
    --db-instance-identifier database-1 \
    --query 'DBInstances[].
{DBInstanceIdentifier:DBInstanceIdentifier,DBName:DBName,Endpoint:Endpoint}' \
    --output json
```

For Windows:

```
aws rds describe-db-instances ^
    --db-instance-identifier database-1 ^
    --query 'DBInstances[].
{DBInstanceIdentifier:DBInstanceIdentifier,DBName:DBName,Endpoint:Endpoint}' ^
```

```
    --output json
```

This command produces output similar to the following example. The `Address` line in the output contains the DNS name.

```
[
    {
        "DBInstanceIdentifier": "database-1",
        "DBName": "DB2DB",
        "Endpoint": {
            "Address": "database-1.123456789012.us-east-2.amazonaws.com",
            "Port": 50000,
            "HostedZoneId": "Z2OC4A7DETW6VH"
        }
    }
]
```

Connecting to your Amazon RDS for Db2 DB instance with IBM Db2 CLP

You can use a command line utility such as IBM Db2 CLP to connect to Amazon RDS for Db2 DB instances. This utility is part of IBM Data Server Runtime Client. To download the client from IBM Fix Central, see IBM Data Server Client Packages Version 11.5 Mod 8 Fix Pack 0 in IBM Support.

Topics

- Terminology
- Installing the client
- Connecting to a DB instance
- Troubleshooting connections to your RDS for Db2 DB instance

Terminology

The following terms help explain commands used when connecting to your RDS for Db2 DB instance.

catalog tcpip node

This command registers a remote database node with a local Db2 client, which makes the node accessible to the client application. To catalog a node, you provide information such as the server's host name, port number, and communication protocol. The cataloged node then

represents a target server where one or more remote databases reside. For more information, see CATALOG TCPIP/TCPIP4/TCPIP6 NODE command in the IBM Db2 documentation.

catalog database

This command registers a remote database with a local Db2 client, which makes the database accessible to the client application. To catalog a database, you provide information such as the database's alias, the node on which it resides, and the authentication type needed to connect to the database. For more information, see CATALOG DATABASE command in the IBM Db2 documentation.

Installing the client

After downloading the package for Linux, install the client using root or administrator privileges.

> **Note**
>
> To install the client on AIX or Windows, follow the same procedure but modify the commands for your operating system.

To install the client on Linux

1. Run **`./db2_install -f sysreq`** and choose **`yes`** to accept the license.
2. Choose the location to install the client.
3. Run **`clientInstallDir/instance/db2icrt -s client`** ***`instance_name`***. Replace *`instance_name`* with a valid operating system user on Linux. In Linux, the Db2 DB instance name is tied to the operating system username.

   This command creates a **`sqllib`** directory in the home directory of the designated user on Linux.

Connecting to a DB instance

To connect to your RDS for Db2 DB instance, you need its DNS name and port number. For information about finding them, see Finding the endpoint. You also need to know the database name, master username, and master password that you defined when you created your RDS for Db2 DB instance. For more information about finding them, see Creating a DB instance.

To connect to an RDS for Db2 DB instance with IBM Db2 CLP

1. Sign in with the username that you specified during the IBM Db2 CLP client installation.
2. Catalog your RDS for Db2 DB instance. In the following example, replace *node_name*, *dns_name*, and *port* with a name for the node in the local catalog, the DNS name for your DB instance, and the port number.

```
db2 catalog TCPIP node node_name remote dns_name server port
```

Example

```
db2 catalog TCPIP node remnode remote database-1.123456789012.us-
east-1.amazonaws.com server 50000
```

3. Catalog the `rdsadmin` database and your database. This will allow you to connect to the `rdsadmin` database to perform some administrative tasks using Amazon RDS stored procedures. For more information, see Administering your RDS for Db2 DB instance.

   In the following example, replace *database_alias*, *node_name*, and *database_name* with aliases for this database, the name of the node defined in the previous step, and the name of your database. `server_encrypt` encrypts your username and password over the network.

```
db2 catalog database rdsadmin [ as database_alias ] at node node_name
 authentication server_encrypt

db2 catalog database database_name [ as database_alias ] at node node_name
 authentication server_encrypt
```

Example

```
db2 catalog database rdsadmin at node remnode authentication server_encrypt

db2 catalog database testdb as rdsdb2 at node remnode authentication server_encrypt
```

4. Connect to your RDS for Db2 database. In the following example, replace *rds_database_alias*, *master_username*, and *master_password* with the name of your database, the master username, and master password of your RDS for Db2 DB instance.

```
db2 connect to rds_database_alias user master_username using master_password
```

This command produces output similar to the following example:

```
Database Connection Information

    Database server        = DB2/LINUXX8664 11.5.9.0
    SQL authorization ID   = ADMIN
    Local database alias   = TESTDB
```

5. Run queries and view results. The following example shows a SQL statement that selects the database you created.

```
db2 "select current server from sysibm.dual"
```

This command produces output similar to the following example:

```
1
    ------------------
    TESTDB

    1 record(s) selected.
```

Troubleshooting connections to your RDS for Db2 DB instance

If you receive the following `NULLID` error, it usually indicates that your client and RDS for Db2 server versions don't match. For supported Db2 client versions, see Supported combinations of clients, drivers and server levels in the IBM Db2 documentation.

```
db2 "select * from syscat.tables"
SQL0805N Package "NULLID.SQLC2O29 0X4141414141454A69" was not found.
SQLSTATE=51002
```

After you receive this error, you must bind packages from your older Db2 client to a Db2 server version supported by RDS for Db2.

To bind packages from an older Db2 client to a newer Db2 server

1. Locate the bind files on the client machine. Typically, these files are located in the **bnd** directory of the Db2 client's installation path and have the extension **.bnd**.

2. Connect to the Db2 server. In the following example, replace *database_name* with the name of your Db2 server. Replace *master_username* and *master_password* with your information. This user has DBADM authority.

```
db2 connect to database_name user master_username using master_password
```

3. Run the bind command to bind the packages.

   a. Navigate to the directory where the bind files exist on the client machine.

   b. Run the bind command for each file.

      The following options are required:

      - `blocking all` – Binds all packages in the bind file in a single database request.
      - `grant public` – Grants permission to public to execute the package.
      - `sqlerror continue` – Specifies that the bind process continues even if errors occur.

      For more information about the bind command see BIND command in the IBM Db2 documentation.

4. Verify that the bind was successful by either querying the `syscat.package` catalog view or checking the message returned after the bind command.

For more information, see DB2 v11.5 Bind File and Package Name List in IBM Support.

Connecting to your Amazon RDS for Db2 DB instance with IBM CLPPlus

You can use a utility such as IBM CLPPlus to connect to an Amazon RDS for Db2 DB instance. This utility is part of IBM Data Server Runtime Client. To download the client from IBM Fix Central, see IBM Data Server Client Packages Version 11.5 Mod 8 Fix Pack 0 in IBM Support.

> **Important**
>
> We recommend that you run IBM CLPPlus on an operating system that supports graphical user interfaces such as macOS, Windows, or Linux with Desktop. If running headless Linux, use switch **-nw** with CLPPlus commands.

Topics

- Installing the client
- Connecting to a DB instance

Installing the client

After downloading the package for Linux, install the client.

> **Note**
>
> To install the client on AIX or Windows, follow the same procedure but modify the commands for your operating system.

To install the client on Linux

1. Run **`./db2_install`**.
2. Run **`clientInstallDir/instance/db2icrt -s client`** ***`instance_name`***. Replace *`instance_name`* with a valid operating system user on Linux. In Linux, the Db2 DB instance name is tied to the operating system username.

   This command creates a **`sqllib`** directory in the home directory of the designated user on Linux.

Connecting to a DB instance

To connect to your RDS for Db2 DB instance, you need its DNS name and port number. For information about finding them, see Finding the endpoint. You also need to know the database name, master username, and master password that you defined when you created your RDS for Db2 DB instance. For more information about finding them, see Creating a DB instance.

To connect to an RDS for Db2 DB instance with IBM CLPPlus

1. Review the command syntax. In the following example, replace *`clientDir`* with the location where the client is installed.

   ```
   cd clientDir/bin
       ./clpplus -h
   ```

2. Configure your Db2 server. In the following example, replace *dsn_name*, *database_name*, *endpoint*, and *port* with the DSN name, database name, endpoint, and port for your RDS for Db2 DB instance. For more information, see Finding the endpoint of your Amazon RDS for Db2 DB instance.

```
db2cli writecfg add -dsn dsn_name -database database_name -host endpoint -port port
 -parameter "Authentication=SERVER_ENCRYPT"
```

3. Connect to your RDS for Db2 DB instance. In the following example, replace *master_username* and *dsn_name* with the master username and DSN name.

```
./clpplus -nw master_username@dsn_name
```

4. A Java Shell window opens. Enter the master password for your RDS for Db2 DB instance.

> **Note**
>
> If a Java Shell window doesn't open, run **`./clpplus -nw`** to use the same command line window.

```
Enter password: *********
```

A connection is made and produces output similar to the following example:

```
Database Connection Information :
---------------------------------
Hostname = database-1.abcdefghij.us-east-1.rds.amazonaws.com
Database server = DB2/LINUXX8664  SQL110590
SQL authorization ID = admin
Local database alias = DB2DB
Port = 50000
```

5. Run queries and view results. The following example shows a SQL statement that selects the database you created.

```
SQL > select current server from sysibm.dual;
```

This command produces output similar to the following example:

```
1
    --------------------
    DB2DB
    SQL>
```

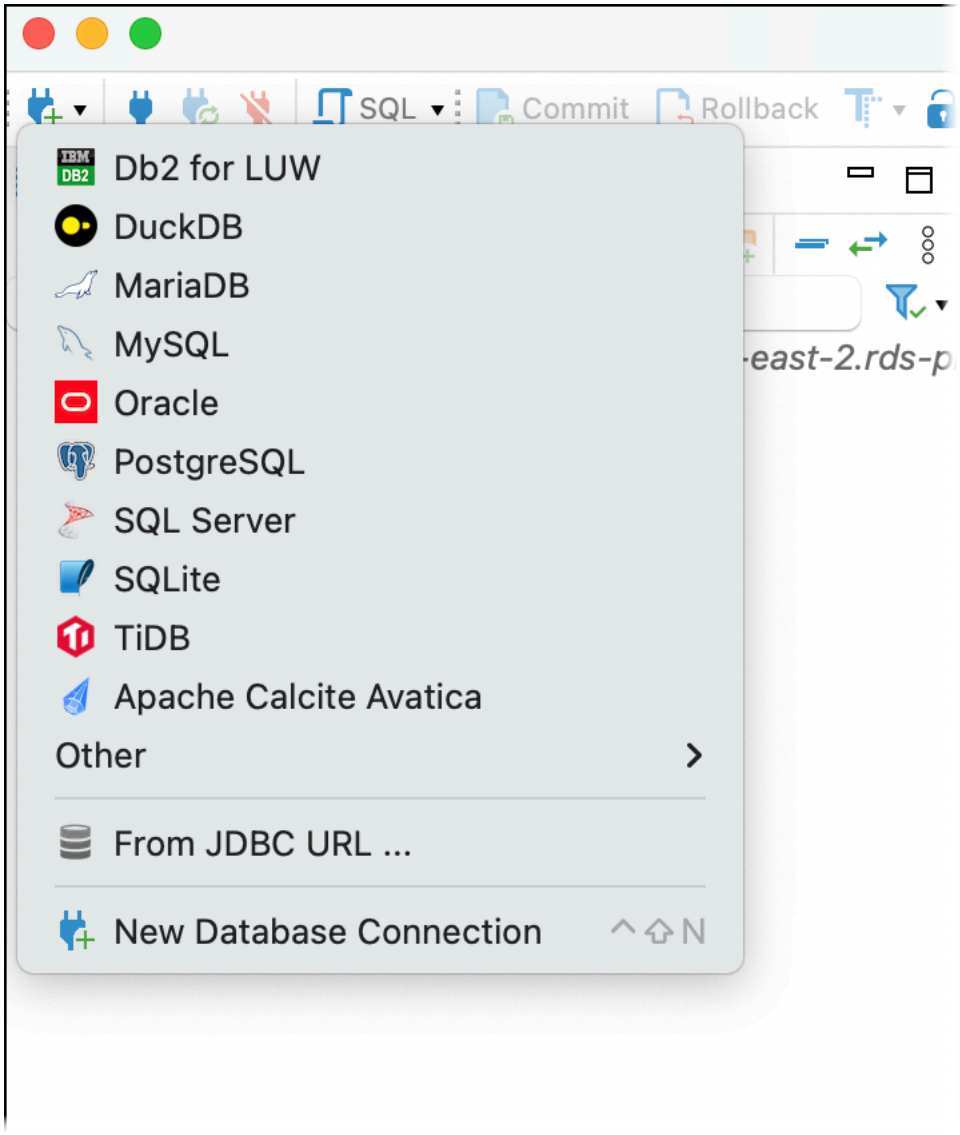
Connecting to your Amazon RDS for Db2 DB instance with DBeaver

You can use third-party tools such as DBeaver to connect to Amazon RDS for Db2 DB instances. To download this utility, see DBeaver Community.

To connect to your RDS for Db2 DB instance, you need its DNS name and port number. For information about finding them, see Finding the endpoint. You also need to know the database name, master username, and master password that you defined when you created your RDS for Db2 DB instance. For more information about finding them, see Creating a DB instance.

To connect to an RDS for Db2 DB instance with DBeaver

1. Start **DBeaver**.
2. Choose the **New Connection** icon in the toolbar and then choose **Db2 for LUW**.



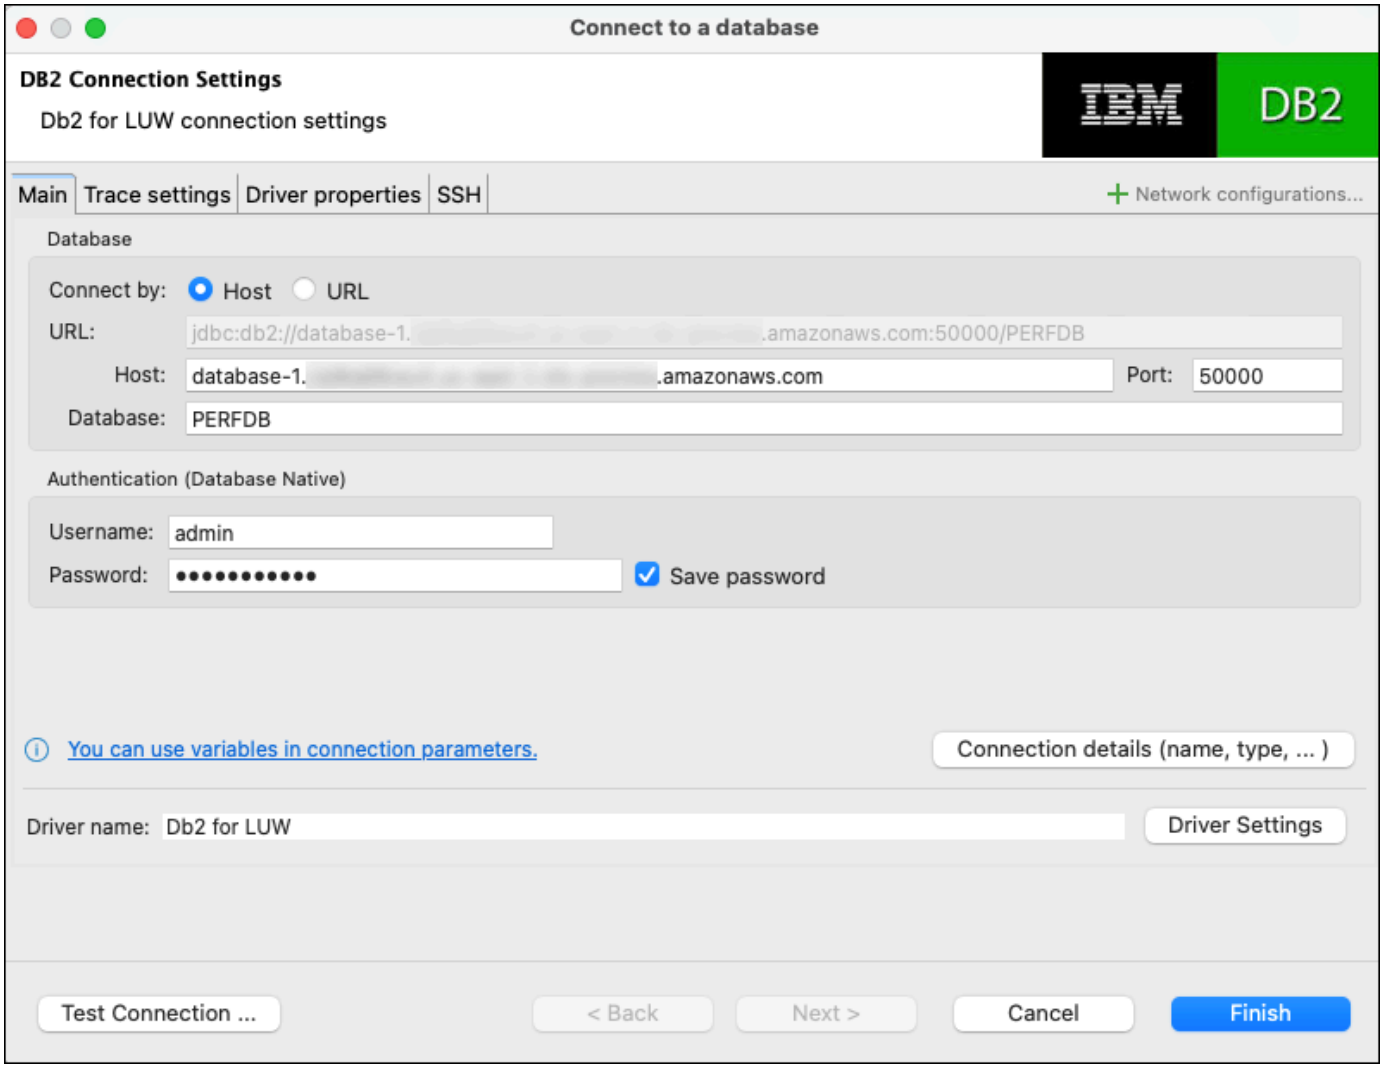
3. In the **Connect to a database** window, provide information for your RDS for Db2 DB instance.

   a. Enter the following information:

      - For **Host**, enter the DNS name of the DB instance.
      - For **Port**, enter the port number for the DB instance.
      - For **Database**, enter the name of the database.
      - For **Username**, enter the name of the database administrator for the DB instance.
      - For **Password**, enter the password of the database administrator for the DB instance.

   b. Select **Save password**.

   c. Choose **Driver Settings**.



4. In the **Edit Driver** window, specify additional security properties.

   a. Choose the **Driver properties** tab.

   b. Add two **User Properties**.

      i. Open the context (right-click) menu, and then choose **Add new property**.

      ii. For **Property Name**, add **encryptionAlgorithm**, and then choose **OK**.

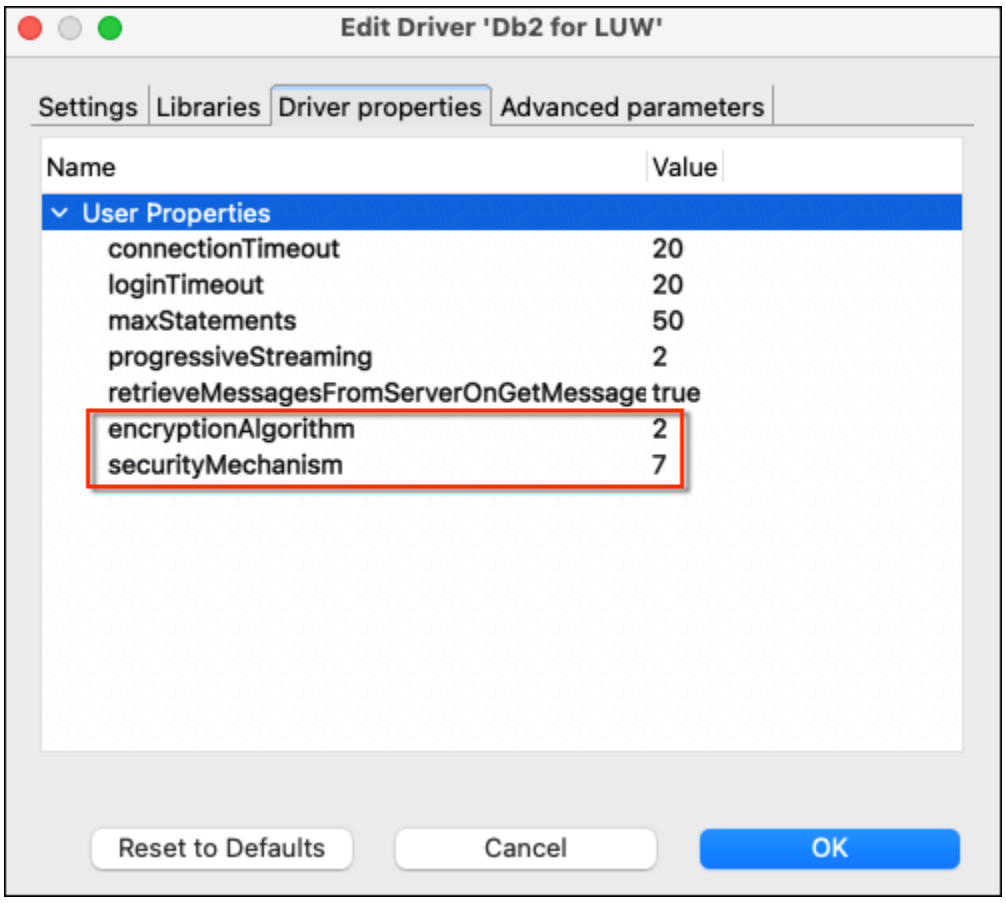
      iii. With the **encryptionAlgorithm** row selected, choose the **Value** column and add **2**.

      iv. Open the context (right-click) menu, and then choose **Add new property**.

      v. For **Property Name**, add **securityMechanism**, and then choose **OK**.

      vi. With the **securityMechanism** row selected, choose the **Value** column and add **7**.

   c. Choose **OK**.

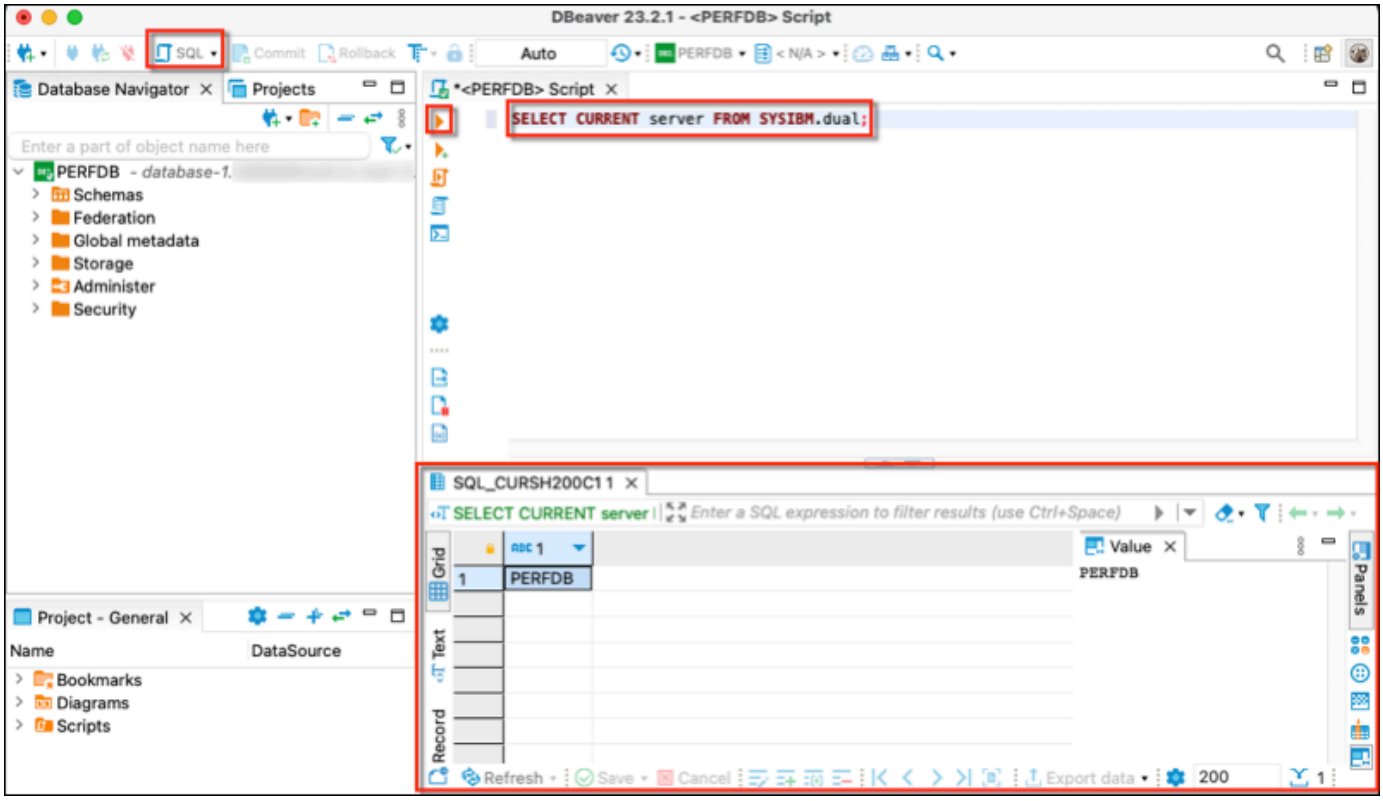


5. In the **Connect to a database** window, choose **Test Connection**. If you don't have a DB2 JBDC driver installed on your computer, then the driver automatically downloads.
6. Choose **OK**.
7. Choose **Finish**.
8. In the **Database Navigation** tab, choose the name of the database. You can now explore objects.

You are now ready to run SQL commands.

To run SQL commands and view the results

1. In the top menu, choose **SQL**. This opens a SQL script panel.
2. In the **Script** panel, enter a SQL command.
3. To run the command, choose the **Execute SQL query** button.
4. In the SQL results panel, view the results of your SQL queries.



Connecting to your Amazon RDS for Db2 DB instance with IBM Db2 Data Management Console

You can connect to your Amazon RDS for Db2 DB instance with IBM Db2 Data Management Console. IBM Db2 Data Management Console can administer and monitor several RDS for Db2 DB instances. To download this utility, see IBM Db2 Data Management Console Version 3.1x releases in IBM Support.

IBM Db2 Data Management Console requires a repository Db2 database to store metadata and performance metrics but can't automatically create a repository for RDS for Db2.

You must first create a repository database to monitor one or more RDS for Db2 DB instances. Then connect to your RDS for Db2 DB instance with IBM Db2 Data Management Console.

Topics

- Creating a repository database to monitor DB instances
- Connecting to RDS for Db2 DB instances with IBM Db2 Data Management Console

Creating a repository database to monitor DB instances

You can use an existing properly sized RDS for Db2 DB instance as a repository for IBM Db2 Data Management Console to monitor other RDS for Db2 DB instances. However, because the admin user doesn't have SYSCTRL authority to create buffer pools and tablespaces, using IBM Db2 Data Management Console repository creation to create a repository database fails. Instead, you must create a repository database to monitor your RDS for Db2 DB instances. You can create a repository database two different ways. You can manually create a buffer pool, a tablespace, and objects for an IBM Db2 Data Management Console repository. Or you can create a separate Amazon EC2 instance to host an IBM Db2 Data Management Console repository.

Topics

Manually creating a buffer pool, a tablespace, and objects

To create a buffer pool, a tablespace, and objects for IBM Db2 Data Management Console to use

1. Allow privileges for buffer pool and tablespaces.

   a. Make changes to scripts, particularly for buffer pools and tablespaces. For more information, see Configuring a repository database in the IBM Db2 Data Management Console documentation.

   b. Connect to the `rdsadmin` database. In the following example, replace *`master_username`* and *`master_password`* with your own information.

   ```
   db2 connect to rdsadmin user master_username using master_password
   ```

   c. Create a buffer pool for IBM Db2 Data Management Console. In the following example, replace *`database_name`* with the name of the repository you created for IBM Db2 Data Management Console to monitor your RDS for Db2 DB instances.

   ```
   db2 "call rdsadmin.create_bufferpool('database_name',
        'BP4CONSOLE', 1000, 'Y', 'Y', 32768)"
   ```

d. Create a tablespace for IBM Db2 Data Management Console. In the following example, replace *database_name* with the name of the repository you created for IBM Db2 Data Management Console to monitor your RDS for Db2 DB instances.

```
db2 "call rdsadmin.create_tablespace('database_name',
     'TS4CONSOLE', 'BP4CONSOLE', 32768)"
```

e. Create a temporary tablespace for IBM Db2 Data Management Console. In the following example, replace *database_name* with the name of the repository you created for IBM Db2 Data Management Console to monitor your RDS for Db2 DB instances.

```
db2 "call rdsadmin.create_tablespace('database_name',
    'TS4CONSOLE_TEMP', 'BP4CONSOLE', 32768, 0, 0, 'T')"
```

2. Manually create IBM Db2 Data Management Console objects. For more information, see Configuring a repository database in the IBM Db2 Data Management Console documentation.

Creating an Amazon EC2 instance to host an IBM Db2 Data Management Console repository

You can create a separate Amazon Elastic Compute Cloud (Amazon EC2) instance to host an IBM Db2 Data Management Console repository. For information about creating an Amazon EC2 instance, see Tutorial: Get started with Amazon EC2 Linux instances in the *Amazon EC2 User Guide*.

Connecting to RDS for Db2 DB instances with IBM Db2 Data Management Console

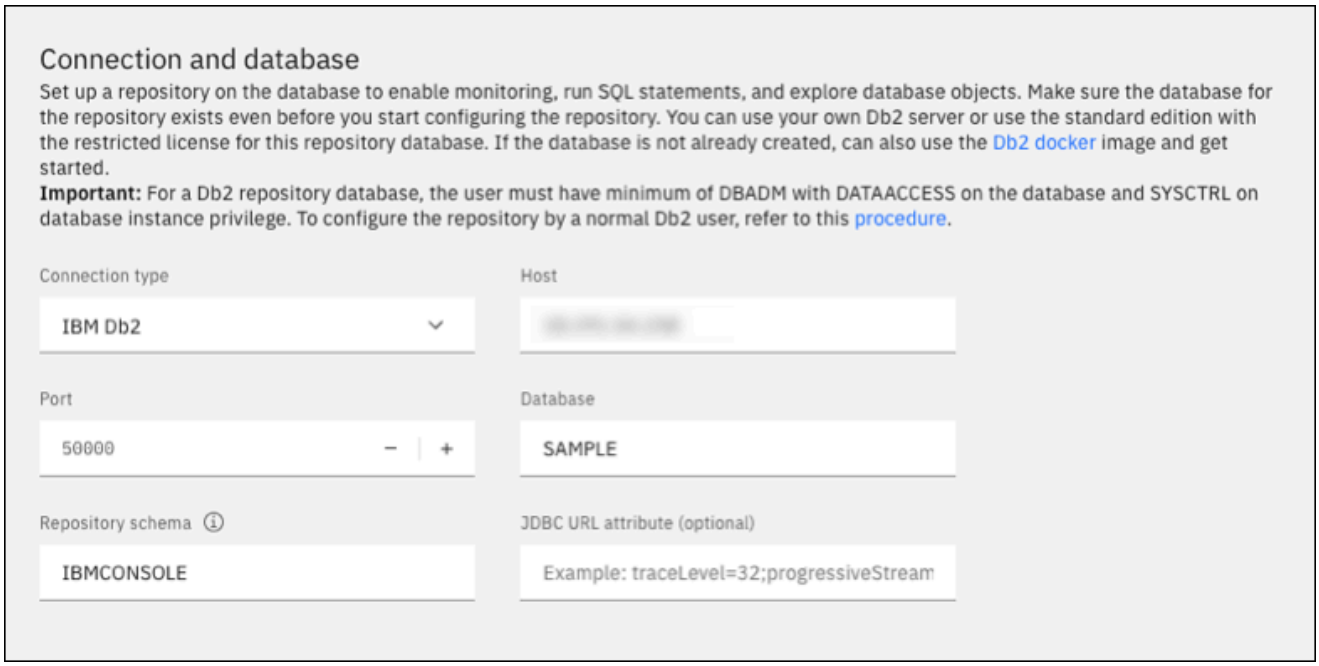
To connect to your RDS for Db2 DB instance, you need its DNS name and port number. For information about finding them, see Finding the endpoint. You also need to know the database name, master username, and master password that you defined when you created your RDS for Db2 DB instance. For more information about finding them, see Creating a DB instance. If you are connecting over the internet, allow traffic to the database port. For more information, see Creating a DB instance.

To connect to RDS for Db2 DB instances with IBM Db2 Data Management Console

1. Start IBM Db2 Data Management Console.
2. Configure the repository.

   a. In the **Connection and database** section, enter the following information for your RDS for Db2 DB instance:

- For **Host**, enter the DNS name of the DB instance.
- For **Port**, enter the port number for the DB instance.
- For **Database**, enter the name of the database.



b. In the **Security and credential** section, enter the following information for your RDS for Db2 DB instance:

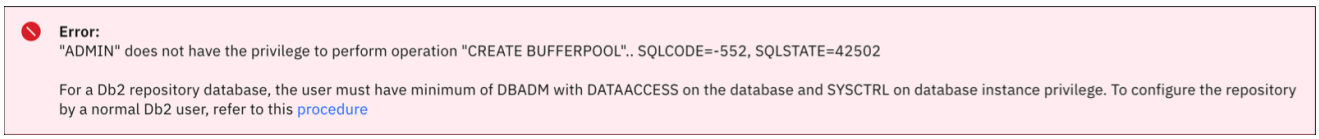
- For **Security type**, choose **Encrypted user and password**.
- For **Username**, enter the name of the database administrator for the DB instance.
- For **Password**, enter the password of the database administrator for the DB instance.

c. Choose **Test connection**.

> **Note**
>
> If the connection is unsuccessful, confirm that the database port is open through the security group's inbound rules. For more information, see Considerations for security groups with Amazon RDS for Db2.

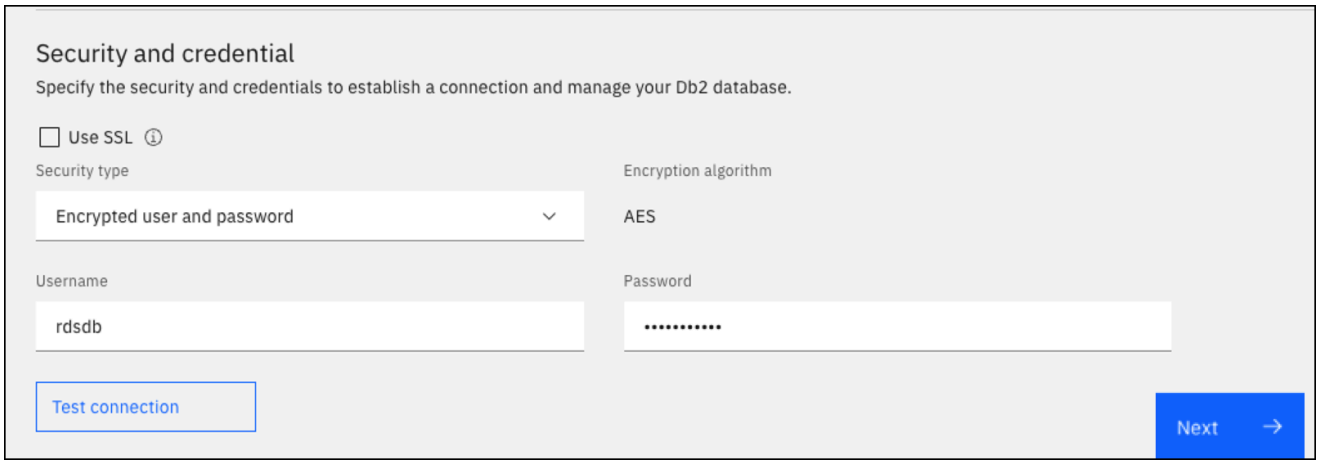
The following error message indicates that the admin user connecting to the RDS for Db2 DB instance doesn't have privileges to create buffer pools or tablespaces. It also indicates

that for Db2 repository databases, the user must have DBADM and DATACCESS on the database. The user must also have SYSCTRL on the database-instance privilege.



Make sure that you created a buffer table, a tablespace, and objects for an IBM Db2 Data Management Console repository to monitor your RDS for Db2 DB instance. Or you can use an Amazon EC2 Db2 DB instance to host an IBM Db2 Data Management Console repository to monitor your RDS for Db2 DB instance. For more information, see Creating a repository database to monitor DB instances.

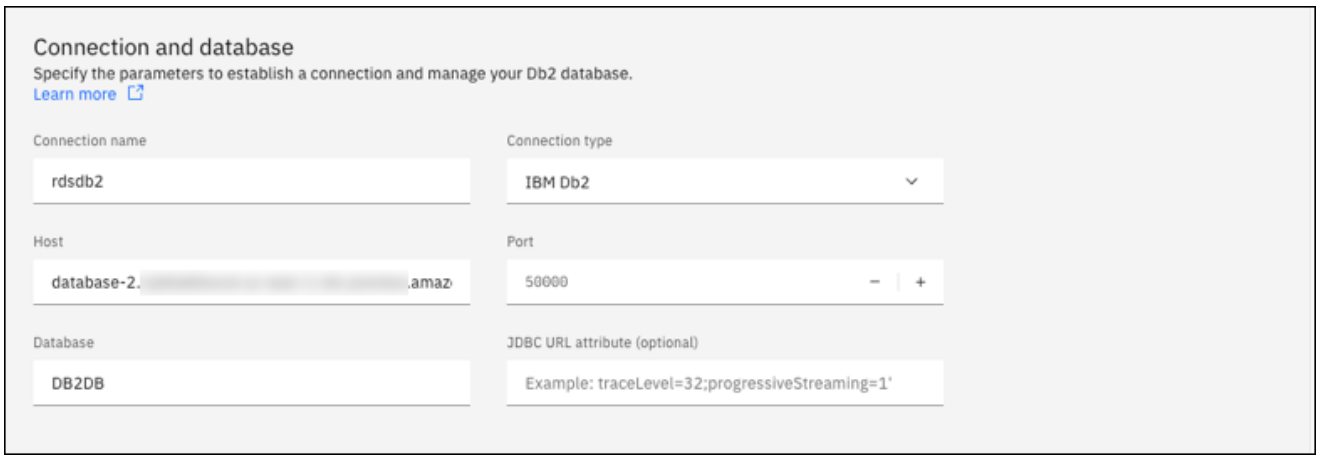
d. After you successfully test your connection, choose **Next**.



3. In the **Set statistics event monitor opt-in** window, choose **Next**.
4. (Optional) Add new connection. If you want to use a different RDS for Db2 DB instance for administration and monitoring, then add a connection to a non-repository RDS for Db2 DB instance.

   a. In the **Connection and database** section, enter the following information for the RDS for Db2 DB instance to use for administration and monitoring:

   - For **Connection name**, enter the Db2 database identifier.
   - For **Host**, enter the DNS name of the DB instance.
   - For **Port**, enter the port number for the DB instance.
   - For **Database**, enter the name of the database.



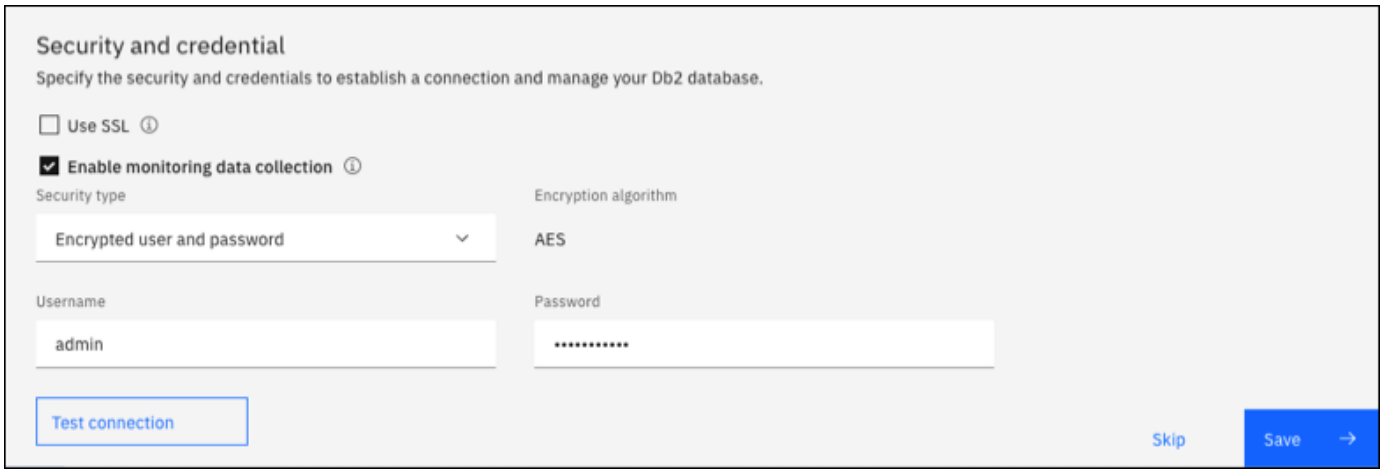
b. In the **Security and credential** section, select **Enable monitoring data collection**.

c. Enter the following information for your RDS for Db2 DB instance:

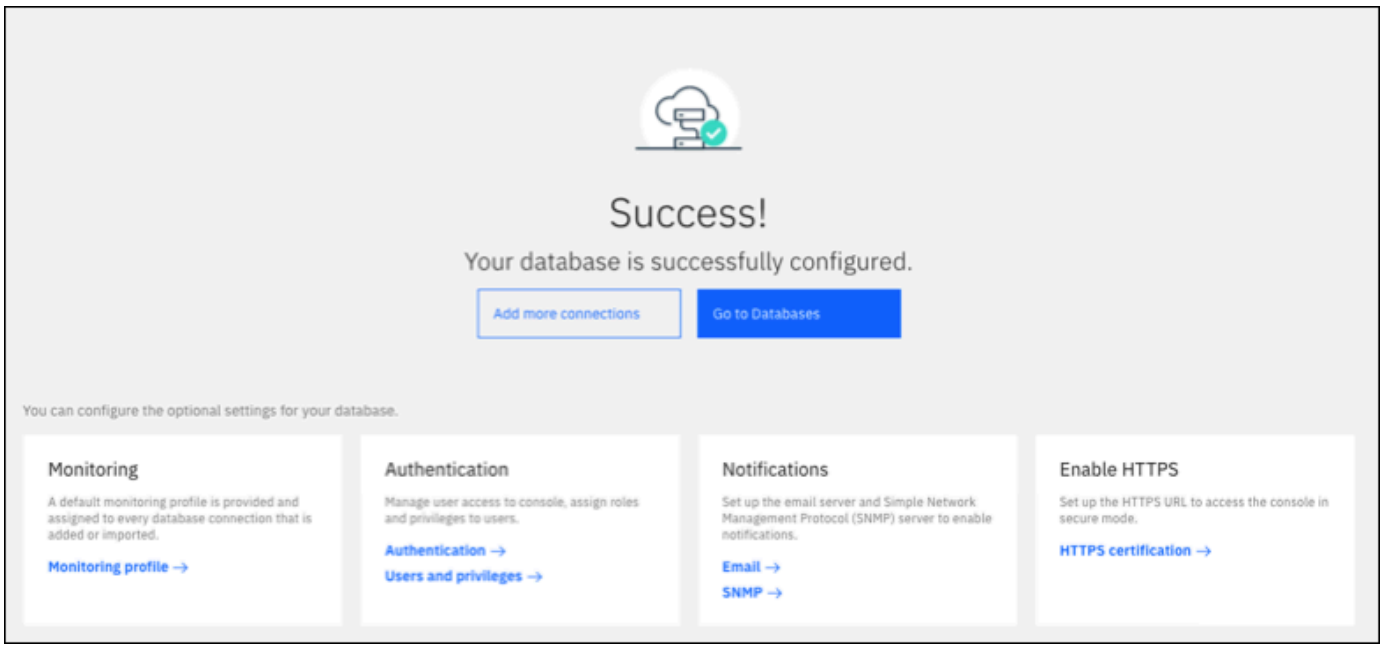
- For **Username**, enter the name of the database administrator for the DB instance.
- For **Password**, enter the password of the database administrator for the DB instance.

d. Choose **Test connection**.

e. After you successfully test your connection, choose **Save**.



After the connection is added, a window similar to the following appears. This window indicates that your database was successfully configured.



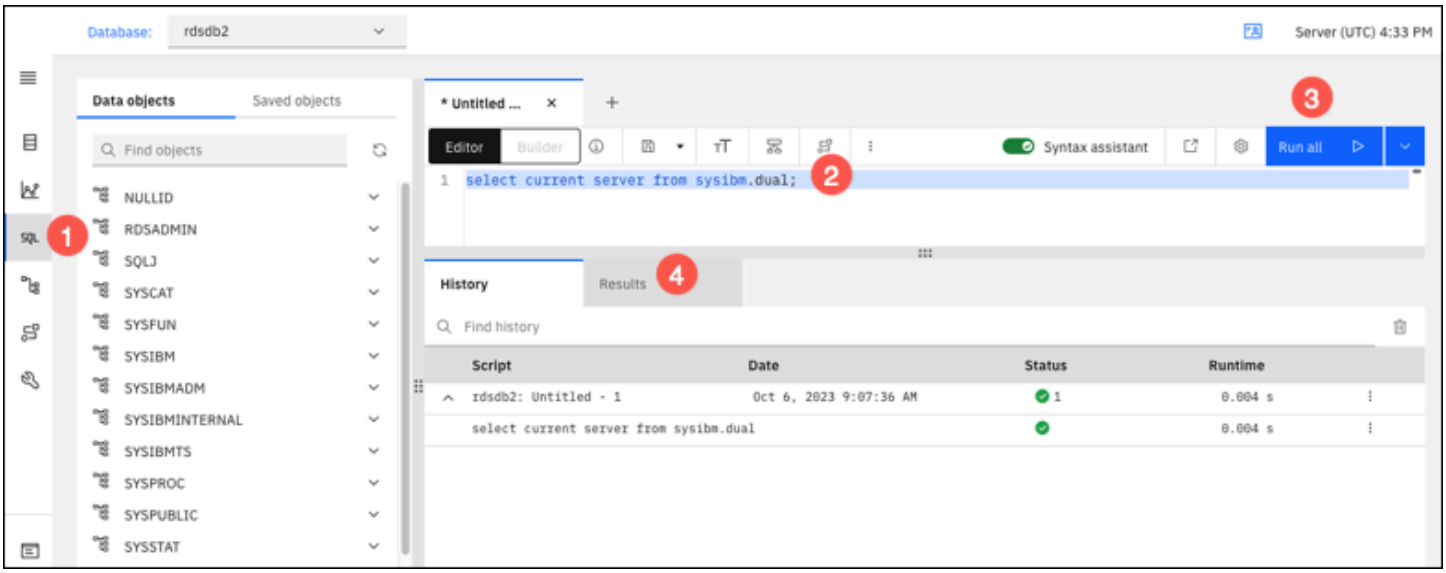
5. Choose **Go to Databases**. A Databases window similar to the following appears. This window is a dashboard that shows metrics, statuses, and connections.

You can now start using IBM Db2 Data Management Console to do the following types of tasks:

- Manage multiple RDS for Db2 DB instances.
- Run SQL commands.
- Explore, create, or change data and database objects.
- Create `EXPLAIN PLAN` statements in SQL.
- Tune queries.

To run SQL commands and view the results

1. In the left navigation bar, choose **SQL**.
2. Enter a SQL command.
3. Choose **Run all**.
4. To view the results, choose the **Results** tab.



Considerations for security groups with Amazon RDS for Db2

For you to connect to your Amazon RDS for Db2 DB instance, it must be associated with a security group that contains the necessary IP addresses and network configuration. Your RDS for Db2 DB instance might use the default security group. If you assigned a default nonconfigured security group when you created the RDS for Db2 DB instance, then the firewall prevents internet connections. For information about creating a new security group, see Controlling access with security groups.

After you create the new security group, you modify your DB instance to associate it with the security group. For more information, see Modifying an Amazon RDS DB instance.

You can enhance security by using SSL to encrypt connections to your DB instance. For more information, see Using SSL/TLS with an Amazon RDS for Db2 DB instance.

Securing Amazon RDS for Db2 DB instance connections

Amazon RDS for Db2 supports ways to improve security for your RDS for Db2 DB instance.

Topics

Using SSL/TLS with an Amazon RDS for Db2 DB instance

SSL is an industry-standard protocol for securing network connections between client and server. After SSL version 3.0, the name was changed to TLS, but we still often refer to the protocol as SSL. Amazon RDS supports SSL encryption for Amazon RDS for Db2 DB instances. Using SSL/TLS, you can encrypt a connection between your application client and your RDS for Db2 DB instance. SSL/TLS support is available in all AWS Regions for RDS for Db2.

To enable SSL/TLS encryption for an RDS for Db2 DB instance, add the Db2 SSL option to the parameter group associated with the DB instance. Amazon RDS uses a second port, as required by Db2, for SSL/TLS connections. Doing this allows both clear text and SSL-encrypted communication to occur at the same time between a DB instance and a Db2 client. For example, you can use the port with clear text communication to communicate with other resources inside a VPC while using the port with SSL-encrypted communication to communicate with resources outside the VPC.

Topics

Creating an SSL/TLS connection

To create an SSL/TLS connection, choose a certificate authority (CA), download a certificate bundle for all AWS Regions, and add parameters to a custom parameter group.

Step 1: Choose a CA and download a certificate

Choose a certificate authority (CA) and download a certificate bundle for all AWS Regions. For more information, see Using SSL/TLS to encrypt a connection to a DB instance or cluster.

Step 2: Update parameters in a custom parameter group

> **Important**
>
> If you're using the Bring Your Own License (BYOL) model for RDS for Db2, modify the custom parameter group that you created for your IBM Customer ID and your IBM Site ID. If you're using a different licensing model for RDS for Db2, then follow the procedure to add parameters to a custom parameter group. For more information, see Amazon RDS for Db2 licensing options.

You can't modify default parameter groups for RDS for Db2 DB instances. Therefore, you must create a custom parameter group, modify it, and then attach it to your RDS for Db2 DB instances. For information about parameter groups, see DB parameter groups for Amazon RDS DB instances.

Use the parameter settings in the following table.

Parameter	Value
`DB2COMM`	`TCPIP,SSL` or `SSL`
`SSL_SVCENAME`	`<any port number except the number used for the non-SSL port>`

To update parameters in a custom parameter group

1. Create a custom parameter group by running the create-db-parameter-group command.

   Include the following required options:

   - `--db-parameter-group-name` – A name for the parameter group that you are creating.
   - `--db-parameter-group-family` – The Db2 engine edition and major version. Valid values: `db2-se-11-5`, `db2-ae-11.5`.
   - `--description` – A description for this parameter group.

   For more information about creating a DB parameter group, see Creating a DB parameter group in Amazon RDS.

2. Modify the parameters in the custom parameter group that you created by running the modify-db-parameter-group command.

   Include the following required options:

   - `--db-parameter-group-name` – The name of the parameter group that you created.
   - `--parameters` – An array of parameter names, values, and the application methods for the parameter update.

   For more information about modifying a parameter group, see Modifying parameters in a DB parameter group in Amazon RDS.
3. Associate the parameter group with your RDS for Db2 DB instance. For more information, see Associating a DB parameter group with a DB instance in Amazon RDS.

Connect to your Db2 database server

Instructions for connecting to your Db2 database server are language-specific.

Java

To connect to your Db2 database server using Java

1. Download the JDBC driver. For more information, see DB2 JDBC Driver Versions and Downloadsin the IBM Support documentation.
2. Create a shell script file with the following content. This script adds all certificates from the bundle to a Java KeyStore.

   > **Important**
   >
   > Verify that `keytool` exists on the path in the script so that the script can locate it. If you use a Db2 client, you can locate the `keytool` under `~sqlib/java/jdk64/jre/bin`.

```
#!/bin/bash
PEM_FILE=$1
PASSWORD=$2
KEYSTORE=$3
```

```
# number of certs in the PEM file
CERTS=$(grep 'END CERTIFICATE' $PEM_FILE| wc -l)
for N in $(seq 0 $(($CERTS - 1))); do
    ALIAS="${PEM_FILE%.*}-$N"
    cat $PEM_FILE |
    awk "n==$N { print }; /END CERTIFICATE/ { n++ }" |
    keytool -noprompt -import -trustcacerts -alias $ALIAS -keystore $KEYSTORE -
storepass $PASSWORD
done
```

3. To run the shell script and import the PEM file with the certificate bundle into a Java KeyStore, run the following command. Replace *shell_file_name.sh* with the name of your shell script file and *password* with the password for your Java KeyStore.

```
./shell_file_name.sh global-bundle.pem password truststore.jks
```

4. To connect to your Db2 server, run the following command. Replace the following placeholders in the example with your RDS for Db2 DB instance information.

   - *ip_address* – The IP address for your DB instance endpoint.
   - *port* – The port number for the SSL connection. This can be any port number except the number that's used for the non-SSL port.
   - *database_name* – The name of your database in your DB instance.
   - *master_username* – The master username for your DB instance.
   - *master_password* – The master password for your DB instance.

```
export trustStorePassword=MyPassword
java -cp ~/dsdriver/jdbc_sqlj_driver/linuxamd64/db2jcc4.jar \
com.ibm.db2.jcc.DB2Jcc -url \
"jdbc:db2://ip_address:port/database_name:\
sslConnection=true;sslTrustStoreLocation=\
~/truststore.jks;\
sslTrustStorePassword=${trustStorePassword};\
sslVersion=TLSv1.2;\
encryptionAlgorithm=2;\
securityMechanism=7;" \
-user master_username -password master_password
```

Node.js

To connect to your Db2 database server using Node.js

1. Install the **node-ibm_db** driver. For more information, see Installing the node-ibm_db driver on Linux and UNIX systems in the IBM Db2 documentation.
2. Create a JavaScript file based on the following content. Replace the following placeholders in the example with your RDS for Db2 DB instance information.

   - *ip_address* – The IP address for your DB instance endpoint.
   - *master_username* – The master username for your DB instance.
   - *master_password* – The master password for your DB instance.
   - *database_name* – The name of your database in your DB instance.
   - *port* – The port number for the SSL connection. This can be any port number except the number that's used for the non-SSL port.

```
var ibmdb = require("ibm_db");
const hostname = "ip_address";
const username = "master_username";
const password = "master_password";
const database = "database_name";
const port = "port";
const certPath = "/root/qa-bundle.pem";
ibmdb.open("DRIVER={DB2};DATABASE=" + database + ";HOSTNAME=" +
 hostname + ";UID=" + username + ";PWD=" + password + ";PORT=" + port +
 ";PROTOCOL=TCPIP;SECURITY=SSL;SSLServerCertificate=" + certPath + ";", function
 (err, conn){
 if (err) return console.log(err);
 conn.close(function () {
 console.log('done');
 });
});
```

3. To run the JavaScript file, run the following command.

```
node ssl-test.js
```

Python

To connect to your Db2 database server using Python

1. Create a Python file with the following content. Replace the following placeholders in the example with your RDS for Db2 DB instance information.

   - *port* – The port number for the SSL connection. This can be any port number except the number that's used for the non-SSL port.
   - *master_username* – The master username for your DB instance.
   - *master_password* – The master password for your DB instance.
   - *database_name* – The name of your database in your DB instance.
   - *ip_address* – The IP address for your DB instance endpoint.

```
import click
import ibm_db
import sys

port = port;
master_user_id = "master_username" # Master id used to create your DB instance
master_password = "master_password" # Master password used to create your DB
 instance
db_name = "database_name" # If not given "db-name'
vpc_customer_private_ip = "ip_address" # Hosts end points - Customer private IP
 Addressicert_path = "/root/ssl/global-bundle.pem" # cert path

@click.command()
@click.option("--path", help="certificate path")
def db2_connect(path):

    try:
        conn =
 ibm_db.connect(f"DATABASE={db_name};HOSTNAME={vpc_customer_private_ip};PORT={port};

 PROTOCOL=TCPIP;UID={master_user_id};PWD={master_password};SECURITY=ssl;SSLServerCertifi
 "", "")
        try:
            ibm_db.exec_immediate(conn, 'create table tablename (a int);')
            print("Query executed successfully")
        except Exception as e:
```

```
            print(e)
        finally:
            ibm_db.close(conn)
            sys.exit(1)
    except Exception as ex:
        print("Trying to connect...")

if __name__ == "__main__":
    db2_connect()
```

2. Create the following shell script, which runs the Python file you created. Replace *python_file_name.py* with the name of your Python script file.

```
#!/bin/bash
PEM_FILE=$1
# number of certs in the PEM file
CERTS=$(grep 'END CERTIFICATE' $PEM_FILE| wc -l)

for N in $(seq 0 $(($CERTS - 1))); do
    ALIAS="${PEM_FILE%.*}-$N"
    cert=`cat $PEM_FILE | awk "n==$N { print }; /END CERTIFICATE/ { n++ }"`
    cat $PEM_FILE | awk "n==$N { print }; /END CERTIFICATE/ { n++ }" >
 $ALIAS.pem
    python3 <python_file_name.py> --path $ALIAS.pem
    output=`echo $?`
    if [ $output == 1 ]; then
        break
    fi
done
```

3. To import the PEM file with the certificate bundle and run the shell script, run the following command. Replace *shell_file_name.sh* with the name of your shell script file.

```
./shell_file_name.sh global-bundle.pem
```

Using Kerberos authentication for Amazon RDS for Db2

You can use Kerberos authentication to authenticate users when they connect to your Amazon RDS for Db2 DB instance. Your DB instance works with AWS Directory Service for Microsoft Active Directory (AWS Managed Microsoft AD) to enable Kerberos authentication. When users

authenticate with an RDS for Db2 DB instance joined to the trusting domain, authentication requests are forwarded to the directory that you create with AWS Directory Service. For more information, see What is AWS Directory Service? in the *AWS Directory Service Administration Guide*.

First, create an AWS Managed Microsoft AD directory to store user credentials. Then, add the domain and other information of your AWS Managed Microsoft AD directory to your RDS for Db2 DB instance. When users authenticate with the RDS for Db2 DB instance, authentication requests are forwarded to the AWS Managed Microsoft AD directory.

Keeping all of your credentials in the same directory can save you time and effort. With this approach, you have a centralized place for storing and managing credentials for multiple DB instances. Using a directory can also improve your overall security profile.

Topics

Region and version availability

Feature availability and support varies across specific versions of each database engine, and across AWS Regions. For more information about version and Region availability of RDS for Db2 with Kerberos authentication, see Supported Regions and DB engines for Kerberos authentication in Amazon RDS.

> **Note**
>
> Kerberos authentication isn't supported for DB instance classes that are deprecated for RDS for Db2 DB instances. For more information, see Amazon RDS for Db2 instance classes.

Overview of Kerberos authentication for RDS for Db2 DB instances

To set up Kerberos authentication for an RDS for Db2 DB instance, complete the following general steps, which are described in more detail later:

1. Use AWS Managed Microsoft AD to create an AWS Managed Microsoft AD directory. You can use the AWS Management Console, the AWS Command Line Interface (AWS CLI), or AWS Directory Service to create the directory. For more information, see Create your AWS Managed Microsoft AD directory in the *AWS Directory Service Administration Guide*.
2. Create an AWS Identity and Access Management (IAM) role that uses the managed IAM policy `AmazonRDSDirectoryServiceAccess`. The IAM role allows Amazon RDS to make calls to your directory.

   For the IAM role to allow access, the AWS Security Token Service (AWS STS) endpoint must be activated in the correct AWS Region for your AWS account. AWS STS endpoints are active by default in all AWS Regions, and you can use them without any further actions. For more information, see Activating and deactivating AWS STS in an AWS Region in the *IAM User Guide*.
3. Create or modify an RDS for Db2 DB instance by using the AWS Management Console, the AWS CLI, or the RDS API with one of the following methods:
   - Create a new RDS for Db2 DB instance using the console, the create-db-instance command, or the CreateDBInstance API operation. For instructions, see Creating an Amazon RDS DB instance.
   - Modify an existing RDS for Db2 DB instance using the console, the modify-db-instance command, or the ModifyDBInstance API operation. For instructions, see Modifying an Amazon RDS DB instance.
   - Restore an RDS for Db2 DB instance from a DB snapshot using the console, the restore-db-instance-from-db-snapshot command, or the RestoreDBInstanceFromDBSnapshot API operation. For instructions, see Restoring to a DB instance.
   - Restore an RDS for Db2 DB instance to a point-in-time using the console, the restore-db-instance-to-point-in-time command, or the RestoreDBInstanceToPointInTime API operation. For instructions, see Restoring a DB instance to a specified time.

   You can locate the DB instance in the same Amazon Virtual Private Cloud (VPC) as the directory or in a different AWS account or VPC. When you create or modify the RDS for Db2 DB instance, do the following tasks:
   - Provide the domain identifier (`d-*` identifier) that was generated when you created your directory.
   - Provide the name of the IAM role that you created.
   - Verify that the DB instance security group can receive inbound traffic from the directory security group.

4. Configure your Db2 client, and verify that traffic can flow between the client host and AWS Directory Service for the following ports:
   - TCP/UDP port 53 – DNS
   - TCP 88 – Kerberos authentication
   - TCP 389 – LDAP
   - TCP 464 – Kerberos authentication

Setting up Kerberos authentication for RDS for Db2 DB instances

You use AWS Directory Service for Microsoft Active Directory (AWS Managed Microsoft AD) to set up Kerberos authentication for an RDS for Db2 DB instance. To set up Kerberos authentication, follow these steps:

Topics

Step 1: Create a directory using AWS Managed Microsoft AD

AWS Directory Service creates a fully managed Active Directory in the AWS Cloud. When you create an AWS Managed Microsoft AD directory, AWS Directory Service creates two domain controllers and DNS servers for you. The directory servers are created in different subnets in a VPC. This redundancy helps ensure that your directory remains accessible even if a failure occurs.

When you create an AWS Managed Microsoft AD directory, AWS Directory Service performs the following tasks on your behalf:

- Sets up an Active Directory within your VPC.
- Creates a directory administrator account with the username `Admin` and the specified password. You use this account to manage your directory.

> **Important**
>
> Make sure to save this password. AWS Directory Service doesn't store this password, and it can't be retrieved or reset.

- Creates a security group for the directory controllers. The security group must permit communication with the RDS for Db2 DB instance.

When you launch AWS Directory Service for Microsoft Active Directory, AWS creates an organizational unit (OU) that contains all of your directory's objects. This OU, which has the NetBIOS name that you entered when you created your directory, is located in the domain root. The domain root is owned and managed by AWS.

The `Admin` account that was created with your AWS Managed Microsoft AD directory has permissions for the most common administrative activities for your OU:

- Create, update, or delete users.
- Add resources to your domain such as file or print servers, and then assign permissions for those resources to users in your OU.
- Create additional OUs and containers.
- Delegate authority.
- Restore deleted objects from the Active Directory Recycle Bin.
- Run Active Directory and Domain Name Service (DNS) modules for Windows PowerShell on the AWS Directory Service.

The `Admin` account also has rights to perform the following domain-wide activities:

- Manage DNS configurations (add, remove, or update records, zones, and forwarders).
- View DNS event logs.
- View security event logs.

To create a directory with AWS Managed Microsoft AD

1. Sign in to the AWS Management Console and open the AWS Directory Service console at https://console.aws.amazon.com/directoryservicev2/.

2. Choose **Set up directory**.
3. Choose **AWS Managed Microsoft AD**. AWS Managed Microsoft AD is the only option currently supported for use with Amazon RDS.
4. Choose **Next**.
5. On the **Enter directory information** page, provide the following information:

   - **Edition** – Choose the edition that meets your requirements.
   - **Directory DNS name** – The fully qualified name for the directory, such as `corp.example.com`.
   - **Directory NetBIOS name** – An optional short name for the directory, such as `CORP`.
   - **Directory description** – An optional description for the directory.
   - **Admin password** – The password for the directory administrator. The directory creation process creates an administrator account with the username `Admin` and this password.

     The directory administrator password can't include the word "admin." The password is case-sensitive and must be 8–64 characters in length. It must also contain at least one character from three of the following four categories:

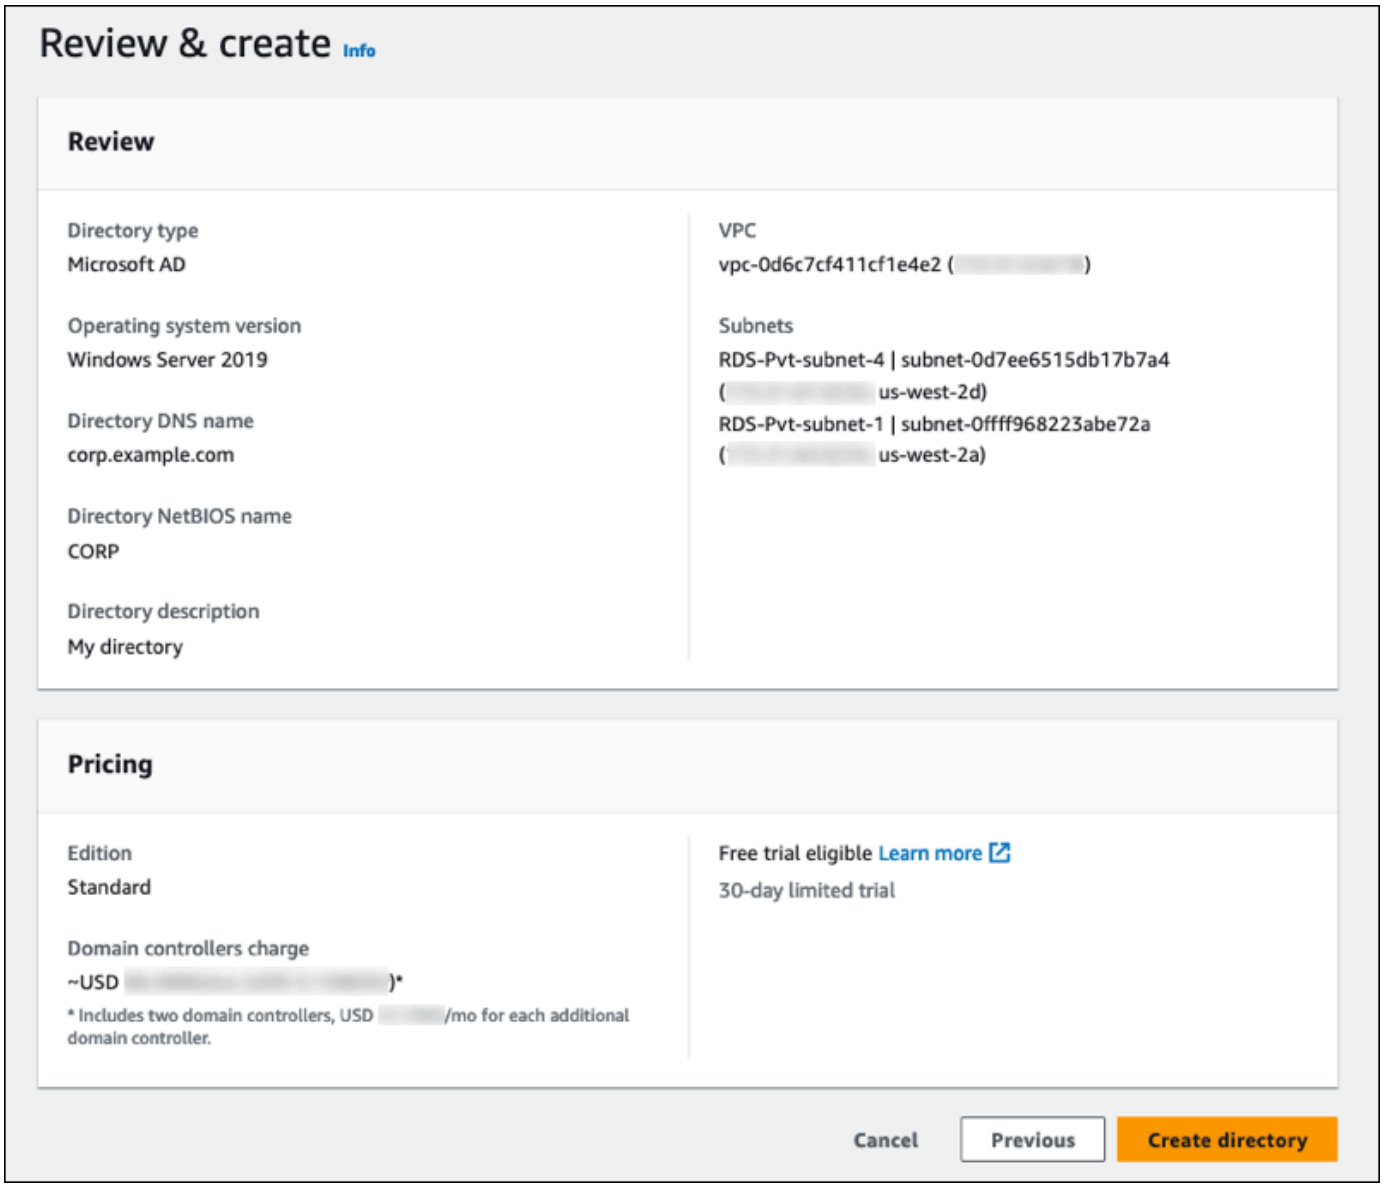
     - Lowercase letters (a–z)
     - Uppercase letters (A–Z)
     - Numbers (0–9)
     - Nonalphanumeric characters (~!@#$%^&*_-+=`|\(){}[]:;"'<>,.?/)
     - Confirm password – Retype the administrator password.

     > **Important**
     >
     > Make sure that you save this password. AWS Directory Service doesn't store this password, and it can't be retrieved or reset.

6. Choose **Next**.
7. On the **Choose VPC and subnets** page, provide the following information:

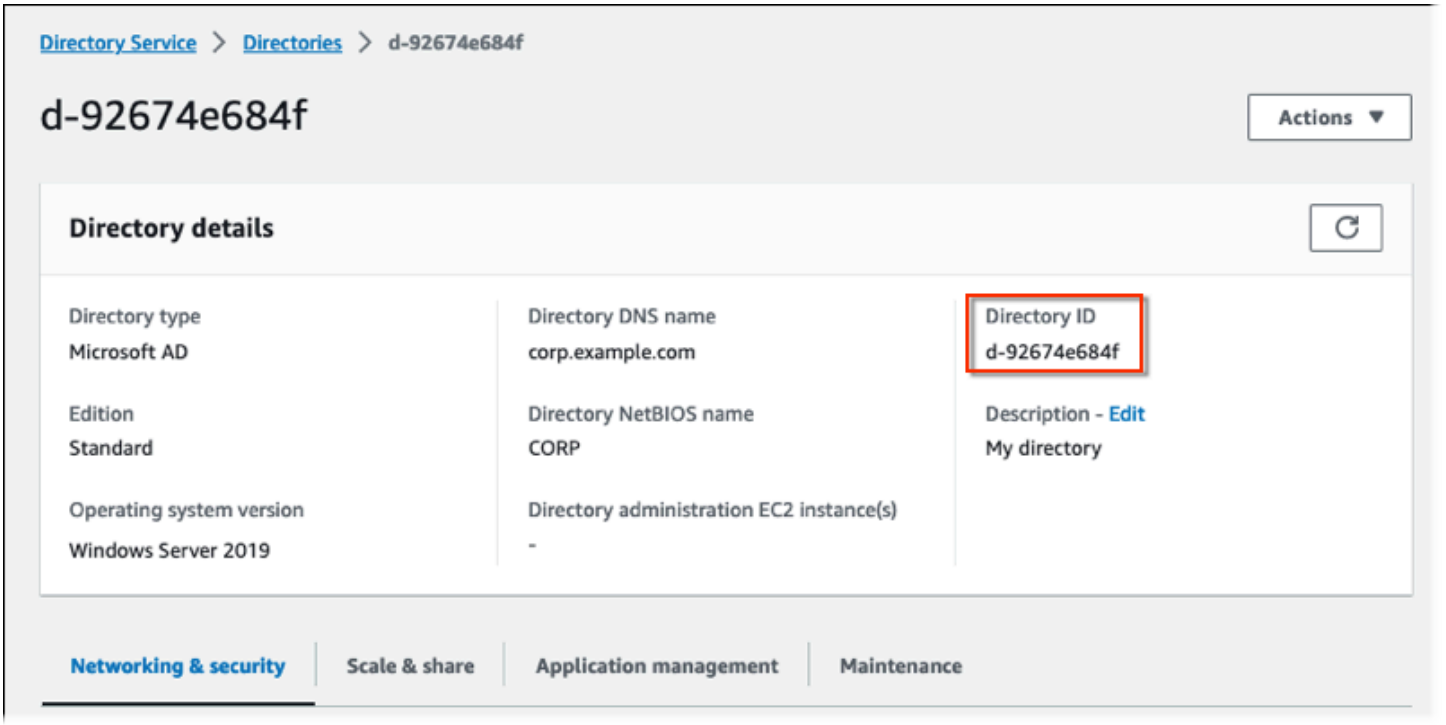
   - **VPC** – Choose the VPC for the directory. You can create the RDS for Db2 DB instance in this same VPC or in a different VPC.
   - **Subnets** – Choose the subnets for the directory servers. The two subnets must be in different Availability Zones.

8. Choose **Next**.
9. Review the directory information. If changes are needed, choose **Previous** and make the changes. When the information is correct, choose **Create directory**.



It takes several minutes for the directory to be created. When it has been successfully created, the **Status** value changes to **Active**.

To see information about your directory, choose the directory ID under **Directory ID**. Make a note of the **Directory ID** value. You need this value when you create or modify your RDS for Db2 DB instance.



Step 2: Create an IAM role for Amazon RDS to access AWS Directory Service

For Amazon RDS to call AWS Directory Service for you, your AWS account needs an IAM role that uses the managed IAM policy `AmazonRDSDirectoryServiceAccess`. This role allows Amazon RDS to make calls to AWS Directory Service.

When you create a DB instance using the AWS Management Console and your console user account has the `iam:CreateRole` permission, the console creates the needed IAM role automatically. In this case, the role name is `rds-directoryservice-kerberos-access-role`. Otherwise, you must create the IAM role manually. When you create this IAM role, choose `Directory Service`, and attach the AWS managed policy `AmazonRDSDirectoryServiceAccess` to it.

For more information about creating IAM roles for a service, see Creating a role to delegate permissions to an AWS service in the *IAM User Guide*.

> **Note**
>
> The IAM role used for Windows Authentication for RDS for Microsoft SQL Server can't be used for RDS for Db2.

As an alternative to using the `AmazonRDSDirectoryServiceAccess` managed policy, you can create policies with the required permissions. In this case, the IAM role must have the following IAM trust policy:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "",
      "Effect": "Allow",
      "Principal": {
        "Service": [
          "directoryservice.rds.amazonaws.com",
          "rds.amazonaws.com"
        ]
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
```

The role must also have the following IAM role policy:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Action": [
        "ds:DescribeDirectories",
        "ds:AuthorizeApplication",
        "ds:UnauthorizeApplication",
        "ds:GetAuthorizedApplicationDetails"
      ],
    "Effect": "Allow",
    "Resource": "*"
    }
  ]
}
```

Step 3: Create and configure users

You can create users by using the Active Directory Users and Computers tool. This is one of the Active Directory Domain Services and Active Directory Lightweight Directory Services tools. For more information, see Add Users and Computers to the Active Directory domain in the Microsoft documentation. In this case, users are individuals or other entities, such as their computers, that are part of the domain and whose identities are being maintained in the directory.

To create users in an AWS Directory Service directory, you must be connected to a Windows-based Amazon EC2 instance that's a member of the AWS Directory Service directory. At the same time, you must be signed in as a user that has privileges to create users. For more information, see Create a user in the *AWS Directory Service Administration Guide*.

Step 4: Create an RDS for Db2 admin group in AWS Managed Microsoft AD

RDS for Db2 doesn't support Kerberos authentication for the master user or the two Amazon RDS reserved users `rdsdb` and `rdsadmin`. Instead, you need to create a new group called `masterdba` in AWS Managed Microsoft AD. For more information, see Create a Group Account in Active Directory in the Microsoft documentation. Any users that you add to this group will have master user privileges.

After you enable Kerberos authentication, the master user loses the `masterdba` role. As a result, the master user won't be able to access the instance local user group membership unless you disable Kerberos authentication. To continue to use the master user with password login, create a user on AWS Managed Microsoft AD with the same name as the master user. Then, add that user to the group `masterdba`.

Step 5: Create or modify an RDS for Db2 DB instance

Create or modify an RDS for Db2 DB instance for use with your directory. You can use the AWS Management Console, the AWS CLI, or the RDS API to associate a DB instance with a directory. You can do this in one of the following ways:

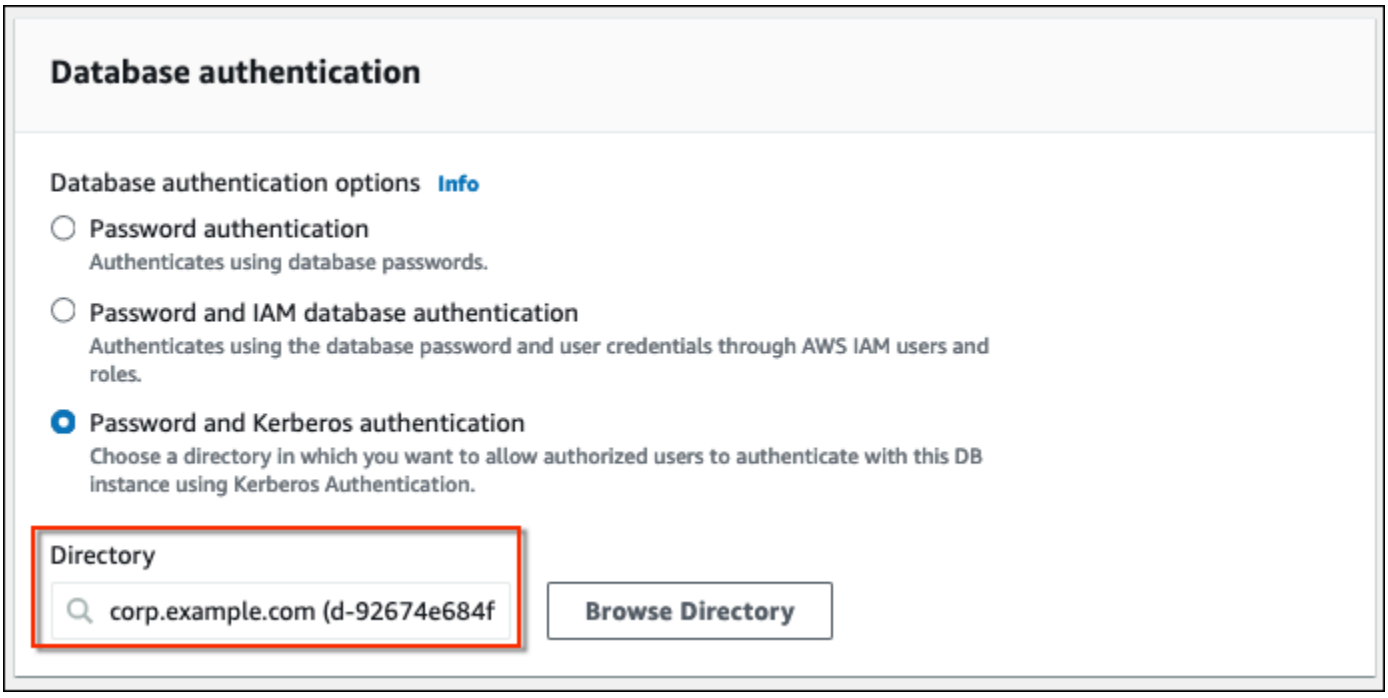
- Create a new RDS for Db2 DB instance using the console, the create-db-instance command, or the CreateDBInstance API operation. For instructions, see Creating an Amazon RDS DB instance.
- Modify an existing RDS for Db2 DB instance using the console, the modify-db-instance command, or the ModifyDBInstance API operation. For instructions, see Modifying an Amazon RDS DB instance.

- Restore an RDS for Db2 DB instance from a DB snapshot using the console, the restore-db-instance-from-db-snapshot command, or the RestoreDBInstanceFromDBSnapshot API operation. For instructions, see Restoring to a DB instance.
- Restore an RDS for Db2 DB instance to a point-in-time using the console, the restore-db-instance-to-point-in-time command, or the RestoreDBInstanceToPointInTime API operation. For instructions, see Restoring a DB instance to a specified time.

Kerberos authentication is only supported for RDS for Db2 DB instances in a VPC. The DB instance can be in the same VPC as the directory, or in a different VPC. The DB instance must use a security group that allows ingress and egress within the directory's VPC so the DB instance can communicate with the directory.

Console

When you use the console to create, modify, or restore a DB instance, choose **Password and Kerberos authentication** in the **Database authentication** section. Then choose **Browse Directory**. Select the directory or choose **Create directory** to use the Directory Service.



AWS CLI

When you use the AWS CLI, the following parameters are required for the DB instance to be able to use the directory that you created:

- For the `--domain` parameter, use the domain identifier ("`d-*`" identifier) generated when you created the directory.
- For the `--domain-iam-role-name` parameter, use the role you created that uses the managed IAM policy `AmazonRDSDirectoryServiceAccess`.

The following example modifies a DB instance to use a directory. Replace the following placeholders in the example with your own values:

- *`db_instance_name`* – The name of your RDS for Db2 DB instance.
- *`directory_id`* – The ID of the AWS Directory Service for Microsoft Active Directory directory that you created.
- *`role_name`* – The name of the IAM role that you created.

```
aws rds modify-db-instance --db-instance-identifier db_instance_name --domain
 d-directory_id --domain-iam-role-name role_name
```

Important

If you modify a DB instance to enable Kerberos authentication, reboot the DB instance after making the change.

Step 6: Configure a Db2 client

To configure a Db2 client

1. Create an **/etc/krb5.conf** file (or equivalent) to point to the domain.

   Note

   For Windows operating systems, create a **C:\windows\krb5.ini** file.

2. Verify that traffic can flow between the client host and AWS Directory Service. Use a network utility such as Netcat for the following tasks:

   a. Verify traffic over DNS for port 53.

b. Verify traffic over TCP/UDP for port 53 and for Kerberos, which includes ports 88 and 464 for AWS Directory Service.

3. Verify that traffic can flow between the client host and the DB instance over the database port. You can use the command db2 to connect and access the database.

The following example is /etc/krb5.conf file content for AWS Managed Microsoft AD:

```
[libdefaults]
default_realm = EXAMPLE.COM
[realms]
EXAMPLE.COM = {
kdc = example.com
admin_server = example.com
}
[domain_realm]
.example.com = EXAMPLE.COM
example.com = EXAMPLE.COM
```

Managing a DB instance in a domain

You can use the AWS Management Console, the AWS CLI, or the RDS API to manage your DB instance and its relationship with your Microsoft Active Directory. For example, you can associate an Active Directory to enable Kerberos authentication. You can also remove the association for an Active Directory to disable Kerberos authentication. You can also move a DB instance to be externally authenticated by one Microsoft Active Directory to another.

For example, using the modify-db-instance CLI command, you can perform the following actions:

- Re-attempt enabling Kerberos authentication for a failed membership by specifying the current membership's directory ID for the `--domain` option.
- Disable Kerberos authentication on a DB instance by specifying `none` for the `--domain` option.
- Move a DB instance from one domain to another by specifying the domain identifier of the new domain for the `--domain` option.

Understanding domain membership

After you create or modify your DB instance, it becomes a member of the domain. You can view the status of the domain membership in the console or by running the describe-db-instances command. The status of the DB instance can be one of the following:

- `kerberos-enabled` – The DB instance has Kerberos authentication enabled.
- `enabling-kerberos` – AWS is in the process of enabling Kerberos authentication on this DB instance.
- `pending-enable-kerberos` – Enabling Kerberos authentication is pending on this DB instance.
- `pending-maintenance-enable-kerberos` – AWS will attempt to enable Kerberos authentication on the DB instance during the next scheduled maintenance window.
- `pending-disable-kerberos` – Disabling Kerberos authentication is pending on this DB instance.
- `pending-maintenance-disable-kerberos` – AWS will attempt to disable Kerberos authentication on the DB instance during the next scheduled maintenance window.
- `enable-kerberos-failed` – A configuration problem prevented AWS from enabling Kerberos authentication on the DB instance. Correct the configuration problem before re-issuing the command to modify the DB instance.
- `disabling-kerberos` – AWS is in the process of disabling Kerberos authentication on this DB instance.

A request to enable Kerberos authentication can fail because of a network connectivity issue or an incorrect IAM role. In some cases, the attempt to enable Kerberos authentication might fail when you create or modify a DB instance. If this happens, verify that you are using the correct IAM role, and then modify the DB instance to join the domain.

Connecting to RDS for Db2 with Kerberos authentication

To connect to RDS for Db2 with Kerberos authentication

1. At a command prompt, run the following command. In the following example, replace *username* with your Microsoft Active Directory username.

   ```
   kinit username
   ```

2. If the RDS for Db2 DB instance is using a publicly accessible VPC, add the IP address for your DB instance endpoint to your `/etc/hosts` file on the Amazon EC2 client. The following example obtains the IP address and then adds it to the `/etc/hosts` file.

```
% dig +short Db2-endpoint.AWS-Region.rds.amazonaws.com
;; Truncated, retrying in TCP mode.
ec2-34-210-197-118.AWS-Region.compute.amazonaws.com.
34.210.197.118

% echo "34.210.197.118  Db2-endpoint.AWS-Region.rds.amazonaws.com" >> /etc/hosts
```

3. Use the following command to log in to an RDS for Db2 DB instance that is associated with Active Directory. Replace *`database_name`* with the name of your RDS for Db2 database.

```
db2 connect to database_name
```

Administering your Amazon RDS for Db2 DB instance

This topic covers the common management tasks that you perform with an Amazon RDS for Db2 DB instance. Some tasks are the same for all Amazon RDS DB instances. Other tasks are specific to RDS for Db2.

The following tasks are common to all RDS databases. There are also tasks specific to RDS for Db2, such as connecting to an RDS for Db2 database with a standard SQL client.

Task area	Relevant documentation
Instance classes, storage, and PIOPS If you are creating a production instance, learn how instance classes, storage types, and Provisioned IOPS work in Amazon RDS.	DB instance classes Amazon RDS storage types
Multi-AZ deployments A production DB instance should use Multi-AZ deployments. Multi-AZ deployments provide increased availability, data durability, and fault tolerance for DB instances.	Configuring and managing a Multi-AZ deployment
Amazon VPC If your AWS account has a default virtual private cloud (VPC), then your DB instance is automatically created inside the default VPC. If your account doesn't have a default VPC, and you want the DB instance in a VPC, create the VPC and subnet groups before you create the DB instance.	Working with a DB instance in a VPC
Security groups By default, DB instances use a firewall that prevents access. Make sure that you create a security group with the correct IP addresses and network configuration to access the DB instance.	Controlling access with security groups
Parameter groups	Adding IBM IDs to a parameter group for RDS for Db2 DB instances

Task area	Relevant documentation
Because your RDS for Db2 DB instance requires that you add the `rds.ibm_customer_id` and `rds.ibm_site_id` parameters, create a parameter group before you create the DB instance. If your DB instance requires other specific database parameters, also add them to this parameter group before you create the DB instance.	Parameter groups for Amazon RDS
Option groups If your DB instance requires specific database options, create an option group before you create the DB instance.	Options for Amazon RDS for Db2 DB instances
Connecting to your DB instance After creating a security group and associating it to a DB instance, you can connect to the DB instance with any standard SQL client application such as IBM Db2 CLP.	Connecting to your Amazon RDS for Db2 DB instance
Backup and restore You can configure your DB instance to take automated storage backups, or take manual storage snapshots, and then restore instances from the backups or snapshots.	Backing up, restoring, and exporting data
Monitoring You can monitor an RDS for Db2 DB instance with IBM Db2 Data Management Console. You can also monitor an RDS for Db2 DB instance by using CloudWatch Amazon RDS metrics, events, and enhanced monitoring.	Connecting to your Amazon RDS for Db2 DB instance with IBM Db2 Data Management Console Viewing metrics in the Amazon RDS console Viewing Amazon RDS events Monitoring OS metrics with Enhanced Monitoring

Task area	Relevant documentation
Log files You can access the log files for your RDS for Db2 DB instance.	Monitoring Amazon RDS log files

Topics

- Performing common system tasks for Amazon RDS for Db2 DB instances
- Performing common database tasks for Amazon RDS for Db2 DB instances

Performing common system tasks for Amazon RDS for Db2 DB instances

You can perform certain common database administrator tasks related to the system on your Amazon RDS DB instances running Db2. To deliver a managed service experience, Amazon RDS doesn't provide shell access to DB instances, and restricts access to certain system procedures and tables that require advanced privileges.

Topics

- Creating a custom database endpoint
- Granting and revoking privileges
- Attaching to the remote RDS for Db2 DB instance

Creating a custom database endpoint

When you migrate to Amazon RDS for Db2, you can use custom database endpoint URLs to minimize changes to your application. For example, if you use `db2.example.com` as your current DNS record, you can add it to Amazon Route 53. In Route 53, you can use private hosted zones to map your current DNS database endpoint to an RDS for Db2 database endpoint. To add a custom A or CNAME record for an Amazon RDS database endpoint, see Registering and managing domains using Amazon Route 53 in the *Amazon Route 53 Developer Guide*.

Note

If you can't transfer your domain to Route 53, you can use your DNS provider to create a CNAME record for the RDS for Db2 database endpoint URL. Consult your DNS provider documentation.

Granting and revoking privileges

Users gain access to databases through membership in groups that are attached to databases.

Use the following procedures to grant and revoke privileges to control access to your database.

These procedures use IBM Db2 CLP running on a local machine to connect to an RDS for Db2 DB instance. Be sure to catalog the TCPIP node and the database to connect to your RDS for Db2 DB instance running on your local machine. For more information, see Connecting to your Amazon RDS for Db2 DB instance with IBM Db2 CLP.

Topics

Granting a user access to your database

To grant a user access to your database

1. Connect to the `rdsadmin` database using the master username and master password for your RDS for Db2 DB instance. In the following example, replace *`master_username`* and *`master_password`* with your own information.

   ```
   db2 connect to rdsadmin user master_username using master_password
   ```

   This command produces output similar to the following example:

   ```
   Database Connection Information

   Database server        = DB2/LINUXX8664 11.5.8.0
   SQL authorization ID   = ADMIN
   Local database alias   = RDSADMIN
   ```

2. Add a user to your authorization list by calling `rdsadmin.add_user`. For more information, see rdsadmin.add_user.

   ```
   db2 "call rdsadmin.add_user(
       'username',
       'password',
       'group_name,group_name')"
   ```

3. (Optional) Add additional groups to the user by calling `rdsadmin.add_groups`. For more information, see rdsadmin.add_groups.

   ```
   db2 "call rdsadmin.add_groups(
       'username',
       'group_name,group_name')"
   ```

4. Confirm the authorities that are available to the user. In the following example, replace *`rds_database_alias`*, *`master_user`*, and *`master_password`* with your own information. Also, replace *`username`* with the user's username.

   ```
   db2 terminate
   db2 connect to rds_database_alias user master_user using master_password
   db2 "SELECT SUBSTR(AUTHORITY,1,20) AUTHORITY, D_USER, D_GROUP, D_PUBLIC
   ```

```
      FROM TABLE (SYSPROC.AUTH_LIST_AUTHORITIES_FOR_AUTHID ('username', 'U') ) AS
T
      ORDER BY AUTHORITY"
```

This command produces output similar to the following example:

```
AUTHORITY            D_USER D_GROUP D_PUBLIC
-------------------- ------ ------- --------
ACCESSCTRL           N      N       N
BINDADD              N      N       N
CONNECT              N      N       N
CREATETAB            N      N       N
CREATE_EXTERNAL_ROUT N      N       N
CREATE_NOT_FENCED_RO N      N       N
CREATE_SECURE_OBJECT N      N       N
DATAACCESS           N      N       N
DBADM                N      N       N
EXPLAIN              N      N       N
IMPLICIT_SCHEMA      N      N       N
LOAD                 N      N       N
QUIESCE_CONNECT      N      N       N
SECADM               N      N       N
SQLADM               N      N       N
SYSADM               *      N       *
SYSCTRL              *      N       *
SYSMAINT             *      N       *
SYSMON               *      N       *
WLMADM               N      N       N
```

5. Grant the RDS for Db2 roles ROLE_NULLID_PACKAGES, ROLE_TABLESPACES, and ROLE_PROCEDURES to the group that you added the user to. For more information, see Amazon RDS for Db2 default roles.

> **Note**
>
> We create RDS for Db2 DB instances in RESTRICTIVE mode. Therefore, the RDS for Db2 roles ROLE_NULLID_PACKAGES, ROLE_TABLESPACES, and ROLE_PROCEDURES grant execute privileges on NULLID packages for IBM Db2 CLP and Dynamic SQL. These roles also grant user privileges on tablespaces.

a. Connect to your Db2 database. In the following example, replace *database_name*, *master_user*, and *master_password* with your own information.

```
db2 connect to database_name user master_user using master_password
```

b. Grant the role ROLE_NULLED_PACKAGES to a group. In the following example, replace *group_name* with the name of the group that you want to add the role to.

```
db2 "grant role ROLE_NULLID_PACKAGES to group group_name"
```

c. Grant the role ROLE_TABLESPACES to the same group. In the following example, replace *group_name* with the name of the group that you want to add the role to.

```
db2 "grant role ROLE_TABLESPACES to group group_name"
```

d. Grant the role ROLE_PROCEDURES to the same group. In the following example, replace *group_name* with the name of the group that you want to add the role to.

```
db2 "grant role ROLE_PROCEDURES to group group_name"
```

6. Grant connect, bindadd, createtab, and IMPLICIT_SCHEMA authorities to the group that you added the user to. In the following example, replace *group_name* with the name of the second group that you added the user to.

```
db2 "grant usage on workload SYSDEFAULTUSERWORKLOAD to public"
db2 "grant connect, bindadd, createtab, implicit_schema on database to
 group group_name"
```

7. Repeat steps 4 through 6 for each additional group that you added the user to.

8. Test the user's access by connecting as the user, creating a table, inserting values into the table, and returning data from the table. In the following example, replace *rds_database_alias*, *username*, and *password* with the name of the database and the user's username and password.

```
db2 connect to rds_database_alias user username using password
db2 "create table t1(c1 int not null)"
db2 "insert into t1 values (1),(2),(3),(4)"
db2 "select * from t1"
```

Changing a user's password

To change a user's password

1. Connect to the `rdsadmin` database using the master username and master password for your RDS for Db2 DB instance. In the following example, replace *`master_username`* and *`master_password`* with your own information.

   ```
   db2 connect to rdsadmin user master_username using master_password
   ```

2. Change the password by calling `rdsadmin.change_password`. For more information, see rdsadmin.change_password.

   ```
   db2 "call rdsadmin.change_password(
       'username',
       'new_password')"
   ```

Adding groups to a user

To add groups to a user

1. Connect to the `rdsadmin` database using the master username and master password for your RDS for Db2 DB instance. In the following example, replace *`master_username`* and *`master_password`* with your own information.

   ```
   db2 connect to rdsadmin user master_username using master_password
   ```

2. Add groups to a user by calling `rdsadmin.add_groups`. For more information, see rdsadmin.add_groups.

   ```
   db2 "call rdsadmin.add_groups(
       'username',
       'group_name,group_name')"
   ```

Removing groups from a user

To remove groups from a user

1. Connect to the `rdsadmin` database using the master username and master password for your RDS for Db2 DB instance. In the following example, replace *`master_username`* and *`master_password`* with your own information.

```
db2 connect to rdsadmin user master_username using master_password
```

2. Remove groups by calling `rdsadmin.remove_groups`. For more information, see rdsadmin.remove_groups.

```
db2 "call rdsadmin.remove_groups(
    'username',
    'group_name,group_name')"
```

Removing a user

To remove a user from the authorization list

1. Connect to the `rdsadmin` database using the master username and master password for your RDS for Db2 DB instance. In the following example, replace *`master_username`* and *`master_password`* with your own information.

```
db2 connect to rdsadmin user master_username using master_password
```

2. Remove a user from your authorization list by calling `rdsadmin.remove_user`. For more information, see rdsadmin.remove_user.

```
db2 "call rdsadmin.remove_user('username')"
```

Listing users

To list users on an authorization list, call the `rdsadmin.list_users` stored procedure. For more information, see rdsadmin.list_users.

```
db2 "call rdsadmin.list_users()"
```

Creating a role

You can use the rdsadmin.create_role stored procedure to create a role.

To create a role

1. Connect to the `rdsadmin` database. In the following example, replace *`master_username`* and *`master_password`* with your information.

```
db2 connect to rdsadmin user master_username using master_password
```

2. Set Db2 to output content.

```
db2 set serveroutput on
```

3. Create a role. For more information, see the section called "rdsadmin.create_role".

```
db2 "call rdsadmin.create_role(
    'database_name',
    'role_name')"
```

4. Set Db2 to not output content.

```
db2 set serveroutput off
```

Granting a role

You can use the rdsadmin.grant_role stored procedure to assign a role to a role, user, or group.

To assign a role

1. Connect to the `rdsadmin` database. In the following example, replace *`master_username`* and *`master_password`* with your information.

```
db2 connect to rdsadmin user master_username using master_password
```

2. Set Db2 to output content.

```
db2 set serveroutput on
```

3. Assign a role. For more information, see the section called "rdsadmin.grant_role".

```
db2 "call rdsadmin.grant_role(
    'database_name',
    'role_name',
    'grantee',
    'admin_option')"
```

4. Set Db2 to not output content.

```
db2 set serveroutput off
```

Revoking a role

You can use the rdsadmin.revoke_role stored procedure to revoke a role from a role, user, or group.

To revoke a role

1. Connect to the `rdsadmin` database. In the following example, replace *`master_username`* and *`master_password`* with your information.

```
db2 connect to rdsadmin user master_username using master_password
```

2. Revoke a role. For more information, see the section called “rdsadmin.revoke_role”.

```
db2 "call rdsadmin.revoke_role(
    ?,
    'database_name',
    'role_name',
    'grantee')"
```

Granting database authorization

The master user, who has `DBADM` authorization, can grant `DBADM`, `ACCESSCTRL`, or `DATAACCESS` authorization to a role, user, or group.

To grant database authorization

1. Connect to the `rdsadmin` database using the master username and master password for your RDS for Db2 DB instance. In the following example, replace *`master_username`* and *`master_password`* with your own information.

```
db2 connect to rdsadmin user master_username using master_password
```

2. Grant a user access by calling `rdsadmin.dbadm_grant`. For more information, see rdsadmin.dbadm_grant.

```
db2 "call rdsadmin.dbadm_grant(
    ?,
    'database_name',
    'authorization',
    'grantee')"
```

Example use case

The following procedure walks you through creating a role, granting DBADM authorization to the role, assigning the role to a user, and granting the role to a group.

1. Connect to the `rdsadmin` database using the master username and master password for your RDS for Db2 DB instance. In the following example, replace *master_username* and *master_password* with your own information.

```
db2 connect to rdsadmin user master_username using master_password
```

2. Create a role called PROD_ROLE for a database called TESTDB. For more information, see rdsadmin.create_role.

```
db2 "call rdsadmin.create_role(
    'TESTDB',
    'PROD_ROLE')"
```

3. Assign the role to a user called PROD_USER. The PROD_USER is given admin authorization to assign roles. For more information, see rdsadmin.grant_role.

```
db2 "call rdsadmin.grant_role(
    ?,
    'TESTDB',
    'PROD_ROLE',
    'USER PROD_USER',
    'Y')"
```

4. (Optional) Provide additional authorization or privileges. The following example grants DBADM authorization to a role named PROD_ROLE for a database called FUNDPROD. For more information, see rdsadmin.dbadm_grant.

```
db2 "call rdsadmin.dbadm_grant(
    ?,
    'FUNDPROD',
    'DBADM',
    'ROLE PROD_ROLE')"
```

5. Terminate your session.

```
db2 terminate
```

6. Connect to the TESTDB database using the master username and master password for your RDS for Db2 DB instance. In the following example, replace *master_username* and *master_password* with your own information.

```
db2 connect to TESTDB user master_username using master_password
```

7. Add more authorizations to the role.

```
db2 "grant connect, implicit_schema on database to role PROD_ROLE"
```

8. Grant the role PROD_ROLE to a group.

```
db2 "grant role PROD_ROLE to group PRODGRP"
```

Users who belong to the group PRODGRP can now perform actions such as connecting to the TESTDB database, creating tables, or creating schemas.

Revoking database authorization

The master user, who has DBADM authorization, can revoke DBADM, ACCESSCTRL, or DATAACCESS authorization from a role, user, or group.

To revoke database authorization

1. Connect to the `rdsadmin` database using the master username and master password for your RDS for Db2 DB instance. In the following example, replace *`master_username`* and *`master_password`* with your own information.

```
db2 connect to rdsadmin user master_username using master_password
```

2. Revoke user access by calling `rdsadmin.dbadm_revoke`. For more information, see rdsadmin.dbadm_revoke.

```
db2 "call rdsadmin.dbadm_revoke(
    ?,
    'database_name',
    'authorization',
    'grantee')"
```

Attaching to the remote RDS for Db2 DB instance

To attach to the remote RDS for Db2 DB instance

1. Run a client-side IBM Db2 CLP session. For information about cataloging your RDS for Db2 DB instance and database, see Connecting to your Amazon RDS for Db2 DB instance with IBM Db2 CLP. Make a note of the master username and master password for your RDS for Db2 DB instance.
2. Attach to the RDS for Db2 DB instance. In the following example, replace *`node_name`*, *`master_username`*, and *`master_password`* with the TCPIP node name that you catalogued and the master username and master password for your RDS for Db2 DB instance.

```
db2 attach to node_name user master_username using master_password
```

After attaching to the remote RDS for Db2 DB instance, you can run the following commands and other `get snapshot` commands. For more information, see GET SNAPSHOT command in the IBM Db2 documentation.

```
db2 list applications
db2 get snapshot for all databases
```

```
db2 get snapshot for database manager
db2 get snapshot for all applications
```

Performing common database tasks for Amazon RDS for Db2 DB instances

You can perform certain common DBA tasks related to databases on your Amazon RDS for Db2 DB instances. To deliver a managed service experience, Amazon RDS doesn't provide shell access to DB instances. Also, the master user can't run commands or utilities requiring SYSADM, SYSMAINT, or SYSCTRL authorities.

Topics

Managing buffer pools

You can create, alter, or drop buffer pools for an RDS for Db2 database. Creating, altering, or dropping buffer pools requires higher-level SYSADM or SYSCTRL authority, which isn't available to the master user. Instead, use Amazon RDS stored procedures.

You can also flush buffer pools.

Topics

Creating a buffer pool

To create a buffer pool for your RDS for Db2 database, call the `rdsadmin.create_bufferpool` stored procedure. For more information, see CREATE BUFFERPOOL statement in the IBM Db2 documentation.

To create a buffer pool

1. Connect to the `rdsadmin` database using the master username and master password for your RDS for Db2 DB instance. In the following example, replace *`master_username`* and *`master_password`* with your own information.

```
db2 "connect to rdsadmin user master_user using master_password"
```

2. Create a buffer pool by calling `rdsadmin.create_bufferpool`. For more information, see rdsadmin.create_bufferpool.

```
db2 "call rdsadmin.create_bufferpool(
    'database_name',
    'buffer_pool_name',
    buffer_pool_size,
    'immediate',
    'automatic',
    page_size,
    number_block_pages,
    block_size)"
```

Altering a buffer pool

To alter a buffer pool for your RDS for Db2 database, call the `rdsadmin.alter_bufferpool` stored procedure. For more information, see ALTER BUFFERPOOL statement in the IBM Db2 documentation.

To alter a buffer pool

1. Connect to the `rdsadmin` database using the master username and master password for your RDS for Db2 DB instance. In the following example, replace *`master_username`* and *`master_password`* with your own information.

```
db2 "connect to rdsadmin user master_username using master_password"
```

2. Alter a buffer pool by calling `rdsadmin.alter_bufferpool`. For more information, see rdsadmin.alter_bufferpool.

```
db2 "call rdsadmin.alter_bufferpool(
    'database_name',
```

```
    'buffer_pool_name',
    buffer_pool_size,
    'immediate',
    'automatic',
    change_number_blocks,
    number_block_pages,
    block_size)"
```

Dropping a buffer pool

To drop a buffer pool for your RDS for Db2 database, call the `rdsadmin.drop_bufferpool` stored procedure. For more information, see Dropping buffer pools in the IBM Db2 documentation.

> **Important**
>
> Make sure that no tablespaces are assigned to the buffer pool that you want to drop.

To drop a buffer pool

1. Connect to the `rdsadmin` database using the master username and master password for your RDS for Db2 DB instance. In the following example, replace *`master_username`* and *`master_password`* with your own information.

   ```
   db2 "connect to rdsadmin user master_user using master_password"
   ```

2. Drop a buffer pool by calling `rdsadmin.drop_bufferpool`. For more information, see rdsadmin.drop_bufferpool.

   ```
   db2 "call rdsadmin.drop_bufferpool(
       'database_name',
       'buffer_pool_name')"
   ```

Flushing the buffer pools

You can flush the buffer pools to force a checkpoint so that RDS for Db2 writes pages from memory to storage.

> **Note**
>
> You don't need to flush the buffer pools. Db2 writes logs synchronously before it commits transactions. The dirty pages might still be in a buffer pool, but Db2 writes them to storage asynchronously. Even if the system shuts down unexpectedly, when you restart the database, Db2 automatically performs crash recovery. During crash recovery, Db2 writes committed changes to the database or rolls back changes for uncommitted transactions.

To flush the buffer pools

1. Connect to your Db2 database using the master username and master password for your RDS for Db2 DB instance. In the following example, replace *rds_database_alias*, *master_username*, and *master_password* with your own information.

```
db2 connect to rds_database_alias user master_username using master_password
```

2. Flush the buffer pools.

```
db2 flush bufferpools all
```

Managing databases

You can create, drop, or restore databases on your RDS for Db2 DB instance. Creating, dropping, or restoring databases requires higher-level SYSADM authority, which isn't available to the master user. Instead, use Amazon RDS stored procedures.

You can also perform common management tasks such as monitoring, maintenance, and the collection of information about your databases.

Topics

- Creating a database
- Configuring settings for a database
- Modifying database parameters
- Configuring log retention
- Dropping a database

- Restoring a database
- Collecting information about databases
- Forcing applications off of databases
- Generating performance reports

Creating a database

To create a database on your RDS for Db2 DB instance, call the `rdsadmin.create_database` stored procedure. For more information, see CREATE DATABASE command in the IBM Db2 documentation.

> **Note**
>
> You can create a database by calling the stored procedure if you didn't specify the name of the database when you created your RDS for Db2 DB instance by using either the Amazon RDS console or the AWS CLI. For more information, see the section called "Usage notes" for `rdsadmin.create_database`.

To create a database

1. Connect to the `rdsadmin` database using the master username and master password for your RDS for Db2 DB instance. In the following example, replace *`master_username`* and *`master_password`* with your own information.

   ```
   db2 "connect to rdsadmin user master_user using master_password"
   ```

2. Create a database by calling `rdsadmin.create_database`. For more information, see rdsadmin.create_database.

   ```
   db2 "call rdsadmin.create_database('database_name')"
   ```

Configuring settings for a database

To configure the settings for a database on your RDS for Db2 DB instance, call the `rdsadmin.set_configuration` stored procedure. For example, you could configure the number of buffers or buffer manipulators to create during a restore operation.

To configure settings for a database

1. Connect to the `rdsadmin` database using the master username and master password for your RDS for Db2 DB instance. In the following example, replace *`master_username`* and *`master_password`* with your own information.

```
db2 "connect to rdsadmin user master_user using master_password"
```

2. (Optional) Check your current configuration settings by calling `rdsadmin.show_configuration`. For more information, see the section called "rdsadmin.show_configuration".

```
db2 "call rdsadmin.show_configuration('name')"
```

3. Configure the settings for the database by calling `rdsadmin.set_configuration`. For more information, see the section called "rdsadmin.set_configuration".

```
db2 "call rdsadmin.set_configuration(
    'name',
    'value')"
```

Modifying database parameters

Amazon RDS for Db2 uses three types of parameters: database manager configuration parameters, registry variables, and database configuration parameters. You can update the first two types through parameter groups and the last type through the rdsadmin.update_db_param stored procedure.

> **Note**
>
> You can only modify the values of existing parameters. You can't add new parameters that RDS for Db2 doesn't support.

For more information these parameters and how to modify their values, see the section called "Db2 parameters".

Configuring log retention

To configure how long Amazon RDS retains log files for your RDS for Db2 database, call the `rdsadmin.set_archive_log_retention` stored procedure.

To configure log retention for a database

1. Connect to the `rdsadmin` database using the master username and master password for your RDS for Db2 DB instance. In the following example, replace *`master_username`* and *`master_password`* with your own information.

```
db2 "connect to rdsadmin user master_user using master_password"
```

2. (Optional) Check your current configuration for log retention by calling `rdsadmin.show_archive_log_retention`. For more information, see the section called "rdsadmin.show_archive_log_retention".

```
db2 "call rdsadmin.show_archive_log_retention(
    ?,
    'database_name')"
```

3. Configure log retention for the database by calling `rdsadmin.set_archive_log_retention`. For more information, see the section called "rdsadmin.set_archive_log_retention".

```
db2 "call rdsadmin.set_archive_log_retention(
    ?,
    'database_name',
    'archive_log_retention_hours')"
```

Dropping a database

To drop a database from your RDS for Db2 DB instance, call the `rdsadmin.drop_database` stored procedure. For more information, see Dropping databases in the IBM Db2 documentation.

> **Note**
>
> You can drop a database by calling the stored procedure only if certain conditions are met. For more information, see the section called "Usage notes" for `rdsadmin.drop_database`.

To drop a database

1. Connect to the `rdsadmin` database using the master username and master password for your RDS for Db2 DB instance. In the following example, replace *`master_username`* and *`master_password`* with your own information.

   ```
   db2 "connect to rdsadmin user master_user using master_password"
   ```

2. Drop a database by calling `rdsadmin.drop_database`. For more information, see rdsadmin.drop_database.

   ```
   db2 "call rdsadmin.drop_database('database_name')"
   ```

Restoring a database

To restore a database on your RDS for Db2 DB instance, call the `rdsadmin.restore_database` stored procedure. For more information, see RESTORE DATABASE command in the IBM Db2 documentation.

> **Note**
>
> You can restore a database by calling the stored procedure if you didn't specify the name of the database when you created your RDS for Db2 DB instance by using either the Amazon RDS console or the AWS CLI. For more information, see the section called "Usage notes" for `rdsadmin.restore_database`.

To restore a database

1. Connect to the `rdsadmin` database using the master username and master password for your RDS for Db2 DB instance. In the following example, replace *`master_username`* and *`master_password`* with your own information.

```
db2 "connect to rdsadmin user master_user using master_password"
```

2. (Optional) Check your current configuration settings to optimize the restore operation by calling `rdsadmin.show_configuration`. For more information, see the section called "rdsadmin.show_configuration".

```
db2 "call rdsadmin.show_configuration('name')"
```

3. Configure the settings to optimize the restore operation by calling `rdsadmin.set_configuration`. Explicitly setting these values can improve the performance when restoring databases with large volumes of data. For more information, see the section called "rdsadmin.set_configuration".

```
db2 "call rdsadmin.set_configuration(
    'name',
    'value')"
```

4. Restore the database by calling `rdsadmin.restore_database`. For more information, see the section called "rdsadmin.restore_database".

```
db2 "call rdsadmin.restore_database(
    ?,
    'database_name',
    's3_bucket_name',
    's3_prefix',
    restore_timestamp,
    'backup_type')"
```

5. Bring the database back online and apply additional transaction logs by calling `rdsadmin.rollforward_database`. For more information, see the section called "rdsadmin.rollforward_database".

```
db2 "call rdsadmin.rollforward_database(
    ?,
    'database_name',
```

```
    's3_bucket_name',
    s3_prefix,
    'rollfoward_to_option',
    'complete_rollforward')"
```

6. If you set `complete_rollforward` to FALSE in the previous step, then you must finish bringing the database back online by calling `rdsadmin.complete_rollforward`. For more information, see the section called “rdsadmin.complete_rollforward”.

```
db2 "call rdsadmin.complete_rollforward(
    ?,
    'database_name')"
```

Collecting information about databases

To collect information about your databases, call the `rdsadmin.db2pd_command` stored procedure. This information can help with monitoring your databases or troubleshooting issues.

To collect information about a database

1. Connect to the `rdsadmin` database using the master username and master password for your RDS for Db2 DB instance. In the following example, replace *`master_username`* and *`master_password`* with your own information.

```
db2 "connect to rdsadmin user master_username using master_password"
```

2. Collect information about the database by calling `rdsadmin.db2pd_command`. For more information, see rdsadmin.db2pd_command.

```
db2 "call rdsadmin.db2pd_command('db2pd_cmd')"
```

Forcing applications off of databases

To force applications off of your RDS for Db2 databases, call the `rdsadmin.force_application` stored procedure. Before you perform maintenance on your databases, force applications off of your databases.

To force applications off of a database

1. Connect to the `rdsadmin` database using the master username and master password for your RDS for Db2 DB instance. In the following example, replace *`master_username`* and *`master_password`* with your own information.

```
db2 "connect to rdsadmin user master_username using master_password"
```

2. Force applications off of a database by calling `rdsadmin.force_application`. For more information, see rdsadmin.force_application.

```
db2 "call rdsadmin.force_application(
    ?,
    'applications')"
```

Generating performance reports

You can generate performance reports with a procedure or a script. For information about using a procedure, see DBSUMMARY procedure - Generate a summary report of system and application performance metrics in the IBM Db2 documentation.

Db2 includes a `db2mon.sh` file in its `~sqllib/sample/perf` directory. Running the script produces a low-cost, extensive SQL metrics report. To download the `db2mon.sh` file and related script files, see the perf directory in the IBM db2-samples GitHub repository.

To generate performance reports with the script

1. Connect to your Db2 database using the master username and master password for your RDS for Db2 DB instance. In the following example, replace *`master_username`* and *`master_password`* with your own information.

```
db2 connect to rdsadmin user master_username using master_password
```

2. Create a buffer pool named `db2monbp` with a page size of 4096 by calling `rdsadmin.create_bufferpool`. For more information, see rdsadmin.create_bufferpool.

```
db2 "call rdsadmin.create_bufferpool('database_name','db2monbp',4096)"
```

3. Create a temporary tablespace named db2montmptbsp that uses the db2monbp buffer pool by calling `rdsadmin.create_tablespace`. For more information, see rdsadmin.create_tablespace.

```
db2 "call rdsadmin.create_tablespace('database_name',\
    'db2montmptbsp','db2monbp',4096,1000,100,'T')"
```

4. Open the db2mon.sh script, and modify the line about connecting to a database.

   a. Remove the following line.

```
db2 -v connect to $dbName
```

   b. Replace the line in the previous step with the following line. In the following example, replace *master_username* and *master_password* with the master username and master password for your RDS for Db2 DB instance.

```
db2 -v connect to $dbName user master_username using master_password
```

   c. Remove the following lines.

```
db2 -v create bufferpool db2monbp

db2 -v create user temporary tablespace db2montmptbsp bufferpool db2monbp

db2 -v drop tablespace db2montmptbsp

db2 -v drop bufferpool db2monbp
```

5. Run the db2mon.sh script to output a report at specified intervals. In the following example, replace *absolute_path* with the complete path to the script file, *rds_database_alias* with the name of your database, and *seconds* with the number of seconds (0 to 3600) between report generation.

```
absolute_path/db2mon.sh rds_database_alias seconds | tee -a db2mon.out
```

Examples

The following example shows that the script file is located in the `perf` directory under the home directory.

```
/home/db2inst1/sqllib/samples/perf/db2mon.sh rds_database_alias seconds | tee -a
 db2mon.out
```

6. Drop the buffer pool and the tablespace that were created for the db2mon.sh file. In the following example, replace *master_username* and *master_password* with the master username and master password for your RDS for Db2 DB instance. Replace *database_name* with the name of your database.

```
db2 connect to rdsadmin user master_username using master_password

db2 "call rdsadmin.drop_tablespace('database_name','db2montmptbsp')"

db2 "call rdsadmin.drop_bufferpool('database_name','db2monbp')"
```

Managing storage

Db2 uses automatic storage to manage the physical storage for database objects such as tables, indexes, and temporary files. Instead of manually allocating storage space and keeping track of which storage paths are being used, automatic storage allows the Db2 system to create and manage storage paths as needed. This can simplify administration of Db2 databases and reduce the likelihood of errors due to human mistakes. For more information, see Automatic storage in the IBM Db2 documentation.

With RDS for Db2, you can dynamically increase the storage size with automatic expansion of the logical volumes and the file system. For more information, see Working with storage for Amazon RDS DB instances.

Managing tablespaces

You can create, alter, rename, or drop tablespaces for an RDS for Db2 database. Creating, altering, renaming, or dropping tablespaces requires higher-level SYSADM authority, which isn't available to the master user. Instead, use Amazon RDS stored procedures.

Topics

- Creating a tablespace
- Altering a tablespace
- Renaming a tablespace

- Dropping a tablespace
- Checking the status of a tablespace
- Returning detailed information about tablespaces
- Listing the state and storage group for a tablespace
- Listing the tablespaces of a table
- Listing tablespace containers

Creating a tablespace

To create a tablespace for your RDS for Db2 database, call the `rdsadmin.create_tablespace` stored procedure. For more information, see CREATE TABLESPACE statement in the IBM Db2 documentation.

> **Important**
>
> To create a tablespace, you must have a buffer pool of the same page size to associate with the tablespace. For more information, see Managing buffer pools.

To create a tablespace

1. Connect to the `rdsadmin` database using the master username and master password for your RDS for Db2 DB instance. In the following example, replace *`master_username`* and *`master_password`* with your own information.

   ```
   db2 "connect to rdsadmin user master_username using master_password"
   ```

2. Create a tablespace by calling `rdsadmin.create_tablespace`. For more information, see rdsadmin.create_tablespace.

   ```
   db2 "call rdsadmin.create_tablespace(
       'database_name',
       'tablespace_name',
       'buffer_pool_name',
       tablespace_initial_size,
       tablespace_increase_size,
       'tablespace_type')"
   ```

Altering a tablespace

To alter a tablespace for your RDS for Db2 database, call the `rdsadmin.alter_tablespace` stored procedure. You can use this stored procedure to change the buffer pool of a tablespace, lower the high water mark, or bring a tablespace online. For more information, see ALTER TABLESPACE statement in the IBM Db2 documentation.

To alter a tablespace

1. Connect to the `rdsadmin` database using the master username and master password for your RDS for Db2 DB instance. In the following example, replace *`master_username`* and *`master_password`* with your own information.

```
db2 "connect to rdsadmin user master_username using master_password"
```

2. Alter a tablespace by calling `rdsadmin.alter_tablespace`. For more information, see rdsadmin.alter_tablespace.

```
db2 "call rdsadmin.alter_tablespace(
    'database_name',
    'tablespace_name',
    'buffer_pool_name',
    buffer_pool_size,
    tablespace_increase_size,
    'max_size', 'reduce_max',
    'reduce_stop',
    'reduce_value',
    'lower_high_water',
    'lower_high_water_stop',
    'switch_online')"
```

Renaming a tablespace

To change the name of a tablespace for your RDS for Db2 database, call the `rdsadmin.rename_tablespace` stored procedure. For more information, see RENAME TABLESPACE statement in the IBM Db2 documentation.

To rename a tablespace

1. Connect to the `rdsadmin` database using the master username and master password for your RDS for Db2 DB instance. In the following example, replace *`master_username`* and *`master_password`* with your own information.

```
db2 "connect to rdsadmin user master_username using master_password"
```

2. Rename a tablespace by calling `rdsadmin.rename_tablespace`. For more information, including restrictions on what you can name a tablespace, see rdsadmin.rename_tablespace.

```
db2 "call rdsadmin.rename_tablespace(
    'database_name',
    'source_tablespace_name',
    'target_tablespace_name')"
```

Dropping a tablespace

To drop a tablespace for your RDS for Db2 database, call the `rdsadmin.drop_tablespace` stored procedure. Before you drop a tablespace, first drop any objects in the tablespace such as tables, indexes, or large objects (LOBs). For more information, see Dropping table spaces in the IBM Db2 documentation.

To drop a tablespace

1. Connect to the `rdsadmin` database using the master username and master password for your RDS for Db2 DB instance. In the following example, replace *`master_username`* and *`master_password`* with your own information.

```
db2 "connect to rdsadmin user master_username using master_password"
```

2. Drop a tablespace by calling `rdsadmin.drop_tablespace`. For more information, see rdsadmin.drop_tablespace.

