SQL_Latin1_General_CP850_BIN	Latin1-General, binary sort order for Unicode Data, SQL Server Sort Order 40 on Code Page 850 for non-Unicode Data
SQL_Latin1_General_CP850_BIN2	Latin1-General, binary code point sort order for Unicode Data, SQL Server Sort Order 40 on Code Page 850 for non-Unicode Data
SQL_Latin1_General_CP850_CI_AI	Latin1-General, case-insensitive, accent-insensitive, kanatype-insensitive, width-insensitive for Unicode Data, SQL Server Sort Order 44 on Code Page 850 for non-Unicode Data
SQL_Latin1_General_CP850_CI_AS	Latin1-General, case-insensitive, accent-sensitive, kanatype-insensitive, width-insensitive for Unicode Data, SQL Server Sort Order 42 on Code Page 850 for non-Unicode Data
SQL_Latin1_General_CP1256_CI_AS	Latin1-General, case-insensitive, accent-sensitive, kanatype-insensitive, width-insensitive for Unicode Data, SQL Server Sort Order 146 on Code Page 1256 for non-Unicode Data

Collation	Description
Thai_CI_AS	Thai, case-insensitive, accent-sensitive, kanatype-insensitive, width-insensitive
Turkish_CI_AS	Turkish, case-insensitive, accent-sensitive, kanatype-insensitive, width-insensitive

To choose the collation:

- If you're using the Amazon RDS console, when creating a new DB instance choose **Additional configuration**, then enter the collation in the **Collation** field. For more information, see Creating an Amazon RDS DB instance.
- If you're using the AWS CLI, use the `--character-set-name` option with the `create-db-instance` command. For more information, see create-db-instance.
- If you're using the Amazon RDS API, use the `CharacterSetName` parameter with the `CreateDBInstance` operation. For more information, see CreateDBInstance.

Database-level collation for Microsoft SQL Server

You can change the default collation at the database, table, or column level by overriding the collation when creating a new database or database object. For example, if your default server collation is SQL_Latin1_General_CP1_CI_AS, you can change it to Mohawk_100_CI_AS for Mohawk collation support. Even arguments in a query can be type-cast to use a different collation if necessary.

For example, the following query would change the default collation for the AccountName column to Mohawk_100_CI_AS

```
CREATE TABLE [dbo].[Account]
 (
     [AccountID] [nvarchar](10) NOT NULL,
     [AccountName] [nvarchar](100) COLLATE Mohawk_100_CI_AS NOT NULL
 ) ON [PRIMARY];
```

The Microsoft SQL Server DB engine supports Unicode by the built-in NCHAR, NVARCHAR, and NTEXT data types. For example, if you need CJK support, use these Unicode data types for

character storage and override the default server collation when creating your databases and tables. Here are several links from Microsoft covering collation and Unicode support for SQL Server:

- Working with collations
- Collation and international terminology
- Using SQL Server collations
- International considerations for databases and database engine applications

Creating a database user

You can create a database user for your Amazon RDS for Microsoft SQL Server DB instance by running a T-SQL script like the following example. Use an application such as SQL Server Management Suite (SSMS). You log into the DB instance as the master user that was created when you created the DB instance.

```
--Initially set context to master database
USE [master];
GO
--Create a server-level login named theirname with password theirpassword
CREATE LOGIN [theirname] WITH PASSWORD = 'theirpassword';
GO
--Set context to msdb database
USE [msdb];
GO
--Create a database user named theirname and link it to server-level login theirname
CREATE USER [theirname] FOR LOGIN [theirname];
GO
```

For an example of adding a database user to a role, see Adding a user to the SQLAgentUser role.

> **Note**
>
> If you get permission errors when adding a user, you can restore privileges by modifying the DB instance master user password. For more information, see Resetting the db_owner role membership for master user.

Determining a recovery model for your Microsoft SQL Server database

In Amazon RDS, the recovery model, retention period, and database status are linked.

It's important to understand the consequences before making a change to one of these settings. Each setting can affect the others. For example:

- If you change a database's recovery model to SIMPLE or BULK_LOGGED while backup retention is enabled, Amazon RDS resets the recovery model to FULL within five minutes. This also results in RDS taking a snapshot of the DB instance.
- If you set backup retention to `0` days, RDS sets the recovery mode to SIMPLE.
- If you change a database's recovery model from SIMPLE to any other option while backup retention is set to `0` days, RDS resets the recovery model to SIMPLE.

> **Important**
>
> Never change the recovery model on Multi-AZ instances, even if it seems you can do so—for example, by using ALTER DATABASE. Backup retention, and therefore FULL recovery mode, is required for Multi-AZ. If you alter the recovery model, RDS immediately changes it back to FULL.
>
> This automatic reset forces RDS to completely rebuild the mirror. During this rebuild, the availability of the database is degraded for about 30-90 minutes until the mirror is ready for failover. The DB instance also experiences performance degradation in the same way it does during a conversion from Single-AZ to Multi-AZ. How long performance is degraded depends on the database storage size—the bigger the stored database, the longer the degradation.

For more information on SQL Server recovery models, see Recovery models (SQL Server) in the Microsoft documentation.

Determining the last failover time

To determine the last failover time, use the following stored procedure:

```
execute msdb.dbo.rds_failover_time;
```

This procedure returns the following information.

Output parameter	Description
errorlog_available_from	Shows the time from when error logs are available in the log directory.
recent_failover_time	Shows the last failover time if it's available from the error logs. Otherwise it shows `null`.

> **Note**
>
> The stored procedure searches all of the available SQL Server error logs in the log directory to retrieve the most recent failover time. If the failover messages have been overwritten by SQL Server, then the procedure doesn't retrieve the failover time.

Example of no recent failover

This example shows the output when there is no recent failover in the error logs. No failover has happened since 2020-04-29 23:59:00.01.

errorlog_available_from	recent_failover_time
2020-04-29 23:59:00.0100000	null

Example of recent failover

This example shows the output when there is a failover in the error logs. The most recent failover was at 2020-05-05 18:57:51.89.

errorlog_available_from	recent_failover_time
2020-04-29 23:59:00.0100000	2020-05-05 18:57:51.8900000

Deny or allow viewing database names

The master user cannot set `DENY VIEW ANY DATABASE TO` *`LOGIN`*
to hide databases from a user.
To change this permission, use the following stored procedure instead:

- Denying database view access to *`LOGIN`*:

```
EXEC msdb.dbo.rds_manage_view_db_permission @permission='DENY',
 @server_principal='LOGIN'

go
```

- Allowing database view access to *`LOGIN`*:

```
EXEC msdb.dbo.rds_manage_view_db_permission @permission='GRANT',
 @server_principal='LOGIN'

go
```

Consider the following when using this stored procedure:

- Database names are hidden from the SSMS and internal DMV (dynamic management views). However, database names are still visible from audit, logs and metadata tables. These are secured `VIEW ANY DATABASE` server permissions. For more information, see DENY Server Permissions.
- Once the permission is reverted to `GRANT` (allowed), the *`LOGIN`* can view all databases.
- If you delete and recreate *`LOGIN`*, the view permission related to the LOGIN is reset to `ALLOW`.
- For Multi-AZ instances, set the `DENY` or `GRANT` permission only for the *`LOGIN`* on the primary host. The changes are propagated to the secondary host automatically.
- This permission only changes whether a login can view the database names. However, access to databases and objects within are managed separately.

Disabling fast inserts during bulk loading

Starting with SQL Server 2016, fast inserts are enabled by default. Fast inserts leverage the minimal logging that occurs while the database is in the simple or bulk logged recovery model

to optimize insert performance. With fast inserts, each bulk load batch acquires new extents, bypassing the allocation lookup for existing extents with available free space to optimize insert performance.

However, with fast inserts bulk loads with small batch sizes can lead to increased unused space consumed by objects. If increasing batch size isn't feasible, enabling trace flag 692 can help reduce unused reserved space, but at the expense of performance. Enabling this trace flag disables fast inserts while bulk loading data into heap or clustered indexes.

You enable trace flag 692 as a startup parameter using DB parameter groups. For more information, see Parameter groups for Amazon RDS.

Trace flag 692 is supported for Amazon RDS on SQL Server 2016 and later. For more information on trace flags, see DBCC TRACEON - trace flags in the Microsoft documentation.

Dropping a Microsoft SQL Server database

You can drop a database on an Amazon RDS DB instance running Microsoft SQL Server in a Single-AZ or Multi-AZ deployment. To drop the database, use the following command:

```
--replace your-database-name with the name of the database you want to drop
EXECUTE msdb.dbo.rds_drop_database  N'your-database-name'
```

> **Note**
>
> Use straight single quotes in the command. Smart quotes will cause an error.

After you use this procedure to drop the database, Amazon RDS drops all existing connections to the database and removes the database's backup history.

Renaming a Microsoft SQL Server database in a Multi-AZ deployment

To rename a Microsoft SQL Server database instance that uses Multi-AZ, use the following procedure:

1. First, turn off Multi-AZ for the DB instance.
2. Rename the database by running `rdsadmin.dbo.rds_modify_db_name`.
3. Then, turn on Multi-AZ Mirroring or Always On Availability Groups for the DB instance, to return it to its original state.

For more information, see Adding Multi-AZ to a Microsoft SQL Server DB instance.

> **Note**
>
> If your instance doesn't use Multi-AZ, you don't need to change any settings before or after running `rdsadmin.dbo.rds_modify_db_name`.

Example: In the following example, the `rdsadmin.dbo.rds_modify_db_name` stored procedure renames a database from **`MOO`** to **`ZAR`**. This is similar to running the statement `DDL ALTER DATABASE [MOO] MODIFY NAME = [ZAR]`.

```
EXEC rdsadmin.dbo.rds_modify_db_name N'MOO', N'ZAR'
GO
```

Resetting the db_owner role membership for master user

If you lock your master user out of the `db_owner` role membership on your RDS for SQL Server database and no other database user can grant the membership, you can restore lost membership by modifying the DB instance master user password.

By changing the DB instance master user password, RDS grants the `db_owner` membership to the databases in the DB instance that might have been accidentally revoked. You can change the DB instance password by using the Amazon RDS console, the AWS CLI command modify-db-instance, or by using the ModifyDBInstance API operation. For more information about modifying a DB instance, see Modifying an Amazon RDS DB instance.

Restoring license-terminated DB instances

Microsoft has requested that some Amazon RDS customers who did not report their Microsoft License Mobility information terminate their DB instance. Amazon RDS takes snapshots of these DB instances, and you can restore from the snapshot to a new DB instance that has the License Included model.

You can restore from a snapshot of Standard Edition to either Standard Edition or Enterprise Edition.

You can restore from a snapshot of Enterprise Edition to either Standard Edition or Enterprise Edition.

To restore from a SQL Server snapshot after Amazon RDS has created a final snapshot of your instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Snapshots**.
3. Choose the snapshot of your SQL Server DB instance. Amazon RDS creates a final snapshot of your DB instance. The name of the terminated instance snapshot is in the format *instance_name*`-final-snapshot`. For example, if your DB instance name is **`mytest.cdxgahslksma.us-east-1.rds.com`**, the final snapshot is called **`mytest-final-snapshot`** and is located in the same AWS Region as the original DB instance.
4. For **Actions**, choose **Restore Snapshot**.

   The **Restore DB Instance** window appears.
5. For **License Model**, choose **license-included**.
6. Choose the SQL Server DB engine that you want to use.
7. For **DB Instance Identifier**, enter the name for the restored DB instance.
8. Choose **Restore DB Instance**.

For more information about restoring from a snapshot, see Restoring to a DB instance.

Transitioning a Microsoft SQL Server database from OFFLINE to ONLINE

You can transition your Microsoft SQL Server database on an Amazon RDS DB instance from `OFFLINE` to `ONLINE`.

SQL Server method	Amazon RDS method
ALTER DATABASE *db_name* SET ONLINE;	EXEC rdsadmin.dbo.rds_set_database_online *db_name*

Using change data capture

Amazon RDS supports change data capture (CDC) for your DB instances running Microsoft SQL Server. CDC captures changes that are made to the data in your tables. It stores metadata about each change, which you can access later. For more information about how CDC works, see Change data capture in the Microsoft documentation.

Before you use CDC with your Amazon RDS DB instances, enable it in the database by running `msdb.dbo.rds_cdc_enable_db`. You must have master user privileges to enable CDC in the Amazon RDS DB instance. After CDC is enabled, any user who is `db_owner` of that database can enable or disable CDC on tables in that database.

> **Important**
>
> During restores, CDC will be disabled. All of the related metadata is automatically removed from the database. This applies to snapshot restores, point-in-time restores, and SQL Server Native restores from S3. After performing one of these types of restores, you can re-enable CDC and re-specify tables to track.

To enable CDC for a DB instance, run the `msdb.dbo.rds_cdc_enable_db` stored procedure.

```
exec msdb.dbo.rds_cdc_enable_db 'database_name'
```

To disable CDC for a DB instance, run the `msdb.dbo.rds_cdc_disable_db` stored procedure.

```
exec msdb.dbo.rds_cdc_disable_db 'database_name'
```

Topics

- Tracking tables with change data capture
- Change data capture jobs
- Change data capture for Multi-AZ instances

Tracking tables with change data capture

After CDC is enabled on the database, you can start tracking specific tables. You can choose the tables to track by running sys.sp_cdc_enable_table.

```
--Begin tracking a table
exec sys.sp_cdc_enable_table
   @source_schema           = N'source_schema'
,  @source_name             = N'source_name'
,  @role_name               = N'role_name'

--The following parameters are optional:

--, @capture_instance       = 'capture_instance'
--, @supports_net_changes   = supports_net_changes
--, @index_name             = 'index_name'
--, @captured_column_list   = 'captured_column_list'
--, @filegroup_name         = 'filegroup_name'
--, @allow_partition_switch = 'allow_partition_switch'
;
```

To view the CDC configuration for your tables, run sys.sp_cdc_help_change_data_capture.

```
--View CDC configuration
exec sys.sp_cdc_help_change_data_capture

--The following parameters are optional and must be used together.
--  'schema_name', 'table_name'
;
```

For more information on CDC tables, functions, and stored procedures in SQL Server documentation, see the following:

- Change data capture stored procedures (Transact-SQL)
- Change data capture functions (Transact-SQL)
- Change data capture tables (Transact-SQL)

Change data capture jobs

When you enable CDC, SQL Server creates the CDC jobs. Database owners (`db_owner`) can view, create, modify, and delete the CDC jobs. However, the RDS system account owns them. Therefore, the jobs aren't visible from native views, procedures, or in SQL Server Management Studio.

To control behavior of CDC in a database, use native SQL Server procedures such as sp_cdc_enable_table and sp_cdc_start_job. To change CDC job parameters, like `maxtrans` and `maxscans`, you can use sp_cdc_change_job..

To get more information regarding the CDC jobs, you can query the following dynamic management views:

- sys.dm_cdc_errors
- sys.dm_cdc_log_scan_sessions
- sysjobs
- sysjobhistory

Change data capture for Multi-AZ instances

If you use CDC on a Multi-AZ instance, make sure the mirror's CDC job configuration matches the one on the principal. CDC jobs are mapped to the `database_id`. If the database IDs on the secondary are different from the principal, then the jobs won't be associated with the correct database. To try to prevent errors after failover, RDS drops and recreates the jobs on the new principal. The recreated jobs use the parameters that the principal recorded before failover.

Although this process runs quickly, it's still possible that the CDC jobs might run before RDS can correct them. Here are three ways to force parameters to be consistent between primary and secondary replicas:

- Use the same job parameters for all the databases that have CDC enabled.
- Before you change the CDC job configuration, convert the Multi-AZ instance to Single-AZ.
- Manually transfer the parameters whenever you change them on the principal.

To view and define the CDC parameters that are used to recreate the CDC jobs after a failover, use `rds_show_configuration` and `rds_set_configuration`.

The following example returns the value set for `cdc_capture_maxtrans`. For any parameter that is set to `RDS_DEFAULT`, RDS automatically configures the value.

```
-- Show configuration for each parameter on either primary and secondary replicas.
exec rdsadmin.dbo.rds_show_configuration 'cdc_capture_maxtrans';
```

To set the configuration on the secondary, run `rdsadmin.dbo.rds_set_configuration`. This procedure sets the parameter values for all of the databases on the secondary server. These settings are used only after a failover. The following example sets the `maxtrans` for all CDC capture jobs to *1000*:

```
--To set values on secondary. These are used after failover.
exec rdsadmin.dbo.rds_set_configuration 'cdc_capture_maxtrans', 1000;
```

To set the CDC job parameters on the principal, use sys.sp_cdc_change_job instead.

Using SQL Server Agent

With Amazon RDS, you can use SQL Server Agent on a DB instance running Microsoft SQL Server Enterprise Edition, Standard Edition, or Web Edition. SQL Server Agent is a Microsoft Windows service that runs scheduled administrative tasks that are called jobs. You can use SQL Server Agent to run T-SQL jobs to rebuild indexes, run corruption checks, and aggregate data in a SQL Server DB instance.

When you create a SQL Server DB instance, the master user is enrolled in the `SQLAgentUserRole` role.

SQL Server Agent can run a job on a schedule, in response to a specific event, or on demand. For more information, see SQL Server Agent in the Microsoft documentation.

> **Note**
>
> Avoid scheduling jobs to run during the maintenance and backup windows for your DB instance. The maintenance and backup processes that are launched by AWS could interrupt a job or cause it to be canceled.
>
> In Multi-AZ deployments, SQL Server Agent jobs are replicated from the primary host to the secondary host when the job replication feature is turned on. For more information, see Turning on SQL Server Agent job replication.
>
> Multi-AZ deployments have a limit of 10,000 SQL Server Agent jobs. If you need a higher limit, request an increase by contacting AWS Support. Open the AWS Support Center page, sign in if necessary, and choose **Create case**. Choose **Service limit increase**. Complete and submit the form.

To view the history of an individual SQL Server Agent job in SQL Server Management Studio (SSMS), open Object Explorer, right-click the job, and then choose **View History**.

Because SQL Server Agent is running on a managed host in a DB instance, some actions aren't supported:

- Running replication jobs and running command-line scripts by using ActiveX, Windows command shell, or Windows PowerShell aren't supported.
- You can't manually start, stop, or restart SQL Server Agent.
- Email notifications through SQL Server Agent aren't available from a DB instance.
- SQL Server Agent alerts and operators aren't supported.
- Using SQL Server Agent to create backups isn't supported. Use Amazon RDS to back up your DB instance.
- Currently, RDS for SQL Server does not support the use SQL Server Agent tokens.

Turning on SQL Server Agent job replication

You can turn on SQL Server Agent job replication by using the following stored procedure:

```
EXECUTE msdb.dbo.rds_set_system_database_sync_objects @object_types = 'SQLAgentJob';
```

You can run the stored procedure on all SQL Server versions supported by Amazon RDS for SQL Server. Jobs in the following categories are replicated:

- [Uncategorized (Local)]
- [Uncategorized (Multi-Server)]
- [Uncategorized]
- Data Collector
- Database Engine Tuning Advisor
- Database Maintenance
- Full-Text

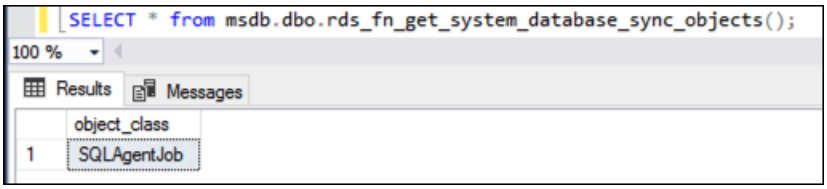
Only jobs that use T-SQL job steps are replicated. Jobs with step types such as SQL Server Integration Services (SSIS), SQL Server Reporting Services (SSRS), Replication, and PowerShell aren't replicated. Jobs that use Database Mail and server-level objects aren't replicated.

> **Important**
>
> The primary host is the source of truth for replication. Before turning on job replication, make sure that your SQL Server Agent jobs are on the primary. If you don't do this, it could lead to the deletion of your SQL Server Agent jobs if you turn on the feature when newer jobs are on the secondary host.

You can use the following function to confirm whether replication is turned on.

```
SELECT * from msdb.dbo.rds_fn_get_system_database_sync_objects();
```

The T-SQL query returns the following if SQL Server Agent jobs are replicating. If they're not replicating, it returns nothing for `object_class`.

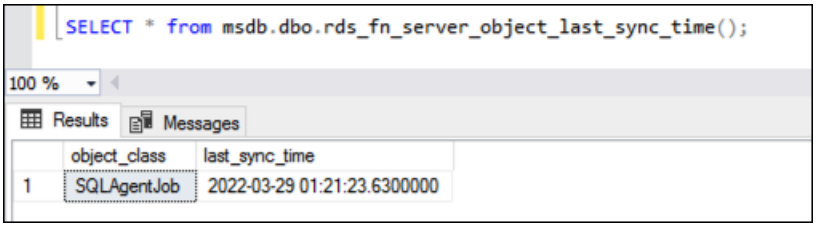


You can use the following function to find the last time objects were synchronized in UTC time.

```
SELECT * from msdb.dbo.rds_fn_server_object_last_sync_time();
```

For example, suppose that you modify a SQL Server Agent job at 01:00. You expect the most recent synchronization time to be after 01:00, indicating that synchronization has taken place.

After synchronization, the values returned for `date_created` and `date_modified` on the secondary node are expected to match.



If you are also using `tempdb` replication, you can enable replication for both SQL Agent jobs and the `tempdb` configuration by providing them in the `@object_type` parameter:

```
EXECUTE msdb.dbo.rds_set_system_database_sync_objects @object_types =
 'SQLAgentJob,TempDbFile';
```

For more information on tempdb replication, see TempDB configuration for Multi-AZ deployments.

Adding a user to the SQLAgentUser role

To allow an additional login or user to use SQL Server Agent, log in as the master user and do the following:

1. Create another server-level login by using the CREATE LOGIN command.
2. Create a user in msdb using CREATE USER command, and then link this user to the login that you created in the previous step.
3. Add the user to the SQLAgentUserRole using the sp_addrolemember system stored procedure.

For example, suppose that your master user name is **admin** and you want to give access to SQL Server Agent to a user named **theirname** with a password **theirpassword**. In that case, you can use the following procedure.

To add a user to the SQLAgentUser role

1. Log in as the master user.
2. Run the following commands:

```
--Initially set context to master database
USE [master];
GO
--Create a server-level login named theirname with password theirpassword
CREATE LOGIN [theirname] WITH PASSWORD = 'theirpassword';
GO
--Set context to msdb database
USE [msdb];
GO
--Create a database user named theirname and link it to server-level login
 theirname
CREATE USER [theirname] FOR LOGIN [theirname];
GO
--Added database user theirname in msdb to SQLAgentUserRole in msdb
```

```
EXEC sp_addrolemember [SQLAgentUserRole], [theirname];
```

Deleting a SQL Server Agent job

You use the `sp_delete_job` stored procedure to delete SQL Server Agent jobs on Amazon RDS for Microsoft SQL Server.

You can't use SSMS to delete SQL Server Agent jobs. If you try to do so, you get an error message similar to the following:

```
The EXECUTE permission was denied on the object 'xp_regread', database
 'mssqlsystemresource', schema 'sys'.
```

As a managed service, RDS is restricted from running procedures that access the Windows registry. When you use SSMS, it tries to run a process (`xp_regread`) for which RDS isn't authorized.

> **Note**
>
> On RDS for SQL Server, only members of the sysadmin role are allowed to update or delete jobs owned by a different login.

To delete a SQL Server Agent job

- Run the following T-SQL statement:

```
EXEC msdb..sp_delete_job @job_name = 'job_name';
```

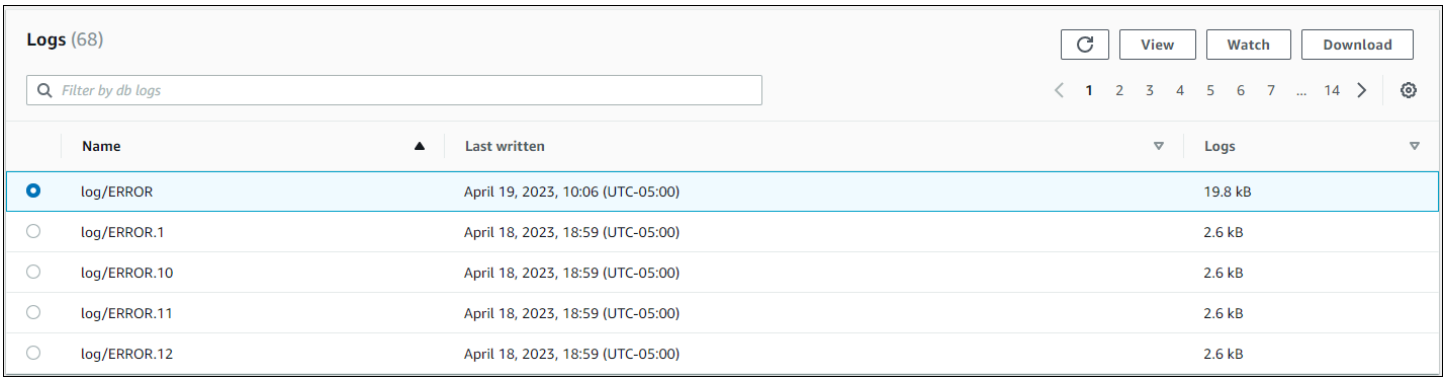
Working with Microsoft SQL Server logs

You can use the Amazon RDS console to view, watch, and download SQL Server Agent logs, Microsoft SQL Server error logs, and SQL Server Reporting Services (SSRS) logs.

Watching log files

If you view a log in the Amazon RDS console, you can see its contents as they exist at that moment. Watching a log in the console opens it in a dynamic state so that you can see updates to it in near-real time.

Only the latest log is active for watching. For example, suppose you have the following logs shown:



Only log/ERROR, as the most recent log, is being actively updated. You can choose to watch others, but they are static and will not update.

Archiving log files

The Amazon RDS console shows logs for the past week through the current day. You can download and archive logs to keep them for reference past that time. One way to archive logs is to load them into an Amazon S3 bucket. For instructions on how to set up an Amazon S3 bucket and upload a file, see Amazon S3 basics in the *Amazon Simple Storage Service Getting Started Guide* and click **Get Started**.

Viewing error and agent logs

To view Microsoft SQL Server error and agent logs, use the Amazon RDS stored procedure `rds_read_error_log` with the following parameters:

- **`@index`** – the version of the log to retrieve. The default value is 0, which retrieves the current error log. Specify 1 to retrieve the previous log, specify 2 to retrieve the one before that, and so on.
- **`@type`** – the type of log to retrieve. Specify 1 to retrieve an error log. Specify 2 to retrieve an agent log.

Example

The following example requests the current error log.

```
EXEC rdsadmin.dbo.rds_read_error_log @index = 0, @type = 1;
```

For more information on SQL Server errors, see Database engine errors in the Microsoft documentation.

Working with trace and dump files

This section describes working with trace files and dump files for your Amazon RDS DB instances running Microsoft SQL Server.

Generating a trace SQL query

```
declare @rc int
declare @TraceID int
declare @maxfilesize bigint

set @maxfilesize = 5

exec @rc = sp_trace_create @TraceID output,  0, N'D:\rdsdbdata\log\rdstest',
 @maxfilesize, NULL
```

Viewing an open trace

```
select * from ::fn_trace_getinfo(default)
```

Viewing trace contents

```
select * from ::fn_trace_gettable('D:\rdsdbdata\log\rdstest.trc', default)
```

Setting the retention period for trace and dump files

Trace and dump files can accumulate and consume disk space. By default, Amazon RDS purges trace and dump files that are older than seven days.

To view the current trace and dump file retention period, use the `rds_show_configuration` procedure, as shown in the following example.

```
exec rdsadmin..rds_show_configuration;
```

To modify the retention period for trace files, use the `rds_set_configuration` procedure and set the `tracefile retention` in minutes. The following example sets the trace file retention period to 24 hours.

```
exec rdsadmin..rds_set_configuration 'tracefile retention', 1440;
```

To modify the retention period for dump files, use the `rds_set_configuration` procedure and set the `dumpfile retention` in minutes. The following example sets the dump file retention period to 3 days.

```
exec rdsadmin..rds_set_configuration 'dumpfile retention', 4320;
```

For security reasons, you cannot delete a specific trace or dump file on a SQL Server DB instance. To delete all unused trace or dump files, set the retention period for the files to 0.

Amazon RDS for MySQL

Amazon RDS supports several versions of MySQL for DB instances. For complete information about the supported versions, see MySQL on Amazon RDS versions.

To create an Amazon RDS for MySQL DB instance, use the Amazon RDS management tools or interfaces. You can then do the following:

- Resize your DB instance
- Authorize connections to your DB instance
- Create and restore from backups or snapshots
- Create Multi-AZ secondaries
- Create read replicas
- Monitor the performance of your DB instance

To store and access the data in your DB instance, you use standard MySQL utilities and applications.

Amazon RDS for MySQL is compliant with many industry standards. For example, you can use RDS for MySQL databases to build HIPAA-compliant applications. You can use RDS for MySQL databases to store healthcare related information, including protected health information (PHI) under a Business Associate Agreement (BAA) with AWS. Amazon RDS for MySQL also meets Federal Risk and Authorization Management Program (FedRAMP) security requirements. In addition, Amazon RDS for MySQL has received a FedRAMP Joint Authorization Board (JAB) Provisional Authority to Operate (P-ATO) at the FedRAMP HIGH Baseline within the AWS GovCloud (US) Regions. For more information on supported compliance standards, see AWS cloud compliance.

For information about the features in each version of MySQL, see The main features of MySQL in the MySQL documentation.

Before creating a DB instance, complete the steps in Setting up your Amazon RDS environment. When you create a DB instance, the RDS master user gets DBA privileges, with some limitations. Use this account for administrative tasks such as creating additional database accounts.

You can create the following:

- DB instances
- DB snapshots

- Point-in-time restores
- Automated backups
- Manual backups

You can use DB instances running MySQL inside a virtual private cloud (VPC) based on Amazon VPC. You can also add features to your MySQL DB instance by turning on various options. Amazon RDS supports Multi-AZ deployments for MySQL as a high-availability, failover solution.

> **Important**
>
> To deliver a managed service experience, Amazon RDS doesn't provide shell access to DB instances. It also restricts access to certain system procedures and tables that need advanced privileges. You can access your database using standard SQL clients such as the mysql client. However, you can't access the host directly by using Telnet or Secure Shell (SSH).

MySQL feature support on Amazon RDS

RDS for MySQL supports most of the features and capabilities of MySQL. Some features might have limited support or restricted privileges.

You can filter new Amazon RDS features on the What's New with Database? page. For **Products**, choose **Amazon RDS**. Then search using keywords such as **`MySQL 2022`**.

> **Note**
>
> The following lists are not exhaustive.

Topics

Supported storage engines for RDS for MySQL

While MySQL supports multiple storage engines with varying capabilities, not all of them are optimized for recovery and data durability. Amazon RDS fully supports the InnoDB storage engine for MySQL DB instances. Amazon RDS features such as Point-In-Time restore and snapshot restore require a recoverable storage engine and are supported for the InnoDB storage engine only. For more information, see MySQL memcached support.

The Federated Storage Engine is currently not supported by Amazon RDS for MySQL.

For user-created schemas, the MyISAM storage engine does not support reliable recovery and can result in lost or corrupt data when MySQL is restarted after a recovery, preventing Point-In-Time restore or snapshot restore from working as intended. However, if you still choose to use MyISAM with Amazon RDS, snapshots can be helpful under some conditions.

> **Note**
>
> System tables in the `mysql` schema can be in MyISAM storage.

If you want to convert existing MyISAM tables to InnoDB tables, you can use the `ALTER TABLE` command (for example, `alter table TABLE_NAME engine=innodb;`). Bear in mind that MyISAM and InnoDB have different strengths and weaknesses, so you should fully evaluate the impact of making this switch on your applications before doing so.

MySQL 5.1, 5.5, and 5.6 are no longer supported in Amazon RDS. However, you can restore existing MySQL 5.1, 5.5, and 5.6 snapshots. When you restore a MySQL 5.1, 5.5, or 5.6 snapshot, the DB instance is automatically upgraded to MySQL 5.7.

Using memcached and other options with MySQL on Amazon RDS

Most Amazon RDS DB engines support option groups that allow you to select additional features for your DB instance. RDS for MySQL DB instances support the `memcached` option, a simple, key-based cache. For more information about `memcached` and other options, see Options for MySQL DB instances. For more information about working with option groups, see Working with option groups.

InnoDB cache warming for MySQL on Amazon RDS

InnoDB cache warming can provide performance gains for your MySQL DB instance by saving the current state of the buffer pool when the DB instance is shut down, and then reloading the buffer pool from the saved information when the DB instance starts up. This bypasses the need for the buffer pool to "warm up" from normal database use and instead preloads the buffer pool with the pages for known common queries. The file that stores the saved buffer pool information only stores metadata for the pages that are in the buffer pool, and not the pages themselves. As a result, the file does not require much storage space. The file size is about 0.2 percent of the cache size. For example, for a 64 GiB cache, the cache warming file size is 128 MiB. For more information on InnoDB cache warming, see Saving and restoring the buffer pool state in the MySQL documentation.

RDS for MySQL DB instances support InnoDB cache warming. To enable InnoDB cache warming, set the `innodb_buffer_pool_dump_at_shutdown` and `innodb_buffer_pool_load_at_startup` parameters to 1 in the parameter group for your DB instance. Changing these parameter values in a parameter group will affect all MySQL DB instances that use that parameter group. To enable InnoDB cache warming for specific MySQL DB instances, you might need to create a new parameter group for those instances. For information on parameter groups, see Parameter groups for Amazon RDS.

InnoDB cache warming primarily provides a performance benefit for DB instances that use standard storage. If you use PIOPS storage, you do not commonly see a significant performance benefit.

Important

If your MySQL DB instance does not shut down normally, such as during a failover, then the buffer pool state will not be saved to disk. In this case, MySQL loads whatever buffer pool file is available when the DB instance is restarted. No harm is done, but the restored buffer pool might not reflect the most recent state of the buffer pool prior to the restart. To ensure that you have a recent state of the buffer pool available to warm the InnoDB cache on startup, we recommend that you periodically dump the buffer pool "on demand." You can create an event to dump the buffer pool automatically and on a regular interval. For example, the following statement creates an event named `periodic_buffer_pool_dump` that dumps the buffer pool every hour.

```
CREATE EVENT periodic_buffer_pool_dump
ON SCHEDULE EVERY 1 HOUR
DO CALL mysql.rds_innodb_buffer_pool_dump_now();
```

For more information on MySQL events, see Event syntax in the MySQL documentation.

Dumping and loading the buffer pool on demand

You can save and load the InnoDB cache "on demand."

- To dump the current state of the buffer pool to disk, call the mysql.rds_innodb_buffer_pool_dump_now stored procedure.
- To load the saved state of the buffer pool from disk, call the mysql.rds_innodb_buffer_pool_load_now stored procedure.
- To cancel a load operation in progress, call the mysql.rds_innodb_buffer_pool_load_abort stored procedure.

MySQL features not supported by Amazon RDS

Amazon RDS doesn't currently support the following MySQL features:

- Authentication Plugin
- Error Logging to the System Log
- InnoDB Tablespace Encryption
- Password Strength Plugin
- Persisted system variables
- Rewriter Query Rewrite Plugin
- Semisynchronous replication
- Transportable tablespace
- X Plugin

> **Note**
>
> Global transaction IDs are supported for all RDS for MySQL 5.7 versions, and for RDS for MySQL 8.0.26 and higher 8.0 versions.

To deliver a managed service experience, Amazon RDS doesn't provide shell access to DB instances. It also restricts access to certain system procedures and tables that require advanced privileges. Amazon RDS supports access to databases on a DB instance using any standard SQL client application. Amazon RDS doesn't allow direct host access to a DB instance by using Telnet, Secure Shell (SSH), or Windows Remote Desktop Connection. When you create a DB instance, you are assigned as *db_owner* for all databases on that instance, and you have all database-level permissions except for those used for backups. Amazon RDS manages backups for you.

MySQL on Amazon RDS versions

For MySQL, version numbers are organized as version = X.Y.Z. In Amazon RDS terminology, X.Y denotes the major version, and Z is the minor version number. For Amazon RDS implementations, a version change is considered major if the major version number changes—for example, going from version 5.7 to 8.0. A version change is considered minor if only the minor version number changes—for example, going from version 8.0.32 to 8.0.34.

Topics

Supported MySQL minor versions on Amazon RDS

Amazon RDS currently supports the following minor versions of MySQL.

> **Note**
>
> Dates with only a month and a year are approximate and are updated with an exact date when it's known.
> Amazon RDS Extended Support isn't available for minor versions.

The following table shows the minor versions of MySQL 8.0 that Amazon RDS currently supports.

MySQL engine version	Community release date	RDS release date	RDS end of standard support date
8.0.39	23 July 2024	12 August 2024	September 2025
8.0.37	30 April 2024	18 June 2024	September 2025
8.0.36	16 January 2024	12 February 2024	March 2025
8.0.35	25 October 2023	9 November 2023	March 2025
8.0.34	18 July 2023	9 August 2023	March 2025
8.0.33	18 April 2023	15 June 2023	March 2025
8.0.32	17 January 2023	7 February 2023	March 2025

The following table shows the minor versions of MySQL 5.7 that are available under Amazon RDS Extended Support.

MySQL engine version	Community release date	RDS release date	RDS end of Extended Support date
5.7.44-RDS.20240808*	Not applicable	28 August 2024	September 2025
5.7.44-RDS.20240529*	Not applicable	25 June 2024	September 2025
5.7.44-RDS.20240408*	Not applicable	17 May 2024	September 2025
5.7.44	25 October 2023	2 November 2023	March 2025

* MySQL Community retired major version 5.7 and won't be releasing new minor versions. This is a minor version that Amazon RDS released with critical security patches and bug fixes for MySQL 5.7 databases that are covered under RDS Extended Support. For more information about these

minor versions, see the section called "RDS Extended Support versions for RDS for MySQL". For more information about RDS Extended Support, see Using Amazon RDS Extended Support.

Minor versions can reach end of standard support before major versions do. For example, minor version 8.0.28 reached its end of standard support date on March 28, 2024 while major version 8.0 will reach this date on July 31, 2026. RDS will support additional 8.0.* minor versions that the MySQL community releases between these dates.

You can specify any currently supported MySQL version when creating a new DB instance. You can specify the major version (such as MySQL 5.7), and any supported minor version for the specified major version. If no version is specified, Amazon RDS defaults to a supported version, typically the most recent version. If a major version is specified but a minor version is not, Amazon RDS defaults to a recent release of the major version you have specified. To see a list of supported versions, as well as defaults for newly created DB instances, use the `describe-db-engine-versions` AWS CLI command.

For example, to list the supported engine versions for RDS for MySQL, run the following CLI command:

```
aws rds describe-db-engine-versions --engine mysql --query "*[].
{Engine:Engine,EngineVersion:EngineVersion}" --output text
```

The default MySQL version might vary by AWS Region. To create a DB instance with a specific minor version, specify the minor version during DB instance creation. You can determine the default minor version for an AWS Region using the following AWS CLI command:

```
aws rds describe-db-engine-versions --default-only --engine mysql
 --engine-version major-engine-version --region region --query "*[].
{Engine:Engine,EngineVersion:EngineVersion}" --output text
```

Replace *`major-engine-version`* with the major engine version, and replace *`region`* with the AWS Region. For example, the following AWS CLI command returns the default MySQL minor engine version for the 5.7 major version and the US West (Oregon) AWS Region (us-west-2):

```
aws rds describe-db-engine-versions --default-only --engine mysql --engine-version 5.7
 --region us-west-2 --query "*[].{Engine:Engine,EngineVersion:EngineVersion}" --output
 text
```

With Amazon RDS, you control when to upgrade your MySQL instance to a new major version supported by Amazon RDS. You can maintain compatibility with specific MySQL versions, test new versions with your application before deploying in production, and perform major version upgrades at times that best fit your schedule.

When automatic minor version upgrade is enabled, your DB instance will be upgraded automatically to new MySQL minor versions as they are supported by Amazon RDS. This patching occurs during your scheduled maintenance window. You can modify a DB instance to enable or disable automatic minor version upgrades.

If you opt out of automatically scheduled upgrades, you can manually upgrade to a supported minor version release by following the same procedure as you would for a major version update. For information, see Upgrading a DB instance engine version.

Amazon RDS currently supports the major version upgrades from MySQL version 5.6 to version 5.7, and from MySQL version 5.7 to version 8.0. Because major version upgrades involve some compatibility risk, they do not occur automatically; you must make a request to modify the DB instance. You should thoroughly test any upgrade before upgrading your production instances. For information about upgrading a MySQL DB instance, see Upgrading the MySQL DB engine.

You can test a DB instance against a new version before upgrading by creating a DB snapshot of your existing DB instance, restoring from the DB snapshot to create a new DB instance, and then initiating a version upgrade for the new DB instance. You can then experiment safely on the upgraded clone of your DB instance before deciding whether or not to upgrade your original DB instance.

MySQL minor versions on Amazon RDS

Minor versions

- MySQL version 8.0.39
- MySQL version 8.0.37

MySQL version 8.0.39

MySQL version 8.0.39 is now available on Amazon RDS. This release contains fixes and improvements added by the MySQL community and Amazon RDS.

New features and enhancements

- Fixed a bug that prevented `sql_log_off` from working properly with the `SESSION_VARIABLES_ADMIN` privilege.
- Fixed a bug that prevented the master user from being able to grant the `SESSION_VARIABLE_ADMIN` privilege other database users.
- Fixed a bug that caused an illegal mix of collation while executing RDS-provided stored procedures.

MySQL version 8.0.37

MySQL version 8.0.37 is now available on Amazon RDS. This release contains fixes and improvements added by the MySQL community and Amazon RDS.

New features and enhancements

Fixed a bug with executing an instant DDL statement followed by an UPDATE that lead to an assertion failure.

Supported MySQL major versions on Amazon RDS

RDS for MySQL major versions are available under standard support at least until community end of life for the corresponding community version. You can continue running a major version past its RDS end of standard support date for a fee. For more information, see Using Amazon RDS Extended Support and Amazon RDS for MySQL pricing.

You can use the following dates to plan your testing and upgrade cycles.

> **Note**
>
> Dates with only a month and a year are approximate and are updated with an exact date when it's known.

MySQL major version	Communit release date	RDS release date	Communit end of life date	RDS end of standard support date	RDS start of Extended Support year 1 pricing date	RDS start of Extended Support year 3 pricing date	RDS end of Extended Support date
MySQL 8.0	19 April 2018	23 October 2018	April 2026	31 July 2026	1 August 2026	1 August 2028	31 July 2029
MySQL 5.7*	21 October 2015	22 February 2016	October 2023	29 February 2024	1 March 2024	1 March 2026	28 February 2027

* MySQL 5.7 is now only available under RDS Extended Support. For more information, see Using Amazon RDS Extended Support.

Amazon RDS Extended Support versions for RDS for MySQL

The following content lists all releases of RDS Extended Support for RDS for MySQL versions.

Releases

- RDS Extended Support for RDS for MySQL version 5.7.44-RDS.20240808
- RDS Extended Support for RDS for MySQL version 5.7.44-RDS.20240529
- RDS Extended Support for RDS for MySQL version 5.7.44-RDS.20240408

RDS Extended Support for RDS for MySQL version 5.7.44-RDS.20240808

RDS Extended Support for RDS for MySQL version 5.7.44-RDS.20240808 is available.

Bugs fixed:

- Fixed assertion failure related to dictionary column index.
- Fixed issue with the `is_binlog_cache_empty()` function.

- Fixed `heap-use-after-free` errors in `sql/item.cc` files.
- Fixed several spatial index issues by disabling them for `index-only` reads.
- Fixed instrumentation issue with the `LOCK_ORDER: CONNECTION_CONTROL` plugin.
- Fixed threads getting stuck with the `CONNECTION_CONTROL` plugin.
- Fixed `PSI_THREAD_INFO` not updating for `PREPARED STATEMENTS`.
- Fixed double processing of FTS index words with `innodb_optimize_fulltext_only`.

CVEs fixed:

- CVE-2024-21177

RDS Extended Support for RDS for MySQL version 5.7.44-RDS.20240529

RDS Extended Support for RDS for MySQL version 5.7.44-RDS.20240529 is available.

Bugs fixed:

- Fixed `field.cc` assertion failure by implementing `fix_after_pullout`.
- Fixed a null pointer failure when returning metadata to the client for certain SQL queries. These queries contained dynamic parameters and subqueries in `SELECT` clauses.
- Fixed incorrect results when using `GROUP BY` for loose index scans, or scans of noncontiguous ranges of an index.
- Fixed loss of GTID information on MySQL crash during persistence.
- Fixed a race condition that could cause an InnoDB transaction to hang indefinitely.
- Fixed a race condition in Group Replication's certification information cleanup.
- Fixed backward index scan issue with concurrent page operations.
- Fixed an inconsistent full-text search (FTS) state issue in concurrent scenarios.
- Fixed assertion issue with change buffer on deleting tables.
- Unified behavior for calling `deinit` function across all plugin types.

CVEs fixed:

- CVE-2024-20963
- CVE-2024-20993

- CVE-2024-20998
- CVE-2024-21009
- CVE-2024-21054
- CVE-2024-21055
- CVE-2024-21057
- CVE-2024-21062
- CVE-2024-21008
- CVE-2024-21013
- CVE-2024-21047
- CVE-2024-21087
- CVE-2024-21096

RDS Extended Support for RDS for MySQL version 5.7.44-RDS.20240408

RDS Extended Support for RDS for MySQL version 5.7.44-RDS.20240408 is available.

This release contains patches for the following CVEs:

- CVE-2024-20963

Working with the Database Preview environment

In July 2023, Oracle announced a new release model for MySQL. This model includes two types of releases: Innovation Releases and LTS releases. Amazon RDS makes MySQL Innovation Releases available in the RDS Preview environment. To learn more about the MySQL Innovation releases, see Introducing MySQL Innovation and Long-Term Support (LTS) versions.

RDS for MySQL DB instances in the Database Preview environment are functionally similar to other RDS for MySQL DB instances. However, you can't use the Database Preview environment for production workloads.

Preview environments have the following limitations:

- Amazon RDS deletes all DB instances 60 days after you create them, along with any backups and snapshots.

- You can only use General Purpose SSD and Provisioned IOPS SSD storage.
- You can't get help from AWS Support with DB instances. Instead, you can post your questions to the AWS-managed Q&A community, AWS re:Post.
- You can't copy a snapshot of a DB instance to a production environment.

The following options are supported by the preview.

- You can create DB instances using db.m6i, db.r6i, db.m6g, db.m5, db.t3, db.r6g, and db.r5 DB instance classes. For more information about RDS instance classes, see DB instance classes.
- You can use both single-AZ and multi-AZ deployments.
- You can use standard MySQL dump and load functions to export databases from or import databases to the Database Preview environment.

Features not supported in the Database Preview environment

The following features aren't available in the Database Preview environment:

- Cross-Region snapshot copy
- Cross-Region read replicas
- RDS Proxy

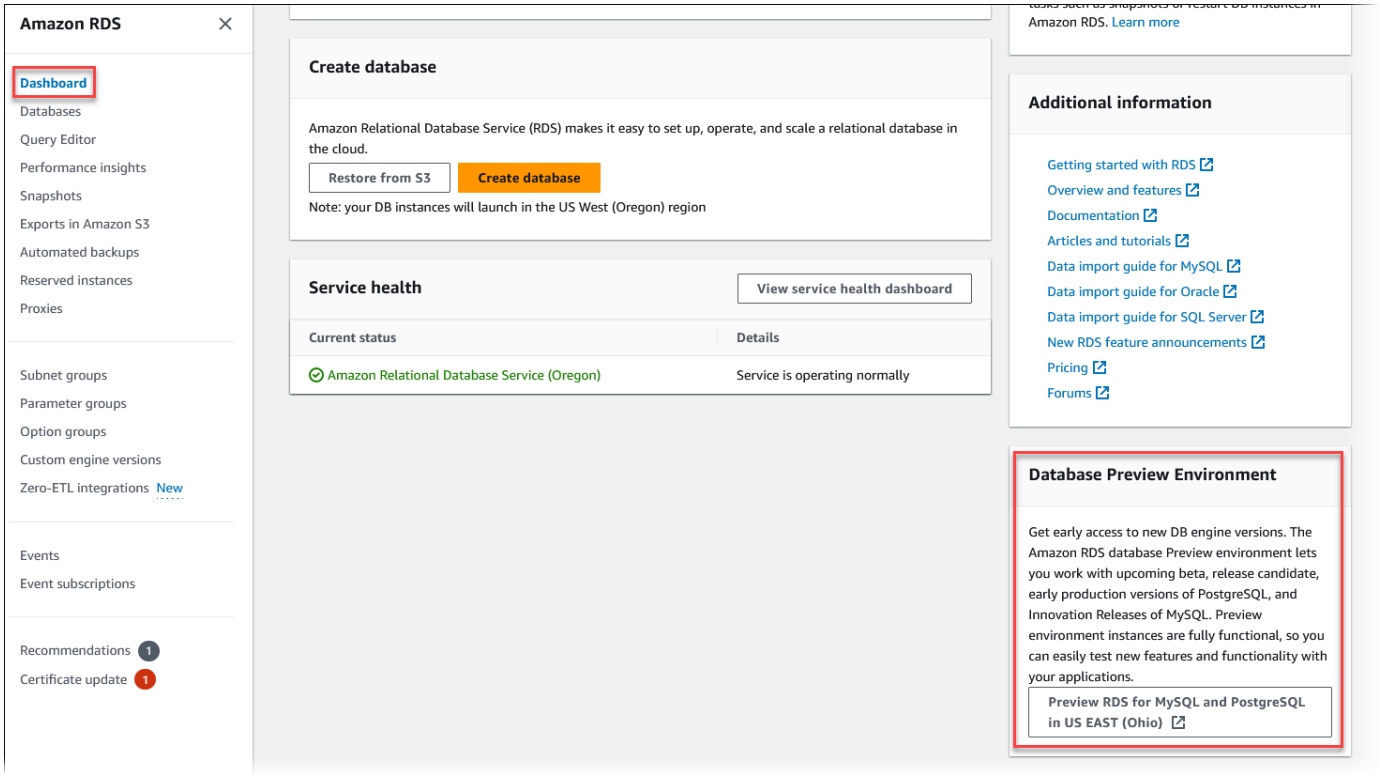
Creating a new DB instance in the Database Preview environment

You can create a DB instance in the Database Preview environment using the AWS Management Console, AWS CLI, or RDS API.