```
db2 "call rdsadmin.drop_tablespace(
    'database_name',
    'tablespace_name')"
```

Checking the status of a tablespace

You can check the status of a tablespace by using the `cast` function.

To check the status of a tablespace

1. Connect to your Db2 database using the master username and master password for your RDS for Db2 DB instance. In the following example, replace *`rds_database_alias`*, *`master_username`*, and *`master_password`* with your own information.

   ```
   db2 connect to rds_database_alias user master_username using master_password
   ```

2. Return a summary output.

   For a summary output:

   ```
   db2 "select cast(tbsp_id as smallint) as tbsp_id,
   cast(tbsp_name as varchar(35)) as tbsp_name,
   cast(tbsp_type as varchar(3)) as tbsp_type,
   cast(tbsp_state as varchar(10)) as state,
   cast(tbsp_content_type as varchar(8)) as contents from
    table(mon_get_tablespace(null,-1)) order by tbsp_id"
   ```

Returning detailed information about tablespaces

You can return information about a tablespace for one member or all members by using the `cast` function.

To return detailed information about tablespaces

1. Connect to your Db2 database using the master username and master password for your RDS for Db2 DB instance. In the following example, replace *`rds_database_alias`*, *`master_username`*, and *`master_password`* with your own information.

   ```
   db2 connect to rds_database_alias user master_username using master_password
   ```

2. Return details about all tablespaces in the database for one member or for all members.

   For one member:

   ```
   db2 "select cast(member as smallint) as member,
   ```

```
cast(tbsp_id as smallint) as tbsp_id,
cast(tbsp_name as varchar(35)) as tbsp_name,
cast(tbsp_type as varchar(3)) as tbsp_type,
cast(tbsp_state as varchar(10)) as state,
cast(tbsp_content_type as varchar(8)) as contents,
cast(tbsp_total_pages as integer) as total_pages,
cast(tbsp_used_pages as integer) as used_pages,
cast(tbsp_free_pages as integer) as free_pages,
cast(tbsp_page_top as integer) as page_hwm,
cast(tbsp_page_size as integer) as page_sz,
cast(tbsp_extent_size as smallint) as extent_sz,
cast(tbsp_prefetch_size as smallint) as prefetch_sz,
cast(tbsp_initial_size as integer) as initial_size,
cast(tbsp_increase_size_percent as smallint) as increase_pct,
cast(storage_group_name as varchar(12)) as stogroup from
 table(mon_get_tablespace(null,-1)) order by member, tbsp_id "
```

For all members:

```
db2 "select cast(member as smallint) as member
cast(tbsp_id as smallint) as tbsp_id,
cast(tbsp_name as varchar(35)) as tbsp_name,
cast(tbsp_type as varchar(3)) as tbsp_type,
cast(tbsp_state as varchar(10)) as state,
cast(tbsp_content_type as varchar(8)) as contents,
cast(tbsp_total_pages as integer) as total_pages,
cast(tbsp_used_pages as integer) as used_pages,
cast(tbsp_free_pages as integer) as free_pages,
cast(tbsp_page_top as integer) as page_hwm,
cast(tbsp_page_size as integer) as page_sz,
cast(tbsp_extent_size as smallint) as extent_sz,
cast(tbsp_prefetch_size as smallint) as prefetch_sz,
cast(tbsp_initial_size as integer) as initial_size,
cast(tbsp_increase_size_percent as smallint) as increase_pct,
cast(storage_group_name as varchar(12)) as stogroup from
 table(mon_get_tablespace(null,-2)) order by member, tbsp_id "
```

Listing the state and storage group for a tablespace

You can list the state and storage group for a tablespace by running a SQL statement.

To list the state and storage group for a tablespace, run the following SQL statement:

```
db2 "SELECT varchar(tbsp_name, 30) as tbsp_name,
                  varchar(TBSP_STATE, 30) state,
                  tbsp_type,
                  varchar(storage_group_name,30) storage_group
FROM TABLE(MON_GET_TABLESPACE('',-2)) AS t"
```

Listing the tablespaces of a table

You can list the tablespaces for a table by running a SQL statement.

To list the tablespaces of a table, run the following SQL statement. In the following example, replace *SCHEMA_NAME* and *TABLE_NAME* with the names of your schema and table:

```
db2 "SELECT
   VARCHAR(SD.TBSPACE,30) AS DATA_SPACE,
   VARCHAR(SL.TBSPACE,30) AS LONG_SPACE,
   VARCHAR(SI.TBSPACE,30) AS INDEX_SPACE
 FROM
   SYSCAT.DATAPARTITIONS P
   JOIN SYSCAT.TABLESPACES SD ON SD.TBSPACEID = P.TBSPACEID
   LEFT JOIN SYSCAT.TABLESPACES SL ON SL.TBSPACEID = P.LONG_TBSPACEID
   LEFT JOIN SYSCAT.TABLESPACES SI ON SI.TBSPACEID = P.INDEX_TBSPACEID
 WHERE
    TABSCHEMA = 'SCHEMA_NAME'
 AND TABNAME   = 'TABLE_NAME'"
```

Listing tablespace containers

You can list all tablespace containers or specific tablespace containers by using the `cast` command.

To list the tablespace containers for a tablespace

1. Connect to your Db2 database using the master username and master password for your RDS for Db2 DB instance. In the following example, replace *rds_database_alias*, *master_username*, and *master_password* with your own information:

   ```
   db2 connect to rds_database_alias user master_username using master_password
   ```

2. Return a list of all tablespace containers in the database or specific tablespace containers.

   For all tablespace containers:

```
db2 "select cast(member as smallint) as member,
cast(tbsp_name as varchar(35)) as tbsp_name,
cast(container_id as smallint) as id,
cast(container_name as varchar(60)) as container_path, container_type as type from
 table(mon_get_container(null,-2)) order by member,tbsp_id,container_id"
```

For specific tablespace containers:

```
db2 "select cast(member as smallint) as member,
cast(tbsp_name as varchar(35)) as tbsp_name,
cast(container_id as smallint) as id,
cast(container_name as varchar(60)) as container_path, container_type as type from
 table(mon_get_container('TBSP_1',-2)) order by member, tbsp_id,container_id"
```

Integrating an Amazon RDS for Db2 DB instance with Amazon S3

You can transfer files between your Amazon RDS for Db2 DB instance and an Amazon Simple Storage Service (Amazon S3) bucket with Amazon RDS stored procedures. For more information, see Amazon RDS for Db2 stored procedure reference.

> **Note**
>
> Your DB instance and your Amazon S3 bucket must be in the same AWS Region.

For RDS for Db2 to integrate with Amazon S3, your DB instance must have access to an Amazon S3 bucket where your RDS for Db2 resides. If you don't currently have an S3 bucket, create a bucket.

Topics

Step 1: Create an IAM policy

In this step, you create an AWS Identity and Access Management (IAM) policy with the permissions required to transfer files from your Amazon S3 bucket to your RDS DB instance. This step assumes that you have already created an S3 bucket. For more information, see Creating a bucket in the *Amazon S3 User Guide*.

Before you create the policy, note the following pieces of information:

- The Amazon Resource Name (ARN) for your bucket
- The ARN for your AWS Key Management Service (AWS KMS) key, if your bucket uses SSE-KMS or SSE-S3 encryption.

Create an IAM policy that includes the following permissions:

```
"kms:GenerateDataKey",
"kms:Decrypt",
```

```
"s3:PutObject",
"s3:GetObject",
"s3:AbortMultipartUpload",
"s3:ListBucket",
"s3:DeleteObject",
"s3:GetObjectVersion",
"s3:ListMultipartUploadParts"
```

You can create an IAM policy by using the AWS Management Console or the AWS Command Line Interface (AWS CLI).

Console

To create an IAM policy to allow Amazon RDS to access your Amazon S3 bucket

1. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation pane, choose **Policies**.
3. Choose **Create policy**, and then choose **JSON**.
4. Add actions by service. To transfer files from an Amazon S3 bucket to Amazon RDS, you must select bucket permissions and object permissions.
5. Expand **Resources**. You must specify your bucket and object resources.
6. Choose **Next**.
7. For **Policy name**, enter a name for this policy.
8. (Optional) For **Description**, enter a description for this policy.
9. Choose **Create policy**.

AWS CLI

To create an IAM policy to allow Amazon RDS to access your Amazon S3 bucket

1. Run the create-policy command. In the following example, replace *iam_policy_name* and *s3_bucket_name* with a name for your IAM policy and the name of the Amazon S3 bucket where your RDS for Db2 database resides.

   For Linux, macOS, or Unix:

   ```
   aws iam create-policy \
   ```

```
    --policy-name iam_policy_name \
    --policy-document '{
      "Version": "2012-10-17",
      "Statement": [
        {
          "Effect": "Allow",
          "Action": [
            "kms:GenerateDataKey",
            "kms:Decrypt",
            "s3:PutObject",
            "s3:GetObject",
            "s3:AbortMultipartUpload",
            "s3:ListBucket",
            "s3:DeleteObject",
            "s3:GetObjectVersion",
            "s3:ListMultipartUploadParts"
          ],
          "Resource": [
            "arn:aws:s3:::s3_bucket_name/*",
            "arn:aws:s3:::s3_bucket_name"
          ]
        }
      ]
    }'
```

For Windows:

```
aws iam create-policy ^
    --policy-name iam_policy_name ^
    --policy-document '{
      "Version": "2012-10-17",
      "Statement": [
        {
          "Effect": "Allow",
            "Action": [
              "s3:PutObject",
              "s3:GetObject",
              "s3:AbortMultipartUpload",
              "s3:ListBucket",
              "s3:DeleteObject",
              "s3:GetObjectVersion",
              "s3:ListMultipartUploadParts"
            ],
```

```
            "Resource": [
              "arn:aws:s3:::s3_bucket_name/*",
              "arn:aws:s3:::s3_bucket_name"
            ]
        }
      ]
    }'
```

2. After the policy is created, note the ARN of the policy. You need the ARN for Step 2: Create an IAM role and attach your IAM policy.

For information about creating an IAM policy, see Creating IAM policies in the IAM User Guide.

Step 2: Create an IAM role and attach your IAM policy

This step assumes that you have created the IAM policy in Step 1: Create an IAM policy. In this step, you create a IAM role for your RDS for Db2 DB instance and then attach your IAM policy to the role.

You can create an IAM role for your DB instance by using the AWS Management Console or the AWS CLI.

Console

To create an IAM role and attach your IAM policy to it

1. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation pane, choose **Roles**.
3. Choose **Create role**.
4. For **Trusted entity type**, select **AWS service**.
5. For **Service or use case**, select **RDS**, and then select **RDS – Add Role to Database**.
6. Choose **Next**.
7. For **Permissions policies**, search for and select the name of the IAM policy that you created.
8. Choose **Next**.
9. For **Role name**, enter a role name.
10. (Optional) For **Description**, enter a description for the new role.
11. Choose **Create role**.

AWS CLI

To create an IAM role and attach your IAM policy to it

1. Run the create-role command. In the following example, replace *iam_role_name* with a name for your IAM role.

   For Linux, macOS, or Unix:

```
aws iam create-role \
    --role-name iam_role_name \
    --assume-role-policy-document '{
      "Version": "2012-10-17",
      "Statement": [
        {
          "Effect": "Allow",
          "Principal": {
            "Service": "rds.amazonaws.com"
          },
          "Action": "sts:AssumeRole"
        }
      ]
    }'
```

   For Windows:

```
aws iam create-role ^
    --role-name iam_role_name ^
    --assume-role-policy-document '{
      "Version": "2012-10-17",
      "Statement": [
        {
          "Effect": "Allow",
          "Principal": {
            "Service": "rds.amazonaws.com"
          },
          "Action": "sts:AssumeRole"
        }
      ]
    }'
```

2. After the role is created, note the ARN of the role. You need the ARN for Step 3: Add your IAM role to your RDS for Db2 DB instance.
3. Run the attach-role-policy command. In the following example, replace *iam_policy_arn* with the ARN of the IAM policy that you created in Step 1: Create an IAM policy. Replace *iam_role_name* with the name of the IAM role that you just created.

   For Linux, macOS, or Unix:

   ```
   aws iam attach-role-policy \
      --policy-arn iam_policy_arn \
      --role-name iam_role_name
   ```

   For Windows:

   ```
   aws iam attach-role-policy ^
      --policy-arn iam_policy_arn ^
      --role-name iam_role_name
   ```

For more information, see Creating a role to delegate permissions to an IAM user in the *IAM User Guide*.

Step 3: Add your IAM role to your RDS for Db2 DB instance

In this step, you add your IAM role to your RDS for Db2 DB instance. Note the following requirements:

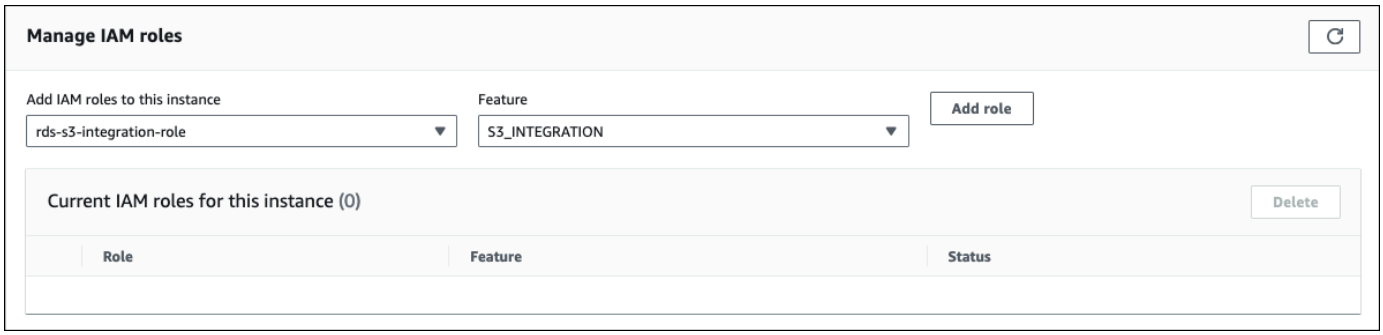
- You must have access to an IAM role with the required Amazon S3 permissions policy attached to it.
- You can only associate one IAM role with your RDS for Db2 DB instance at a time.
- Your RDS for Db2 DB instance must be in the **Available** state.

You can add an IAM role to your DB instance by using the AWS Management Console or the AWS CLI.

Console

To add an IAM role to your RDS for Db2 DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.
3. Choose your RDS for Db2 DB instance name.
4. On the **Connectivity & security** tab, scroll down to the **Manage IAM roles** section at the bottom of the page.
5. For **Add IAM roles to this instance**, choose the role that you created in Step 2: Create an IAM role and attach your IAM policy.
6. For **Feature**, choose **S3_INTEGRATION**.
7. Choose **Add role**.



AWS CLI

To add an IAM role to your RDS for Db2 DB instance, run the add-role-to-db-instance command. In the following example, replace *db_instance_name* and *iam_role_arn* with the name of your DB instance and the ARN of the IAM role that you created in Step 2: Create an IAM role and attach your IAM policy.

For Linux, macOS, or Unix:

```
aws rds add-role-to-db-instance \
    --db-instance-identifier db_instance_name \
    --feature-name S3_INTEGRATION \
    --role-arn iam_role_arn \
```

For Windows:

```
aws rds add-role-to-db-instance ^
    --db-instance-identifier db_instance_name ^
    --feature-name S3_INTEGRATION ^
    --role-arn iam_role_arn ^
```

To confirm that the role was successfully added to your RDS for Db2 DB instance, run the describe-db-instances command. In the following example, replace *db_instance_name* with the name of your DB instance.

For Linux, macOS, or Unix:

```
aws rds describe-db-instances \
    --filters "Name=db-instance-id,Values=db_instance_name" \
    --query 'DBInstances[].AssociatedRoles'
```

For Windows:

```
aws rds describe-db-instances ^
    --filters "Name=db-instance-id,Values=db_instance_name" ^
    --query 'DBInstances[].AssociatedRoles'
```

This command produces output similar to the following example:

```
[
    [
        {
            "RoleArn": "arn:aws:iam::0123456789012:role/rds-db2-s3-role",
            "FeatureName": "S3_INTEGRATION",
            "Status": "ACTIVE"
        }
    ]
]
```

Migrating data to Db2 on Amazon RDS

You can migrate self-managed Db2 databases to Amazon RDS for Db2 by using either AWS or native Db2 tools.

Topics

Migration approaches that use AWS

In Amazon RDS, there are several ways you can migrate data from a Db2 database to Amazon RDS for Db2. You can perform a one-time migration of your Db2 database from Linux, AIX, or Windows environments to Amazon RDS for Db2. To minimize downtime, you can perform a near-zero downtime migration. You can migrate your data by saving it to Amazon S3 and loading it one table at a time into your Db2 database. You can also perform a synchronous migration through replication or use AWS Database Migration Service.

For one-time migrations for Linux-based Db2 databases, Amazon RDS only supports offline and online backups. Amazon RDS doesn't support incremental and Delta backups. For near-zero migrations for Linux-based Db2 databases, Amazon RDS requires online backups. We recommend that you use online backups for near-zero downtime migrations and offline backups for migrations that can handle downtime.

Topics

One-time migration from Linux to Linux environments

With this migration approach, you back up your self-managed Db2 database to an Amazon S3 bucket. Then, you use Amazon RDS stored procedures to restore your Db2 database to an Amazon

RDS for Db2 DB instance. For more information about using Amazon S3, see Integrating an Amazon RDS for Db2 DB instance with Amazon S3.

Backup and restore for RDS for Db2 follows the IBM Db2 supported upgrade paths and restrictions. For more information, see Supported upgrade paths for Db2 servers and Upgrade restrictions for Db2 servers in the IBM Db2 documentation.

Topics

- Limitations and recommendations for using native restore
- Backing up your database to Amazon S3
- Creating a default automatic storage group
- Restoring your Db2 database

Limitations and recommendations for using native restore

The following limitations and recommendations apply to using native restore:

- Amazon RDS only supports migrating on-premises versions of Db2 that match supported RDS for Db2 versions. For more information about the supported versions, see Supported Db2 minor versions on Amazon RDS.
- Amazon RDS only supports offline and online backups for native restore. Amazon RDS doesn't support incremental or Delta backups.
- You can't restore from an Amazon S3 bucket in an AWS Region that is different from the Region where your RDS for Db2 DB instance is located.
- You can't restore a database if your RDS for Db2 DB instance already contains a database.
- Amazon S3 limits the size of files that are uploaded to an Amazon S3 bucket to 5 TB. If your database backup file exceeds 5 TB, then split the backup file into smaller files.
- Amazon RDS doesn't support non-fenced external routines, incremental restores, or Delta restores.
- You can't restore from an encrypted source database, but you can restore to an encrypted Amazon RDS DB instance.

When you restore your database, the backup is copied and then extracted on your RDS for Db2 DB instance. We recommend that you provision storage space for your RDS for Db2 DB instance that is equal to or greater than the sum of the backup size plus the original database's size on disk.

The maximum size of the restored database is the maximum database size that is supported minus the size of the backup. For example, if the maximum database size that is supported is 64 TiB and the size of the backup is 30 TiB, then the maximum size of the restored database is 34 TiB.

```
64 TiB - 30 TiB = 34 TiB
```

Backing up your database to Amazon S3

To back up your database on Amazon S3, you need the following AWS components:

- *An Amazon S3 bucket to store your backup files*: Upload any backup files that you want to migrate to Amazon RDS. We recommend that you use offline backups for migrations that can handle downtime. If you already have an S3 bucket, you can use that bucket. If you don't have an S3 bucket, see Creating a bucket in the *Amazon S3 User Guide*.

  > **Note**
  >
  > If your database is large and would take a long time to transfer to an S3 bucket, you can order an AWS Snow Family device and ask AWS to perform the backup. After you copy your files to the device and return it to the Snow Family team, the team transfers your backed-up images to your S3 bucket. For more information, see the AWS Snow Family documentation.

- *An IAM role to access the S3 bucket*: If you already have an IAM role, you can use that role. If you don't have a role, see Step 2: Create an IAM role and attach your IAM policy.
- *An IAM policy with trust relationships and permissions attached to your IAM role*: For more information, see Step 1: Create an IAM policy.
- *The IAM role added to your RDS for Db2 DB instance*: For more information, see Step 3: Add your IAM role to your RDS for Db2 DB instance.

Creating a default automatic storage group

Your source database must have a default automatic storage group. If your database doesn't have a default automatic storage group, you must create one.

To create a default automatic storage group

1. Connect to your source database. In the following example, replace *source_database* with the name of your database.

```
db2 connect to source_database
```

2. Create an automatic storage group and set it as the default. In the following example, replace *storage_path* with the absolute path to where the storage group is located.

```
db2 "create stogroup IBMSTOGROUP ON storage_path set as default"
```

3. Terminate backend processes.

```
db2 terminate
```

4. Deactivate the database and stop all database services. In the following example, replace *source_database* with the name of the database that you created the storage group for.

```
db2 deactivate db source_database
```

5. Back up the database. In the following example, replace *source_database* with the name of the database that you created the storage group for. Replace *file_system_path* with the absolute path to where you want to back up the database.

```
db2 backup database source_database to file_system_path
```

Restoring your Db2 database

After you back up your database on Amazon S3 and create an automatic storage group, you are ready to restore your Db2 database to your RDS for Db2 DB instance.

To restore your Db2 database to your RDS for Db2 DB instance

1. Connect to your RDS for Db2 DB instance. For more information, see Connecting to your Amazon RDS for Db2 DB instance.
2. (Optional) To make sure your database is configured with the optimal settings for the restore operation, you can call the section called “rdsadmin.show_configuration” to check the values for `RESTORE_DATABASE_PARALLELISM` and `RESTORE_DATABASE_NUM_BUFFERS`. Call the

section called “rdsadmin.set_configuration” to change these values, as needed. Explicitly setting these values can improve the performance when restoring databases with large volumes of data.

3. Restore your database by calling `rdsadmin.restore_database`. For more information, see rdsadmin.restore_database.

Near-zero downtime migration for Linux-based Db2 databases

With this migration approach, you migrate a Linux-based Db2 database from one self-managed Db2 database (source) to Amazon RDS for Db2. This approach results in minimal to no outage or downtime for the application or users. This approach backs up your database and restores it with log replay, which helps prevent disruptions to ongoing operations and provides high availability of your database.

To achieve near-zero downtime migration, RDS for Db2 implements restore with log replay. This approach takes a backup of your self-managed Linux-based Db2 database and restores it on the RDS for Db2 server. With Amazon RDS stored procedures, you then apply subsequent transaction logs to bring the database up to date.

Topics

- Limitations and recommendations for near-zero downtime migration
- Backing up your database to Amazon S3
- Creating a default automatic storage group
- Migrating your Db2 database

Limitations and recommendations for near-zero downtime migration

The following limitations and recommendations apply to using near-zero downtime migration:

- Amazon RDS requires an online backup for near-zero downtime migration. This is because Amazon RDS keeps your database in a rollforward pending state as you upload your archived transaction logs. For more information, see the section called “Migrating your Db2 database”.
- You can't restore from an Amazon S3 bucket in an AWS Region that is different from the Region where your RDS for Db2 DB instance is located.
- You can't restore a database if your RDS for Db2 DB instance already contains a database.

- Amazon S3 limits the size of files uploaded to an S3 bucket to 5 TB. If your database backup file exceeds 5 TB, then split the backup file into smaller files.
- Amazon RDS doesn't support non-fenced external routines, incremental restores, or Delta restores.
- You can't restore from an encrypted source database, but you can restore to an encrypted Amazon RDS DB instance.

When you restore your database, Amazon RDS copies your backup and then extracts it on your RDS for Db2 DB instance. We recommend that you provision storage space for your RDS for Db2 DB instance that is equal to or greater than the sum of the backup size plus the original database's size on disk.

The maximum size of the restored database is the maximum database size that is supported minus the size of the backup. For example, if the maximum database size that is supported is 64 TiB and the size of the backup is 30 TiB, then the maximum size of the restored database is 34 TiB.

```
64 TiB - 30 TiB = 34 TiB
```

Backing up your database to Amazon S3

To back up your database on Amazon S3, you need the following AWS components:

- *An Amazon S3 bucket to store your backup files*: Upload any backup files that you want to migrate to Amazon RDS. Amazon RDS requires an online backup for near-zero downtime migration. If you already have an S3 bucket, you can use that bucket. If you don't have an S3 bucket, see Creating a bucket in the *Amazon S3 User Guide*.

  > **Note**
  >
  > If your database is large and would take a long time to transfer to an S3 bucket, you can order an AWS Snow Family device and ask AWS to perform the backup. After you copy your files to the device and return it to the Snow Family team, the team transfers your backed-up images to your S3 bucket. For more information, see the AWS Snow Family documentation.

- *An IAM role to access the S3 bucket*: If you already have an AWS Identity and Access Management (IAM) role, you can use that role. If you don't have a role, see Step 2: Create an IAM role and attach your IAM policy.

- *An IAM policy with trust relationships and permissions attached to your IAM role*: For more information, see Step 1: Create an IAM policy.
- *The IAM role added to your RDS for Db2 DB instance*: For more information, see Step 3: Add your IAM role to your RDS for Db2 DB instance.

Creating a default automatic storage group

Your source database must have a default automatic storage group. If your database doesn't have a default automatic storage group, you must create one.

To create a default automatic storage group

1. Connect to your source database. In the following example, replace *source_database* with the name of your database.

```
db2 connect to source_database
```

2. Create an automatic storage group and set it as the default. In the following example, replace *storage_path* with the absolute path to where the storage group is located.

```
db2 "create stogroup IBMSTOGROUP ON storage_path set as default"
```

3. Terminate backend processes.

```
db2 terminate
```

Migrating your Db2 database

After you back up your database on Amazon S3 and create an automatic storage group, you are ready to migrate your Db2 database to your RDS for Db2 DB instance.

To perform a near-zero downtime migration

1. Perform an online backup of your source database. For more information, see BACKUP DATABASE command in the IBM Db2 documentation.
2. Copy the backup of your database to an Amazon S3 bucket. For information about using Amazon S3, see the Amazon Simple Storage Service User Guide.

3. Connect to the `rdsadmin` server with the *`master_username`* and *`master_password`* for your RDS for Db2 DB instance.

```
db2 connect to rdsadmin user master_username using master_password
```

4. (Optional) To make sure your database is configured with the optimal settings for the restore operation, you can call the section called "rdsadmin.show_configuration" to check the values for `RESTORE_DATABASE_PARALLELISM` and `RESTORE_DATABASE_NUM_BUFFERS`. Call the section called "rdsadmin.set_configuration" to change these values, as needed. Explicitly setting these values can improve the performance when restoring databases with large volumes of data.
5. Restore the backup on the RDS for Db2 server by calling `rdsadmin.restore_database`. Set `backup_type` to `ONLINE`. For more information, see rdsadmin.restore_database.
6. Copy your archive logs from your source server to your S3 bucket. For more information, see Archive logging in the IBM Db2 documentation.
7. Apply archive logs as many times as needed by calling `rdsadmin.rollforward_database`. Set `complete_rollforward` to `FALSE` to keep the database in a `ROLL-FORWARD PENDING` state. For more information, see rdsadmin.rollforward_database.
8. After you apply all of the archive logs, bring the database online by calling `rdsadmin.complete_rollforward`. For more information, see rdsadmin.complete_rollforward.
9. Switch application connections to the RDS for Db2 server by either updating your application endpoints for the database or by updating the DNS endpoints to redirect traffic to the RDS for Db2 server. You can also use the Db2 automatic client reroute feature on your self-managed Db2 database with the RDS for Db2 database endpoint. For more information, see Automatic client reroute description and setup in the IBM Db2 documentation.
10. (Optional) Shut down your source database.

Migration by loading data from Amazon S3

With this migration approach, you first save data from a single table into a data file that you place in an Amazon S3 bucket. Then, you use the LOAD command to load the data from that data file into a table in your Amazon RDS for Db2 database. For more information about using Amazon S3, see Integrating an Amazon RDS for Db2 DB instance with Amazon S3.

Topics

- Saving your data to Amazon S3
- Loading your data into RDS for Db2 tables

Saving your data to Amazon S3

To save data from a single table to Amazon S3, use a database utility to extract the data from your database management system (DBMS) into a CSV file. Then, upload the data file to Amazon S3.

For storing data files on Amazon S3, you need the following AWS components:

- *An Amazon S3 bucket to store your backup files*: If you already have an S3 bucket, you can use that bucket. If you don't have an S3 bucket, see Creating a bucket in the *Amazon S3 User Guide*.
- *An IAM role to access the S3 bucket*: If you already have an IAM role, you can use that role. If you don't have a role, see Step 2: Create an IAM role and attach your IAM policy.
- *An IAM policy with trust relationships and permissions attached to your IAM role*: For more information, see Step 1: Create an IAM policy.
- *The IAM role added to your RDS for Db2 DB instance*: For more information, see Step 3: Add your IAM role to your RDS for Db2 DB instance.

Loading your data into RDS for Db2 tables

After you save your data files to Amazon S3, you can load the data from these files into individual tables on your RDS for Db2 DB instance.

To load your Db2 table data into your RDS for Db2 DB database table

1. Connect to the `rdsadmin` database using the master username and master password for your RDS for Db2 DB instance. In the following example, replace *`master_username`* and *`master_password`* with your own information.

   ```
   db2 connect to rdsadmin user master_username using master_password
   ```

2. Catalog a storage access alias that points to the Amazon S3 bucket where your saved files are stored. Take note of the name of this alias for use in the next step. You only need to perform this step once if you plan to load multiple tables from data files stored in the same Amazon S3 bucket.

The following example catalogs an alias named *my_s3_alias* that grants a user named *jorge_souza* access to a bucket named *amzn-s3-demo-bucket*.

```
db2 "call rdsadmin.catalog_storage_access(?, 'my_s3_alias', 'amzn-s3-demo-bucket',
 'USER', 'jorge_souza')"
```

For more information about this stored procedure, See the section called "rdsadmin.catalog_storage_access".

3. Run the LOAD command using the storage access alias that points to your Amazon S3 bucket.

> **Note**
>
> If the LOAD command returns an error, then you might need to create a VPC gateway endpoint for Amazon S3 and add outbound rules to the security group. For more information, see the section called "File I/O error".

The following example loads data from a data file named *my_s3_datafile.csv* into a table named *my_db2_table*. The example assumes that the data file is in the Amazon S3 bucket that the alias named *my_s3_alias* points to.

```
db2 "load from db2remote://my_s3_alias//my_s3_datafile.csv of DEL insert
 into my_db2_table";
```

The following example loads LOBs from a data file named *my_table1_export.ixf* into a table named *my_db2_table*. The example assumes that the data file is in the Amazon S3 bucket that the alias named *my_s3_alias* points to.

```
db2 "call sysproc.admin_cmd('load from
 "db2remote://my_s3_alias//my_table1_export.ixf" of ixf
        lobs from "db2remote://my_s3_alias//" xml from "db2remote://my_s3_alias//"
        modified by lobsinfile implicitlyhiddeninclude identityoverride
 generatedoverride periodoverride transactionidoverride
        messages on server
        replace into "my_schema"."my_db2_table"
                              nonrecoverable
        indexing mode incremental allow no access')"
```

Repeat this step for each data file in the Amazon S3 bucket that you want to load into a table in your RDS for Db2 DB instance.

For more information about the `LOAD` command, see LOAD command.

One-time migration from AIX or Windows to Linux environments

With this migration approach, you use native Db2 tools to back up your self-managed Db2 database to an Amazon S3 bucket. Native Db2 tools include the `export` utility, the `db2move` system command, or the `db2look` system command. Your Db2 database can either be self-managed or in Amazon Elastic Compute Cloud (Amazon EC2). You can move data from your AIX or Windows system to your Amazon S3 bucket. Then, use a Db2 client to load data directly from the S3 bucket to your Amazon RDS for Db2 database. Downtime depends on the size of your database. For more information about using Amazon S3, see Integrating an Amazon RDS for Db2 DB instance with Amazon S3.

To migrate your Db2 database to RDS for Db2

1. Prepare to back up your database. Configure sufficient storage amount to hold the backup on your self-managed Db2 system.
2. Back up your database.
   a. Run the db2look system command to extract the data definition language (DDL) file for all objects.
   b. Run either the Db2 export utility, the db2move system command, or a CREATE EXTERNAL TABLE statement to unload the Db2 table data to storage on your Db2 system.
3. Move your backup to an Amazon S3 bucket. For more information, see Integrating an Amazon RDS for Db2 DB instance with Amazon S3.

> **Note**
>
> If your database is large and would take a long time to transfer to an S3 bucket, you can order an AWS Snow Family device and ask AWS to perform the backup. After you copy your files to the device and return it to the Snow Family team, the team transfers your backed-up images to your S3 bucket. For more information, see the AWS Snow Family documentation.

4. Use a Db2 client to load data directly from your S3 bucket to your RDS for Db2 database.

Synchronous migrations from Linux to Linux environments

With this migration approach, you set up replication between your self-managed Db2 database and your Amazon RDS for Db2 DB instance. Changes made to the self-managed database replicates to the RDS for Db2 DB instance in near real-time. This approach can provide continuous availability and minimize downtime during the migration process.

Using AWS Database Migration Service (AWS DMS)

You can use AWS DMS for one-time migrations and then synchronize from Db2 on Linux, Unix, and Windows to Amazon RDS for Db2. For more information, see What is AWS Database Migration Service?.

Native Db2 tools

You can use several native Db2 tools, utilities, and commands to move data directly from a Db2 database to an Amazon RDS for Db2 database. To use these native Db2 tools, you must be able to connect your client machine to an RDS for Db2 DB instance. For more information, see Connecting a client machine to an Amazon RDS for Db2 DB instance.

> **Note**
>
> Another way to move your data is to first save it to an Amazon S3 bucket, and then use the `LOAD` command to transfer that data into a table in your RDS for Db2 database. This method provides the best performance when migrating a large amount of data because of good network connectivity between RDS for Db2 and S3. For more information, see the section called "Migration by loading data from Amazon S3".

Tool name	Use case	Limitations
db2look	Copying metadata from a self-managed Db2 database to an RDS for Db2 database.	• You must modify the syntax for creating buffer pools, creating tablespaces, and creating roles to match the

Tool name	Use case	Limitations
		syntax used by the RDS for Db2 stored procedures.
IMPORT command	Migrating small tables and tables with large objects (LOBs) from a client machine to the RDS for Db2 DB instance.	• Slower than the LOAD utility due to INSERT and DELETE logging operations. • Poor performance with limited network bandwidth.
INGEST utility	Continually streaming data from files and pipes *without* large objects (LOBs) on the client machine to the RDS for Db2 DB instance. Supports INSERT and MERGE operation s.	• Can't stream data files that contain LOBs. Use the IMPORT command instead. • Connectivity required between self-managed Db2 database and RDS for Db2 database.
INSERT command	Copying data in small tables from a self-managed Db2 database to an RDS for Db2 database.	• Connectivity required between self-managed Db2 database and RDS for Db2 database. • Poor performance with limited network bandwidth.
LOAD CLIENT command	Migrating small tables *without* large objects (LOBs) from a client machine to the RDS for Db2 DB instance.	• Can't migrate data files that contain LOBs. Use the IMPORT command instead. • Poor performance with limited network bandwidth.

Connecting a client machine to an Amazon RDS for Db2 DB instance

To use any of the native Db2 tools to move data from a Db2 database to an Amazon RDS for Db2 database, you must first connect your client machine to an RDS for Db2 DB instance.

The client machine can be any of the following:

- An Amazon Elastic Compute Cloud (Amazon EC2) instance on Linux, Windows, or macOS. This instance should be in the same virtual private cloud (VPC) as your RDS for Db2 DB instance, AWS Cloud9, or AWS CloudShell.
- A self-managed Db2 instance in an Amazon EC2 instance. The instances should be in the same VPC.
- A self-managed Db2 instance in an Amazon EC2 instance. The instances can be in different VPCs if you enabled VPC peering. For more information, see Create a VPC peering connection in the *Amazon Virtual Private Cloud VPC Peering Guide*.
- A local machine running Linux, Windows, or macOS in a self-managed environment. You must either have public connectivity to RDS for Db2 or enable VPN connectivity between self-managed Db2 instances and AWS.

To connect your client machine to your RDS for Db2 DB instance, log in to your client machine with IBM Db2 Data Management Console. For more information, see Creating an Amazon RDS DB instance and IBM Db2 Data Management Console.

You can use AWS Database Migration Service (AWS DMS) to run queries against the database, run an SQL execution plan, and monitor the database. For more information, see What is AWS Database Migration Service? in the *AWS Database Migration Service User Guide*.

After you successfully connect your client machine to your RDS for Db2 DB instance, you are ready to use any native Db2 tool to copy data. For more information, see Native Db2 tools.

db2look tool

db2look is a native Db2 tool that extracts data definition language (DDL) files, objects, authorizations, configurations, WLM, and database layouts. You can use db2look to copy database metadata from a self-managed Db2 database to an Amazon RDS for Db2 database. For more information, see Mimicking databases using db2look in the IBM Db2 documentation.

To copy the database metadata

1. Run the db2look tool on your self-managed Db2 system to extract the DDL file. In the following example, replace *database_name* with the name of your Db2 database.

```
db2look -d database_name -e -l -a -f -wlm -cor -createdb -printdbcfg -o db2look.sql
```

2. If your client machine has access to the source (self-managed Db2) database and the RDS for Db2 DB instance, you can create the `db2look.sql` file on the client machine by directly attaching to the remote instance. Then catalog the remote self-managed Db2 instance.

   a. Catalog the node. In the following example, replace *dns_ip_address* and *port* with the DNS name or the IP address and the port number of the self-managed Db2 database.

   ```
   db2 catalog tcpip node srcnode REMOTE dns_ip_address server port
   ```

   b. Catalog the database. In the following example, replace *source_database_name* and *source_database_alias* with the name of the self-managed Db2 database and the alias that you want to use for this database.

   ```
   db2 catalog database source_database_name as source_database_alias at node
    srcnode \
       authentication server_encrypt
   ```

   c. Attach to the source database. In the following example, replace *source_database_alias*, *user_id*, and *user_password* with the alias that you created in the previous step and the user ID and password for the self-managed Db2 database.

   ```
   db2look -d source_database_alias -i user_id -w user_password -e -l -a -f -wlm \
       -cor -createdb -printdbcfg -o db2look.sql
   ```

3. If you can't access the remote self-managed Db2 database from the client machine, copy the `db2look.sql` file to the client machine. Then catalog the RDS for Db2 DB instance.

   a. Catalog the node. In the following example, replace *dns_ip_address* and *port* with the DNS name or the IP address and the port number of the RDS for Db2 DB instance.

   ```
   db2 catalog tcpip node remnode REMOTE dns_ip_address server port
   ```

   b. Catalog the database. In the following example, replace *rds_database_name* and *rds_database_alias* with the name of the RDS for Db2 database and the alias that you want to use for this database.

   ```
   db2 catalog database rds_database_name as rds_database_alias at node remnode \
       authentication server_encrypt
   ```

c. Catalog the admin database that manages RDS for Db2. You can't use this database to store any data.

```
db2 catalog database rdsadmin as rdsadmin at node remnode authentication
 server_encrypt
```

4. Create buffer pools and tablespaces. The administrator doesn't have privileges to create buffer pools or tablespaces. However, you can use Amazon RDS stored procedures to create them.

a. Find the names and definitions of the buffer pools and tablespaces in the `db2look.sql` file.

b. Connect to Amazon RDS using the master username and master password for your RDS for Db2 DB instance. In the following example, replace *`master_username`* and *`master_password`* with your own information.

```
db2 connect to rdsadmin user master_username using master_password
```

c. Create a buffer pool by calling `rdsadmin.create_bufferpool`. For more information, see rdsadmin.create_bufferpool.

```
db2 "call rdsadmin.create_bufferpool(
    'database_name',
    'buffer_pool_name',
    buffer_pool_size,
    'immediate',
    'automatic',
    page_size,
    number_block_pages,
    block_size)"
```

d. Create a tablespace by calling `rdsadmin.create_tablespace`. For more information, see rdsadmin.create_tablespace.

```
db2 "call rdsadmin.create_tablespace(
    'database_name',
    'tablespace_name',
    'buffer_pool_name',
    tablespace_initial_size,
    tablespace_increase_size,
    'tablespace_type')"
```

e. Repeat steps c or d for each additional buffer pool or tablespace that you want to add.

f. Terminate your connection.

```
db2 terminate
```

5. Create tables and objects.

a. Connect to your RDS for Db2 database using the master username and master password for your RDS for Db2 DB instance. In the following example, replace *rds_database_name*, *master_username*, and *master_password* with your own information.

```
db2 connect to rds_database_name user master_username using master_password
```

b. Run the `db2look.sql` file.

```
db2 -tvf db2look.sql
```

c. Terminate your connection.

```
db2 terminate
```

IMPORT command with a client machine

You can use the `IMPORT` command from a client machine to import your data into the Amazon RDS for Db2 server.

> **Important**
>
> The `IMPORT` command method is useful for migrating small tables and tables that include large objects (LOBs). The `IMPORT` command is slower than the `LOAD` utility because of the `INSERT` and `DELETE` logging operations. If your network bandwidth between the client machine and RDS for Db2 is limited, we recommend that you use a different migration approach. For more information, see Native Db2 tools.

To import data into the RDS for Db2 server

1. Log in to your client machine with IBM Db2 Data Management Console. For more information, see Connecting to your Amazon RDS for Db2 DB instance with IBM Db2 Data Management Console.
2. Catalog the RDS for Db2 database on the client machine.

   a. Catalog the node. In the following example, replace *dns_ip_address* and *port* with the DNS name or the IP address and the port number of the self-managed Db2 database.

   ```
   db2 catalog tcpip node srcnode REMOTE dns_ip_address server port
   ```

   b. Catalog the database. In the following example, replace *source_database_name* and *source_database_alias* with the name of the self-managed Db2 database and the alias that you want to use for this database.

   ```
   db2 catalog database source_database_name as source_database_alias at node
    srcnode \
       authentication server_encrypt
   ```

3. Attach to the source database. In the following example, replace *source_database_alias*, *user_id*, and *user_password* with the alias you created in the previous step and the user ID and password for the self-managed Db2 database.

   ```
   db2look -d source_database_alias -i user_id -w user_password -e -l -a -f -wlm \
       -cor -createdb -printdbcfg -o db2look.sql
   ```

4. Generate the data file by using the EXPORT command on your self-managed Db2 system. In the following example, replace *directory* with the directory on your client machine where your data file exists. Replace *file_name* and *table_name* with the name of the data file and the name of the table.

   ```
   db2 "export to /directory/file_name.txt of del lobs to /directory/lobs/ \
       modified by coldel\| select * from table_name"
   ```

5. Connect to your RDS for Db2 database using the master username and master password for your RDS for Db2 DB instance. In the following example, replace *rds_database_alias*, *master_username,* and *master_password* with your own information.

```
db2 connect to rds_database_alias user master_username using master_password
```

6. Use the IMPORT command to import data from a file on the client machine into the remote RDS for Db2 database. For more information, see IMPORT command in the IBM Db2 documentation. In the following example, replace *directory* and *file_name* with the directory on your client machine where your data file exists and the name of the data file. Replace *SCHEMA_NAME* and *TABLE_NAME* with the name of your schema and table.

```
db2 "IMPORT from /directory/file_name.tbl OF DEL LOBS FROM /directory/lobs/ \
    modified by coldel\| replace into SCHEMA_NAME.TABLE_NAME"
```

7. Terminate your connection.

```
db2 terminate
```

INGEST utility

You can use the INGEST utility to continually stream data from files and pipes on a client machine to a target Amazon RDS for Db2 DB instance. The INGEST utility supports INSERT and MERGE operations. For more information, see Ingest utility in the IBM Db2 documentation.

Because the INGEST utility supports nicknames, you can use the utility to transfer data from your self-managed Db2 database to an RDS for Db2 database. This approach works as long as network connectivity exists between the two databases.

> **Important**
>
> The INGEST utility doesn't support large objects (LOBs). Use the IMPORT command instead.

To use the RESTARTABLE feature of the INGEST utility, run the following command on the RDS for Db2 database.

```
db2 "call sysproc.sysinstallobjects('INGEST','C',NULL,NULL)"
```

INSERT command from a self-managed Db2 database to an Amazon RDS for Db2 database

You can use the INSERT command from a self-managed Db2 server to insert your data into an Amazon RDS for Db2 database. With this migration approach, you use a nickname for the remote RDS for Db2 DB instance. Your self-managed Db2 database (source) must be able to connect to the RDS for Db2 database (target).

> **Important**
>
> The INSERT command method is useful for migrating small tables. If your network bandwidth between your self-managed Db2 database and RDS for Db2 database is limited, we recommend that you use a different migration approach. For more information, see Native Db2 tools.

To copy data from a self-managed Db2 database to an RDS for Db2 database

1. Catalog the RDS for Db2 DB instance on the self-managed Db2 instance.

   a. Catalog the node. In the following example, replace *dns_ip_address* and *port* with the DNS name or the IP address and the port number of the self-managed Db2 database.

   ```
   db2 catalog tcpip node remnode REMOTE dns_ip_address SERVER port
   ```

   b. Catalog the database. In the following example, replace *rds_database_name* with the name of the database on your RDS for Db2 DB instance.

   ```
   db2 catalog database rds_database_name as remdb at node remnode \
       authentication server_encrypt
   ```

2. Enable federation on the self-managed Db2 instance. In the following example, replace *source_database_name* with the name of your database on the self-managed Db2 instance.

   ```
   db2 update dbm cfg using FEDERATED YES source_database_name
   ```

3. Create tables on the RDS for Db2 DB instance.

   a. Catalog the node. In the following example, replace *dns_ip_address* and *port* with the DNS name or the IP address and the port number of the self-managed Db2 database.

```
db2 catalog tcpip node srcnode REMOTE dns_ip_address server port
```

b. Catalog the database. In the following example, replace *source_database_name* and *source_database_alias* with the name of the self-managed Db2 database and the alias that you want to use for this database.

```
db2 catalog database source_database_name as source_database_alias at node
 srcnode \
    authentication server_encrypt
```

4. Attach to the source database. In the following example, replace *source_database_alias*, *user_id*, and *user_password* with the alias that you created in the previous step and the user ID and password for the self-managed Db2 database.

```
db2look -d source_database_alias -i user_id -w user_password -e -l -a -f -wlm \
    -cor -createdb -printdbcfg -o db2look.sql
```

5. Set up federation, and create a nickname for the RDS for Db2 database table on the self-managed Db2 instance.

a. Connect to your local database. In the following example, replace *source_database_name* with the name of the database on your self-managed Db2 instance.

```
db2 connect to source_database_name
```

b. Create a wrapper to access Db2 data sources.

```
db2 create wrapper drda
```

c. Define a data source on a federated database. In the following example, replace *admin* and *admin_password* with your credentials for your self-managed Db2 instance. Replace *rds_database_name* with the name of the database on your RDS for Db2 DB instance.

```
db2 "create server rdsdb2 type DB2/LUW version '11.5.9.0' \
    wrapper drda authorization "admin" password "admin_password" \
    options( dbname 'rds_database_name', node 'remnode')"
```

d. Map the users on the two databases. In the following example, replace *master_username* and *master_password* with your credentials for your RDS for Db2 DB instance.

```
db2 "create user mapping for user server rdsdb2 \
    options (REMOTE_AUTHID 'master_username', REMOTE_PASSWORD
 'master_password')"
```

e. Verify the connection to the RDS for Db2 server.

```
db2 set passthru rdsdb2
```

f. Create a nickname for the table in the remote RDS for Db2 database. In the following example, replace *NICKNAME* and *TABLE_NAME* with a nickname for the table and the name of the table.

```
db2 create nickname REMOTE.NICKNAME for RDSDB2.TABLE_NAME.NICKNAME
```

6. Insert data into the table in the remote RDS for Db2 database. Use the nickname in a `select` statement on the local table in the self-managed Db2 instance. In the following example, replace *NICKNAME* and *TABLE_NAME* with a nickname for the table and the name of the table.

```
db2 "INSERT into REMOTE.NICKNAME select * from RDS2DB2.TABLE_NAME.NICKNAME"
```

LOAD command with a client machine

You can use the `LOAD CLIENT` command to load data from a file on a client machine to the RDS for Db2 server. Because no SSH connectivity exists to the RDS for Db2 server, you can use the `LOAD CLIENT` command on either your self-managed Db2 server or your Db2 client machine.

> **Important**
>
> The `LOAD CLIENT` command method is useful for migrating small tables. If your network bandwidth between the client and RDS for Db2 is limited, we recommend that you use a different migration approach. For more information, see the Native Db2 tools.
> If your data file includes references to large object file names, then the `LOAD` command won't work because large objects (LOBs) need to reside on the Db2 server. If you try to load

LOBs from the client machine to the RDS for Db2 server, you will receive an SQL3025N error. Use the IMPORT command instead.

To load data to the RDS for Db2 server

1. Log in to your client machine with IBM Db2 Data Management Console. For more information, see Connecting to your Amazon RDS for Db2 DB instance with IBM Db2 Data Management Console.
2. Catalog the RDS for Db2 database on the client machine.

   a. Catalog the node. In the following example, replace *dns_ip_address* and *port* with the DNS name or the IP address and the port number of the self-managed Db2 database.

   ```
   db2 catalog tcpip node srcnode REMOTE dns_ip_address server port
   ```

   b. Catalog the database. In the following example, replace *source_database_name* and *source_database_alias* with the name of the self-managed Db2 database and the alias that you want to use for this database.

   ```
   db2 catalog database source_database_name as source_database_alias at node
    srcnode \
       authentication server_encrypt
   ```

3. Attach to the source database. In the following example, replace *source_database_alias*, *user_id*, and *user_password* with the alias you that created in the previous step and the user ID and password for the self-managed Db2 database.

   ```
   db2look -d source_database_alias -i user_id -w user_password -e -l -a -f -wlm \
       -cor -createdb -printdbcfg -o db2look.sql
   ```

4. Generate the data file by using the EXPORT command on your self-managed Db2 system. In the following example, replace *directory* with the directory on your client machine where your data file exists. Replace *file_name* and *TABLE_NAME* with the name of the data file and the name of the table.

   ```
   db2 "export to /directory/file_name.txt of del modified by coldel\| \
       select * from TPCH.TABLE_NAME"
   ```

5. Connect to your RDS for Db2 database using the master username and master password for your RDS for Db2 DB instance. In the following example, replace *rds_database_alias*, *master_username*, and *master_password* with your own information.

```
db2 connect to rds_database_alias user master_username using master_password
```

6. Use the LOAD command to load data from a file on the client machine to the remote RDS for Db2 database. For more information, see LOAD command in the IBM Db2 documentation. In the following example, replace *directory* with the directory on your client machine where your data file exists. Replace *file_name* and *TABLE_NAME* with the name of the data file and the name of the table.

```
db2 "LOAD CLIENT from /directory/file_name.txt \
    modified by coldel\| replace into TPCH.TABLE_NAME \
    nonrecoverable without prompting"
```

7. Terminate your connection.

```
db2 terminate
```

Amazon RDS for Db2 federation

You can use your Amazon RDS for Db2 database as a federated database. After setting up federation for RDS for Db2, you will be able to access and query data across multiple databases from your RDS for Db2 database. Federation saves you from needing to migrate data to your RDS for Db2 database or consolidate data into a single database.

By using your RDS for Db2 database as a federated database, you can continue to access to all RDS for Db2 features and can take advantage of various AWS services, all while keeping your data in different databases. You can set up both homogeneous federation which connects different databases of the same type, or heterogeneous federation which connects different databases of different types.

You first connect your Db2 database in RDS for Db2 to remote databases. Then you can run queries against all your connected databases. For example, you can run a SQL JOIN statement that join tables in your RDS for Db2 database with tables in a remote Db2 on z/OS database.

Topics

Homogeneous federation

You can set up homogeneous federation between your RDS for Db2 database and the following Db2 family of products:

- Db2 for Linux, UNIX, Windows (LUW)
- Db2 iSeries
- Db2 for z/OS

RDS for Db2 homogeneous federation doesn't support the following actions:

- Running `CATALOG` commands to set up a node directory and a remote database on an RDS for Db2 host database
- Settting up Workload Balancing (WLB) when federating to Db2 on z/OS
- Configuring the IBM data server driver configuration file (`db2dsdriver.cfg`)

RDS for Db2 homogeneous federation has the following requirements:

- You must create the DRDA wrapper in UNFENCED mode. If you don't, then federation won't work in RDS for Db2.
- You must allow incoming and outgoing traffic from your RDS for Db2 host database to your remote host databases. For more information, see Provide access to your DB instance in your VPC by creating a security group.

Topics

Step 1: Create a DRDA wrapper and a federated server

For homogeneous federation, create a DRDA wrapper and a federated server. The connection to the remote host uses HOST, PORT, and DBNAME.

Choose one of the following methods based on the type of your remote Db2 database:

- **Db2 for Linux, UNIX, and Windows (LUX) database** – Run the following SQL commands. In the following example, replace *server_name* with the name of the server that you will use for federation. Replace *db2_version* with the version of your remote Db2 database. Replace *username* and *password* with your credentials for the remote Db2 database you want to connect to. Replace *db_name*, *dns_name*, and *port* with the appropriate values for the remote Db2 database you want to connect to.

```
create wrapper drda options(DB2_FENCED 'N');
create server server_name type DB2/LUW wrapper drda version 'db2_version'
 authorization "master_username" password "master_password" options (add DBNAME
 'db_name',add HOST 'dns_name',add PORT 'port');
```

Example

```
create wrapper drda options(DB2_FENCED 'N');
```

```
create server SERVER1 type DB2/LUW wrapper drda version '11.5' authorization
 "sysuser" password "******" options (add DBNAME 'TESTDB2',add HOST
 'ip-123-45-67-899.us-west-1.compute.internal',add PORT '25010');
```

- **Db2 iSeries** – Run the following SQL commands. In the following example, replace *wrapper_name* and *library_name* with a name for your DRDA wrapper and the wrapper library file. Replace *server_name* with the name of the server that you will use for federation. Replace *db2_version* with the version of your remote Db2 database. Replace *username* and *password* with your credentials for the remote Db2 database you want to connect to. Replace *dns_name*, *port*, and *db_name* with the appropriate values for the remote Db2 database you want to connect to.

```
create wrapper wrapper_name library 'library name' options(DB2_FENCED 'N');
create server server_name type db2/mvs version db2_version wrapper wrapper_name
 authorization "sername" password "password" options (HOST 'dns_name', PORT 'port',
 DBNAME 'db_name');
```

Example

```
create wrapper WRAPPER1 library 'libdb2drda.so' options(DB2_FENCED 'N');
create server SERVER1 type db2/mvs version 11 wrapper WRAPPER1 authorization
 "sysuser" password "******" options (HOST 'test1.123.com', PORT '446', DBNAME
 'STLEC1');
```

- **Db2 for z/OS** – Run the following SQL commands. In the following example, replace *wrapper_name* and *library_name* with a name for your DRDA wrapper and the wrapper library file. Replace *server_name* with the name of the server that you will use for federation. Replace *db2_version* with the version of your remote Db2 database. Replace *username* and *password* with your credentials for the remote Db2 database you want to connect to. Replace *dns_name*, *port*, and *db_name* with the appropriate values for the remote Db2 database you want to connect to.

```
create wrapper wrapper_name library 'library_name' options(DB2_FENCED 'N');
create server server_name type db2/mvs version db2_version wrapper wrapper_name
 authorization "username" password "password" options (HOST 'dns_name', PORT 'port',
 DBNAME 'db_name');
```

Example

```
create wrapper WRAPPER1 library 'libdb2drda.so' OPTIONS(DB2_FENCED 'N');
create server SERVER1 type db2/mvs version 11 wrapper WRAPPER1 authorization
 "sysuser" password "******" options (HOST 'test1.123.com', PORT '446', DBNAME
 'STLEC1');
```

Step 2: Create a user mapping

Create a user mapping to associate your federated server with your data source server by running the following SQL command. In the following example, replace *server_name* with the name of the remote server than you want to perform operations on. This is the server that you created in step 1. Replace *username* and *password* with your credentials for this remote server.

```
create user mapping for user server server_name options (REMOTE_AUTHID 'username',
 REMOTE_PASSWORD 'password');
```

For more information, see User mappings in the IBM Db2 documentation.

Step 3: Check the connection

Confirm that setting up your federation was successful by checking the connection. Open a session to send native SQL commands to your remote data source using the SET PASSTHRU command, and then create a table on the remote data server.

1. Open and close a session to submit SQL to a data source. In the following example, replace *server_name* with the name of the server that you created for federation in step 1.

   ```
   set passthru server_name;
   ```

2. Create a new table. In the following example, replace *column_name*, *data_type*, and *value* with the appropriate items for your table.

   ```
   create table table_name
    ( column_name data_type(value), column_name data_type(value);
   ```

   For more information, see CREATE TABLE statement in the IBM Db2 documentation.

3. Create an index, insert values for rows into the table, and reset the connection. Resetting the connection drops the connection but retains the back-end processes. In the following

example, replace *index_name*, *table_name*, *column_name*, and *columnx_value* with your information.

```
create index index_name on table_name(column_name);
insert into table_name values(column1_value,column2_value,column3_value);
insert into table_name values(column1_value,column2_value,column3_value);
set passthru reset;

connect reset;
```

4. Connect to your remote Db2 database, create a nickname for your remote server, and perform operations. When you are done accessing data in the remote Db2 database, reset and then terminate the connection. In the following example, replace *database_name* with the name of your remote Db2 database. Replace *nickname* with a name. Replace *server_name* and *table_name* with the name of the remote server and table on that server that you want to perform operations on. Replace *username* with the information for your remote server. Replace *sql_command* with the operation to perform on the remote server.

```
connect to database_name;
create nickname nickname for server_name."username"."table_name";
select sql_command from nickname;
connect reset;
terminate;
```

Example

The following example creates a pass-through session to allow operations on the federated server `testdb10`.

Next, it creates the table `t1` with three columns with different data types.

Then, the example creates the index `i1_t1` on three columns in table `t1`. Afterwards, it inserts two rows with values for these three columns, and then disconnects.

Last, the example connects to the remote Db2 database `testdb2` and creates a nickname for the table `t1` in the federated server `testdb10`. It creates the nickname with the username TESTUSER for that data source. An SQL command outputs all data from the table `t1`. The example disconnects and ends the session.

```
set passthru testdbl0;
```

```
create table t1 ( c1 decimal(13,0), c2 char(200), c3 int);

create index i1_t1 on t1(c3);
insert into t1 values(1,'Test',1);
insert into t1 values(2,'Test 2',2);
connect reset;

connect to testdb2;
create nickname remote_t1 for testdb10."TESTUSER"."T1";
select * from remote_t1;
connect reset;
terminate;
```

Heterogeneous federation

You can set up heterogeneous federation between your RDS for Db2 database and other data sources such as Oracle and Microsoft SQL Server. For a complete list of data sources that Db2 LUW supports, see Data Source Support Matrix of Federation Bundled in Db2 LUW V11.5 on the IBM Support site.

RDS for Db2 heterogeneous federation doesn't support the following items:

- Native wrappers for the other data sources
- JDBC wrappers for the other data sources
- Federation to Sybase, Informix, and Teradata data sources because these data sources require client software installation on RDS for Db2

RDS for Db2 heterogeneous federation has the following requirements:

- RDS for Db2 only supports the ODBC wrapper method.
- If you create an explicit definition of a wrapper, then you must set the option `DB2_FENCED` to `'N'`. For a list of valid wrapper options for ODBC, see ODBC options in the IBM Db2 documentation.
- You must allow incoming and outgoing traffic from your RDS for Db2 host database to your remote host database. For more information, see Provide access to your DB instance in your VPC by creating a security group.

For information about federation to Oracle, see How to query Oracle by using Db2 Federation and the ODBC driver? on the IBM Support site.

For more information about data sources that support federation, see Data Source Support Matrix of Federation Bundled in Db2 LUW V11.5 on the IBM Support site.

Topics

Step 1: Create an ODBC wrapper

Create a wrapper by running the following command:

```
db2 "create wrapper odbc options( module '/home/rdsdb/sqllib/federation/odbc/lib/
libodbc.so')"
```

Step 2: Create a federated server

Create a federated server by running the following command. In the following example, replace *server_name* with the name of the server that you will use for federation. Replace *wrapper_type* with the appropriate wrapper. Replace *db_version* with the version of your remote database. Replace *dns_name*, *port*, and *service_name* with the appropriate values for the remote database that you want to connect to.

```
db2 "create server server_name type wrapper_type version db_version options (HOST
 'dns_name', PORT 'port', SERVICE_NAME 'service_name')“
```

For information about wrapper types, see Data Source Support Matrix of Federation Bundled in Db2 LUW V11.5 on the IBM Support site.

Example

The following example creates a federated server for a remote Oracle database.

```
db2 "create server server1 type oracle_odbc version 12.1 options (HOST
 'test1.amazon.com', PORT '1521', SERVICE_NAME 'pdborcl.amazon.com')“
```

Step 3: Create a user mapping

Create a user mapping to associate your federated server with your data source server by running the following SQL command. In the following example, replace *server_name* with the name of the remote server than you want to perform operations on. This is the server that you created in step 2. Replace *username* and *password* with your credentials for this remote server.

```
create user mapping for user server server_name options (REMOTE_AUTHID 'username',
 REMOTE_PASSWORD 'password');
```

For more information, see User mappings in the IBM Db2 documentation.

Step 4: Check the connection

Confirm that setting up your federation was successful by checking the connection. Open a session to send native SQL commands to your remote data source using the SET PASSTHRU command, and then create a table on the remote data server.

1. Open and close a session to submit SQL to a data source. In the following example, replace *server_name* with the name of the server that you created for federation in step 2.

   ```
   set passthru server_name;
   ```

2. Create a new table. In the following example, replace *column_name*, *data_type*, and *value* with the appropriate items for your table.

   ```
   create table table_name
    ( column_name data_type(value), column_name data_type(value);
   ```

   For more information, see CREATE TABLE statement in the IBM Db2 documentation.

3. Create an index, insert values for rows into the table, and reset the connection. Resetting the connection drops the connection but retains the back-end processes. In the following example, replace *index_name*, *table_name*, *column_name*, and *columnx_value* with your information.

   ```
   create index index_name on table_name(column_name);
   ```

```
insert into table_name values(column1_value,column2_value,column3_value);
insert into table_name values(column1_value,column2_value,column3_value);
set passthru reset;

connect reset;
```

4. Connect to your remote Db2 database, create a nickname for your remote server, and perform operations. When you are done accessing data in the remote Db2 database, reset and then terminate the connection. In the following example, replace *database_name* with the name of your remote Db2 database. Replace *nickname* with a name. Replace *server_name* and *table_name* with the name of the remote server and table on that server that you want to perform operations on. Replace *username* with the information for your remote server. Replace *sql_command* with the operation to perform on the remote server.

```
connect to database_name;
create nickname nickname for server_name."username"."table_name";
select sql_command from nickname;
connect reset;
terminate;
```

Example

The following example creates a pass-through session to allow operations on the federated server `testdb10`.

Next, it creates the table `t1` with three columns with different data types.

Then, the example creates the index `i1_t1` on three columns in table `t1`. Afterwards, it inserts two rows with values for these three columns, and then disconnects.

Last, the example connects to the remote Db2 database `testdb2` and creates a nickname for the table `t1` in the federated server `testdb10`. It creates the nickname with the username TESTUSER for that data source. An SQL command outputs all data from the table `t1`. The example disconnects and ends the session.

```
set passthru testdbl0;

create table t1 ( c1 decimal(13,0), c2 char(200), c3 int);

create index i1_t1 on t1(c3);
```

```
insert into t1 values(1,'Test',1);
insert into t1 values(2,'Test 2',2);
connect reset;

connect to testdb2;
create nickname remote_t1 for testdbl0."TESTUSER"."T1";
select * from remote_t1;
connect reset;
terminate;
```

Options for Amazon RDS for Db2 DB instances

The following shows the options, or additional features, that are available for Amazon RDS instances running the Db2 DB engine. To enable these options, you can add them to a custom option group, and then associate the option group with your DB instance. For more information about working with option groups, see Working with option groups.

Amazon RDS supports the following options for Db2:

Option	Option ID
Db2 audit logging	DB2_AUDIT

Db2 audit logging

With Db2 audit logging, Amazon RDS records database activity, including users logging on to the database and queries run against the database. RDS uploads the completed audit logs to your Amazon S3 bucket, using the AWS Identity and Access Management (IAM) role that you provide.

Topics

Setting up Db2 audit logging

To enable audit logging for an Amazon RDS for Db2 database, you enable the `DB2_AUDIT` option on the RDS for Db2 DB instance. Then, configure an audit policy to enable the feature for the specific database. To enable the option on the RDS for Db2 DB instance, you configure the option settings for the `DB2_AUDIT` option. You do so by providing the Amazon Resource Names (ARNs) for your Amazon S3 bucket and the IAM role with permissions to access your bucket.

To set up Db2 audit logging for an RDS for Db2 database, complete the following steps.

Topics

Step 1: Create an Amazon S3 bucket

If you haven't already done so, create an Amazon S3 bucket where Amazon RDS can upload your RDS for Db2 database's audit log files. The following restrictions apply to the S3 bucket that you use as a target for audit files:

- It must be in the same AWS Region as your RDS for Db2 DB instance.
- It must not be open to the public.
- It can't use S3 Object Lock.
- The bucket owner must also be the IAM role owner.

To learn how to create an Amazon S3 bucket, see Creating a bucket in the *Amazon S3 User Guide*.

After you enable audit logging, Amazon RDS automatically sends the logs from your DB instance to the following locations:

- DB instance level logs – *bucket_name*/db2-audit-logs/*dbi_resource_id*/*date_time_utc*/
- Database level logs – *bucket_name*/db2-audit-logs/*dbi_resource_id*/*date_time_utc*/*db_name*/

Take note of the Amazon Resource Name (ARN) for your bucket. This information is needed to complete subsequent steps.

Step 2: Create an IAM policy

Create an IAM policy with the permissions required to transfer audit log files from your DB instance to your Amazon S3 bucket. This step assumes that you have an S3 bucket.

Before you create the policy, gather the following information:

- The ARN for your bucket.
- The ARN for your AWS Key Management Service (AWS KMS) key, if your bucket uses SSE-KMS encryption.

Create an IAM policy that includes the following permissions:

```
"s3:ListBucket",
 "s3:GetBucketACL",
 "s3:GetBucketLocation",
 "s3:PutObject",
 "s3:ListMultipartUploadParts",
 "s3:AbortMultipartUpload",
 "s3:ListAllMyBuckets"
```

> **Note**
>
> Amazon RDS needs the `s3:ListAllMyBuckets` action internally to verify that the same AWS account owns both the S3 bucket and the RDS for Db2 DB instance.

If your bucket uses SSE-KMS encryption, also include the following permissions:

```
"kms:GenerateDataKey",
 "kms:Decrypt"
```

You can create an IAM policy by using the AWS Management Console or the AWS Command Line Interface (AWS CLI).

Console

To create an IAM policy to allow Amazon RDS to access your Amazon S3 bucket

1. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation pane, choose **Policies**.
3. Choose **Create policy**, and then choose **JSON**.
4. In **Add actions**, filter by **S3**. Add access **ListBucket**, **GetBucketAcl**, and **GetBucketLocation**.
5. For **Add a resource**, choose **Add**. For **Resource type**, choose **bucket**, and enter the name of your bucket. Then, choose **Add resource**.
6. Choose **Add new statement**.
7. In **Add actions**, filter by **S3**. Add access **PutObject**, **ListMultipartUploadParts**, and **AbortMultipartUpload**.
8. For **Add a resource**, choose **Add**. For **Resource type**, choose **object**, and enter *`your bucket name/*`*. Then, choose **Add resource**.
9. Choose **Add new statement**.
10. In **Add actions**, filter by **S3**. Add access **ListAllMyBuckets**.
11. For **Add a resource**, choose **Add**. For **Resource type**, choose **All Resources**. Then, choose **Add resource**.
12. If you're using your own KMS keys to encrypt the data:

1. Choose **Add new statement**.
2. In **Add actions**, filter by KMS. Add access **GenerateDataKey** and **Decrypt**.
3. For **Add a resource**, choose **Add**. For **Resource type**, choose **All Resources**. Then, choose **Add resource**.

13. Choose **Next**.
14. For **Policy name**, enter a name for this policy.
15. (Optional) For **Description**, enter a description for this policy.
16. Choose **Create policy**.

AWS CLI

To create an IAM policy to allow Amazon RDS to access your Amazon S3 bucket

1. Run the create-policy command. In the following example, replace *iam_policy_name* and *amzn-s3-demo-bucket* with a name for your IAM policy and the name of your target Amazon S3 bucket.

   For Linux, macOS, or Unix:

```
aws iam create-policy \
    --policy-name iam_policy_name \
    --policy-document '{
        "Version": "2012-10-17",
        "Statement": [
            {
                "Sid": "Statement1",
                "Effect": "Allow",
                "Action": [
                    "s3:ListBucket",
                    "s3:GetBucketAcl",
                    "s3:GetBucketLocation"
                ],
                "Resource": [
                    "arn:aws:s3:::amzn-s3-demo-bucket"
                ]
            },
            {
                "Sid": "Statement2",
                "Effect": "Allow",
```

```
                "Action": [
                    "s3:PutObject",
                    "s3:ListMultipartUploadParts",
                    "s3:AbortMultipartUpload"
                ],
                "Resource": [
                    "arn:aws:s3:::amzn-s3-demo-bucket/*"
                ]
            },
            {
                "Sid": "Statement3",
                "Effect": "Allow",
                "Action": [
                    "s3:ListAllMyBuckets"
                ],
                "Resource": [
                    "*"
                ]
            },
            {
                "Sid": "Statement4",
                "Effect": "Allow",
                "Action": [
                    "kms:GenerateDataKey",
                    "kms:Decrypt"
                ],
                "Resource": [
                    "*"
                ]
            }
        ]
  }'
```

For Windows:

```
aws iam create-policy ^
    --policy-name iam_policy_name ^
    --policy-document '{
        "Version": "2012-10-17",
        "Statement": [
            {
                "Sid": "Statement1",
                "Effect": "Allow",
```

```
                "Action": [
                    "s3:ListBucket",
                    "s3:GetBucketAcl",
                    "s3:GetBucketLocation"
                ],
                "Resource": [
                    "arn:aws:s3:::amzn-s3-demo-bucket"
                ]
            },
            {
                "Sid": "Statement2",
                "Effect": "Allow",
                "Action": [
                    "s3:PutObject",
                    "s3:ListMultipartUploadParts",
                    "s3:AbortMultipartUpload"
                ],
                "Resource": [
                    "arn:aws:s3:::amzn-s3-demo-bucket/*"
                ]
            },
            {
                "Sid": "Statement3",
                "Effect": "Allow",
                "Action": [
                    "s3:ListAllMyBuckets"
                ],
                "Resource": [
                    "*"
                ]
            },
            {
                "Sid": "Statement4",
                "Effect": "Allow",
                "Action": [
                    "kms:GenerateDataKey",
                    "kms:Decrypt"
                ],
                "Resource": [
                    "*"
                ]
            }
        ]
```

```
}'
```

2. After the policy is created, note the ARN of the policy. You need the ARN for Step 3: Create an IAM role and attach your IAM policy.

For information about creating an IAM policy, see Creating IAM policies in the IAM User Guide.

Step 3: Create an IAM role and attach your IAM policy

This step assumes that you created the IAM policy in Step 2: Create an IAM policy. In this step, you create an IAM role for your RDS for Db2 DB instance and then attach your IAM policy to the role.

You can create an IAM role for your DB instance by using the console or the AWS CLI.

Console

To create an IAM role and attach your IAM policy to it

1. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation pane, choose **Roles**.
3. Choose **Create role**.
4. For **Trusted entity type**, select **AWS service**.
5. For **Service or use case**, select **RDS**, and then select **RDS – Add Role to Database**.
6. Choose **Next**.
7. For **Permissions policies**, search for and select the name of the IAM policy that you created.
8. Choose **Next**.
9. For **Role name**, enter a role name.
10. (Optional) For **Description**, enter a description for the new role.
11. Choose **Create role**.

AWS CLI

To create an IAM role and attach your IAM policy to it

1. Run the create-role command. In the following example, replace *iam_role_name* with a name for your IAM role.

For Linux, macOS, or Unix:

```
aws iam create-role \
    --role-name iam_role_name \
    --assume-role-policy-document '{
      "Version": "2012-10-17",
      "Statement": [
        {
          "Effect": "Allow",
          "Principal": {
            "Service": "rds.amazonaws.com"
          },
          "Action": "sts:AssumeRole"
        }
      ]
    }'
```

For Windows:

```
aws iam create-role ^
    --role-name iam_role_name ^
    --assume-role-policy-document '{
      "Version": "2012-10-17",
      "Statement": [
        {
          "Effect": "Allow",
          "Principal": {
            "Service": "rds.amazonaws.com"
          },
          "Action": "sts:AssumeRole"
        }
      ]
    }'
```

2. After the role is created, note the ARN of this role. You need this ARN for the next step, Step 4: Configure an option group for Db2 audit logging.

3. Run the attach-role-policy command. In the following example, replace *iam_policy_arn* with the ARN of the IAM policy that you created in Step 2: Create an IAM policy. Replace *iam_role_name* with the name of the IAM role that you just created.

   For Linux, macOS, or Unix:

```
aws iam attach-role-policy \
   --policy-arn iam_policy_arn \
   --role-name iam_role_name
```

For Windows:

```
aws iam attach-role-policy ^
   --policy-arn iam_policy_arn ^
   --role-name iam_role_name
```

For more information, see Creating a role to delegate permissions to an IAM user in the *IAM User Guide*.

Step 4: Configure an option group for Db2 audit logging

The process for adding the Db2 audit logging option to an RDS for Db2 DB instance is as follows:

1. Create a new option group, or copy or modify an existing option group.
2. Add and configure all required options.
3. Associate the option group with the DB instance.

After you add the Db2 audit logging option, you don't need to restart your DB instance. As soon as the option group is active, you can create audits and store audit logs in your S3 bucket.

To add and configure Db2 audit logging on a DB instance's option group

1. Choose one of the following:
   - Use an existing option group.
   - Create a custom DB option group, and use that option group. For more information, see Creating an option group.
2. Add the **DB2_AUDIT** option to the option group, and configure the option settings. For more information about adding options, see Adding an option to an option group.
   - For **IAM_ROLE_ARN**, enter the ARN of the IAM role that you created in the section called "Create an IAM role and attach your IAM policy".

- For **S3_BUCKET_ARN**, enter the ARN of the S3 bucket to use for your Db2 audit logs. The bucket must be in the same Region as your RDS for Db2 DB instance. The policy associated with the IAM role you entered must allow the required operations on this resource.

3. Apply the option group to a new or existing DB instance. Choose one of the following:

   - If you are creating a new DB instance, apply the option group when you launch the instance.
   - On an existing DB instance, apply the option group by modifying the instance and then attaching the new option group. For more information, see Modifying an Amazon RDS DB instance.

Step 5: Configure the audit policy

To configure the audit policy for your RDS for Db2 database, connect to the `rdsadmin` database using the master username and master password for your RDS for Db2 DB instance. Then, call the `rdsadmin.configure_db_audit` stored procedure with the DB name of your database and the applicable parameter values.

The following example connects to the database and configures an audit policy for `testdb` with the categories AUDIT, CHECKING, OBJMAINT, SECMAINT, SYSADMIN, and VALIDATE. The status value `BOTH` logs success and failures, and the `ERROR TYPE` is `NORMAL` by default. For more information about how to use this stored procedure, see the section called "rdsadmin.configure_db_audit".

```
db2 "connect to rdsadmin user master_user using master_password"
db2 "call rdsadmin.configure_db_audit('testdb', 'ALL', 'BOTH', ?)"
```

Step 6: Check the audit configuration

To make sure that your audit policy is set up correctly, check the status of your audit configuration.

To check the configuration, connect to the `rdsadmin` database using the master username and master password for your RDS for Db2 DB instance. Then, run the following SQL statement with the DB name of your database. In the following example, the DB name is *testdb*.

```
db2 "select task_id, task_type, database_name, lifecycle,
    varchar(bson_to_json(task_input_params), 500) as task_params,
    cast(task_output as varchar(500)) as task_output
    from table(rdsadmin.get_task_status(null,'testdb','CONFIGURE_DB_AUDIT'))"
```

```
Sample Output

TASK_ID              TASK_TYPE            DATABASE_NAME       LIFECYCLE
-------------------- -------------------- --------------- -------------
                   2  CONFIGURE_DB_AUDIT            DB2DB       SUCCESS

... continued ...
TASK_PARAMS
------------------------------------------------------------
{ "AUDIT_CATEGORY" : "ALL", "CATEGORY_SETTING" : "BOTH" }

... continued ...
                                          TASK_OUTPUT
-------------------------------------------------
2023-12-22T20:27:03.029Z Task execution has started.

2023-12-22T20:27:04.285Z Task execution has completed successfully.
```

Managing Db2 audit logging

After you set up Db2 audit logging, you can modify the audit policy for a specific database, or disable audit logging at the database level or for the entire DB instance. You can also change the Amazon S3 bucket where your log files are uploaded to.

Topics

- Modifying a Db2 audit policy
- Modifying the location of your log files
- Disabling Db2 audit logging

Modifying a Db2 audit policy

To modify the audit policy for a specific RDS for Db2 database, run the `rdsadmin.configure_db_audit` stored procedure. With this stored procedure, you can change the categories, category settings, and error type configuration of the audit policy. For more information, see the section called “rdsadmin.configure_db_audit”.

Modifying the location of your log files

To change the Amazon S3 bucket where your log files are uploaded to, do one of the following:

- Modify the current option group attached to your RDS for Db2 DB instance – Update the `S3_BUCKET_ARN` setting for the `DB2_AUDIT` option to point to the new bucket. Also, make sure to update the IAM policy attached to the IAM role specified by the `IAM_ROLE_ARN` setting in the attached option group. This IAM policy must provide your new bucket with the required access permissions. For information about the permissions required in the IAM policy, see Create an IAM policy.
- Attach your RDS for Db2 DB instance to a different option group – Modify your DB instance to change the option group that's attached to it. Make sure that the new option group is configured with the correct `S3_BUCKET_ARN` and `IAM_ROLE_ARN` settings. For information about how to configure these settings for the `DB2_AUDIT` option, see Configure an option group.

When you modify the option group, make sure that you apply the changes immediately. For more information, see the section called “Modifying a DB instance”.

Disabling Db2 audit logging

To disable Db2 audit logging, do one of the following:

- Disable audit logging for the RDS for Db2 DB instance – Modify your DB instance and remove the option group with the `DB2_AUDIT` option from it. For more information, see the section called “Modifying a DB instance”.
- Disable audit logging for a specific database – Stop audit logging and remove the audit policy by calling `rdsadmin.disable_db_audit` with the DB name of your database. For more information, see the section called “rdsadmin.disable_db_audit”.

```
db2 "call rdsadmin.disable_db_audit(
    'db_name')"
```

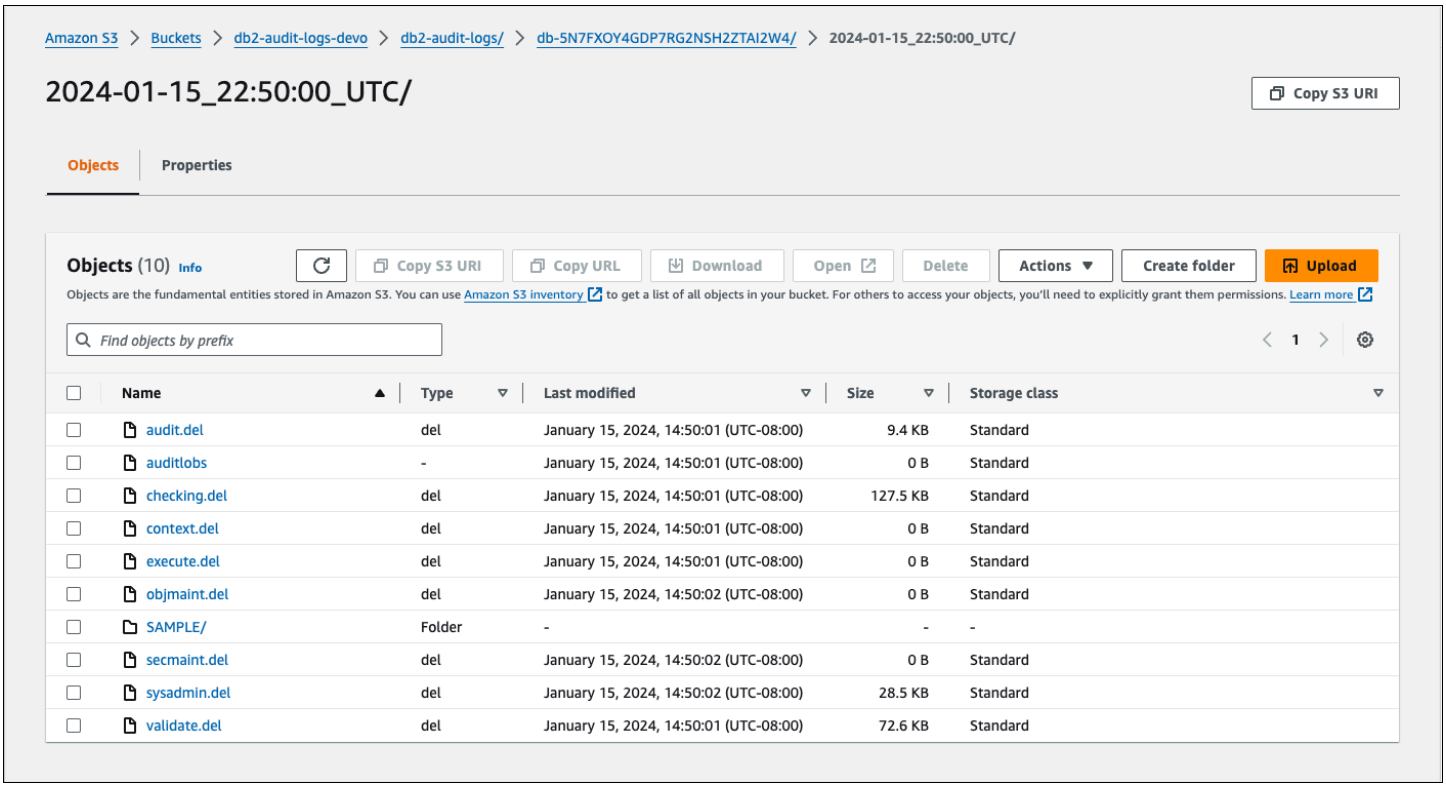
Viewing audit logs

After you enable Db2 audit logging, wait for at least one hour before viewing the audit data in your Amazon S3 bucket. Amazon RDS automatically sends the logs from your RDS for Db2 DB instance to the following locations:

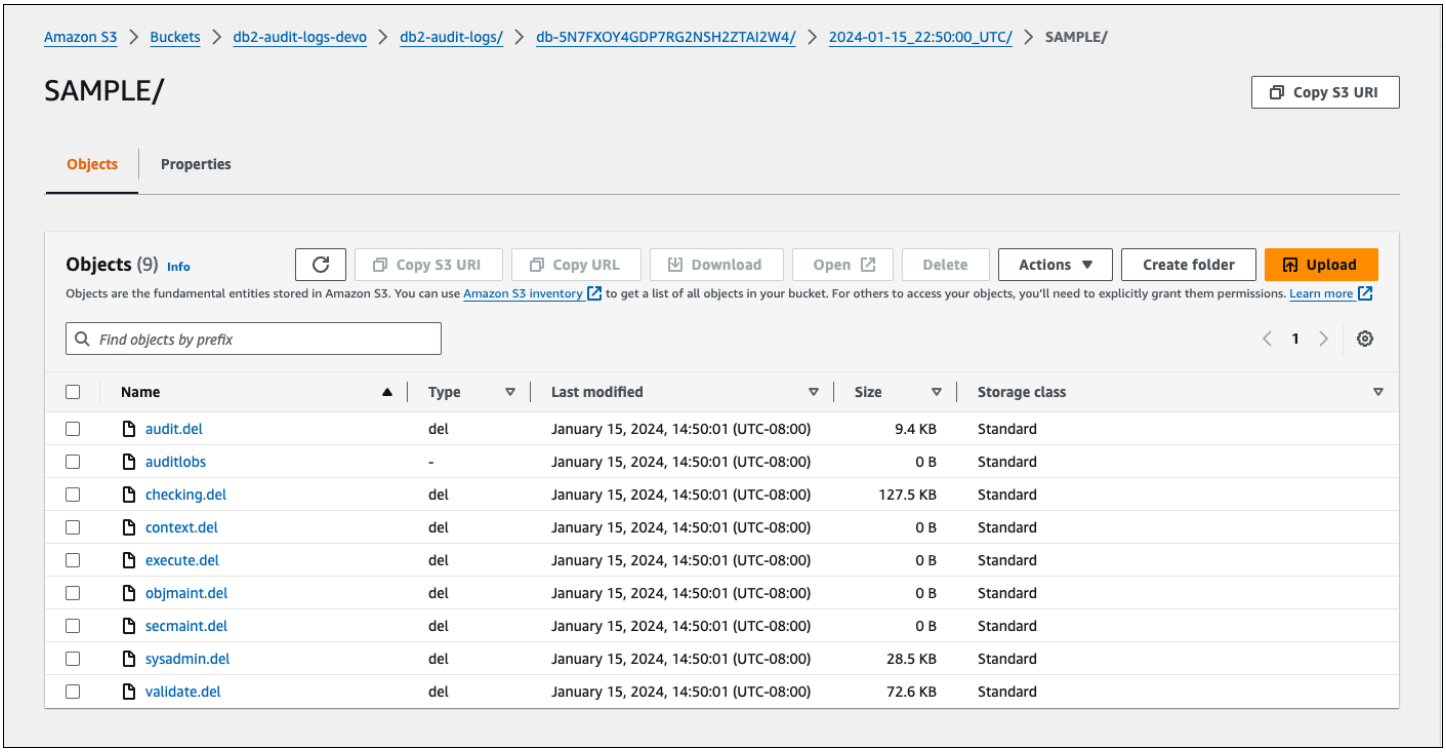
- DB instance level logs – *bucket_name*`/db2-audit-logs/`*dbi_resource_id*`/`*date_time_utc*`/`

- Database level logs – *bucket_name*/db2-audit-logs/*dbi_resource_id*/*date_time_utc*/*db_name*/

The following example screenshot of the Amazon S3 console shows a list of folders for RDS for Db2 DB instance level log files.



The following example screenshot of the Amazon S3 console shows database level log files for the RDS for Db2 DB instance.



Troubleshooting Db2 audit logging

Use the following information to troubleshoot common issues with Db2 audit logging.

Can't configure the audit policy

If calling the stored procedure `rdsadmin.configure_db_audit` returns an error, it could be that the option group with the `DB2_AUDIT` option isn't associated with the RDS for Db2 DB instance. Modify the DB instance to add the option group, and then try calling the stored procedure again. For more information, see Modifying an Amazon RDS DB instance.

No data in the Amazon S3 bucket

If logging data is missing from the Amazon S3 bucket, check the following:

- The Amazon S3 bucket is in the same Region as your RDS for Db2 DB instance.
- The role you specified in the `IAM_ROLE_ARN` option setting is configured with the required permissions to upload logs to your Amazon S3 bucket. For more information, see Create an IAM policy.
- The ARNs for the `IAM_ROLE_ARN` and `S3_BUCKET_ARN` option settings are correct in the option group associated with your RDS for Db2 DB instance. For more information, see Configure an option group.

You can check the task status of your audit logging configuration by connecting to the database and running a SQL statement. For more information, see Check the audit configuration.

You can also check events to find out more about why logs might be missing. For information about how to view events, see the section called “Viewing logs, events, and streams in the Amazon RDS console”.

External stored procedures for Amazon RDS for Db2

You can create external routines and register them with your Amazon RDS for Db2 databases as external stored procedures. Currently, RDS for Db2 only supports Java-based routines for external stored procedures.

Java-based external stored procedures

Java-based external stored procedures are external Java routines that you register with your RDS for Db2 database as external stored procedures.

Topics

- Limitations for Java-based external stored procedures
- Configuring Java-based external stored procedures

Limitations for Java-based external stored procedures

Before you develop your external routine, consider the following limitations and restrictions.

To create your external routine, make sure to use the Java Development Kit (JDK) provided by Db2. For more information, see Java software support for Db2 database products.

Your Java program can create files only in the `/tmp` directory, and Amazon RDS doesn't support enabling executable or Set User ID (SUID) permissions on these files. Your Java program also can't use socket system calls or the following system calls:

- _sysctl
- acct
- afs_syscall
- bpf
- capset
- chown
- chroot
- create_module
- delete_module

- fanotify_init
- fanotify_mark
- finit_module
- fsconfig
- fsopen
- fspick
- get_kernel_syms
- getpmsg
- init_module
- mount
- move_mount
- nfsservctl
- open_by_handle_at
- open_tree
- pivot_root
- putpmsg
- query_module
- quotactl
- reboot
- security
- setdomainname
- setfsuid
- sethostname
- sysfs
- tuxcall
- umount2
- uselib
- ustat
- vhangup
- vserver

For additional restrictions on external routines for Db2, see Restrictions on external routines in the IBM Db2 documentation.

Configuring Java-based external stored procedures

To configure an external stored procedure, create a .jar file with your external routine, install it on your RDS for Db2 database, and then register it as an external stored procedure.

Topics

Step 1: Enable external stored procedures

To enable external stored procedures, in a custom parameter group associated with your DB instance, set the parameter `db2_alternate_authz_behaviour` to one of the following values:

- `EXTERNAL_ROUTINE_DBADM` – Implicitly grants any user, group, or role with `DBADM` authority the `CREATE_EXTERNAL_ROUTINE` permission.
- `EXTERNAL_ROUTINE_DBAUTH` – Allows a user with `DBADM` authority to grant `CREATE_EXTERNAL_ROUTINE` permission to any user, group, or role. In this case, no user, group, or role is implicitly granted this permission, not even a user with `DBADM` authority.

For more information about this setting, see GRANT (database authorities) statement in the IBM Db2 documentation.

You can create and modify a custom parameter group by using the AWS Management Console, the AWS CLI, or the Amazon RDS API.

Console

To configure the db2_alternate_authz_behaviour parameter in a custom parameter group

1. If you want to use a different custom DB parameter group than the one your DB instance is using, create a new DB parameter group. If you're using the Bring Your Own License (BYOL) model, make sure that the new custom parameter group includes the IBM IDs. For information

about these IDs, see the section called "IBM IDs for Bring Your Own License for Db2". For more information about creating a DB parameter group, see Creating a DB parameter group in Amazon RDS.

2. Set the value for the `db2_alternate_authz_behaviour` parameter in your custom parameter group. For more information about modifying a parameter group, see Modifying parameters in a DB parameter group in Amazon RDS.

AWS CLI

To configure the db2_alternate_authz_behaviour parameter in a custom parameter group

1. If you want to use a different custom DB parameter group than the one your DB instance is using, create a custom parameter group by running the create-db-parameter-group command. If you're using the Bring Your Own License (BYOL) model, make sure that the new custom parameter group includes the IBM IDs. For information about these IDs, see the section called "IBM IDs for Bring Your Own License for Db2".

   Include the following required options:

   - `--db-parameter-group-name` – A name for the parameter group that you are creating.
   - `--db-parameter-group-family` – The Db2 engine edition and major version. Valid values are `db2-se-11.5` and `db2-ae-11.5`.
   - `--description` – A description for this parameter group.

   For more information about creating a DB parameter group, see Creating a DB parameter group in Amazon RDS.

   The following example shows you how to create a custom parameter group named `MY_EXT_SP_PARAM_GROUP` for the parameter group family `db2-se-11.5`.

   For Linux, macOS, or Unix:

```
aws rds create-db-parameter-group \
--region us-east-1 \
--db-parameter-group-name MY_EXT_SP_PARAM_GROUP \
--db-parameter-group-family db2-se-11.5 \
--description "test db2 external routines"
```

For Windows:

```
aws rds create-db-parameter-group ^
--region us-east-1 ^
--db-parameter-group-name MY_EXT_SP_PARAM_GROUP ^
--db-parameter-group-family db2-se-11.5 ^
--description "test db2 external routines"
```

2. Modify the `db2_alternate_authz_behaviour` parameter in your custom parameter group by running the [modify-db-parameter-group] command.

   Include the following required options:

   - `--db-parameter-group-name` – The name of the parameter group that you created.
   - `--parameters` – An array of parameter names, values, and the application methods for the parameter update.

   For more information about modifying a parameter group, see [Modifying parameters in a DB parameter group in Amazon RDS].

   The following example shows you how to modify the parameter group `MY_EXT_SP_PARAM_GROUP` by setting the value of `db2_alternate_authz_behaviour` to `EXTERNAL_ROUTINE_DBADM`.

   For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group \
    --db-parameter-group-name MY_EXT_SP_PARAM_GROUP \
    --parameters
 "ParameterName='db2_alternate_authz_behaviour',ParameterValue='EXTERNAL_ROUTINE_DBADM',App
```

   For Windows:

```
aws rds modify-db-parameter-group ^
    --db-parameter-group-name MY_EXT_SP_PARAM_GROUP ^
    --parameters
 "ParameterName='db2_alternate_authz_behaviour',ParameterValue='EXTERNAL_ROUTINE_DBADM',App
```

RDS API

To configure the db2_alternate_authz_behaviour parameter in a custom parameter group

1. If you want to use a different custom DB parameter group than the one your DB instance is using, create a new DB parameter group by using the Amazon RDS API CreateDBParameterGroup operation. If you're using the Bring Your Own License (BYOL) model, make sure that the new custom parameter group includes the IBM Db2 IDs. For information about these IDs, see the section called “IBM IDs for Bring Your Own License for Db2”.

   Include the following required parameters:

   - `DBParameterGroupName`
   - `DBParameterGroupFamily`
   - `Description`

   For more information about creating a DB parameter group, see Creating a DB parameter group in Amazon RDS.
2. Modify the `db2_alternate_authz_behaviour` parameter in your custom parameter group that you created by using the RDS API ModifyDBParameterGroup operation.

   Include the following required parameters:

   - `DBParameterGroupName`
   - `Parameters`

   For more information about modifying a parameter group, see Modifying parameters in a DB parameter group in Amazon RDS.

Step 2: Install the .jar file with your external routine

After you create your Java routine, create the .jar file and then run `db2 "call sqlj.install_jar('file:`*`file_path`*`',`*`jar_ID`*`)"` to install it on your RDS for Db2 database.

The following example shows you how to create a Java routine and install it on an RDS for Db2 database. The example includes sample code for a simple routine that you can use to test the process. This example makes the following assumptions:

- The Java code is compiled on a server where Db2 is installed. This is a best practice because not compiling with the IBM-provided JDK can result in unexplained errors.
- The server has the RDS for Db2 database cataloged locally.

If you'd like to try out the process with the following sample code, copy it and then save it to a file named `MYJAVASP.java`.

```
import java.sql.*;
public class MYJAVASP
{
public static void my_JAVASP (String inparam) throws SQLException, Exception
{
try
{
// Obtain the calling context's connection details.
Connection myConn = DriverManager.getConnection("jdbc:default:connection");
String myQuery = "INSERT INTO TEST.TEST_TABLE VALUES (?, CURRENT DATE)";
PreparedStatement myStmt = myConn.prepareStatement(myQuery);
myStmt.setString(1, inparam);
myStmt.executeUpdate();
}
catch (SQLException sql_ex)
{
throw sql_ex;
}
catch (Exception ex)
{
throw ex;
}
}
```

The following command compiles the Java routine.

```
~/sqllib/java/jdk64/bin/javac MYJAVASP.java
```

The following command creates the .jar file.

```
~/sqllib/java/jdk64/bin/jar cvf MYJAVASP.jar MYJAVASP.class
```

The following commands connect to the database named MY_DB2_DATABASE and install the .jar file.

```
db2 "connect to MY_DB2_DATABASE user master_username using master_password"

db2 "call sqlj.install_jar('file:/tmp/MYJAVASP.jar','MYJAVASP')"
db2 "call sqlj.refresh_classes()"
```

Step 3: Register the external stored procedure

After you install the .jar file on your RDS for Db2 database, register it as a stored procedure by running the db2 CREATE PROCEDURE or db2 REPLACE PROCEDURE command.

The following example shows you how to connect to the database and register the Java routine created in the previous step as a stored procedure.

```
db2 "connect to MY_DB2_DATABASE user master_username using master_password"

create procedure TESTSP.MYJAVASP (in input char(6))
specific myjavasp
dynamic result sets 0
deterministic
language java
parameter style java
no dbinfo
fenced
threadsafe
modifies sql data
program type sub
external name 'MYJAVASP!my_JAVASP';
```

Step 4: Validate the external stored procedure

Use the following steps to test the sample external stored procedure that was registered in the previous step.

To validate the external stored procedure

1. Create a table like TEST.TEST_TABLE in the following example.

   ```
   db2 "create table TEST.TEST_TABLE(C1 char(6), C2 date)"
   ```

2. Call the new external stored procedure. The call returns a status of `0`.

```
db2 "call TESTSP.MYJAVASP('test')"
Return Status = 0
```

3. Query the table you created in step 1 to verify the results of the stored procedure call.

```
db2 "SELECT * from TEST.TEST_TABLE"
```

The query produces output similar to the following example:

```
C1     C2
------ ----------
test   02/05/2024
```

Known issues and limitations for Amazon RDS for Db2

The following items are known issues and limitations for working with Amazon RDS for Db2:

Topics

Authentication limitation

Amazon RDS sets DB2AUTH to JCC_ENFORCE_SECMEC. Because JCC_ENFORCE_SECMEC can't be modified, Amazon RDS enforces password encryption on JDBC connections.

Non-fenced routines

RDS for Db2 doesn't support the creation of non-fenced routines and the migration of these routines by backing up and restoring data. To check if your database contains any non-fenced routines, run the following SQL command:

```
SELECT 'COUNT:' || count(*) FROM SYSCAT.ROUTINES where fenced='N' and routineschema not
 in ('SQLJ','SYSCAT','SYSFUN','SYSIBM','SYSIBMADM','SYSPROC','SYSTOOLS')
```

Non-automatic storage tablespaces during migration

RDS for Db2 doesn't support the creation of new non-automatic storage tablespaces. When you use native restore for a one-time migration of your database, RDS for Db2 automatically converts your non-automatic storage tablespaces to automatic ones, and then restores your database to RDS for Db2. For information about one-time migrations, see One-time migration from Linux to Linux environments and One-time migration from AIX or Windows to Linux environments.

Amazon RDS for Db2 stored procedure reference

Amazon RDS provides system stored procedures that you can use with Amazon RDS for Db2 DB instances running the Db2 engine.

Keep in mind the following points when running these stored procedures:

- You can only run the stored procedures from the Db2 command line tool, not in an SQL client application such as DBeaver.
- Before running the stored procedures, you must first connect to the `rdsadmin` database as the master user for your RDS for Db2 DB instance. In the following example, replace *`master_username`* and *`master_password`* with your own information.

```
db2 "connect to rdsadmin user master_user using master_password"
```

- The stored procedures return the ERR_MESSAGE parameter, which indicates whether the stored procedure ran successfully or not and why it didn't run successfully.

  Examples

  The following example indicates that the stored procedure ran successfully.

```
Parameter Name : ERR_MESSAGE
Parameter Value : -
Return Status = 0
```

  The following example indicates that the stored procedure didn't run successfully because the Amazon S3 bucket name used in the stored procedure wasn't valid.

```
Parameter Name : ERR_MESSAGE
Parameter Value : Invalid S3 bucket name
Return Status = -1006
```

Topics

- Managing databases
- Managing storage access
- Managing tablespaces

Granting and revoking privileges

The following stored procedures grant and revoke privileges for Amazon RDS for Db2 databases. To run these procedures, the master user must first connect to the `rdsadmin` database.

Topics

rdsadmin.create_role

Creates a role.

Syntax

```
db2 "call rdsadmin.create_role(
    'database_name',
    'role_name')"
```

Parameters

The following parameters are required:

database_name

The name of the database the command will run on. The data type is `varchar`.

role_name

The name of the role that you want to create. The data type is `varchar`.

Usage notes

For information about checking the status of creating a role, see rdsadmin.get_task_status.

Examples

The following example creates a role called `MY_ROLE` for database `DB2DB`.

```
db2 "call rdsadmin.create_role(
    'DB2DB',
    'MY_ROLE')"
```

rdsadmin.grant_role

Assigns a role to a role, user, or group.

Syntax

```
db2 "call rdsadmin.grant_role(
    ?,
    'database_name',
    'role_name',
    'grantee',
    'admin_option')"
```

Parameters

The following output parameter is required:

?

A parameter marker that outputs the unique identifier for the task. This parameter only accepts ?.

The following input parameters are required:

database_name

The name of the database the command will run on. The data type is varchar.

role_name

The name of the role that you want to create. The data type is varchar.

grantee

The role, user, or group to receive authorization. The data type is varchar. Valid values: ROLE, USER, GROUP, PUBLIC.

Format must be value followed by name. Separate multiple values and names with commas. Example: 'USER *user1*, *user2*, GROUP *group1*, *group2*'. Replace the names with your own information.

The following input parameter is optional:

admin_option

Specifies whether the grantee ROLE has DBADM authorization to assign roles. The data type is char. The default is N.

Usage notes

For information about checking the status of assigning a role, see rdsadmin.get_task_status.

Examples

The following example assigns a role called ROLE_TEST for database TESTDB to the role called role1, the user called user1, and the group called group1. ROLE_TEST is given admin authorization to assign roles.

```
db2 "call rdsadmin.grant_role(
    ?,
    'TESTDB',
    'ROLE_TEST',
    'ROLE role1, USER user1, GROUP group1',
    'Y')"
```

The following example assigns a role called ROLE_TEST for database TESTDB to PUBLIC. ROLE_TEST isn't given admin authorization to assign roles.

```
db2 "call rdsadmin.grant_role(
    ?,
    'TESTDB',
    'ROLE_TEST',
    'PUBLIC')"
```

rdsadmin.revoke_role

Revokes a role from a role, user, or group.

Syntax

```
db2 "call rdsadmin.revoke_role(
    ?,
    'database_name',
    'role_name',
    'grantee')"
```

Parameters

The following output parameter is required:

?

A parameter marker that outputs the unique identifier for the task. This parameter only accepts ?.

The following input parameters are required:

database_name

The name of the database the command will run on. The data type is varchar.

role_name

The name of the role that you want to revoke. The data type is varchar.

grantee

The role, user, or group to lose authorization. The data type is `varchar`. Valid values: `ROLE`, `USER`, `GROUP`, `PUBLIC`.

Format must be value followed by name. Separate multiple values and names with commas. Example: 'USER *user1*, *user2*, GROUP *group1*, *group2*'. Replace the names with your own information.

Usage notes

For information about checking the status of assigning a role, see rdsadmin.get_task_status.

Examples

The following example revokes a role called `ROLE_TEST` for database `TESTDB` from the role called `role1`, the user called `user1`, and the group called `group1`.

```
db2 "call rdsadmin.revoke_role(
    ?,
    'TESTDB',
    'ROLE_TEST',
    'ROLE role1, USER user1, GROUP group1')"
```

The following example revokes a role called `ROLE_TEST` for database `TESTDB` from `PUBLIC`.

```
db2 "call rdsadmin.revoke_role(
    ?,
    'TESTDB',
    'ROLE_TEST',
    'PUBLIC')"
```

rdsadmin.add_user

Adds a user to an authorization list.

Syntax

```
db2 "call rdsadmin.add_user(
    'username',
    'password',
```

```
    'group_name,group_name')"
```

Parameters

The following parameters are required:

username

A user's username. The data type is `varchar`.

password

A user's password. The data type is `varchar`.

The following parameter is optional:

group_name

The name of a group that you want to add the user to. The data type is `varchar`. The default is an empty string or null.

Usage notes

You can add a user to one or more groups by separating the group names with commas.

You can create a group when you create a new user, or when you add a group to an existing user. You can't create a group by itself.

> **Note**
>
> The maximum number of users that you can add by calling `rdsadmin.add_user` is 5,000.

For information about checking the status of adding a user, see rdsadmin.get_task_status.

Examples

The following example creates a user called `jorge_souza` and assigns the user to the groups called `sales` and `inside_sales`.

```
db2 "call rdsadmin.add_user(
```

```
    'jorge_souza',
    '*******',
    'sales,inside_sales')"
```

rdsadmin.change_password

Changes a user's password.

Syntax

```
db2 "call rdsadmin.change_password(
    'username',
    'new_password')"
```

Parameters

The following parameters are required:

username

A user's username. The data type is `varchar`.

new_password

A new password for the user. The data type is `varchar`.

Usage notes

For information about checking the status of changing a password, see rdsadmin.get_task_status.

Examples

The following example changes the password for `jorge_souza`.

```
db2 "call rdsadmin.change_password(
    'jorge_souza',
    '*******')"
```

rdsadmin.list_users

Lists users on an authorization list.

Syntax

```
db2 "call rdsadmin.list_users()"
```

Usage notes

For information about checking the status of listing users, see rdsadmin.get_task_status.

rdsadmin.remove_user

Removes user from authorization list.

Syntax

```
db2 "call rdsadmin.remove_user('username')"
```

Parameters

The following parameter is required:

username

A user's username. The data type is `varchar`.

Usage notes

For information about checking the status of removing a user, see rdsadmin.get_task_status.

Examples

The following example removes `jorge_souza` from being able to access databases in RDS for Db2 DB instances.

```
db2 "call rdsadmin.remove_user('jorge_souza')"
```

rdsadmin.add_groups

Adds groups to a user.

Syntax

```
db2 "call rdsadmin.add_groups(
```

```
    'username',
    'group_name,group_name')"
```

Parameters

The following parameters are required:

username

A user's username. The data type is `varchar`.

group_name

The name of a group that you want to add the user to. The data type is `varchar`. The default is an empty string.

Usage notes

You can add one or more groups to a user by separating the group names with commas. For information about checking the status of adding groups, see rdsadmin.get_task_status.

Examples

The following example adds the `direct_sales` and `b2b_sales` groups to user `jorge_souza`.

```
db2 "call rdsadmin.add_groups(
    'jorge_souza',
    'direct_sales,b2b_sales')"
```

rdsadmin.remove_groups

Removes groups from a user.

Syntax

```
db2 "call rdsadmin.remove_groups(
    'username',
    'group_name,group_name')"
```

Parameters

The following parameters are required:

username

A user's username. The data type is `varchar`.

group_name

The name of a group that you want to remove the user from. The data type is `varchar`.

Usage notes

You can remove one or more groups from a user by separating the group names with commas.

For information about checking the status of removing groups, see rdsadmin.get_task_status.

Examples

The following example removes the `direct_sales` and `b2b_sales` groups from user `jorge_souza`.

```
db2 "call rdsadmin.remove_groups(
    'jorge_souza',
    'direct_sales,b2b_sales')"
```

rdsadmin.dbadm_grant

Grants DBADM, ACCESSCTRL, or DATAACCESS authorization to a role, user, or group.

Syntax

```
db2 "call rdsadmin.dbadm_grant(
    ?,
    'database_name',
    'authorization',
    'grantee')"
```

Parameters

The following output parameter is required:

?

A parameter marker that outputs the unique identifier for the task. This parameter only accepts ?.

The following input parameters are required:

database_name

The name of the database the command will run on. The data type is varchar.

authorization

The type of authorization to grant. The data type is varchar. Valid values: DBADM, ACCESSCTRL, DATAACCESS.

Separate multiple types with commas.

grantee

The role, user, or group to receive authorization. The data type is varchar. Valid values: ROLE, USER, GROUP.

Format must be value followed by name. Separate multiple values and names with commas. Example: 'USER *user1*, *user2*, GROUP *group1*, *group2*'. Replace the names with your own information.

Usage notes

The role to receive access must exist.

For information about checking the status of granting database admin access, see rdsadmin.get_task_status.

Examples

The following example grants database admin access to the database named TESTDB for the role ROLE_DBA.

```
db2 "call rdsadmin.dbadm_grant(
    ?,
    'TESTDB',
    'DBADM',
    'ROLE ROLE_DBA')"
```

The following example grants database admin access to the database named TESTDB for user1 and group1.

```
db2 "call rdsadmin.dbadm_grant(
    ?,
    'TESTDB',
    'DBADM',
    'USER user1, GROUP group1')"
```

The following example grants database admin access to the database named TESTDB for user1, user2, group1, and group2.

```
db2 "call rdsadmin.dbadm_grant(
    ?,
    'TESTDB',
    'DBADM',
    'USER user1, user2, GROUP group1, group2')"
```

rdsadmin.dbadm_revoke

Revokes DBADM, ACCESSCTRL, or DATAACCESS authorization from a role, user, or group.

Syntax

```
db2 "call rdsadmin.dbadm_revoke(
    ?,
    'database_name',
    'authorization',
    'grantee')"
```

Parameters

The following output parameter is required:

?

The unique identifier for the task. This parameter only accepts ?.

The following input parameters are required:

database_name

The name of the database the command will run on. The data type is varchar.

authorization

The type of authorization to revoke. The data type is `varchar`. Valid values: `DBADM`, `ACCESSCTRL`, `DATAACCESS`.

Separate multiple types with commas.

grantee

The role, user, or group to revoke authorization from. The data type is `varchar`. Valid values: `ROLE`, `USER`, `GROUP`.

Format must be value followed by name. Separate multiple values and names with commas. Example: 'USER *user1*, *user2*, GROUP *group1*, *group2*'. Replace the names with your own information.

Usage notes

For information about checking the status of revoking database admin access, see rdsadmin.get_task_status.

Examples

The following example revokes database admin access to the database named `TESTDB` for the role `ROLE_DBA`.

```
db2 "call rdsadmin.dbadm_revoke(
    ?,
    'TESTDB',
    'DBADM',
    'ROLE ROLE_DBA')"
```

The following example revokes database admin access to the database named `TESTDB` for `user1` and `group1`.

```
db2 "call rdsadmin.dbadm_revoke(
    ?,
    'TESTDB',
    'DBADM',
    'USER user1, GROUP group1')"
```

The following example revokes database admin access to the database named TESTDB for user1, user2, group1, and group2.

```
db2 "call rdsadmin.dbadm_revoke(
    ?,
    'TESTDB',
    'DBADM',
    'USER user1, user2, GROUP group1, group2')"
```

Managing audit policies

The following stored procedures manage audit policies for Amazon RDS for Db2 databases that use audit logging. For more information, see the section called “Db2 audit logging”. To run these procedures, the master user must first connect to the `rdsadmin` database.

Topics

rdsadmin.configure_db_audit

Configures the audit policy for the RDS for Db2 database specified by *db_name*. If the policy you're configuring doesn't exist, calling this stored procedure creates it. If this policy does exist, calling this stored procedure modifies it with the parameter values that you provide.

Syntax

```
db2 "call rdsadmin.configure_db_audit(
    'db_name',
    'category',
    'category_setting',
    '?')"
```

Parameters

The following parameters are required.

db_name

The DB name of the RDS for Db2 database to configure the audit policy for. The data type is `varchar`.

category

The name of the category to configure this audit policy for. The data type is `varchar`. The following are valid values for this parameter:

- `ALL` – With `ALL`, Amazon RDS doesn't include the `CONTEXT`, `EXECUTE`, or `ERROR` categories.
- `AUDIT`

- CHECKING
- CONTEXT
- ERROR
- EXECUTE – You can configure this category with data or without data. With data means to also log input data values provided for any host variables and parameter markers. The default is without data. For more information, see the description of the *category_setting* parameter and the the section called “Examples”.
- OBJMAINT
- SECMAINT
- SYSADMIN
- VALIDATE

For more information about these categories, see the IBM Db2 documentation.

category_setting

The setting for the specified audit category. The data type is varchar.

The following table shows the valid category setting values for each category.

Category	Valid category settings
ALL	BOTH|FAILURE|SUCCESS|NONE
AUDIT	
CHECKING	
CONTEXT	
OBJMAINT	
SECMAINT	
SYSADMIN	
VALIDATE	
ERROR	AUDIT|NORMAL . The default is NORMAL.

Category	Valid category settings
EXECUTE	BOTH,WITH|BOTH,WITHOUT|FAILURE,WITH|FAILURE,WITHOUT|SUCCESS,WITH|SUCCESS,WITHOUT|NONE

Usage notes

Before you call `rdsadmin.configure_db_audit`, make sure the RDS for Db2 DB instance with the database you're configuring the audit policy for is associated with an option group that has the `DB2_AUDIT` option. For more information, see the section called “Setting up Db2 audit logging”.

After you configure the audit policy, you can check the status of the audit configuration for the database by following the steps in Check the audit configuration.

Specifying `ALL` for the `category` parameter doesn't include the `CONTEXT`, `EXECUTE`, or `ERROR` categories. To add these categories to your audit policy, call `rdsadmin.configure_db_audit` separately with each category that you want to add. For more information, see the section called “Examples”.

Examples

The following examples create or modify the audit policy for a database named `TESTDB`. In examples 1 through 5, if the `ERROR` category wasn't previously configured, this category is set to `NORMAL` (the default). To change that setting to `AUDIT`, follow Example 6: Specifying the ERROR category.

Example 1: Specifying the `ALL` category

```
db2 "call rdsadmin.configure_db_audit('TESTDB', 'ALL', 'BOTH', ?)"
```

In the example, the call configures the `AUDIT`, `CHECKING`, `OBJMAINT`, `SECMAINT`, `SYSADMIN`, and `VALIDATE` categories in the audit policy. Specifying `BOTH` means that both successful and failing events will be audited for each of these categories.

Example 2: Specifying the `EXECUTE` category with data

```
db2 "call rdsadmin.configure_db_audit('TESTDB', 'EXECUTE', 'SUCCESS,WITH', ?)"
```

In the example, the call configures the EXECUTE category in the audit policy. Specifying SUCCESS,WITH means that logs for this category will include only successful events, and will include input data values provided for host variables and parameter markers.

Example 3: Specifying the EXECUTE category without data

```
db2 "call rdsadmin.configure_db_audit('TESTDB', 'EXECUTE', 'FAILURE,WITHOUT', ?)"
```

In the example, the call configures the EXECUTE category in the audit policy. Specifying FAILURE,WITHOUT means that logs for this category will include only failing events, and won't include input data values provided for host variables and parameter markers.

Example 4: Specifying the EXECUTE category without status events

```
db2 "call rdsadmin.configure_db_audit('TESTDB', 'EXECUTE', 'NONE', ?)"
```

In the example, the call configures the EXECUTE category in the audit policy. Specifying NONE means that no events in this category will be audited.

Example 5: Specifying the OBJMAINT category

```
db2 "call rdsadmin.configure_db_audit('TESTDB', 'OBJMAINT', 'NONE', ?)"
```

In the example, the call configures the OBJMAINT category in the audit policy. Specifying NONE means that no events in this category will be audited.

Example 6: Specifying the ERROR category

```
db2 "call rdsadmin.configure_db_audit('TESTDB', 'ERROR', 'AUDIT', ?)"
```

In the example, the call configures the ERROR category in the audit policy. Specifying AUDIT means that all errors, including errors occurring within audit logging itself, are captured in the logs. The default error type is NORMAL. With NORMAL, errors generated by the audit are ignored and only the SQLCODEs for errors associated with the operation being performed are captured.

rdsadmin.disable_db_audit

Stops audit logging for the RDS for Db2 database specified by *db_name* and removes the audit policy configured for it.

> **Note**
>
> This stored procedure only removes audit policies that were configured by calling the section called "rdsadmin.configure_db_audit".

Syntax

```
db2 "call rdsadmin.disable_db_audit('db_name')"
```

Parameters

The following parameters are required.

db_name

The DB name of the RDS for Db2 database to disable audit logging for. The data type is `varchar`.

Usage notes

Calling `rdsadmin.disable_db_audit` doesn't disable audit logging for the RDS for Db2 DB instance. To disable audit logging at the DB instance level, remove the option group from the DB instance. For more information, see Disabling Db2 audit logging.

Examples

The following example disables audit logging for a database named `TESTDB`.

```
db2 "call rdsadmin.disable_db_audit('TESTDB')"
```

Managing buffer pools

The following stored procedures manage buffer pools for Amazon RDS for Db2 databases. To run these procedures, the master user must first connect to the `rdsadmin` database.

Topics

rdsadmin.create_bufferpool

Creates a buffer pool.

Syntax

```
db2 "call rdsadmin.create_bufferpool(
    'database_name',
    'buffer_pool_name',
    buffer_pool_size,
    'immediate',
    'automatic',
    page_size,
    number_block_pages,
    block_size)"
```

Parameters

The following parameters are required:

database_name

The name of the database to run the command on. The data type is `varchar`.

buffer_pool_name

The name of the buffer pool to create. The data type is `varchar`.

The following parameters are optional:

buffer_pool_size

The size of the buffer pool in number of pages. The data type is `integer`. The default is `-1`.

immediate

Specifies whether the command runs immediately. The data type is `char`. The default is `Y`.

automatic

Specifies whether to set the buffer pool to automatic. The data type is `char`. The default is `Y`.

page_size

The page size of the buffer pool. The data type is `integer`. Valid values: `4096`, `8192`, `16384`, `32768`. The default is `8192`.

number_block_pages

The number of block pages in the buffer pools. The data type is `integer`. The default is `0`.

block_size

The block size for the block pages. The data type is `integer`. Valid values: `2` to `256`. The default is `32`.

Usage notes

For information about checking the status of creating a buffer pool, see rdsadmin.get_task_status.

Examples

The following example creates a buffer pool called `BP8` for a database called `TESTDB` with default parameters, so the buffer pool uses an 8 KB page size.

```
db2 "call rdsadmin.create_bufferpool(
    'TESTDB',
    'BP8')"
```

The following example creates a buffer pool called `BP16` for a database called `TESTDB` that uses a 16 KB page size with an initial page count of 1,000 and is set to automatic. Db2 runs the command immediately. If you use an initial page count of -1, then Db2 will use automatic allocation of pages.

```
db2 "call rdsadmin.create_bufferpool(
    'TESTDB',
    'BP16',
    1000,
    'Y',
    'Y',
    16384)"
```

The following example creates a buffer pool called BP16 for a database called TESTDB. This buffer pool has a 16 KB page size with an initial page count of 10,000. Db2 runs the command immediately using 500 block pages with a block size of 512.

```
db2 "call rdsadmin.create_bufferpool(
    'TESTDB',
    'BP16',
    10000,
    'Y',
    'Y',
    16384,
    500,
    512)"
```

rdsadmin.alter_bufferpool

Alters a buffer pool.

Syntax

```
db2 "call rdsadmin.alter_bufferpool(
    'database_name',
    'buffer_pool_name',
    buffer_pool_size,
    'immediate',
    'automatic',
    change_number_blocks,
    number_block_pages,
    block_size)"
```

Parameters

The following parameters are required:

database_name

The name of the database to run the command on. The data type is `varchar`.

buffer_pool_name

The name of the buffer pool to alter. The data type is `varchar`.

buffer_pool_size

The size of the buffer pool in number of pages. The data type is `integer`.

The following parameters are optional:

immediate

Specifies whether the command runs immediately. The data type is `char`. The default is `Y`.

automatic

Specifies whether to set the buffer pool to automatic. The data type is `char`. The default is `N`.

change_number_blocks

Specifies whether there is a change to the number of block pages in the buffer pool. The data type is `char`. The default is `N`.

number_block_pages

The number of block pages in the buffer pools. The data type is `integer`. The default is `0`.

block_size

The block size for the block pages. The data type is `integer`. Valid values: 2 to 256. The default is 32.

Usage notes

For information about checking the status of altering a buffer pool, see rdsadmin.get_task_status.

Examples

The following example alters a buffer pool called BP16 for a database called TESTDB to non-automatic, and changes the size to 10,000 pages. Db2 runs this command immediately.

```
db2 "call rdsadmin.alter_bufferpool(
    'TESTDB',
    'BP16',
    10000,
    'Y',
    'N')"
```

rdsadmin.drop_bufferpool

Drops a buffer pool.

Syntax

```
db2 "call rdsadmin.drop_bufferpool(
    'database_name',
    'buffer_pool_name'"
```

Parameters

The following parameters are required:

database_name

The name of the database that the buffer pool belongs to. The data type is `varchar`.

buffer_pool_name

The name of the buffer pool to drop. The data type is `varchar`.

Usage notes

For information about checking the status of dropping a buffer pool, see rdsadmin.get_task_status.

Examples

The following example drops a buffer pool called BP16 for a database called TESTDB.

```
db2 "call rdsadmin.drop_bufferpool(
    'TESTDB',
    'BP16')"
```

Managing databases

The following stored procedures manage databases for Amazon RDS for Db2. To run these procedures, the master user must first connect to the `rdsadmin` database.

Topics

rdsadmin.create_database

Creates a database.

Syntax

```
db2 "call rdsadmin.create_database('database_name')"
```

Parameters

> **Note**
>
> This stored procedure doesn't validate the combination of required parameters. When you call rdsadmin.get_task_status, the user-defined function could return an error because of a combination of `database_codeset`, `database_territory`, and `database_collation`

that is not valid. For more information, see Choosing the code page, territory, and collation for your database in the IBM Db2 documentation.

The following parameter is required:

database_name

The name of the database to create. The data type is varchar.

The following parameters are optional:

database_page_size

The default page size of the database. Valid values: 4096, 8192, 16384, 32768. The data type is integer. The default is 8192.

Important

Amazon RDS supports write atomicity for 4 KiB, 8 KiB, and 16 KiB pages. In contrast, 32 KiB pages risk *torn writes*, or partial data being written to the desk. If you use 32 KiB pages, we recommend that you enable point-in-time recovery and automated backups. Otherwise, you run the risk of being unable to recover from torn pages. For more information, see the section called "Introduction to backups" and the section called "Point-in-time recovery".

database_code_set

The code set for the database. The data type is varchar. The default is UTF-8.

database_territory

The two-letter country code for the database. The data type is varchar. The default is US.

database_collation

The collation sequence that determines how character strings stored in the database are sorted and compared. The data type is varchar.

Valid values:

- COMPATIBILITY – An IBM Db2 Version 2 collation sequence.
- EBCDIC_819_037 – ISO Latin code page, collation; CCSID 037 (EBCDIC US English).
- EBCDIC_819_500 – ISO Latin code page, collation; CCSID 500 (EBCDIC International).
- EBCDIC_850_037 – ASCII Latin code page, collation; CCSID 037 (EBCDIC US English).
- EBCDIC_850_500 – ASCII Latin code page, collation; CCSID 500 (EBCDIC International).
- EBCDIC_932_5026 – ASCII Japanese code page, collation; CCSID 037 (EBCDIC US English).
- EBCDIC_932_5035 – ASCII Japanese code page, collation; CCSID 500 (EBCDIC International).
- EBCDIC_1252_037 – Windows Latin code page, collation; CCSID 037 (EBCDIC US English).
- EBCDIC_1252_500 – Windows Latin code page, collation; CCSID 500 (EBCDIC International).
- IDENTITY – Default collation. Strings are compared byte for byte.
- IDENTITY_16BIT – The Compatibility Encoding Scheme for UTF-16: 8-bit (CESU-8) collation sequence. For more information, see Unicode Technical Report #26 on the Unicode Consortium website.
- NLSCHAR – Only for use with the Thai code page (CP874).
- SYSTEM – If you use SYSTEM, the database uses the collation sequence automatically for database_codeset and database_territory.

The default is IDENTITY.

Additionally, RDS for Db2 supports the following groups of collations: language-aware-collation and locale-sensitive-collation. For more information, see Choosing a collation for a Unicode database in the IBM Db2 documentation.

database_autoconfigure_str

The AUTOCONFIGURE command syntax, for example, 'AUTOCONFIGURE APPLY DB'. The data type is varchar. The default is an empty string or null.

For more information, see AUTOCONFIGURE command in the IBM Db2 documentation.

Usage notes

You can create a database by calling rdsadmin.create_database if you didn't specify the name of the database when you created your RDS for Db2 DB instance by using either the Amazon RDS console or the AWS CLI. For more information, see Creating a DB instance.

Special considerations:

- The `CREATE DATABASE` command sent to the Db2 instance uses the `RESTRICTIVE` option.
- RDS for Db2 uses only `AUTOMATIC STORAGE`.
- RDS for Db2 uses the default values for `NUMSEGS` and `DFT_EXTENT_SZ`.
- RDS for Db2 uses storage encryption and doesn't support database encryption.

For more information about these considerations, see CREATE DATABASE command in the IBM Db2 documentation.

Before calling `rdsadmin.create_database`, you must connect to the `rdsadmin` database. In the following example, replace *`master_username`* and *`master_password`* with your RDS for Db2 DB instance information:

```
db2 connect to rdsadmin user master_username using master_password
```

For information about checking the status of creating a database, see rdsadmin.get_task_status.

Examples

The following example creates a database called `TESTJP` with a correct combination of the *`database_code_set`*, *`database_territory`*, and *`database_collation`* parameters for Japan:

```
db2 "call rdsadmin.create_database('TESTJP', 4096, 'IBM-437', 'JP', 'SYSTEM')"
```

rdsadmin.drop_database

Drops a database.

Syntax

```
db2 "call rdsadmin.drop_database('database_name')"
```

Parameters

The following parameter is required:

`database_name`

The name of the database to drop. The data type is `varchar`.

Usage notes

You can drop a database by calling `rdsadmin.drop_database` only if the following conditions are met:

- You didn't specify the name of the database when you created your RDS for Db2 DB instance by using either the Amazon RDS console or the AWS CLI. For more information, see Creating a DB instance.
- You created the database by calling the the section called “rdsadmin.create_database” stored procedure.
- You restored the database from an offline or backed-up image by calling the the section called “rdsadmin.restore_database” stored procedure.

Before calling `rdsadmin.drop_database`, you must connect to the `rdsadmin` database. In the following example, replace *`master_username`* and *`master_password`* with your RDS for Db2 DB instance information:

```
db2 connect to rdsadmin user master_username using master_password
```

For information about checking the status of dropping a database, see rdsadmin.get_task_status.

Examples

The following example drops a database called TESTDB:

```
db2 "call rdsadmin.drop_database('TESTDB')"
```

Response examples

If you pass an incorrect database name, then the stored procedure returns the following response example:

```
SQL0438N Application raised error or warning with diagnostic text: "Cannot
drop database. Database with provided name does not exist". SQLSTATE=99993
```

If you created the database using either the Amazon RDS console or the AWS CLI, then the stored procedure returns the following response example:

```
Return Status = 0
```

After receiving `Return Status = 0`, call the the section called “rdsadmin.get_task_status” stored procedure. A response similar to the following example explains the status:

```
1 ERROR DROP_DATABASE RDSDB 2023-10-10-16.33.03.744122 2023-10-10-16.33.30.143797 -
 2023-10-10-16.33.30.098857 Task execution has started.
2023-10-10-16.33.30.143797 Caught exception during executing task id 1, Aborting task.
Reason Dropping database created via rds CreateDBInstance api is not allowed.
Only database created using rdsadmin.create_database can be dropped
```

rdsadmin.update_db_param

Updates database parameters.

Syntax

```
db2 "call rdsadmin.update_db_param(
    'database_name',
    'parameter_to_modify',
    'changed_value')"
```

Parameters

The following parameters are required:

database_name

The name of the database to run the task for. The data type is `varchar`.

parameter_to_modify

The name of the parameter to modify. The data type is `varchar`. For more information, see Amazon RDS for Db2 parameters.

changed_value

The value to change the parameter value to. The data type is `varchar`.

Usage notes

For information about checking the status of updating database parameters, see rdsadmin.get_task_status.

Examples

The following example updates the `archretrydelay` parameter to `100` for a database called `TESTDB`:

```
db2 "call rdsadmin.update_db_param(
    'TESTDB',
    'archretrydelay',
    '100')"
```

The following example defers the validation of created objects on a database called `TESTDB` to avoid dependency checking:

```
db2 "call rdsadmin.update_db_param(
    'TESTDB',
    'auto_reval',
    'deferred_force')"
```

Response examples

If you attempt to modify a database configuration parameter that isn't supported or modifiable, then the stored procedure returns the following response example:

```
SQL0438N Application raised error or warning with diagnostic text: "Parameter
is either not supported or not modifiable to customers". SQLSTATE=99993
```

rdsadmin.set_configuration

Configures specific settings for the database.

Syntax

```
db2 "call rdsadmin.set_configuration(
    'name',
    'value')"
```

Parameters

The following parameters are required:

name

The name of the configuration setting. The data type is `varchar`.

value

The value for the configuration setting. The data type is `varchar`.

Usage notes

The following table shows the configuration settings that you can control with `rdsadmin.set_configuration`.

Name	Description
`RESTORE_DATABASE_NUM_BUFFERS`	The number of buffers to create during a restore operation. This value must be less than the total memory size of the DB instance class. If this setting isn't configured, Db2 determines the value to use during the restore operation. For more information, see the IBM Db2 documentation.
`RESTORE_DATABASE_PARALLELISM`	The number of buffer manipulators to create during a restore operation. This value must be less than double the number of vCPUs for the DB instance. If this setting isn't configured, Db2 determines the value to use during the restore operation. For more information, see the IBM Db2 documentation.

Examples

The following example sets the `RESTORE_DATABASE_PARALLELISM` configuration to `8`.

```
db2 "call rdsadmin.set_configuration(
    'RESTORE_DATABASE_PARALLELISM',
    '8')"
```

The following example sets the `RESTORE_DATABASE_NUM_BUFFERS` configuration to `150`.

```
db2 "call rdsadmin.set_configuration(
    'RESTORE_DATABASE_NUM_BUFFERS',
```

```
    '150')"
```

rdsadmin.show_configuration

Returns the current settings that you can set by using the stored procedure `rdsadmin.set_configuration`.

Syntax

```
db2 "call rdsadmin.show_configuration(
    'name')"
```

Parameters

The following parameter is optional:

name

The name of the configuration setting to return information about. The data type is `varchar`.

The following configuration names are valid:

- RESTORE_DATABASE_NUM_BUFFERS – The number of buffers to create during a restore operation.
- RESTORE_DATABASE_PARALLELISM – The number of buffer manipulators to create during a restore operation.

Usage notes

If you don't specify the name of a configuration setting, `rdsadmin.show_configuration` returns information for all configuration settings that you can set by using the stored procedure `rdsadmin.set_configuration`.

Examples

The following example returns information about the current `RESTORE_DATABASE_PARALLELISM` configuration.

```
db2 "call rdsadmin.show_configuration(
    'RESTORE_DATABASE_PARALLELISM')"
```

rdsadmin.restore_database

Restores a database.

Syntax

```
db2 "call rdsadmin.restore_database(
    ?,
    'database_name',
    's3_bucket_name',
    's3_prefix',
    restore_timestamp,
    'backup_type')"
```

Parameters

The following output parameter is required:

?

A parameter marker that outputs an error message. This parameter only accepts ?.

The following input parameters are required:

database_name

The name of the database to restore. This name must match the name of the database in the backup image. The data type is `varchar`.

s3_bucket_name

The name of the Amazon S3 bucket where your backup resides. The data type is `varchar`.

s3_prefix

The prefix to use for file matching during download. The data type is `varchar`.

If this parameter is empty, then all files in the Amazon S3 bucket will be downloaded. The following is an example prefix:

```
backupfolder/SAMPLE.0.rdsdb.DBPART000.20230615010101
```

restore_timestamp

The timestamp of the database backup image. The data type is `varchar`.

The timestamp is included in the backup file name. For example, `20230615010101` is the timestamp for the file name `SAMPLE.0.rdsdb.DBPART000.20230615010101.001`.

backup_type

The type of backup. The data type is `varchar`. Valid values: `OFFLINE`, `ONLINE`.

Use `ONLINE` for near-zero downtime migrations. For more information, see Near-zero downtime migration for Linux-based Db2 databases.

Usage notes

You can restore a database by calling `rdsadmin.restore_database` if you didn't specify the name of the database when you created your RDS for Db2 DB instance by using either the Amazon RDS console or the AWS CLI. For more information, see Creating a DB instance.

Before restoring a database, you must provision storage space for your RDS for Db2 DB instance that is equal to or greater than the sum of the size of your backup and the original Db2 database on disk. When you restore the backup, Amazon RDS extracts the backup file on your RDS for Db2 DB instance.

Each backup file must be 5 TB or smaller. If a backup file exceeds 5 TB, then you must split the backup file into smaller files.

To restore all files using the `rdsadmin.restore_database` stored procedure, don't include the file number suffix after the timestamp in the file names. For example, the *s3_prefix* `backupfolder/SAMPLE.0.rdsdb.DBPART000.20230615010101` restores the following files:

```
SAMPLE.0.rdsdb.DBPART000.20230615010101.001
SAMPLE.0.rdsdb.DBPART000.20230615010101.002
SAMPLE.0.rdsdb.DBPART000.20230615010101.003
SAMPLE.0.rdsdb.DBPART000.20230615010101.004
SAMPLE.0.rdsdb.DBPART000.20230615010101.005
```

To improve the performance of database restore operations, you can configure the number of buffers and buffer manipulators for RDS to use. To check the current configuration, use the

section called “rdsadmin.show_configuration”. To change the configuration, use the section called “rdsadmin.set_configuration”.

For information about checking the status of restoring your database, see rdsadmin.get_task_status.

To bring the database online and apply additional transaction logs after restoring the database, see rdsadmin.rollforward_database.

Examples

The following example restores an offline backup with a single file or multiple files that have the *s3_prefix* backupfolder/SAMPLE.0.rdsdb.DBPART000.20230615010101:

```
db2 "call rdsadmin.restore_database(
    ?,
    'SAMPLE',
    'amzn-s3-demo-bucket',
    'backupfolder/SAMPLE.0.rdsdb.DBPART000.20230615010101',
    20230615010101,
    'OFFLINE')"
```

rdsadmin.rollforward_database

Brings the database online and applies additional transaction logs after restoring a database by calling rdsadmin.restore_database.

Syntax

```
db2 "call rdsadmin.rollforward_database(
    ?,
    'database_name',
    's3_bucket_name',
    s3_prefix,
    'rollfoward_to_option',
    'complete_rollforward')"
```

Parameters

The following output parameter is required:

?

A parameter marker that outputs an error message. This parameter only accepts ?.

The following input parameters are required:

database_name

The name of the database to perform the operation on. The data type is varchar.

s3_bucket_name

The name of the Amazon S3 bucket where your backup resides. The data type is varchar.

s3_prefix

The prefix to use for file matching during download. The data type is varchar.

If this parameter is empty, then all files in the S3 bucket will be downloaded. The following example is an example prefix:

```
backupfolder/SAMPLE.0.rdsdb.DBPART000.20230615010101
```

The following input parameters are optional:

rollforward_to_option

The point to which you want to roll forward. The data type is varchar. Valid values: END_OF_LOGS, END_OF_BACKUP. The default is END OF LOGS.

complete_rollforward

Specifies whether to complete the roll-forward process. The data type is varchar. The default is TRUE.

If TRUE, then after completion, the database is online and accessible. If FALSE, then the database remains in a ROLL-FORWARD PENDING state.

Usage notes

After you call rdsadmin.restore_database, you must call `rollforward_database` to apply archive logs from an S3 bucket. You can also use this stored procedure to restore additional transaction logs after calling `rdsadmin.restore_database`.

If you set `complete_rollforward` to `FALSE`, then your database is in a `ROLL-FORWARD PENDING` state and offline. To bring the database online, you must call rdsadmin.complete_rollforward.

For information about checking the status of rolling forward the database, see rdsadmin.get_task_status.

Examples

The following example rolls forward to an online backup of the database with transaction logs and then brings the database online:

```
db2 "call rdsadmin.rollforward_database(
    ?,
    null,
    null,
    'END_OF_LOGS',
    'TRUE')"
```

The following example rolls forward to an online backup of the database without transaction logs, and then brings the database online:

```
db2 "call rdsadmin.rollforward_database(
    ?,
    'TESTDB',
    'amzn-s3-demo-bucket',
    'logsfolder/,
    'END_OF_BACKUP',
    'TRUE')"
```

The following example rolls forward to an online backup of the database with transaction logs, and then doesn't bring the database online:

```
db2 "call rdsadmin.rollforward_database(
```

```
    ?,
    'TESTDB',
    null,
    'onlinebackup/TESTDB',
    'END_OF_LOGS',
    'FALSE')"
```

The following example rolls forward to an online backup of the database with additional transaction logs, and then doesn't bring the database online:

```
db2 "call rdsadmin.rollforward_database(
    ?,
    'TESTDB',
    'amzn-s3-demo-bucket',
    'logsfolder/S0000155.LOG',
    'END_OF_LOGS',
    'FALSE')"
```

rdsadmin.complete_rollforward

Brings database online from a `ROLL-FORWARD PENDING` state.

Syntax

```
db2 "call rdsadmin.complete_rollforward(
    ?,
    'database_name')"
```

Parameters

The following output parameter is required:

?

A parameter marker that outputs an error message. This parameter only accepts `?`.

The following input parameter is required:

database_name

The name of the database that you want to bring online. The data type is `varchar`.

Usage notes

If you called rdsadmin.rollforward_database with `complete_rollforward` set to `FALSE`, then your database is in a `ROLL-FORWARD PENDING` state and offline. To complete the roll-forward process and bring the database online, call `rdsadmin.complete_rollforward`.

For information about checking the status of completing the roll-forward process, see rdsadmin.get_task_status.

Examples

The following example brings the TESTDB database online:

```
db2 "call rdsadmin.complete_rollfoward(
    ?,
    'TESTDB')"
```

rdsadmin.db2pd_command

Collects information about an RDS for Db2 database.

Syntax

```
db2 "call rdsadmin.db2pd_command('db2pd_cmd')"
```

Parameters

The following input parameter is required:

db2pd_cmd

The name of the db2pd command that you want to run. The data type is `varchar`.

The parameter must start with a hyphen. For a list of parameters, see db2pd - Monitor and troubleshoot Db2 database command in the IBM Db2 documentation.

The following options aren't supported:

- `-addnode`
- `-alldatabases`
- `-alldbp`
- `-alldbs`

- `-allmembers`
- `-alm_in_memory`
- `-cfinfo`
- `-cfpool`
- `-command`
- `-dbpartitionnum`
- `-debug`
- `-dump`
- `-everything`
- `-file | -o`
- `-ha`
- `-interactive`
- `-member`
- `-pages`

  > **Note**
  >
  > `-pages summary` is supported.

- `-pdcollection`
- `-repeat`
- `-stack`
- `-totalmem`

The `file` suboption isn't supported, for example, `db2pd -db testdb -tcbstats file=tcbstat.out`.

The use of `stacks` isn't supported, for example, `db2pd -edus interval=5 top=10 stacks`.

Usage notes

This stored procedure gathers information that can help with monitoring and troubleshooting RDS for Db2 databases.

The stored procedure uses the IBM db2pd utility to run various commands. The db2pd utility requires SYSADM authorization, which the RDS for Db2 master user doesn't have. However, with the Amazon RDS stored procedure, the master user is able to use the utility to run various commands. For more information about the utility, see db2pd - Monitor and troubleshoot Db2 database command in the IBM Db2 documentation.

The output is restricted to a maximum of 2 GB.

For information about checking the status of collecting information about the database, see rdsadmin.get_task_status.

Examples

The following example returns the uptime of an RDS for Db2 DB instance:

```
db2 "call rdsadmin.db2pd_command('-')"
```

The following example returns the uptime of a database called TESTDB:

```
db2 "call rdsadmin.db2pd_command('-db TESTDB -')"
```

The following example returns the memory usage of an RDS for Db2 DB instance:

```
db2 "call rdsadmin.db2pd_command('-dbptnmem')"
```

The following example returns the memory sets of an RDS for Db2 DB instance and a database called TESTDB:

```
db2 "call rdsadmin.db2pd_command('-inst -db TESTDB -memsets')"
```

rdsadmin.force_application

Forces applications off of an RDS for Db2 database.

Syntax

```
db2 "call rdsadmin.force_application(
    ?,
```

```
    'applications')"
```

Parameters

The following output parameter is required:

?

A parameter marker that outputs an error message. This parameter only accepts ?.

The following input parameter is required:

applications

The applications that you want to force off of an RDS for Db2 database. The data type is `varchar`. Valid values: `ALL` or *application_handle*.

Separate the names of multiple applications with commas. Example: '*application_handle_1*, *application_handle_2*'.

Usage notes

This stored procedure forces all applications off of a database so you can perform maintenance.

The stored procedure uses the IBM `FORCE APPLICATION` command. The `FORCE APPLICATION` command requires `SYSADM`, `SYSMAINT`, or `SYSCTRL` authorization, which the RDS for Db2 master user doesn't have. However, with the Amazon RDS stored procedure, the master user is able to use the command. For more information, see FORCE APPLICATION command in the IBM Db2 documentation.

For information about checking the status of forcing applications off of a database, see rdsadmin.get_task_status.

Examples

The following example forces all applications off of an RDS for Db2 database:

```
db2 "call rdsadmin.force_application(
    ?,
```

```
    'ALL')"
```

The following example forces application handles 9991, 8891, and 1192 off of an RDS for Db2 database:

```
db2 "call rdsadmin.force_application(
    ?,
    '9991, 8891, 1192')"
```

rdsadmin.set_archive_log_retention

Configures the amount of time (in hours) to retain archive log files for the specified RDS for Db2 database.

Syntax

```
db2 "call rdsadmin.set_archive_log_retention(
    ?,
    'database_name',
    'archive_log_retention_hours')"
```

Parameters

The following output parameter is required:

?

A parameter marker that outputs an error message. This parameter only accepts ?.

The following input parameters are required:

database_name

The name of the database to configure archive log retention for. The data type is `varchar`.

archive_log_retention_hours

The number of hours to retain the archive log files. The data type is `smallint`. The default is `0`, and the maximum is 168 (7 days).

If the value is `0`, Amazon RDS doesn't retain the archive log files.

Usage notes

By default, RDS for Db2 retains logs for 5 minutes. We recommend that if you use replication tools such as AWS DMS for change data capture (CDC) or IBM Q Replication, you set log retention in those tools for longer than 5 minutes.

You can view the current archive log retention setting by calling the section called "rdsadmin.show_archive_log_retention".

You can't configure the archive log retention setting on the `rdsadmin` database.

Examples

The following example sets the archive log retention time for a database called `TESTDB` to 24 hours.

```
db2 "call rdsadmin.set_archive_log_retention(
    ?,
    'TESTDB',
    '24')"
```

The following example disables archive log retention for a database called `TESTDB`.

```
db2 "call rdsadmin.set_archive_log_retention(
    ?,
    'TESTDB',
    '0')"
```

rdsadmin.show_archive_log_retention

Returns the current archive log retention setting for the specified database.

Syntax

```
db2 "call rdsadmin.show_archive_log_retention(
    ?,
    'database_name')"
```

Parameters

The following output parameter is required:

?

A parameter marker that outputs an error message. This parameter only accepts ?.

The following input parameter is required:

database_name

The name of the database to show the archive log retention setting for. The data type is `varchar`.

Examples

The following example shows the archive log retention setting for a database called `TESTDB`.

```
db2 "call rdsadmin.show_archive_log_retention(
    ?
    'TESTDB')"
```

Managing storage access

The following stored procedures manage storage access for RDS for Db2 databases that use Amazon S3 for migrating data. For more information, see the section called "Migration by loading data from Amazon S3".

Topics

- rdsadmin.catalog_storage_access
- rdsadmin.uncatalog_storage_access

rdsadmin.catalog_storage_access

Catalogs a storage alias for accessing an Amazon S3 bucket with Db2 data files.

Syntax

```
db2 "call rdsadmin.catalog_storage_access(
    ?,
    'alias',
    's3_bucket_name',
    'grantee_type',
    'grantee'
    )"
```

Parameters

The following output parameter is required:

?

A parameter marker that outputs an error message. The datatype is `varchar`.

The following input parameters are required:

alias

The alias name for accessing remote storage in an Amazon S3 bucket. The datatype is `varchar`.

s3_bucket_name

The name of the Amazon S3 bucket where your data resides. The data type is `varchar`.

grantee_type

The type of grantee to receive authorization. The data type is `varchar`. Valid values: USER, GROUP.

grantee

The user or group to receive authorization. The data type is `varchar`.

Usage notes

Amazon RDS includes the cataloged alias in the IAM role that you added to your RDS for Db2 DB instance. If you remove the IAM role from your DB instance, then Amazon RDS deletes the alias. For more information, see the section called “Migration by loading data from Amazon S3”.

For information about checking the status of cataloging your alias, see rdsadmin.get_task_status.

Examples

The following example registers an alias called SAMPLE. The user `jorge_souza` is granted access to the Amazon S3 bucket called `amzn-s3-demo-bucket`.

```
db2 "call rdsadmin.catalog_storage_access(
    ?,
    'SAMPLE',
    'amzn-s3-demo-bucket',
    'USER',
    'jorge_souza')"
```

rdsadmin.uncatalog_storage_access

Removes a storage access alias.

Syntax

```
db2 "call rdsadmin.uncatalog_storage_access(
    ?,
    'alias')"
```

Parameters

The following output parameter is required:

?

A parameter marker that outputs an error message. The datatype is `varchar`.

The following input parameter is required:

alias

The name of the storage alias to remove. The datatype is `varchar`.

Usage notes

For information about checking the status of removing your alias, see rdsadmin.get_task_status.

Examples

The following example removes an alias called SAMPLE. This alias no longer provides access to the Amazon S3 bucket it was associated with.

```
db2 "call rdsadmin.uncatalog_storage_access(
    ?,
    'SAMPLE')"
```

Managing tablespaces

The following stored procedures manage tablespaces for Amazon RDS for Db2 databases. To run these procedures, the master user must first connect to the `rdsadmin` database.

Topics

rdsadmin.create_tablespace

Creates a tablespace.

Syntax

```
db2 "call rdsadmin.create_tablespace(
    'database_name',
    'tablespace_name',
    'buffer_pool_name',
    tablespace_page_size,
    tablespace_initial_size,
    tablespace_increase_size,
    'tablespace_type')"
```

Parameters

The following parameters are required:

database_name

The name of the database to create the tablespace in. The data type is `varchar`.

tablespace_name

The name of the tablespace to create. The data type is `varchar`.

The tablespace name has the following restrictions:

- It can't be the same as the name of an existing tablespace in this database.

- It can only contain the characters _$#@a-zA-Z0-9.
- It can't start with _ or $.
- It can't start with SYS.

The following parameters are optional:

buffer_pool_name

The name of the buffer pool to assign the tablespace. The data type is varchar. The default is an empty string.

> **Important**
>
> You must already have a buffer pool of the same page size to associate with the tablespace.

tablespace_page_size

The page size of the tablespace in bytes. The data type is integer. Valid values: 4096, 8192, 16384, 32768. The default is the page size used when you created the database by calling rdsadmin.create_database.

> **Important**
>
> Amazon RDS supports write atomicity for 4 KiB, 8 KiB, and 16 KiB pages. In contrast, 32 KiB pages risk torn writes, or partial data being written to the desk. If you use 32 KiB pages, we recommend that you enable point-in-time recovery and automated backups. Otherwise, you run the risk of being unable to recover from torn pages. For more information, see the section called “Introduction to backups” and the section called “Point-in-time recovery”.

tablespace_initial_size

The initial size of the tablespace in kilobytes (KB). The data type is integer. Valid values: 48 or higher. The default is null.

If you don't set a value, Db2 sets an appropriate value for you.

> **Note**
>
> This parameter isn't applicable for temporary tablespaces because the system manages temporary tablespaces.

tablespace_increase_size

The percentage by which to increase the tablespace when it becomes full. The data type is `integer`. Valid values: 1–100. The default is null.

If you don't set a value, Db2 sets an appropriate value for you.

> **Note**
>
> This parameter isn't applicable for temporary tablespaces because the system manages temporary tablespaces.

tablespace_type

The type of the tablespace. The data type is `char`. Valid values: U (for user data), T (for user temporary data), or S (for system temporary data). The default is U.

Usage notes

RDS for Db2 always creates a large database for data.

For information about checking the status of creating a tablespace, see rdsadmin.get_task_status.

Examples

The following example creates a tablespace called SP8 and assigns a buffer pool called BP8 for a database called TESTDB. The tablespace has an initial tablespace page size of 4,096 bytes, an initial tablespace of 1,000 KB, and a table size increase set to 50%.

```
db2 "call rdsadmin.create_tablespace(
    'TESTDB',
    'SP8',
    'BP8',
```

```
    4096,
    1000,
    50)"
```

The following example creates a temporary tablespace called SP8. It assigns a buffer pool called BP8 that is 8 KiB in size for a database called TESTDB.

```
db2 "call rdsadmin.create_tablespace(
    'TESTDB',
    'SP8',
    'BP8',
    8192,
    NULL,
    NULL,
    'T')"
```

rdsadmin.alter_tablespace

Alters a tablespace.

Syntax

```
db2 "call rdsadmin.alter_tablespace(
    'database_name',
    'tablespace_name',
    'buffer_pool_name',
    tablespace_increase_size,
    'max_size',
    'reduce_max',
    'reduce_stop',
    'reduce_value',
    'lower_high_water',
    'lower_high_water_stop',
    'switch_online')"
```

Parameters

The following parameters are required:

database_name

The name of the database that uses the tablespace. The data type is `varchar`.

tablespace_name

The name of the tablespace to alter. The data type is varchar.

The following parameters are optional:

buffer_pool_name

The name of the buffer pool to assign the tablespace. The data type is varchar. The default is an empty string.

> **Important**
>
> You must already have a buffer pool of the same page size to associate with the tablespace.

tablespace_increase_size

The percentage by which to increase the tablespace when it becomes full. The data type is integer. Valid values: 1–100. The default is 0.

max_size

The maximum size for the tablespace. The data type is varchar. Valid values: *integer* K | M | G, or NONE. The default is NONE.

reduce_max

Specifies whether to reduce the high water mark to its maximum limit. The data type is char. The default is N.

reduce_stop

Specifies whether to interrupt a previous reduce_max or reduce_value command. The data type is char. The default is N.

reduce_value

The number or percentage to reduce the tablespace high water mark by. The data type is varchar. Valid values: *integer* K| M | G, or 1–100. The default is N.

lower_high_water

Specifies whether to run the ALTER TABLESPACE LOWER HIGH WATER MARK command. The data type is char. The default is N.

lower_high_water_stop

Specifies whether to run the ALTER TABLESPACE LOWER HIGH WATER MARK STOP command. The data type is char. The default is N.

switch_online

Specifies whether to run the ALTER TABLESPACE SWITCH ONLINE command. The data type is char. The default is N.

Usage notes

The optional parameters reduce_max, reduce_stop, reduce_value, lower_high_water, lower_high_water_stop, and switch_online are mutually exclusive. You can't combine them with any other optional parameter, such as buffer_pool_name, in the rdsadmin.alter_tablespace command. If you combine these parameters with any other optional parameter in the rdsadmin.alter_tablespace command, then when you run rdsadmin.get_task_status, Db2 will return an error like the following:

```
DB21034E  The command was processed as an SQL statement because it was not a valid
 Command Line Processor command.  During SQL processing it returned:
SQL1763N  Invalid ALTER TABLESPACE statement for table space "TBSP_TEST" due to reason
 "12"
```

For information about checking the status of altering a tablespace, see rdsadmin.get_task_status.

Examples

The following example alters a tablespace called SP8 and assigns a buffer pool called BP8 for a database called TESTDB to lower the high water mark.

```
db2 "call rdsadmin.alter_tablespace(
    'TESTDB',
    'SP8',
    'BP8',
    NULL,
```

```
    NULL,
    'Y')"
```

The following example runs the REDUCE MAX command on a tablespace called TBSP_TEST in the database TESTDB.

```
db2 "call rdsadmin.alter_tablespace(
    'TESTDB',
    'TBSP_TEST',
    NULL,
    NULL,
    NULL,
    'Y')"
```

The following example runs the REDUCE STOP command on a tablespace called TBSP_TEST in the database TESTDB.

```
db2 "call rdsadmin.alter_tablespace(
    'TESTDB',
    'TBSP_TEST',
    NULL,
    NULL,
    NULL,
    NULL,
    'Y')"
```

rdsadmin.rename_tablespace

Renames a tablespace.

Syntax

```
db2 "call rdsadmin.rename_tablespace(
    ?,
    'database_name',
    'source_tablespace_name',
    'target_tablespace_name')"
```

Parameters

The following parameters are required:

?

A parameter marker that outputs an error message. This parameter only accepts ?.

database_name

The name of the database that the tablespace belongs to. The data type is `varchar`.

source_tablespace_name

The name of the tablespace to rename. The data type is `varchar`.

target_tablespace_name

The new name of the tablespace. The data type is `varchar`.

The new name has the following restrictions:

- It can't be the same as the name of an existing tablespace.
- It can only contain the characters `_$#@a-zA-Z0-9`.
- It can't start with _ or $.
- It can't start with SYS.

Usage notes

For information about checking the status of renaming a tablespace, see rdsadmin.get_task_status.

You can't rename tablespaces that belong to the `rdsadmin` database.

Examples

The following example renames a tablespace called SP8 to SP9 in a database called TESTDB.

```
db2 "call rdsadmin.rename_tablespace(
    ?,
    'TESTDB',
    'SP8'.
    'SP9')"
```

rdsadmin.drop_tablespace

Drops a tablespace.

Syntax

```
db2 "call rdsadmin.drop_tablespace(
    'database_name',
    'tablespace_name')"
```

Parameters

The following parameters are required:

database_name

The name of the database that the tablespace belongs to. The data type is `varchar`.

tablespace_name

The name of the tablespace to drop. The data type is `varchar`.

Usage notes

For information about checking the status of dropping a tablespace, see rdsadmin.get_task_status.

Examples

The following example drops a tablespace called SP8 from a database called TESTDB.

```
db2 "call rdsadmin.drop_tablespace(
    'TESTDB',
    'SP8')"
```

Amazon RDS for Db2 user-defined function reference

These topics describe user-defined functions that are available for Amazon RDS DB instances running the Db2 engine.

Topics

Checking a task status

You can use the `rdsadmin.get_task_status` user-defined function to check the status of the following tasks for Amazon RDS for Db2. This list is not exhaustive.

- Creating, altering, or dropping a buffer pool
- Creating, altering, or dropping a tablespace
- Creating or dropping a database
- Restoring a database backup from Amazon S3
- Rolling forward database logs from Amazon S3

rdsadmin.get_task_status

Returns the status of a task.

Syntax

```
db2 "select task_id, task_type, database_name, lifecycle,
    varchar(bson_to_json(task_input_params), 500) as task_params,
    cast(task_output as varchar(500)) as task_output
    from table(rdsadmin.get_task_status(task_id,'database_name','task_type'))"
```

Parameters

The following parameters are optional. If you do not provide any parameters, the user-defined function returns the status of all tasks for all databases. Amazon RDS retains task history for 35 days.

`task_id`

The ID of the task being run. This ID is returned when you run a task. Default: `0`.

`database_name`

The name of the database for which the task is being run.

`task_type`

The type of the task to query. Valid values: `ADD_GROUPS`, `ADD_USER`, `ALTER_BUFFERPOOL`, `ALTER_TABLESPACE`, `CHANGE_PASSWORD`, `COMPLETE_ROLLFORWARD`, `CREATE_BUFFERPOOL`,

CREATE_DATABASE, CREATE_ROLE, CREATE_TABLESPACE, DROP_BUFFERPOOL, DROP_DATABASE, DROP_TABLESPACE, LIST_USERS, REMOVE_GROUPS, REMOVE_USER, RESTORE_DB, ROLLFORWARD_DB_LOG, ROLLFORWARD_STATUS, UPDATE_DB_PARAM.

Examples

The following example displays the columns returned when `rdsadmin.get_task_status` is called.

```
db2 "describe select * from table(rdsadmin.get_task_status())"
```

The following example lists the status of all tasks.

```
db2 "select task_id, task_type, database_name, lifecycle,
    varchar(bson_to_json(task_input_params), 500) as task_params,
    cast(task_output as varchar(500)) as task_output
    from table(rdsadmin.get_task_status(null,null,null))"
```

The following example lists the status of a specific task.

```
db2 "select task_id, task_type, database_name,
    varchar(bson_to_json(task_input_params), 500) as task_params
    from table(rdsadmin.get_task_status(1,null,null))"
```

The following example lists the status of a specific task and database.

```
db2 "select task_id, task_type, database_name,
    varchar(bson_to_json(task_input_params), 500) as task_params
    from table(rdsadmin.get_task_status(2,'SAMPLE',null))"
```

The following example lists the status of all ADD_GROUPS tasks.

```
db2 "select task_id, task_type, database_name,
    varchar(bson_to_json(task_input_params), 500) as task_params
    from table(rdsadmin.get_task_status(null,null,'add_groups'))"
```

The following example lists the status of all tasks for a specific database.

```
db2 "select task_id, task_type, database_name,
```

```
    varchar(bson_to_json(task_input_params), 500) as task_params
    from table(rdsadmin.get_task_status(null,'testdb', null))"
```

The following example outputs the JSON values as columns.

```
db2 "select varchar(r.task_type,25) as task_type, varchar(r.lifecycle,10) as lifecycle,
 r.created_at, u.* from
    table(rdsadmin.get_task_status(null,null,'restore_db')) as r,
 json_table(r.task_input_params, 'strict $' columns(s3_prefix varchar(500)
    null on empty, s3_bucket_name varchar(500) null on empty) error on error ) as U"
```

Response

The `rdsadmin.get_task_status` user-defined function returns the following columns:

`TASK_ID`

The ID of the task.

`TASK_TYPE`

Depends on the input parameters.

- `ADD_GROUPS` – Adds groups.
- `ADD_USER` – Adds a user.
- `ALTER_BUFFERPOOL` – Alters a buffer pool.
- `ALTER_TABLESPACE` – Alters a tablespace.
- `CHANGE_PASSWORD` – Changes a user's password.
- `COMPLETE_ROLLFORWARD` – Completes an `rdsadmin.rollforward_database` task and activates a database.
- `CREATE_BUFFERPOOL` – Creates a buffer pool.
- `CREATE_DATABASE` – Creates a database.
- `CREATE_ROLE` – Creates a Db2 role for a user.
- `CREATE_TABLESPACE` – Creates a tablespace.
- `DROP_BUFFERPOOL` – Drops a buffer pool.
- `DROP_DATABASE` – Drops a database.
- `DROP_TABLESPACE` – Drops a tablespace.

- LIST_USERS – Lists all users.
- REMOVE_GROUPS – Removes groups.
- REMOVE_USER – Removes a user.
- RESTORE_DB – Restores a full database.
- ROLLFORWARD_DB_LOG – Performs an rdsadmin.rollforward_database task on database logs.
- ROLLFORWARD_STATUS – Returns the status of an rdsadmin.rollforward_database task.
- UPDATE_DB_PARAM – Updates the data parameters.

DATABASE_NAME

The name of the database with which the task is associated.

COMPLETED_WORK_BYTES

The number of bytes restored by the task.

DURATION_MINS

The time taken to complete the task.

LIFECYCLE

The status of the task. Possible statuses:

- CREATED – After a task is submitted to Amazon RDS, Amazon RDS sets the status to CREATED.
- IN_PROGRESS – After a task starts, Amazon RDS sets the status to IN_PROGRESS. It can take up to 5 minutes for a status to change from CREATED to IN_PROGRESS.
- SUCCESS – After a task completes, Amazon RDS sets the status to SUCCESS.
- ERROR – If a restore task fails, Amazon RDS sets the status to ERROR. For more information about the error, see TASK_OUPUT.

CREATED_BY

The authid that created the command.

CREATED_AT

The date and time when the task was created.

LAST_UPDATED_AT

The data and time when the task was last updated.

TASK_INPUT_PARAMS

The parameters differ based on the task type. All of the input parameters are represented as a JSON object. For example, the JSON keys for the RESTORE_DB task are the following:

- DBNAME
- RESTORE_TIMESTAMP
- S3_BUCKET_NAME
- S3_PREFIX

TASK_OUTPUT

Additional information about the task. If an error occurs during native restore, this column includes information about the error.

Response examples

The following response example shows that a database called TESTJP was successfully created. For more information, see the the section called “rdsadmin.create_database” stored procedure.

```
`1 SUCCESS CREATE_DATABASE RDSDB 2023-10-24-18.32.44.962689 2023-10-24-18.34.50.038523
 1 TESTJP { "CODESET" : "IBM-437", "TERRITORY" : "JP", "COLLATION" : "SYSTEM",
 "AUTOCONFIGURE_CMD" : "", "PAGESIZE" : 4096 }
2023-10-24-18.33.30.079048 Task execution has started.

2023-10-24-18.34.50.038523 Task execution has completed successfully`.
```

The following response example explains why dropping a database failed. For more information, see the the section called “rdsadmin.drop_database” stored procedure.

```
1 ERROR DROP_DATABASE RDSDB 2023-10-10-16.33.03.744122 2023-10-10-16.33.30.143797 -
 2023-10-10-16.33.30.098857 Task execution has started.
2023-10-10-16.33.30.143797 Caught exception during executing task id 1, Aborting task.
Reason Dropping database created via rds CreateDBInstance api is not allowed.
Only database created using rdsadmin.create_database can be dropped
```

The following response example shows the successful restoration of a database. For more information, see the the section called “rdsadmin.restore_database” stored procedure.

```
1 RESTORE_DB  SAMPLE  SUCCESS

{ "S3_BUCKET_NAME" : "amzn-s3-demo-bucket", "S3_PREFIX" :

Troubleshooting for Amazon RDS for Db2

The following content can help you troubleshoot issues that you encounter with RDS for Db2.

For more information about general Amazon RDS troubleshooting issues, see Troubleshooting for Amazon RDS.

Topics

File I/O error

When you use the LOAD command, you might encounter a file I/O error. For example, you run the following LOAD command:

```
db2 "call sysproc.admin_cmd('load from "DB2REMOTE://s3test//public/datapump/t6.del" of
 del lobs from "DB2REMOTE://s3test/public/datapump/" modified by lobsinfile MESSAGES ON
 SERVER insert INTO RDSDB.t6 nonrecoverable ')"
```

The LOAD command returns the following message:

```
 Result set 1
 --------------

 ROWS_READ            ROWS_SKIPPED         ROWS_LOADED          ROWS_REJECTED
ROWS_DELETED         ROWS_COMMITTED       ROWS_PARTITIONED     NUM_AGENTINFO_ENTRIES
MSG_RETRIEVAL

MSG_REMOVAL
 -------------------- -------------------- -------------------- --------------------
-------------------- -------------------- -------------------- --------------------
--------------------------------------------------------------------------------------
--------------------------------------------------------------------------------------
                    -                    -                    -                    -
                   -                    -                    -                    -
SELECT SQLCODE, MSG FROM TABLE(SYSPROC.ADMIN_GET_MSGS('1594987316_285548770')) AS MSG
```

```
                                                                                CALL
 SYSPROC.ADMIN_REMOVE_MSGS('1594987316_285548770')

  1 record(s) selected.

  Return Status = 0

SQL20397W  Routine "SYSPROC.ADMIN_CMD" execution has completed, but at least
one error, "SQL1652", was encountered during the execution. More information
is available.  SQLSTATE=01H52
```

To view the error message, you run the SQL command as suggested in the previous response. `SELECT SQLCODE, MSG FROM TABLE(SYSPROC.ADMIN_GET_MSGS('1594987316_285548770')) AS MSG` returns the following message:

```
SQLCODE   MSG
---------
 ------------------------------------------------------------------------------------------
SQL2025N  An I/O error occurred. Error code “438”. Media on which this error occurred:
 “DB2REMOTE://s3test//public/datapump/t6.del”

SQL3500W The utility is beginning the LOAD phase at time “07/05/2024 21:21:48.082954”

SQL1652N File I/O error occurred
```

The Db2 diagnostic logs contain a log file similar to the following one:

```
2024-07-05-21.20.09.440609+000 I1191321E864          LEVEL: Error
PID     : 2710                 TID : 139619509200640 PROC : db2sysc 0

```

This file I/O error could result from a number of different scenarios. For example, your RDS for Db2 DB instance and your Amazon S3 bucket might not use the same VPC or be in the same AWS Region. Regardless of the scenario, the solution is the same: You need to create a VPC gateway endpoint, and then add outbound rules to your security group.

Topics

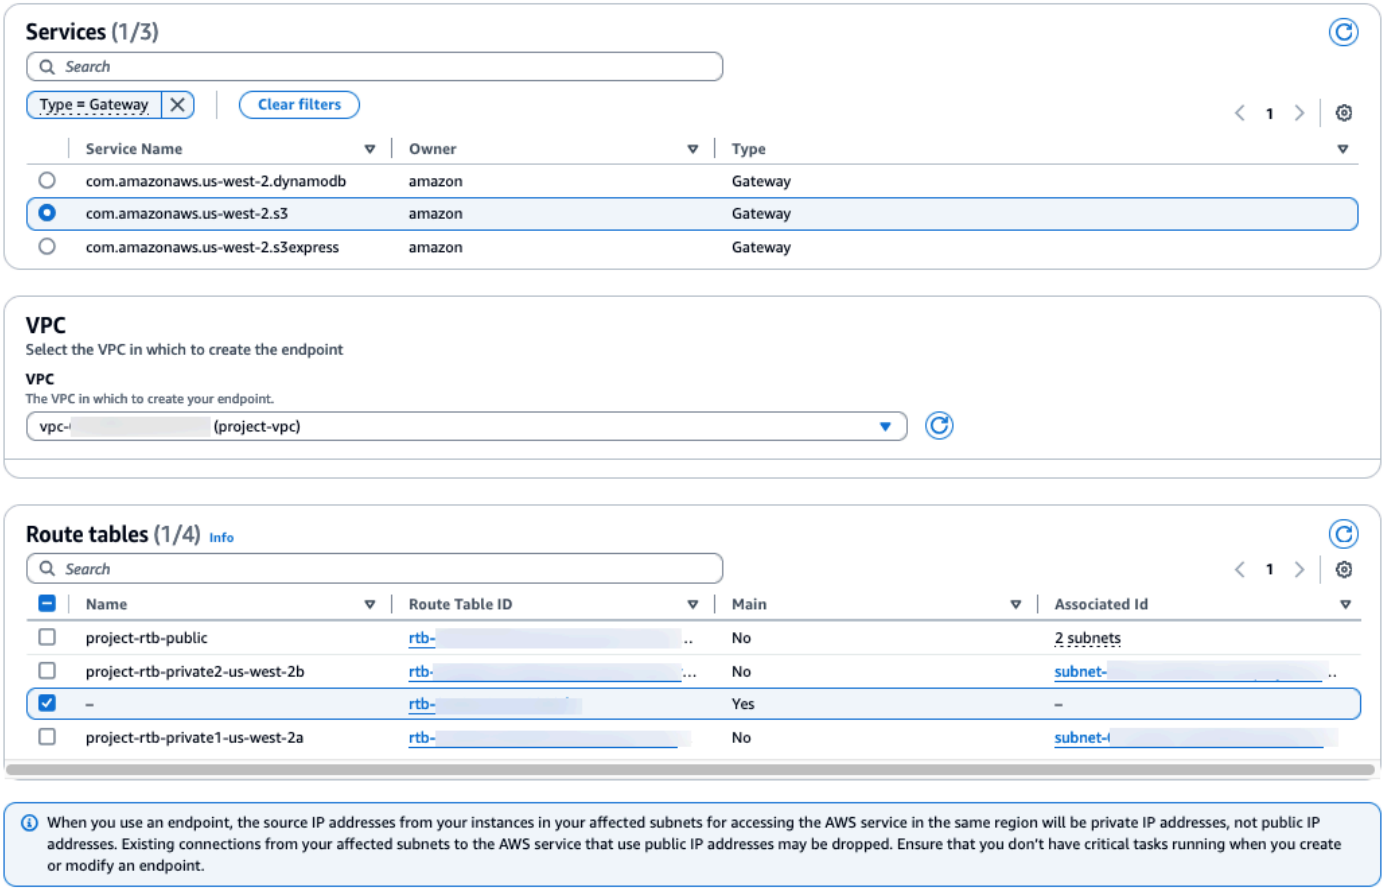
Step 1: Create a VPC gateway endpoint for Amazon S3

When you first create an RDS for Db2 DB instance, Amazon RDS creates the DB instance with three private subnets, a security group, and no public access. The security group prevents any S3 traffic from leaving the private subnet.

To allow traffic between your RDS for Db2 DB instance and S3, you need to create a gateway endpoint that connects to S3. When you create the endpoint, be sure to select the route table that you want to associate with this endpoint.

> **Note**
>
> If you encounter an error when you are creating the VPC endpoint that states that the selected route table already has a route, do one of the following options:
>
> - Create a new VPC. Then, when you create the gateway endpoint, select the new VPC. For more information, see Create a VPC in the *Amazon VPC User Guide*.
> - Create the gateway endpoint without selecting a route table. After you create the gateway endpoint, create a new route table and associate it with the VPC gateway

endpoint. For more information, see Create a custom route table and Control traffic entering your VPC with a gateway route table in the *Amazon VPC User Guide*.

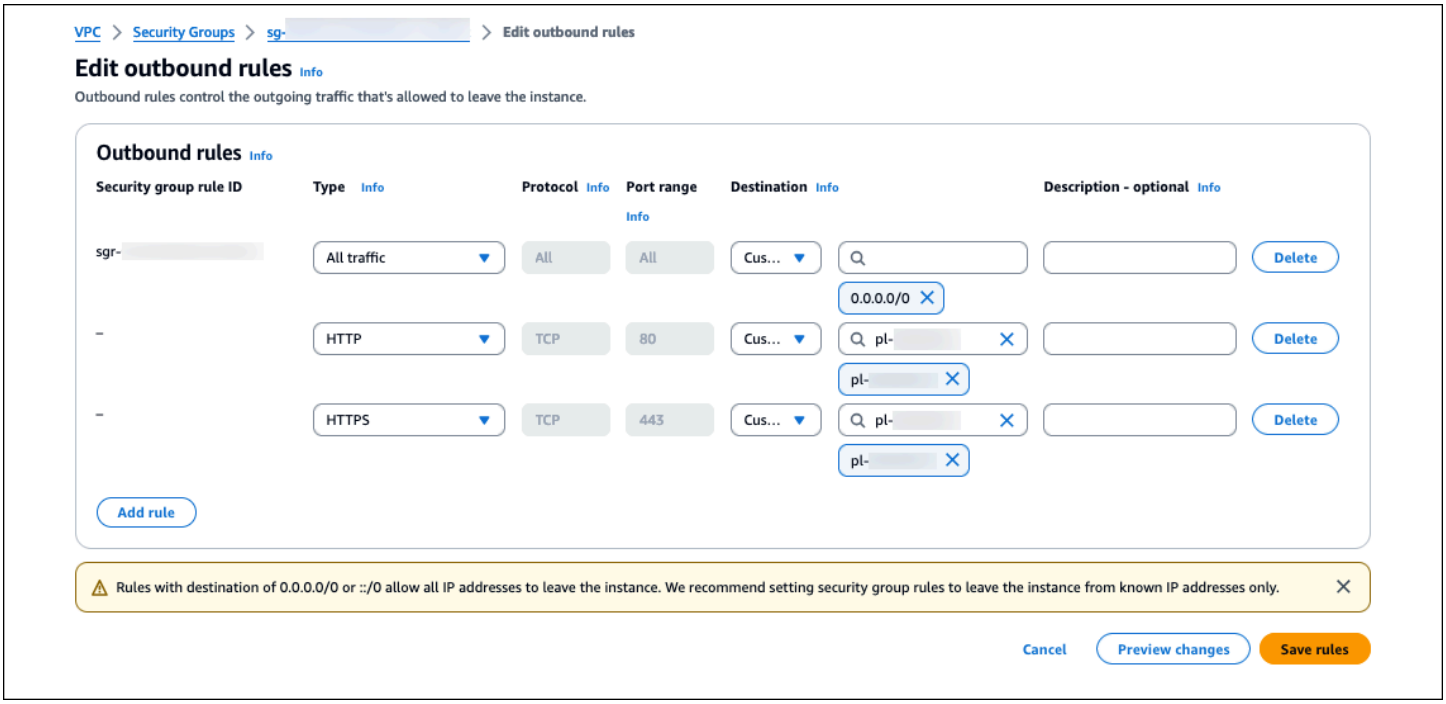


For more information, see Create a gateway endpoint in the *Amazon VPC User Guide*.

Step 2: Add outbound rules to the security group

This step assumes that you created a gateway endpoint in Step 1: Create a VPC gateway endpoint for Amazon S3. In this step, you add outbound rules to a private subnet in the security group for your VPC. These outbound rules allow HTTP and HTTPS traffic.

For the **Destination** value, open the context (right-click) menu for **Search**, and under **Prefix lists,** choose the prefix of the gateway endpoint that you created. The format of the prefix is `com.amazonaws.`*`AWS Region`*`.s3`, for example, `com.amazonaws.us-west-2.s3`.



For more information, see Security group rules in the *Amazon VPC User Guide*.

Amazon RDS for MariaDB

Amazon RDS supports DB instances that run the following versions of MariaDB:

- MariaDB 10.11
- MariaDB 10.6
- MariaDB 10.5
- MariaDB 10.4
- MariaDB 10.3 (RDS end of standard support scheduled for October 23, 2023)

For more information about minor version support, see MariaDB on Amazon RDS versions.

To create a MariaDB DB instance, use the Amazon RDS management tools or interfaces. You can then use the Amazon RDS tools to perform management actions for the DB instance. These include actions such as the following:

- Reconfiguring or resizing the DB instance
- Authorizing connections to the DB instance
- Creating and restoring from backups or snapshots
- Creating Multi-AZ secondaries
- Creating read replicas
- Monitoring the performance of your DB instance

To store and access the data in your DB instance, use standard MariaDB utilities and applications.

MariaDB is available in all of the AWS Regions. For more information about AWS Regions, see Regions, Availability Zones, and Local Zones.

You can use Amazon RDS for MariaDB databases to build HIPAA-compliant applications. You can store healthcare-related information, including protected health information (PHI), under a Business Associate Agreement (BAA) with AWS. For more information, see HIPAA compliance. AWS Services in Scope have been fully assessed by a third-party auditor and result in a certification, attestation of compliance, or Authority to Operate (ATO). For more information, see AWS services in scope by compliance program.

Before creating a DB instance, complete the steps in Setting up your Amazon RDS environment. When you create a DB instance, the RDS master user gets DBA privileges, with some limitations. Use this account for administrative tasks such as creating additional database accounts.

You can create the following:

- DB instances
- DB snapshots
- Point-in-time restores
- Automated backups
- Manual backups

You can use DB instances running MariaDB inside a virtual private cloud (VPC) based on Amazon VPC. You can also add features to your MariaDB DB instance by enabling various options. Amazon RDS supports Multi-AZ deployments for MariaDB as a high-availability, failover solution.

> **Important**
>
> To deliver a managed service experience, Amazon RDS doesn't provide shell access to DB instances. It also restricts access to certain system procedures and tables that need advanced privileges. You can access your database using standard SQL clients such as the mysql client. However, you can't access the host directly by using Telnet or Secure Shell (SSH).

MariaDB feature support on Amazon RDS for MariaDB major versions

In the following sections, find information about MariaDB feature support on Amazon RDS for MariaDB major versions:

Topics

- MariaDB 10.11 support on Amazon RDS
- MariaDB 10.6 support on Amazon RDS
- MariaDB 10.5 support on Amazon RDS

- MariaDB 10.4 support on Amazon RDS
- MariaDB 10.3 support on Amazon RDS

For information about supported minor versions of Amazon RDS for MariaDB, see MariaDB on Amazon RDS versions.

MariaDB 10.11 support on Amazon RDS

Amazon RDS supports the following new features for your DB instances running MariaDB version 10.11 or higher.

- **Password Reuse Check plugin** – You can use the MariaDB Password Reuse Check plugin to prevent users from reusing passwords and to set the retention period of passwords. For more information, see Password Reuse Check Plugin.
- **GRANT TO PUBLIC authorization** – You can grant privileges to all users who have access to your server. For more information, see GRANT TO PUBLIC.
- **Separation of SUPER and READ ONLY ADMIN privileges** – You can remove READ ONLY ADMIN privileges from all users, even users that previously had SUPER privileges.
- **Security** – You can now set option `--ssl` as the default for your MariaDB client. MariaDB no longer silently disables SSL if the configuration is incorrect.
- **SQL commands and functions** – You can now use the `SHOW ANALYZE FORMAT=JSON` command and the functions `ROW_NUMBER`, `SFORMAT`, and `RANDOM_BYTES`. `SFORMAT` allows string formatting and is enabled by default. You can convert partition to table and table to partition in a single command. There are also several improvements around `JSON_*()` functions. `DES_ENCRYPT` and `DES_DECRYPT` functions were deprecated for version 10.10 and higher. For more information, see SFORMAT.
- **InnoDB enhancements** – These enhancements include the following items:
  - Performance improvements in the redo log to reduce write amplification and to improve concurrency.
  - The ability for you to change the undo tablespace without reinitializing the data directory. This enhancement reduces control plane overhead. It requires restarting but it doesn't require reinitialization after changing undo tablespace.
  - Support for `CHECK TABLE ... EXTENDED` and for descending indexes internally.
  - Improvements to bulk insert.
- **Binlog changes** – These changes include the following items:

  - Logging `ALTER` in two phases to decrease replication latency. The `binlog_alter_two_phase` parameter is disabled by default, but can be enabled through parameter groups.
  - Logging `explicit_defaults_for_timestamp`.
  - No longer logging `INCIDENT_EVENT` if the transaction can be safely rolled back.
- **Replication improvement**s – MariaDB version 10.11 DB instances use GTID replication by default if the master supports it. Also, `Seconds_Behind_Master` is more precise.
- **Clients** – You can use new command-line options for `mysqlbinglog` and `mariadb-dump`. You can use `mariadb-dump` to dump and restore historical data.
- **System versioning** – You can modify history. MariaDB automatically creates new partitions.
- **Atomic DDL** – `CREATE OR REPLACE` is now atomic. Either the statement succeeds or it's completely reversed.
- **Redo log write** – Redo log writes asynchronously.
- **Stored functions** – Stored functions now support the same `IN`, `OUT`, and `INOUT` parameters as in stored procedures.
- **Deprecated or removed parameters** – The following parameters have been deprecated or removed for MariaDB version 10.11 DB instances:
  - innodb_change_buffering
  - innodb_disallow_writes
  - innodb_log_write_ahead_size
  - innodb_prefix_index_cluster_optimization
  - keep_files_on_create
  - old
- **Dynamic parameters** – The following parameters are now dynamic for MariaDB version 10.11 DB instances:
  - innodb_log_file_size
  - innodb_write_io_threads
  - innodb_read_io_threads
- **New default values for parameters** – The following parameters have new default values for MariaDB version 10.11 DB instances:
  - The default value of the explicit_defaults_for_timestamp parameter changed from `OFF` to `ON`.
  - The default value of the optimizer_prune_level parameter changed from 1 to 2.

- **New valid values for parameters** – The following parameters have new valid values for MariaDB version 10.11 DB instances:
  - The valid values for the old parameter were merged into those for the old_mode parameter.
  - The valid values for the histogram_type parameter now include `JSON_HB`.
  - The valid value range for the innodb_log_buffer_size parameter is now `262144` to `4294967295` (256KB to 4096MB).
  - The valid value range for the innodb_log_file_size parameter is now `4194304` to `512GB` (4MB to 512GB).
  - The valid values for the optimizer_prune_level parameter now include 2.
- **New parameters** – The following parameters are new for MariaDB version 10.11 DB instances:
  - The binlog_alter_two_phase parameter can improve replication performance.
  - The log_slow_min_examined_row_limit parameter can improve performance.
  - The log_slow_query parameter and the log_slow_query_file parameter are aliases for `slow_query_log` and `slow_query_log_file`, respectively.
  - optimizer_extra_pruning_depth
  - system_versioning_insert_history

For a list of all features and documentation, see the following information on the MariaDB website.

Versions	Changes and improvements	Release notes
MariaDB 10.7	Changes and improvements in MariaDB 10.7	Release notes - MariaDB 10.7 series
MariaDB 10.8	Changes and improvements in MariaDB 10.8	Release notes - MariaDB 10.8 series
MariaDB 10.9	Changes and improvements in MariaDB 10.9	Release notes - MariaDB 10.9 series
MariaDB 10.10	Changes and improvements in MariaDB 10.10	Release notes - MariaDB 10.10 series
MariaDB 10.11	Changes and improvements in MariaDB 10.11	Release notes - MariaDB 10.11 series

For a list of unsupported features, see MariaDB features not supported by Amazon RDS.

MariaDB 10.6 support on Amazon RDS

Amazon RDS supports the following new features for your DB instances running MariaDB version 10.6 or higher:

- **MyRocks storage engine** – You can use the MyRocks storage engine with RDS for MariaDB to optimize storage consumption of your write-intensive, high-performance web applications. For more information, see Supported storage engines for MariaDB on Amazon RDS and MyRocks.
- **AWS Identity and Access Management (IAM) DB authentication** – You can use IAM DB authentication for better security and central management of connections to your MariaDB DB instances. For more information, see IAM database authentication for MariaDB, MySQL, and PostgreSQL.
- **Upgrade options** – You can now upgrade to RDS for MariaDB version 10.6 from any prior major release (10.3, 10.4, 10.5). You can also restore a snapshot of an existing MySQL 5.6 or 5.7 DB instance to a MariaDB 10.6 instance. For more information, see Upgrading the MariaDB DB engine.
- **Delayed replication** – You can now set a configurable time period for which a read replica lags behind the source database. In a standard MariaDB replication configuration, there is minimal replication delay between the source and the replica. With delayed replication, you can set an intentional delay as a strategy for disaster recovery. For more information, see Configuring delayed replication with MariaDB.
- **Oracle PL/SQL compatibility** – By using RDS for MariaDB version 10.6, you can more easily migrate your legacy Oracle applications to Amazon RDS. For more information, see SQL_MODE=ORACLE.
- **Atomic DDL** – Your dynamic data language (DDL) statements can be relatively crash-safe with RDS for MariaDB version 10.6. `CREATE TABLE`, `ALTER TABLE`, `RENAME TABLE`, `DROP TABLE`, `DROP DATABASE` and related DDL statements are now atomic. Either the statement succeeds, or it's completely reversed. For more information, see Atomic DDL.
- **Other enhancements** – These enhancements include a `JSON_TABLE` function for transforming JSON data to relational format within SQL, and faster empty table data load with Innodb. They also include new `sys_schema` for analysis and troubleshooting, optimizer enhancement for ignoring unused indexes, and performance improvements. For more information, see JSON_TABLE.

- **New default values for parameters** – The following parameters have new default values for MariaDB version 10.6 DB instances:
  - The default value for the following parameters has changed from `utf8` to `utf8mb3`:
    - character_set_client
    - character_set_connection
    - character_set_results
    - character_set_system

    Although the default values have changed for these parameters, there is no functional change. For more information, see Supported Character Sets and Collations in the MariaDB documentation.
  - The default value of the collation_connection parameter has changed from `utf8_general_ci` to `utf8mb3_general_ci`. Although the default value has changed for this parameter, there is no functional change.
  - The default value of the old_mode parameter has changed from unset to `UTF8_IS_UTF8MB3`. Although the default value has changed for this parameter, there is no functional change.

For a list of all MariaDB 10.6 features and their documentation, see Changes and improvements in MariaDB 10.6 and Release notes - MariaDB 10.6 series on the MariaDB website.

For a list of unsupported features, see MariaDB features not supported by Amazon RDS.

MariaDB 10.5 support on Amazon RDS

Amazon RDS supports the following new features for your DB instances running MariaDB version 10.5 or later:

- **InnoDB enhancements** – MariaDB version 10.5 includes InnoDB enhancements. For more information, see InnoDB: Performance Improvements etc. in the MariaDB documentation.
- **Performance schema updates** – MariaDB version 10.5 includes performance schema updates. For more information, see Performance Schema Updates to Match MySQL 5.7 Instrumentation and Tables in the MariaDB documentation.
- **One file in the InnoDB redo log** – In versions of MariaDB before version 10.5, the value of the `innodb_log_files_in_group` parameter was set to 2. In MariaDB version 10.5, the value of this parameter is set to 1.

If you are upgrading from a prior version to MariaDB version 10.5, and you don't modify the parameters, the `innodb_log_file_size` parameter value is unchanged. However, it applies to one log file instead of two. The result is that your upgraded MariaDB version 10.5 DB instance uses half of the redo log size that it was using before the upgrade. This change can have a noticeable performance impact. To address this issue, you can double the value of the `innodb_log_file_size` parameter. For information about modifying parameters, see Modifying parameters in a DB parameter group in Amazon RDS.

- **SHOW SLAVE STATUS command not supported** – In versions of MariaDB before version 10.5, the `SHOW SLAVE STATUS` command required the `REPLICATION SLAVE` privilege. In MariaDB version 10.5, the equivalent `SHOW REPLICA STATUS` command requires the `REPLICATION REPLICA ADMIN` privilege. This new privilege isn't granted to the RDS master user.

  Instead of using the `SHOW REPLICA STATUS` command, run the new `mysql.rds_replica_status` stored procedure to return similar information. For more information, see mysql.rds_replica_status.

- **SHOW RELAYLOG EVENTS command not supported** – In versions of MariaDB before version 10.5, the `SHOW RELAYLOG EVENTS` command required the `REPLICATION SLAVE` privilege. In MariaDB version 10.5, this command requires the `REPLICATION REPLICA ADMIN` privilege. This new privilege isn't granted to the RDS master user.

- **New default values for parameters** – The following parameters have new default values for MariaDB version 10.5 DB instances:

  - The default value of the max_connections parameter has changed to `LEAST({DBInstanceClassMemory/25165760},12000)`. For information about the `LEAST` parameter function, see DB parameter functions.
  - The default value of the innodb_adaptive_hash_index parameter has changed to `OFF` (`0`).
  - The default value of the innodb_checksum_algorithm parameter has changed to `full_crc32`.
  - The default value of the innodb_log_file_size parameter has changed to 2 GB.

For a list of all MariaDB 10.5 features and their documentation, see Changes and improvements in MariaDB 10.5 and Release notes - MariaDB 10.5 series on the MariaDB website.

For a list of unsupported features, see MariaDB features not supported by Amazon RDS.

MariaDB 10.4 support on Amazon RDS

Amazon RDS supports the following new features for your DB instances running MariaDB version 10.4 or later:

- **User account security enhancements** – Password expiration and account locking improvements
- **Optimizer enhancements** – Optimizer trace feature
- **InnoDB enhancements** – Instant DROP COLUMN support and instant VARCHAR extension for `ROW_FORMAT=DYNAMIC` and `ROW_FORMAT=COMPACT`
- **New parameters** – Including tcp_nodedelay, tls_version, and gtid_cleanup_batch_size

For a list of all MariaDB 10.4 features and their documentation, see Changes and improvements in MariaDB 10.4 and Release notes - MariaDB 10.4 series on the MariaDB website.

For a list of unsupported features, see MariaDB features not supported by Amazon RDS.

MariaDB 10.3 support on Amazon RDS

Amazon RDS supports the following new features for your DB instances running MariaDB version 10.3 or later:

- **Oracle compatibility** – PL/SQL compatibility parser, sequences, INTERSECT and EXCEPT to complement UNION, new TYPE OF and ROW TYPE OF declarations, and invisible columns
- **Temporal data processing** – System versioned tables for querying of past and present states of the database
- **Flexibility** – User-defined aggregates, storage-independent column compression, and proxy protocol support to relay the client IP address to the server
- **Manageability** – Instant ADD COLUMN operations and fast-fail data definition language (DDL) operations

For a list of all MariaDB 10.3 features and their documentation, see Changes & improvements in MariaDB 10.3 and Release notes - MariaDB 10.3 series on the MariaDB website.

For a list of unsupported features, see MariaDB features not supported by Amazon RDS.

Supported storage engines for MariaDB on Amazon RDS

RDS for MariaDB supports the following storage engines.

Topics

Other storage engines aren't currently supported by RDS for MariaDB.

The InnoDB storage engine

Although MariaDB supports multiple storage engines with varying capabilities, not all of them are optimized for recovery and data durability. InnoDB is the recommended storage engine for MariaDB DB instances on Amazon RDS. Amazon RDS features such as point-in-time restore and snapshot restore require a recoverable storage engine and are supported only for the recommended storage engine for the MariaDB version.

For more information, see InnoDB.

The MyRocks storage engine

The MyRocks storage engine is available in RDS for MariaDB version 10.6 and higher. Before using the MyRocks storage engine in a production database, we recommend that you perform thorough benchmarking and testing to verify any potential benefits over InnoDB for your use case.

The default parameter group for MariaDB version 10.6 includes MyRocks parameters. For more information, see Parameters for MariaDB and Parameter groups for Amazon RDS.

To create a table that uses the MyRocks storage engine, specify `ENGINE=RocksDB` in the `CREATE TABLE` statement. The following example creates a table that uses the MyRocks storage engine.

```
CREATE TABLE test (a INT NOT NULL, b CHAR(10)) ENGINE=RocksDB;
```

We strongly recommend that you don't run transactions that span both InnoDB and MyRocks tables. MariaDB doesn't guarantee ACID (atomicity, consistency, isolation, durability) for transactions across storage engines. Although it is possible to have both InnoDB and MyRocks tables in a DB instance, we don't recommend this approach except during a migration from one storage engine to the other. When both InnoDB and MyRocks tables exist in a DB instance, each storage engine has its own buffer pool, which might cause performance to degrade.

MyRocks doesn’t support `SERIALIZABLE` isolation or gap locks. So, generally you can't use MyRocks with statement-based replication. For more information, see MyRocks and Replication.

Currently, you can modify only the following MyRocks parameters:

- rocksdb_block_cache_size
- rocksdb_bulk_load
- rocksdb_bulk_load_size
- rocksdb_deadlock_detect
- rocksdb_deadlock_detect_depth
- rocksdb_max_latest_deadlocks

The MyRocks storage engine and the InnoDB storage engine can compete for memory based on the settings for the `rocksdb_block_cache_size` and `innodb_buffer_pool_size` parameters. In some cases, you might only intend to use the MyRocks storage engine on a particular DB instance. If so, we recommend setting the `innodb_buffer_pool_size minimal` parameter to a minimal value and setting the `rocksdb_block_cache_size` as high as possible.

You can access MyRocks log files by using the `DescribeDBLogFiles` and `DownloadDBLogFilePortion` operations.

For more information about MyRocks, see MyRocks on the MariaDB website.

Cache warming for MariaDB on Amazon RDS

InnoDB cache warming can provide performance gains for your MariaDB DB instance by saving the current state of the buffer pool when the DB instance is shut down, and then reloading the buffer pool from the saved information when the DB instance starts up. This approach bypasses the need for the buffer pool to "warm up" from normal database use and instead preloads the buffer pool with the pages for known common queries. For more information on cache warming, see Dumping and restoring the buffer pool in the MariaDB documentation.

Cache warming is enabled by default on MariaDB 10.3 and higher DB instances.
To enable it, set the `innodb_buffer_pool_dump_at_shutdown` and `innodb_buffer_pool_load_at_startup` parameters to 1 in the parameter group for your DB instance. Changing these parameter values in a parameter group affects all MariaDB DB instances that use that parameter group. To enable cache warming for specific MariaDB DB instances, you might need to create a new parameter group for those DB instances. For information on parameter groups, see Parameter groups for Amazon RDS.

Cache warming primarily provides a performance benefit for DB instances that use standard storage. If you use PIOPS storage, you don't commonly see a significant performance benefit.

Important

If your MariaDB DB instance doesn't shut down normally, such as during a failover, then the buffer pool state isn't saved to disk. In this case, MariaDB loads whatever buffer pool file is available when the DB instance is restarted. No harm is done, but the restored buffer pool might not reflect the most recent state of the buffer pool before the restart. To ensure that you have a recent state of the buffer pool available to warm the cache on startup, we recommend that you periodically dump the buffer pool "on demand." You can dump or load the buffer pool on demand.

You can create an event to dump the buffer pool automatically and at a regular interval. For example, the following statement creates an event named `periodic_buffer_pool_dump` that dumps the buffer pool every hour.

```
CREATE EVENT periodic_buffer_pool_dump
   ON SCHEDULE EVERY 1 HOUR
   DO CALL mysql.rds_innodb_buffer_pool_dump_now();
```

For more information, see Events in the MariaDB documentation.

Dumping and loading the buffer pool on demand

You can save and load the cache on demand using the following stored procedures:

- To dump the current state of the buffer pool to disk, call the mysql.rds_innodb_buffer_pool_dump_now stored procedure.
- To load the saved state of the buffer pool from disk, call the mysql.rds_innodb_buffer_pool_load_now stored procedure.
- To cancel a load operation in progress, call the mysql.rds_innodb_buffer_pool_load_abort stored procedure.

MariaDB features not supported by Amazon RDS

The following MariaDB features are not supported on Amazon RDS:

- S3 storage engine
- Authentication plugin – GSSAPI
- Authentication plugin – Unix Socket
- AWS Key Management encryption plugin
- Delayed replication for MariaDB versions lower than 10.6
- Native MariaDB encryption at rest for InnoDB and Aria

  You can enable encryption at rest for a MariaDB DB instance by following the instructions in Encrypting Amazon RDS resources.
- HandlerSocket
- JSON table type for MariaDB versions lower than 10.6
- MariaDB ColumnStore
- MariaDB Galera Cluster
- Multisource replication
- MyRocks storage engine for MariaDB versions lower than 10.6
- Password validation plugin, `simple_password_check`, and `cracklib_password_check`
- Spider storage engine
- Sphinx storage engine
- TokuDB storage engine
- Storage engine-specific object attributes, as described in Engine-defined new Table/Field/Index attributes in the MariaDB documentation
- Table and tablespace encryption
- Hashicorp Key Management plugin
- Running two upgrades in parallel

To deliver a managed service experience, Amazon RDS doesn't provide shell access to DB instances, and it restricts access to certain system procedures and tables that require advanced privileges. Amazon RDS supports access to databases on a DB instance using any standard SQL client application. Amazon RDS doesn't allow direct host access to a DB instance by using Telnet, Secure Shell (SSH), or Windows Remote Desktop Connection.

MariaDB on Amazon RDS versions

For MariaDB, version numbers are organized as version X.Y.Z. In Amazon RDS terminology, X.Y denotes the major version, and Z is the minor version number. For Amazon RDS implementations, a version change is considered major if the major version number changes, for example going from version 10.5 to 10.6. A version change is considered minor if only the minor version number changes, for example going from version 10.6.14 to 10.6.16.

Topics

Supported MariaDB minor versions on Amazon RDS

Amazon RDS currently supports the following minor versions of MariaDB.

> **Note**
>
> Dates with only a month and a year are approximate and are updated with an exact date when it's known.

The following table shows the minor versions of MariaDB 10.11 that Amazon RDS currently supports.

MariaDB engine version	Community release date	RDS release date	RDS end of standard support date
10.11.9	8 August 2024	4 September 2024	March 2026
10.11.8	16 May 2024	14 June 2024	September 2025
10.11.7	7 February 2024	26 February 2024	March 2025

MariaDB engine version	Community release date	RDS release date	RDS end of standard support date
10.11.6	13 November 2023	12 December 2023	March 2025
10.11.5	14 August 2023	7 September 2023	March 2025
10.11.4	7 June 2023	21 August 2023	March 2025

The following table shows the minor versions of MariaDB 10.6 that Amazon RDS currently supports.

MariaDB engine version	Community release date	RDS release date	RDS end of standard support date
10.6.19	8 August 2024	4 September 2024	March 2026
10.6.18	16 May 2024	14 June 2024	September 2025
10.6.17	7 February 2024	26 February 2024	March 2025
10.6.16	13 November 2023	12 December 2023	March 2025
10.6.15	14 August 2023	7 September 2023	March 2025
10.6.14	7 June 2023	22 June 2023	March 2025
10.6.13	10 May 2023	15 June 2023	March 2025

The following table shows the minor versions of MariaDB 10.5 that Amazon RDS currently supports.

MariaDB engine version	Community release date	RDS release date	RDS end of standard support date
10.5.26	8 August 2024	4 September 2024	March 2026
10.5.25	16 May 2024	14 June 2024	September 2025

MariaDB engine version	Community release date	RDS release date	RDS end of standard support date
10.5.24	7 February 2024	26 February 2024	March 2025
10.5.23	13 November 2023	12 December 2023	March 2025
10.5.22	14 August 2023	7 September 2023	March 2025
10.5.21	7 June 2023	22 June 2023	March 2025
10.5.20	10 May 2023	15 June 2023	March 2025

The following table shows the minor versions of MariaDB 10.4 that Amazon RDS currently supports.

MariaDB engine version	Community release date	RDS release date	RDS end of standard support date
10.4.34	16 May 2024	14 June 2024	February 2025
10.4.33	7 February 2024	26 February 2024	February 2025
10.4.32	13 November 2023	12 December 2023	February 2025
10.4.31	14 August 2023	7 September 2023	February 2025
10.4.30	7 June 2023	22 June 2023	February 2025
10.4.29	10 May 2023	15 June 2023	February 2025

You can specify any currently supported MariaDB version when creating a new DB instance. You can specify the major version (such as MariaDB 10.5), and any supported minor version for the specified major version. If no version is specified, Amazon RDS defaults to a supported version, typically the most recent version. If a major version is specified but a minor version is not, Amazon RDS defaults to a recent release of the major version you have specified. To see a list of supported versions, as well as defaults for newly created DB instances, use the `describe-db-engine-versions` AWS CLI command.

For example, to list the supported engine versions for RDS for MariaDB, run the following CLI command:

```
aws rds describe-db-engine-versions --engine mariadb --query "*[].
{Engine:Engine,EngineVersion:EngineVersion}" --output text
```

The default MariaDB version might vary by AWS Region. To create a DB instance with a specific minor version, specify the minor version during DB instance creation. You can determine the default minor version for an AWS Region using the following AWS CLI command:

```
aws rds describe-db-engine-versions --default-only --engine mariadb
 --engine-version major-engine-version --region region --query "*[].
{Engine:Engine,EngineVersion:EngineVersion}" --output text
```

Replace *major-engine-version* with the major engine version, and replace *region* with the AWS Region. For example, the following AWS CLI command returns the default MariaDB minor engine version for the 10.5 major version and the US West (Oregon) AWS Region (us-west-2):

```
aws rds describe-db-engine-versions --default-only --engine mariadb --engine-version
 10.5 --region us-west-2 --query "*[].{Engine:Engine,EngineVersion:EngineVersion}" --
output text
```

Supported MariaDB major versions on Amazon RDS

RDS for MariaDB major versions remain available at least until community end of life for the corresponding community version. You can use the following dates to plan your testing and upgrade cycles. If Amazon extends support for an RDS for MariaDB version for longer than originally stated, we plan to update this table to reflect the later date.

> **Note**
>
> Dates with only a month and a year are approximate and are updated with an exact date when it's known.

MariaDB major version	Community release date	RDS release date	Community end of life date	RDS end of standard support date
MariaDB 10.11	16 February 2023	21 August 2023	16 February 2028	February 2028
MariaDB 10.6	6 July 2021	3 February 2022	6 July 2026	July 2026
MariaDB 10.5	24 June 2020	21 January 2021	24 June 2025	June 2025
MariaDB 10.4	18 June 2019	6 April 2020	18 June 2024	February 2025

Working with the Database Preview environment

RDS for MariaDB DB instances in the Database Preview environment are functionally similar to other RDS for MariaDB DB instances. However, you can't use the Database Preview environment for production workloads.

Preview environments have the following limitations:

- Amazon RDS deletes all DB instances 60 days after you create them, along with any backups and snapshots.
- You can only use General Purpose SSD and Provisioned IOPS SSD storage.
- You can't get help from AWS Support with DB instances. Instead, you can post your questions to the AWS-managed Q&A community, AWS re:Post.
- You can't copy a snapshot of a DB instance to a production environment.

The following options are supported by the preview.

- You can create DB instances using db.m6i, db.r6i, db.m6g, db.m5, db.t3, db.r6g, and db.r5 DB instance classes. For more information about RDS instance classes, see DB instance classes.
- You can use both single-AZ and Multi-AZ deployments.
- You can use standard MariaDB dump and load functions to export databases from or import databases to the Database Preview environment.

Features not supported in the Database Preview environment

The following features aren't available in the Database Preview environment:

- Cross-Region snapshot copy
- Cross-Region read replicas
- RDS Proxy

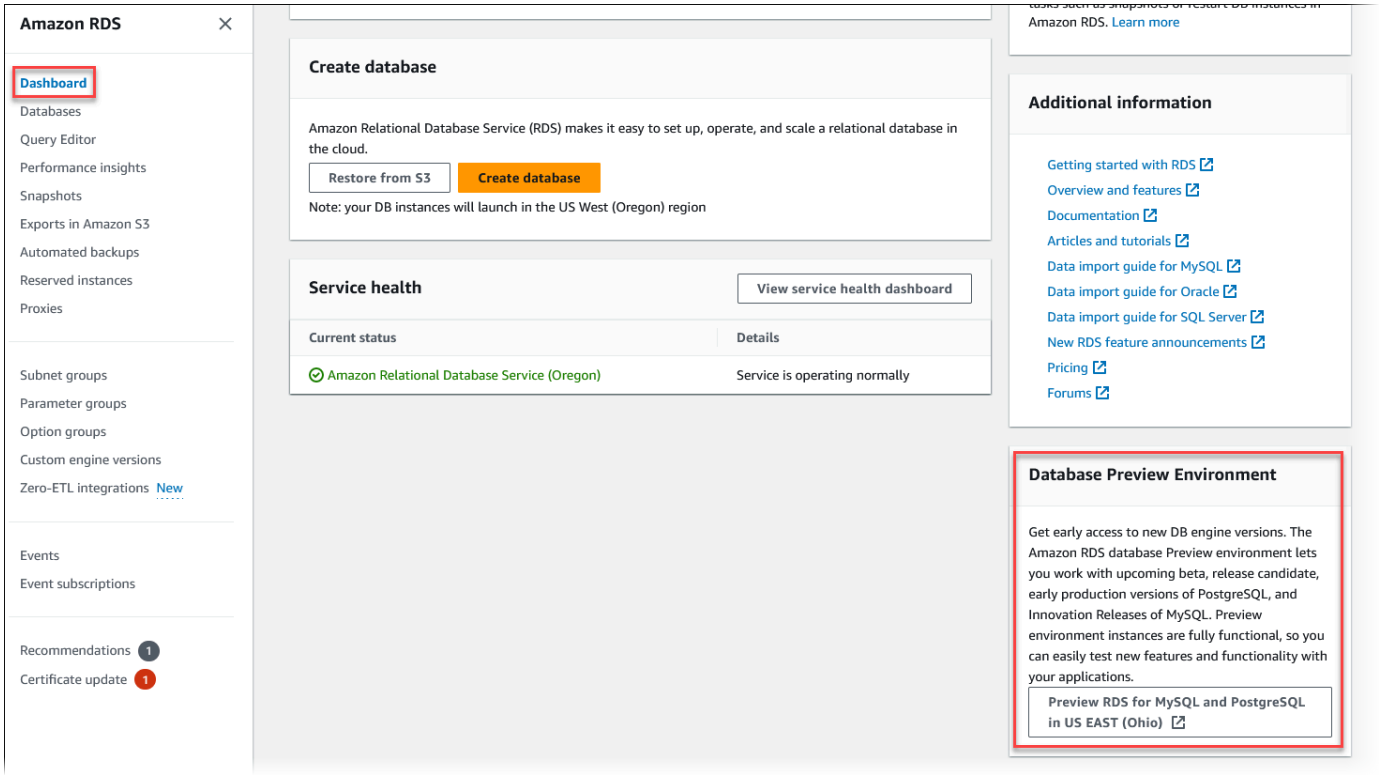
Creating a new DB instance in the Database Preview environment

You can create a DB instance in the Database Preview environment using the AWS Management Console, AWS CLI, or RDS API.

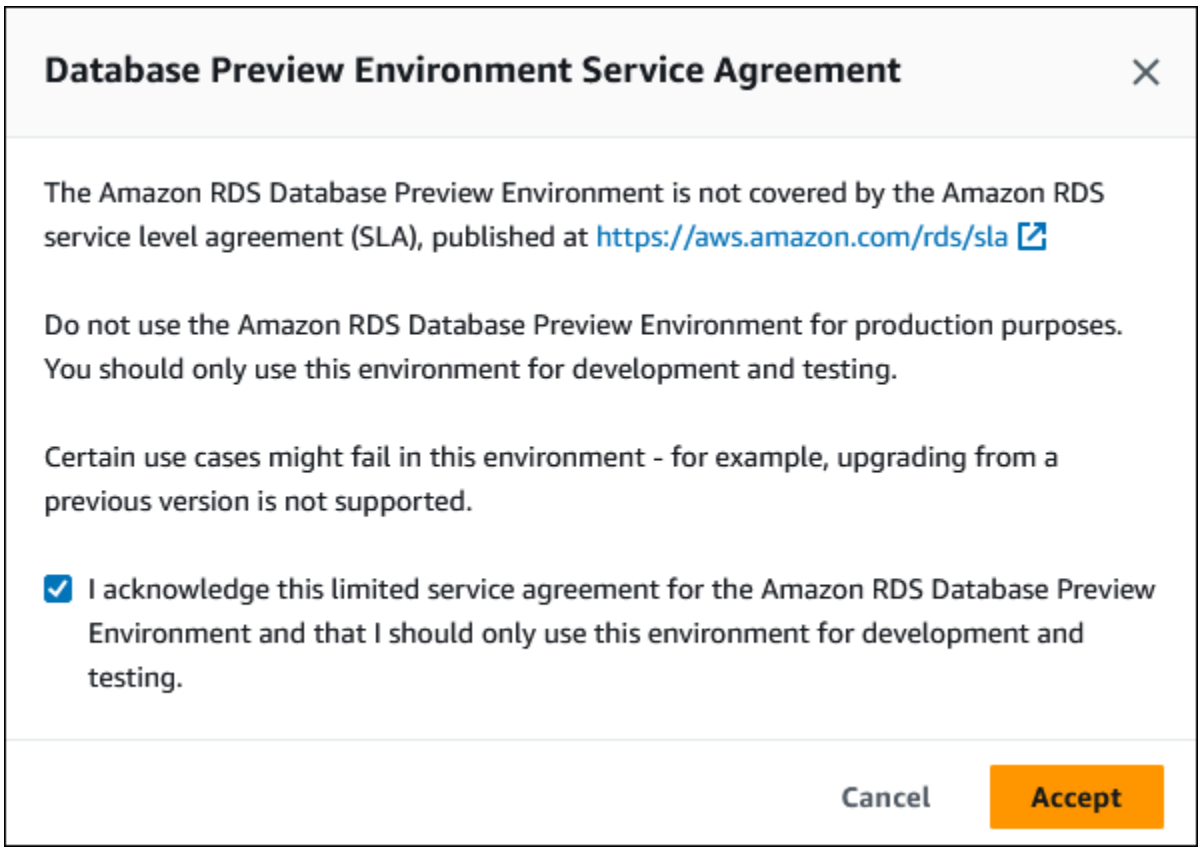
Console

To create a DB instance in the Database Preview environment

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Choose **Dashboard** from the navigation pane.
3. In the **Dashboard** page, locate the **Database Preview Environment** section, as shown in the following image.



You can navigate directly to the Database Preview environment. Before you can proceed, you must acknowledge and accept the limitations.



4. To create the RDS for MariaDB DB instance, follow the same process that you would for creating any Amazon RDS DB instance. For more information, see the Console procedure in Creating a DB instance.

AWS CLI

To create a DB instance in the Database Preview environment using the AWS CLI, use the following endpoint.

```
rds-preview.us-east-2.amazonaws.com
```

To create the RDS for MariaDB DB instance, follow the same process that you would for creating any Amazon RDS DB instance. For more information, see the AWS CLI procedure in Creating a DB instance.

RDS API

To create a DB instance in the Database Preview environment using the RDS API, use the following endpoint.

```
rds-preview.us-east-2.amazonaws.com
```

To create the RDS for MariaDB DB instance, follow the same process that you would for creating any Amazon RDS DB instance. For more information, see the RDS API procedure in Creating a DB instance.

MariaDB version 11.4 in the Database Preview environment

MariaDB version 11.4 is now available in the Amazon RDS Database Preview environment. MariaDB version 11.4 contains several improvements that are described in Changes and improvements in MariaDB 11.4. You can use the Database Preview environment to test your workloads against this release before it is available in all AWS Regions for production workloads.

For information on the Database Preview environment, see the section called "The Database Preview environment". To access the Preview Environment from the console, select rds-preview/.

Deprecated versions for Amazon RDS for MariaDB

Amazon RDS for MariaDB versions 10.0, 10.1, 10.2, and 10.3 are deprecated.

For information about the Amazon RDS deprecation policy for MariaDB, see Amazon RDS FAQs.

Connecting to a DB instance running the MariaDB database engine

After Amazon RDS provisions your DB instance, you can use any standard MariaDB client application or utility to connect to the instance. In the connection string, you specify the Domain Name System (DNS) address from the DB instance endpoint as the host parameter. You also specify the port number from the DB instance endpoint as the port parameter.

You can connect to an Amazon RDS for MariaDB DB instance by using tools like the MySQL command-line client. For more information on using the MySQL command-line client, see mysql command-line client in the MariaDB documentation. One GUI-based application that you can use to connect is Heidi. For more information, see the Download HeidiSQL page. For information about installing MySQL (including the MySQL command-line client), see Installing and upgrading MySQL.

Most Linux distributions include the MariaDB client instead of the Oracle MySQL client. To install the MySQL command-line client on Amazon Linux 2023, run the following command:

```
sudo dnf install mariadb105
```

To install the MySQL command-line client on Amazon Linux 2, run the following command:

```
sudo yum install mariadb
```

To install the MySQL command-line client on most DEB-based Linux distributions, run the following command.

```
apt-get install mariadb-client
```

To check the version of your MySQL command-line client, run the following command.

```
mysql --version
```

To read the MySQL documentation for your current client version, run the following command.

```
man mysql
```

To connect to a DB instance from outside of a virtual private cloud (VPC) based on Amazon VPC, the DB instance must be publicly accessible. Also, access must be granted using the inbound rules

of the DB instance's security group, and other requirements must be met. For more information, see Can't connect to Amazon RDS DB instance.

You can use SSL encryption on connections to a MariaDB DB instance. For information, see Using SSL/TLS with a MariaDB DB instance.

Topics

Finding the connection information for a MariaDB DB instance

The connection information for a DB instance includes its endpoint, port, and a valid database user, such as the master user. For example, suppose that an endpoint value is `mydb.123456789012.us-east-1.rds.amazonaws.com`. In this case, the port value is `3306`, and the database user is `admin`. Given this information, you specify the following values in a connection string:

- For host or host name or DNS name, specify `mydb.123456789012.us-east-1.rds.amazonaws.com`.
- For port, specify `3306`.
- For user, specify `admin`.

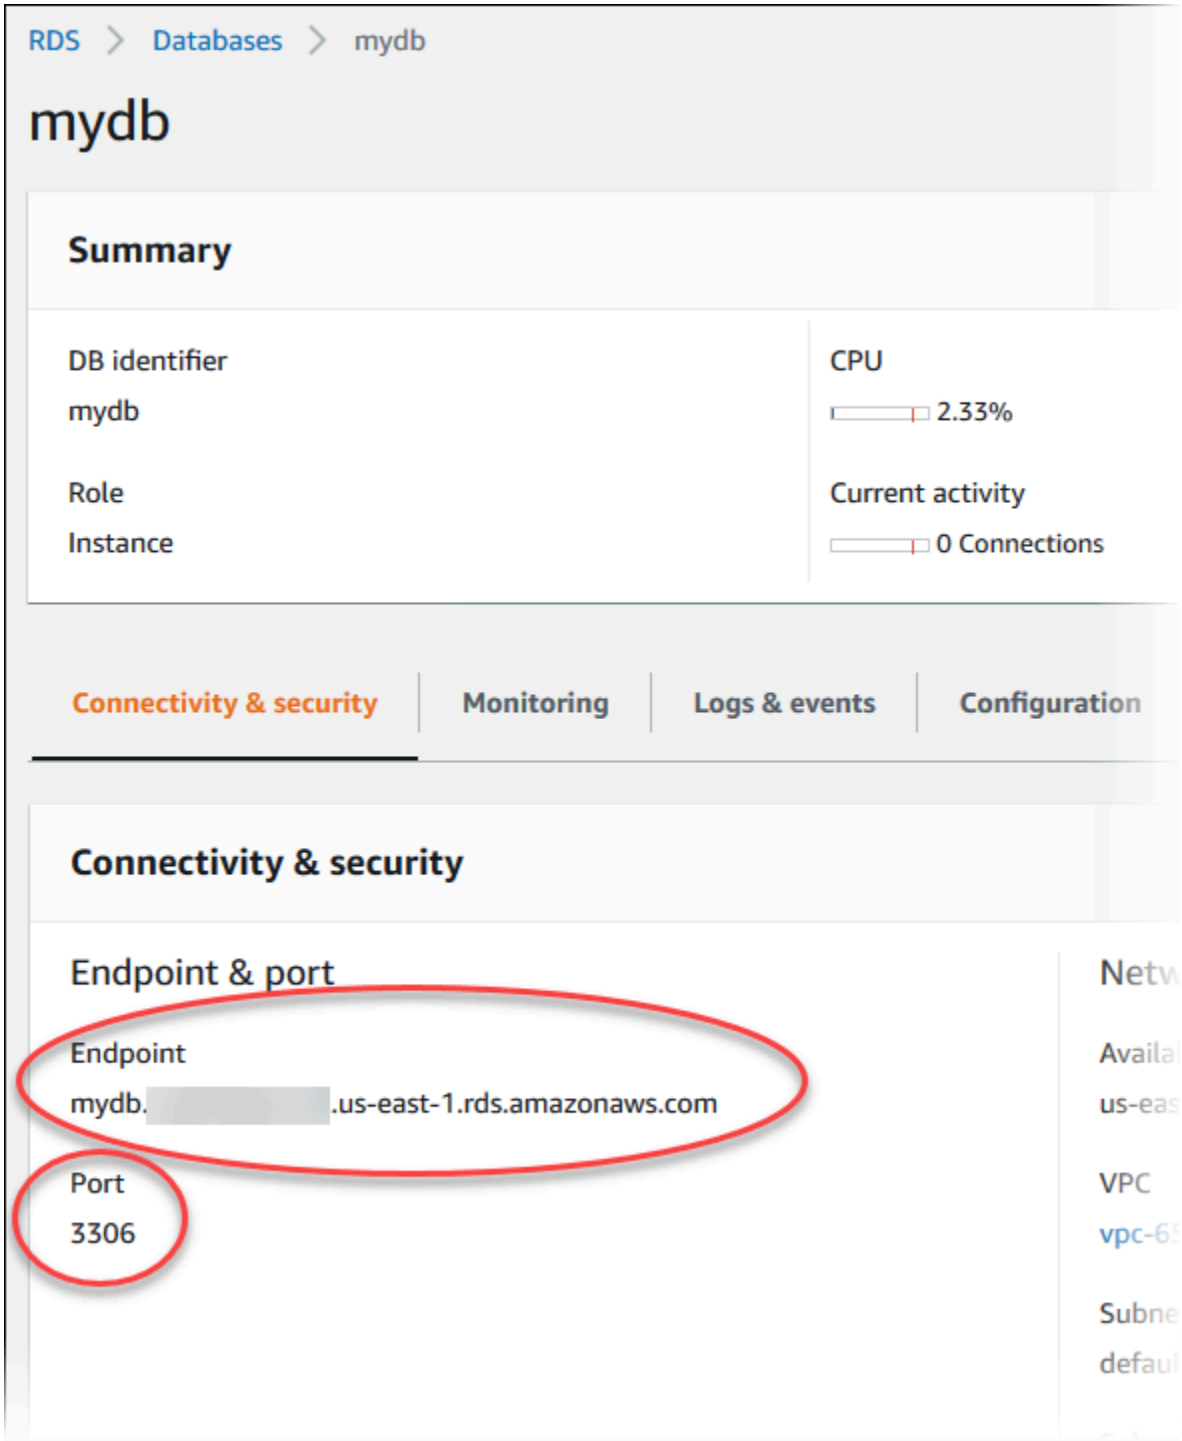
To connect to a DB instance, use any client for the MariaDB DB engine. For example, you might use the MySQL command-line client or MySQL Workbench.

To find the connection information for a DB instance, you can use the AWS Management Console, the AWS Command Line Interface (AWS CLI) describe-db-instances command, or the Amazon RDS API DescribeDBInstances operation to list its details.

Console

To find the connection information for a DB instance in the AWS Management Console

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases** to display a list of your DB instances.
3. Choose the name of the MariaDB DB instance to display its details.
4. On the **Connectivity & security** tab, copy the endpoint. Also, note the port number. You need both the endpoint and the port number to connect to the DB instance.



5. If you need to find the master user name, choose the **Configuration** tab and view the **Master username** value.

AWS CLI

To find the connection information for a MariaDB DB instance by using the AWS CLI, call the describe-db-instances command. In the call, query for the DB instance ID, endpoint, port, and master user name.

For Linux, macOS, or Unix:

```
aws rds describe-db-instances \
  --filters "Name=engine,Values=mariadb" \
  --query "*[].[DBInstanceIdentifier,Endpoint.Address,Endpoint.Port,MasterUsername]"
```

For Windows:

```
aws rds describe-db-instances ^
  --filters "Name=engine,Values=mariadb" ^
  --query "*[].[DBInstanceIdentifier,Endpoint.Address,Endpoint.Port,MasterUsername]"
```

Your output should be similar to the following.

```
[
    [
        "mydb1",
        "mydb1.123456789012.us-east-1.rds.amazonaws.com",
        3306,
        "admin"
    ],
    [
        "mydb2",
        "mydb2.123456789012.us-east-1.rds.amazonaws.com",
        3306,
        "admin"
    ]
]
```

RDS API

To find the connection information for a DB instance by using the Amazon RDS API, call the DescribeDBInstances operation. In the output, find the values for the endpoint address, endpoint port, and master user name.

Connecting from the MySQL command-line client (unencrypted)

> **Important**
>
> Only use an unencrypted MySQL connection when the client and server are in the same VPC and the network is trusted. For information about using encrypted connections, see Connecting from the MySQL command-line client with SSL/TLS (encrypted).

To connect to a DB instance using the MySQL command-line client, enter the following command at a command prompt on a client computer. Doing this connects you to a database on a MariaDB DB instance. Substitute the DNS name (endpoint) for your DB instance for *<endpoint>* and the master user name that you used for *<mymasteruser>*. Provide the master password that you used when prompted for a password.

```
mysql -h <endpoint> -P 3306 -u <mymasteruser> -p
```

After you enter the password for the user, you see output similar to the following.

```
Welcome to the MariaDB monitor.  Commands end with ; or \g.
Your MariaDB connection id is 31
Server version: 10.6.10-MariaDB-log Source distribution

Copyright (c) 2000, 2018, Oracle, MariaDB Corporation Ab and others.

Type 'help;' or '\h' for help. Type '\c' to clear the current input statement.

MariaDB [(none)]>
```

Connecting to RDS for MariaDB with the Amazon Web Services (AWS) JDBC Driver

The Amazon Web Services (AWS) JDBC Driver is designed as an advanced JDBC wrapper. This wrapper is complementary to and extends the functionality of an existing JDBC driver. The driver is drop-in compatible with the community MySQL Connector/J driver and the community MariaDB Connector/J driver.

To install the AWS JDBC Driver, append the AWS JDBC Driver .jar file (located in the application CLASSPATH), and keep references to the respective community driver. Update the respective connection URL prefix as follows:

- `jdbc:mysql://` to `jdbc:aws-wrapper:mysql://`
- `jdbc:mariadb://` to `jdbc:aws-wrapper:mariadb://`

For more information about the AWS JDBC Driver and complete instructions for using it, see the Amazon Web Services (AWS) JDBC Driver GitHub repository.

Connecting to RDS for MariaDB with the Amazon Web Services (AWS) Python Driver

The Amazon Web Services (AWS) Python Driver is designed as an advanced Python wrapper. This wrapper is complementary to and extends the functionality of the open-source Psycopg driver. The AWS Python Driver supports Python versions 3.8 and higher. You can install the `aws-advanced-python-wrapper` package using the `pip` command, along with the `psycopg` open-source packages.

For more information about the AWS Python Driver and complete instructions for using it, see the Amazon Web Services (AWS) Python Driver GitHub repository.

Troubleshooting connections to your MariaDB DB instance

Two common causes of connection failures to a new DB instance are the following:

- The DB instance was created using a security group that doesn't authorize connections from the device or Amazon EC2 instance where the MariaDB application or utility is running. The DB instance must have a VPC security group that authorizes the connections. For more information, see Amazon VPC and Amazon RDS.

  You can add or edit an inbound rule in the security group. For **Source**, choose **My IP**. This allows access to the DB instance from the IP address detected in your browser.
- The DB instance was created using the default port of 3306, and your company has firewall rules blocking connections to that port from devices in your company network. To fix this failure, recreate the instance with a different port.

For more information on connection issues, see Can't connect to Amazon RDS DB instance.

Securing MariaDB DB instance connections

You can manage the security of your MariaDB DB instances.

Topics

MariaDB security on Amazon RDS

Security for MariaDB DB instances is managed at three levels:

- AWS Identity and Access Management controls who can perform Amazon RDS management actions on DB instances. When you connect to AWS using IAM credentials, your IAM account must have IAM policies that grant the permissions required to perform Amazon RDS management operations. For more information, see Identity and access management for Amazon RDS.
- When you create a DB instance, you use a VPC security group to control which devices and Amazon EC2 instances can open connections to the endpoint and port of the DB instance. These connections can be made using Secure Socket Layer (SSL) and Transport Layer Security (TLS). In addition, firewall rules at your company can control whether devices running at your company can open connections to the DB instance.
- Once a connection has been opened to a MariaDB DB instance, authentication of the login and permissions are applied the same way as in a stand-alone instance of MariaDB. Commands such as `CREATE USER`, `RENAME USER`, `GRANT`, `REVOKE`, and `SET PASSWORD` work just as they do in stand-alone databases, as does directly modifying database schema tables.

When you create an Amazon RDS DB instance, the master user has the following default privileges:

- `alter`
- `alter routine`
- `create`
- `create routine`
- `create temporary tables`

- `create user`
- `create view`
- `delete`
- `drop`
- `event`
- `execute`
- `grant option`
- `index`
- `insert`
- `lock tables`
- `process`
- `references`
- `reload`

  This privilege is limited on MariaDB DB instances. It doesn't grant access to the FLUSH LOGS or FLUSH TABLES WITH READ LOCK operations.
- `replication client`
- `replication slave`
- `select`
- `show databases`
- `show view`
- `trigger`
- `update`

For more information about these privileges, see User account management in the MariaDB documentation.

> **Note**
>
> Although you can delete the master user on a DB instance, we don't recommend doing so. To recreate the master user, use the `ModifyDBInstance` API or the `modify-db-instance` AWS CLI and specify a new master user password with the appropriate

parameter. If the master user does not exist in the instance, the master user is created with the specified password.

To provide management services for each DB instance, the `rdsadmin` user is created when the DB instance is created. Attempting to drop, rename, change the password for, or change privileges for the `rdsadmin` account results in an error.

To allow management of the DB instance, the standard `kill` and `kill_query` commands have been restricted. The Amazon RDS commands `mysql.rds_kill`, `mysql.rds_kill_query`, and `mysql.rds_kill_query_id` are provided for use in MariaDB and also MySQL so that you can end user sessions or queries on DB instances.

Encrypting client connections to MariaDB DB instances with SSL/TLS

Secure Sockets Layer (SSL) is an industry-standard protocol for securing network connections between client and server. After SSL version 3.0, the name was changed to Transport Layer Security (TLS). Amazon RDS supports SSL/TLS encryption for MariaDB DB instances. Using SSL/TLS, you can encrypt a connection between your application client and your MariaDB DB instance. SSL/TLS support is available in all AWS Regions.

Topics

- Using SSL/TLS with a MariaDB DB instance
- Requiring SSL/TLS for all connections to a MariaDB DB instance
- Connecting from the MySQL command-line client with SSL/TLS (encrypted)

Using SSL/TLS with a MariaDB DB instance

Amazon RDS creates an SSL/TLS certificate and installs the certificate on the DB instance when Amazon RDS provisions the instance. These certificates are signed by a certificate authority. The SSL/TLS certificate includes the DB instance endpoint as the Common Name (CN) for the SSL/TLS certificate to guard against spoofing attacks.

An SSL/TLS certificate created by Amazon RDS is the trusted root entity and should work in most cases but might fail if your application does not accept certificate chains. If your application does not accept certificate chains, you might need to use an intermediate certificate to connect to your AWS Region. For example, you must use an intermediate certificate to connect to the AWS GovCloud (US) Regions using SSL/TLS.

For information about downloading certificates, see Using SSL/TLS to encrypt a connection to a DB instance or cluster. For more information about using SSL/TLS with MySQL, see Updating applications to connect to MariaDB instances using new SSL/TLS certificates.

Amazon RDS for MariaDB supports Transport Layer Security (TLS) versions 1.3, 1.2, 1.1, and 1.0. TLS support depends on the MariaDB minor version. The following table shows the TLS support for MariaDB minor versions.

TLS version	MariaDB 10.11	MariaDB 10.6	MariaDB 10.5	MariaDB 10.4
TLS 1.3	All minor versions	All minor versions	All minor versions	All minor versions
TLS 1.2	All minor versions	All minor versions	All minor versions	All minor versions
TLS 1.1	10.11.6 and lower	10.6.16 and lower	10.5.23 and lower	10.4.32 and lower
TLS 1.0	10.11.6 and lower	10.6.16 and lower	10.5.23 and lower	10.4.32 and lower

You can require SSL/TLS connections for specific users accounts. For example, you can use one of the following statements, depending on your MariaDB version, to require SSL/TLS connections on the user account `encrypted_user`.

Use the following statement.

```
ALTER USER 'encrypted_user'@'%' REQUIRE SSL;
```

For more information on SSL/TLS connections with MariaDB, see Securing Connections for Client and Server in the MariaDB documentation.

Requiring SSL/TLS for all connections to a MariaDB DB instance

Use the `require_secure_transport` parameter to require that all user connections to your MariaDB DB instance use SSL/TLS. By default, the `require_secure_transport` parameter is set

to OFF. You can set the `require_secure_transport` parameter to ON to require SSL/TLS for connections to your DB instance.

> **Note**
>
> The `require_secure_transport` parameter is only supported for MariaDB version 10.5 and higher.

You can set the `require_secure_transport` parameter value by updating the DB parameter group for your DB instance. You don't need to reboot your DB instance for the change to take effect.

When the `require_secure_transport` parameter is set to ON for a DB instance, a database client can connect to it if it can establish an encrypted connection. Otherwise, an error message similar to the following is returned to the client:

```
ERROR 1045 (28000): Access denied for user 'USER'@'localhost' (using password: YES |
 NO)
```

For information about setting parameters, see Modifying parameters in a DB parameter group in Amazon RDS.

For more information about the `require_secure_transport` parameter, see the MariaDB documentation.

Connecting from the MySQL command-line client with SSL/TLS (encrypted)

The `mysql` client program parameters are slightly different if you are using the MySQL 5.7 version, the MySQL 8.0 version, or the MariaDB version.

To find out which version you have, run the `mysql` command with the `--version` option. In the following example, the output shows that the client program is from MariaDB.

```
$ mysql --version
mysql  Ver 15.1 Distrib 10.5.15-MariaDB, for osx10.15 (x86_64) using readline 5.1
```

Most Linux distributions, such as Amazon Linux, CentOS, SUSE, and Debian have replaced MySQL with MariaDB, and the `mysql` version in them is from MariaDB.

To connect to your DB instance using SSL/TLS, follow these steps:

To connect to a DB instance with SSL/TLS using the MySQL command-line client

1. Download a root certificate that works for all AWS Regions.

   For information about downloading certificates, see Using SSL/TLS to encrypt a connection to a DB instance or cluster.

2. Use a MySQL command-line client to connect to a DB instance with SSL/TLS encryption. For the `-h` parameter, substitute the DNS name (endpoint) for your DB instance. For the `--ssl-ca` parameter, substitute the SSL/TLS certificate file name. For the `-P` parameter, substitute the port for your DB instance. For the `-u` parameter, substitute the user name of a valid database user, such as the master user. Enter the master user password when prompted.

   The following example shows how to launch the client using the `--ssl-ca` parameter using the MariaDB client:

   ```
   mysql -h mysql-instance1.123456789012.us-east-1.rds.amazonaws.com --ssl-ca=global-bundle.pem --ssl -P 3306 -u myadmin -p
   ```

   To require that the SSL/TLS connection verifies the DB instance endpoint against the endpoint in the SSL/TLS certificate, enter the following command:

   ```
   mysql -h mysql-instance1.123456789012.us-east-1.rds.amazonaws.com --ssl-ca=global-bundle.pem --ssl-verify-server-cert -P 3306 -u myadmin -p
   ```

   The following example shows how to launch the client using the `--ssl-ca` parameter using the MySQL 5.7 client or later:

   ```
   mysql -h mysql-instance1.123456789012.us-east-1.rds.amazonaws.com --ssl-ca=global-bundle.pem --ssl-mode=REQUIRED -P 3306 -u myadmin -p
   ```

3. Enter the master user password when prompted.

You should see output similar to the following.

```
Welcome to the MariaDB monitor.  Commands end with ; or \g.
Your MariaDB connection id is 31
Server version: 10.6.10-MariaDB-log Source distribution
```

```

Type 'help;' or '\h' for help. Type '\c' to clear the current input statement.

MariaDB [(none)]>
```

Updating applications to connect to MariaDB instances using new SSL/TLS certificates

As of January 13, 2023, Amazon RDS has published new Certificate Authority (CA) certificates for connecting to your RDS DB instances using Secure Socket Layer or Transport Layer Security (SSL/TLS). Following, you can find information about updating your applications to use the new certificates.

This topic can help you to determine whether your applications require certificate verification to connect to your DB instances.

> **Note**
>
> Some applications are configured to connect to MariaDB only if they can successfully verify the certificate on the server. For such applications, you must update your client application trust stores to include the new CA certificates.
> You can specify the following SSL modes: `disabled`, `preferred`, and `required`. When you use the `preferred` SSL mode and the CA certificate doesn't exist or isn't up to date, the connection falls back to not using SSL and still connects successfully.
> We recommend avoiding `preferred` mode. In `preferred` mode, if the connection encounters an invalid certificate, it stops using encryption and proceeds unencrypted.

After you update your CA certificates in the client application trust stores, you can rotate the certificates on your DB instances. We strongly recommend testing these procedures in a development or staging environment before implementing them in your production environments.

For more information about certificate rotation, see Rotating your SSL/TLS certificate. For more information about downloading certificates, see Using SSL/TLS to encrypt a connection to a DB instance or cluster. For information about using SSL/TLS with MariaDB DB instances, see Using SSL/TLS with a MariaDB DB instance.

Topics

Determining whether a client requires certificate verification in order to connect

You can check whether JDBC clients and MySQL clients require certificate verification to connect.

JDBC

The following example with MySQL Connector/J 8.0 shows one way to check an application's JDBC connection properties to determine whether successful connections require a valid certificate. For more information on all of the JDBC connection options for MySQL, see Configuration properties in the MySQL documentation.

When using the MySQL Connector/J 8.0, an SSL connection requires verification against the server CA certificate if your connection properties have `sslMode` set to `VERIFY_CA` or `VERIFY_IDENTITY`, as in the following example.

```
Properties properties = new Properties();
properties.setProperty("sslMode", "VERIFY_IDENTITY");
properties.put("user", DB_USER);
properties.put("password", DB_PASSWORD);
```

Note

If you use either the MySQL Java Connector v5.1.38 or later, or the MySQL Java Connector v8.0.9 or later to connect to your databases, even if you haven't explicitly configured your applications to use SSL/TLS when connecting to your databases, these client drivers default to using SSL/TLS. In addition, when using SSL/TLS, they perform partial certificate verification and fail to connect if the database server certificate is expired.
Specify a password other than the prompt shown here as a security best practice.

MySQL

The following examples with the MySQL Client show two ways to check a script's MySQL connection to determine whether successful connections require a valid certificate. For more information on all of the connection options with the MySQL Client, see Client-side configuration for encrypted connections in the MySQL documentation.

When using the MySQL 5.7 or MySQL 8.0 Client, an SSL connection requires verification against the server CA certificate if for the `--ssl-mode` option you specify `VERIFY_CA` or `VERIFY_IDENTITY`, as in the following example.

```
mysql -h mysql-database.rds.amazonaws.com -uadmin -ppassword --ssl-ca=/tmp/ssl-cert.pem
 --ssl-mode=VERIFY_CA
```

When using the MySQL 5.6 Client, an SSL connection requires verification against the server CA certificate if you specify the `--ssl-verify-server-cert` option, as in the following example.

```
mysql -h mysql-database.rds.amazonaws.com -uadmin -ppassword --ssl-ca=/tmp/ssl-cert.pem
 --ssl-verify-server-cert
```

Updating your application trust store

For information about updating the trust store for MySQL applications, see Using TLS/SSL with MariaDB Connector/J in the MariaDB documentation.

For information about downloading the root certificate, see Using SSL/TLS to encrypt a connection to a DB instance or cluster.

For sample scripts that import certificates, see Sample script for importing certificates into your trust store.

> **Note**
>
> When you update the trust store, you can retain older certificates in addition to adding the new certificates.

If you are using the MariaDB Connector/J JDBC driver in an application, set the following properties in the application.

```
System.setProperty("javax.net.ssl.trustStore", certs);
System.setProperty("javax.net.ssl.trustStorePassword", "password");
```

When you start the application, set the following properties.

```
java -Djavax.net.ssl.trustStore=/path_to_truststore/MyTruststore.jks -
Djavax.net.ssl.trustStorePassword=my_truststore_password com.companyName.MyApplication
```

Note

Specify passwords other than the prompts shown here as a security best practice.

Example Java code for establishing SSL connections

The following code example shows how to set up the SSL connection using JDBC.

```
private static final String DB_USER = "admin";

        private static final String DB_USER = "user name";
        private static final String DB_PASSWORD = "password";
        // This key store has only the prod root ca.
        private static final String KEY_STORE_FILE_PATH = "file-path-to-keystore";
        private static final String KEY_STORE_PASS = "keystore-password";

    public static void main(String[] args) throws Exception {
        Class.forName("org.mariadb.jdbc.Driver");

        System.setProperty("javax.net.ssl.trustStore", KEY_STORE_FILE_PATH);
        System.setProperty("javax.net.ssl.trustStorePassword", KEY_STORE_PASS);

        Properties properties = new Properties();
```

```
        properties.put("user", DB_USER);
        properties.put("password", DB_PASSWORD);

        Connection connection = DriverManager.getConnection("jdbc:mysql://ssl-mariadb-
public.cni62e2e7kwh.us-east-1.rds.amazonaws.com:3306?useSSL=true",properties);
        Statement stmt=connection.createStatement();

        ResultSet rs=stmt.executeQuery("SELECT 1 from dual");

        return;
    }
```

Important

After you have determined that your database connections use SSL/TLS and have updated your application trust store, you can update your database to use the rds-ca-rsa2048-g1 certificates. For instructions, see step 3 in Updating your CA certificate by modifying your DB instance or cluster.

Specify a password other than the prompt shown here as a security best practice.

Improving query performance for RDS for MariaDB with Amazon RDS Optimized Reads

You can achieve faster query processing for RDS for MariaDB with Amazon RDS Optimized Reads. An RDS for MariaDB DB instance that uses RDS Optimized Reads can achieve up to 2x faster query processing compared to a DB instance that doesn't use it.

Topics

Overview of RDS Optimized Reads

When you use an RDS for MariaDB DB instance that has RDS Optimized Reads turned on, your DB instance achieves faster query performance through the use of an instance store. An *instance store* provides temporary block-level storage for your DB instance. The storage is located on Non-Volatile Memory Express (NVMe) solid state drives (SSDs) that are physically attached to the host server. This storage is optimized for low latency, high random I/O performance, and high sequential read throughput.

RDS Optimized Reads is turned on by default when a DB instance uses a DB instance class with an instance store, such as db.m5d or db.m6gd. With RDS Optimized Reads, some temporary objects are stored on the instance store. These temporary objects include internal temporary files, internal on-disk temp tables, memory map files, and binary log (binlog) cache files. For more information about the instance store, see Amazon EC2 instance store in the *Amazon Elastic Compute Cloud User Guide for Linux Instances*.

The workloads that generate temporary objects in MariaDB for query processing can take advantage of the instance store for faster query processing. This type of workload includes queries involving sorts, hash aggregations, high-load joins, Common Table Expressions (CTEs), and queries on unindexed columns. These instance store volumes provide higher IOPS and performance, regardless of the storage configurations used for persistent Amazon EBS storage. Because RDS

Optimized Reads offloads operations on temporary objects to the instance store, the input/output operations per second (IOPS) or throughput of the persistent storage (Amazon EBS) can now be used for operations on persistent objects. These operations include regular data file reads and writes and background engine operations, such as flushing and insert buffer merges.

> **Note**
>
> Both manual and automated RDS snapshots contain only the engine files for persistent objects. The temporary objects created in the instance store aren't included in RDS snapshots.

Use cases for RDS Optimized Reads

If you have workloads that rely heavily on temporary objects, such as internal tables or files, for their query execution, then you can benefit from turning on RDS Optimized Reads. The following use cases are candidates for RDS Optimized Reads:

- Applications that run analytical queries with complex common table expressions (CTEs), derived tables, and grouping operations
- Read replicas that serve heavy read traffic with unoptimized queries
- Applications that run on-demand or dynamic reporting queries that involve complex operations, such as queries with `GROUP BY` and `ORDER BY` clauses
- Workloads that use internal temporary tables for query processing

  You can monitor the engine status variable `created_tmp_disk_tables` to determine the number of disk-based temporary tables created on your DB instance.
- Applications that create large temporary tables, either directly or in procedures, to store intermediate results
- Database queries that perform grouping or ordering on non-indexed columns

Best practices for RDS Optimized Reads

Use the following best practices for RDS Optimized Reads:

- Add retry logic for read-only queries in case they fail because the instance store is full during the execution.

- Monitor the storage space available on the instance store with the CloudWatch metric `FreeLocalStorage`. If the instance store is reaching its limit because of workload on the DB instance, modify the DB instance to use a larger DB instance class.
- When your DB instance has sufficient memory but is still reaching the storage limit on the instance store, increase the `binlog_cache_size` value to maintain the session-specific binlog entries in memory. This configuration prevents writing the binlog entries to temporary binlog cache files on disk.

  The `binlog_cache_size` parameter is session-specific. You can change the value for each new session. The setting for this parameter can increase the memory utilization on the DB instance during peak workload. Therefore, consider increasing the parameter value based on the workload pattern of your application and available memory on the DB instance.
- Use the default value of `MIXED` for the `binlog_format`. Depending on the size of the transactions, setting `binlog_format` to `ROW` can result in large binlog cache files on the instance store.
- Avoid performing bulk changes in a single transaction. These types of transactions can generate large binlog cache files on the instance store and can cause issues when the instance store is full. Consider splitting writes into multiple small transactions to minimize storage use for binlog cache files.

Using RDS Optimized Reads

When you provision an RDS for MariaDB DB instance with one of the following DB instance classes in a Single-AZ DB instance deployment or Multi-AZ DB instance deployment, the DB instance automatically uses RDS Optimized Reads.

To turn on RDS Optimized Reads, do one of the following:

- Create an RDS for MariaDB DB instance using one of these DB instance classes. For more information, see Creating an Amazon RDS DB instance.
- Modify an existing RDS for MariaDB DB instance to use one of these DB instance classes. For more information, see Modifying an Amazon RDS DB instance.

RDS Optimized Reads is available in all AWS Regions where one or more of the DB instance classes with local NVMe SSD storage are supported. For information about DB instance classes, see the section called “DB instance classes”.

DB instance class availability differs for AWS Regions. To determine whether a DB instance class is supported in a specific AWS Region, see the section called "Determining DB instance class support in AWS Regions".

If you don't want to use RDS Optimized Reads, modify your DB instance so that it doesn't use a DB instance class that supports the feature.

Monitoring DB instances that use RDS Optimized Reads

You can monitor DB instances that use RDS Optimized Reads with the following CloudWatch metrics:

- `FreeLocalStorage`
- `ReadIOPSLocalStorage`
- `ReadLatencyLocalStorage`
- `ReadThroughputLocalStorage`
- `WriteIOPSLocalStorage`
- `WriteLatencyLocalStorage`
- `WriteThroughputLocalStorage`

These metrics provide data about available instance store storage, IOPS, and throughput. For more information about these metrics, see Amazon CloudWatch instance-level metrics for Amazon RDS.

Limitations for RDS Optimized Reads

The following limitations apply to RDS Optimized Reads:

- RDS Optimized Reads is supported for the following RDS for MariaDB versions:
  - 10.11.4 and higher 10.11 versions
  - 10.6.7 and higher 10.6 versions
  - 10.5.16 and higher 10.5 versions
  - 10.4.25 and higher 10.4 versions

  For information about RDS for MariaDB versions, see MariaDB on Amazon RDS versions.
- You can't change the location of temporary objects to persistent storage (Amazon EBS) on the DB instance classes that support RDS Optimized Reads.

- When binary logging is enabled on a DB instance, the maximum transaction size is limited by the size of the instance store. In MariaDB, any session that requires more storage than the value of `binlog_cache_size` writes transaction changes to temporary binlog cache files, which are created on the instance store.
- Transactions can fail when the instance store is full.

Improving write performance with Amazon RDS Optimized Writes for MariaDB

You can improve the performance of write transactions with RDS Optimized Writes for MariaDB. When your RDS for MariaDB database uses RDS Optimized Writes, it can achieve up to two times higher write transaction throughput.

Topics

Overview of RDS Optimized Writes

When you turn on RDS Optimized Writes, your RDS for MariaDB databases write only once when flushing data to durable storage without the need for the doublewrite buffer. The databases continue to provide ACID property protections for reliable database transactions, along with improved performance.

Relational databases, like MariaDB, provide the *ACID properties* of atomicity, consistency, isolation, and durability for reliable database transactions. To help provide these properties, MariaDB uses a data storage area called the *doublewrite buffer* that prevents partial page write errors. These errors occur when there is a hardware failure while the database is updating a page, such as in the case of a power outage. A MariaDB database can detect partial page writes and recover with a copy of the page in the doublewrite buffer. While this technique provides protection, it also results in extra write operations. For more information about the MariaDB doublewrite buffer, see InnoDB Doublewrite Buffer in the MariaDB documentation.

With RDS Optimized Writes turned on, RDS for MariaDB databases write only once when flushing data to durable storage without using the doublewrite buffer. RDS Optimized Writes is useful if you run write-heavy workloads on your RDS for MariaDB databases. Examples of databases with write-heavy workloads include ones that support digital payments, financial trading, and gaming applications.

These databases run on DB instance classes that use the AWS Nitro System. Because of the hardware configuration in these systems, the database can write 16-KiB pages directly to data files reliably and durably in one step. The AWS Nitro System makes RDS Optimized Writes possible.

You can set the new database parameter `rds.optimized_writes` to control the RDS Optimized Writes feature for RDS for MariaDB databases. Access this parameter in the DB parameter groups of RDS for MariaDB for the following versions:

- 10.11.4 and higher 10.11 versions
- 10.6.10 and higher 10.6 versions

Set the parameter using the following values:

- `AUTO` – Turn on RDS Optimized Writes if the database supports it. Turn off RDS Optimized Writes if the database doesn't support it. This setting is the default.
- `OFF` – Turn off RDS Optimized Writes even if the database supports it.

If you migrate an RDS for MariaDB database that is configured to use RDS Optimized Writes to a DB instance class that doesn't support the feature, RDS automatically turns off RDS Optimized Writes for the database.

When RDS Optimized Writes is turned off, the database uses the MariaDB doublewrite buffer.

To determine whether an RDS for MariaDB database is using RDS Optimized Writes, view the current value of the `innodb_doublewrite` parameter for the database. If the database is using RDS Optimized Writes, this parameter is set to `FALSE` (`0`).

Using RDS Optimized Writes

You can turn on RDS Optimized Writes when you create an RDS for MariaDB database with the RDS console, the AWS CLI, or the RDS API. RDS Optimized Writes is turned on automatically when both of the following conditions apply during database creation:

- You specify a DB engine version and DB instance class that support RDS Optimized Writes.
  - RDS Optimized Writes is supported for the following RDS for MariaDB versions:
    - 10.11.4 and higher 10.11 versions
    - 10.6.10 and higher 10.6 versions

For information about RDS for MariaDB versions, see MariaDB on Amazon RDS versions.

- RDS Optimized Writes is supported for RDS for MariaDB databases that use the following DB instance classes:
  - db.m7g
  - db.m6g
  - db.m6gd
  - db.m6i
  - db.m5
  - db.m5d
  - db.r7g
  - db.r6g
  - db.r6gd
  - db.r6i
  - db.r5
  - db.r5b
  - db.r5d
  - db.x2idn
  - db.x2iedn

  For information about DB instance classes, see the section called "DB instance classes".

  DB instance class availability differs for AWS Regions. To determine whether a DB instance class is supported in a specific AWS Region, see the section called "Determining DB instance class support in AWS Regions".
- In the parameter group associated with the database, the `rds.optimized_writes` parameter is set to AUTO. In default parameter groups, this parameter is always set to AUTO.

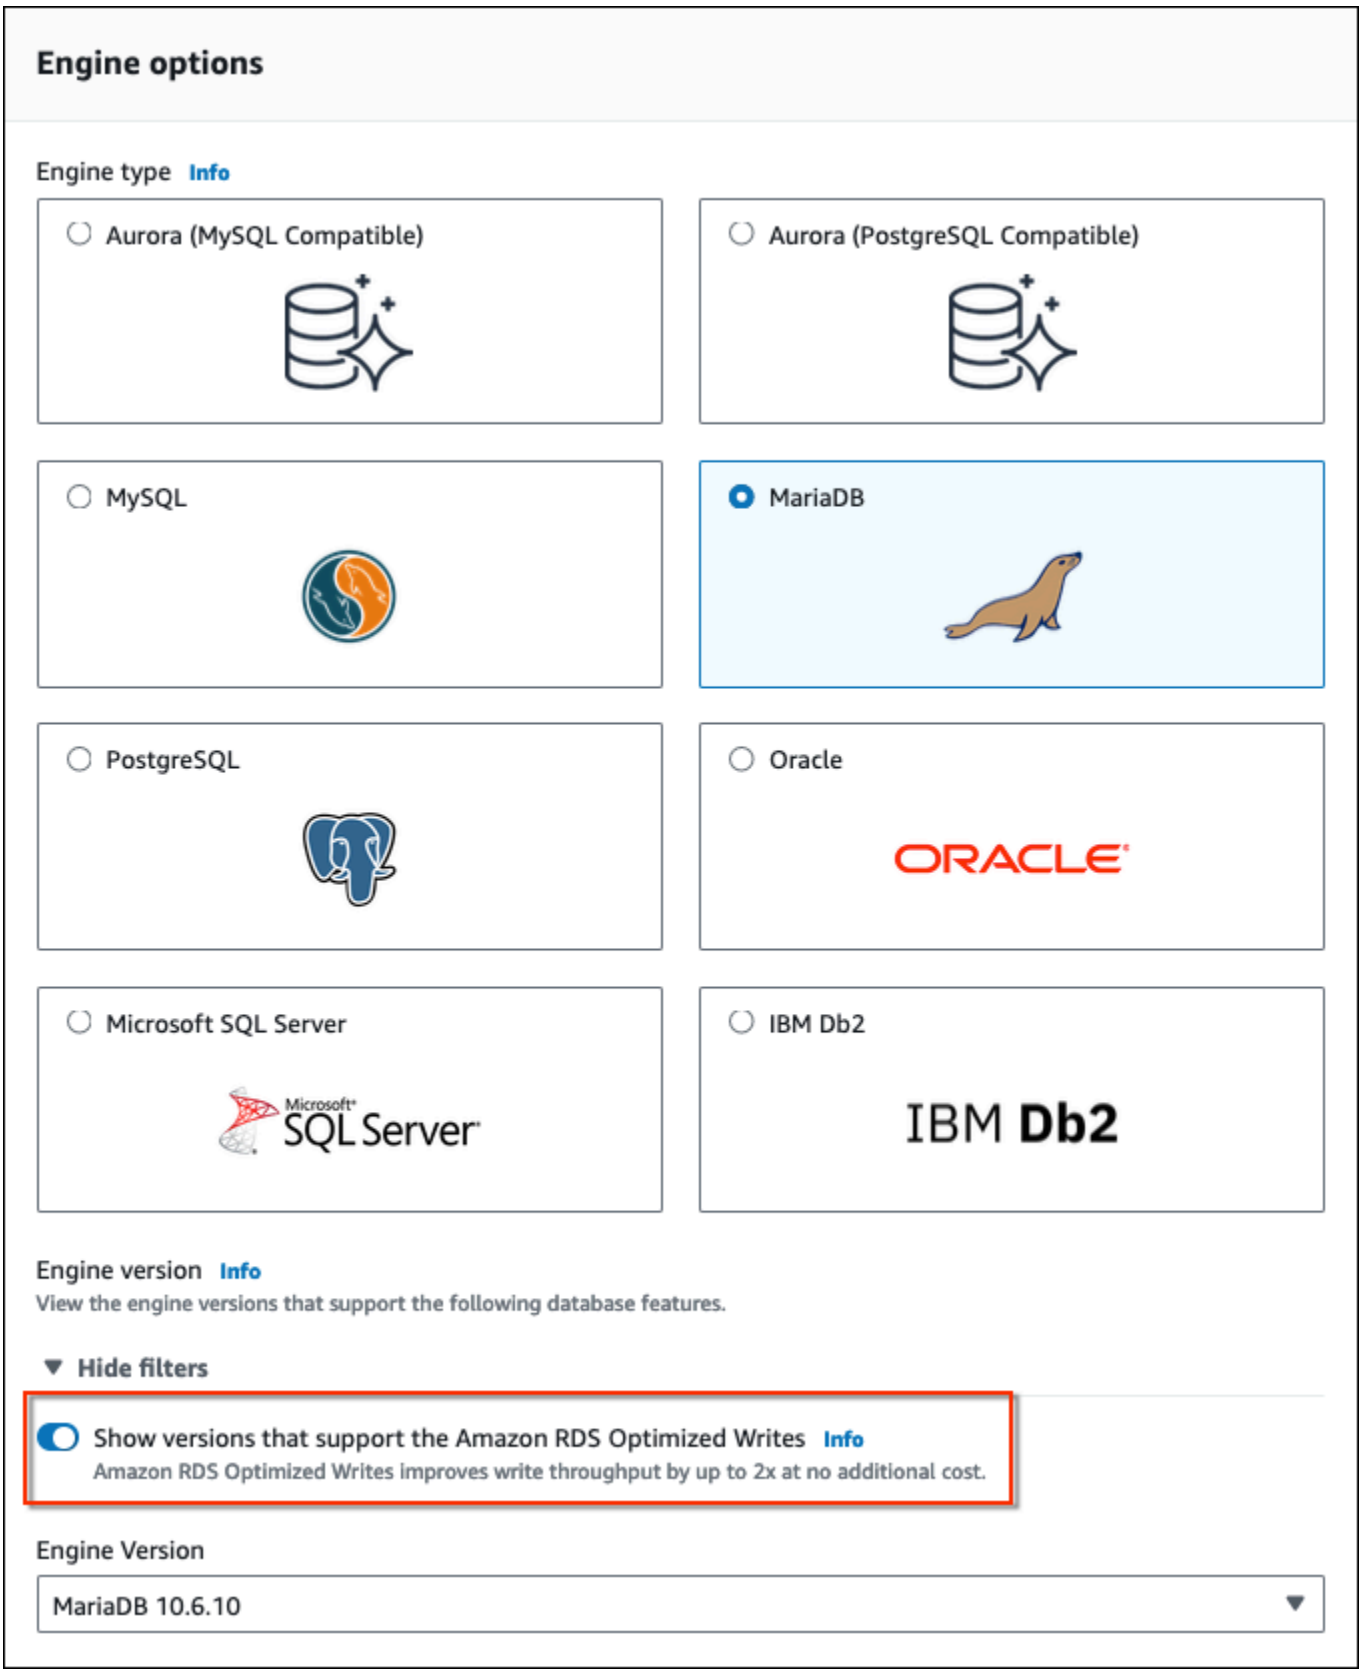
If you want to use a DB engine version and DB instance class that support RDS Optimized Writes, but you don't want to use this feature, then specify a custom parameter group when you create the database. In this parameter group, set the `rds.optimized_writes` parameter to OFF. If you want the database to use RDS Optimized Writes later, you can set the parameter to AUTO to turn it on. For information about creating custom parameter groups and setting parameters, see Parameter groups for Amazon RDS.

For information about creating a DB instance, see Creating an Amazon RDS DB instance.

Console

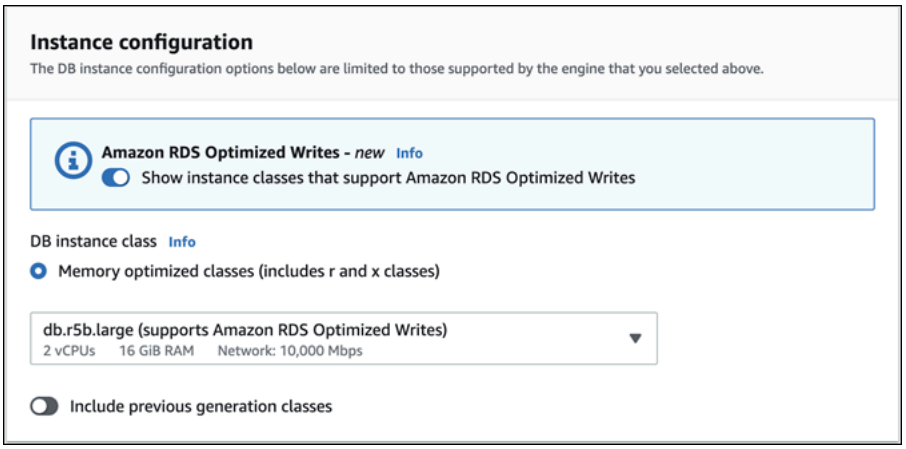
When you use the RDS console to create an RDS for MariaDB database, you can filter for the DB engine versions and DB instance classes that support RDS Optimized Writes. After you turn on the filters, you can choose from the available DB engine versions and DB instance classes.

To choose a DB engine version that supports RDS Optimized Writes, filter for the RDS for MariaDB DB engine versions that support it in **Engine version**, and then choose a version.



Engine options
Engine type Info
Aurora (MySQL Compatible)
Aurora (PostgreSQL Compatible)
MySQL
MariaDB
PostgreSQL
Oracle
ORACLE
Microsoft SQL Server
Microsoft SQL Server
IBM Db2
IBM Db2
Engine version Info
View the engine versions that support the following database features.
Hide filters
Show versions that support the Amazon RDS Optimized Writes Info
Amazon RDS Optimized Writes improves write throughput by up to 2x at no additional cost.
Engine Version
MariaDB 10.6.10

In the **Instance configuration** section, filter for the DB instance classes that support RDS Optimized Writes, and then choose a DB instance class.



After you make these selections, you can choose other settings that meet your requirements and finish creating the RDS for MariaDB database with the console.

AWS CLI

To create a DB instance by using the AWS CLI, use the create-db-instance command. Make sure the `--engine-version` and `--db-instance-class` values support RDS Optimized Writes. In addition, make sure the parameter group associated with the DB instance has the `rds.optimized_writes` parameter set to AUTO. This example associates the default parameter group with the DB instance.

Example Creating a DB instance that uses RDS Optimized Writes

For Linux, macOS, or Unix:

```
aws rds create-db-instance \
    --db-instance-identifier mydbinstance \
    --engine mariadb \
    --engine-version 10.6.10 \
    --db-instance-class db.r5b.large \
    --manage-master-user-password \
    --master-username admin \
    --allocated-storage 200
```

For Windows:

```
aws rds create-db-instance ^
    --db-instance-identifier mydbinstance ^
```

```
    --engine mariadb ^
    --engine-version 10.6.10 ^
    --db-instance-class db.r5b.large ^
    --manage-master-user-password ^
    --master-username admin ^
    --allocated-storage 200
```

RDS API

You can create a DB instance using the CreateDBInstance operation. When you use this operation, make sure the `EngineVersion` and `DBInstanceClass` values support RDS Optimized Writes. In addition, make sure the parameter group associated with the DB instance has the `rds.optimized_writes` parameter set to `AUTO`.

Enabling RDS Optimized Writes on an existing database

In order to modify an existing RDS for MariaDB database to turn on RDS Optimized Writes, the database must have been created with a supported DB engine version and DB instance class. In addition, the database must have been created *after* RDS Optimized Writes was released on March 7, 2023, as the required underlying file system configuration is incompatible with that of databases created before it was released. If these conditions are met, you can turn on RDS Optimized Writes by setting the `rds.optimized_writes` parameter to `AUTO`.

If your database was *not* created with a supported engine version, instance class, or file system configuration, you can use RDS Blue/Green Deployments to migrate to a supported configuration. While creating the blue/green deployment, do the following:

- Select **Enable Optimized Writes on green database**, then specify an engine version and DB instance class that supports RDS Optimized Writes. For a list of supported engine versions and instance classes, see the section called “Using with a new database”.
- Under **Storage**, choose **Upgrade storage file system configuration**. This option upgrades the database to a compatible underlying file system configuration.

When you create the blue/green deployment, if the `rds.optimized_writes` parameter is set to `AUTO`, RDS Optimized Writes will be automatically enabled on the green environment. You can then switch over the blue/green deployment, which promotes the green environment to be the new production environment.

For more information, see the section called “Creating a blue/green deployment”.

Limitations for RDS Optimized Writes

When you're restoring an RDS for MariaDB database from a snapshot, you can only turn on RDS Optimized Writes for the database if all of the following conditions apply:

- The snapshot was created from a database that supports RDS Optimized Writes.
- The snapshot was created from a database that was created *after* RDS Optimized Writes was released.
- The snapshot is restored to a database that supports RDS Optimized Writes.
- The restored database is associated with a parameter group that has the `rds.optimized_writes` parameter set to `AUTO`.

Upgrading the MariaDB DB engine

When Amazon RDS supports a new version of a database engine, you can upgrade your DB instances to the new version. There are two kinds of upgrades for MariaDB DB instances: major version upgrades and minor version upgrades.

Major version upgrades can contain database changes that are not backward-compatible with existing applications. As a result, you must manually perform major version upgrades of your DB instances. You can initiate a major version upgrade by modifying your DB instance. However, before you perform a major version upgrade, we recommend that you follow the instructions in Major version upgrades for MariaDB.

In contrast, *minor version upgrades* include only changes that are backward-compatible with existing applications. You can initiate a minor version upgrade manually by modifying your DB instance. Or you can enable the **Auto minor version upgrade** option when creating or modifying a DB instance. Doing so means that your DB instance is automatically upgraded after Amazon RDS tests and approves the new version. For information about performing an upgrade, see Upgrading a DB instance engine version.

If your MariaDB DB instance is using read replicas, you must upgrade all of the read replicas before upgrading the source instance. If your DB instance is in a Multi-AZ deployment, both the writer and standby replicas are upgraded. Your DB instance might not be available until the upgrade is complete.

For more information about MariaDB supported versions and version management, see MariaDB on Amazon RDS versions.

Database engine upgrades require downtime. The duration of the downtime varies based on the size of your DB instance.

> **Tip**
>
> You can minimize the downtime required for DB instance upgrade by using a blue/green deployment. For more information, see Using Amazon RDS Blue/Green Deployments for database updates.

Topics

- MariaDB version numbers
- RDS version number
- Major version upgrades for MariaDB
- Upgrading a MariaDB DB instance
- Automatic minor version upgrades for MariaDB
- Using a read replica to reduce downtime when upgrading a MariaDB database

Overview of upgrading

When you use the AWS Management Console to upgrade a DB instance, it shows the valid upgrade targets for the DB instance. You can also use the following AWS CLI command to identify the valid upgrade targets for a DB instance:

For Linux, macOS, or Unix:

```
aws rds describe-db-engine-versions \
  --engine mariadb \
  --engine-version version-number \
  --query "DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}" --
output text
```

For Windows:

```
aws rds describe-db-engine-versions ^
  --engine mariadb ^
  --engine-version version-number ^
  --query "DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}" --
output text
```

For example, to identify the valid upgrade targets for a MariaDB version 10.5.17 DB instance, run the following AWS CLI command:

For Linux, macOS, or Unix:

```
aws rds describe-db-engine-versions \
  --engine mariadb \
  --engine-version 10.5.17 \
```

```
  --query "DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}" --
output text
```

For Windows:

```
aws rds describe-db-engine-versions ^
  --engine mariadb ^
  --engine-version 10.5.17 ^
  --query "DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}" --
output text
```

Amazon RDS takes two or more DB snapshots during the upgrade process. Amazon RDS takes up to two snapshots of the DB instance *before* making any upgrade changes. If the upgrade doesn't work for your databases, you can restore one of these snapshots to create a DB instance running the old version. Amazon RDS takes another snapshot of the DB instance when the upgrade completes. Amazon RDS takes these snapshots regardless of whether AWS Backup manages the backups for the DB instance.

> **Note**
>
> Amazon RDS only takes DB snapshots if you have set the backup retention period for your DB instance to a number greater than 0. To change your backup retention period, see Modifying an Amazon RDS DB instance.

After the upgrade is complete, you can't revert to the previous version of the database engine. If you want to return to the previous version, restore the first DB snapshot taken to create a new DB instance.

You control when to upgrade your DB instance to a new version supported by Amazon RDS. This level of control helps you maintain compatibility with specific database versions and test new versions with your application before deploying in production. When you are ready, you can perform version upgrades at the times that best fit your schedule.

If your DB instance is using read replication, you must upgrade all of the Read Replicas before upgrading the source instance.

If your DB instance is in a Multi-AZ deployment, both the primary and standby DB instances are upgraded. The primary and standby DB instances are upgraded at the same time and you will

experience an outage until the upgrade is complete. The time for the outage varies based on your database engine, engine version, and the size of your DB instance.

MariaDB version numbers

The version numbering sequence for the RDS for MariaDB database engine is either in the form of *major.minor.patch.YYYYMMDD* or *major.minor.patch*, for example, 10.11.5.R2.20231201 or 10.4.30. The format used depends on the MariaDB engine version.

major

The major version number is both the integer and the first fractional part of the version number, for example, 10.11. A major version upgrade increases the major part of the version number. For example, an upgrade from *10.5*.20 to 10.6.12 is a major version upgrade, where *10.5* and *10.6* are the major version numbers.

minor

The minor version number is the third part of the version number, for example, the 5 in 10.11.5.

patch

The patch is the fourth part of the version number, for example, the R2 in 10.11.5.R2. An RDS patch version includes important bug fixes added to a minor version after its release.

YYYYMMDD

The date is the fifth part of the version number, for example, the 20231201 in 10.11.5.R2.20231201. An RDS date version is a security patch that includes important security fixes added to a minor version after its release. It doesn't include any fixes that might change an engine's behavior.

The following table explains the naming scheme for RDS for MariaDB version 10.11.

10.11 minor version	Naming scheme
≥5	New DB instances use *major.minor.patch.YYMMDD*, for example, 10.11.5.R2.20231201.

10.11 minor version	Naming scheme
	Existing DB instances might use *major.minor.patch*, for example, 10.11.5.R2, until your next major or minor version upgrade.
< 5	Existing DB instances use *major.minor.patch*, for example, 10.11.4.R2.

The following table explains the naming scheme for RDS for MariaDB version 10.6.

10.6 minor version	Naming scheme
≥ 14	New DB instances use *major.minor.patch.YYMMDD*, for example, 10.6.14.R2.20231201. Existing DB instances might use *major.minor.patch*, for example, 10.6.14.R2, until your next major or minor version upgrade.
< 14	Existing DB instances use *major.minor.patch*, for example, 10.6.13.R2.

The following table explains the naming scheme for RDS for MariaDB version 10.5.

10.5 minor version	Naming scheme
≥ 21	New DB instances use *major.minor.patch.YYMMDD*, for example, 10.5.21.R2.20231201. Existing DB instances might use *major.minor.patch*, for example, 10.5.21.R2, until your next major or minor version upgrade.
< 21	Existing DB instances use *major.minor.patch*, for example, 10.5.20.R2.

The following table explains the naming scheme for RDS for MariaDB version 10.4.

10.4 minor version	Naming scheme
≥ 30	New DB instances use *major.minor.patch.YYMMDD*, for example, 10.4.30.R2.20231201. Existing DB instances might use *major.minor.patch*, for example, 10.4.30.R2, until your next major or minor version upgrade.
< 30	Existing DB instances use *major.minor.patch*, for example, 10.4.29.R2.

RDS version number

RDS version numbers use either the *major*.*minor*.*patch* or the *major*.*minor*.*patch*.*YYYYMMDD* naming scheme. An RDS patch version includes important bug fixes added to a minor version after its release. An RDS date version (*YYMMDD*) is a security patch. A security patch doesn't include any fixes that might change the engine's behavior.

To identify the Amazon RDS version number of your database, you must first create the `rds_tools` extension by using the following command:

```
CREATE EXTENSION rds_tools;
```

You can find out the RDS version number of your RDS for MariaDB database with the following SQL query:

```
mysql> select mysql.rds_version();
```

For example, querying an RDS for MariaDB 10.6.14 database returns the following output:

```
+---------------------+
| mysql.rds_version() |
+---------------------+
| 10.6.14.R2.20231201  |
+---------------------+
```

```
1 row in set (0.01 sec)
```

Major version upgrades for MariaDB

Major version upgrades can contain database changes that are not backward-compatible with existing applications. As a result, Amazon RDS doesn't apply major version upgrades automatically. You must manually modify your DB instance. We recommend that you thoroughly test any upgrade before applying it to your production instances.

Amazon RDS supports the following in-place upgrades for major versions of the MariaDB database engine:

- Any MariaDB version to MariaDB 10.11
- Any MariaDB version to MariaDB 10.6
- MariaDB 10.4 to MariaDB 10.5
- MariaDB 10.3 to MariaDB 10.4

To perform a major version upgrade to a MariaDB version lower than 10.6, upgrade to each major version in order. For example, to upgrade from version 10.3 to version 10.5, upgrade in the following order: 10.3 to 10.4 and then 10.4 to 10.5.

If you are using a custom parameter group, and you perform a major version upgrade, you must specify either a default parameter group for the new DB engine version or create your own custom parameter group for the new DB engine version. Associating the new parameter group with the DB instance requires a customer-initiated database reboot after the upgrade completes. The instance's parameter group status will show `pending-reboot` if the instance needs to be rebooted to apply the parameter group changes. An instance's parameter group status can be viewed in the AWS Management Console or by using a "describe" call such as `describe-db-instances`.

Upgrading a MariaDB DB instance

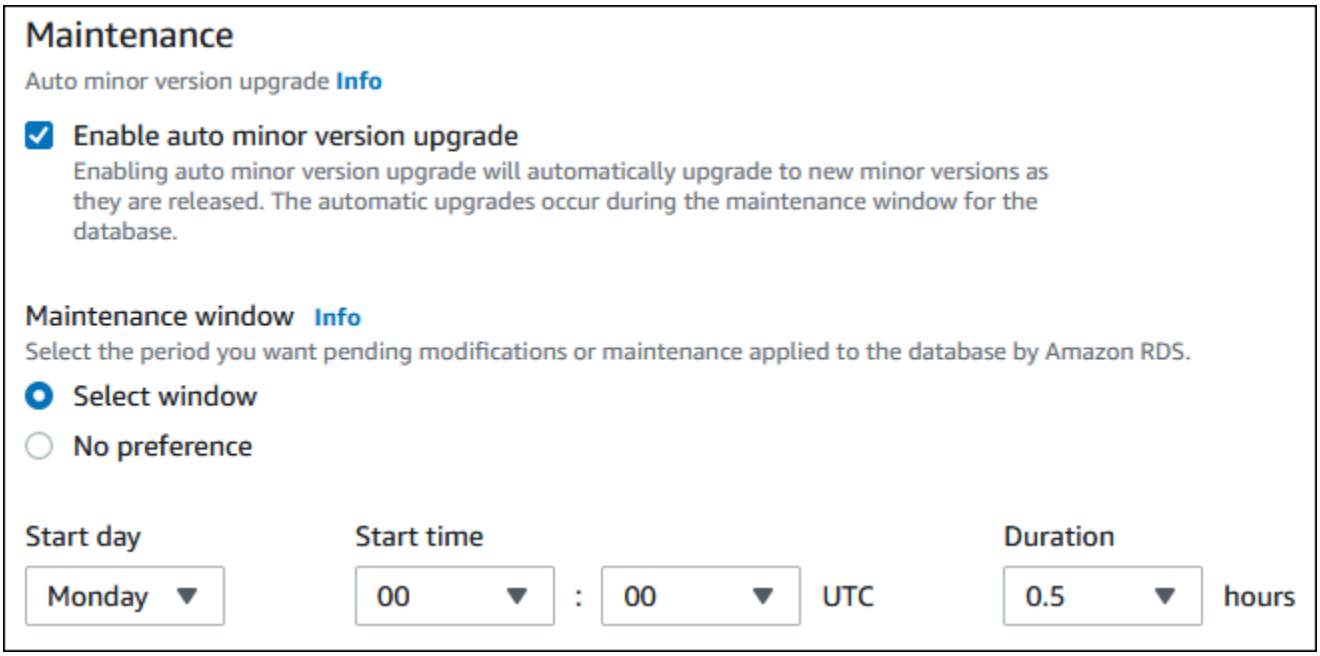
For information about manually or automatically upgrading a MariaDB DB instance, see Upgrading a DB instance engine version.

Automatic minor version upgrades for MariaDB

If you specify the following settings when creating or modifying a DB instance, you can have your DB instance automatically upgraded.

- The **Auto minor version upgrade** setting is enabled.
- The **Backup retention period** setting is greater than 0.

In the AWS Management Console, these settings are under **Additional configuration**. The following image shows the **Auto minor version upgrade** setting.



For more information about these settings, see Settings for DB instances.

For some RDS for MariaDB major versions in some AWS Regions, one minor version is designated by RDS as the automatic upgrade version. After a minor version has been tested and approved by Amazon RDS, the minor version upgrade occurs automatically during your maintenance window. RDS doesn't automatically set newer released minor versions as the automatic upgrade version. Before RDS designates a newer automatic upgrade version, several criteria are considered, such as the following:

- Known security issues
- Bugs in the MariaDB community version
- Overall fleet stability since the minor version was released

> **Note**
>
> Support for using TLS version 1.0 and 1.1 was removed starting with specific minor versions of MariaDB. For information about supported MariaDB minor versions, see the section called "SSL/TLS support".

You can use the following AWS CLI command to determine the current automatic minor upgrade target version for a specified MariaDB minor version in a specific AWS Region.

For Linux, macOS, or Unix:

```
aws rds describe-db-engine-versions \
--engine mariadb \
--engine-version minor-version \
--region region \
--query "DBEngineVersions[*].ValidUpgradeTarget[*].
{AutoUpgrade:AutoUpgrade,EngineVersion:EngineVersion}" \
--output text
```

For Windows:

```
aws rds describe-db-engine-versions ^
--engine mariadb ^
--engine-version minor-version ^
--region region ^
--query "DBEngineVersions[*].ValidUpgradeTarget[*].
{AutoUpgrade:AutoUpgrade,EngineVersion:EngineVersion}" ^
--output text
```

For example, the following AWS CLI command determines the automatic minor upgrade target for MariaDB minor version 10.5.16 in the US East (Ohio) AWS Region (us-east-2).

For Linux, macOS, or Unix:

```
aws rds describe-db-engine-versions \
--engine mariadb \
--engine-version 10.5.16 \
--region us-east-2 \
--query "DBEngineVersions[*].ValidUpgradeTarget[*].
{AutoUpgrade:AutoUpgrade,EngineVersion:EngineVersion}" \
```

```
--output table
```

For Windows:

```
aws rds describe-db-engine-versions ^
--engine mariadb ^
--engine-version 10.5.16 ^
--region us-east-2 ^
--query "DBEngineVersions[*].ValidUpgradeTarget[*].
{AutoUpgrade:AutoUpgrade,EngineVersion:EngineVersion}" ^
--output table
```

Your output is similar to the following.