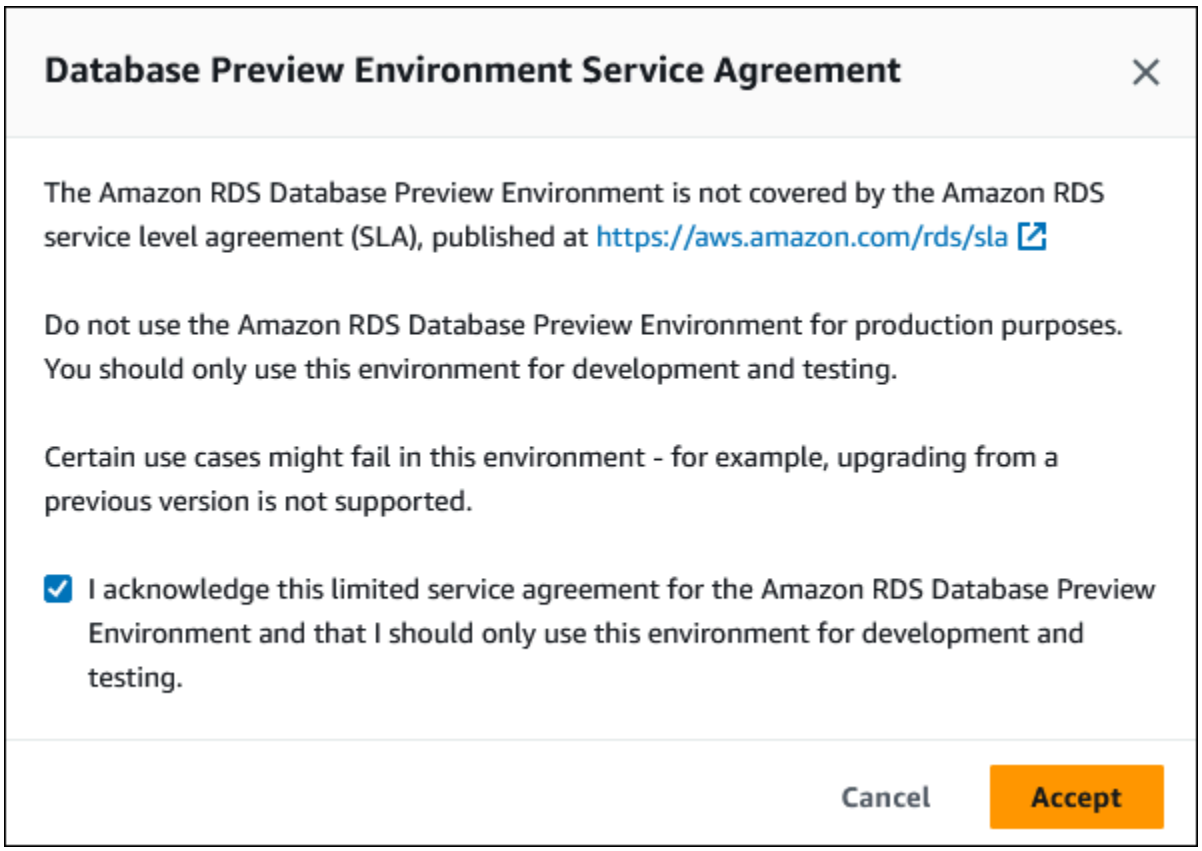
Console

To create a DB instance in the Database Preview environment

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Choose **Dashboard** from the navigation pane.
3. In the **Dashboard** page, locate the **Database Preview Environment** section, as shown in the following image.



You can navigate directly to the Database Preview environment. Before you can proceed, you must acknowledge and accept the limitations.



4. To create the RDS for MySQL DB instance, follow the same process that you would for creating any Amazon RDS DB instance. For more information, see the Console procedure in Creating a DB instance.

AWS CLI

To create a DB instance in the Database Preview environment using the AWS CLI, use the following endpoint.

```
rds-preview.us-east-2.amazonaws.com
```

To create the RDS for MySQL DB instance, follow the same process that you would for creating any Amazon RDS DB instance. For more information, see the AWS CLI procedure in Creating a DB instance.

RDS API

To create a DB instance in the Database Preview environment using the RDS API, use the following endpoint.

```
rds-preview.us-east-2.amazonaws.com
```

To create the RDS for MySQL DB instance, follow the same process that you would for creating any Amazon RDS DB instance. For more information, see the RDS API procedure in Creating a DB instance.

MySQL version 8.4 in the Database Preview environment

MySQL version 8.4 is now available in the Amazon RDS Database Preview environment. MySQL version 8.4 is the latest LTS release from the community, and contains several improvements that are described in Changes in MySQL 8.4.0. You can use the Database Preview environment to test your workloads against this release before it is available in all AWS Regions for production workloads.

MySQL version 8.4 in the Database Preview environment might differ from what Amazon RDS releases in all AWS Regions for production workloads. The following list includes features that could change. This list isn't exhaustive.

- The RDS for MySQL 8.4 parameter group definition. For example, Amazon RDS might add, remove, or rename parameters, and might change the parameter default values.
- The privilege model.
- The TLS library.

For information on the Database Preview environment, see the section called “ The Database Preview environment”. To access the Preview Environment from the console, select https://console.aws.amazon.com/rds-preview/.

MySQL version 8.3 in the Database Preview environment

MySQL version 8.3 is now available in the Amazon RDS Database Preview environment. MySQL version 8.3 contains several improvements that are described in Changes in MySQL 8.3.0.

For information on the Database Preview environment, see the section called “ The Database Preview environment”. To access the Preview Environment from the console, select https://console.aws.amazon.com/rds-preview/.

MySQL version 8.2 in the Database Preview environment

MySQL version 8.2 is now available in the Amazon RDS Database Preview environment. MySQL version 8.2 contains several improvements that are described in Changes in MySQL 8.2.0.

For information on the Database Preview environment, see the section called " The Database Preview environment". To access the Preview Environment from the console, select https://console.aws.amazon.com/rds-preview/.

MySQL version 8.1 in the Database Preview environment

MySQL version 8.1 is now available in the Amazon RDS Database Preview environment. MySQL version 8.1 contains several improvements that are described in Changes in MySQL 8.1.0.

For information on the Database Preview environment, see the section called " The Database Preview environment". To access the Preview Environment from the console, select https://console.aws.amazon.com/rds-preview/.

Deprecated versions for Amazon RDS for MySQL

Amazon RDS for MySQL version 5.1, 5.5, and 5.6 are deprecated.

For information about the Amazon RDS deprecation policy for MySQL, see Amazon RDS FAQs.

Connecting to a DB instance running the MySQL database engine

Before you can connect to a DB instance running the MySQL database engine, you must create a DB instance. For information, see Creating an Amazon RDS DB instance. After Amazon RDS provisions your DB instance, you can use any standard MySQL client application or utility to connect to the instance. In the connection string, you specify the DNS address from the DB instance endpoint as the host parameter, and specify the port number from the DB instance endpoint as the port parameter.

To authenticate to your RDS DB instance, you can use one of the authentication methods for MySQL and AWS Identity and Access Management (IAM) database authentication:

- To learn how to authenticate to MySQL using one of the authentication methods for MySQL, see Authentication method in the MySQL documentation.
- To learn how to authenticate to MySQL using IAM database authentication, see IAM database authentication for MariaDB, MySQL, and PostgreSQL.

You can connect to a MySQL DB instance by using tools like the MySQL command-line client. For more information on using the MySQL command-line client, see mysql - the MySQL command-line client in the MySQL documentation. One GUI-based application you can use to connect is MySQL Workbench. For more information, see the Download MySQL Workbench page. For information about installing MySQL (including the MySQL command-line client), see Installing and upgrading MySQL.

To connect to a DB instance from outside of its Amazon VPC, the DB instance must be publicly accessible, access must be granted using the inbound rules of the DB instance's security group, and other requirements must be met. For more information, see Can't connect to Amazon RDS DB instance.

You can use Secure Sockets Layer (SSL) or Transport Layer Security (TLS) encryption on connections to a MySQL DB instance. For information, see Using SSL/TLS with a MySQL DB instance. If you are using AWS Identity and Access Management (IAM) database authentication, make sure to use an SSL/TLS connection. For information, see IAM database authentication for MariaDB, MySQL, and PostgreSQL.

You can also connect to a DB instance from a web server. For more information, see Tutorial: Create a web server and an Amazon RDS DB instance.

> **Note**
>
> For information on connecting to a MariaDB DB instance, see Connecting to a DB instance running the MariaDB database engine.

Contents

Finding the connection information for an RDS for MySQL DB instance

The connection information for a DB instance includes its endpoint, port, and a valid database user, such as the master user. For example, suppose that an endpoint value is `mydb.123456789012.us-east-1.rds.amazonaws.com`. In this case, the port value is `3306`, and the database user is `admin`. Given this information, you specify the following values in a connection string:

- For host or host name or DNS name, specify `mydb.123456789012.us-east-1.rds.amazonaws.com`.
- For port, specify `3306`.
- For user, specify `admin`.

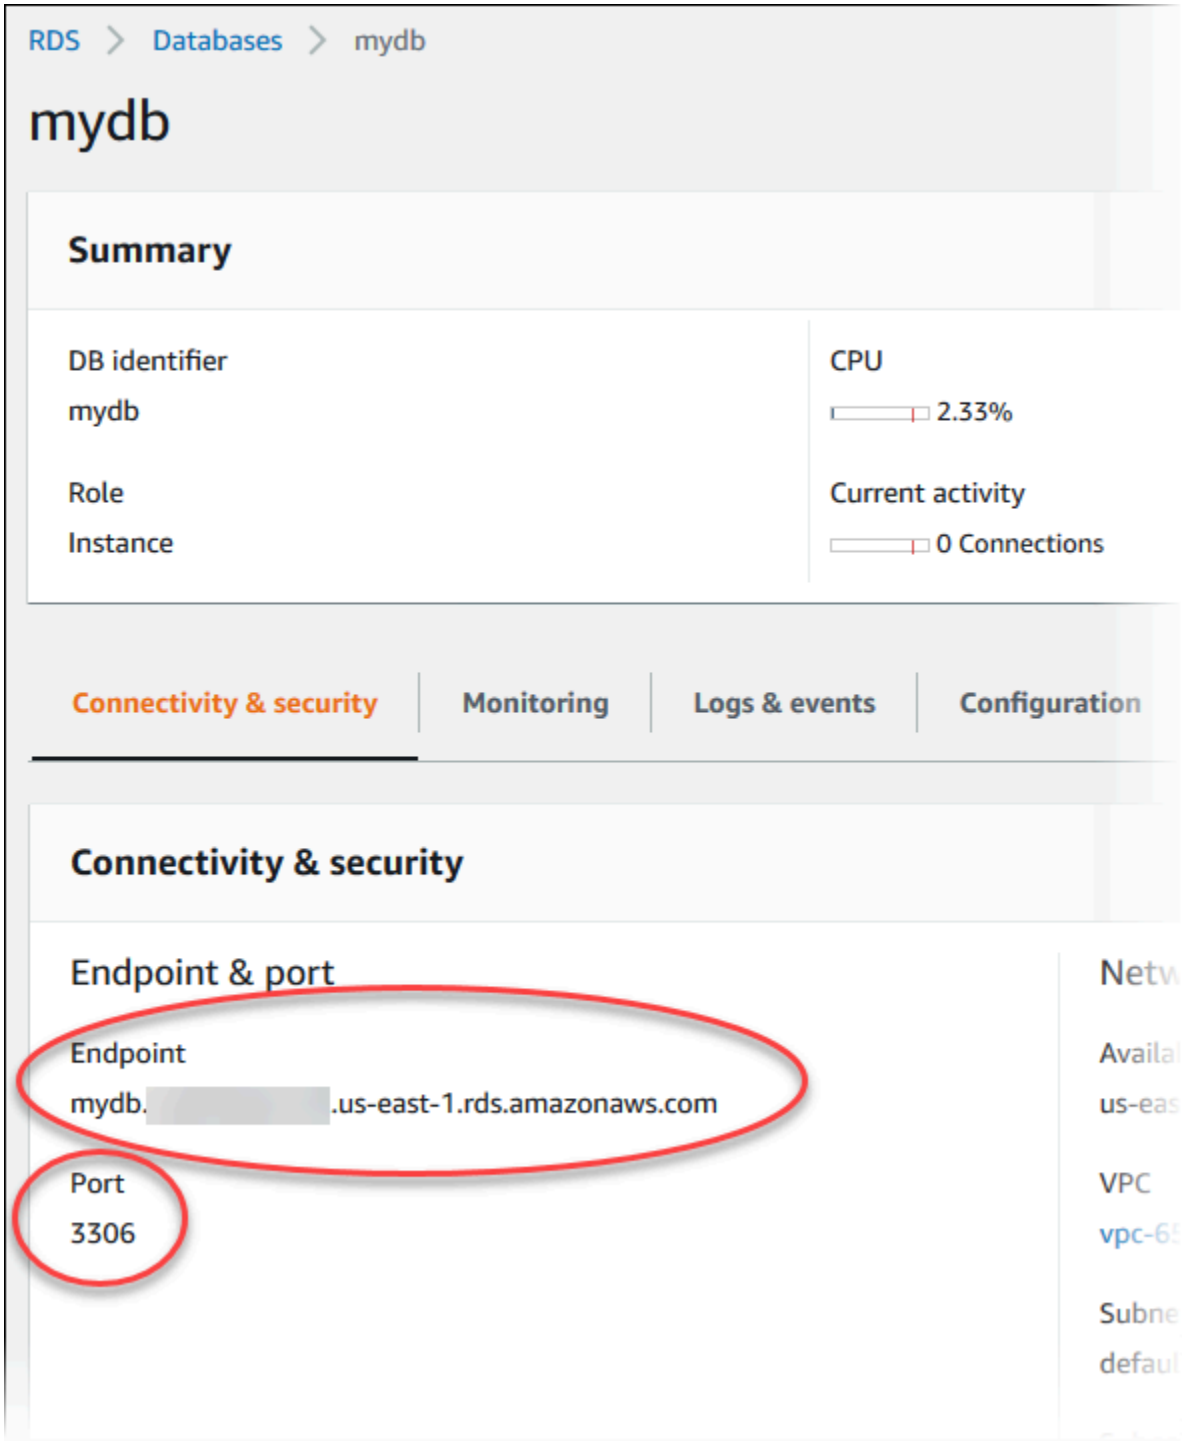
To connect to a DB instance, use any client for the MySQL DB engine. For example, you might use the MySQL command-line client or MySQL Workbench.

To find the connection information for a DB instance, you can use the AWS Management Console, the AWS CLI describe-db-instances command, or the Amazon RDS API DescribeDBInstances operation to list its details.

Console

To find the connection information for a DB instance in the AWS Management Console

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases** to display a list of your DB instances.
3. Choose the name of the MySQL DB instance to display its details.
4. On the **Connectivity & security** tab, copy the endpoint. Also, note the port number. You need both the endpoint and the port number to connect to the DB instance.



5. If you need to find the master user name, choose the **Configuration** tab and view the **Master username** value.

AWS CLI

To find the connection information for a MySQL DB instance by using the AWS CLI, call the describe-db-instances command. In the call, query for the DB instance ID, endpoint, port, and master user name.

For Linux, macOS, or Unix:

```
aws rds describe-db-instances \
  --filters "Name=engine,Values=mysql" \
  --query "*[].[DBInstanceIdentifier,Endpoint.Address,Endpoint.Port,MasterUsername]"
```

For Windows:

```
aws rds describe-db-instances ^
  --filters "Name=engine,Values=mysql" ^
  --query "*[].[DBInstanceIdentifier,Endpoint.Address,Endpoint.Port,MasterUsername]"
```

Your output should be similar to the following.

```
[
    [
        "mydb1",
        "mydb1.123456789012.us-east-1.rds.amazonaws.com",
        3306,
        "admin"
    ],
    [
        "mydb2",
        "mydb2.123456789012.us-east-1.rds.amazonaws.com",
        3306,
        "admin"
    ]
]
```

RDS API

To find the connection information for a DB instance by using the Amazon RDS API, call the DescribeDBInstances operation. In the output, find the values for the endpoint address, endpoint port, and master user name.

Installing the MySQL command-line client

Most Linux distributions include the MariaDB client instead of the Oracle MySQL client. To install the MySQL command-line client on Amazon Linux 2023, run the following command:

```
sudo dnf install mariadb105
```

To install the MySQL command-line client on Amazon Linux 2, run the following command:

```
sudo yum install mariadb
```

To install the MySQL command-line client on most DEB-based Linux distributions, run the following command:

```
apt-get install mariadb-client
```

To check the version of your MySQL command-line client, run the following command:

```
mysql --version
```

To read the MySQL documentation for your current client version, run the following command:

```
man mysql
```

Connecting from the MySQL command-line client (unencrypted)

> **Important**
>
> Only use an unencrypted MySQL connection when the client and server are in the same VPC and the network is trusted. For information about using encrypted connections, see Connecting from the MySQL command-line client with SSL/TLS (encrypted).

To connect to a DB instance using the MySQL command-line client, enter the following command at the command prompt. For the -h parameter, substitute the DNS name (endpoint) for your DB instance. For the -P parameter, substitute the port for your DB instance. For the -u parameter, substitute the user name of a valid database user, such as the master user. Enter the master user password when prompted.

```
mysql -h mysql-instance1.123456789012.us-east-1.rds.amazonaws.com -P 3306 -
u mymasteruser -p
```

After you enter the password for the user, you should see output similar to the following.

```
Welcome to the MySQL monitor.  Commands end with ; or \g.
Your MySQL connection id is 9738
Server version: 8.0.28 Source distribution

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql>
```

Connecting from MySQL Workbench

To connect from MySQL Workbench

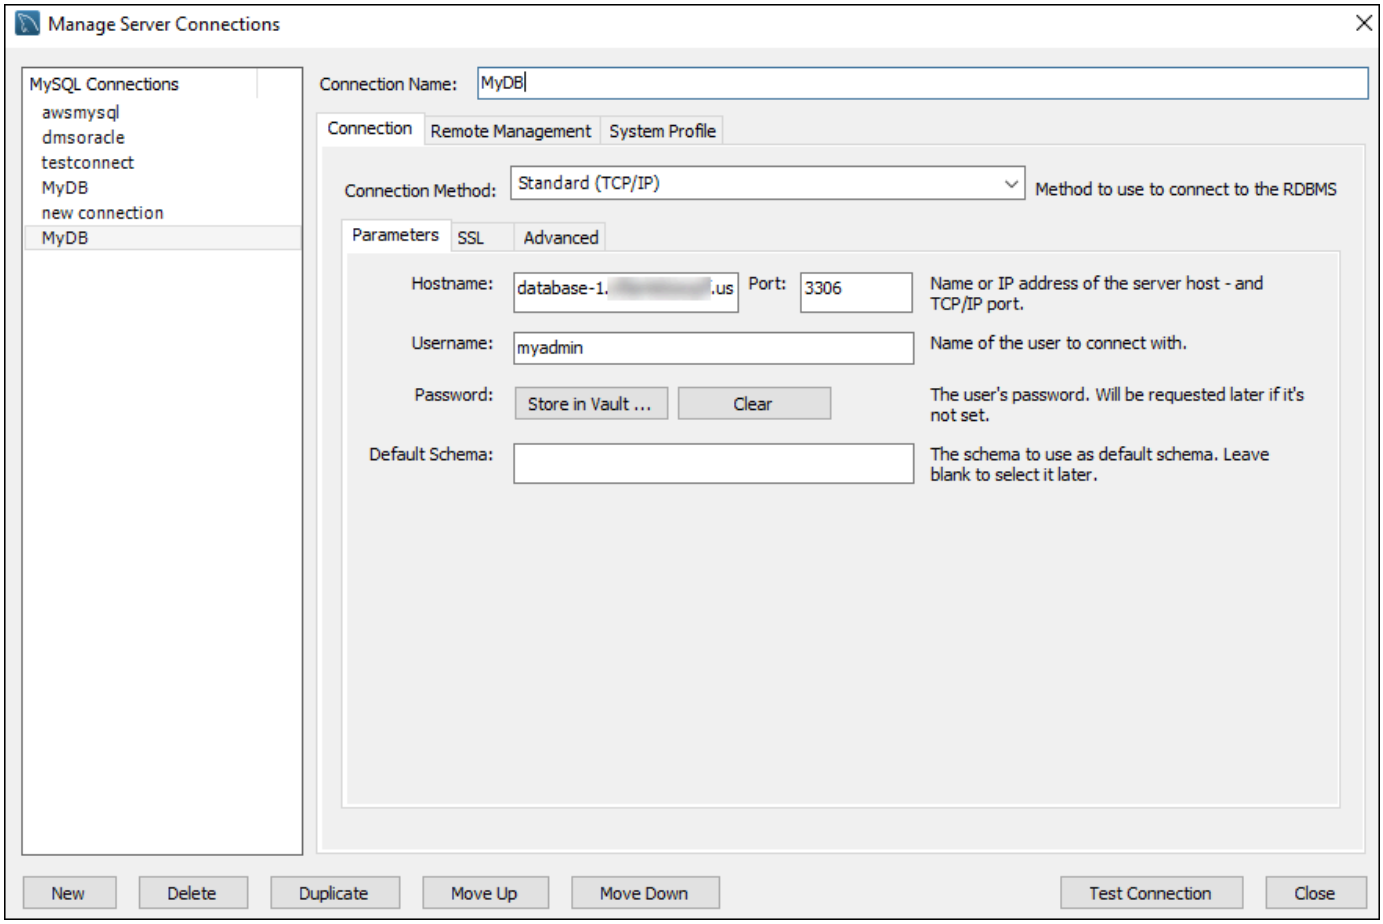
1. Download and install MySQL Workbench at Download MySQL Workbench.
2. Open MySQL Workbench.

3. From **Database**, choose **Manage Connections**.
4. In the **Manage Server Connections** window, choose **New**.
5. In the **Connect to Database** window, enter the following information:

   - **Stored Connection** – Enter a name for the connection, such as **MyDB**.
   - **Hostname** – Enter the DB instance endpoint.

- **Port** – Enter the port used by the DB instance.
- **Username** – Enter the user name of a valid database user, such as the master user.
- **Password** – Optionally, choose **Store in Vault** and then enter and save the password for the user.

The window looks similar to the following:



You can use the features of MySQL Workbench to customize connections. For example, you can use the **SSL** tab to configure SSL/TLS connections. For information about using MySQL Workbench, see the MySQL Workbench documentation. Encrypting client connections to MySQL DB instances with SSL/TLS, see Encrypting client connections to MySQL DB instances with SSL/TLS.

6. Optionally, choose **Test Connection** to confirm that the connection to the DB instance is successful.
7. Choose **Close**.
8. From **Database**, choose **Connect to Database**.

9. From **Stored Connection**, choose your connection.
10. Choose **OK**.

Connecting to RDS for MySQL with the Amazon Web Services (AWS) JDBC Driver

The Amazon Web Services (AWS) JDBC Driver is designed as an advanced JDBC wrapper. This wrapper is complementary to and extends the functionality of an existing JDBC driver. The driver is drop-in compatible with the community MySQL Connector/J driver and the community MariaDB Connector/J driver.

To install the AWS JDBC Driver, append the AWS JDBC Driver .jar file (located in the application CLASSPATH), and keep references to the respective community driver. Update the respective connection URL prefix as follows:

- `jdbc:mysql://` to `jdbc:aws-wrapper:mysql://`
- `jdbc:mariadb://` to `jdbc:aws-wrapper:mariadb://`

For more information about the AWS JDBC Driver and complete instructions for using it, see the Amazon Web Services (AWS) JDBC Driver GitHub repository.

Connecting to RDS for MySQL with the Amazon Web Services (AWS) Python Driver

The Amazon Web Services (AWS) Python Driver is designed as an advanced Python wrapper. This wrapper is complementary to and extends the functionality of the open-source Psycopg driver. The AWS Python Driver supports Python versions 3.8 and higher. You can install the `aws-advanced-python-wrapper` package using the `pip` command, along with the `psycopg` open-source packages.

For more information about the AWS Python Driver and complete instructions for using it, see the Amazon Web Services (AWS) Python Driver GitHub repository.

Connecting to RDS for MySQL with the Amazon Web Services (AWS) ODBC Driver for MySQL

The AWS ODBC Driver for MySQL is a client driver designed for the high availability of RDS for MySQL. The driver can exist alongside the MySQL Connector/ODBC driver and is compatible with the same workflows.

For more information about the AWS ODBC Driver for MySQL and complete instructions for installing and using it, see the Amazon Web Services (AWS) ODBC Driver for MySQL GitHub repository.

Troubleshooting connections to your MySQL DB instance

Two common causes of connection failures to a new DB instance are:

- The DB instance was created using a security group that doesn't authorize connections from the device or Amazon EC2 instance where the MySQL application or utility is running. The DB instance must have a VPC security group that authorizes the connections. For more information, see Amazon VPC and Amazon RDS.

  You can add or edit an inbound rule in the security group. For **Source**, choose **My IP**. This allows access to the DB instance from the IP address detected in your browser.
- The DB instance was created using the default port of 3306, and your company has firewall rules blocking connections to that port from devices in your company network. To fix this failure, recreate the instance with a different port.

For more information on connection issues, see Can't connect to Amazon RDS DB instance.

Securing MySQL DB instance connections

You can manage the security of your MySQL DB instances.

Topics

MySQL security on Amazon RDS

Security for MySQL DB instances is managed at three levels:

- AWS Identity and Access Management controls who can perform Amazon RDS management actions on DB instances. When you connect to AWS using IAM credentials, your IAM account must have IAM policies that grant the permissions required to perform Amazon RDS management operations. For more information, see Identity and access management for Amazon RDS.
- When you create a DB instance, you use a VPC security group to control which devices and Amazon EC2 instances can open connections to the endpoint and port of the DB instance. These connections can be made using Secure Sockets Layer (SSL) and Transport Layer Security (TLS). In addition, firewall rules at your company can control whether devices running at your company can open connections to the DB instance.
- To authenticate login and permissions for a MySQL DB instance, you can take either of the following approaches, or a combination of them.

  You can take the same approach as with a stand-alone instance of MySQL. Commands such as `CREATE USER`, `RENAME USER`, `GRANT`, `REVOKE`, and `SET PASSWORD` work just as they do in on-premises databases, as does directly modifying database schema tables. However, directly modifying the database schema tables isn't a best practice, and starting from RDS for MySQL version 8.0.36, it isn't supported. For information, see Access control and account management in the MySQL documentation.

  You can also use IAM database authentication. With IAM database authentication, you authenticate to your DB instance by using an IAM user or IAM role and an authentication token.

An *authentication token* is a unique value that is generated using the Signature Version 4 signing process. By using IAM database authentication, you can use the same credentials to control access to your AWS resources and your databases. For more information, see IAM database authentication for MariaDB, MySQL, and PostgreSQL.

Another option is Kerberos authentication for RDS for MySQL. The DB instance works with AWS Directory Service for Microsoft Active Directory (AWS Managed Microsoft AD) to enable Kerberos authentication. When users authenticate with a MySQL DB instance joined to the trusting domain, authentication requests are forwarded. Forwarded requests go to the domain directory that you create with AWS Directory Service. For more information, see Using Kerberos authentication for MySQL.

When you create an Amazon RDS DB instance, the master user has the following default privileges:

Engine version	System privilege	Database role
RDS for MySQL version 8.0.36 and higher	SELECT, INSERT, UPDATE, DELETE, CREATE, DROP, RELOAD, PROCESS, REFERENCES , INDEX, ALTER, SHOW DATABASES , CREATE TEMPORARY TABLES, LOCK TABLES, EXECUTE, REPLICATION SLAVE, REPLICATION CLIENT , CREATE VIEW, SHOW VIEW, CREATE ROUTINE, ALTER ROUTINE, CREATE USER, EVENT, TRIGGER, CREATE ROLE, DROP ROLE, APPLICATION_PASSWORD_ADMIN , ROLE_ADMIN , SET_USER_ID , XA_RECOVER_ADMIN	rds_superuser_role For more information about rds_superuser_role , see Role-based privilege model.
RDS for MySQL versions lower than 8.0.36	SELECT, INSERT, UPDATE, DELETE, CREATE, DROP, RELOAD, PROCESS, REFERENCES , INDEX, ALTER, SHOW DATABASES , CREATE TEMPORARY TABLES, LOCK TABLES, EXECUTE, REPLICATION CLIENT , CREATE VIEW, SHOW VIEW, CREATE ROUTINE, ALTER ROUTINE, CREATE USER, EVENT, TRIGGER, REPLICATION SLAVE	—

> **Note**
>
> Although it is possible to delete the master user on the DB instance, it is not recommended. To recreate the master user, use the ModifyDBInstance RDS API operation or the modify-db-instance AWS CLI command and specify a new master user password with the appropriate parameter. If the master user does not exist in the instance, the master user is created with the specified password.

To provide management services for each DB instance, the `rdsadmin` user is created when the DB instance is created. Attempting to drop, rename, change the password, or change privileges for the `rdsadmin` account will result in an error.

To allow management of the DB instance, the standard `kill` and `kill_query` commands have been restricted. The Amazon RDS commands `rds_kill` and `rds_kill_query` are provided to allow you to end user sessions or queries on DB instances.

Using the Password Validation Plugin for RDS for MySQL

MySQL provides the `validate_password` plugin for improved security. The plugin enforces password policies using parameters in the DB parameter group for your MySQL DB instance. The plugin is supported for DB instances running MySQL version 5.7 and 8.0. For more information about the `validate_password` plugin, see The Password Validation Plugin in the MySQL documentation.

To enable the validate_password plugin for a MySQL DB instance

1. Connect to your MySQL DB instance and run the following command.

   ```
   INSTALL PLUGIN validate_password SONAME 'validate_password.so';
   ```

2. Configure the parameters for the plugin in the DB parameter group used by the DB instance.

   For more information about the parameters, see Password Validation Plugin options and variables in the MySQL documentation.

   For more information about modifying DB instance parameters, see Modifying parameters in a DB parameter group in Amazon RDS.

After installing and enabling the `password_validate` plugin, reset existing passwords to comply with your new validation policies.

Amazon RDS doesn't validate passwords. The MySQL DB instance performs password validation. If you set a user password with the AWS Management Console, the `modify-db-instance` AWS CLI command, or the `ModifyDBInstance` RDS API operation, the change can succeed even if the new password doesn't satisfy your password policies. However, a new password is set in the MySQL DB instance only if it satisfies the password policies. In this case, Amazon RDS records the following event.

```
"RDS-EVENT-0067" - An attempt to reset the master password for the DB instance has
 failed.
```

For more information about Amazon RDS events, see Working with Amazon RDS event notification.

Encrypting client connections to MySQL DB instances with SSL/TLS

Secure Sockets Layer (SSL) is an industry-standard protocol for securing network connections between client and server. After SSL version 3.0, the name was changed to Transport Layer Security (TLS). Amazon RDS supports SSL/TLS encryption for MySQL DB instances. Using SSL/TLS, you can encrypt a connection between your application client and your MySQL DB instance. SSL/TLS support is available in all AWS Regions for MySQL.

Topics

- Using SSL/TLS with a MySQL DB instance
- Requiring SSL/TLS for all connections to a MySQL DB instance
- Connecting from the MySQL command-line client with SSL/TLS (encrypted)

Using SSL/TLS with a MySQL DB instance

Amazon RDS creates an SSL/TLS certificate and installs the certificate on the DB instance when Amazon RDS provisions the instance. These certificates are signed by a certificate authority. The SSL/TLS certificate includes the DB instance endpoint as the Common Name (CN) for the SSL/TLS certificate to guard against spoofing attacks.

An SSL/TLS certificate created by Amazon RDS is the trusted root entity and should work in most cases but might fail if your application does not accept certificate chains. If your application does not accept certificate chains, you might need to use an intermediate certificate to connect to your AWS Region. For example, you must use an intermediate certificate to connect to the AWS GovCloud (US) Regions using SSL/TLS.

For information about downloading certificates, see Using SSL/TLS to encrypt a connection to a DB instance or cluster. For more information about using SSL/TLS with MySQL, see Updating applications to connect to MySQL DB instances using new SSL/TLS certificates.

MySQL uses OpenSSL for secure connections. Amazon RDS for MySQL supports Transport Layer Security (TLS) versions 1.0, 1.1, 1.2, and 1.3. TLS support depends on the MySQL version. The following table shows the TLS support for MySQL versions.

MySQL version	TLS 1.0	TLS 1.1	TLS 1.2	TLS 1.3
MySQL 8.0	Not supported	Not supported	Supported	Supported
MySQL 5.7	Supported	Supported	Supported	Not supported

You can require SSL/TLS connections for specific users accounts. For example, you can use one of the following statements, depending on your MySQL version, to require SSL/TLS connections on the user account `encrypted_user`.

To do so, use the following statement.

```
ALTER USER 'encrypted_user'@'%' REQUIRE SSL;
```

For more information on SSL/TLS connections with MySQL, see the Using encrypted connections in the MySQL documentation.

Requiring SSL/TLS for all connections to a MySQL DB instance

Use the `require_secure_transport` parameter to require that all user connections to your MySQL DB instance use SSL/TLS. By default, the `require_secure_transport` parameter is set to `OFF`. You can set the `require_secure_transport` parameter to `ON` to require SSL/TLS for connections to your DB instance.

You can set the `require_secure_transport` parameter value by updating the DB parameter group for your DB instance. You don't need to reboot your DB instance for the change to take effect.

When the `require_secure_transport` parameter is set to `ON` for a DB instance, a database client can connect to it if it can establish an encrypted connection. Otherwise, an error message similar to the following is returned to the client:

```
MySQL Error 3159 (HY000): Connections using insecure transport are prohibited while --
require_secure_transport=ON.
```

For information about setting parameters, see Modifying parameters in a DB parameter group in Amazon RDS.

For more information about the `require_secure_transport` parameter, see the MySQL documentation.

Connecting from the MySQL command-line client with SSL/TLS (encrypted)

The `mysql` client program parameters are slightly different if you are using the MySQL 5.7 version, the MySQL 8.0 version, or the MariaDB version.

To find out which version you have, run the `mysql` command with the `--version` option. In the following example, the output shows that the client program is from MariaDB.

```
$ mysql --version
mysql  Ver 15.1 Distrib 10.5.15-MariaDB, for osx10.15 (x86_64) using readline 5.1
```

Most Linux distributions, such as Amazon Linux, CentOS, SUSE, and Debian have replaced MySQL with MariaDB, and the `mysql` version in them is from MariaDB.

To connect to your DB instance using SSL/TLS, follow these steps:

To connect to a DB instance with SSL/TLS using the MySQL command-line client

1. Download a root certificate that works for all AWS Regions.

   For information about downloading certificates, see Using SSL/TLS to encrypt a connection to a DB instance or cluster.
2. Use a MySQL command-line client to connect to a DB instance with SSL/TLS encryption. For the `-h` parameter, substitute the DNS name (endpoint) for your DB instance. For the `--ssl-ca`

parameter, substitute the SSL/TLS certificate file name. For the `-P` parameter, substitute the port for your DB instance. For the `-u` parameter, substitute the user name of a valid database user, such as the master user. Enter the master user password when prompted.

The following example shows how to launch the client using the `--ssl-ca` parameter using the MySQL 5.7 client or later:

```
mysql -h mysql-instance1.123456789012.us-east-1.rds.amazonaws.com --ssl-ca=global-bundle.pem --ssl-mode=REQUIRED -P 3306 -u myadmin -p
```

To require that the SSL/TLS connection verifies the DB instance endpoint against the endpoint in the SSL/TLS certificate, enter the following command:

```
mysql -h mysql-instance1.123456789012.us-east-1.rds.amazonaws.com --ssl-ca=global-bundle.pem --ssl-mode=VERIFY_IDENTITY -P 3306 -u myadmin -p
```

The following example shows how to launch the client using the `--ssl-ca` parameter using the MariaDB client:

```
mysql -h mysql-instance1.123456789012.us-east-1.rds.amazonaws.com --ssl-ca=global-bundle.pem --ssl -P 3306 -u myadmin -p
```

3. Enter the master user password when prompted.

You will see output similar to the following.

```
Welcome to the MySQL monitor.  Commands end with ; or \g.
Your MySQL connection id is 9738
Server version: 8.0.28 Source distribution

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql>
```

Updating applications to connect to MySQL DB instances using new SSL/TLS certificates

As of January 13, 2023, Amazon RDS has published new Certificate Authority (CA) certificates for connecting to your RDS DB instances using Secure Socket Layer or Transport Layer Security

(SSL/TLS). Following, you can find information about updating your applications to use the new certificates.

This topic can help you to determine whether any client applications use SSL/TLS to connect to your DB instances. If they do, you can further check whether those applications require certificate verification to connect.

> **Note**
>
> Some applications are configured to connect to MySQL DB instances only if they can successfully verify the certificate on the server. For such applications, you must update your client application trust stores to include the new CA certificates.
> You can specify the following SSL modes: `disabled`, `preferred`, and `required`. When you use the `preferred` SSL mode and the CA certificate doesn't exist or isn't up to date, the connection falls back to not using SSL and connects without encryption.
> Because these later versions use the OpenSSL protocol, an expired server certificate doesn't prevent successful connections unless the `required` SSL mode is specified.
> We recommend avoiding `preferred` mode. In `preferred` mode, if the connection encounters an invalid certificate, it stops using encryption and proceeds unencrypted.

After you update your CA certificates in the client application trust stores, you can rotate the certificates on your DB instances. We strongly recommend testing these procedures in a development or staging environment before implementing them in your production environments.

For more information about certificate rotation, see Rotating your SSL/TLS certificate. For more information about downloading certificates, see Using SSL/TLS to encrypt a connection to a DB instance or cluster. For information about using SSL/TLS with MySQL DB instances, see Using SSL/TLS with a MySQL DB instance.

Topics

- Determining whether any applications are connecting to your MySQL DB instance using SSL
- Determining whether a client requires certificate verification to connect
- Updating your application trust store
- Example Java code for establishing SSL connections

Determining whether any applications are connecting to your MySQL DB instance using SSL

If you are using Amazon RDS for MySQL version 5.7 or 8.0 and the Performance Schema is enabled, run the following query to check if connections are using SSL/TLS. For information about enabling the Performance Schema, see Performance Schema quick start in the MySQL documentation.

```
mysql> SELECT id, user, host, connection_type
       FROM performance_schema.threads pst
       INNER JOIN information_schema.processlist isp
       ON pst.processlist_id = isp.id;
```

In this sample output, you can see both your own session (`admin`) and an application logged in as `webapp1` are using SSL.

```
+----+-----------------+------------------+-----------------+
| id | user            | host             | connection_type |
+----+-----------------+------------------+-----------------+
|  8 | admin           | 10.0.4.249:42590 | SSL/TLS         |
|  4 | event_scheduler | localhost        | NULL            |
| 10 | webapp1         | 159.28.1.1:42189 | SSL/TLS         |
+----+-----------------+------------------+-----------------+
3 rows in set (0.00 sec)
```

Determining whether a client requires certificate verification to connect

You can check whether JDBC clients and MySQL clients require certificate verification to connect.

JDBC

The following example with MySQL Connector/J 8.0 shows one way to check an application's JDBC connection properties to determine whether successful connections require a valid certificate. For more information on all of the JDBC connection options for MySQL, see Configuration properties in the MySQL documentation.

When using the MySQL Connector/J 8.0, an SSL connection requires verification against the DB server certificate if your connection properties have `sslMode` set to `VERIFY_CA` or `VERIFY_IDENTITY`, as in the following example.

```
Properties properties = new Properties();
properties.setProperty("sslMode", "VERIFY_IDENTITY");
properties.put("user", DB_USER);
properties.put("password", DB_PASSWORD);
```

Note

If you use either the MySQL Java Connector v5.1.38 or later, or the MySQL Java Connector v8.0.9 or later to connect to your databases, even if you haven't explicitly configured your applications to use SSL/TLS when connecting to your databases, these client drivers default to using SSL/TLS. In addition, when using SSL/TLS, they perform partial certificate verification and fail to connect if the database server certificate is expired.

MySQL

The following examples with the MySQL Client show two ways to check a script's MySQL connection to determine whether successful connections require a valid certificate. For more information on all of the connection options with the MySQL Client, see Client-side configuration for encrypted connections in the MySQL documentation.

When using the MySQL 5.7 or MySQL 8.0 Client, an SSL connection requires verification against the server CA certificate if for the `--ssl-mode` option you specify `VERIFY_CA` or `VERIFY_IDENTITY`, as in the following example.

```
mysql -h mysql-database.rds.amazonaws.com -uadmin -ppassword --ssl-ca=/tmp/ssl-cert.pem
 --ssl-mode=VERIFY_CA
```

When using the MySQL 5.6 Client, an SSL connection requires verification against the server CA certificate if you specify the `--ssl-verify-server-cert` option, as in the following example.

```
mysql -h mysql-database.rds.amazonaws.com -uadmin -ppassword --ssl-ca=/tmp/ssl-cert.pem
 --ssl-verify-server-cert
```

Updating your application trust store

For information about updating the trust store for MySQL applications, see Installing SSL certificates in the MySQL documentation.

For information about downloading the root certificate, see Using SSL/TLS to encrypt a connection to a DB instance or cluster.

For sample scripts that import certificates, see Sample script for importing certificates into your trust store.

> **Note**
>
> When you update the trust store, you can retain older certificates in addition to adding the new certificates.

If you are using the mysql JDBC driver in an application, set the following properties in the application.

```
System.setProperty("javax.net.ssl.trustStore", certs);
System.setProperty("javax.net.ssl.trustStorePassword", "password");
```

When you start the application, set the following properties.

```
java -Djavax.net.ssl.trustStore=/path_to_trust_store/MyTruststore.jks -
Djavax.net.ssl.trustStorePassword=my_trust_store_password com.companyName.MyApplication
```

> **Note**
>
> Specify a password other than the prompt shown here as a security best practice.

Example Java code for establishing SSL connections

The following code example shows how to set up the SSL connection that validates the server certificate using JDBC.

```
public class MySQLSSLTest {

        private static final String DB_USER = "username";
        private static final String DB_PASSWORD = "password";
        // This trust store has only the prod root ca.
        private static final String TRUST_STORE_FILE_PATH = "file-path-to-trust-store";
        private static final String TRUST_STORE_PASS = "trust-store-password";

        public static void test(String[] args) throws Exception {
            Class.forName("com.mysql.jdbc.Driver");

            System.setProperty("javax.net.ssl.trustStore", TRUST_STORE_FILE_PATH);
            System.setProperty("javax.net.ssl.trustStorePassword", TRUST_STORE_PASS);

            Properties properties = new Properties();
            properties.setProperty("sslMode", "VERIFY_IDENTITY");
            properties.put("user", DB_USER);
            properties.put("password", DB_PASSWORD);

            Connection connection = null;
            Statement stmt = null;
            ResultSet rs = null;
            try {
                connection =
 DriverManager.getConnection("jdbc:mysql://mydatabase.123456789012.us-
east-1.rds.amazonaws.com:3306",properties);
                stmt = connection.createStatement();
                rs=stmt.executeQuery("SELECT 1 from dual");
            } finally {
                if (rs != null) {
                    try {
                        rs.close();
                    } catch (SQLException e) {
                    }
                }
                if (stmt != null) {
```

```
                try {
                     stmt.close();
                 } catch (SQLException e) {
                }
            }
            if (connection != null) {
                try {
                    connection.close();
                } catch (SQLException e) {
                    e.printStackTrace();
                }
            }
        }
        return;
    }
}
```

Important

After you have determined that your database connections use SSL/TLS and have updated your application trust store, you can update your database to use the rds-ca-rsa2048-g1 certificates. For instructions, see step 3 in Updating your CA certificate by modifying your DB instance or cluster.
Specify a password other than the prompt shown here as a security best practice.

Using Kerberos authentication for MySQL

You can use Kerberos authentication to authenticate users when they connect to your MySQL DB instance. The DB instance works with AWS Directory Service for Microsoft Active Directory (AWS Managed Microsoft AD) to enable Kerberos authentication. When users authenticate with a MySQL DB instance joined to the trusting domain, authentication requests are forwarded. Forwarded requests go to the domain directory that you create with AWS Directory Service.

Keeping all of your credentials in the same directory can save you time and effort. With this approach, you have a centralized place for storing and managing credentials for multiple DB instances. Using a directory can also improve your overall security profile.

Region and version availability

Feature availability and support varies across specific versions of each database engine, and across AWS Regions. For more information on version and Region availability of Amazon RDS with Kerberos authentication, see Supported Regions and DB engines for Kerberos authentication in Amazon RDS.

Overview of Setting up Kerberos authentication for MySQL DB instances

To set up Kerberos authentication for a MySQL DB instance, complete the following general steps, described in more detail later:

1. Use AWS Managed Microsoft AD to create an AWS Managed Microsoft AD directory. You can use the AWS Management Console, the AWS CLI, or the AWS Directory Service to create the directory. For details about doing so, see Create your AWS Managed Microsoft AD directory in the *AWS Directory Service Administration Guide*.
2. Create an AWS Identity and Access Management (IAM) role that uses the managed IAM policy `AmazonRDSDirectoryServiceAccess`. The role allows Amazon RDS to make calls to your directory.

   For the role to allow access, the AWS Security Token Service (AWS STS) endpoint must be activated in the AWS Region for your AWS account. AWS STS endpoints are active by default in all AWS Regions, and you can use them without any further actions. For more information, see Activating and deactivating AWS STS in an AWS Region in the *IAM User Guide*.
3. Create and configure users in the AWS Managed Microsoft AD directory using the Microsoft Active Directory tools. For more information about creating users in your Active Directory, see Manage users and groups in AWS managed Microsoft AD in the *AWS Directory Service Administration Guide*.
4. Create or modify a MySQL DB instance. If you use either the CLI or RDS API in the create request, specify a domain identifier with the `Domain` parameter. Use the `d-*` identifier that was generated when you created your directory and the name of the role that you created.

   If you modify an existing MySQL DB instance to use Kerberos authentication, set the domain and IAM role parameters for the DB instance. Locate the DB instance in the same VPC as the domain directory.
5. Use the Amazon RDS master user credentials to connect to the MySQL DB instance. Create the user in MySQL using the `CREATE USER` clause `IDENTIFIED WITH 'auth_pam'`. Users that you create this way can log in to the MySQL DB instance using Kerberos authentication.

Setting up Kerberos authentication for MySQL DB instances

You use AWS Managed Microsoft AD to set up Kerberos authentication for a MySQL DB instance. To set up Kerberos authentication, you take the following steps.

Step 1: Create a directory using AWS Managed Microsoft AD

AWS Directory Service creates a fully managed Active Directory in the AWS Cloud. When you create an AWS Managed Microsoft AD directory, AWS Directory Service creates two domain controllers and Domain Name System (DNS) servers on your behalf. The directory servers are created in different subnets in a VPC. This redundancy helps make sure that your directory remains accessible even if a failure occurs.

When you create an AWS Managed Microsoft AD directory, AWS Directory Service performs the following tasks on your behalf:

- Sets up an Active Directory within the VPC.
- Creates a directory administrator account with the user name Admin and the specified password. You use this account to manage your directory.

  > **Note**
  >
  > Be sure to save this password. AWS Directory Service doesn't store it. You can reset it, but you can't retrieve it.

- Creates a security group for the directory controllers.

When you launch an AWS Managed Microsoft AD, AWS creates an Organizational Unit (OU) that contains all of your directory's objects. This OU has the NetBIOS name that you typed when you created your directory and is located in the domain root. The domain root is owned and managed by AWS.

The Admin account that was created with your AWS Managed Microsoft AD directory has permissions for the most common administrative activities for your OU:

- Create, update, or delete users
- Add resources to your domain such as file or print servers, and then assign permissions for those resources to users in your OU
- Create additional OUs and containers

- Delegate authority
- Restore deleted objects from the Active Directory Recycle Bin
- Run AD and DNS Windows PowerShell modules on the Active Directory Web Service

The Admin account also has rights to perform the following domain-wide activities:

- Manage DNS configurations (add, remove, or update records, zones, and forwarders)
- View DNS event logs
- View security event logs

To create a directory with AWS Managed Microsoft AD

1. Sign in to the AWS Management Console and open the AWS Directory Service console at https://console.aws.amazon.com/directoryservicev2/.
2. In the navigation pane, choose **Directories** and choose **Set up Directory**.
3. Choose **AWS Managed Microsoft AD**. AWS Managed Microsoft AD is the only option that you can currently use with Amazon RDS.
4. Enter the following information:

   Directory DNS name

   The fully qualified name for the directory, such as **`corp.example.com`**.

   Directory NetBIOS name

   The short name for the directory, such as **`CORP`**.

   Directory description

   (Optional) A description for the directory.

   Admin password

   The password for the directory administrator. The directory creation process creates an administrator account with the user name Admin and this password.