```
---------------------------------
|    DescribeDBEngineVersions    |
+--------------+-----------------+
|  AutoUpgrade |  EngineVersion  |
+--------------+-----------------+
|  True        |  10.5.17        |
|  False       |  10.5.18        |
|  False       |  10.5.19        |
|  False       |  10.6.5         |
|  False       |  10.6.7         |
|  False       |  10.6.8         |
|  False       |  10.6.10        |
|  False       |  10.6.11        |
|  False       |  10.6.12        |
+--------------+-----------------+
```

In this example, the `AutoUpgrade` value is `True` for MariaDB version 10.5.17. So, the automatic minor upgrade target is MariaDB version 10.5.17, which is highlighted in the output.

A MariaDB DB instance is automatically upgraded during your maintenance window if the following criteria are met:

- The **Auto minor version upgrade** setting is enabled.
- The **Backup retention period** setting is greater than 0.
- The DB instance is running a minor DB engine version that is less than the current automatic upgrade minor version.

For more information, see Automatically upgrading the minor engine version.

Using a read replica to reduce downtime when upgrading a MariaDB database

In most cases, a blue/green deployment is the best option to reduce downtime when upgrading a MariaDB DB instance. For more information, see Using Amazon RDS Blue/Green Deployments for database updates.

If you can't use a blue/green deployment and your MariaDB DB instance is currently in use with a production application, you can use the following procedure to upgrade the database version for your DB instance. This procedure can reduce the amount of downtime for your application.

By using a read replica, you can perform most of the maintenance steps ahead of time and minimize the necessary changes during the actual outage. With this technique, you can test and prepare the new DB instance without making any changes to your existing DB instance.

The following procedure shows an example of upgrading from MariaDB version 10.5 to MariaDB version 10.6. You can use the same general steps for upgrades to other major versions.

To upgrade a MariaDB database while a DB instance is in use

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Create a read replica of your MariaDB 10.5 DB instance. This process creates an upgradable copy of your database. Other read replicas of the DB instance might also exist.
    a. In the console, choose **Databases**, and then choose the DB instance that you want to upgrade.
    b. For **Actions**, choose **Create read replica**.
    c. Provide a value for **DB instance identifier** for your read replica and ensure that the **DB instance class** and other settings match your MariaDB 10.5 DB instance.
    d. Choose **Create read replica**.
3. (Optional) When the read replica has been created and **Status** shows **Available**, convert the read replica into a Multi-AZ deployment and enable backups.

By default, a read replica is created as a Single-AZ deployment with backups disabled. Because the read replica ultimately becomes the production DB instance, it is a best practice to configure a Multi-AZ deployment and enable backups now.

a. In the console, choose **Databases**, and then choose the read replica that you just created.

b. Choose **Modify**.

c. For **Multi-AZ deployment**, choose **Create a standby instance**.

d. For **Backup Retention Period**, choose a positive nonzero value, such as 3 days, and then choose **Continue**.

e. For **Scheduling of modifications**, choose **Apply immediately**.

f. Choose **Modify DB instance**.

4. When the read replica **Status** shows **Available**, upgrade the read replica to MariaDB 10.6.

a. In the console, choose **Databases**, and then choose the read replica that you just created.

b. Choose **Modify**.

c. For **DB engine version**, choose the MariaDB 10.6 version to upgrade to, and then choose **Continue**.

d. For **Scheduling of modifications**, choose **Apply immediately**.

e. Choose **Modify DB instance** to start the upgrade.

5. When the upgrade is complete and **Status** shows **Available**, verify that the upgraded read replica is up-to-date with the source MariaDB 10.5 DB instance. To verify, connect to the read replica and run the `SHOW REPLICA STATUS` command. If the `Seconds_Behind_Master` field is `0`, then replication is up-to-date.

> **Note**
>
> Previous versions of MariaDB used `SHOW SLAVE STATUS` instead of `SHOW REPLICA STATUS`. If you are using a MariaDB version before 10.6, then use `SHOW SLAVE STATUS`.

6. (Optional) Create a read replica of your read replica.

If you want the DB instance to have a read replica after it is promoted to a standalone DB instance, you can create the read replica now.

a. In the console, choose **Databases**, and then choose the read replica that you just upgraded.

b. For **Actions**, choose **Create read replica**.

c. Provide a value for **DB instance identifier** for your read replica and ensure that the **DB instance class** and other settings match your MariaDB 10.5 DB instance.

d. Choose **Create read replica**.

7. (Optional) Configure a custom DB parameter group for the read replica.

   If you want the DB instance to use a custom parameter group after it is promoted to a standalone DB instance, you can create the DB parameter group now and associate it with the read replica.

   a. Create a custom DB parameter group for MariaDB 10.6. For instructions, see Creating a DB parameter group in Amazon RDS.

   b. Modify the parameters that you want to change in the DB parameter group you just created. For instructions, see Modifying parameters in a DB parameter group in Amazon RDS.

   c. In the console, choose **Databases**, and then choose the read replica.

   d. Choose **Modify**.

   e. For **DB parameter group**, choose the MariaDB 10.6 DB parameter group you just created, and then choose **Continue**.

   f. For **Scheduling of modifications**, choose **Apply immediately**.

   g. Choose **Modify DB instance** to start the upgrade.

8. Make your MariaDB 10.6 read replica a standalone DB instance.

   Important

   When you promote your MariaDB 10.6 read replica to a standalone DB instance, it is no longer a replica of your MariaDB 10.5 DB instance. We recommend that you promote your MariaDB 10.6 read replica during a maintenance window when your source MariaDB 10.5 DB instance is in read-only mode and all write operations are suspended. When the promotion is completed, you can direct your write operations to the upgraded MariaDB 10.6 DB instance to ensure that no write operations are lost. In addition, we recommend that, before promoting your MariaDB 10.6 read replica, you perform all necessary data definition language (DDL) operations on your MariaDB

10.6 read replica. An example is creating indexes. This approach avoids negative effects on the performance of the MariaDB 10.6 read replica after it has been promoted. To promote a read replica, use the following procedure.

a. In the console, choose **Databases**, and then choose the read replica that you just upgraded.
b. For **Actions**, choose **Promote**.
c. Choose **Yes** to enable automated backups for the read replica instance. For more information, see Introduction to backups.
d. Choose **Continue**.
e. Choose **Promote Read Replica**.

9. You now have an upgraded version of your MariaDB database. At this point, you can direct your applications to the new MariaDB 10.6 DB instance.

Importing data into a MariaDB DB instance

You can use several different techniques to import data into an RDS for MariaDB DB instance. The best approach depends on the source of the data, the amount of data, and whether the import is done one time or is ongoing. If you are migrating an application along with the data, also consider the amount of downtime that you are willing to experience.

Find techniques to import data into an RDS for MariaDB DB instance in the following table.

Source	Amount of data	One time or ongoing	Applicati on downtim	Technique	More informati on
Existing MariaDB DB instance	Any	One time or ongoing	Minimal	Create a read replica for ongoing replication. Promote the read replica for one-time creation of a new DB instance.	Working with DB instance read replicas
Existing MariaDB or MySQL database	Small	One time	Some	Copy the data directly to your MySQL DB instance using a command-line utility.	Importing data from a MariaDB or MySQL database to a MariaDB or MySQL DB instance
Data not stored in an	Medium	One time	Some	Create flat files and import them using MySQL `LOAD DATA LOCAL INFILE` statements.	Importing data from any source

Source	Amount of data	One time or ongoing	Applicati on downtim	Technique	More informati on
existing database					to a MariaDB or MySQL DB instance
Existing MariaDB or MySQL database on premises or on Amazon EC2	Any	Ongoing	Minimal	Configure replication with an existing MariaDB or MySQL database as the replication source. You can configure replication into a MariaDB DB instance using MariaDB global transaction identifiers (GTIDs) when the external instance is MariaDB version 10.0.24 or higher, or using binary log coordinates for MySQL instances or MariaDB instances on earlier versions than 10.0.24. MariaDB GTIDs are implemented differently than MySQL GTIDs, which aren't supported by Amazon RDS.	Configuri ng binary log file position replicati on with an external source instance Importing data to an Amazon RDS MariaDB or MySQL DB instance with reduced downtime

Source	Amount of data	One time or ongoing	Applicati on downtim	Technique	More informati on
Any existing database	Any	One time or ongoing	Minimal	Use AWS Database Migration Service to migrate the database with minimal downtime and, for many database DB engines, continue ongoing replication.	What is AWS Database Migration Service and Using a MySQL-com patible database as a target for AWS DMS in the *AWS Database Migration Service User Guide*

Note

The mysql system database contains authentication and authorization information required to log into your DB instance and access your data. Dropping, altering, renaming, or truncating tables, data, or other contents of the mysql database in your DB instance can result in errors and might render the DB instance and your data inaccessible. If this occurs, the DB instance can be restored from a snapshot using the AWS CLI `restore-db-`

instance-from-db-snapshot or recovered using restore-db-instance-to-point-in-time commands.

Importing data from a MariaDB or MySQL database to a MariaDB or MySQL DB instance

You can also import data from an existing MariaDB or MySQL database to a MySQL or MariaDB DB instance. You do so by copying the database with mysqldump and piping it directly into the MariaDB or MySQL DB instance. The `mysqldump` command line utility is commonly used to make backups and transfer data from one MariaDB or MySQL server to another. It's included with MySQL and MariaDB client software.

Note

If you are importing or exporting large amounts of data with a MySQL DB instance, it's more reliable and faster to move data in and out of Amazon RDS by using `xtrabackup` backup files and Amazon S3. For more information, see Restoring a backup into a MySQL DB instance.

A typical `mysqldump` command to move data from an external database to an Amazon RDS DB instance looks similar to the following.

```
mysqldump -u local_user \
    --databases database_name \
    --single-transaction \
    --compress \
    --order-by-primary  \
    -plocal_password | mysql -u RDS_user \
        --port=port_number \
        --host=host_name \
        -pRDS_password
```

Important

Make sure not to leave a space between the `-p` option and the entered password. Specify credentials other than the prompts shown here as a security best practice.

Make sure that you're aware of the following recommendations and considerations:

- Exclude the following schemas from the dump file: `sys`, `performance_schema`, and `information_schema`. The `mysqldump` utility excludes these schemas by default.
- If you need to migrate users and privileges, consider using a tool that generates the data control language (DCL) for recreating them, such as the pt-show-grants utility.
- To perform the import, make sure the user doing so has access to the DB instance. For more information, see Controlling access with security groups.

The parameters used are as follows:

- `-u` *`local_user`* – Use to specify a user name. In the first usage of this parameter, you specify the name of a user account on the local MariaDB or MySQL database identified by the `--databases` parameter.
- `--databases` *`database_name`* – Use to specify the name of the database on the local MariaDB or MySQL instance that you want to import into Amazon RDS.
- `--single-transaction` – Use to ensure that all of the data loaded from the local database is consistent with a single point in time. If there are other processes changing the data while `mysqldump` is reading it, using this parameter helps maintain data integrity.
- `--compress` – Use to reduce network bandwidth consumption by compressing the data from the local database before sending it to Amazon RDS.
- `--order-by-primary` – Use to reduce load time by sorting each table's data by its primary key.
- `-p`*`local_password`* – Use to specify a password. In the first usage of this parameter, you specify the password for the user account identified by the first `-u` parameter.
- `-u` *`RDS_user`* – Use to specify a user name. In the second usage of this parameter, you specify the name of a user account on the default database for the MariaDB or MySQL DB instance identified by the `--host` parameter.
- `--port` *`port_number`* – Use to specify the port for your MariaDB or MySQL DB instance. By default, this is 3306 unless you changed the value when creating the instance.
- `--host` *`host_name`* – Use to specify the Domain Name System (DNS) name from the Amazon RDS DB instance endpoint, for example, `myinstance.123456789012.us-east-1.rds.amazonaws.com`. You can find the endpoint value in the instance details in the Amazon RDS Management Console.

- -p*RDS_password* – Use to specify a password. In the second usage of this parameter, you specify the password for the user account identified by the second -u parameter.

Make sure to create any stored procedures, triggers, functions, or events manually in your Amazon RDS database. If you have any of these objects in the database that you are copying, then exclude them when you run mysqldump. To do so, include the following parameters with your mysqldump command: --routines=0 --triggers=0 --events=0.

The following example copies the world sample database on the local host to a MySQL DB instance.

For Linux, macOS, or Unix:

```
sudo mysqldump -u localuser \
    --databases world \
    --single-transaction \
    --compress \
    --order-by-primary  \
    --routines=0 \
    --triggers=0 \
    --events=0 \
    -plocalpassword | mysql -u rdsuser \
        --port=3306 \
        --host=myinstance.123456789012.us-east-1.rds.amazonaws.com \
        -prdspassword
```

For Windows, run the following command in a command prompt that has been opened by right-clicking **Command Prompt** on the Windows programs menu and choosing **Run as administrator**:

```
mysqldump -u localuser ^
    --databases world ^
    --single-transaction ^
    --compress ^
    --order-by-primary  ^
    --routines=0 ^
    --triggers=0 ^
    --events=0 ^
    -plocalpassword | mysql -u rdsuser ^
        --port=3306 ^
        --host=myinstance.123456789012.us-east-1.rds.amazonaws.com ^
        -prdspassword
```

Note

Specify credentials other than the prompts shown here as a security best practice.

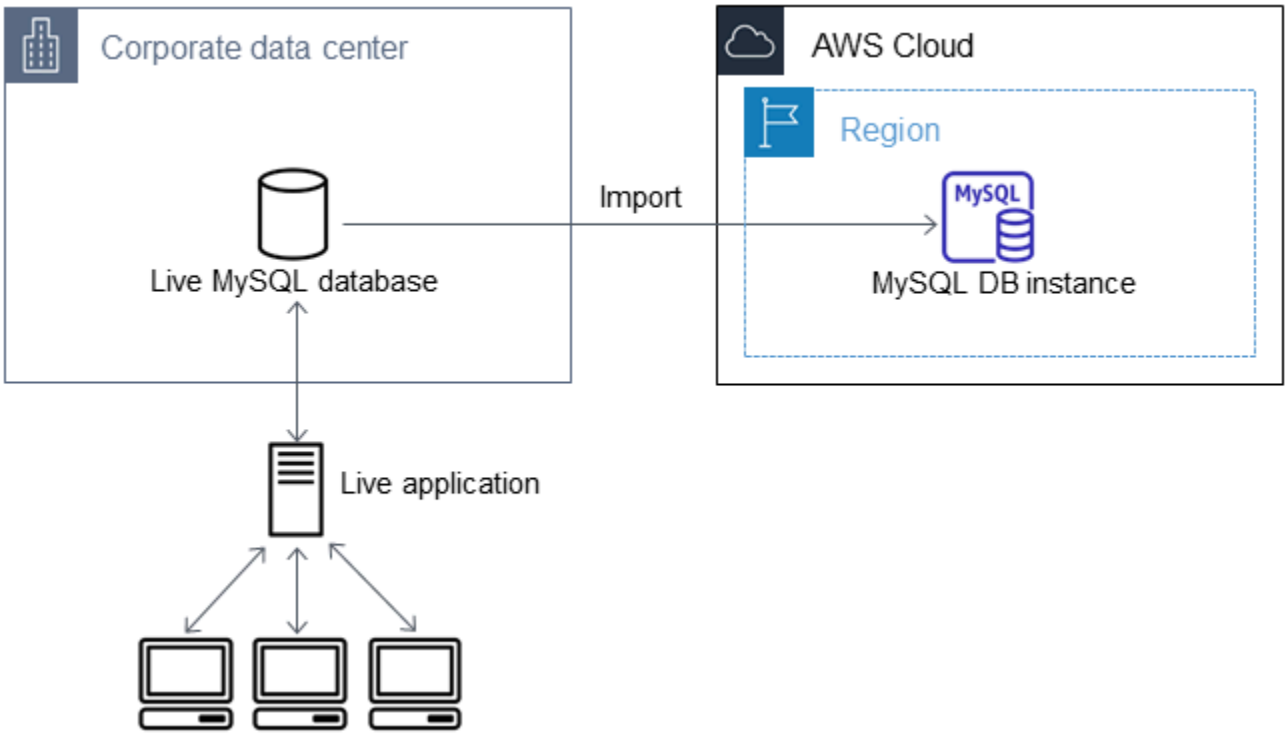
Importing data to an Amazon RDS MariaDB or MySQL DB instance with reduced downtime

In some cases, you might need to import data from an external MariaDB or MySQL database that supports a live application to a MariaDB DB instance, a MySQL DB instance, or a MySQL Multi-AZ DB cluster. Use the following procedure to minimize the impact on availability of applications. This procedure can also help if you are working with a very large database. Using this procedure, you can reduce the cost of the import by reducing the amount of data that is passed across the network to AWS.

In this procedure, you transfer a copy of your database data to an Amazon EC2 instance and import the data into a new Amazon RDS database. You then use replication to bring the Amazon RDS database up-to-date with your live external instance, before redirecting your application to the Amazon RDS database. Configure MariaDB replication based on global transaction identifiers (GTIDs) if the external instance is MariaDB 10.0.24 or higher and the target instance is RDS for MariaDB. Otherwise, configure replication based on binary log coordinates. We recommend GTID-based replication if your external database supports it because GTID-based replication is a more reliable method. For more information, see Global transaction ID in the MariaDB documentation.

Note

If you want to import data into a MySQL DB instance and your scenario supports it, we recommend moving data in and out of Amazon RDS by using backup files and Amazon S3. For more information, see Restoring a backup into a MySQL DB instance.

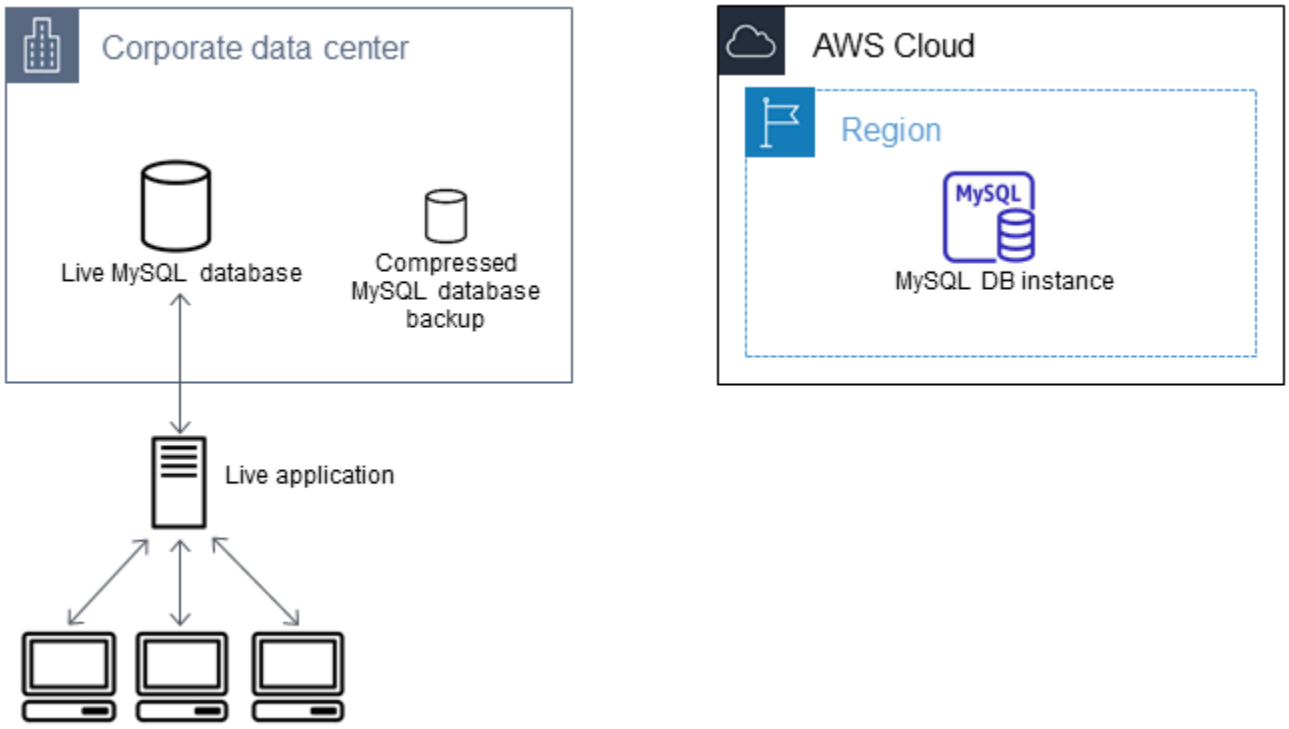


Note

We don't recommend that you use this procedure with source MySQL databases from MySQL versions earlier than version 5.5 because of potential replication issues. For more information, see Replication compatibility between MySQL versions in the MySQL documentation.

Create a copy of your existing database

The first step in the process of migrating a large amount of data to an RDS for MariaDB or RDS for MySQL database with minimal downtime is to create a copy of the source data.



You can use the mysqldump utility to create a database backup in either SQL or delimited-text format. We recommend that you do a test run with each format in a non-production environment to see which method minimizes the amount of time that mysqldump runs.

We also recommend that you weigh mysqldump performance against the benefit offered by using the delimited-text format for loading. A backup using delimited-text format creates a tab-separated text file for each table being dumped. To reduce the amount of time required to import your database, you can load these files in parallel using the `LOAD DATA LOCAL INFILE` command. For more information about choosing a mysqldump format and then loading the data, see Using mysqldump for backups in the MySQL documentation.

Before you start the backup operation, make sure to set the replication options on the MariaDB or MySQL database that you are copying to Amazon RDS. The replication options include turning on binary logging and setting a unique server ID. Setting these options causes your server to start logging database transactions and prepares it to be a source replication instance later in this process.

Note

Use the `--single-transaction` option with mysqldump because it dumps a consistent state of the database. To ensure a valid dump file, don't run data definition language (DDL)

statements while mysqldump is running. You can schedule a maintenance window for these operations.
Exclude the following schemas from the dump file: `sys`, `performance_schema`, and `information_schema`. The mysqldump utility excludes these schemas by default.
To migrate users and privileges, consider using a tool that generates the data control language (DCL) for recreating them, such as the pt-show-grants utility.

To set replication options

1. Edit the `my.cnf` file (this file is usually under `/etc`).

   ```
   sudo vi /etc/my.cnf
   ```

   Add the `log_bin` and `server_id` options to the `[mysqld]` section. The `log_bin` option provides a file name identifier for binary log files. The `server_id` option provides a unique identifier for the server in source-replica relationships.

   The following example shows the updated `[mysqld]` section of a `my.cnf` file.

   ```
   [mysqld]
   log-bin=mysql-bin
   server-id=1
   ```

   For more information, see the MySQL documentation.

2. For replication with a Multi-AZ DB cluster, set the `ENFORCE_GTID_CONSISTENCY` and the `GTID_MODE` parameter to `ON`.

   ```
   mysql> SET @@GLOBAL.ENFORCE_GTID_CONSISTENCY = ON;
   ```

   ```
   mysql> SET @@GLOBAL.GTID_MODE = ON;
   ```

   These settings aren't required for replication with a DB instance.

3. Restart the `mysql` service.

   ```
   sudo service mysqld restart
   ```

To create a backup copy of your existing database

1. Create a backup of your data using the mysqldump utility, specifying either SQL or delimited-text format.

   Specify `--master-data=2` to create a backup file that can be used to start replication between servers. For more information, see the mysqldump documentation.

   To improve performance and ensure data integrity, use the `--order-by-primary` and `--single-transaction` options of mysqldump.

   To avoid including the MySQL system database in the backup, do not use the `--all-databases` option with mysqldump. For more information, see Creating a data snapshot using mysqldump in the MySQL documentation.

   Use chmod if necessary to make sure that the directory where the backup file is being created is writeable.

   > **Important**
   >
   > On Windows, run the command window as an administrator.

   - To produce SQL output, use the following command.

     For Linux, macOS, or Unix:

     ```
     sudo mysqldump \
         --databases database_name \
         --master-data=2  \
         --single-transaction \
         --order-by-primary \
         -r backup.sql \
         -u local_user \
         -p password
     ```

     > **Note**
     >
     > Specify credentials other than the prompts shown here as a security best practice.

For Windows:

```
mysqldump ^
    --databases database_name ^
    --master-data=2  ^
    --single-transaction ^
    --order-by-primary ^
    -r backup.sql ^
    -u local_user ^
    -p password
```

> **Note**
>
> Specify credentials other than the prompts shown here as a security best practice.

- To produce delimited-text output, use the following command.

  For Linux, macOS, or Unix:

```
sudo mysqldump \
    --tab=target_directory \
    --fields-terminated-by ',' \
    --fields-enclosed-by '"' \
    --lines-terminated-by 0x0d0a \
    database_name \
    --master-data=2 \
    --single-transaction \
    --order-by-primary \
    -p password
```

  For Windows:

```
mysqldump ^
    --tab=target_directory ^
    --fields-terminated-by "," ^
    --fields-enclosed-by """ ^
    --lines-terminated-by 0x0d0a ^
    database_name ^
    --master-data=2 ^
    --single-transaction ^
```

```
    --order-by-primary ^
    -p password
```

> **Note**
>
> Specify credentials other than the prompts shown here as a security best practice. Make sure to create any stored procedures, triggers, functions, or events manually in your Amazon RDS database. If you have any of these objects in the database that you are copying, exclude them when you run mysqldump. To do so, include the following arguments with your mysqldump command: `--routines=0 --triggers=0 --events=0`.

When using the delimited-text format, a `CHANGE MASTER TO` comment is returned when you run mysqldump. This comment contains the master log file name and position. If the external instance is other than MariaDB version 10.0.24 or higher, note the values for `MASTER_LOG_FILE` and `MASTER_LOG_POS`. You need these values when setting up replication.

```
-- Position to start replication or point-in-time recovery from
--
-- CHANGE MASTER TO MASTER_LOG_FILE='mysql-bin-changelog.000031',
 MASTER_LOG_POS=107;
```

If you are using SQL format, you can get the master log file name and position in the `CHANGE MASTER TO` comment in the backup file. If the external instance is MariaDB version 10.0.24 or higher, you can get the GTID in the next step.

2. If the external instance you are using is MariaDB version 10.0.24 or higher, you use GTID-based replication. Run `SHOW MASTER STATUS` on the external MariaDB instance to get the binary log file name and position, then convert them to a GTID by running `BINLOG_GTID_POS` on the external MariaDB instance.

   ```
   SELECT BINLOG_GTID_POS('binary log file name', binary log file position);
   ```

   Note the GTID returned; you need it to configure replication.

3. Compress the copied data to reduce the amount of network resources needed to copy your data to the Amazon RDS database. Note the size of the backup file. You need this information when

determining how large an Amazon EC2 instance to create. When you are done, compress the backup file using GZIP or your preferred compression utility.

- To compress SQL output, use the following command.

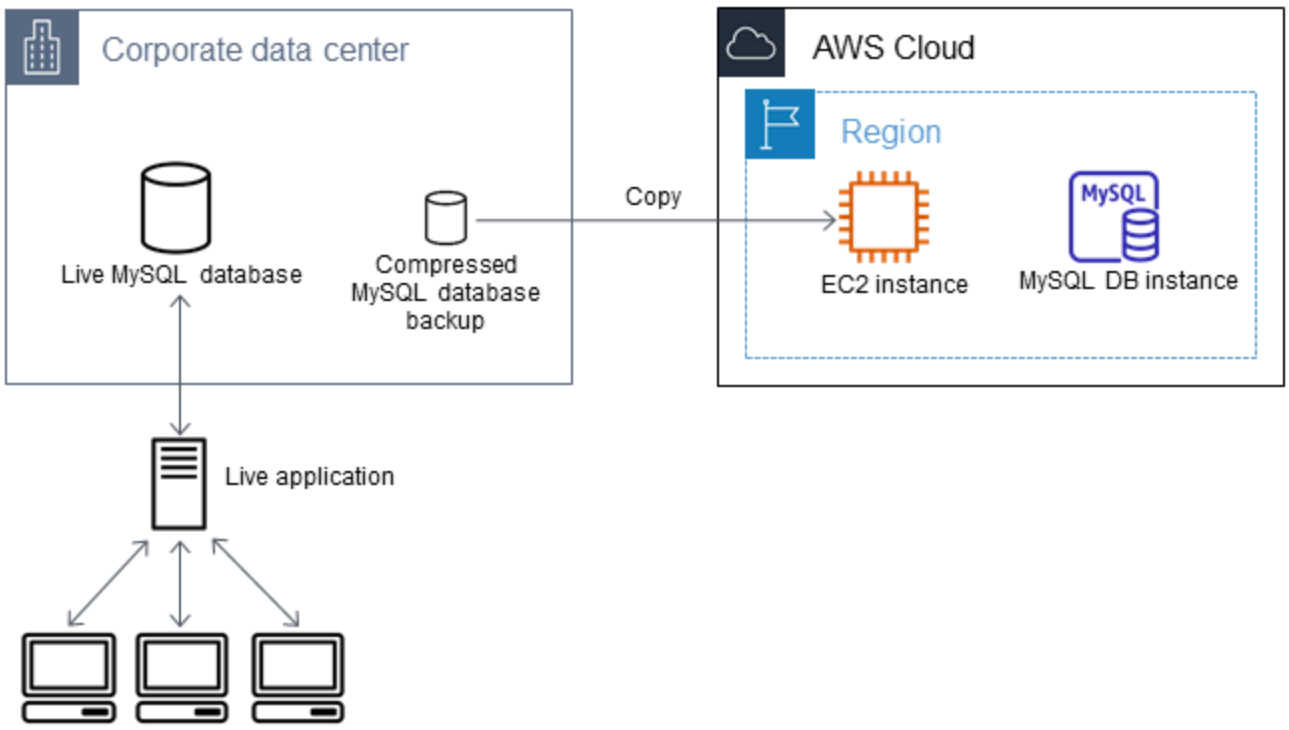
```
gzip backup.sql
```

- To compress delimited-text output, use the following command.

```
tar -zcvf backup.tar.gz target_directory
```

Create an Amazon EC2 instance and copy the compressed database

Copying your compressed database backup file to an Amazon EC2 instance takes fewer network resources than doing a direct copy of uncompressed data between database instances. After your data is in Amazon EC2, you can copy it from there directly to your MariaDB or MySQL database. For you to save on the cost of network resources, your Amazon EC2 instance must be in the same AWS Region as your Amazon RDS DB instance. Having the Amazon EC2 instance in the same AWS Region as your Amazon RDS database also reduces network latency during the import.



To create an Amazon EC2 instance and copy your data

1. In the AWS Region where you plan to create the RDS database, create a virtual private cloud (VPC), a VPC security group, and a VPC subnet. Ensure that the inbound rules for your VPC security group allow the IP addresses required for your application to connect to AWS. You can specify a range of IP addresses (for example, `203.0.113.0/24`), or another VPC security group. You can use the Amazon VPC Management Console to create and manage VPCs, subnets, and security groups. For more information, see Getting started with Amazon VPC in the *Amazon Virtual Private Cloud Getting Started Guide*.
2. Open the Amazon EC2 Management Console and choose the AWS Region to contain both your Amazon EC2 instance and your Amazon RDS database. Launch an Amazon EC2 instance using the VPC, subnet, and security group that you created in Step 1. Ensure that you select an instance type with enough storage for your database backup file when it is uncompressed. For details on Amazon EC2 instances, see Getting started with Amazon EC2 Linux instances in the *Amazon Elastic Compute Cloud User Guide for Linux*.
3. To connect to your Amazon RDS database from your Amazon EC2 instance, edit your VPC security group. Add an inbound rule specifying the private IP address of your EC2 instance. You can find the private IP address on the **Details** tab of the **Instance** pane in the EC2 console window. To edit the VPC security group and add an inbound rule, choose **Security Groups** in the EC2 console navigation pane, choose your security group, and then add an inbound rule for MySQL or Aurora specifying the private IP address of your EC2 instance. To learn how to add an inbound rule to a VPC security group, see Adding and removing rules in the *Amazon VPC User Guide*.
4. Copy your compressed database backup file from your local system to your Amazon EC2 instance. Use `chmod` if necessary to make sure that you have write permission for the target directory of the Amazon EC2 instance. You can use `scp` or a Secure Shell (SSH) client to copy the file. The following is an example.

   ```
   scp -r -i key pair.pem backup.sql.gz ec2-user@EC2 DNS:/target_directory/backup.sql.gz
   ```

   > **Important**
   >
   > Be sure to copy sensitive data using a secure network transfer protocol.

5. Connect to your Amazon EC2 instance and install the latest updates and the MySQL client tools using the following commands.

```
sudo yum update -y
sudo yum install mysql -y
```

For more information, see Connect to your instance in the *Amazon Elastic Compute Cloud User Guide for Linux*.

> **Important**
>
> This example installs the MySQL client on an Amazon Machine Image (AMI) for an Amazon Linux distribution. To install the MySQL client on a different distribution, such as Ubuntu or Red Hat Enterprise Linux, this example doesn't work. For information about installing MySQL, see Installing and Upgrading MySQL in the MySQL documentation.

6. While connected to your Amazon EC2 instance, decompress your database backup file. The following are examples.
   - To decompress SQL output, use the following command.

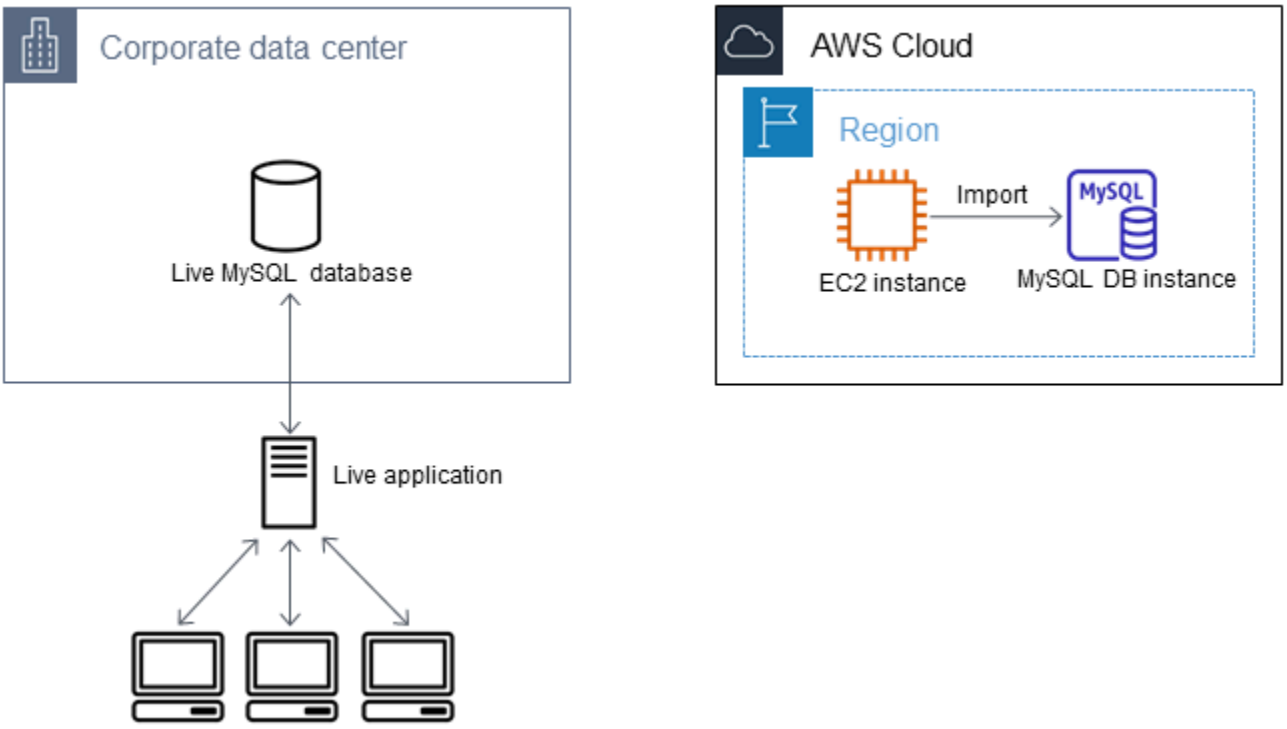
     ```
     gzip backup.sql.gz -d
     ```

   - To decompress delimited-text output, use the following command.

     ```
     tar xzvf backup.tar.gz
     ```

Create a MySQL or MariaDB database and import data from your Amazon EC2 instance

By creating a MariaDB DB instance, a MySQL DB instance, or a MySQL Multi-AZ DB cluster in the same AWS Region as your Amazon EC2 instance, you can import the database backup file from EC2 faster than over the internet.



To create a MariaDB or MySQL database and import your data

1. Determine which DB instance class and what amount of storage space is required to support the expected workload for this Amazon RDS database. As part of this process, decide what is sufficient space and processing capacity for your data load procedures. Also decide what is required to handle the production workload. You can estimate this based on the size and resources of the source MariaDB or MySQL database. For more information, see DB instance classes.
2. Create a DB instance or Multi-AZ DB cluster in the AWS Region that contains your Amazon EC2 instance.

   To create a MySQL Multi-AZ DB cluster, follow the instructions in Creating a Multi-AZ DB cluster.

   To create a MariaDB or MySQL DB instance, follow the instructions in Creating an Amazon RDS DB instance and use the following guidelines:

   - Specify a DB engine version that is compatible with your source DB instance, as follows:
     - If your source instance is MySQL 5.5.x, the Amazon RDS DB instance must be MySQL.
     - If your source instance is MySQL 5.6.x or 5.7.x, the Amazon RDS DB instance must be MySQL or MariaDB.

- If your source instance is MySQL 8.0.x, the Amazon RDS DB instance must be MySQL 8.0.x.
- If your source instance is MariaDB 5.5 or higher, the Amazon RDS DB instance must be MariaDB.

- Specify the same virtual private cloud (VPC) and VPC security group as for your Amazon EC2 instance. This approach ensures that your Amazon EC2 instance and your Amazon RDS instance are visible to each other over the network. Make sure your DB instance is publicly accessible. To set up replication with your source database as described later, your DB instance must be publicly accessible.
- Don't configure multiple Availability Zones, backup retention, or read replicas until after you have imported the database backup. When that import is completed, you can configure Multi-AZ and backup retention for the production instance.

3. Review the default configuration options for the Amazon RDS database. If the default parameter group for the database doesn't have the configuration options that you want, find a different one that does or create a new parameter group. For more information on creating a parameter group, see Parameter groups for Amazon RDS.
4. Connect to the new Amazon RDS database as the master user. Create the users required to support the administrators, applications, and services that need to access the instance. The hostname for the Amazon RDS database is the **Endpoint** value for this instance without including the port number. An example is `mysampledb.123456789012.us-west-2.rds.amazonaws.com`. You can find the endpoint value in the database details in the Amazon RDS Management Console.
5. Connect to your Amazon EC2 instance. For more information, see Connect to your instance in the *Amazon Elastic Compute Cloud User Guide for Linux*.
6. Connect to your Amazon RDS database as a remote host from your Amazon EC2 instance using the `mysql` command. The following is an example.

   ```
   mysql -h host_name -P 3306 -u db_master_user -p
   ```

   The hostname is the Amazon RDS database endpoint.
7. At the `mysql` prompt, run the `source` command and pass it the name of your database dump file to load the data into the Amazon RDS DB instance:

   - For SQL format, use the following command.

     ```
     mysql> source backup.sql;
     ```

- For delimited-text format, first create the database, if it isn't the default database you created when setting up the Amazon RDS database.

```
mysql> create database database_name;
mysql> use database_name;
```

Then create the tables.

```
mysql> source table1.sql
mysql> source table2.sql
etc...
```

Then import the data.

```
mysql> LOAD DATA LOCAL INFILE 'table1.txt' INTO TABLE table1 FIELDS TERMINATED BY
 ',' ENCLOSED BY '"' LINES TERMINATED BY '0x0d0a';
mysql> LOAD DATA LOCAL INFILE 'table2.txt' INTO TABLE table2 FIELDS TERMINATED BY
 ',' ENCLOSED BY '"' LINES TERMINATED BY '0x0d0a';
etc...
```

To improve performance, you can perform these operations in parallel from multiple connections so that all of your tables are created and then loaded at the same time.

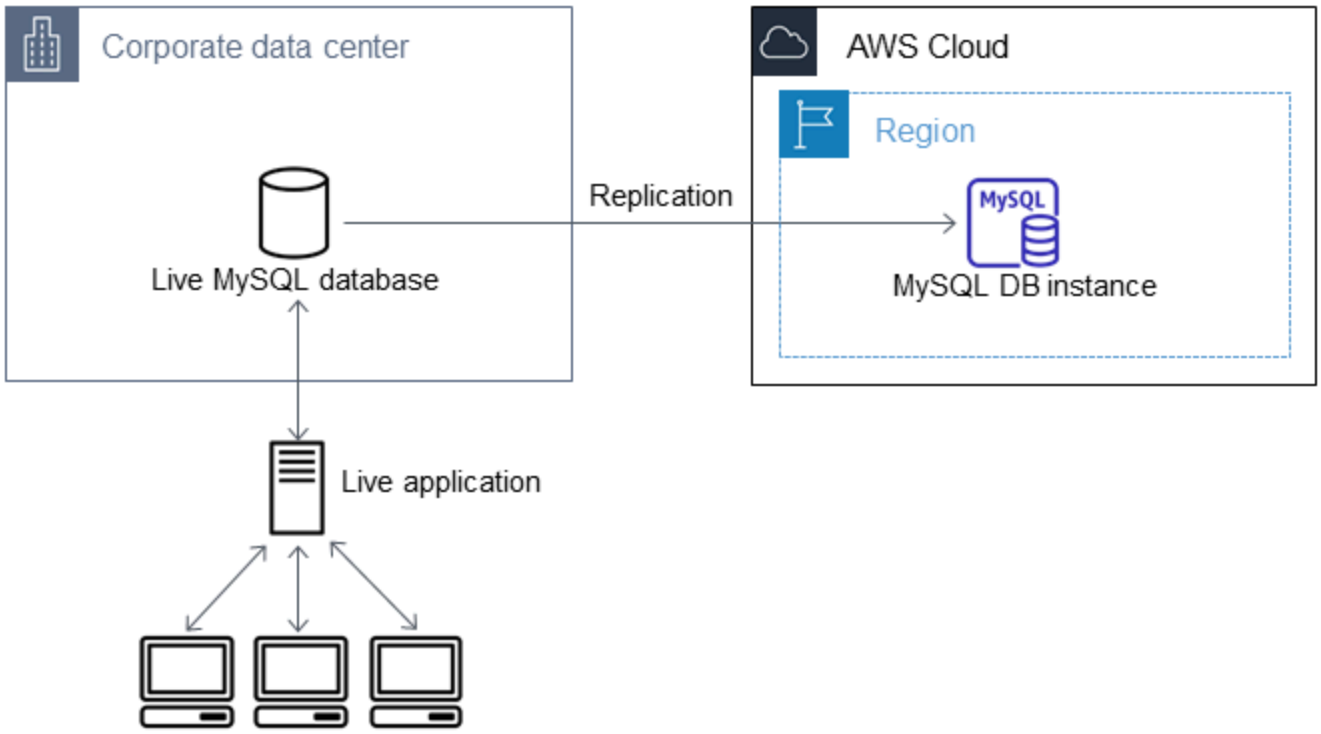
> **Note**
>
> If you used any data-formatting options with mysqldump when you initially dumped the table, make sure to use the same options with `LOAD DATA LOCAL INFILE` to ensure proper interpretation of the data file contents.

8. Run a simple `SELECT` query against one or two of the tables in the imported database to verify that the import was successful.

If you no longer need the Amazon EC2 instance used in this procedure, terminate the EC2 instance to reduce your AWS resource usage. To terminate an EC2 instance, see Terminating an instance in the *Amazon EC2 User Guide*.

Replicate between your external database and new Amazon RDS database

Your source database was likely updated during the time that it took to copy and transfer the data to the MariaDB or MySQL database. Thus, you can use replication to bring the copied database up-to-date with the source database.



The permissions required to start replication on an Amazon RDS database are restricted and not available to your Amazon RDS master user. Because of this, make sure to use either the Amazon RDS mysql.rds_set_external_master command or the mysql.rds_set_external_master_gtid command to configure replication, and the mysql.rds_start_replication command to start replication between your live database and your Amazon RDS database.

To start replication

Earlier, you turned on binary logging and set a unique server ID for your source database. Now you can set up your Amazon RDS database as a replica with your live database as the source replication instance.

1. In the Amazon RDS Management Console, add the IP address of the server that hosts the source database to the VPC security group for the Amazon RDS database. For more information on modifying a VPC security group, see Security groups for your VPC in the *Amazon Virtual Private Cloud User Guide*.

You might also need to configure your local network to permit connections from the IP address of your Amazon RDS database, so that it can communicate with your source instance. To find the IP address of the Amazon RDS database, use the `host` command.

```
host rds_db_endpoint
```

The hostname is the DNS name from the Amazon RDS database endpoint, for example `myinstance.123456789012.us-east-1.rds.amazonaws.com`. You can find the endpoint value in the instance details in the Amazon RDS Management Console.

2. Using the client of your choice, connect to the source instance and create a user to be used for replication. This account is used solely for replication and must be restricted to your domain to improve security. The following is an example.

   MySQL 5.5, 5.6, and 5.7

   ```
   CREATE USER 'repl_user'@'mydomain.com' IDENTIFIED BY 'password';
   ```

   MySQL 8.0

   ```
   CREATE USER 'repl_user'@'mydomain.com' IDENTIFIED WITH mysql_native_password BY
    'password';
   ```

   > **Note**
   >
   > Specify credentials other than the prompts shown here as a security best practice.

3. For the source instance, grant `REPLICATION CLIENT` and `REPLICATION SLAVE` privileges to your replication user. For example, to grant the `REPLICATION CLIENT` and `REPLICATION SLAVE` privileges on all databases for the '`repl_user`' user for your domain, issue the following command.

   MySQL 5.5, 5.6, and 5.7

   ```
   GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'mydomain.com'
    IDENTIFIED BY 'password';
   ```

   MySQL 8.0

```
GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'mydomain.com';
```

> **Note**
>
> Specify credentials other than the prompts shown here as a security best practice.

4. If you used SQL format to create your backup file and the external instance is not MariaDB 10.0.24 or higher, look at the contents of that file.

   ```
   cat backup.sql
   ```

   The file includes a `CHANGE MASTER TO` comment that contains the master log file name and position. This comment is included in the backup file when you use the `--master-data` option with mysqldump. Note the values for `MASTER_LOG_FILE` and `MASTER_LOG_POS`.

   ```
   --
   -- Position to start replication or point-in-time recovery from
   --

   -- CHANGE MASTER TO MASTER_LOG_FILE='mysql-bin-changelog.000031', MASTER_LOG_POS=107;
   ```

   If you used delimited text format to create your backup file and the external instance isn't MariaDB 10.0.24 or higher, you should already have binary log coordinates from step 1 of the procedure at "To create a backup copy of your existing database" in this topic.

   If the external instance is MariaDB 10.0.24 or higher, you should already have the GTID from which to start replication from step 2 of the procedure at "To create a backup copy of your existing database" in this topic.

5. Make the Amazon RDS database the replica. If the external instance isn't MariaDB 10.0.24 or higher, connect to the Amazon RDS database as the master user and identify the source database as the source replication instance by using the mysql.rds_set_external_master command. Use the master log file name and master log position that you determined in the previous step if you have a SQL format backup file. Or use the name and position that you determined when creating the backup files if you used delimited-text format. The following is an example.

   ```
   CALL mysql.rds_set_external_master ('myserver.mydomain.com', 3306,
   ```

```
    'repl_user', 'password', 'mysql-bin-changelog.000031', 107, 0);
```

> **Note**
>
> Specify credentials other than the prompts shown here as a security best practice.

If the external instance is MariaDB 10.0.24 or higher, connect to the Amazon RDS database as the master user and identify the source database as the source replication instance by using the mysql.rds_set_external_master_gtid command. Use the GTID that you determined in step 2 of the procedure at "To create a backup copy of your existing database" in this topic.. The following is an example.

```
CALL mysql.rds_set_external_master_gtid ('source_server_ip_address', 3306,
 'ReplicationUser', 'password', 'GTID', 0);
```

The `source_server_ip_address` is the IP address of source replication instance. An EC2 private DNS address is currently not supported.

> **Note**
>
> Specify credentials other than the prompts shown here as a security best practice.

6. On the Amazon RDS database, issue the mysql.rds_start_replication command to start replication.

```
CALL mysql.rds_start_replication;
```

7. On the Amazon RDS database, run the SHOW REPLICA STATUS command to determine when the replica is up-to-date with the source replication instance. The results of the `SHOW REPLICA STATUS` command include the `Seconds_Behind_Master` field. When the `Seconds_Behind_Master` field returns 0, then the replica is up-to-date with the source replication instance.

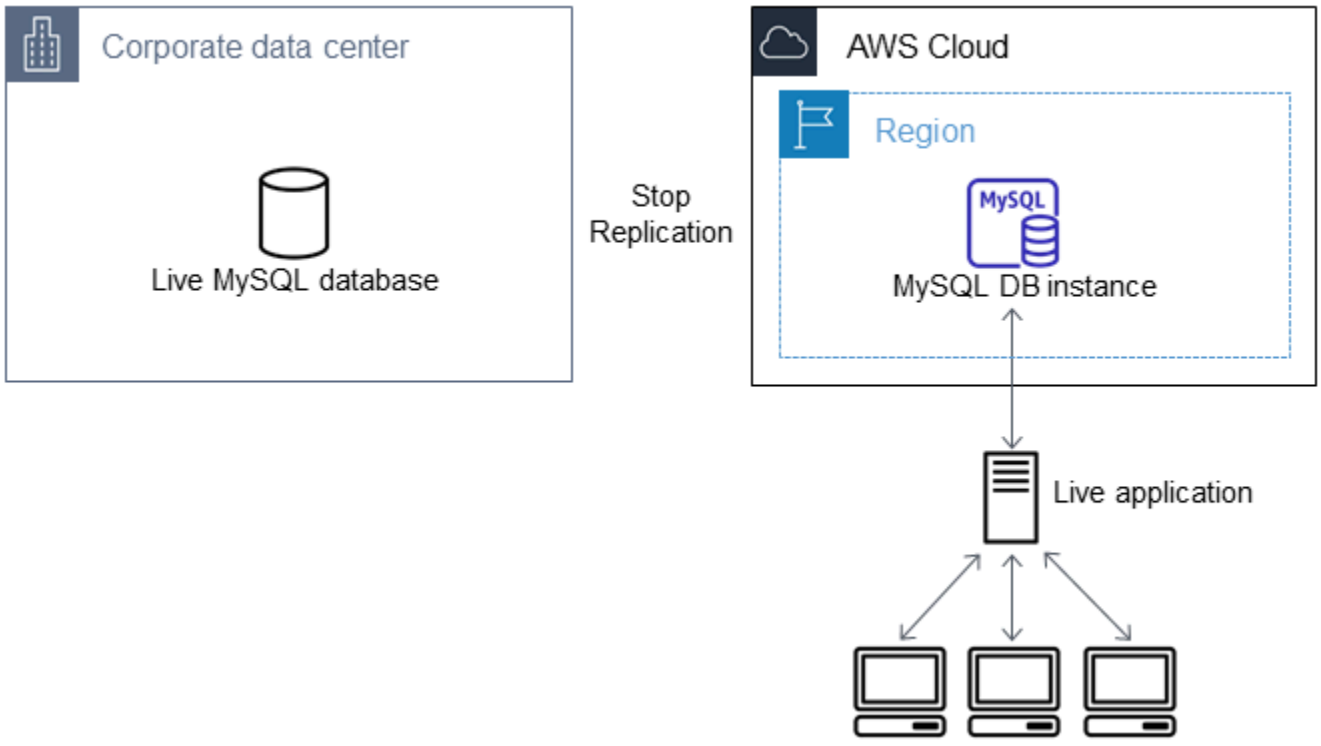
> **Note**
>
> Previous versions of MySQL used `SHOW SLAVE STATUS` instead of `SHOW REPLICA STATUS`. If you are using a MySQL version before 8.0.23, then use `SHOW SLAVE STATUS`.

For a MariaDB 10.5, 10.6, or 10.11 DB instance, run the mysql.rds_replica_status procedure instead of the MySQL command.

8. After the Amazon RDS database is up-to-date, turn on automated backups so you can restore that database if needed. You can turn on or modify automated backups for your Amazon RDS database using the Amazon RDS Management Console. For more information, see Introduction to backups.

Redirect your live application to your Amazon RDS instance

After the MariaDB or MySQL database is up-to-date with the source replication instance, you can now update your live application to use the Amazon RDS instance.



To redirect your live application to your MariaDB or MySQL database and stop replication

1. To add the VPC security group for the Amazon RDS database, add the IP address of the server that hosts the application. For more information on modifying a VPC security group, see Security groups for your VPC in the *Amazon Virtual Private Cloud User Guide*.
2. Verify that the `Seconds_Behind_Master` field in the SHOW REPLICA STATUS command results is 0, which indicates that the replica is up-to-date with the source replication instance.

```
SHOW REPLICA STATUS;
```

> **Note**
>
> Previous versions of MySQL used `SHOW SLAVE STATUS` instead of `SHOW REPLICA STATUS`. If you are using a MySQL version before 8.0.23, then use `SHOW SLAVE STATUS`.

   For a MariaDB 10.5, 10.6, or 10.11 DB instance, run the mysql.rds_replica_status procedure instead of the MySQL command.
3. Close all connections to the source when their transactions complete.
4. Update your application to use the Amazon RDS database. This update typically involves changing the connection settings to identify the hostname and port of the Amazon RDS database, the user account and password to connect with, and the database to use.
5. Connect to the DB instance.

   For a Multi-AZ DB cluster, connect to the writer DB instance.
6. Stop replication for the Amazon RDS instance using the mysql.rds_stop_replication command.

```
CALL mysql.rds_stop_replication;
```

7. Run the mysql.rds_reset_external_master command on your Amazon RDS database to reset the replication configuration so this instance is no longer identified as a replica.

```
CALL mysql.rds_reset_external_master;
```

8. Turn on additional Amazon RDS features such as Multi-AZ support and read replicas. For more information, see Configuring and managing a Multi-AZ deployment and Working with DB instance read replicas.

Importing data from any source to a MariaDB or MySQL DB instance

We recommend creating DB snapshots of the target Amazon RDS DB instance before and after the data load. Amazon RDS DB snapshots are complete backups of your DB instance that can be used to restore your DB instance to a known state. When you initiate a DB snapshot, I/O operations to your DB instance are momentarily suspended while your database is backed up.

Creating a DB snapshot immediately before the load makes it possible for you to restore the database to its state before the load, if you need to. A DB snapshot taken immediately after the load protects you from having to load the data again in case of a mishap and can also be used to seed new database instances.

The following list shows the steps to take. Each step is discussed in more detail following.

1. Create flat files containing the data to be loaded.
2. Stop any applications accessing the target DB instance.
3. Create a DB snapshot.
4. Consider turning off Amazon RDS automated backups.
5. Load the data.
6. Enable automated backups again.

Step 1: Create flat files containing the data to be loaded

Use a common format, such as comma-separated values (CSV), to store the data to be loaded. Each table must have its own file; you can't combine data for multiple tables in the same file. Give each file the same name as the table it corresponds to. The file extension can be anything you like. For example, if the table name is `sales`, the file name might be `sales.csv` or `sales.txt`, but not `sales_01.csv`.

Whenever possible, order the data by the primary key of the table being loaded. Doing this drastically improves load times and minimizes disk storage requirements.

The speed and efficiency of this procedure depends on keeping the size of the files small. If the uncompressed size of any individual file is larger than 1 GiB, split it into multiple files and load each one separately.

On Unix-like systems (including Linux), use the `split` command. For example, the following command splits the `sales.csv` file into multiple files of less than 1 GiB, splitting only at line breaks (-C 1024m). The new files are named `sales.part_00`, `sales.part_01`, and so on.

```
split -C 1024m -d sales.csv sales.part_
```

Similar utilities are available for other operating systems.

Step 2: Stop any applications accessing the target DB instance

Before starting a large load, stop all application activity accessing the target DB instance that you plan to load to. We recommend this particularly if other sessions will be modifying the tables being loaded or tables that they reference. Doing this reduces the risk of constraint violations occurring during the load and improves load performance. It also makes it possible to restore the DB instance to the point just before the load without losing changes made by processes not involved in the load.

Of course, this might not be possible or practical. If you can't stop applications from accessing the DB instance before the load, take steps to ensure the availability and integrity of your data. The specific steps required vary greatly depending upon specific use cases and site requirements.

Step 3: Create a DB snapshot

If you plan to load data into a new DB instance that contains no data, you can skip this step. Otherwise, creating a DB snapshot of your DB instance makes it possible for you to restore the DB instance to the point just before the load, if it becomes necessary. As previously mentioned, when you initiate a DB snapshot, I/O operations to your DB instance are suspended for a few minutes while the database is backed up.

The example following uses the AWS CLI `create-db-snapshot` command to create a DB snapshot of the `AcmeRDS` instance and give the DB snapshot the identifier `"preload"`.

For Linux, macOS, or Unix:

```
aws rds create-db-snapshot \
    --db-instance-identifier AcmeRDS \
    --db-snapshot-identifier preload
```

For Windows:

```
aws rds create-db-snapshot ^
    --db-instance-identifier AcmeRDS ^
    --db-snapshot-identifier preload
```

You can also use the restore from DB snapshot functionality to create test DB instances for dry runs or to undo changes made during the load.

Keep in mind that restoring a database from a DB snapshot creates a new DB instance that, like all DB instances, has a unique identifier and endpoint. To restore the DB instance without changing the endpoint, first delete the DB instance so that you can reuse the endpoint.

For example, to create a DB instance for dry runs or other testing, you give the DB instance its own identifier. In the example, AcmeRDS-2" is the identifier. The example connects to the DB instance using the endpoint associated with AcmeRDS-2.

For Linux, macOS, or Unix:

```
aws rds restore-db-instance-from-db-snapshot \
    --db-instance-identifier AcmeRDS-2 \
    --db-snapshot-identifier preload
```

For Windows:

```
aws rds restore-db-instance-from-db-snapshot ^
    --db-instance-identifier AcmeRDS-2 ^
    --db-snapshot-identifier preload
```

To reuse the existing endpoint, first delete the DB instance and then give the restored database the same identifier.

For Linux, macOS, or Unix:

```
aws rds delete-db-instance \
    --db-instance-identifier AcmeRDS \
    --final-db-snapshot-identifier AcmeRDS-Final

aws rds restore-db-instance-from-db-snapshot \
    --db-instance-identifier AcmeRDS \
    --db-snapshot-identifier preload
```

For Windows:

```
aws rds delete-db-instance ^
    --db-instance-identifier AcmeRDS ^
    --final-db-snapshot-identifier AcmeRDS-Final

aws rds restore-db-instance-from-db-snapshot ^
    --db-instance-identifier AcmeRDS ^
    --db-snapshot-identifier preload
```

The preceding example takes a final DB snapshot of the DB instance before deleting it. This is optional but recommended.

Step 4: Consider turning off Amazon RDS automated backups

> **Warning**
>
> Do not turn off automated backups if you need to perform point-in-time recovery.

Turning off automated backups erases all existing backups, so point-in-time recovery isn't possible after automated backups have been turned off. Disabling automated backups is a performance optimization and isn't required for data loads. Manual DB snapshots aren't affected by turning off automated backups. All existing manual DB snapshots are still available for restore.

Turning off automated backups reduces load time by about 25 percent and reduces the amount of storage space required during the load. If you plan to load data into a new DB instance that contains no data, turning off backups is an easy way to speed up the load and avoid using the additional storage needed for backups. However, in some cases you might plan to load into a DB instance that already contains data. If so, weigh the benefits of turning off backups against the impact of losing the ability to perform point-in-time-recovery.

DB instances have automated backups turned on by default (with a one day retention period). To turn off automated backups, set the backup retention period to zero. After the load, you can turn backups back on by setting the backup retention period to a nonzero value. To turn on or turn off backups, Amazon RDS shuts the DB instance down and restarts it to turn MariaDB or MySQL logging on or off.

Use the AWS CLI `modify-db-instance` command to set the backup retention to zero and apply the change immediately. Setting the retention period to zero requires a DB instance restart, so wait until the restart has completed before proceeding.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier AcmeRDS \
    --apply-immediately \
    --backup-retention-period 0
```

For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier AcmeRDS ^
    --apply-immediately ^
    --backup-retention-period 0
```

You can check the status of your DB instance with the AWS CLI `describe-db-instances` command. The following example displays the DB instance status of the AcmeRDS DB instance.

```
aws rds describe-db-instances --db-instance-identifier AcmeRDS --query "*[].
{DBInstanceStatus:DBInstanceStatus}"
```

When the DB instance status is `available`, you're ready to proceed.

Step 5: Load the data

Use the MySQL `LOAD DATA LOCAL INFILE` statement to read rows from your flat files into the database tables.

The following example shows you how to load data from a file named `sales.txt` into a table named `Sales` in the database.

```
mysql> LOAD DATA LOCAL INFILE 'sales.txt' INTO TABLE Sales FIELDS TERMINATED BY ' '
 ENCLOSED BY '' ESCAPED BY '\\';
Query OK, 1 row affected (0.01 sec)
Records: 1  Deleted: 0  Skipped: 0  Warnings: 0
```

For more information about the `LOAD DATA` statement, see the MySQL documentation.

Step 6: Turn Amazon RDS automated backups back on

After the load is finished, turn Amazon RDS automated backups on by setting the backup retention period back to its preload value. As noted earlier, Amazon RDS restarts the DB instance, so be prepared for a brief outage.

The following example uses the AWS CLI `modify-db-instance` command to turn on automated backups for the `AcmeRDS` DB instance and set the retention period to one day.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier AcmeRDS \
    --backup-retention-period 1 \
    --apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier AcmeRDS ^
    --backup-retention-period 1 ^
    --apply-immediately
```

Working with MariaDB replication in Amazon RDS

You usually use read replicas to configure replication between Amazon RDS DB instances. For general information about read replicas, see Working with DB instance read replicas. For specific information about working with read replicas on Amazon RDS for MariaDB, see Working with MariaDB read replicas.

You can also configure replication based on binary log coordinates for a MariaDB DB instance. For MariaDB instances, you can also configure replication based on global transaction IDs (GTIDs), which provides better crash safety. For more information, see Configuring GTID-based replication with an external source instance.

The following are other replication options available with RDS for MariaDB:

- You can set up replication between an RDS for MariaDB DB instance and a MySQL or MariaDB instance that is external to Amazon RDS. For information about configuring replication with an external source, see Configuring binary log file position replication with an external source instance.
- You can configure replication to import databases from a MySQL or MariaDB instance that is external to Amazon RDS, or to export databases to such instances. For more information, see Importing data to an Amazon RDS MariaDB or MySQL DB instance with reduced downtime and Exporting data from a MySQL DB instance by using replication.

For any of these replication options, you can use either row-based replication, statement-based, or mixed replication. Row-based replication only replicates the changed rows that result from a SQL statement. Statement-based replication replicates the entire SQL statement. Mixed replication uses statement-based replication when possible, but switches to row-based replication when SQL statements that are unsafe for statement-based replication are run. In most cases, mixed replication is recommended. The binary log format of the DB instance determines whether replication is row-based, statement-based, or mixed. For information about setting the binary log format, see Binary logging format.

Topics

Working with MariaDB read replicas

Following, you can find specific information about working with read replicas on Amazon RDS for MariaDB. For general information about read replicas and instructions for using them, see Working with DB instance read replicas.

- Configuring replication filters with MariaDB
- Configuring delayed replication with MariaDB
- Updating read replicas with MariaDB
- Working with Multi-AZ read replica deployments with MariaDB
- Using cascading read replicas with RDS for MariaDB
- Monitoring MariaDB read replicas
- Starting and stopping replication with MariaDB read replicas
- Troubleshooting a MariaDB read replica problem

Configuring read replicas with MariaDB

Before a MariaDB DB instance can serve as a replication source, make sure to turn on automatic backups on the source DB instance by setting the backup retention period to a value other than 0. This requirement also applies to a read replica that is the source DB instance for another read replica.

You can create up to 15 read replicas from one DB instance within the same Region. For replication to operate effectively, each read replica should have as the same amount of compute and storage resources as the source DB instance. If you scale the source DB instance, also scale the read replicas.

RDS for MariaDB supports cascading read replicas. To learn how to configure cascading read replicas, see Using cascading read replicas with RDS for MariaDB.

You can run multiple read replica create and delete actions at the same time that reference the same source DB instance. When you perform these actions, stay within the limit of 15 read replicas for each source instance.

Configuring replication filters with MariaDB

You can use replication filters to specify which databases and tables are replicated with a read replica. Replication filters can include databases and tables in replication or exclude them from replication.

The following are some use cases for replication filters:

- To reduce the size of a read replica. With replication filtering, you can exclude the databases and tables that aren't needed on the read replica.
- To exclude databases and tables from read replicas for security reasons.
- To replicate different databases and tables for specific use cases at different read replicas. For example, you might use specific read replicas for analytics or sharding.
- For a DB instance that has read replicas in different AWS Regions, to replicate different databases or tables in different AWS Regions.

> **Note**
>
> You can also use replication filters to specify which databases and tables are replicated with a primary MariaDB DB instance that is configured as a replica in an inbound replication topology. For more information about this configuration, see Configuring binary log file position replication with an external source instance.

Topics

- Setting replication filtering parameters for RDS for MariaDB
- Replication filtering limitations for RDS for MariaDB
- Replication filtering examples for RDS for MariaDB

Setting replication filtering parameters for RDS for MariaDB

To configure replication filters, set the following replication filtering parameters on the read replica:

- `replicate-do-db` – Replicate changes to the specified databases. When you set this parameter for a read replica, only the databases specified in the parameter are replicated.
- `replicate-ignore-db` – Don't replicate changes to the specified databases. When the `replicate-do-db` parameter is set for a read replica, this parameter isn't evaluated.
- `replicate-do-table` – Replicate changes to the specified tables. When you set this parameter for a read replica, only the tables specified in the parameter are replicated. Also, when the

`replicate-do-db` or `replicate-ignore-db` parameter is set, the database that includes the specified tables must be included in replication with the read replica.

- `replicate-ignore-table` – Don't replicate changes to the specified tables. When the `replicate-do-table` parameter is set for a read replica, this parameter isn't evaluated.
- `replicate-wild-do-table` – Replicate tables based on the specified database and table name patterns. The `%` and _ wildcard characters are supported. When the `replicate-do-db` or `replicate-ignore-db` parameter is set, make sure to include the database that includes the specified tables in replication with the read replica.
- `replicate-wild-ignore-table` – Don't replicate tables based on the specified database and table name patterns. The `%` and _ wildcard characters are supported. When the `replicate-do-table` or `replicate-wild-do-table` parameter is set for a read replica, this parameter isn't evaluated.

The parameters are evaluated in the order that they are listed. For more information about how these parameters work, see the MariaDB documentation.

By default, each of these parameters has an empty value. On each read replica, you can use these parameters to set, change, and delete replication filters. When you set one of these parameters, separate each filter from others with a comma.

You can use the `%` and _ wildcard characters in the `replicate-wild-do-table` and `replicate-wild-ignore-table` parameters. The `%` wildcard matches any number of characters, and the _ wildcard matches only one character.

The binary logging format of the source DB instance is important for replication because it determines the record of data changes. The setting of the `binlog_format` parameter determines whether the replication is row-based or statement-based. For more information, see Binary logging format.

> **Note**
>
> All data definition language (DDL) statements are replicated as statements, regardless of the `binlog_format` setting on the source DB instance.

Replication filtering limitations for RDS for MariaDB

The following limitations apply to replication filtering for RDS for MariaDB:

- Each replication filtering parameter has a 2,000-character limit.
- Commas aren't supported in replication filters.
- The MariaDB `binlog_do_db` and `binlog_ignore_db` options for binary log filtering aren't supported.
- Replication filtering doesn't support XA transactions.

  For more information, see Restrictions on XA Transactions in the MySQL documentation.
- Replication filtering isn't supported for RDS for MariaDB version 10.2.

Replication filtering examples for RDS for MariaDB

To configure replication filtering for a read replica, modify the replication filtering parameters in the parameter group associated with the read replica.

> **Note**
>
> You can't modify a default parameter group. If the read replica is using a default parameter group, create a new parameter group and associate it with the read replica. For more information on DB parameter groups, see Parameter groups for Amazon RDS.

You can set parameters in a parameter group using the AWS Management Console, AWS CLI, or RDS API. For information about setting parameters, see Modifying parameters in a DB parameter group in Amazon RDS. When you set parameters in a parameter group, all of the DB instances associated with the parameter group use the parameter settings. If you set the replication filtering parameters in a parameter group, make sure that the parameter group is associated only with read replicas. Leave the replication filtering parameters empty for source DB instances.

The following examples set the parameters using the AWS CLI. These examples set `ApplyMethod` to `immediate` so that the parameter changes occur immediately after the CLI command completes. If you want a pending change to be applied after the read replica is rebooted, set `ApplyMethod` to `pending-reboot`.

The following examples set replication filters:

- Including databases in replication
- Including tables in replication

- Including tables in replication with wildcard characters
- Escaping wildcard characters in names
- Excluding databases from replication
- Excluding tables from replication
- Excluding tables from replication using wildcard characters

Example Including databases in replication

The following example includes the `mydb1` and `mydb2` databases in replication. When you set `replicate-do-db` for a read replica, only the databases specified in the parameter are replicated.

For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group \
  --db-parameter-group-name myparametergroup \
  --parameters "[{"ParameterName": "replicate-do-db", "ParameterValue": "mydb1,mydb2",
 "ApplyMethod":"immediate"}]"
```

For Windows:

```
aws rds modify-db-parameter-group ^
  --db-parameter-group-name myparametergroup ^
  --parameters "[{"ParameterName": "replicate-do-db", "ParameterValue": "mydb1,mydb2",
 "ApplyMethod":"immediate"}]"
```

Example Including tables in replication

The following example includes the `table1` and `table2` tables in database `mydb1` in replication.

For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group \
  --db-parameter-group-name myparametergroup \
  --parameters "[{"ParameterName": "replicate-do-table", "ParameterValue":
 "mydb1.table1,mydb1.table2", "ApplyMethod":"immediate"}]"
```

For Windows:

```
aws rds modify-db-parameter-group ^
  --db-parameter-group-name myparametergroup ^
  --parameters "[{"ParameterName": "replicate-do-table", "ParameterValue":
 "mydb1.table1,mydb1.table2", "ApplyMethod":"immediate"}]"
```

Example Including tables in replication using wildcard characters

The following example includes tables with names that begin with `orders` and `returns` in database `mydb` in replication.

For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group \
  --db-parameter-group-name myparametergroup \
  --parameters "[{"ParameterName": "replicate-wild-do-table", "ParameterValue":
 "mydb.orders%,mydb.returns%", "ApplyMethod":"immediate"}]"
```

For Windows:

```
aws rds modify-db-parameter-group ^
  --db-parameter-group-name myparametergroup ^
  --parameters "[{"ParameterName": "replicate-wild-do-table", "ParameterValue":
 "mydb.orders%,mydb.returns%", "ApplyMethod":"immediate"}]"
```

Example Escaping wildcard characters in names

The following example shows you how to use the escape character \ to escape a wildcard character that is part of a name.

Assume that you have several table names in database `mydb1` that start with `my_table`, and you want to include these tables in replication. The table names include an underscore, which is also a wildcard character, so the example escapes the underscore in the table names.

For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group \
  --db-parameter-group-name myparametergroup \
  --parameters "[{"ParameterName": "replicate-wild-do-table", "ParameterValue": "my
\_table%", "ApplyMethod":"immediate"}]"
```

For Windows:

```
aws rds modify-db-parameter-group ^
  --db-parameter-group-name myparametergroup ^
  --parameters "[{"ParameterName": "replicate-wild-do-table", "ParameterValue": "my
\_table%", "ApplyMethod":"immediate"}]"
```

Example Excluding databases from replication

The following example excludes the `mydb1` and `mydb2` databases from replication.

For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group \
  --db-parameter-group-name myparametergroup \
  --parameters "[{"ParameterName": "replicate-ignore-db", "ParameterValue":
 "mydb1,mydb2", "ApplyMethod":"immediate"}]"
```

For Windows:

```
aws rds modify-db-parameter-group ^
  --db-parameter-group-name myparametergroup ^
  --parameters "[{"ParameterName": "replicate-ignore-db", "ParameterValue":
 "mydb1,mydb2", "ApplyMethod":"immediate"}]"
```

Example Excluding tables from replication

The following example excludes tables `table1` and `table2` in database `mydb1` from replication.

For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group \
  --db-parameter-group-name myparametergroup \
  --parameters "[{"ParameterName": "replicate-ignore-table", "ParameterValue":
 "mydb1.table1,mydb1.table2", "ApplyMethod":"immediate"}]"
```

For Windows:

```
aws rds modify-db-parameter-group ^
  --db-parameter-group-name myparametergroup ^
```

```
  --parameters "[{"ParameterName": "replicate-ignore-table", "ParameterValue":
 "mydb1.table1,mydb1.table2", "ApplyMethod":"immediate"}]"
```

Example Excluding tables from replication using wildcard characters

The following example excludes tables with names that begin with `orders` and `returns` in database `mydb` from replication.

For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group \
  --db-parameter-group-name myparametergroup \
  --parameters "[{"ParameterName": "replicate-wild-ignore-table", "ParameterValue":
 "mydb.orders%,mydb.returns%", "ApplyMethod":"immediate"}]"
```

For Windows:

```
aws rds modify-db-parameter-group ^
  --db-parameter-group-name myparametergroup ^
  --parameters "[{"ParameterName": "replicate-wild-ignore-table", "ParameterValue":
 "mydb.orders%,mydb.returns%", "ApplyMethod":"immediate"}]"
```

Viewing the replication filters for a read replica

You can view the replication filters for a read replica in the following ways:

- Check the settings of the replication filtering parameters in the parameter group associated with the read replica.

  For instructions, see Viewing parameter values for a DB parameter group in Amazon RDS.
- In a MariaDB client, connect to the read replica and run the `SHOW REPLICA STATUS` statement.

  In the output, the following fields show the replication filters for the read replica:
  - `Replicate_Do_DB`
  - `Replicate_Ignore_DB`
  - `Replicate_Do_Table`
  - `Replicate_Ignore_Table`
  - `Replicate_Wild_Do_Table`
  - `Replicate_Wild_Ignore_Table`

For more information about these fields, see Checking Replication Status in the MySQL documentation.

> **Note**
>
> Previous versions of MariaDB used `SHOW SLAVE STATUS` instead of `SHOW REPLICA STATUS`. If you are using a MariaDB version before 10.5, then use `SHOW SLAVE STATUS`.

Configuring delayed replication with MariaDB

You can use delayed replication as a strategy for disaster recovery. With delayed replication, you specify the minimum amount of time, in seconds, to delay replication from the source to the read replica. In the event of a disaster, such as a table deleted unintentionally, you complete the following steps to recover from the disaster quickly:

- Stop replication to the read replica before the change that caused the disaster is sent to it.

  To stop replication, use the mysql.rds_stop_replication stored procedure.
- Promote the read replica to be the new source DB instance by using the instructions in Promoting a read replica to be a standalone DB instance.

> **Note**
>
> - Delayed replication is supported for MariaDB 10.6 and higher.
> - Use stored procedures to configure delayed replication. You can't configure delayed replication with the AWS Management Console, the AWS CLI, or the Amazon RDS API.
> - You can use replication based on global transaction identifiers (GTIDs) in a delayed replication configuration.

Topics

- Configuring delayed replication during read replica creation
- Modifying delayed replication for an existing read replica
- Promoting a read replica

Configuring delayed replication during read replica creation

To configure delayed replication for any future read replica created from a DB instance, run the mysql.rds_set_configuration stored procedure with the `target delay` parameter.

To configure delayed replication during read replica creation

1. Using a MariaDB client, connect to the MariaDB DB instance to be the source for read replicas as the master user.
2. Run the mysql.rds_set_configuration stored procedure with the `target delay` parameter.

   For example, run the following stored procedure to specify that replication is delayed by at least one hour (3,600 seconds) for any read replica created from the current DB instance.

   ```
   call mysql.rds_set_configuration('target delay', 3600);
   ```

   > **Note**
   >
   > After running this stored procedure, any read replica you create using the AWS CLI or Amazon RDS API is configured with replication delayed by the specified number of seconds.

Modifying delayed replication for an existing read replica

To modify delayed replication for an existing read replica, run the mysql.rds_set_source_delay stored procedure.

To modify delayed replication for an existing read replica

1. Using a MariaDB client, connect to the read replica as the master user.
2. Use the mysql.rds_stop_replication stored procedure to stop replication.
3. Run the mysql.rds_set_source_delay stored procedure.

   For example, run the following stored procedure to specify that replication to the read replica is delayed by at least one hour (3600 seconds).

   ```
   call mysql.rds_set_source_delay(3600);
   ```

4. Use the mysql.rds_start_replication stored procedure to start replication.

Promoting a read replica

After replication is stopped, in a disaster recovery scenario, you can promote a read replica to be the new source DB instance. For information about promoting a read replica, see Promoting a read replica to be a standalone DB instance.

Updating read replicas with MariaDB

Read replicas are designed to support read queries, but you might need occasional updates. For example, you might need to add an index to speed the specific types of queries accessing the replica. You can enable updates by setting the `read_only` parameter to **0** in the DB parameter group for the read replica.

Working with Multi-AZ read replica deployments with MariaDB

You can create a read replica from either single-AZ or Multi-AZ DB instance deployments. You use Multi-AZ deployments to improve the durability and availability of critical data, but you can't use the Multi-AZ secondary to serve read-only queries. Instead, you can create read replicas from high-traffic Multi-AZ DB instances to offload read-only queries. If the source instance of a Multi-AZ deployment fails over to the secondary, any associated read replicas automatically switch to use the secondary (now primary) as their replication source. For more information, see Configuring and managing a Multi-AZ deployment.

You can create a read replica as a Multi-AZ DB instance. Amazon RDS creates a standby of your replica in another Availability Zone for failover support for the replica. Creating your read replica as a Multi-AZ DB instance is independent of whether the source database is a Multi-AZ DB instance.

Using cascading read replicas with RDS for MariaDB

RDS for MariaDB supports cascading read replicas. With *cascading read replicas*, you can scale reads without adding overhead to your source RDS for MariaDB DB instance.

With cascading read replicas, your RDS for MariaDB DB instance sends data to the first read replica in the chain. That read replica then sends data to the second replica in the chain, and so on. The end result is that all read replicas in the chain have the changes from the RDS for MariaDB DB instance, but without the overhead solely on the source DB instance.

You can create a series of up to three read replicas in a chain from a source RDS for MariaDB DB instance. For example, suppose that you have an RDS for MariaDB DB instance, `mariadb-main`. You can do the following:

- Starting with `mariadb-main`, create the first read replica in the chain, `read-replica-1`.
- Next, from `read-replica-1`, create the next read replica in the chain, `read-replica-2`.
- Finally, from `read-replica-2`, create the third read replica in the chain, `read-replica-3`.

You can't create another read replica beyond this third cascading read replica in the series for `mariadb-main`. A complete series of instances from an RDS for MariaDB source DB instance through to the end of a series of cascading read replicas can consist of at most four DB instances.

For cascading read replicas to work, each source RDS for MariaDB DB instance must have automated backups turned on. To turn on automatic backups on a read replica, first create the read replica, and then modify the read replica to turn on automatic backups. For more information, see Creating a read replica.

As with any read replica, you can promote a read replica that's part of a cascade. Promoting a read replica from within a chain of read replicas removes that replica from the chain. For example, suppose that you want to move some of the workload from your `mariadb-main` DB instance to a new instance for use by the accounting department only. Assuming the chain of three read replicas from the example, you decide to promote `read-replica-2`. The chain is affected as follows:

- Promoting `read-replica-2` removes it from the replication chain.
  - It is now a full read/write DB instance.
  - It continues replicating to `read-replica-3`, just as it was doing before promotion.
- Your `mariadb-main` continues replicating to `read-replica-1`.

For more information about promoting read replicas, see Promoting a read replica to be a standalone DB instance.

Monitoring MariaDB read replicas

For MariaDB read replicas, you can monitor replication lag in Amazon CloudWatch by viewing the Amazon RDS `ReplicaLag` metric. The `ReplicaLag` metric reports the value of the `Seconds_Behind_Master` field of the `SHOW REPLICA STATUS` command.

> **Note**
>
> Previous versions of MariaDB used `SHOW SLAVE STATUS` instead of `SHOW REPLICA STATUS`. If you are using a MariaDB version before 10.5, then use `SHOW SLAVE STATUS`.

Common causes for replication lag for MariaDB are the following:

- A network outage.
- Writing to tables with indexes on a read replica. If the `read_only` parameter is not set to 0 on the read replica, it can break replication.
- Using a nontransactional storage engine such as MyISAM. Replication is only supported for the InnoDB storage engine on MariaDB.

When the `ReplicaLag` metric reaches 0, the replica has caught up to the source DB instance. If the `ReplicaLag` metric returns -1, then replication is currently not active. `ReplicaLag` = -1 is equivalent to `Seconds_Behind_Master` = `NULL`.

Starting and stopping replication with MariaDB read replicas

You can stop and restart the replication process on an Amazon RDS DB instance by calling the system stored procedures mysql.rds_stop_replication and mysql.rds_start_replication. You can do this when replicating between two Amazon RDS instances for long-running operations such as creating large indexes. You also need to stop and start replication when importing or exporting databases. For more information, see Importing data to an Amazon RDS MariaDB or MySQL database with reduced downtime and Exporting data from a MySQL DB instance by using replication.

If replication is stopped for more than 30 consecutive days, either manually or due to a replication error, Amazon RDS ends replication between the source DB instance and all read replicas. It does so to prevent increased storage requirements on the source DB instance and long failover times. The read replica DB instance is still available. However, replication can't be resumed because the binary logs required by the read replica are deleted from the source DB instance after replication is ended. You can create a new read replica for the source DB instance to reestablish replication.

Troubleshooting a MariaDB read replica problem

The replication technologies for MariaDB are asynchronous. Because they are asynchronous, occasional `BinLogDiskUsage` increases on the source DB instance and `ReplicaLag` on the read replica are to be expected. For example, a high volume of write operations to the source DB instance can occur in parallel. In contrast, write operations to the read replica are serialized using a single I/O thread, which can lead to a lag between the source instance and read replica. For more information about read-only replicas in the MariaDB documentation, go to Replication overview.

You can do several things to reduce the lag between updates to a source DB instance and the subsequent updates to the read replica, such as the following:

- Sizing a read replica to have a storage size and DB instance class comparable to the source DB instance.
- Ensuring that parameter settings in the DB parameter groups used by the source DB instance and the read replica are compatible. For more information and an example, see the discussion of the `max_allowed_packet` parameter later in this section.

Amazon RDS monitors the replication status of your read replicas and updates the `Replication State` field of the read replica instance to `Error` if replication stops for any reason. An example might be if DML queries run on your read replica conflict with the updates made on the source DB instance.

You can review the details of the associated error thrown by the MariaDB engine by viewing the `Replication Error` field. Events that indicate the status of the read replica are also generated, including RDS-EVENT-0045, RDS-EVENT-0046, and RDS-EVENT-0047. For more information about events and subscribing to events, see Working with Amazon RDS event notification. If a MariaDB error message is returned, review the error in the MariaDB error message documentation.

One common issue that can cause replication errors is when the value for the `max_allowed_packet` parameter for a read replica is less than the `max_allowed_packet` parameter for the source DB instance. The `max_allowed_packet` parameter is a custom parameter that you can set in a DB parameter group that is used to specify the maximum size of DML code that can be run on the database. In some cases, the `max_allowed_packet` parameter value in the DB parameter group associated with a source DB instance is smaller than the `max_allowed_packet` parameter value in the DB parameter group associated with the source's read replica. In these cases, the replication process can throw an error (Packet bigger than

'max_allowed_packet' bytes) and stop replication. You can fix the error by having the source and read replica use DB parameter groups with the same `max_allowed_packet` parameter values.

Other common situations that can cause replication errors include the following:

- Writing to tables on a read replica. If you are creating indexes on a read replica, you need to have the `read_only` parameter set to **0** to create the indexes. If you are writing to tables on the read replica, it might break replication.
- Using a non-transactional storage engine such as MyISAM. read replicas require a transactional storage engine. Replication is only supported for the InnoDB storage engine on MariaDB.
- Using unsafe nondeterministic queries such as `SYSDATE()`. For more information, see Determination of safe and unsafe statements in binary logging.

If you decide that you can safely skip an error, you can follow the steps described in Skipping the current replication error. Otherwise, you can delete the read replica and create an instance using the same DB instance identifier so that the endpoint remains the same as that of your old read replica. If a replication error is fixed, the `Replication State` changes to *replicating*.

For MariaDB DB instances, in some cases read replicas can't be switched to the secondary if some binary log (binlog) events aren't flushed during the failure. In these cases, manually delete and recreate the read replicas. You can reduce the chance of this happening by setting the following parameter values: `sync_binlog=1` and `innodb_flush_log_at_trx_commit=1`. These settings might reduce performance, so test their impact before implementing the changes in a production environment.

Configuring GTID-based replication with an external source instance

You can set up replication based on global transaction identifiers (GTIDs) from an external MariaDB instance of version 10.0.24 or higher into an RDS for MariaDB DB instance. Follow these guidelines when you set up an external source instance and a replica on Amazon RDS:

- Monitor failover events for the RDS for MariaDB DB instance that is your replica. If a failover occurs, then the DB instance that is your replica might be recreated on a new host with a different network address. For information on how to monitor failover events, see Working with Amazon RDS event notification.
- Maintain the binary logs (binlogs) on your source instance until you have verified that they have been applied to the replica. This maintenance ensures that you can restore your source instance in the event of a failure.

- Turn on automated backups on your MariaDB DB instance on Amazon RDS. Turning on automated backups ensures that you can restore your replica to a particular point in time if you need to resynchronize your source instance and replica. For information on backups and Point-In-Time Restore, see Backing up, restoring, and exporting data.

> **Note**
>
> The permissions required to start replication on a MariaDB DB instance are restricted and not available to your Amazon RDS master user. Because of this, you must use the Amazon RDS mysql.rds_set_external_master_gtid and mysql.rds_start_replication commands to set up replication between your live database and your RDS for MariaDB database.

To start replication between an external source instance and a MariaDB DB instance on Amazon RDS, use the following procedure.

To start replication

1. Make the source MariaDB instance read-only:

```
mysql> FLUSH TABLES WITH READ LOCK;
mysql> SET GLOBAL read_only = ON;
```

2. Get the current GTID of the external MariaDB instance. You can do this by using `mysql` or the query editor of your choice to run `SELECT @@gtid_current_pos;`.

   The GTID is formatted as `<domain-id>-<server-id>-<sequence-id>`. A typical GTID looks something like **`0-1234510749-1728`**. For more information about GTIDs and their component parts, see Global transaction ID in the MariaDB documentation.

3. Copy the database from the external MariaDB instance to the MariaDB DB instance using `mysqldump`. For very large databases, you might want to use the procedure in Importing data to an Amazon RDS MariaDB or MySQL database with reduced downtime.

   For Linux, macOS, or Unix:

```
mysqldump \
    --databases database_name \
    --single-transaction \
    --compress \
```

```
    --order-by-primary \
    -u local_user \
    -plocal_password | mysql \
        --host=hostname \
        --port=3306 \
        -u RDS_user_name \
        -pRDS_password
```

For Windows:

```
mysqldump ^
    --databases database_name ^
    --single-transaction ^
    --compress ^
    --order-by-primary \
    -u local_user \
    -plocal_password | mysql ^
        --host=hostname ^
        --port=3306 ^
        -u RDS_user_name ^
        -pRDS_password
```

> **Note**
>
> Make sure that there isn't a space between the `-p` option and the entered password. Specify a password other than the prompt shown here as a security best practice.

Use the `--host`, `--user (-u)`, `--port` and `-p` options in the `mysql` command to specify the host name, user name, port, and password to connect to your MariaDB DB instance. The host name is the DNS name from the MariaDB DB instance endpoint, for example `myinstance.123456789012.us-east-1.rds.amazonaws.com`. You can find the endpoint value in the instance details in the Amazon RDS Management Console.

4. Make the source MariaDB instance writeable again.

```
mysql> SET GLOBAL read_only = OFF;
mysql> UNLOCK TABLES;
```

5. In the Amazon RDS Management Console, add the IP address of the server that hosts the external MariaDB database to the VPC security group for the MariaDB DB instance. For more

information on modifying a VPC security group, go to Security groups for your VPC in the *Amazon Virtual Private Cloud User Guide*.

The IP address can change when the following conditions are met:

- You are using a public IP address for communication between the external source instance and the DB instance.
- The external source instance was stopped and restarted.

If these conditions are met, verify the IP address before adding it.

You might also need to configure your local network to permit connections from the IP address of your MariaDB DB instance, so that it can communicate with your external MariaDB instance. To find the IP address of the MariaDB DB instance, use the `host` command.

```
host db_instance_endpoint
```

The host name is the DNS name from the MariaDB DB instance endpoint.

6. Using the client of your choice, connect to the external MariaDB instance and create a MariaDB user to be used for replication. This account is used solely for replication and must be restricted to your domain to improve security. The following is an example.

```
CREATE USER 'repl_user'@'mydomain.com' IDENTIFIED BY 'password';
```

> **Note**
>
> Specify a password other than the prompt shown here as a security best practice.

7. For the external MariaDB instance, grant `REPLICATION CLIENT` and `REPLICATION SLAVE` privileges to your replication user. For example, to grant the `REPLICATION CLIENT` and `REPLICATION SLAVE` privileges on all databases for the '`repl_user`' user for your domain, issue the following command.

```
GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'mydomain.com';
```

8. Make the MariaDB DB instance the replica. Connect to the MariaDB DB instance as the master user and identify the external MariaDB database as the replication source instance by using the

mysql.rds_set_external_master_gtid command. Use the GTID that you determined in Step 2. The following is an example.

```
CALL mysql.rds_set_external_master_gtid ('mymasterserver.mydomain.com', 3306,
 'repl_user', 'password', 'GTID', 0);
```

> **Note**
>
> Specify a password other than the prompt shown here as a security best practice.

9. On the MariaDB DB instance, issue the mysql.rds_start_replication command to start replication.

```
CALL mysql.rds_start_replication;
```

Configuring binary log file position replication with an external source instance

You can set up replication between an RDS for MySQL or MariaDB DB instance and a MySQL or MariaDB instance that is external to Amazon RDS using binary log file replication.

Topics

Before you begin

You can configure replication using the binary log file position of replicated transactions.

The permissions required to start replication on an Amazon RDS DB instance are restricted and not available to your Amazon RDS master user. Because of this, make sure that you use the Amazon RDS mysql.rds_set_external_master and mysql.rds_start_replication commands to set up replication between your live database and your Amazon RDS database.

To set the binary logging format for a MySQL or MariaDB database, update the `binlog_format` parameter. If your DB instance uses the default DB instance parameter group, create a new DB

parameter group to modify `binlog_format` settings. We recommend that you use the default setting for `binlog_format`, which is `MIXED`. However, you can also set `binlog_format` to `ROW` or `STATEMENT` if you need a specific binary log (binlog) format. Reboot your DB instance for the change to take effect.

For information about setting the `binlog_format` parameter, see Configuring RDS for MySQL binary logging. For information about the implications of different MySQL replication types, see Advantages and disadvantages of statement-based and row-based replication in the MySQL documentation.

> **Note**
>
> Starting with RDS for MySQL version 8.0.36, Amazon RDS doesn't replicate the `mysql` database. Therefore, if there are users on the external database that you need on the Amazon RDS replica, make sure to create them manually.

Configuring binary log file position replication with an external source instance

Follow these guidelines when you set up an external source instance and a replica on Amazon RDS:

- Monitor failover events for the Amazon RDS DB instance that is your replica. If a failover occurs, then the DB instance that is your replica might be recreated on a new host with a different network address. For information on how to monitor failover events, see Working with Amazon RDS event notification.
- Maintain the binlogs on your source instance until you have verified that they have been applied to the replica. This maintenance makes sure that you can restore your source instance in the event of a failure.
- Turn on automated backups on your Amazon RDS DB instance. Turning on automated backups makes sure that you can restore your replica to a particular point in time if you need to re-synchronize your source instance and replica. For information on backups and point-in-time restore, see Backing up, restoring, and exporting data.

To configure binary log file replication with an external source instance

1. Make the source MySQL or MariaDB instance read-only.

```
mysql> FLUSH TABLES WITH READ LOCK;
```

```
mysql> SET GLOBAL read_only = ON;
```

2. Run the `SHOW MASTER STATUS` command on the source MySQL or MariaDB instance to determine the binlog location.

   You receive output similar to the following example.

```
File                        Position
-------------------------------------
 mysql-bin-changelog.000031      107
-------------------------------------
```

3. Copy the database from the external instance to the Amazon RDS DB instance using `mysqldump`. For very large databases, you might want to use the procedure in [Importing data to an Amazon RDS MariaDB or MySQL database with reduced downtime].

   For Linux, macOS, or Unix:

```
mysqldump --databases database_name \
    --single-transaction \
    --compress \
    --order-by-primary \
    -u local_user \
    -plocal_password | mysql \
        --host=hostname \
        --port=3306 \
        -u RDS_user_name \
        -pRDS_password
```

   For Windows:

```
mysqldump --databases database_name ^
    --single-transaction ^
    --compress ^
    --order-by-primary ^
    -u local_user ^
    -plocal_password | mysql ^
        --host=hostname ^
        --port=3306 ^
        -u RDS_user_name ^
        -pRDS_password
```

> **Note**
>
> Make sure that there isn't a space between the `-p` option and the entered password.

To specify the host name, user name, port, and password to connect to your Amazon RDS DB instance, use the `--host`, `--user (-u)`, `--port` and `-p` options in the `mysql` command. The host name is the Domain Name Service (DNS) name from the Amazon RDS DB instance endpoint, for example `myinstance.123456789012.us-east-1.rds.amazonaws.com`. You can find the endpoint value in the instance details in the AWS Management Console.

4. Make the source MySQL or MariaDB instance writeable again.

```
mysql> SET GLOBAL read_only = OFF;
mysql> UNLOCK TABLES;
```

For more information on making backups for use with replication, see the MySQL documentation.

5. In the AWS Management Console, add the IP address of the server that hosts the external database to the virtual private cloud (VPC) security group for the Amazon RDS DB instance. For more information on modifying a VPC security group, see Security groups for your VPC in the *Amazon Virtual Private Cloud User Guide*.

   The IP address can change when the following conditions are met:

   - You are using a public IP address for communication between the external source instance and the DB instance.
   - The external source instance was stopped and restarted.

   If these conditions are met, verify the IP address before adding it.

   You might also need to configure your local network to permit connections from the IP address of your Amazon RDS DB instance. You do this so that your local network can communicate with your external MySQL or MariaDB instance. To find the IP address of the Amazon RDS DB instance, use the `host` command.

```
host db_instance_endpoint
```

The host name is the DNS name from the Amazon RDS DB instance endpoint.

6. Using the client of your choice, connect to the external instance and create a user to use for replication. Use this account solely for replication and restrict it to your domain to improve security. The following is an example.

```
CREATE USER 'repl_user'@'mydomain.com' IDENTIFIED BY 'password';
```

> **Note**
>
> Specify a password other than the prompt shown here as a security best practice.

7. For the external instance, grant `REPLICATION CLIENT` and `REPLICATION SLAVE` privileges to your replication user. For example, to grant the `REPLICATION CLIENT` and `REPLICATION SLAVE` privileges on all databases for the '`repl_user`' user for your domain, issue the following command.

```
GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'mydomain.com';
```

8. Make the Amazon RDS DB instance the replica. To do so, first connect to the Amazon RDS DB instance as the master user. Then identify the external MySQL or MariaDB database as the source instance by using the mysql.rds_set_external_master command. Use the master log file name and master log position that you determined in step 2. The following is an example.

```
CALL mysql.rds_set_external_master ('mymasterserver.mydomain.com', 3306,
 'repl_user', 'password', 'mysql-bin-changelog.000031', 107, 0);
```

> **Note**
>
> On RDS for MySQL, you can choose to use delayed replication by running the mysql.rds_set_external_master_with_delay stored procedure instead. On RDS for MySQL, one reason to use delayed replication is to turn on disaster recovery with the mysql.rds_start_replication_until stored procedure. Currently, RDS for MariaDB supports delayed replication but doesn't support the `mysql.rds_start_replication_until` procedure.

9. On the Amazon RDS DB instance, issue the mysql.rds_start_replication command to start replication.

```
CALL mysql.rds_start_replication;
```

Options for MariaDB database engine

Following, you can find descriptions for options, or additional features, that are available for Amazon RDS instances running the MariaDB DB engine. To turn on these options, you add them to a custom option group, and then associate the option group with your DB instance. For more information about working with option groups, see Working with option groups.

Amazon RDS supports the following options for MariaDB:

Option ID	Engine versions
MARIADB_AUDIT_PLUGIN	MariaDB 10.3 and higher

MariaDB Audit Plugin support

Amazon RDS supports using the MariaDB Audit Plugin on MariaDB database instances. The MariaDB Audit Plugin records database activity such as users logging on to the database, queries run against the database, and more. The record of database activity is stored in a log file.

Audit Plugin option settings

Amazon RDS supports the following settings for the MariaDB Audit Plugin option.

> **Note**
>
> If you don't configure an option setting in the RDS console, RDS uses the default setting.

Option setting	Valid values	Default value	Description
SERVER_AUDIT_FILE_PATH	/rdsdbdata/log/audit/	/rdsdbdata/log/audit/	The location of the log file. The log file contains the record of the activity specified in SERVER_AUDIT_EVENTS . For more information, see Viewing and listing database log files and MariaDB database log files.

Option setting	Valid values	Default value	Description
SERVER_AUDIT_FILE_ROTATE_SIZE	1–1000000000	1000000	The size in bytes that when reached, causes the file to rotate. For more information, see Log file size.
SERVER_AUDIT_FILE_ROTATIONS	0–100	9	The number of log rotations to save when `server_audit_output_type=file` . If set to 0, then the log file never rotates. For more information, see Log file size and Downloading a database log file.

Option setting	Valid values	Default value	Description
SERVER_AUDIT_EVENTS	CONNECT, QUERY, TABLE, QUERY_DDL , QUERY_DML , QUERY_DML_NO_SELECT , QUERY_DCL	CONNECT, QUERY	The types of activity to record in the log. Installing the MariaDB Audit Plugin is itself logged. • CONNECT: Log successful and unsuccessful connections to the database, and disconnections from the database. • QUERY: Log the text of all queries run against the database. • TABLE: Log tables affected by queries when the queries are run against the database. • QUERY_DDL : Similar to the QUERY event, but returns only data definition language (DDL) queries (CREATE, ALTER, and so on). • QUERY_DML : Similar to the QUERY event, but returns only data manipulation language (DML) queries (INSERT, UPDATE, and so on, and also SELECT). • QUERY_DML_NO_SELECT : Similar to the QUERY_DML event, but doesn't log SELECT queries. • QUERY_DCL : Similar to the QUERY event, but returns only data control language (DCL) queries (GRANT, REVOKE, and so on).
SERVER_AUDIT_INCL_USERS	Multiple comma-separated values	None	Include only activity from the specified users. By default, activity is recorded for all users. SERVER_AUDIT_INCL_USERS and SERVER_AUDIT_EXCL_USERS are mutually exclusive. If you add values to SERVER_AUDIT_INCL_USERS , make sure no values are added to SERVER_AUDIT_EXCL_USERS .

Option setting	Valid values	Default value	Description
SERVER_AUDIT_EXCL_USERS	Multiple comma-separated values	None	Exclude activity from the specified users. By default, activity is recorded for all users. SERVER_AUDIT_INCL_USERS and SERVER_AUDIT_EXCL_USERS are mutually exclusive. If you add values to SERVER_AUDIT_EXCL_USERS, make sure no values are added to SERVER_AUDIT_INCL_USERS. The rdsadmin user queries the database every second to check the health of the database. Depending on your other settings, this activity can possibly cause the size of your log file to grow very large, very quickly. If you don't need to record this activity, add the rdsadmin user to the SERVER_AUDIT_EXCL_USERS list. **Note** CONNECT activity is always recorded for all users, even if the user is specified for this option setting.
SERVER_AUDIT_LOGGING	ON	ON	Logging is active. The only valid value is ON. Amazon RDS does not support deactivating logging. If you want to deactivate logging, remove the MariaDB Audit Plugin. For more information, see Removing the MariaDB Audit Plugin.
SERVER_AUDIT_QUERY_LOG_LIMIT	0–2147483647	1024	The limit on the length of the query string in a record.

Adding the MariaDB Audit Plugin

The general process for adding the MariaDB Audit Plugin to a DB instance is the following:

1. Create a new option group, or copy or modify an existing option group.
2. Add the option to the option group.
3. Associate the option group with the DB instance.

After you add the MariaDB Audit Plugin, you don't need to restart your DB instance. As soon as the option group is active, auditing begins immediately.

To add the MariaDB Audit Plugin

1. Determine the option group you want to use. You can create a new option group or use an existing option group. If you want to use an existing option group, skip to the next step. Otherwise, create a custom DB option group. Choose **mariadb** for **Engine**, and choose **10.3** or higher for **Major engine version**. For more information, see Creating an option group.
2. Add the **MARIADB_AUDIT_PLUGIN** option to the option group, and configure the option settings. For more information about adding options, see Adding an option to an option group. For more information about each setting, see Audit Plugin option settings.
3. Apply the option group to a new or existing DB instance.
   - For a new DB instance, you apply the option group when you launch the instance. For more information, see Creating an Amazon RDS DB instance.
   - For an existing DB instance, you apply the option group by modifying the DB instance and attaching the new option group. For more information, see Modifying an Amazon RDS DB instance.

Viewing and downloading the MariaDB Audit Plugin log

After you enable the MariaDB Audit Plugin, you access the results in the log files the same way you access any other text-based log files. The audit log files are located at `/rdsdbdata/log/audit/`. For information about viewing the log file in the console, see Viewing and listing database log files. For information about downloading the log file, see Downloading a database log file.

Modifying MariaDB Audit Plugin settings

After you enable the MariaDB Audit Plugin, you can modify settings for the plugin. For more information about how to modify option settings, see Modifying an option setting. For more information about each setting, see Audit Plugin option settings.

Removing the MariaDB Audit Plugin

Amazon RDS doesn't support turning off logging in the MariaDB Audit Plugin. However, you can remove the plugin from a DB instance. When you remove the MariaDB Audit Plugin, the DB instance is restarted automatically to stop auditing.

To remove the MariaDB Audit Plugin from a DB instance, do one of the following:

- Remove the MariaDB Audit Plugin option from the option group it belongs to. This change affects all DB instances that use the option group. For more information, see Removing an option from an option group
- Modify the DB instance and specify a different option group that doesn't include the plugin. This change affects a single DB instance. You can specify the default (empty) option group, or a different custom option group. For more information, see Modifying an Amazon RDS DB instance.

Parameters for MariaDB

By default, a MariaDB DB instance uses a DB parameter group that is specific to a MariaDB database. This parameter group contains some but not all of the parameters contained in the Amazon RDS DB parameter groups for the MySQL database engine. It also contains a number of new, MariaDB-specific parameters. For information about working with parameter groups and setting parameters, see Parameter groups for Amazon RDS.

Viewing MariaDB parameters

RDS for MariaDB parameters are set to the default values of the storage engine that you have selected. For more information about MariaDB parameters, see the MariaDB documentation. For more information about MariaDB storage engines, see Supported storage engines for MariaDB on Amazon RDS.

You can view the parameters available for a specific RDS for MariaDB version using the RDS console or the AWS CLI. For information about viewing the parameters in a MariaDB parameter group in the RDS console, see Viewing parameter values for a DB parameter group in Amazon RDS.

Using the AWS CLI, you can view the parameters for an RDS for MariaDB version by running the `describe-engine-default-parameters` command. Specify one of the following values for the `--db-parameter-group-family` option:

- `mariadb10.11`
- `mariadb10.6`
- `mariadb10.5`
- `mariadb10.4`
- `mariadb10.3`

For example, to view the parameters for RDS for MariaDB version 10.6, run the following command.

```
aws rds describe-engine-default-parameters --db-parameter-group-family mariadb10.6
```

Your output looks similar to the following.

```
{
```

```
    "EngineDefaults": {
        "Parameters": [
            {
                "ParameterName": "alter_algorithm",
                "Description": "Specify the alter table algorithm.",
                "Source": "engine-default",
                "ApplyType": "dynamic",
                "DataType": "string",
                "AllowedValues": "DEFAULT,COPY,INPLACE,NOCOPY,INSTANT",
                "IsModifiable": true
            },
            {
                "ParameterName": "analyze_sample_percentage",
                "Description": "Percentage of rows from the table ANALYZE TABLE will
 sample to collect table statistics.",
                "Source": "engine-default",
                "ApplyType": "dynamic",
                "DataType": "float",
                "AllowedValues": "0-100",
                "IsModifiable": true
            },
            {
                "ParameterName": "aria_block_size",
                "Description": "Block size to be used for Aria index pages.",
                "Source": "engine-default",
                "ApplyType": "static",
                "DataType": "integer",
                "AllowedValues": "1024-32768",
                "IsModifiable": false
            },
            {
                "ParameterName": "aria_checkpoint_interval",
                "Description": "Interval in seconds between automatic checkpoints.",
                "Source": "engine-default",
                "ApplyType": "dynamic",
                "DataType": "integer",
                "AllowedValues": "0-4294967295",
                "IsModifiable": true
            },
        ...
```

To list only the modifiable parameters for RDS for MariaDB version 10.6, run the following command.

For Linux, macOS, or Unix:

```
aws rds describe-engine-default-parameters --db-parameter-group-family mariadb10.6 \
   --query 'EngineDefaults.Parameters[?IsModifiable==`true`]'
```

For Windows:

```
aws rds describe-engine-default-parameters --db-parameter-group-family mariadb10.6 ^
   --query "EngineDefaults.Parameters[?IsModifiable==`true`]"
```

MySQL parameters that aren't available

The following MySQL parameters are not available in MariaDB-specific DB parameter groups:

- bind_address
- binlog_error_action
- binlog_gtid_simple_recovery
- binlog_max_flush_queue_time
- binlog_order_commits
- binlog_row_image
- binlog_rows_query_log_events
- binlogging_impossible_mode
- block_encryption_mode
- core_file
- default_tmp_storage_engine
- div_precision_increment
- end_markers_in_json
- enforce_gtid_consistency
- eq_range_index_dive_limit
- explicit_defaults_for_timestamp
- gtid_executed
- gtid-mode
- gtid_next
- gtid_owned

- gtid_purged
- log_bin_basename
- log_bin_index
- log_bin_use_v1_row_events
- log_slow_admin_statements
- log_slow_slave_statements
- log_throttle_queries_not_using_indexes
- master-info-repository
- optimizer_trace
- optimizer_trace_features
- optimizer_trace_limit
- optimizer_trace_max_mem_size
- optimizer_trace_offset
- relay_log_info_repository
- rpl_stop_slave_timeout
- slave_parallel_workers
- slave_pending_jobs_size_max
- slave_rows_search_algorithms
- storage_engine
- table_open_cache_instances
- timed_mutexes
- transaction_allow_batching
- validate-password
- validate_password_dictionary_file
- validate_password_length
- validate_password_mixed_case_count
- validate_password_number_count
- validate_password_policy
- validate_password_special_char_count

For more information on MySQL parameters, see the MySQL documentation.

Migrating data from a MySQL DB snapshot to a MariaDB DB instance

You can migrate an RDS for MySQL DB snapshot to a new DB instance running MariaDB using the AWS Management Console, the AWS CLI, or Amazon RDS API. You must use a DB snapshot that was created from an Amazon RDS DB instance running MySQL 5.6 or 5.7. To learn how to create an RDS for MySQL DB snapshot, see Creating a DB snapshot for a Single-AZ DB instance.

Migrating the snapshot doesn't affect the original DB instance from which the snapshot was taken. You can test and validate the new DB instance before diverting traffic to it as a replacement for the original DB instance.

After you migrate from MySQL to MariaDB, the MariaDB DB instance is associated with the default DB parameter group and option group. After you restore the DB snapshot, you can associate a custom DB parameter group with the new DB instance. However, a MariaDB parameter group has a different set of configurable system variables. For information about the differences between MySQL and MariaDB system variables, see System Variable Differences between MariaDB and MySQL. To learn about DB parameter groups, see Parameter groups for Amazon RDS. To learn about option groups, see Working with option groups.

Performing the migration

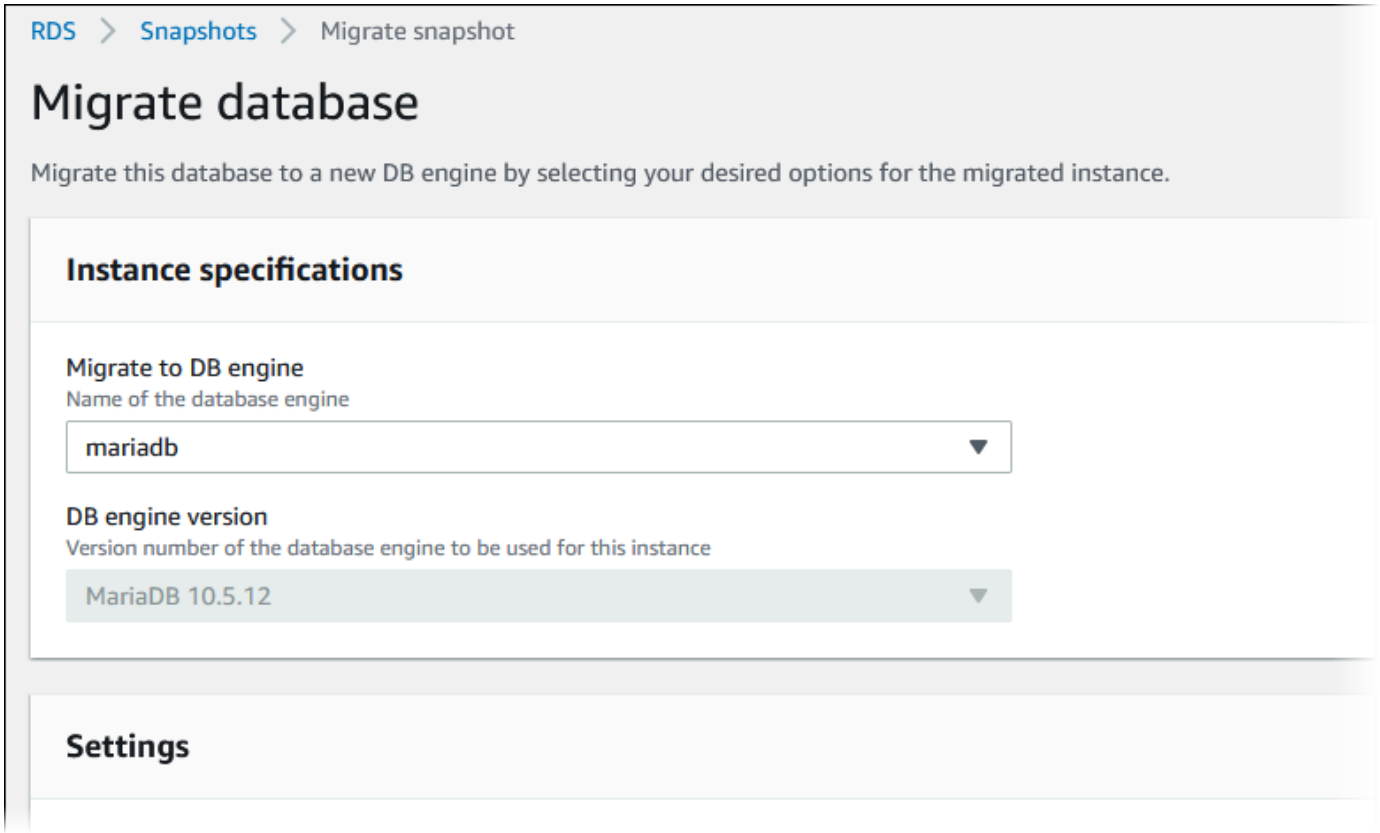
You can migrate an RDS for MySQL DB snapshot to a new MariaDB DB instance using the AWS Management Console, the AWS CLI, or the RDS API.

Console

To migrate a MySQL DB snapshot to a MariaDB DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Snapshots**, and then select the MySQL DB snapshot you want to migrate.
3. For **Actions**, choose **Migrate snapshot**. The **Migrate database** page appears.
4. For **Migrate to DB Engine**, choose **mariadb**.

   Amazon RDS selects the **DB engine version** automatically. You can't change the DB engine version.



5. For the remaining sections, specify your DB instance settings. For information about each setting, see Settings for DB instances.
6. Choose **Migrate**.

AWS CLI

To migrate data from a MySQL DB snapshot to a MariaDB DB instance, use the AWS CLI `restore-db-instance-from-db-snapshot` command with the following parameters:

- --db-instance-identifier – Name of the DB instance to create from the DB snapshot.
- --db-snapshot-identifier – The identifier for the DB snapshot to restore from.
- --engine – The database engine to use for the new instance.

Example

For Linux, macOS, or Unix:

```
aws rds restore-db-instance-from-db-snapshot \
    --db-instance-identifier newmariadbinstance \
```

```
    --db-snapshot-identifier mysqlsnapshot \
    --engine mariadb
```

For Windows:

```
aws rds restore-db-instance-from-db-snapshot ^
    --db-instance-identifier newmariadbinstance ^
    --db-snapshot-identifier mysqlsnapshot ^
    --engine mariadb
```

API

To migrate data from a MySQL DB snapshot to a MariaDB DB instance, call the Amazon RDS API operation `RestoreDBInstanceFromDBSnapshot`.

Incompatibilities between MariaDB and MySQL

Incompatibilities between MySQL and MariaDB include the following:

- You can't migrate a DB snapshot created with MySQL 8.0 to MariaDB.
- If the source MySQL database uses a SHA256 password hash, make sure to reset user passwords that are SHA256 hashed before you connect to the MariaDB database. The following code shows how to reset a password that is SHA256 hashed.

  ```
  SET old_passwords = 0;
  UPDATE mysql.user SET plugin = 'mysql_native_password',
  Password = PASSWORD('new_password')
  WHERE (User, Host) = ('master_user_name', %);
  FLUSH PRIVILEGES;
  ```

- If your RDS master user account uses the SHA-256 password hash, make sure to reset the password using the AWS Management Console, the `modify-db-instance` AWS CLI command, or the ModifyDBInstance RDS API operation. For information about modifying a DB instance, see Modifying an Amazon RDS DB instance.
- MariaDB doesn't support the Memcached plugin. However, the data used by the Memcached plugin is stored as InnoDB tables. After you migrate a MySQL DB snapshot, you can access the data used by the Memcached plugin using SQL. For more information about the innodb_memcache database, see InnoDB memcached Plugin Internals.

MariaDB on Amazon RDS SQL reference

Following, you can find descriptions of system stored procedures that are available for Amazon RDS instances running the MariaDB DB engine.

You can use the system stored procedures that are available for MySQL DB instances and MariaDB DB instances. These stored procedures are documented at RDS for MySQL stored procedure reference. MariaDB DB instances support all of the stored procedures, except for `mysql.rds_start_replication_until` and `mysql.rds_start_replication_until_gtid`.

Additionally, the following system stored procedures are supported only for Amazon RDS DB instances running MariaDB:

- mysql.rds_replica_status
- mysql.rds_set_external_master_gtid
- mysql.rds_kill_query_id

mysql.rds_replica_status

Shows the replication status of a MariaDB read replica.

Call this procedure on the read replica to show status information on essential parameters of the replica threads.

Syntax

```
CALL mysql.rds_replica_status;
```

Usage notes

This procedure is only supported for MariaDB DB instances running MariaDB version 10.5 and higher.

This procedure is the equivalent of the `SHOW REPLICA STATUS` command. This command isn't supported for MariaDB version 10.5 and higher DB instances.

In prior versions of MariaDB, the equivalent `SHOW SLAVE STATUS` command required the `REPLICATION SLAVE` privilege. In MariaDB version 10.5 and higher, it requires the `REPLICATION`

`REPLICA ADMIN` privilege. To protect the RDS management of MariaDB 10.5 and higher DB instances, this new privilege isn't granted to the RDS master user.

Examples

The following example shows the status of a MariaDB read replica:

```
call mysql.rds_replica_status;
```

The response is similar to the following:

```
*************************** 1. row ***************************
               Replica_IO_State: Waiting for master to send event
                    Source_Host: XX.XX.XX.XXX
                    Source_User: rdsrepladmin
                    Source_Port: 3306

```

mysql.rds_set_external_master_gtid

Configures GTID-based replication from a MariaDB instance running external to Amazon RDS to a MariaDB DB instance. This stored procedure is supported only where the external MariaDB instance is version 10.0.24 or higher. When setting up replication where one or both instances do not support MariaDB global transaction identifiers (GTIDs), use mysql.rds_set_external_master.

Using GTIDs for replication provides crash-safety features not offered by binary log replication, so we recommend it in cases where the replicating instances support it.

Syntax

```
CALL mysql.rds_set_external_master_gtid(
  host_name
  , host_port
```

```
  , replication_user_name
  , replication_user_password
  , gtid
  , ssl_encryption
);
```

Parameters

host_name

String. The host name or IP address of the MariaDB instance running external to Amazon RDS that will become the source instance.

host_port

Integer. The port used by the MariaDB instance running external to Amazon RDS to be configured as the source instance. If your network configuration includes SSH port replication that converts the port number, specify the port number that is exposed by SSH.

replication_user_name

String. The ID of a user with `REPLICATION SLAVE` permissions in the MariaDB DB instance to be configured as the read replica.

replication_user_password

String. The password of the user ID specified in `replication_user_name`.

gtid

String. The global transaction ID on the source instance that replication should start from.

You can use `@@gtid_current_pos` to get the current GTID if the source instance has been locked while you are configuring replication, so the binary log doesn't change between the points when you get the GTID and when replication starts.

Otherwise, if you are using `mysqldump` version 10.0.13 or greater to populate the replica instance prior to starting replication, you can get the GTID position in the output by using the `--master-data` or `--dump-slave` options. If you are not using `mysqldump` version 10.0.13 or greater, you can run the `SHOW MASTER STATUS` or use those same `mysqldump` options to get the binary log file name and position, then convert them to a GTID by running `BINLOG_GTID_POS` on the external MariaDB instance:

```
SELECT BINLOG_GTID_POS('<binary log file name>', <binary log file position>);
```

For more information about the MariaDB implementation of GTIDs, go to Global transaction ID in the MariaDB documentation.

ssl_encryption

A value that specifies whether Secure Socket Layer (SSL) encryption is used on the replication connection. 1 specifies to use SSL encryption, 0 specifies to not use encryption. The default is 0.

> **Note**
>
> The `MASTER_SSL_VERIFY_SERVER_CERT` option isn't supported. This option is set to 0, which means that the connection is encrypted, but the certificates aren't verified.

Usage notes

The `mysql.rds_set_external_master_gtid` procedure must be run by the master user. It must be run on the MariaDB DB instance that you are configuring as the replica of a MariaDB instance running external to Amazon RDS. Before running `mysql.rds_set_external_master_gtid`, you must have configured the instance of MariaDB running external to Amazon RDS as a source instance. For more information, see Importing data into a MariaDB DB instance.

> **Warning**
>
> Do not use `mysql.rds_set_external_master_gtid` to manage replication between two Amazon RDS DB instances. Use it only when replicating with a MariaDB instance running external to RDS. For information about managing replication between Amazon RDS DB instances, see Working with DB instance read replicas.

After calling `mysql.rds_set_external_master_gtid` to configure an Amazon RDS DB instance as a read replica, you can call mysql.rds_start_replication on the replica to start the replication process. You can call mysql.rds_reset_external_master to remove the read replica configuration.

When `mysql.rds_set_external_master_gtid` is called, Amazon RDS records the time, user, and an action of "set master" in the `mysql.rds_history` and `mysql.rds_replication_status` tables.

Examples

When run on a MariaDB DB instance, the following example configures it as the replica of an instance of MariaDB running external to Amazon RDS.

```
call mysql.rds_set_external_master_gtid
 ('Sourcedb.some.com',3306,'ReplicationUser','SomePassW0rd','0-123-456',0);
```

mysql.rds_kill_query_id

Ends a query running against the MariaDB server.

Syntax

```
CALL mysql.rds_kill_query_id(queryID);
```

Parameters

queryID

Integer. The identity of the query to be ended.

Usage notes

To stop a query running against the MariaDB server, use the `mysql.rds_kill_query_id` procedure and pass in the ID of that query. To obtain the query ID, query the MariaDB Information schema PROCESSLIST table, as shown following:

```
SELECT USER, HOST, COMMAND, TIME, STATE, INFO, QUERY_ID FROM
                INFORMATION_SCHEMA.PROCESSLIST WHERE USER = '<user name>';
```

The connection to the MariaDB server is retained.

Examples

The following example ends a query with a query ID of 230040:

```
call mysql.rds_kill_query_id(230040);
```

Local time zone for MariaDB DB instances

By default, the time zone for a MariaDB DB instance is Universal Time Coordinated (UTC). You can set the time zone for your DB instance to the local time zone for your application instead.

To set the local time zone for a DB instance, set the `time_zone` parameter in the parameter group for your DB instance to one of the supported values listed later in this section. When you set the `time_zone` parameter for a parameter group, all DB instances and read replicas that are using that parameter group change to use the new local time zone. For information on setting parameters in a parameter group, see Parameter groups for Amazon RDS.

After you set the local time zone, all new connections to the database reflect the change. If you have any open connections to your database when you change the local time zone, you won't see the local time zone update until after you close the connection and open a new connection.

You can set a different local time zone for a DB instance and one or more of its read replicas. To do this, use a different parameter group for the DB instance and the replica or replicas and set the `time_zone` parameter in each parameter group to a different local time zone.

If you are replicating across AWS Regions, then the source DB instance and the read replica use different parameter groups (parameter groups are unique to an AWS Region). To use the same local time zone for each instance, you must set the `time_zone` parameter in the instance's and read replica's parameter groups.

When you restore a DB instance from a DB snapshot, the local time zone is set to UTC. You can update the time zone to your local time zone after the restore is complete. If you restore a DB instance to a point in time, then the local time zone for the restored DB instance is the time zone setting from the parameter group of the restored DB instance.

The Internet Assigned Numbers Authority (IANA) publishes new time zones at https://www.iana.org/time-zones several times a year. Every time RDS releases a new minor maintenance release of MariaDB, it ships with the latest time zone data at the time of the release. When you use the latest RDS for MariaDB versions, you have recent time zone data from RDS. To ensure that your DB instance has recent time zone data, we recommend upgrading to a higher DB engine version. Alternatively, you can modify the time zone tables in MariaDB DB instances manually. To do so, you can use SQL commands or run the mysql_tzinfo_to_sql tool in a SQL client. After updating the time zone data manually, reboot your DB instance so that the changes take effect. RDS doesn't modify or reset the time zone data of running DB instances. New time zone data is installed only when you perform a database engine version upgrade.

You can set your local time zone to one of the following values.

Zone	Time zone
Africa/Cairo	Asia/Riyadh
Africa/Casablanca	Asia/Seoul
Africa/Harare	Asia/Shanghai
Africa/Monrovia	Asia/Singapore
Africa/Nairobi	Asia/Taipei
Africa/Tripoli	Asia/Tehran
Africa/Windhoek	Asia/Tokyo

Known issues and limitations for RDS for MariaDB

The following items are known issues and limitations when using RDS for MariaDB.

> **Note**
>
> This list is not exhaustive.

Topics

MariaDB file size limits in Amazon RDS

For MariaDB DB instances, the maximum size of a table is 16 TB when using InnoDB file-per-table tablespaces. This limit also constrains the system tablespace to a maximum size of 16 TB. InnoDB file-per-table tablespaces (with tables each in their own tablespace) are set by default for MariaDB DB instances. This limit isn't related to the maximum storage limit for MariaDB DB instances. For more information about the storage limit, see Amazon RDS DB instance storage.

There are advantages and disadvantages to using InnoDB file-per-table tablespaces, depending on your application. To determine the best approach for your application, see File-per-table tablespaces in the MySQL documentation.

We don't recommend allowing tables to grow to the maximum file size. In general, a better practice is to partition data into smaller tables, which can improve performance and recovery times.

One option that you can use for breaking up a large table into smaller tables is partitioning. *Partitioning* distributes portions of your large table into separate files based on rules that you specify. For example, if you store transactions by date, you can create partitioning rules that distribute older transactions into separate files using partitioning. Then periodically, you can archive the historical transaction data that doesn't need to be readily available to your application. For more information, see Partitioning in the MySQL documentation.

To determine the size of all InnoDB tablespaces

- Use the following SQL command to determine if any of your tables are too large and are candidates for partitioning.

> **Note**
>
> For MariaDB 10.6 and higher, this query also returns the size of the InnoDB system tablespace.
> For MariaDB versions earlier than 10.6, you can't determine the size of the InnoDB system tablespace by querying the system tables. We recommend that you upgrade to a later version.

```
SELECT SPACE,NAME,ROUND((ALLOCATED_SIZE/1024/1024/1024), 2)
as "Tablespace Size (GB)"
FROM information_schema.INNODB_SYS_TABLESPACES ORDER BY 3 DESC;
```

To determine the size of non-InnoDB user tables

- Use the following SQL command to determine if any of your non-InnoDB user tables are too large.

```
SELECT TABLE_SCHEMA, TABLE_NAME, round(((DATA_LENGTH + INDEX_LENGTH+DATA_FREE)
/ 1024 / 1024/ 1024), 2) As "Approximate size (GB)" FROM information_schema.TABLES
WHERE TABLE_SCHEMA NOT IN ('mysql', 'information_schema', 'performance_schema')
and ENGINE<>'InnoDB';
```

To enable InnoDB file-per-table tablespaces

- Set the `innodb_file_per_table` parameter to 1 in the parameter group for the DB instance.

To disable InnoDB file-per-table tablespaces

- Set the `innodb_file_per_table` parameter to `0` in the parameter group for the DB instance.

For information on updating a parameter group, see Parameter groups for Amazon RDS.

When you have enabled or disabled InnoDB file-per-table tablespaces, you can issue an ALTER TABLE command. You can use this command to move a table from the global tablespace to its own tablespace. Or you can move a table from its own tablespace to the global tablespace. Following is an example.

```
ALTER TABLE table_name ENGINE=InnoDB, ALGORITHM=COPY;
```

InnoDB reserved word

InnoDB is a reserved word for RDS for MariaDB. You can't use this name for a MariaDB database.

Custom ports

Amazon RDS blocks connections to custom port 33060 for the MariaDB engine. Choose a different port for your MariaDB engine.

Performance Insights

InnoDB counters are not visible in Performance Insights for RDS for MariaDB version 10.11 because the MariaDB community no longer supports them.

Amazon RDS for Microsoft SQL Server

Amazon RDS supports several versions and editions of Microsoft SQL Server. The following table shows the most recent supported minor version of each major version. For the full list of supported versions, editions, and RDS engine versions, see Microsoft SQL Server versions on Amazon RDS.

Major version	Service Pack / GDR	Cumulative Update	Minor version	Knowledge Base Article	Release Date
SQL Server 2022	Not applicable	CU14	16.0.4135.4	KB5038325	September 04, 2024
SQL Server 2019	Not applicable	CU28	15.0.4385.2	KB5039747	September 04, 2024
SQL Server 2017	GDR	CU31	14.0.3471.2	KB5040940	August 12, 2024
SQL Server 2016	SP3 GDR	Not applicable	13.0.6441.1	KB5040946	August 12, 2024

For information about licensing for SQL Server, see Licensing Microsoft SQL Server on Amazon RDS. For information about SQL Server builds, see this Microsoft support article about Where to find information about the latest SQL Server builds.

With Amazon RDS, you can create DB instances and DB snapshots, point-in-time restores, and automated or manual backups. DB instances running SQL Server can be used inside a VPC. You can also use Secure Sockets Layer (SSL) to connect to a DB instance running SQL Server, and you can use transparent data encryption (TDE) to encrypt data at rest. Amazon RDS currently supports Multi-AZ deployments for SQL Server using SQL Server Database Mirroring (DBM) or Always On Availability Groups (AGs) as a high-availability, failover solution.

To deliver a managed service experience, Amazon RDS does not provide shell access to DB instances, and it restricts access to certain system procedures and tables that require advanced privileges. Amazon RDS supports access to databases on a DB instance using any standard SQL client application such as Microsoft SQL Server Management Studio. Amazon RDS does not allow direct host access to a DB instance via Telnet, Secure Shell (SSH), or Windows Remote Desktop

Connection. When you create a DB instance, the master user is assigned to the *db_owner* role for all user databases on that instance, and has all database-level permissions except for those that are used for backups. Amazon RDS manages backups for you.

Before creating your first DB instance, you should complete the steps in the setting up section of this guide. For more information, see Setting up your Amazon RDS environment.

- Common DBA tasks for Microsoft SQL Server

Common management tasks for Microsoft SQL Server on Amazon RDS

The following are the common management tasks you perform with an Amazon RDS for SQL Server DB instance, with links to relevant documentation for each task.

Task area	Description	Relevant documentation
Instance classes, storage, and PIOPS	If you are creating a DB instance for production purposes, you should understand how instance classes, storage types, and Provisioned IOPS work in Amazon RDS.	DB instance class support for Microsoft SQL Server Amazon RDS storage types
Multi-AZ deployments	A production DB instance should use Multi-AZ deployments. Multi-AZ deployments provide increased availability, data durability, and fault tolerance for DB instances. Multi-AZ deployments for SQL Server are implemented using SQL Server's native DBM or AGs technology.	Configuring and managing a Multi-AZ deployment Multi-AZ deployments using Microsoft SQL Server Database Mirroring or Always On availability groups
Amazon Virtual Private Cloud (VPC)	If your AWS account has a default VPC, then your DB instance is automatically created inside the default	Working with a DB instance in a VPC

Task area	Description	Relevant documentation
	VPC. If your account does not have a default VPC, and you want the DB instance in a VPC, you must create the VPC and subnet groups before you create the DB instance.	
Security groups	By default, DB instances are created with a firewall that prevents access to them. You therefore must create a security group with the correct IP addresses and network configuration to access the DB instance.	Controlling access with security groups
Parameter groups	If your DB instance is going to require specific database parameters, you should create a parameter group before you create the DB instance.	Parameter groups for Amazon RDS
Option groups	If your DB instance is going to require specific database options, you should create an option group before you create the DB instance.	Options for the Microsoft SQL Server database engine
Connecting to your DB instance	After creating a security group and associating it to a DB instance, you can connect to the DB instance using any standard SQL client application such as Microsoft SQL Server Management Studio.	Connecting to a DB instance running the Microsoft SQL Server database engine

Task area	Description	Relevant documentation
Backup and restore	When you create your DB instance, you can configure it to take automated backups. You can also back up and restore your databases manually by using full backup files (.bak files).	Introduction to backups Importing and exporting SQL Server databases using native backup and restore
Monitoring	You can monitor your SQL Server DB instance by using CloudWatch Amazon RDS metrics, events, and enhanced monitoring.	Viewing metrics in the Amazon RDS console Viewing Amazon RDS events
Log files	You can access the log files for your SQL Server DB instance.	Monitoring Amazon RDS log files Microsoft SQL Server database log files

There are also advanced administrative tasks for working with SQL Server DB instances. For more information, see the following documentation:

- Common DBA tasks for Microsoft SQL Server.
- Working with AWS Managed Active Directory with RDS for SQL Server
- Accessing the tempdb database

Limitations for Microsoft SQL Server DB instances

The Amazon RDS implementation of Microsoft SQL Server on a DB instance has some limitations that you should be aware of:

- The maximum number of databases supported on a DB instance depends on the instance class type and the availability mode—Single-AZ, Multi-AZ Database Mirroring (DBM), or Multi-AZ

Availability Groups (AGs). The Microsoft SQL Server system databases don't count toward this limit.

The following table shows the maximum number of supported databases for each instance class type and availability mode. Use this table to help you decide if you can move from one instance class type to another, or from one availability mode to another. If your source DB instance has more databases than the target instance class type or availability mode can support, modifying the DB instance fails. You can see the status of your request in the **Events** pane.

Instance class type	Single-AZ	Multi-AZ with DBM	Multi-AZ with Always On AGs
db.*.micro to db.*.medium	30	N/A	N/A
db.*.large	30	30	30
db.*.xlarge to db.*.16xlarge	100	50	75
db.*.24xlarge	100	50	100

* Represents the different instance class types.

For example, let's say that your DB instance runs on a db.*.16xlarge with Single-AZ and that it has 76 databases. You modify the DB instance to upgrade to using Multi-AZ Always On AGs. This upgrade fails, because your DB instance contains more databases than your target configuration can support. If you upgrade your instance class type to db.*.24xlarge instead, the modification succeeds.

If the upgrade fails, you see events and messages similar to the following:

- Unable to modify database instance class. The instance has 76 databases, but after conversion it would only support 75.
- Unable to convert the DB instance to Multi-AZ: The instance has 76 databases, but after conversion it would only support 75.

If the point-in-time restore or snapshot restore fails, you see events and messages similar to the following:

  - Database instance put into incompatible-restore. The instance has 76 databases, but after conversion it would only support 75.
- The following ports are reserved for Amazon RDS, and you can't use them when you create a DB instance: `1234`, `1434`, `3260`, `3343`, `3389`, `47001`, and `49152-49156`.
- Client connections from IP addresses within the range 169.254.0.0/16 are not permitted. This is the Automatic Private IP Addressing Range (APIPA), which is used for local-link addressing.
- SQL Server Standard Edition uses only a subset of the available processors if the DB instance has more processors than the software limits (24 cores, 4 sockets, and 128GB RAM). Examples of this are the db.m5.24xlarge and db.r5.24xlarge instance classes.

  For more information, see the table of scale limits under Editions and supported features of SQL Server 2019 (15.x) in the Microsoft documentation.
- Amazon RDS for SQL Server doesn't support importing data into the msdb database.
- You can't rename databases on a DB instance in a SQL Server Multi-AZ deployment.
- Make sure that you use these guidelines when setting the following DB parameters on RDS for SQL Server:
  - `max server memory (mb)` >= 256 MB
  - `max worker threads` >= (number of logical CPUs * 7)

  For more information on setting DB parameters, see Parameter groups for Amazon RDS.
- The maximum storage size for SQL Server DB instances is the following:
  - General Purpose (SSD) storage – 16 TiB for all editions
  - Provisioned IOPS storage – 16 TiB for all editions
  - Magnetic storage – 1 TiB for all editions

  If you have a scenario that requires a larger amount of storage, you can use sharding across multiple DB instances to get around the limit. This approach requires data-dependent routing logic in applications that connect to the sharded system. You can use an existing sharding framework, or you can write custom code to enable sharding. If you use an existing framework, the framework can't install any components on the same server as the DB instance.
- The minimum storage size for SQL Server DB instances is the following:
  - General Purpose (SSD) storage – 20 GiB for Enterprise, Standard, Web, and Express Editions
  - Provisioned IOPS storage – 20 GiB for Enterprise, Standard, Web, and Express Editions
  - Magnetic storage – 20 GiB for Enterprise, Standard, Web, and Express Editions

- Amazon RDS doesn't support running these services on the same server as your RDS DB instance:
  - Data Quality Services
  - Master Data Services

  To use these features, we recommend that you install SQL Server on an Amazon EC2 instance, or use an on-premises SQL Server instance. In these cases, the EC2 or SQL Server instance acts as the Master Data Services server for your SQL Server DB instance on Amazon RDS. You can install SQL Server on an Amazon EC2 instance with Amazon EBS storage, pursuant to Microsoft licensing policies.
- Because of limitations in Microsoft SQL Server, restoring to a point in time before successfully running `DROP DATABASE` might not reflect the state of that database at that point in time. For example, the dropped database is typically restored to its state up to 5 minutes before the `DROP DATABASE` command was issued. This type of restore means that you can't restore the transactions made during those few minutes on your dropped database. To work around this, you can reissue the `DROP DATABASE` command after the restore operation is completed. Dropping a database removes the transaction logs for that database.
- For SQL Server, you create your databases after you create your DB instance. Database names follow the usual SQL Server naming rules with the following differences:
  - Database names can't start with `rdsadmin`.
  - They can't start or end with a space or a tab.
  - They can't contain any of the characters that create a new line.
  - They can't contain a single quote (`'`).
  - RDS for SQL Server currently does not support automatic minor version updates. For more information, see Version management in Amazon RDS.
- SQL Server Web Edition only allows you to use the **Dev/Test** template when creating a new RDS for SQL Server DB instance.

DB instance class support for Microsoft SQL Server

The computation and memory capacity of a DB instance is determined by its DB instance class. The DB instance class you need depends on your processing power and memory requirements. For more information, see DB instance classes.

The following list of DB instance classes supported for Microsoft SQL Server is provided here for your convenience. For the most current list, see the RDS console: https://console.aws.amazon.com/rds/.

Not all DB instance classes are available on all supported SQL Server minor versions. For example, some newer DB instance classes such as db.r6i aren't available on older minor versions. You can use the describe-orderable-db-instance-options AWS CLI command to find out which DB instance classes are available for your SQL Server edition and version.

SQL Server edition	2022 support range	2019 support range	2017 and 2016 support range

Express Edition	db.t3.mic ro –db.t3.xlarge	db.t3.mic ro –db.t3.xlarge	db.t3.mic ro –db.t3.xlarge

Microsoft SQL Server security

The Microsoft SQL Server database engine uses role-based security. The master user name that you specify when you create a DB instance is a SQL Server Authentication login that is a member of the `processadmin`, `public`, and `setupadmin` fixed server roles.

Any user who creates a database is assigned to the db_owner role for that database and has all database-level permissions except for those that are used for backups. Amazon RDS manages backups for you.

The following server-level roles aren't available in Amazon RDS for SQL Server:

- bulkadmin
- dbcreator
- diskadmin
- securityadmin
- serveradmin
- sysadmin

The following server-level permissions aren't available on RDS for SQL Server DB instances:

- ALTER ANY DATABASE
- ALTER ANY EVENT NOTIFICATION
- ALTER RESOURCES
- ALTER SETTINGS (you can use the DB parameter group API operations to modify parameters; for more information, see Parameter groups for Amazon RDS)
- AUTHENTICATE SERVER
- CONTROL_SERVER

- CREATE DDL EVENT NOTIFICATION
- CREATE ENDPOINT
- CREATE SERVER ROLE
- CREATE TRACE EVENT NOTIFICATION
- DROP ANY DATABASE
- EXTERNAL ACCESS ASSEMBLY
- SHUTDOWN (You can use the RDS reboot option instead)
- UNSAFE ASSEMBLY
- ALTER ANY AVAILABILITY GROUP
- CREATE ANY AVAILABILITY GROUP

Compliance program support for Microsoft SQL Server DB instances

AWS Services in scope have been fully assessed by a third-party auditor and result in a certification, attestation of compliance, or Authority to Operate (ATO). For more information, see AWS services in scope by compliance program.

HIPAA support for Microsoft SQL Server DB instances

You can use Amazon RDS for Microsoft SQL Server databases to build HIPAA-compliant applications. You can store healthcare-related information, including protected health information (PHI), under a Business Associate Agreement (BAA) with AWS. For more information, see HIPAA compliance.

Amazon RDS for SQL Server supports HIPAA for the following versions and editions:

- SQL Server 2022 Enterprise, Standard, and Web Editions
- SQL Server 2019 Enterprise, Standard, and Web Editions
- SQL Server 2017 Enterprise, Standard, and Web Editions
- SQL Server 2016 Enterprise, Standard, and Web Editions

To enable HIPAA support on your DB instance, set up the following three components.

Component	Details
Auditing	To set up auditing, set the parameter `rds.sqlserver_audit` to the value `fedramp_hipaa`. If your DB instance is not already using a custom DB parameter group, you must create a custom parameter group and attach it to your DB instance before you can modify the `rds.sqlserver_audit` parameter. For more information, see Parameter groups for Amazon RDS.
Transport encryption	To set up transport encryption, force all connections to your DB instance to use Secure Sockets Layer (SSL). For more information, see Forcing connections to your DB instance to use SSL.
Encryption at rest	To set up encryption at rest, you have two options: 1. If you're running SQL Server 2016–2022 Enterprise Edition or 2022 Standard Edition, you can use Transparent Data Encryption (TDE) to achieve encryption at rest. For more information, see Support for Transparent Data Encryption in SQL Server. 2. You can set up encryption at rest by using AWS Key Management Service (AWS KMS) encryption keys. For more information, see Encrypting Amazon RDS resources.

SSL support for Microsoft SQL Server DB instances

You can use SSL to encrypt connections between your applications and your Amazon RDS DB instances running Microsoft SQL Server. You can also force all connections to your DB instance to use SSL. If you force connections to use SSL, it happens transparently to the client, and the client doesn't have to do any work to use SSL.

SSL is supported in all AWS Regions and for all supported SQL Server editions. For more information, see Using SSL with a Microsoft SQL Server DB instance.

Microsoft SQL Server versions on Amazon RDS

You can specify any currently supported Microsoft SQL Server version when creating a new DB instance. You can specify the Microsoft SQL Server major version (such as Microsoft SQL Server 14.00), and any supported minor version for the specified major version. If no version is specified, Amazon RDS defaults to a supported version, typically the most recent version. If a major version is specified but a minor version is not, Amazon RDS defaults to a recent release of the major version you have specified.

The following table shows the supported versions for all editions and all AWS Regions, except where noted. You can also use the `describe-db-engine-versions` AWS CLI command to see a list of supported versions, as well as defaults for newly created DB instances. The following table shows the SQL Server versions supported in RDS:

Major version	Minor version	RDS API `EngineVersion` and CLI `engine-version`
SQL Server 2022	16.00.4135.4 (CU14)	`16.00.4135.4.v1`
	16.00.4131.2 (CU13)	`16.00.4131.2.v1`
	16.00.4125.3 (CU13)	`16.00.4125.3.v1`
	16.00.4120.1 (CU12 GDR)	`16.00.4120.1.v1`
	16.00.4115.5 (CU12)	`16.00.4115.5.v1`
	16.00.4105.2 (CU11)	`16.00.4105.2.v1`
	16.00.4095.4 (CU10)	`16.00.4095.4.v1`
	16.00.4085.2 (CU9)	`16.00.4085.2.v1`
SQL Server 2019	15.00.4385.2 (CU28)	`15.00.4385.2.v1`
	15.00.4382.1 (CU27)	`15.00.4382.1.v1`
	15.00.4375.4 (CU27)	`15.00.4375.4.v1`
	15.00.4365.2 (CU26)	`15.00.4365.2.v1`

Major version	Minor version	RDS API `EngineVersion` and CLI `engine-version`
	15.00.4355.3 (CU25)	`15.00.4355.3.v1`
	15.00.4345.5 (CU24)	`15.00.4345.5.v1`
	15.00.4335.1 (CU23)	`15.00.4335.1.v1`
	15.00.4322.2 (CU22)	`15.00.4322.2.v1`
	15.00.4316.3 (CU21)	`15.00.4316.3.v1`
	15.00.4312.2 (CU20)	`15.00.4312.2.v1`
	15.00.4236.7 (CU16)	`15.00.4236.7.v1`
	15.00.4198.2 (CU15)	`15.00.4198.2.v1`
	15.00.4153.1 (CU12)	`15.00.4153.1.v1`
	15.00.4073.23 (CU8)	`15.00.4073.23.v1`
	15.00.4043.16 (CU5)	`15.00.4043.16.v1`

Major version	Minor version	RDS API `EngineVersion` and CLI `engine-version`
SQL Server 2017	14.00.3471.2 (CU31)	`14.00.3471.2.v1`
	14.00.3465.1 (CU31)	`14.00.3465.1.v1`
	14.00.3460.9 (CU31)	`14.00.3460.9.v1`
	14.00.3451.2 (CU30)	`14.00.3451.2.v1`
	14.00.3421.10 (CU27)	`14.00.3421.10.v1`
	14.00.3401.7 (CU25)	`14.00.3401.7.v1`
	14.00.3381.3 (CU23)	`14.00.3381.3.v1`
	14.00.3356.20 (CU22)	`14.00.3356.20.v1`
	14.00.3294.2 (CU20)	`14.00.3294.2.v1`
	14.00.3281.6 (CU19)	`14.00.3281.6.v1`
SQL Server 2016	13.00.6441.1 (GDR)	`13.00.6441.1.v1`
	13.00.6435.1 (GDR)	`13.00.6435.1.v1`
	13.00.6430.49 (GDR)	`13.00.6430.49.v1`
	13.00.6419.1 (SP3 + Hotfix)	`13.00.6419.1.v1`
	13.00.6300.2 (SP3)	`13.00.6300.2.v1`

Version management in Amazon RDS

Amazon RDS includes flexible version management that enables you to control when and how your DB instance is patched or upgraded. This enables you to do the following for your DB engine:

- Maintain compatibility with database engine patch versions.

- Test new patch versions to verify that they work with your application before you deploy them in production.
- Plan and perform version upgrades to meet your service level agreements and timing requirements.

Microsoft SQL Server engine patching in Amazon RDS

Amazon RDS periodically aggregates official Microsoft SQL Server database patches into a DB instance engine version that's specific to Amazon RDS. For more information about the Microsoft SQL Server patches in each engine version, see Version and feature support on Amazon RDS.

Currently, you manually perform all engine upgrades on your DB instance. For more information, see Upgrading the Microsoft SQL Server DB engine.

Deprecation schedule for major engine versions of Microsoft SQL Server on Amazon RDS

The following table displays the planned schedule of deprecations for major engine versions of Microsoft SQL Server.

Date	Information
July 9, 2024	Microsoft will stop critical patch updates for SQL Server 2014. For more informatio Server 2014 in the Microsoft documentation.
June 1, 2024	Amazon RDS plans to end support of Microsoft SQL Server 2014 on RDS for SQL Se remaining instances will be scheduled to migrate to SQL Server 2016 (latest minor more information, see Announcement: Amazon RDS for SQL Server ending suppor major versions. To avoid an automatic upgrade from Microsoft SQL Server 2014, you can upgrade a ient to you. For more information, see Upgrading a DB instance engine version.
July 12, 2022	Microsoft will stop critical patch updates for SQL Server 2012. For more informatio Server 2012 in the Microsoft documentation.

Date	Information
June 1, 2022	Amazon RDS plans to end support of Microsoft SQL Server 2012 on RDS for SQL Se remaining instances will be scheduled to migrate to SQL Server 2014 (latest minor more information, see Announcement: Amazon RDS for SQL Server ending support major versions. To avoid an automatic upgrade from Microsoft SQL Server 2012, you can upgrade a convenient to you. For more information, see Upgrading a DB instance engine versi
September 1, 2021	Amazon RDS is starting to disable the creation of new RDS for SQL Server DB instar SQL Server 2012. For more information, see Announcement: Amazon RDS for SQL S for SQL Server 2012 major versions.
July 12, 2019	The Amazon RDS team deprecated support for Microsoft SQL Server 2008 R2 in Ju instances of Microsoft SQL Server 2008 R2 are migrating to SQL Server 2012 (lates available). To avoid an automatic upgrade from Microsoft SQL Server 2008 R2, you can upgrad convenient to you. For more information, see Upgrading a DB instance engine versi
April 25, 2019	Before the end of April 2019, you will no longer be able to create new Amazon RDS database instances using Microsoft SQL Server 2008R2.

Microsoft SQL Server features on Amazon RDS

The supported SQL Server versions on Amazon RDS include the following features. In general, a version also includes features from the previous versions, unless otherwise noted in the Microsoft documentation.

Topics

- Microsoft SQL Server 2022 features
- Microsoft SQL Server 2019 features
- Microsoft SQL Server 2017 features
- Microsoft SQL Server 2016 features
- Microsoft SQL Server 2014 end of support on Amazon RDS

- Microsoft SQL Server 2012 end of support on Amazon RDS
- Microsoft SQL Server 2008 R2 end of support on Amazon RDS

Microsoft SQL Server 2022 features

SQL Server 2022 includes many new features, such as the following:

- Parameter Sensitive Plan Optimization – allows multiple cached plans for a single parameterized statement, potentially reducing issues with parameter sniffing.
- SQL Server Ledger – provides the ability to cryptographically prove that your data hasn't been altered without authorization.
- Instant file initialization for transaction log file growth events – results in faster execution of log growth events up to 64MB, including for databases with TDE enabled.
- System page latch concurrency enhancements – reduces page latch contention while allocating and deallocating data pages and extents, providing significant performance enhancements to `tempdb` heavy workloads.

For the full list of SQL Server 2022 features, see What's new in SQL Server 2022 (16.x) in the Microsoft documentation.

For a list of unsupported features, see Features not supported and features with limited support.

Microsoft SQL Server 2019 features

SQL Server 2019 includes many new features, such as the following:

- Accelerated database recovery (ADR) – Reduces crash recovery time after a restart or a long-running transaction rollback.
- Intelligent Query Processing (IQP):
  - Row mode memory grant feedback – Corrects excessive grants automatically, that would otherwise result in wasted memory and reduced concurrency.
  - Batch mode on rowstore – Enables batch mode execution for analytic workloads without requiring columnstore indexes.
  - Table variable deferred compilation – Improves plan quality and overall performance for queries that reference table variables.
- Intelligent performance:

  - `OPTIMIZE_FOR_SEQUENTIAL_KEY` index option – Improves throughput for high-concurrency inserts into indexes.
  - Improved indirect checkpoint scalability – Helps databases with heavy DML workloads.
  - Concurrent Page Free Space (PFS) updates – Enables handling as a shared latch rather than an exclusive latch.
- Monitoring improvements:
  - `WAIT_ON_SYNC_STATISTICS_REFRESH` wait type – Shows accumulated instance-level time spent on synchronous statistics refresh operations.
  - Database-scoped configurations – Include `LIGHTWEIGHT_QUERY_PROFILING` and `LAST_QUERY_PLAN_STATS`.
  - Dynamic management functions (DMFs) – Include `sys.dm_exec_query_plan_stats` and `sys.dm_db_page_info`.
- Verbose truncation warnings – The data truncation error message defaults to include table and column names and the truncated value.
- Resumable online index creation – In SQL Server 2017, only resumable online index rebuild is supported.

For the full list of SQL Server 2019 features, see What's new in SQL Server 2019 (15.x) in the Microsoft documentation.

For a list of unsupported features, see Features not supported and features with limited support.

Microsoft SQL Server 2017 features

SQL Server 2017 includes many new features, such as the following:

- Adaptive query processing
- Automatic plan correction (an automatic tuning feature)
- GraphDB
- Resumable index rebuilds

For the full list of SQL Server 2017 features, see What's new in SQL Server 2017 in the Microsoft documentation.

For a list of unsupported features, see Features not supported and features with limited support.

Microsoft SQL Server 2016 features

Amazon RDS supports the following features of SQL Server 2016:

- Always Encrypted
- JSON Support
- Operational Analytics
- Query Store
- Temporal Tables

For the full list of SQL Server 2016 features, see What's new in SQL Server 2016 in the Microsoft documentation.

Microsoft SQL Server 2014 end of support on Amazon RDS

SQL Server 2014 has reached its end of support on Amazon RDS.

RDS is upgrading all existing DB instances that are still using SQL Server 2014 to the latest minor version of SQL Server 2016. For more information, see Version management in Amazon RDS.

Microsoft SQL Server 2012 end of support on Amazon RDS

SQL Server 2012 has reached its end of support on Amazon RDS.

RDS is upgrading all existing DB instances that are still using SQL Server 2012 to the latest minor version of SQL Server 2016. For more information, see Version management in Amazon RDS.

Microsoft SQL Server 2008 R2 end of support on Amazon RDS

SQL Server 2008 R2 has reached its end of support on Amazon RDS.

RDS is upgrading all existing DB instances that are still using SQL Server 2008 R2 to the latest minor version of SQL Server 2012. For more information, see Version management in Amazon RDS.

Change data capture support for Microsoft SQL Server DB instances

Amazon RDS supports change data capture (CDC) for your DB instances running Microsoft SQL Server. CDC captures changes that are made to the data in your tables, and stores metadata about

each change that you can access later. For more information, see Change data capture in the Microsoft documentation.

Amazon RDS supports CDC for the following SQL Server editions and versions:

- Microsoft SQL Server Enterprise Edition (All versions)
- Microsoft SQL Server Standard Edition:
  - 2022
  - 2019
  - 2017
  - 2016 version 13.00.4422.0 SP1 CU2 and later

To use CDC with your Amazon RDS DB instances, first enable or disable CDC at the database level by using RDS-provided stored procedures. After that, any user that has the `db_owner` role for that database can use the native Microsoft stored procedures to control CDC on that database. For more information, see Using change data capture.

You can use CDC and AWS Database Migration Service to enable ongoing replication from SQL Server DB instances.

Features not supported and features with limited support

The following Microsoft SQL Server features aren't supported on Amazon RDS:

- Backing up to Microsoft Azure Blob Storage
- Buffer pool extension
- Custom password policies
- Data Quality Services
- Database Log Shipping
- Database snapshots (Amazon RDS supports only DB instance snapshots)
- Extended stored procedures, including xp_cmdshell
- FILESTREAM support
- File tables
- Machine Learning and R Services (requires OS access to install it)

- Maintenance plans
- Performance Data Collector
- Policy-Based Management
- PolyBase
- Replication
- Resource Governor
- Server-level triggers
- Service Broker endpoints
- Stretch database
- TRUSTWORTHY database property (requires sysadmin role)
- T-SQL endpoints (all operations using CREATE ENDPOINT are unavailable)
- WCF Data Services

The following Microsoft SQL Server features have limited support on Amazon RDS:

- Distributed queries/linked servers. For more information, see Implement linked servers with Amazon RDS for Microsoft SQL Server.
- Common Runtime Language (CLR). On RDS for SQL Server 2016 and lower versions, CLR is supported in SAFE mode and using assembly bits only. CLR isn't supported on RDS for SQL Server 2017 and higher versions. For more information, see Common Runtime Language Integration in the Microsoft documentation.
- Link servers with Oracle OLEDB in Amazon RDS for SQL Server. For more information, see Support for Linked Servers with Oracle OLEDB in Amazon RDS for SQL Server.

The following features aren't supported on Amazon RDS with SQL Server 2022:

- Suspend database for snapshot
- External Data Source
- Backup and restore to S3 compatible object storage
- Object store integration
- TLS 1.3 and MS-TDS 8.0
- Backup compression offloading with QAT
- SQL Server Analysis Services (SSAS)

- Database mirroring with Multi-AZ deployments. SQL Server Always On is the only supported method with Multi-AZ deployments.

Multi-AZ deployments using Microsoft SQL Server Database Mirroring or Always On availability groups

Amazon RDS supports Multi-AZ deployments for DB instances running Microsoft SQL Server by using SQL Server Database Mirroring (DBM) or Always On Availability Groups (AGs). Multi-AZ deployments provide increased availability, data durability, and fault tolerance for DB instances. In the event of planned database maintenance or unplanned service disruption, Amazon RDS automatically fails over to the up-to-date secondary replica so database operations can resume quickly without manual intervention. The primary and secondary instances use the same endpoint, whose physical network address transitions to the passive secondary replica as part of the failover process. You don't have to reconfigure your application when a failover occurs.

Amazon RDS manages failover by actively monitoring your Multi-AZ deployment and initiating a failover when a problem with your primary occurs. Failover doesn't occur unless the standby and primary are fully in sync. Amazon RDS actively maintains your Multi-AZ deployment by automatically repairing unhealthy DB instances and re-establishing synchronous replication. You don't have to manage anything. Amazon RDS handles the primary, the witness, and the standby instance for you. When you set up SQL Server Multi-AZ, RDS configures passive secondary instances for all of the databases on the instance.

For more information, see Multi-AZ deployments for Amazon RDS for Microsoft SQL Server.

Using Transparent Data Encryption to encrypt data at rest

Amazon RDS supports Microsoft SQL Server Transparent Data Encryption (TDE), which transparently encrypts stored data. Amazon RDS uses option groups to enable and configure these features. For more information about the TDE option, see Support for Transparent Data Encryption in SQL Server.

Functions and stored procedures for Amazon RDS for Microsoft SQL Server

Following, you can find a list of the Amazon RDS functions and stored procedures that help automate SQL Server tasks.

Task type	Procedure or function	Where it's used
Administrative tasks	`rds_drop_database`	Dropping a Microsoft SQL Server database
	`rds_failover_time`	Determining the last failover time
	`rds_manage_view_db_permission`	Deny or allow viewing database names
	`rds_modify_db_name`	Renaming a Microsoft SQL Server database in a Multi-AZ deployment
	`rds_read_error_log`	Viewing error and agent logs
	`rds_set_configuration`	This operation is used to set various DB instance configurations: • Change data capture for Multi-AZ instances • Setting the retention period for trace and dump files • Compressing backup files

Task type	Procedure or function	Where it's used
	`rds_set_database_online`	Transitioning a Microsoft SQL Server database from OFFLINE to ONLINE

	`rds_set_system_database_sync_objects`
	
	`rds_fn_get_system_database_sync_objects`
	
	`rds_fn_server_object_last_sync_time`
		Turning on SQL Server Agent job replication

	`rds_show_configuration`	To see the values that are set using `rds_set_configuration`, see these topics: • Change data capture for Multi-AZ instances • Setting the retention period for trace and dump files
	`rds_shrink_tempdbfile`	Shrinking the tempdb database
Change data capture (CDC)	`rds_cdc_disable_db`	Disabling CDC

Task type	Procedure or function	Where it's used
	`rds_cdc_enable_db`	Enabling CDC
Database Mail	`rds_fn_sysmail_allitems`	Viewing messages, logs, and attachments
	`rds_fn_sysmail_event_log`	Viewing messages, logs, and attachments
	`rds_fn_sysmail_mailattachments`	Viewing messages, logs, and attachments
	`rds_sysmail_control`	This operation is used in starting and stopping the mail queue: • Starting the mail queue • Stopping the mail queue
	`rds_sysmail_delete_mailitems_sp`	Deleting messages
Native backup and restore	`rds_backup_database`	Backing up a database
	`rds_cancel_task`	Canceling a task

Task type	Procedure or function	Where it's used
	`rds_finish_restore`	Finishing a database restore
	`rds_restore_database`	Restoring a database
	`rds_restore_log`	Restoring a log
Amazon S3 file transfer	`rds_delete_from_filesystem`	Deleting files on the RDS DB instance
	`rds_download_from_s3`	Downloading files from an Amazon S3 bucket to a SQL Server DB instance
	`rds_gather_file_details`	Listing files on the RDS DB instance
	`rds_upload_to_s3`	Uploading files from a SQL Server DB instance to an Amazon S3 bucket
Microsoft Distributed Transaction Coordinator (MSDTC)	`rds_msdtc_transaction_tracing`	Using transaction tracing
SQL Server Audit	`rds_fn_get_audit_file`	Viewing audit logs

Task type	Procedure or function	Where it's used

Transparent Data Encryption	`rds_backup_tde_certificate`
	
	`rds_drop_tde_certificate`
	
	`rds_restore_tde_certificate`
	
	`rds_fn_list_user_tde_certificates`
		Support for Transparent Data Encryption in SQL Server

Task type	Procedure or function	Where it's used
Microsoft Business Intelligence (MSBI)	`rds_msbi_task`	This operation is used with SQL Server Analysis Services (SSAS): • Deploying SSAS projects on Amazon RDS • Adding a domain user as a database administrator • Backing up an SSAS database • Restoring an SSAS database This operation is also used with SQL Server Integration Services (SSIS): • Administrative permissions on SSISDB • Deploying an SSIS project This operation is also used with SQL Server Reporting Services (SSRS): • Granting access to domain users • Revoking system-level permissions
	`rds_fn_task_status`	This operation shows the status of MSBI tasks: • SSAS: Monitoring the status of a deployment task • SSIS: Monitoring the status of a deployment task • SSRS: Monitoring the status of a task
SSIS	`rds_drop_ssis_database`	Dropping the SSISDB database
	`rds_sqlagent_proxy`	Creating an SSIS proxy

Task type	Procedure or function	Where it's used
SSRS	`rds_drop_ssrs_databases`	Deleting the SSRS databases

Local time zone for Microsoft SQL Server DB instances

The time zone of an Amazon RDS DB instance running Microsoft SQL Server is set by default. The current default is Coordinated Universal Time (UTC). You can set the time zone of your DB instance to a local time zone instead, to match the time zone of your applications.

You set the time zone when you first create your DB instance. You can create your DB instance by using the AWS Management Console, the Amazon RDS API CreateDBInstance action, or the AWS CLI create-db-instance command.

If your DB instance is part of a Multi-AZ deployment (using SQL Server DBM or AGs), then when you fail over, your time zone remains the local time zone that you set. For more information, see Multi-AZ deployments using Microsoft SQL Server Database Mirroring or Always On availability groups.

When you request a point-in-time restore, you specify the time to restore to. The time is shown in your local time zone. For more information, see Restoring a DB instance to a specified time.

The following are limitations to setting the local time zone on your DB instance:

- You can't modify the time zone of an existing SQL Server DB instance.
- You can't restore a snapshot from a DB instance in one time zone to a DB instance in a different time zone.
- We strongly recommend that you don't restore a backup file from one time zone to a different time zone. If you restore a backup file from one time zone to a different time zone, you must audit your queries and applications for the effects of the time zone change. For more information, see Importing and exporting SQL Server databases using native backup and restore.

Supported time zones

You can set your local time zone to one of the values listed in the following table.

Time zone	Standard time offset	Description	Notes
Afghanistan Standard Time	(UTC+04:30)	Kabul	This time zone doesn't observe daylight saving time.
Alaskan Standard Time	(UTC–09:00)	Alaska	
Aleutian Standard Time	(UTC–10:00)	Aleutian Islands	
Altai Standard Time	(UTC+07:00)	Barnaul, Gorno-Altaysk	
Arab Standard Time	(UTC+03:00)	Kuwait, Riyadh	This time zone doesn't observe daylight saving time.
Arabian Standard Time	(UTC+04:00)	Abu Dhabi, Muscat	
Arabic Standard Time	(UTC+03:00)	Baghdad	This time zone doesn't observe daylight saving time.
Argentina Standard Time	(UTC–03:00)	City of Buenos Aires	This time zone doesn't observe daylight saving time.

Licensing Microsoft SQL Server on Amazon RDS

When you set up an Amazon RDS DB instance for Microsoft SQL Server, the software license is included.

This means that you don't need to purchase SQL Server licenses separately. AWS holds the license for the SQL Server database software. Amazon RDS pricing includes the software license, underlying hardware resources, and Amazon RDS management capabilities.

Amazon RDS supports the following Microsoft SQL Server editions:

- Enterprise
- Standard
- Web
- Express

> **Note**
>
> Licensing for SQL Server Web Edition supports only public and internet-accessible webpages, websites, web applications, and web services. This level of support is required for compliance with Microsoft's usage rights. For more information, see AWS service terms.

Amazon RDS supports Multi-AZ deployments for DB instances running Microsoft SQL Server by using SQL Server Database Mirroring (DBM) or Always On Availability Groups (AGs). There are no additional licensing requirements for Multi-AZ deployments. For more information, see Multi-AZ deployments for Amazon RDS for Microsoft SQL Server.

Restoring license-terminated DB instances

Amazon RDS takes snapshots of license-terminated DB instances. If your instance is terminated for licensing issues, you can restore it from the snapshot to a new DB instance. New DB instances have a license included.

For more information, see Restoring license-terminated DB instances.

Development and test

Because of licensing requirements, we can't offer SQL Server Developer Edition on Amazon RDS. You can use Express Edition for many development, testing, and other nonproduction needs. However, if you need the full feature capabilities of an enterprise-level installation of SQL Server for development, you can download and install SQL Server Developer Edition on RDS Custom for SQL Server using a CEV with BYOM. For more information, see Preparing a CEV using Bring Your Own Media (BYOM). Dedicated infrastructure isn't required for Developer Edition. By using your own host, you also gain access to other programmability features that are not accessible on Amazon RDS. For more information on the difference between SQL Server editions, see Editions and supported features of SQL Server 2019 in the Microsoft documentation.

Connecting to a DB instance running the Microsoft SQL Server database engine

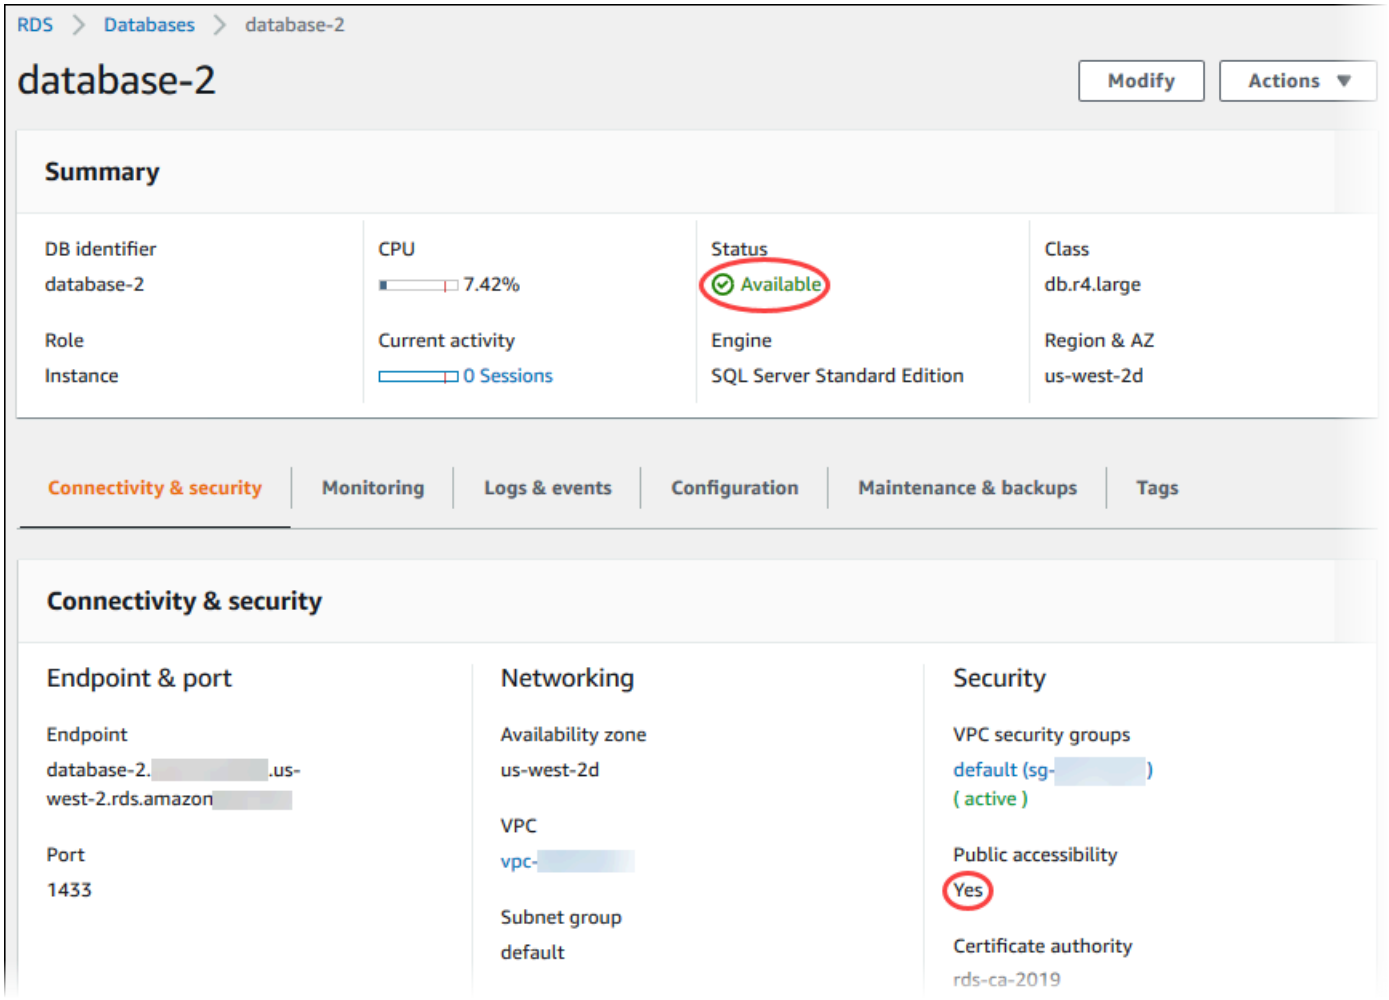
After Amazon RDS provisions your DB instance, you can use any standard SQL client application to connect to the DB instance. In this topic, you connect to your DB instance by using either Microsoft SQL Server Management Studio (SSMS) or SQL Workbench/J.

For an example that walks you through the process of creating and connecting to a sample DB instance, see Creating and connecting to a Microsoft SQL Server DB instance.

Before you connect

Before you can connect to your DB instance, it has to be available and accessible.

1. Make sure that its status is `available`. You can check this on the details page for your instance in the AWS Management Console or by using the describe-db-instances AWS CLI command.



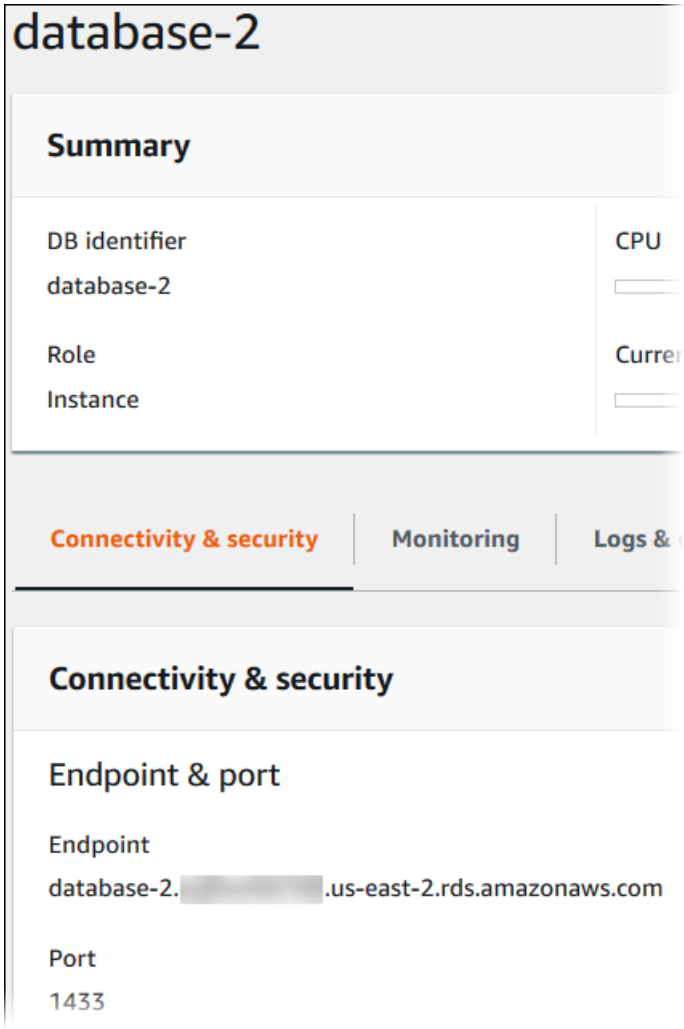
2. Make sure that it is accessible to your source. Depending on your scenario, it may not need to be publicly accessible. For more information, see Amazon VPC and Amazon RDS.
3. Make sure that the inbound rules of your VPC security group allow access to your DB instance. For more information, see Can't connect to Amazon RDS DB instance.

Finding the DB instance endpoint and port number

You need both the endpoint and the port number to connect to the DB instance.

To find the endpoint and port

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the upper-right corner of the Amazon RDS console, choose the AWS Region of your DB instance.
3. Find the Domain Name System (DNS) name (endpoint) and port number for your DB instance:
    a. Open the RDS console and choose **Databases** to display a list of your DB instances.
    b. Choose the SQL Server DB instance name to display its details.
    c. On the **Connectivity & security** tab, copy the endpoint.



d. Note the port number.

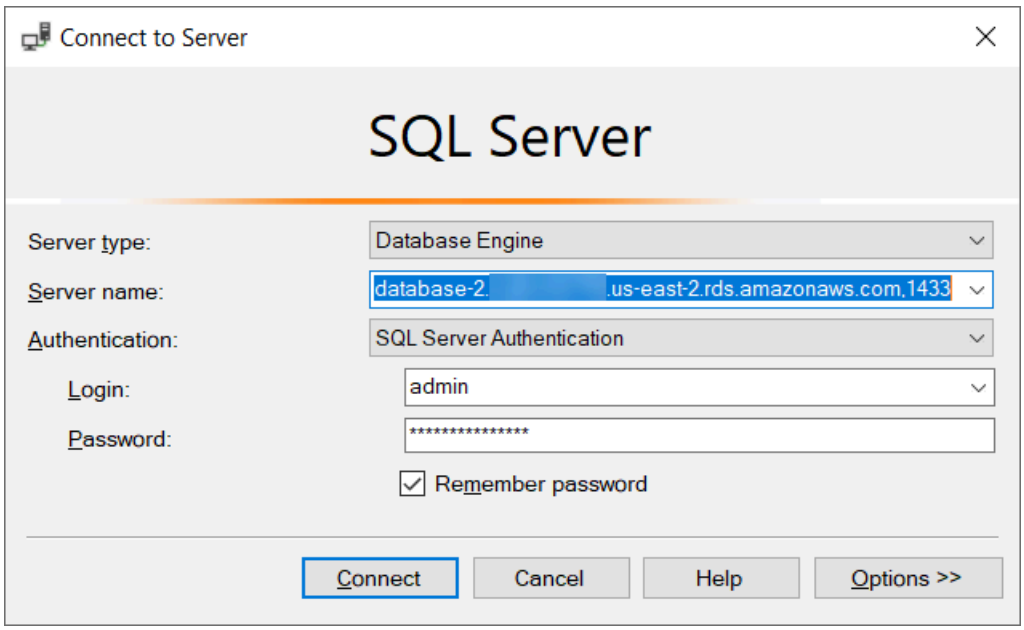
Connecting to your DB instance with Microsoft SQL Server Management Studio

In this procedure, you connect to your sample DB instance by using Microsoft SQL Server Management Studio (SSMS). To download a standalone version of this utility, see Download SQL Server Management Studio (SSMS) in the Microsoft documentation.

To connect to a DB instance using SSMS

1. Start SQL Server Management Studio.

   The **Connect to Server** dialog box appears.



2. Provide the information for your DB instance:

   a. For **Server type**, choose **Database Engine**.

   b. For **Server name**, enter the DNS name (endpoint) and port number of your DB instance, separated by a comma.

   > **Important**
   >
   > Change the colon between the endpoint and port number to a comma.

   Your server name should look like the following example.

   ```
   database-2.cg034itsfake.us-east-1.rds.amazonaws.com,1433
   ```

   c. For **Authentication**, choose **SQL Server Authentication**.

   d. For **Login**, enter the master user name for your DB instance.

   e. For **Password**, enter the password for your DB instance.

3. Choose **Connect**.

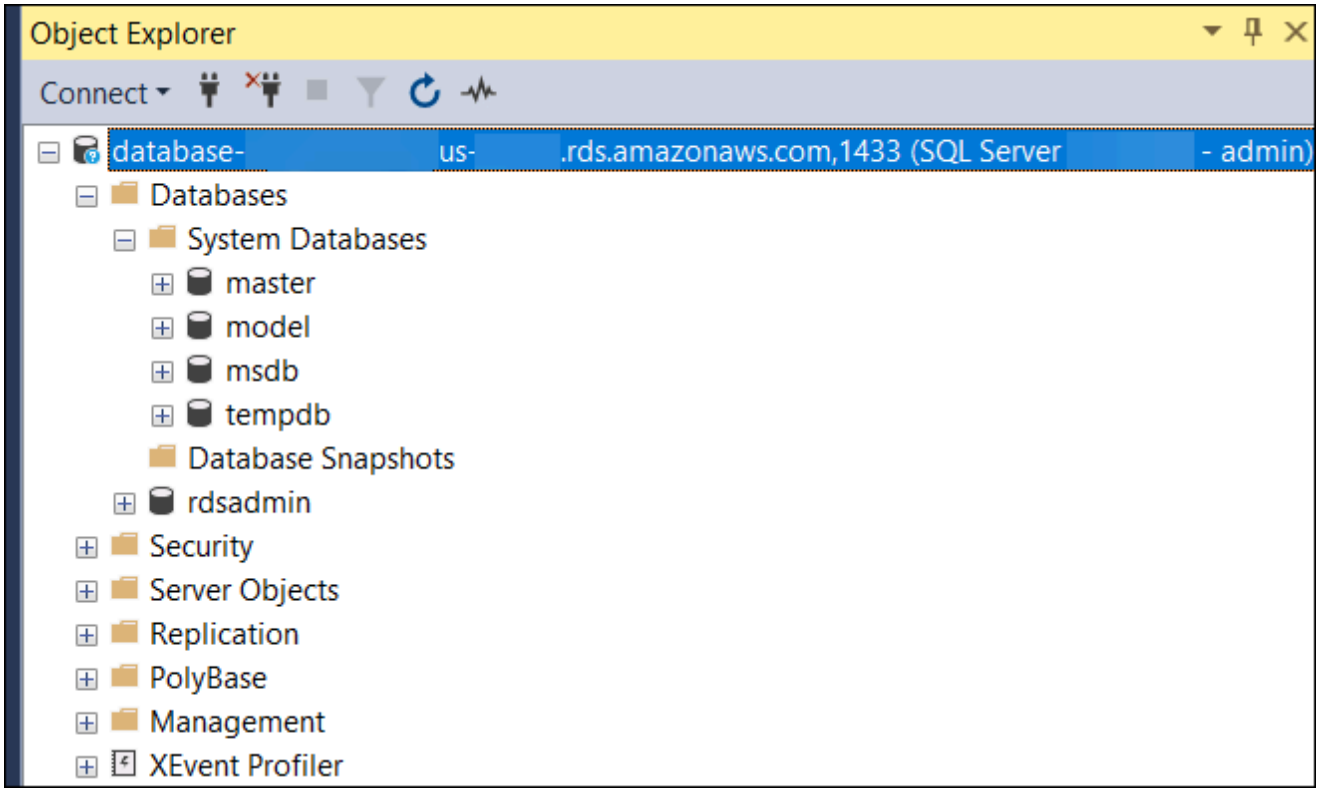
   After a few moments, SSMS connects to your DB instance.

   If you can't connect to your DB instance, see Security group considerations and Troubleshooting connections to your SQL Server DB instance.

4. Your SQL Server DB instance comes with SQL Server's standard built-in system databases (`master`, `model`, `msdb`, and `tempdb`). To explore the system databases, do the following:

   a. In SSMS, on the **View** menu, choose **Object Explorer**.

   b. Expand your DB instance, expand **Databases**, and then expand **System Databases**.



5. Your SQL Server DB instance also comes with a database named `rdsadmin`. Amazon RDS uses this database to store the objects that it uses to manage your database. The `rdsadmin` database also includes stored procedures that you can run to perform advanced tasks. For more information, see Common DBA tasks for Microsoft SQL Server.

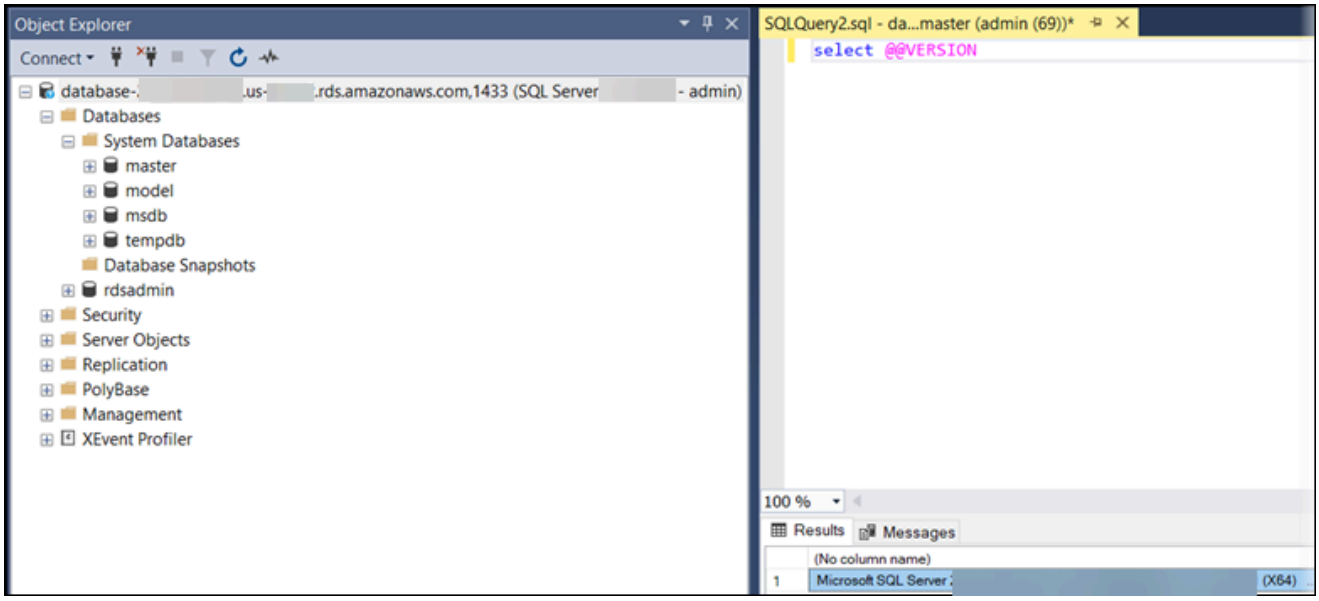
6. You can now start creating your own databases and running queries against your DB instance and databases as usual. To run a test query against your DB instance, do the following:

   a. In SSMS, on the **File** menu point to **New** and then choose **Query with Current Connection**.

   b. Enter the following SQL query.

```
select @@VERSION
```

   c. Run the query. SSMS returns the SQL Server version of your Amazon RDS DB instance.



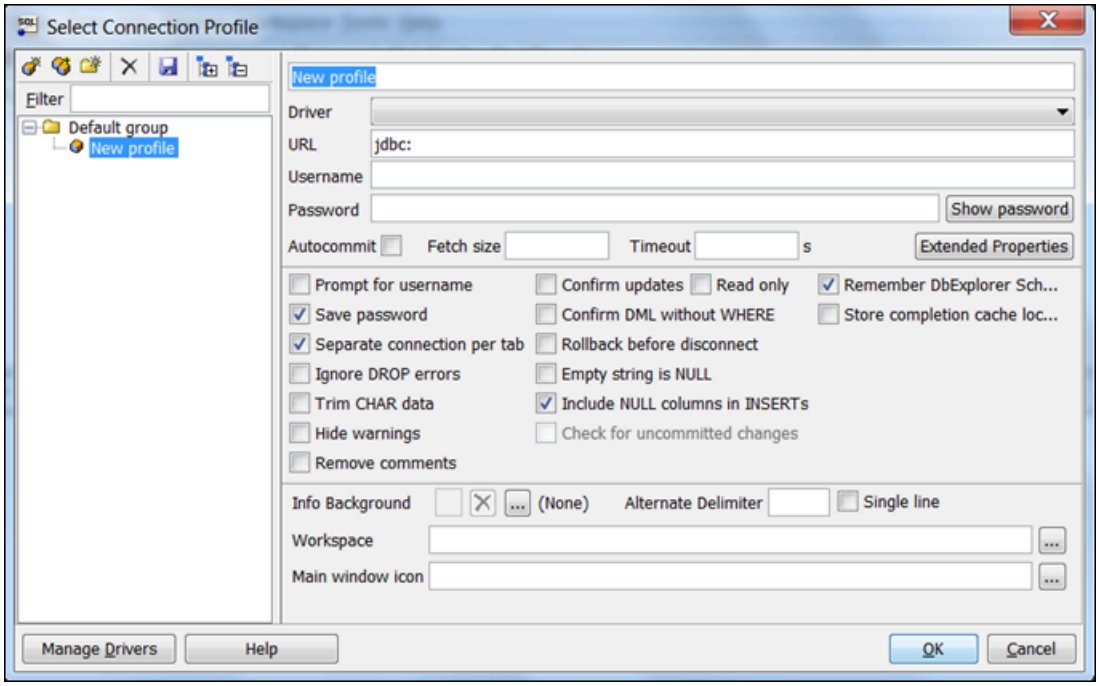
Connecting to your DB instance with SQL Workbench/J

This example shows how to connect to a DB instance running the Microsoft SQL Server database engine by using the SQL Workbench/J database tool. To download SQL Workbench/J, see SQL Workbench/J.

SQL Workbench/J uses JDBC to connect to your DB instance. You also need the JDBC driver for SQL Server. To download this driver, see Microsoft JDBC Driver 6.0 for SQL Server.

To connect to a DB instance using SQL Workbench/J

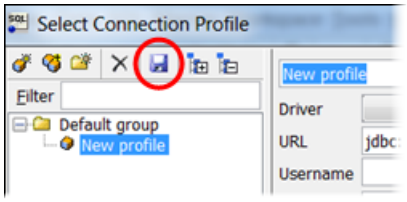
1. Open SQL Workbench/J. The **Select Connection Profile** dialog box appears, as shown following.



2. In the first box at the top of the dialog box, enter a name for the profile.
3. For **Driver**, choose **`SQL JDBC 4.0`**.
4. For **URL**, enter **`jdbc:sqlserver://`**, then enter the endpoint of your DB instance. For example, the URL value might be the following.

```
jdbc:sqlserver://sqlsvr-pdz.abcd12340.us-west-2.rds.amazonaws.com:1433
```

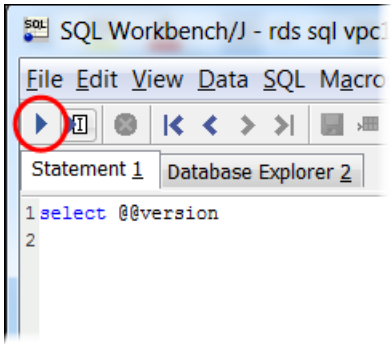
5. For **Username**, enter the master user name for the DB instance.
6. For **Password**, enter the password for the master user.
7. Choose the save icon in the dialog toolbar, as shown following.



8. Choose **OK**. After a few moments, SQL Workbench/J connects to your DB instance. If you can't connect to your DB instance, see Security group considerations and Troubleshooting connections to your SQL Server DB instance.
9. In the query pane, enter the following SQL query.

```
select @@VERSION
```

10. Choose the `Execute` icon in the toolbar, as shown following.



The query returns the version information for your DB instance, similar to the following.

```
Microsoft SQL Server 2017 (RTM-CU22) (KB4577467) - 14.0.3356.20 (X64)
```

Security group considerations

To connect to your DB instance, your DB instance must be associated with a security group. This security group contains the IP addresses and network configuration that you use to access the DB instance. You might have associated your DB instance with an appropriate security group when you created your DB instance. If you assigned a default, no-configured security group when you created your DB instance, your DB instance firewall prevents connections.

In some cases, you might need to create a new security group to make access possible. For instructions on creating a new security group, see Controlling access with security groups. For a topic that walks you through the process of setting up rules for your VPC security group, see Tutorial: Create a VPC for use with a DB instance (IPv4 only).

After you have created the new security group, modify your DB instance to associate it with the security group. For more information, see Modifying an Amazon RDS DB instance.

You can enhance security by using SSL to encrypt connections to your DB instance. For more information, see Using SSL with a Microsoft SQL Server DB instance.

Troubleshooting connections to your SQL Server DB instance

The following table shows error messages that you might encounter when you attempt to connect to your SQL Server DB instance.

Issue	Troubleshooting suggestions
Could not open a connection to SQL Server – Microsoft SQL Server, Error: 53	Make sure that you specified the server name correctly. For **Server name**, enter the DNS name and port number of your sample DB instance, separated by a comma. **Important** If you have a colon between the DNS name and port number, change the colon to a comma. Your server name should look like the following example. `sample-instance.cg034itsfake.us-east-1.rds.amazonaws.com,1433`
No connection could be made because the target machine actively refused it – Microsoft SQL Server, Error: 10061	You were able to reach the DB instance but the connection was refused. This issue is usually caused by specifying the user name or password incorrectly. Verify the user name and password, then retry.
A network-related or instance-specific error occurred while establishing a connection to SQL Server. The server was not found or was not accessible... The wait operation timed out – Microsoft SQL Server, Error: 258	The access rules enforced by your local firewall and the IP addresses authorized to access your DB instance might not match. The problem is most likely the inbound rules in your security group. For more information, see Security in Amazon RDS. Your database instance must be publicly accessible. To connect to it from outside of the VPC, the instance must have a public IP address assigned.

Note

For more information on connection issues, see Can't connect to Amazon RDS DB instance.

Working with Active Directory with RDS for SQL Server

You can join an RDS for SQL Server DB instance to a Microsoft Active Directory (AD) domain. Your AD domain can be hosted on AWS Managed AD within AWS, or on a Self Managed AD in a location of your choice, including your corporate data centers, on AWS EC2, or with other cloud providers.

You can authenticate domain users using NTLM authentication with Self Managed Active Directory. You can use Kerberos and NTLM authentication with AWS Managed Active Directory.

In the following sections, you can find information about working with Self Managed Active Directory and AWS Managed Active Directory for Microsoft SQL Server on Amazon RDS.

Topics

Working with Self Managed Active Directory with an Amazon RDS for SQL Server DB instance

You can join your RDS for SQL Server DB instances directly to your self-managed Active Directory (AD) domain, regardless of where your AD is hosted: in corporate data centers, on AWS EC2, or with other cloud providers. With self-managed AD, you use NTLM authentication to directly control authentication of users and services on your RDS for SQL Server DB instances without using intermediary domains and forest trusts. When users authenticate with an RDS for SQL Server DB instance joined to your self-managed AD domain, authentication requests are forwarded to a self-managed AD domain that you specify.

Topics

Region and version availability

Amazon RDS supports Self Managed AD for SQL Server using NTLM in all AWS Regions.

Requirements

Make sure you've met the following requirements before joining an RDS for SQL Server DB instance to your self-managed AD domain.

Topics

- Configure your AD domain service account

Configure your on-premises AD

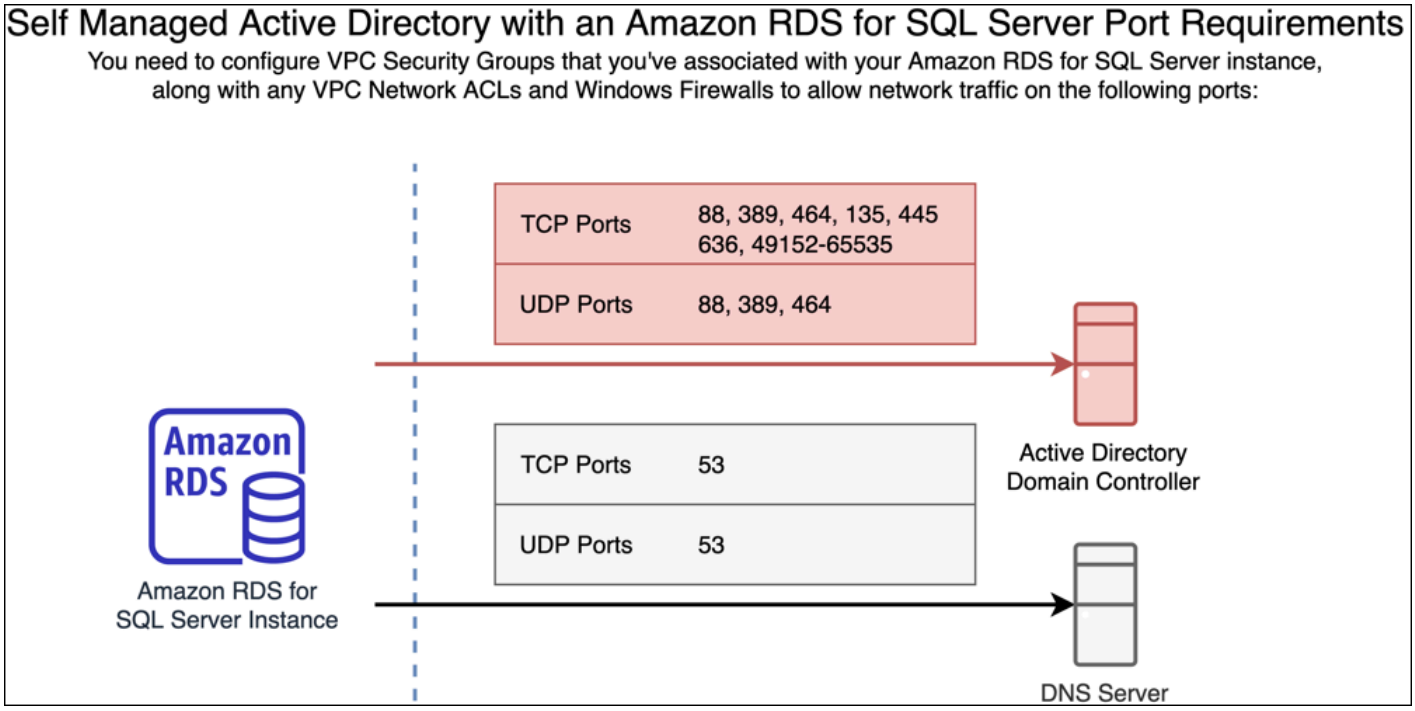
Make sure that you have an on-premises or other self-managed Microsoft AD that you can join the Amazon RDS for SQL Server instance to. Your on-premises AD should have the following configuration:

- If you have Active Directory sites defined, make sure the subnets in the VPC associated with your RDS for SQL Server DB instance are defined in your Active Directory site. Confirm there aren't any conflicts between the subnets in your VPC and the subnets in your other AD sites.
- Your AD domain controller has a domain functional level of Windows Server 2008 R2 or higher.
- Your AD domain name can't be in Single Label Domain (SLD) format. RDS for SQL Server does not support SLD domains.
- The fully qualified domain name (FQDN) for your AD can't exceed 47 characters.

Configure your network connectivity

Make sure that you have met the following network configurations:

- Connectivity configured between the Amazon VPC where you want to create the RDS for SQL Server DB instance and your self-managed Active Directory. You can set up connectivity using AWS Direct Connect, AWS VPN, VPC peering, or AWS Transit Gateway.
- For VPC security groups, the default security group for your default Amazon VPC is already added to your RDS for SQL Server DB instance in the console. Ensure that the security group and the VPC network ACLs for the subnet(s) where you're creating your RDS for SQL Server DB instance allow traffic on the ports and in the directions shown in the following diagram.



The following table identifies the role of each port.

Protocol	Ports	Role
TCP/UDP	53	Domain Name System (DNS)
TCP/UDP	88	Kerberos authentication
TCP/UDP	464	Change/Set password
TCP/UDP	389	Lightweight Directory Access Protocol (LDAP)
TCP	135	Distributed Computing Environment / End Point Mapper (DCE / EPMAP)
TCP	445	Directory Services SMB file sharing

Protocol	Ports	Role
TCP	636	Lightweight Directory Access Protocol over TLS/SSL (LDAPS)
TCP	49152 - 65535	Ephemeral ports for RPC

- Generally, the domain DNS servers are located in the AD domain controllers. You do not need to configure the VPC DHCP option set to use this feature. For more information, see DHCP option sets in the *Amazon VPC User Guide*.

> **Important**
>
> If you're using VPC network ACLs, you must also allow outbound traffic on dynamic ports (49152-65535) from your RDS for SQL Server DB instance. Ensure that these traffic rules are also mirrored on the firewalls that apply to each of the AD domain controllers, DNS servers, and RDS for SQL Server DB instances.
> While VPC security groups require ports to be opened only in the direction that network traffic is initiated, most Windows firewalls and VPC network ACLs require ports to be open in both directions.

Configure your AD domain service account

Make sure that you have met the following requirements for an AD domain service account:

- Make sure that you have a service account in your self-managed AD domain with delegated permissions to join computers to the domain. A domain service account is a user account in your self-managed AD that has been delegated permission to perform certain tasks.
- The domain service account needs to be delegated the following permissions in the Organizational Unit (OU) that you're joining your RDS for SQL Server DB instance to:
  - Validated ability to write to the DNS host name
  - Validated ability to write to the service principal name
  - Create and delete computer objects

These represent the minimum set of permissions that are required to join computer objects to your self-managed Active Directory. For more information, see Errors when attempting to join computers to a domain in the Microsoft Windows Server documentation.

> **Important**
>
> Do not move computer objects that RDS for SQL Server creates in the Organizational Unit after your DB instance is created. Moving the associated objects will cause your RDS for SQL Server DB instance to become misconfigured. If you need to move the computer objects created by Amazon RDS, use the ModifyDBInstance RDS API operation to modify the domain parameters with the desired location of the computer objects.

Limitations

The following limitations apply for Self Managed AD for SQL Server.

- NTLM is the only supported authentication type. Kerberos authentication is not supported. If you need to use kerberos authentication, you can use AWS Managed AD instead of self-managed AD.
- The Microsoft Distributed Transaction Coordinator (MSDTC) service isn't supported, as it requires Kerberos authentication.
- Your RDS for SQL Server DB instances do not use the Network Time Protocol (NTP) server of your self-managed AD domain. They use an AWS NTP service instead.
- SQL Server linked servers must use SQL authentication to connect to other RDS for SQL Server DB instances joined to your self-managed AD domain.
- Microsoft Group Policy Object (GPO) settings from your self-managed AD domain are not applied to RDS for SQL Server DB instances.

Overview of setting up Self Managed Active Directory

To set up self-managed AD for an RDS for SQL Server DB instance, take the following steps, explained in greater detail in Setting up Self Managed Active Directory:

In your AD domain:

- Create an Organizational Unit (OU).

- Create an AD domain user.
- Delegate control to the AD domain user.

From the AWS Management Console or API:

- Create a AWS KMS key.
- Create a secret using AWS Secrets Manager.
- Create or modify an RDS for SQL Server DB instance and join it to your self-managed AD domain.

Setting up Self Managed Active Directory

To set up Self Managed AD, take the following steps.

Topics

Step 1: Create an Organizational Unit in your AD

> **Important**
>
> We recommend creating a dedicated OU and service credential scoped to that OU for any AWS account that owns an RDS for SQL Server DB instance joined your self-managed AD domain. By dedicating an OU and service credential, you can avoid conflicting permissions and follow the principal of least privilege.

To create an OU in your AD

1. Connect to your AD domain as a domain administrator.

2. Open **Active Directory Users and Computers** and select the domain where you want to create your OU.
3. Right-click the domain and choose **New**, then **Organizational Unit**.
4. Enter a name for the OU.
5. Keep the box selected for **Protect container from accidental deletion**.
6. Click **OK**. Your new OU will appear under your domain.

Step 2: Create an AD domain user in your AD

The domain user credentials will be used for the secret in AWS Secrets Manager.

To create an AD domain user in your AD

1. Open **Active Directory Users and Computers** and select the domain and OU where you want to create your user.
2. Right-click the **Users** object and choose **New**, then **User**.
3. Enter a first name, last name, and logon name for the user. Click **Next**.
4. Enter a password for the user. Don't select **"User must change password at next login"**. Don't select **"Account is disabled"**. Click **Next**.
5. Click **OK**. Your new user will appear under your domain.

Step 3: Delegate control to the AD user

To delegate control to the AD domain user in your domain

1. Open **Active Directory Users and Computers** MMC snap-in and select the domain where you want to create your user.
2. Right-click the OU that you created earlier and choose **Delegate Control**.
3. On the **Delegation of Control Wizard**, click **Next**.
4. On the **Users or Groups** section, click **Add**.
5. On the **Select Users, Computers, or Groups** section, enter the AD user you created and click **Check Names**. If your AD user check is successful, click **OK**.
6. On the **Users or Groups** section, confirm your AD user was added and click **Next**.
7. On the **Tasks to Delegate** section, choose **Create a custom task to delegate** and click **Next**.
8. On the **Active Directory Object Type** section:

a. Choose **Only the following objects in the folder**.
b. Select **Computer Objects**.
c. Select **Create selected objects in this folder**.
d. Select **Delete selected objects in this folder** and click **Next**.

9. On the **Permissions** section:

a. Keep **General** selected.
b. Select **Validated write to DNS host name**.
c. Select **Validated write to service principal name** and click **Next**.

10. For **Completing the Delegation of Control Wizard**, review and confirm your settings and click **Finish**.

Step 4: Create an AWS KMS key

The KMS key is used to encrypt your AWS secret.

To create an AWS KMS key

> **Note**
>
> For **Encryption Key**, don't use the AWS default KMS key. Be sure to create the AWS KMS key in the same AWS account that contains the RDS for SQL Server DB instance that you want to join to your self-managed AD.

1. In the AWS KMS console, choose **Create key**.
2. For **Key Type**, choose **Symmetric**.
3. For **Key Usage**, choose **Encrypt and decrypt**.
4. For **Advanced options**:

a. For **Key material origin**, choose **KMS**.
b. For **Regionality**, choose **Single-Region key** and click **Next**.

5. For **Alias**, provide a name for the KMS key.
6. (Optional) For **Description**, provide a description of the KMS key.
7. (Optional) For **Tags**, provide a tag the KMS key and click **Next**.

8. For **Key administrators**, provide the name of an IAM user and select it.
9. For **Key deletion**, keep the box selected for **Allow key administrators to delete this key** and click **Next**.
10. For **Key users**, provide the same IAM user from the previous step and select it. Click **Next**.
11. Review the configuration.
12. For **Key policy**, include the following to the policy **Statement**:

```
{
    "Sid": "Allow use of the KMS key on behalf of RDS",
    "Effect": "Allow",
    "Principal": {
        "Service": [
            "rds.amazonaws.com"
        ]
    },
    "Action": "kms:Decrypt",
    "Resource": "*"
}
```

13. Click **Finish**.

Step 5: Create an AWS secret

To create a secret

> **Note**
>
> Be sure to create the secret in the same AWS account that contains the RDS for SQL Server DB instance that you want to join to your self-managed AD.

1. In AWS Secrets Manager, choose **Store a new secret**.
2. For **Secret type**, choose **Other type of secret**.
3. For **Key/value pairs**, add your two keys:
    a. For the first key, enter `CUSTOMER_MANAGED_ACTIVE_DIRECTORY_USERNAME`.
    b. For the value of the first key, enter the name of the AD user that you created on your domain in a previous step.

c. For the second key, enter `CUSTOMER_MANAGED_ACTIVE_DIRECTORY_PASSWORD`.

d. For the value of the second key, enter the password that you created for the AD user on your domain.

4. For **Encryption key**, enter the KMS key that you created in a previous step and click **Next**.
5. For **Secret name**, enter a descriptive name that helps you find your secret later.
6. (Optional) For **Description**, enter a description for the secret name.
7. For **Resource permission**, click **Edit**.
8. Add the following policy to the permission policy:

> **Note**
>
> We recommend that you use the `aws:sourceAccount` and `aws:sourceArn` conditions in the policy to avoid the *confused deputy* problem. Use your AWS account for `aws:sourceAccount` and the RDS for SQL Server DB instance ARN for `aws:sourceArn`. For more information, see Preventing cross-service confused deputy problems.

```
{
    "Version": "2012-10-17",
    "Statement":
    [
        {
            "Effect": "Allow",
            "Principal":
            {
                "Service": "rds.amazonaws.com"
            },
            "Action": "secretsmanager:GetSecretValue",
            "Resource": "*",
            "Condition":
            {
                "StringEquals":
                {
                    "aws:sourceAccount": "123456789012"
                },
                "ArnLike":
                {
```

```
                    "aws:sourceArn": "arn:aws:rds:us-west-2:123456789012:db:*"
                }
            }
        }
    ]
}
```

9. Click **Save** then click **Next**.
10. For **Configure rotation settings**, keep the default values and choose **Next**.
11. Review the settings for the secret and click **Store**.
12. Choose the secret you created and copy the value for the **Secret ARN**. This will be used in the next step to set up self-managed Active Directory.

Step 6: Create or modify a SQL Server DB instance

You can use the console, CLI, or RDS API to associate an RDS for SQL Server DB instance with a self-managed AD domain. You can do this in one of the following ways:

- Create a new SQL Server DB instance using the console, the create-db-instance CLI command, or the CreateDBInstance RDS API operation.

  For instructions, see Creating an Amazon RDS DB instance.
- Modify an existing SQL Server DB instance using the console, the modify-db-instance CLI command, or the ModifyDBInstance RDS API operation.

  For instructions, see Modifying an Amazon RDS DB instance.
- Restore a SQL Server DB instance from a DB snapshot using the console, the restore-db-instance-from-db-snapshot CLI command, or the RestoreDBInstanceFromDBSnapshot RDS API operation.

  For instructions, see Restoring to a DB instance.
- Restore a SQL Server DB instance to a point-in-time using the console, the restore-db-instance-to-point-in-time CLI command, or the RestoreDBInstanceToPointInTime RDS API operation.

  For instructions, see Restoring a DB instance to a specified time.

When you use the AWS CLI, the following parameters are required for the DB instance to be able to use the self-managed Active Directory domain that you created:

- For the `--domain-fqdn` parameter, use the fully qualified domain name (FQDN) of your self-managed Active Directory.
- For the `--domain-ou` parameter, use the OU that you created in your self-managed AD.
- For the `--domain-auth-secret-arn` parameter, use the value of the **Secret ARN** that you created in a previous step.
- For the `--domain-dns-ips` parameter, use the primary and secondary IPv4 addresses of the DNS servers for your self-managed AD. If you don't have a secondary DNS server IP address, enter the primary IP address twice.

The following example CLI commands show how to create, modify, and remove an RDS for SQL Server DB instance with a self-managed AD domain.

> **Important**
>
> If you modify a DB instance to join it to or remove it from a self-managed AD domain, a reboot of the DB instance is required for the modification to take effect. You can choose to apply the changes immediately or wait until the next maintenance window. Choosing the **Apply Immediately** option will cause downtime for a single-AZ DB instance. A multi-AZ DB instance will perform a failover before completing a reboot. For more information, see Schedule modifications setting.

The following CLI command creates a new RDS for SQL Server DB instance and joins it to a self-managed AD domain.

For Linux, macOS, or Unix:

```
aws rds create-db-instance \
    --db-instance-identifier my-DB-instance \
    --db-instance-class db.m5.xlarge \
    --allocated-storage 50 \
    --engine sqlserver-se \
    --engine-version 15.00.4043.16.v1 \
    --license-model license-included \
    --master-username my-master-username \
    --master-user-password my-master-password \
    --domain-fqdn my_AD_domain.my_AD.my_domain \
    --domain-ou OU=my-AD-test-OU,DC=my-AD-test,DC=my-AD,DC=my-domain \
```

```
    --domain-auth-secret-arn "arn:aws:secretsmanager:region:account-number:secret:my-
AD-test-secret-123456" \
    --domain-dns-ips "10.11.12.13" "10.11.12.14"
```

For Windows:

```
aws rds create-db-instance ^
    --db-instance-identifier my-DB-instance ^
    --db-instance-class db.m5.xlarge ^
    --allocated-storage 50 ^
    --engine sqlserver-se ^
    --engine-version 15.00.4043.16.v1 ^
    --license-model license-included ^
    --master-username my-master-username ^
    --master-user-password my-master-password ^
    --domain-fqdn my-AD-test.my-AD.mydomain ^
    --domain-ou OU=my-AD-test-OU,DC=my-AD-test,DC=my-AD,DC=my-domain ^
    --domain-auth-secret-arn "arn:aws:secretsmanager:region:account-number:secret:my-
AD-test-secret-123456" \ ^
    --domain-dns-ips "10.11.12.13" "10.11.12.14"
```

The following CLI command modifies an existing RDS for SQL Server DB instance to use a self-managed Active Directory domain.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier my-DB-instance \
    --domain-fqdn my_AD_domain.my_AD.my_domain \
    --domain-ou OU=my-AD-test-OU,DC=my-AD-test,DC=my-AD,DC=my-domain \
    --domain-auth-secret-arn "arn:aws:secretsmanager:region:account-number:secret:my-
AD-test-secret-123456" \
    --domain-dns-ips "10.11.12.13" "10.11.12.14"
```

For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier my-DBinstance ^
    --domain-fqdn my_AD_domain.my_AD.my_domain ^
    --domain-ou OU=my-AD-test-OU,DC=my-AD-test,DC=my-AD,DC=my-domain ^
    --domain-auth-secret-arn "arn:aws:secretsmanager:region:account-number:secret:my-
AD-test-secret-123456" ^
```

```
    --domain-dns-ips "10.11.12.13" "10.11.12.14"
```

The following CLI command removes an RDS for SQL Server DB instance from a self-managed Active Directory domain.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier my-DB-instance \
    --disable-domain
```

For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier my-DB-instance ^
    --disable-domain
```

Step 7: Create Windows Authentication SQL Server logins

Use the Amazon RDS master user credentials to connect to the SQL Server DB instance as you do for any other DB instance. Because the DB instance is joined to the self-managed AD domain, you can provision SQL Server logins and users. You do this from the AD users and groups utility in your self-managed AD domain. Database permissions are managed through standard SQL Server permissions granted and revoked to these Windows logins.

In order for a self-managed AD user to authenticate with SQL Server, a SQL Server Windows login must exist for the self-managed AD user or a self-managed Active Directory group that the user is a member of. Fine-grained access control is handled through granting and revoking permissions on these SQL Server logins. A self-managed AD user that doesn't have a SQL Server login or belong to a self-managed AD group with such a login can't access the SQL Server DB instance.

The ALTER ANY LOGIN permission is required to create a self-managed AD SQL Server login. If you haven't created any logins with this permission, connect as the DB instance's master user using SQL Server Authentication and create your self-managed AD SQL Server logins under the context of the master user.

You can run a data definition language (DDL) command such as the following to create a SQL Server login for an self-managed AD user or group.

> **Note**
>
> Specify users and groups using the pre-Windows 2000 login name in the format *my_AD_domain**my_AD_domain_user*. You can't use a user principal name (UPN) in the format *my_AD_domain_user*@*my_AD_domain*.

```
USE [master]
GO
CREATE LOGIN [my_AD_domain\my_AD_domain_user] FROM WINDOWS WITH DEFAULT_DATABASE =
 [master], DEFAULT_LANGUAGE = [us_english];
GO
```

For more information, see CREATE LOGIN (Transact-SQL) in the Microsoft Developer Network documentation.

Users (both humans and applications) from your domain can now connect to the RDS for SQL Server instance from a self-managed AD domain-joined client machine using Windows authentication.

Managing a DB instance in a self-managed Active Directory Domain

You can use the console, AWS CLI, or the Amazon RDS API to manage your DB instance and its relationship with your self-managed AD domain. For example, you can move the DB instance into, out of, or between domains.

For example, using the Amazon RDS API, you can do the following:

- To reattempt a self-managed domain join for a failed membership, use the ModifyDBInstance API operation and specify the same set of parameters:
  - `--domain-fqdn`
  - `--domain-dns-ips`
  - `--domain-ou`
  - `--domain-auth-secret-arn`
- To remove a DB instance from a self-managed domain, use the `ModifyDBInstance` API operation and specify `--disable-domain` for the domain parameter.
- To move a DB instance from one self-managed domain to another, use the `ModifyDBInstance` API operation and specify the domain parameters for the new domain:

- `--domain-fqdn`
- `--domain-dns-ips`
- `--domain-ou`
- `--domain-auth-secret-arn`

- To list self-managed AD domain membership for each DB instance, use the DescribeDBInstances API operation.

Understanding self-managed Active Directory Domain membership

After you create or modify your DB instance, the instance becomes a member of the self-managed AD domain. The AWS console indicates the status of the self-managed Active Directory domain membership for the DB instance. The status of the DB instance can be one of the following:

- **joined** – The instance is a member of the AD domain.
- **joining** – The instance is in the process of becoming a member of the AD domain.
- **pending-join** – The instance membership is pending.
- **pending-maintenance-join** – AWS will attempt to make the instance a member of the AD domain during the next scheduled maintenance window.
- **pending-removal** – The removal of the instance from the AD domain is pending.
- **pending-maintenance-removal** – AWS will attempt to remove the instance from the AD domain during the next scheduled maintenance window.
- **failed** – A configuration problem has prevented the instance from joining the AD domain. Check and fix your configuration before reissuing the instance modify command.
- **removing** – The instance is being removed from the self-managed AD domain.

A request to become a member of a self-managed AD domain can fail because of a network connectivity issue. For example, you might create a DB instance or modify an existing instance and have the attempt fail for the DB instance to become a member of a self-managed AD domain. In this case, either reissue the command to create or modify the DB instance or modify the newly created instance to join the self-managed AD domain.

Troubleshooting self-managed Active Directory

The following are issues you might encounter when you set up or modify self-managed AD.

Error Code	Description	Common causes	Troubleshooting suggestions
Error 2 / 0x2	The system cannot find the file specified.	The format or location for the Organizational Unit (OU) specified with the `–domain-ou` parameter is invalid. The domain service account specified via AWS Secrets Manager lack the permissions required to join the OU.	Review the `–domain-ou` parameter. Ensure the domain service account has the correct permissions to the OU. For more information, see Configure your AD domain service account.
Error 5 / 0x5	Access is denied.	Misconfigured permissions for the domain service account, or the computer account already exists in the domain.	Review the domain service account permissions in the domain, and verify that the RDS computer account is not duplicated in the domain. You can verify the name of the RDS computer account by running `SELECT @@SERVERNAME` on your RDS for SQL Server DB instance. If you are using Multi-AZ, try rebooting with failover and then verify that the RDS computer account again. For more information, see Rebooting a DB instance.
Error 87 / 0x57	The parameter is incorrect.	The domain service account specified via AWS Secrets Manager doesn't have the correct	Review the requirements for the domain service account. For more information, see

Error Code	Description	Common causes	Troubleshooting suggestions
		permissions. The user profile may also be corrupted.	Configure your AD domain service account.
Error 234 / 0xEA	Specified Organizational Unit (OU) does not exist.	The OU specified with the –domain-ou parameter doesn't exist in your self-managed AD.	Review the –domain-ou parameter and ensure the specified OU exists in your self-managed AD.
Error 1326 / 0x52E	The user name or password is incorrect.	The domain service account credentials provided in AWS Secrets Manager contains an unknown username or bad password. The domain account may also be disabled in your self-managed AD.	Ensure the credentials provided in AWS Secrets Manager are correct and the domain account is enabled in your self-managed Active Directory.
Error 1355 / 0x54B	The specified domain either does not exist or could not be contacted.	The domain is down, the specified set of DNS IPs are unreachable, or the specified FQDN is unreachable.	Review the –domain-dns-ips and –domain-fqdn parameters to ensure they're correct. Review the networking configuration of your RDS for SQL Server DB instance and ensure your self-managed AD is reachable. For more information, see Configure your network connectivity.

Error Code	Description	Common causes	Troubleshooting suggestions
Error 1722 / 0x6BA	The RPC server is unavailable.	There was an issue reaching the RPC service of your AD domain. This might be a service or network issue.	Validate that the RPC service is running on your domain controllers and that the TCP ports 135 and 49152-65535 are reachable on your domain from your RDS for SQL Server DB instance.
Error 2224 / 0x8B0	The user account already exists.	The computer account that's attempting to be added to your self-managed AD already exists.	Identify the computer account by running SELECT @@SERVERNAME on your RDS for SQL Server DB instance and then carefully remove it from your self-managed AD.
Error 2242 / 0x8c2	The password of this user has expired.	The password for the domain service account specified via AWS Secrets Manager has expired.	Update the password for the domain service account used to join your RDS for SQL Server DB instance to your self-managed AD.

Restoring a SQL Server DB instance and then adding it to a self-managed Active Directory domain

You can restore a DB snapshot or do point-in-time recovery (PITR) for a SQL Server DB instance and then add it to a self-managed Active Directory domain. Once the DB instance is restored, modify the instance using the process explained in Step 6: Create or modify a SQL Server DB instance to add the DB instance to a self-managed AD domain.

Working with AWS Managed Active Directory with RDS for SQL Server

You can use AWS Managed Microsoft AD to authenticate users with Windows Authentication when they connect to your RDS for SQL Server DB instance. The DB instance works with AWS Directory Service for Microsoft Active Directory, also called AWS Managed Microsoft AD, to enable Windows Authentication. When users authenticate with a SQL Server DB instance joined to the trusting domain, authentication requests are forwarded to the domain directory that you create with AWS Directory Service.

Region and version availability

Amazon RDS supports using only AWS Managed Microsoft AD for Windows Authentication. RDS doesn't support using AD Connector. For more information, see the following:

- Application compatibility policy for AWS Managed Microsoft AD
- Application compatibility policy for AD Connector

For information on version and Region availability, see Kerberos authentication with RDS for SQL Server.

Overview of setting up Windows authentication

Amazon RDS uses mixed mode for Windows Authentication. This approach means that the *master user* (the name and password used to create your SQL Server DB instance) uses SQL Authentication. Because the master user account is a privileged credential, you should restrict access to this account.

To get Windows Authentication using an on-premises or self-hosted Microsoft Active Directory, create a forest trust. The trust can be one-way or two-way. For more information on setting up forest trusts using AWS Directory Service, see When to create a trust relationship in the *AWS Directory Service Administration Guide*.

To set up Windows authentication for a SQL Server DB instance, do the following steps, explained in greater detail in Setting up Windows Authentication for SQL Server DB instances:

1. Use AWS Managed Microsoft AD, either from the AWS Management Console or AWS Directory Service API, to create an AWS Managed Microsoft AD directory.
2. If you use the AWS CLI or Amazon RDS API to create your SQL Server DB instance, create an AWS Identity and Access Management (IAM) role. This role uses the managed IAM policy

`AmazonRDSDirectoryServiceAccess` and allows Amazon RDS to make calls to your directory. If you use the console to create your SQL Server DB instance, AWS creates the IAM role for you.

For the role to allow access, the AWS Security Token Service (AWS STS) endpoint must be activated in the AWS Region for your AWS account. AWS STS endpoints are active by default in all AWS Regions, and you can use them without any further actions. For more information, see Managing AWS STS in an AWS Region in the *IAM User Guide*.

3. Create and configure users and groups in the AWS Managed Microsoft AD directory using the Microsoft Active Directory tools. For more information about creating users and groups in your Active Directory, see Manage users and groups in AWS Managed Microsoft AD in the *AWS Directory Service Administration Guide*.
4. If you plan to locate the directory and the DB instance in different VPCs, enable cross-VPC traffic.
5. Use Amazon RDS to create a new SQL Server DB instance either from the console, AWS CLI, or Amazon RDS API. In the create request, you provide the domain identifier ("`d-*`" identifier) that was generated when you created your directory and the name of the role you created. You can also modify an existing SQL Server DB instance to use Windows Authentication by setting the domain and IAM role parameters for the DB instance.
6. Use the Amazon RDS master user credentials to connect to the SQL Server DB instance as you do any other DB instance. Because the DB instance is joined to the AWS Managed Microsoft AD domain, you can provision SQL Server logins and users from the Active Directory users and groups in their domain. (These are known as SQL Server "Windows" logins.) Database permissions are managed through standard SQL Server permissions granted and revoked to these Windows logins.

Creating the endpoint for Kerberos authentication

Kerberos-based authentication requires that the endpoint be the customer-specified host name, a period, and then the fully qualified domain name (FQDN). For example, the following is an example of an endpoint you might use with Kerberos-based authentication. In this example, the SQL Server DB instance host name is `ad-test` and the domain name is `corp-ad.company.com`.

```
ad-test.corp-ad.company.com
```

If you want to make sure your connection is using Kerberos, run the following query:

```
SELECT net_transport, auth_scheme
  FROM sys.dm_exec_connections
 WHERE session_id = @@SPID;
```

Setting up Windows Authentication for SQL Server DB instances

You use AWS Directory Service for Microsoft Active Directory, also called AWS Managed Microsoft AD, to set up Windows Authentication for a SQL Server DB instance. To set up Windows Authentication, take the following steps.

Step 1: Create a directory using the AWS Directory Service for Microsoft Active Directory

AWS Directory Service creates a fully managed, Microsoft Active Directory in the AWS Cloud. When you create an AWS Managed Microsoft AD directory, AWS Directory Service creates two domain controllers and Domain Name Service (DNS) servers on your behalf. The directory servers are created in two subnets in two different Availability Zones within a VPC. This redundancy helps ensure that your directory remains accessible even if a failure occurs.

When you create an AWS Managed Microsoft AD directory, AWS Directory Service performs the following tasks on your behalf:

- Sets up a Microsoft Active Directory within the VPC.
- Creates a directory administrator account with the user name Admin and the specified password. You use this account to manage your directory.
- Creates a security group for the directory controllers.

When you launch an AWS Directory Service for Microsoft Active Directory, AWS creates an Organizational Unit (OU) that contains all your directory's objects. This OU, which has the NetBIOS name that you typed when you created your directory, is located in the domain root. The domain root is owned and managed by AWS.

The *admin* account that was created with your AWS Managed Microsoft AD directory has permissions for the most common administrative activities for your OU:

- Create, update, or delete users, groups, and computers.
- Add resources to your domain such as file or print servers, and then assign permissions for those resources to users and groups in your OU.

- Create additional OUs and containers.
- Delegate authority.
- Create and link group policies.
- Restore deleted objects from the Active Directory Recycle Bin.
- Run AD and DNS Windows PowerShell modules on the Active Directory Web Service.

The admin account also has rights to perform the following domain-wide activities:

- Manage DNS configurations (add, remove, or update records, zones, and forwarders).
- View DNS event logs.
- View security event logs.

To create a directory with AWS Managed Microsoft AD

1. In the AWS Directory Service console navigation pane, choose **Directories** and choose **Set up directory**.
2. Choose **AWS Managed Microsoft AD**. This is the only option currently supported for use with Amazon RDS.
3. Choose **Next**.
4. On the **Enter directory information** page, provide the following information:

   Edition

   Choose the edition that meets your requirements.

   Directory DNS name

   The fully qualified name for the directory, such as `corp.example.com`. Names longer than 47 characters aren't supported by SQL Server.

   Directory NetBIOS name

   An optional short name for the directory, such as `CORP`.

   Directory description

   An optional description for the directory.

Admin password

The password for the directory administrator. The directory creation process creates an administrator account with the user name Admin and this password.

The directory administrator password can't include the word `admin`. The password is case-sensitive and must be 8–64 characters in length. It must also contain at least one character from three of the following four categories:

- Lowercase letters (a-z)
- Uppercase letters (A-Z)
- Numbers (0-9)
- Non-alphanumeric characters (~!@#$%^&*_-+=`|\(){}[]:;"'<>,.?/)

Confirm password

Retype the administrator password.

5. Choose **Next**.
6. On the **Choose VPC and subnets** page, provide the following information:

VPC

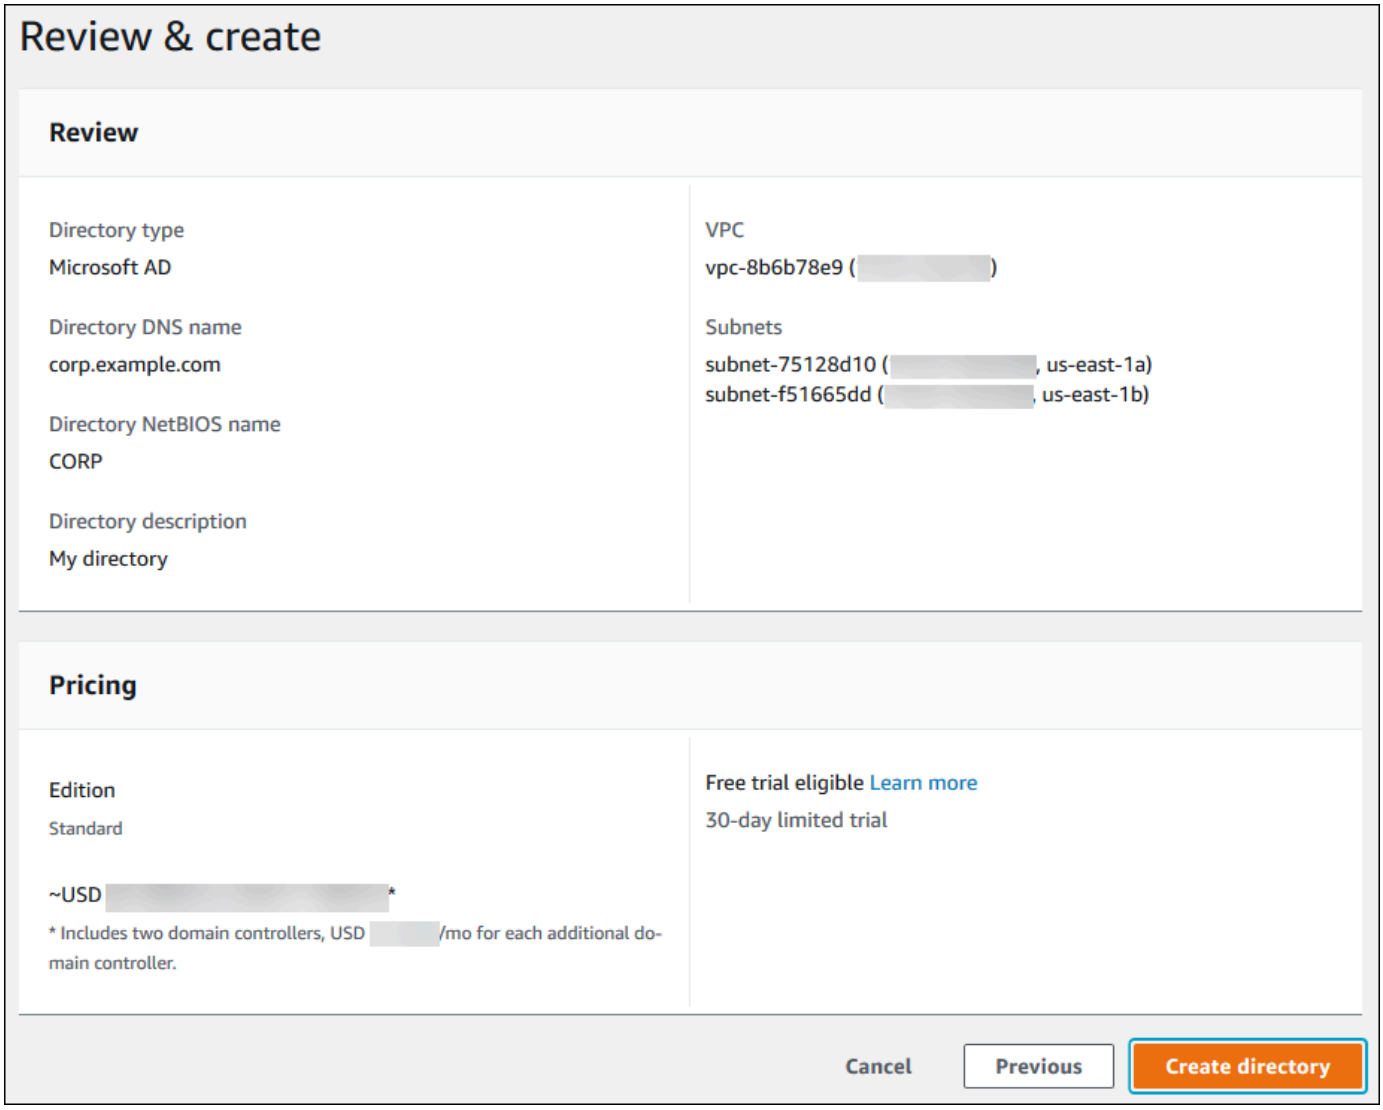
Choose the VPC for the directory.

> **Note**
>
> You can locate the directory and the DB instance in different VPCs, but if you do so, make sure to enable cross-VPC traffic. For more information, see Step 4: Enable cross-VPC traffic between the directory and the DB instance.

Subnets

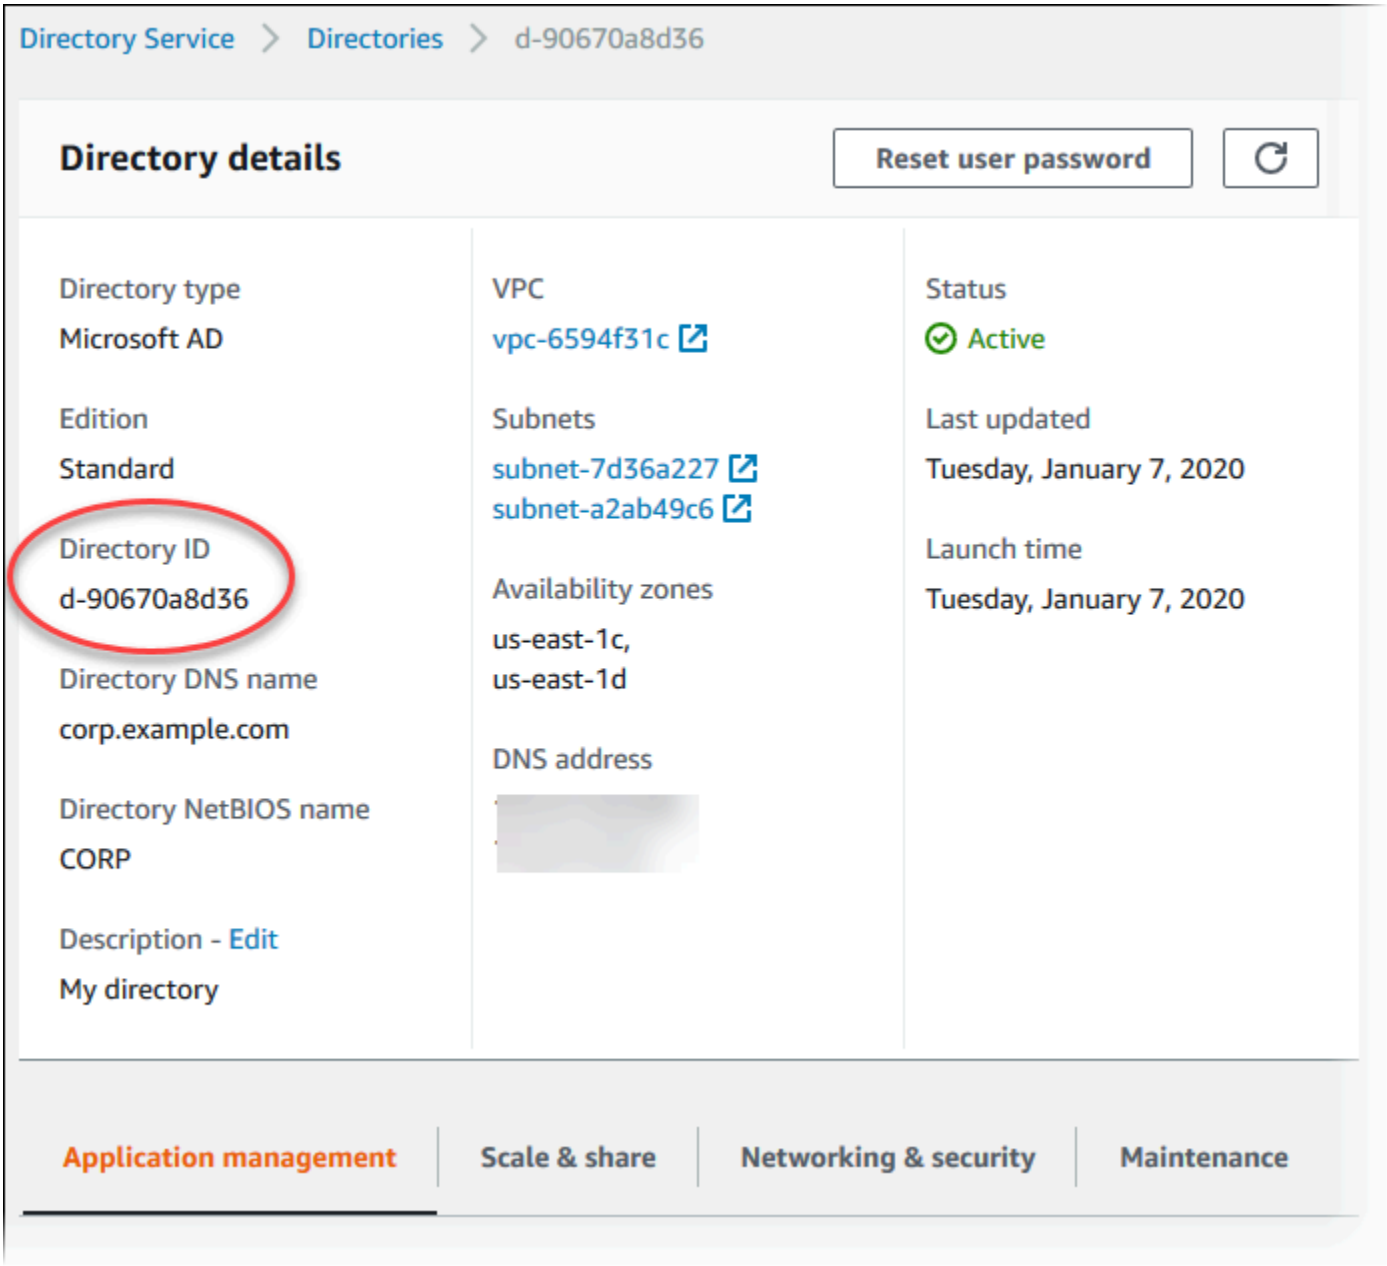
Choose the subnets for the directory servers. The two subnets must be in different Availability Zones.

7. Choose **Next**.
8. Review the directory information. If changes are needed, choose **Previous**. When the information is correct, choose **Create directory**.



It takes several minutes for the directory to be created. When it has been successfully created, the **Status** value changes to **Active**.

To see information about your directory, choose the directory ID in the directory listing. Make a note of the **Directory ID**. You need this value when you create or modify your SQL Server DB instance.



Step 2: Create the IAM role for use by Amazon RDS

If you use the console to create your SQL Server DB instance, you can skip this step. If you use the CLI or RDS API to create your SQL Server DB instance, you must create an IAM role that uses the `AmazonRDSDirectoryServiceAccess` managed IAM policy. This role allows Amazon RDS to make calls to the AWS Directory Service for you.

If you are using a custom policy for joining a domain, rather than using the AWS-managed `AmazonRDSDirectoryServiceAccess` policy, make sure that you allow the

`ds:GetAuthorizedApplicationDetails` action. This requirement is effective starting July 2019, due to a change in the AWS Directory Service API.

The following IAM policy, `AmazonRDSDirectoryServiceAccess`, provides access to AWS Directory Service.

Example IAM policy for providing access to AWS Directory Service

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Action": [
            "ds:DescribeDirectories",
            "ds:AuthorizeApplication",
            "ds:UnauthorizeApplication",
            "ds:GetAuthorizedApplicationDetails"
        ],
      "Effect": "Allow",
      "Resource": "*"
    }
  ]
}
```

We recommend using the `aws:SourceArn` and `aws:SourceAccount` global condition context keys in resource-based trust relationships to limit the service's permissions to a specific resource. This is the most effective way to protect against the confused deputy problem.

You might use both global condition context keys and have the `aws:SourceArn` value contain the account ID. In this case, the `aws:SourceAccount` value and the account in the `aws:SourceArn` value must use the same account ID when used in the same statement.

- Use `aws:SourceArn` if you want cross-service access for a single resource.
- Use `aws:SourceAccount` if you want to allow any resource in that account to be associated with the cross-service use.

In the trust relationship, make sure to use the `aws:SourceArn` global condition context key with the full Amazon Resource Name (ARN) of the resources accessing the role. For Windows Authentication, make sure to include the DB instances, as shown in the following example.

Example trust relationship with global condition context key for Windows Authentication

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "Service": "rds.amazonaws.com"
            },
            "Action": "sts:AssumeRole",
            "Condition": {
                "StringEquals": {
                    "aws:SourceArn": [
                        "arn:aws:rds:Region:my_account_ID:db:db_instance_identifier"
                    ]
                }
            }
        }
    ]
}
```

Create an IAM role using this IAM policy and trust relationship. For more information about creating IAM roles, see Creating customer managed policies in the *IAM User Guide*.

Step 3: Create and configure users and groups

You can create users and groups with the Active Directory Users and Computers tool. This tool is one of the Active Directory Domain Services and Active Directory Lightweight Directory Services tools. Users represent individual people or entities that have access to your directory. Groups are very useful for giving or denying privileges to groups of users, rather than having to apply those privileges to each individual user.

To create users and groups in an AWS Directory Service directory, you must be connected to a Windows EC2 instance that is a member of the AWS Directory Service directory. You must also be logged in as a user that has privileges to create users and groups. For more information, see Add users and groups (Simple AD and AWS Managed Microsoft AD) in the *AWS Directory Service Administration Guide*.

Step 4: Enable cross-VPC traffic between the directory and the DB instance

If you plan to locate the directory and the DB instance in the same VPC, skip this step and move on to Step 5: Create or modify a SQL Server DB instance.

If you plan to locate the directory and the DB instance in different VPCs, configure cross-VPC traffic using VPC peering or AWS Transit Gateway.

The following procedure enables traffic between VPCs using VPC peering. Follow the instructions in What is VPC peering? in the *Amazon Virtual Private Cloud Peering Guide*.

To enable cross-VPC traffic using VPC peering

1. Set up appropriate VPC routing rules to ensure that network traffic can flow both ways.
2. Ensure that the DB instance's security group can receive inbound traffic from the directory's security group.
3. Ensure that there is no network access control list (ACL) rule to block traffic.

If a different AWS account owns the directory, you must share the directory.

To share the directory between AWS accounts

1. Start sharing the directory with the AWS account that the DB instance will be created in by following the instructions in Tutorial: Sharing your AWS Managed Microsoft AD directory for seamless EC2 domain-join in the *AWS Directory Service Administration Guide*.
2. Sign in to the AWS Directory Service console using the account for the DB instance, and ensure that the domain has the SHARED status before proceeding.
3. While signed into the AWS Directory Service console using the account for the DB instance, note the **Directory ID** value. You use this directory ID to join the DB instance to the domain.

Step 5: Create or modify a SQL Server DB instance

Create or modify a SQL Server DB instance for use with your directory. You can use the console, CLI, or RDS API to associate a DB instance with a directory. You can do this in one of the following ways:

- Create a new SQL Server DB instance using the console, the create-db-instance CLI command, or the CreateDBInstance RDS API operation.

For instructions, see Creating an Amazon RDS DB instance.

- Modify an existing SQL Server DB instance using the console, the modify-db-instance CLI command, or the ModifyDBInstance RDS API operation.

  For instructions, see Modifying an Amazon RDS DB instance.
- Restore a SQL Server DB instance from a DB snapshot using the console, the restore-db-instance-from-db-snapshot CLI command, or the RestoreDBInstanceFromDBSnapshot RDS API operation.

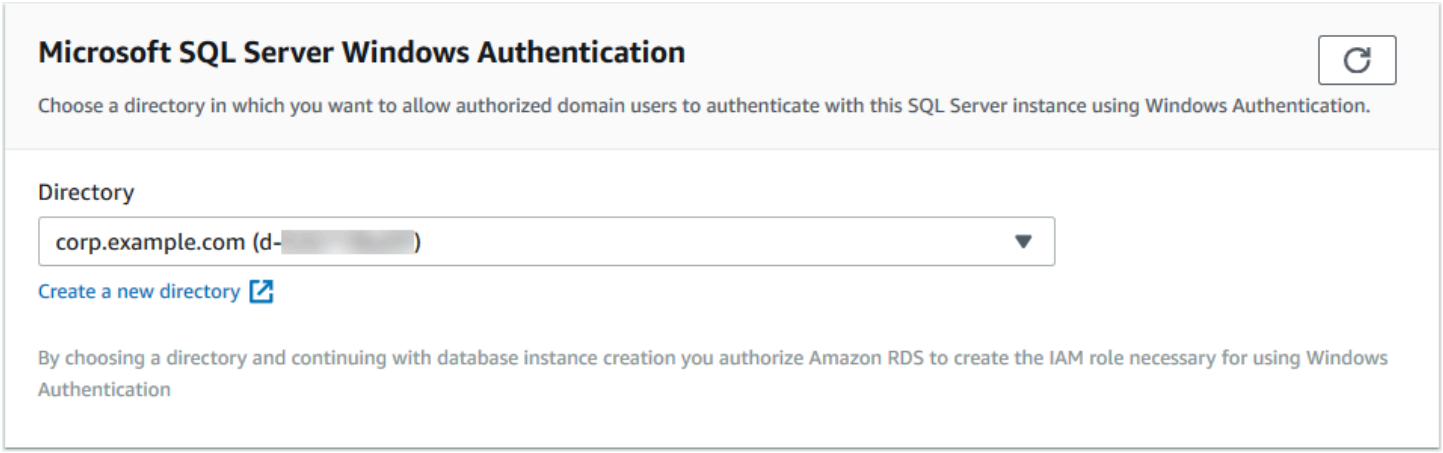
  For instructions, see Restoring to a DB instance.
- Restore a SQL Server DB instance to a point-in-time using the console, the restore-db-instance-to-point-in-time CLI command, or the RestoreDBInstanceToPointInTime RDS API operation.

  For instructions, see Restoring a DB instance to a specified time.

Windows Authentication is only supported for SQL Server DB instances in a VPC.

For the DB instance to be able to use the domain directory that you created, the following is required:

- For **Directory**, you must choose the domain identifier (d-*ID*) generated when you created the directory.
- Make sure that the VPC security group has an outbound rule that lets the DB instance communicate with the directory.



When you use the AWS CLI, the following parameters are required for the DB instance to be able to use the directory that you created:

- For the `--domain` parameter, use the domain identifier (`d-ID`) generated when you created the directory.
- For the `--domain-iam-role-name` parameter, use the role that you created that uses the managed IAM policy `AmazonRDSDirectoryServiceAccess`.

For example, the following CLI command modifies a DB instance to use a directory.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier mydbinstance \
    --domain d-ID \
    --domain-iam-role-name role-name
```

For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier mydbinstance ^
    --domain d-ID ^
    --domain-iam-role-name role-name
```

Important

If you modify a DB instance to enable Kerberos authentication, reboot the DB instance after making the change.

Step 6: Create Windows Authentication SQL Server logins

Use the Amazon RDS master user credentials to connect to the SQL Server DB instance as you do any other DB instance. Because the DB instance is joined to the AWS Managed Microsoft AD domain, you can provision SQL Server logins and users. You do this from the Active Directory users and groups in your domain. Database permissions are managed through standard SQL Server permissions granted and revoked to these Windows logins.

For an Active Directory user to authenticate with SQL Server, a SQL Server Windows login must exist for the user or a group that the user is a member of. Fine-grained access control is handled

through granting and revoking permissions on these SQL Server logins. A user that doesn't have a SQL Server login or belong to a group with such a login can't access the SQL Server DB instance.

The ALTER ANY LOGIN permission is required to create an Active Directory SQL Server login. If you haven't created any logins with this permission, connect as the DB instance's master user using SQL Server Authentication.

Run a data definition language (DDL) command such as the following example to create a SQL Server login for an Active Directory user or group.

> **Note**
>
> Specify users and groups using the pre-Windows 2000 login name in the format *domainName**login_name*. You can't use a user principal name (UPN) in the format *login_name*@*DomainName*.
> You can only create a Windows Authentication login on an RDS for SQL Server instance by using T-SQL statements. You can't use the SQL Server Management studio to create a Windows Authentication login.