   The directory administrator password and can't include the word "admin." The password is case-sensitive and must be 8–64 characters in length. It must also contain at least one character from three of the following four categories:

- Lowercase letters (a–z)
- Uppercase letters (A–Z)
- Numbers (0–9)
- Non-alphanumeric characters (~!@#$%^&*_-+=`|\(){}[]:;"'<>,.?/)

Confirm password

The administrator password retyped.

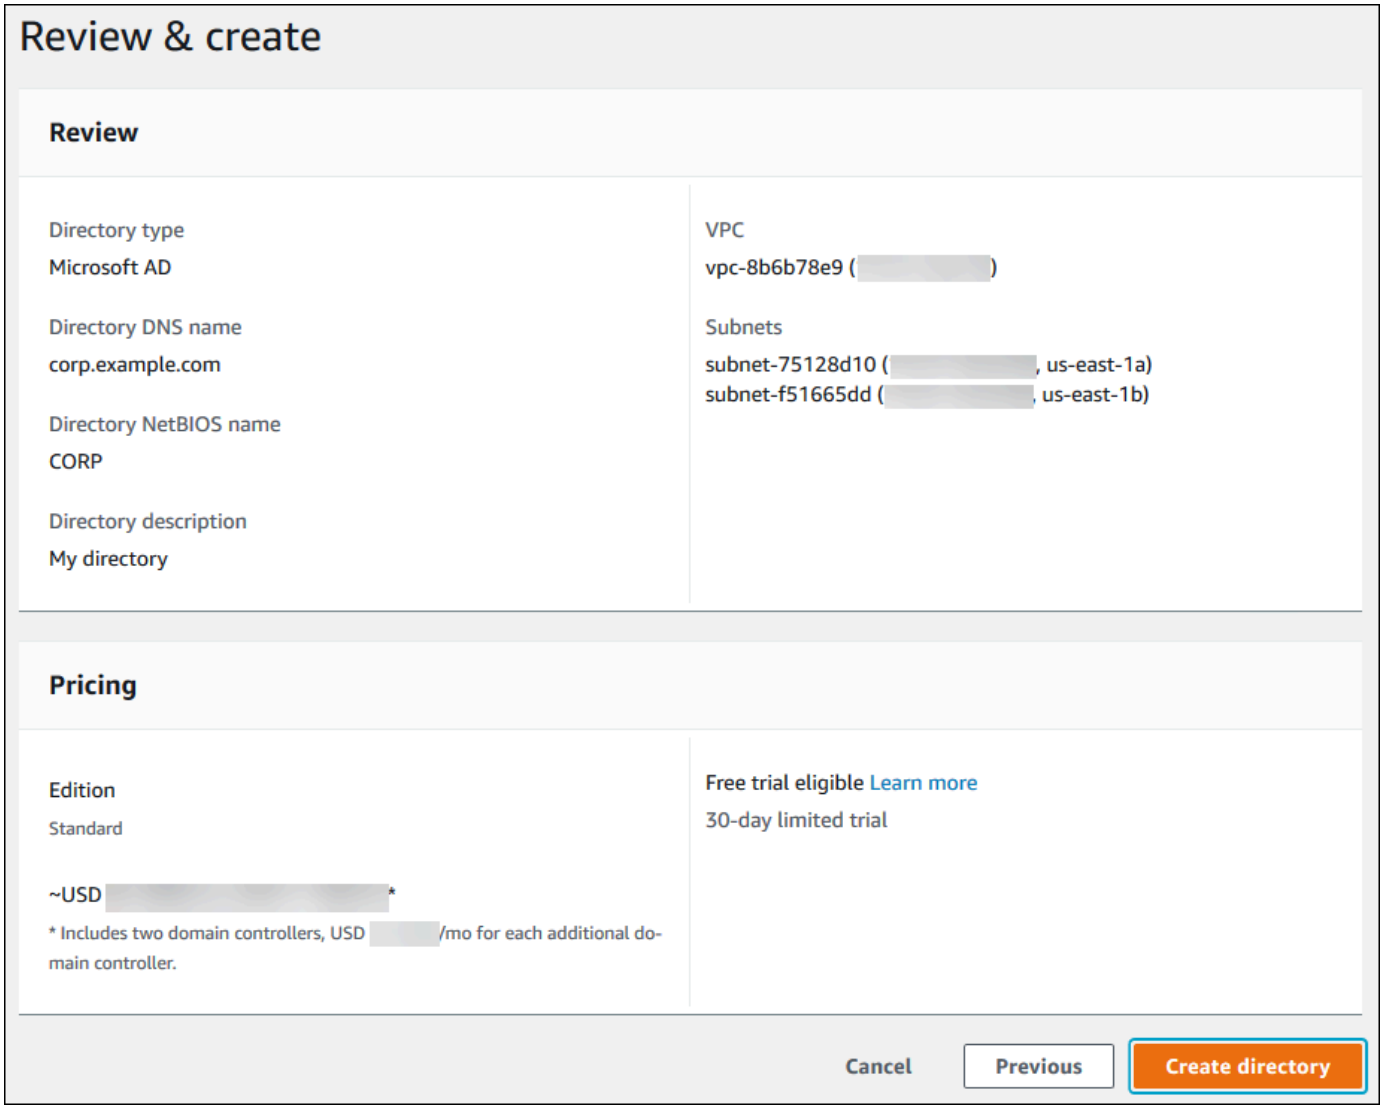
5. Choose **Next**.
6. Enter the following information in the **Networking** section and then choose **Next**:

   VPC

   The VPC for the directory. Create the MySQL DB instance in this same VPC.

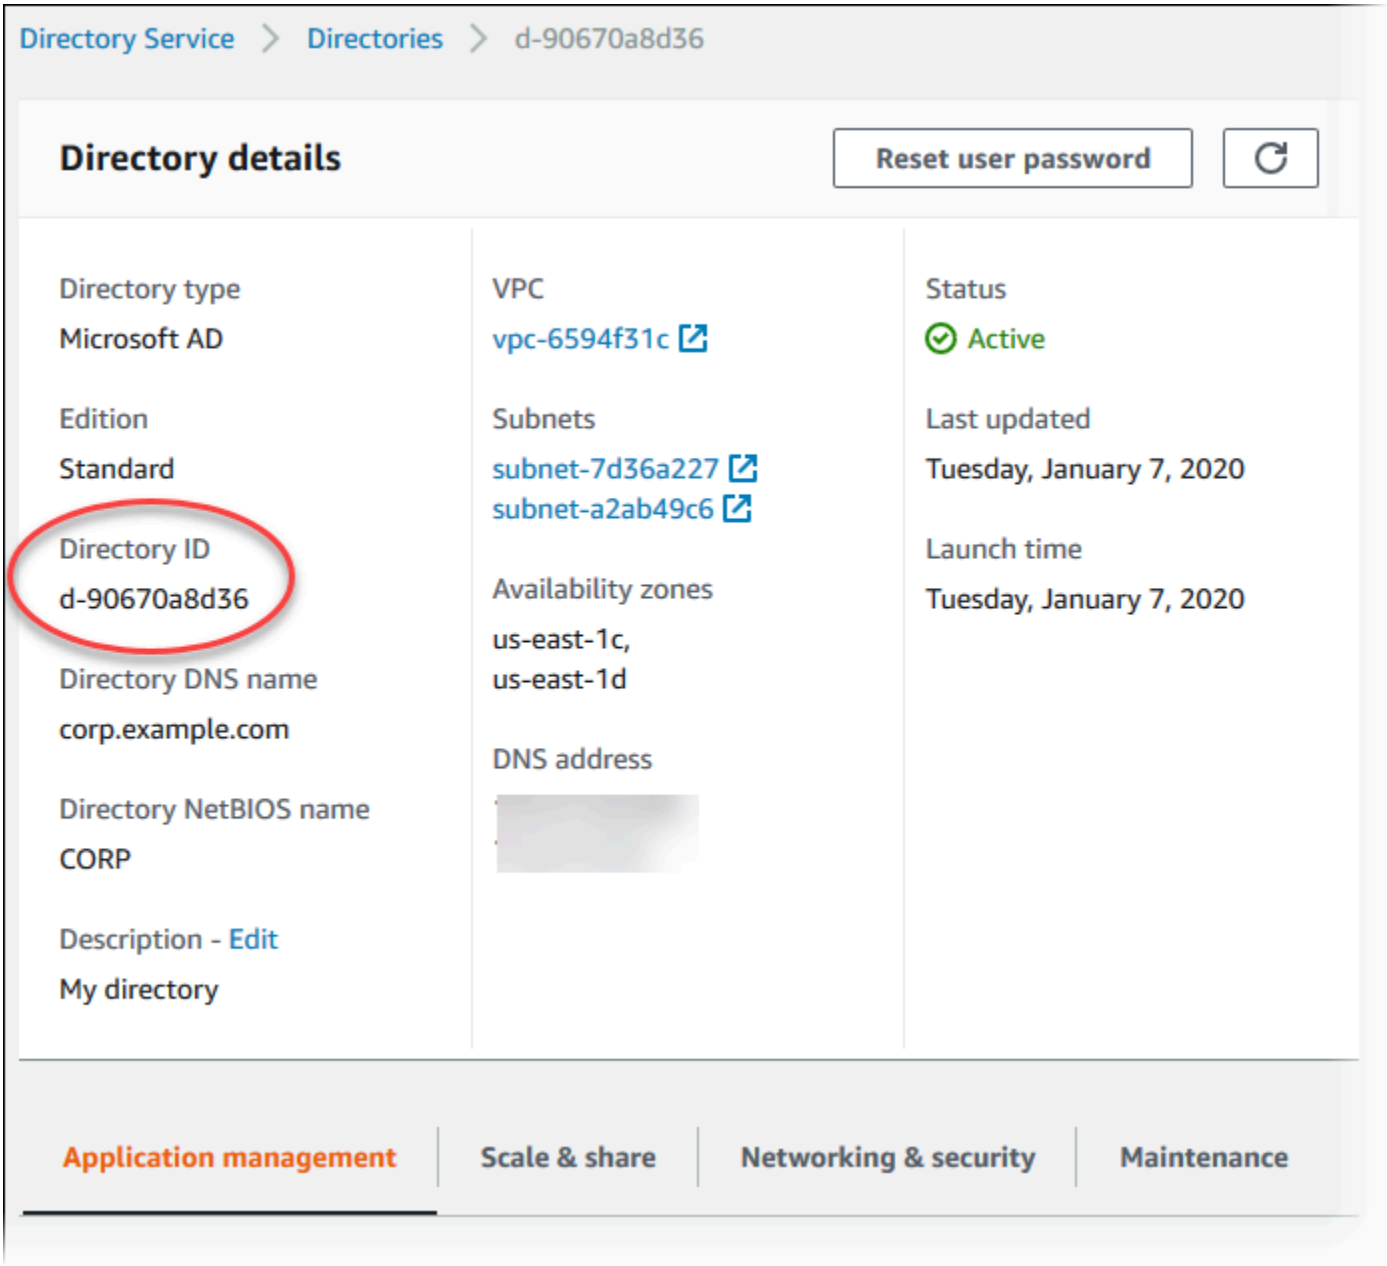
   Subnets

   Subnets for the directory servers. The two subnets must be in different Availability Zones.
7. Review the directory information and make any necessary changes. When the information is correct, choose **Create directory**.



It takes several minutes for the directory to be created. When it has been successfully created, the **Status** value changes to **Active**.

To see information about your directory, choose the directory name in the directory listing. Note the **Directory ID** value because you need this value when you create or modify your MySQL DB instance.



Step 2: Create the IAM role for use by Amazon RDS

For Amazon RDS to call AWS Directory Service for you, an IAM role that uses the managed IAM policy `AmazonRDSDirectoryServiceAccess` is required. This role allows Amazon RDS to make calls to the AWS Directory Service.

When a DB instance is created using the AWS Management Console and the console user has the `iam:CreateRole` permission, the console creates this role automatically. In this case, the role name is `rds-directoryservice-kerberos-access-role`. Otherwise, you must create the

IAM role manually. When you create this IAM role, choose `Directory Service`, and attach the AWS managed policy `AmazonRDSDirectoryServiceAccess` to it.

For more information about creating IAM roles for a service, see Creating a role to delegate permissions to an AWS service in the *IAM User Guide*.

> **Note**
>
> The IAM role used for Windows Authentication for RDS for SQL Server can't be used for RDS for MySQL.

Optionally, you can create policies with the required permissions instead of using the managed IAM policy `AmazonRDSDirectoryServiceAccess`. In this case, the IAM role must have the following IAM trust policy.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "",
      "Effect": "Allow",
      "Principal": {
        "Service": [
          "directoryservice.rds.amazonaws.com",
          "rds.amazonaws.com"
        ]
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
```

The role must also have the following IAM role policy.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Action": [
        "ds:DescribeDirectories",
```

```
        "ds:AuthorizeApplication",
        "ds:UnauthorizeApplication",
        "ds:GetAuthorizedApplicationDetails"
      ],
    "Effect": "Allow",
    "Resource": "*"
    }
  ]
}
```

Step 3: Create and configure users

You can create users with the Active Directory Users and Computers tool. This tool is part of the Active Directory Domain Services and Active Directory Lightweight Directory Services tools. Users represent individual people or entities that have access to your directory.

To create users in an AWS Directory Service directory, you must be connected to an Amazon EC2 instance based on Microsoft Windows. This instance must be a member of the AWS Directory Service directory and be logged in as a user that has privileges to create users. For more information, see Manage users and groups in AWS Managed Microsoft AD in the *AWS Directory Service Administration Guide*.

Step 4: Create or modify a MySQL DB instance

Create or modify a MySQL DB instance for use with your directory. You can use the console, CLI, or RDS API to associate a DB instance with a directory. You can do this in one of the following ways:

- Create a new MySQL DB instance using the console, the create-db-instance CLI command, or the CreateDBInstance RDS API operation.

  For instructions, see Creating an Amazon RDS DB instance.
- Modify an existing MySQL DB instance using the console, the modify-db-instance CLI command, or the ModifyDBInstance RDS API operation.

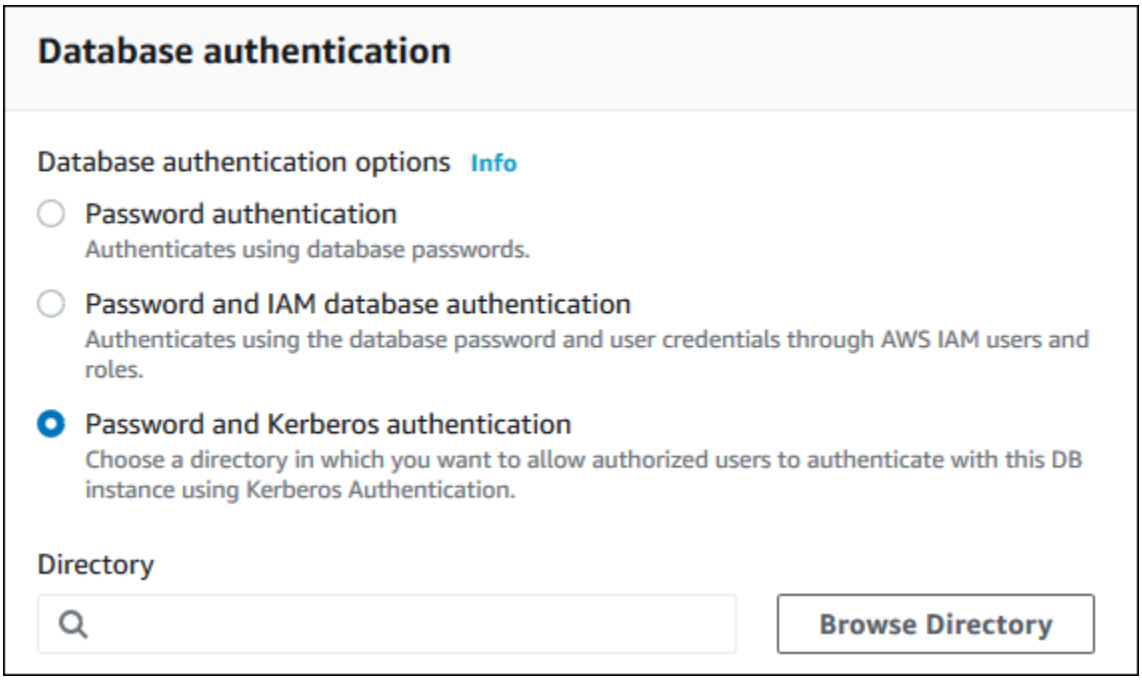
  For instructions, see Modifying an Amazon RDS DB instance.
- Restore a MySQL DB instance from a DB snapshot using the console, the restore-db-instance-from-db-snapshot CLI command, or the RestoreDBInstanceFromDBSnapshot RDS API operation.

  For instructions, see Restoring to a DB instance.
- Restore a MySQL DB instance to a point-in-time using the console, the restore-db-instance-to-point-in-time CLI command, or the RestoreDBInstanceToPointInTime RDS API operation.

For instructions, see Restoring a DB instance to a specified time.

Kerberos authentication is only supported for MySQL DB instances in a VPC. The DB instance can be in the same VPC as the directory, or in a different VPC. The DB instance must use a security group that allows egress within the directory's VPC so the DB instance can communicate with the directory.

When you use the console to create, modify, or restore a DB instance, choose **Password and Kerberos authentication** in the **Database authentication** section. Choose **Browse Directory** and then select the directory, or choose **Create a new directory**.



When you use the AWS CLI or RDS API, associate a DB instance with a directory. The following parameters are required for the DB instance to use the domain directory you created:

- For the `--domain` parameter, use the domain identifier ("d-*" identifier) generated when you created the directory.
- For the `--domain-iam-role-name` parameter, use the role you created that uses the managed IAM policy `AmazonRDSDirectoryServiceAccess`.

For example, the following CLI command modifies a DB instance to use a directory.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier mydbinstance \
    --domain d-ID \
    --domain-iam-role-name role-name
```

For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier mydbinstance ^
    --domain d-ID ^
    --domain-iam-role-name role-name
```

Important

If you modify a DB instance to enable Kerberos authentication, reboot the DB instance after making the change.

Step 5: Create Kerberos authentication MySQL logins

Use the Amazon RDS master user credentials to connect to the MySQL DB instance as you do any other DB instance. The DB instance is joined to the AWS Managed Microsoft AD domain. Thus, you can provision MySQL logins and users from the Active Directory users in your domain. Database permissions are managed through standard MySQL permissions that are granted to and revoked from these logins.

You can allow an Active Directory user to authenticate with MySQL. To do this, first use the Amazon RDS master user credentials to connect to the MySQL DB instance as with any other DB instance. After you're logged in, create an externally authenticated user with PAM (Pluggable Authentication Modules) in MySQL by running the following command. Replace *testuser* with the user name.

```
CREATE USER 'testuser'@'%' IDENTIFIED WITH 'auth_pam';
```

Users (both humans and applications) from your domain can now connect to the DB instance from a domain joined client machine using Kerberos authentication.

Important

We strongly recommended that clients use SSL/TLS connections when using PAM authentication. If they don't use SSL/TLS connections, the password might be sent as clear text in some cases. To require an SSL/TLS encrypted connection for your AD user, run the following command and replace *testuser* with the user name:

```
ALTER USER 'testuser'@'%' REQUIRE SSL;
```

For more information, see Using SSL/TLS with a MySQL DB instance.

Managing a DB instance in a domain

You can use the CLI or the RDS API to manage your DB instance and its relationship with your managed Active Directory. For example, you can associate an Active Directory for Kerberos authentication and disassociate an Active Directory to disable Kerberos authentication. You can also move a DB instance to be externally authenticated by one Active Directory to another.

For example, using the Amazon RDS API, you can do the following:

- To reattempt enabling Kerberos authentication for a failed membership, use the `ModifyDBInstance` API operation and specify the current membership's directory ID.
- To update the IAM role name for membership, use the `ModifyDBInstance` API operation and specify the current membership's directory ID and the new IAM role.
- To disable Kerberos authentication on a DB instance, use the `ModifyDBInstance` API operation and specify none as the domain parameter.
- To move a DB instance from one domain to another, use the `ModifyDBInstance` API operation and specify the domain identifier of the new domain as the domain parameter.
- To list membership for each DB instance, use the `DescribeDBInstances` API operation.

Understanding domain membership

After you create or modify your DB instance, it becomes a member of the domain. You can view the status of the domain membership for the DB instance by running the describe-db-instances CLI command. The status of the DB instance can be one of the following:

- `kerberos-enabled` – The DB instance has Kerberos authentication enabled.
- `enabling-kerberos` – AWS is in the process of enabling Kerberos authentication on this DB instance.
- `pending-enable-kerberos` – The enabling of Kerberos authentication is pending on this DB instance.
- `pending-maintenance-enable-kerberos` – AWS will attempt to enable Kerberos authentication on the DB instance during the next scheduled maintenance window.
- `pending-disable-kerberos` – The disabling of Kerberos authentication is pending on this DB instance.
- `pending-maintenance-disable-kerberos` – AWS will attempt to disable Kerberos authentication on the DB instance during the next scheduled maintenance window.
- `enable-kerberos-failed` – A configuration problem has prevented AWS from enabling Kerberos authentication on the DB instance. Check and fix your configuration before reissuing the DB instance modify command.
- `disabling-kerberos` – AWS is in the process of disabling Kerberos authentication on this DB instance.

A request to enable Kerberos authentication can fail because of a network connectivity issue or an incorrect IAM role. For example, suppose that you create a DB instance or modify an existing DB instance and the attempt to enable Kerberos authentication fails. If this happens, re-issue the modify command or modify the newly created DB instance to join the domain.

Connecting to MySQL with Kerberos authentication

To connect to MySQL with Kerberos authentication, you must log in using the Kerberos authentication type.

To create a database user that you can connect to using Kerberos authentication, use an `IDENTIFIED WITH` clause on the `CREATE USER` statement. For instructions, see Step 5: Create Kerberos authentication MySQL logins.

To avoid errors, use the MariaDB `mysql` client. You can download MariaDB software at https://downloads.mariadb.org/.

At a command prompt, connect to one of the endpoints associated with your MySQL DB instance. Follow the general procedures in Connecting to a DB instance running the MySQL database engine.

When you're prompted for the password, enter the Kerberos password associated with that user name.

Restoring a MySQL DB instance and adding it to a domain

You can restore a DB snapshot or complete a point-in-time restore for a MySQL DB instance and then add it to a domain. After the DB instance is restored, modify the DB instance using the process explained in Step 4: Create or modify a MySQL DB instance to add the DB instance to a domain.

Kerberos authentication MySQL limitations

The following limitations apply to Kerberos authentication for MySQL:

- Only an AWS Managed Microsoft AD is supported. However, you can join RDS for MySQL DB instances to shared Managed Microsoft AD domains owned by different accounts in the same AWS Region.
- You must reboot the DB instance after enabling the feature.
- The domain name length can't be longer than 61 characters.
- You can't enable Kerberos authentication and IAM authentication at the same time. Choose one authentication method or the other for your MySQL DB instance.
- Don't modify the DB instance port after enabling the feature.
- Don't use Kerberos authentication with read replicas.
- If you have auto minor version upgrade turned on for a MySQL DB instance that is using Kerberos authentication, you must turn off Kerberos authentication and then turn it back on after an automatic upgrade. For more information about auto minor version upgrades, see Automatic minor version upgrades for MySQL.
- To delete a DB instance with this feature enabled, first disable the feature. To do so, use the `modify-db-instance` CLI command for the DB instance and specify `none` for the `--domain` parameter.

  If you use the CLI or RDS API to delete a DB instance with this feature enabled, expect a delay.
- RDS for MySQL doesn't support Kerberos authentication across a forest trust between your on-premise or self-hosted AD and the AWS Managed Microsoft AD.

Improving query performance for RDS for MySQL with Amazon RDS Optimized Reads

You can achieve faster query processing for RDS for MySQL with Amazon RDS Optimized Reads. An RDS for MySQL DB instance or Multi-AZ DB cluster that uses RDS Optimized Reads can achieve up to 2x faster query processing compared to a DB instance or cluster that doesn't use it.

Topics

Overview of RDS Optimized Reads

When you use an RDS for MySQL DB instance or Multi-AZ DB cluster that has RDS Optimized Reads turned on, it achieves faster query performance through the use of an instance store. An *instance store* provides temporary block-level storage for your DB instance or Multi-AZ DB cluster. The storage is located on Non-Volatile Memory Express (NVMe) solid state drives (SSDs) that are physically attached to the host server. This storage is optimized for low latency, high random I/O performance, and high sequential read throughput.

RDS Optimized Reads is turned on by default when a DB instance or Multi-AZ DB cluster uses a DB instance class with an instance store, such as db.m5d or db.m6gd. With RDS Optimized Reads, some temporary objects are stored on the instance store. These temporary objects include internal temporary files, internal on-disk temp tables, memory map files, and binary log (binlog) cache files. For more information about the instance store, see Amazon EC2 instance store in the *Amazon Elastic Compute Cloud User Guide for Linux Instances*.

The workloads that generate temporary objects in MySQL for query processing can take advantage of the instance store for faster query processing. This type of workload includes queries involving sorts, hash aggregations, high-load joins, Common Table Expressions (CTEs), and queries on unindexed columns. These instance store volumes provide higher IOPS and performance,

regardless of the storage configurations used for persistent Amazon EBS storage. Because RDS Optimized Reads offloads operations on temporary objects to the instance store, the input/output operations per second (IOPS) or throughput of the persistent storage (Amazon EBS) can now be used for operations on persistent objects. These operations include regular data file reads and writes, and background engine operations, such as flushing and insert buffer merges.

> **Note**
>
> Both manual and automated RDS snapshots only contain engine files for persistent objects. The temporary objects created in the instance store aren't included in RDS snapshots.

Use cases for RDS Optimized Reads

If you have workloads that rely heavily on temporary objects, such as internal tables or files, for their query execution, then you can benefit from turning on RDS Optimized Reads. The following use cases are candidates for RDS Optimized Reads:

- Applications that run analytical queries with complex common table expressions (CTEs), derived tables, and grouping operations
- Read replicas that serve heavy read traffic with unoptimized queries
- Applications that run on-demand or dynamic reporting queries that involve complex operations, such as queries with `GROUP BY` and `ORDER BY` clauses
- Workloads that use internal temporary tables for query processing

  You can monitor the engine status variable `created_tmp_disk_tables` to determine the number of disk-based temporary tables created on your DB instance.
- Applications that create large temporary tables, either directly or in procedures, to store intermediate results
- Database queries that perform grouping or ordering on non-indexed columns

Best practices for RDS Optimized Reads

Use the following best practices for RDS Optimized Reads:

- Add retry logic for read-only queries in case they fail because the instance store is full during the execution.

- Monitor the storage space available on the instance store with the CloudWatch metric `FreeLocalStorage`. If the instance store is reaching its limit because of workload on the DB instance, modify the DB instance to use a larger DB instance class.
- When your DB instance or Multi-AZ DB cluster has sufficient memory but is still reaching the storage limit on the instance store, increase the `binlog_cache_size` value to maintain the session-specific binlog entries in memory. This configuration prevents writing the binlog entries to temporary binlog cache files on disk.

  The `binlog_cache_size` parameter is session-specific. You can change the value for each new session. The setting for this parameter can increase the memory utilization on the DB instance during peak workload. Therefore, consider increasing the parameter value based on the workload pattern of your application and available memory on the DB instance.
- Use the default value of `MIXED` for the `binlog_format`. Depending on the size of the transactions, setting `binlog_format` to `ROW` can result in large binlog cache files on the instance store.
- Set the internal_tmp_mem_storage_engine parameter to `TempTable`, and set the temptable_max_mmap parameter to match the size of the available storage on the instance store.
- Avoid performing bulk changes in a single transaction. These types of transactions can generate large binlog cache files on the instance store and can cause issues when the instance store is full. Consider splitting writes into multiple small transactions to minimize storage use for binlog cache files.
- Use the default value of `ABORT_SERVER` for the `binlog_error_action` parameter. Doing so avoids issues with the binary logging on DB instances with backups enabled.

Using RDS Optimized Reads

When you provision an RDS for MySQL DB instance with one of the following DB instance classes in a Single-AZ DB instance deployment, Multi-AZ DB instance deployment, or Multi-AZ DB cluster deployment, the DB instance automatically uses RDS Optimized Reads.

To turn on RDS Optimized Reads, do one of the following:

- Create an RDS for MySQL DB instance or Multi-AZ DB cluster using one of these DB instance classes. For more information, see Creating an Amazon RDS DB instance.

- Modify an existing RDS for MySQL DB instance or Multi-AZ DB cluster to use one of these DB instance classes. For more information, see Modifying an Amazon RDS DB instance.

RDS Optimized Reads is available in all AWS Regions RDS where one or more of the DB instance classes with local NVMe SSD storage are supported. For information about DB instance classes, see the section called "DB instance classes".

DB instance class availability differs for AWS Regions. To determine whether a DB instance class is supported in a specific AWS Region, see the section called "Determining DB instance class support in AWS Regions".

If you don't want to use RDS Optimized Reads, modify your DB instance or Multi-AZ DB cluster so that it doesn't use a DB instance class that supports the feature.

Monitoring DB instances that use RDS Optimized Reads

You can monitor DB instances that use RDS Optimized Reads with the following CloudWatch metrics:

- `FreeLocalStorage`
- `ReadIOPSLocalStorage`
- `ReadLatencyLocalStorage`
- `ReadThroughputLocalStorage`
- `WriteIOPSLocalStorage`
- `WriteLatencyLocalStorage`
- `WriteThroughputLocalStorage`

These metrics provide data about available instance store storage, IOPS, and throughput. For more information about these metrics, see Amazon CloudWatch instance-level metrics for Amazon RDS.

Limitations for RDS Optimized Reads

The following limitations apply to RDS Optimized Reads:

- RDS Optimized Reads is supported for RDS for MySQL version 8.0.28 and higher. For information about RDS for MySQL versions, see MySQL on Amazon RDS versions.

- You can't change the location of temporary objects to persistent storage (Amazon EBS) on the DB instance classes that support RDS Optimized Reads.
- When binary logging is enabled on a DB instance, the maximum transaction size is limited by the size of the instance store. In MySQL, any session that requires more storage than the value of `binlog_cache_size` writes transaction changes to temporary binlog cache files, which are created on the instance store.
- Transactions can fail when the instance store is full.

Improving write performance with RDS Optimized Writes for MySQL

You can improve the performance of write transactions with RDS Optimized Writes for MySQL. When your RDS for MySQL database uses RDS Optimized Writes, it can achieve up to two times higher write transaction throughput.

Topics

Overview of RDS Optimized Writes

When you turn on RDS Optimized Writes, your RDS for MySQL databases write only once when flushing data to durable storage without the need for the doublewrite buffer. The databases continue to provide ACID property protections for reliable database transactions, along with improved performance.

Relational databases, like MySQL, provide the *ACID properties* of atomicity, consistency, isolation, and durability for reliable database transactions. To help provide these properties, MySQL uses a data storage area called the *doublewrite buffer* that prevents partial page write errors. These errors occur when there is a hardware failure while the database is updating a page, such as in the case of a power outage. A MySQL database can detect partial page writes and recover with a copy of the page in the doublewrite buffer. While this technique provides protection, it also results in extra write operations. For more information about the MySQL doublewrite buffer, see Doublewrite Buffer in the MySQL documentation.

With RDS Optimized Writes turned on, RDS for MySQL databases write only once when flushing data to durable storage without using the doublewrite buffer. RDS Optimized Writes is useful if you run write-heavy workloads on your RDS for MySQL databases. Examples of databases with write-heavy workloads include ones that support digital payments, financial trading, and gaming applications.

These databases run on DB instance classes that use the AWS Nitro System. Because of the hardware configuration in these systems, the database can write 16-KiB pages directly to data files reliably and durably in one step. The AWS Nitro System makes RDS Optimized Writes possible.

You can set the new database parameter `rds.optimized_writes` to control the RDS Optimized Writes feature for RDS for MySQL databases. Access this parameter in the DB parameter groups of RDS for MySQL version 8.0. Set the parameter using the following values:

- `AUTO` – Turn on RDS Optimized Writes if the database supports it. Turn off RDS Optimized Writes if the database doesn't support it. This setting is the default.
- `OFF` – Turn off RDS Optimized Writes even if the database supports it.

If you have an existing database with an engine version, DB instance class, and/or file system format that doesn't support RDS Optimized Writes, you can enable the feature by creating a blue/green deployment. For more information, see the section called “Enabling on an existing database”.

If you migrate an RDS for MySQL database that is configured to use RDS Optimized Writes to a DB instance class that doesn't support the feature, RDS automatically turns off RDS Optimized Writes for the database.

When RDS Optimized Writes is turned off, the database uses the MySQL doublewrite buffer.

To determine whether an RDS for MySQL database is using RDS Optimized Writes, view the current value of the `innodb_doublewrite` parameter for the database. If the database is using RDS Optimized Writes, this parameter is set to `FALSE` (`0`).

Using RDS Optimized Writes

You can turn on RDS Optimized Writes when you create an RDS for MySQL database with the RDS console, the AWS CLI, or the RDS API. RDS Optimized Writes is turned on automatically when both of the following conditions apply during database creation:

- You specify a DB engine version and DB instance class that support RDS Optimized Writes.
  - RDS Optimized Writes is supported for RDS for MySQL version 8.0.30 and higher. For information about RDS for MySQL versions, see MySQL on Amazon RDS versions.
  - RDS Optimized Writes is supported for RDS for MySQL databases that use the following DB instance classes:

- db.m7g
- db.m6g
- db.m6gd
- db.m6i
- db.m5
- db.m5d
- db.r7g
- db.r6g
- db.r6gd
- db.r6i
- db.r5
- db.r5b
- db.r5d
- db.x2idn
- db.x2iedn

  For information about DB instance classes, see the section called "DB instance classes".

  DB instance class availability differs for AWS Regions. To determine whether a DB instance class is supported in a specific AWS Region, see the section called "Determining DB instance class support in AWS Regions".

  To upgrade your database to a DB instance class that supports RDS Optimized Writes, you can create a blue/green deployment. For more information, see the section called "Enabling on an existing database".

- In the parameter group associated with the database, the `rds.optimized_writes` parameter is set to AUTO. In default parameter groups, this parameter is always set to AUTO.

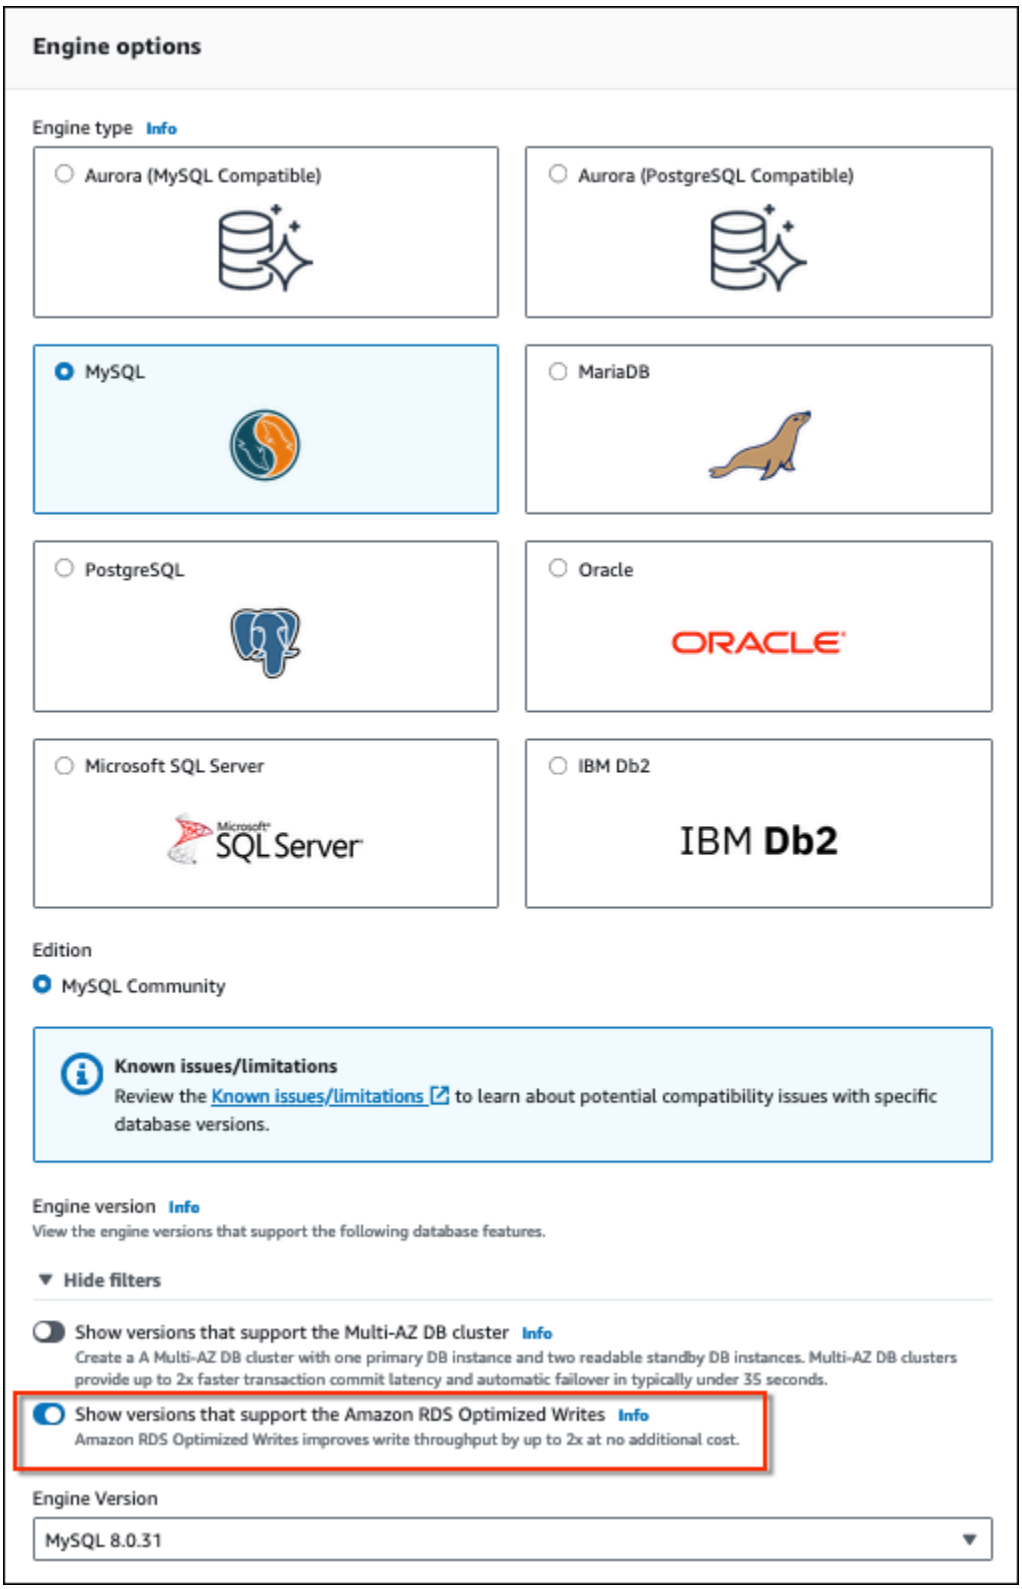
If you want to use a DB engine version and DB instance class that support RDS Optimized Writes, but you don't want to use this feature, then specify a custom parameter group when you create the database. In this parameter group, set the `rds.optimized_writes` parameter to OFF. If you want the database to use RDS Optimized Writes later, you can set the parameter to AUTO to turn it on. For information about creating custom parameter groups and setting parameters, see Parameter groups for Amazon RDS.

For information about creating a DB instance, see Creating an Amazon RDS DB instance.

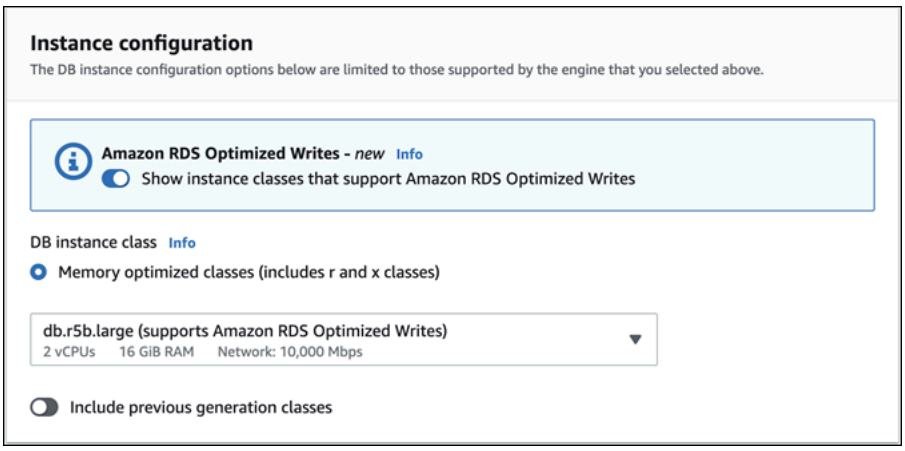
Console

When you use the RDS console to create an RDS for MySQL database, you can filter for the DB engine versions and DB instance classes that support RDS Optimized Writes. After you turn on the filters, you can choose from the available DB engine versions and DB instance classes.

To choose a DB engine version that supports RDS Optimized Writes, filter for the RDS for MySQL DB engine versions that support it in **Engine version**, and then choose a version.



In the **Instance configuration** section, filter for the DB instance classes that support RDS Optimized Writes, and then choose a DB instance class.



After you make these selections, you can choose other settings that meet your requirements and finish creating the RDS for MySQL database with the console.

AWS CLI

To create a DB instance by using the AWS CLI, use the create-db-instance command. Make sure the `--engine-version` and `--db-instance-class` values support RDS Optimized Writes. In addition, make sure the parameter group associated with the DB instance has the `rds.optimized_writes` parameter set to AUTO. This example associates the default parameter group with the DB instance.

Example Creating a DB instance that uses RDS Optimized Writes

For Linux, macOS, or Unix:

```
aws rds create-db-instance \
    --db-instance-identifier mydbinstance \
    --engine mysql \
    --engine-version 8.0.30 \
    --db-instance-class db.r5b.large \
    --manage-master-user-password \
    --master-username admin \
    --allocated-storage 200
```

For Windows:

```
aws rds create-db-instance ^
    --db-instance-identifier mydbinstance ^
    --engine mysql ^
```

```
    --engine-version 8.0.30 ^
    --db-instance-class db.r5b.large ^
    --manage-master-user-password ^
    --master-username admin ^
    --allocated-storage 200
```

RDS API

You can create a DB instance using the CreateDBInstance operation. When you use this operation, make sure the `EngineVersion` and `DBInstanceClass` values support RDS Optimized Writes. In addition, make sure the parameter group associated with the DB instance has the `rds.optimized_writes` parameter set to AUTO.

Enabling RDS Optimized Writes on an existing database

In order to modify an existing RDS for MySQL database to turn on RDS Optimized Writes, the database must have been created with a supported DB engine version and DB instance class. In addition, the database must have been created *after* RDS Optimized Writes was released on November 27, 2022, as the required underlying file system configuration is incompatible with that of databases created before it was released. If these conditions are met, you can turn on RDS Optimized Writes by setting the `rds.optimized_writes` parameter to AUTO.

If your database was *not* created with a supported engine version, instance class, or file system configuration, you can use RDS Blue/Green Deployments to migrate to a supported configuration. While creating the blue/green deployment, do the following:

- Select **Enable Optimized Writes on green database**, then specify an engine version and DB instance class that supports RDS Optimized Writes. For a list of supported engine versions and instance classes, see Using RDS Optimized Writes.
- Under **Storage**, choose **Upgrade storage file system configuration**. This option upgrades the database to a compatible underlying file system configuration.

When you create the blue/green deployment, if the `rds.optimized_writes` parameter is set to AUTO, RDS Optimized Writes will be automatically enabled on the green environment. You can then switch over the blue/green deployment, which promotes the green environment to be the new production environment.

For more information, see the section called “Creating a blue/green deployment”.

Limitations for RDS Optimized Writes

When you're restoring an RDS for MySQL database from a snapshot, you can only turn on RDS Optimized Writes for the database if all of the following conditions apply:

- The snapshot was created from a database that supports RDS Optimized Writes.
- The snapshot was created from a database that was created *after* RDS Optimized Writes was released.
- The snapshot is restored to a database that supports RDS Optimized Writes.
- The restored database is associated with a parameter group that has the `rds.optimized_writes` parameter set to `AUTO`.

Upgrading the MySQL DB engine

When Amazon RDS supports a new version of a database engine, you can upgrade your DB instances to the new version. There are two kinds of upgrades for MySQL databases: major version upgrades and minor version upgrades.

Major version upgrades

Major version upgrades can contain database changes that are not backward-compatible with existing applications. As a result, you must manually perform major version upgrades of your DB instances. You can initiate a major version upgrade by modifying your DB instance. Before you perform a major version upgrade, we recommend that you follow the instructions in Major version upgrades for MySQL.

For major version upgrades of Multi-AZ DB instance deployments, Amazon RDS simultaneously upgrades both the primary and standby replicas. Your DB instance won't be available until the upgrade completes. Currently, Amazon RDS doesn't support major version upgrades for Multi-AZ DB cluster deployments.

> **Tip**
>
> You can minimize the downtime required for a major version upgrade by using a blue/green deployment. For more information, see Using Amazon RDS Blue/Green Deployments for database updates.

Minor version upgrades

Minor version upgrades include only changes that are backward-compatible with existing applications. You can initiate a minor version upgrade manually by modifying your DB instance. Or, you can enable the **Auto minor version upgrade** option when creating or modifying a DB instance. Doing so means that Amazon RDS automatically upgrades your DB instance after testing and approving the new version. For information about performing an upgrade, see Upgrading a DB instance engine version.

When you perform a minor version upgrade of a Multi-AZ DB cluster, Amazon RDS upgrades the reader DB instances one at a time. Then, one of the reader DB instances switches to be the new writer DB instance. Amazon RDS then upgrades the old writer instance (which is now a reader instance).

> **Note**
>
> The downtime for a minor version upgrade of a Multi-AZ DB *instance* deployment can last for several minutes. Multi-AZ DB clusters typically reduce the downtime of minor version upgrades to approximately 35 seconds. When used with RDS Proxy, you can further reduce downtime to one second or less. For more information, see *Using RDS Proxy*. Alternately, you can use an open source database proxy such as ProxySQL,PgBouncer, or the AWS JDBC Driver for MySQL.

If your MySQL DB instance uses read replicas, then you must upgrade all of the read replicas before upgrading the source instance.

Topics

Overview of upgrading

When you use the AWS Management Console to upgrade a DB instance, it shows the valid upgrade targets for the DB instance. You can also use the following AWS CLI command to identify the valid upgrade targets for a DB instance:

For Linux, macOS, or Unix:

```
aws rds describe-db-engine-versions \
  --engine mysql \
  --engine-version version-number \
  --query "DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}" --
output text
```

For Windows:

```
aws rds describe-db-engine-versions ^
  --engine mysql ^
  --engine-version version-number ^
  --query "DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}" --
output text
```

For example, to identify the valid upgrade targets for a MySQL version 8.0.28 DB instance, run the following AWS CLI command:

For Linux, macOS, or Unix:

```
aws rds describe-db-engine-versions \
  --engine mysql \
  --engine-version 8.0.28 \
  --query "DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}" --
output text
```

For Windows:

```
aws rds describe-db-engine-versions ^
  --engine mysql ^
  --engine-version 8.0.28 ^
  --query "DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}" --
output text
```

Amazon RDS takes two or more DB snapshots during the upgrade process. Amazon RDS takes up to two snapshots of the DB instance *before* making any upgrade changes. If the upgrade doesn't work for your databases, you can restore one of these snapshots to create a DB instance running the old version. Amazon RDS takes another snapshot of the DB instance when the upgrade completes. Amazon RDS takes these snapshots regardless of whether AWS Backup manages the backups for the DB instance.

> **Note**
>
> Amazon RDS only takes DB snapshots if you have set the backup retention period for your DB instance to a number greater than 0. To change your backup retention period, see Modifying an Amazon RDS DB instance.

After the upgrade is complete, you can't revert to the previous version of the database engine. If you want to return to the previous version, restore the first DB snapshot taken to create a new DB instance.

You control when to upgrade your DB instance to a new version supported by Amazon RDS. This level of control helps you maintain compatibility with specific database versions and test new versions with your application before deploying in production. When you are ready, you can perform version upgrades at the times that best fit your schedule.

If your DB instance uses read replication, then you must upgrade all of the read replicas before upgrading the source instance.

MySQL version numbers

The version numbering sequence for the RDS for MySQL database engine is either in the form of *major.minor.patch.YYYYMMDD* or *major.minor.patch*, for example, 8.0.33.R2.20231201 or 5.7.44. The format used depends on the MySQL engine version. For information about RDS Extended Support version numbering, see Amazon RDS Extended Support version naming.

major

The major version number is both the integer and the first fractional part of the version number, for example, 8.0. A major version upgrade increases the major part of the version number. For example, an upgrade from *5.7*.44 to 8.0.33 is a major version upgrade, where *5.7* and *8.0* are the major version numbers.

minor

The minor version number is the third part of the version number, for example, the 33 in 8.0.33.

patch

The patch is the fourth part of the version number, for example, the R2 in 8.0.33.R2. An RDS patch version includes important bug fixes added to a minor version after its release.

YYYYMMDD

The date is the fifth part of the version number, for example, the 20231201 in 8.0.33.R2.20231201. An RDS date version is a security patch that includes important security fixes added to a minor version after its release. It doesn't include any fixes that might change an engine's behavior.

The following table explains the naming scheme for RDS for MySQL version 8.0.

8.0 minor version	Naming scheme
≥ 33	New DB instances use *major.minor.patch.YYMMDD*, for example, 8.0.33.R2.20231201. Existing DB instances might use *major.minor.patch*, for example, 8.0.33.R2, until your next major or minor version upgrade.
< 33	Existing DB instances use *major.minor.patch*, for example, 8.0.32.R2.