```
USE [master]
GO
CREATE LOGIN [mydomain\myuser] FROM WINDOWS WITH DEFAULT_DATABASE = [master],
 DEFAULT_LANGUAGE = [us_english];
GO
```

For more information, see CREATE LOGIN (Transact-SQL) in the Microsoft Developer Network documentation.

Users (both humans and applications) from your domain can now connect to the RDS for SQL Server instance from a domain-joined client machine using Windows authentication.

Managing a DB instance in a Domain

You can use the console, AWS CLI, or the Amazon RDS API to manage your DB instance and its relationship with your domain. For example, you can move the DB instance into, out of, or between domains.

For example, using the Amazon RDS API, you can do the following:

- To reattempt a domain join for a failed membership, use the ModifyDBInstance API operation and specify the current membership's directory ID.
- To update the IAM role name for membership, use the `ModifyDBInstance` API operation and specify the current membership's directory ID and the new IAM role.
- To remove a DB instance from a domain, use the `ModifyDBInstance` API operation and specify none as the domain parameter.
- To move a DB instance from one domain to another, use the `ModifyDBInstance` API operation and specify the domain identifier of the new domain as the domain parameter.
- To list membership for each DB instance, use the DescribeDBInstances API operation.

Understanding Domain membership

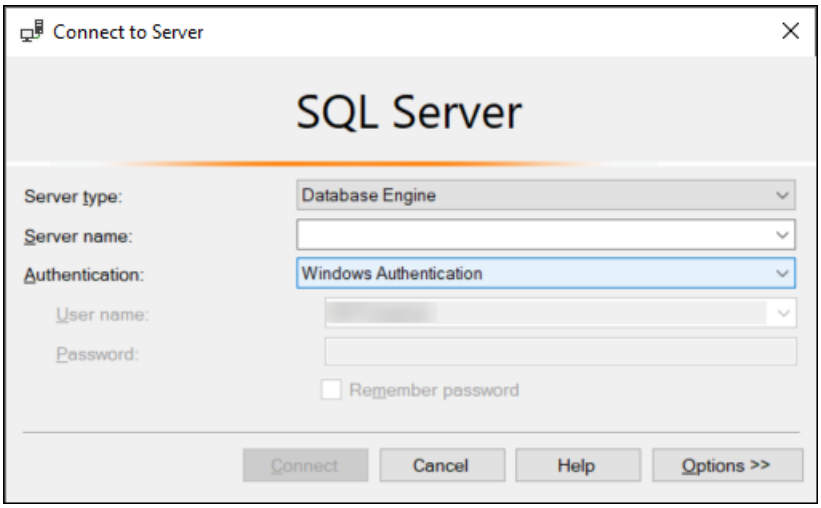
After you create or modify your DB instance, the instance becomes a member of the domain. The AWS console indicates the status of the domain membership for the DB instance. The status of the DB instance can be one of the following:

- **joined** – The instance is a member of the domain.
- **joining** – The instance is in the process of becoming a member of the domain.
- **pending-join** – The instance membership is pending.
- **pending-maintenance-join** – AWS will attempt to make the instance a member of the domain during the next scheduled maintenance window.
- **pending-removal** – The removal of the instance from the domain is pending.
- **pending-maintenance-removal** – AWS will attempt to remove the instance from the domain during the next scheduled maintenance window.
- **failed** – A configuration problem has prevented the instance from joining the domain. Check and fix your configuration before reissuing the instance modify command.
- **removing** – The instance is being removed from the domain.

A request to become a member of a domain can fail because of a network connectivity issue or an incorrect IAM role. For example, you might create a DB instance or modify an existing instance and have the attempt fail for the DB instance to become a member of a domain. In this case, either reissue the command to create or modify the DB instance or modify the newly created instance to join the domain.

Connecting to SQL Server with Windows authentication

To connect to SQL Server with Windows Authentication, you must be logged into a domain-joined computer as a domain user. After launching SQL Server Management Studio, choose **Windows Authentication** as the authentication type, as shown following.



Restoring a SQL Server DB instance and then adding it to a domain

You can restore a DB snapshot or do point-in-time recovery (PITR) for a SQL Server DB instance and then add it to a domain. Once the DB instance is restored, modify the instance using the process explained in Step 5: Create or modify a SQL Server DB instance to add the DB instance to a domain.

Updating applications to connect to Microsoft SQL Server DB instances using new SSL/TLS certificates

As of January 13, 2023, Amazon RDS has published new Certificate Authority (CA) certificates for connecting to your RDS DB instances using Secure Socket Layer or Transport Layer Security (SSL/TLS). Following, you can find information about updating your applications to use the new certificates.

This topic can help you to determine whether any client applications use SSL/TLS to connect to your DB instances. If they do, you can further check whether those applications require certificate verification to connect.

> **Note**
>
> Some applications are configured to connect to SQL Server DB instances only if they can successfully verify the certificate on the server.
> For such applications, you must update your client application trust stores to include the new CA certificates.

After you update your CA certificates in the client application trust stores, you can rotate the certificates on your DB instances. We strongly recommend testing these procedures in a development or staging environment before implementing them in your production environments.

For more information about certificate rotation, see Rotating your SSL/TLS certificate. For more information about downloading certificates, see Using SSL/TLS to encrypt a connection to a DB instance or cluster. For information about using SSL/TLS with Microsoft SQL Server DB instances, see Using SSL with a Microsoft SQL Server DB instance.

Topics

Determining whether any applications are connecting to your Microsoft SQL Server DB instance using SSL

Check the DB instance configuration for the value of the `rds.force_ssl` parameter. By default, the `rds.force_ssl` parameter is set to 0 (off). If the `rds.force_ssl` parameter is set to 1 (on), clients are required to use SSL/TLS for connections. For more information about parameter groups, see Parameter groups for Amazon RDS.

Run the following query to get the current encryption option for all the open connections to a DB instance. The column `ENCRYPT_OPTION` returns `TRUE` if the connection is encrypted.

```
select SESSION_ID,
    ENCRYPT_OPTION,
    NET_TRANSPORT,
    AUTH_SCHEME
    from SYS.DM_EXEC_CONNECTIONS
```

This query shows only the current connections. It doesn't show whether applications that have connected and disconnected in the past have used SSL.

Determining whether a client requires certificate verification in order to connect

You can check whether different types of clients require certificate verification to connect.

> **Note**
>
> If you use connectors other than the ones listed, see the specific connector's documentation for information about how it enforces encrypted connections. For more information, see Connection modules for Microsoft SQL databases in the Microsoft SQL Server documentation.

SQL Server Management Studio

Check whether encryption is enforced for SQL Server Management Studio connections:

1. Launch SQL Server Management Studio.
2. For **Connect to server**, enter the server information, login user name, and password.
3. Choose **Options**.
4. Check if **Encrypt connection** is selected in the connect page.

For more information about SQL Server Management Studio, see Use SQL Server Management Studio.

Sqlcmd

The following example with the `sqlcmd` client shows how to check a script's SQL Server connection to determine whether successful connections require a valid certificate. For more information, see Connecting with sqlcmd in the Microsoft SQL Server documentation.

When using `sqlcmd`, an SSL connection requires verification against the server certificate if you use the `-N` command argument to encrypt connections, as in the following example.

```
$ sqlcmd -N -S dbinstance.rds.amazon.com -d ExampleDB
```

> **Note**
>
> If `sqlcmd` is invoked with the `-C` option, it trusts the server certificate, even if that doesn't match the client-side trust store.

ADO.NET

In the following example, the application connects using SSL, and the server certificate must be verified.

```
using SQLC = Microsoft.Data.SqlClient;

...
```

```
    static public void Main()
    {
        using (var connection = new SQLC.SqlConnection(
            "Server=tcp:dbinstance.rds.amazon.com;" +
            "Database=ExampleDB;User ID=LOGIN_NAME;" +
            "Password=YOUR_PASSWORD;" +
            "Encrypt=True;TrustServerCertificate=False;"
            ))
        {
            connection.Open();
            ...
        }
```

Java

In the following example, the application connects using SSL, and the server certificate must be verified.

```
String connectionUrl =
    "jdbc:sqlserver://dbinstance.rds.amazon.com;" +
    "databaseName=ExampleDB;integratedSecurity=true;" +
    "encrypt=true;trustServerCertificate=false";
```

To enable SSL encryption for clients that connect using JDBC, you might need to add the Amazon RDS certificate to the Java CA certificate store. For instructions, see Configuring the client for encryption in the Microsoft SQL Server documentation. You can also provide the trusted CA certificate file name directly by appending `trustStore=`*`path-to-certificate-trust-store-file`* to the connection string.

> **Note**
>
> If you use `TrustServerCertificate=true` (or its equivalent) in the connection string, the connection process skips the trust chain validation. In this case, the application connects even if the certificate can't be verified. Using `TrustServerCertificate=false` enforces certificate validation and is a best practice.

Updating your application trust store

You can update the trust store for applications that use Microsoft SQL Server. For instructions, see Encrypting specific connections. Also, see Configuring the client for encryption in the Microsoft SQL Server documentation.

If you are using an operating system other than Microsoft Windows, see the software distribution documentation for SSL/TLS implementation for information about adding a new root CA certificate. For example, OpenSSL and GnuTLS are popular options. Use the implementation method to add trust to the RDS root CA certificate. Microsoft provides instructions for configuring certificates on some systems.

For information about downloading the root certificate, see Using SSL/TLS to encrypt a connection to a DB instance or cluster.

For sample scripts that import certificates, see Sample script for importing certificates into your trust store.

> **Note**
>
> When you update the trust store, you can retain older certificates in addition to adding the new certificates.

Upgrading the Microsoft SQL Server DB engine

When Amazon RDS supports a new version of a database engine, you can upgrade your DB instances to the new version. There are two kinds of upgrades for SQL Server DB instances: major version upgrades and minor version upgrades.

Major version upgrades can contain database changes that are not backward-compatible with existing applications. As a result, you must manually perform major version upgrades of your DB instances. You can initiate a major version upgrade by modifying your DB instance. However, before you perform a major version upgrade, we recommend that you test the upgrade by following the steps described in Testing an upgrade.

In contrast, *minor version upgrades* include only changes that are backward-compatible with existing applications. You can initiate a minor version upgrade manually by modifying your DB instance.

In the following example, the CLI command returns a response showing `AutoUpgrade` is **true**, indicating that upgrades are automatic.

```
...

"ValidUpgradeTarget": [
    {
        "Engine": "sqlserver-se",
        "EngineVersion": "14.00.3281.6.v1",
        "Description": "SQL Server 2017 14.00.3281.6.v1",
        "AutoUpgrade": true,
        "IsMajorVersionUpgrade": false
    }

...
```

For more information about performing upgrades, see Upgrading a SQL Server DB instance. For information about what SQL Server versions are available on Amazon RDS, see Amazon RDS for Microsoft SQL Server.

Topics

- Overview of upgrading
- Major version upgrades

- Multi-AZ and in-memory optimization considerations
- Read replica considerations
- Option group considerations
- Parameter group considerations
- Testing an upgrade
- Upgrading a SQL Server DB instance
- Upgrading deprecated DB instances before support ends

Overview of upgrading

Amazon RDS takes two DB snapshots during the upgrade process. The first DB snapshot is of the DB instance before any upgrade changes have been made. The second DB snapshot is taken after the upgrade finishes.

> **Note**
>
> Amazon RDS only takes DB snapshots if you have set the backup retention period for your DB instance to a number greater than 0. To change your backup retention period, see Modifying an Amazon RDS DB instance.

After an upgrade is completed, you can't revert to the previous version of the database engine. If you want to return to the previous version, restore from the DB snapshot that was taken before the upgrade to create a new DB instance.

During a minor or major version upgrade of SQL Server, the **Free Storage Space** and **Disk Queue Depth** metrics will display -1. After the upgrade is completed, both metrics will return to normal.

Major version upgrades

Amazon RDS currently supports the following major version upgrades to a Microsoft SQL Server DB instance.

You can upgrade your existing DB instance to SQL Server 2017 or 2019 from any version except SQL Server 2008. To upgrade from SQL Server 2008, first upgrade to one of the other versions.

Current version	Supported upgrade versions
SQL Server 2019	SQL Server 2022
SQL Server 2017	SQL Server 2022 SQL Server 2019
SQL Server 2016	SQL Server 2022 SQL Server 2019 SQL Server 2017

You can use an AWS CLI query, such as the following example, to find the available upgrades for a particular database engine version.

Example

For Linux, macOS, or Unix:

```
aws rds describe-db-engine-versions \
    --engine sqlserver-se \
    --engine-version 14.00.3281.6.v1 \
    --query "DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}" \
    --output table
```

For Windows:

```
aws rds describe-db-engine-versions ^
    --engine sqlserver-se ^
    --engine-version 14.00.3281.6.v1 ^
    --query "DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}" ^
    --output table
```

The output shows that you can upgrade version 14.00.3281.6 to the latest available SQL Server 2017 or 2019 versions.

```
-------------------------
```

```
|DescribeDBEngineVersions|
+------------------------+
|      EngineVersion     |
+------------------------+
|  14.00.3294.2.v1       |
|  14.00.3356.20.v1      |
|  14.00.3381.3.v1       |
|  14.00.3401.7.v1       |
|  14.00.3421.10.v1      |
|  14.00.3451.2.v1       |
|  15.00.4043.16.v1      |
|  15.00.4073.23.v1      |
|  15.00.4153.1.v1       |
|  15.00.4198.2.v1       |
|  15.00.4236.7.v1       |
+------------------------+
```

Database compatibility level

You can use Microsoft SQL Server database compatibility levels to adjust some database behaviors to mimic previous versions of SQL Server. For more information, see Compatibility level in the Microsoft documentation. When you upgrade your DB instance, all existing databases remain at their original compatibility level.

You can change the compatibility level of a database by using the ALTER DATABASE command. For example, to change a database named `customeracct` to be compatible with SQL Server 2016, issue the following command:

```
ALTER DATABASE customeracct SET COMPATIBILITY_LEVEL = 130
```

Multi-AZ and in-memory optimization considerations

Amazon RDS supports Multi-AZ deployments for DB instances running Microsoft SQL Server by using SQL Server Database Mirroring (DBM) or Always On Availability Groups (AGs). For more information, see Multi-AZ deployments for Amazon RDS for Microsoft SQL Server.

If your DB instance is in a Multi-AZ deployment, both the primary and standby instances are upgraded. Amazon RDS does rolling upgrades. You have an outage only for the duration of a failover.

SQL Server 2016 through 2019 Enterprise Edition support in-memory optimization.

Read replica considerations

During a database version upgrade, Amazon RDS upgrades all of your read replicas along with the primary DB instance. Amazon RDS does not support database version upgrades on the read replicas separately. For more information on read replicas, see Working with read replicas for Microsoft SQL Server in Amazon RDS.

When you perform a database version upgrade of the primary DB instance, all its read-replicas are also automatically upgraded. Amazon RDS will upgrade all of the read replicas simultaneously before upgrading the primary DB instance. Read replicas may not be available until the database version upgrade on the primary DB instance is complete.

Option group considerations

If your DB instance uses a custom DB option group, in some cases Amazon RDS can't automatically assign your DB instance a new option group. For example, when you upgrade to a new major version, you must specify a new option group. We recommend that you create a new option group, and add the same options to it as your existing custom option group.

For more information, see Creating an option group or Copying an option group.

Parameter group considerations

If your DB instance uses a custom DB parameter group:

- Amazon RDS automatically reboots the DB instance after an upgrade.
- In some cases, RDS can't automatically assign a new parameter group to your DB instance.

  For example, when you upgrade to a new major version, you must specify a new parameter group. We recommend that you create a new parameter group, and configure the parameters as in your existing custom parameter group.

For more information, see Creating a DB parameter group in Amazon RDS or Copying a DB parameter group in Amazon RDS.

Testing an upgrade

Before you perform a major version upgrade on your DB instance, you should thoroughly test your database, and all applications that access the database, for compatibility with the new version. We recommend that you use the following procedure.

To test a major version upgrade

1. Review Upgrade SQL Server in the Microsoft documentation for the new version of the database engine to see if there are compatibility issues that might affect your database or applications.
2. If your DB instance uses a custom option group, create a new option group compatible with the new version you are upgrading to. For more information, see Option group considerations.
3. If your DB instance uses a custom parameter group, create a new parameter group compatible with the new version you are upgrading to. For more information, see Parameter group considerations.
4. Create a DB snapshot of the DB instance to be upgraded. For more information, see Creating a DB snapshot for a Single-AZ DB instance.
5. Restore the DB snapshot to create a new test DB instance. For more information, see Restoring to a DB instance.
6. Modify this new test DB instance to upgrade it to the new version, by using one of the following methods:

   - Console
   - AWS CLI
   - RDS API
7. Evaluate the storage used by the upgraded instance to determine if the upgrade requires additional storage.
8. Run as many of your quality assurance tests against the upgraded DB instance as needed to ensure that your database and application work correctly with the new version. Implement any new tests needed to evaluate the impact of any compatibility issues you identified in step 1. Test all stored procedures and functions. Direct test versions of your applications to the upgraded DB instance.
9. If all tests pass, then perform the upgrade on your production DB instance. We recommend that you do not allow write operations to the DB instance until you confirm that everything is working correctly.

Upgrading a SQL Server DB instance

For information about manually or automatically upgrading a SQL Server DB instance, see the following:

- Upgrading a DB instance engine version
- Best practices for upgrading SQL Server 2008 R2 to SQL Server 2016 on Amazon RDS for SQL Server

> **Important**
>
> If you have any snapshots that are encrypted using AWS KMS, we recommend that you initiate an upgrade before support ends.

Upgrading deprecated DB instances before support ends

After a major version is deprecated, you can't install it on new DB instances. RDS will try to automatically upgrade all existing DB instances.

If you need to restore a deprecated DB instance, you can do point-in-time recovery (PITR) or restore a snapshot. Doing this gives you temporary access a DB instance that uses the version that is being deprecated. However, after a major version is fully deprecated, these DB instances will also be automatically upgraded to a supported version.

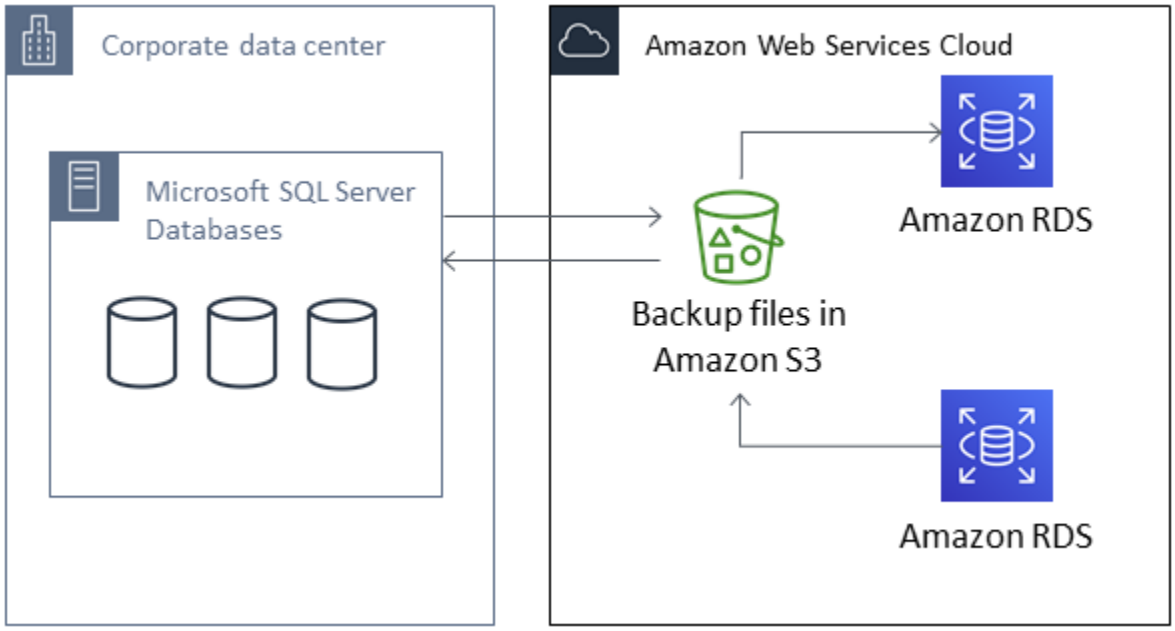
Importing and exporting SQL Server databases using native backup and restore

Amazon RDS supports native backup and restore for Microsoft SQL Server databases using full backup files (.bak files). When you use RDS, you access files stored in Amazon S3 rather than using the local file system on the database server.

For example, you can create a full backup from your local server, store it on S3, and then restore it onto an existing Amazon RDS DB instance. You can also make backups from RDS, store them on S3, and then restore them wherever you want.

Native backup and restore is available in all AWS Regions for Single-AZ and Multi-AZ DB instances, including Multi-AZ DB instances with read replicas. Native backup and restore is available for all editions of Microsoft SQL Server supported on Amazon RDS.

The following diagram shows the supported scenarios.



Using native .bak files to back up and restore databases is usually the fastest way to back up and restore databases. There are many additional advantages to using native backup and restore. For example, you can do the following:

- Migrate databases to or from Amazon RDS.
- Move databases between RDS for SQL Server DB instances.

- Migrate data, schemas, stored procedures, triggers, and other database code inside .bak files.
- Backup and restore single databases, instead of entire DB instances.
- Create copies of databases for development, testing, training, and demonstrations.
- Store and transfer backup files with Amazon S3, for an added layer of protection for disaster recovery.
- Create native backups of databases that have Transparent Data Encryption (TDE) turned on, and restore those backups to on-premises databases. For more information, see Support for Transparent Data Encryption in SQL Server.
- Restore native backups of on-premises databases that have TDE turned on to RDS for SQL Server DB instances. For more information, see Support for Transparent Data Encryption in SQL Server.

Contents

Limitations and recommendations

The following are some limitations to using native backup and restore:

- You can't back up to, or restore from, an Amazon S3 bucket in a different AWS Region from your Amazon RDS DB instance.
- You can't restore a database with the same name as an existing database. Database names are unique.
- We strongly recommend that you don't restore backups from one time zone to a different time zone. If you restore backups from one time zone to a different time zone, you must audit your queries and applications for the effects of the time zone change.
- Amazon S3 has a size limit of 5 TB per file. For native backups of larger databases, you can use multifile backup.
- The maximum database size that can be backed up to S3 depends on the available memory, CPU, I/O, and network resources on the DB instance. The larger the database, the more memory the backup agent consumes. Our testing shows that you can make a compressed backup of a 16-TB

database on our newest-generation instance types from `2xlarge` instance sizes and larger, given sufficient system resources.

- You can't back up to or restore from more than 10 backup files at the same time.
- A differential backup is based on the last full backup. For differential backups to work, you can't take a snapshot between the last full backup and the differential backup. If you want a differential backup, but a manual or automated snapshot exists, then do another full backup before proceeding with the differential backup.
- Differential and log restores aren't supported for databases with files that have their file_guid (unique identifier) set to `NULL`.
- You can run up to two backup or restore tasks at the same time.
- You can't perform native log backups from SQL Server on Amazon RDS.
- RDS supports native restores of databases up to 16 TB. Native restores of databases on SQL Server Express Edition are limited to 10 GB.
- You can't do a native backup during the maintenance window, or any time Amazon RDS is in the process of taking a snapshot of the database. If a native backup task overlaps with the RDS daily backup window, the native backup task is canceled.
- On Multi-AZ DB instances, you can only natively restore databases that are backed up in the full recovery model.
- Restoring from differential backups on Multi-AZ instances isn't supported.
- Calling the RDS procedures for native backup and restore within a transaction isn't supported.
- Use a symmetric encryption AWS KMS key to encrypt your backups. Amazon RDS doesn't support asymmetric KMS keys. For more information, see Creating symmetric encryption KMS keys in the *AWS Key Management Service Developer Guide*.
- Native backup files are encrypted with the specified KMS key using the "Encryption-Only" crypto mode. When you are restoring encrypted backup files, be aware that they were encrypted with the "Encryption-Only" crypto mode.
- You can't restore a database that contains a FILESTREAM file group.

If your database can be offline while the backup file is created, copied, and restored, we recommend that you use native backup and restore to migrate it to RDS. If your on-premises database can't be offline, we recommend that you use the AWS Database Migration Service to migrate your database to Amazon RDS. For more information, see What is AWS Database Migration Service?

Native backup and restore isn't intended to replace the data recovery capabilities of the cross-region snapshot copy feature. We recommend that you use snapshot copy to copy your database snapshot to another AWS Region for cross-region disaster recovery in Amazon RDS. For more information, see Copying a DB snapshot.

Setting up for native backup and restore

To set up for native backup and restore, you need three components:

1. An Amazon S3 bucket to store your backup files.

   You must have an S3 bucket to use for your backup files and then upload backups you want to migrate to RDS. If you already have an Amazon S3 bucket, you can use that. If you don't, you can create a bucket. Alternatively, you can choose to have a new bucket created for you when you add the SQLSERVER_BACKUP_RESTORE option by using the AWS Management Console.

   For information on using S3, see the Amazon Simple Storage Service User Guide
2. An AWS Identity and Access Management (IAM) role to access the bucket.

   If you already have an IAM role, you can use that. You can choose to have a new IAM role created for you when you add the SQLSERVER_BACKUP_RESTORE option by using the AWS Management Console. Alternatively, you can create a new one manually.

   If you want to create a new IAM role manually, take the approach discussed in the next section. Do the same if you want to attach trust relationships and permissions policies to an existing IAM role.
3. The SQLSERVER_BACKUP_RESTORE option added to an option group on your DB instance.

   To enable native backup and restore on your DB instance, you add the SQLSERVER_BACKUP_RESTORE option to an option group on your DB instance. For more information and instructions, see Support for native backup and restore in SQL Server.

Manually creating an IAM role for native backup and restore

If you want to manually create a new IAM role to use with native backup and restore, you can do so. In this case, you create a role to delegate permissions from the Amazon RDS service to your Amazon S3 bucket. When you create an IAM role, you attach a trust relationship and a permissions policy. The trust relationship allows RDS to assume this role. The permissions policy defines the

actions this role can perform. For more information about creating the role, see Creating a role to delegate permissions to an AWS service.

For the native backup and restore feature, use trust relationships and permissions policies similar to the examples in this section. In the following example, we use the service principal name `rds.amazonaws.com` as an alias for all service accounts. In the other examples, we specify an Amazon Resource Name (ARN) to identify another account, user, or role that we're granting access to in the trust policy.

We recommend using the `aws:SourceArn` and `aws:SourceAccount` global condition context keys in resource-based trust relationships to limit the service's permissions to a specific resource. This is the most effective way to protect against the confused deputy problem.

You might use both global condition context keys and have the `aws:SourceArn` value contain the account ID. In this case, the `aws:SourceAccount` value and the account in the `aws:SourceArn` value must use the same account ID when used in the same statement.

- Use `aws:SourceArn` if you want cross-service access for a single resource.
- Use `aws:SourceAccount` if you want to allow any resource in that account to be associated with the cross-service use.

In the trust relationship, make sure to use the `aws:SourceArn` global condition context key with the full ARN of the resources accessing the role. For native backup and restore, make sure to include both the DB option group and the DB instances, as shown in the following example.

Example trust relationship with global condition context key for native backup and restore

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": "rds.amazonaws.com"
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
```

The following example uses an ARN to specify a resource. For more information on using ARNs, see Amazon resource names (ARNs).

Example permissions policy for native backup and restore without encryption support

```
{
    "Version": "2012-10-17",
    "Statement":
    [
        {
        "Effect": "Allow",
        "Action":
            [
                "s3:ListBucket",
                "s3:GetBucketLocation"
            ],
        "Resource": "arn:aws:s3:::amzn-s3-demo-bucket"
        },
        {
        "Effect": "Allow",
        "Action":
            [
                "s3:GetObjectAttributes",
                "s3:GetObject",
                "s3:PutObject",
                "s3:ListMultipartUploadParts",
                "s3:AbortMultipartUpload"
            ],
        "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/*"
        }
    ]
}
```

Example permissions policy for native backup and restore with encryption support

If you want to encrypt your backup files, include an encryption key in your permissions policy. For more information about encryption keys, see Getting started in the *AWS Key Management Service Developer Guide*.

Note

You must use a symmetric encryption KMS key to encrypt your backups. Amazon RDS doesn't support asymmetric KMS keys. For more information, see Creating symmetric encryption KMS keys in the *AWS Key Management Service Developer Guide*.
The IAM role must also be a key user and key administrator for the KMS key, that is, it must be specified in the key policy. For more information, see Creating symmetric encryption KMS keys in the *AWS Key Management Service Developer Guide*.

```
{
    "Version": "2012-10-17",
    "Statement":
    [
        {
        "Effect": "Allow",
        "Action":
            [
                "kms:DescribeKey",
                "kms:GenerateDataKey",
                "kms:Encrypt",
                "kms:Decrypt"
            ],
        "Resource": "arn:aws:kms:region:account-id:key/key-id"
        },
        {
        "Effect": "Allow",
        "Action":
            [
                "s3:ListBucket",
                "s3:GetBucketLocation"
            ],
        "Resource": "arn:aws:s3:::amzn-s3-demo-bucket"
        },
        {
        "Effect": "Allow",
        "Action":
            [
                "s3:GetObjectAttributes",
                "s3:GetObject",
                "s3:PutObject",
```

```
                "s3:ListMultipartUploadParts",
                "s3:AbortMultipartUpload"
            ],
        "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/*"
        }
    ]
}
```

Using native backup and restore

After you have enabled and configured native backup and restore, you can start using it. First, you connect to your Microsoft SQL Server database, and then you call an Amazon RDS stored procedure to do the work. For instructions on connecting to your database, see Connecting to a DB instance running the Microsoft SQL Server database engine.

Some of the stored procedures require that you provide an Amazon Resource Name (ARN) to your Amazon S3 bucket and file. The format for your ARN is `arn:aws:s3:::bucket_name/file_name.extension`. Amazon S3 doesn't require an account number or AWS Region in ARNs.

If you also provide an optional KMS key, the format for the ARN of the key is `arn:aws:kms:region:account-id:key/key-id`. For more information, see Amazon resource names (ARNs) and AWS service namespaces. You must use a symmetric encryption KMS key to encrypt your backups. Amazon RDS doesn't support asymmetric KMS keys. For more information, see Creating symmetric encryption KMS keys in the *AWS Key Management Service Developer Guide*.

> **Note**
>
> Whether or not you use a KMS key, the native backup and restore tasks enable server-side Advanced Encryption Standard (AES) 256-bit encryption by default for files uploaded to S3.

For instructions on how to call each stored procedure, see the following topics:

- Backing up a database
- Restoring a database
- Restoring a log
- Finishing a database restore
- Working with partially restored databases
- Canceling a task
- Tracking the status of tasks

Backing up a database

To back up your database, use the `rds_backup_database` stored procedure.

> **Note**
>
> You can't back up a database during the maintenance window, or while Amazon RDS is taking a snapshot.

Usage

```
exec msdb.dbo.rds_backup_database
 @source_db_name='database_name',
 @s3_arn_to_backup_to='arn:aws:s3:::bucket_name/file_name.extension',
 [@kms_master_key_arn='arn:aws:kms:region:account-id:key/key-id'],
 [@overwrite_s3_backup_file=0|1],
 [@type='DIFFERENTIAL|FULL'],
 [@number_of_files=n];
```

The following parameters are required:

- `@source_db_name` – The name of the database to back up.
- `@s3_arn_to_backup_to` – The ARN indicating the Amazon S3 bucket to use for the backup, plus the name of the backup file.

  The file can have any extension, but `.bak` is usually used.

The following parameters are optional:

- `@kms_master_key_arn` – The ARN for the symmetric encryption KMS key to use to encrypt the item.
  - You can't use the default encryption key. If you use the default key, the database won't be backed up.
  - If you don't specify a KMS key identifier, the backup file won't be encrypted. For more information, see Encrypting Amazon RDS resources.
  - When you specify a KMS key, client-side encryption is used.
  - Amazon RDS doesn't support asymmetric KMS keys. For more information, see Creating symmetric encryption KMS keys in the *AWS Key Management Service Developer Guide*.
- `@overwrite_s3_backup_file` – A value that indicates whether to overwrite an existing backup file.

- `0` – Doesn't overwrite an existing file. This value is the default.

  Setting `@overwrite_s3_backup_file` to 0 returns an error if the file already exists.

- `1` – Overwrites an existing file that has the specified name, even if it isn't a backup file.

- `@type` – The type of backup.
  - `DIFFERENTIAL` – Makes a differential backup.
  - `FULL` – Makes a full backup. This value is the default.

  A differential backup is based on the last full backup. For differential backups to work, you can't take a snapshot between the last full backup and the differential backup. If you want a differential backup, but a snapshot exists, then do another full backup before proceeding with the differential backup.

  You can look for the last full backup or snapshot using the following example SQL query:

  ```
  select top 1
  database_name
  ,  backup_start_date
  ,  backup_finish_date
  from    msdb.dbo.backupset
  where   database_name='mydatabase'
  and     type = 'D'
  order by backup_start_date desc;
  ```

- `@number_of_files` – The number of files into which the backup will be divided (chunked). The maximum number is 10.
  - Multifile backup is supported for both full and differential backups.
  - If you enter a value of 1 or omit the parameter, a single backup file is created.

  Provide the prefix that the files have in common, then suffix that with an asterisk (`*`). The asterisk can be anywhere in the *`file_name`* part of the S3 ARN. The asterisk is replaced by a series of alphanumeric strings in the generated files, starting with `1-of-`*`number_of_files`*.

  For example, if the file names in the S3 ARN are `backup*.bak` and you set `@number_of_files=4`, the backup files generated are `backup1-of-4.bak`, `backup2-of-4.bak`, `backup3-of-4.bak`, and `backup4-of-4.bak`.

  - If any of the file names already exists, and `@overwrite_s3_backup_file` is 0, an error is returned.

- Multifile backups can only have one asterisk in the *file_name* part of the S3 ARN.
- Single-file backups can have any number of asterisks in the *file_name* part of the S3 ARN. Asterisks aren't removed from the generated file name.

Examples

Example of differential backup

```
exec msdb.dbo.rds_backup_database
@source_db_name='mydatabase',
@s3_arn_to_backup_to='arn:aws:s3:::mybucket/backup1.bak',
@overwrite_s3_backup_file=1,
@type='DIFFERENTIAL';
```

Example of full backup with encryption

```
exec msdb.dbo.rds_backup_database
@source_db_name='mydatabase',
@s3_arn_to_backup_to='arn:aws:s3:::mybucket/backup1.bak',
@kms_master_key_arn='arn:aws:kms:us-east-1:123456789012:key/AKIAIOSFODNN7EXAMPLE',
@overwrite_s3_backup_file=1,
@type='FULL';
```

Example of multifile backup

```
exec msdb.dbo.rds_backup_database
@source_db_name='mydatabase',
@s3_arn_to_backup_to='arn:aws:s3:::mybucket/backup*.bak',
@number_of_files=4;
```

Example of multifile differential backup

```
exec msdb.dbo.rds_backup_database
@source_db_name='mydatabase',
@s3_arn_to_backup_to='arn:aws:s3:::mybucket/backup*.bak',
@type='DIFFERENTIAL',
@number_of_files=4;
```

Example of multifile backup with encryption

```
exec msdb.dbo.rds_backup_database
@source_db_name='mydatabase',
@s3_arn_to_backup_to='arn:aws:s3:::mybucket/backup*.bak',
@kms_master_key_arn='arn:aws:kms:us-east-1:123456789012:key/AKIAIOSFODNN7EXAMPLE',
@number_of_files=4;
```

Example of multifile backup with S3 overwrite

```
exec msdb.dbo.rds_backup_database
@source_db_name='mydatabase',
@s3_arn_to_backup_to='arn:aws:s3:::mybucket/backup*.bak',
@overwrite_s3_backup_file=1,
@number_of_files=4;
```

Example of single-file backup with the @number_of_files parameter

This example generates a backup file named `backup*.bak`.

```
exec msdb.dbo.rds_backup_database
@source_db_name='mydatabase',
@s3_arn_to_backup_to='arn:aws:s3:::mybucket/backup*.bak',
@number_of_files=1;
```

Restoring a database

To restore your database, call the `rds_restore_database` stored procedure. Amazon RDS creates an initial snapshot of the database after the restore task is complete and the database is open.

Usage

```
exec msdb.dbo.rds_restore_database
 @restore_db_name='database_name',
 @s3_arn_to_restore_from='arn:aws:s3:::bucket_name/file_name.extension',
 @with_norecovery=0|1,
 [@kms_master_key_arn='arn:aws:kms:region:account-id:key/key-id'],
 [@type='DIFFERENTIAL|FULL'];
```

The following parameters are required:

- `@restore_db_name` – The name of the database to restore. Database names are unique. You can't restore a database with the same name as an existing database.
- `@s3_arn_to_restore_from` – The ARN indicating the Amazon S3 prefix and names of the backup files used to restore the database.
  - For a single-file backup, provide the entire file name.
  - For a multifile backup, provide the prefix that the files have in common, then suffix that with an asterisk (*).
  - If `@s3_arn_to_restore_from` is empty, the following error message is returned: S3 ARN prefix cannot be empty.

The following parameter is required for differential restores, but optional for full restores:

- `@with_norecovery` – The recovery clause to use for the restore operation.
  - Set it to `0` to restore with RECOVERY. In this case, the database is online after the restore.
  - Set it to `1` to restore with NORECOVERY. In this case, the database remains in the RESTORING state after restore task completion. With this approach, you can do later differential restores.
  - For DIFFERENTIAL restores, specify `0` or `1`.
  - For `FULL` restores, this value defaults to `0`.

The following parameters are optional:

- `@kms_master_key_arn` – If you encrypted the backup file, the KMS key to use to decrypt the file.

  When you specify a KMS key, client-side encryption is used.
- `@type` – The type of restore. Valid types are `DIFFERENTIAL` and `FULL`. The default value is `FULL`.

> **Note**
>
> For differential restores, either the database must be in the RESTORING state or a task must already exist that restores with NORECOVERY.
> You can't restore later differential backups while the database is online.
> You can't submit a restore task for a database that already has a pending restore task with RECOVERY.

Full restores with NORECOVERY and differential restores aren't supported on Multi-AZ instances.
Restoring a database on a Multi-AZ instance with read replicas is similar to restoring a database on a Multi-AZ instance. You don't have to take any additional actions to restore a database on a replica.

Examples

Example of single-file restore

```
exec msdb.dbo.rds_restore_database
@restore_db_name='mydatabase',
@s3_arn_to_restore_from='arn:aws:s3:::mybucket/backup1.bak';
```

Example of multifile restore

To avoid errors when restoring multiple files, make sure that all the backup files have the same prefix, and that no other files use that prefix.

```
exec msdb.dbo.rds_restore_database
@restore_db_name='mydatabase',
@s3_arn_to_restore_from='arn:aws:s3:::mybucket/backup*';
```

Example of full database restore with RECOVERY

The following three examples perform the same task, full restore with RECOVERY.

```
exec msdb.dbo.rds_restore_database
@restore_db_name='mydatabase',
@s3_arn_to_restore_from='arn:aws:s3:::mybucket/backup1.bak';
```

```
exec msdb.dbo.rds_restore_database
@restore_db_name='mydatabase',
@s3_arn_to_restore_from='arn:aws:s3:::mybucket/backup1.bak',
[@type='DIFFERENTIAL|FULL'];
```

```
exec msdb.dbo.rds_restore_database
@restore_db_name='mydatabase',
@s3_arn_to_restore_from='arn:aws:s3:::mybucket/backup1.bak',
```

```
@type='FULL',
@with_norecovery=0;
```

Example of full database restore with encryption

```
exec msdb.dbo.rds_restore_database
@restore_db_name='mydatabase',
@s3_arn_to_restore_from='arn:aws:s3:::mybucket/backup1.bak',
@kms_master_key_arn='arn:aws:kms:us-east-1:123456789012:key/AKIAIOSFODNN7EXAMPLE';
```

Example of full database restore with NORECOVERY

```
exec msdb.dbo.rds_restore_database
@restore_db_name='mydatabase',
@s3_arn_to_restore_from='arn:aws:s3:::mybucket/backup1.bak',
@type='FULL',
@with_norecovery=1;
```

Example of differential restore with NORECOVERY

```
exec msdb.dbo.rds_restore_database
@restore_db_name='mydatabase',
@s3_arn_to_restore_from='arn:aws:s3:::mybucket/backup1.bak',
@type='DIFFERENTIAL',
@with_norecovery=1;
```

Example of differential restore with RECOVERY

```
exec msdb.dbo.rds_restore_database
@restore_db_name='mydatabase',
@s3_arn_to_restore_from='arn:aws:s3:::mybucket/backup1.bak',
@type='DIFFERENTIAL',
@with_norecovery=0;
```

Restoring a log

To restore your log, call the `rds_restore_log` stored procedure.

Usage

```
exec msdb.dbo.rds_restore_log
```

```
@restore_db_name='database_name',
@s3_arn_to_restore_from='arn:aws:s3:::bucket_name/log_file_name.extension',
[@kms_master_key_arn='arn:aws:kms:region:account-id:key/key-id'],
[@with_norecovery=0|1],
[@stopat='datetime'];
```

The following parameters are required:

- `@restore_db_name` – The name of the database whose log to restore.
- `@s3_arn_to_restore_from` – The ARN indicating the Amazon S3 prefix and name of the log file used to restore the log. The file can have any extension, but `.trn` is usually used.

  If `@s3_arn_to_restore_from` is empty, the following error message is returned: S3 ARN prefix cannot be empty.

The following parameters are optional:

- `@kms_master_key_arn` – If you encrypted the log, the KMS key to use to decrypt the log.
- `@with_norecovery` – The recovery clause to use for the restore operation. This value defaults to 1.
  - Set it to `0` to restore with RECOVERY. In this case, the database is online after the restore. You can't restore further log backups while the database is online.
  - Set it to `1` to restore with NORECOVERY. In this case, the database remains in the RESTORING state after restore task completion. With this approach, you can do later log restores.
- `@stopat` – A value that specifies that the database is restored to its state at the date and time specified (in datetime format). Only transaction log records written before the specified date and time are applied to the database.

  If this parameter isn't specified (it is NULL), the complete log is restored.

> **Note**
>
> For log restores, either the database must be in a state of restoring or a task must already exist that restores with NORECOVERY.
> You can't restore log backups while the database is online.
> You can't submit a log restore task on a database that already has a pending restore task with RECOVERY.

Log restores aren't supported on Multi-AZ instances.

Examples

Example of log restore

```
exec msdb.dbo.rds_restore_log
@restore_db_name='mydatabase',
@s3_arn_to_restore_from='arn:aws:s3:::mybucket/mylog.trn';
```

Example of log restore with encryption

```
exec msdb.dbo.rds_restore_log
@restore_db_name='mydatabase',
@s3_arn_to_restore_from='arn:aws:s3:::mybucket/mylog.trn',
@kms_master_key_arn='arn:aws:kms:us-east-1:123456789012:key/AKIAIOSFODNN7EXAMPLE';
```

Example of log restore with NORECOVERY

The following two examples perform the same task, log restore with NORECOVERY.

```
exec msdb.dbo.rds_restore_log
@restore_db_name='mydatabase',
@s3_arn_to_restore_from='arn:aws:s3:::mybucket/mylog.trn',
@with_norecovery=1;
```

```
exec msdb.dbo.rds_restore_log
@restore_db_name='mydatabase',
@s3_arn_to_restore_from='arn:aws:s3:::mybucket/mylog.trn';
```

Example of log restore with RECOVERY

```
exec msdb.dbo.rds_restore_log
@restore_db_name='mydatabase',
@s3_arn_to_restore_from='arn:aws:s3:::mybucket/mylog.trn',
@with_norecovery=0;
```

Example of log restore with STOPAT clause

```
exec msdb.dbo.rds_restore_log
```

```
@restore_db_name='mydatabase',
@s3_arn_to_restore_from='arn:aws:s3:::mybucket/mylog.trn',
@with_norecovery=0,
@stopat='2019-12-01 03:57:09';
```

Finishing a database restore

If the last restore task on the database was performed using `@with_norecovery=1`, the database is now in the RESTORING state. Open this database for normal operation by using the `rds_finish_restore` stored procedure.

Usage

```
exec msdb.dbo.rds_finish_restore @db_name='database_name';
```

> **Note**
>
> To use this approach, the database must be in the RESTORING state without any pending restore tasks.
> The `rds_finish_restore` procedure isn't supported on Multi-AZ instances.
> To finish restoring the database, use the master login. Or use the user login that most recently restored the database or log with NORECOVERY.

Working with partially restored databases

Dropping a partially restored database

To drop a partially restored database (left in the RESTORING state), use the `rds_drop_database` stored procedure.

```
exec msdb.dbo.rds_drop_database @db_name='database_name';
```

> **Note**
>
> You can't submit a DROP database request for a database that already has a pending restore or finish restore task.
> To drop the database, use the master login. Or use the user login that most recently restored the database or log with NORECOVERY.

Snapshot restore and point-in-time recovery behavior for partially restored databases

Partially restored databases in the source instance (left in the RESTORING state) are dropped from the target instance during snapshot restore and point-in-time recovery.

Canceling a task

To cancel a backup or restore task, call the `rds_cancel_task` stored procedure.

> **Note**
>
> You can't cancel a FINISH_RESTORE task.

Usage

```
exec msdb.dbo.rds_cancel_task @task_id=ID_number;
```

The following parameter is required:

- `@task_id` – The ID of the task to cancel. You can get the task ID by calling `rds_task_status`.

Tracking the status of tasks

To track the status of your backup and restore tasks, call the `rds_task_status` stored procedure. If you don't provide any parameters, the stored procedure returns the status of all tasks. The status for tasks is updated approximately every two minutes. Task history is retained for 36 days.

Usage

```
exec msdb.dbo.rds_task_status
 [@db_name='database_name'],
 [@task_id=ID_number];
```

The following parameters are optional:

- `@db_name` – The name of the database to show the task status for.
- `@task_id` – The ID of the task to show the task status for.

Examples

Example of listing the status for a specific task

```
exec msdb.dbo.rds_task_status @task_id=5;
```

Example of listing the status for a specific database and task

```
exec msdb.dbo.rds_task_status
@db_name='my_database',
@task_id=5;
```

Example of listing all tasks and their statuses on a specific database

```
exec msdb.dbo.rds_task_status @db_name='my_database';
```

Example of listing all tasks and their statuses on the current instance

```
exec msdb.dbo.rds_task_status;
```

Response

The `rds_task_status` stored procedure returns the following columns.

Column	Description
`task_id`	The ID of the task.

`task_type`	Task type depending on the input parameters, as follows:
	• For backup tasks:
	  • BACKUP_DB – Full database backup
	  • BACKUP_DB_DIFFERENTIAL – Differential database backup
	• For restore tasks:
	  •

Column	Description
	RESTORE_DB – Full database restore with RECOVERY • RESTORE_DB_NORECOVERY – Full database restore with NORECOVERY • RESTORE_DB_DIFFERENTIAL – Differential database restore with R ECOVERY • RESTORE_DB_DIFFERENTIAL_NORECOVERY – Differential database restore with NORECOVERY • RESTORE_DB_LOG – Log restore with RECOVERY • RESTORE_DB_LOG_NORECOVERY – Log restore with NORECOVERY • For tasks that finish a restore: • FINISH_RESTORE – Finish restore and open database Amazon RDS creates an initial snapshot of the database after it is open on completion of the following restore tasks: • RESTORE_DB • RESTORE_DB_DIFFERENTIAL • RESTORE_DB_LOG • FINISH_RESTORE
`database_name`	The name of the database that the task is associated with.
`% complete`	The progress of the task as a percent value.

Column	Description
duration (mins)	The amount of time spent on the task, in minutes.
lifecycle	The status of the task. The possible statuses are the following: • CREATED – As soon as you call rds_backup_database or rds_restore_database, a task is created and the status is set to CREATED. • IN_PROGRESS – After a backup or restore task starts, the status is set to IN_PROGRESS. It can take up to 5 minutes for the status to change from CREATED to IN_PROGRESS. • SUCCESS – After a backup or restore task completes, the status is set to SUCCESS. • ERROR – If a backup or restore task fails, the status is set to ERROR. For more information about the error, see the task_info column. • CANCEL_REQUESTED – As soon as you call rds_cancel_task, the status of the task is set to CANCEL_REQUESTED. • CANCELLED – After a task is successfully canceled, the status of the task is set to CANCELLED.
task_info	Additional information about the task. If an error occurs while backing up or restoring a database, this column contains information about the error. For a list of possible errors, and mitigation strategies, see Troubleshooting.
last_updated	The date and time that the task status was last updated. The status is updated after every 5 percent of progress.
created_at	The date and time that the task was created.

Column	Description
S3_object_arn	The ARN indicating the Amazon S3 prefix and the name of the file that is being backed up or restored.
overwrite_s3_backup_file	The value of the @overwrite_s3_backup_file parameter specified when calling a backup task. For more information, see Backing up a database.
KMS_master_key_arn	The ARN for the KMS key used for encryption (for backup) and decryption (for restore).
filepath	Not applicable to native backup and restore tasks.
overwrite_file	Not applicable to native backup and restore tasks.

Compressing backup files

To save space in your Amazon S3 bucket, you can compress your backup files. For more information about compressing backup files, see Backup compression in the Microsoft documentation.

Compressing your backup files is supported for the following database editions:

- Microsoft SQL Server Enterprise Edition
- Microsoft SQL Server Standard Edition

To turn on compression for your backup files, run the following code:

```
exec rdsadmin.dbo.rds_set_configuration 'S3 backup compression', 'true';
```

To turn off compression for your backup files, run the following code:

```
exec rdsadmin.dbo.rds_set_configuration 'S3 backup compression', 'false';
```

Troubleshooting

The following are issues you might encounter when you use native backup and restore.

Issue	Troubleshooting suggestions
Database backup/restore option is not enabled yet or is in the process of being enabled. Please try again later.	Make sure that you have added the SQLSERVER_BACKUP_RESTORE option to the DB option group associated with your DB instance. For more information, see Adding the native backup and restore option.
Access Denied	The backup or restore process can't access the backup file. This is usually caused by issues like the following: • Referencing the incorrect bucket. Referencing the bucket using an incorrect format. Referencing a file name without using the ARN. • Incorrect permissions on the bucket file. For example, if it is created by a different account that is trying to access it now, add the correct permissions. • An IAM policy that is incorrect or incomplete. Your IAM role must include all the necessary elements, including, for example, the correct version. These are highlighted in Importing and exporting SQL Server databases using native backup and restore.
BACKUP DATABASE WITH COMPRESSION isn't supported on <edition_name> Edition	Compressing your backup files is only supported for Microsoft SQL Server Enterprise Edition and Standard Edition. For more information, see Compressing backup files.
Key <ARN> does not exist	You attempted to restore an encrypted backup, but didn't provide a valid encryption key. Check your encryption key and retry. For more information, see Restoring a database.
Please reissue task with correct type and overwrite property	If you attempt to back up your database and provide the name of a file that already exists, but set the overwrite property to false, the save operation fails. To fix this error, either provide the name

Issue	Troubleshooting suggestions
	of a file that doesn't already exist, or set the overwrite property to true. For more information, see Backing up a database. It's also possible that you intended to restore your database, but called the `rds_backup_database` stored procedure accidentally. In that case, call the `rds_restore_database` stored procedure instead. For more information, see Restoring a database. If you intended to restore your database and called the `rds_restore_database` stored procedure, make sure that you provided the name of a valid backup file. For more information, see Using native backup and restore.
Please specify a bucket that is in the same region as RDS instance	You can't back up to, or restore from, an Amazon S3 bucket in a different AWS Region from your Amazon RDS DB instance. You can use Amazon S3 replication to copy the backup file to the correct AWS Region. For more information, see Cross-Region replication in the Amazon S3 documentation.
The specified bucket does not exist	Verify that you have provided the correct ARN for your bucket and file, in the correct format. For more information, see Using native backup and restore.
User <ARN> is not authorized to perform <kms action> on resource <ARN>	You requested an encrypted operation, but didn't provide correct AWS KMS permissions. Verify that you have the correct permissions, or add them. For more information, see Setting up for native backup and restore.

Issue	Troubleshooting suggestions
The Restore task is unable to restore from more than 10 backup file(s). Please reduce the number of files matched and try again.	Reduce the number of files that you're trying to restore from. You can make each individual file larger if necessary.
Database '*database_name* ' already exists. Two databases that differ only by case or accent are not allowed. Choose a different database name.	You can't restore a database with the same name as an existing database. Database names are unique.

Importing and exporting SQL Server data using other methods

Following, you can find information about using snapshots to import your Microsoft SQL Server data to Amazon RDS. You can also find information about using snapshots to export your data from an RDS DB instance running SQL Server.

If your scenario supports it, it's easier to move data in and out of Amazon RDS by using the native backup and restore functionality. For more information, see Importing and exporting SQL Server databases using native backup and restore.

> **Note**
>
> Amazon RDS for Microsoft SQL Server doesn't support importing data into the `msdb` database.

Importing data into RDS for SQL Server by using a snapshot

To import data into a SQL Server DB instance by using a snapshot

1. Create a DB instance. For more information, see Creating an Amazon RDS DB instance.
2. Stop applications from accessing the destination DB instance.

   If you prevent access to your DB instance while you are importing data, data transfer is faster. Additionally, you don't need to worry about conflicts while data is being loaded if other applications cannot write to the DB instance at the same time. If something goes wrong and you have to roll back to an earlier database snapshot, the only changes that you lose are the imported data. You can import this data again after you resolve the issue.

   For information about controlling access to your DB instance, see Controlling access with security groups.
3. Create a snapshot of the target database.

   If the target database is already populated with data, we recommend that you take a snapshot of the database before you import the data. If something goes wrong with the data import or you want to discard the changes, you can restore the database to its previous state by using the snapshot. For information about database snapshots, see Creating a DB snapshot for a Single-AZ DB instance.

> **Note**
>
> When you take a database snapshot, I/O operations to the database are suspended for a moment (milliseconds) while the backup is in progress.

4. Disable automated backups on the target database.

   Disabling automated backups on the target DB instance improves performance while you are importing your data because Amazon RDS doesn't log transactions when automatic backups are disabled. However, there are some things to consider. Automated backups are required to perform a point-in-time recovery. Thus, you can't restore the database to a specific point in time while you are importing data. Additionally, any automated backups that were created on the DB instance are erased unless you choose to retain them.

   Choosing to retain the automated backups can help protect you against accidental deletion of data. Amazon RDS also saves the database instance properties along with each automated backup to make it easy to recover. Using this option lets you can restore a deleted database instance to a specified point in time within the backup retention period even after deleting it. Automated backups are automatically deleted at the end of the specified backup window, just as they are for an active database instance.

   You can also use previous snapshots to recover the database, and any snapshots that you have taken remain available. For information about automated backups, see Introduction to backups.

5. Disable foreign key constraints, if applicable.

   If you need to disable foreign key constraints, you can do so with the following script.

```
--Disable foreign keys on all tables
    DECLARE @table_name SYSNAME;
    DECLARE @cmd NVARCHAR(MAX);
    DECLARE table_cursor CURSOR FOR SELECT name FROM sys.tables;

    OPEN table_cursor;
    FETCH NEXT FROM table_cursor INTO @table_name;

    WHILE @@FETCH_STATUS = 0 BEGIN
      SELECT @cmd = 'ALTER TABLE '+QUOTENAME(@table_name)+' NOCHECK CONSTRAINT
 ALL';
```

```
      EXEC (@cmd);
      FETCH NEXT FROM table_cursor INTO @table_name;
    END

    CLOSE table_cursor;
    DEALLOCATE table_cursor;

    GO
```

6. Drop indexes, if applicable.
7. Disable triggers, if applicable.

   If you need to disable triggers, you can do so with the following script.

```
--Disable triggers on all tables
    DECLARE @enable BIT = 0;
    DECLARE @trigger SYSNAME;
    DECLARE @table SYSNAME;
    DECLARE @cmd NVARCHAR(MAX);
    DECLARE trigger_cursor CURSOR FOR SELECT trigger_object.name trigger_name,
     table_object.name table_name
    FROM sysobjects trigger_object
    JOIN sysobjects table_object ON trigger_object.parent_obj = table_object.id
    WHERE trigger_object.type = 'TR';

    OPEN trigger_cursor;
    FETCH NEXT FROM trigger_cursor INTO @trigger, @table;

    WHILE @@FETCH_STATUS = 0 BEGIN
      IF @enable = 1
         SET @cmd = 'ENABLE ';
      ELSE
         SET @cmd = 'DISABLE ';

      SET @cmd = @cmd + ' TRIGGER dbo.'+QUOTENAME(@trigger)+' ON
 dbo.'+QUOTENAME(@table)+' ';
      EXEC (@cmd);
      FETCH NEXT FROM trigger_cursor INTO @trigger, @table;
    END

    CLOSE trigger_cursor;
    DEALLOCATE trigger_cursor;
```

```
GO
```

8. Query the source SQL Server instance for any logins that you want to import to the destination DB instance.

   SQL Server stores logins and passwords in the `master` database. Because Amazon RDS doesn't grant access to the `master` database, you cannot directly import logins and passwords into your destination DB instance. Instead, you must query the `master` database on the source SQL Server instance to generate a data definition language (DDL) file. This file should include all logins and passwords that you want to add to the destination DB instance. This file also should include role memberships and permissions that you want to transfer.

   For information about querying the `master` database, see Transfer logins and passwords between instances of SQL Server in the Microsoft Knowledge Base.

   The output of the script is another script that you can run on the destination DB instance. The script in the Knowledge Base article has the following code:

   ```
   p.type IN
   ```

   Every place `p.type` appears, use the following code instead:

   ```
   p.type = 'S'
   ```

9. Import the data using the method in Import the data.
10. Grant applications access to the target DB instance.

    When your data import is complete, you can grant access to the DB instance to those applications that you blocked during the import. For information about controlling access to your DB instance, see Controlling access with security groups.

11. Enable automated backups on the target DB instance.

    For information about automated backups, see Introduction to backups.

12. Enable foreign key constraints.

    If you disabled foreign key constraints earlier, you can now enable them with the following script.

    ```
    --Enable foreign keys on all tables
    ```

```
    DECLARE @table_name SYSNAME;
    DECLARE @cmd NVARCHAR(MAX);
    DECLARE table_cursor CURSOR FOR SELECT name FROM sys.tables;

    OPEN table_cursor;
    FETCH NEXT FROM table_cursor INTO @table_name;

    WHILE @@FETCH_STATUS = 0 BEGIN
      SELECT @cmd = 'ALTER TABLE '+QUOTENAME(@table_name)+' CHECK CONSTRAINT ALL';
      EXEC (@cmd);
      FETCH NEXT FROM table_cursor INTO @table_name;
    END

    CLOSE table_cursor;
    DEALLOCATE table_cursor;
```

13. Enable indexes, if applicable.
14. Enable triggers, if applicable.

    If you disabled triggers earlier, you can now enable them with the following script.

```
--Enable triggers on all tables
    DECLARE @enable BIT = 1;
    DECLARE @trigger SYSNAME;
    DECLARE @table SYSNAME;
    DECLARE @cmd NVARCHAR(MAX);
    DECLARE trigger_cursor CURSOR FOR SELECT trigger_object.name trigger_name,
     table_object.name table_name
    FROM sysobjects trigger_object
    JOIN sysobjects table_object ON trigger_object.parent_obj = table_object.id
    WHERE trigger_object.type = 'TR';

    OPEN trigger_cursor;
    FETCH NEXT FROM trigger_cursor INTO @trigger, @table;

    WHILE @@FETCH_STATUS = 0 BEGIN
      IF @enable = 1
         SET @cmd = 'ENABLE ';
      ELSE
         SET @cmd = 'DISABLE ';

      SET @cmd = @cmd + ' TRIGGER dbo.'+QUOTENAME(@trigger)+' ON
 dbo.'+QUOTENAME(@table)+' ';
```

```
    EXEC (@cmd);
    FETCH NEXT FROM trigger_cursor INTO @trigger, @table;
END

CLOSE trigger_cursor;
DEALLOCATE trigger_cursor;
```

Import the data

Microsoft SQL Server Management Studio is a graphical SQL Server client that is included in all Microsoft SQL Server editions except the Express Edition. SQL Server Management Studio Express is available from Microsoft as a free download. To find this download, see the Microsoft website.

> **Note**
>
> SQL Server Management Studio is available only as a Windows-based application.

SQL Server Management Studio includes the following tools, which are useful in importing data to a SQL Server DB instance:

- Generate and Publish Scripts Wizard
- Import and Export Wizard
- Bulk copy

Generate and Publish Scripts Wizard

The Generate and Publish Scripts Wizard creates a script that contains the schema of a database, the data itself, or both. You can generate a script for a database in your local SQL Server deployment. You can then run the script to transfer the information that it contains to an Amazon RDS DB instance.

> **Note**
>
> For databases of 1 GiB or larger, it's more efficient to script only the database schema. You then use the Import and Export Wizard or the bulk copy feature of SQL Server to transfer the data.

For detailed information about the Generate and Publish Scripts Wizard, see the Microsoft SQL Server documentation.

In the wizard, pay particular attention to the advanced options on the **Set Scripting Options** page to ensure that everything you want your script to include is selected. For example, by default, database triggers are not included in the script.

When the script is generated and saved, you can use SQL Server Management Studio to connect to your DB instance and then run the script.

Import and Export Wizard

The Import and Export Wizard creates a special Integration Services package, which you can use to copy data from your local SQL Server database to the destination DB instance. The wizard can filter which tables and even which tuples within a table are copied to the destination DB instance.

> **Note**
>
> The Import and Export Wizard works well for large datasets, but it might not be the fastest way to remotely export data from your local deployment. For an even faster way, consider the SQL Server bulk copy feature.

For detailed information about the Import and Export Wizard, see the Microsoft SQL Server documentation.

In the wizard, on the **Choose a Destination** page, do the following:

- For **Server Name**, type the name of the endpoint for your DB instance.
- For the server authentication mode, choose **Use SQL Server Authentication**.
- For **User name** and **Password**, type the credentials for the master user that you created for the DB instance.

Bulk copy

The SQL Server bulk copy feature is an efficient means of copying data from a source database to your DB instance. Bulk copy writes the data that you specify to a data file, such as an ASCII file. You can then run bulk copy again to write the contents of the file to the destination DB instance.

This section uses the **bcp** utility, which is included with all editions of SQL Server. For detailed information about bulk import and export operations, see the Microsoft SQL Server documentation.

> **Note**
>
> Before you use bulk copy, you must first import your database schema to the destination DB instance. The Generate and Publish Scripts Wizard, described earlier in this topic, is an excellent tool for this purpose.

The following command connects to the local SQL Server instance. It generates a tab-delimited file of a specified table in the C:\ root directory of your existing SQL Server deployment. The table is specified by its fully qualified name, and the text file has the same name as the table that is being copied.

```
bcp dbname.schema_name.table_name out C:\table_name.txt -n -S localhost -U username -
P password -b 10000
```

The preceding code includes the following options:

- `-n` specifies that the bulk copy uses the native data types of the data to be copied.
- `-S` specifies the SQL Server instance that the *bcp* utility connects to.
- `-U` specifies the user name of the account to log in to the SQL Server instance.
- `-P` specifies the password for the user specified by `-U`.
- `-b` specifies the number of rows per batch of imported data.

> **Note**
>
> There might be other parameters that are important to your import situation. For example, you might need the `-E` parameter that pertains to identity values. For more information; see the full description of the command line syntax for the **bcp** utility in the Microsoft SQL Server documentation.

For example, suppose that a database named `store` that uses the default schema, dbo, contains a table named `customers`. The user account `admin`, with the password `insecure`, copies 10,000 rows of the `customers` table to a file named `customers.txt`.

```
bcp store.dbo.customers out C:\customers.txt -n -S localhost -U admin -P insecure -b
 10000
```

After you generate the data file, you can upload the data to your DB instance by using a similar command. Beforehand, create the database and schema on the target DB instance. Then use the `in` argument to specify an input file instead of `out` to specify an output file. Instead of using localhost to specify the local SQL Server instance, specify the endpoint of your DB instance. If you use a port other than 1433, specify that too. The user name and password are the master user and password for your DB instance. The syntax is as follows.

```
bcp dbname.schema_name.table_name
     in C:\table_name.txt -n -S endpoint,port -U master_user_name -
P master_user_password -b 10000
```

To continue the previous example, suppose that the master user name is `admin`, and the password is `insecure`. The endpoint for the DB instance is `rds.ckz2kqd4qsn1.us-east-1.rds.amazonaws.com`, and you use port 4080. The command is as follows.

```
bcp store.dbo.customers in C:\customers.txt -n -S rds.ckz2kqd4qsn1.us-
east-1.rds.amazonaws.com,4080 -U admin -P insecure -b 10000
```

> **Note**
>
> Specify a password other than the prompt shown here as a security best practice.

Exporting data from RDS for SQL Server

You can choose one of the following options to export data from an RDS for SQL Server DB instance:

- **Native database backup using a full backup file (.bak)** – Using .bak files to backup databases is heavily optimized, and is usually the fastest way to export data. For more information, see Importing and exporting SQL Server databases using native backup and restore.

- **SQL Server Import and Export Wizard** – For more information, see SQL Server Import and Export Wizard.
- **SQL Server Generate and Publish Scripts Wizard and bcp utility** – For more information, see SQL Server Generate and Publish Scripts Wizard and bcp utility.

SQL Server Import and Export Wizard

You can use the SQL Server Import and Export Wizard to copy one or more tables, views, or queries from your RDS for SQL Server DB instance to another data store. This choice is best if the target data store is not SQL Server. For more information, see SQL Server Import and Export Wizard in the SQL Server documentation.

The SQL Server Import and Export Wizard is available as part of Microsoft SQL Server Management Studio. This graphical SQL Server client is included in all Microsoft SQL Server editions except the Express Edition. SQL Server Management Studio is available only as a Windows-based application. SQL Server Management Studio Express is available from Microsoft as a free download. To find this download, see the Microsoft website.

To use the SQL Server Import and Export Wizard to export data

1. In SQL Server Management Studio, connect to your RDS for SQL Server DB instance. For details on how to do this, see Connecting to a DB instance running the Microsoft SQL Server database engine.
2. In **Object Explorer**, expand **Databases**, open the context (right-click) menu for the source database, choose **Tasks**, and then choose **Export Data**. The wizard appears.
3. On the **Choose a Data Source** page, do the following:
    a. For **Data source**, choose **`SQL Server Native Client 11.0`**.
    b. Verify that the **Server name** box shows the endpoint of your RDS for SQL Server DB instance.
    c. Select **Use SQL Server Authentication**. For **User name** and **Password**, type the master user name and password of your DB instance.
    d. Verify that the **Database** box shows the database from which you want to export data.
    e. Choose **Next**.
4. On the **Choose a Destination** page, do the following:
    a. For **Destination**, choose **`SQL Server Native Client 11.0`**.

> **Note**
>
> Other target data sources are available. These include .NET Framework data providers, OLE DB providers, SQL Server Native Client providers, ADO.NET providers, Microsoft Office Excel, Microsoft Office Access, and the Flat File source. If you choose to target one of these data sources, skip the remainder of step 4. For details on the connection information to provide next, see Choose a destination in the SQL Server documentation.

b. For **Server name**, type the server name of the target SQL Server DB instance.

c. Choose the appropriate authentication type. Type a user name and password if necessary.

d. For **Database**, choose the name of the target database, or choose **New** to create a new database to contain the exported data.

If you choose **New**, see Create database in the SQL Server documentation for details on the database information to provide.

e. Choose **Next**.

5. On the **Table Copy or Query** page, choose **Copy data from one or more tables or views** or **Write a query to specify the data to transfer**. Choose **Next**.
6. If you chose **Write a query to specify the data to transfer**, you see the **Provide a Source Query** page. Type or paste in a SQL query, and then choose **Parse** to verify it. Once the query validates, choose **Next**.
7. On the **Select Source Tables and Views** page, do the following:

a. Select the tables and views that you want to export, or verify that the query you provided is selected.

b. Choose **Edit Mappings** and specify database and column mapping information. For more information, see Column mappings in the SQL Server documentation.

c. (Optional) To see a preview of data to be exported, select the table, view, or query, and then choose **Preview**.

d. Choose **Next**.

8. On the **Run Package** page, verify that **Run immediately** is selected. Choose **Next**.
9. On the **Complete the Wizard** page, verify that the data export details are as you expect. Choose **Finish**.

10. On the **The execution was successful** page, choose **Close**.

SQL Server Generate and Publish Scripts Wizard and bcp utility

You can use the SQL Server Generate and Publish Scripts Wizard to create scripts for an entire database or just selected objects. You can run these scripts on a target SQL Server DB instance to recreate the scripted objects. You can then use the bcp utility to bulk export the data for the selected objects to the target DB instance. This choice is best if you want to move a whole database (including objects other than tables) or large quantities of data between two SQL Server DB instances. For a full description of the bcp command-line syntax, see bcp utility in the Microsoft SQL Server documentation.

The SQL Server Generate and Publish Scripts Wizard is available as part of Microsoft SQL Server Management Studio. This graphical SQL Server client is included in all Microsoft SQL Server editions except the Express Edition. SQL Server Management Studio is available only as a Windows-based application. SQL Server Management Studio Express is available from Microsoft as a free download.

To use the SQL Server Generate and Publish Scripts Wizard and the bcp utility to export data

1. In SQL Server Management Studio, connect to your RDS for SQL Server DB instance. For details on how to do this, see Connecting to a DB instance running the Microsoft SQL Server database engine.
2. In **Object Explorer**, expand the **Databases** node and select the database you want to script.
3. Follow the instructions in Generate and publish scripts Wizard in the SQL Server documentation to create a script file.
4. In SQL Server Management Studio, connect to your target SQL Server DB instance.
5. With the target SQL Server DB instance selected in **Object Explorer**, choose **Open** on the **File** menu, choose **File**, and then open the script file.
6. If you have scripted the entire database, review the CREATE DATABASE statement in the script. Make sure that the database is being created in the location and with the parameters that you want. For more information, see CREATE DATABASE in the SQL Server documentation.
7. If you are creating database users in the script, check to see if server logins exist on the target DB instance for those users. If not, create logins for those users; the scripted commands to create the database users fail otherwise. For more information, see Create a login in the SQL Server documentation.

8. Choose **!Execute** on the SQL Editor menu to run the script file and create the database objects. When the script finishes, verify that all database objects exist as expected.
9. Use the bcp utility to export data from the RDS for SQL Server DB instance into files. Open a command prompt and type the following command.

   ```
   bcp database_name.schema_name.table_name out data_file -n -S aws_rds_sql_endpoint -
   U username -P password
   ```

   The preceding code includes the following options:

   - *table_name* is the name of one of the tables that you've recreated in the target database and now want to populate with data.
   - *data_file* is the full path and name of the data file to be created.
   - `-n` specifies that the bulk copy uses the native data types of the data to be copied.
   - `-S` specifies the SQL Server DB instance to export from.
   - `-U` specifies the user name to use when connecting to the SQL Server DB instance.
   - `-P` specifies the password for the user specified by `-U`.

   The following shows an example command.

   ```
   bcp world.dbo.city out C:\Users\JohnDoe\city.dat -n -S sql-jdoe.1234abcd.us-
   west-2.rds.amazonaws.com,1433 -U JohnDoe -P ClearTextPassword
   ```

   Repeat this step until you have data files for all of the tables you want to export.
10. Prepare your target DB instance for bulk import of data by following the instructions at Basic guidelines for bulk importing data in the SQL Server documentation.
11. Decide on a bulk import method to use after considering performance and other concerns discussed in About bulk import and bulk export operations in the SQL Server documentation.
12. Bulk import the data from the data files that you created using the bcp utility. To do so, follow the instructions at either Import and export bulk data by using the bcp utility or Import bulk data by using BULK INSERT or OPENROWSET(BULK...) in the SQL Server documentation, depending on what you decided in step 11.

Working with read replicas for Microsoft SQL Server in Amazon RDS

You usually use read replicas to configure replication between Amazon RDS DB instances. For general information about read replicas, see Working with DB instance read replicas.

In this section, you can find specific information about working with read replicas on Amazon RDS for SQL Server.

- Synchronizing database users and objects with a SQL Server read replica
- Troubleshooting a SQL Server read replica problem

Configuring read replicas for SQL Server

Before a DB instance can serve as a source instance for replication, you must enable automatic backups on the source DB instance. To do so, you set the backup retention period to a value other than 0. Setting this type of deployment also enforces that automatic backups are enabled.

Creating a SQL Server read replica doesn't require an outage for the primary DB instance. Amazon RDS sets the necessary parameters and permissions for the source DB instance and the read replica without any service interruption. A snapshot is taken of the source DB instance, and this snapshot becomes the read replica. No outage occurs when you delete a read replica.

You can create up to 15 read replicas from one source DB instance. For replication to operate effectively, we recommend that you configure each read replica with the same amount of compute and storage resources as the source DB instance. If you scale the source DB instance, also scale the read replicas.

The SQL Server DB engine version of the source DB instance and all of its read replicas must be the same. Amazon RDS upgrades the primary immediately after upgrading the read replicas, regardless of the maintenance window. For more information about upgrading the DB engine version, see Upgrading the Microsoft SQL Server DB engine.

For a read replica to receive and apply changes from the source, it should have sufficient compute and storage resources. If a read replica reaches compute, network, or storage resource capacity, the read replica stops receiving or applying changes from its source. You can modify the storage and CPU resources of a read replica independently from its source and other read replicas.

For more information about how to create a read replica, see Creating a read replica.

Read replica limitations with SQL Server

The following limitations apply to SQL Server read replicas on Amazon RDS:

- Read replicas are only available on the SQL Server Enterprise Edition (EE) engine.
- Read replicas are available for SQL Server versions 2016–2022.
- You can create up to 15 read replicas from one source DB instance. Replication might lag when your source DB instance has more than 5 read replicas.
- Read replicas are only available for DB instances running on DB instance classes with four or more vCPUs.
- A read replica supports up to 100 databases depending on the instance class type and availability mode. You must create databases on the source DB instance to automatically replicate them to the read replicas. You can't choose individual databases to replicate. For more information, see Limitations for Microsoft SQL Server DB instances.
- You can't drop a database from a read replica. To drop a database, drop it from the source DB instance with the `rds_drop_database` stored procedure. For more information, see Dropping a Microsoft SQL Server database.
- If the source DB instance uses Transparent Data Encryption (TDE) to encrypt data, the read replica also automatically configures TDE.

  If the source DB instance uses a KMS key to encrypt data, read replicas in the same region use the same KMS key. For cross-region read replicas, you must specify a KMS key from the read replica's region when creating the read replica. You can't change the KMS key for a read replica.
- Read replicas have the same time zone and collation as the source DB instance, regardless of Availabilty Zone they're created in.
- The following aren't supported on Amazon RDS for SQL Server:
  - Backup retention of read replicas
  - Point-in-time recovery from read replicas
  - Manual snapshots of read replicas
  - Multi-AZ read replicas
  - Creating read replicas of read replicas
  - Synchronization of user logins to read replicas

- Amazon RDS for SQL Server doesn't intervene to mitigate high replica lag between a source DB instance and its read replicas. Make sure that the source DB instance and its read replicas are sized properly, in terms of computing power and storage, to suit their operational load.
- You can replicate between the AWS GovCloud (US-East) and AWS GovCloud (US-West) Regions, but not into or out of AWS GovCloud (US) Regions.

Option considerations for RDS for SQL Server replicas

Before you create an RDS for SQL Server replica, consider the following requirements, restrictions, and recommendations:

- If your SQL Server replica is in the same Region as its source DB instance, make sure that it belongs to the same option group as the source DB instance. Modifications to the source option group or source option group membership propagate to replicas. These changes are applied to the replicas immediately after they are applied to the source DB instance, regardless of the replica's maintenance window.

  For more information about option groups, see Working with option groups.
- When you create a SQL Server cross-Region replica, Amazon RDS creates a dedicated option group for it.

  You can't remove an SQL Server cross-Region replica from its dedicated option group. No other DB instances can use the dedicated option group for a SQL Server cross-Region replica.

  The following options are replicated options. To add replicated options to a SQL Server cross-Region replica, add it to the source DB instance's option group. The option is also installed on all of the source DB instance's replicas.

  - `TDE`

  The following options are non-replicated options. You can add or remove non-replicated options from a dedicated option group.

  - `MSDTC`
  - `SQLSERVER_AUDIT`
  - To enable the `SQLSERVER_AUDIT` option on cross-Region read replica, add the `SQLSERVER_AUDIT` option on the dedicated option group on the cross-region read replica and the source instance's option group. By adding the `SQLSERVER_AUDIT` option on the source instance of SQL Server cross-Region read replica, you can create Server Level Audit Object

and Server Level Audit Specifications on each of the cross-Region read replicas of the source instance. To allow the cross-Region read replicas access to upload the completed audit logs to an Amazon S3 bucket, add the `SQLSERVER_AUDIT` option to the dedicated option group and configure the option settings. The Amazon S3 bucket that you use as a target for audit files must be in the same Region as the cross-Region read replica. You can modify the option setting of the `SQLSERVER_AUDIT` option for each cross region read replica independently so each can access an Amazon S3 bucket in their respective Region.

The following options are not supported for cross-Region read replicas.

- `SSRS`
- `SSAS`
- `SSIS`

The following options are partially supported for cross-Region read replicas.

- `SQLSERVER_BACKUP_RESTORE`
- The source DB instance of a SQL Server cross-Region replica can have the `SQLSERVER_BACKUP_RESTORE` option, but you can not perform native restores on the source DB instance until you delete all its cross-Region replicas. Any existing native restore tasks will be cancelled during the creation of a cross-Region replica. You can't add the `SQLSERVER_BACKUP_RESTORE` option to a dedicated option group.

  For more information on native backup and restore, see Importing and exporting SQL Server databases using native backup and restore

When you promote a SQL Server cross-Region read replica, the promoted replica behaves the same as other SQL Server DB instances, including the management of its options. For more information about option groups, see Working with option groups.

Synchronizing database users and objects with a SQL Server read replica

Any logins, custom server roles, SQL agent jobs, or other server-level objects that exist in the primary DB instance at the time of creating a read replica are expected to be present in the newly created read replica. However, any server-level objects that are created in the primary DB instance after the creation of the read replica will not be automatically replicated, and you must create them manually in the read replica.

The database users are automatically replicated from the primary DB instance to the read replica. As the read replica database is in read-only mode, the security identifier (SID) of the database user cannot be updated in the database. Therefore, when creating SQL logins in the read replica, it's essential to ensure that the SID of that login matches the SID of the corresponding SQL login in the primary DB instance. If you don't synchronize the SIDs of the SQL logins, they won't be able to access the database in the read replica. Windows Active Directory (AD) Authenticated Logins do not experience this issue because the SQL Server obtains the SID from the Active Directory.

To synchronize a SQL login from the primary DB instance to the read replica

1. Connect to the primary DB instance.
2. Create a new SQL login in the primary DB instance.

```
USE [master]
GO
CREATE LOGIN TestLogin1
WITH PASSWORD = 'REPLACE WITH PASSWORD';
```

> **Note**
>
> Specify a password other than the prompt shown here as a security best practice.

3. Create a new database user for the SQL login in the database.

```
USE [REPLACE WITH YOUR DB NAME]
GO
CREATE USER TestLogin1 FOR LOGIN TestLogin1;
GO
```

4. Check the SID of the newly created SQL login in primary DB instance.

```
SELECT name, sid FROM sys.server_principals WHERE name =  TestLogin1;
```

5. Connect to the read replica. Create the new SQL login.

```
CREATE LOGIN TestLogin1 WITH PASSWORD = 'REPLACE WITH PASSWORD', SID=[REPLACE WITH
 sid FROM STEP #4];
```

Alternately, if you have access to the read replica database, you can fix the orphaned user as follows:

1. Connect to the read replica.
2. Identify the orphaned users in the database.

```
USE [REPLACE WITH YOUR DB NAME]
GO
EXEC sp_change_users_login 'Report';
GO
```

3. Create a new SQL login for the orphaned database user.

```
CREATE LOGIN TestLogin1 WITH PASSWORD = 'REPLACE WITH PASSWORD', SID=[REPLACE WITH
 sid FROM STEP #2];
```

Example:

```
CREATE LOGIN TestLogin1 WITH PASSWORD = 'TestPa$$word#1',
 SID=[0x1A2B3C4D5E6F7G8H9I0J1K2L3M4N5O6P];
```

> **Note**
>
> Specify a password other than the prompt shown here as a security best practice.

Troubleshooting a SQL Server read replica problem

You can monitor replication lag in Amazon CloudWatch by viewing the Amazon RDS `ReplicaLag` metric. For information about replication lag time, see Monitoring read replication.

If replication lag is too long, you can use the following query to get information about the lag.

```
SELECT AR.replica_server_name
     , DB_NAME (ARS.database_id) 'database_name'
     , AR.availability_mode_desc
     , ARS.synchronization_health_desc
     , ARS.last_hardened_lsn
     , ARS.last_redone_lsn
     , ARS.secondary_lag_seconds
```

```
FROM sys.dm_hadr_database_replica_states ARS
INNER JOIN sys.availability_replicas AR ON ARS.replica_id = AR.replica_id
--WHERE DB_NAME(ARS.database_id) = 'database_name'
ORDER BY AR.replica_server_name;
```

Multi-AZ deployments for Amazon RDS for Microsoft SQL Server

Multi-AZ deployments provide increased availability, data durability, and fault tolerance for DB instances. In the event of planned database maintenance or unplanned service disruption, Amazon RDS automatically fails over to the up-to-date secondary DB instance. This functionality lets database operations resume quickly without manual intervention. The primary and standby instances use the same endpoint, whose physical network address transitions to the secondary replica as part of the failover process. You don't have to reconfigure your application when a failover occurs.

Amazon RDS supports Multi-AZ deployments for Microsoft SQL Server by using either SQL Server Database Mirroring (DBM) or Always On Availability Groups (AGs). Amazon RDS monitors and maintains the health of your Multi-AZ deployment. If problems occur, RDS automatically repairs unhealthy DB instances, reestablishes synchronization, and initiates failovers. Failover only occurs if the standby and primary are fully in sync. You don't have to manage anything.

When you set up SQL Server Multi-AZ, RDS automatically configures all databases on the instance to use DBM or AGs. Amazon RDS handles the primary, the witness, and the secondary DB instance for you. Because configuration is automatic, RDS selects DBM or Always On AGs based on the version of SQL Server that you deploy.

Amazon RDS supports Multi-AZ with Always On AGs for the following SQL Server versions and editions:

- SQL Server 2022:
  - Standard Edition
  - Enterprise Edition
- SQL Server 2019:
  - Standard Edition 15.00.4073.23 and higher
  - Enterprise Edition
- SQL Server 2017:
  - Standard Edition 14.00.3401.7 and higher
  - Enterprise Edition 14.00.3049.1 and higher
- SQL Server 2016: Enterprise Edition 13.00.5216.0 and higher

Amazon RDS supports Multi-AZ with DBM for the following SQL Server versions and editions, except for the versions noted previously:

- SQL Server 2019: Standard Edition 15.00.4043.16
- SQL Server 2017: Standard and Enterprise Editions
- SQL Server 2016: Standard and Enterprise Editions

You can use the following SQL query to determine whether your SQL Server DB instance is Single-AZ, Multi-AZ with DBM, or Multi-AZ with Always On AGs.

```
SELECT CASE WHEN dm.mirroring_state_desc IS NOT NULL THEN 'Multi-AZ (Mirroring)'
    WHEN dhdrs.group_database_id IS NOT NULL THEN 'Multi-AZ (AlwaysOn)'
    ELSE 'Single-AZ'
    END 'high_availability'
FROM sys.databases sd
LEFT JOIN sys.database_mirroring dm ON sd.database_id = dm.database_id
LEFT JOIN sys.dm_hadr_database_replica_states dhdrs ON sd.database_id =
 dhdrs.database_id AND dhdrs.is_local = 1
WHERE DB_NAME(sd.database_id) = 'rdsadmin';
```

The output resembles the following:

```
high_availability
Multi-AZ (AlwaysOn)
```

Adding Multi-AZ to a Microsoft SQL Server DB instance

When you create a new SQL Server DB instance using the AWS Management Console, you can add Multi-AZ with Database Mirroring (DBM) or Always On AGs. You do so by choosing **Yes (Mirroring / Always On)** from **Multi-AZ deployment**. For more information, see Creating an Amazon RDS DB instance.

When you modify an existing SQL Server DB instance using the console, you can add Multi-AZ with DBM or AGs by choosing **Yes (Mirroring / Always On)** from **Multi-AZ deployment** on the **Modify DB instance** page. For more information, see Modifying an Amazon RDS DB instance.

> **Note**
>
> If your DB instance is running Database Mirroring (DBM)—not Always On Availability Groups (AGs)—you might need to disable in-memory optimization before you add Multi-AZ. Disable in-memory optimization with DBM before you add Multi-AZ if your DB instance runs SQL Server 2016 or 2017 Enterprise Edition and has in-memory optimization enabled. If your DB instance is running AGs, it doesn't require this step.

Removing Multi-AZ from a Microsoft SQL Server DB instance

When you modify an existing SQL Server DB instance using the AWS Management Console, you can remove Multi-AZ with DBM or AGs. You can do this by choosing **No (Mirroring / Always On)** from **Multi-AZ deployment** on the **Modify DB instance** page. For more information, see Modifying an Amazon RDS DB instance.

Microsoft SQL Server Multi-AZ deployment limitations, notes, and recommendations

The following are some limitations when working with Multi-AZ deployments on RDS for SQL Server DB instances:

- Cross-Region Multi-AZ isn't supported.
- Stopping an RDS for SQL Server DB instance in a multi-AZ deployment isn't supported.
- You can't configure the secondary DB instance to accept database read activity.
- Multi-AZ with Always On Availability Groups (AGs) supports in-memory optimization.
- Multi-AZ with Always On Availability Groups (AGs) doesn't support Kerberos authentication for the availability group listener. This is because the listener has no Service Principal Name (SPN).
- You can't rename a database on a SQL Server DB instance that is in a SQL Server Multi-AZ deployment. If you need to rename a database on such an instance, first turn off Multi-AZ for the DB instance, then rename the database. Finally, turn Multi-AZ back on for the DB instance.
- You can only restore Multi-AZ DB instances that are backed up using the full recovery model.
- Multi-AZ deployments have a limit of 10,000 SQL Server Agent jobs.

If you need a higher limit, request an increase by contacting AWS Support. Open the AWS Support Center page, sign in if necessary, and choose **Create case**. Choose **Service limit increase**. Complete and submit the form.

- You can't have an offline database on a SQL Server DB instance that is in a SQL Server Multi-AZ deployment.

The following are some notes about working with Multi-AZ deployments on RDS for SQL Server DB instances:

- Amazon RDS exposes the Always On AGs availability group listener endpoint. The endpoint is visible in the console, and is returned by the `DescribeDBInstances` API operation as an entry in the endpoints field.
- Amazon RDS supports availability group multisubnet failovers.
- To use SQL Server Multi-AZ with a SQL Server DB instance in a virtual private cloud (VPC), first create a DB subnet group that has subnets in at least two distinct Availability Zones. Then assign the DB subnet group to the primary replica of the SQL Server DB instance.
- When a DB instance is modified to be a Multi-AZ deployment, during the modification it has a status of **modifying**. Amazon RDS creates the standby, and makes a backup of the primary DB instance. After the process is complete, the status of the primary DB instance becomes **available**.
- Multi-AZ deployments maintain all databases on the same node. If a database on the primary host fails over, all your SQL Server databases fail over as one atomic unit to your standby host. Amazon RDS provisions a new healthy host, and replaces the unhealthy host.
- Multi-AZ with DBM or AGs supports a single standby replica.
- Users, logins, and permissions are automatically replicated for you on the secondary. You don't need to recreate them. User-defined server roles are only replicated in DB instances that use Always On AGs for Multi-AZ deployments.
- In Multi-AZ deployments, RDS for SQL Server creates SQL Server logins to allow Always On AGs or Database Mirroring. RDS creates logins with the following pattern, `db_<dbiResourceId>_node1_login`, `db_<dbiResourceId>_node2_login`, and `db_<dbiResourceId>_witness_login`.
- RDS for SQL Server creates a SQL Server login to allow access to read replicas. RDS creates a login with the following pattern, `db_<readreplica_dbiResourceId>_node_login`.

- In Multi-AZ deployments, SQL Server Agent jobs are replicated from the primary host to the secondary host when the job replication feature is turned on. For more information, see Turning on SQL Server Agent job replication.
- You might observe elevated latencies compared to a standard DB instance deployment (in a single Availability Zone) because of the synchronous data replication.
- Failover times are affected by the time it takes to complete the recovery process. Large transactions increase the failover time.
- In SQL Server Multi-AZ deployments, reboot with failover reboots only the primary DB instance. After the failover, the primary DB instance becomes the new secondary DB instance. Parameters might not be updated for Multi-AZ instances. For reboot without failover, both the primary and secondary DB instances reboot, and parameters are updated after the reboot. If the DB instance is unresponsive, we recommend reboot without failover.

The following are some recommendations for working with Multi-AZ deployments on RDS for Microsoft SQL Server DB instances:

- For databases used in production or preproduction, we recommend the following options:
  - Multi-AZ deployments for high availability
  - "Provisioned IOPS" for fast, consistent performance
  - "Memory optimized" rather than "General purpose"
- You can't select the Availability Zone (AZ) for the secondary instance, so when you deploy application hosts, take this into account. Your database might fail over to another AZ, and the application hosts might not be in the same AZ as the database. For this reason, we recommend that you balance your application hosts across all AZs in the given AWS Region.
- For best performance, don't enable Database Mirroring or Always On AGs during a large data load operation. If you want your data load to be as fast as possible, finish loading data before you convert your DB instance to a Multi-AZ deployment.
- Applications that access the SQL Server databases should have exception handling that catches connection errors. The following code sample shows a try/catch block that catches a communication error. In this example, the `break` statement exits the `while` loop if the connection is successful, but retries up to 10 times if an exception is thrown.

```
int RetryMaxAttempts = 10;
int RetryIntervalPeriodInSeconds = 1;
int iRetryCount = 0;
```

```
while (iRetryCount < RetryMaxAttempts)
{
   using (SqlConnection connection = new SqlConnection(DatabaseConnString))
   {
      using (SqlCommand command = connection.CreateCommand())
      {
         command.CommandText = "INSERT INTO SOME_TABLE VALUES ('SomeValue');";
         try
         {
            connection.Open();
            command.ExecuteNonQuery();
            break;
         }
         catch (Exception ex)
         {
            Logger(ex.Message);
            iRetryCount++;
         }
         finally {
            connection.Close();
         }
      }
   }
   Thread.Sleep(RetryIntervalPeriodInSeconds * 1000);
}
```

- Don't use the `Set Partner Off` command when working with Multi-AZ instances. For example, don't do the following.

```
--Don't do this
ALTER DATABASE db1 SET PARTNER off
```

- Don't set the recovery mode to `simple`. For example, don't do the following.

```
--Don't do this
ALTER DATABASE db1 SET RECOVERY simple
```

- Don't use the DEFAULT_DATABASE parameter when creating new logins on Multi-AZ DB instances, because these settings can't be applied to the standby mirror. For example, don't do the following.

```
--Don't do this
```

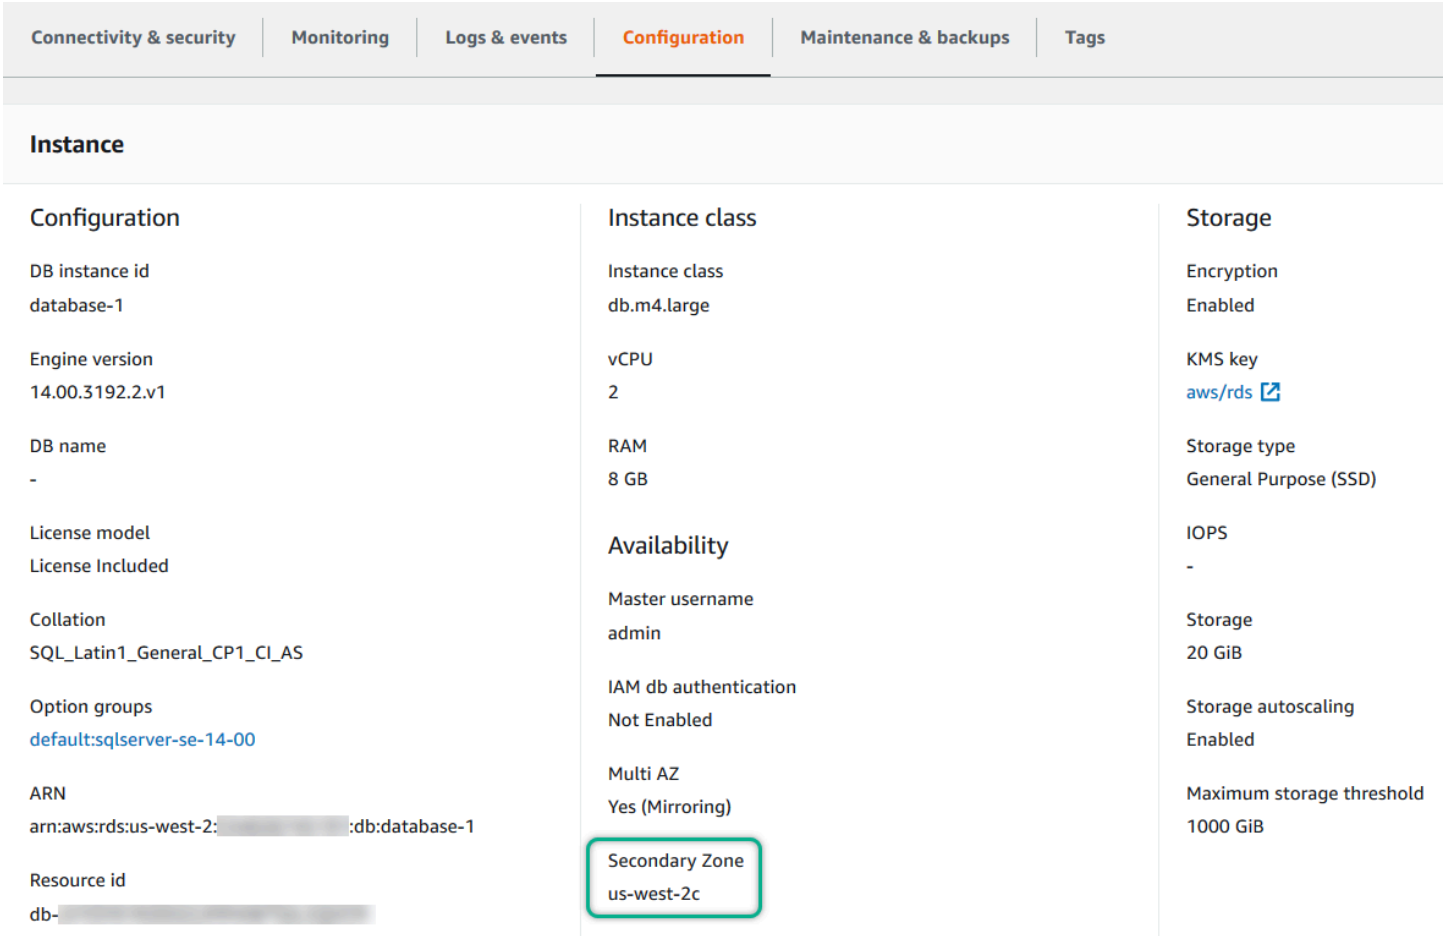
```
CREATE LOGIN [test_dba] WITH PASSWORD=foo, DEFAULT_DATABASE=[db2]
```

Also, don't do the following.

```
--Don't do this
ALTER LOGIN [test_dba] SET DEFAULT_DATABASE=[db3]
```

Determining the location of the secondary

You can determine the location of the secondary replica by using the AWS Management Console. You need to know the location of the secondary if you are setting up your primary DB instance in a VPC.



You can also view the Availability Zone of the secondary using the AWS CLI command `describe-db-instances` or RDS API operation `DescribeDBInstances`. The output shows the secondary AZ where the standby mirror is located.

Migrating from Database Mirroring to Always On Availability Groups

In version 14.00.3049.1 of Microsoft SQL Server Enterprise Edition, Always On Availability Groups (AGs) are enabled by default.

To migrate from Database Mirroring (DBM) to AGs, first check your version. If you are using a DB instance with a version prior to Enterprise Edition 13.00.5216.0, modify the instance to patch it to 13.00.5216.0 or later. If you are using a DB instance with a version prior to Enterprise Edition 14.00.3049.1, modify the instance to patch it to 14.00.3049.1 or later.

If you want to upgrade a mirrored DB instance to use AGs, run the upgrade first, modify the instance to remove Multi-AZ, and then modify it again to add Multi-AZ. This converts your instance to use Always On AGs.

Additional features for Microsoft SQL Server on Amazon RDS

In the following sections, you can find information about augmenting Amazon RDS instances running the Microsoft SQL Server DB engine.

Topics

Using Password Policy for SQL Server logins on RDS for SQL Server

Amazon RDS allows you to set the password policy for your Amazon RDS DB instance running Microsoft SQL Server. Use this to set complexity, length, and lockout requirements for logins that use SQL Server Authentication to authenticate to your DB instance.

Key terms

Login

In SQL Server, a server-level principal that can authenticate to a database instance is referred to as a **login**. Other database engines might refer to this principal as a *user*. In RDS for SQL Server, a login can authenticate using SQL Server Authentication or Windows Authentication.

SQL Server login

A login that uses a username and password to authenticate using SQL Server Authentication is a SQL Server login. The password policy you configure through DB parameters only applies to SQL Server logins.

Windows login

A login that is based on a Windows principal and authenticates using Windows Authentication is a Windows login. You can configure the password policy for your Windows logins in Active Directory. For more information, see Working with Active Directory with RDS for SQL Server.

Enabling and disabling policy for each login

Each SQL Server login has flags for `CHECK_POLICY` and `CHECK_EXPIRATION`. By default, new logins are created with `CHECK_POLICY` set to `ON` and `CHECK_EXPIRATION` set to `OFF`.

If `CHECK_POLICY` is enabled for a login, RDS for SQL Server validates the password against the complexity and minimum length requirements. Lockout policies also apply. An example T-SQL statement to enable `CHECK_POLICY` and `CHECK_EXPIRATION`:

```
ALTER LOGIN [master_user] WITH CHECK_POLICY = ON, CHECK_EXPIRATION = ON;
```

If `CHECK_EXPIRATION` is enabled, passwords are subject to password age policies. The T-SQL statement to check if `CHECK_POLICY` and `CHECK_EXPIRATION` are set:

```
SELECT name, is_policy_checked, is_expiration_checked FROM sys.sql_logins;
```

Password policy parameters

All password policy parameters are dynamic and do not require DB reboot to take effect. The following table lists the DB parameters you can set to modify the password policy for SQL Server logins:

DB parameter	Description	Allowed Values	Default Value	

rds.password_complexity_enabled	Password complexity requirements must be satisfied when creating or changing passwords for SQL Server logins. The following constraints must be met:
	• The password must include characters from three of the following categories:
	  • Latin lowercase letter (a through z)
	  • Latin uppercase letter (A through Z)
	  • Non-alpha numeric
		0,1	0	

DB parameter	Description	Allowed Values	Default Value	
	characters such as: exclamation point (!), dollar sign ($), number sign (#), or percent (%). • The password doesn't contain the account name of the user.			
rds.password_min_length	The minimum number of characters required in a password for a SQL Server login.	0-14	0	
rds.password_min_age	The minimum number of days a SQL Server login password must be used before the user can change it. Passwords can be changed immediately when set to 0.	0-998	0	

DB parameter	Description	Allowed Values	Default Value	
rds.password_max_age	The maximum number of days a SQL Server login password can be used after which the user is required to change it. Passwords never expire when set to 0.	0-999	42	
rds.password_lockout_threshold	The number of consecutive failed login attempts that cause a SQL Server login to become locked out.	0-999	0	
rds.password_lockout_duration	The number of minutes a locked out SQL Server login must wait before being unlocked.	1-60	10	

DB parameter	Description	Allowed Values	Default Value	
rds.password_lockout_reset_counter_after	The number of minutes that must elapse after a failed login attempt before the failed login attempt counter is reset to 0.	1-60	10	

> **Note**
>
> For more information about SQL Server password policy, see Password Policy.
> The password complexity and minimum length policies also apply to DB users in contained databases. For more information, see Contained Databases.

The following constraints apply to the password policy parameters:

- The `rds.password_min_age` parameter must be less than `rds.password_max_age` parameter, unless `rds.password_max_age` is set to 0
- The `rds.password_lockout_reset_counter_after` parameter must be less than or equal to the `rds.password_lockout_duration` parameter.
- If `rds.password_lockout_threshold` is set to 0, `rds.password_lockout_duration` and `rds.password_lockout_reset_counter_after` do not apply.

Considerations for existing logins

After modifying the password policy on an instance, existing passwords for logins are **not** retroactively evaluated against the new password complexity and length requirements. Only new passwords are validated against the new policy.

SQL Server **does** evaluate existing passwords for age requirements.

It is possible for passwords to expire immediately once a password policy is modified. For example, if a login has `CHECK_EXPIRATION` enabled and its password was last changed 100 days ago and you set the `rds.password_max_age` parameter to 5 days, the password immediately expires and the login needs to change their password at their next attempt to log in.

> **Note**
>
> RDS for SQL Server doesn't support password history policies. History policies prevent logins from reusing previously used passwords.

Considerations for Multi-AZ deployments

The failed login attempt counter and lockout state for Multi-AZ instances does not replicate between nodes. In the event of a login being locked out when a Multi-AZ instance fails over, it is possible for the login to be already unlocked on the new node.

Password considerations for the master login

When you create an RDS for SQL Server DB instance, the master user password is not evaluated against the password policy. A new master password is also not evaluated against the password when performing operations to the master user, specifically when setting `MasterUserPassword` in the `ModifyDBInstance` command. In both cases, you can set a password for the master user that does not satisfy your password policy, and the operation still succeeds. If the policy is not satisfied, RDS attempts to raise an RDS event, with the recommendation to set a strong password. Take care to only use strong passwords for the master user.

RDS attempts to generate the following event messages when the master user password does not meet the password policy requirements:

- The master user was created, but the password doesn't meet the minimum length requirement of your password policy. Consider using a stronger password.
- The master user was created, but the password doesn't meet the complexity requirement of your password policy. Consider using a stronger password.
- The master user password was reset, but the password doesn't meet the minimum length requirement of your password policy. Consider using a stronger password.
- The master user password was reset, but the password doesn't meet the complexity requirement of your password policy. Consider using a stronger password.

By default, the master user is created with `CHECK_POLICY` and `CHECK_EXPIRATION` set to `OFF`. To apply the password policy to the master user, you must manually enable these flags for the master user after DB instance creation. After you enable these flags, modify the master user password directly in SQL Server (eg. via T-SQL statements or SSMS) to validate the new password against the password policy.

> **Note**
>
> If the master user gets locked out, you can unlock the user by resetting the master user password using the `ModifyDBInstance` command.

Modifying the master user password

You can modify the master user password by using the ModifyDBInstance command.

> **Note**
>
> When you reset the master user password, RDS resets various permissions for the master user and the master user might lose certain permissions. Resetting the master user password also unlocks the master user, if it was locked out.

RDS validates the new master user password and attempts to emit an RDS event if the password does not satisfy the policy. RDS sets the password even if it does not satisfy the password policy.

Using SSL with a Microsoft SQL Server DB instance

You can use Secure Sockets Layer (SSL) to encrypt connections between your client applications and your Amazon RDS DB instances running Microsoft SQL Server. SSL support is available in all AWS regions for all supported SQL Server editions.

When you create a SQL Server DB instance, Amazon RDS creates an SSL certificate for it. The SSL certificate includes the DB instance endpoint as the Common Name (CN) for the SSL certificate to guard against spoofing attacks.

There are 2 ways to use SSL to connect to your SQL Server DB instance:

- Force SSL for all connections — this happens transparently to the client, and the client doesn't have to do any work to use SSL.
- Encrypt specific connections — this sets up an SSL connection from a specific client computer, and you must do work on the client to encrypt connections.

For information about Transport Layer Security (TLS) support for SQL Server, see TLS 1.2 support for Microsoft SQL Server.

Forcing connections to your DB instance to use SSL

You can force all connections to your DB instance to use SSL. If you force connections to use SSL, it happens transparently to the client, and the client doesn't have to do any work to use SSL.

If you want to force SSL, use the `rds.force_ssl` parameter. By default, the `rds.force_ssl` parameter is set to `0 (off)`. Set the `rds.force_ssl` parameter to `1 (on)` to force connections to use SSL. The `rds.force_ssl` parameter is static, so after you change the value, you must reboot your DB instance for the change to take effect.

To force all connections to your DB instance to use SSL

1. Determine the parameter group that is attached to your DB instance:

    a. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.

    b. In the top right corner of the Amazon RDS console, choose the AWS Region of your DB instance.

c. In the navigation pane, choose **Databases**, and then choose the name of your DB instance to show its details.

d. Choose the **Configuration** tab. Find the **Parameter group** in the section.

2. If necessary, create a new parameter group. If your DB instance uses the default parameter group, you must create a new parameter group. If your DB instance uses a nondefault parameter group, you can choose to edit the existing parameter group or to create a new parameter group. If you edit an existing parameter group, the change affects all DB instances that use that parameter group.

   To create a new parameter group, follow the instructions in Creating a DB parameter group in Amazon RDS.

3. Edit your new or existing parameter group to set the `rds.force_ssl` parameter to `true`. To edit the parameter group, follow the instructions in Modifying parameters in a DB parameter group in Amazon RDS.

4. If you created a new parameter group, modify your DB instance to attach the new parameter group. Modify the **DB Parameter Group** setting of the DB instance. For more information, see Modifying an Amazon RDS DB instance.

5. Reboot your DB instance. For more information, see Rebooting a DB instance.

Encrypting specific connections

You can force all connections to your DB instance to use SSL, or you can encrypt connections from specific client computers only. To use SSL from a specific client, you must obtain certificates for the client computer, import certificates on the client computer, and then encrypt the connections from the client computer.

> **Note**
>
> All SQL Server instances created after August 5, 2014, use the DB instance endpoint in the Common Name (CN) field of the SSL certificate. Prior to August 5, 2014, SSL certificate verification was not available for VPC-based SQL Server instances. If you have a VPC-based SQL Server DB instance that was created before August 5, 2014, and you want to use SSL certificate verification and ensure that the instance endpoint is included as the CN for the SSL certificate for that DB instance, then rename the instance. When you rename a

DB instance, a new certificate is deployed and the instance is rebooted to enable the new certificate.

Obtaining certificates for client computers

To encrypt connections from a client computer to an Amazon RDS DB instance running Microsoft SQL Server, you need a certificate on your client computer.

To obtain that certificate, download the certificate to your client computer. You can download a root certificate that works for all regions. You can also download a certificate bundle that contains both the old and new root certificate. In addition, you can download region-specific intermediate certificates. For more information about downloading certificates, see Using SSL/TLS to encrypt a connection to a DB instance or cluster.

After you have downloaded the appropriate certificate, import the certificate into your Microsoft Windows operating system by following the procedure in the section following.

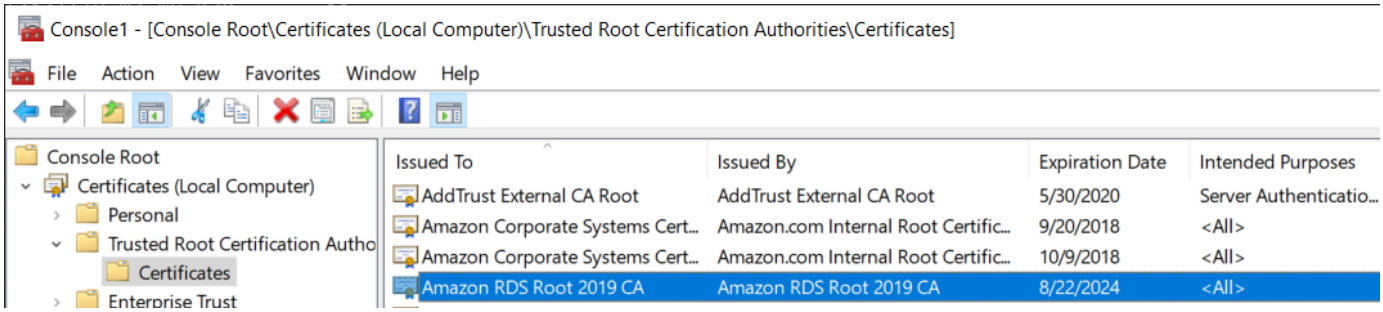
Importing certificates on client computers

You can use the following procedure to import your certificate into the Microsoft Windows operating system on your client computer.

To import the certificate into your Windows operating system:

1. On the **Start** menu, type **Run** in the search box and press **Enter**.
2. In the **Open** box, type **`MMC`** and then choose **OK**.
3. In the MMC console, on the **File** menu, choose **Add/Remove Snap-in**.
4. In the **Add or Remove Snap-ins** dialog box, for **Available snap-ins**, select **`Certificates`**, and then choose **Add**.
5. In the **Certificates snap-in** dialog box, choose **Computer account**, and then choose **Next**.
6. In the **Select computer** dialog box, choose **Finish**.
7. In the **Add or Remove Snap-ins** dialog box, choose **OK**.
8. In the MMC console, expand **Certificates**, open the context (right-click) menu for **Trusted Root Certification Authorities**, choose **All Tasks**, and then choose **Import**.
9. On the first page of the Certificate Import Wizard, choose **Next**.

10. On the second page of the Certificate Import Wizard, choose **Browse**. In the browse window, change the file type to **All files (*.*)** because .pem is not a standard certificate extension. Locate the .pem file that you downloaded previously.
11. Choose **Open** to select the certificate file, and then choose **Next**.
12. On the third page of the Certificate Import Wizard, choose **Next**.
13. On the fourth page of the Certificate Import Wizard, choose **Finish**. A dialog box appears indicating that the import was successful.
14. In the MMC console, expand **Certificates**, expand **Trusted Root Certification Authorities**, and then choose **Certificates**. Locate the certificate to confirm it exists, as shown here.



Encrypting connections to an Amazon RDS DB instance running Microsoft SQL Server

After you have imported a certificate into your client computer, you can encrypt connections from the client computer to an Amazon RDS DB instance running Microsoft SQL Server.

For SQL Server Management Studio, use the following procedure. For more information about SQL Server Management Studio, see Use SQL Server management studio.

To encrypt connections from SQL Server Management Studio

1. Launch SQL Server Management Studio.
2. For **Connect to server**, type the server information, login user name, and password.
3. Choose **Options**.
4. Select **Encrypt connection**.
5. Choose **Connect**.
6. Confirm that your connection is encrypted by running the following query. Verify that the query returns `true` for `encrypt_option`.

```
select ENCRYPT_OPTION from SYS.DM_EXEC_CONNECTIONS where SESSION_ID = @@SPID
```

For any other SQL client, use the following procedure.

To encrypt connections from other SQL clients

1. Append `encrypt=true` to your connection string. This string might be available as an option, or as a property on the connection page in GUI tools.

   > **Note**
   >
   > To enable SSL encryption for clients that connect using JDBC, you might need to add the Amazon RDS SQL certificate to the Java CA certificate (cacerts) store. You can do this by using the keytool utility.

2. Confirm that your connection is encrypted by running the following query. Verify that the query returns `true` for `encrypt_option`.

   ```
   select ENCRYPT_OPTION from SYS.DM_EXEC_CONNECTIONS where SESSION_ID = @@SPID
   ```

Configuring security protocols and ciphers

You can turn certain security protocols and ciphers on and off using DB parameters. The security parameters that you can configure (except for TLS version 1.2) are shown in the following table.

DB parameter	Allowed values (default in bold)	Description
rds.tls10	**default**, enabled, disabled	TLS 1.0.
rds.tls11	**default**, enabled, disabled	TLS 1.1.
rds.tls12	**default**	TLS 1.2. You can't modify this value.
rds.fips	**0**, 1	When you set the parameter to 1, RDS forces the use of modules that are compliant with the Federal Information Processing Standard (FIPS) 140-2 standard. For more information, see Use SQL Server 2016 in FIPS 140-2-compliant mode in the Microsoft documentation.
rds.rc4	**default**, enabled, disabled	RC4 stream cipher.
rds.diffie-hellman	**default**, enabled, disabled	Diffie-Hellman key-exchange encryption.
rds.diffie-hellman-min-key-bit-length	**default**, 1024, 2048, 3072, 4096	Minimum bit length for Diffie-Hellman keys.
rds.curve25519	**default**, enabled, disabled	Curve25519 elliptic-curve encryption cipher. This parameter isn't supported for all engine versions.

DB parameter	Allowed values (default in bold)	Description
rds.3des168	**default**, enabled, disabled	Triple Data Encryption Standard (DES) encryption cipher with a 168-bit key length.

Note

For minor engine versions after 16.00.4120.1, 15.00.4365.2, 14.00.3465.1, 13.00.6435.1, and 12.00.6449.1, the default setting for the DB parameters `rds.tls10`, `rds.tls11`, `rds.rc4`, `rds.curve25519`, and `rds.3des168` is *disabled*. Otherwise the default setting is *enabled*.

For minor engine versions after 16.00.4120.1, 15.00.4365.2, 14.00.3465.1, 13.00.6435.1, and 12.00.6449.1, the default setting for `rds.diffie-hellman-min-key-bit-lengthis` 3072. Otherwise the default setting is 2048.

Use the following process to configure the security protocols and ciphers:

1. Create a custom DB parameter group.
2. Modify the parameters in the parameter group.
3. Associate the DB parameter group with your DB instance.

For more information on DB parameter groups, see Parameter groups for Amazon RDS.

Creating the security-related parameter group

Create a parameter group for your security-related parameters that corresponds to the SQL Server edition and version of your DB instance.

Console

The following procedure creates a parameter group for SQL Server Standard Edition 2016.

To create the parameter group

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Parameter groups**.
3. Choose **Create parameter group**.
4. In the **Create parameter group** pane, do the following:
   a. For **Parameter group family**, choose **sqlserver-se-13.0**.
   b. For **Group name**, enter an identifier for the parameter group, such as **`sqlserver-ciphers-se-13`**.
   c. For **Description**, enter **`Parameter group for security protocols and ciphers`**.
5. Choose **Create**.

CLI

The following procedure creates a parameter group for SQL Server Standard Edition 2016.

To create the parameter group

- Run one of the following commands.

  Example

  For Linux, macOS, or Unix:

```
aws rds create-db-parameter-group \
    --db-parameter-group-name sqlserver-ciphers-se-13 \
    --db-parameter-group-family "sqlserver-se-13.0" \
    --description "Parameter group for security protocols and ciphers"
```

  For Windows:

```
aws rds create-db-parameter-group ^
    --db-parameter-group-name sqlserver-ciphers-se-13 ^
    --db-parameter-group-family "sqlserver-se-13.0" ^
    --description "Parameter group for security protocols and ciphers"
```

Modifying security-related parameters

Modify the security-related parameters in the parameter group that corresponds to the SQL Server edition and version of your DB instance.

Console

The following procedure modifies the parameter group that you created for SQL Server Standard Edition 2016. This example turns off TLS version 1.0.

To modify the parameter group

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Parameter groups**.
3. Choose the parameter group, such as **sqlserver-ciphers-se-13**.
4. Under **Parameters**, filter the parameter list for **rds**.
5. Choose **Edit parameters**.
6. Choose **rds.tls10**.
7. For **Values**, choose **disabled**.
8. Choose **Save changes**.

CLI

The following procedure modifies the parameter group that you created for SQL Server Standard Edition 2016. This example turns off TLS version 1.0.

To modify the parameter group

- Run one of the following commands.

  Example

  For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group \
    --db-parameter-group-name sqlserver-ciphers-se-13 \
    --parameters
 "ParameterName='rds.tls10',ParameterValue='disabled',ApplyMethod=pending-reboot"
```

For Windows:

```
aws rds modify-db-parameter-group ^
    --db-parameter-group-name sqlserver-ciphers-se-13 ^
    --parameters
 "ParameterName='rds.tls10',ParameterValue='disabled',ApplyMethod=pending-reboot"
```

Associating the security-related parameter group with your DB instance

To associate the parameter group with your DB instance, use the AWS Management Console or the AWS CLI.

Console

You can associate the parameter group with a new or existing DB instance:

- For a new DB instance, associate it when you launch the instance. For more information, see Creating an Amazon RDS DB instance.
- For an existing DB instance, associate it by modifying the instance. For more information, see Modifying an Amazon RDS DB instance.

CLI

You can associate the parameter group with a new or existing DB instance.

To create a DB instance with the parameter group

- Specify the same DB engine type and major version as you used when creating the parameter group.

  Example

  For Linux, macOS, or Unix:

```
aws rds create-db-instance \
    --db-instance-identifier mydbinstance \
    --db-instance-class db.m5.2xlarge \
    --engine sqlserver-se \
    --engine-version 13.00.5426.0.v1 \
```

```
    --allocated-storage 100 \
    --master-user-password secret123 \
    --master-username admin \
    --storage-type gp2 \
    --license-model li \
    --db-parameter-group-name sqlserver-ciphers-se-13
```

For Windows:

```
aws rds create-db-instance ^
    --db-instance-identifier mydbinstance ^
    --db-instance-class db.m5.2xlarge ^
    --engine sqlserver-se ^
    --engine-version 13.00.5426.0.v1 ^
    --allocated-storage 100 ^
    --master-user-password secret123 ^
    --master-username admin ^
    --storage-type gp2 ^
    --license-model li ^
    --db-parameter-group-name sqlserver-ciphers-se-13
```

> **Note**
>
> Specify a password other than the prompt shown here as a security best practice.

To modify a DB instance and associate the parameter group

- Run one of the following commands.

  Example

  For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier mydbinstance \
    --db-parameter-group-name sqlserver-ciphers-se-13 \
    --apply-immediately
```

  For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier mydbinstance ^
    --db-parameter-group-name sqlserver-ciphers-se-13 ^
    --apply-immediately
```

Integrating an Amazon RDS for SQL Server DB instance with Amazon S3

You can transfer files between a DB instance running Amazon RDS for SQL Server and an Amazon S3 bucket. By doing this, you can use Amazon S3 with SQL Server features such as BULK INSERT. For example, you can download .csv, .xml, .txt, and other files from Amazon S3 to the DB instance host and import the data from `D:\S3\` into the database. All files are stored in `D:\S3\` on the DB instance.

The following limitations apply:

- Files in the `D:\S3` folder are deleted on the standby replica after a failover on Multi-AZ instances. For more information, see Multi-AZ limitations for S3 integration.
- The DB instance and the S3 bucket must be in the same AWS Region.
- If you run more than one S3 integration task at a time, the tasks run sequentially, not in parallel.

> **Note**
>
> S3 integration tasks share the same queue as native backup and restore tasks. At maximum, you can have only two tasks in progress at any time in this queue. Therefore, two running native backup and restore tasks will block any S3 integration tasks.

- You must re-enable the S3 integration feature on restored instances. S3 integration isn't propagated from the source instance to the restored instance. Files in `D:\S3` are deleted on a restored instance.
- Downloading to the DB instance is limited to 100 files. In other words, there can't be more than 100 files in `D:\S3\`.
- Only files without file extensions or with the following file extensions are supported for download: .abf, .asdatabase, .bcp, .configsettings, .csv, .dat, .deploymentoptions, .deploymenttargets, .fr and .xmla.
- The S3 bucket must have the same owner as the related AWS Identity and Access Management (IAM) role. Therefore, cross-account S3 integration isn't supported.
- The S3 bucket can't be open to the public.
- The file size for uploads from RDS to S3 is limited to 50 GB per file.
- The file size for downloads from S3 to RDS is limited to the maximum supported by S3.

Topics

For more information on working with files in Amazon S3, see Getting started with Amazon Simple Storage Service.

Prerequisites for integrating RDS for SQL Server with S3

Before you begin, find or create the S3 bucket that you want to use. Also, add permissions so that the RDS DB instance can access the S3 bucket. To configure this access, you create both an IAM policy and an IAM role.

Console

To create an IAM policy for access to Amazon S3

1. In the IAM Management Console, choose **Policies** in the navigation pane.
2. Create a new policy, and use the **Visual editor** tab for the following steps.
3. For **Service**, enter **S3** and then choose the **S3** service.
4. For **Actions**, choose the following to grant the access that your DB instance requires:

    - `ListAllMyBuckets` – required
    - `ListBucket` – required
    - `GetBucketACL` – required
    - `GetBucketLocation` – required
    - `GetObject` – required for downloading files from S3 to `D:\S3\`
    - `PutObject` – required for uploading files from `D:\S3\` to S3

- `ListMultipartUploadParts` – required for uploading files from `D:\S3\` to S3
- `AbortMultipartUpload` – required for uploading files from `D:\S3\` to S3

5. For **Resources**, the options that display depend on which actions you choose in the previous step. You might see options for **bucket**, **object**, or both. For each of these, add the appropriate Amazon Resource Name (ARN).

   For **bucket**, add the ARN for the bucket that you want to use. For example, if your bucket is named *amzn-s3-demo-bucket*, set the ARN to `arn:aws:s3:::`*amzn-s3-demo-bucket*.

   For **object**, enter the ARN for the bucket and then choose one of the following:

   - To grant access to all files in the specified bucket, choose **Any** for both **Bucket name** and **Object name**.
   - To grant access to specific files or folders in the bucket, provide ARNs for the specific buckets and objects that you want SQL Server to access.

6. Follow the instructions in the console until you finish creating the policy.

   The preceding is an abbreviated guide to setting up a policy. For more detailed instructions on creating IAM policies, see Creating IAM policies in the *IAM User Guide.*

To create an IAM role that uses the IAM policy from the previous procedure

1. In the IAM Management Console, choose **Roles** in the navigation pane.
2. Create a new IAM role, and choose the following options as they appear in the console:

   - **AWS service**
   - **RDS**
   - **RDS – Add Role to Database**

   Then choose **Next:Permissions** at the bottom.

3. For **Attach permissions policies**, enter the name of the IAM policy that you previously created. Then choose the policy from the list.
4. Follow the instructions in the console until you finish creating the role.

   The preceding is an abbreviated guide to setting up a role. If you want more detailed instructions on creating roles, see IAM roles in the *IAM User Guide.*

AWS CLI

To grant Amazon RDS access to an Amazon S3 bucket, use the following process:

1. Create an IAM policy that grants Amazon RDS access to an S3 bucket.
2. Create an IAM role that Amazon RDS can assume on your behalf to access your S3 buckets.

   For more information, see Creating a role to delegate permissions to an IAM user in the *IAM User Guide*.
3. Attach the IAM policy that you created to the IAM role that you created.

To create the IAM policy

Include the appropriate actions to grant the access your DB instance requires:

- `ListAllMyBuckets` – required
- `ListBucket` – required
- `GetBucketACL` – required
- `GetBucketLocation` – required
- `GetObject` – required for downloading files from S3 to `D:\S3\`
- `PutObject` – required for uploading files from `D:\S3\` to S3
- `ListMultipartUploadParts` – required for uploading files from `D:\S3\` to S3
- `AbortMultipartUpload` – required for uploading files from `D:\S3\` to S3

1. The following AWS CLI command creates an IAM policy named `rds-s3-integration-policy` with these options. It grants access to a bucket named *`amzn-s3-demo-bucket`*.

   Example

   For Linux, macOS, or Unix:

```
aws iam create-policy \
  --policy-name rds-s3-integration-policy \
  --policy-document '{
        "Version": "2012-10-17",
        "Statement": [
            {
                "Effect": "Allow",
```

```
                "Action": "s3:ListAllMyBuckets",
                "Resource": "*"
            },
            {
                "Effect": "Allow",
                "Action": [
                    "s3:ListBucket",
                    "s3:GetBucketACL",
                    "s3:GetBucketLocation"
                ],
                "Resource": "arn:aws:s3:::amzn-s3-demo-bucket"
            },
            {
                "Effect": "Allow",
                "Action": [
                    "s3:GetObject",
                    "s3:PutObject",
                    "s3:ListMultipartUploadParts",
                    "s3:AbortMultipartUpload"
                ],
                "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/key_prefix/*"
            }
        ]
    }'
```

For Windows:

Make sure to change the line endings to the ones supported by your interface (^ instead of \). Also, in Windows, you must escape all double quotes with a \. To avoid the need to escape the quotes in the JSON, you can save it to a file instead and pass that in as a parameter.

First, create the `policy.json` file with the following permission policy:

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": "s3:ListAllMyBuckets",
            "Resource": "*"
        },
        {
            "Effect": "Allow",
```

```
            "Action": [
                "s3:ListBucket",
                "s3:GetBucketACL",
                "s3:GetBucketLocation"
            ],
            "Resource": "arn:aws:s3:::amzn-s3-demo-bucket"
        },
        {
            "Effect": "Allow",
            "Action": [
                "s3:GetObject",
                "s3:PutObject",
                "s3:ListMultipartUploadParts",
                "s3:AbortMultipartUpload"
            ],
            "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/key_prefix/*"
        }
    ]
}
```

Then use the following command to create the policy:

```
aws iam create-policy ^
     --policy-name rds-s3-integration-policy ^
     --policy-document file://file_path/assume_role_policy.json
```

2. After the policy is created, note the Amazon Resource Name (ARN) of the policy. You need the ARN for a later step.

To create the IAM role

- The following AWS CLI command creates the `rds-s3-integration-role` IAM role for this purpose.

  Example

  For Linux, macOS, or Unix:

```
aws iam create-role \
    --role-name rds-s3-integration-role \
    --assume-role-policy-document '{
      "Version": "2012-10-17",
```

```
      "Statement": [
        {
          "Effect": "Allow",
          "Principal": {
             "Service": "rds.amazonaws.com"
           },
          "Action": "sts:AssumeRole"
        }
      ]
    }'
```

For Windows:

Make sure to change the line endings to the ones supported by your interface (^ instead of \). Also, in Windows, you must escape all double quotes with a \. To avoid the need to escape the quotes in the JSON, you can save it to a file instead and pass that in as a parameter.