The following table explains the naming scheme for RDS for MySQL version 5.7.

5.7 minor version	Naming scheme
≥ 42	New DB instances use *major.minor.patch.YYMMDD*, for example, 5.7.42.R2.20231201. Existing DB instances might use *major.minor.patch*, for example, 5.7.42.R2, until your next major or minor version upgrade.

RDS version number

RDS version numbers use either the *`major`*`.`*`minor`*`.`*`patch`* or the *`major`*`.`*`minor`*`.`*`patch`*`.`*`YYYYMMDD`* naming scheme. An RDS patch version includes important bug fixes added to a minor version after its release. An RDS date version (*`YYMMDD`*) is a security patch. A security patch doesn't include any fixes that might change the engine's behavior. For information about RDS Extended Support version numbering, see Amazon RDS Extended Support version naming.

To identify the Amazon RDS version number of your database, you must first create the `rds_tools` extension by using the following command:

```
CREATE EXTENSION rds_tools;
```

You can find out the RDS version number of your RDS for MySQL database with the following SQL query:

```
mysql> select mysql.rds_version();
```

For example, querying an RDS for MySQL 8.0.34 database returns the following output:

```
+---------------------+
| mysql.rds_version() |
+---------------------+
| 8.0.34.R2.20231201  |
+---------------------+
1 row in set (0.01 sec)
```

Major version upgrades for MySQL

Amazon RDS supports the following in-place upgrades for major versions of the MySQL database engine:

- MySQL 5.6 to MySQL 5.7
- MySQL 5.7 to MySQL 8.0

> **Note**
>
> You can only create MySQL version 5.7 and 8.0 DB instances with latest-generation and current-generation DB instance classes, in addition to the db.m3 previous-generation DB instance class.
>
> In some cases, you want to upgrade a MySQL version 5.6 DB instance running on a previous-generation DB instance class (other than db.m3) to a MySQL version 5.7 DB instance. In these cases, first modify the DB instance to use a latest-generation or current-generation DB instance class. After you do this, you can then modify the DB instance to use the MySQL version 5.7 database engine. For information on Amazon RDS DB instance classes, see DB instance classes.

Topics

Overview of MySQL major version upgrades

Major version upgrades can contain database changes that are not backward-compatible with existing applications. As a result, Amazon RDS doesn't apply major version upgrades automatically; you must manually modify your DB instance. We recommend that you thoroughly test any upgrade before applying it to your production instances.

To perform a major version upgrade for a MySQL version 5.6 DB instance on Amazon RDS to MySQL version 5.7 or later, first perform any available OS updates. After OS updates are complete, upgrade to each major version: 5.6 to 5.7 and then 5.7 to 8.0. MySQL DB instances created before April 24, 2014, show an available OS update until the update has been applied. For more information on OS updates, see Applying updates for a DB instance.

During a major version upgrade of MySQL, Amazon RDS runs the MySQL binary `mysql_upgrade` to upgrade tables, if necessary. Also, Amazon RDS empties the `slow_log` and `general_log` tables during a major version upgrade. To preserve log information, save the log contents before the major version upgrade.

MySQL major version upgrades typically complete in about 10 minutes. Some upgrades might take longer because of the DB instance class size or because the instance doesn't follow certain operational guidelines in Best practices for Amazon RDS. If you upgrade a DB instance from the Amazon RDS console, the status of the DB instance indicates when the upgrade is complete. If you upgrade using the AWS Command Line Interface (AWS CLI), use the describe-db-instances command and check the `Status` value.

Upgrades to MySQL version 5.7 might be slow

MySQL version 5.6.4 introduced a new date and time format for the `datetime`, `time`, and `timestamp` columns that allows fractional components in date and time values. When upgrading a DB instance to MySQL version 5.7, MySQL forces the conversion of all date and time column types to the new format.

Because this conversion rebuilds your tables, it might take a considerable amount of time to complete the DB instance upgrade. The forced conversion occurs for any DB instances that are running a version before MySQL version 5.6.4. It also occurs for any DB instances that were upgraded from a version before MySQL version 5.6.4 to a version other than 5.7.

If your DB instance runs a version before MySQL version 5.6.4, or was upgraded from a version before 5.6.4, we recommend an extra step. In these cases, we recommend that you convert the `datetime`, `time`, and `timestamp` columns in your database before upgrading your DB instance to MySQL version 5.7. This conversion can significantly reduce the amount of time required to upgrade the DB instance to MySQL version 5.7. To upgrade your date and time columns to the new format, issue the `ALTER TABLE <table_name> FORCE;` command for each table that contains date or time columns. Because altering a table locks the table as read-only, we recommend that you perform this update during a maintenance window.

To find all tables in your database that have `datetime`, `time`, or `timestamp` columns and create an `ALTER TABLE <table_name> FORCE;` command for each table, use the following query.

```
SET show_old_temporals = ON;
   SELECT table_schema, table_name,column_name, column_type
   FROM information_schema.columns
   WHERE column_type LIKE '%/* 5.5 binary format */';
   SET show_old_temporals = OFF;
```

Prechecks for upgrades from MySQL 5.7 to 8.0

MySQL 8.0 includes a number of incompatibilities with MySQL 5.7. These incompatibilities can cause problems during an upgrade from MySQL 5.7 to MySQL 8.0. So, some preparation might be required on your database for the upgrade to be successful. The following is a general list of these incompatibilities:

- There must be no tables that use obsolete data types or functions.
- There must be no orphan *.frm files.
- Triggers must not have a missing or empty definer or an invalid creation context.
- There must be no partitioned table that uses a storage engine that does not have native partitioning support.
- There must be no keyword or reserved word violations. Some keywords might be reserved in MySQL 8.0 that were not reserved previously.

For more information, see Keywords and reserved words in the MySQL documentation.

- There must be no tables in the MySQL 5.7 `mysql` system database that have the same name as a table used by the MySQL 8.0 data dictionary.
- There must be no obsolete SQL modes defined in your `sql_mode` system variable setting.
- There must be no tables or stored procedures with individual `ENUM` or `SET` column elements that exceed 255 characters or 1020 bytes in length.
- Before upgrading to MySQL 8.0.13 or higher, there must be no table partitions that reside in shared InnoDB tablespaces.
- There must be no queries and stored program definitions from MySQL 8.0.12 or lower that use `ASC` or `DESC` qualifiers for `GROUP BY` clauses.
- Your MySQL 5.7 installation must not use features that are not supported in MySQL 8.0.

  For more information, see Features removed in MySQL 8.0 in the MySQL documentation.
- There must be no foreign key constraint names longer than 64 characters.
- For improved Unicode support, consider converting objects that use the `utf8mb3` charset to use the `utf8mb4` charset. The `utf8mb3` character set is deprecated. Also, consider using `utf8mb4` for character set references instead of `utf8`, because currently `utf8` is an alias for the `utf8mb3` charset.

  For more information, see The utf8mb3 character set (3-byte UTF-8 unicode encoding) in the MySQL documentation.

When you start an upgrade from MySQL 5.7 to 8.0, Amazon RDS runs prechecks automatically to detect these incompatibilities. For information about upgrading to MySQL 8.0, see Upgrading MySQL in the MySQL documentation.

These prechecks are mandatory. You can't choose to skip them. The prechecks provide the following benefits:

- They enable you to avoid unplanned downtime during the upgrade.
- If there are incompatibilities, Amazon RDS prevents the upgrade and provides a log for you to learn about them. You can then use the log to prepare your database for the upgrade to MySQL 8.0 by reducing the incompatibilities. For detailed information about removing incompatibilities, see Preparing your installation for upgrade in the MySQL documentation and Upgrading to MySQL 8.0? Here is what you need to know... on the MySQL Server Blog.

The prechecks include some that are included with MySQL and some that were created specifically by the Amazon RDS team. For information about the prechecks provided by MySQL, see Upgrade checker utility.

The prechecks run before the DB instance is stopped for the upgrade, meaning that they don't cause any downtime when they run. If the prechecks find an incompatibility, Amazon RDS automatically cancels the upgrade before the DB instance is stopped. Amazon RDS also generates an event for the incompatibility. For more information about Amazon RDS events, see Working with Amazon RDS event notification.

Amazon RDS records detailed information about each incompatibility in the log file `PrePatchCompatibility.log`. In most cases, the log entry includes a link to the MySQL documentation for correcting the incompatibility. For more information about viewing log files, see Viewing and listing database log files.

Due to the nature of the prechecks, they analyze the objects in your database. This analysis results in resource consumption and increases the time for the upgrade to complete.

> **Note**
>
> Amazon RDS runs all of these prechecks only for an upgrade from MySQL 5.7 to MySQL 8.0. For an upgrade from MySQL 5.6 to MySQL 5.7, prechecks are limited to confirming that there are no orphan tables and that there is enough storage space to rebuild tables. Prechecks aren't run for upgrades to releases lower than MySQL 5.7.

Rollback after failure to upgrade from MySQL 5.7 to 8.0

When you upgrade a DB instance from MySQL version 5.7 to MySQL version 8.0, the upgrade can fail. In particular, it can fail if the data dictionary contains incompatibilities that weren't captured by the prechecks. In this case, the database fails to start up successfully in the new MySQL 8.0 version. At this point, Amazon RDS rolls back the changes performed for the upgrade. After the rollback, the MySQL DB instance is running MySQL version 5.7. When an upgrade fails and is rolled back, Amazon RDS generates an event with the event ID RDS-EVENT-0188.

Typically, an upgrade fails because there are incompatibilities in the metadata between the databases in your DB instance and the target MySQL version. When an upgrade fails, you can view the details about these incompatibilities in the `upgradeFailure.log` file. Resolve the incompatibilities before attempting to upgrade again.

During an unsuccessful upgrade attempt and rollback, your DB instance is restarted. Any pending parameter changes are applied during the restart and persist after the rollback.

For more information about upgrading to MySQL 8.0, see the following topics in the MySQL documentation:

- Preparing Your Installation for Upgrade
- Upgrading to MySQL 8.0? Here is what you need to know…

> **Note**
>
> Currently, automatic rollback after upgrade failure is supported only for MySQL 5.7 to 8.0 major version upgrades.

Testing an upgrade

Before you perform a major version upgrade on your DB instance, thoroughly test your database for compatibility with the new version. In addition, thoroughly test all applications that access the database for compatibility with the new version. We recommend that you use the following procedure.

To test a major version upgrade

1. Review the upgrade documentation for the new version of the database engine to see if there are compatibility issues that might affect your database or applications:
   - Changes in MySQL 5.6
   - Changes in MySQL 5.7
   - Changes in MySQL 8.0
2. If your DB instance is a member of a custom DB parameter group, create a new DB parameter group with your existing settings that is compatible with the new major version. Specify the new DB parameter group when you upgrade your test instance, so your upgrade testing ensures that it works correctly. For more information about creating a DB parameter group, see Parameter groups for Amazon RDS.
3. Create a DB snapshot of the DB instance to be upgraded. For more information, see Creating a DB snapshot for a Single-AZ DB instance.

4. Restore the DB snapshot to create a new test DB instance. For more information, see Restoring to a DB instance.
5. Modify this new test DB instance to upgrade it to the new version, using one of the methods detailed following. If you created a new parameter group in step 2, specify that parameter group.
6. Evaluate the storage used by the upgraded instance to determine if the upgrade requires additional storage.
7. Run as many of your quality assurance tests against the upgraded DB instance as needed to ensure that your database and application work correctly with the new version. Implement any new tests needed to evaluate the impact of any compatibility issues that you identified in step 1. Test all stored procedures and functions. Direct test versions of your applications to the upgraded DB instance.
8. If all tests pass, then perform the upgrade on your production DB instance. We recommend that you don't allow write operations to the DB instance until you confirm that everything is working correctly.

Upgrading a MySQL DB instance

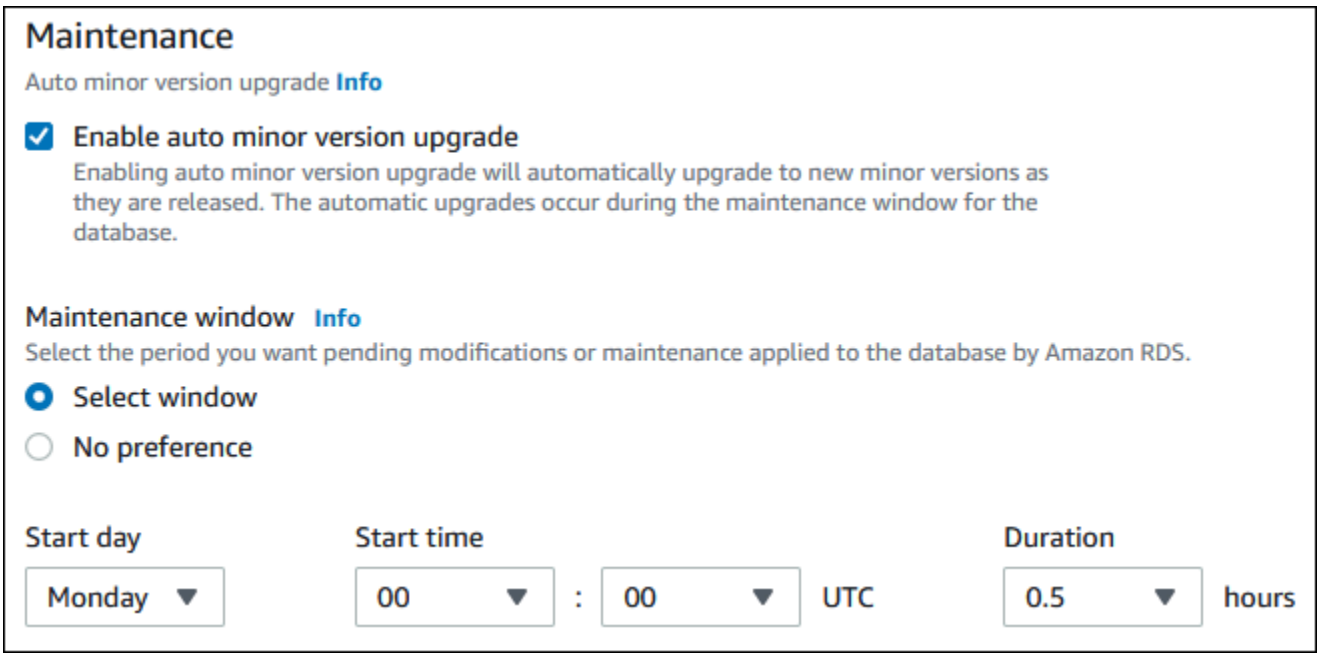
For information about manually or automatically upgrading a MySQL DB instance, see Upgrading a DB instance engine version.

Automatic minor version upgrades for MySQL

If you specify the following settings when creating or modifying a DB instance, you can have your DB instance automatically upgraded.

- The **Auto minor version upgrade** setting is enabled.
- The **Backup retention period** setting is greater than 0.

In the AWS Management Console, these settings are under **Additional configuration**. The following image shows the **Auto minor version upgrade** setting.



For more information about these settings, see Settings for DB instances.

For some RDS for MySQL major versions in some AWS Regions, one minor version is designated by RDS as the automatic upgrade version. After a minor version has been tested and approved by Amazon RDS, the minor version upgrade occurs automatically during your maintenance window. RDS doesn't automatically set newer released minor versions as the automatic upgrade version. Before RDS designates a newer automatic upgrade version, several criteria are considered, such as the following:

- Known security issues
- Bugs in the MySQL community version
- Overall fleet stability since the minor version was released

You can use the following AWS CLI command to determine the current automatic minor upgrade target version for a specified MySQL minor version in a specific AWS Region.

For Linux, macOS, or Unix:

```
aws rds describe-db-engine-versions \
--engine mysql \
--engine-version minor-version \
--region region \
--query "DBEngineVersions[*].ValidUpgradeTarget[*].
{AutoUpgrade:AutoUpgrade,EngineVersion:EngineVersion}" \
```

```
--output text
```

For Windows:

```
aws rds describe-db-engine-versions ^
--engine mysql ^
--engine-version minor-version ^
--region region ^
--query "DBEngineVersions[*].ValidUpgradeTarget[*].
{AutoUpgrade:AutoUpgrade,EngineVersion:EngineVersion}" ^
--output text
```

For example, the following AWS CLI command determines the automatic minor upgrade target for MySQL minor version 8.0.11 in the US East (Ohio) AWS Region (us-east-2).

For Linux, macOS, or Unix:

```
aws rds describe-db-engine-versions \
--engine mysql \
--engine-version 8.0.11 \
--region us-east-2 \
--query "DBEngineVersions[*].ValidUpgradeTarget[*].
{AutoUpgrade:AutoUpgrade,EngineVersion:EngineVersion}" \
--output table
```

For Windows:

```
aws rds describe-db-engine-versions ^
--engine mysql ^
--engine-version 8.0.11 ^
--region us-east-2 ^
--query "DBEngineVersions[*].ValidUpgradeTarget[*].
{AutoUpgrade:AutoUpgrade,EngineVersion:EngineVersion}" ^
--output table
```

Your output is similar to the following.

```
---------------------------------
|    DescribeDBEngineVersions    |
+--------------+-----------------+
```

```
|  AutoUpgrade |  EngineVersion  |
+--------------+-----------------+
|  False       |  8.0.15         |
|  False       |  8.0.16         |
|  False       |  8.0.17         |
|  False       |  8.0.19         |
|  False       |  8.0.20         |
|  False       |  8.0.21         |
|  True        |  8.0.23         |
|  False       |  8.0.25         |
+--------------+-----------------+
```

In this example, the `AutoUpgrade` value is `True` for MySQL version 8.0.23. So, the automatic minor upgrade target is MySQL version 8.0.23, which is highlighted in the output.

A MySQL DB instance is automatically upgraded during your maintenance window if the following criteria are met:

- The **Auto minor version upgrade** setting is enabled.
- The **Backup retention period** setting is greater than 0.
- The DB instance is running a minor DB engine version that is less than the current automatic upgrade minor version.

For more information, see Automatically upgrading the minor engine version.

Using a read replica to reduce downtime when upgrading a MySQL database

In most cases, a blue/green deployment is the best option to reduce downtime when upgrading a MySQL DB instance. For more information, see Using Amazon RDS Blue/Green Deployments for database updates.

If you can't use a blue/green deployment and your MySQL DB instance is currently in use with a production application, you can use the following procedure to upgrade the database version for your DB instance. This procedure can reduce the amount of downtime for your application.

By using a read replica, you can perform most of the maintenance steps ahead of time and minimize the necessary changes during the actual outage. With this technique, you can test and prepare the new DB instance without making any changes to your existing DB instance.

The following procedure shows an example of upgrading from MySQL version 5.7 to MySQL version 8.0. You can use the same general steps for upgrades to other major versions.

> **Note**
>
> When you are upgrading from MySQL version 5.7 to MySQL version 8.0, complete the prechecks before performing the upgrade. For more information, see Prechecks for upgrades from MySQL 5.7 to 8.0.

To upgrade a MySQL database while a DB instance is in use

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Create a read replica of your MySQL 5.7 DB instance. This process creates an upgradable copy of your database. Other read replicas of the DB instance might also exist.
   a. In the console, choose **Databases**, and then choose the DB instance that you want to upgrade.
   b. For **Actions**, choose **Create read replica**.
   c. Provide a value for **DB instance identifier** for your read replica and ensure that the **DB instance class** and other settings match your MySQL 5.7 DB instance.
   d. Choose **Create read replica**.
3. (Optional) When the read replica has been created and **Status** shows **Available**, convert the read replica into a Multi-AZ deployment and enable backups.

   By default, a read replica is created as a Single-AZ deployment with backups disabled. Because the read replica ultimately becomes the production DB instance, it is a best practice to configure a Multi-AZ deployment and enable backups now.

   a. In the console, choose **Databases**, and then choose the read replica that you just created.
   b. Choose **Modify**.
   c. For **Multi-AZ deployment**, choose **Create a standby instance**.
   d. For **Backup Retention Period**, choose a positive nonzero value, such as 3 days, and then choose **Continue**.
   e. For **Scheduling of modifications**, choose **Apply immediately**.

f. Choose **Modify DB instance**.

4. When the read replica **Status** shows **Available**, upgrade the read replica to MySQL 8.0:

   a. In the console, choose **Databases**, and then choose the read replica that you just created.

   b. Choose **Modify**.

   c. For **DB engine version**, choose the MySQL 8.0 version to upgrade to, and then choose **Continue**.

   d. For **Scheduling of modifications**, choose **Apply immediately**.

   e. Choose **Modify DB instance** to start the upgrade.

5. When the upgrade is complete and **Status** shows **Available**, verify that the upgraded read replica is up-to-date with the source MySQL 5.7 DB instance. To verify, connect to the read replica and run the `SHOW REPLICA STATUS` command. If the `Seconds_Behind_Master` field is `0`, then replication is up-to-date.

   > **Note**
   >
   > Previous versions of MySQL used `SHOW SLAVE STATUS` instead of `SHOW REPLICA STATUS`. If you are using a MySQL version before 8.0.23, then use `SHOW SLAVE STATUS`.

6. (Optional) Create a read replica of your read replica.

   If you want the DB instance to have a read replica after it is promoted to a standalone DB instance, you can create the read replica now.

   a. In the console, choose **Databases**, and then choose the read replica that you just upgraded.

   b. For **Actions**, choose **Create read replica**.

   c. Provide a value for **DB instance identifier** for your read replica and ensure that the **DB instance class** and other settings match your MySQL 5.7 DB instance.

   d. Choose **Create read replica**.

7. (Optional) Configure a custom DB parameter group for the read replica.

   If you want the DB instance to use a custom parameter group after it is promoted to a standalone DB instance, you can create the DB parameter group now and associate it with the read replica.

a. Create a custom DB parameter group for MySQL 8.0. For instructions, see Creating a DB parameter group in Amazon RDS.

b. Modify the parameters that you want to change in the DB parameter group you just created. For instructions, see Modifying parameters in a DB parameter group in Amazon RDS.

c. In the console, choose **Databases**, and then choose the read replica.

d. Choose **Modify**.

e. For **DB parameter group**, choose the MySQL 8.0 DB parameter group you just created, and then choose **Continue**.

f. For **Scheduling of modifications**, choose **Apply immediately**.

g. Choose **Modify DB instance** to start the upgrade.

8. Make your MySQL 8.0 read replica a standalone DB instance.

> **Important**
>
> When you promote your MySQL 8.0 read replica to a standalone DB instance, it is no longer a replica of your MySQL 5.7 DB instance. We recommend that you promote your MySQL 8.0 read replica during a maintenance window when your source MySQL 5.7 DB instance is in read-only mode and all write operations are suspended. When the promotion is completed, you can direct your write operations to the upgraded MySQL 8.0 DB instance to ensure that no write operations are lost.
> In addition, we recommend that, before promoting your MySQL 8.0 read replica, you perform all necessary data definition language (DDL) operations on your MySQL 8.0 read replica. An example is creating indexes. This approach avoids negative effects on the performance of the MySQL 8.0 read replica after it has been promoted. To promote a read replica, use the following procedure.

a. In the console, choose **Databases**, and then choose the read replica that you just upgraded.

b. For **Actions**, choose **Promote**.

c. Choose **Yes** to enable automated backups for the read replica instance. For more information, see Introduction to backups.

d. Choose **Continue**.

e. Choose **Promote Read Replica**.

9. You now have an upgraded version of your MySQL database. At this point, you can direct your applications to the new MySQL 8.0 DB instance.

Upgrading a MySQL DB snapshot engine version

With Amazon RDS, you can create a storage volume DB snapshot of your MySQL DB instance. When you create a DB snapshot, the snapshot is based on the engine version used by your DB instance. In addition to upgrading the DB engine version of your DB instance, you can also upgrade the engine version for your DB snapshots. For RDS for MySQL, you can upgrade a version 5.7 snapshot to version 8.0. You can upgrade encrypted or unencrypted DB snapshots.

The following versions support MySQL DB snapshot upgrade:

- You can upgrade from RDS for MySQL snapshot version 5.7.16 and higher 5.7 versions.
- You can upgrade to RDS for MySQL snapshot version 8.0.28 and higher, except for versions 8.0.29, 8.0.30, and 8.0.31.

  You can't upgrade versions 5.7.40, 5.7.41, and 5.7.42 to version 8.0.28, but you can upgrade these versions to version 8.0.32 and higher.

After restoring a DB snapshot upgraded to a new engine version, make sure to test that the upgrade was successful. For more information about a major version upgrade, see the section called “Upgrading the MySQL DB engine”. To learn how to restore a DB snapshot, see the section called “Restoring to a DB instance”.

> **Note**
>
> You can't upgrade automated DB snapshots that were created during the automated backup process.

You can upgrade a DB snapshot using the AWS Management Console, AWS CLI, or RDS API.

Console

To upgrade a DB snapshot

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Snapshots**.
3. Choose the snapshot that you want to upgrade.

4. For **Actions**, choose **Upgrade snapshot**. The **Upgrade snapshot** page appears.
5. Choose the **New engine version** to upgrade to.
6. Choose **Save changes** to upgrade the snapshot.

   During the upgrade process, all snapshot actions are disabled for this DB snapshot. Also, the DB snapshot status changes from **Available** to **Upgrading**, and then changes to **Active** upon completion. If the DB snapshot can't be upgraded because of snapshot corruption issues, the status changes to **Unavailable**. You can't recover the snapshot from this state.

   > **Note**
   >
   > If the DB snapshot upgrade fails, the snapshot is rolled back to the original state with the original version.

AWS CLI

To upgrade a DB snapshot to a new database engine version, use the AWS CLI modify-db-snapshot command.

Options

- `--db-snapshot-identifier` – The identifier of the DB snapshot to upgrade. The identifier must be a unique Amazon Resource Name (ARN). For more information, see Amazon Resource Names (ARNs) in Amazon RDS.
- `--engine-version` – The engine version to upgrade the DB snapshot to.

Example

For Linux, macOS, or Unix:

```
aws rds modify-db-snapshot \
    --db-snapshot-identifier my_db_snapshot \
    --engine-version new_version
```

For Windows:

```
aws rds modify-db-snapshot ^
```

```
    --db-snapshot-identifier my_db_snapshot ^
    --engine-version new_version
```

RDS API

To upgrade a DB snapshot to a new database engine version, call the RDS API ModifyDBSnapshot operation.

Parameters

- `DBSnapshotIdentifier` – The identifier of the DB snapshot to upgrade. The identifier must be a unique Amazon Resource Name (ARN). For more information, see Amazon Resource Names (ARNs) in Amazon RDS.
- `EngineVersion` – The engine version to upgrade the DB snapshot to.

Importing data into a MySQL DB instance

You can use several different techniques to import data into an RDS for MySQL DB instance. The best approach depends on the source of the data, the amount of data, and whether the import is done one time or is ongoing. If you are migrating an application along with the data, also consider the amount of downtime that you are willing to experience.

Overview

Find techniques to import data into an RDS for MySQL DB instance in the following table.

Source	Amount of data	One time or ongoing	Applicati on downtim	Technique	More informati on
Existing MySQL database on premises or on Amazon EC2	Any	One time	Some	Create a backup of your on-premis es database, store it on Amazon S3, and then restore the backup file to a new Amazon RDS DB instance running MySQL.	Restoring a backup into a MySQL DB instance
Any existing database	Any	One time or ongoing	Minimal	Use AWS Database Migration Service to migrate the database with minimal downtime and, for many database DB engines, continue ongoing replication.	What is AWS Database Migration Service and Using a MySQL-com patible database as a target

Source	Amount of data	One time or ongoing	Applicati on downtim	Technique	More informati on
					for AWS DMS in the *AWS Database Migration Service User Guide*
Existing MySQL DB instance	Any	One time or ongoing	Minimal	Create a read replica for ongoing replication. Promote the read replica for one-time creation of a new DB instance.	Working with DB instance read replicas
Existing MariaDB or MySQL database	Small	One time	Some	Copy the data directly to your MySQL DB instance using a command-line utility.	Importing data from an external MariaDB or MySQL database to an RDS for MariaDB or RDS for MySQL DB instance

Source	Amount of data	One time or ongoing	Applicati on downtim	Technique	More informati on
Data not stored in an existing database	Medium	One time	Some	Create flat files and import them using MySQL `LOAD DATA LOCAL INFILE` statements.	Importing data from any source to a MariaDB or MySQL DB instance

Source	Amount of data	One time or ongoing	Applicati on downtim	Technique	More informati on
Existing MariaDB or MySQL database on premises or on Amazon EC2	Any	Ongoing	Minimal	Configure replication with an existing MariaDB or MySQL database as the replication source.	Configuri ng binary log file position replicati on with an external source instance Importing data to an Amazon RDS MariaDB or MySQL database with reduced downtime

Note

The `'mysql'` system database contains authentication and authorization information required to log in to your DB instance and access your data. Dropping, altering, renaming, or truncating tables, data, or other contents of the `'mysql'` database in your DB instance can result in error and might render the DB instance and your data inaccessible. If this occurs, you can restore the DB instance from a snapshot using the AWS CLI `restore-db-`

`instance-from-db-snapshot` command. You can recover the DB instance using the AWS CLI `restore-db-instance-to-point-in-time` command.

Importing data considerations

Following, you can find additional technical information related to loading data into MySQL. This information is intended for advanced users who are familiar with the MySQL server architecture.

Binary log

Data loads incur a performance penalty and require additional free disk space (up to four times more) when binary logging is enabled versus loading the same data with binary logging turned off. The severity of the performance penalty and the amount of free disk space required is directly proportional to the size of the transactions used to load the data.

Transaction size

Transaction size plays an important role in MySQL data loads. It has a major influence on resource consumption, disk space utilization, resume process, time to recover, and input format (flat files or SQL). This section describes how transaction size affects binary logging and makes the case for disabling binary logging during large data loads. As noted earlier, binary logging is enabled and disabled by setting the Amazon RDS automated backup retention period. Non-zero values enable binary logging, and zero disables it. We also describe the impact of large transactions on InnoDB and why it's important to keep transaction sizes small.

Small transactions

For small transactions, binary logging doubles the number of disk writes required to load the data. This effect can severely degrade performance for other database sessions and increase the time required to load the data. The degradation experienced depends in part upon the upload rate, other database activity taking place during the load, and the capacity of your Amazon RDS DB instance.

The binary logs also consume disk space roughly equal to the amount of data loaded until they are backed up and removed. Fortunately, Amazon RDS minimizes this by backing up and removing binary logs on a frequent basis.

Large transactions

Large transactions incur a 3X penalty for IOPS and disk consumption with binary logging enabled. This is due to the binary log cache spilling to disk, consuming disk space and incurring additional IO for each write. The cache cannot be written to the binlog until the transaction commits or rolls back, so it consumes disk space in proportion to the amount of data loaded. When the transaction commits, the cache must be copied to the binlog, creating a third copy of the data on disk.

Because of this, there must be at least three times as much free disk space available to load the data compared to loading with binary logging disabled. For example, 10 GiB of data loaded as a single transaction consumes at least 30 GiB disk space during the load. It consumes 10 GiB for the table + 10 GiB for the binary log cache + 10 GiB for the binary log itself. The cache file remains on disk until the session that created it terminates or the session fills its binary log cache again during another transaction. The binary log must remain on disk until backed up, so it might be some time before the extra 20 GiB is freed.

If the data was loaded using LOAD DATA LOCAL INFILE, yet another copy of the data is created if the database has to be recovered from a backup made before the load. During recovery, MySQL extracts the data from the binary log into a flat file. MySQL then runs LOAD DATA LOCAL INFILE, just as in the original transaction. However, this time the input file is local to the database server. Continuing with the example preceding, recovery fails unless there is at least 40 GiB free disk space available.

Disable binary logging

Whenever possible, disable binary logging during large data loads to avoid the resource overhead and addition disk space requirements. In Amazon RDS, disabling binary logging is as simple as setting the backup retention period to zero. If you do this, we recommend that you take a DB snapshot of the database instance immediately before the load. By doing this, you can quickly and easily undo changes made during loading if you need to.

After the load, set the backup retention period back to an appropriate (no zero) value.

You can't set the backup retention period to zero if the DB instance is a source DB instance for read replicas.

InnoDB

The information in this section provides a strong argument for keeping transaction sizes small when using InnoDB.

Undo

InnoDB generates undo to support features such as transaction rollback and MVCC. Undo is stored in the InnoDB system tablespace (usually ibdata1) and is retained until removed by the purge thread. The purge thread cannot advance beyond the undo of the oldest active transaction, so it is effectively blocked until the transaction commits or completes a rollback. If the database is processing other transactions during the load, their undo also accumulates in the system tablespace and cannot be removed even if they commit and no other transaction needs the undo for MVCC. In this situation, all transactions (including read-only transactions) that access any of the rows changed by any transaction (not just the load transaction) slow down. The slowdown occurs because transactions scan through undo that could have been purged if not for the long-running load transaction.

Undo is stored in the system tablespace, and the system tablespace never shrinks in size. Thus, large data load transactions can cause the system tablespace to become quite large, consuming disk space that you can't reclaim without recreating the database from scratch.

Rollback

InnoDB is optimized for commits. Rolling back a large transaction can take a very, very long time. In some cases, it might be faster to perform a point-in-time recovery or restore a DB snapshot.

Input data format

MySQL can accept incoming data in one of two forms: flat files and SQL. This section points out some key advantages and disadvantages of each.

Flat files

Loading flat files with LOAD DATA LOCAL INFILE can be the fastest and least costly method of loading data as long as transactions are kept relatively small. Compared to loading the same data with SQL, flat files usually require less network traffic, lowering transmission costs and load much faster due to the reduced overhead in the database.

One big transaction

LOAD DATA LOCAL INFILE loads the entire flat file as one transaction. This isn't necessarily a bad thing. If the size of the individual files can be kept small, this has a number of advantages:

- Resume capability – Keeping track of which files have been loaded is easy. If a problem arises during the load, you can pick up where you left off with little effort. Some data might have to be retransmitted to Amazon RDS, but with small files, the amount retransmitted is minimal.
- Load data in parallel – If you've got IOPS and network bandwidth to spare with a single file load, loading in parallel might save time.
- Throttle the load rate – Data load having a negative impact on other processes? Throttle the load by increasing the interval between files.

Be careful

The advantages of LOAD DATA LOCAL INFILE diminish rapidly as transaction size increases. If breaking up a large set of data into smaller ones isn't an option, SQL might be the better choice.

SQL

SQL has one main advantage over flat files: it's easy to keep transaction sizes small. However, SQL can take significantly longer to load than flat files and it can be difficult to determine where to resume the load after a failure. For example, mysqldump files are not restartable. If a failure occurs while loading a mysqldump file, the file requires modification or replacement before the load can resume. The alternative is to restore to the point in time before the load and replay the file after the cause of the failure has been corrected.

Take checkpoints using Amazon RDS snapshots

If you have a load that's going to take several hours or even days, loading without binary logging isn't a very attractive prospect unless you can take periodic checkpoints. This is where the Amazon RDS DB snapshot feature comes in very handy. A DB snapshot creates a point-in-time consistent copy of your database instance which can be used restore the database to that point in time after a crash or other mishap.

To create a checkpoint, simply take a DB snapshot. Any previous DB snapshots taken for checkpoints can be removed without affecting durability or restore time.

Snapshots are fast too, so frequent checkpointing doesn't add significantly to load time.

Decreasing load time

Here are some additional tips to reduce load times:

- Create all secondary indexes before loading. This is counter-intuitive for those familiar with other databases. Adding or modifying a secondary index causes MySQL to create a new table with the index changes, copy the data from the existing table to the new table, and drop the original table.
- Load data in PK order. This is particularly helpful for InnoDB tables, where load times can be reduced by 75–80 percent and data file size cut in half.
- Disable foreign key constraints foreign_key_checks=0. For flat files loaded with LOAD DATA LOCAL INFILE, this is required in many cases. For any load, disabling FK checks provides significant performance gains. Just be sure to enable the constraints and verify the data after the load.
- Load in parallel unless already near a resource limit. Use partitioned tables when appropriate.
- Use multi-value inserts when loading with SQL to minimize overhead when running statements. When using mysqldump, this is done automatically.
- Reduce InnoDB log IO innodb_flush_log_at_trx_commit=0
- If you are loading data into a DB instance that does not have read replicas, set the sync_binlog parameter to 0 while loading data. When data loading is complete, set the sync_binlog parameter to back to 1.
- Load data before converting the DB instance to a Multi-AZ deployment. However, if the DB instance already uses a Multi-AZ deployment, switching to a Single-AZ deployment for data loading is not recommended, because doing so only provides marginal improvements.

> **Note**
>
> Using innodb_flush_log_at_trx_commit=0 causes InnoDB to flush its logs every second instead of at each commit. This provides a significant speed advantage, but can lead to data loss during a crash. Use with caution.

Topics

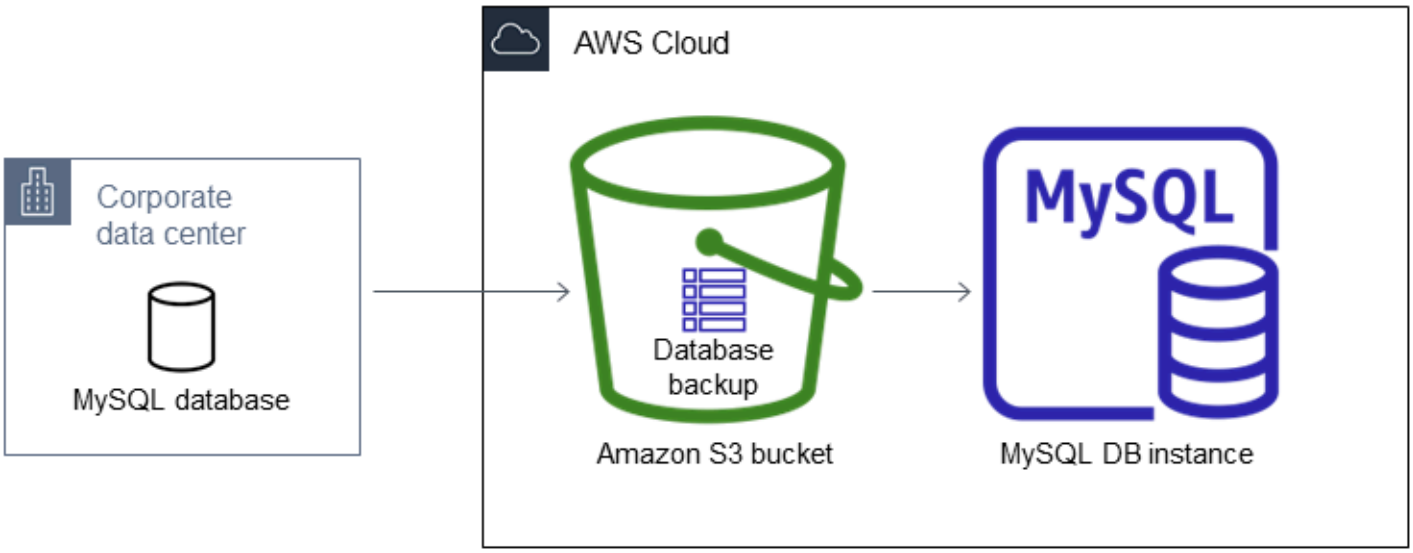
- Restoring a backup into a MySQL DB instance
- Importing data from an external MariaDB or MySQL database to an RDS for MariaDB or RDS for MySQL DB instance
- Importing data to an Amazon RDS MariaDB or MySQL database with reduced downtime
- Importing data from any source to a MariaDB or MySQL DB instance

Restoring a backup into a MySQL DB instance

Amazon RDS supports importing MySQL databases by using backup files. You can create a backup of your database, store it on Amazon S3, and then restore the backup file onto a new Amazon RDS DB instance running MySQL.

The scenario described in this section restores a backup of an on-premises database. You can use this technique for databases in other locations, such as Amazon EC2 or non-AWS cloud services, as long as the database is accessible.

You can find the supported scenario in the following diagram.



Importing backup files from Amazon S3 is supported for MySQL in all AWS Regions.

We recommend that you import your database to Amazon RDS by using backup files if your on-premises database can be offline while the backup file is created, copied, and restored. If your database can't be offline, you can use binary log (binlog) replication to update your database after you have migrated to Amazon RDS through Amazon S3 as explained in this topic. For more information, see Configuring binary log file position replication with an external source instance. You can also use the AWS Database Migration Service to migrate your database to Amazon RDS. For more information, see What is AWS Database Migration Service?

Limitations and recommendations for importing backup files from Amazon S3 to Amazon RDS

The following are some limitations and recommendations for importing backup files from Amazon S3:

- You can only import your data to a new DB instance, not an existing DB instance.
- You must use Percona XtraBackup to create the backup of your on-premises database.
- You can't import data from a DB snapshot export to Amazon S3.
- You can't migrate from a source database that has tables defined outside of the default MySQL data directory.
- You must import your data to the default minor version of your MySQL major version in your AWS Region. For example, if your major version is MySQL 8.0, and the default minor version for your AWS Region is 8.0.35, then you must import your data into a MySQL version 8.0.35 DB instance. You can upgrade your DB instance after importing. For information about determining the default minor version, see MySQL on Amazon RDS versions.
- Backward migration is not supported for both major versions and minor versions. For example, you can't migrate from version 8.0 to version 5.7, and you can't migrate from version 8.0.32 to version 8.0.31.
- You can't import a MySQL 5.5 or 5.6 database.
- You can't import an on-premises MySQL database from one major version to another. For example, you can't import a MySQL 5.7 database to an RDS for MySQL 8.0 database. You can upgrade your DB instance after you complete the import.
- You can't restore from an encrypted source database, but you can restore to an encrypted Amazon RDS DB instance.
- You can't restore from an encrypted backup in the Amazon S3 bucket.
- You can't restore from an Amazon S3 bucket in a different AWS Region than your Amazon RDS DB instance.
- Importing from Amazon S3 is not supported on the db.t2.micro DB instance class. However, you can restore to a different DB instance class, and change the DB instance class later. For more information about instance classes, see Hardware specifications for DB instance classes.
- Amazon S3 limits the size of a file uploaded to an Amazon S3 bucket to 5 TB. If a backup file exceeds 5 TB, then you must split the backup file into smaller files.
- When you restore the database, the backup is copied and then extracted on your DB instance. Therefore, provision storage space for your DB instance that is equal to or greater than the sum of the backup size, plus the original database's size on disk.
- Amazon RDS limits the number of files uploaded to an Amazon S3 bucket to 1 million. If the backup data for your database, including all full and incremental backups, exceeds 1 million files, use a Gzip (.gz), tar (.tar.gz), or Percona xbstream (.xbstream) file to store full and incremental

backup files in the Amazon S3 bucket. Percona XtraBackup 8.0 only supports Percona xbstream for compression.

- User accounts are not imported automatically. Save your user accounts from your source database and add them to your new DB instance later.
- Functions are not imported automatically. Save your functions from your source database and add them to your new DB instance later.
- Stored procedures are not imported automatically. Save your stored procedures from your source database and add them to your new DB instance later.
- Time zone information is not imported automatically. Record the time zone information for your source database, and set the time zone of your new DB instance later. For more information, see Local time zone for MySQL DB instances.
- The `innodb_data_file_path` parameter must be configured with only one data file that uses the default data file name `"ibdata1:12M:autoextend"`. Databases with two data files, or with a data file with a different name, can't be migrated using this method.

  The following are examples of file names that are not allowed: `"innodb_data_file_path=ibdata1:50M; ibdata2:50M:autoextend"` and `"innodb_data_file_path=ibdata01:50M:autoextend"`.
- The maximum size of the restored database is the maximum database size supported minus the size of the backup. So, if the maximum database size supported is 64 TiB, and the size of the backup is 30 TiB, then the maximum size of the restored database is 34 TiB, as in the following example:

  ```
  64 TiB - 30 TiB = 34 TiB
  ```

  For information about the maximum database size supported by Amazon RDS for MySQL, see General Purpose SSD storage and Provisioned IOPS SSD storage.

Overview of setting up to import backup files from Amazon S3 to Amazon RDS

These are the components you need to set up to import backup files from Amazon S3 to Amazon RDS:

- An Amazon S3 bucket to store your backup files.
- A backup of your on-premises database created by Percona XtraBackup.
- An AWS Identity and Access Management (IAM) role to allow Amazon RDS to access the bucket.

If you already have an Amazon S3 bucket, you can use that. If you don't have an Amazon S3 bucket, you can create a new one. If you want to create a new bucket, see Creating a bucket.

Use the Percona XtraBackup tool to create your backup. For more information, see Creating your database backup.

If you already have an IAM role, you can use that. If you don't have an IAM role, you can create a new one manually. Alternatively, you can choose to have a new IAM role created for you in your account by the wizard when you restore the database by using the AWS Management Console. If you want to create a new IAM role manually, or attach trust and permissions policies to an existing IAM role, see Creating an IAM role manually. If you want to have a new IAM role created for you, follow the procedure in Console.

Creating your database backup

Use the Percona XtraBackup software to create your backup. We recommend that you use the latest version of Percona XtraBackup. You can install Percona XtraBackup from Download Percona XtraBackup.

Warning

When creating a database backup, XtraBackup might save credentials in the xtrabackup_info file. Make sure you examine that file so that the `tool_command` setting in it doesn't contain any sensitive information.

Note

For MySQL 8.0 migration, you must use Percona XtraBackup 8.0. Percona XtraBackup 8.0.12 and higher versions support migration of all versions of MySQL. If you are migrating to RDS for MySQL 8.0.20 or higher, you must use Percona XtraBackup 8.0.12 or higher.
For MySQL 5.7 migrations, you can also use Percona XtraBackup 2.4. For migrations of earlier MySQL versions, you can also use Percona XtraBackup 2.3 or 2.4.

You can create a full backup of your MySQL database files using Percona XtraBackup. Alternatively, if you already use Percona XtraBackup to back up your MySQL database files, you can upload your existing full and incremental backup directories and files.

For more information about backing up your database with Percona XtraBackup, see Percona XtraBackup - documentation and The xtrabackup binary on the Percona website.

Creating a full backup with Percona XtraBackup

To create a full backup of your MySQL database files that can be restored from Amazon S3, use the Percona XtraBackup utility (`xtrabackup`) to back up your database.

For example, the following command creates a backup of a MySQL database and stores the files in the folder `/on-premises/s3-restore/backup` folder.

```
xtrabackup --backup --user=<myuser> --password=<password> --target-dir=</on-premises/
s3-restore/backup>
```

If you want to compress your backup into a single file (which can be split later, if needed), you can save your backup in one of the following formats:

- Gzip (.gz)
- tar (.tar)
- Percona xbstream (.xbstream)

> **Note**
>
> Percona XtraBackup 8.0 only supports Percona xbstream for compression.

The following command creates a backup of your MySQL database split into multiple Gzip files.

```
xtrabackup --backup --user=<myuser> --password=<password> --stream=tar \
   --target-dir=</on-premises/s3-restore/backup> | gzip - | split -d --bytes=500MB \
   - </on-premises/s3-restore/backup/backup>.tar.gz
```

The following command creates a backup of your MySQL database split into multiple tar files.

```
xtrabackup --backup --user=<myuser> --password=<password> --stream=tar \
   --target-dir=</on-premises/s3-restore/backup> | split -d --bytes=500MB \
   - </on-premises/s3-restore/backup/backup>.tar
```

The following command creates a backup of your MySQL database split into multiple xbstream files.

```
xtrabackup --backup --user=<myuser> --password=<password> --stream=xbstream \
   --target-dir=</on-premises/s3-restore/backup> | split -d --bytes=500MB \
   - </on-premises/s3-restore/backup/backup>.xbstream
```

Note

If you see the following error, it might be caused by mixing file formats in your command:

```
ERROR:/bin/tar: This does not look like a tar archive
```

Using incremental backups with Percona XtraBackup

If you already use Percona XtraBackup to perform full and incremental backups of your MySQL database files, you don't need to create a full backup and upload the backup files to Amazon S3. Instead, you can save a significant amount of time by copying your existing backup directories and files to your Amazon S3 bucket. For more information about creating incremental backups using Percona XtraBackup, see Incremental backup.

When copying your existing full and incremental backup files to an Amazon S3 bucket, you must recursively copy the contents of the base directory. Those contents include the full backup and also all incremental backup directories and files. This copy must preserve the directory structure in the Amazon S3 bucket. Amazon RDS iterates through all files and directories. Amazon RDS uses the `xtrabackup-checkpoints` file that is included with each incremental backup to identify the base directory, and to order incremental backups by log sequence number (LSN) range.

Backup considerations for Percona XtraBackup

Amazon RDS consumes your backup files based on the file name. Name your backup files with the appropriate file extension based on the file format—for example, `.xbstream` for files stored using the Percona xbstream format.

Amazon RDS consumes your backup files in alphabetical order and also in natural number order. Use the `split` option when you issue the `xtrabackup` command to ensure that your backup files are written and named in the proper order.

Amazon RDS doesn't support partial backups created using Percona XtraBackup. You can't use the following options to create a partial backup when you back up the source files for your database: `--tables`, `--tables-exclude`, `--tables-file`, `--databases`, `--databases-exclude`, or `--databases-file`.

Amazon RDS supports incremental backups created using Percona XtraBackup. For more information about creating incremental backups using Percona XtraBackup, see Incremental backup.

Creating an IAM role manually

If you don't have an IAM role, you can create a new one manually. However, if you restore the database by using the AWS Management Console, we recommend that you follow the procedure in Console and choose to have RDS create this new IAM role for you.

To manually create a new IAM role for importing your database from Amazon S3, create a role to delegate permissions from Amazon RDS to your Amazon S3 bucket. When you create an IAM role, you attach trust and permissions policies. To import your backup files from Amazon S3, use trust and permissions policies similar to the following examples. For more information about creating the role, see Creating a role to delegate permissions to an AWS service.

The trust and permissions policies require that you provide an Amazon Resource Name (ARN). For more information about ARN formatting, see Amazon Resource Names (ARNs) and AWS service namespaces.

Example trust policy for importing from Amazon S3

```
{
    "Version": "2012-10-17",
    "Statement":
    [{
        "Effect": "Allow",
        "Principal": {"Service":  "rds.amazonaws.com"},
        "Action": "sts:AssumeRole"
    }]
}
```

Example permissions policy for importing from Amazon S3 — IAM user permissions

In the following example, replace *`iam_user_id`* with your own value.

```
{
    "Version":"2012-10-17",
    "Statement":
    [
        {
            "Sid":"AllowS3AccessRole",
            "Effect":"Allow",
            "Action":"iam:PassRole",
            "Resource":"arn:aws:iam::iam_user_id:role/S3Access"
        }
    ]
}
```

Example permissions policy for importing from Amazon S3 — role permissions

In the following example, replace *amzn-s3-demo-bucket* and *prefix* with your own values.

```
{
    "Version": "2012-10-17",
    "Statement":
    [
        {
        "Effect": "Allow",
        "Action":
            [
                "s3:ListBucket",
                "s3:GetBucketLocation"
            ],
        "Resource": "arn:aws:s3:::amzn-s3-demo-bucket"
        },
        {
        "Effect": "Allow",
        "Action":
            [
                "s3:GetObject"
            ],
        "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/prefix*"
        },
        { // If your bucket is encrypted, include the following permission. This
 permission allows decryption of your AWS KMS key.
        "Effect": "Allow",
        "Action":
            [
```

```
                "kms:Decrypt"
            ],
        "Resource": [
            "arn:aws:kms:region:customer_id:key/key_id*"
            ]
        }
    ]
}
```

> **Note**
>
> If you include a file name prefix, include the asterisk (*) after the prefix. If you don't want to specify a prefix, specify only an asterisk.

Importing data from Amazon S3 to a new MySQL DB instance

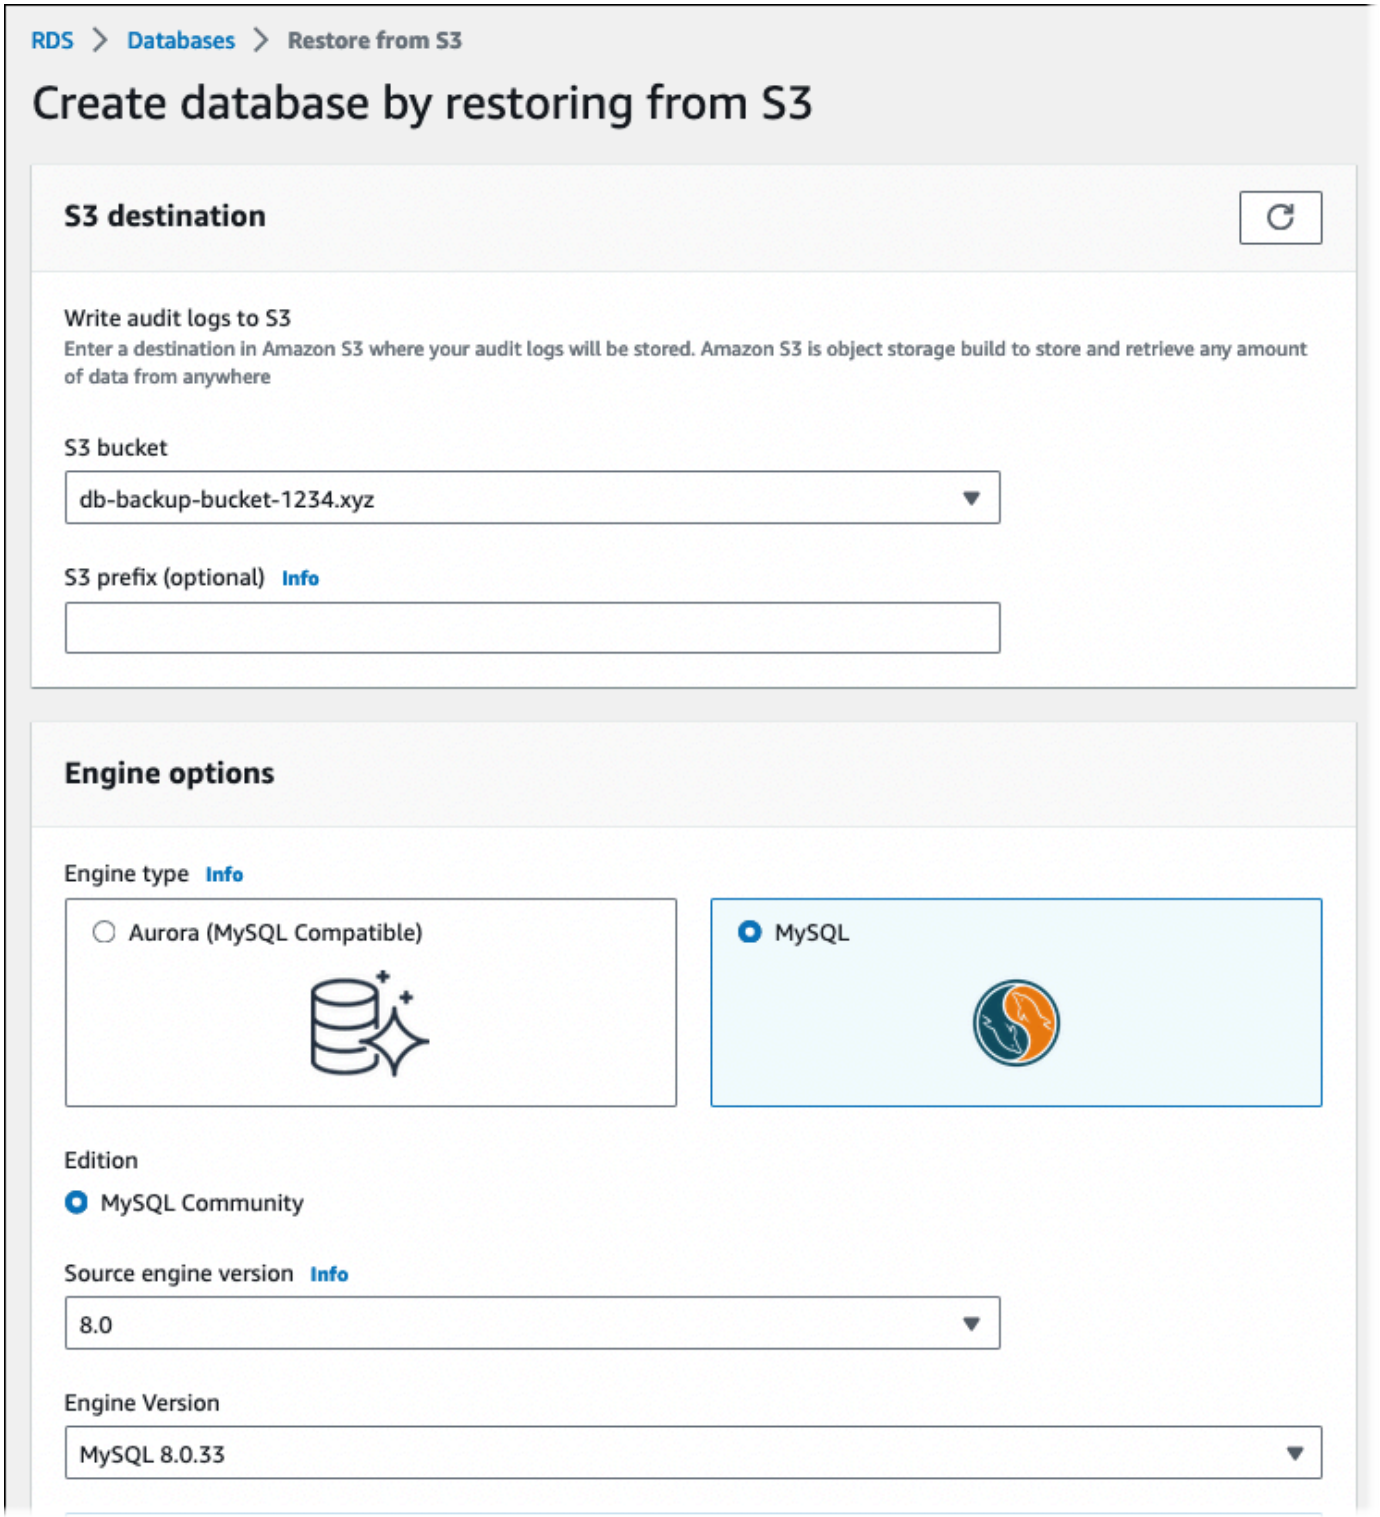
You can import data from Amazon S3 to a new MySQL DB instance using the AWS Management Console, AWS CLI, or RDS API.

Console

To import data from Amazon S3 to a new MySQL DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the top right corner of the Amazon RDS console, choose the AWS Region in which to create your DB instance. Choose the same AWS Region as the Amazon S3 bucket that contains your database backup.
3. In the navigation pane, choose **Databases**.
4. Choose **Restore from S3**.

   The **Create database by restoring from S3** page appears.



5. Under **S3 destination**:

   a. Choose the **S3 bucket** that contains the backup.

b. (Optional) For **S3 prefix**, enter the file path prefix for the files stored in your Amazon S3 bucket.

   If you don't specify a prefix, then RDS creates your DB instance using all of the files and folders in the root folder of the S3 bucket. If you do specify a prefix, then RDS creates your DB instance using the files and folders in the S3 bucket where the path for the file begins with the specified prefix.

   For example, suppose that you store your backup files on S3 in a subfolder named backups, and you have multiple sets of backup files, each in its own directory (gzip_backup1, gzip_backup2, and so on). In this case, you specify a prefix of backups/gzip_backup1 to restore from the files in the gzip_backup1 folder.

6. Under **Engine options**:

   a. For **Engine type**, choose **MySQL**.

   b. For **Source engine version**, choose the MySQL major version of your source database.

   c. For **Engine Version**, choose the default minor version of your MySQL major version in your AWS Region.

      In the AWS Management Console, only the default minor version is available. You can upgrade your DB instance after importing.

7. For **IAM role**, create or choose IAM role with the required trust policy and permissions policy that allows Amazon RDS to access your Amazon S3 bucket. Perform one of the following actions:

   - (Recommended) Choose **Create a new role**, and enter the **IAM role name**. With this option, RDS automatically creates the role with the trust policy and permissions policy for you.
   - Choose an existing IAM role. Make sure that this role meets all of the criteria in the section called “Creating an IAM role manually”.

8. Specify your DB instance information. For information about each setting, see Settings for DB instances.

   > **Note**
   >
   > Be sure to allocate enough memory for your new DB instance so that the restore operation can succeed.

You can also choose **Enable storage autoscaling** to allow for future growth automatically.

9. Choose additional settings as needed.
10. Choose **Create database**.

AWS CLI

To import data from Amazon S3 to a new MySQL DB instance by using the AWS CLI, call the restore-db-instance-from-s3 command with the following parameters. For information about each setting, see Settings for DB instances.

> **Note**
>
> Be sure to allocate enough memory for your new DB instance so that the restore operation can succeed.
> You can also use the `--max-allocated-storage` parameter to enable storage autoscaling and allow for future growth automatically.

- `--allocated-storage`
- `--db-instance-identifier`
- `--db-instance-class`
- `--engine`
- `--master-username`
- `--manage-master-user-password`
- `--s3-bucket-name`
- `--s3-ingestion-role-arn`
- `--s3-prefix`
- `--source-engine`
- `--source-engine-version`

Example

For Linux, macOS, or Unix:

```
aws rds restore-db-instance-from-s3 \
    --allocated-storage 250 \
    --db-instance-identifier myidentifier \
    --db-instance-class db.m5.large \
    --engine mysql \
    --master-username admin \
    --manage-master-user-password \
    --s3-bucket-name amzn-s3-demo-bucket \
    --s3-ingestion-role-arn arn:aws:iam::account-number:role/rolename \
    --s3-prefix bucketprefix \
    --source-engine mysql \
    --source-engine-version 8.0.32 \
    --max-allocated-storage 1000
```

For Windows:

```
aws rds restore-db-instance-from-s3 ^
    --allocated-storage 250 ^
    --db-instance-identifier myidentifier ^
    --db-instance-class db.m5.large ^
    --engine mysql ^
    --master-username admin ^
    --manage-master-user-password ^
    --s3-bucket-name amzn-s3-demo-bucket ^
    --s3-ingestion-role-arn arn:aws:iam::account-number:role/rolename ^
    --s3-prefix bucketprefix ^
    --source-engine mysql ^
    --source-engine-version 8.0.32 ^
    --max-allocated-storage 1000
```

RDS API

To import data from Amazon S3 to a new MySQL DB instance by using the Amazon RDS API, call the RestoreDBInstanceFromS3 operation.

Importing data from an external MariaDB or MySQL database to an RDS for MariaDB or RDS for MySQL DB instance

You can also import data from an existing MariaDB or MySQL database to a MySQL or MariaDB DB instance. You do so by copying the database with mysqldump and piping it directly into the MariaDB or MySQL DB instance. The `mysqldump` command line utility is commonly used to make

backups and transfer data from one MariaDB or MySQL server to another. It's included with MySQL and MariaDB client software.

> **Note**
>
> If you are importing or exporting large amounts of data with a MySQL DB instance, it's more reliable and faster to move data in and out of Amazon RDS by using `xtrabackup` backup files and Amazon S3. For more information, see Restoring a backup into a MySQL DB instance.

A typical `mysqldump` command to move data from an external database to an Amazon RDS DB instance looks similar to the following.

```
mysqldump -u local_user \
    --databases database_name \
    --single-transaction \
    --compress \
    --order-by-primary  \
    -plocal_password | mysql -u RDS_user \
        --port=port_number \
        --host=host_name \
        -pRDS_password
```

> **Important**
>
> Make sure not to leave a space between the `-p` option and the entered password. Specify credentials other than the prompts shown here as a security best practice.

Make sure that you're aware of the following recommendations and considerations:

- Exclude the following schemas from the dump file: `sys`, `performance_schema`, and `information_schema`. The `mysqldump` utility excludes these schemas by default.
- If you need to migrate users and privileges, consider using a tool that generates the data control language (DCL) for recreating them, such as the pt-show-grants utility.
- To perform the import, make sure the user doing so has access to the DB instance. For more information, see Controlling access with security groups.

The parameters used are as follows:

- `-u` *`local_user`* – Use to specify a user name. In the first usage of this parameter, you specify the name of a user account on the local MariaDB or MySQL database identified by the `--databases` parameter.
- `--databases` *`database_name`* – Use to specify the name of the database on the local MariaDB or MySQL instance that you want to import into Amazon RDS.
- `--single-transaction` – Use to ensure that all of the data loaded from the local database is consistent with a single point in time. If there are other processes changing the data while `mysqldump` is reading it, using this parameter helps maintain data integrity.
- `--compress` – Use to reduce network bandwidth consumption by compressing the data from the local database before sending it to Amazon RDS.
- `--order-by-primary` – Use to reduce load time by sorting each table's data by its primary key.
- `-p`*`local_password`* – Use to specify a password. In the first usage of this parameter, you specify the password for the user account identified by the first `-u` parameter.
- `-u` *`RDS_user`* – Use to specify a user name. In the second usage of this parameter, you specify the name of a user account on the default database for the MariaDB or MySQL DB instance identified by the `--host` parameter.
- `--port` *`port_number`* – Use to specify the port for your MariaDB or MySQL DB instance. By default, this is 3306 unless you changed the value when creating the instance.
- `--host` *`host_name`* – Use to specify the Domain Name System (DNS) name from the Amazon RDS DB instance endpoint, for example, `myinstance.123456789012.us-east-1.rds.amazonaws.com`. You can find the endpoint value in the instance details in the Amazon RDS Management Console.
- `-p`*`RDS_password`* – Use to specify a password. In the second usage of this parameter, you specify the password for the user account identified by the second `-u` parameter.

Make sure to create any stored procedures, triggers, functions, or events manually in your Amazon RDS database. If you have any of these objects in the database that you are copying, then exclude them when you run `mysqldump`. To do so, include the following parameters with your `mysqldump` command: `--routines=0 --triggers=0 --events=0`.

The following example copies the `world` sample database on the local host to a MySQL DB instance.

For Linux, macOS, or Unix:

```
sudo mysqldump -u localuser \
    --databases world \
    --single-transaction \
    --compress \
    --order-by-primary  \
    --routines=0 \
    --triggers=0 \
    --events=0 \
    -plocalpassword | mysql -u rdsuser \
        --port=3306 \
        --host=myinstance.123456789012.us-east-1.rds.amazonaws.com \
        -prdspassword
```

For Windows, run the following command in a command prompt that has been opened by right-clicking **Command Prompt** on the Windows programs menu and choosing **Run as administrator**:

```
mysqldump -u localuser ^
    --databases world ^
    --single-transaction ^
    --compress ^
    --order-by-primary  ^
    --routines=0 ^
    --triggers=0 ^
    --events=0 ^
    -plocalpassword | mysql -u rdsuser ^
        --port=3306 ^
        --host=myinstance.123456789012.us-east-1.rds.amazonaws.com ^
        -prdspassword
```

> **Note**
>
> Specify credentials other than the prompts shown here as a security best practice.

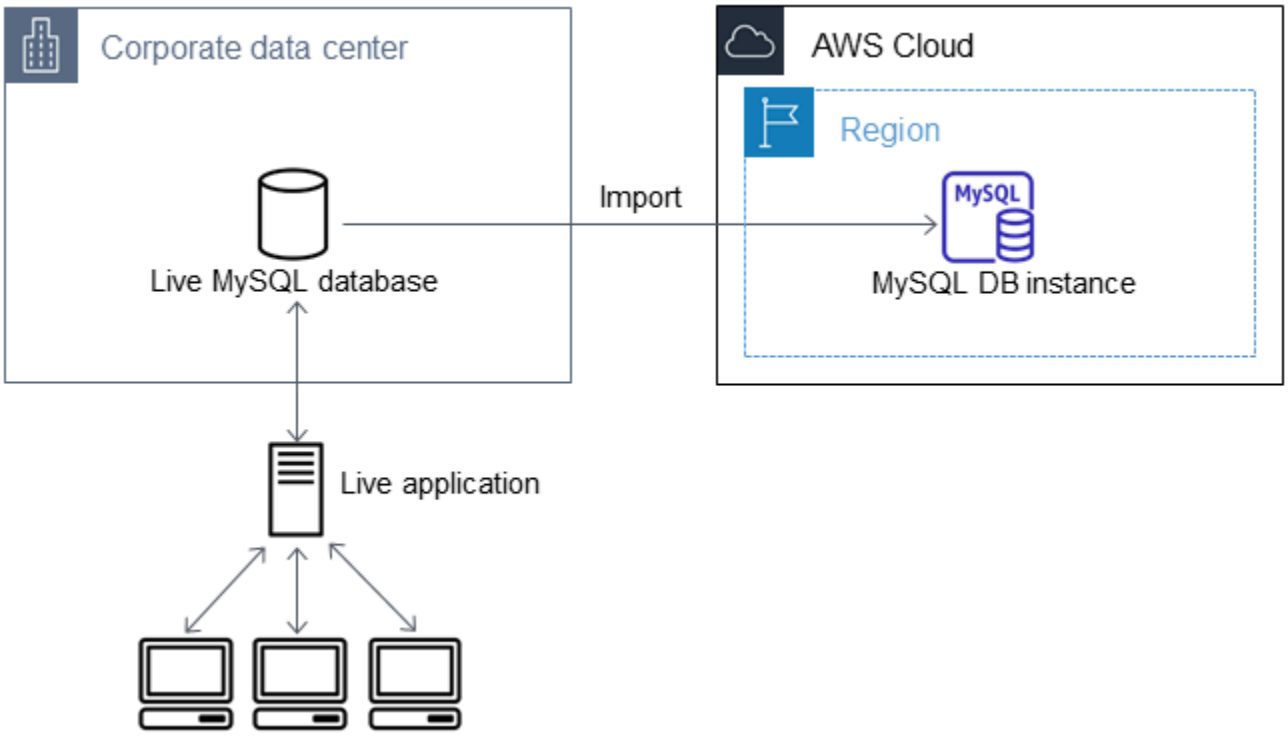
Importing data to an Amazon RDS MariaDB or MySQL database with reduced downtime

In some cases, you might need to import data from an external MariaDB or MySQL database that supports a live application to a MariaDB DB instance, a MySQL DB instance, or a MySQL Multi-AZ

DB cluster. Use the following procedure to minimize the impact on availability of applications. This procedure can also help if you are working with a very large database. Using this procedure, you can reduce the cost of the import by reducing the amount of data that is passed across the network to AWS.

In this procedure, you transfer a copy of your database data to an Amazon EC2 instance and import the data into a new Amazon RDS database. You then use replication to bring the Amazon RDS database up-to-date with your live external instance, before redirecting your application to the Amazon RDS database. Configure MariaDB replication based on global transaction identifiers (GTIDs) if the external instance is MariaDB 10.0.24 or higher and the target instance is RDS for MariaDB. Otherwise, configure replication based on binary log coordinates. We recommend GTID-based replication if your external database supports it because GTID-based replication is a more reliable method. For more information, see Global transaction ID in the MariaDB documentation.

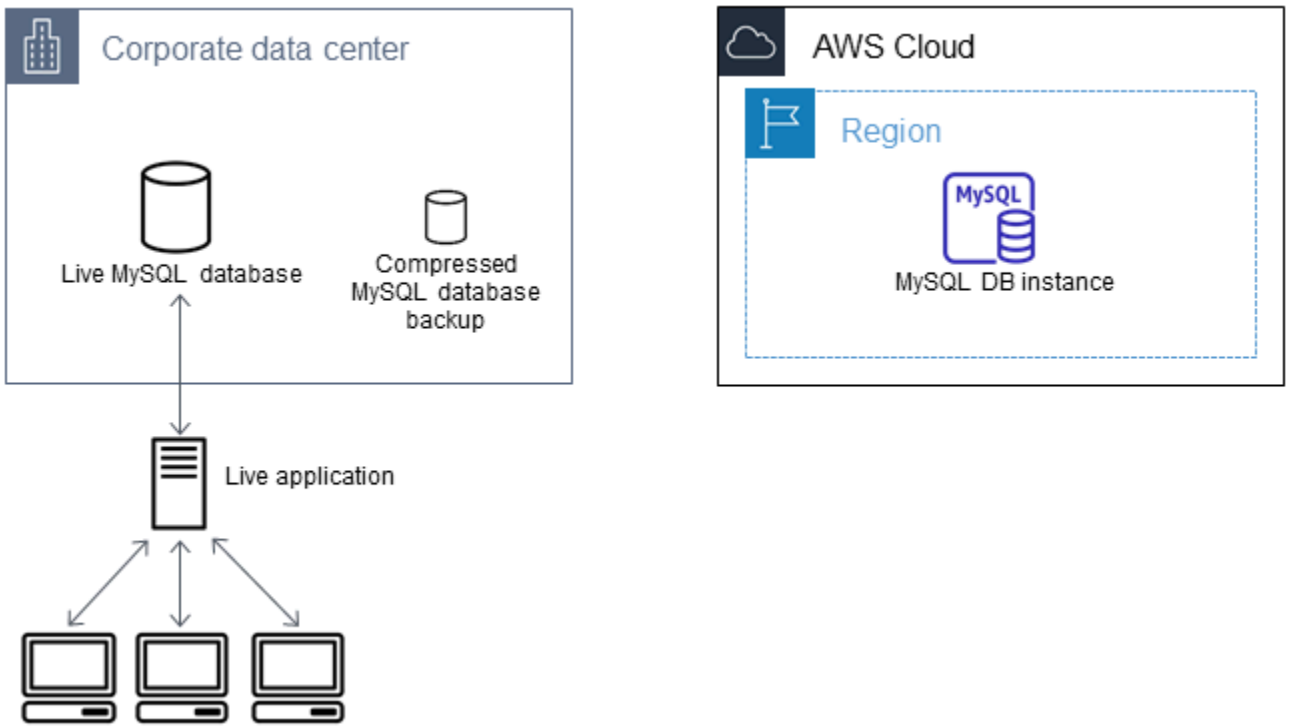
> **Note**
>
> If you want to import data into a MySQL DB instance and your scenario supports it, we recommend moving data in and out of Amazon RDS by using backup files and Amazon S3. For more information, see Restoring a backup into a MySQL DB instance.



> **Note**
>
> We don't recommend that you use this procedure with source MySQL databases from MySQL versions earlier than version 5.5 because of potential replication issues. For more information, see Replication compatibility between MySQL versions in the MySQL documentation.

Create a copy of your existing database

The first step in the process of migrating a large amount of data to an RDS for MariaDB or RDS for MySQL database with minimal downtime is to create a copy of the source data.



You can use the mysqldump utility to create a database backup in either SQL or delimited-text format. We recommend that you do a test run with each format in a non-production environment to see which method minimizes the amount of time that mysqldump runs.

We also recommend that you weigh mysqldump performance against the benefit offered by using the delimited-text format for loading. A backup using delimited-text format creates a tab-separated text file for each table being dumped. To reduce the amount of time required to import your database, you can load these files in parallel using the `LOAD DATA LOCAL INFILE`

command. For more information about choosing a mysqldump format and then loading the data, see Using mysqldump for backups in the MySQL documentation.

Before you start the backup operation, make sure to set the replication options on the MariaDB or MySQL database that you are copying to Amazon RDS. The replication options include turning on binary logging and setting a unique server ID. Setting these options causes your server to start logging database transactions and prepares it to be a source replication instance later in this process.

> **Note**
>
> Use the `--single-transaction` option with mysqldump because it dumps a consistent state of the database. To ensure a valid dump file, don't run data definition language (DDL) statements while mysqldump is running. You can schedule a maintenance window for these operations.
> Exclude the following schemas from the dump file: `sys`, `performance_schema`, and `information_schema`. The mysqldump utility excludes these schemas by default.
> To migrate users and privileges, consider using a tool that generates the data control language (DCL) for recreating them, such as the pt-show-grants utility.

To set replication options

1. Edit the `my.cnf` file (this file is usually under `/etc`).

   ```
   sudo vi /etc/my.cnf
   ```

   Add the `log_bin` and `server_id` options to the `[mysqld]` section. The `log_bin` option provides a file name identifier for binary log files. The `server_id` option provides a unique identifier for the server in source-replica relationships.

   The following example shows the updated `[mysqld]` section of a `my.cnf` file.

   ```
   [mysqld]
   log-bin=mysql-bin
   server-id=1
   ```

   For more information, see the MySQL documentation.

2. For replication with a Multi-AZ DB cluster, set the ENFORCE_GTID_CONSISTENCY and the GTID_MODE parameter to ON.

```
mysql> SET @@GLOBAL.ENFORCE_GTID_CONSISTENCY = ON;
```

```
mysql> SET @@GLOBAL.GTID_MODE = ON;
```

   These settings aren't required for replication with a DB instance.

3. Restart the mysql service.

```
sudo service mysqld restart
```

To create a backup copy of your existing database

1. Create a backup of your data using the mysqldump utility, specifying either SQL or delimited-text format.

   Specify `--master-data=2` to create a backup file that can be used to start replication between servers. For more information, see the mysqldump documentation.

   To improve performance and ensure data integrity, use the `--order-by-primary` and `--single-transaction` options of mysqldump.

   To avoid including the MySQL system database in the backup, do not use the `--all-databases` option with mysqldump. For more information, see Creating a data snapshot using mysqldump in the MySQL documentation.

   Use chmod if necessary to make sure that the directory where the backup file is being created is writeable.

   > **Important**
   >
   > On Windows, run the command window as an administrator.

   - To produce SQL output, use the following command.

     For Linux, macOS, or Unix:

```
sudo mysqldump \
    --databases database_name \
    --master-data=2  \
    --single-transaction \
    --order-by-primary \
    -r backup.sql \
    -u local_user \
    -p password
```

> **Note**
>
> Specify credentials other than the prompts shown here as a security best practice.

For Windows:

```
mysqldump ^
    --databases database_name ^
    --master-data=2  ^
    --single-transaction ^
    --order-by-primary ^
    -r backup.sql ^
    -u local_user ^
    -p password
```

> **Note**
>
> Specify credentials other than the prompts shown here as a security best practice.

- To produce delimited-text output, use the following command.

  For Linux, macOS, or Unix:

```
sudo mysqldump \
    --tab=target_directory \
    --fields-terminated-by ',' \
    --fields-enclosed-by '"' \
    --lines-terminated-by 0x0d0a \
    database_name \
```

```
    --master-data=2 \
    --single-transaction \
    --order-by-primary \
    -p password
```

For Windows:

```
mysqldump ^
    --tab=target_directory ^
    --fields-terminated-by "," ^
    --fields-enclosed-by """ ^
    --lines-terminated-by 0x0d0a ^
    database_name ^
    --master-data=2 ^
    --single-transaction ^
    --order-by-primary ^
    -p password
```

> **Note**
>
> Specify credentials other than the prompts shown here as a security best practice. Make sure to create any stored procedures, triggers, functions, or events manually in your Amazon RDS database. If you have any of these objects in the database that you are copying, exclude them when you run mysqldump. To do so, include the following arguments with your mysqldump command: `--routines=0 --triggers=0 --events=0`.

When using the delimited-text format, a `CHANGE MASTER TO` comment is returned when you run mysqldump. This comment contains the master log file name and position. If the external instance is other than MariaDB version 10.0.24 or higher, note the values for `MASTER_LOG_FILE` and `MASTER_LOG_POS`. You need these values when setting up replication.

```
-- Position to start replication or point-in-time recovery from
--
-- CHANGE MASTER TO MASTER_LOG_FILE='mysql-bin-changelog.000031',
 MASTER_LOG_POS=107;
```

If you are using SQL format, you can get the master log file name and position in the `CHANGE MASTER TO` comment in the backup file. If the external instance is MariaDB version 10.0.24 or higher, you can get the GTID in the next step.

2. If the external instance you are using is MariaDB version 10.0.24 or higher, you use GTID-based replication. Run `SHOW MASTER STATUS` on the external MariaDB instance to get the binary log file name and position, then convert them to a GTID by running `BINLOG_GTID_POS` on the external MariaDB instance.

```
SELECT BINLOG_GTID_POS('binary log file name', binary log file position);
```

   Note the GTID returned; you need it to configure replication.

3. Compress the copied data to reduce the amount of network resources needed to copy your data to the Amazon RDS database. Note the size of the backup file. You need this information when determining how large an Amazon EC2 instance to create. When you are done, compress the backup file using GZIP or your preferred compression utility.

   - To compress SQL output, use the following command.

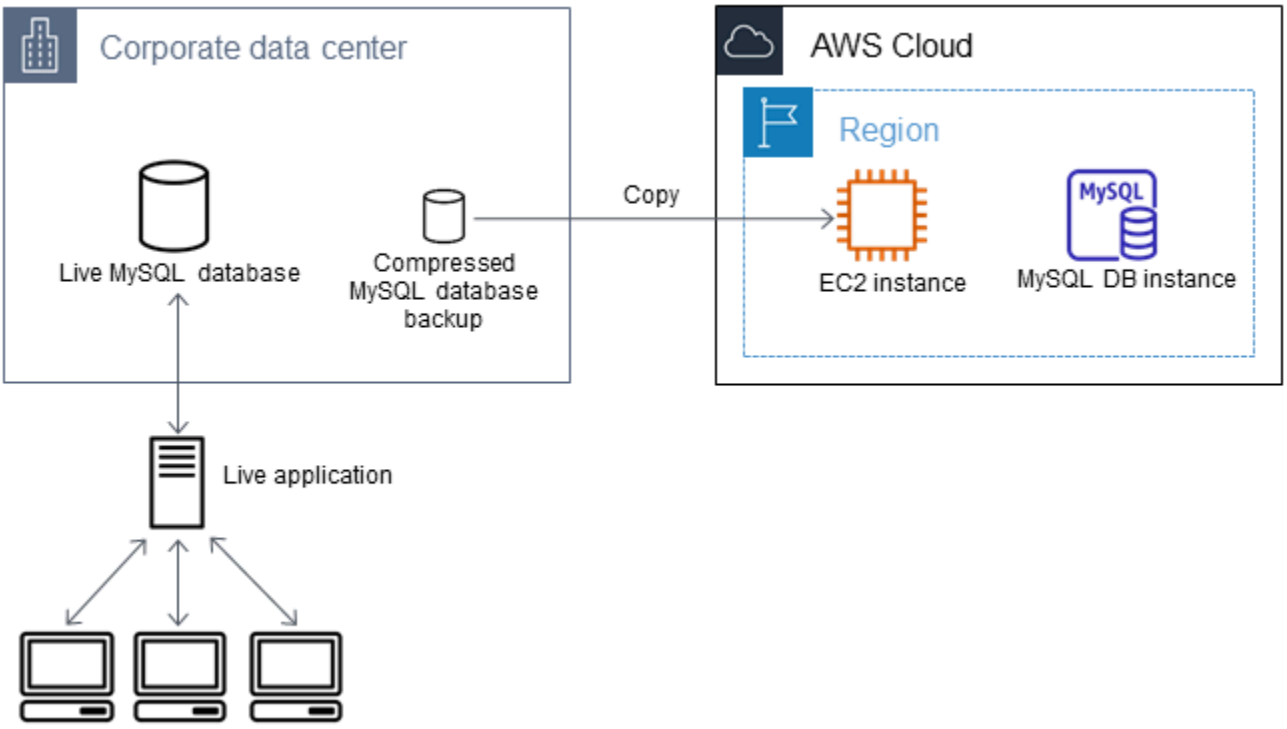
```
gzip backup.sql
```

   - To compress delimited-text output, use the following command.

```
tar -zcvf backup.tar.gz target_directory
```

Create an Amazon EC2 instance and copy the compressed database

Copying your compressed database backup file to an Amazon EC2 instance takes fewer network resources than doing a direct copy of uncompressed data between database instances. After your data is in Amazon EC2, you can copy it from there directly to your MariaDB or MySQL database. For you to save on the cost of network resources, your Amazon EC2 instance must be in the same AWS Region as your Amazon RDS DB instance. Having the Amazon EC2 instance in the same AWS Region as your Amazon RDS database also reduces network latency during the import.



To create an Amazon EC2 instance and copy your data

1. In the AWS Region where you plan to create the RDS database, create a virtual private cloud (VPC), a VPC security group, and a VPC subnet. Ensure that the inbound rules for your VPC security group allow the IP addresses required for your application to connect to AWS. You can specify a range of IP addresses (for example, `203.0.113.0/24`), or another VPC security group. You can use the Amazon VPC Management Console to create and manage VPCs, subnets, and security groups. For more information, see Getting started with Amazon VPC in the *Amazon Virtual Private Cloud Getting Started Guide*.
2. Open the Amazon EC2 Management Console and choose the AWS Region to contain both your Amazon EC2 instance and your Amazon RDS database. Launch an Amazon EC2 instance using the VPC, subnet, and security group that you created in Step 1. Ensure that you select an instance type with enough storage for your database backup file when it is uncompressed. For details on Amazon EC2 instances, see Getting started with Amazon EC2 Linux instances in the *Amazon Elastic Compute Cloud User Guide for Linux*.
3. To connect to your Amazon RDS database from your Amazon EC2 instance, edit your VPC security group. Add an inbound rule specifying the private IP address of your EC2 instance. You can find the private IP address on the **Details** tab of the **Instance** pane in the EC2 console window. To edit the VPC security group and add an inbound rule, choose **Security Groups** in the EC2 console navigation pane, choose your security group, and then add an inbound rule for

MySQL or Aurora specifying the private IP address of your EC2 instance. To learn how to add an inbound rule to a VPC security group, see Adding and removing rules in the *Amazon VPC User Guide*.

4. Copy your compressed database backup file from your local system to your Amazon EC2 instance. Use `chmod` if necessary to make sure that you have write permission for the target directory of the Amazon EC2 instance. You can use `scp` or a Secure Shell (SSH) client to copy the file. The following is an example.

```
scp -r -i key pair.pem backup.sql.gz ec2-user@EC2 DNS:/target_directory/backup.sql.gz
```

> **Important**
>
> Be sure to copy sensitive data using a secure network transfer protocol.

5. Connect to your Amazon EC2 instance and install the latest updates and the MySQL client tools using the following commands.

```
sudo yum update -y
sudo yum install mysql -y
```

For more information, see Connect to your instance in the *Amazon Elastic Compute Cloud User Guide for Linux*.

> **Important**
>
> This example installs the MySQL client on an Amazon Machine Image (AMI) for an Amazon Linux distribution. To install the MySQL client on a different distribution, such as Ubuntu or Red Hat Enterprise Linux, this example doesn't work. For information about installing MySQL, see Installing and Upgrading MySQL in the MySQL documentation.

6. While connected to your Amazon EC2 instance, decompress your database backup file. The following are examples.

   - To decompress SQL output, use the following command.

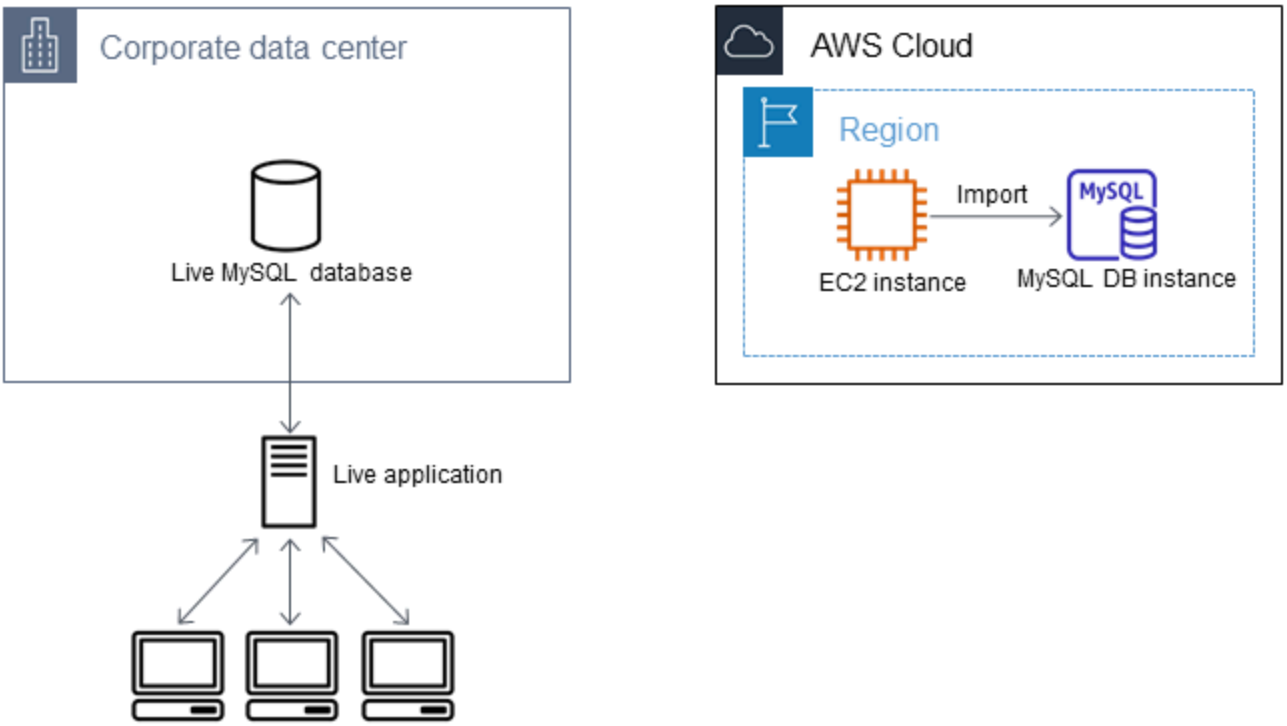
     ```
     gzip backup.sql.gz -d
     ```

   - To decompress delimited-text output, use the following command.

```
tar xzvf backup.tar.gz
```

Create a MySQL or MariaDB database and import data from your Amazon EC2 instance

By creating a MariaDB DB instance, a MySQL DB instance, or a MySQL Multi-AZ DB cluster in the same AWS Region as your Amazon EC2 instance, you can import the database backup file from EC2 faster than over the internet.



To create a MariaDB or MySQL database and import your data

1. Determine which DB instance class and what amount of storage space is required to support the expected workload for this Amazon RDS database. As part of this process, decide what is sufficient space and processing capacity for your data load procedures. Also decide what is required to handle the production workload. You can estimate this based on the size and resources of the source MariaDB or MySQL database. For more information, see DB instance classes.
2. Create a DB instance or Multi-AZ DB cluster in the AWS Region that contains your Amazon EC2 instance.

To create a MySQL Multi-AZ DB cluster, follow the instructions in Creating a Multi-AZ DB cluster.

To create a MariaDB or MySQL DB instance, follow the instructions in Creating an Amazon RDS DB instance and use the following guidelines:

- Specify a DB engine version that is compatible with your source DB instance, as follows:
  - If your source instance is MySQL 5.5.x, the Amazon RDS DB instance must be MySQL.
  - If your source instance is MySQL 5.6.x or 5.7.x, the Amazon RDS DB instance must be MySQL or MariaDB.
  - If your source instance is MySQL 8.0.x, the Amazon RDS DB instance must be MySQL 8.0.x.
  - If your source instance is MariaDB 5.5 or higher, the Amazon RDS DB instance must be MariaDB.
- Specify the same virtual private cloud (VPC) and VPC security group as for your Amazon EC2 instance. This approach ensures that your Amazon EC2 instance and your Amazon RDS instance are visible to each other over the network. Make sure your DB instance is publicly accessible. To set up replication with your source database as described later, your DB instance must be publicly accessible.
- Don't configure multiple Availability Zones, backup retention, or read replicas until after you have imported the database backup. When that import is completed, you can configure Multi-AZ and backup retention for the production instance.

3. Review the default configuration options for the Amazon RDS database. If the default parameter group for the database doesn't have the configuration options that you want, find a different one that does or create a new parameter group. For more information on creating a parameter group, see Parameter groups for Amazon RDS.
4. Connect to the new Amazon RDS database as the master user. Create the users required to support the administrators, applications, and services that need to access the instance. The hostname for the Amazon RDS database is the **Endpoint** value for this instance without including the port number. An example is `mysampledb.123456789012.us-west-2.rds.amazonaws.com`. You can find the endpoint value in the database details in the Amazon RDS Management Console.
5. Connect to your Amazon EC2 instance. For more information, see Connect to your instance in the *Amazon Elastic Compute Cloud User Guide for Linux*.

6. Connect to your Amazon RDS database as a remote host from your Amazon EC2 instance using the `mysql` command. The following is an example.

```
mysql -h host_name -P 3306 -u db_master_user -p
```

   The hostname is the Amazon RDS database endpoint.

7. At the `mysql` prompt, run the `source` command and pass it the name of your database dump file to load the data into the Amazon RDS DB instance:

   - For SQL format, use the following command.

```
mysql> source backup.sql;
```

   - For delimited-text format, first create the database, if it isn't the default database you created when setting up the Amazon RDS database.

```
mysql> create database database_name;
mysql> use database_name;
```

     Then create the tables.

```
mysql> source table1.sql
mysql> source table2.sql
etc...
```

     Then import the data.

```
mysql> LOAD DATA LOCAL INFILE 'table1.txt' INTO TABLE table1 FIELDS TERMINATED BY
 ',' ENCLOSED BY '"' LINES TERMINATED BY '0x0d0a';
mysql> LOAD DATA LOCAL INFILE 'table2.txt' INTO TABLE table2 FIELDS TERMINATED BY
 ',' ENCLOSED BY '"' LINES TERMINATED BY '0x0d0a';
etc...
```

     To improve performance, you can perform these operations in parallel from multiple connections so that all of your tables are created and then loaded at the same time.

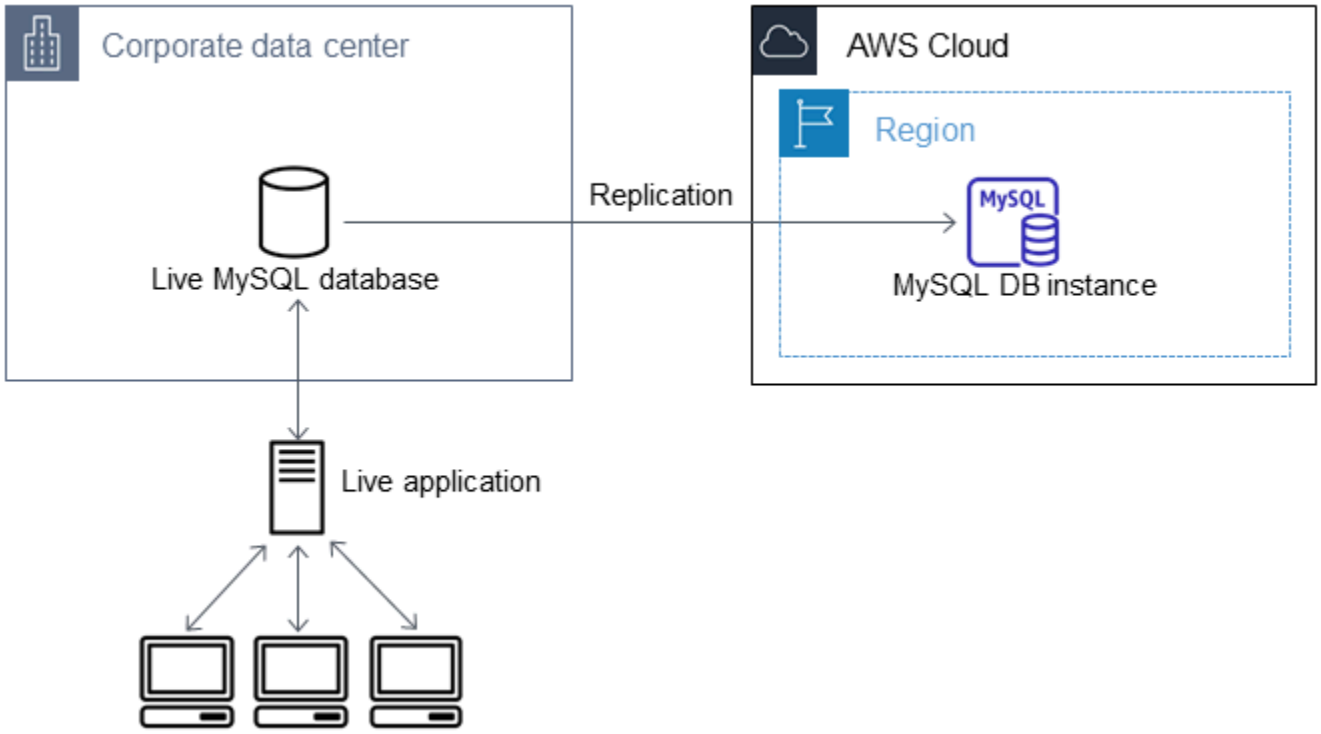
> **Note**
>
> If you used any data-formatting options with mysqldump when you initially dumped the table, make sure to use the same options with `LOAD DATA LOCAL INFILE` to ensure proper interpretation of the data file contents.

8. Run a simple `SELECT` query against one or two of the tables in the imported database to verify that the import was successful.

If you no longer need the Amazon EC2 instance used in this procedure, terminate the EC2 instance to reduce your AWS resource usage. To terminate an EC2 instance, see Terminating an instance in the *Amazon EC2 User Guide*.

Replicate between your external database and new Amazon RDS database

Your source database was likely updated during the time that it took to copy and transfer the data to the MariaDB or MySQL database. Thus, you can use replication to bring the copied database up-to-date with the source database.



The permissions required to start replication on an Amazon RDS database are restricted and not available to your Amazon RDS master user. Because of this, make sure to use either the

Amazon RDS mysql.rds_set_external_master command or the mysql.rds_set_external_master_gtid command to configure replication, and the mysql.rds_start_replication command to start replication between your live database and your Amazon RDS database.

To start replication

Earlier, you turned on binary logging and set a unique server ID for your source database. Now you can set up your Amazon RDS database as a replica with your live database as the source replication instance.

1. In the Amazon RDS Management Console, add the IP address of the server that hosts the source database to the VPC security group for the Amazon RDS database. For more information on modifying a VPC security group, see Security groups for your VPC in the *Amazon Virtual Private Cloud User Guide*.

   You might also need to configure your local network to permit connections from the IP address of your Amazon RDS database, so that it can communicate with your source instance. To find the IP address of the Amazon RDS database, use the `host` command.

   ```
   host rds_db_endpoint
   ```

   The hostname is the DNS name from the Amazon RDS database endpoint, for example `myinstance.123456789012.us-east-1.rds.amazonaws.com`. You can find the endpoint value in the instance details in the Amazon RDS Management Console.

2. Using the client of your choice, connect to the source instance and create a user to be used for replication. This account is used solely for replication and must be restricted to your domain to improve security. The following is an example.

   MySQL 5.5, 5.6, and 5.7

   ```
   CREATE USER 'repl_user'@'mydomain.com' IDENTIFIED BY 'password';
   ```

   MySQL 8.0

   ```
   CREATE USER 'repl_user'@'mydomain.com' IDENTIFIED WITH mysql_native_password BY
    'password';
   ```

> **Note**
>
> Specify credentials other than the prompts shown here as a security best practice.

3. For the source instance, grant `REPLICATION CLIENT` and `REPLICATION SLAVE` privileges to your replication user. For example, to grant the `REPLICATION CLIENT` and `REPLICATION SLAVE` privileges on all databases for the '`repl_user`' user for your domain, issue the following command.

   MySQL 5.5, 5.6, and 5.7

   ```
   GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'mydomain.com'
    IDENTIFIED BY 'password';
   ```

   MySQL 8.0

   ```
   GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'mydomain.com';
   ```

   > **Note**
   >
   > Specify credentials other than the prompts shown here as a security best practice.