First, create the `assume_role_policy.json` file with the following policy:

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "Service": [
                    "rds.amazonaws.com"
                ]
            },
            "Action": "sts:AssumeRole"
        }
    ]
}
```

Then use the following command to create the IAM role:

```
aws iam create-role ^
     --role-name rds-s3-integration-role ^
     --assume-role-policy-document file://file_path/assume_role_policy.json
```

Example of using the global condition context key to create the IAM role

We recommend using the aws:SourceArn and aws:SourceAccount global condition context keys in resource-based policies to limit the service's permissions to a specific resource. This is the most effective way to protect against the confused deputy problem.

You might use both global condition context keys and have the aws:SourceArn value contain the account ID. In this case, the aws:SourceAccount value and the account in the aws:SourceArn value must use the same account ID when used in the same policy statement.

- Use aws:SourceArn if you want cross-service access for a single resource.
- Use aws:SourceAccount if you want to allow any resource in that account to be associated with the cross-service use.

In the policy, make sure to use the aws:SourceArn global condition context key with the full Amazon Resource Name (ARN) of the resources accessing the role. For S3 integration, make sure to include the DB instance ARNs, as shown in the following example.

For Linux, macOS, or Unix:

```
aws iam create-role \
    --role-name rds-s3-integration-role \
    --assume-role-policy-document '{
      "Version": "2012-10-17",
      "Statement": [
        {
          "Effect": "Allow",
          "Principal": {
             "Service": "rds.amazonaws.com"
           },
          "Action": "sts:AssumeRole",
                "Condition": {
                    "StringEquals": {

 "aws:SourceArn":"arn:aws:rds:Region:my_account_ID:db:db_instance_identifier"
                    }
                }
        }
      ]
```

```
    }'
```

For Windows:

Add the global condition context key to `assume_role_policy.json`.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "Service": [
                    "rds.amazonaws.com"
                ]
            },
            "Action": "sts:AssumeRole",
            "Condition": {
                "StringEquals": {

 "aws:SourceArn":"arn:aws:rds:Region:my_account_ID:db:db_instance_identifier"
                }
            }
        }
    ]
}
```

To attach the IAM policy to the IAM role

- The following AWS CLI command attaches the policy to the role named `rds-s3-integration-role`. Replace *`your-policy-arn`* with the policy ARN that you noted in a previous step.

  Example

  For Linux, macOS, or Unix:

```
aws iam attach-role-policy \
    --policy-arn your-policy-arn \
    --role-name rds-s3-integration-role
```

For Windows:

```
aws iam attach-role-policy ^
    --policy-arn your-policy-arn ^
    --role-name rds-s3-integration-role
```

Enabling RDS for SQL Server integration with S3

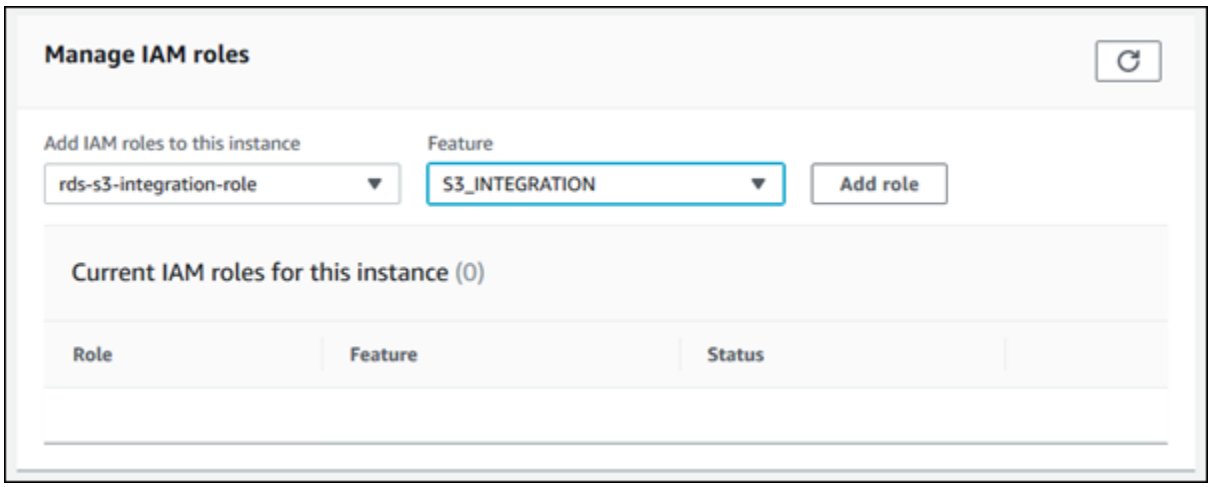
In the following section, you can find how to enable Amazon S3 integration with Amazon RDS for SQL Server. To work with S3 integration, your DB instance must be associated with the IAM role that you previously created before you use the `S3_INTEGRATION` feature-name parameter.

> **Note**
>
> To add an IAM role to a DB instance, the status of the DB instance must be **available**.

Console

To associate your IAM role with your DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Choose the RDS for SQL Server DB instance name to display its details.
3. On the **Connectivity & security** tab, in the **Manage IAM roles** section, choose the IAM role to add for **Add IAM roles to this instance**.
4. For **Feature**, choose **S3_INTEGRATION**.



5. Choose **Add role**.

AWS CLI

To add the IAM role to the RDS for SQL Server DB instance

- The following AWS CLI command adds your IAM role to an RDS for SQL Server DB instance named *mydbinstance*.

  Example

  For Linux, macOS, or Unix:

```
aws rds add-role-to-db-instance \
    --db-instance-identifier mydbinstance \
    --feature-name S3_INTEGRATION \
    --role-arn your-role-arn
```

  For Windows:

```
aws rds add-role-to-db-instance ^
    --db-instance-identifier mydbinstance ^
    --feature-name S3_INTEGRATION ^
    --role-arn your-role-arn
```

  Replace *your-role-arn* with the role ARN that you noted in a previous step. `S3_INTEGRATION` must be specified for the `--feature-name` option.

Transferring files between RDS for SQL Server and Amazon S3

You can use Amazon RDS stored procedures to download and upload files between Amazon S3 and your RDS DB instance. You can also use Amazon RDS stored procedures to list and delete files on the RDS instance.

The files that you download from and upload to S3 are stored in the `D:\S3` folder. This is the only folder that you can use to access your files. You can organize your files into subfolders, which are created for you when you include the destination folder during download.

Some of the stored procedures require that you provide an Amazon Resource Name (ARN) to your S3 bucket and file. The format for your ARN is `arn:aws:s3:::`*`amzn-s3-demo-bucket`*`/file_name`. Amazon S3 doesn't require an account number or AWS Region in ARNs.

S3 integration tasks run sequentially and share the same queue as native backup and restore tasks. At maximum, you can have only two tasks in progress at any time in this queue. It can take up to five minutes for the task to begin processing.

Downloading files from an Amazon S3 bucket to a SQL Server DB instance

To download files from an S3 bucket to an RDS for SQL Server DB instance, use the Amazon RDS stored procedure `msdb.dbo.rds_download_from_s3` with the following parameters.

Parameter name	Data type	Default	Required	Description
`@s3_arn_of_file`	NVARCHAR	–	Required	The S3 ARN of the file to download, for example: `arn:aws:s3:::` *`amzn-s3-demo-bucket`* `/mydata.csv`
`@rds_file_path`	NVARCHAR	–	Optional	The file path for the RDS instance. If not specified, the file path is `D:\S3\`*`<filename in s3>`*. RDS supports absolute paths and relative paths. If you

Parameter name	Data type	Default	Required	Description
				want to create a subfolder, include it in the file path.
`@overwrite_file`	INT	0	Optional	Overwrite the existing file: 0 = Don't overwrite 1 = Overwrite

You can download files without a file extension and files with the following file extensions: .bcp, .csv, .dat, .fmt, .info, .lst, .tbl, .txt, and .xml.

> **Note**
>
> Files with the .ispac file extension are supported for download when SQL Server Integration Services is enabled. For more information on enabling SSIS, see SQL Server Integration Services.
> Files with the following file extensions are supported for download when SQL Server Analysis Services is
> enabled: .abf, .asdatabase, .configsettings, .deploymentoptions, .deploymenttargets, and .xmla. For more information on enabling SSAS, see SQL Server Analysis Services.

The following example shows the stored procedure to download files from S3.

```
exec msdb.dbo.rds_download_from_s3
     @s3_arn_of_file='arn:aws:s3:::amzn-s3-demo-bucket/bulk_data.csv',
     @rds_file_path='D:\S3\seed_data\data.csv',
     @overwrite_file=1;
```

The example `rds_download_from_s3` operation creates a folder named `seed_data` in `D:\S3\`, if the folder doesn't exist yet. Then the example downloads the source file `bulk_data.csv` from S3 to a new file named `data.csv` on the DB instance. If the file previously existed, it's overwritten because the `@overwrite_file` parameter is set to 1.

Uploading files from a SQL Server DB instance to an Amazon S3 bucket

To upload files from an RDS for SQL Server DB instance to an S3 bucket, use the Amazon RDS stored procedure `msdb.dbo.rds_upload_to_s3` with the following parameters.

Parameter name	Data type	Default	Required	Description
`@s3_arn_of_file`	NVARCHAR	–	Required	The S3 ARN of the file to be created in S3, for example: `arn:aws:s3::: amzn-s3-demo-bucket /mydata.csv`
`@rds_file_path`	NVARCHAR	–	Required	The file path of the file to upload to S3. Absolute and relative paths are supported.
`@overwrite_file`	INT	–	Optional	Overwrite the existing file: 0 = Don't overwrite 1 = Overwrite

The following example uploads the file named `data.csv` from the specified location in `D:\S3\seed_data\` to a file `new_data.csv` in the S3 bucket specified by the ARN.

```
exec msdb.dbo.rds_upload_to_s3
  @rds_file_path='D:\S3\seed_data\data.csv',
  @s3_arn_of_file='arn:aws:s3:::amzn-s3-demo-bucket/new_data.csv',
  @overwrite_file=1;
```

If the file previously existed in S3, it's overwritten because the @overwrite_file parameter is set to 1.

Listing files on the RDS DB instance

To list the files available on the DB instance, use both a stored procedure and a function. First, run the following stored procedure to gather file details from the files in `D:\S3\`.

```
exec msdb.dbo.rds_gather_file_details;
```

The stored procedure returns the ID of the task. Like other tasks, this stored procedure runs asynchronously. As soon as the status of the task is SUCCESS, you can use the task ID in the `rds_fn_list_file_details` function to list the existing files and directories in D:\S3\, as shown following.

```
SELECT * FROM msdb.dbo.rds_fn_list_file_details(TASK_ID);
```

The `rds_fn_list_file_details` function returns a table with the following columns.

Output parameter	Description
`filepath`	Absolute path of the file (for example, `D:\S3\mydata.csv`)
`size_in_bytes`	File size (in bytes)
`last_modified_utc`	Last modification date and time in UTC format
`is_directory`	Option that indicates whether the item is a directory (`true/false`)

Deleting files on the RDS DB instance

To delete the files available on the DB instance, use the Amazon RDS stored procedure `msdb.dbo.rds_delete_from_filesystem` with the following parameters.

Parameter name	Data type	Default	Required	Description
`@rds_file_path`	NVARCHAR	–	Required	The file path of the file to delete. Absolute

Parameter name	Data type	Default	Required	Description
				and relative paths are supported.
`@force_delete`	INT	0	Optional	To delete a directory, this flag must be included and set to 1. 1 = delete a directory This parameter is ignored if you are deleting a file.

To delete a directory, the `@rds_file_path` must end with a backslash (\) and `@force_delete` must be set to 1.

The following example deletes the file `D:\S3\delete_me.txt`.

```
exec msdb.dbo.rds_delete_from_filesystem
    @rds_file_path='D:\S3\delete_me.txt';
```

The following example deletes the directory `D:\S3\example_folder\`.

```
exec msdb.dbo.rds_delete_from_filesystem
    @rds_file_path='D:\S3\example_folder\',
    @force_delete=1;
```

Monitoring the status of a file transfer task

To track the status of your S3 integration task, call the `rds_fn_task_status` function. It takes two parameters. The first parameter should always be `NULL` because it doesn't apply to S3 integration. The second parameter accepts a task ID.

To see a list of all tasks, set the first parameter to `NULL` and the second parameter to `0`, as shown in the following example.

```
SELECT * FROM msdb.dbo.rds_fn_task_status(NULL,0);
```

To get a specific task, set the first parameter to NULL and the second parameter to the task ID, as shown in the following example.

```
SELECT * FROM msdb.dbo.rds_fn_task_status(NULL,42);
```

The rds_fn_task_status function returns the following information.

Output parameter	Description
task_id	The ID of the task.
task_type	For S3 integration, tasks can have the following task types: • DOWNLOAD_FROM_S3 • UPLOAD_TO_S3 • LIST_FILES_ON_DISK • DELETE_FILES_ON_DISK
database_name	Not applicable to S3 integration tasks.
% complete	The progress of the task as a percentage.
duration(mins)	The amount of time spent on the task, in minutes.
lifecycle	The status of the task. Possible statuses are the following: • CREATED – After you call one of the S3 integration stored procedures, a task is created and the status is set to CREATED. • IN_PROGRESS – After a task starts, the status is set to IN_PROGRESS . It can take up to five minutes for the status to change from CREATED to IN_PROGRESS . • SUCCESS – After a task completes, the status is set to SUCCESS.

Output parameter	Description
	• ERROR – If a task fails, the status is set to ERROR. For more information about the error, see the `task_info` column. • `CANCEL_REQUESTED` – After you call `rds_cancel_task`, the status of the task is set to `CANCEL_REQUESTED`. • `CANCELLED` – After a task is successfully canceled, the status of the task is set to `CANCELLED`.
`task_info`	Additional information about the task. If an error occurs during processing, this column contains information about the error.
`last_updated`	The date and time that the task status was last updated.
`created_at`	The date and time that the task was created.
`S3_object_arn`	The ARN of the S3 object downloaded from or uploaded to.
`overwrite_S3_backup_file`	Not applicable to S3 integration tasks.
`KMS_master_key_arn`	Not applicable to S3 integration tasks.
`filepath`	The file path on the RDS DB instance.
`overwrite_file`	An option that indicates if an existing file is overwritten.
`task_metadata`	Not applicable to S3 integration tasks.

Canceling a task

To cancel S3 integration tasks, use the `msdb.dbo.rds_cancel_task` stored procedure with the `task_id` parameter. Delete and list tasks that are in progress can't be cancelled. The following example shows a request to cancel a task.

```
exec msdb.dbo.rds_cancel_task @task_id = 1234;
```

To get an overview of all tasks and their task IDs, use the `rds_fn_task_status` function as described in Monitoring the status of a file transfer task.

Multi-AZ limitations for S3 integration

On Multi-AZ instances, files in the `D:\S3` folder are deleted on the standby replica after a failover. A failover can be planned, for example, during DB instance modifications such as changing the instance class or upgrading the engine version. Or a failover can be unplanned, during an outage of the primary.

> **Note**
>
> We don't recommend using the `D:\S3` folder for file storage. The best practice is to upload created files to Amazon S3 to make them durable, and download files when you need to import data.

To determine the last failover time, you can use the `msdb.dbo.rds_failover_time` stored procedure. For more information, see Determining the last failover time.

Example of no recent failover

This example shows the output when there is no recent failover in the error logs. No failover has happened since 2020-04-29 23:59:00.01.

Therefore, all files downloaded after that time that haven't been deleted using the `rds_delete_from_filesystem` stored procedure are still accessible on the current host. Files downloaded before that time might also be available.

errorlog_available_from	recent_failover_time

errorlog_available_from	recent_failover_time
2020-04-29 23:59:00.0100000	null

Example of recent failover

This example shows the output when there is a failover in the error logs. The most recent failover was at 2020-05-05 18:57:51.89.

All files downloaded after that time that haven't been deleted using the `rds_delete_from_filesystem` stored procedure are still accessible on the current host.

errorlog_available_from	recent_failover_time
2020-04-29 23:59:00.0100000	2020-05-05 18:57:51.8900000

Disabling RDS for SQL Server integration with S3

Following, you can find how to disable Amazon S3 integration with Amazon RDS for SQL Server. Files in `D:\S3\` aren't deleted when disabling S3 integration.

> **Note**
>
> To remove an IAM role from a DB instance, the status of the DB instance must be `available`.

Console

To disassociate your IAM role from your DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Choose the RDS for SQL Server DB instance name to display its details.
3. On the **Connectivity & security** tab, in the **Manage IAM roles** section, choose the IAM role to remove.

4. Choose **Delete**.

AWS CLI

To remove the IAM role from the RDS for SQL Server DB instance

- The following AWS CLI command removes the IAM role from a RDS for SQL Server DB instance named *mydbinstance*.

  Example

  For Linux, macOS, or Unix:

```
aws rds remove-role-from-db-instance \
    --db-instance-identifier mydbinstance \
    --feature-name S3_INTEGRATION \
    --role-arn your-role-arn
```

  For Windows:

```
aws rds remove-role-from-db-instance ^
    --db-instance-identifier mydbinstance ^
    --feature-name S3_INTEGRATION ^
    --role-arn your-role-arn
```

  Replace *your-role-arn* with the appropriate IAM role ARN for the `--feature-name` option.

Using Database Mail on Amazon RDS for SQL Server

You can use Database Mail to send email messages to users from your Amazon RDS on SQL Server database instance. The messages can contain files and query results. Database Mail includes the following components:

- **Configuration and security objects** – These objects create profiles and accounts, and are stored in the `msdb` database.
- **Messaging objects** – These objects include the sp_send_dbmail stored procedure used to send messages, and data structures that hold information about messages. They're stored in the `msdb` database.
- **Logging and auditing objects** – Database Mail writes logging information to the `msdb` database and the Microsoft Windows application event log.
- **Database Mail executable** – `DatabaseMail.exe` reads from a queue in the `msdb` database and sends email messages.

RDS supports Database Mail for all SQL Server versions on the Web, Standard, and Enterprise Editions.

Limitations

The following limitations apply to using Database Mail on your SQL Server DB instance:

- Database Mail isn't supported for SQL Server Express Edition.
- Modifying Database Mail configuration parameters isn't supported. To see the preset (default) values, use the sysmail_help_configure_sp stored procedure.
- File attachments aren't fully supported. For more information, see Working with file attachments.
- The maximum file attachment size is 1 MB.
- Database Mail requires additional configuration on Multi-AZ DB instances. For more information, see Considerations for Multi-AZ deployments.
- Configuring SQL Server Agent to send email messages to predefined operators isn't supported.

Enabling Database Mail

Use the following process to enable Database Mail for your DB instance:

1. Create a new parameter group.
2. Modify the parameter group to set the `database mail xps` parameter to 1.
3. Associate the parameter group with the DB instance.

Creating the parameter group for Database Mail

Create a parameter group for the `database mail xps` parameter that corresponds to the SQL Server edition and version of your DB instance.

> **Note**
>
> You can also modify an existing parameter group. Follow the procedure in Modifying the parameter that enables Database Mail.

Console

The following example creates a parameter group for SQL Server Standard Edition 2016.

To create the parameter group

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Parameter groups**.
3. Choose **Create parameter group**.
4. In the **Create parameter group** pane, do the following:
   a. For **Parameter group family**, choose **sqlserver-se-13.0**.
   b. For **Group name**, enter an identifier for the parameter group, such as **`dbmail-sqlserver-se-13`**.
   c. For **Description**, enter **`Database Mail XPs`**.
5. Choose **Create**.

CLI

The following example creates a parameter group for SQL Server Standard Edition 2016.

To create the parameter group

- Use one of the following commands.

  Example

  For Linux, macOS, or Unix:

```
aws rds create-db-parameter-group \
    --db-parameter-group-name dbmail-sqlserver-se-13 \
    --db-parameter-group-family "sqlserver-se-13.0" \
    --description "Database Mail XPs"
```

  For Windows:

```
aws rds create-db-parameter-group ^
    --db-parameter-group-name dbmail-sqlserver-se-13 ^
    --db-parameter-group-family "sqlserver-se-13.0" ^
    --description "Database Mail XPs"
```

Modifying the parameter that enables Database Mail

Modify the `database mail xps` parameter in the parameter group that corresponds to the SQL Server edition and version of your DB instance.

To enable Database Mail, set the `database mail xps` parameter to 1.

Console

The following example modifies the parameter group that you created for SQL Server Standard Edition 2016.

To modify the parameter group

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Parameter groups**.
3. Choose the parameter group, such as **dbmail-sqlserver-se-13**.
4. Under **Parameters**, filter the parameter list for **`mail`**.
5. Choose **database mail xps**.

6. Choose **Edit parameters**.
7. Enter **1**.
8. Choose **Save changes**.

CLI

The following example modifies the parameter group that you created for SQL Server Standard Edition 2016.

To modify the parameter group

- Use one of the following commands.

  Example

  For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group \
    --db-parameter-group-name dbmail-sqlserver-se-13 \
    --parameters "ParameterName='database mail
 xps',ParameterValue=1,ApplyMethod=immediate"
```

  For Windows:

```
aws rds modify-db-parameter-group ^
    --db-parameter-group-name dbmail-sqlserver-se-13 ^
    --parameters "ParameterName='database mail
 xps',ParameterValue=1,ApplyMethod=immediate"
```

Associating the parameter group with the DB instance

You can use the AWS Management Console or the AWS CLI to associate the Database Mail parameter group with the DB instance.

Console

You can associate the Database Mail parameter group with a new or existing DB instance.

- For a new DB instance, associate it when you launch the instance. For more information, see Creating an Amazon RDS DB instance.

- For an existing DB instance, associate it by modifying the instance. For more information, see Modifying an Amazon RDS DB instance.

CLI

You can associate the Database Mail parameter group with a new or existing DB instance.

To create a DB instance with the Database Mail parameter group

- Specify the same DB engine type and major version as you used when creating the parameter group.

  Example

  For Linux, macOS, or Unix:

```
aws rds create-db-instance \
    --db-instance-identifier mydbinstance \
    --db-instance-class db.m5.2xlarge \
    --engine sqlserver-se \
    --engine-version 13.00.5426.0.v1 \
    --allocated-storage 100 \
    --manage-master-user-password \
    --master-username admin \
    --storage-type gp2 \
    --license-model li
    --db-parameter-group-name dbmail-sqlserver-se-13
```

  For Windows:

```
aws rds create-db-instance ^
    --db-instance-identifier mydbinstance ^
    --db-instance-class db.m5.2xlarge ^
    --engine sqlserver-se ^
    --engine-version 13.00.5426.0.v1 ^
    --allocated-storage 100 ^
    --manage-master-user-password ^
    --master-username admin ^
    --storage-type gp2 ^
    --license-model li ^
    --db-parameter-group-name dbmail-sqlserver-se-13
```

To modify a DB instance and associate the Database Mail parameter group

- Use one of the following commands.

  Example

  For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier mydbinstance \
    --db-parameter-group-name dbmail-sqlserver-se-13 \
    --apply-immediately
```

  For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier mydbinstance ^
    --db-parameter-group-name dbmail-sqlserver-se-13 ^
    --apply-immediately
```

Configuring Database Mail

You perform the following tasks to configure Database Mail:

1. Create the Database Mail profile.
2. Create the Database Mail account.
3. Add the Database Mail account to the Database Mail profile.
4. Add users to the Database Mail profile.

> **Note**
>
> To configure Database Mail, make sure that you have `execute` permission on the stored procedures in the `msdb` database.

Creating the Database Mail profile

To create the Database Mail profile, you use the sysmail_add_profile_sp stored procedure. The following example creates a profile named `Notifications`.

To create the profile

- Use the following SQL statement.

```
USE msdb
GO

EXECUTE msdb.dbo.sysmail_add_profile_sp
    @profile_name         = 'Notifications',
    @description          = 'Profile used for sending outgoing notifications using
 Amazon SES.';
GO
```

Creating the Database Mail account

To create the Database Mail account, you use the sysmail_add_account_sp stored procedure. The following example creates an account named SES on an RDS for SQL Server DB instance in a private VPC, using Amazon Simple Email Service.

Using Amazon SES requires the following parameters:

- `@email_address` – An Amazon SES verified identity. For more information, see Verified identities in Amazon SES.
- `@mailserver_name` – An Amazon SES SMTP endpoint. For more information, see Connecting to an Amazon SES SMTP endpoint.
- `@username` – An Amazon SES SMTP user name. For more information, see Obtaining Amazon SES SMTP credentials.

  Don't use an AWS Identity and Access Management user name.
- `@password` – An Amazon SES SMTP password. For more information, see Obtaining Amazon SES SMTP credentials.

To create the account

- Use the following SQL statement.

```
USE msdb
GO

EXECUTE msdb.dbo.sysmail_add_account_sp
    @account_name        = 'SES',
    @description         = 'Mail account for sending outgoing notifications.',
    @email_address       = 'nobody@example.com',
    @display_name        = 'Automated Mailer',
    @mailserver_name     = 'vpce-0a1b2c3d4e5f-01234567.email-smtp.us-
west-2.vpce.amazonaws.com',
    @port                = 587,
    @enable_ssl          = 1,
    @username            = 'Smtp_Username',
    @password            = 'Smtp_Password';
GO
```

> **Note**
>
> Specify credentials other than the prompts shown here as a security best practice.

Adding the Database Mail account to the Database Mail profile

To add the Database Mail account to the Database Mail profile, you use the sysmail_add_profileaccount_sp stored procedure. The following example adds the SES account to the `Notifications` profile.

To add the account to the profile

- Use the following SQL statement.

```
USE msdb
GO

EXECUTE msdb.dbo.sysmail_add_profileaccount_sp
    @profile_name        = 'Notifications',
    @account_name        = 'SES',
```

```
    @sequence_number     = 1;
GO
```

Adding users to the Database Mail profile

To grant permission for an `msdb` database principal to use a Database Mail profile, you use the sysmail_add_principalprofile_sp stored procedure. A *principal* is an entity that can request SQL Server resources. The database principal must map to a SQL Server authentication user, a Windows Authentication user, or a Windows Authentication group.

The following example grants public access to the `Notifications` profile.

To add a user to the profile

- Use the following SQL statement.

```
USE msdb
GO

EXECUTE msdb.dbo.sysmail_add_principalprofile_sp
    @profile_name       = 'Notifications',
    @principal_name     = 'public',
    @is_default         = 1;
GO
```

Amazon RDS stored procedures and functions for Database Mail

Microsoft provides stored procedures for using Database Mail, such as creating, listing, updating, and deleting accounts and profiles. In addition, RDS provides the stored procedures and functions for Database Mail shown in the following table.

Procedure/Function	Description
rds_fn_sysmail_allitems	Shows sent messages, including those submitted by other users.
rds_fn_sysmail_event_log	Shows events, including those for messages submitted by other users.

Procedure/Function	Description
rds_fn_sysmail_mailattachments	Shows attachments, including those to messages submitted by other users.
rds_sysmail_control	Starts and stops the mail queue (DatabaseMail.exe process).
rds_sysmail_delete_mailitems_sp	Deletes email messages sent by all users from the Database Mail internal tables.

Sending email messages using Database Mail

You use the sp_send_dbmail stored procedure to send email messages using Database Mail.

Usage

```
EXEC msdb.dbo.sp_send_dbmail
@profile_name = 'profile_name',
@recipients = 'recipient1@example.com[; recipient2; ... recipientn]',
@subject = 'subject',
@body = 'message_body',
[@body_format = 'HTML'],
[@file_attachments = 'file_path1; file_path2; ... file_pathn'],
[@query = 'SQL_query'],
[@attach_query_result_as_file = 0|1]';
```

The following parameters are required:

- `@profile_name` – The name of the Database Mail profile from which to send the message.
- `@recipients` – The semicolon-delimited list of email addresses to which to send the message.
- `@subject` – The subject of the message.
- @body – The body of the message. You can also use a declared variable as the body.

The following parameters are optional:

- `@body_format` – This parameter is used with a declared variable to send email in HTML format.
- `@file_attachments` – The semicolon-delimited list of message attachments. File paths must be absolute paths.

- `@query` – A SQL query to run. The query results can be attached as a file or included in the body of the message.
- `@attach_query_result_as_file` – Whether to attach the query result as a file. Set to 0 for no, 1 for yes. The default is 0.

Examples

The following examples demonstrate how to send email messages.

Example of sending a message to a single recipient

```
USE msdb
GO

EXEC msdb.dbo.sp_send_dbmail
     @profile_name       = 'Notifications',
     @recipients         = 'nobody@example.com',
     @subject            = 'Automated DBMail message - 1',
     @body               = 'Database Mail configuration was successful.';
GO
```

Example of sending a message to multiple recipients

```
USE msdb
GO

EXEC msdb.dbo.sp_send_dbmail
     @profile_name       = 'Notifications',
     @recipients         = 'recipient1@example.com;recipient2@example.com',
     @subject            = 'Automated DBMail message - 2',
     @body               = 'This is a message.';
GO
```

Example of sending a SQL query result as a file attachment

```
USE msdb
GO

EXEC msdb.dbo.sp_send_dbmail
     @profile_name       = 'Notifications',
     @recipients         = 'nobody@example.com',
```

```
     @subject            = 'Test SQL query',
     @body               = 'This is a SQL query test.',
     @query              = 'SELECT * FROM abc.dbo.test',
     @attach_query_result_as_file = 1;
GO
```

Example of sending a message in HTML format

```
USE msdb
GO

DECLARE @HTML_Body as NVARCHAR(500) = 'Hi, <h4> Heading </h4> </br> See the report. <b>
 Regards </b>';

EXEC msdb.dbo.sp_send_dbmail
     @profile_name       = 'Notifications',
     @recipients         = 'nobody@example.com',
     @subject            = 'Test HTML message',
     @body               = @HTML_Body,
     @body_format        = 'HTML';
GO
```

Example of sending a message using a trigger when a specific event occurs in the database

```
USE AdventureWorks2017
GO
IF OBJECT_ID ('Production.iProductNotification', 'TR') IS NOT NULL
DROP TRIGGER Purchasing.iProductNotification
GO

CREATE TRIGGER iProductNotification ON Production.Product
   FOR INSERT
   AS
   DECLARE @ProductInformation nvarchar(255);
   SELECT
   @ProductInformation = 'A new product, ' + Name + ', is now available for $' +
 CAST(StandardCost AS nvarchar(20)) + '!'
   FROM INSERTED i;

EXEC msdb.dbo.sp_send_dbmail
     @profile_name       = 'Notifications',
     @recipients         = 'nobody@example.com',
     @subject            = 'New product information',
```

```
    @body                = @ProductInformation;
GO
```

Viewing messages, logs, and attachments

You use RDS stored procedures to view messages, event logs, and attachments.

To view all email messages

- Use the following SQL query.

```
SELECT * FROM msdb.dbo.rds_fn_sysmail_allitems(); --WHERE sent_status='sent' or
 'failed' or 'unsent'
```

To view all email event logs

- Use the following SQL query.

```
SELECT * FROM msdb.dbo.rds_fn_sysmail_event_log();
```

To view all email attachments

- Use the following SQL query.

```
SELECT * FROM msdb.dbo.rds_fn_sysmail_mailattachments();
```

Deleting messages

You use the `rds_sysmail_delete_mailitems_sp` stored procedure to delete messages.

> **Note**
>
> RDS automatically deletes mail table items when DBMail history data reaches 1 GB in size, with a retention period of at least 24 hours.
> If you want to keep mail items for a longer period, you can archive them. For more information, see Create a SQL Server Agent job to archive Database Mail messages and event logs in the Microsoft documentation.

To delete all email messages

- Use the following SQL statement.

```
DECLARE @GETDATE datetime
SET @GETDATE = GETDATE();
EXECUTE msdb.dbo.rds_sysmail_delete_mailitems_sp @sent_before = @GETDATE;
GO
```

To delete all email messages with a particular status

- Use the following SQL statement to delete all failed messages.

```
DECLARE @GETDATE datetime
SET @GETDATE = GETDATE();
EXECUTE msdb.dbo.rds_sysmail_delete_mailitems_sp @sent_status = 'failed';
GO
```

Starting the mail queue

You use the `rds_sysmail_control` stored procedure to start the Database Mail process.

> **Note**
>
> Enabling Database Mail automatically starts the mail queue.

To start the mail queue

- Use the following SQL statement.

```
EXECUTE msdb.dbo.rds_sysmail_control start;
GO
```

Stopping the mail queue

You use the `rds_sysmail_control` stored procedure to stop the Database Mail process.

To stop the mail queue

- Use the following SQL statement.

```
EXECUTE msdb.dbo.rds_sysmail_control stop;
GO
```

Working with file attachments

The following file attachment extensions aren't supported in Database Mail messages from RDS on SQL
Server: .ade, .adp, .apk, .appx, .appxbundle, .bat, .bak, .cab, .chm, .cmd, .com, .cpl, .dll, .dmg, .exe, .hta, .inf1 and .wsh.

Database Mail uses the Microsoft Windows security context of the current user to control access to files. Users who log in with SQL Server Authentication can't attach files using the `@file_attachments` parameter with the `sp_send_dbmail` stored procedure. Windows doesn't allow SQL Server to provide credentials from a remote computer to another remote computer. Therefore, Database Mail can't attach files from a network share when the command is run from a computer other than the computer running SQL Server.

However, you can use SQL Server Agent jobs to attach files. For more information on SQL Server Agent, see Using SQL Server Agent and SQL Server Agent in the Microsoft documentation.

Considerations for Multi-AZ deployments

When you configure Database Mail on a Multi-AZ DB instance, the configuration isn't automatically propagated to the secondary. We recommend converting the Multi-AZ instance to a Single-AZ instance, configuring Database Mail, and then converting the DB instance back to Multi-AZ. Then both the primary and secondary nodes have the Database Mail configuration.

If you create a read replica from your Multi-AZ instance that has Database Mail configured, the replica inherits the configuration, but without the password to the SMTP server. Update the Database Mail account with the password.

Removing the SMTP (port 25) restriction

By default, AWS blocks outbound traffic on SMTP (port 25) for RDS for SQL Server DB instances. This is done to prevent spam based on the elastic network interface owner's policies. You can

remove this restriction if needed. For more information, see How do I remove the restriction on port 25 from my Amazon EC2 instance or Lambda function?.

Instance store support for the tempdb database on Amazon RDS for SQL Server

An *instance store* provides temporary block-level storage for your DB instance. This storage is located on disks that are physically attached to the host computer. These disks have Non-Volatile Memory Express (NVMe) instance storage that is based on solid-state drives (SSDs). This storage is optimized for low latency, very high random I/O performance, and high sequential read throughput.

By placing `tempdb` data files and `tempdb` log files on the instance store, you can achieve lower read and write latencies compared to standard storage based on Amazon EBS.

> **Note**
>
> SQL Server database files and database log files aren't placed on the instance store.

Enabling the instance store

When RDS provisions DB instances with one of the following instance classes, the `tempdb` database is automatically placed onto the instance store:

- db.m5d
- db.r5d
- db.x2iedn

To enable the instance store, do one of the following:

- Create a SQL Server DB instance using one of these instance types. For more information, see Creating an Amazon RDS DB instance.
- Modify an existing SQL Server DB instance to use one of them. For more information, see Modifying an Amazon RDS DB instance.

The instance store is available in all AWS Regions where one or more of these instance types are supported. For more information on the `db.m5d` and `db.r5d` instance classes, see DB instance classes. For more information on the instance classes supported by Amazon RDS for SQL Server, see DB instance class support for Microsoft SQL Server.

File location and size considerations

On instances without an instance store, RDS stores the `tempdb` data and log files in the `D:\rdsdbdata\DATA` directory. Both files start at 8 MB by default.

On instances with an instance store, RDS stores the `tempdb` data and log files in the `T:\rdsdbdata\DATA` directory.

When `tempdb` has only one data file (`tempdb.mdf`) and one log file (`templog.ldf`), `templog.ldf` starts at 8 MB by default and `tempdb.mdf` starts at 80% or more of the instance's storage capacity. Twenty percent of the storage capacity or 200 GB, whichever is less, is kept free to start. Multiple `tempdb` data files split the 80% disk space evenly, while log files always have an 8-MB initial size.

For example, if you modify your DB instance class from `db.m5.2xlarge` to `db.m5d.2xlarge`, the size of `tempdb` data files increases from 8 MB each to 234 GB in total.

> **Note**
>
> Besides the `tempdb` data and log files on the instance store (`T:\rdsdbdata\DATA`), you can still create extra `tempdb` data and log files on the data volume (`D:\rdsdbdata\DATA`). Those files always have an 8 MB initial size.

Backup considerations

You might need to retain backups for long periods, incurring costs over time. The `tempdb` data and log blocks can change very often depending on the workload. This can greatly increase the DB snapshot size.

When `tempdb` is on the instance store, snapshots don't include temporary files. This means that snapshot sizes are smaller and consume less of the free backup allocation compared to EBS-only storage.

Disk full errors

If you use all of the available space in the instance store, you might receive errors such as the following:

- The transaction log for database 'tempdb' is full due to 'ACTIVE_TRANSACTION'.

- Could not allocate space for object 'dbo.SORT temporary run storage: 140738941419520' in database 'tempdb' because the 'PRIMARY' filegroup is full. Create disk space by deleting unneeded files, dropping objects in the filegroup, adding additional files to the filegroup, or setting autogrowth on for existing files in the filegroup.

You can do one or more of the following when the instance store is full:

- Adjust your workload or the way you use `tempdb`.
- Scale up to use a DB instance class with more NVMe storage.
- Stop using the instance store, and use an instance class with only EBS storage.
- Use a mixed mode by adding secondary data or log files for `tempdb` on the EBS volume.

Removing the instance store

To remove the instance store, modify your SQL Server DB instance to use an instance type that doesn't support instance store, such as db.m5, db.r5, or db.x1e.

> **Note**
>
> When you remove the instance store, the temporary files are moved to the `D:\rdsdbdata\DATA` directory and reduced in size to 8 MB.

Using extended events with Amazon RDS for Microsoft SQL Server

You can use extended events in Microsoft SQL Server to capture debugging and troubleshooting information for Amazon RDS for SQL Server. Extended events replace SQL Trace and Server Profiler, which have been deprecated by Microsoft. Extended events are similar to profiler traces but with more granular control on the events being traced. Extended events are supported for SQL Server versions 2016 and later on Amazon RDS. For more information, see Extended events overview in the Microsoft documentation.

Extended events are turned on automatically for users with master user privileges in Amazon RDS for SQL Server.

Topics

Limitations and recommendations

When using extended events on RDS for SQL Server, the following limitations apply:

- Extended events are supported only for the Enterprise and Standard Editions.
- You can't alter default extended event sessions.
- Make sure to set the session memory partition mode to `NONE`.
- Session event retention mode can be either `ALLOW_SINGLE_EVENT_LOSS` or `ALLOW_MULTIPLE_EVENT_LOSS`.
- Event Tracing for Windows (ETW) targets aren't supported.
- Make sure that file targets are in the `D:\rdsdbdata\log` directory.
- For pair matching targets, set the `respond_to_memory_pressure` property to 1.
- Ring buffer target memory can't be greater than 4 MB.
- The following actions aren't supported:
  - `debug_break`
  - `create_dump_all_threads`

- `create_dump_single_threads`

- The `rpc_completed` event is supported on the following versions and later: 15.0.4083.2, 14.0.3370.1, 13.0.5865.1, 12.0.6433.1, 11.0.7507.2.

Configuring extended events on RDS for SQL Server

On RDS for SQL Server, you can configure the values of certain parameters of extended event sessions. The following table describes the configurable parameters.

Parameter name	Description
`xe_session_max_memory`	Specifies the maximum amount of memory to allocate t corresponds to the `max_memory` setting of the event s
`xe_session_max_event_size`	Specifies the maximum memory size allowed for large e `_size` setting of the event session.
`xe_session_max_dispatch_latency`	Specifies the amount of time that events are buffered in session targets. This value corresponds to the `max_disp`
`xe_file_target_size`	Specifies the maximum size of the file target. This value file target.
`xe_file_retention`	Specifies the retention time in days for files generated b

> **Note**
>
> Setting `xe_file_retention` to zero causes .xel files to be removed automatically after the lock on these files is released by SQL Server. The lock is released whenever an .xel file reaches the size limit set in `xe_file_target_size`.

You can use the `rdsadmin.dbo.rds_show_configuration` stored procedure to show the current values of these parameters. For example, use the following SQL statement to view the current setting of `xe_session_max_memory`.

```
exec rdsadmin.dbo.rds_show_configuration 'xe_session_max_memory'
```

You can use the `rdsadmin.dbo.rds_set_configuration` stored procedure to modify them. For example, use the following SQL statement to set `xe_session_max_memory` to 4 MB.

```
exec rdsadmin.dbo.rds_set_configuration 'xe_session_max_memory', 4
```

Considerations for Multi-AZ deployments

When you create an extended event session on a primary DB instance, it doesn't propagate to the standby replica. You can fail over and create the extended event session on the new primary DB instance. Or you can remove and then re-add the Multi-AZ configuration to propagate the extended event session to the standby replica. RDS stops all nondefault extended event sessions on the standby replica, so that these sessions don't consume resources on the standby. Because of this, after a standby replica becomes the primary DB instance, make sure to manually start the extended event sessions on the new primary.

> **Note**
>
> This approach applies to both Always On Availability Groups and Database Mirroring.

You can also use a SQL Server Agent job to track the standby replica and start the sessions if the standby becomes the primary. For example, use the following query in your SQL Server Agent job step to restart event sessions on a primary DB instance.

```
BEGIN
    IF (DATABASEPROPERTYEX('rdsadmin','Updateability')='READ_WRITE'
    AND DATABASEPROPERTYEX('rdsadmin','status')='ONLINE'
    AND (DATABASEPROPERTYEX('rdsadmin','Collation') IS NOT NULL OR
 DATABASEPROPERTYEX('rdsadmin','IsAutoClose')=1)
    )
    BEGIN
        IF NOT EXISTS (SELECT 1 FROM sys.dm_xe_sessions WHERE name='xe1')
            ALTER EVENT SESSION xe1 ON SERVER STATE=START
        IF NOT EXISTS (SELECT 1 FROM sys.dm_xe_sessions WHERE name='xe2')
            ALTER EVENT SESSION xe2 ON SERVER STATE=START
    END
END
```

This query restarts the event sessions `xe1` and `xe2` on a primary DB instance if these sessions are in a stopped state. You can also add a schedule with a convenient interval to this query.

Querying extended event files

You can either use SQL Server Management Studio or the `sys.fn_xe_file_target_read_file` function to view data from extended events that use file targets. For more information on this function, see sys.fn_xe_file_target_read_file (Transact-SQL) in the Microsoft documentation.

Extended event file targets can only write files to the `D:\rdsdbdata\log` directory on RDS for SQL Server.

As an example, use the following SQL query to list the contents of all files of extended event sessions whose names start with `xe`.

```
SELECT * FROM sys.fn_xe_file_target_read_file('d:\rdsdbdata\log\xe*', null,null,null);
```

Access to transaction log backups with RDS for SQL Server

With access to transaction log backups for RDS for SQL Server, you can list the transaction log backup files for a database and copy them to a target Amazon S3 bucket. By copying transaction log backups in an Amazon S3 bucket, you can use them in combination with full and differential database backups to perform point in time database restores. You use RDS stored procedures to set up access to transaction log backups, list available transaction log backups, and copy them to your Amazon S3 bucket.

Access to transaction log backups provides the following capabilities and benefits:

- List and view the metadata of available transaction log backups for a database on an RDS for SQL Server DB instance.
- Copy available transaction log backups from RDS for SQL Server to a target Amazon S3 bucket.
- Perform point-in-time restores of databases without the need to restore an entire DB instance. For more information on restoring a DB instance to a point in time, see Restoring a DB instance to a specified time.

Availability and support

Access to transaction log backups is supported in all AWS Regions. Access to transaction log backups is available for all editions and versions of Microsoft SQL Server supported on Amazon RDS.

Requirements

The following requirements must be met before enabling access to transaction log backups:

- Automated backups must be enabled on the DB instance and the backup retention must be set to a value of one or more days. For more information on enabling automated backups and configuring a retention policy, see Enabling automated backups.
- An Amazon S3 bucket must exist in the same account and Region as the source DB instance. Before enabling access to transaction log backups, choose an existing Amazon S3 bucket or create a new bucket to use for your transaction log backup files.
- An Amazon S3 bucket permissions policy must be configured as follows to allow Amazon RDS to copy transaction log files into it:

  1. Set the object account ownership property on the bucket to **Bucket Owner Preferred**.

2. Add the following policy. There will be no policy by default, so use the bucket Access Control Lists (ACL) to edit the bucket policy and add it.

   The following example uses an ARN to specify a resource. We recommend using the `SourceArn` and `SourceAccount` global condition context keys in resource-based trust relationships to limit the service's permissions to a specific resource. For more information on working with ARNs, see Amazon resource names (ARNs) and Amazon Resource Names (ARNs) in Amazon RDS.

   Example of an Amazon S3 permissions policy for access to transaction log backups

```
    {
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "Only allow writes to my bucket with bucket owner full control",
            "Effect": "Allow",
            "Principal": {
                "Service": "backups.rds.amazonaws.com"
            },
            "Action": "s3:PutObject",
            "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/{customer_path}/*",
            "Condition": {
                "StringEquals": {
                    "s3:x-amz-acl": "bucket-owner-full-control",
                    "aws:sourceAccount": "{customer_account}",
                    "aws:sourceArn": "{db_instance_arn}"
                }
            }
        }
    ]
}
```

- An AWS Identity and Access Management (IAM) role to access the Amazon S3 bucket. If you already have an IAM role, you can use that. You can choose to have a new IAM role created for you when you add the `SQLSERVER_BACKUP_RESTORE` option by using the AWS Management Console. Alternatively, you can create a new one manually. For more information on creating and configuring an IAM role with `SQLSERVER_BACKUP_RESTORE`, see Manually creating an IAM role for native backup and restore.

- The SQLSERVER_BACKUP_RESTORE option must be added to an option group on your DB instance. For more information on adding the SQLSERVER_BACKUP_RESTORE option, see Support for native backup and restore in SQL Server.

  > **Note**
  >
  > If your DB instance has storage encryption enabled, the AWS KMS (KMS) actions and key must be provided in the IAM role provided in the native backup and restore option group.

  Optionally, if you intend to use the `rds_restore_log` stored procedure to perform point in time database restores, we recommend using the same Amazon S3 path for the native backup and restore option group and access to transaction log backups. This method ensures that when Amazon RDS assumes the role from the option group to perform the restore log functions, it has access to retrieve transaction log backups from the same Amazon S3 path.
- If the DB instance is encrypted, regardless of encryption type (AWS managed key or customer managed key), you must provide a customer managed KMS key in the IAM role and in the `rds_tlog_backup_copy_to_S3` stored procedure.

Limitations and recommendations

Access to transaction log backups has the following limitations and recommendations:

- You can list and copy up to the last seven days of transaction log backups for any DB instance that has backup retention configured between one to 35 days.
- The Amazon S3 bucket used for access to transaction log backups must exist in the same account and Region as the source DB instance. Cross-account and cross-region copy is not supported.
- Only one Amazon S3 bucket can be configured as a target to copy transaction log backups into. You can choose a new target Amazon S3 bucket with the `rds_tlog_copy_setup` stored procedure. For more information on choosing a new target Amazon S3 bucket, see Setting up access to transaction log backups.
- You cannot specify the KMS key when using the `rds_tlog_backup_copy_to_S3` stored procedure if your RDS instance is not enabled for storage encryption.
- Multi-account copying is not supported. The IAM role used for copying will only permit write access to Amazon S3 buckets within the owner account of the DB instance.
- Only two concurrent tasks of any type may be run on an RDS for SQL Server DB instance.

- Only one copy task can run for a single database at a given time. If you want to copy transaction log backups for multiple databases on the DB instance, use a separate copy task for each database.
- If you copy a transaction log backup that already exists with the same name in the Amazon S3 bucket, the existing transaction log backup will be overwritten.
- You can only run the stored procedures that are provided with access to transaction log backups on the primary DB instance. You can't run these stored procedures on an RDS for SQL Server read replica or on a secondary instance of a Multi-AZ DB cluster.
- If the RDS for SQL Server DB instance is rebooted while the `rds_tlog_backup_copy_to_S3` stored procedure is running, the task will automatically restart from the beginning when the DB instance is back online. Any transaction log backups that had been copied to the Amazon S3 bucket while the task was running before the reboot will be overwritten.
- The Microsoft SQL Server system databases and the `RDSAdmin` database cannot be configured for access to transaction log backups.
- Copying to buckets encrypted by SSE-KMS isn't supported.

Setting up access to transaction log backups

To set up access to transaction log backups, complete the list of requirements in the Requirements section, and then run the `rds_tlog_copy_setup` stored procedure. The procedure will enable the access to transaction log backups feature at the DB instance level. You don't need to run it for each individual database on the DB instance.

> **Important**
>
> The database user must be granted the `db_owner` role within SQL Server on each database to configure and use the access to transaction log backups feature.

Example usage:

```
exec msdb.dbo.rds_tlog_copy_setup
@target_s3_arn='arn:aws:s3:::amzn-s3-demo-bucket/myfolder';
```

The following parameter is required:

- `@target_s3_arn` – The ARN of the target Amazon S3 bucket to copy transaction log backups files to.

Example of setting an Amazon S3 target bucket:

```
exec msdb.dbo.rds_tlog_copy_setup @target_s3_arn='arn:aws:s3:::amzn-s3-demo-logging-bucket/mytestdb1';
```

To validate the configuration, call the `rds_show_configuration` stored procedure.

Example of validating the configuration:

```
exec rdsadmin.dbo.rds_show_configuration @name='target_s3_arn_for_tlog_copy';
```

To modify access to transaction log backups to point to a different Amazon S3 bucket, you can view the current Amazon S3 bucket value and re-run the `rds_tlog_copy_setup` stored procedure using a new value for the `@target_s3_arn`.

Example of viewing the existing Amazon S3 bucket configured for access to transaction log backups

```
exec rdsadmin.dbo.rds_show_configuration @name='target_s3_arn_for_tlog_copy';
```

Example of updating to a new target Amazon S3 bucket

```
exec msdb.dbo.rds_tlog_copy_setup @target_s3_arn='arn:aws:s3:::amzn-s3-demo-logging-bucket1/mynewfolder';
```

Listing available transaction log backups

With RDS for SQL Server, databases configured to use the full recovery model and a DB instance backup retention set to one or more days have transaction log backups automatically enabled. By enabling access to transaction log backups, up to seven days of those transaction log backups are made available for you to copy into your Amazon S3 bucket.

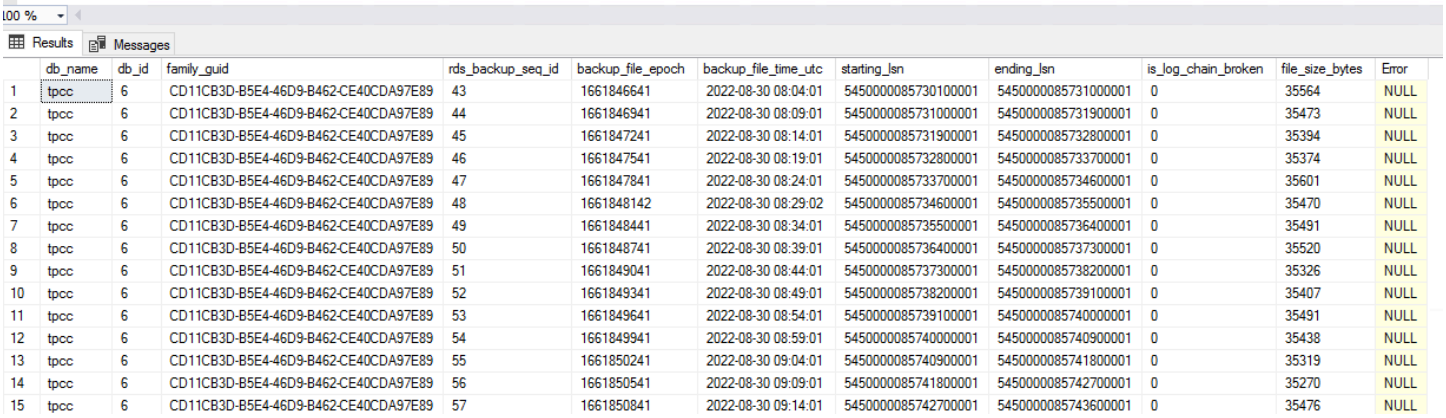
After you have enabled access to transaction log backups, you can start using it to list and copy available transaction log backup files.

Listing transaction log backups

To list all transaction log backups available for an individual database, call the `rds_fn_list_tlog_backup_metadata` function. You can use an `ORDER BY` or a `WHERE` clause when calling the function.

Example of listing and filtering available transaction log backup files

```
SELECT * from msdb.dbo.rds_fn_list_tlog_backup_metadata('mydatabasename');
SELECT * from msdb.dbo.rds_fn_list_tlog_backup_metadata('mydatabasename') WHERE
 rds_backup_seq_id = 3507;
SELECT * from msdb.dbo.rds_fn_list_tlog_backup_metadata('mydatabasename') WHERE
 backup_file_time_utc > '2022-09-15 20:44:01' ORDER BY backup_file_time_utc DESC;
```



100 %

The `rds_fn_list_tlog_backup_metadata` function returns the following output:

Column name	Data type	Description
db_name	sysname	The database name provided to list the transacti on log backups for.
db_id	int	The internal database identifier for the input parameter db_name.

Column name	Data type	Description
family_guid	uniqueidentifier	The unique ID of the original database at creation. This value remains the same when the database is restored, even to a different database name.
rds_backup_seq_id	int	The ID that RDS uses internally to maintain a sequence number for each transaction log backup file.
backup_file_epoch	bigint	The epoch time that a transaction backup file was generated.
backup_file_time_utc	datetime	The UTC time-converted value for the backup_file_epoch value.
starting_lsn	numeric(25,0)	The log sequence number of the first or oldest log record of a transaction log backup file.
ending_lsn	numeric(25,0)	The log sequence number of the last or next log record of a transaction log backup file.
is_log_chain_broken	bit	A boolean value indicating if the log chain is broken between the current transaction log backup file and the previous transaction log backup file.
file_size_bytes	bigint	The size of the transactional backup set in bytes.
Error	varchar(4000)	Error message if the rds_fn_list_tlog_backup_metadata function throws an exception. NULL if no exceptions.

Copying transaction log backups

To copy a set of available transaction log backups for an individual database to your Amazon S3 bucket, call the rds_tlog_backup_copy_to_S3 stored procedure. The

`rds_tlog_backup_copy_to_S3` stored procedure will initiate a new task to copy transaction log backups.

> **Note**
>
> The `rds_tlog_backup_copy_to_S3` stored procedure will copy the transaction log backups without validating against `is_log_chain_broken` attribute. For this reason, you should manually confirm an unbroken log chain before running the `rds_tlog_backup_copy_to_S3` stored procedure. For further explanation, see Validating the transaction log backup log chain.

Example usage of the `rds_tlog_backup_copy_to_S3` stored procedure

```
exec msdb.dbo.rds_tlog_backup_copy_to_S3
 @db_name='mydatabasename',
 [@kms_key_arn='arn:aws:kms:region:account-id:key/key-id'],
 [@backup_file_start_time='2022-09-01 01:00:15'],
 [@backup_file_end_time='2022-09-01 21:30:45'],
 [@starting_lsn=149000000112100001],
 [@ending_lsn=149000000120400001],
 [@rds_backup_starting_seq_id=5],
 [@rds_backup_ending_seq_id=10];
```

The following input parameters are available:

Parameter	Description
`@db_name`	The name of the database to copy transaction log backups for
`@kms_key_arn`	A customer managed KMS key. If you encrypt your DB instance with an AWS managed KMS key, you must create a customer managed key. If you encrypt your DB instance with a customer managed key, you can use the same KMS key ARN.
`@backup_file_start_time`	The UTC timestamp as provided from the `[backup_file_time_utc]` column of the `rds_fn_list_tlog_backup_metadata` function.

Parameter	Description
`@backup_file_end_time`	The UTC timestamp as provided from the `[backup_file_time_utc]` column of the `rds_fn_list_tlog_backup_metadata` function.
`@starting_lsn`	The log sequence number (LSN) as provided from the `[starting_lsn]` column of the `rds_fn_list_tlog_backup_metadata` function
`@ending_lsn`	The log sequence number (LSN) as provided from the `[ending_lsn]` column of the `rds_fn_list_tlog_backup_metadata` function.
`@rds_backup_starting_seq_id`	The sequence ID as provided from the `[rds_backup_seq_id]` column of the `rds_fn_list_tlog_backup_metadata` function.
`@rds_backup_ending_seq_id`	The sequence ID as provided from the `[rds_backup_seq_id]` column of the `rds_fn_list_tlog_backup_metadata` function.

You can specify a set of either the time, LSN, or sequence ID parameters. Only one set of parameters are required.

You can also specify just a single parameter in any of the sets. For example, by providing a value for only the `backup_file_end_time` parameter, all available transaction log backup files prior to that time within the seven-day limit will be copied to your Amazon S3 bucket.

Following are the valid input parameter combinations for the `rds_tlog_backup_copy_to_S3` stored procedure.

Parameters provided	Expected result	
`exec msdb.dbo.rds_tlog_`	Copies transaction log backups from the last seven days	

Parameters provided	Expected result
`backup_copy_to_S3 @db_name = 'testdb1', @backup_file_start_time='2022-08-23 00:00:00', @backup_file_end_time='2022-08-30 00:00:00';`	and exist between the provided range of `backup_file_start_time` and `backup_file_end_time` . In this example, the stored procedure will copy transaction log backups that were generated between '2022-08-23 00:00:00' and '2022-08-30 00:00:00'.
`exec msdb.dbo.rds_tlog_backup_copy_to_S3 @db_name = 'testdb1', @backup_file_start_time='2022-08-23 00:00:00';`	Copies transaction log backups from the last seven days and starting from the provided `backup_file_start_time` . In this example, the stored procedure will copy transaction log backups from '2022-08-23 00:00:00' up to the latest transaction log backup.

Parameters provided	Expected result	
`exec msdb.dbo.rds_tlog_backup_copy_to_S3 @db_name = 'testdb1', @backup_file_end_time='2022-08-30 00:00:00';`	Copies transaction log backups from the last seven days up to the provided `backup_file_end_time` . In this example, the stored procedure will copy transaction log backups from '2022-08-23 00:00:00 up to '2022-08-30 00:00:00'.	

Parameters provided	Expected result	

`exec msdb.dbo.rds_tlog_backup_copy_to_S3`
 	
`@db_name='testdb1',`
 	
`@starting_lsn =14900000 00040007,`
 	
`@ending_lsn = 149000000 0050009;`
	Copies transaction log backups that are available from the last seven days and are between the provided range of the `starting_lsn` and `ending_lsn` . In this example, the stored procedure will copy transaction log backups from the last seven days with an LSN range between 149000000 0040007 and 149000000 0050009.	

Parameters provided	Expected result	
`exec msdb.dbo.rds_tlog_backup_copy_to_S3 @db_name='testdb1', @starting_lsn =14900000 00040007;`	Copies transacti on log backups that are available from the last seven days, beginning from the provided `starting_lsn` . In this example, the stored procedure will copy transaction log backups from LSN 149000000 0040007 up to the latest transaction log backup.	
`exec msdb.dbo.rds_tlog_backup_copy_to_S3 @db_name='testdb1', @ending_lsn =14900000 00050009;`	Copies transaction log backups that are available from the last seven days, up to the provided `ending_lsn` . In this example, the stored procedure will copy transacti on log backups beginning from the last seven days up to lsn 149000000 0050009.	

Parameters provided	Expected result	
`exec msdb.dbo.rds_tlog_backup_copy_to_S3 @db_name='testdb1', @rds_backup_starting_seq_id= 2000, @rds_backup_ending_seq_id= 5000;`	Copies transaction log backups that are available from the last seven days, and exist between the provided range of `rds_backup_starting_seq_id` and `rds_backup_ending_seq_id` . In this example, the stored procedure will copy transaction log backups beginning from the last seven days and within the provided rds backup sequence id range, starting from seq_id 2000 up to seq_id 5000.	

Parameters provided	Expected result
`exec msdb.dbo.rds_tlog_backup_copy_to_S3 @db_name='testdb1', @rds_backup_starting_seq_id= 2000;`	Copies transaction log backups that are available from the last seven days, beginning from the provided `rds_backup_starting_seq_id` . In this example, the stored procedure will copy transaction log backups beginning from seq_id 2000, up to the latest transaction log backup.
`exec msdb.dbo.rds_tlog_backup_copy_to_S3 @db_name='testdb1', @rds_backup_ending_seq_id= 5000;`	Copies transaction log backups that are available from the last seven days, up to the provided `rds_backup_ending_seq_id` . In this example, the stored procedure will copy transaction log backups beginning from the last seven days, up to seq_id 5000.

Parameters provided	Expected result	
`exec msdb.dbo.rds_tlog_backup_copy_to_S3 @db_name='testdb1', @rds_backup_starting_seq_id= 2000; @rds_backup_ending_seq_id= 2000;`	Copies a single transaction log backup with the provided `rds_backup_starting_seq_id` , if available within the last seven days. In this example, the stored procedure will copy a single transaction log backup that has a seq_id of 2000, if it exists within the last seven days.	

Validating the transaction log backup log chain

Databases configured for access to transaction log backups must have automated backup retention enabled. Automated backup retention sets the databases on the DB instance to the FULL recovery model. To support point in time restore for a database, avoid changing the database recovery model, which can result in a broken log chain. We recommend keeping the database set to the FULL recovery model.

To manually validate the log chain before copying transaction log backups, call the `rds_fn_list_tlog_backup_metadata` function and review the values in the `is_log_chain_broken` column. A value of "1" indicates the log chain was broken between the current log backup and the previous log backup.

The following example shows a broken log chain in the output from the `rds_fn_list_tlog_backup_metadata` stored procedure.

rds_sequence_id	first_lsn	last_lsn	is_log_chain_broken
43	90023	90457	0
44	90457	90985	0
45	90987	92034	1

In a normal log chain, the log sequence number (LSN) value for first_lsn for given rds_sequence_id should match the value of last_lsn in the preceding rds_sequence_id. In the image, the rds_sequence_id of 45 has a first_lsn value 90987, which does not match the last_lsn value of 90985 for preceeding rds_sequence_id 44.

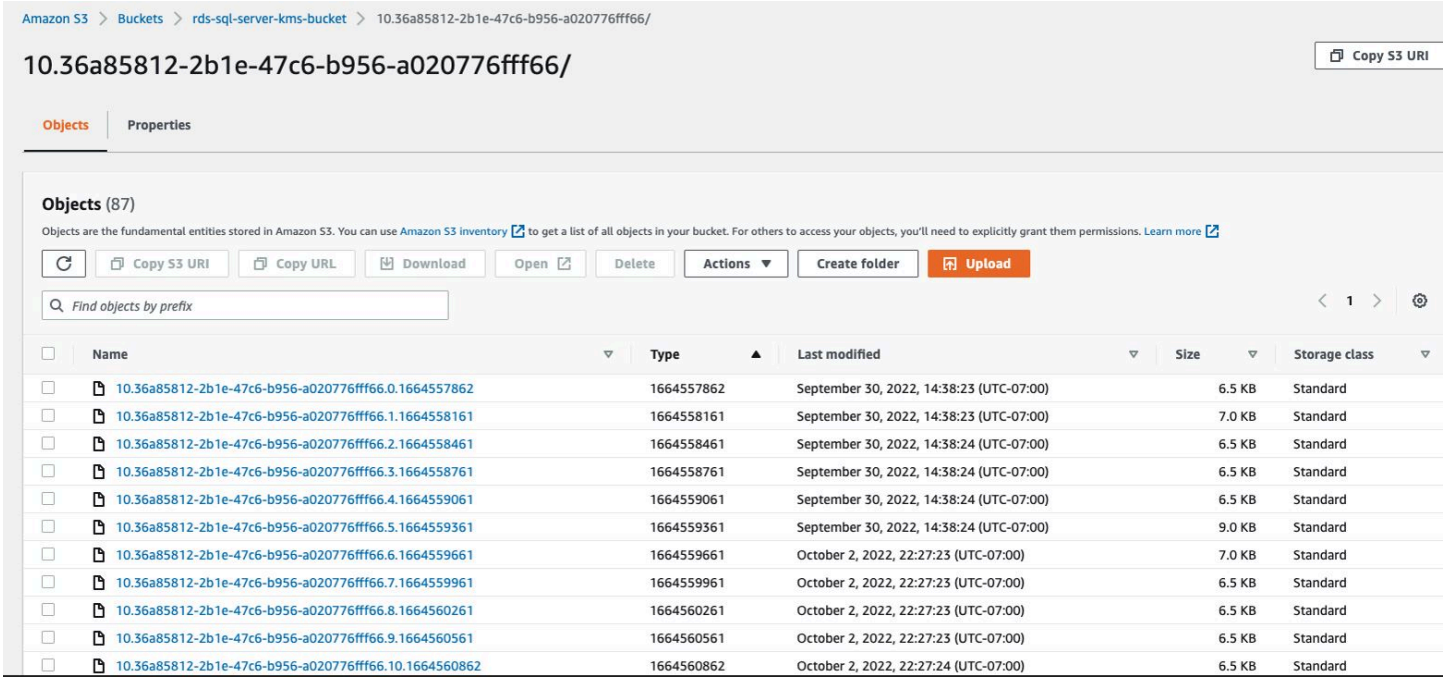
For more information about SQL Server transaction log architecture and log sequence numbers, see Transaction Log Logical Architecture in the Microsoft SQL Server documentation.

Amazon S3 bucket folder and file structure

Transaction log backups have the following standard structure and naming convention within an Amazon S3 bucket:

- A new folder is created under the `target_s3_arn` path for each database with the naming structure as `{db_id}.{family_guid}`.
- Within the folder, transaction log backups have a filename structure as `{db_id}.{family_guid}.{rds_backup_seq_id}.{backup_file_epoch}`.
- You can view the details of `family_guid,db_id,rds_backup_seq_id` and `backup_file_epoch` with the `rds_fn_list_tlog_backup_metadata`function.

The following example shows the folder and file structure of a set of transaction log backups within an Amazon S3 bucket.



Tracking the status of tasks

To track the status of your copy tasks, call the `rds_task_status` stored procedure. If you don't provide any parameters, the stored procedure returns the status of all tasks.

Example usage:

```
exec msdb.dbo.rds_task_status
  @db_name='database_name',
  @task_id=ID_number;
```

The following parameters are optional:

- `@db_name` – The name of the database to show the task status for.
- `@task_id` – The ID of the task to show the task status for.

Example of listing the status for a specific task ID:

```
exec msdb.dbo.rds_task_status @task_id=5;
```

Example of listing the status for a specific database and task:

```
exec msdb.dbo.rds_task_status@db_name='my_database',@task_id=5;
```

Example of listing all tasks and their status for a specific database:

```
exec msdb.dbo.rds_task_status @db_name='my_database';
```

Example of listing all tasks and their status on the current DB instance:

```
exec msdb.dbo.rds_task_status;
```

Canceling a task

To cancel a running task, call the `rds_cancel_task` stored procedure.

Example usage:

```
exec msdb.dbo.rds_cancel_task @task_id=ID_number;
```

The following parameter is required:

- `@task_id` – The ID of the task to cancel. You can view the task ID by calling the `rds_task_status` stored procedure.

For more information on viewing and canceling running tasks, see Importing and exporting SQL Server databases using native backup and restore.

Troubleshooting access to transaction log backups

The following are issues you might encounter when you use the stored procedures for access to transaction log backups.

Stored Procedure	Error Message	Issue	Troubleshooting suggestions
rds_tlog_copy_setup	Backups are disabled on this DB instance. Enable DB instance backups with a retention of at least "1" and try again.	Automated backups are not enabled for the DB instance.	DB instance backup retention must be enabled with a retention of at least one day. For more information on enabling automated backups and configuring backup retention, see Backup retention period.
rds_tlog_copy_setup	Error running the rds_tlog_copy_setup stored procedure. Reconnect to the RDS endpoint and try again.	An internal error occurred.	Reconnect to the RDS endpoint and run the `rds_tlog_copy_setup` stored procedure again.
rds_tlog_copy_setup	Running the rds_tlog_backup_copy_setup stored procedure inside a transacti	The stored procedure was attempted within a transaction using `BEGIN` and `END`.	Avoid using `BEGIN` and `END` when running the `rds_tlog_copy_setup` stored procedure.

Stored Procedure	Error Message	Issue	Troubleshooting suggestions
	on is not supported . Verify that the session has no open transacti ons and try again.		
rds_tlog_ copy_setup	The S3 bucket name for the input parameter `@target_s 3_arn` should contain at least one character other than a space.	An incorrect value was provided for the input parameter `@target_s3_arn` .	Ensure the input parameter `@target_s3_arn` specifies the complete Amazon S3 bucket ARN.

Stored Procedure	Error Message	Issue	Troubleshooting suggestions
rds_tlog_copy_setup	The SQLSERVER_BACKUP_RESTORE option isn't enabled or is in the process of being enabled. Enable the option or try again later.	The SQLSERVER_BACKUP_RESTORE option is not enabled on the DB instance or was just enabled and pending internal activation.	Enable the SQLSERVER_BACKUP_RESTORE option as specified in the Requirements section. Wait a few minutes and run the rds_tlog_copy_setup stored procedure again.
rds_tlog_copy_setup	The target S3 arn for the input parameter @target_s3_arn can't be empty or null.	An NULL value was provided for the input parameter @target_s3_arn , or the value wasn't provided.	Ensure the input parameter @target_s3_arn specifies the complete Amazon S3 bucket ARN.
rds_tlog_copy_setup	The target S3 arn for the input parameter @target_s3_arn must begin with arn:aws.	The input parameter @target_s3_arn was provide without arn:aws on the front.	Ensure the input parameter @target_s3_arn specifies the complete Amazon S3 bucket ARN.

Stored Procedure	Error Message	Issue	Troubleshooting suggestions
rds_tlog_copy_setup	The target S3 ARN is already set to the provided value.	The `rds_tlog_copy_setup` stored procedure previously ran and was configured with an Amazon S3 bucket ARN.	To modify the Amazon S3 bucket value for access to transaction log backups, provide a different `target S3 ARN`.
rds_tlog_copy_setup	Unable to generate credentials for enabling Access to Transaction Log Backups. Confirm the S3 path ARN provided with `rds_tlog_copy_setup`, and try again later.	There was an unspecified error while generating credentials to enable access to transaction log backups.	Review your setup configuration and try again.

Stored Procedure	Error Message	Issue	Troubleshooting suggestions
rds_tlog_copy_setup	You cannot run the rds_tlog_copy_setup stored procedure while there are pending tasks. Wait for the pending tasks to complete and try again.	Only two tasks may run at any time. There are pending tasks awaiting completion.	View pending tasks and wait for them to complete. For more information on monitoring task status, see Tracking the status of tasks.
rds_tlog_backup_copy_to_S3	A T-log backup file copy task has already been issued for database: %s with task Id: %d, please try again later.	Only one copy task may run at any time for a given database. There is a pending copy task awaiting completion.	View pending tasks and wait for them to complete. For more information on monitoring task status, see Tracking the status of tasks.

Stored Procedure	Error Message	Issue	Troubleshooting suggestions
rds_tlog_backup_copy_to_S3	At least one of these three parameter sets must be provided. SET-1:(@backup_file_start_time, @backup_file_end_time) | SET-2:(@starting_lsn, @ending_lsn) | SET-3:(@rds_backup_starting_seq_id, @rds_backup_ending_seq_id)	None of the three parameter sets were provided, or a provided parameter set is missing a required parameter.	You can specify either the time, lsn, or sequence ID parameters. One set from these three sets of parameters are required. For more information on required parameters, see Copying transaction log backups.

Stored Procedure	Error Message	Issue	Troubleshooting suggestions
rds_tlog_backup_copy_to_S3	Backups are disabled on your instance. Please enable backups and try again in some time.	Automated backups are not enabled for the DB instance.	For more information on enabling automated backups and configuring backup retention, see Backup retention period.
rds_tlog_backup_copy_to_S3	Cannot find the given database %s.	The value provided for input parameter `@db_name` does not match a database name on the DB instance.	Use the correct database name. To list all databases by name, run `SELECT * from sys.databases`
rds_tlog_backup_copy_to_S3	Cannot run the rds_tlog_backup_copy_to_S3 stored procedure for SQL Server system databases or the rdsadmin database.	The value provided for input parameter `@db_name` matches a SQL Server system database name or the RDSAdmin database.	The following databases are not allowed to be used with access to transaction log backups: `master, model, msdb, tempdb, RDSAdmin.`

Stored Procedure	Error Message	Issue	Troubleshooting suggestions
rds_tlog_backup_copy_to_S3	Database name for the input parameter @db_name can't be empty or null.	The value provided for input parameter `@db_name` was empty or `NULL`.	Use the correct database name. To list all databases by name, run `SELECT * from sys.databases`
rds_tlog_backup_copy_to_S3	DB instance backup retention period must be set to at least 1 to run the rds_tlog_backup_copy_setup stored procedure.	Automated backups are not enabled for the DB instance.	For more information on enabling automated backups and configuring backup retention, see Backup retention period.
rds_tlog_backup_copy_to_S3	Error running the stored procedure rds_tlog_backup_copy_to_S3. Reconnect to the RDS endpoint and try again.	An internal error occurred.	Reconnect to the RDS endpoint and run the `rds_tlog_backup_copy_to_S3` stored procedure again.

Stored Procedure	Error Message	Issue	Troubleshooting suggestions
rds_tlog_backup_copy_to_S3	Only one of these three parameter sets can be provided. SET-1:(@backup_file_start_time, @backup_file_end_time) | SET-2:(@starting_lsn, @ending_lsn) | SET-3:(@rds_backup_starting_seq_id, @rds_backup_ending_seq_id)	Multiple parameter sets were provided.	You can specify either the time, lsn, or sequence ID parameters. One set from these three sets of parameters are required. For more information on required parameters, see Copying transaction log backups.

Stored Procedure	Error Message	Issue	Troubleshooting suggestions
rds_tlog_backup_copy_to_S3	Running the rds_tlog_backup_copy_to_S3 stored procedure inside a transaction is not supported. Verify that the session has no open transactions and try again.	The stored procedure was attempted within a transaction using `BEGIN` and `END`.	Avoid using `BEGIN` and `END` when running the `rds_tlog_backup_copy_to_S3` stored procedure.

Stored Procedure	Error Message	Issue	Troubleshooting suggestions
rds_tlog_backup_copy_to_S3	The provided parameters fall outside of the transaction backup log retention period. To list of available transaction log backup files, run the rds_fn_list_tlog_backup_metadata function.	There are no available transactional log backups for the provided input parameters that fit in the copy retention window.	Try again with a valid set of parameters. For more information on required parameters, see Copying transaction log backups.

Stored Procedure	Error Message	Issue	Troubleshooting suggestions
rds_tlog_backup_copy_to_S3	There was a permissions error in processing the request. Ensure the bucket is in the same Account and Region as the DB Instance, and confirm the S3 bucket policy permissions against the template in the public documentation.	There was an issue detected with the provided S3 bucket or its policy permissions.	Confirm your setup for access to transaction log backups is correct. For more information on setup requirements for your S3 bucket, see Requirements.

Stored Procedure	Error Message	Issue	Troubleshooting suggestions
rds_tlog_backup_copy_to_S3	Running the `rds_tlog_backup_copy_to_S3` stored procedure on an RDS read replica instance isn't permitted.	The stored procedure was attempted on a RDS read replica instance.	Connect to the RDS primary DB instance to run the `rds_tlog_backup_copy_to_S3` stored procedure.
rds_tlog_backup_copy_to_S3	The LSN for the input parameter `@starting_lsn` must be less than `@ending_lsn .`	The value provided for input parameter `@starting_lsn` was greater than the value provided for input parameter `@ending_lsn .`	Ensure the value provided for input parameter `@starting_lsn` is less than the value provided for input parameter `@ending_lsn .`

Stored Procedure	Error Message	Issue	Troubleshooting suggestions
rds_tlog_backup_copy_to_S3	The `rds_tlog_backup_copy_to_S3` stored procedure can only be performed by the members of `db_owner` role in the source database.	The `db_owner` role has not been granted for the account attempting to run the `rds_tlog_backup_copy_to_S3` stored procedure on the provided `db_name`.	Ensure the account running the stored procedure is permissioned with the `db_owner` role for the provided `db_name`.
rds_tlog_backup_copy_to_S3	The sequence ID for the input parameter `@rds_backup_starting_seq_id` must be less than or equal to `@rds_backup_ending_seq_id` .	The value provided for input parameter `@rds_backup_starting_seq_id` was greater than the value provided for input parameter `@rds_backup_ending_seq_id` .	Ensure the value provided for input parameter `@rds_backup_starting_seq_id` is less than the value provided for input parameter `@rds_backup_ending_seq_id` .

Stored Procedure	Error Message	Issue	Troubleshooting suggestions
rds_tlog_backup_copy_to_S3	The SQLSERVER_BACKUP_RESTORE option isn't enabled or is in the process of being enabled. Enable the option or try again later.	The SQLSERVER_BACKUP_RESTORE option is not enabled on the DB instance or was just enabled and pending internal activation.	Enable the SQLSERVER_BACKUP_RESTORE option as specified in the Requirements section. Wait a few minutes and run the rds_tlog_backup_copy_to_S3 stored procedure again.
rds_tlog_backup_copy_to_S3	The start time for the input parameter @backup_file_start_time must be less than @backup_file_end_time .	The value provided for input parameter @backup_file_start_time was greater than the value provided for input parameter @backup_file_end_time .	Ensure the value provided for input parameter @backup_file_start_time is less than the value provided for input parameter @backup_file_end_time .

Stored Procedure	Error Message	Issue	Troubleshooting suggestions
rds_tlog_backup_copy_to_S3	We were unable to process the request due to a lack of access. Please check your setup and permissions for the feature.	There may be an issue with the Amazon S3 bucket permissions, or the Amazon S3 bucket provided is in another account or Region.	Ensure the Amazon S3 bucket policy permissions are permissioned to allow RDS access. Ensure the Amazon S3 bucket is in the same account and Region as the DB instance.
rds_tlog_backup_copy_to_S3	You cannot provide a KMS Key ARN as input parameter to the stored procedure for instances that are not storage-encrypted.	When storage encryption is not enabled on the DB instance, the input parameter `@kms_key_arn` should not be provided.	Do not provide an input parameter for `@kms_key_arn` .

Stored Procedure	Error Message	Issue	Troubleshooting suggestions
rds_tlog_backup_copy_to_S3	You must provide a KMS Key ARN as input parameter to the stored procedure for storage encrypted instances.	When storage encryption is enabled on the DB instance, the input parameter `@kms_key_arn` must be provided.	Provide an input parameter for `@kms_key_arn` with a value that matches the ARN of the Amazon S3 bucket to use for transaction log backups.
rds_tlog_backup_copy_to_S3	You must run the `rds_tlog_copy_setup` stored procedure and set the `@target_s3_arn` , before running the `rds_tlog_backup_copy_to_S3` stored procedure.	The access to transaction log backups setup procedure was not completed before attempting to run the `rds_tlog_backup_copy_to_S3` stored procedure.	Run the `rds_tlog_copy_setup` stored procedure before running the `rds_tlog_backup_copy_to_S3` stored procedure . For more information on running the setup procedure for access to transaction log backups, see Setting up access to transaction log backups.

Options for the Microsoft SQL Server database engine

In this section, you can find descriptions for options that are available for Amazon RDS instances running the Microsoft SQL Server DB engine. To enable these options, you add them to an option group, and then associate the option group with your DB instance. For more information, see Working with option groups.

If you're looking for optional features that aren't added through RDS option groups (such as SSL, Microsoft Windows Authentication, and Amazon S3 integration), see Additional features for Microsoft SQL Server on Amazon RDS.

Amazon RDS supports the following options for Microsoft SQL Server DB instances.

Option	Option ID	Engine editions
Linked Servers with Oracle OLEDB	`OLEDB_ORACLE`	SQL Server Enterprise Edition SQL Server Standard Edition
Native backup and restore	`SQLSERVER_BACKUP_RESTORE`	SQL Server Enterprise Edition SQL Server Standard Edition SQL Server Web Edition SQL Server Express Edition
Transparent Data Encryption	`TRANSPARENT_DATA_ENCRYPTION` (RDS console)	SQL Server 2016–2022 Enterprise Edition SQL Server 2022 Standard Edition

Option	Option ID	Engine editions
	TDE (AWS CLI and RDS API)	
SQL Server Audit	SQLSERVER_AUDIT	In RDS, starting with SQL Server 2016, all editions of SQL Server support server-level audits, and Enterprise Edition also supports database-level audits. Starting with SQL Server SQL Server 2016 (13.x) SP1, all editions support both server-level and database-level audits. For more information, see SQL Server Audit (database engine) in the SQL Server documentation.
SQL Server Analysis Services	SSAS	SQL Server Enterprise Edition SQL Server Standard Edition

Option	Option ID	Engine editions
SQL Server Integration Services	SSIS	SQL Server Enterprise Edition SQL Server Standard Edition
SQL Server Reporting Services	SSRS	SQL Server Enterprise Edition SQL Server Standard Edition
Microsoft Distributed Transaction Coordinator	MSDTC	In RDS, starting with SQL Server 2016, all editions of SQL Server support distributed transactions.

Listing the available options for SQL Server versions and editions

You can use the `describe-option-group-options` AWS CLI command to list the available options for SQL Server versions and editions, and the settings for those options.

The following example shows the options and option settings for SQL Server 2019 Enterprise Edition. The `--engine-name` option is required.

```
aws rds describe-option-group-options --engine-name sqlserver-ee --major-engine-version
 15.00
```

The output resembles the following:

```
{
    "OptionGroupOptions": [
        {
            "Name": "MSDTC",
            "Description": "Microsoft Distributed Transaction Coordinator",
```

```
            "EngineName": "sqlserver-ee",
            "MajorEngineVersion": "15.00",
            "MinimumRequiredMinorEngineVersion": "4043.16.v1",
            "PortRequired": true,
            "DefaultPort": 5000,
            "OptionsDependedOn": [],
            "OptionsConflictsWith": [],
            "Persistent": false,
            "Permanent": false,
            "RequiresAutoMinorEngineVersionUpgrade": false,
            "VpcOnly": false,
            "OptionGroupOptionSettings": [
                {
                    "SettingName": "ENABLE_SNA_LU",
                    "SettingDescription": "Enable support for SNA LU protocol",
                    "DefaultValue": "true",
                    "ApplyType": "DYNAMIC",
                    "AllowedValues": "true,false",
                    "IsModifiable": true,
                    "IsRequired": false,
                    "MinimumEngineVersionPerAllowedValue": []
                },
        ...

        {
            "Name": "TDE",
            "Description": "SQL Server - Transparent Data Encryption",
            "EngineName": "sqlserver-ee",
            "MajorEngineVersion": "15.00",
            "MinimumRequiredMinorEngineVersion": "4043.16.v1",
            "PortRequired": false,
            "OptionsDependedOn": [],
            "OptionsConflictsWith": [],
            "Persistent": true,
            "Permanent": false,
            "RequiresAutoMinorEngineVersionUpgrade": false,
            "VpcOnly": false,
            "OptionGroupOptionSettings": []
        }
    ]
}
```

Support for Linked Servers with Oracle OLEDB in Amazon RDS for SQL Server

Linked servers with the Oracle Provider for OLEDB on RDS for SQL Server lets you access external data sources on an Oracle database. You can read data from remote Oracle data sources and run commands against remote Oracle database servers outside of your RDS for SQL Server DB instance. Using linked servers with Oracle OLEDB, you can:

- Directly access data sources other than SQL Server
- Query against diverse Oracle data sources with the same query without moving the data
- Issue distributed queries, updates, commands, and transactions on data sources across an enterprise ecosystem
- Integrate connections to an Oracle database from within the Microsoft Business Intelligence suite (SSIS, SSRS, SSAS)
- Migrate from an Oracle database to RDS for SQL Server

You can activate one or more linked servers for Oracle on either an existing or new RDS for SQL Server DB instance. Then you can integrate external Oracle data sources with your DB instance.

Contents

Supported versions and Regions

RDS for SQL Server supports linked servers with Oracle OLEDB in all Regions for SQL Server Standard and Enterprise Editions on the following versions:

- SQL Server 2022, all versions
- SQL Server 2019, all versions
- SQL Server 2017, all versions

Linked servers with Oracle OLEDB is supported for the following Oracle Database versions:

- Oracle Database 21c, all versions
- Oracle Database 19c, all versions
- Oracle Database 18c, all versions

Limitations and recommendations

Keep in mind the following limitations and recommendations that apply to linked servers with Oracle OLEDB:

- Allow network traffic by adding the applicable TCP port in the security group for each RDS for SQL Server DB instance. For example, if you're configuring a linked server between an EC2 Oracle DB instance and an RDS for SQL Server DB instance, then you must allow traffic from the IP address of the EC2 Oracle DB instance. You also must allow traffic on the port that SQL Server is using to listen for database communication. For more information on security groups, see Controlling access with security groups.
- Perform a reboot of the RDS for SQL Server DB instance after turning on, turning off, or modifying the `OLEDB_ORACLE` option in your option group. The option group status displays `pending_reboot` for these events and is required.
- Only simple authentication is supported with a user name and password for the Oracle data source.
- Open Database Connectivity (ODBC) drivers are not supported. Only the latest version of the OLEDB driver is supported.
- Distributed transactions (XA) are supported. To activate distributed transactions, turn on the `MSDTC` option in the Option Group for your DB instance and make sure XA transactions are turned on. For more information, see Support for Microsoft Distributed Transaction Coordinator in RDS for SQL Server.
- Creating data source names (DSNs) to use as a shortcut for a connection string is not supported.
- OLEDB driver tracing is not supported. You can use SQL Server Extended Events to trace OLEDB events. For more information, see Set up Extended Events in RDS for SQL Server.

- Access to the catalogs folder for an Oracle linked server is not supported using SQL Server Management Studio (SSMS).

Activating linked servers with Oracle

Activate linked servers with Oracle by adding the `OLEDB_ORACLE` option to your RDS for SQL Server DB instance. Use the following process:

1. Create a new option group, or choose an existing option group.
2. Add the `OLEDB_ORACLE` option to the option group.
3. Choose a version of the OLEDB driver to use.
4. Associate the option group with the DB instance.
5. Reboot the DB instance.

Creating the option group for OLEDB_ORACLE

To work with linked servers with Oracle, create an option group or modify an option group that corresponds to the SQL Server edition and version of the DB instance that you plan to use. To complete this procedure, use the AWS Management Console or the AWS CLI.

Console

The following procedure creates an option group for SQL Server Standard Edition 2019.

To create the option group

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Option groups**.
3. Choose **Create group**.
4. In the **Create option group** window, do the following:
    a. For **Name**, enter a name for the option group that is unique within your AWS account, such as **`oracle-oledb-se-2019`**. The name can contain only letters, digits, and hyphens.
    b. For **Description**, enter a brief description of the option group, such as **`OLEDB_ORACLE option group for SQL Server SE 2019`**. The description is used for display purposes.

c. For **Engine**, choose **sqlserver-se**.

d. For **Major engine version**, choose **15.00**.

5. Choose **Create**.

CLI

The following procedure creates an option group for SQL Server Standard Edition 2019.

To create the option group

- Run one of the following commands.

  Example

  For Linux, macOS, or Unix:

```
aws rds create-option-group \
    --option-group-name oracle-oledb-se-2019 \
    --engine-name sqlserver-se \
    --major-engine-version 15.00 \
    --option-group-description "OLEDB_ORACLE option group for SQL Server SE 2019"
```

  For Windows:

```
aws rds create-option-group ^
    --option-group-name oracle-oledb-se-2019 ^
    --engine-name sqlserver-se ^
    --major-engine-version 15.00 ^
    --option-group-description "OLEDB_ORACLE option group for SQL Server SE 2019"
```

Adding the OLEDB_ORACLE option to the option group

Next, use the AWS Management Console or the AWS CLI to add the OLEDB_ORACLE option to your option group.

Console

To add the OLEDB_ORACLE option

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Option groups**.
3. Choose the option group that you just created, which is **oracle-oledb-se-2019** in this example.
4. Choose **Add option**.
5. Under **Option details**, choose **OLEDB_ORACLE** for **Option name**.
6. Under **Scheduling**, choose whether to add the option immediately or at the next maintenance window.
7. Choose **Add option**.

CLI

To add the OLEDB_ORACLE option

- Add the `OLEDB_ORACLE` option to the option group.

  Example

  For Linux, macOS, or Unix:

```
aws rds add-option-to-option-group \
    --option-group-name oracle-oledb-se-2019 \
    --options OptionName=OLEDB_ORACLE \
    --apply-immediately
```

  For Windows:

```
aws rds add-option-to-option-group ^
    --option-group-name oracle-oledb-se-2019 ^
    --options OptionName=OLEDB_ORACLE ^
    --apply-immediately
```

Associating the option group with your DB instance

To associate the OLEDB_ORACLE option group and parameter group with your DB instance, use the AWS Management Console or the AWS CLI

Console

To finish activating linked servers for Oracle, associate your OLEDB_ORACLE option group with a new or existing DB instance:

- For a new DB instance, associate them when you launch the instance. For more information, see Creating an Amazon RDS DB instance.
- For an existing DB instance, associate them by modifying the instance. For more information, see Modifying an Amazon RDS DB instance.

CLI

You can associate the OLEDB_ORACLE option group and parameter group with a new or existing DB instance.

To create an instance with the OLEDB_ORACLE option group and parameter group

- Specify the same DB engine type and major version that you used when creating the option group.

  Example

  For Linux, macOS, or Unix:

```
aws rds create-db-instance \
    --db-instance-identifier mytestsqlserveroracleoledbinstance \
    --db-instance-class db.m5.2xlarge \
    --engine sqlserver-se \
    --engine-version 15.0.4236.7.v1 \
    --allocated-storage 100 \
    --manage-master-user-password \
    --master-username admin \
    --storage-type gp2 \
    --license-model li \
    --domain-iam-role-name my-directory-iam-role \
    --domain my-domain-id \
    --option-group-name oracle-oledb-se-2019 \
```

```
    --db-parameter-group-name my-parameter-group-name
```

For Windows:

```
aws rds create-db-instance ^
    --db-instance-identifier mytestsqlserveroracleoledbinstance ^
    --db-instance-class db.m5.2xlarge ^
    --engine sqlserver-se ^
    --engine-version 15.0.4236.7.v1 ^
    --allocated-storage 100 ^
    --manage-master-user-password ^
    --master-username admin ^
    --storage-type gp2 ^
    --license-model li ^
    --domain-iam-role-name my-directory-iam-role ^
    --domain my-domain-id ^
    --option-group-name oracle-oledb-se-2019 ^
    --db-parameter-group-name my-parameter-group-name
```

To modify an instance and associate the `OLEDB_ORACLE` option group

- Run one of the following commands.

  Example

  For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier mytestsqlserveroracleoledbinstance \
    --option-group-name oracle-oledb-se-2019 \
    --db-parameter-group-name my-parameter-group-name \
    --apply-immediately
```

  For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier mytestsqlserveroracleoledbinstance ^
    --option-group-name oracle-oledb-se-2019 ^
    --db-parameter-group-name my-parameter-group-name ^
    --apply-immediately
```

Modifying OLEDB provider properties

You can view and change the properties of the OLEDB provider. Only the `master` user can perform this task. All linked servers for Oracle that are created on the DB instance use the same properties of that OLEDB provider. Call the `sp_MSset_oledb_prop` stored procedure to change the properties of the OLEDB provider.

To change the OLEDB provider properties

```
USE [master]
GO
EXEC sp_MSset_oledb_prop N'OraOLEDB.Oracle', N'AllowInProcess', 1
EXEC sp_MSset_oledb_prop N'OraOLEDB.Oracle', N'DynamicParameters', 0
GO
```

The following properties can be modified:

Property name	Recommended Value (1 = On, 0 = Off)	Description
`Dynamic parameter`	1	Allows SQL placeholders (represented by '?') in parameterized queries.
`Nested queries`	1	Allows nested `SELECT` statements in the `FROM` clause, such as sub-queries.
`Level zero only`	0	Only base-level OLEDB interfaces are called against the provider.
`Allow inprocess`	1	If turned on, Microsoft SQL Server allows the provider to be instantiated as an in-process server. Set this property to 1 to use Oracle linked servers.
`Non transacted updates`	0	If non-zero, SQL Server allows updates.

Property name	Recommended Value (1 = On, 0 = Off)	Description
`Index as access path`	False	If non-zero, SQL Server attempts to use indexes of the provider to fetch data.
`Disallow adhoc access`	False	If set, SQL Server does not allow running pass-through queries against the OLEDB provider. While this option can be checked, it is sometimes appropriate to run pass-through queries.
`Supports LIKE operator`	1	Indicates that the provider supports queries using the LIKE keyword.

Modifying OLEDB driver properties

You can view and change the properties of the OLEDB driver when creating a linked server for Oracle. Only the `master` user can perform this task. Driver properties define how the OLEDB driver handles data when working with a remote Oracle data source. Driver properties are specific to each Oracle linked server created on the DB instance. Call the `master.dbo.sp_addlinkedserver` stored procedure to change the properties of the OLEDB driver.

Example: To create a linked server and change the OLEDB driver `FetchSize` property

```
EXEC master.dbo.sp_addlinkedserver
@server = N'Oracle_link2',
@srvproduct=N'Oracle',
@provider=N'OraOLEDB.Oracle',
@datasrc=N'my-oracle-test.cnetsipka.us-west-2.rds.amazonaws.com:1521/ORCL',
@provstr='FetchSize=200'
GO
```

```
EXEC master.dbo.sp_addlinkedsrvlogin
@rmtsrvname=N'Oracle_link2',
@useself=N'False',
@locallogin=NULL,
```

```
@rmtuser=N'master',
@rmtpassword='Test#1234'
GO
```

> **Note**
>
> Specify a password other than the prompt shown here as a security best practice.

Deactivating linked servers with Oracle

To deactivate linked servers with Oracle, remove the `OLEDB_ORACLE` option from its option group.

> **Important**
>
> Removing the option doesn't delete the existing linked server configurations on the DB instance. You must manually drop them to remove them from the DB instance.
> You can reactivate the `OLEDB_ORACLE` option after removal to reuse the linked server configurations that were previously configured on the DB instance.

Console

The following procedure removes the `OLEDB_ORACLE` option.

To remove the OLEDB_ORACLE option from its option group

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Option groups**.
3. Choose the option group with the `OLEDB_ORACLE` option (`oracle-oledb-se-2019` in the previous examples).
4. Choose **Delete option**.
5. Under **Deletion options**, choose **OLEDB_ORACLE** for **Options to delete**.
6. Under **Apply immediately**, choose **Yes** to delete the option immediately, or **No** to delete it during the next maintenance window.
7. Choose **Delete**.

CLI

The following procedure removes the OLEDB_ORACLE option.

To remove the OLEDB_ORACLE option from its option group

- Run one of the following commands.

  Example

  For Linux, macOS, or Unix:

```
aws rds remove-option-from-option-group \
    --option-group-name oracle-oledb-se-2019 \
    --options OLEDB_ORACLE \
    --apply-immediately
```

  For Windows:

```
aws rds remove-option-from-option-group ^
    --option-group-name oracle-oledb-se-2019 ^
    --options OLEDB_ORACLE ^
    --apply-immediately
```

Support for native backup and restore in SQL Server

By using native backup and restore for SQL Server databases, you can create a differential or full backup of your on-premises database and store the backup files on Amazon S3. You can then restore to an existing Amazon RDS DB instance running SQL Server. You can also back up an RDS for SQL Server database, store it on Amazon S3, and restore it in other locations. In addition, you can restore the backup to an on-premises server, or a different Amazon RDS DB instance running SQL Server. For more information, see Importing and exporting SQL Server databases using native backup and restore.

Amazon RDS supports native backup and restore for Microsoft SQL Server databases by using differential and full backup files (.bak files).

Adding the native backup and restore option

The general process for adding the native backup and restore option to a DB instance is the following:

1. Create a new option group, or copy or modify an existing option group.
2. Add the `SQLSERVER_BACKUP_RESTORE` option to the option group.
3. Associate an AWS Identity and Access Management (IAM) role with the option. The IAM role must have access to an S3 bucket to store the database backups.

   That is, the option must have as its option setting a valid Amazon Resource Name (ARN) in the format `arn:aws:iam::`*`account-id`*`:role/`*`role-name`*. For more information, see Amazon Resource Names (ARNs) in the *AWS General Reference.*

   The IAM role must also have a trust relationship and a permissions policy attached. The trust relationship allows RDS to assume the role, and the permissions policy defines the actions that the role can perform. For more information, see Manually creating an IAM role for native backup and restore.
4. Associate the option group with the DB instance.

After you add the native backup and restore option, you don't need to restart your DB instance. As soon as the option group is active, you can begin backing up and restoring immediately.

Console

To add the native backup and restore option

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Option groups**.
3. Create a new option group or use an existing option group. For information on how to create a custom DB option group, see Creating an option group.

   To use an existing option group, skip to the next step.
4. Add the **SQLSERVER_BACKUP_RESTORE** option to the option group. For more information about adding options, see Adding an option to an option group.
5. Do one of the following:

   - To use an existing IAM role and Amazon S3 settings, choose an existing IAM role for **IAM Role**. If you use an existing IAM role, RDS uses the Amazon S3 settings configured for this role.
   - To create a new role and configure Amazon S3 settings, do the following:

     1. For **IAM role**, choose **Create a new role**.
     2. For **S3 bucket**, choose an S3 bucket from the list.
     3. For **S3 prefix (optional)**, specify a prefix to use for the files stored in your Amazon S3 bucket.

        This prefix can include a file path but doesn't have to. If you provide a prefix, RDS attaches that prefix to all backup files. RDS then uses the prefix during a restore to identify related files and ignore irrelevant files. For example, you might use the S3 bucket for purposes besides holding backup files. In this case, you can use the prefix to have RDS perform native backup and restore only on a particular folder and its subfolders.

        If you leave the prefix blank, then RDS doesn't use a prefix to identify backup files or files to restore. As a result, during a multiple-file restore, RDS attempts to restore every file in every folder of the S3 bucket.
     4. Choose the **Enable encryption** check box to encrypt the backup file. Leave the check box cleared (the default) to have the backup file unencrypted.

If you chose **Enable encryption**, choose an encryption key for **AWS KMS key**. For more information about encryption keys, see Getting started in the *AWS Key Management Service Developer Guide.*

6. Choose **Add option**.
7. Apply the option group to a new or existing DB instance:
   - For a new DB instance, apply the option group when you launch the instance. For more information, see Creating an Amazon RDS DB instance.
   - For an existing DB instance, apply the option group by modifying the instance and attaching the new option group. For more information, see Modifying an Amazon RDS DB instance.

CLI

This procedure makes the following assumptions:

- You're adding the SQLSERVER_BACKUP_RESTORE option to an option group that already exists. For more information about adding options, see Adding an option to an option group.
- You're associating the option with an IAM role that already exists and has access to an S3 bucket to store the backups.
- You're applying the option group to a DB instance that already exists. For more information, see Modifying an Amazon RDS DB instance.

To add the native backup and restore option

1. Add the SQLSERVER_BACKUP_RESTORE option to the option group.

   Example

   For Linux, macOS, or Unix:

```
aws rds add-option-to-option-group \
 --apply-immediately \
 --option-group-name mybackupgroup \
 --options "OptionName=SQLSERVER_BACKUP_RESTORE, \
   OptionSettings=[{Name=IAM_ROLE_ARN,Value=arn:aws:iam::account-id:role/role-
name}]"
```

For Windows:

```
aws rds add-option-to-option-group ^
 --option-group-name mybackupgroup ^
 --options "[{\"OptionName\": \"SQLSERVER_BACKUP_RESTORE\", ^
 \"OptionSettings\": [{\"Name\": \"IAM_ROLE_ARN\", ^
 \"Value\": \"arn:aws:iam::account-id:role/role-name"}]}]" ^
 --apply-immediately
```

> **Note**
>
> When using the Windows command prompt, you must escape double quotes (") in JSON code by prefixing them with a backslash (\).

2. Apply the option group to the DB instance.

Example

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
 --db-instance-identifier mydbinstance \
 --option-group-name mybackupgroup \
 --apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^
 --db-instance-identifier mydbinstance ^
 --option-group-name mybackupgroup ^
 --apply-immediately
```

Modifying native backup and restore option settings

After you enable the native backup and restore option, you can modify the settings for the option. For more information about how to modify option settings, see Modifying an option setting.

Removing the native backup and restore option

You can turn off native backup and restore by removing the option from your DB instance. After you remove the native backup and restore option, you don't need to restart your DB instance.

To remove the native backup and restore option from a DB instance, do one of the following:

- Remove the option from the option group it belongs to. This change affects all DB instances that use the option group. For more information, see Removing an option from an option group.
- Modify the DB instance and specify a different option group that doesn't include the native backup and restore option. This change affects a single DB instance. You can specify the default (empty) option group, or a different custom option group. For more information, see Modifying an Amazon RDS DB instance.

Support for Transparent Data Encryption in SQL Server

Amazon RDS supports using Transparent Data Encryption (TDE) to encrypt stored data on your DB instances running Microsoft SQL Server. TDE automatically encrypts data before it is written to storage, and automatically decrypts data when the data is read from storage.

Amazon RDS supports TDE for the following SQL Server versions and editions:

- SQL Server 2022 Standard and Enterprise Editions
- SQL Server 2019 Standard and Enterprise Editions
- SQL Server 2017 Enterprise Edition
- SQL Server 2016 Enterprise Edition

Transparent Data Encryption for SQL Server provides encryption key management by using a two-tier key architecture. A certificate, which is generated from the database master key, is used to protect the data encryption keys. The database encryption key performs the actual encryption and decryption of data on the user database. Amazon RDS backs up and manages the database master key and the TDE certificate.

Transparent Data Encryption is used in scenarios where you need to encrypt sensitive data. For example, you might want to provide data files and backups to a third party, or address security-related regulatory compliance issues. You can't encrypt the system databases for SQL Server, such as the `model` or `master` databases.

A detailed discussion of Transparent Data Encryption is beyond the scope of this guide, but make sure that you understand the security strengths and weaknesses of each encryption algorithm and key. For information about Transparent Data Encryption for SQL Server, see Transparent Data Encryption (TDE) in the Microsoft documentation.

Topics

Turning on TDE for RDS for SQL Server

To turn on Transparent Data Encryption for an RDS for SQL Server DB instance, specify the TDE option in an RDS option group that's associated with that DB instance:

1. Determine whether your DB instance is already associated with an option group that has the TDE option. To view the option group that a DB instance is associated with, use the RDS console, the describe-db-instance AWS CLI command, or the API operation DescribeDBInstances.
2. If the DB instance isn't associated with an option group that has TDE turned on, you have two choices. You can create an option group and add the TDE option, or you can modify the associated option group to add it.

   > **Note**
   >
   > In the RDS console, the option is named `TRANSPARENT_DATA_ENCRYPTION`. In the AWS CLI and RDS API, it's named `TDE`.

   For information about creating or modifying an option group, see Working with option groups. For information about adding an option to an option group, see Adding an option to an option group.
3. Associate the DB instance with the option group that has the TDE option. For information about associating a DB instance with an option group, see Modifying an Amazon RDS DB instance.

Option group considerations

The TDE option is a persistent option. You can't remove it from an option group unless all DB instances and backups are no longer associated with the option group. After you add the TDE option to an option group, the option group can be associated only with DB instances that use TDE. For more information about persistent options in an option group, see Option groups overview.

Because the TDE option is a persistent option, you can have a conflict between the option group and an associated DB instance. You can have a conflict in the following situations:

- The current option group has the TDE option, and you replace it with an option group that doesn't have the TDE option.

- You restore from a DB snapshot to a new DB instance that doesn't have an option group that contains the TDE option. For more information about this scenario, see Option group considerations.

SQL Server performance considerations

Using Transparent Data Encryption can affect the performance of a SQL Server DB instance.

Performance for unencrypted databases can also be degraded if the databases are on a DB instance that has at least one encrypted database. As a result, we recommend that you keep encrypted and unencrypted databases on separate DB instances.

Encrypting data on RDS for SQL Server

When the TDE option is added to an option group, Amazon RDS generates a certificate that's used in the encryption process. You can then use the certificate to run SQL statements that encrypt data in a database on the DB instance.

The following example uses the RDS-created certificate called `RDSTDECertificateName` to encrypt a database called `myDatabase`.

```
---------- Turning on TDE -------------

-- Find an RDS TDE certificate to use
USE [master]
GO
SELECT name FROM sys.certificates WHERE name LIKE 'RDSTDECertificate%'
GO

USE [myDatabase]
GO
-- Create a database encryption key (DEK) using one of the certificates from the
 previous step
CREATE DATABASE ENCRYPTION KEY WITH ALGORITHM = AES_256
ENCRYPTION BY SERVER CERTIFICATE [RDSTDECertificateName]
GO

-- Turn on encryption for the database
ALTER DATABASE [myDatabase] SET ENCRYPTION ON
GO
```

```
-- Verify that the database is encrypted
USE [master]
GO
SELECT name FROM sys.databases WHERE is_encrypted = 1
GO
SELECT db_name(database_id) as DatabaseName, * FROM sys.dm_database_encryption_keys
GO
```

The time that it takes to encrypt a SQL Server database using TDE depends on several factors. These include the size of the DB instance, whether the instance uses Provisioned IOPS storage, the amount of data, and other factors.

Backing up and restoring TDE certificates on RDS for SQL Server

RDS for SQL Server provides stored procedures for backing up, restoring, and dropping TDE certificates. RDS for SQL Server also provides a function for viewing restored user TDE certificates.

User TDE certificates are used to restore databases to RDS for SQL Server that are on-premises and have TDE turned on. These certificates have the prefix `UserTDECertificate_`. After restoring databases, and before making them available to use, RDS modifies the databases that have TDE turned on to use RDS-generated TDE certificates. These certificates have the prefix `RDSTDECertificate`.

User TDE certificates remain on the RDS for SQL Server DB instance, unless you drop them using the `rds_drop_tde_certificate` stored procedure. For more information, see Dropping restored TDE certificates.

You can use a user TDE certificate to restore other databases from the source DB instance. The databases to restore must use the same TDE certificate and have TDE turned on. You don't have to import (restore) the same certificate again.

Topics

Prerequisites

Before you can back up or restore TDE certificates on RDS for SQL Server, make sure to perform the following tasks. The first three are described in Setting up for native backup and restore.

1. Create Amazon S3 buckets for storing files to back up and restore.

   We recommend that you use separate buckets for database backups and for TDE certificate backups.
2. Create an IAM role for backing up and restoring files.

   The IAM role must be both a user and an administrator for the AWS KMS key.

   In addition to the permissions required for SQL Server native backup and restore, the IAM role also requires the following permissions:
   - `s3:GetBucketACL`, `s3:GetBucketLocation`, and `s3:ListBucket` on the S3 bucket resource
   - `s3:ListAllMyBuckets` on the * resource
3. Add the `SQLSERVER_BACKUP_RESTORE` option to an option group on your DB instance.

   This is in addition to the `TRANSPARENT_DATA_ENCRYPTION` (`TDE`) option.
4. Make sure that you have a symmetric encryption KMS key. You have the following options:
   - If you have an existing KMS key in your account, you can use it. No further action is necessary.
   - If you don't have an existing symmetric encryption KMS key in your account, create a KMS key by following the instructions in Creating keys in the *AWS Key Management Service Developer Guide*.
5. Enable Amazon S3 integration to transfer files between the DB instance and Amazon S3.

   For more information on enabling Amazon S3 integration, see Integrating an Amazon RDS for SQL Server DB instance with Amazon S3.

Limitations

Using stored procedures to back up and restore TDE certificates has the following limitations:

- Both the `SQLSERVER_BACKUP_RESTORE` and `TRANSPARENT_DATA_ENCRYPTION` (`TDE`) options must be added to the option group that you associated with your DB instance.
- TDE certificate backup and restore aren't supported on Multi-AZ DB instances.

- Canceling TDE certificate backup and restore tasks isn't supported.
- You can't use a user TDE certificate for TDE encryption of any other database on your RDS for SQL Server DB instance. You can use it to restore only other databases from the source DB instance that have TDE turned on and that use the same TDE certificate.
- You can drop only user TDE certificates.
- The maximum number of user TDE certificates supported on RDS is 10. If the number exceeds 10, drop unused TDE certificates and try again.
- The certificate name can't be empty or null.
- When restoring a certificate, the certificate name can't include the keyword `RDSTDECERTIFICATE`, and must start with the `UserTDECertificate_` prefix.
- The `@certificate_name` parameter can include only the following characters: a-z, 0-9, @, $, #, and underscore (_).
- The file extension for `@certificate_file_s3_arn` must be .cer (case-insensitive).
- The file extension for `@private_key_file_s3_arn` must be .pvk (case-insensitive).
- The S3 metadata for the private key file must include the `x-amz-meta-rds-tde-pwd` tag. For more information, see Backing up and restoring TDE certificates for on-premises databases.

Backing up a TDE certificate

To back up TDE certificates, use the `rds_backup_tde_certificate` stored procedure. It has the following syntax.

```
EXECUTE msdb.dbo.rds_backup_tde_certificate
    @certificate_name='UserTDECertificate_certificate_name |
 RDSTDECertificatetimestamp',
    @certificate_file_s3_arn='arn:aws:s3:::bucket_name/certificate_file_name.cer',
    @private_key_file_s3_arn='arn:aws:s3:::bucket_name/key_file_name.pvk',
    @kms_password_key_arn='arn:aws:kms:region:account-id:key/key-id',
    [@overwrite_s3_files=0|1];
```

The following parameters are required:

- `@certificate_name` – The name of the TDE certificate to back up.
- `@certificate_file_s3_arn` – The destination Amazon Resource Name (ARN) for the certificate backup file in Amazon S3.

- `@private_key_file_s3_arn` – The destination S3 ARN of the private key file that secures the TDE certificate.
- `@kms_password_key_arn` – The ARN of the symmetric KMS key used to encrypt the private key password.

The following parameter is optional:

- `@overwrite_s3_files` – Indicates whether to overwrite the existing certificate and private key files in S3:
  - `0` – Doesn't overwrite the existing files. This value is the default.

    Setting `@overwrite_s3_files` to 0 returns an error if a file already exists.
  - `1` – Overwrites an existing file that has the specified name, even if it isn't a backup file.

Example of backing up a TDE certificate

```
EXECUTE msdb.dbo.rds_backup_tde_certificate
    @certificate_name='RDSTDECertificate20211115T185333',
    @certificate_file_s3_arn='arn:aws:s3:::TDE_certs/mycertfile.cer',
    @private_key_file_s3_arn='arn:aws:s3:::TDE_certs/mykeyfile.pvk',
    @kms_password_key_arn='arn:aws:kms:us-
west-2:123456789012:key/AKIAIOSFODNN7EXAMPLE',
    @overwrite_s3_files=1;
```

Restoring a TDE certificate

You use the `rds_restore_tde_certificate` stored procedure to restore (import) user TDE certificates. It has the following syntax.

```
EXECUTE msdb.dbo.rds_restore_tde_certificate
    @certificate_name='UserTDECertificate_certificate_name',
    @certificate_file_s3_arn='arn:aws:s3:::bucket_name/certificate_file_name.cer',
    @private_key_file_s3_arn='arn:aws:s3:::bucket_name/key_file_name.pvk',
    @kms_password_key_arn='arn:aws:kms:region:account-id:key/key-id';
```

The following parameters are required:

- `@certificate_name` – The name of the TDE certificate to restore. The name must start with the `UserTDECertificate_` prefix.

- `@certificate_file_s3_arn` – The S3 ARN of the backup file used to restore the TDE certificate.
- `@private_key_file_s3_arn` – The S3 ARN of the private key backup file of the TDE certificate to be restored.
- `@kms_password_key_arn` – The ARN of the symmetric KMS key used to encrypt the private key password.

Example of restoring a TDE certificate

```
EXECUTE msdb.dbo.rds_restore_tde_certificate
    @certificate_name='UserTDECertificate_myTDEcertificate',
    @certificate_file_s3_arn='arn:aws:s3:::TDE_certs/mycertfile.cer',
    @private_key_file_s3_arn='arn:aws:s3:::TDE_certs/mykeyfile.pvk',
    @kms_password_key_arn='arn:aws:kms:us-
west-2:123456789012:key/AKIAIOSFODNN7EXAMPLE';
```

Viewing restored TDE certificates

You use the `rds_fn_list_user_tde_certificates` function to view restored (imported) user TDE certificates. It has the following syntax.

```
SELECT * FROM msdb.dbo.rds_fn_list_user_tde_certificates();
```

The output resembles the following. Not all columns are shown here.

name	certif te_id	princi _id	pvt_ke ncrypt _type_ c	issuer me	cert_s al_num	thumbp t	subjec	start_ e	expiry te	pvt_key_l ast_backu p_date
UserTD rtific _tde_c	343	1	ENCRYP _BY_MA R_KEY	AnyCom y Shippi	79 3e 57 a3 69 fd 1d	0x6BB2 341103 80B FE1BA2 C69509 5B5	AnyCom y Shippi	2022-0 5 19:49: 000000	2023-0 5 19:49: 000000	NULL

					9e 47 2c 32 67 1d 9c ca af				

Dropping restored TDE certificates

To drop restored (imported) user TDE certificates that you aren't using, use the `rds_drop_tde_certificate` stored procedure. It has the following syntax.

```
EXECUTE msdb.dbo.rds_drop_tde_certificate
 @certificate_name='UserTDECertificate_certificate_name';
```

The following parameter is required:

- `@certificate_name` – The name of the TDE certificate to drop.

You can drop only restored (imported) TDE certificates. You can't drop RDS-created certificates.

Example of dropping a TDE certificate

```
EXECUTE msdb.dbo.rds_drop_tde_certificate
 @certificate_name='UserTDECertificate_myTDEcertificate';
```

Backing up and restoring TDE certificates for on-premises databases

You can back up TDE certificates for on-premises databases, then later restore them to RDS for SQL Server. You can also restore an RDS for SQL Server TDE certificate to an on-premises DB instance.

The following procedure backs up a TDE certificate and private key. The private key is encrypted using a data key generated from your symmetric encryption KMS key.

To back up an on-premises TDE certificate

1. Generate the data key using the AWS CLI generate-data-key command.

```
aws kms generate-data-key \
    --key-id my_KMS_key_ID \
    --key-spec AES_256
```

The output resembles the following.

```
{
"CiphertextBlob": "AQIDAHimL2NEoAlOY6Bn7LJfnxi/OZe9kTQo/
XQXduug1rmerwGiL7g5ux4av9GfZLxYTDATAAAAfjB8BgkqhkiG9w0B
BwagbzBtAgEAMGgGCSqGSIb3DQEHATAeBglghkgBZQMEAS4wEQQMyCxLMi7GRZgKqD65AgEQgDtjvZLJo2cQ31Vetng
2RezQy3sAS6ZHrCjfnfn0c65bFdhsXxjSMnudIY7AKw==",
"Plaintext": "U/fpGtmzGCYBi8A2+0/9qcRQRK2zmG/aOn939ZnKi/0=",
"KeyId": "arn:aws:kms:us-west-2:123456789012:key/1234abcd-00ee-99ff-88dd-
aa11bb22cc33"
}
```

You use the plain text output in the next step as the private key password.

2. Back up your TDE certificate as shown in the following example.

```
BACKUP CERTIFICATE myOnPremTDEcertificate TO FILE = 'D:\tde-cert-backup.cer'
WITH PRIVATE KEY (
FILE = 'C:\Program Files\Microsoft SQL Server\MSSQL14.MSSQLSERVER\MSSQL\DATA\cert-
backup-key.pvk',
ENCRYPTION BY PASSWORD = 'U/fpGtmzGCYBi8A2+0/9qcRQRK2zmG/aOn939ZnKi/0=');
```

3. Save the certificate backup file to your Amazon S3 certificate bucket.
4. Save the private key backup file to your S3 certificate bucket, with the following tag in the file's metadata:
   - Key – `x-amz-meta-rds-tde-pwd`
   - Value – The `CiphertextBlob` value from generating the data key, as in the following example.

```
AQIDAHimL2NEoAlOY6Bn7LJfnxi/OZe9kTQo/
XQXduug1rmerwGiL7g5ux4av9GfZLxYTDATAAAAfjB8BgkqhkiG9w0B
BwagbzBtAgEAMGgGCSqGSIb3DQEHATAeBglghkgBZQMEAS4wEQQMyCxLMi7GRZgKqD65AgEQgDtjvZLJo2cQ31Vet
```

```
2RezQy3sAS6ZHrCjfnfn0c65bFdhsXxjSMnudIY7AKw==
```

The following procedure restores an RDS for SQL Server TDE certificate to an on-premises DB instance. You copy and restore the TDE certificate on your destination DB instance using the certificate backup, corresponding private key file, and data key. The restored certificate is encrypted by the database master key of the new server.

To restore a TDE certificate

1. Copy the TDE certificate backup file and private key file from Amazon S3 to the destination instance. For more information on copying files from Amazon S3, see Transferring files between RDS for SQL Server and Amazon S3.
2. Use your KMS key to decrypt the output cipher text to retrieve the plain text of the data key. The cipher text is located in the S3 metadata of the private key backup file.

   ```
   aws kms decrypt \
       --key-id my_KMS_key_ID \
       --ciphertext-blob fileb://exampleCiphertextFile | base64 -d \
       --output text \
       --query Plaintext
   ```

   You use the plain text output in the next step as the private key password.
3. Use the following SQL command to restore your TDE certificate.

   ```
   CREATE CERTIFICATE myOnPremTDEcertificate FROM FILE='D:\tde-cert-backup.cer'
   WITH PRIVATE KEY (FILE = N'D:\tde-cert-key.pvk',
   DECRYPTION BY PASSWORD = 'plain_text_output');
   ```

For more information on KMS decryption, see decrypt in the KMS section of the *AWS CLI Command Reference*.

After the TDE certificate is restored on the destination DB instance, you can restore encrypted databases with that certificate.

> **Note**
>
> You can use the same TDE certificate to encrypt multiple SQL Server databases on the source DB instance. To migrate multiple databases to a destination instance, copy the TDE certificate associated with them to the destination instance only once.

Turning off TDE for RDS for SQL Server

To turn off TDE for an RDS for SQL Server DB instance, first make sure that there are no encrypted objects left on the DB instance. To do so, either decrypt the objects or drop them. If any encrypted objects exist on the DB instance, you can't turn off TDE for the DB instance. When you use the console to remove the TDE option from an option group, the console indicates that it's processing. In addition, an error event is created if the option group is associated with an encrypted DB instance or DB snapshot.

The following example removes the TDE encryption from a database called `customerDatabase`.

```
------------- Removing TDE ---------------

USE [customerDatabase]
GO

-- Turn off encryption of the database
ALTER DATABASE [customerDatabase]
SET ENCRYPTION OFF
GO

-- Wait until the encryption state of the database becomes 1. The state is 5
 (Decryption in progress) for a while
SELECT db_name(database_id) as DatabaseName, * FROM sys.dm_database_encryption_keys
GO

-- Drop the DEK used for encryption
DROP DATABASE ENCRYPTION KEY
GO

-- Alter to SIMPLE Recovery mode so that your encrypted log gets truncated
USE [master]
GO
ALTER DATABASE [customerDatabase] SET RECOVERY SIMPLE
```

```
GO
```

When all objects are decrypted, you have two options:

1. You can modify the DB instance to be associated with an option group without the TDE option.
2. You can remove the TDE option from the option group.

SQL Server Audit

In Amazon RDS, you can audit Microsoft SQL Server databases by using the built-in SQL Server auditing mechanism. You can create audits and audit specifications in the same way that you create them for on-premises database servers.

RDS uploads the completed audit logs to your S3 bucket, using the IAM role that you provide. If you enable retention, RDS keeps your audit logs on your DB instance for the configured period of time.

For more information, see SQL Server Audit (database engine) in the Microsoft SQL Server documentation.

SQL Server Audit with Database Activity Streams

You can use Database Activity Streams for RDS to integrate SQL Server Audit events with database activity monitoring tools from Imperva, McAfee, and IBM. For more information about auditing with Database Activity Streams for RDS SQL Server, see Auditing in Microsoft SQL Server

Topics

- Support for SQL Server Audit
- Adding SQL Server Audit to the DB instance options
- Using SQL Server Audit
- Viewing audit logs
- Using SQL Server Audit with Multi-AZ instances
- Configuring an S3 bucket
- Manually creating an IAM role for SQL Server Audit

Support for SQL Server Audit

In Amazon RDS, starting with SQL Server 2016, all editions of SQL Server support server-level audits, and the Enterprise edition also supports database-level audits. Starting with SQL Server 2016 (13.x) SP1, all editions support both server-level and database-level audits. For more information, see SQL Server Audit (database engine) in the SQL Server documentation.

RDS supports configuring the following option settings for SQL Server Audit.

Option setting	Valid values	Description
IAM_ROLE_ARN	A valid Amazon Resource Name (ARN) in the format arn:aws:iam:: *account-id* :role/*role-name* .	The ARN of the IAM role that grants access to the S3 bucket where you want to store your audit logs. For more informati on, see Amazon Resource Names (ARNs) in the *AWS General Reference.*
S3_BUCKET_ARN	A valid ARN in the format arn:aws:s3::: *amzn-s3-demo-bucket* or arn:aws:s3::: *amzn-s3-demo-bucket* /key-pref ix	The ARN for the S3 bucket where you want to store your audit logs.
ENABLE_COMPRESSION	true or false	Controls audit log compressi on. By default, compression is enabled (set to true).
RETENTION_TIME	0 to 840	The retention time (in hours) that SQL Server audit records are kept on your RDS instance. By default, retention is disabled.

Adding SQL Server Audit to the DB instance options

Enabling SQL Server Audit requires two steps: enabling the option on the DB instance, and enabling the feature inside SQL Server. The process for adding the SQL Server Audit option to a DB instance is as follows:

1. Create a new option group, or copy or modify an existing option group.
2. Add and configure all required options.
3. Associate the option group with the DB instance.

After you add the SQL Server Audit option, you don't need to restart your DB instance. As soon as the option group is active, you can create audits and store audit logs in your S3 bucket.

To add and configure SQL Server Audit on a DB instance's option group

1. Choose one of the following:
   - Use an existing option group.
   - Create a custom DB option group and use that option group. For more information, see Creating an option group.
2. Add the **SQLSERVER_AUDIT** option to the option group, and configure the option settings. For more information about adding options, see Adding an option to an option group.
   - For **IAM role**, if you already have an IAM role with the required policies, you can choose that role. To create a new IAM role, choose **Create a New Role**. For information about the required policies, see Manually creating an IAM role for SQL Server Audit.
   - For **Select S3 destination**, if you already have an S3 bucket that you want to use, choose it. To create an S3 bucket, choose **Create a New S3 Bucket**.
   - For **Enable Compression**, leave this option chosen to compress audit files. Compression is enabled by default. To disable compression, clear **Enable Compression**.
   - For **Audit log retention**, to keep audit records on the DB instance, choose this option. Specify a retention time in hours. The maximum retention time is 35 days.
3. Apply the option group to a new or existing DB instance. Choose one of the following:
   - If you are creating a new DB instance, apply the option group when you launch the instance.
   - On an existing DB instance, apply the option group by modifying the instance and then attaching the new option group. For more information, see Modifying an Amazon RDS DB instance.

Modifying the SQL Server Audit option

After you enable the SQL Server Audit option, you can modify the settings. For information about how to modify option settings, see Modifying an option setting.

Removing SQL Server Audit from the DB instance options

You can turn off the SQL Server Audit feature by disabling audits and then deleting the option.

To remove auditing

1. Disable all of the audit settings inside SQL Server. To learn where audits are running, query the SQL Server security catalog views. For more information, see Security catalog views in the Microsoft SQL Server documentation.
2. Delete the SQL Server Audit option from the DB instance. Choose one of the following:
   - Delete the SQL Server Audit option from the option group that the DB instance uses. This change affects all DB instances that use the same option group. For more information, see Removing an option from an option group.
   - Modify the DB instance, and then choose an option group without the SQL Server Audit option. This change affects only the DB instance that you modify. You can specify the default (empty) option group, or a different custom option group. For more information, see Modifying an Amazon RDS DB instance.
3. After you delete the SQL Server Audit option from the DB instance, you don't need to restart the instance. Remove unneeded audit files from your S3 bucket.

Using SQL Server Audit

You can control server audits, server audit specifications, and database audit specifications the same way that you control them for on-premises database servers.

Creating audits

You create server audits in the same way that you create them for on-premises database servers. For information about how to create server audits, see CREATE SERVER AUDIT in the Microsoft SQL Server documentation.

To avoid errors, adhere to the following limitations:

- Don't exceed the maximum number of supported server audits per instance of 50.
- Instruct SQL Server to write data to a binary file.
- Don't use `RDS_` as a prefix in the server audit name.
- For `FILEPATH`, specify `D:\rdsdbdata\SQLAudit`.
- For `MAXSIZE`, specify a size between 2 MB and 50 MB.
- Don't configure `MAX_ROLLOVER_FILES` or `MAX_FILES`.

- Don't configure SQL Server to shut down the DB instance if it fails to write the audit record.

Creating audit specifications

You create server audit specifications and database audit specifications the same way that you create them for on-premises database servers. For information about creating audit specifications, see CREATE SERVER AUDIT SPECIFICATION and CREATE DATABASE AUDIT SPECIFICATION in the Microsoft SQL Server documentation.

To avoid errors, don't use RDS_ as a prefix in the name of the database audit specification or server audit specification.

Viewing audit logs

Your audit logs are stored in `D:\rdsdbdata\SQLAudit`.

After SQL Server finishes writing to an audit log file—when the file reaches its size limit—Amazon RDS uploads the file to your S3 bucket. If retention is enabled, Amazon RDS moves the file into the retention folder: `D:\rdsdbdata\SQLAudit\transmitted`.

For information about configuring retention, see Adding SQL Server Audit to the DB instance options.

Audit records are kept on the DB instance until the audit log file is uploaded. You can view the audit records by running the following command.

```
SELECT   *
 FROM     msdb.dbo.rds_fn_get_audit_file
             ('D:\rdsdbdata\SQLAudit\*.sqlaudit'
             , default
             , default )
```

You can use the same command to view audit records in your retention folder by changing the filter to `D:\rdsdbdata\SQLAudit\transmitted\*.sqlaudit`.

```
SELECT   *
 FROM     msdb.dbo.rds_fn_get_audit_file
             ('D:\rdsdbdata\SQLAudit\transmitted\*.sqlaudit'
             , default
```

```
                , default )
```

Using SQL Server Audit with Multi-AZ instances

For Multi-AZ instances, the process for sending audit log files to Amazon S3 is similar to the process for Single-AZ instances. However, there are some important differences:

- Database audit specification objects are replicated to all nodes.
- Server audits and server audit specifications aren't replicated to secondary nodes. Instead, you have to create or modify them manually.

To capture server audits or a server audit specification from both nodes:

1. Create a server audit or a server audit specification on the primary node.
2. Fail over to the secondary node and create a server audit or a server audit specification with the same name and GUID on the secondary node. Use the `AUDIT_GUID` parameter to specify the GUID.

Configuring an S3 bucket

The audit log files are automatically uploaded from the DB instance to your S3 bucket. The following restrictions apply to the S3 bucket that you use as a target for audit files:

- It must be in the same AWS Region as the DB instance.
- It must not be open to the public.
- The bucket owner must also be the IAM role owner.
- Your IAM role must have permissions for the customer-managed KMS key associated with the S3 bucket server-side encryption.

The target key that is used to store the data follows this naming schema: *`amzn-s3-demo-bucket`*`/key-prefix/instance-name/audit-name/node_file-name.ext`

> **Note**
>
> You set both the bucket name and the key prefix values with the (`S3_BUCKET_ARN`) option setting.

The schema is composed of the following elements:

- ***amzn-s3-demo-bucket*** – The name of your S3 bucket.
- **key-prefix** – The custom key prefix you want to use for audit logs.
- **instance-name** – The name of your Amazon RDS instance.
- **audit-name** – The name of the audit.
- **node** – The identifier of the node that is the source of the audit logs (node1 or node2). There is one node for a Single-AZ instance and two replication nodes for a Multi-AZ instance. These are not primary and secondary nodes, because the roles of primary and secondary change over time. Instead, the node identifier is a simple label.
  - **node1** – The first replication node (Single-AZ has one node only).
  - **node2** – The second replication node (Multi-AZ has two nodes).
- **file-name** – The target file name. The file name is taken as-is from SQL Server.
- **ext** – The extension of the file (`zip` or `sqlaudit`):
  - **zip** – If compression is enabled (default).
  - **sqlaudit** – If compression is disabled.