4. If you used SQL format to create your backup file and the external instance is not MariaDB 10.0.24 or higher, look at the contents of that file.

   ```
   cat backup.sql
   ```

   The file includes a `CHANGE MASTER TO` comment that contains the master log file name and position. This comment is included in the backup file when you use the `--master-data` option with mysqldump. Note the values for `MASTER_LOG_FILE` and `MASTER_LOG_POS`.

   ```
   --
   -- Position to start replication or point-in-time recovery from
   --

   -- CHANGE MASTER TO MASTER_LOG_FILE='mysql-bin-changelog.000031', MASTER_LOG_POS=107;
   ```

If you used delimited text format to create your backup file and the external instance isn't MariaDB 10.0.24 or higher, you should already have binary log coordinates from step 1 of the procedure at "To create a backup copy of your existing database" in this topic.

If the external instance is MariaDB 10.0.24 or higher, you should already have the GTID from which to start replication from step 2 of the procedure at "To create a backup copy of your existing database" in this topic.

5. Make the Amazon RDS database the replica. If the external instance isn't MariaDB 10.0.24 or higher, connect to the Amazon RDS database as the master user and identify the source database as the source replication instance by using the mysql.rds_set_external_master command. Use the master log file name and master log position that you determined in the previous step if you have a SQL format backup file. Or use the name and position that you determined when creating the backup files if you used delimited-text format. The following is an example.

```
CALL mysql.rds_set_external_master ('myserver.mydomain.com', 3306,
    'repl_user', 'password', 'mysql-bin-changelog.000031', 107, 0);
```

> **Note**
>
> Specify credentials other than the prompts shown here as a security best practice.

If the external instance is MariaDB 10.0.24 or higher, connect to the Amazon RDS database as the master user and identify the source database as the source replication instance by using the mysql.rds_set_external_master_gtid command. Use the GTID that you determined in step 2 of the procedure at "To create a backup copy of your existing database" in this topic.. The following is an example.

```
CALL mysql.rds_set_external_master_gtid ('source_server_ip_address', 3306,
 'ReplicationUser', 'password', 'GTID', 0);
```

The `source_server_ip_address` is the IP address of source replication instance. An EC2 private DNS address is currently not supported.

> **Note**
>
> Specify credentials other than the prompts shown here as a security best practice.

6. On the Amazon RDS database, issue the mysql.rds_start_replication command to start replication.

```
CALL mysql.rds_start_replication;
```

7. On the Amazon RDS database, run the SHOW REPLICA STATUS command to determine when the replica is up-to-date with the source replication instance. The results of the `SHOW REPLICA STATUS` command include the `Seconds_Behind_Master` field. When the `Seconds_Behind_Master` field returns 0, then the replica is up-to-date with the source replication instance.

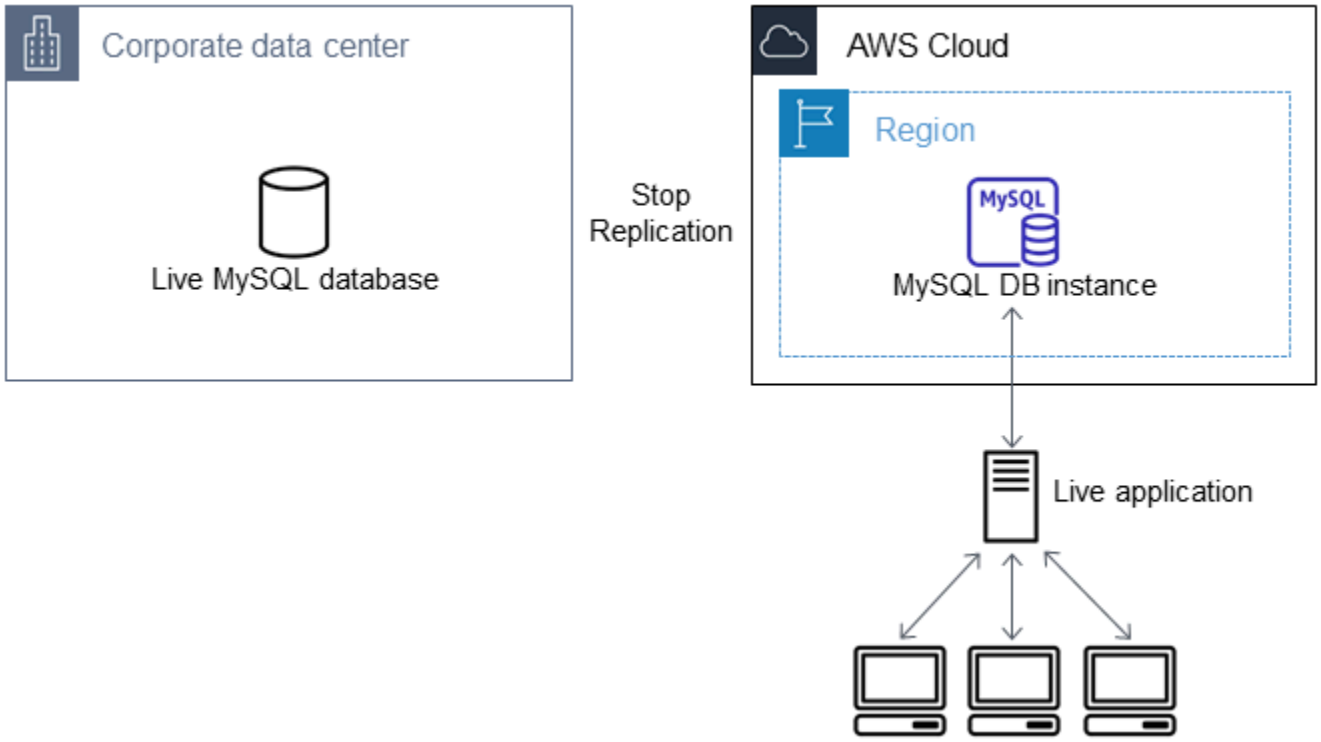
   > **Note**
   >
   > Previous versions of MySQL used `SHOW SLAVE STATUS` instead of `SHOW REPLICA STATUS`. If you are using a MySQL version before 8.0.23, then use `SHOW SLAVE STATUS`.

   For a MariaDB 10.5, 10.6, or 10.11 DB instance, run the mysql.rds_replica_status procedure instead of the MySQL command.

8. After the Amazon RDS database is up-to-date, turn on automated backups so you can restore that database if needed. You can turn on or modify automated backups for your Amazon RDS database using the Amazon RDS Management Console. For more information, see Introduction to backups.

Redirect your live application to your Amazon RDS instance

After the MariaDB or MySQL database is up-to-date with the source replication instance, you can now update your live application to use the Amazon RDS instance.



To redirect your live application to your MariaDB or MySQL database and stop replication

1. To add the VPC security group for the Amazon RDS database, add the IP address of the server that hosts the application. For more information on modifying a VPC security group, see Security groups for your VPC in the *Amazon Virtual Private Cloud User Guide*.
2. Verify that the `Seconds_Behind_Master` field in the SHOW REPLICA STATUS command results is 0, which indicates that the replica is up-to-date with the source replication instance.

   ```
   SHOW REPLICA STATUS;
   ```

   > **Note**
   >
   > Previous versions of MySQL used `SHOW SLAVE STATUS` instead of `SHOW REPLICA STATUS`. If you are using a MySQL version before 8.0.23, then use `SHOW SLAVE STATUS`.

   For a MariaDB 10.5, 10.6, or 10.11 DB instance, run the mysql.rds_replica_status procedure instead of the MySQL command.
3. Close all connections to the source when their transactions complete.

4. Update your application to use the Amazon RDS database. This update typically involves changing the connection settings to identify the hostname and port of the Amazon RDS database, the user account and password to connect with, and the database to use.
5. Connect to the DB instance.

   For a Multi-AZ DB cluster, connect to the writer DB instance.
6. Stop replication for the Amazon RDS instance using the mysql.rds_stop_replication command.

```
CALL mysql.rds_stop_replication;
```

7. Run the mysql.rds_reset_external_master command on your Amazon RDS database to reset the replication configuration so this instance is no longer identified as a replica.

```
CALL mysql.rds_reset_external_master;
```

8. Turn on additional Amazon RDS features such as Multi-AZ support and read replicas. For more information, see Configuring and managing a Multi-AZ deployment and Working with DB instance read replicas.

Importing data from any source to a MariaDB or MySQL DB instance

We recommend creating DB snapshots of the target Amazon RDS DB instance before and after the data load. Amazon RDS DB snapshots are complete backups of your DB instance that can be used to restore your DB instance to a known state. When you initiate a DB snapshot, I/O operations to your DB instance are momentarily suspended while your database is backed up.

Creating a DB snapshot immediately before the load makes it possible for you to restore the database to its state before the load, if you need to. A DB snapshot taken immediately after the load protects you from having to load the data again in case of a mishap and can also be used to seed new database instances.

The following list shows the steps to take. Each step is discussed in more detail following.

1. Create flat files containing the data to be loaded.
2. Stop any applications accessing the target DB instance.
3. Create a DB snapshot.
4. Consider turning off Amazon RDS automated backups.

5. Load the data.
6. Enable automated backups again.

Step 1: Create flat files containing the data to be loaded

Use a common format, such as comma-separated values (CSV), to store the data to be loaded. Each table must have its own file; you can't combine data for multiple tables in the same file. Give each file the same name as the table it corresponds to. The file extension can be anything you like. For example, if the table name is `sales`, the file name might be `sales.csv` or `sales.txt`, but not `sales_01.csv`.

Whenever possible, order the data by the primary key of the table being loaded. Doing this drastically improves load times and minimizes disk storage requirements.

The speed and efficiency of this procedure depends on keeping the size of the files small. If the uncompressed size of any individual file is larger than 1 GiB, split it into multiple files and load each one separately.

On Unix-like systems (including Linux), use the `split` command. For example, the following command splits the `sales.csv` file into multiple files of less than 1 GiB, splitting only at line breaks (-C 1024m). The new files are named `sales.part_00`, `sales.part_01`, and so on.

```
split -C 1024m -d sales.csv sales.part_
```

Similar utilities are available for other operating systems.

Step 2: Stop any applications accessing the target DB instance

Before starting a large load, stop all application activity accessing the target DB instance that you plan to load to. We recommend this particularly if other sessions will be modifying the tables being loaded or tables that they reference. Doing this reduces the risk of constraint violations occurring during the load and improves load performance. It also makes it possible to restore the DB instance to the point just before the load without losing changes made by processes not involved in the load.

Of course, this might not be possible or practical. If you can't stop applications from accessing the DB instance before the load, take steps to ensure the availability and integrity of your data. The specific steps required vary greatly depending upon specific use cases and site requirements.

Step 3: Create a DB snapshot

If you plan to load data into a new DB instance that contains no data, you can skip this step. Otherwise, creating a DB snapshot of your DB instance makes it possible for you to restore the DB instance to the point just before the load, if it becomes necessary. As previously mentioned, when you initiate a DB snapshot, I/O operations to your DB instance are suspended for a few minutes while the database is backed up.

The example following uses the AWS CLI `create-db-snapshot` command to create a DB snapshot of the AcmeRDS instance and give the DB snapshot the identifier `"preload"`.

For Linux, macOS, or Unix:

```
aws rds create-db-snapshot \
    --db-instance-identifier AcmeRDS \
    --db-snapshot-identifier preload
```

For Windows:

```
aws rds create-db-snapshot ^
    --db-instance-identifier AcmeRDS ^
    --db-snapshot-identifier preload
```

You can also use the restore from DB snapshot functionality to create test DB instances for dry runs or to undo changes made during the load.

Keep in mind that restoring a database from a DB snapshot creates a new DB instance that, like all DB instances, has a unique identifier and endpoint. To restore the DB instance without changing the endpoint, first delete the DB instance so that you can reuse the endpoint.

For example, to create a DB instance for dry runs or other testing, you give the DB instance its own identifier. In the example, AcmeRDS-2" is the identifier. The example connects to the DB instance using the endpoint associated with AcmeRDS-2.

For Linux, macOS, or Unix:

```
aws rds restore-db-instance-from-db-snapshot \
    --db-instance-identifier AcmeRDS-2 \
    --db-snapshot-identifier preload
```

For Windows:

```
aws rds restore-db-instance-from-db-snapshot ^
    --db-instance-identifier AcmeRDS-2 ^
    --db-snapshot-identifier preload
```

To reuse the existing endpoint, first delete the DB instance and then give the restored database the same identifier.

For Linux, macOS, or Unix:

```
aws rds delete-db-instance \
    --db-instance-identifier AcmeRDS \
    --final-db-snapshot-identifier AcmeRDS-Final

aws rds restore-db-instance-from-db-snapshot \
    --db-instance-identifier AcmeRDS \
    --db-snapshot-identifier preload
```

For Windows:

```
aws rds delete-db-instance ^
    --db-instance-identifier AcmeRDS ^
    --final-db-snapshot-identifier AcmeRDS-Final

aws rds restore-db-instance-from-db-snapshot ^
    --db-instance-identifier AcmeRDS ^
    --db-snapshot-identifier preload
```

The preceding example takes a final DB snapshot of the DB instance before deleting it. This is optional but recommended.

Step 4: Consider turning off Amazon RDS automated backups

> **Warning**
>
> Do not turn off automated backups if you need to perform point-in-time recovery.

Turning off automated backups erases all existing backups, so point-in-time recovery isn't possible after automated backups have been turned off. Disabling automated backups is a performance

optimization and isn't required for data loads. Manual DB snapshots aren't affected by turning off automated backups. All existing manual DB snapshots are still available for restore.

Turning off automated backups reduces load time by about 25 percent and reduces the amount of storage space required during the load. If you plan to load data into a new DB instance that contains no data, turning off backups is an easy way to speed up the load and avoid using the additional storage needed for backups. However, in some cases you might plan to load into a DB instance that already contains data. If so, weigh the benefits of turning off backups against the impact of losing the ability to perform point-in-time-recovery.

DB instances have automated backups turned on by default (with a one day retention period). To turn off automated backups, set the backup retention period to zero. After the load, you can turn backups back on by setting the backup retention period to a nonzero value. To turn on or turn off backups, Amazon RDS shuts the DB instance down and restarts it to turn MariaDB or MySQL logging on or off.

Use the AWS CLI `modify-db-instance` command to set the backup retention to zero and apply the change immediately. Setting the retention period to zero requires a DB instance restart, so wait until the restart has completed before proceeding.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier AcmeRDS \
    --apply-immediately \
    --backup-retention-period 0
```

For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier AcmeRDS ^
    --apply-immediately ^
    --backup-retention-period 0
```

You can check the status of your DB instance with the AWS CLI `describe-db-instances` command. The following example displays the DB instance status of the AcmeRDS DB instance.

```
aws rds describe-db-instances --db-instance-identifier AcmeRDS --query "*[].
{DBInstanceStatus:DBInstanceStatus}"
```

When the DB instance status is `available`, you're ready to proceed.

Step 5: Load the data

Use the MySQL `LOAD DATA LOCAL INFILE` statement to read rows from your flat files into the database tables.

The following example shows you how to load data from a file named `sales.txt` into a table named `Sales` in the database.

```
mysql> LOAD DATA LOCAL INFILE 'sales.txt' INTO TABLE Sales FIELDS TERMINATED BY ' '
 ENCLOSED BY '' ESCAPED BY '\\';
Query OK, 1 row affected (0.01 sec)
Records: 1  Deleted: 0  Skipped: 0  Warnings: 0
```

For more information about the `LOAD DATA` statement, see the MySQL documentation.

Step 6: Turn Amazon RDS automated backups back on

After the load is finished, turn Amazon RDS automated backups on by setting the backup retention period back to its preload value. As noted earlier, Amazon RDS restarts the DB instance, so be prepared for a brief outage.

The following example uses the AWS CLI `modify-db-instance` command to turn on automated backups for the `AcmeRDS` DB instance and set the retention period to one day.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier AcmeRDS \
    --backup-retention-period 1 \
    --apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier AcmeRDS ^
    --backup-retention-period 1 ^
    --apply-immediately
```

Working with MySQL replication in Amazon RDS

You usually use read replicas to configure replication between Amazon RDS DB instances. For general information about read replicas, see Working with DB instance read replicas. For specific information about working with read replicas on Amazon RDS for MySQL, see Working with MySQL read replicas.

You can use global transaction identifiers (GTIDs) for replication with RDS for MySQL. For more information, see Using GTID-based replication.

You can also set up replication between an RDS for MySQL DB instance and a MariaDB or MySQL instance that is external to Amazon RDS. For information about configuring replication with an external source, see Configuring binary log file position replication with an external source instance.

For any of these replication options, you can use either row-based replication, statement-based, or mixed replication. Row-based replication only replicates the changed rows that result from a SQL statement. Statement-based replication replicates the entire SQL statement. Mixed replication uses statement-based replication when possible, but switches to row-based replication when SQL statements that are unsafe for statement-based replication are run. In most cases, mixed replication is recommended. The binary log format of the DB instance determines whether replication is row-based, statement-based, or mixed. For information about setting the binary log format, see Configuring RDS for MySQL binary logging.

> **Note**
>
> You can configure replication to import databases from a MariaDB or MySQL instance that is external to Amazon RDS, or to export databases to such instances. For more information, see Importing data to an Amazon RDS MariaDB or MySQL database with reduced downtime and Exporting data from a MySQL DB instance by using replication.

Topics

Working with MySQL read replicas

Following, you can find specific information about working with read replicas on RDS for MySQL. For general information about read replicas and instructions for using them, see Working with DB instance read replicas.

For more information about MySQL read replicas, see the following topics.

- Configuring replication filters with MySQL
- Configuring delayed replication with MySQL
- Updating read replicas with MySQL
- Working with Multi-AZ read replica deployments with MySQL
- Using cascading read replicas with RDS for MySQL
- Monitoring replication lag for MySQL read replicas
- Starting and stopping replication with MySQL read replicas
- Troubleshooting a MySQL read replica problem

Configuring read replicas with MySQL

Before a MySQL DB instance can serve as a replication source, make sure to enable automatic backups on the source DB instance. To do this, set the backup retention period to a value other than 0. This requirement also applies to a read replica that is the source DB instance for another read replica. Automatic backups are supported for read replicas running any version of MySQL. You can configure replication based on binary log coordinates for a MySQL DB instance.

On RDS for MySQL version 5.7.44 and higher MySQL 5.7 versions and RDS for MySQL 8.0.28 and higher 8.0 versions, you can configure replication using global transaction identifiers (GTIDs). For more information, see Using GTID-based replication.

You can create up to 15 read replicas from one DB instance within the same Region. For replication to operate effectively, each read replica should have the same amount of compute and storage resources as the source DB instance. If you scale the source DB instance, also scale the read replicas.

RDS for MySQL supports cascading read replicas. To learn how to configure cascading read replicas, see Using cascading read replicas with RDS for MySQL.

You can run multiple read replica create and delete actions at the same time that reference the same source DB instance. When you perform these actions, stay within the limit of 15 read replicas for each source instance.

A read replica of a MySQL DB instance can't use a lower DB engine version than its source DB instance.

Preparing MySQL DB instances that use MyISAM

If your MySQL DB instance uses a nontransactional engine such as MyISAM, you need to perform the following steps to successfully set up your read replica. These steps are required to make sure that the read replica has a consistent copy of your data. These steps are not required if all of your tables use a transactional engine such as InnoDB.

1. Stop all data manipulation language (DML) and data definition language (DDL) operations on non-transactional tables in the source DB instance and wait for them to complete. SELECT statements can continue running.
2. Flush and lock the tables in the source DB instance.
3. Create the read replica using one of the methods in the following sections.
4. Check the progress of the read replica creation using, for example, the `DescribeDBInstances` API operation. Once the read replica is available, unlock the tables of the source DB instance and resume normal database operations.

Configuring replication filters with MySQL

You can use replication filters to specify which databases and tables are replicated with a read replica. Replication filters can include databases and tables in replication or exclude them from replication.

The following are some use cases for replication filters:

- To reduce the size of a read replica. With replication filtering, you can exclude the databases and tables that aren't needed on the read replica.
- To exclude databases and tables from read replicas for security reasons.
- To replicate different databases and tables for specific use cases at different read replicas. For example, you might use specific read replicas for analytics or sharding.
- For a DB instance that has read replicas in different AWS Regions, to replicate different databases or tables in different AWS Regions.

> **Note**
>
> You can also use replication filters to specify which databases and tables are replicated with a primary MySQL DB instance that is configured as a replica in an inbound replication topology. For more information about this configuration, see Configuring binary log file position replication with an external source instance.

Topics

Setting replication filtering parameters for RDS for MySQL

To configure replication filters, set the following replication filtering parameters on the read replica:

- `replicate-do-db` – Replicate changes to the specified databases. When you set this parameter for a read replica, only the databases specified in the parameter are replicated.
- `replicate-ignore-db` – Don't replicate changes to the specified databases. When the `replicate-do-db` parameter is set for a read replica, this parameter isn't evaluated.
- `replicate-do-table` – Replicate changes to the specified tables. When you set this parameter for a read replica, only the tables specified in the parameter are replicated. Also, when the `replicate-do-db` or `replicate-ignore-db` parameter is set, make sure to include the database that includes the specified tables in replication with the read replica.
- `replicate-ignore-table` – Don't replicate changes to the specified tables. When the `replicate-do-table` parameter is set for a read replica, this parameter isn't evaluated.
- `replicate-wild-do-table` – Replicate tables based on the specified database and table name patterns. The `%` and `_` wildcard characters are supported. When the `replicate-do-db` or `replicate-ignore-db` parameter is set, make sure to include the database that includes the specified tables in replication with the read replica.
- `replicate-wild-ignore-table` – Don't replicate tables based on the specified database and table name patterns. The `%` and `_` wildcard characters are supported. When the `replicate-do-`

`table` or `replicate-wild-do-table` parameter is set for a read replica, this parameter isn't evaluated.

The parameters are evaluated in the order that they are listed. For more information about how these parameters work, see the MySQL documentation:

- For general information, see Replica Server Options and Variables.
- For information about how database replication filtering parameters are evaluated, see Evaluation of Database-Level Replication and Binary Logging Options.
- For information about how table replication filtering parameters are evaluated, see Evaluation of Table-Level Replication Options.

By default, each of these parameters has an empty value. On each read replica, you can use these parameters to set, change, and delete replication filters. When you set one of these parameters, separate each filter from others with a comma.

You can use the `%` and _ wildcard characters in the `replicate-wild-do-table` and `replicate-wild-ignore-table` parameters. The `%` wildcard matches any number of characters, and the _ wildcard matches only one character.

The binary logging format of the source DB instance is important for replication because it determines the record of data changes. The setting of the `binlog_format` parameter determines whether the replication is row-based or statement-based. For more information, see Configuring RDS for MySQL binary logging.

> **Note**
>
> All data definition language (DDL) statements are replicated as statements, regardless of the `binlog_format` setting on the source DB instance.

Replication filtering limitations for RDS for MySQL

The following limitations apply to replication filtering for RDS for MySQL:

- Each replication filtering parameter has a 2,000-character limit.

- Commas aren't supported in replication filters for parameter values. In a list of parameters, commas can only be used as value separators. For example, `ParameterValue='`a,b`'` isn't supported, but `ParameterValue='a,b'` is.
- The MySQL `--binlog-do-db` and `--binlog-ignore-db` options for binary log filtering aren't supported.
- Replication filtering doesn't support XA transactions.

  For more information, see Restrictions on XA Transactions in the MySQL documentation.

Replication filtering examples for RDS for MySQL

To configure replication filtering for a read replica, modify the replication filtering parameters in the parameter group associated with the read replica.

> **Note**
>
> You can't modify a default parameter group. If the read replica is using a default parameter group, create a new parameter group and associate it with the read replica. For more information on DB parameter groups, see Parameter groups for Amazon RDS.

You can set parameters in a parameter group using the AWS Management Console, AWS CLI, or RDS API. For information about setting parameters, see Modifying parameters in a DB parameter group in Amazon RDS. When you set parameters in a parameter group, all of the DB instances associated with the parameter group use the parameter settings. If you set the replication filtering parameters in a parameter group, make sure that the parameter group is associated only with read replicas. Leave the replication filtering parameters empty for source DB instances.

The following examples set the parameters using the AWS CLI. These examples set `ApplyMethod` to `immediate` so that the parameter changes occur immediately after the CLI command completes. If you want a pending change to be applied after the read replica is rebooted, set `ApplyMethod` to `pending-reboot`.

The following examples set replication filters:

- Including databases in replication
- Including tables in replication
- Including tables in replication with wildcard characters

- Excluding databases from replication
- Excluding tables from replication
- Excluding tables from replication using wildcard characters

Example Including databases in replication

The following example includes the `mydb1` and `mydb2` databases in replication.

For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group \
  --db-parameter-group-name myparametergroup \
  --parameters "ParameterName=replicate-do-
db,ParameterValue='mydb1,mydb2',ApplyMethod=immediate"
```

For Windows:

```
aws rds modify-db-parameter-group ^
  --db-parameter-group-name myparametergroup ^
  --parameters "ParameterName=replicate-do-
db,ParameterValue='mydb1,mydb2',ApplyMethod=immediate"
```

Example Including tables in replication

The following example includes the `table1` and `table2` tables in database `mydb1` in replication.

For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group \
  --db-parameter-group-name myparametergroup \
  --parameters "ParameterName=replicate-do-
table,ParameterValue='mydb1.table1,mydb1.table2',ApplyMethod=immediate"
```

For Windows:

```
aws rds modify-db-parameter-group ^
  --db-parameter-group-name myparametergroup ^
```

```
  --parameters "ParameterName=replicate-do-
table,ParameterValue='mydb1.table1,mydb1.table2',ApplyMethod=immediate"
```

Example Including tables in replication using wildcard characters

The following example includes tables with names that begin with `order` and `return` in database `mydb` in replication.

For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group \
  --db-parameter-group-name myparametergroup \
  --parameters "ParameterName=replicate-wild-do-table,ParameterValue='mydb.order
%,mydb.return%',ApplyMethod=immediate"
```

For Windows:

```
aws rds modify-db-parameter-group ^
  --db-parameter-group-name myparametergroup ^
  --parameters "ParameterName=replicate-wild-do-table,ParameterValue='mydb.order
%,mydb.return%',ApplyMethod=immediate"
```

Example Excluding databases from replication

The following example excludes the `mydb5` and `mydb6` databases from replication.

For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group \
  --db-parameter-group-name myparametergroup \
  --parameters "ParameterName=replicate-ignore-
db,ParameterValue='mydb5,mydb6',ApplyMethod=immediate"
```

For Windows:

```
aws rds modify-db-parameter-group ^
  --db-parameter-group-name myparametergroup ^
```

```
  --parameters "ParameterName=replicate-ignore-
db,ParameterValue='mydb5,mydb6',ApplyMethod=immediate"
```

Example Excluding tables from replication

The following example excludes tables `table1` in database `mydb5` and `table2` in database `mydb6` from replication.

For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group \
  --db-parameter-group-name myparametergroup \
  --parameters "ParameterName=replicate-ignore-
table,ParameterValue='mydb5.table1,mydb6.table2',ApplyMethod=immediate"
```

For Windows:

```
aws rds modify-db-parameter-group ^
  --db-parameter-group-name myparametergroup ^
  --parameters "ParameterName=replicate-ignore-
table,ParameterValue='mydb5.table1,mydb6.table2',ApplyMethod=immediate"
```

Example Excluding tables from replication using wildcard characters

The following example excludes tables with names that begin with `order` and `return` in database `mydb7` from replication.

For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group \
  --db-parameter-group-name myparametergroup \
  --parameters "ParameterName=replicate-wild-ignore-table,ParameterValue='mydb7.order
%,mydb7.return%',ApplyMethod=immediate"
```

For Windows:

```
aws rds modify-db-parameter-group ^
  --db-parameter-group-name myparametergroup ^
  --parameters "ParameterName=replicate-wild-ignore-table,ParameterValue='mydb7.order
%,mydb7.return%',ApplyMethod=immediate"
```

Viewing the replication filters for a read replica

You can view the replication filters for a read replica in the following ways:

- Check the settings of the replication filtering parameters in the parameter group associated with the read replica.

  For instructions, see Viewing parameter values for a DB parameter group in Amazon RDS.
- In a MySQL client, connect to the read replica and run the `SHOW REPLICA STATUS` statement.

  In the output, the following fields show the replication filters for the read replica:
  - `Replicate_Do_DB`
  - `Replicate_Ignore_DB`
  - `Replicate_Do_Table`
  - `Replicate_Ignore_Table`
  - `Replicate_Wild_Do_Table`
  - `Replicate_Wild_Ignore_Table`

  For more information about these fields, see Checking Replication Status in the MySQL documentation.

> **Note**
>
> Previous versions of MySQL used `SHOW SLAVE STATUS` instead of `SHOW REPLICA STATUS`. If you are using a MySQL version before 8.0.23, then use `SHOW SLAVE STATUS`.

Configuring delayed replication with MySQL

You can use delayed replication as a strategy for disaster recovery. With delayed replication, you specify the minimum amount of time, in seconds, to delay replication from the source to the read replica. In the event of a disaster, such as a table deleted unintentionally, you complete the following steps to recover from the disaster quickly:

- Stop replication to the read replica before the change that caused the disaster is sent to it.

  Use the mysql.rds_stop_replication stored procedure to stop replication.
- Start replication and specify that replication stops automatically at a log file location.

You specify a location just before the disaster using the mysql.rds_start_replication_until stored procedure.

- Promote the read replica to be the new source DB instance by using the instructions in Promoting a read replica to be a standalone DB instance.

> **Note**
>
> - On RDS for MySQL 8.0, delayed replication is supported for MySQL 8.0.28 and higher. On RDS for MySQL 5.7, delayed replication is supported for MySQL 5.7.44 and higher.
> - Use stored procedures to configure delayed replication. You can't configure delayed replication with the AWS Management Console, the AWS CLI, or the Amazon RDS API.
> - On RDS for MySQL 5.7.44 and higher MySQL 5.7 versions and RDS for MySQL 8.0.28 and higher 8.0 versions, you can use replication based on global transaction identifiers (GTIDs) in a delayed replication configuration. If you use GTID-based replication, use the mysql.rds_start_replication_until_gtid stored procedure instead of the mysql.rds_start_replication_until stored procedure. For more information about GTID-based replication, see Using GTID-based replication.

Topics

Configuring delayed replication during read replica creation

To configure delayed replication for any future read replica created from a DB instance, run the mysql.rds_set_configuration stored procedure with the `target delay` parameter.

To configure delayed replication during read replica creation

1. Using a MySQL client, connect to the MySQL DB instance to be the source for read replicas as the master user.

2. Run the mysql.rds_set_configuration stored procedure with the `target delay` parameter.

   For example, run the following stored procedure to specify that replication is delayed by at least one hour (3,600 seconds) for any read replica created from the current DB instance.

   ```
   call mysql.rds_set_configuration('target delay', 3600);
   ```

   > **Note**
   >
   > After running this stored procedure, any read replica you create using the AWS CLI or Amazon RDS API is configured with replication delayed by the specified number of seconds.

Modifying delayed replication for an existing read replica

To modify delayed replication for an existing read replica, run the mysql.rds_set_source_delay stored procedure.

To modify delayed replication for an existing read replica

1. Using a MySQL client, connect to the read replica as the master user.
2. Use the mysql.rds_stop_replication stored procedure to stop replication.
3. Run the mysql.rds_set_source_delay stored procedure.

   For example, run the following stored procedure to specify that replication to the read replica is delayed by at least one hour (3600 seconds).

   ```
   call mysql.rds_set_source_delay(3600);
   ```

4. Use the mysql.rds_start_replication stored procedure to start replication.

Setting a location to stop replication to a read replica

After stopping replication to the read replica, you can start replication and then stop it at a specified binary log file location using the mysql.rds_start_replication_until stored procedure.

To start replication to a read replica and stop replication at a specific location

1. Using a MySQL client, connect to the source MySQL DB instance as the master user.
2. Run the mysql.rds_start_replication_until stored procedure.

   The following example initiates replication and replicates changes until it reaches location `120` in the `mysql-bin-changelog.000777` binary log file. In a disaster recovery scenario, assume that location `120` is just before the disaster.

```
call mysql.rds_start_replication_until(
  'mysql-bin-changelog.000777',
  120);
```

Replication stops automatically when the stop point is reached. The following RDS event is generated: `Replication has been stopped since the replica reached the stop point specified by the rds_start_replication_until stored procedure`.

Promoting a read replica

After replication is stopped, in a disaster recovery scenario, you can promote a read replica to be the new source DB instance. For information about promoting a read replica, see Promoting a read replica to be a standalone DB instance.

Updating read replicas with MySQL

Read replicas are designed to support read queries, but you might need occasional updates. For example, you might need to add an index to optimize the specific types of queries accessing the replica.

Although you can enable updates by setting the `read_only` parameter to `0` in the DB parameter group for the read replica, we recommend that you don't do so because it can cause problems if the read replica becomes incompatible with the source DB instance. For maintenance operations, we recommend that you use blue/green deployments. For more information, see Using Blue/Green Deployments for database updates.

If you disable read-only on a read replica, change the value of the `read_only` parameter back to 1 as soon as possible.

Working with Multi-AZ read replica deployments with MySQL

You can create a read replica from either single-AZ or Multi-AZ DB instance deployments. You use Multi-AZ deployments to improve the durability and availability of critical data, but you can't use the Multi-AZ secondary to serve read-only queries. Instead, you can create read replicas from high-traffic Multi-AZ DB instances to offload read-only queries. If the source instance of a Multi-AZ deployment fails over to the secondary, any associated read replicas automatically switch to use the secondary (now primary) as their replication source. For more information, see Configuring and managing a Multi-AZ deployment.

You can create a read replica as a Multi-AZ DB instance. Amazon RDS creates a standby of your replica in another Availability Zone for failover support for the replica. Creating your read replica as a Multi-AZ DB instance is independent of whether the source database is a Multi-AZ DB instance.

Using cascading read replicas with RDS for MySQL

RDS for MySQL supports cascading read replicas. With *cascading read replicas*, you can scale reads without adding overhead to your source RDS for MySQL DB instance.

With cascading read replicas, your RDS for MySQL DB instance sends data to the first read replica in the chain. That read replica then sends data to the second replica in the chain, and so on. The end result is that all read replicas in the chain have the changes from the RDS for MySQL DB instance, but without the overhead solely on the source DB instance.

You can create a series of up to three read replicas in a chain from a source RDS for MySQL DB instance. For example, suppose that you have an RDS for MySQL DB instance, `mysql-main`. You can do the following:

- Starting with `mysql-main`, create the first read replica in the chain, `read-replica-1`.
- Next, from `read-replica-1`, create the next read replica in the chain, `read-replica-2`.
- Finally, from `read-replica-2`, create the third read replica in the chain, `read-replica-3`.

You can't create another read replica beyond this third cascading read replica in the series for `mysql-main`. A complete series of instances from an RDS for MySQL source DB instance through to the end of a series of cascading read replicas can consist of at most four DB instances.

For cascading read replicas to work, each source RDS for MySQL DB instance must have automated backups turned on. To turn on automatic backups on a read replica, first create the read replica,

and then modify the read replica to turn on automatic backups. For more information, see Creating a read replica.

As with any read replica, you can promote a read replica that's part of a cascade. Promoting a read replica from within a chain of read replicas removes that replica from the chain. For example, suppose that you want to move some of the workload from your `mysql-main` DB instance to a new instance for use by the accounting department only. Assuming the chain of three read replicas from the example, you decide to promote `read-replica-2`. The chain is affected as follows:

- Promoting `read-replica-2` removes it from the replication chain.
  - It is now a full read/write DB instance.
  - It continues replicating to `read-replica-3`, just as it was doing before promotion.
- Your `mysql-main` continues replicating to `read-replica-1`.

For more information about promoting read replicas, see Promoting a read replica to be a standalone DB instance.

Monitoring replication lag for MySQL read replicas

For MySQL read replicas, you can monitor replication lag in Amazon CloudWatch by viewing the Amazon RDS `ReplicaLag` metric. The `ReplicaLag` metric reports the value of the `Seconds_Behind_Master` field of the `SHOW REPLICA STATUS` command.

> **Note**
>
> Previous versions of MySQL used `SHOW SLAVE STATUS` instead of `SHOW REPLICA STATUS`. If you are using a MySQL version before 8.0.23, then use `SHOW SLAVE STATUS`.

Common causes for replication lag for MySQL are the following:

- A network outage.
- Writing to tables that have different indexes on a read replica. If the `read_only` parameter is set to `0` on the read replica, replication can break if the read replica becomes incompatible with the source DB instance. After you've performed maintenance tasks on the read replica, we recommend that you set the `read_only` parameter back to 1.

- Using a nontransactional storage engine such as MyISAM. Replication is only supported for the InnoDB storage engine on MySQL.

When the `ReplicaLag` metric reaches 0, the replica has caught up to the source DB instance. If the `ReplicaLag` metric returns -1, then replication is currently not active. `ReplicaLag` = -1 is equivalent to `Seconds_Behind_Master` = `NULL`.

Starting and stopping replication with MySQL read replicas

You can stop and restart the replication process on an Amazon RDS DB instance by calling the system stored procedures mysql.rds_stop_replication and mysql.rds_start_replication. You can do this when replicating between two Amazon RDS instances for long-running operations such as creating large indexes. You also need to stop and start replication when importing or exporting databases. For more information, see Importing data to an Amazon RDS MariaDB or MySQL database with reduced downtime and Exporting data from a MySQL DB instance by using replication.

If replication is stopped for more than 30 consecutive days, either manually or due to a replication error, Amazon RDS terminates replication between the source DB instance and all read replicas. It does so to prevent increased storage requirements on the source DB instance and long failover times. The read replica DB instance is still available. However, replication can't be resumed because the binary logs required by the read replica are deleted from the source DB instance after replication is terminated. You can create a new read replica for the source DB instance to reestablish replication.

Troubleshooting a MySQL read replica problem

For MySQL DB instances, in some cases read replicas present replication errors or data inconsistencies (or both) between the read replica and its source DB instance. This problem occurs when some binary log (binlog) events or InnoDB redo logs aren't flushed during a failure of the read replica or the source DB instance. In these cases, manually delete and recreate the read replicas. You can reduce the chance of this happening by setting the following parameter values: `sync_binlog=1` and `innodb_flush_log_at_trx_commit=1`. These settings might reduce performance, so test their impact before implementing the changes in a production environment.

> **Warning**
>
> In the parameter group associated with the source DB instance, we recommend keeping these parameter values: `sync_binlog=1` and `innodb_flush_log_at_trx_commit=1`.

These parameters are dynamic. If you don't want to use these settings, we recommend temporarily setting those values before executing any operation on the source DB instance that might cause it to restart. These operations include, but are not limited to, rebooting, rebooting with failover, upgrading the database version, and changing the DB instance class or its storage. The same recommendation applies to creating new read replicas for the source DB instance.
Failure to follow this guidance increases the risk of read replicas presenting replication errors or data inconsistencies (or both) between the read replica and its source DB instance.

The replication technologies for MySQL are asynchronous. Because they are asynchronous, occasional `BinLogDiskUsage` increases on the source DB instance and `ReplicaLag` on the read replica are to be expected. For example, a high volume of write operations to the source DB instance can occur in parallel. In contrast, write operations to the read replica are serialized using a single I/O thread, which can lead to a lag between the source instance and read replica. For more information about read-only replicas in the MySQL documentation, see Replication implementation details.

You can do several things to reduce the lag between updates to a source DB instance and the subsequent updates to the read replica, such as the following:

- Sizing a read replica to have a storage size and DB instance class comparable to the source DB instance.
- Ensuring that parameter settings in the DB parameter groups used by the source DB instance and the read replica are compatible. For more information and an example, see the discussion of the `max_allowed_packet` parameter later in this section.

Amazon RDS monitors the replication status of your read replicas and updates the `Replication State` field of the read replica instance to `Error` if replication stops for any reason. An example might be if DML queries run on your read replica conflict with the updates made on the source DB instance.

You can review the details of the associated error thrown by the MySQL engine by viewing the `Replication Error` field. Events that indicate the status of the read replica are also generated, including RDS-EVENT-0045, RDS-EVENT-0046, and RDS-EVENT-0047. For more information about events and subscribing to events, see Working with Amazon RDS event notification. If a MySQL error message is returned, review the error number in the MySQL error message documentation.

One common issue that can cause replication errors is when the value for the `max_allowed_packet` parameter for a read replica is less than the `max_allowed_packet` parameter for the source DB instance. The `max_allowed_packet` parameter is a custom parameter that you can set in a DB parameter group. You use `max_allowed_packet` to specify the maximum size of DML code that can be run on the database. In some cases, the `max_allowed_packet` value in the DB parameter group associated with a read replica is smaller than the `max_allowed_packet` value in the DB parameter group associated with the source DB instance. In these cases, the replication process can throw the error `Packet bigger than 'max_allowed_packet' bytes` and stop replication. To fix the error, have the source DB instance and read replica use DB parameter groups with the same `max_allowed_packet` parameter values.

Other common situations that can cause replication errors include the following:

- Writing to tables on a read replica. In some cases, you might create indexes on a read replica that are different from the indexes on the source DB instance. If you do, set the `read_only` parameter to `0` to create the indexes. If you write to tables on the read replica, it might break replication if the read replica becomes incompatible with the source DB instance. After you perform maintenance tasks on the read replica, we recommend that you set the `read_only` parameter back to 1.
- Using a non-transactional storage engine such as MyISAM. Read replicas require a transactional storage engine. Replication is only supported for the InnoDB storage engine on MySQL.
- Using unsafe nondeterministic queries such as SYSDATE(). For more information, see Determination of safe and unsafe statements in binary logging.

If you decide that you can safely skip an error, you can follow the steps described in the section Skipping the current replication error. Otherwise, you can first delete the read replica. Then you create an instance using the same DB instance identifier so that the endpoint remains the same as that of your old read replica. If a replication error is fixed, the `Replication State` changes to *replicating*.

Using GTID-based replication

The following content explains how to use global transaction identifiers (GTIDs) with binary log (binlog) replication among Amazon RDS for MySQL DB instances.

If you use binlog replication and aren't familiar with GTID-based replication with MySQL, see Replication with global transaction identifiers in the MySQL documentation.

GTID-based replication is supported for all RDS for MySQL 5.7 versions, and RDS for MySQL version 8.0.26 and higher MySQL 8.0 versions. All MySQL DB instances in a replication configuration must meet this requirement.

Topics

Overview of global transaction identifiers (GTIDs)

Global transaction identifiers (GTIDs) are unique identifiers generated for committed MySQL transactions. You can use GTIDs to make binlog replication simpler and easier to troubleshoot.

MySQL uses two different types of transactions for binlog replication:

- *GTID transactions* – Transactions that are identified by a GTID.
- *Anonymous transactions* – Transactions that don't have a GTID assigned.

In a replication configuration, GTIDs are unique across all DB instances. GTIDs simplify replication configuration because when you use them, you don't have to refer to log file positions. GTIDs also make it easier to track replicated transactions and determine whether the source instance and replicas are consistent.

You can use GTID-based replication to replicate data with RDS for MySQL read replicas. You can configure GTID-based replication when you are creating new read replicas, or you can convert existing read replicas to use GTID-based replication.

You can also use GTID-based replication in a delayed replication configuration with RDS for MySQL. For more information, see Configuring delayed replication with MySQL.

Parameters for GTID-based replication

Use the following parameters to configure GTID-based replication.

Parameter	Valid values	Description
gtid_mode	OFF, OFF_PERMISSIVE , ON_PERMISSIVE , ON	OFF specifies that new transactions are anonymous transactions (that is, don't have GTIDs), and a transaction must be anonymous to be replicated. OFF_PERMISSIVE specifies that new transactions are anonymous transactions, but all transactions can be replicated. ON_PERMISSIVE specifies that new transactions are GTID transactions, but all transactions can be replicated. ON specifies that new transactions are GTID transactions, and a transaction must be a GTID transaction to be replicated.
enforce_gtid_consistency	OFF, ON, WARN	OFF allows transactions to violate GTID consistency. ON prevents transactions from violating GTID consistency. WARN allows transactions to violate GTID consistency but generates a warning when a violation occurs.

Note

In the AWS Management Console, the gtid_mode parameter appears as gtid-mode.

For GTID-based replication, use these settings for the parameter group for your DB instance or read replica:

- `ON` and `ON_PERMISSIVE` apply only to outgoing replication from an RDS DB instance. Both of these values cause your RDS DB instance to use GTIDs for transactions that are replicated. `ON` requires that the target database also use GTID-based replication. `ON_PERMISSIVE` makes GTID-based replication optional on the target database.
- `OFF_PERMISSIVE`, if set, means that your RDS DB instances can accept incoming replication from a source database. They can do this regardless of whether the source database uses GTID-based replication.
- `OFF`, if set, means that your RDS DB instance only accepts incoming replication from source databases that don't use GTID-based replication.

For more information about parameter groups, see Parameter groups for Amazon RDS.

Enabling GTID-based replication for new read replicas for RDS for MySQL

When GTID-based replication is enabled for an RDS for MySQL DB instance, GTID-based replication is configured automatically for read replicas of the DB instance.

To enable GTID-based replication for new read replicas

1. Make sure that the parameter group associated with the DB instance has the following parameter settings:

   - `gtid_mode` – `ON` or `ON_PERMISSIVE`
   - `enforce_gtid_consistency` – `ON`

   For more information about setting configuration parameters using parameter groups, see Parameter groups for Amazon RDS.
2. If you changed the parameter group of the DB instance, reboot the DB instance. For more information on how to do so, see Rebooting a DB instance.
3. Create one or more read replicas of the DB instance. For more information on how to do so, see Creating a read replica.

Amazon RDS attempts to establish GTID-based replication between the MySQL DB instance and the read replicas using the `MASTER_AUTO_POSITION`. If the attempt fails, Amazon RDS uses log file positions for replication with the read replicas. For more information about the `MASTER_AUTO_POSITION`, see GTID auto-positioning in the MySQL documentation.

Enabling GTID-based replication for existing read replicas for RDS for MySQL

For an existing MySQL DB instance with read replicas that doesn't use GTID-based replication, you can configure GTID-based replication between the DB instance and the read replicas.

To enable GTID-based replication for existing read replicas

1. If the DB instance or any read replica is using an 8.0 version of RDS for MySQL version lower than 8.0.26, upgrade the DB instance or read replica to 8.0.26 or a higher MySQL 8.0 version. All RDS for MySQL 5.7 versions support GTID-based replication.

   For more information, see Upgrading the MySQL DB engine.

2. (Optional) Reset the GTID parameters and test the behavior of the DB instance and read replicas:

   a. Make sure that the parameter group associated with the DB instance and each read replica has the `enforce_gtid_consistency` parameter set to `WARN`.

      For more information about setting configuration parameters using parameter groups, see Parameter groups for Amazon RDS.

   b. If you changed the parameter group of the DB instance, reboot the DB instance. If you changed the parameter group for a read replica, reboot the read replica.

      For more information, see Rebooting a DB instance.

   c. Run your DB instance and read replicas with your normal workload and monitor the log files.

      If you see warnings about GTID-incompatible transactions, adjust your application so that it only uses GTID-compatible features. Make sure that the DB instance is not generating any warnings about GTID-incompatible transactions before proceeding to the next step.

3. Reset the GTID parameters for GTID-based replication that allows anonymous transactions until the read replicas have processed all of them.

a. Make sure that the parameter group associated with the DB instance and each read replica has the following parameter settings:

- `gtid_mode` – `ON_PERMISSIVE`
- `enforce_gtid_consistency` – `ON`

b. If you changed the parameter group of the DB instance, reboot the DB instance. If you changed the parameter group for a read replica, reboot the read replica.

4. Wait for all of your anonymous transactions to be replicated. To check that these are replicated, do the following:

a. Run the following statement on your source DB instance.

```
SHOW MASTER STATUS;
```

Note the values in the `File` and `Position` columns.

b. On each read replica, use the file and position information from its source instance in the previous step to run the following query.

```
SELECT MASTER_POS_WAIT('file', position);
```

For example, if the file name is `mysql-bin-changelog.000031` and the position is `107`, run the following statement.

```
SELECT MASTER_POS_WAIT('mysql-bin-changelog.000031', 107);
```

If the read replica is past the specified position, the query returns immediately. Otherwise, the function waits. Proceed to the next step when the query returns for all read replicas.

5. Reset the GTID parameters for GTID-based replication only.

a. Make sure that the parameter group associated with the DB instance and each read replica has the following parameter settings:

- `gtid_mode` – `ON`
- `enforce_gtid_consistency` – `ON`

b. Reboot the DB instance and each read replica.

6. On each read replica, run the following procedure.

```
CALL mysql.rds_set_master_auto_position(1);
```

Disabling GTID-based replication for a MySQL DB instance with read replicas

You can disable GTID-based replication for a MySQL DB instance with read replicas.

To disable GTID-based replication for a MySQL DB instance with read replicas

1. On each read replica, run the following procedure:

   ```
   CALL mysql.rds_set_master_auto_position(0);
   ```

2. Reset the `gtid_mode` to `ON_PERMISSIVE`.

   a. Make sure that the parameter group associated with the MySQL DB instance and each read replica has `gtid_mode` set to `ON_PERMISSIVE`.

      For more information about setting configuration parameters using parameter groups, see Parameter groups for Amazon RDS.

   b. Reboot the MySQL DB instance and each read replica. For more information about rebooting, see Rebooting a DB instance.

3. Reset the `gtid_mode` to `OFF_PERMISSIVE`.

   a. Make sure that the parameter group associated with the MySQL DB instance and each read replica has `gtid_mode` set to `OFF_PERMISSIVE`.

   b. Reboot the MySQL DB instance and each read replica.

4. Wait for all of the GTID transactions to be applied on all of the read replicas. To check that these are applied, do the following steps:

   a. On the MySQL DB instance, run the `SHOW MASTER STATUS` command.

      Your output should be similar to the following output.

      ```
      File                        Position
      ------------------------------------
      mysql-bin-changelog.000031      107
      ```

```
-----------------------------------
```

Note the file and position in your output.

b. On each read replica, use the file and position information from its source instance in the previous step to run the following query:

For MySQL 8.0.26 and higher MySQL 8.0 versions

```
SELECT SOURCE_POS_WAIT('file', position);
```

For MySQL 5.7 versions

```
SELECT MASTER_POS_WAIT('file', position);
```

For example, if the file name is `mysql-bin-changelog.000031` and the position is `107`, run the following statement:

For MySQL 8.0.26 and higher MySQL 8.0 versions

```
SELECT SOURCE_POS_WAIT('mysql-bin-changelog.000031', 107);
```

For MySQL 5.7 versions

```
SELECT MASTER_POS_WAIT('mysql-bin-changelog.000031', 107);
```

5. Reset the GTID parameters to disable GTID-based replication.

a. Make sure that the parameter group associated with the MySQL DB instance and each read replica has the following parameter settings:

- `gtid_mode` – `OFF`
- `enforce_gtid_consistency` – `OFF`

b. Reboot the MySQL DB instance and each read replica.

Configuring binary log file position replication with an external source instance

You can set up replication between an RDS for MySQL or MariaDB DB instance and a MySQL or MariaDB instance that is external to Amazon RDS using binary log file replication.

Topics

Before you begin

You can configure replication using the binary log file position of replicated transactions.

The permissions required to start replication on an Amazon RDS DB instance are restricted and not available to your Amazon RDS master user. Because of this, make sure that you use the Amazon RDS mysql.rds_set_external_master and mysql.rds_start_replication commands to set up replication between your live database and your Amazon RDS database.

To set the binary logging format for a MySQL or MariaDB database, update the `binlog_format` parameter. If your DB instance uses the default DB instance parameter group, create a new DB parameter group to modify `binlog_format` settings. We recommend that you use the default setting for `binlog_format`, which is `MIXED`. However, you can also set `binlog_format` to `ROW` or `STATEMENT` if you need a specific binary log (binlog) format. Reboot your DB instance for the change to take effect.

For information about setting the `binlog_format` parameter, see Configuring RDS for MySQL binary logging. For information about the implications of different MySQL replication types, see Advantages and disadvantages of statement-based and row-based replication in the MySQL documentation.

> **Note**
>
> Starting with RDS for MySQL version 8.0.36, Amazon RDS doesn't replicate the `mysql` database. Therefore, if there are users on the external database that you need on the Amazon RDS replica, make sure to create them manually.

Configuring binary log file position replication with an external source instance

Follow these guidelines when you set up an external source instance and a replica on Amazon RDS:

- Monitor failover events for the Amazon RDS DB instance that is your replica. If a failover occurs, then the DB instance that is your replica might be recreated on a new host with a different network address. For information on how to monitor failover events, see Working with Amazon RDS event notification.
- Maintain the binlogs on your source instance until you have verified that they have been applied to the replica. This maintenance makes sure that you can restore your source instance in the event of a failure.
- Turn on automated backups on your Amazon RDS DB instance. Turning on automated backups makes sure that you can restore your replica to a particular point in time if you need to re-synchronize your source instance and replica. For information on backups and point-in-time restore, see Backing up, restoring, and exporting data.

To configure binary log file replication with an external source instance

1. Make the source MySQL or MariaDB instance read-only.

```
mysql> FLUSH TABLES WITH READ LOCK;
mysql> SET GLOBAL read_only = ON;
```

2. Run the `SHOW MASTER STATUS` command on the source MySQL or MariaDB instance to determine the binlog location.

   You receive output similar to the following example.

```
File                        Position
------------------------------------
 mysql-bin-changelog.000031      107
------------------------------------
```

3. Copy the database from the external instance to the Amazon RDS DB instance using `mysqldump`. For very large databases, you might want to use the procedure in Importing data to an Amazon RDS MariaDB or MySQL database with reduced downtime.

   For Linux, macOS, or Unix:

```
mysqldump --databases database_name \
    --single-transaction \
    --compress \
    --order-by-primary \
    -u local_user \
    -plocal_password | mysql \
        --host=hostname \
        --port=3306 \
        -u RDS_user_name \
        -pRDS_password
```

For Windows:

```
mysqldump --databases database_name ^
    --single-transaction ^
    --compress ^
    --order-by-primary ^
    -u local_user ^
    -plocal_password | mysql ^
        --host=hostname ^
        --port=3306 ^
        -u RDS_user_name ^
        -pRDS_password
```

> **Note**
>
> Make sure that there isn't a space between the `-p` option and the entered password.

To specify the host name, user name, port, and password to connect to your Amazon RDS DB instance, use the `--host`, `--user (-u)`, `--port` and `-p` options in the `mysql` command. The host name is the Domain Name Service (DNS) name from the Amazon RDS DB instance endpoint, for example `myinstance.123456789012.us-east-1.rds.amazonaws.com`. You can find the endpoint value in the instance details in the AWS Management Console.

4. Make the source MySQL or MariaDB instance writeable again.

```
mysql> SET GLOBAL read_only = OFF;
mysql> UNLOCK TABLES;
```

For more information on making backups for use with replication, see the MySQL documentation.

5. In the AWS Management Console, add the IP address of the server that hosts the external database to the virtual private cloud (VPC) security group for the Amazon RDS DB instance. For more information on modifying a VPC security group, see Security groups for your VPC in the *Amazon Virtual Private Cloud User Guide*.

   The IP address can change when the following conditions are met:

   - You are using a public IP address for communication between the external source instance and the DB instance.
   - The external source instance was stopped and restarted.

   If these conditions are met, verify the IP address before adding it.

   You might also need to configure your local network to permit connections from the IP address of your Amazon RDS DB instance. You do this so that your local network can communicate with your external MySQL or MariaDB instance. To find the IP address of the Amazon RDS DB instance, use the `host` command.

   ```
   host db_instance_endpoint
   ```

   The host name is the DNS name from the Amazon RDS DB instance endpoint.

6. Using the client of your choice, connect to the external instance and create a user to use for replication. Use this account solely for replication and restrict it to your domain to improve security. The following is an example.

   ```
   CREATE USER 'repl_user'@'mydomain.com' IDENTIFIED BY 'password';
   ```

   > **Note**
   >
   > Specify a password other than the prompt shown here as a security best practice.

7. For the external instance, grant `REPLICATION CLIENT` and `REPLICATION SLAVE` privileges to your replication user. For example, to grant the `REPLICATION CLIENT` and `REPLICATION`

SLAVE privileges on all databases for the 'repl_user' user for your domain, issue the following command.

```
GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'mydomain.com';
```

8. Make the Amazon RDS DB instance the replica. To do so, first connect to the Amazon RDS DB instance as the master user. Then identify the external MySQL or MariaDB database as the source instance by using the mysql.rds_set_external_master command. Use the master log file name and master log position that you determined in step 2. The following is an example.

```
CALL mysql.rds_set_external_master ('mymasterserver.mydomain.com', 3306,
 'repl_user', 'password', 'mysql-bin-changelog.000031', 107, 0);
```

> **Note**
>
> On RDS for MySQL, you can choose to use delayed replication by running the mysql.rds_set_external_master_with_delay stored procedure instead. On RDS for MySQL, one reason to use delayed replication is to turn on disaster recovery with the mysql.rds_start_replication_until stored procedure. Currently, RDS for MariaDB supports delayed replication but doesn't support the mysql.rds_start_replication_until procedure.

9. On the Amazon RDS DB instance, issue the mysql.rds_start_replication command to start replication.

```
CALL mysql.rds_start_replication;
```

Configuring multi-source-replication for RDS for MySQL

With multi-source replication, you can set up an Amazon RDS for MySQL DB instance as a replica that receives binary log events from more than one RDS for MySQL source DB instance. Multi-source replication is supported for RDS for MySQL DB instances running the following engine versions:

- 8.0.35 and higher minor versions
- 5.7.44 and higher minor versions

For information about MySQL multi-source replication, see MySQL Multi-Source Replication in the MySQL documentation. The MySQL documentation contains detailed information about this feature, while this topic describes how to configure and manage the multi-source replication channels on your RDS for MySQL DB instances.

Topics

Use cases for multi-source replication

The following cases are good candidates for using multi-source replication on RDS for MySQL:

- Applications that need to merge or combine multiple shards on separate DB instances into a single shard.
- Applications that need to generate reports from data consolidated from multiple sources.
- Requirements to create consolidated long-term backups of data that's distributed among multiple RDS for MySQL DB instances.

Considerations and best practices for multi-source replication

Before you use multi-source replication on RDS for MySQL, review the following considerations and best practices:

- Make sure that a DB instance configured as a multi-source replica has sufficient resources such as throughput, memory, CPU, and IOPS to handle the workload from multiple source instances.
- Regularly monitor resource utilization on your multi-source replica and adjust the storage or instance configuration to handle the workload without straining resources.
- You can configure multi-threaded replication on a multi-source replica by setting the system variable `replica_parallel_workers` to a value greater than `0`. In this case, the number of

threads allocated to each channel is the value of this variable, plus one coordinator thread to manage the applier threads.

- Configure replication filters appropriately to avoid conflicts. To replicate an entire database to another database on a replica, you can use the `--replicate-rewrite-db` option. For example, you can replicate all tables in database A to database B on a replica instance. This approach can be helpful when all source instances are using the same schema naming convention. For information about the `--replicate-rewrite-db` option, see Replica Server Options and Variables in the MySQL documentation.
- To avoid replication errors, avoid writing to the replica. We recommended that you enable the `read_only` parameter on multi-source replicas to block write operations. Doing so helps to eliminate replication issues caused by conflicting write operations.
- To increase the performance of read operations such as sorts and high-load joins that are executed on the multi-source replica, consider using RDS Optimized Reads. This feature can help with queries that depend on large temporary tables or sort files. For more information, see the section called “Improving query performance with RDS Optimized Reads”.
- To minimize replication lag and improve the performance of a multi-source replica, consider enabling optimized writes. For more information, see the section called “Improving write performance with RDS Optimized Writes for MySQL”.
- Perform management operations (such as changing configuration) on one channel at a time, and avoid performing changes to multiple channels from multiple connections. These practices can lead to conflicts in replication operations. For example, simultaneously executing `rds_skip_repl_error_for_channel` and `rds_start_replication_for_channel` procedures from multiple connections can cause skipping of events on a different channel than intended.
- You can enable backups on a multi-source replication instance and export data from that instance to an Amazon S3 bucket to store it for long-term purposes. However, it's important to also configure backups with appropriate retention on the individual source instances. For information about exporting snapshot data to Amazon S3, see the section called “Exporting DB snapshot data to Amazon S3”.
- To distribute the read workload on a multi-source replica, you can create read replicas from a multi-source replica. You can locate these read replicas in different AWS Regions based on your application's requirements. For more information about read replicas, see the section called “MySQL read replicas”.

Prerequisites for multi-source replication

Before you configure multi-source replication, complete the following prerequisites.

- Make sure that each source RDS for MySQL DB instance has automatic backups enabled. Enabling automatic backups enables binary logging. To learn how to enable automatic backups, see the section called "Enabling automated backups".
- To avoid replication errors, we recommended that you block write operations to the source DB instances. You can do so by setting the `read-only` parameter to `ON` in a custom parameter group attached to the RDS for MySQL source DB instance. You can use the AWS Management Console or the AWS CLI to create a new custom parameter group or to modify an existing one. For more information, see the section called "Creating a DB parameter group" and the section called "Modifying parameters in a DB parameter group".
- For each source DB instance, add the IP address of the instance to the Amazon virtual private cloud (VPC) security group for the multi-source DB instance. To identify the IP address of a source DB instance, you can run the command `dig` *`RDS Endpoint`*. Run the command from an Amazon EC2 instance in the same VPC as the destination multi-source DB instance.
- For each source DB instance, use a client to connect to the DB instance and create a database user with the required privileges for replication, as in the following example.

```
CREATE USER 'repl_user' IDENTIFIED BY 'password';
GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user';
```

Configuring multi-source replication channels on RDS for MySQL DB instances

Configuring multi-source replication channels is similar to configuring single source replication. For multi-source replication, you first turn on binary logging on the source instance. Then, you import data from the sources to the multi-source replica. Then, you start replication from each source by using the binary log coordinates or by using GTID auto-positioning.

To configure an RDS for MySQL DB instance as a multi-source replica of two or more RDS for MySQL DB instances, perform the following steps.

Topics

- Step 1: Import data from the source DB instances to the multi-source replica
- Step 2: Start replication from the source DB instances to the multi-source replica

Step 1: Import data from the source DB instances to the multi-source replica

Perform the following steps on each source DB instance.

Before you import the data from a source to the multi-source replica, determine the current binary log file and position by running the `SHOW MASTER STATUS` command. Take note of these details for use in the next step. In this example output, the file is `mysql-bin-changelog.000031` and the position is `107`.

```
File                          Position
-----------------------------------
mysql-bin-changelog.000031      107
-----------------------------------
```

Now copy the database from the source DB instance to the multi-source replica by using `mysqldump`, as in the following example.

```
mysqldump --databases database_name \
 --single-transaction \
 --compress \
 --order-by-primary \
 -u RDS_user_name \
 -p RDS_password \
 --host=RDS Endpoint | mysql \
 --host=RDS Endpoint \
 --port=3306 \
 -u RDS_user_name \
-p RDS_password
```

After copying the database, you can set the read-only parameter to `OFF` on the source DB instance.

Step 2: Start replication from the source DB instances to the multi-source replica

For each source DB instance, use the master user credentials to connect to the instance, and run the following two stored procedures. These stored procedures configure replication on a channel and start replication. This example uses the binlog file name and position from the example output in the previous step.

```
CALL mysql.rds_set_external_source_for_channel('mysourcehost.example.com', 3306,
 'repl_user', 'password', 'mysql-bin-changelog.000031', 107, 0, 'channel_1');
```

```
CALL mysql.rds_start_replication_for_channel('channel_1');
```

For more information about using these stored procedures and others to set up and manage your replication channels, see the section called “Managing multi-source replication”.

Using filters with multi-source replication

You can use replication filters to specify which databases and tables are replicated with in multi-source replica. Replication filters can include databases and tables in replication or exclude them from replication. For more information on replication filters, see the section called “Configuring replication filters”.

With multi-source replication, you can configure replication filters globally or at the channel level. Channel-level filtering is available only with supported DB instances running version 8.0. The following examples show how to configure filters globally or at the channel level.

Note the following requirements and behavior with filtering in multi-source replication:

- Back quotes (``) around the channel names are required.
- If you change replication filters in the parameter group, the multi-source replica's `sql_thread` for all channels with updates are restarted to apply the changes dynamically. If an update involves a global filter, then all replication channels in the running state are restarted.
- All global filters are applied before any channel-specific filters.
- If a filter is applied globally and at the channel level, then only the channel-level filter is applied. For example, if the filters are `replicate_ignore_db="db1,`channel_22`:db2"`, then `replicate_ignore_db` set to `db1` is applied to all channels except for `channel_22`, and only `channel_22` ignores changes from `db2`.

Example 1: Setting a global filter

In the following example, the `temp_data` database is excluded from replication in every channel.

For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group \
--db-parameter-group-name myparametergroup \
--parameters "ParameterName=replicate-ignore-
db,ParameterValue='temp_data',ApplyMethod=immediate"
```

Example 2: Setting a channel-level filter

In the following example, changes from the `sample22` database are only included in channel `channel_22`. Similarly, changes from the `sample99` database are only included in channel `channel_99`.

For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group \
--db-parameter-group-name myparametergroup \
--parameters "ParameterName=replicate-do-db,ParameterValue='\`channel_22\`:sample22,
\`channel_99\`:sample99',ApplyMethod=immediate"
```

Monitoring multi-source replication channels

You can monitor individual channels in a multi-source replica by using the following methods:

- To monitor the status of all channels or a specific channel, connect to the multi-source replica and run the `SHOW REPLICA STATUS` or `SHOW REPLICA STATUS FOR CHANNEL 'channel_name'` command. For more information, see Checking Replication Status in the MySQL documentation.
- To receive notification when a replication channel is started, stopped, or removed, use RDS event notification. For more information, see the section called “Working with Amazon RDS event notification”.
- To monitor the lag for a specific channel, check the `ReplicationChannelLag` metric for it. Data points for this metric have a period of 60 seconds (1 minute) are available for 15 days. To locate the replication channel lag for a channel, use the instance identifier and the replication channel name. To receive notification when this lag exceeds a particular threshold, you can set up a CloudWatch alarm. For more information, see the section called “Monitoring RDS with CloudWatch”.

Limitations for multi-source replication on RDS for MySQL

The following limitations apply to multi-source replication on RDS for MySQL:

- Currently, RDS for MySQL supports configuring a maximum of 15 channels for a multi-source replica.
- A read replica instance can't be configured as a multi-source replica.

- To configure multi-source replication on RDS for MySQL running engine version 5.7, Performance Schema must be enabled on the replica instance. Enabling Performance Schema is optional on RDS for MySQL running engine version 8.0.
- For RDS for MySQL running engine version 5.7, replication filters apply to all replication channels. For RDS for MySQL running engine version 8.0, you can configure filters that apply to all replication channels or to individual channels.
- Restoring an RDS snapshot or performing a Point-in-time-Restore (PITR) doesn't restore multi-source replica channel configurations.
- When you create a read replica of a multi-source replica, it only replicates data from the multi-source instance. It doesn't restore any channel configuration.
- MySQL doesn't support setting up a different number of parallel workers for each channel. Every channel gets the same number of parallel workers based on the `replica_parallel_workers` value.

The following additional limitations apply if your multi-source replication target is a Multi-AZ DB cluster:

- A channel must be configured for a source RDS for MySQL instance before any writes to that instance occur.
- Each source RDS for MySQL instance must have GTID-based replication enabled.
- A failover event on the DB cluster removes the multi-source replication configuration. Restoring that configuration requires repeating the configuration steps.

Configuring active-active clusters for RDS for MySQL

You can set up an active-active cluster for RDS for MySQL by using the MySQL Group Replication plugin. The Group Replication plugin is supported for RDS for MySQL DB instances running version 8.0.35 and higher minor versions.

For information about MySQL Group Replication, see Group Replication in the MySQL documentation. The MySQL documentation contains detailed information about this feature, while this topic describes how to configure and manage the plugin on your RDS for MySQL DB instances.

> **Note**
>
> For the sake of brevity, all mentions of "active-active" cluster in this topic refer to active-active clusters using the MySQL Group Replication plugin.

Topics

Use cases for active-active clusters

The following cases are good candidates for using active-active clusters:

- Applications that need all of the DB instances in the cluster to support write operations. The Group Replication plugin keeps the data consistent on each DB instance in the active-active cluster. For more information about how this works, see Group Replication in the MySQL documentation.
- Applications that require continuous availability of the database. With an active-active cluster, the data is retained on the all of the DB instances in the cluster. If one DB instance fails, the application can reroute traffic to another DB instance in the cluster.
- Applications that might need to split read and write operations among different DB instances in the cluster for load balancing purposes. With an active-active cluster, your applications can send read traffic to specific DB instances and write traffic to others. You can also switch which DB instances to send reads or writes to at any time.

Considerations and best practices for active-active clusters

Before you use RDS for MySQL active-active clusters, review the following considerations and best practices:

- Active-active clusters can't have more than nine DB instances.
- With the Group Replication plugin, you can control the transaction consistency guarantees of the active-active cluster. For more information, see Transaction Consistency Guarantees in the MySQL documentation.
- Conflicts are possible when different DB instances update the same row in an active-active cluster. For information about conflicts and conflict resolution, see Group Replication in the MySQL documentation.
- For fault tolerance, include at least three DB instances in your active-active cluster. It is possible to configure an active-active cluster with only one or two DB instances, but the cluster won't be fault tolerant. For information about fault tolerance, see Fault-tolerance in the MySQL documentation.
- When a DB instance joins an existing active-active cluster and is running the same engine version as the lowest engine version in the cluster, the DB instance joins in read-write mode.
- When a DB instance joins an existing active-active cluster and is running a higher engine version than the lowest engine version in the cluster, the DB instance must remain in read-only mode.
- If you enable Group Replication for a DB instance by setting its `rds.group_replication_enabled` parameter to 1 in the DB parameter group, but replication hasn't started or has failed to start, the DB instance is placed in super-read-only mode to

prevent data inconsistencies. For information about super-read-only mode, see the MySQL documentation.

- You can upgrade a DB instance in an active-active cluster, but the DB instance is read-only until all of the other DB instances in the active-active cluster are upgraded to same engine version or a higher engine version. When you upgrade a DB instance, the DB instance automatically joins the same active-active cluster when the upgrade completes. To avoid an unintended switch to read-only mode for a DB instance, disable automatic minor version upgrades for it. For information about upgrading a MySQL DB instance, see Upgrading the MySQL DB engine.
- You can add a DB instance in a Multi-AZ DB instance deployment to an existing active-active cluster. You can also convert a Single-AZ DB instance in an active-active cluster to a Multi-AZ DB instance deployment. If a primary DB instance in a Multi-AZ deployment fails, that primary instance fails over to the standby instance. The new primary DB instance automatically joins the same cluster after failover completes. For more information about Multi-AZ DB instance deployments, see Multi-AZ DB instance deployments.
- We recommend that the DB instances in an active-active cluster have different time ranges for their maintenance windows. This practice avoids multiple DB instances in the cluster going offline for maintenance at the same time. For more information, see The Amazon RDS maintenance window.
- Active-active clusters can use SSL for connections between DB instances. To configure SSL connections, set the group_replication_recovery_use_ssl and group_replication_ssl_mode parameters. The values for these parameters must match for all DB instances in the active-active cluster.

  Currently, active-active clusters don't support certificate authority (CA) verification for connections between AWS Regions. So, the group_replication_ssl_mode parameter must be set to `DISABLED` (the default) or `REQUIRED` for cross-Region clusters.
- An RDS for MySQL active-active cluster runs in multi-primary mode. The default value of the group_replication_enforce_update_everywhere_checks is `ON` and the parameter is static. When this parameter is set to `ON`, applications can't insert into a table that has cascading foreign key constraints.
- An RDS for MySQL active-active cluster uses the MySQL communication stack for connection security instead of XCOM. For more information, see Communication Stack for Connection Security Management in the MySQL documentation.

- When a DB parameter group is associated with a DB instance in an active-active cluster, we recommend only associating this DB parameter group with other DB instances that are in the cluster.
- Active-active clusters only support RDS for MySQL DB instances. These DB instances must be running supported versions of the DB engine.
- When a DB instance in an active-active cluster has an unexpected failure, RDS starts recovery of the DB instance automatically. If the DB instance doesn't recover, we recommend replacing it with a new DB instance by performing a point-in-time recovery with a healthy DB instance in the cluster. For instructions, see Adding a DB instance to an active-active cluster using point-in-time recovery.
- You can delete a DB instance in an active-active cluster without affecting the other DB instances in the cluster. For information about deleting a DB instance, see Deleting a DB instance.

Prerequisites for a cross-VPC active-active cluster

You can configure an active-active cluster with DB instances in more than one VPC. The VPCs can be in the same AWS Region or different AWS Regions.

> **Note**
>
> Sending traffic between multiple AWS Regions might incur additional costs. For more information, see Overview of Data Transfer Costs for Common Architectures.

If you are configuring an active-active cluster in a single VPC, you can skip these steps and move on to Setting up an active-active cluster with new DB instances.

To prepare for an active-active cluster with DB instances in more than one VPC

1. Make sure the IPv4 address ranges in the CIDR blocks meet the following requirements:

   - The IPv4 address ranges in the CIDR blocks of the VPCs can't overlap.
   - All of the IPv4 address ranges in the CIDR blocks either must be lower than `128.0.0.0/`*`subnet_mask`* or higher than 128.0.0.0/*`subnet_mask`*.

   The following ranges illustrate these requirements:

- `10.1.0.0/16` in one VPC and `10.2.0.0/16` in the other VPC is supported.
- `172.1.0.0/16` in one VPC and `172.2.0.0/16` in the other VPC is supported.
- `10.1.0.0/16` in one VPC and `10.1.0.0/16` in the other VPC *is not* supported because the ranges overlap.
- `10.1.0.0/16` in one VPC and `172.1.0.0/16` in the other VPC *is not* supported because one is below `128.0.0.0/subnet_mask` and the other is above `128.0.0.0/subnet_mask`.

For information about CIDR blocks, see VPC CIDR blocks in the *Amazon VPC User Guide*.

2. In each VPC, make sure DNS resolution and DNS hostnames are both enabled.

   For instructions, see View and update DNS attributes for your VPC in the *Amazon VPC User Guide*.

3. Configure the VPCs so that you can route traffic between them in one of the following ways:

   - Create a VPC peering connection between the VPCs.

     For instructions, see Create a VPC peering connection in the *Amazon VPC Peering Guide*. In each VPC, make sure there are inbound rules for your security groups that reference security groups in the peered VPC. Doing so allows traffic to flow to and from instances that are associated with the referenced security group in the peered VPC. For instructions, see Update your security groups to reference peer security groups in the *Amazon VPC Peering Guide*.

   - Create a transit gateway between the VPCs.

     For instructions, see Getting started with transit gateways in *Amazon VPC Transit Gateways*. In each VPC, make sure there are inbound rules for your security groups that allow traffic from the other VPC, such as inbound rules that specify the CIDR of the other VPC. Doing so allows traffic to flow to and from instances that are associated with the referenced security group in the active-active cluster. For more information, see Control traffic to your AWS resources using security groups in the *Amazon VPC User Guide*.

Required parameter settings for active-active clusters

The following parameter settings are required when you are setting up an RDS for MySQL active-active cluster.

Parameter	Description	Required setting
binlog_format	Sets the binary logging format. The default value for RDS for MySQL is MIXED. For more information, see the MySQL documentation.	ROW
enforce_gtid_consistency	Enforces GTID consistency for statement execution. The default value for RDS for MySQL is OFF. For more information, see the MySQL documentation.	ON
group_replication_group_name	Sets the Group Replication name to a UUID. The UUID format is 11111111-2222-3333-4444-555555555555. You can generate a MySQL UUID by connecting to a MySQL DB instance and running SELECT UUID(). The value must be the same for all of the DB instances in the active-active cluster. For more information, see the MySQL documentation.	A MySQL UUID
gtid-mode	Controls GTID-based logging. The default value for RDS for MySQL is OFF_PERMISSIVE. For more information, see the MySQL documentation.	ON

Parameter	Description	Required setting
`rds.custom_dns_resolution`	Specifies whether to allow DNS resolution from the Amazon DNS server in your VPC. DNS resolution must be enabled when Group Replication is enabled with the `rds.group_replication_enabled` parameter. DNS resolution can't be enabled when Group Replication is disabled with the `rds.group_replication_enabled` parameter. For more information, see Amazon DNS server in the *Amazon VPC User Guide*.	1
`rds.group_replication_enabled`	Specifies whether Group Replication is enabled for a DB instance. Group Replication must be enabled on a DB instance in an active-active cluster.	1
`slave_preserve_commit_order`	Controls the order that transactions are committed on a replica. The default value for RDS for MySQL is `ON`. For more information, see the MySQL documentation.	`ON`

Converting an existing DB instance to an active-active cluster

The DB engine version of the DB instance you want to migrate to an active-active cluster must be MySQL 8.0.35 or higher. If you need to upgrade the engine version, see Upgrading the MySQL DB engine.

If you are setting up an active-active cluster with DB instances in more than one VPC, make sure you complete the prerequisites in Prerequisites for a cross-VPC active-active cluster.

Complete the following steps to migrate an existing DB instance to an active-active cluster for RDS for MySQL.

Topics

Step 1: Set the active-active cluster parameters in one or more custom parameter groups

The RDS for MySQL DB instances in an active-active cluster must be associated with a custom parameter group that has the correct setting for required parameters. For information about the parameters and the required setting for each one, see Required parameter settings for active-active clusters.

You can set these parameters in new parameter groups or in existing parameter groups. However, to avoid accidentally affecting DB instances that aren't part of the active-active cluster, we strongly recommend that you create a new custom parameter group. The DB instances in an active-active cluster can be associated with the same DB parameter group or with different DB parameter groups.

You can use the AWS Management Console or the AWS CLI to create a new custom parameter group. For more information, see Creating a DB parameter group in Amazon RDS. The following example runs the create-db-parameter-group AWS CLI command to create a custom DB parameter group named *myactivepg*:

For Linux, macOS, or Unix:

```
aws rds create-db-parameter-group \
  --db-parameter-group-name myactivepg \
  --db-parameter-group-family mysql8.0 \
  --description "Parameter group for active-active clusters"
```

For Windows:

```
aws rds create-db-parameter-group ^
  --db-parameter-group-name myactivepg ^
  --db-parameter-group-family mysql8.0 ^
  --description "Parameter group for active-active clusters"
```

You can also use the AWS Management Console or the AWS CLI to set the parameters in the custom parameter group. For more information, see Modifying parameters in a DB parameter group in Amazon RDS.

The following example runs the modify-db-parameter-group AWS CLI command to set the parameters:

For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group \
  --db-parameter-group-name myactivepg \
  --parameters
 "ParameterName='rds.group_replication_enabled',ParameterValue='1',ApplyMethod=pending-
reboot" \

 "ParameterName='rds.custom_dns_resolution',ParameterValue='1',ApplyMethod=pending-
reboot" \

 "ParameterName='enforce_gtid_consistency',ParameterValue='ON',ApplyMethod=pending-
reboot" \
               "ParameterName='gtid-mode',ParameterValue='ON',ApplyMethod=pending-
reboot" \
```

```
 "ParameterName='binlog_format',ParameterValue='ROW',ApplyMethod=immediate" \

 "ParameterName='slave_preserve_commit_order',ParameterValue='ON',ApplyMethod=immediate"
 \

 "ParameterName='group_replication_group_name',ParameterValue='11111111-2222-3333-4444-55555555
reboot"
```

For Windows:

```
aws rds modify-db-parameter-group ^
  --db-parameter-group-name myactivepg ^
  --parameters
 "ParameterName='rds.group_replication_enabled',ParameterValue='1',ApplyMethod=pending-
reboot" ^

 "ParameterName='rds.custom_dns_resolution',ParameterValue='1',ApplyMethod=pending-
reboot" ^

 "ParameterName='enforce_gtid_consistency',ParameterValue='ON',ApplyMethod=pending-
reboot" ^
               "ParameterName='gtid-mode',ParameterValue='ON',ApplyMethod=pending-
reboot" ^

 "ParameterName='binlog_format',ParameterValue='ROW',ApplyMethod=immediate" ^

 "ParameterName='slave_preserve_commit_order',ParameterValue='ON',ApplyMethod=immediate"
 ^

 "ParameterName='group_replication_group_name',ParameterValue='11111111-2222-3333-4444-55555555
reboot"
```

Step 2: Associate the DB instance with a DB parameter group that has the required Group Replication parameters set

Associate the DB instance with a parameter group you created or modified in the previous step. For instructions, see Associating a DB parameter group with a DB instance in Amazon RDS.

Reboot the DB instance for the new parameter settings to take effect. For instructions, see Rebooting a DB instance.

Step 3: Create the active-active cluster

In the DB parameter group associated with the DB instance, set the `group_replication_group_seeds` parameter to the endpoint of the DB instance you are converting.

You can use the AWS Management Console or the AWS CLI to set the parameter. You don't need to reboot the DB instance after setting this parameter. For more information about setting parameters, see Modifying parameters in a DB parameter group in Amazon RDS.

The following example runs the modify-db-parameter-group AWS CLI command to set the parameters:

For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group \
  --db-parameter-group-name myactivepg \
  --parameters
 "ParameterName='group_replication_group_seeds',ParameterValue='myactivedb1.123456789012.us-east-1.rds.amazonaws.com:3306',ApplyMethod=immediate"
```

For Windows:

```
aws rds modify-db-parameter-group ^
  --db-parameter-group-name myactivepg ^
  --parameters
 "ParameterName='group_replication_group_seeds',ParameterValue='myactivedb1.123456789012.us-east-1.rds.amazonaws.com:3306',ApplyMethod=immediate"
```

Step 4: Create additional RDS for MySQL DB instances for the active-active cluster

To create additional DB instances for the active-active cluster, perform point-in-time recovery on the DB instance you are converting. For instructions, see Adding a DB instance to an active-active cluster using point-in-time recovery.

An active-active cluster can have up to nine DB instances. Perform point-in-time recovery on the DB instance until you have the number of DB instances you want for the cluster. When you perform point-in-recovery, make sure you associate the DB instance you are adding with a DB parameter group that has `rds.group_replication_enabled` set to 1. Otherwise, Group Replication won't start on the newly added DB instance.

Step 5: Initialize the group on the DB instance you are converting

Initialize the group and start replication:

1. Connect to that DB instance you are converting in a SQL client. For more information about connecting to an RDS for MySQL DB instance, see Connecting to a DB instance running the MySQL database engine.
2. In the SQL client, run the following stored procedures and replace *group_replication_user_password* with the password for the `rdsgrprepladmin` user. The `rdsgrprepladmin` user is reserved for Group Replication connections in an active-active cluster. The password for this user must be the same on all of the DB instances in an active-active cluster.

```
call mysql.rds_set_configuration('binlog retention hours', 168); -- 7 days binlog
call mysql.rds_group_replication_create_user('group_replication_user_password');
call
 mysql.rds_group_replication_set_recovery_channel('group_replication_user_password');
call mysql.rds_group_replication_start(1);
```

   This example sets the `binlog retention hours` value to 168, which means that binary log files are retained for seven days on the DB instance. You can adjust this value to meet your requirements.

   This example specifies 1 in the `mysql.rds_group_replication_start` stored procedure to initialize a new group with the current DB instance.

   For more information about the stored procedures called in the example, see Managing active-active clusters.

Step 6: Start replication on the other DB instances in the active-active cluster

For each of the DB instances in the active-active cluster, use a SQL client to connect to the instance, and run the following stored procedures. Replace *group_replication_user_password* with the password for the `rdsgrprepladmin` user.

```
call mysql.rds_set_configuration('binlog retention hours', 168); -- 7 days binlog
call mysql.rds_group_replication_create_user('group_replication_user_password');
call
 mysql.rds_group_replication_set_recovery_channel('group_replication_user_password');
```

```
call mysql.rds_group_replication_start(0);
```

This example sets the `binlog retention hours` value to 168, which means that binary log files are retained for seven days on each DB instance. You can adjust this value to meet your requirements.

This example specifies `0` in the `mysql.rds_group_replication_start` stored procedure to join the current DB instance to an existing group.

> **Tip**
>
> Make sure you run these stored procedures on all of the other DB instances in the active-active cluster.

Step 7: (Recommended) Check the status of the active-active cluster

To make sure each member of the cluster is configured correctly, check the status of the cluster by connecting to a DB instance in the active-active cluster, and running the following SQL command:

```
SELECT * FROM performance_schema.replication_group_members;
```

Your output should show `ONLINE` for the `MEMBER_STATE` of each DB instance, as in the following sample output:

```
+---------------------------+--------------------------------------
+---------------+-------------+-------------+-------------+---------------
+----------------------------+
| CHANNEL_NAME              | MEMBER_ID                            | MEMBER_HOST    |
 MEMBER_PORT | MEMBER_STATE | MEMBER_ROLE | MEMBER_VERSION | MEMBER_COMMUNICATION_STACK
 |
+---------------------------+--------------------------------------
+---------------+-------------+-------------+-------------+---------------
+----------------------------+
| group_replication_applier | 9854d4a2-5d7f-11ee-b8ec-0ec88c43c251 | ip-10-15-3-137 |
      3306 | ONLINE       | PRIMARY     | 8.0.35         | MySQL                       |
| group_replication_applier | 9e2e9c28-5d7f-11ee-8039-0e5d58f05fef | ip-10-15-3-225 |
      3306 | ONLINE       | PRIMARY     | 8.0.35         | MySQL                       |
| group_replication_applier | a6ba332d-5d7f-11ee-a025-0a5c6971197d | ip-10-15-1-83  |
      3306 | ONLINE       | PRIMARY     | 8.0.35         | MySQL                       |
```

```
+--------------------------+--------------------------------------
+---------------+-------------+-------------+-------------+---------------
+--------------------------+
3 rows in set (0.00 sec)
```

For information about the possible MEMBER_STATE values, see Group Replication Server States in the MySQL documentation.

Setting up an active-active cluster with new DB instances

Complete the following steps to set up an active-active cluster using new RDS for MySQL DB instances.

If you are setting up an active-active cluster with DB instances in more than one VPC, make sure you complete the prerequisites in Prerequisites for a cross-VPC active-active cluster.

Topics

- Step 1: Set the active-active cluster parameters in one or more custom parameter groups
- Step 2: Create new RDS for MySQL DB instances for the active-active cluster
- Step 4: Specify the DB instances in the active-active cluster
- Step 5: Initialize the group on a DB instance and start replication
- Step 6: Start replication on the other DB instances in the active-active cluster
- Step 7: (Recommended) Check the status of the active-active cluster
- Step 8: (Optional) Import data into a DB instance in the active-active cluster

Step 1: Set the active-active cluster parameters in one or more custom parameter groups

The RDS for MySQL DB instances in an active-active cluster must be associated with a custom parameter group that has the correct setting for required parameters. For information about the parameters and the required setting for each one, see Required parameter settings for active-active clusters.

You can set these parameters in new parameter groups or in existing parameter groups. However, to avoid accidentally affecting DB instances that aren't part of the active-active cluster, we strongly recommend that you create a new custom parameter group. The DB instances in an active-active

cluster can be associated with the same DB parameter group or with different DB parameter groups.

You can use the AWS Management Console or the AWS CLI to create a new custom parameter group. For more information, see Creating a DB parameter group in Amazon RDS. The following example runs the create-db-parameter-group AWS CLI command to create a custom DB parameter group named *myactivepg*:

For Linux, macOS, or Unix:

```
aws rds create-db-parameter-group \
  --db-parameter-group-name myactivepg \
  --db-parameter-group-family mysql8.0 \
  --description "Parameter group for active-active clusters"
```

For Windows:

```
aws rds create-db-parameter-group ^
  --db-parameter-group-name myactivepg ^
  --db-parameter-group-family mysql8.0 ^
  --description "Parameter group for active-active clusters"
```

You can also use the AWS Management Console or the AWS CLI to set the parameters in the custom parameter group. For more information, see Modifying parameters in a DB parameter group in Amazon RDS.

The following example runs the modify-db-parameter-group AWS CLI command to set the parameters:

For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group \
  --db-parameter-group-name myactivepg \
  --parameters
 "ParameterName='rds.group_replication_enabled',ParameterValue='1',ApplyMethod=pending-
reboot" \

 "ParameterName='rds.custom_dns_resolution',ParameterValue='1',ApplyMethod=pending-
reboot" \

 "ParameterName='enforce_gtid_consistency',ParameterValue='ON',ApplyMethod=pending-
reboot" \
```

```
               "ParameterName='gtid-mode',ParameterValue='ON',ApplyMethod=pending-
reboot" \

 "ParameterName='binlog_format',ParameterValue='ROW',ApplyMethod=immediate" \

 "ParameterName='slave_preserve_commit_order',ParameterValue='ON',ApplyMethod=immediate"
 \

 "ParameterName='group_replication_group_name',ParameterValue='11111111-2222-3333-4444-55555555
reboot"
```

For Windows:

```
aws rds modify-db-parameter-group ^
  --db-parameter-group-name myactivepg ^
  --parameters
 "ParameterName='rds.group_replication_enabled',ParameterValue='1',ApplyMethod=pending-
reboot" ^

 "ParameterName='rds.custom_dns_resolution',ParameterValue='1',ApplyMethod=pending-
reboot" ^

 "ParameterName='enforce_gtid_consistency',ParameterValue='ON',ApplyMethod=pending-
reboot" ^
               "ParameterName='gtid-mode',ParameterValue='ON',ApplyMethod=pending-
reboot" ^

 "ParameterName='binlog_format',ParameterValue='ROW',ApplyMethod=immediate" ^

 "ParameterName='slave_preserve_commit_order',ParameterValue='ON',ApplyMethod=immediate"
 ^

 "ParameterName='group_replication_group_name',ParameterValue='11111111-2222-3333-4444-55555555
reboot"
```

Step 2: Create new RDS for MySQL DB instances for the active-active cluster

Active-active clusters are supported for version 8.0.35 and higher RDS for MySQL DB instances. You can create up to nine new DB instances for the cluster.

You can use the AWS Management Console or the AWS CLI to create new DB instances. For more information about creating a DB instance, see Creating an Amazon RDS DB instance. When you

create the DB instance, associate it with a DB parameter group that you created or modified in the previous step.

Step 4: Specify the DB instances in the active-active cluster

In the DB parameter group associated with each DB instance, set the `group_replication_group_seeds` parameter to the endpoints of the DB instances you want to include in the cluster.

You can use the AWS Management Console or the AWS CLI to set the parameter. You don't need to reboot the DB instance after setting this parameter. For more information about setting parameters, see Modifying parameters in a DB parameter group in Amazon RDS.

The following example runs the modify-db-parameter-group AWS CLI command to set the parameters:

For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group \
  --db-parameter-group-name myactivepg \
  --parameters
 "ParameterName='group_replication_group_seeds',ParameterValue='myactivedb1.123456789012.us-
east-1.rds.amazonaws.com:3306,myactivedb2.123456789012.us-
east-1.rds.amazonaws.com:3306,myactivedb3.123456789012.us-
east-1.rds.amazonaws.com:3306',ApplyMethod=immediate"
```

For Windows:

```
aws rds modify-db-parameter-group ^
  --db-parameter-group-name myactivepg ^
  --parameters
 "ParameterName='group_replication_group_seeds',ParameterValue='myactivedb1.123456789012.us-
east-1.rds.amazonaws.com:3306,myactivedb2.123456789012.us-
east-1.rds.amazonaws.com:3306,myactivedb3.123456789012.us-
east-1.rds.amazonaws.com:3306',ApplyMethod=immediate"
```

Tip

Make sure you set the `group_replication_group_seeds` parameter in each DB parameter group that is associated with a DB instance in the active-active cluster.

Step 5: Initialize the group on a DB instance and start replication

You can choose any new DB to initialize the group and start replication. To do so, complete the following steps:

1. Choose a DB instance in the active-active cluster, and connect to that DB instance in a SQL client. For more information about connecting to an RDS for MySQL DB instance, see Connecting to a DB instance running the MySQL database engine.
2. In the SQL client, run the following stored procedures and replace *group_replication_user_password* with the password for the `rdsgrprepladmin` user. The `rdsgrprepladmin` user is reserved for Group Replication connections in an active-active cluster. The password for this user must be the same on all of the DB instances in an active-active cluster.

```
call mysql.rds_set_configuration('binlog retention hours', 168); -- 7 days binlog
call mysql.rds_group_replication_create_user('group_replication_user_password');
call
 mysql.rds_group_replication_set_recovery_channel('group_replication_user_password');
call mysql.rds_group_replication_start(1);
```

   This example sets the `binlog retention hours` value to 168, which means that binary log files are retained for seven days on the DB instance. You can adjust this value to meet your requirements.

   This example specifies 1 in the `mysql.rds_group_replication_start` stored procedure to initialize a new group with the current DB instance.

   For more information about the stored procedures called in the example, see Managing active-active clusters.

Step 6: Start replication on the other DB instances in the active-active cluster

For each of the DB instances in the active-active cluster, use a SQL client to connect to the instance, and run the following stored procedures. Replace *group_replication_user_password* with the password for the `rdsgrprepladmin` user.