Manually creating an IAM role for SQL Server Audit

Typically, when you create a new option, the AWS Management Console creates the IAM role and the IAM trust policy for you. However, you can manually create a new IAM role to use with SQL Server Audits, so that you can customize it with any additional requirements you might have. To do this, you create an IAM role and delegate permissions so that the Amazon RDS service can use your Amazon S3 bucket. When you create this IAM role, you attach trust and permissions policies. The trust policy allows Amazon RDS to assume this role. The permission policy defines the actions that this role can do. For more information, see Creating a role to delegate permissions to an AWS service in the *AWS Identity and Access Management User Guide*.

You can use the examples in this section to create the trust relationships and permissions policies you need.

The following example shows a trust relationship for SQL Server Audit. It uses the *service principal* `rds.amazonaws.com` to allow RDS to write to the S3 bucket. A *service principal* is an identifier that is used to grant permissions to a service. Anytime you allow access to `rds.amazonaws.com` in this way, you are allowing RDS to perform an action on your behalf. For more information about service principals, see AWS JSON policy elements: Principal.

Example trust relationship for SQL Server Audit

```
{
     "Version": "2012-10-17",
     "Statement": [
         {
             "Effect": "Allow",
             "Principal": {
                 "Service": "rds.amazonaws.com"
             },
             "Action": "sts:AssumeRole"
         }
     ]
 }
```

We recommend using the `aws:SourceArn` and `aws:SourceAccount` global condition context keys in resource-based trust relationships to limit the service's permissions to a specific resource. This is the most effective way to protect against the confused deputy problem.

You might use both global condition context keys and have the `aws:SourceArn` value contain the account ID. In this case, the `aws:SourceAccount` value and the account in the `aws:SourceArn` value must use the same account ID when used in the same statement.

- Use `aws:SourceArn` if you want cross-service access for a single resource.
- Use `aws:SourceAccount` if you want to allow any resource in that account to be associated with the cross-service use.

In the trust relationship, make sure to use the `aws:SourceArn` global condition context key with the full Amazon Resource Name (ARN) of the resources accessing the role. For SQL Server Audit, make sure to include both the DB option group and the DB instances, as shown in the following example.

Example trust relationship with global condition context key for SQL Server Audit

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
```

```
                "Service": "rds.amazonaws.com"
            },
            "Action": "sts:AssumeRole",
            "Condition": {
                "StringEquals": {
                    "aws:SourceArn": [
                        "arn:aws:rds:Region:my_account_ID:db:db_instance_identifier",
                        "arn:aws:rds:Region:my_account_ID:og:option_group_name"
                    ]
                }
            }
        }
    ]
}
```

In the following example of a permissions policy for SQL Server Audit, we specify an ARN for the Amazon S3 bucket. You can use ARNs to identify a specific account, user, or role that you want grant access to. For more information about using ARNs, see Amazon resource names (ARNs).

Example permissions policy for SQL Server Audit

```
{
     "Version": "2012-10-17",
     "Statement": [
         {
             "Effect": "Allow",
             "Action": "s3:ListAllMyBuckets",
             "Resource": "*"
         },
         {
             "Effect": "Allow",
             "Action": [
                 "s3:ListBucket",
                 "s3:GetBucketACL",
                 "s3:GetBucketLocation"
             ],
             "Resource": "arn:aws:s3:::amzn-s3-demo-bucket"
         },
         {
             "Effect": "Allow",
             "Action": [
                 "s3:PutObject",
                 "s3:ListMultipartUploadParts",
```

```
                "s3:AbortMultipartUpload"
            ],
            "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/key_prefix/*"
        }
    ]
}
```

Note

The `s3:ListAllMyBuckets` action is required for verifying that the same AWS account owns both the S3 bucket and the SQL Server DB instance. The action lists the names of the buckets in the account.

S3 bucket namespaces are global. If you accidentally delete your bucket, another user can create a bucket with the same name in a different account. Then the SQL Server Audit data is written to the new bucket.

Support for SQL Server Analysis Services in Amazon RDS for SQL Server

Microsoft SQL Server Analysis Services (SSAS) is part of the Microsoft Business Intelligence (MSBI) suite. SSAS is an online analytical processing (OLAP) and data mining tool that is installed within SQL Server. You use SSAS to analyze data to help make business decisions. SSAS differs from the SQL Server relational database because SSAS is optimized for queries and calculations common in a business intelligence environment.

You can turn on SSAS for existing or new DB instances. It's installed on the same DB instance as your database engine. For more information on SSAS, see the Microsoft Analysis services documentation.

Amazon RDS supports SSAS for SQL Server Standard and Enterprise Editions on the following versions:

- Tabular mode:
  - SQL Server 2019, version 15.00.4043.16.v1 and higher
  - SQL Server 2017, version 14.00.3223.3.v1 and higher
  - SQL Server 2016, version 13.00.5426.0.v1 and higher
- Multidimensional mode:
  - SQL Server 2019, version 15.00.4153.1.v1 and higher
  - SQL Server 2017, version 14.00.3381.3.v1 and higher
  - SQL Server 2016, version 13.00.5882.1.v1 and higher

Contents

- Monitoring the status of a deployment task
- Using SSAS on Amazon RDS
  - Setting up a Windows-authenticated user for SSAS
  - Adding a domain user as a database administrator
  - Creating an SSAS proxy
  - Scheduling SSAS database processing using SQL Server Agent
  - Revoking SSAS access from the proxy
- Backing up an SSAS database
- Restoring an SSAS database
  - Restoring a DB instance to a specified time
- Changing the SSAS mode
- Turning off SSAS
- Troubleshooting SSAS issues

Limitations

The following limitations apply to using SSAS on RDS for SQL Server:

- RDS for SQL Server supports running SSAS in Tabular or Multidimensional mode. For more information, see Comparing tabular and multidimensional solutions in the Microsoft documentation.
- You can only use one SSAS mode at a time. Before changing modes, make sure to delete all of the SSAS databases.

  For more information, see Changing the SSAS mode.
- Multi-AZ instances aren't supported.
- Instances must use self-managed Active Directory or AWS Directory Service for Microsoft Active Directory for SSAS authentication. For more information, see Working with Active Directory with RDS for SQL Server.
- Users aren't given SSAS server administrator access, but they can be granted database-level administrator access.
- The only supported port for accessing SSAS is 2383.
- You can't deploy projects directly. We provide an RDS stored procedure to do this. For more information, see Deploying SSAS projects on Amazon RDS.

- Processing during deployment isn't supported.
- Using .xmla files for deployment isn't supported.
- SSAS project input files and database backup output files can only be in the `D:\S3` folder on the DB instance.

Turning on SSAS

Use the following process to turn on SSAS for your DB instance:

1. Create a new option group, or choose an existing option group.
2. Add the SSAS option to the option group.
3. Associate the option group with the DB instance.
4. Allow inbound access to the virtual private cloud (VPC) security group for the SSAS listener port.
5. Turn on Amazon S3 integration.

Creating an option group for SSAS

Use the AWS Management Console or the AWS CLI to create an option group that corresponds to the SQL Server engine and version of the DB instance that you plan to use.

> **Note**
>
> You can also use an existing option group if it's for the correct SQL Server engine and version.

Console

The following console procedure creates an option group for SQL Server Standard Edition 2017.

To create the option group

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Option groups**.
3. Choose **Create group**.
4. In the **Create option group** pane, do the following:

a. For **Name**, enter a name for the option group that is unique within your AWS account, such as **`ssas-se-2017`**. The name can contain only letters, digits, and hyphens.

b. For **Description**, enter a brief description of the option group, such as **`SSAS option group for SQL Server SE 2017`**. The description is used for display purposes.

c. For **Engine**, choose **sqlserver-se**.

d. For **Major engine version**, choose **14.00**.

5. Choose **Create**.

CLI

The following CLI example creates an option group for SQL Server Standard Edition 2017.

To create the option group

- Use one of the following commands.

  Example

  For Linux, macOS, or Unix:

```
aws rds create-option-group \
    --option-group-name ssas-se-2017 \
    --engine-name sqlserver-se \
    --major-engine-version 14.00 \
    --option-group-description "SSAS option group for SQL Server SE 2017"
```

  For Windows:

```
aws rds create-option-group ^
    --option-group-name ssas-se-2017 ^
    --engine-name sqlserver-se ^
    --major-engine-version 14.00 ^
    --option-group-description "SSAS option group for SQL Server SE 2017"
```

Adding the SSAS option to the option group

Next, use the AWS Management Console or the AWS CLI to add the SSAS option to the option group.

Console

To add the SSAS option

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Option groups**.
3. Choose the option group that you just created.
4. Choose **Add option**.
5. Under **Option details**, choose **SSAS** for **Option name**.
6. Under **Option settings**, do the following:

   a. For **Max memory**, enter a value in the range 10–80.

      Max memory specifies the upper threshold above which SSAS begins releasing memory more aggressively to make room for requests that are running, and also new high-priority requests. The number is a percentage of the total memory of the DB instance. The allowed values are 10–80, and the default is 45.

   b. For **Mode**, choose the SSAS server mode, **Tabular** or **Multidimensional**.

      If you don't see the **Mode** option setting, it means that Multidimensional mode isn't supported in your AWS Region. For more information, see Limitations.

      Tabular is the default.

   c. For **Security groups**, choose the VPC security group to associate with the option.

   > **Note**
   >
   > The port for accessing SSAS, 2383, is prepopulated.

7. Under **Scheduling**, choose whether to add the option immediately or at the next maintenance window.
8. Choose **Add option**.

CLI

To add the SSAS option

1. Create a JSON file, for example `ssas-option.json`, with the following parameters:

   - `OptionGroupName` – The name of option group that you created or chose previously (`ssas-se-2017` in the following example).
   - `Port` – The port that you use to access SSAS. The only supported port is 2383.
   - `VpcSecurityGroupMemberships` – Memberships for VPC security groups for your RDS DB instance.
   - `MAX_MEMORY` – The upper threshold above which SSAS should begin releasing memory more aggressively to make room for requests that are running, and also new high-priority requests. The number is a percentage of the total memory of the DB instance. The allowed values are 10–80, and the default is 45.
   - `MODE` – The SSAS server mode, either `Tabular` or `Multidimensional`. `Tabular` is the default.

     If you receive an error that the `MODE` option setting isn't valid, it means that Multidimensional mode isn't supported in your AWS Region. For more information, see Limitations.

   The following is an example of a JSON file with SSAS option settings.

   ```
   {
   "OptionGroupName": "ssas-se-2017",
   "OptionsToInclude": [
    {
    "OptionName": "SSAS",
    "Port": 2383,
    "VpcSecurityGroupMemberships": ["sg-0abcdef123"],
    "OptionSettings": [{"Name":"MAX_MEMORY","Value":"60"},
   {"Name":"MODE","Value":"Multidimensional"}]
    }],
   "ApplyImmediately": true
   }
   ```

2. Add the SSAS option to the option group.

Example

For Linux, macOS, or Unix:

```
aws rds add-option-to-option-group \
    --cli-input-json file://ssas-option.json \
    --apply-immediately
```

For Windows:

```
aws rds add-option-to-option-group ^
    --cli-input-json file://ssas-option.json ^
    --apply-immediately
```

Associating the option group with your DB instance

You can use the console or the CLI to associate the option group with your DB instance.

Console

Associate your option group with a new or existing DB instance:

- For a new DB instance, associate the option group with the DB instance when you launch the instance. For more information, see Creating an Amazon RDS DB instance.
- For an existing DB instance, modify the instance and associate the new option group with it. For more information, see Modifying an Amazon RDS DB instance.

> **Note**
>
> If you use an existing instance, it must already have an Active Directory domain and AWS Identity and Access Management (IAM) role associated with it. If you create a new instance, specify an existing Active Directory domain and IAM role. For more information, see Working with Active Directory with RDS for SQL Server.

CLI

You can associate your option group with a new or existing DB instance.

> **Note**
>
> If you use an existing instance, it must already have an Active Directory domain and IAM role associated with it. If you create a new instance, specify an existing Active Directory domain and IAM role. For more information, see Working with Active Directory with RDS for SQL Server.

To create a DB instance that uses the option group

- Specify the same DB engine type and major version that you used when creating the option group.

  Example

  For Linux, macOS, or Unix:

```
aws rds create-db-instance \
    --db-instance-identifier myssasinstance \
    --db-instance-class db.m5.2xlarge \
    --engine sqlserver-se \
    --engine-version 14.00.3223.3.v1 \
    --allocated-storage 100 \
    --manage-master-user-password \
    --master-username admin \
    --storage-type gp2 \
    --license-model li \
    --domain-iam-role-name my-directory-iam-role \
    --domain my-domain-id \
    --option-group-name ssas-se-2017
```

  For Windows:

```
aws rds create-db-instance ^
    --db-instance-identifier myssasinstance ^
    --db-instance-class db.m5.2xlarge ^
    --engine sqlserver-se ^
    --engine-version 14.00.3223.3.v1 ^
    --allocated-storage 100 ^
    --manage-master-user-password ^
    --master-username admin ^
```

```
    --storage-type gp2 ^
    --license-model li ^
    --domain-iam-role-name my-directory-iam-role ^
    --domain my-domain-id ^
    --option-group-name ssas-se-2017
```

To modify a DB instance to associate the option group

- Use one of the following commands.

  Example

  For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier myssasinstance \
    --option-group-name ssas-se-2017 \
    --apply-immediately
```

  For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier myssasinstance ^
    --option-group-name ssas-se-2017 ^
    --apply-immediately
```

Allowing inbound access to your VPC security group

Create an inbound rule for the specified SSAS listener port in the VPC security group associated with your DB instance. For more information about setting up security groups, see Provide access to your DB instance in your VPC by creating a security group.

Enabling Amazon S3 integration

To download model configuration files to your host for deployment, use Amazon S3 integration. For more information, see Integrating an Amazon RDS for SQL Server DB instance with Amazon S3.

Deploying SSAS projects on Amazon RDS

On RDS, you can't deploy SSAS projects directly by using SQL Server Management Studio (SSMS). To deploy projects, use an RDS stored procedure.

> **Note**
>
> Using .xmla files for deployment isn't supported.

Before you deploy projects, make sure of the following:

- Amazon S3 integration is turned on. For more information, see Integrating an Amazon RDS for SQL Server DB instance with Amazon S3.
- The `Processing Option` configuration setting is set to `Do Not Process`. This setting means that no processing happens after deployment.
- You have both the *`myssasproject`*`.asdatabase` and *`myssasproject`*`.deploymentoptions` files. They're automatically generated when you build the SSAS project.

To deploy an SSAS project on RDS

1. Download the `.asdatabase` (SSAS model) file from your S3 bucket to your DB instance, as shown in the following example. For more information on the download parameters, see Downloading files from an Amazon S3 bucket to a SQL Server DB instance.

```
exec msdb.dbo.rds_download_from_s3
@s3_arn_of_file='arn:aws:s3:::bucket_name/myssasproject.asdatabase',
[@rds_file_path='D:\S3\myssasproject.asdatabase'],
[@overwrite_file=1];
```

2. Download the `.deploymentoptions` file from your S3 bucket to your DB instance.

```
exec msdb.dbo.rds_download_from_s3
@s3_arn_of_file='arn:aws:s3:::bucket_name/myssasproject.deploymentoptions',
[@rds_file_path='D:\S3\myssasproject.deploymentoptions'],
[@overwrite_file=1];
```

3. Deploy the project.

```
exec msdb.dbo.rds_msbi_task
@task_type='SSAS_DEPLOY_PROJECT',
@file_path='D:\S3\myssasproject.asdatabase';
```

Monitoring the status of a deployment task

To track the status of your deployment (or download) task, call the `rds_fn_task_status` function. It takes two parameters. The first parameter should always be `NULL` because it doesn't apply to SSAS. The second parameter accepts a task ID.

To see a list of all tasks, set the first parameter to `NULL` and the second parameter to `0`, as shown in the following example.

```
SELECT * FROM msdb.dbo.rds_fn_task_status(NULL,0);
```

To get a specific task, set the first parameter to `NULL` and the second parameter to the task ID, as shown in the following example.

```
SELECT * FROM msdb.dbo.rds_fn_task_status(NULL,42);
```

The `rds_fn_task_status` function returns the following information.

Output parameter	Description
`task_id`	The ID of the task.
`task_type`	For SSAS, tasks can have the following task types: • `SSAS_DEPLOY_PROJECT` • `SSAS_ADD_DB_ADMIN_MEMBER` • `SSAS_BACKUP_DB` • `SSAS_RESTORE_DB`
`database_name`	Not applicable to SSAS tasks.
`% complete`	The progress of the task as a percentage.

Output parameter	Description
duration (mins)	The amount of time spent on the task, in minutes.
lifecycle	The status of the task. Possible statuses are the following: • CREATED – After you call one of the SSAS stored procedures, a task is created and the status is set to CREATED. • IN_PROGRESS – After a task starts, the status is set to IN_PROGRESS. It can take up to five minutes for the status to change from CREATED to IN_PROGRESS. • SUCCESS – After a task completes, the status is set to SUCCESS. • ERROR – If a task fails, the status is set to ERROR. For more information about the error, see the task_info column. • CANCEL_REQUESTED – After you call rds_cancel_task, the status of the task is set to CANCEL_REQUESTED. • CANCELLED – After a task is successfully canceled, the status of the task is set to CANCELLED.

Output parameter	Description
task_info	Additional information about the task. If an error occurs during processing, this column contains information about the error. For more information, see Troubleshooting SSAS issues.
last_updated	The date and time that the task status was last updated.
created_at	The date and time that the task was created.
S3_object_arn	Not applicable to SSAS tasks.
overwrite_S3_backup_file	Not applicable to SSAS tasks.
KMS_master_key_arn	Not applicable to SSAS tasks.
filepath	Not applicable to SSAS tasks.
overwrite_file	Not applicable to SSAS tasks.
task_metadata	Metadata associated with the SSAS task.

Using SSAS on Amazon RDS

After deploying the SSAS project, you can directly process the OLAP database on SSMS.

To use SSAS on RDS

1. In SSMS, connect to SSAS using the user name and password for the Active Directory domain.
2. Expand **Databases**. The newly deployed SSAS database appears.
3. Locate the connection string, and update the user name and password to give access to the source SQL database. Doing this is required for processing SSAS objects.

a. For Tabular mode, do the following:

   1. Expand the **Connections** tab.
   2. Open the context (right-click) menu for the connection object, and then choose **Properties**.
   3. Update the user name and password in the connection string.

b. For Multidimensional mode, do the following:

   1. Expand the **Data Sources** tab.
   2. Open the context (right-click) menu for the data source object, and then choose **Properties**.
   3. Update the user name and password in the connection string.

4. Open the context (right-click) menu for the SSAS database that you created and choose **Process Database**.

   Depending on the size of the input data, the processing operation might take several minutes to complete.

Topics

- Setting up a Windows-authenticated user for SSAS
- Adding a domain user as a database administrator
- Creating an SSAS proxy
- Scheduling SSAS database processing using SQL Server Agent
- Revoking SSAS access from the proxy

Setting up a Windows-authenticated user for SSAS

The main administrator user (sometimes called the master user) can use the following code example to set up a Windows-authenticated login and grant the required procedure permissions. Doing this grants permissions to the domain user to run SSAS customer tasks, use S3 file transfer procedures, create credentials, and work with the SQL Server Agent proxy. For more information, see Credentials (database engine) and Create a SQL Server Agent proxy in the Microsoft documentation.

You can grant some or all of the following permissions as needed to Windows-authenticated users.

Example

```
-- Create a server-level domain user login, if it doesn't already exist
USE [master]
GO
CREATE LOGIN [mydomain\user_name] FROM WINDOWS
GO

-- Create domain user, if it doesn't already exist
USE [msdb]
GO
CREATE USER [mydomain\user_name] FOR LOGIN [mydomain\user_name]
GO

-- Grant necessary privileges to the domain user
USE [master]
GO
GRANT ALTER ANY CREDENTIAL TO [mydomain\user_name]
GO

USE [msdb]
GO
GRANT EXEC ON msdb.dbo.rds_msbi_task TO [mydomain\user_name] with grant option
GRANT SELECT ON msdb.dbo.rds_fn_task_status TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.rds_task_status TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.rds_cancel_task TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.rds_download_from_s3 TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.rds_upload_to_s3 TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.rds_delete_from_filesystem TO [mydomain\user_name] with grant
 option
GRANT EXEC ON msdb.dbo.rds_gather_file_details TO [mydomain\user_name] with grant
 option
GRANT EXEC ON msdb.dbo.sp_add_proxy TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.sp_update_proxy TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.sp_grant_login_to_proxy TO [mydomain\user_name] with grant
 option
GRANT EXEC ON msdb.dbo.sp_revoke_login_from_proxy TO [mydomain\user_name] with grant
 option
GRANT EXEC ON msdb.dbo.sp_delete_proxy TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.sp_enum_login_for_proxy to [mydomain\user_name] with grant
 option
GRANT EXEC ON msdb.dbo.sp_enum_proxy_for_subsystem TO [mydomain\user_name] with grant
 option
GRANT EXEC ON msdb.dbo.rds_sqlagent_proxy TO [mydomain\user_name] with grant option
```

```
ALTER ROLE [SQLAgentUserRole] ADD MEMBER [mydomain\user_name]
GO
```

Adding a domain user as a database administrator

You can add a domain user as an SSAS database administrator in the following ways:

- A database administrator can use SSMS to create a role with `admin` privileges, then add users to that role.
- You can use the following stored procedure.

  ```
  exec msdb.dbo.rds_msbi_task
  @task_type='SSAS_ADD_DB_ADMIN_MEMBER',
  @database_name='myssasdb',
  @ssas_role_name='exampleRole',
  @ssas_role_member='domain_name\domain_user_name';
  ```

  The following parameters are required:

  - `@task_type` – The type of the MSBI task, in this case `SSAS_ADD_DB_ADMIN_MEMBER`.
  - `@database_name` – The name of the SSAS database to which you're granting administrator privileges.
  - `@ssas_role_name` – The SSAS database administrator role name. If the role doesn't already exist, it's created.
  - `@ssas_role_member` – The SSAS database user that you're adding to the administrator role.

Creating an SSAS proxy

To be able to schedule SSAS database processing using SQL Server Agent, create an SSAS credential and an SSAS proxy. Run these procedures as a Windows-authenticated user.

To create the SSAS credential

- Create the credential for the proxy. To do this, you can use SSMS or the following SQL statement.

  ```
  USE [master]
  GO
  CREATE CREDENTIAL [SSAS_Credential] WITH IDENTITY = N'mydomain\user_name', SECRET =
   N'mysecret'
  ```

```
GO
```

> **Note**
>
> IDENTITY must be a domain-authenticated login. Replace *mysecret* with the password for the domain-authenticated login.

To create the SSAS proxy

1. Use the following SQL statement to create the proxy.

```
USE [msdb]
GO
EXEC msdb.dbo.sp_add_proxy
 @proxy_name=N'SSAS_Proxy',@credential_name=N'SSAS_Credential',@description=N''
GO
```

2. Use the following SQL statement to grant access to the proxy to other users.

```
USE [msdb]
GO
EXEC msdb.dbo.sp_grant_login_to_proxy
 @proxy_name=N'SSAS_Proxy',@login_name=N'mydomain\user_name'
GO
```

3. Use the following SQL statement to give the SSAS subsystem access to the proxy.

```
USE [msdb]
GO
EXEC msdb.dbo.rds_sqlagent_proxy
 @task_type='GRANT_SUBSYSTEM_ACCESS',@proxy_name='SSAS_Proxy',@proxy_subsystem='SSAS'
GO
```

To view the proxy and grants on the proxy

1. Use the following SQL statement to view the grantees of the proxy.

```
USE [msdb]
GO
```

```
EXEC sp_help_proxy
GO
```

2. Use the following SQL statement to view the subsystem grants.

```
USE [msdb]
GO
EXEC msdb.dbo.sp_enum_proxy_for_subsystem
GO
```

Scheduling SSAS database processing using SQL Server Agent

After you create the credential and proxy and grant SSAS access to the proxy, you can create a SQL Server Agent job to schedule SSAS database processing.

To schedule SSAS database processing

- Use SSMS or T-SQL for creating the SQL Server Agent job. The following example uses T-SQL. You can further configure its job schedule through SSMS or T-SQL.
  - The `@command` parameter outlines the XML for Analysis (XMLA) command to be run by the SQL Server Agent job. This example configures SSAS Multidimensional database processing.
  - The `@server` parameter outlines the target SSAS server name of the SQL Server Agent job.

    To call the SSAS service within the same RDS DB instance where the SQL Server Agent job resides, use `localhost:2383`.

    To call the SSAS service from outside the RDS DB instance, use the RDS endpoint. You can also use the Kerberos Active Directory (AD) endpoint (*`your-DB-instance-name`*`.`*`your-AD-domain-name`*) if the RDS DB instances are joined by the same domain. For external DB instances, make sure to properly configure the VPC security group associated with the RDS DB instance for a secure connection.

  You can further edit the query to support various XMLA operations. Make edits either by directly modifying the T-SQL query or by using the SSMS UI following SQL Server Agent job creation.

```
USE [msdb]
GO
```

```
DECLARE @jobId BINARY(16)
EXEC msdb.dbo.sp_add_job @job_name=N'SSAS_Job',
    @enabled=1,
    @notify_level_eventlog=0,
    @notify_level_email=0,
    @notify_level_netsend=0,
    @notify_level_page=0,
    @delete_level=0,
    @category_name=N'[Uncategorized (Local)]',
    @job_id = @jobId OUTPUT
GO
EXEC msdb.dbo.sp_add_jobserver
    @job_name=N'SSAS_Job',
    @server_name = N'(local)'
GO
EXEC msdb.dbo.sp_add_jobstep @job_name=N'SSAS_Job',
 @step_name=N'Process_SSAS_Object',
    @step_id=1,
    @cmdexec_success_code=0,
    @on_success_action=1,
    @on_success_step_id=0,
    @on_fail_action=2,
    @on_fail_step_id=0,
    @retry_attempts=0,
    @retry_interval=0,
    @os_run_priority=0, @subsystem=N'ANALYSISCOMMAND',
    @command=N'<Batch xmlns="http://schemas.microsoft.com/analysisservices/2003/
engine">
        <Parallel>
            <Process xmlns:xsd="http://www.w3.org/2001/XMLSchema"
 xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
                xmlns:ddl2="http://schemas.microsoft.com/analysisservices/2003/
engine/2" xmlns:ddl2_2="http://schemas.microsoft.com/analysisservices/2003/

analysisservices/2012/engine/400/400" xmlns:ddl500="http://schemas.microsoft.com/
analysisservices/2013/engine/500"
                xmlns:ddl500_500="http://schemas.microsoft.com/
analysisservices/2013/engine/500/500">
                <Object>
                    <DatabaseID>Your_SSAS_Database_ID</DatabaseID>
                </Object>
                <Type>ProcessFull</Type>
                <WriteBackTableCreation>UseExisting</WriteBackTableCreation>
            </Process>
        </Parallel>
    </Batch>',
    @server=N'localhost:2383',
    @database_name=N'master',
    @flags=0,
    @proxy_name=N'SSAS_Proxy'
GO
```

Revoking SSAS access from the proxy

You can revoke access to the SSAS subsystem and delete the SSAS proxy using the following stored procedures.

To revoke access and delete the proxy

1. Revoke subsystem access.

```
USE [msdb]
GO
EXEC msdb.dbo.rds_sqlagent_proxy
 @task_type='REVOKE_SUBSYSTEM_ACCESS',@proxy_name='SSAS_Proxy',@proxy_subsystem='SSAS'
GO
```

2. Revoke the grants on the proxy.

```
USE [msdb]
GO
EXEC msdb.dbo.sp_revoke_login_from_proxy
 @proxy_name=N'SSAS_Proxy',@name=N'mydomain\user_name'
GO
```

3. Delete the proxy.

```
USE [msdb]
GO
EXEC dbo.sp_delete_proxy @proxy_name = N'SSAS_Proxy'
GO
```

Backing up an SSAS database

You can create SSAS database backup files only in the `D:\S3` folder on the DB instance. To move the backup files to your S3 bucket, use Amazon S3.

You can back up an SSAS database as follows:

- A domain user with the `admin` role for a particular database can use SSMS to back up the database to the `D:\S3` folder.

  For more information, see Adding a domain user as a database administrator.
- You can use the following stored procedure. This stored procedure doesn't support encryption.

```
exec msdb.dbo.rds_msbi_task
@task_type='SSAS_BACKUP_DB',
@database_name='myssasdb',
@file_path='D:\S3\ssas_db_backup.abf',
[@ssas_apply_compression=1],
[@ssas_overwrite_file=1];
```

  The following parameters are required:

  - `@task_type` – The type of the MSBI task, in this case SSAS_BACKUP_DB.
  - `@database_name` – The name of the SSAS database that you're backing up.
  - `@file_path` – The path for the SSAS backup file. The `.abf` extension is required.

  The following parameters are optional:

  - `@ssas_apply_compression` – Whether to apply SSAS backup compression. Valid values are 1 (Yes) and 0 (No).
  - `@ssas_overwrite_file` – Whether to overwrite the SSAS backup file. Valid values are 1 (Yes) and 0 (No).

Restoring an SSAS database

Use the following stored procedure to restore an SSAS database from a backup.

You can't restore a database if there is an existing SSAS database with the same name. The stored procedure for restoring doesn't support encrypted backup files.

```
exec msdb.dbo.rds_msbi_task
@task_type='SSAS_RESTORE_DB',
@database_name='mynewssasdb',
@file_path='D:\S3\ssas_db_backup.abf';
```

The following parameters are required:

- `@task_type` – The type of the MSBI task, in this case `SSAS_RESTORE_DB`.
- `@database_name` – The name of the new SSAS database that you're restoring to.
- `@file_path` – The path to the SSAS backup file.

Restoring a DB instance to a specified time

Point-in-time recovery (PITR) doesn't apply to SSAS databases. If you do PITR, only the SSAS data in the last snapshot before the requested time is available on the restored instance.

To have up-to-date SSAS databases on a restored DB instance

1. Back up your SSAS databases to the `D:\S3` folder on the source instance.
2. Transfer the backup files to the S3 bucket.
3. Transfer the backup files from the S3 bucket to the `D:\S3` folder on the restored instance.
4. Run the stored procedure to restore the SSAS databases onto the restored instance.

   You can also reprocess the SSAS project to restore the databases.

Changing the SSAS mode

You can change the mode in which SSAS runs, either Tabular or Multidimensional. To change the mode, use the AWS Management Console or the AWS CLI to modify the options settings in the SSAS option.

> **Important**
>
> You can only use one SSAS mode at a time. Make sure to delete all of the SSAS databases before changing the mode, or you receive an error.

Console

The following Amazon RDS console procedure changes the SSAS mode to Tabular and sets the `MAX_MEMORY` parameter to 70 percent.

To modify the SSAS option

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Option groups**.
3. Choose the option group with the SSAS option that you want to modify (`ssas-se-2017` in the previous examples).
4. Choose **Modify option**.
5. Change the option settings:
   a. For **Max memory**, enter **70**.
   b. For **Mode**, choose **Tabular**.
6. Choose **Modify option**.

AWS CLI

The following AWS CLI example changes the SSAS mode to Tabular and sets the `MAX_MEMORY` parameter to 70 percent.

For the CLI command to work, make sure to include all of the required parameters, even if you're not modifying them.

To modify the SSAS option

- Use one of the following commands.

Example

For Linux, macOS, or Unix:

```
aws rds add-option-to-option-group \
    --option-group-name ssas-se-2017 \
    --options
 "OptionName=SSAS,VpcSecurityGroupMemberships=sg-12345e67,OptionSettings=[{Name=MAX_MEMORY,
{Name=MODE,Value=Tabular}]" \
    --apply-immediately
```

For Windows:

```
aws rds add-option-to-option-group ^
    --option-group-name ssas-se-2017 ^
    --options
 OptionName=SSAS,VpcSecurityGroupMemberships=sg-12345e67,OptionSettings=[{Name=MAX_MEMORY,V
{Name=MODE,Value=Tabular}] ^
    --apply-immediately
```

Turning off SSAS

To turn off SSAS, remove the SSAS option from its option group.

> **Important**
>
> Before you remove the SSAS option, delete your SSAS databases.
> We highly recommend that you back up your SSAS databases before deleting them and removing the SSAS option.

Console

To remove the SSAS option from its option group

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Option groups**.

3. Choose the option group with the SSAS option that you want to remove (`ssas-se-2017` in the previous examples).
4. Choose **Delete option**.
5. Under **Deletion options**, choose **SSAS** for **Options to delete**.
6. Under **Apply immediately**, choose **Yes** to delete the option immediately, or **No** to delete it at the next maintenance window.
7. Choose **Delete**.

AWS CLI

To remove the SSAS option from its option group

- Use one of the following commands.

  Example

  For Linux, macOS, or Unix:

```
aws rds remove-option-from-option-group \
    --option-group-name ssas-se-2017 \
    --options SSAS \
    --apply-immediately
```

  For Windows:

```
aws rds remove-option-from-option-group ^
    --option-group-name ssas-se-2017 ^
    --options SSAS ^
    --apply-immediately
```

Troubleshooting SSAS issues

You might encounter the following issues when using SSAS.

Issue	Type	Troubleshooting suggestions
Unable to configure the SSAS option. The requested SSAS mode	RDS event	You can't change the SSAS mode if you still have SSAS databases that use the current

Issue	Type	Troubleshooting suggestions
is *new_mode*, but the current DB instance has *number current_mode* databases. Delete the existing databases before switching to *new_mode* mode. To regain access to *current_mode* mode for database deletion, either update the current DB option group, or attach a new option group with %s as the MODE option setting value for the SSAS option.		mode. Delete the SSAS databases, then try again.
Unable to remove the SSAS option because there are *number* existing *mode* databases. The SSAS option can't be removed until all SSAS databases are deleted. Add the SSAS option again, delete all SSAS databases, and try again.	RDS event	You can't turn off SSAS if you still have SSAS databases. Delete the SSAS databases , then try again.
The SSAS option isn't enabled or is in the process of being enabled. Try again later.	RDS stored procedure	You can't run SSAS stored procedures when the option is turned off, or when it's being turned on.

Issue	Type	Troubleshooting suggestions
The SSAS option is configured incorrectly. Make sure that the option group membership status is "in-sync" , and review the RDS event logs for relevant SSAS configuration error messages. Following these investiga tions, try again. If errors continue to occur, contact AWS Support.	RDS stored procedure	You can't run SSAS stored procedures when your option group membership isn't in the `in-sync` status. This puts the SSAS option in an incorrect configuration state. If your option group membership status changes to `failed` due to SSAS option modification, there are two possible reasons: 1. The SSAS option was removed without the SSAS databases being deleted. 2. The SSAS mode was updated from Tabular to Multidimensional, or from Multidimenisonal to Tabular, without the existing SSAS databases being deleted. Reconfigure the SSAS option, because RDS allows only one SSAS mode at a time, and doesn't support SSAS option removal with SSAS databases present. Check the RDS event logs for configuration errors for your SSAS instance, and resolve the issues accordingly.
Deployment failed. The change can only be deployed on a server running in *`deployment_file_mode`* mode. The current server mode is *`current_mode`* .	RDS stored procedure	You can't deploy a Tabular database to a Multidimensional server, or a Multidime nsional database to a Tabular server. Make sure that you're using files with the correct mode, and verify that the `MODE` option setting is set to the appropriate value.

Issue	Type	Troubleshooting suggestions
The restore failed. The backup file can only be restored on a server running in *restore_file_mode* mode. The current server mode is *current_mode* .	RDS stored procedure	You can't restore a Tabular database to a Multidimensional server, or a Multidimensional database to a Tabular server. Make sure that you're using files with the correct mode, and verify that the MODE option setting is set to the appropriate value.
The restore failed. The backup file and the RDS DB instance versions are incompatible.	RDS stored procedure	You can't restore an SSAS database with a version incompatible to the SQL Server instance version. For more information, see Compatibility levels for tabular models and Compatibility level of a multidimensional database in the Microsoft documentation.
The restore failed. The backup file specified in the restore operation is damaged or is not an SSAS backup file. Make sure that @rds_file_path is correctly formatted.	RDS stored procedure	You can't restore an SSAS database with a damaged file. Make sure that the file isn't damaged or corrupted. This error can also be raised when `@rds_file_path` isn't correctly formatted (for example, it has double backslashes as in `D:\S3\\incorrect_format.abf`).

Issue	Type	Troubleshooting suggestions
The restore failed. The restored database name can't contain any reserved words or invalid character s: . , ; ' ` : / \\ * | ? \" & % $! + = ( ) [ ] { } < >, or be longer than 100 characters.	RDS stored procedure	The restored database name can't contain any reserved words or characters that aren't valid, or be longer than 100 charac ters. For SSAS object naming conventions, see Object naming rules in the Microsoft documentation.
An invalid role name was provided. The role name can't contain any reserved strings.	RDS stored procedure	The role name can't contain any reserved strings. For SSAS object naming conventions, see Object naming rules in the Microsoft documentation.
An invalid role name was provided. The role name can't contain any of the following reserved characters: . , ; ' ` : / \\ * | ? \" & % $! + = ( ) [ ] { } < >	RDS stored procedure	The role name can't contain any reserved characters. For SSAS object naming conventions, see Object naming rules in the Microsoft documentation.

Support for SQL Server Integration Services in Amazon RDS for SQL Server

Microsoft SQL Server Integration Services (SSIS) is a component that you can use to perform a broad range of data migration tasks. SSIS is a platform for data integration and workflow applications. It features a data warehousing tool used for data extraction, transformation, and loading (ETL). You can also use this tool to automate maintenance of SQL Server databases and updates to multidimensional cube data.

SSIS projects are organized into packages saved as XML-based .dtsx files. Packages can contain control flows and data flows. You use data flows to represent ETL operations. After deployment, packages are stored in SQL Server in the SSISDB database. SSISDB is an online transaction processing (OLTP) database in the full recovery mode.

Amazon RDS for SQL Server supports running SSIS directly on an RDS DB instance. You can enable SSIS on an existing or new DB instance. SSIS is installed on the same DB instance as your database engine.

RDS supports SSIS for SQL Server Standard and Enterprise Editions on the following versions:

- SQL Server 2022, all versions
- SQL Server 2019, version 15.00.4043.16.v1 and higher
- SQL Server 2017, version 14.00.3223.3.v1 and higher
- SQL Server 2016, version 13.00.5426.0.v1 and higher

Contents

- Setting up a Windows-authenticated user for SSIS
- Deploying an SSIS project
- Monitoring the status of a deployment task
- Using SSIS
  - Setting database connection managers for SSIS projects
  - Creating an SSIS proxy
  - Scheduling an SSIS package using SQL Server Agent
  - Revoking SSIS access from the proxy
- Disabling SSIS
- Dropping the SSISDB database

Limitations and recommendations

The following limitations and recommendations apply to running SSIS on RDS for SQL Server:

- The DB instance must have an associated parameter group with the `clr enabled` parameter set to 1. For more information, see Modifying the parameter for SSIS.

  > **Note**
  >
  > If you enable the `clr enabled` parameter on SQL Server 2017 or 2019, you can't use the common language runtime (CLR) on your DB instance. For more information, see Features not supported and features with limited support.

- The following control flow tasks are supported:
  - Analysis Services Execute DDL Task
  - Analysis Services Processing Task
  - Bulk Insert Task
  - Check Database Integrity Task
  - Data Flow Task
  - Data Mining Query Task
  - Data Profiling Task
  - Execute Package Task

  - Execute SQL Server Agent Job Task
  - Execute SQL Task
  - Execute T-SQL Statement Task
  - Notify Operator Task
  - Rebuild Index Task
  - Reorganize Index Task
  - Shrink Database Task
  - Transfer Database Task
  - Transfer Jobs Task
  - Transfer Logins Task
  - Transfer SQL Server Objects Task
  - Update Statistics Task
- Only project deployment is supported.
- Running SSIS packages by using SQL Server Agent is supported.
- SSIS log records can be inserted only into user-created databases.
- Use only the `D:\S3` folder for working with files. Files placed in any other directory are deleted. Be aware of a few other file location details:
  - Place SSIS project input and output files in the `D:\S3` folder.
  - For the Data Flow Task, change the location for `BLOBTempStoragePath` and `BufferTempStoragePath` to a file inside the `D:\S3` folder. The file path must start with `D:\S3\`.
  - Ensure that all parameters, variables, and expressions used for file connections point to the `D:\S3` folder.
  - On Multi-AZ instances, files created by SSIS in the `D:\S3` folder are deleted after a failover. For more information, see Multi-AZ limitations for S3 integration.
  - Upload the files created by SSIS in the `D:\S3` folder to your Amazon S3 bucket to make them durable.
- Import Column and Export Column transformations and the Script component on the Data Flow Task aren't supported.
- You can't enable dump on running SSIS packages, and you can't add data taps on SSIS packages.
- The SSIS Scale Out feature isn't supported.

- You can't deploy projects directly. We provide RDS stored procedures to do this. For more information, see Deploying an SSIS project.
- Build SSIS project (.ispac) files with the `DoNotSavePasswords` protection mode for deploying on RDS.
- SSIS isn't supported on Always On instances with read replicas.
- You can't back up the SSISDB database that is associated with the `SSIS` option.
- Importing and restoring the SSISDB database from other instances of SSIS isn't supported.
- You can connect to other SQL Server DB instances or to an Oracle data source. Connecting to other database engines, such as MySQL or PostgreSQL, isn't supported for SSIS on RDS for SQL Server. For more information on connecting to an Oracle data source, see Linked Servers with Oracle OLEDB.

Enabling SSIS

You enable SSIS by adding the SSIS option to your DB instance. Use the following process:

1. Create a new option group, or choose an existing option group.
2. Add the `SSIS` option to the option group.
3. Create a new parameter group, or choose an existing parameter group.
4. Modify the parameter group to set the `clr enabled` parameter to 1.
5. Associate the option group and parameter group with the DB instance.
6. Enable Amazon S3 integration.

> **Note**
>
> If a database with the name SSISDB or a reserved SSIS login already exists on the DB instance, you can't enable SSIS on the instance.

Creating the option group for SSIS

To work with SSIS, create an option group or modify an option group that corresponds to the SQL Server edition and version of the DB instance that you plan to use. To do this, use the AWS Management Console or the AWS CLI.

Console

The following procedure creates an option group for SQL Server Standard Edition 2016.

To create the option group

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Option groups**.
3. Choose **Create group**.
4. In the **Create option group** window, do the following:
   a. For **Name**, enter a name for the option group that is unique within your AWS account, such as **`ssis-se-2016`**. The name can contain only letters, digits, and hyphens.
   b. For **Description**, enter a brief description of the option group, such as **`SSIS option group for SQL Server SE 2016`**. The description is used for display purposes.
   c. For **Engine**, choose **sqlserver-se**.
   d. For **Major engine version**, choose **13.00**.
5. Choose **Create**.

CLI

The following procedure creates an option group for SQL Server Standard Edition 2016.

To create the option group

- Run one of the following commands.

  Example

  For Linux, macOS, or Unix:

```
aws rds create-option-group \
    --option-group-name ssis-se-2016 \
    --engine-name sqlserver-se \
    --major-engine-version 13.00 \
    --option-group-description "SSIS option group for SQL Server SE 2016"
```

  For Windows:

```
aws rds create-option-group ^
    --option-group-name ssis-se-2016 ^
    --engine-name sqlserver-se ^
    --major-engine-version 13.00 ^
    --option-group-description "SSIS option group for SQL Server SE 2016"
```

Adding the SSIS option to the option group

Next, use the AWS Management Console or the AWS CLI to add the SSIS option to your option group.

Console

To add the SSIS option

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Option groups**.
3. Choose the option group that you just created, **ssis-se-2016** in this example.
4. Choose **Add option**.
5. Under **Option details**, choose **SSIS** for **Option name**.
6. Under **Scheduling**, choose whether to add the option immediately or at the next maintenance window.
7. Choose **Add option**.

CLI

To add the SSIS option

- Add the SSIS option to the option group.

  Example

  For Linux, macOS, or Unix:

```
aws rds add-option-to-option-group \
    --option-group-name ssis-se-2016 \
```

```
    --options OptionName=SSIS \
    --apply-immediately
```

For Windows:

```
aws rds add-option-to-option-group ^
    --option-group-name ssis-se-2016 ^
    --options OptionName=SSIS ^
    --apply-immediately
```

Creating the parameter group for SSIS

Create or modify a parameter group for the `clr enabled` parameter that corresponds to the SQL Server edition and version of the DB instance that you plan to use for SSIS.

Console

The following procedure creates a parameter group for SQL Server Standard Edition 2016.

To create the parameter group

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Parameter groups**.
3. Choose **Create parameter group**.
4. In the **Create parameter group** pane, do the following:
   a. For **Parameter group family**, choose **sqlserver-se-13.0**.
   b. For **Group name**, enter an identifier for the parameter group, such as **`ssis-sqlserver-se-13`**.
   c. For **Description**, enter **`clr enabled parameter group`**.
5. Choose **Create**.

CLI

The following procedure creates a parameter group for SQL Server Standard Edition 2016.

To create the parameter group

- Run one of the following commands.

  Example

  For Linux, macOS, or Unix:

```
aws rds create-db-parameter-group \
    --db-parameter-group-name ssis-sqlserver-se-13 \
    --db-parameter-group-family "sqlserver-se-13.0" \
    --description "clr enabled parameter group"
```

  For Windows:

```
aws rds create-db-parameter-group ^
    --db-parameter-group-name ssis-sqlserver-se-13 ^
    --db-parameter-group-family "sqlserver-se-13.0" ^
    --description "clr enabled parameter group"
```

Modifying the parameter for SSIS

Modify the `clr enabled` parameter in the parameter group that corresponds to the SQL Server edition and version of your DB instance. For SSIS, set the `clr enabled` parameter to 1.

Console

The following procedure modifies the parameter group that you created for SQL Server Standard Edition 2016.

To modify the parameter group

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Parameter groups**.
3. Choose the parameter group, such as **ssis-sqlserver-se-13**.
4. Under **Parameters**, filter the parameter list for **`clr`**.
5. Choose **clr enabled**.
6. Choose **Edit parameters**.

7. From **Values**, choose **1**.
8. Choose **Save changes**.

CLI

The following procedure modifies the parameter group that you created for SQL Server Standard Edition 2016.

To modify the parameter group

- Run one of the following commands.

  Example

  For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group \
    --db-parameter-group-name ssis-sqlserver-se-13 \
    --parameters "ParameterName='clr
 enabled',ParameterValue=1,ApplyMethod=immediate"
```

  For Windows:

```
aws rds modify-db-parameter-group ^
    --db-parameter-group-name ssis-sqlserver-se-13 ^
    --parameters "ParameterName='clr
 enabled',ParameterValue=1,ApplyMethod=immediate"
```

Associating the option group and parameter group with your DB instance

To associate the SSIS option group and parameter group with your DB instance, use the AWS Management Console or the AWS CLI

> **Note**
>
> If you use an existing instance, it must already have an Active Directory domain and AWS Identity and Access Management (IAM) role associated with it. If you create a new instance,

specify an existing Active Directory domain and IAM role. For more information, see Working with Active Directory with RDS for SQL Server.

Console

To finish enabling SSIS, associate your SSIS option group and parameter group with a new or existing DB instance:

- For a new DB instance, associate them when you launch the instance. For more information, see Creating an Amazon RDS DB instance.
- For an existing DB instance, associate them by modifying the instance. For more information, see Modifying an Amazon RDS DB instance.

CLI

You can associate the SSIS option group and parameter group with a new or existing DB instance.

To create an instance with the SSIS option group and parameter group

- Specify the same DB engine type and major version as you used when creating the option group.

  Example

  For Linux, macOS, or Unix:

```
aws rds create-db-instance \
    --db-instance-identifier myssisinstance \
    --db-instance-class db.m5.2xlarge \
    --engine sqlserver-se \
    --engine-version 13.00.5426.0.v1 \
    --allocated-storage 100 \
    --manage-master-user-password \
    --master-username admin \
    --storage-type gp2 \
    --license-model li \
    --domain-iam-role-name my-directory-iam-role \
    --domain my-domain-id \
    --option-group-name ssis-se-2016 \
```

```
    --db-parameter-group-name ssis-sqlserver-se-13
```

For Windows:

```
aws rds create-db-instance ^
    --db-instance-identifier myssisinstance ^
    --db-instance-class db.m5.2xlarge ^
    --engine sqlserver-se ^
    --engine-version 13.00.5426.0.v1 ^
    --allocated-storage 100 ^
    --manage-master-user-password ^
    --master-username admin ^
    --storage-type gp2 ^
    --license-model li ^
    --domain-iam-role-name my-directory-iam-role ^
    --domain my-domain-id ^
    --option-group-name ssis-se-2016 ^
    --db-parameter-group-name ssis-sqlserver-se-13
```

To modify an instance and associate the SSIS option group and parameter group

- Run one of the following commands.

  Example

  For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier myssisinstance \
    --option-group-name ssis-se-2016 \
    --db-parameter-group-name ssis-sqlserver-se-13 \
    --apply-immediately
```

  For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier myssisinstance ^
    --option-group-name ssis-se-2016 ^
    --db-parameter-group-name ssis-sqlserver-se-13 ^
    --apply-immediately
```

Enabling S3 integration

To download SSIS project (.ispac) files to your host for deployment, use S3 file integration. For more information, see Integrating an Amazon RDS for SQL Server DB instance with Amazon S3.

Administrative permissions on SSISDB

When the instance is created or modified with the SSIS option, the result is an SSISDB database with the ssis_admin and ssis_logreader roles granted to the master user. The master user has the following privileges in SSISDB:

- alter on ssis_admin role
- alter on ssis_logreader role
- alter any user

Because the master user is a SQL-authenticated user, you can't use the master user for executing SSIS packages. The master user can use these privileges to create new SSISDB users and add them to the ssis_admin and ssis_logreader roles. Doing this is useful for giving access to your domain users for using SSIS.

Setting up a Windows-authenticated user for SSIS

The master user can use the following code example to set up a Windows-authenticated login in SSISDB and grant the required procedure permissions. Doing this grants permissions to the domain user to deploy and run SSIS packages, use S3 file transfer procedures, create credentials, and work with the SQL Server Agent proxy. For more information, see Credentials (database engine) and Create a SQL Server Agent proxy in the Microsoft documentation.

> **Note**
>
> You can grant some or all of the following permissions as needed to Windows-authenticated users.

Example

```
-- Create a server-level SQL login for the domain user, if it doesn't already exist
USE [master]
GO
CREATE LOGIN [mydomain\user_name] FROM WINDOWS
```

```
GO

-- Create a database-level account for the domain user, if it doesn't already exist

USE [SSISDB]
GO
CREATE USER [mydomain\user_name] FOR LOGIN [mydomain\user_name]

-- Add SSIS role membership to the domain user
ALTER ROLE [ssis_admin] ADD MEMBER [mydomain\user_name]
ALTER ROLE [ssis_logreader] ADD MEMBER [mydomain\user_name]
GO

-- Add MSDB role membership to the domain user
USE [msdb]
GO
CREATE USER [mydomain\user_name] FOR LOGIN [mydomain\user_name]

-- Grant MSDB stored procedure privileges to the domain user
GRANT EXEC ON msdb.dbo.rds_msbi_task TO [mydomain\user_name] with grant option
GRANT SELECT ON msdb.dbo.rds_fn_task_status TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.rds_task_status TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.rds_cancel_task TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.rds_download_from_s3 TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.rds_upload_to_s3 TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.rds_delete_from_filesystem TO [mydomain\user_name] with grant
 option
GRANT EXEC ON msdb.dbo.rds_gather_file_details TO [mydomain\user_name] with grant
 option
GRANT EXEC ON msdb.dbo.sp_add_proxy TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.sp_update_proxy TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.sp_grant_login_to_proxy TO [mydomain\user_name] with grant
 option
GRANT EXEC ON msdb.dbo.sp_revoke_login_from_proxy TO [mydomain\user_name] with grant
 option
GRANT EXEC ON msdb.dbo.sp_delete_proxy TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.sp_enum_login_for_proxy to [mydomain\user_name] with grant
 option
GRANT EXEC ON msdb.dbo.sp_enum_proxy_for_subsystem TO [mydomain\user_name]  with grant
 option
GRANT EXEC ON msdb.dbo.rds_sqlagent_proxy TO [mydomain\user_name] WITH GRANT OPTION

-- Add the SQLAgentUserRole privilege to the domain user
```

```
USE [msdb]
GO
ALTER ROLE [SQLAgentUserRole] ADD MEMBER [mydomain\user_name]
GO

-- Grant the ALTER ANY CREDENTIAL privilege to the domain user
USE [master]
GO
GRANT ALTER ANY CREDENTIAL TO [mydomain\user_name]
GO
```

Deploying an SSIS project

On RDS, you can't deploy SSIS projects directly by using SQL Server Management Studio (SSMS) or SSIS procedures. To download project files from Amazon S3 and then deploy them, use RDS stored procedures.

To run the stored procedures, log in as any user that you granted permissions for running the stored procedures. For more information, see Setting up a Windows-authenticated user for SSIS.

To deploy the SSIS project

1. Download the project (.ispac) file.

   ```
   exec msdb.dbo.rds_download_from_s3
   @s3_arn_of_file='arn:aws:s3:::bucket_name/ssisproject.ispac',
   [@rds_file_path='D:\S3\ssisproject.ispac'],
   [@overwrite_file=1];
   ```

2. Submit the deployment task, making sure of the following:

   - The folder is present in the SSIS catalog.
   - The project name matches the project name that you used while developing the SSIS project.

   ```
   exec msdb.dbo.rds_msbi_task
   @task_type='SSIS_DEPLOY_PROJECT',
   @folder_name='DEMO',
   @project_name='ssisproject',
   @file_path='D:\S3\ssisproject.ispac';
   ```

Monitoring the status of a deployment task

To track the status of your deployment task, call the `rds_fn_task_status` function. It takes two parameters. The first parameter should always be `NULL` because it doesn't apply to SSIS. The second parameter accepts a task ID.

To see a list of all tasks, set the first parameter to `NULL` and the second parameter to `0`, as shown in the following example.

```
SELECT * FROM msdb.dbo.rds_fn_task_status(NULL,0);
```

To get a specific task, set the first parameter to `NULL` and the second parameter to the task ID, as shown in the following example.

```
SELECT * FROM msdb.dbo.rds_fn_task_status(NULL,42);
```

The `rds_fn_task_status` function returns the following information.

Output parameter	Description
`task_id`	The ID of the task.
`task_type`	`SSIS_DEPLOY_PROJECT`
`database_name`	Not applicable to SSIS tasks.
`% complete`	The progress of the task as a percentage.
`duration (mins)`	The amount of time spent on the task, in minutes.
`lifecycle`	The status of the task. Possible statuses are the following: • `CREATED` – After you call the `msdb.dbo.rds_msbi_task` stored procedure, a task is created and the status is set to `CREATED`.

Output parameter	Description
	• IN_PROGRESS – After a task starts, the status is set to IN_PROGRESS . It can take up to five minutes for the status to change from CREATED to IN_PROGRESS . • SUCCESS – After a task completes, the status is set to SUCCESS. • ERROR – If a task fails, the status is set to ERROR. For more information about the error, see the task_info column. • CANCEL_REQUESTED – After you call rds_cancel_task , the status of the task is set to CANCEL_REQUESTED . • CANCELLED – After a task is successfully canceled, the status of the task is set to CANCELLED .
task_info	Additional information about the task. If an error occurs during processing, this column contains information about the error.
last_updated	The date and time that the task status was last updated.
created_at	The date and time that the task was created.
S3_object_arn	Not applicable to SSIS tasks.
overwrite_S3_backup_file	Not applicable to SSIS tasks.
KMS_master_key_arn	Not applicable to SSIS tasks.

Output parameter	Description
`filepath`	Not applicable to SSIS tasks.
`overwrite_file`	Not applicable to SSIS tasks.
`task_metadata`	Metadata associated with the SSIS task.

Using SSIS

After deploying the SSIS project into the SSIS catalog, you can run packages directly from SSMS or schedule them by using SQL Server Agent. You must use a Windows-authenticated login for executing SSIS packages. For more information, see Setting up a Windows-authenticated user for SSIS.

Topics

- Setting database connection managers for SSIS projects
- Creating an SSIS proxy
- Scheduling an SSIS package using SQL Server Agent
- Revoking SSIS access from the proxy

Setting database connection managers for SSIS projects

When you use a connection manager, you can use these types of authentication:

- For local database connections using AWS Managed Active Directory, you can use SQL authentication or Windows authentication. For Windows authentication, use *`DB_instance_name`*`.`*`fully_qualified_domain_name`* as the server name of the connection string.

  An example is `myssisinstance.corp-ad.example.com`, where `myssisinstance` is the DB instance name and `corp-ad.example.com` is the fully qualified domain name.
- For remote connections, always use SQL authentication.

- For local database connections using self-managed Active Directory, you can use SQL authentication or Windows authentication. For Windows authentication, use `.` or *`LocalHost`* as the server name of the connection string.

Creating an SSIS proxy

To be able to schedule SSIS packages using SQL Server Agent, create an SSIS credential and an SSIS proxy. Run these procedures as a Windows-authenticated user.

To create the SSIS credential

- Create the credential for the proxy. To do this, you can use SSMS or the following SQL statement.

```
USE [master]
GO
CREATE CREDENTIAL [SSIS_Credential] WITH IDENTITY = N'mydomain\user_name', SECRET =
 N'mysecret'
GO
```

> **Note**
>
> IDENTITY must be a domain-authenticated login. Replace *`mysecret`* with the password for the domain-authenticated login.
> Whenever the SSISDB primary host is changed, alter the SSIS proxy credentials to allow the new host to access them.

To create the SSIS proxy

1. Use the following SQL statement to create the proxy.

```
USE [msdb]
GO
EXEC msdb.dbo.sp_add_proxy
 @proxy_name=N'SSIS_Proxy',@credential_name=N'SSIS_Credential',@description=N''
GO
```

2. Use the following SQL statement to grant access to the proxy to other users.

```
USE [msdb]
GO
EXEC msdb.dbo.sp_grant_login_to_proxy
 @proxy_name=N'SSIS_Proxy',@login_name=N'mydomain\user_name'
GO
```

3. Use the following SQL statement to give the SSIS subsystem access to the proxy.

```
USE [msdb]
GO
EXEC msdb.dbo.rds_sqlagent_proxy
 @task_type='GRANT_SUBSYSTEM_ACCESS',@proxy_name='SSIS_Proxy',@proxy_subsystem='SSIS'
GO
```

To view the proxy and grants on the proxy

1. Use the following SQL statement to view the grantees of the proxy.

```
USE [msdb]
GO
EXEC sp_help_proxy
GO
```

2. Use the following SQL statement to view the subsystem grants.

```
USE [msdb]
GO
EXEC msdb.dbo.sp_enum_proxy_for_subsystem
GO
```

Scheduling an SSIS package using SQL Server Agent

After you create the credential and proxy and grant SSIS access to the proxy, you can create a SQL Server Agent job to schedule the SSIS package.

To schedule the SSIS package

- You can use SSMS or T-SQL for creating the SQL Server Agent job. The following example uses T-SQL.

```
USE [msdb]
GO
DECLARE @jobId BINARY(16)
EXEC msdb.dbo.sp_add_job @job_name=N'MYSSISJob',
@enabled=1,
@notify_level_eventlog=0,
@notify_level_email=2,
@notify_level_page=2,
@delete_level=0,
@category_name=N'[Uncategorized (Local)]',
@job_id = @jobId OUTPUT
GO
EXEC msdb.dbo.sp_add_jobserver @job_name=N'MYSSISJob',@server_name=N'(local)'
GO
EXEC msdb.dbo.sp_add_jobstep
 @job_name=N'MYSSISJob',@step_name=N'ExecuteSSISPackage',
@step_id=1,
@cmdexec_success_code=0,
@on_success_action=1,
@on_fail_action=2,
@retry_attempts=0,
@retry_interval=0,
@os_run_priority=0,
@subsystem=N'SSIS',
@command=N'/ISSERVER "\"\SSISDB\MySSISFolder\MySSISProject\MySSISPackage.dtsx\"" /
SERVER "\"my-rds-ssis-instance.corp-ad.company.com/\""
/Par "\"$ServerOption::LOGGING_LEVEL(Int16)\"";1 /Par
 "\"$ServerOption::SYNCHRONIZED(Boolean)\"";True /CALLERINFO SQLAGENT /REPORTING
 E',
@database_name=N'master',
@flags=0,
@proxy_name=N'SSIS_Proxy'
GO
```

Revoking SSIS access from the proxy

You can revoke access to the SSIS subsystem and delete the SSIS proxy using the following stored procedures.

To revoke access and delete the proxy

1. Revoke subsystem access.

```
USE [msdb]
GO
EXEC msdb.dbo.rds_sqlagent_proxy
 @task_type='REVOKE_SUBSYSTEM_ACCESS',@proxy_name='SSIS_Proxy',@proxy_subsystem='SSIS'
GO
```

2. Revoke the grants on the proxy.

```
USE [msdb]
GO
EXEC msdb.dbo.sp_revoke_login_from_proxy
 @proxy_name=N'SSIS_Proxy',@name=N'mydomain\user_name'
GO
```

3. Delete the proxy.

```
USE [msdb]
GO
EXEC dbo.sp_delete_proxy @proxy_name = N'SSIS_Proxy'
GO
```

Disabling SSIS

To disable SSIS, remove the SSIS option from its option group.

> **Important**
>
> Removing the option doesn't delete the SSISDB database, so you can safely remove the option without losing the SSIS projects.
> You can re-enable the SSIS option after removal to reuse the SSIS projects that were previously deployed to the SSIS catalog.

Console

The following procedure removes the SSIS option.

To remove the SSIS option from its option group

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Option groups**.
3. Choose the option group with the SSIS option (`ssis-se-2016` in the previous examples).
4. Choose **Delete option**.
5. Under **Deletion options**, choose **SSIS** for **Options to delete**.
6. Under **Apply immediately**, choose **Yes** to delete the option immediately, or **No** to delete it at the next maintenance window.
7. Choose **Delete**.

CLI

The following procedure removes the SSIS option.

To remove the SSIS option from its option group

- Run one of the following commands.

  Example

  For Linux, macOS, or Unix:

```
aws rds remove-option-from-option-group \
    --option-group-name ssis-se-2016 \
    --options SSIS \
    --apply-immediately
```

  For Windows:

```
aws rds remove-option-from-option-group ^
    --option-group-name ssis-se-2016 ^
    --options SSIS ^
    --apply-immediately
```

Dropping the SSISDB database

After removing the SSIS option, the SSISDB database isn't deleted. To drop the SSISDB database, use the `rds_drop_ssis_database` stored procedure after removing the SSIS option.

To drop the SSIS database

- Use the following stored procedure.

```
USE [msdb]
GO
EXEC dbo.rds_drop_ssis_database
GO
```

After dropping the SSISDB database, if you re-enable the SSIS option you get a fresh SSISDB catalog.

Support for SQL Server Reporting Services in Amazon RDS for SQL Server

Microsoft SQL Server Reporting Services (SSRS) is a server-based application used for report generation and distribution. It's part of a suite of SQL Server services that also includes SQL Server Analysis Services (SSAS) and SQL Server Integration Services (SSIS). SSRS is a service built on top of SQL Server. You can use it to collect data from various data sources and present it in a way that's easily understandable and ready for analysis.

Amazon RDS for SQL Server supports running SSRS directly on RDS DB instances. You can use SSRS with existing or new DB instances.

RDS supports SSRS for SQL Server Standard and Enterprise Editions on the following versions:

- SQL Server 2022, all versions
- SQL Server 2019, version 15.00.4043.16.v1 and higher
- SQL Server 2017, version 14.00.3223.3.v1 and higher
- SQL Server 2016, version 13.00.5820.21.v1 and higher

Contents

- Using SSRS Email to send reports
- Revoking system-level permissions
- Monitoring the status of a task
- Turning off SSRS
- Deleting the SSRS databases

Limitations and recommendations

The following limitations and recommendations apply to running SSRS on RDS for SQL Server:

- You can't use SSRS on DB instances that have read replicas.
- Instances must use self-managed Active Directory or AWS Directory Service for Microsoft Active Directory for SSRS web portal and web server authentication. For more information, see Working with Active Directory with RDS for SQL Server.
- You can't back up the reporting server databases that are created with the SSRS option.
- Importing and restoring report server databases from other instances of SSRS isn't supported. For more information, see Report server databases.
- You can't configure SSRS to listen on the default SSL port (443). The allowed values are 1150–49511, except 1234, 1434, 3260, 3343, 3389, and 47001.
- Subscriptions through a Microsoft Windows file share aren't supported.
- Using Reporting Services Configuration Manager isn't supported.
- Creating and modifying roles isn't supported.
- Modifying report server properties isn't supported.
- System administrator and system user roles aren't granted.
- You can't edit system-level role assignments through the web portal.

Turning on SSRS

Use the following process to turn on SSRS for your DB instance:

1. Create a new option group, or choose an existing option group.
2. Add the SSRS option to the option group.
3. Associate the option group with the DB instance.

4. Allow inbound access to the virtual private cloud (VPC) security group for the SSRS listener port.

Creating an option group for SSRS

To work with SSRS, create an option group that corresponds to the SQL Server engine and version of the DB instance that you plan to use. To do this, use the AWS Management Console or the AWS CLI.

> **Note**
>
> You can also use an existing option group if it's for the correct SQL Server engine and version.

Console

The following procedure creates an option group for SQL Server Standard Edition 2017.

To create the option group

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Option groups**.
3. Choose **Create group**.
4. In the **Create option group** pane, do the following:
   a. For **Name**, enter a name for the option group that is unique within your AWS account, such as **`ssrs-se-2017`**. The name can contain only letters, digits, and hyphens.
   b. For **Description**, enter a brief description of the option group, such as **`SSRS option group for SQL Server SE 2017`**. The description is used for display purposes.
   c. For **Engine**, choose **sqlserver-se**.
   d. For **Major engine version**, choose **14.00**.
5. Choose **Create**.

CLI

The following procedure creates an option group for SQL Server Standard Edition 2017.

To create the option group

- Run one of the following commands.

Example

For Linux, macOS, or Unix:

```
aws rds create-option-group \
    --option-group-name ssrs-se-2017 \
    --engine-name sqlserver-se \
    --major-engine-version 14.00 \
    --option-group-description "SSRS option group for SQL Server SE 2017"
```

For Windows:

```
aws rds create-option-group ^
    --option-group-name ssrs-se-2017 ^
    --engine-name sqlserver-se ^
    --major-engine-version 14.00 ^
    --option-group-description "SSRS option group for SQL Server SE 2017"
```

Adding the SSRS option to your option group

Next, use the AWS Management Console or the AWS CLI to add the SSRS option to your option group.

Console

To add the SSRS option

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Option groups**.
3. Choose the option group that you just created, then choose **Add option**.
4. Under **Option details**, choose **SSRS** for **Option name**.
5. Under **Option settings**, do the following:

    a. Enter the port for the SSRS service to listen on. The default is 8443. For a list of allowed values, see Limitations and recommendations.

b. Enter a value for **Max memory**.

Max memory specifies the upper threshold above which no new memory allocation requests are granted to report server applications. The number is a percentage of the total memory of the DB instance. The allowed values are 10–80.

c. For **Security groups**, choose the VPC security group to associate with the option. Use the same security group that is associated with your DB instance.

6. To use SSRS Email to send reports, choose the **Configure email delivery options** check box under **Email delivery in reporting services**, and then do the following:

a. For **Sender email address**, enter the email address to use in the **From** field of messages sent by SSRS Email.

Specify a user account that has permission to send mail from the SMTP server.

b. For **SMTP server**, specify the SMTP server or gateway to use.

It can be an IP address, the NetBIOS name of a computer on your corporate intranet, or a fully qualified domain name.

c. For **SMTP port**, enter the port to use to connect to the mail server. The default is 25.

d. To use authentication:

i. Select the **Use authentication** check box.

ii. For **Secret Amazon Resource Name (ARN)** enter the AWS Secrets Manager ARN for the user credentials.

Use the following format:

```
arn:aws:secretsmanager:Region:AccountId:secret:SecretName-6RandomChara
```

For example:

```
arn:aws:secretsmanager:us-west-2:123456789012:secret:MySecret-a1b2c3
```

For more information on creating the secret, see Using SSRS Email to send reports.

e. Select the **Use Secure Sockets Layer (SSL)** check box to encrypt email messages using SSL.

7. Under **Scheduling**, choose whether to add the option immediately or at the next maintenance window.
8. Choose **Add option**.

CLI

To add the SSRS option

1. Create a JSON file, for example `ssrs-option.json`.
   a. Set the following required parameters:
      - `OptionGroupName` – The name of option group that you created or chose previously (`ssrs-se-2017` in the following example).
      - `Port` – The port for the SSRS service to listen on. The default is 8443. For a list of allowed values, see Limitations and recommendations.
      - `VpcSecurityGroupMemberships` – VPC security group memberships for your RDS DB instance.
      - `MAX_MEMORY` – The upper threshold above which no new memory allocation requests are granted to report server applications. The number is a percentage of the total memory of the DB instance. The allowed values are 10–80.
   b. (Optional) Set the following parameters to use SSRS Email:
      - `SMTP_ENABLE_EMAIL` – Set to `true` to use SSRS Email. The default is `false`.
      - `SMTP_SENDER_EMAIL_ADDRESS` – The email address to use in the **From** field of messages sent by SSRS Email. Specify a user account that has permission to send mail from the SMTP server.
      - `SMTP_SERVER` – The SMTP server or gateway to use. It can be an IP address, the NetBIOS name of a computer on your corporate intranet, or a fully qualified domain name.
      - `SMTP_PORT` – The port to use to connect to the mail server. The default is 25.
      - `SMTP_USE_SSL` – Set to `true` to encrypt email messages using SSL. The default is `true`.
      - `SMTP_EMAIL_CREDENTIALS_SECRET_ARN` – The Secrets Manager ARN that holds the user credentials. Use the following format:

arn:aws:secretsmanager:*Region*:*AccountId*:secret:*SecretName*-6RandomCharact

For more information on creating the secret, see Using SSRS Email to send reports.

- SMTP_USE_ANONYMOUS_AUTHENTICATION – Set to `true` and don't include SMTP_EMAIL_CREDENTIALS_SECRET_ARN if you don't want to use authentication.

  The default is `false` when SMTP_ENABLE_EMAIL is `true`.

The following example includes the SSRS Email parameters, using the secret ARN.

```
{
"OptionGroupName": "ssrs-se-2017",
"OptionsToInclude": [
 {
 "OptionName": "SSRS",
 "Port": 8443,
 "VpcSecurityGroupMemberships": ["sg-0abcdef123"],
 "OptionSettings": [
            {"Name": "MAX_MEMORY","Value": "60"},
            {"Name": "SMTP_ENABLE_EMAIL","Value": "true"}
            {"Name": "SMTP_SENDER_EMAIL_ADDRESS","Value": "nobody@example.com"},
            {"Name": "SMTP_SERVER","Value": "email-smtp.us-west-2.amazonaws.com"},
            {"Name": "SMTP_PORT","Value": "25"},
            {"Name": "SMTP_USE_SSL","Value": "true"},
            {"Name": "SMTP_EMAIL_CREDENTIALS_SECRET_ARN","Value":
 "arn:aws:secretsmanager:us-west-2:123456789012:secret:MySecret-a1b2c3"}
            ]
 }],
"ApplyImmediately": true
}
```

2. Add the SSRS option to the option group.

   Example

   For Linux, macOS, or Unix:

```
aws rds add-option-to-option-group \
    --cli-input-json file://ssrs-option.json \
    --apply-immediately
```

For Windows:

```
aws rds add-option-to-option-group ^
    --cli-input-json file://ssrs-option.json ^
    --apply-immediately
```

Associating your option group with your DB instance

Use the AWS Management Console or the AWS CLI to associate your option group with your DB instance.

If you use an existing DB instance, it must already have an Active Directory domain and AWS Identity and Access Management (IAM) role associated with it. If you create a new instance, specify an existing Active Directory domain and IAM role. For more information, see Working with Active Directory with RDS for SQL Server.

Console

You can associate your option group with a new or existing DB instance:

- For a new DB instance, associate the option group when you launch the instance. For more information, see Creating an Amazon RDS DB instance.
- For an existing DB instance, modify the instance and associate the new option group. For more information, see Modifying an Amazon RDS DB instance.

CLI

You can associate your option group with a new or existing DB instance.

To create a DB instance that uses your option group

- Specify the same DB engine type and major version as you used when creating the option group.

  Example

  For Linux, macOS, or Unix:

```
aws rds create-db-instance \
```

```
    --db-instance-identifier myssrsinstance \
    --db-instance-class db.m5.2xlarge \
    --engine sqlserver-se \
    --engine-version 14.00.3223.3.v1 \
    --allocated-storage 100 \
    --manage-master-user-password  \
    --master-username admin \
    --storage-type gp2 \
    --license-model li \
    --domain-iam-role-name my-directory-iam-role \
    --domain my-domain-id \
    --option-group-name ssrs-se-2017
```

For Windows:

```
aws rds create-db-instance ^
    --db-instance-identifier myssrsinstance ^
    --db-instance-class db.m5.2xlarge ^
    --engine sqlserver-se ^
    --engine-version 14.00.3223.3.v1 ^
    --allocated-storage 100 ^
    --manage-master-user-password ^
    --master-username admin ^
    --storage-type gp2 ^
    --license-model li ^
    --domain-iam-role-name my-directory-iam-role ^
    --domain my-domain-id ^
    --option-group-name ssrs-se-2017
```

To modify a DB instance to use your option group

- Run one of the following commands.

  Example

  For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier myssrsinstance \
    --option-group-name ssrs-se-2017 \
    --apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier myssrsinstance ^
    --option-group-name ssrs-se-2017 ^
    --apply-immediately
```

Allowing inbound access to your VPC security group

To allow inbound access to the VPC security group associated with your DB instance, create an inbound rule for the specified SSRS listener port. For more information about setting up security groups, see Provide access to your DB instance in your VPC by creating a security group.

Report server databases

When your DB instance is associated with the SSRS option, two new databases are created on your DB instance:

- `rdsadmin_ReportServer`
- `rdsadmin_ReportServerTempDB`

These databases act as the ReportServer and ReportServerTempDB databases. SSRS stores its data in the ReportServer database and caches its data in the ReportServerTempDB database. For more information, see Report Server Database in the Microsoft documentation.

RDS owns and manages these databases, so database operations on them such as ALTER and DROP aren't permitted. Access isn't permitted on the `rdsadmin_ReportServerTempDB` database. However, you can perform read operations on the `rdsadmin_ReportServer`database.

SSRS log files

You can list, view, and download SSRS log files. SSRS log files follow a naming convention of ReportServerService_*timestamp*.log. These report server logs are located in the `D:\rdsdbdata\Log\SSRS` directory. (The `D:\rdsdbdata\Log` directory is also the parent directory for error logs and SQL Server Agent logs.). For more information, see Viewing and listing database log files.

For existing SSRS instances, restarting the SSRS service might be necessary to access report server logs. You can restart the service by updating the SSRS option.

For more information, see Working with Microsoft SQL Server logs.

Accessing the SSRS web portal

Use the following process to access the SSRS web portal:

1. Turn on Secure Sockets Layer (SSL).
2. Grant access to domain users.
3. Access the web portal using a browser and the domain user credentials.

Using SSL on RDS

SSRS uses the HTTPS SSL protocol for its connections. To work with this protocol, import an SSL certificate into the Microsoft Windows operating system on your client computer.

For more information on SSL certificates, see Using SSL/TLS to encrypt a connection to a DB instance or cluster. For more information about using SSL with SQL Server, see Using SSL with a Microsoft SQL Server DB instance.

Granting access to domain users

In a new SSRS activation, there are no role assignments in SSRS. To give a domain user or user group access to the web portal, RDS provides a stored procedure.

To grant access to a domain user on the web portal

- Use the following stored procedure.

```
exec msdb.dbo.rds_msbi_task
@task_type='SSRS_GRANT_PORTAL_PERMISSION',
@ssrs_group_or_username=N'AD_domain\user';
```

The domain user or user group is granted the RDS_SSRS_ROLE system role. This role has the following system-level tasks granted to it:

- Run reports
- Manage jobs
- Manage shared schedules

- View shared schedules

The item-level role of `Content Manager` on the root folder is also granted.

Accessing the web portal

After the `SSRS_GRANT_PORTAL_PERMISSION` task finishes successfully, you have access to the portal using a web browser. The web portal URL has the following format.

```
https://rds_endpoint:port/Reports
```

In this format, the following applies:

- *`rds_endpoint`* – The endpoint for the RDS DB instance that you're using with SSRS.

  You can find the endpoint on the **Connectivity & security** tab for your DB instance. For more information, see Connecting to a DB instance running the Microsoft SQL Server database engine.
- *`port`* – The listener port for SSRS that you set in the SSRS option.

To access the web portal

1. Enter the web portal URL in your browser.

   ```
   https://myssrsinstance.cg034itsfake.us-east-1.rds.amazonaws.com:8443/Reports
   ```
2. Log in with the credentials for a domain user that you granted access with the `SSRS_GRANT_PORTAL_PERMISSION` task.

Deploying reports to SSRS

After you have access to the web portal, you can deploy reports to it. You can use the Upload tool in the web portal to upload reports, or deploy directly from SQL Server data tools (SSDT). When deploying from SSDT, ensure the following:

- The user who launched SSDT has access to the SSRS web portal.
- The `TargetServerURL` value in the SSRS project properties is set to the HTTPS endpoint of the RDS DB instance suffixed with `ReportServer`, for example:

```
https://myssrsinstance.cg034itsfake.us-east-1.rds.amazonaws.com:8443/ReportServer
```

Configuring the report data source

After you deploy a report to SSRS, you should configure the report data source. When configuring the report data source, ensure the following:

- For RDS for SQL Server DB instances joined to AWS Directory Service for Microsoft Active Directory, use the fully qualified domain name (FQDN) as the data source name of the connection string. An example is *`myssrsinstance.corp-ad.example.com`*, where *`myssrsinstance`* is the DB instance name and *`corp-ad.example.com`* is the fully qualified domain name.
- For RDS for SQL Server DB instances joined to self-managed Active Directory, use `.`, or *`LocalHost`* as the data source name of the connection string.

Using SSRS Email to send reports

SSRS includes the SSRS Email extension, which you can use to send reports to users.

To configure SSRS Email, use the SSRS option settings. For more information, see Adding the SSRS option to your option group.

After configuring SSRS Email, you can subscribe to reports on the report server. For more information, see Email delivery in Reporting Services in the Microsoft documentation.

Integration with AWS Secrets Manager is required for SSRS Email to function on RDS. To integrate with Secrets Manager, you create a secret.

> **Note**
>
> If you change the secret later, you also have to update the SSRS option in the option group.

To create a secret for SSRS Email

1. Follow the steps in Create a secret in the *AWS Secrets Manager User Guide*.

    a. For **Select secret type**, choose **Other type of secrets**.

b. For **Key/value pairs**, enter the following:

- **SMTP_USERNAME** – Enter a user with permission to send mail from the SMTP server.
- **SMTP_PASSWORD** – Enter a password for the SMTP user.

c. For **Encryption key**, don't use the default AWS KMS key. Use your own existing key, or create a new one.

The KMS key policy must allow the `kms:Decrypt` action, for example:

```
{
    "Sid": "Allow use of the key",
    "Effect": "Allow",
    "Principal": {
        "Service": [
            "rds.amazonaws.com"
        ]
    },
    "Action": [
        "kms:Decrypt"
    ],
    "Resource": "*"
}
```

2. Follow the steps in Attach a permissions policy to a secret in the *AWS Secrets Manager User Guide*. The permissions policy gives the `secretsmanager:GetSecretValue` action to the `rds.amazonaws.com` service principal.

We recommend that you use the `aws:sourceAccount` and `aws:sourceArn` conditions in the policy to avoid the *confused deputy* problem. Use your AWS account for `aws:sourceAccount` and the option group ARN for `aws:sourceArn`. For more information, see Preventing cross-service confused deputy problems.

The following example shows a permissions policy.

```
{
  "Version" : "2012-10-17",
  "Statement" : [ {
    "Effect" : "Allow",
    "Principal" : {
      "Service" : "rds.amazonaws.com"
    },
```

```
    "Action" : "secretsmanager:GetSecretValue",
    "Resource" : "*",
    "Condition" : {
      "StringEquals" : {
        "aws:sourceAccount" : "123456789012"
      },
      "ArnLike" : {
        "aws:sourceArn" : "arn:aws:rds:us-west-2:123456789012:og:ssrs-se-2017"
      }
    }
  } ]
}
```

For more examples, see Permissions policy examples for AWS Secrets Manager in the *AWS Secrets Manager User Guide*.

Revoking system-level permissions

The RDS_SSRS_ROLE system role doesn't have sufficient permissions to delete system-level role assignments. To remove a user or user group from RDS_SSRS_ROLE, use the same stored procedure that you used to grant the role but use the SSRS_REVOKE_PORTAL_PERMISSION task type.

To revoke access from a domain user for the web portal

- Use the following stored procedure.

```
exec msdb.dbo.rds_msbi_task
@task_type='SSRS_REVOKE_PORTAL_PERMISSION',
@ssrs_group_or_username=N'AD_domain\user';
```

Doing this deletes the user from the RDS_SSRS_ROLE system role. It also deletes the user from the `Content Manager` item-level role if the user has it.

Monitoring the status of a task

To track the status of your granting or revoking task, call the `rds_fn_task_status` function. It takes two parameters. The first parameter should always be NULL because it doesn't apply to SSRS. The second parameter accepts a task ID.

To see a list of all tasks, set the first parameter to NULL and the second parameter to 0, as shown in the following example.

```
SELECT * FROM msdb.dbo.rds_fn_task_status(NULL,0);
```

To get a specific task, set the first parameter to NULL and the second parameter to the task ID, as shown in the following example.

```
SELECT * FROM msdb.dbo.rds_fn_task_status(NULL,42);
```

The rds_fn_task_status function returns the following information.

Output parameter	Description
task_id	The ID of the task.
task_type	For SSRS, tasks can have the following task types: • SSRS_GRANT_PORTAL_PERMISSION • SSRS_REVOKE_PORTAL_PERMISSION
database_name	Not applicable to SSRS tasks.
% complete	The progress of the task as a percentage.
duration (mins)	The amount of time spent on the task, in minutes.
lifecycle	The status of the task. Possible statuses are the following: • CREATED – After you call one of the SSRS stored procedures, a task is created and the status is set to CREATED. • IN_PROGRESS – After a task starts, the status is set to IN_PROGRESS . It can take

Output parameter	Description
	up to five minutes for the status to change from CREATED to IN_PROGRESS . • SUCCESS – After a task completes, the status is set to SUCCESS. • ERROR – If a task fails, the status is set to ERROR. For more information about the error, see the task_info column. • CANCEL_REQUESTED – After you call the rds_cancel_task stored procedure, the status of the task is set to CANCEL_REQUESTED . • CANCELLED – After a task is successfully canceled, the status of the task is set to CANCELLED .
task_info	Additional information about the task. If an error occurs during processing, this column contains information about the error.
last_updated	The date and time that the task status was last updated.
created_at	The date and time that the task was created.
S3_object_arn	Not applicable to SSRS tasks.
overwrite_S3_backup_file	Not applicable to SSRS tasks.
KMS_master_key_arn	Not applicable to SSRS tasks.
filepath	Not applicable to SSRS tasks.
overwrite_file	Not applicable to SSRS tasks.

Output parameter	Description
`task_metadata`	Metadata associated with the SSRS task.

Turning off SSRS

To turn off SSRS, remove the SSRS option from its option group. Removing the option doesn't delete the SSRS databases. For more information, see Deleting the SSRS databases.

You can turn SSRS on again by adding back the SSRS option. If you have also deleted the SSRS databases, readding the option on the same DB instance creates new report server databases.

Console

To remove the SSRS option from its option group

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Option groups**.
3. Choose the option group with the SSRS option (`ssrs-se-2017` in the previous examples).
4. Choose **Delete option**.
5. Under **Deletion options**, choose **SSRS** for **Options to delete**.
6. Under **Apply immediately**, choose **Yes** to delete the option immediately, or **No** to delete it at the next maintenance window.
7. Choose **Delete**.

CLI

To remove the SSRS option from its option group

- Run one of the following commands.

  Example

  For Linux, macOS, or Unix:

```
aws rds remove-option-from-option-group \
    --option-group-name ssrs-se-2017 \
```

```
    --options SSRS \
    --apply-immediately
```

For Windows:

```
aws rds remove-option-from-option-group ^
    --option-group-name ssrs-se-2017 ^
    --options SSRS ^
    --apply-immediately
```

Deleting the SSRS databases

Removing the SSRS option doesn't delete the report server databases. To delete them, use the following stored procedure.

To delete the report server databases, be sure to remove the SSRS option first.

To delete the SSRS databases

- Use the following stored procedure.

```
exec msdb.dbo.rds_drop_ssrs_databases
```

Support for Microsoft Distributed Transaction Coordinator in RDS for SQL Server

A *distributed transaction* is a database transaction in which two or more network hosts are involved. RDS for SQL Server supports distributed transactions among hosts, where a single host can be one of the following:

- RDS for SQL Server DB instance
- On-premises SQL Server host
- Amazon EC2 host with SQL Server installed
- Any other EC2 host or RDS DB instance with a database engine that supports distributed transactions

In RDS, starting with SQL Server 2012 (version 11.00.5058.0.v1 and later), all editions of RDS for SQL Server support distributed transactions. The support is provided using Microsoft Distributed Transaction Coordinator (MSDTC). For in-depth information about MSDTC, see Distributed Transaction Coordinator in the Microsoft documentation.

Contents

Limitations

The following limitations apply to using MSDTC on RDS for SQL Server:

- MSDTC isn't supported on instances using SQL Server Database Mirroring. For more information, see Transactions - availability groups and database mirroring.
- The `in-doubt xact resolution` parameter must be set to 1 or 2. For more information, see Modifying the parameter for MSDTC.
- MSDTC requires all hosts participating in distributed transactions to be resolvable using their host names. RDS automatically maintains this functionality for domain-joined instances. However, for standalone instances make sure to configure the DNS server manually.
- Java Database Connectivity (JDBC) XA transactions are supported for SQL Server 2017 version 14.00.3223.3 and higher, and SQL Server 2019.
- Distributed transactions that depend on client dynamic link libraries (DLLs) on RDS instances aren't supported.
- Using custom XA dynamic link libraries isn't supported.

Enabling MSDTC

Use the following process to enable MSDTC for your DB instance:

1. Create a new option group, or choose an existing option group.
2. Add the `MSDTC` option to the option group.
3. Create a new parameter group, or choose an existing parameter group.
4. Modify the parameter group to set the `in-doubt xact resolution` parameter to 1 or 2.
5. Associate the option group and parameter group with the DB instance.

Creating the option group for MSDTC

Use the AWS Management Console or the AWS CLI to create an option group that corresponds to the SQL Server engine and version of your DB instance.

> **Note**
>
> You can also use an existing option group if it's for the correct SQL Server engine and version.

Console

The following procedure creates an option group for SQL Server Standard Edition 2016.

To create the option group

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Option groups**.
3. Choose **Create group**.
4. In the **Create option group** pane, do the following:
   a. For **Name**, enter a name for the option group that is unique within your AWS account, such as **`msdtc-se-2016`**. The name can contain only letters, digits, and hyphens.
   b. For **Description**, enter a brief description of the option group, such as **`MSDTC option group for SQL Server SE 2016`**. The description is used for display purposes.
   c. For **Engine**, choose **sqlserver-se**.
   d. For **Major engine version**, choose **13.00**.
5. Choose **Create**.

CLI

The following example creates an option group for SQL Server Standard Edition 2016.

To create the option group

- Use one of the following commands.

  Example

  For Linux, macOS, or Unix:

```
aws rds create-option-group \
    --option-group-name msdtc-se-2016 \
    --engine-name sqlserver-se \
    --major-engine-version 13.00 \
    --option-group-description "MSDTC option group for SQL Server SE 2016"
```

For Windows:

```
aws rds create-option-group ^
    --option-group-name msdtc-se-2016 ^
    --engine-name sqlserver-se ^
    --major-engine-version 13.00 ^
    --option-group-description "MSDTC option group for SQL Server SE 2016"
```

Adding the MSDTC option to the option group

Next, use the AWS Management Console or the AWS CLI to add the MSDTC option to the option group.

The following option settings are required:

- **Port** – The port that you use to access MSDTC. Allowed values are 1150–49151 except for 1234, 1434, 3260, 3343, 3389, and 47001. The default value is 5000.

  Make sure that the port you want to use is enabled in your firewall rules. Also, make sure as needed that this port is enabled in the inbound and outbound rules for the security group associated with your DB instance. For more information, see Can't connect to Amazon RDS DB instance.
- **Security groups** – The VPC security group memberships for your RDS DB instance.
- **Authentication type** – The authentication mode between hosts. The following authentication types are supported:
  - Mutual – The RDS instances are mutually authenticated to each other using integrated authentication. If this option is selected, all instances associated with this option group must be domain-joined.
  - None – No authentication is performed between hosts. We don't recommend using this mode in production environments.

- **Transaction log size** – The size of the MSDTC transaction log. Allowed values are 4–1024 MB. The default size is 4 MB.

The following option settings are optional:

- **Enable inbound connections** – Whether to allow inbound MSDTC connections to instances associated with this option group.
- **Enable outbound connections** – Whether to allow outbound MSDTC connections from instances associated with this option group.
- **Enable XA** – Whether to allow XA transactions. For more information on the XA protocol, see XA specification.
- **Enable SNA LU** – Whether to allow the SNA LU protocol to be used for distributed transactions. For more information on SNA LU protocol support, see Managing IBM CICS LU 6.2 transactions in the Microsoft documentation.

Console

To add the MSDTC option

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Option groups**.
3. Choose the option group that you just created.
4. Choose **Add option**.
5. Under **Option details**, choose **MSDTC** for **Option name**.
6. Under **Option settings**:
    a. For **Port**, enter the port number for accessing MSDTC. The default is **5000**.
    b. For **Security groups**, choose the VPC security group to associate with the option.
    c. For **Authentication type**, choose **Mutual** or **None**.
    d. For **Transaction log size**, enter a value from 4–1024. The default is **4**.
7. Under **Additional configuration**, do the following:
    a. For **Connections**, as needed choose **Enable inbound connections** and **Enable outbound connections**.

b. For **Allowed protocols**, as needed choose **Enable XA** and **Enable SNA LU**.

8. Under **Scheduling**, choose whether to add the option immediately or at the next maintenance window.
9. Choose **Add option**.

   To add this option, no reboot is required.

CLI

To add the MSDTC option

1. Create a JSON file, for example `msdtc-option.json`, with the following required parameters.

```
{
"OptionGroupName":"msdtc-se-2016",
"OptionsToInclude": [
 {
 "OptionName":"MSDTC",
 "Port":5000,
 "VpcSecurityGroupMemberships":["sg-0abcdef123"],
 "OptionSettings":[{"Name":"AUTHENTICATION","Value":"MUTUAL"},
{"Name":"TRANSACTION_LOG_SIZE","Value":"4"}]
 }],
"ApplyImmediately": true
}
```

2. Add the MSDTC option to the option group.

   Example

   For Linux, macOS, or Unix:

```
aws rds add-option-to-option-group \
    --cli-input-json file://msdtc-option.json \
    --apply-immediately
```

   For Windows:

```
aws rds add-option-to-option-group ^
```

```
    --cli-input-json file://msdtc-option.json ^
    --apply-immediately
```

No reboot is required.

Creating the parameter group for MSDTC

Create or modify a parameter group for the `in-doubt xact resolution` parameter that corresponds to the SQL Server edition and version of your DB instance.

Console

The following example creates a parameter group for SQL Server Standard Edition 2016.

To create the parameter group

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Parameter groups**.
3. Choose **Create parameter group**.
4. In the **Create parameter group** pane, do the following:
   a. For **Parameter group family**, choose **sqlserver-se-13.0**.
   b. For **Group name**, enter an identifier for the parameter group, such as **`msdtc-sqlserver-se-13`**.
   c. For **Description**, enter **`in-doubt xact resolution`**.
5. Choose **Create**.

CLI

The following example creates a parameter group for SQL Server Standard Edition 2016.

To create the parameter group

- Use one of the following commands.

  Example

  For Linux, macOS, or Unix:

```
aws rds create-db-parameter-group \
    --db-parameter-group-name msdtc-sqlserver-se-13 \
    --db-parameter-group-family "sqlserver-se-13.0" \
    --description "in-doubt xact resolution"
```

For Windows:

```
aws rds create-db-parameter-group ^
    --db-parameter-group-name msdtc-sqlserver-se-13 ^
    --db-parameter-group-family "sqlserver-se-13.0" ^
    --description "in-doubt xact resolution"
```

Modifying the parameter for MSDTC

Modify the `in-doubt xact resolution` parameter in the parameter group that corresponds to the SQL Server edition and version of your DB instance.

For MSDTC, set the `in-doubt xact resolution` parameter to one of the following:

- 1 – `Presume commit`. Any MSDTC in-doubt transactions are presumed to have committed.
- 2 – `Presume abort`. Any MSDTC in-doubt transactions are presumed to have stopped.

For more information, see in-doubt xact resolution server configuration option in the Microsoft documentation.

Console

The following example modifies the parameter group that you created for SQL Server Standard Edition 2016.

To modify the parameter group

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Parameter groups**.
3. Choose the parameter group, such as **msdtc-sqlserver-se-13**.
4. Under **Parameters**, filter the parameter list for **`xact`**.

5. Choose **in-doubt xact resolution**.
6. Choose **Edit parameters**.
7. Enter **1** or **2**.
8. Choose **Save changes**.

CLI

The following example modifies the parameter group that you created for SQL Server Standard Edition 2016.

To modify the parameter group

- Use one of the following commands.

  Example

  For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group \
    --db-parameter-group-name msdtc-sqlserver-se-13 \
    --parameters "ParameterName='in-doubt xact
 resolution',ParameterValue=1,ApplyMethod=immediate"
```

  For Windows:

```
aws rds modify-db-parameter-group ^
    --db-parameter-group-name msdtc-sqlserver-se-13 ^
    --parameters "ParameterName='in-doubt xact
 resolution',ParameterValue=1,ApplyMethod=immediate"
```

Associating the option group and parameter group with the DB instance

You can use the AWS Management Console or the AWS CLI to associate the MSDTC option group and parameter group with the DB instance.

Console

You can associate the MSDTC option group and parameter group with a new or existing DB instance.

- For a new DB instance, associate them when you launch the instance. For more information, see Creating an Amazon RDS DB instance.
- For an existing DB instance, associate them by modifying the instance. For more information, see Modifying an Amazon RDS DB instance.

> **Note**
>
> If you use an domain-joined existing DB instance, it must already have an Active Directory domain and AWS Identity and Access Management (IAM) role associated with it. If you create a new domain-joined instance, specify an existing Active Directory domain and IAM role. For more information, see Working with AWS Managed Active Directory with RDS for SQL Server.

CLI

You can associate the MSDTC option group and parameter group with a new or existing DB instance.

> **Note**
>
> If you use an existing domain-joined DB instance, it must already have an Active Directory domain and IAM role associated with it. If you create a new domain-joined instance, specify an existing Active Directory domain and IAM role. For more information, see Working with AWS Managed Active Directory with RDS for SQL Server.

To create a DB instance with the MSDTC option group and parameter group

- Specify the same DB engine type and major version as you used when creating the option group.

  Example

  For Linux, macOS, or Unix:

```
aws rds create-db-instance \
    --db-instance-identifier mydbinstance \
    --db-instance-class db.m5.2xlarge \
```

```
    --engine sqlserver-se \
    --engine-version 13.00.5426.0.v1 \
    --allocated-storage 100 \
    --manage-master-user-password \
    --master-username admin \
    --storage-type gp2 \
    --license-model li \
    --domain-iam-role-name my-directory-iam-role \
    --domain my-domain-id \
    --option-group-name msdtc-se-2016 \
    --db-parameter-group-name msdtc-sqlserver-se-13
```

For Windows:

```
aws rds create-db-instance ^
    --db-instance-identifier mydbinstance ^
    --db-instance-class db.m5.2xlarge ^
    --engine sqlserver-se ^
    --engine-version 13.00.5426.0.v1 ^
    --allocated-storage 100 ^
    --manage-master-user-password ^
    --master-username admin ^
    --storage-type gp2 ^
    --license-model li ^
    --domain-iam-role-name my-directory-iam-role ^
    --domain my-domain-id ^
    --option-group-name msdtc-se-2016 ^
    --db-parameter-group-name msdtc-sqlserver-se-13
```

To modify a DB instance and associate the MSDTC option group and parameter group

- Use one of the following commands.

  Example

  For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier mydbinstance \
    --option-group-name msdtc-se-2016 \
    --db-parameter-group-name msdtc-sqlserver-se-13 \
```

```
    --apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier mydbinstance ^
    --option-group-name msdtc-se-2016 ^
    --db-parameter-group-name msdtc-sqlserver-se-13 ^
    --apply-immediately
```

Using distributed transactions

In Amazon RDS for SQL Server, you run distributed transactions in the same way as distributed transactions running on-premises:

- Using .NET framework `System.Transactions` promotable transactions, which optimizes distributed transactions by deferring their creation until they're needed.

  In this case, promotion is automatic and doesn't require you to make any intervention. If there's only one resource manager within the transaction, no promotion is performed. For more information about implicit transaction scopes, see Implementing an implicit transaction using transaction scope in the Microsoft documentation.

  Promotable transactions are supported with these .NET implementations:

  - Starting with ADO.NET 2.0, `System.Data.SqlClient` supports promotable transactions with SQL Server. For more information, see System.Transactions integration with SQL Server in the Microsoft documentation.
  - ODP.NET supports `System.Transactions`. A local transaction is created for the first connection opened in the `TransactionsScope` scope to Oracle Database 11g release 1 (version 11.1) and later. When a second connection is opened, this transaction is automatically promoted to a distributed transaction. For more information about distributed transaction support in ODP.NET, see Microsoft Distributed Transaction Coordinator integration in the Microsoft documentation.
- Using the `BEGIN DISTRIBUTED TRANSACTION` statement. For more information, see BEGIN DISTRIBUTED TRANSACTION (Transact-SQL) in the Microsoft documentation.

Using XA transactions

Starting from RDS for SQL Server 2017 version14.00.3223.3, you can control distributed transactions using JDBC. When you set the `Enable XA` option setting to `true` in the `MSDTC` option, RDS automatically enables JDBC transactions and grants the `SqlJDBCXAUser` role to the `guest` user. This allows executing distributed transactions through JDBC. For more information, including a code example, see Understanding XA transactions in the Microsoft documentation.

Using transaction tracing

RDS supports controlling MSDTC transaction traces and downloading them from the RDS DB instance for troubleshooting. You can control transaction tracing sessions by running the following RDS stored procedure.

```
exec msdb.dbo.rds_msdtc_transaction_tracing 'trace_action',
[@traceall='0|1'],
[@traceaborted='0|1'],
[@tracelong='0|1'];
```

The following parameter is required:

- `trace_action` – The tracing action. It can be `START`, `STOP`, or `STATUS`.

The following parameters are optional:

- `@traceall` – Set to 1 to trace all distributed transactions. The default is 0.
- `@traceaborted` – Set to 1 to trace canceled distributed transactions. The default is 0.
- `@tracelong` – Set to 1 to trace long-running distributed transactions. The default is 0.

Example of START tracing action

To start a new transaction tracing session, run the following example statement.

```
exec msdb.dbo.rds_msdtc_transaction_tracing 'START',
@traceall='0',
@traceaborted='1',
@tracelong='1';
```

> **Note**
>
> Only one transaction tracing session can be active at one time. If a new tracing session START command is issued while a tracing session is active, an error is returned and the active tracing session remains unchanged.

Example of STOP tracing action

To stop a transaction tracing session, run the following statement.

```
exec msdb.dbo.rds_msdtc_transaction_tracing 'STOP'
```

This statement stops the active transaction tracing session and saves the transaction trace data into the log directory on the RDS DB instance. The first row of the output contains the overall result, and the following lines indicate details of the operation.

The following is an example of a successful tracing session stop.

```
OK: Trace session has been successfully stopped.
Setting log file to: D:\rdsdbdata\MSDTC\Trace\dtctrace.log
Examining D:\rdsdbdata\MSDTC\Trace\msdtctr.mof for message formats,  8 found.
Searching for TMF files on path: (null)
Logfile D:\rdsdbdata\MSDTC\Trace\dtctrace.log:
 OS version    10.0.14393  (Currently running on 6.2.9200)
 Start Time    <timestamp>
 End Time      <timestamp>
 Timezone is   @tzres.dll,-932 (Bias is 0mins)
 BufferSize            16384 B
 Maximum File Size     10 MB
 Buffers  Written      Not set (Logger may not have been stopped).
 Logger Mode Settings (11000002) ( circular paged
 ProcessorCount         1
Processing completed   Buffers: 1, Events: 3, EventsLost: 0 :: Format Errors: 0,
 Unknowns: 3
Event traces dumped to d:\rdsdbdata\Log\msdtc_<timestamp>.log
```

You can use the detailed information to query the name of the generated log file. For more information about downloading log files from the RDS DB instance, see Monitoring Amazon RDS log files.

The trace session logs remain on the instance for 35 days. Any older trace session logs are automatically deleted.

Example of STATUS tracing action

To trace the status of a transaction tracing session, run the following statement.

```
exec msdb.dbo.rds_msdtc_transaction_tracing 'STATUS'
```

This statement outputs the following as separate rows of the result set.

```
OK
SessionStatus: <Started|Stopped>
TraceAll: <True|False>
TraceAborted: <True|False>
TraceLongLived: <True|False>
```

The first line indicates the overall result of the operation: `OK` or `ERROR` with details, if applicable. The subsequent lines indicate details about the tracing session status:

- `SessionStatus` can be one of the following:
  - `Started` if a tracing session is running.
  - `Stopped` if no tracing session is running.
- The tracing session flags can be `True` or `False` depending on how they were set in the `START` command.

Modifying the MSDTC option

After you enable the `MSDTC` option, you can modify its settings. For information about how to modify option settings, see Modifying an option setting.

> **Note**
>
> Some changes to MSDTC option settings require the MSDTC service to be restarted. This requirement can affect running distributed transactions.

Disabling MSDTC

To disable MSDTC, remove the `MSDTC` option from its option group.

Console

To remove the MSDTC option from its option group

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Option groups**.
3. Choose the option group with the `MSDTC` option (`msdtc-se-2016` in the previous examples).
4. Choose **Delete option**.
5. Under **Deletion options**, choose **MSDTC** for **Options to delete**.
6. Under **Apply immediately**, choose **Yes** to delete the option immediately, or **No** to delete it at the next maintenance window.
7. Choose **Delete**.

CLI

To remove the MSDTC option from its option group

- Use one of the following commands.

  Example

  For Linux, macOS, or Unix:

```
aws rds remove-option-from-option-group \
    --option-group-name msdtc-se-2016 \
    --options MSDTC \
    --apply-immediately
```

  For Windows:

```
aws rds remove-option-from-option-group ^
    --option-group-name msdtc-se-2016 ^
    --options MSDTC ^
```

```
    --apply-immediately
```

Troubleshooting MSDTC for RDS for SQL Server

In some cases, you might have trouble establishing a connection between MSDTC running on a client computer and the MSDTC service running on an RDS for SQL Server DB instance. If so, make sure of the following:

- The inbound rules for the security group associated with the DB instance are configured correctly. For more information, see Can't connect to Amazon RDS DB instance.
- Your client computer is configured correctly.
- The MSDTC firewall rules on your client computer are enabled.

To configure the client computer

1. Open **Component Services**.

   Or, in **Server Manager**, choose **Tools**, and then choose **Component Services**.
2. Expand **Component Services**, expand **Computers**, expand **My Computer**, and then expand **Distributed Transaction Coordinator**.
3. Open the context (right-click) menu for **Local DTC** and choose **Properties**.
4. Choose the **Security** tab.
5. Choose all of the following:

   - **Network DTC Access**
   - **Allow Inbound**
   - **Allow Outbound**
6. Make sure that the correct authentication mode is chosen:

   - **Mutual Authentication Required** – The client machine is joined to the same domain as other nodes participating in distributed transaction, or there is a trust relationship configured between domains.
   - **No Authentication Required** – All other cases.
7. Choose **OK** to save your changes.
8. If prompted to restart the service, choose **Yes**.

To enable MSDTC firewall rules

1. Open Windows Firewall, then choose **Advanced settings**.

   Or, in **Server Manager**, choose **Tools**, and then choose **Windows Firewall with Advanced Security**.

   > **Note**
   >
   > Depending on your operating system, Windows Firewall might be called Windows Defender Firewall.

2. Choose **Inbound Rules** in the left pane.
3. Enable the following firewall rules, if they are not already enabled:

   - **Distributed Transaction Coordinator (RPC)**
   - **Distributed Transaction Coordinator (RPC)-EPMAP**
   - **Distributed Transaction Coordinator (TCP-In)**
4. Close Windows Firewall.

Common DBA tasks for Microsoft SQL Server

This section describes the Amazon RDS-specific implementations of some common DBA tasks for DB instances that are running the Microsoft SQL Server database engine. In order to deliver a managed service experience, Amazon RDS does not provide shell access to DB instances, and it restricts access to certain system procedures and tables that require advanced privileges.

> **Note**
>
> When working with a SQL Server DB instance, you can run scripts to modify a newly created database, but you cannot modify the [model] database, the database used as the model for new databases.

Topics

- Working with trace and dump files

Accessing the tempdb database on Microsoft SQL Server DB instances on Amazon RDS

You can access the tempdb database on your Microsoft SQL Server DB instances on Amazon RDS. You can run code on tempdb by using Transact-SQL through Microsoft SQL Server Management Studio (SSMS), or any other standard SQL client application. For more information about connecting to your DB instance, see Connecting to a DB instance running the Microsoft SQL Server database engine.

The master user for your DB instance is granted CONTROL access to tempdb so that this user can modify the tempdb database options. The master user isn't the database owner of the tempdb database. If necessary, the master user can grant CONTROL access to other users so that they can also modify the tempdb database options.

> **Note**
>
> You can't run Database Console Commands (DBCC) on the tempdb database.

Modifying tempdb database options

You can modify the database options on the tempdb database on your Amazon RDS DB instances. For more information about which options can be modified, see tempdb database in the Microsoft documentation.

Database options such as the maximum file size options are persistent after you restart your DB instance. You can modify the database options to optimize performance when importing data, and to prevent running out of storage.

Optimizing performance when importing data

To optimize performance when importing large amounts of data into your DB instance, set the SIZE and FILEGROWTH properties of the tempdb database to large numbers. For more information about how to optimize tempdb, see Optimizing tempdb performance in the Microsoft documentation.

The following example demonstrates setting the size to 100 GB and file growth to 10 percent.

```
alter database[tempdb] modify file (NAME = N'templog', SIZE=100GB, FILEGROWTH = 10%)
```

Preventing storage problems

To prevent the tempdb database from using all available disk space, set the MAXSIZE property. The following example demonstrates setting the property to 2048 MB.

```
alter database [tempdb] modify file (NAME = N'templog', MAXSIZE = 2048MB)
```

Shrinking the tempdb database

There are two ways to shrink the tempdb database on your Amazon RDS DB instance. You can use the rds_shrink_tempdbfile procedure, or you can set the SIZE property,

Using the rds_shrink_tempdbfile procedure

You can use the Amazon RDS procedure msdb.dbo.rds_shrink_tempdbfile to shrink the tempdb database. You can only call rds_shrink_tempdbfile if you have CONTROL access to tempdb. When you call rds_shrink_tempdbfile, there is no downtime for your DB instance.

The rds_shrink_tempdbfile procedure has the following parameters.

Parameter name	Data type	Default	Required	Description
@temp_filename	SYSNAME	—	required	The logical name of the file to shrink.
@target_size	int	null	optional	The new size for the file, in megabytes.

The following example gets the names of the files for the tempdb database.

```
use tempdb;
GO

select name, * from sys.sysfiles;
GO
```

The following example shrinks a tempdb database file named test_file, and requests a new size of 10 megabytes:

```
exec msdb.dbo.rds_shrink_tempdbfile @temp_filename = N'test_file', @target_size = 10;
```

Setting the SIZE property

You can also shrink the tempdb database by setting the SIZE property and then restarting your DB instance. For more information about restarting your DB instance, see Rebooting a DB instance.

The following example demonstrates setting the SIZE property to 1024 MB.

```
alter database [tempdb] modify file (NAME = N'templog', SIZE = 1024MB)
```

TempDB configuration for Multi-AZ deployments

If your RDS for SQL Server DB instance is in a Multi-AZ Deployment using Database Mirroring (DBM) or Always On Availability Groups (AGs), keep in mind the following considerations for using the tempdb database.

You can't replicate tempdb data from your primary DB instance to your secondary DB instance. When you fail over to a secondary DB instance, tempdb on that secondary DB instance will be empty.

You can synchronize the configuration of the tempdb database options, including its file sizing and autogrowth settings, from your primary DB instance to your secondary DB instance. Synchronizing the tempDB configuration is supported on all RDS for SQL Server versions. You can turn on automatic synchronization of the tempdb configuration by using the following stored procedure:

```
EXECUTE msdb.dbo.rds_set_system_database_sync_objects @object_types = 'TempDbFile';
```

> **Important**
>
> Before using the rds_set_system_database_sync_objects stored procedure, ensure you've set your preferred tempdb configuration on your primary DB instance, rather than on your secondary DB instance. If you made the configuration change on your secondary DB instance, your preferred tempdb configuration could be deleted when you turn on automatic synchronization.

You can use the following function to confirm whether automatic synchronization of the tempdb configuration is turned on:

```
SELECT * from msdb.dbo.rds_fn_get_system_database_sync_objects();
```

When automatic synchronization of the tempdb configuration is turned on, there will be a return value for the object_class field. When it's turned off, no value is returned.

You can use the following function to find the last time objects were synchronized, in UTC time:

```
SELECT * from msdb.dbo.rds_fn_server_object_last_sync_time();
```

For example, if you modified the tempdb configuration at 01:00 and then run the rds_fn_server_object_last_sync_time function, the value returned for last_sync_time should be after 01:00, indicating that an automatic synchronization occurred.

If you are also using SQL Server Agent job replication, you can enable replication for both SQL Agent jobs and the tempdb configuration by providing them in the @object_type parameter:

```
EXECUTE msdb.dbo.rds_set_system_database_sync_objects @object_types =
 'SQLAgentJob,TempDbFile';
```

For more information on SQL Server Agent job replication, see Turning on SQL Server Agent job replication.

As an alternative to using the rds_set_system_database_sync_objects stored procedure to ensure that tempdb configuration changes are automatically synchronized, you can use one of the following manual methods:

> **Note**
>
> We recommend turning on automatic synchronization of the tempdb configuration by using the rds_set_system_database_sync_objects stored procedure. Using automatic synchronization prevents the need to perform these manual tasks each time you change your tempdb configuration.

- First modify your DB instance and turn Multi-AZ off, then modify tempdb, and finally turn Multi-AZ back on. This method doesn't involve any downtime.

  For more information, see Modifying an Amazon RDS DB instance.

- First modify `tempdb` in the original primary instance, then fail over manually, and finally modify `tempdb` in the new primary instance. This method involves downtime.

  For more information, see Rebooting a DB instance.

Analyzing your database workload on an Amazon RDS for SQL Server DB instance with Database Engine Tuning Advisor

Database Engine Tuning Advisor is a client application provided by Microsoft that analyzes database workload and recommends an optimal set of indexes for your Microsoft SQL Server databases based on the kinds of queries you run. Like SQL Server Management Studio, you run Tuning Advisor from a client computer that connects to your Amazon RDS DB instance that is running SQL Server. The client computer can be a local computer that you run on premises within your own network or it can be an Amazon EC2 Windows instance that is running in the same region as your Amazon RDS DB instance.

This section shows how to capture a workload for Tuning Advisor to analyze. This is the preferred process for capturing a workload because Amazon RDS restricts host access to the SQL Server instance. For more information, see Database Engine Tuning Advisor in the Microsoft documentation.

To use Tuning Advisor, you must provide what is called a workload to the advisor. A workload is a set of Transact-SQL statements that run against a database or databases that you want to tune. Database Engine Tuning Advisor uses trace files, trace tables, Transact-SQL scripts, or XML files as workload input when tuning databases. When working with Amazon RDS, a workload can be a file on a client computer or a database table on an Amazon RDS for SQL Server DB accessible to your client computer. The file or the table must contain queries against the databases you want to tune in a format suitable for replay.

For Tuning Advisor to be most effective, a workload should be as realistic as possible. You can generate a workload file or table by performing a trace against your DB instance. While a trace is running, you can either simulate a load on your DB instance or run your applications with a normal load.

There are two types of traces: client-side and server-side. A client-side trace is easier to set up and you can watch trace events being captured in real-time in SQL Server Profiler. A server-side trace is more complex to set up and requires some Transact-SQL scripting. In addition, because the trace is written to a file on the Amazon RDS DB instance, storage space is consumed by the trace. It is

important to track of how much storage space a running server-side trace uses because the DB instance could enter a storage-full state and would no longer be available if it runs out of storage space.

For a client-side trace, when a sufficient amount of trace data has been captured in the SQL Server Profiler, you can then generate the workload file by saving the trace to either a file on your local computer or in a database table on a DB instance that is available to your client computer. The main disadvantage of using a client-side trace is that the trace may not capture all queries when under heavy loads. This could weaken the effectiveness of the analysis performed by the Database Engine Tuning Advisor. If you need to run a trace under heavy loads and you want to ensure that it captures every query during a trace session, you should use a server-side trace.

For a server-side trace, you must get the trace files on the DB instance into a suitable workload file or you can save the trace to a table on the DB instance after the trace completes. You can use the SQL Server Profiler to save the trace to a file on your local computer or have the Tuning Advisor read from the trace table on the DB instance.

Running a client-side trace on a SQL Server DB instance

To run a client-side trace on a SQL Server DB instance

1. Start SQL Server Profiler. It is installed in the Performance Tools folder of your SQL Server instance folder. You must load or define a trace definition template to start a client-side trace.
2. In the SQL Server Profiler File menu, choose **New Trace**. In the **Connect to Server** dialog box, enter the DB instance endpoint, port, master user name, and password of the database you would like to run a trace on.
3. In the **Trace Properties** dialog box, enter a trace name and choose a trace definition template. A default template, TSQL_Replay, ships with the application. You can edit this template to define your trace. Edit events and event information under the **Events Selection** tab of the **Trace Properties** dialog box.

   For more information about trace definition templates and using the SQL Server Profiler to specify a client-side trace, see Database Engine Tuning Advisor in the Microsoft documentation.
4. Start the client-side trace and watch SQL queries in real-time as they run against your DB instance.
5. Select **Stop Trace** from the **File** menu when you have completed the trace. Save the results as a file or as a trace table on you DB instance.

Running a server-side trace on a SQL Server DB instance

Writing scripts to create a server-side trace can be complex and is beyond the scope of this document. This section contains sample scripts that you can use as examples. As with a client-side trace, the goal is to create a workload file or trace table that you can open using the Database Engine Tuning Advisor.

The following is an abridged example script that starts a server-side trace and captures details to a workload file. The trace initially saves to the file RDSTrace.trc in the D:\RDSDBDATA\Log directory and rolls-over every 100 MB so subsequent trace files are named RDSTrace_1.trc, RDSTrace_2.trc, etc.

```
DECLARE @file_name NVARCHAR(245) = 'D:\RDSDBDATA\Log\RDSTrace';
DECLARE @max_file_size BIGINT = 100;
DECLARE @on BIT = 1
DECLARE @rc INT
DECLARE @traceid INT

EXEC @rc = sp_trace_create @traceid OUTPUT, 2, @file_name, @max_file_size
IF (@rc = 0) BEGIN
   EXEC sp_trace_setevent @traceid, 10, 1, @on
   EXEC sp_trace_setevent @traceid, 10, 2, @on
   EXEC sp_trace_setevent @traceid, 10, 3, @on
 . . .
   EXEC sp_trace_setfilter @traceid, 10, 0, 7, N'SQL Profiler'
   EXEC sp_trace_setstatus @traceid, 1
   END
```

The following example is a script that stops a trace. Note that a trace created by the previous script continues to run until you explicitly stop the trace or the process runs out of disk space.

```
DECLARE @traceid INT
SELECT @traceid = traceid FROM ::fn_trace_getinfo(default)
WHERE property = 5 AND value = 1 AND traceid <> 1

IF @traceid IS NOT NULL BEGIN
   EXEC sp_trace_setstatus @traceid, 0
   EXEC sp_trace_setstatus @traceid, 2
END
```

You can save server-side trace results to a database table and use the database table as the workload for the Tuning Advisor by using the fn_trace_gettable function. The following commands load the results of all files named RDSTrace.trc in the D:\rdsdbdata\Log directory, including all rollover files like RDSTrace_1.trc, into a table named RDSTrace in the current database.

```
SELECT * INTO RDSTrace
FROM fn_trace_gettable('D:\rdsdbdata\Log\RDSTrace.trc', default);
```

To save a specific rollover file to a table, for example the RDSTrace_1.trc file, specify the name of the rollover file and substitute 1 instead of default as the last parameter to fn_trace_gettable.

```
SELECT * INTO RDSTrace_1
FROM fn_trace_gettable('D:\rdsdbdata\Log\RDSTrace_1.trc', 1);
```

Running Tuning Advisor with a trace

Once you create a trace, either as a local file or as a database table, you can then run Tuning Advisor against your DB instance. Using Tuning Advisor with Amazon RDS is the same process as when working with a standalone, remote SQL Server instance. You can either use the Tuning Advisor UI on your client machine or use the dta.exe utility from the command line. In both cases, you must connect to the Amazon RDS DB instance using the endpoint for the DB instance and provide your master user name and master user password when using Tuning Advisor.

The following code example demonstrates using the dta.exe command line utility against an Amazon RDS DB instance with an endpoint of **`dta.cnazcmklsdei.us-east-1.rds.amazonaws.com`**. The example includes the master user name **`admin`** and the master user password **`test`**, the example database to tune is named machine named **`C:\RDSTrace.trc`**. The example command line code also specifies a trace session named **`RDSTrace1`** and specifies output files to the local machine named **`RDSTrace.sql`** for the SQL output script, **`RDSTrace.txt`** for a result file, and **`RDSTrace.xml`** for an XML file of the analysis. There is also an error table specified on the RDSDTA database named **`RDSTraceErrors`**.

```
dta -S dta.cnazcmklsdei.us-east-1.rds.amazonaws.com -U admin -P test -D RDSDTA -
if C:\RDSTrace.trc -s RDSTrace1 -of C:\ RDSTrace.sql -or C:\ RDSTrace.txt -ox C:\
 RDSTrace.xml -e RDSDTA.dbo.RDSTraceErrors
```

Here is the same example command line code except the input workload is a table on the remote Amazon RDS instance named **`RDSTrace`** which is on the **`RDSDTA`** database.

```
dta -S dta.cnazcmklsdei.us-east-1.rds.amazonaws.com -U admin -P test -D RDSDTA -it
 RDSDTA.dbo.RDSTrace -s RDSTrace1 -of C:\ RDSTrace.sql -or C:\ RDSTrace.txt -ox C:\
 RDSTrace.xml -e RDSDTA.dbo.RDSTraceErrors
```

For a full list of dta utility command-line parameters, see dta Utility in the Microsoft documentation.

Changing the db_owner to the rdsa account for your database

When you create or restore a database in an RDS for SQL Server DB instance, Amazon RDS sets the owner of the database to `rdsa`. If you have a Multi-AZ deployment using SQL Server Database Mirroring (DBM) or Always On Availability Groups (AGs), Amazon RDS sets the owner of the database on the secondary DB instance to `NT AUTHORITY\SYSTEM`. The owner of the secondary database can't be changed until the secondary DB instance is promoted to the primary role. In most cases, setting the owner of the database to `NT AUTHORITY\SYSTEM` isn't problematic when executing queries, however, can throw errors when executing system stored procedures such as `sys.sp_updatestats` that require elevated permissions to execute.

You can use the following query to identify the owner of the databases owned by `NT AUTHORITY\SYSTEM`:

```
SELECT name FROM sys.databases WHERE SUSER_SNAME(owner_sid) = 'NT AUTHORITY\SYSTEM';
```

You can use the Amazon RDS stored procedure `rds_changedbowner_to_rdsa` to change the owner of the database to `rdsa`. The following databases are not allowed to be used with `rds_changedbowner_to_rdsa`: `master, model, msdb, rdsadmin, rdsadmin_ReportServer, rdsadmin_ReportServerTempDB, SSISDB`.

To change the owner of the database to `rdsa`, call the `rds_changedbowner_to_rdsa` stored procedure and provide the name of the database.

Example usage:

```
exec msdb.dbo.rds_changedbowner_to_rdsa 'TestDB1';
```

The following parameter is required:

- @db_name – The name of the database to change the owner of the database to `rdsa`.

Important

You can't use `rds_changedbowner_to_rdsa` to change ownership of a database to a login other than `rdsa`. For example, you can't change the ownership to the login with which you created the database. To restore lost membership in the `db_owner` role for your master user when no other database user can be used to grant the membership, reset the master user password to obtain membership in the `db_owner` role. For more information, see Resetting the db_owner role membership for master user.

Collations and character sets for Microsoft SQL Server

SQL Server supports collations at multiple levels. You set the default server collation when you create the DB instance. You can override the collation in the database, table, or column level.

Topics

- Server-level collation for Microsoft SQL Server
- Database-level collation for Microsoft SQL Server

Server-level collation for Microsoft SQL Server

When you create a Microsoft SQL Server DB instance, you can set the server collation that you want to use. If you don't choose a different collation, the server-level collation defaults to SQL_Latin1_General_CP1_CI_AS. The server collation is applied by default to all databases and database objects.

Note

You can't change the collation when you restore from a DB snapshot.

Currently, Amazon RDS supports the following server collations:

Collation	Description
Arabic_CI_AS	Arabic, case-insensitive, accent-sensitive, kanatype-insensitive, width-insensitive

Collation	Description
Chinese_PRC_BIN2	Chinese-PRC, binary code point sort order
Chinese_PRC_CI_AS	Chinese-PRC, case-insensitive, accent-se nsitive, kanatype-insensitive, width-insensitive
Chinese_Taiwan_Stroke_CI_AS	Chinese-Taiwan-Stroke, case-insensitive, accent-sensitive, kanatype-insensitive, width-insensitive
Danish_Norwegian_CI_AS	Danish-Norwegian, case-insensitive, accent-se nsitive, kanatype-insensitive, width-insensitive
Finnish_Swedish_CI_AS	Finnish, Swedish, and Swedish (Finland), case-insensitive, accent-sensitive, kanatype-insensitive, width-insensitive
French_CI_AS	French, case-insensitive, accent-sensitive, kanatype-insensitive, width-insensitive
Hebrew_BIN	Hebrew, binary sort
Hebrew_CI_AS	Hebrew, case-insensitive, accent-sensitive, kanatype-insensitive, width-insensitive
Japanese_BIN	Japanese, binary sort
Japanese_CI_AS	Japanese, case-insensitive, accent-sensitive, kanatype-insensitive, width-insensitive
Japanese_CS_AS	Japanese, case-sensitive, accent-sensitive, kanatype-insensitive, width-insensitive
Japanese_XJIS_140_CI_AS	Japanese, case-insensitive, accent-sensitive, kanatype-insensitive, width-insensitive, supplementary characters, variation selector insensitive

Collation	Description
Japanese_XJIS_140_CI_AS_KS_VSS	Japanese, case-insensitive, accent-sensitive, kanatype-sensitive, width-insensitive, supplementary characters, variation selector sensitive
Japanese_XJIS_140_CI_AS_VSS	Japanese, case-insensitive, accent-sensitive, kanatype-insensitive, width-insensitive, supplementary characters, variation selector sensitive
Japanese_XJIS_140_CS_AS_KS_WS	Japanese, case-sensitive, accent-sensitive, kanatype-sensitive, width-sensitive, supplementary characters, variation selector insensitive
Korean_Wansung_CI_AS	Korean-Wansung, case-insensitive, accent-se nsitive, kanatype-insensitive, width-insensitive
Latin1_General_100_BIN	Latin1-General-100, binary sort
Latin1_General_100_BIN2	Latin1-General-100, binary code point sort order
Latin1_General_100_BIN2_UTF8	Latin1-General-100, binary code point sort order, UTF-8 encoded
Latin1_General_100_CI_AS	Latin1-General-100, case-insensitive, accent-sensitive, kanatype-insensitive, width-ins ensitive
Latin1_General_100_CI_AS_SC_UTF8	Latin1-General-100, case-insensitive, accent-sensitive, supplementary characters, UTF-8 encoded
Latin1_General_BIN	Latin1-General, binary sort
Latin1_General_BIN2	Latin1-General, binary code point sort order

Collation	Description
Latin1_General_CI_AI	Latin1-General, case-insensitive, accent-in sensitive, kanatype-insensitive, width-ins ensitive
Latin1_General_CI_AS	Latin1-General, case-insensitive, accent-se nsitive, kanatype-insensitive, width-insensitive
Latin1_General_CI_AS_KS	Latin1-General, case-insensitive, accent-se nsitive, kanatype-sensitive, width-insensitive
Latin1_General_CS_AS	Latin1-General, case-sensitive, accent-se nsitive, kanatype-insensitive, width-insensitive
Modern_Spanish_CI_AS	Modern-Spanish, case-insensitive, accent-se nsitive, kanatype-insensitive, width-insensitive
Polish_CI_AS	Polish, case-insensitive, accent-sensitive, kanatype-insensitive, width-insensitive
SQL_1xCompat_CP850_CI_AS	Latin1-General, case-insensitive, accent-se nsitive, kanatype-insensitive, width-insensitive for Unicode Data, SQL Server Sort Order 49 on Code Page 850 for non-Unicode Data
SQL_Latin1_General_CP1_CI_AI	Latin1-General, case-insensitive, accent-in sensitive, kanatype-insensitive, width-ins ensitive for Unicode Data, SQL Server Sort Order 54 on Code Page 1252 for non-Unicode Data
SQL_Latin1_General_CP1_CI_AS (default)	Latin1-General, case-insensitive, accent-se nsitive, kanatype-insensitive, width-insensitive for Unicode Data, SQL Server Sort Order 52 on Code Page 1252 for non-Unicode Data

Collation	Description
SQL_Latin1_General_CP1_CS_AS	Latin1-General, case-sensitive, accent-sensitive, kanatype-insensitive, width-insensitive for Unicode Data, SQL Server Sort Order 51 on Code Page 1252 for non-Unicode Data
SQL_Latin1_General_CP437_CI_AI	Latin1-General, case-insensitive, accent-insensitive, kanatype-insensitive, width-insensitive for Unicode Data, SQL Server Sort Order 34 on Code Page 437 for non-Unicode Data