```
call mysql.rds_set_configuration('binlog retention hours', 168); -- 7 days binlog
call mysql.rds_group_replication_create_user('group_replication_user_password');
```

```
call
 mysql.rds_group_replication_set_recovery_channel('group_replication_user_password');
call mysql.rds_group_replication_start(0);
```

This example sets the `binlog retention hours` value to 168, which means that binary log files are retained for seven days on each DB instance. You can adjust this value to meet your requirements.

This example specifies `0` in the `mysql.rds_group_replication_start` stored procedure to join the current DB instance to an existing group.

> **Tip**
>
> Make sure you run these stored procedures on all of the other DB instances in the active-active cluster.

Step 7: (Recommended) Check the status of the active-active cluster

To make sure each member of the cluster is configured correctly, check the status of the cluster by connecting to a DB instance in the active-active cluster, and running the following SQL command:

```
SELECT * FROM performance_schema.replication_group_members;
```

Your output should show `ONLINE` for the `MEMBER_STATE` of each DB instance, as in the following sample output:

```
+---------------------------+--------------------------------------
+---------------+-------------+--------------+-------------+----------------
+----------------------------+
| CHANNEL_NAME              | MEMBER_ID                            | MEMBER_HOST    |
 MEMBER_PORT | MEMBER_STATE | MEMBER_ROLE | MEMBER_VERSION | MEMBER_COMMUNICATION_STACK
 |
+---------------------------+--------------------------------------
+---------------+-------------+--------------+-------------+----------------
+----------------------------+
| group_replication_applier | 9854d4a2-5d7f-11ee-b8ec-0ec88c43c251 | ip-10-15-3-137 |
      3306 | ONLINE       | PRIMARY     | 8.0.35         | MySQL                       |
| group_replication_applier | 9e2e9c28-5d7f-11ee-8039-0e5d58f05fef | ip-10-15-3-225 |
      3306 | ONLINE       | PRIMARY     | 8.0.35         | MySQL                       |
```

```
| group_replication_applier | a6ba332d-5d7f-11ee-a025-0a5c6971197d | ip-10-15-1-83  |
      3306 | ONLINE       | PRIMARY     | 8.0.35         | MySQL                         |
+---------------------------+--------------------------------------
+---------------+-------------+-------------+-------------+---------------
+----------------------------+
3 rows in set (0.00 sec)
```

For information about the possible MEMBER_STATE values, see Group Replication Server States in the MySQL documentation.

Step 8: (Optional) Import data into a DB instance in the active-active cluster

You can import data from a MySQL database into a DB instance in the active-active cluster. After the data is imported, Group Replication replicates it to the other DB instances in the cluster.

For information about importing data, see Importing data to an Amazon RDS MariaDB or MySQL database with reduced downtime.

Adding a DB instance to an active-active cluster

You can add a DB instance to an active-active cluster by restoring a DB snapshot or by restoring a DB instance to a point in time. An active-active cluster can include up to nine DB instances.

When you recover a DB instance to a point in time, it usually includes more recent transactions than a DB instance that was restored from a DB snapshot. When the DB instance has more recent transactions, fewer transactions need to be applied when you start replication. So, using point-in-time recovery to add a DB instance to a cluster is usually faster than restoring from a DB snapshot.

Topics

- Adding a DB instance to an active-active cluster using point-in-time recovery
- Adding a DB instance to an active-active cluster using a DB snapshot

Adding a DB instance to an active-active cluster using point-in-time recovery

You can add a DB instance to an active-active cluster by performing point-in-time recovery on a DB instance in the cluster.

For information about recovering a DB instance to a point in time in a different AWS Region, see Replicating automated backups to another AWS Region.

To add a DB instance to an active-active cluster using point-in-time recovery

1. Create a new DB instance by performing point-in-time recovery on a DB instance in the active-active cluster.

   You can perform point-in-time recovery on any DB instance in the cluster to create the new DB instance. For instructions, see Restoring a DB instance to a specified time.

   > **Important**
   >
   > During point-in-time-recovery, associate the new DB instance with a DB parameter group that has the active-active cluster parameters set. Otherwise, Group Replication won't start on the new DB instance. For information about the parameters and the required setting for each one, see Required parameter settings for active-active clusters.

   > **Tip**
   >
   > If you take a snapshot of the DB instance before you start point-in-time recovery, you might be able to reduce the amount of time required to apply transactions on the new DB instance.

2. Add the DB instance to the `group_replication_group_seeds` parameter in each DB parameter group associated with a DB instance in the active-active cluster, including the DB parameter group that you associated with the new DB instance.

   For more information about setting parameters, see Modifying parameters in a DB parameter group in Amazon RDS.

3. In a SQL client, connect to the new DB instance, and call the mysql.rds_group_replication_set_recovery_channel stored procedure. Replace *`group_replication_user_password`* with the password for the `rdsgrprepladmin` user.

   ```
   call
    mysql.rds_group_replication_set_recovery_channel('group_replication_user_password');
   ```

4. Using the SQL client, call the mysql.rds_group_replication_start stored procedure to start replication:

```
call mysql.rds_group_replication_start(0);
```

Adding a DB instance to an active-active cluster using a DB snapshot

You can add a DB instance to an active-active cluster by creating a DB snapshot of a DB instance in the cluster and then restoring the DB snapshot.

For information about copying a snapshot to a different AWS Region, see the section called "Cross-Region copying".

To add a DB instance to an active-active cluster using a DB snapshot

1. Create a DB snapshot of a DB instance in the active-active cluster.

   You can create a DB snapshot of any DB instance in the cluster. For instructions, see Creating a DB snapshot for a Single-AZ DB instance.
2. Restore a DB instance from the DB snapshot.

   During the snapshot restore operation, associate the new DB instance with a DB parameter group that has the active-active cluster parameters set. For information about the parameters and the required setting for each one, see Required parameter settings for active-active clusters.

   For information about restoring a DB instance from a DB snapshot, see Restoring to a DB instance.
3. Add the DB instance to the `group_replication_group_seeds` parameter in each DB parameter group associated with a DB instance in the active-active cluster, including the DB parameter group that you associated with the new DB instance.

   For more information about setting parameters, see Modifying parameters in a DB parameter group in Amazon RDS.
4. In a SQL client, connect to the new DB instance, and call the mysql.rds_group_replication_set_recovery_channel stored procedure. Replace *`group_replication_user_password`* with the password for the `rdsgrprepladmin` user.

   ```
   call
    mysql.rds_group_replication_set_recovery_channel('group_replication_user_password');
   ```

5. Using the SQL client, call the mysql.rds_group_replication_start stored procedure to start replication:

```
call mysql.rds_group_replication_start(0);
```

Monitoring active-active clusters

You can monitor your active-active cluster by connecting to a DB instance in the cluster, and running the following SQL command:

```
SELECT * FROM performance_schema.replication_group_members;
```

Your output should show ONLINE for the MEMBER_STATE of each DB instance, as in the following sample output:

```
+---------------------------+--------------------------------------
+---------------+-------------+--------------+-------------+----------------
+----------------------------+
| CHANNEL_NAME              | MEMBER_ID                            | MEMBER_HOST    |
 MEMBER_PORT | MEMBER_STATE | MEMBER_ROLE | MEMBER_VERSION | MEMBER_COMMUNICATION_STACK
 |
+---------------------------+--------------------------------------
+---------------+-------------+--------------+-------------+----------------
+----------------------------+
| group_replication_applier | 9854d4a2-5d7f-11ee-b8ec-0ec88c43c251 | ip-10-15-3-137 |
      3306 | ONLINE       | PRIMARY     | 8.0.35         | MySQL                       |
| group_replication_applier | 9e2e9c28-5d7f-11ee-8039-0e5d58f05fef | ip-10-15-3-225 |
      3306 | ONLINE       | PRIMARY     | 8.0.35         | MySQL                       |
| group_replication_applier | a6ba332d-5d7f-11ee-a025-0a5c6971197d | ip-10-15-1-83  |
      3306 | ONLINE       | PRIMARY     | 8.0.35         | MySQL                       |
+---------------------------+--------------------------------------
+---------------+-------------+--------------+-------------+----------------
+----------------------------+
3 rows in set (0.00 sec)
```

For information about the possible MEMBER_STATE values, see Group Replication Server States in the MySQL documentation.

Stopping Group Replication on a DB instance in an active-active cluster

You can stop Group Replication on a DB instance in an active-active cluster. When you stop Group Replication, the DB instance is placed in super-read-only mode until replication is restarted or that DB instance is removed from the active-active cluster. For information about super-read-only mode, see the MySQL documentation.

To stop Group Replication temporarily for an active-active cluster

1. Connect to a DB instance in the active-active cluster using a SQL client.

   For more information about connecting to an RDS for MySQL DB instance, see Connecting to a DB instance running the MySQL database engine.

2. In the SQL client, call the mysql.rds_group_replication_stop stored procedure:

```
call mysql.rds_group_replication_stop();
```

Renaming a DB instance in an active-active cluster

You can change the name of a DB instance in an active-active cluster. To rename more than one DB instance in an active-active cluster, do so one DB instance at a time. So, rename one DB instance and rejoin it to the cluster before you rename the next DB instance.

To rename a DB instance in an active-active cluster

1. Connect to the DB instance in a SQL client, and call the mysql.rds_group_replication_stop stored procedure:

```
call mysql.rds_group_replication_stop();
```

2. Rename the DB instance by following the instructions in Renaming a DB instance.
3. Modify the `group_replication_group_seeds` parameter in each DB parameter group associated with a DB instance in the active-active cluster.

   In the parameter setting, replace the old DB instance endpoint with the new DB instance endpoint. For more information about setting parameters, see Modifying parameters in a DB parameter group in Amazon RDS.

4. Connect to the DB instance in a SQL client, and call the mysql.rds_group_replication_start stored procedure:

```
call mysql.rds_group_replication_start(0);
```

Removing a DB instance from an active-active cluster

When you remove a DB instance from an active-active cluster, it reverts to a standalone DB instance.

To remove a DB instance from an active-active cluster

1. Connect to the DB instance in a SQL client, and call the mysql.rds_group_replication_stop stored procedure:

```
call mysql.rds_group_replication_stop();
```

2. Modify the `group_replication_group_seeds` parameter for the DB instances that will remain in the active-active cluster.

   In the `group_replication_group_seeds` parameter, delete the DB instance that you are removing from the active-active cluster. For more information about setting parameters, see Modifying parameters in a DB parameter group in Amazon RDS.

3. Modify the parameters of the DB instance you are removing from the active-active cluster so that it is no longer part of the cluster.

   You can either associate the DB instance with a different parameter group, or modify the parameters in the DB parameter group associated with the DB instance. The parameters to modify include `group_replication_group_name`, `rds.group_replication_enabled`, and `group_replication_group_seeds`. For more information about active-active cluster parameters, see Required parameter settings for active-active clusters.

   If you modify the parameters in a DB parameter group, make sure the DB parameter group isn't associated with other DB instances in the active-active cluster.

4. Reboot the DB instance you removed from the active-active cluster for the new parameter settings to take effect.

   For instructions, see Rebooting a DB instance.

Limitations for RDS for MySQL active-active clusters

The following limitations apply to active-active clusters for RDS for MySQL:

- The master user name can't be `rdsgrprepladmin` for DB instances in an active-active cluster. This user name is reserved for Group Replication connections.
- For DB instances with read replicas in active-active clusters, a prolonged replication status other than `Replicating` can cause log files to exceed storage limits. For information about the status of read replicas, see Monitoring read replication.
- Blue/green deployments aren't supported for DB instances in an active-active cluster. For more information, see Using Amazon RDS Blue/Green Deployments for database updates.
- Kerberos authentication isn't supported for DB instances in an active-active cluster. For more information, see Using Kerberos authentication for MySQL.
- The DB instances in a Multi-AZ DB cluster can't be added to an active-active cluster.

  However, the DB instances in a Multi-AZ DB instance deployment can be added to an active-active cluster.

  For more information, see Configuring and managing a Multi-AZ deployment.
- Tables that don't have a primary key aren't replicated in an active-active cluster because writes are rejected by the Group Replication plugin.
- Non-InnoDB tables aren't replicated in an active-active cluster.
- Active-active clusters don't support concurrent DML and DDL statements on different DB instances in the cluster.
- You can't configure an active-active cluster to use single-primary mode for the group's replication mode. For this configuration, we recommend using a Multi-AZ DB cluster instead. For more information, see Multi-AZ DB cluster deployments.
- Multi-source replication isn't supported for DB instances in an active-active cluster.
- A cross-Region active-active cluster can't enforce certificate authority (CA) verification for Group Replication connections.

Exporting data from a MySQL DB instance by using replication

To export data from an RDS for MySQL DB instance to a MySQL instance running external to Amazon RDS, you can use replication. In this scenario, the MySQL DB instance is the *source MySQL DB instance*, and the MySQL instance running external to Amazon RDS is the *external MySQL database*.

The external MySQL database can run either on-premises in your data center, or on an Amazon EC2 instance. The external MySQL database must run the same version as the source MySQL DB instance, or a later version.

Replication to an external MySQL database is only supported during the time it takes to export a database from the source MySQL DB instance. The replication should be terminated when the data has been exported and applications can start accessing the external MySQL instance.

The following list shows the steps to take. Each step is discussed in more detail in later sections.

1. Prepare an external MySQL DB instance.
2. Prepare the source MySQL DB instance for replication.
3. Use the mysqldump utility to transfer the database from the source MySQL DB instance to the external MySQL database.
4. Start replication to the external MySQL database.
5. After the export completes, stop replication.

Prepare an external MySQL database

Perform the following steps to prepare the external MySQL database.

To prepare the external MySQL database

1. Install the external MySQL database.
2. Connect to the external MySQL database as the master user. Then create the users required to support the administrators, applications, and services that access the database.
3. Follow the directions in the MySQL documentation to prepare the external MySQL database as a replica. For more information, see Setting the Replica Configuration in the MySQL documentation.

4. Configure an egress rule for the external MySQL database to operate as a read replica during the export. The egress rule allows the external MySQL database to connect to the source MySQL DB instance during replication. Specify an egress rule that allows Transmission Control Protocol (TCP) connections to the port and IP address of the source MySQL DB instance.

   Specify the appropriate egress rules for your environment:

   - If the external MySQL database is running in an Amazon EC2 instance in a virtual private cloud (VPC) based on the Amazon VPC service, specify the egress rules in a VPC security group. For more information, see Controlling access with security groups.
   - If the external MySQL database is installed on-premises, specify the egress rules in a firewall.
5. If the external MySQL database is running in a VPC, configure rules for the VPC access control list (ACL) rules in addition to the security group egress rule:

   - Configure an ACL ingress rule allowing TCP traffic to ports 1024–65535 from the IP address of the source MySQL DB instance.
   - Configure an ACL egress rule allowing outbound TCP traffic to the port and IP address of the source MySQL DB instance.

   For more information about Amazon VPC network ACLs, see Network ACLs in *Amazon VPC User Guide.*
6. (Optional) Set the `max_allowed_packet` parameter to the maximum size to avoid replication errors. We recommend this setting.

Prepare the source MySQL DB instance

Perform the following steps to prepare the source MySQL DB instance as the replication source.

To prepare the source MySQL DB instance

1. Ensure that your client computer has enough disk space available to save the binary logs while setting up replication.
2. Connect to the source MySQL DB instance, and create a replication account by following the directions in Creating a User for Replication in the MySQL documentation.
3. Configure ingress rules on the system running the source MySQL DB instance to allow the external MySQL database to connect during replication. Specify an ingress rule that allows

TCP connections to the port used by the source MySQL DB instance from the IP address of the external MySQL database.

4. Specify the egress rules:

   - If the source MySQL DB instance is running in a VPC, specify the ingress rules in a VPC security group. For more information, see Controlling access with security groups.

5. If source MySQL DB instance is running in a VPC, configure VPC ACL rules in addition to the security group ingress rule:

   - Configure an ACL ingress rule to allow TCP connections to the port used by the Amazon RDS instance from the IP address of the external MySQL database.
   - Configure an ACL egress rule to allow TCP connections from ports 1024–65535 to the IP address of the external MySQL database.

   For more information about Amazon VPC network ACLs, see Network ACLs in the *Amazon VPC User Guide.*

6. Ensure that the backup retention period is set long enough that no binary logs are purged during the export. If any of the logs are purged before the export has completed, you must restart replication from the beginning. For more information about setting the backup retention period, see Introduction to backups.

7. Use the `mysql.rds_set_configuration` stored procedure to set the binary log retention period long enough that the binary logs aren't purged during the export. For more information, see Accessing MySQL binary logs.

8. Create an Amazon RDS read replica from the source MySQL DB instance to further ensure that the binary logs of the source MySQL DB instance are not purged. For more information, see Creating a read replica.

9. After the Amazon RDS read replica has been created, call the `mysql.rds_stop_replication` stored procedure to stop the replication process. The source MySQL DB instance no longer purges its binary log files, so they are available for the replication process.

10. (Optional) Set both the `max_allowed_packet` parameter and the `slave_max_allowed_packet` parameter to the maximum size to avoid replication errors. The maximum size for both parameters is 1 GB. We recommend this setting for both parameters. For information about setting parameters, see Modifying parameters in a DB parameter group in Amazon RDS.

Copy the database

Perform the following steps to copy the database.

To copy the database

1. Connect to the RDS read replica of the source MySQL DB instance, and run the MySQL `SHOW REPLICA STATUS\G` statement. Note the values for the following:

   - `Master_Host`
   - `Master_Port`
   - `Master_Log_File`
   - `Exec_Master_Log_Pos`

   > **Note**
   >
   > Previous versions of MySQL used `SHOW SLAVE STATUS` instead of `SHOW REPLICA STATUS`. If you are using a MySQL version before 8.0.23, then use `SHOW SLAVE STATUS`.

2. Use the mysqldump utility to create a snapshot, which copies the data from Amazon RDS to your local client computer. Ensure that your client computer has enough space to hold the `mysqldump` files from the databases to be replicated. This process can take several hours for very large databases. Follow the directions in Creating a Data Snapshot Using mysqldump in the MySQL documentation.

   The following example runs `mysqldump` on a client and writes the dump to a file.

   For Linux, macOS, or Unix:

   ```
   mysqldump -h source_MySQL_DB_instance_endpoint \
       -u user \
       -ppassword \
       --port=3306 \
       --single-transaction \
       --routines \
       --triggers \
       --databases  database database2 > path/rds-dump.sql
   ```

For Windows:

```
mysqldump -h source_MySQL_DB_instance_endpoint ^
    -u user ^
    -ppassword ^
    --port=3306 ^
    --single-transaction ^
    --routines ^
    --triggers ^
    --databases  database database2 > path\rds-dump.sql
```

You can load the backup file into the external MySQL database. For more information, see Reloading SQL-Format Backups in the MySQL documentation. You can run another utility to load the data into the external MySQL database.

Complete the export

Perform the following steps to complete the export.

To complete the export

1. Use the MySQL `CHANGE MASTER` statement to configure the external MySQL database. Specify the ID and password of the user granted `REPLICATION SLAVE` permissions. Specify the `Master_Host`, `Master_Port`, `Relay_Master_Log_File`, and `Exec_Master_Log_Pos` values that you got from the MySQL `SHOW REPLICA STATUS\G` statement that you ran on the RDS read replica. For more information, see CHANGE MASTER TO Statement in the MySQL documentation.

   > **Note**
   >
   > Previous versions of MySQL used `SHOW SLAVE STATUS` instead of `SHOW REPLICA STATUS`. If you are using a MySQL version before 8.0.23, then use `SHOW SLAVE STATUS`.

2. Use the MySQL `START REPLICA` command to initiate replication from the source MySQL DB instance to the external MySQL database.

Doing this starts replication from the source MySQL DB instance and exports all source changes that have occurred after you stopped replication from the Amazon RDS read replica.

> **Note**
>
> Previous versions of MySQL used `START SLAVE` instead of `START REPLICA`. If you are using a MySQL version before 8.0.23, then use `START SLAVE`.

3. Run the MySQL `SHOW REPLICA STATUS\G` command on the external MySQL database to verify that it is operating as a read replica. For more information about interpreting the results, see SHOW SLAVE | REPLICA STATUS Statement in the MySQL documentation.
4. After replication on the external MySQL database has caught up with the source MySQL DB instance, use the MySQL `STOP REPLICA` command to stop replication from the source MySQL DB instance.

> **Note**
>
> Previous versions of MySQL used `STOP SLAVE` instead of `STOP REPLICA`. If you are using a MySQL version before 8.0.23, then use `STOP SLAVE`.

5. On the Amazon RDS read replica, call the `mysql.rds_start_replication` stored procedure. Doing this allows Amazon RDS to start purging the binary log files from the source MySQL DB instance.

Options for MySQL DB instances

Following, you can find a description of options, or additional features, that are available for Amazon RDS instances running the MySQL DB engine. To enable these options, you can add them to a custom option group, and then associate the option group with your DB instance. For more information about working with option groups, see Working with option groups.

Amazon RDS supports the following options for MySQL:

Option	Option ID	Engine versions
MariaDB Audit Plugin support for MySQL	`MARIADB_AUDIT_PLUGIN`	MySQL 8.0.28 and higher 8.0 versions All MySQL 5.7 versions
MySQL memcached support	`MEMCACHED`	All MySQL 5.7 and 8.0 versions

MariaDB Audit Plugin support for MySQL

Amazon RDS offers an audit plugin for MySQL database instances based on the open source MariaDB Audit Plugin. For more information, see the Audit Plugin for MySQL Server GitHub repository.

> **Note**
>
> The audit plugin for MySQL is based on the MariaDB Audit Plugin. Throughout this article, we refer to it as MariaDB Audit Plugin.

The MariaDB Audit Plugin records database activity, including users logging on to the database and queries run against the database. The record of database activity is stored in a log file.

> **Note**
>
> Currently, the MariaDB Audit Plugin is only supported for the following RDS for MySQL versions:
>
> - MySQL 8.0.28 and higher 8.0 versions
> - All MySQL 5.7 versions

Audit Plugin option settings

Amazon RDS supports the following settings for the MariaDB Audit Plugin option.

Option setting	Valid values	Default value	Description
SERVER_AUDIT_FILE_PATH	/rdsdbdata/log/audit/	/rdsdbdata/log/audit/	The location of the log file. The log file contains the record of the activity specified in SERVER_AUDIT_EVENTS . For more information, see Viewing and listing database log files and MySQL database log files.

Option setting	Valid values	Default value	Description
SERVER_AUDIT_FILE_ROTATE_SIZE	1–1000000000	1000000	The size in bytes that when reached, causes the file to rotate. For more information, see Overview of RDS for MySQL database logs.
SERVER_AUDIT_FILE_ROTATIONS	0–100	9	The number of log rotations to save when server_audit_output_type=file . If set to 0, then the log file never rotates. For more information, see Overview of RDS for MySQL database logs and Downloading a database log file.

Option setting	Valid values	Default value	Description
SERVER_AUDIT_EVENTS	CONNECT, QUERY, QUERY_DDL, QUERY_DML, QUERY_DML_NO_SELECT, QUERY_DCL	CONNECT, QUERY	The types of activity to record in the log. Installing the MariaDB Audit Plugin is itself logged. • CONNECT: Log successful and unsuccessful connections to the database, and disconnections from the database. • QUERY: Log the text of all queries run against the database. • QUERY_DDL : Similar to the QUERY event, but returns only data definition language (DDL) queries (CREATE, ALTER, and so on). • QUERY_DML : Similar to the QUERY event, but returns only data manipulation language (DML) queries (INSERT, UPDATE, and so on, and also SELECT). • QUERY_DML_NO_SELECT : Similar to the QUERY_DML event, but doesn't log SELECT queries. The QUERY_DML_NO_SELECT setting is supported only for RDS for MySQL 5.7.34 and higher 5.7 versions, and 8.0.25 and higher 8.0 versions. • QUERY_DCL : Similar to the QUERY event, but returns only data control language (DCL) queries (GRANT, REVOKE, and so on). For MySQL, TABLE is not supported.

Option setting	Valid values	Default value	Description
SERVER_AUDIT_INCL_USERS	Multiple comma-separated values	None	Include only activity from the specified users. By default, activity is recorded for all users. SERVER_AUDIT_INCL_USERS and SERVER_AUDIT_EXCL_USERS are mutually exclusive. If you add values to SERVER_AUDIT_INCL_USERS, make sure no values are added to SERVER_AUDIT_EXCL_USERS.
SERVER_AUDIT_EXCL_USERS	Multiple comma-separated values	None	Exclude activity from the specified users. By default, activity is recorded for all users. SERVER_AUDIT_INCL_USERS and SERVER_AUDIT_EXCL_USERS are mutually exclusive. If you add values to SERVER_AUDIT_EXCL_USERS, make sure no values are added to SERVER_AUDIT_INCL_USERS. The rdsadmin user queries the database every second to check the health of the database. Depending on your other settings, this activity can possibly cause the size of your log file to grow very large, very quickly. If you don't need to record this activity, add the rdsadmin user to the SERVER_AUDIT_EXCL_USERS list. **Note** CONNECT activity is always recorded for all users, even if the user is specified for this option setting.

Option setting	Valid values	Default value	Description
SERVER_AUDIT_LOGGING	ON	ON	Logging is active. The only valid value is ON. Amazon RDS does not support deactivating logging. If you want to deactivate logging, remove the MariaDB Audit Plugin. For more information, see Removing the MariaDB Audit Plugin.
SERVER_AUDIT_QUERY_LOG_LIMIT	0–2147483647	1024	The limit on the length of the query string in a record.

Adding the MariaDB Audit Plugin

The general process for adding the MariaDB Audit Plugin to a DB instance is the following:

- Create a new option group, or copy or modify an existing option group
- Add the option to the option group
- Associate the option group with the DB instance

After you add the MariaDB Audit Plugin, you don't need to restart your DB instance. As soon as the option group is active, auditing begins immediately.

> **Important**
>
> Adding the MariaDB Audit Plugin to a DB instance might cause an outage. We recommend adding the MariaDB Audit Plugin during a maintenance window or during a time of low database workload.

To add the MariaDB Audit Plugin

1. Determine the option group you want to use. You can create a new option group or use an existing option group. If you want to use an existing option group, skip to the next step.

Otherwise, create a custom DB option group. Choose **mysql** for **Engine**, and choose **5.7** or **8.0** for **Major engine version**. For more information, see Creating an option group.

2. Add the **MARIADB_AUDIT_PLUGIN** option to the option group, and configure the option settings. For more information about adding options, see Adding an option to an option group. For more information about each setting, see Audit Plugin option settings.
3. Apply the option group to a new or existing DB instance.

   - For a new DB instance, you apply the option group when you launch the instance. For more information, see Creating an Amazon RDS DB instance.
   - For an existing DB instance, you apply the option group by modifying the instance and attaching the new option group. For more information, see Modifying an Amazon RDS DB instance.

Audit log format

Log files are represented as comma-separated variable (CSV) files in UTF-8 format.

> **Tip**
>
> Log file entries are not in sequential order. To order the entries, use the timestamp value. To see the latest events, you might have to review all log files. For more flexibility in sorting and searching the log data, turn on the setting to upload the audit logs to CloudWatch and view them using the CloudWatch interface.
> To view audit data with more types of fields and with output in JSON format, you can also use the Database Activity Streams feature. For more information, see Monitoring Amazon RDS with Database Activity Streams.

The audit log files include the following comma-delimited information in rows, in the specified order:

Field	Description
timestamp	The `YYYYMMDD` followed by the `HH:MI:SS` (24-hour clock) for the logged event.
serverhost	The name of the instance that the event is logged for.

Field	Description
username	The connected user name of the user.
host	The host that the user connected from.
connectionid	The connection ID number for the logged operation.
queryid	The query ID number, which can be used for finding the relational table events and related queries. For `TABLE` events, multiple lines are added.
operation	The recorded action type. Possible values are: `CONNECT`, `QUERY`, `READ`, `WRITE`, `CREATE`, `ALTER`, `RENAME`, and `DROP`.
database	The active database, as set by the `USE` command.
object	For `QUERY` events, this value indicates the query that the database performed. For `TABLE` events, it indicates the table name.
retcode	The return code of the logged operation.
connection_type	The security state of the connection to the server. Possible values are: • `0` – Undefined • 1 – TCP/IP • 2 – Socket • 3 – Named pipe • 4 – SSL/TLS • 5 – Shared memory This field is included only for RDS for MySQL version 5.7.34 and higher 5.7 versions, and all 8.0 versions.

Viewing and downloading the MariaDB Audit Plugin log

After you enable the MariaDB Audit Plugin, you access the results in the log files the same way you access any other text-based log files. The audit log files are located at `/rdsdbdata/log/audit/`.

For information about viewing the log file in the console, see Viewing and listing database log files. For information about downloading the log file, see Downloading a database log file.

Modifying MariaDB Audit Plugin settings

After you enable the MariaDB Audit Plugin, you can modify the settings. For more information about how to modify option settings, see Modifying an option setting. For more information about each setting, see Audit Plugin option settings.

Removing the MariaDB Audit Plugin

Amazon RDS doesn't support turning off logging in the MariaDB Audit Plugin. However, you can remove the plugin from a DB instance. When you remove the MariaDB Audit Plugin, the DB instance is restarted automatically to stop auditing.

To remove the MariaDB Audit Plugin from a DB instance, do one of the following:

- Remove the MariaDB Audit Plugin option from the option group it belongs to. This change affects all DB instances that use the option group. For more information, see Removing an option from an option group
- Modify the DB instance and specify a different option group that doesn't include the plugin. This change affects a single DB instance. You can specify the default (empty) option group, or a different custom option group. For more information, see Modifying an Amazon RDS DB instance.

MySQL memcached support

Amazon RDS supports using the memcached interface to InnoDB tables that was introduced in MySQL 5.6. The memcached API enables applications to use InnoDB tables in a manner similar to NoSQL key-value data stores.

The memcached interface is a simple, key-based cache. Applications use memcached to insert, manipulate, and retrieve key-value data pairs from the cache. MySQL 5.6 introduced a plugin that implements a daemon service that exposes data from InnoDB tables through the memcached protocol. For more information about the MySQL memcached plugin, see InnoDB integration with memcached.

To enable memcached support for an RDS for MySQL DB instance

1. Determine the security group to use for controlling access to the memcached interface. If the set of applications already using the SQL interface are the same set that will access the memcached interface, you can use the existing VPC security group used by the SQL interface. If a different set of applications will access the memcached interface, define a new VPC or DB security group. For more information about managing security groups, see Controlling access with security groups
2. Create a custom DB option group, selecting MySQL as the engine type and version. For more information about creating an option group, see Creating an option group.
3. Add the MEMCACHED option to the option group. Specify the port that the memcached interface will use, and the security group to use in controlling access to the interface. For more information about adding options, see Adding an option to an option group.
4. Modify the option settings to configure the memcached parameters, if necessary. For more information about how to modify option settings, see Modifying an option setting.
5. Apply the option group to an instance. Amazon RDS enables memcached support for that instance when the option group is applied:

   - You enable memcached support for a new instance by specifying the custom option group when you launch the instance. For more information about launching a MySQL instance, see Creating an Amazon RDS DB instance.
   - You enable memcached support for an existing instance by specifying the custom option group when you modify the instance. For more information about modifying a DB instance, see Modifying an Amazon RDS DB instance.

6. Specify which columns in your MySQL tables can be accessed through the memcached interface. The memcached plug-in creates a catalog table named containers in a dedicated database named innodb_memcache. You insert a row into the containers table to map an InnoDB table for access through memcached. You specify a column in the InnoDB table that is used to store the memcached key values, and one or more columns that are used to store the data values associated with the key. You also specify a name that a memcached application uses to refer to that set of columns. For details on inserting rows in the containers table, see InnoDB memcached plugin internals. For an example of mapping an InnoDB table and accessing it through memcached, see Writing applications for the InnoDB memcached plugin.
7. If the applications accessing the memcached interface are on different computers or EC2 instances than the applications using the SQL interface, add the connection information for those computers to the VPC security group associated with the MySQL instance. For more information about managing security groups, see Controlling access with security groups.

You turn off the memcached support for an instance by modifying the instance and specifying the default option group for your MySQL version. For more information about modifying a DB instance, see Modifying an Amazon RDS DB instance.

MySQL memcached security considerations

The memcached protocol does not support user authentication. For more information about MySQL memcached security considerations, see Security Considerations for the InnoDB memcached Plugin in the MySQL documentation.

You can take the following actions to help increase the security of the memcached interface:

- Specify a different port than the default of 11211 when adding the MEMCACHED option to the option group.
- Ensure that you associate the memcached interface with a VPC security group that limits access to known, trusted client addresses and EC2 instances. For more information about managing security groups, see Controlling access with security groups.

MySQL memcached connection information

To access the memcached interface, an application must specify both the DNS name of the Amazon RDS instance and the memcached port number. For example, if an instance has a DNS name of my-

cache-instance.cg034hpkmmjt.region.rds.amazonaws.com and the memcached interface is using port 11212, the connection information specified in PHP would be:

```
<?php

$cache = new Memcache;
$cache->connect('my-cache-instance.cg034hpkmmjt.region.rds.amazonaws.com',11212);
?>
```

To find the DNS name and memcached port of a MySQL DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the top right corner of the AWS Management Console, select the region that contains the DB instance.
3. In the navigation pane, choose **Databases**.
4. Choose the MySQL DB instance name to display its details.
5. In the **Connect** section, note the value of the **Endpoint** field. The DNS name is the same as the endpoint. Also, note that the port in the **Connect** section is not used to access the memcached interface.
6. In the **Details** section, note the name listed in the **Option Group** field.
7. In the navigation pane, choose **Option groups**.
8. Choose the name of the option group used by the MySQL DB instance to show the option group details. In the **Options** section, note the value of the **Port** setting for the **MEMCACHED** option.

MySQL memcached option settings

Amazon RDS exposes the MySQL memcached parameters as option settings in the Amazon RDS MEMCACHED option.

MySQL memcached parameters

- DAEMON_MEMCACHED_R_BATCH_SIZE – an integer that specifies how many memcached read operations (get) to perform before doing a COMMIT to start a new transaction. The allowed

values are 1 to 4294967295; the default is 1. The option does not take effect until the instance is restarted.

- DAEMON_MEMCACHED_W_BATCH_SIZE – an integer that specifies how many memcached write operations, such as add, set, or incr, to perform before doing a COMMIT to start a new transaction. The allowed values are 1 to 4294967295; the default is 1. The option does not take effect until the instance is restarted.
- INNODB_API_BK_COMMIT_INTERVAL – an integer that specifies how often to auto-commit idle connections that use the InnoDB memcached interface. The allowed values are 1 to 1073741824; the default is 5. The option takes effect immediately, without requiring that you restart the instance.
- INNODB_API_DISABLE_ROWLOCK – a Boolean that disables (1 (true)) or enables (0 (false)) the use of row locks when using the InnoDB memcached interface. The default is 0 (false). The option does not take effect until the instance is restarted.
- INNODB_API_ENABLE_MDL – a Boolean that when set to 0 (false) locks the table used by the InnoDB memcached plugin, so that it cannot be dropped or altered by DDL through the SQL interface. The default is 0 (false). The option does not take effect until the instance is restarted.
- INNODB_API_TRX_LEVEL – an integer that specifies the transaction isolation level for queries processed by the memcached interface. The allowed values are 0 to 3. The default is 0. The option does not take effect until the instance is restarted.

Amazon RDS configures these MySQL memcached parameters, and they cannot be modified: DAEMON_MEMCACHED_LIB_NAME, DAEMON_MEMCACHED_LIB_PATH, and INNODB_API_ENABLE_BINLOG. The parameters that MySQL administrators set by using daemon_memcached_options are available as individual MEMCACHED option settings in Amazon RDS.

MySQL daemon_memcached_options parameters

- BINDING_PROTOCOL – a string that specifies the binding protocol to use. The allowed values are auto, ascii, or binary. The default is auto, which means the server automatically negotiates the protocol with the client. The option does not take effect until the instance is restarted.
- BACKLOG_QUEUE_LIMIT – an integer that specifies how many network connections can be waiting to be processed by memcached. Increasing this limit may reduce errors received by a client that is not able to connect to the memcached instance, but does not improve the performance of the server. The allowed values are 1 to 2048; the default is 1024. The option does not take effect until the instance is restarted.

- CAS_DISABLED – a Boolean that enables (1 (true)) or disables (0 (false)) the use of compare and swap (CAS), which reduces the per-item size by 8 bytes. The default is 0 (false). The option does not take effect until the instance is restarted.
- CHUNK_SIZE – an integer that specifies the minimum chunk size, in bytes, to allocate for the smallest item's key, value, and flags. The allowed values are 1 to 48. The default is 48 and you can significantly improve memory efficiency with a lower value. The option does not take effect until the instance is restarted.
- CHUNK_SIZE_GROWTH_FACTOR – a float that controls the size of new chunks. The size of a new chunk is the size of the previous chunk times CHUNK_SIZE_GROWTH_FACTOR. The allowed values are 1 to 2; the default is 1.25. The option does not take effect until the instance is restarted.
- ERROR_ON_MEMORY_EXHAUSTED – a Boolean that when set to 1 (true) specifies that memcached will return an error rather than evicting items when there is no more memory to store items. If set to 0 (false), memcached will evict items if there is no more memory. The default is 0 (false). The option does not take effect until the instance is restarted.
- MAX_SIMULTANEOUS_CONNECTIONS – an integer that specifies the maximum number of concurrent connections. Setting this value to anything under 10 prevents MySQL from starting. The allowed values are 10 to 1024; the default is 1024. The option does not take effect until the instance is restarted.
- VERBOSITY – a string that specifies the level of information logged in the MySQL error log by the memcached service. The default is v. The option does not take effect until the instance is restarted. The allowed values are:
  - v – Logs errors and warnings while running the main event loop.
  - vv – In addition to the information logged by v, also logs each client command and the response.
  - vvv – In addition to the information logged by vv, also logs internal state transitions.

Amazon RDS configures these MySQL DAEMON_MEMCACHED_OPTIONS parameters, they cannot be modified: DAEMON_PROCESS, LARGE_MEMORY_PAGES, MAXIMUM_CORE_FILE_LIMIT, MAX_ITEM_SIZE, LOCK_DOWN_PAGE_MEMORY, MASK, IDFILE, REQUESTS_PER_EVENT, SOCKET, and USER.

Parameters for MySQL

By default, a MySQL DB instance uses a DB parameter group that is specific to a MySQL database. This parameter group contains parameters for the MySQL database engine. For information about working with parameter groups and setting parameters, see Parameter groups for Amazon RDS.

RDS for MySQL parameters are set to the default values of the storage engine that you have selected. For more information about MySQL parameters, see the MySQL documentation. For more information about MySQL storage engines, see Supported storage engines for RDS for MySQL.

You can view the parameters available for a specific RDS for MySQL version using the RDS console or the AWS CLI. For information about viewing the parameters in a MySQL parameter group in the RDS console, see Viewing parameter values for a DB parameter group in Amazon RDS.

Using the AWS CLI, you can view the parameters for an RDS for MySQL version by running the `describe-engine-default-parameters` command. Specify one of the following values for the `--db-parameter-group-family` option:

- `mysql8.0`
- `mysql5.7`

For example, to view the parameters for RDS for MySQL version 8.0, run the following command.

```
aws rds describe-engine-default-parameters --db-parameter-group-family mysql8.0
```

Your output looks similar to the following.

```
{
    "EngineDefaults": {
        "Parameters": [
            {
                "ParameterName": "activate_all_roles_on_login",
                "ParameterValue": "0",
                "Description": "Automatically set all granted roles as active after the
 user has authenticated successfully.",
                "Source": "engine-default",
                "ApplyType": "dynamic",
                "DataType": "boolean",
                "AllowedValues": "0,1",
                "IsModifiable": true
```

```
            },
            {
                "ParameterName": "allow-suspicious-udfs",
                "Description": "Controls whether user-defined functions that have only
 an xxx symbol for the main function can be loaded",
                "Source": "engine-default",
                "ApplyType": "static",
                "DataType": "boolean",
                "AllowedValues": "0,1",
                "IsModifiable": false
            },
            {
                "ParameterName": "auto_generate_certs",
                "Description": "Controls whether the server autogenerates SSL key and
 certificate files in the data directory, if they do not already exist.",
                "Source": "engine-default",
                "ApplyType": "static",
                "DataType": "boolean",
                "AllowedValues": "0,1",
                "IsModifiable": false
            },
        ...
```

To list only the modifiable parameters for RDS for MySQL version 8.0, run the following command.

For Linux, macOS, or Unix:

```
aws rds describe-engine-default-parameters --db-parameter-group-family mysql8.0 \
   --query 'EngineDefaults.Parameters[?IsModifiable==`true`]'
```

For Windows:

```
aws rds describe-engine-default-parameters --db-parameter-group-family mysql8.0 ^
   --query "EngineDefaults.Parameters[?IsModifiable==`true`]"
```

Common DBA tasks for MySQL DB instances

In the following content, you can find descriptions of the Amazon RDS-specific implementations of some common DBA tasks for DB instances running the MySQL database engine. To deliver a managed service experience, Amazon RDS doesn't provide shell access to DB instances. Also, it restricts access to certain system procedures and tables that require advanced privileges.

For information about working with MySQL log files on Amazon RDS, see MySQL database log files.

Topics

Understanding predefined users

Amazon RDS automatically creates several predefined users with new RDS for MySQL DB instances. Predefined users and their privileges can't be changed. You can't drop, rename, or modify privileges for these predefined users. Attempting to do so results in an error.

- **rdsadmin** – A user that's created to handle many of the management tasks that the administrator with `superuser` privileges would perform on a standalone MySQL database. This user is used internally by RDS for MySQL for many management tasks.
- **rdsrepladmin** – A user that's used internally by Amazon RDS to support replication activities on RDS for MySQL DB instances and clusters.

Role-based privilege model

Starting with RDS for MySQL version 8.0.36, you can't modify the tables in the `mysql` database directly. In particular, you can't create database users by performing data manipulation language (DML) operations on the `grant` tables. Instead, you use MySQL account-management statements

such as CREATE USER, GRANT, and REVOKE to grant role-based privileges to users. You also can't create other kinds of objects such as stored procedures in the mysql database. You can still query the mysql tables. If you use binary log replication, changes made directly to the mysql tables on the source DB instance aren't replicated to the target cluster.

In some cases, your application might use shortcuts to create users or other objects by inserting into the mysql tables. If so, change your application code to use the corresponding statements such as CREATE USER.

To export metadata for database users during the migration from an external MySQL database, use one of the following methods:

- Use MySQL Shell's instance dump utility with a filter to exclude users, roles, and grants. The following example shows you the command syntax to use. Make sure that outputUrl is empty.

  ```
  mysqlsh user@host -- util.dumpInstance(outputUrl,{excludeSchemas:['mysql'],users:
   true})
  ```

  For more information, see Instance Dump Utility, Schema Dump Utility, and Table Dump Utility in the MySQL Reference Manual.
- Use the mysqlpump client utility. This example includes all tables except for tables in the mysql system database. It also includes CREATE USER and GRANT statements to reproduce all MySQL users in the migrated database.

  ```
  mysqlpump --exclude-databases=mysql --users
  ```

To simplify managing permissions for many users or applications, you can use the CREATE ROLE statement to create a role that has a set of permissions. Then you can use the GRANT and SET ROLE statements and the current_role function to assign roles to users or applications, switch the current role, and check which roles are in effect. For more information on the role-based permission system in MySQL 8.0, see Using Roles in the MySQL Reference Manual.

> **Important**
>
> We strongly recommend that you do not use the master user directly in your applications. Instead, adhere to the best practice of using a database user created with the minimal privileges required for your application.

Starting with version 8.0.36, RDS for MySQL includes a special role that has all of the following privileges. This role is named `rds_superuser_role`. The primary administrative user for each DB instance already has this role granted. The `rds_superuser_role` role includes the following privileges for all database objects:

- ALTER
- APPLICATION_PASSWORD_ADMIN
- ALTER ROUTINE
- CREATE
- CREATE ROLE
- CREATE ROUTINE
- CREATE TEMPORARY TABLES
- CREATE USER
- CREATE VIEW
- DELETE
- DROP
- DROP ROLE
- EVENT
- EXECUTE
- INDEX
- INSERT
- LOCK TABLES
- PROCESS
- REFERENCES
- RELOAD
- REPLICATION CLIENT
- REPLICATION SLAVE
- ROLE_ADMIN
- SET_USER_ID
- SELECT
- SHOW DATABASES

- SHOW VIEW
- TRIGGER
- UPDATE
- XA_RECOVER_ADMIN

The role definition also includes WITH GRANT OPTION so that an administrative user can grant that role to other users. In particular, the administrator must grant any privileges needed to perform binary log replication with the MySQL cluster as the target.

Tip

To see the full details of the permissions, use the following statement.

```
SHOW GRANTS FOR rds_superuser_role@'%';
```

When you grant access by using roles in RDS for MySQL version 8.0.36 and higher, you also activate the role by using the SET ROLE *role_name* or SET ROLE ALL statement. The following example shows how. Substitute the appropriate role name for CUSTOM_ROLE.

```
# Grant role to user
mysql> GRANT CUSTOM_ROLE TO 'user'@'domain-or-ip-address'

# Check the current roles for your user. In this case, the CUSTOM_ROLE role has not
 been activated.
# Only the rds_superuser_role is currently in effect.
mysql> SELECT CURRENT_ROLE();
+--------------------------+
| CURRENT_ROLE()           |
+--------------------------+
| `rds_superuser_role`@`%` |
+--------------------------+
1 row in set (0.00 sec)

# Activate all roles associated with this user using SET ROLE.
# You can activate specific roles or all roles.
# In this case, the user only has 2 roles, so we specify ALL.
mysql> SET ROLE ALL;
Query OK, 0 rows affected (0.00 sec)
```

```
# Verify role is now active
mysql> SELECT CURRENT_ROLE();
+-------------------------------------------------+

```

Dynamic privileges

Dynamic privileges are MySQL privileges that you can explicitly grant by using the GRANT statement. Depending on your version of RDS for MySQL, RDS allows you to grant only specific dynamic privileges. RDS disallows some of these privileges because they can interfere with the specific database operations, such as replication and backup.

The following table shows which of these privileges you can grant for different MySQL versions. If you are upgrading from a MySQL version lower than 8.0.36 to version 8.0.36 or higher, you might have to update your application code if granting a particular privilege is no longer allowed.

Privilege	MySQL 8.0.35 and lower	MySQL 8.0.36 and higher
APPLICATION_PASSWORD_ADMIN	Allowed	Allowed
AUDIT_ABORT_EXEMPT	Allowed	Disallowed
AUDIT_ADMIN	Disallowed	Disallowed
AUTHENTICATION_POLICY_ADMIN	Allowed	Disallowed
BACKUP_ADMIN	Allowed	Disallowed
BINLOG_ADMIN	Allowed	Disallowed
BINLOG_ENCRYPTION_ADMIN	Disallowed	Disallowed
CLONE_ADMIN	Disallowed	Disallowed

Privilege	MySQL 8.0.35 and lower	MySQL 8.0.36 and higher
CONNECTION_ADMIN	Allowed	Disallowed
ENCRYPTION_KEY_ADMIN	Disallowed	Disallowed
FIREWALL_ADMIN	Disallowed	Disallowed
FIREWALL_EXEMPT	Allowed	Disallowed
FIREWALL_USER	Disallowed	Disallowed
FLUSH_OPTIMIZER_COSTS	Allowed	Allowed
FLUSH_STATUS	Allowed	Allowed
FLUSH_TABLES	Allowed	Allowed
FLUSH_USER_RESOURCES	Allowed	Allowed
GROUP_REPLICATION_ADMIN	Disallowed	Disallowed
GROUP_REPLICATION_STREAM	Disallowed	Disallowed
INNODB_REDO_LOG_ENABLE	Disallowed	Disallowed
MASKING_DICTIONARIES_ADMIN	Disallowed	Disallowed
NDB_STORED_USER	Disallowed	Disallowed
PASSWORDLESS_USER_ADMIN	Disallowed	Disallowed
PERSIST_RO_VARIABLES_ADMIN	Disallowed	Disallowed
REPLICATION_APPLIER	Allowed	Disallowed
REPLICATION_SLAVE_ADMIN	Disallowed	Disallowed

Privilege	MySQL 8.0.35 and lower	MySQL 8.0.36 and higher
RESOURCE_GROUP_ADMIN	Allowed	Disallowed
RESOURCE_GROUP_USER	Allowed	Disallowed
REPLICATION_APPLIER	Allowed	Disallowed
ROLE_ADMIN	Allowed	Allowed
SENSITIVE_VARIABLES_OBSERVER	Allowed	Allowed
SERVICE_CONNECTION_ADMIN	Allowed	Disallowed
SESSION_VARIABLES_ADMIN	Allowed	Allowed
SET_USER_ID	Allowed	Allowed
SHOW_ROUTINE	Allowed	Allowed
SKIP_QUERY_REWRITE	Disallowed	Disallowed
SYSTEM_USER	Disallowed	Disallowed
SYSTEM_VARIABLES_ADMIN	Disallowed	Disallowed
TABLE_ENCRYPTION_ADMIN	Disallowed	Disallowed
TELEMETRY_LOG_ADMIN	Allowed	Disallowed
TP_CONNECTION_ADMIN	Disallowed	Disallowed
VERSION_TOKEN_ADMIN	Disallowed	Disallowed
XA_RECOVER_ADMIN	Allowed	Allowed

Ending a session or query

You can end user sessions or queries on DB instances by using the `rds_kill` and `rds_kill_query` commands. First connect to your MySQL DB instance, then issue the appropriate command as shown following. For more information, see Connecting to a DB instance running the MySQL database engine.

```
CALL mysql.rds_kill(thread-ID)
CALL mysql.rds_kill_query(thread-ID)
```

For example, to end the session that is running on thread 99, you would type the following:

```
CALL mysql.rds_kill(99);
```

To end the query that is running on thread 99, you would type the following:

```
CALL mysql.rds_kill_query(99);
```

Skipping the current replication error

You can skip an error on your read replica if the error is causing your read replica to stop responding and the error doesn't affect the integrity of your data.

> **Note**
>
> First verify that the error in question can be safely skipped. In a MySQL utility, connect to the read replica and run the following MySQL command.
>
> ```
> SHOW REPLICA STATUS\G
> ```
>
> For information about the values returned, see the MySQL documentation.
> Previous versions of and MySQL used `SHOW SLAVE STATUS` instead of `SHOW REPLICA STATUS`. If you are using a MySQL version before 8.0.23, then use `SHOW SLAVE STATUS`.

You can skip an error on your read replica in the following ways.

Topics

- Calling the mysql.rds_skip_repl_error procedure
- Setting the slave_skip_errors parameter

Calling the mysql.rds_skip_repl_error procedure

Amazon RDS provides a stored procedure that you can call to skip an error on your read replicas. First connect to your read replica, then issue the appropriate commands as shown following. For more information, see Connecting to a DB instance running the MySQL database engine.

To skip the error, issue the following command.

```
CALL mysql.rds_skip_repl_error;
```

This command has no effect if you run it on the source DB instance, or on a read replica that hasn't encountered a replication error.

For more information, such as the versions of MySQL that support `mysql.rds_skip_repl_error`, see mysql.rds_skip_repl_error.

> **Important**
>
> If you attempt to call `mysql.rds_skip_repl_error` and encounter the following error: `ERROR 1305 (42000): PROCEDURE mysql.rds_skip_repl_error does not exist`, then upgrade your MySQL DB instance to the latest minor version or one of the minimum minor versions listed in mysql.rds_skip_repl_error.

Setting the slave_skip_errors parameter

To skip one or more errors, you can set the `slave_skip_errors` static parameter on the read replica. You can set this parameter to skip one or more specific replication error codes. Currently, you can set this parameter only for RDS for MySQL 5.7 DB instances. After you change the setting for this parameter, make sure to reboot your DB instance for the new setting to take effect. For information about setting this parameter, see the MySQL documentation.

We recommend setting this parameter in a separate DB parameter group. You can associate this DB parameter group only with the read replicas that need to skip errors. Following this best practice reduces the potential impact on other DB instances and read replicas.

Important

Setting a nondefault value for this parameter can lead to replication inconsistency. Only set this parameter to a nondefault value if you have exhausted other options to resolve the problem and you are sure of the potential impact on your read replica's data.

Working with InnoDB tablespaces to improve crash recovery times

Every table in MySQL consists of a table definition, data, and indexes. The MySQL storage engine InnoDB stores table data and indexes in a *tablespace*. InnoDB creates a global shared tablespace that contains a data dictionary and other relevant metadata, and it can contain table data and indexes. InnoDB can also create separate tablespaces for each table and partition. These separate tablespaces are stored in files with a .ibd extension and the header of each tablespace contains a number that uniquely identifies it.

Amazon RDS provides a parameter in a MySQL parameter group called `innodb_file_per_table`. This parameters controls whether InnoDB adds new table data and indexes to the shared tablespace (by setting the parameter value to 0) or to individual tablespaces (by setting the parameter value to 1). Amazon RDS sets the default value for `innodb_file_per_table` parameter to 1, which allows you to drop individual InnoDB tables and reclaim storage used by those tables for the DB instance. In most use cases, setting the `innodb_file_per_table` parameter to 1 is the recommended setting.

You should set the `innodb_file_per_table` parameter to 0 when you have a large number of tables, such as over 1000 tables when you use standard (magnetic) or general purpose SSD storage or over 10,000 tables when you use Provisioned IOPS storage. When you set this parameter to 0, individual tablespaces are not created and this can improve the time it takes for database crash recovery.

MySQL processes each metadata file, which includes tablespaces, during the crash recovery cycle. The time it takes MySQL to process the metadata information in the shared tablespace is negligible compared to the time it takes to process thousands of tablespace files when there are multiple tablespaces. Because the tablespace number is stored within the header of each file, the aggregate time to read all the tablespace files can take up to several hours. For example, a million InnoDB tablespaces on standard storage can take from five to eight hours to process during a crash recovery cycle. In some cases, InnoDB can determine that it needs additional cleanup after a crash recovery cycle so it will begin another crash recovery cycle, which will extend the recovery time.

Keep in mind that a crash recovery cycle also entails rolling-back transactions, fixing broken pages, and other operations in addition to the processing of tablespace information.

Since the `innodb_file_per_table` parameter resides in a parameter group, you can change the parameter value by editing the parameter group used by your DB instance without having to reboot the DB instance. After the setting is changed, for example, from 1 (create individual tables) to 0 (use shared tablespace), new InnoDB tables will be added to the shared tablespace while existing tables continue to have individual tablespaces. To move an InnoDB table to the shared tablespace, you must use the `ALTER TABLE` command.

Migrating multiple tablespaces to the shared tablespace

You can move an InnoDB table's metadata from its own tablespace to the shared tablespace, which will rebuild the table metadata according to the `innodb_file_per_table` parameter setting. First connect to your MySQL DB instance, then issue the appropriate commands as shown following. For more information, see Connecting to a DB instance running the MySQL database engine.

```
ALTER TABLE table_name ENGINE = InnoDB, ALGORITHM=COPY;
```

For example, the following query returns an `ALTER TABLE` statement for every InnoDB table that is not in the shared tablespace.

For MySQL 5.7 DB instances:

```
SELECT CONCAT('ALTER TABLE `',
REPLACE(LEFT(NAME , INSTR((NAME), '/') - 1), '`', '``'), '`.`',
REPLACE(SUBSTR(NAME FROM INSTR(NAME, '/') + 1), '`', '``'), '` ENGINE=InnoDB,
 ALGORITHM=COPY;') AS Query
FROM INFORMATION_SCHEMA.INNODB_SYS_TABLES
WHERE SPACE <> 0 AND LEFT(NAME, INSTR((NAME), '/') - 1) NOT IN ('mysql','');
```

For MySQL 8.0 DB instances:

```
SELECT CONCAT('ALTER TABLE `',
REPLACE(LEFT(NAME , INSTR((NAME), '/') - 1), '`', '``'), '`.`',
REPLACE(SUBSTR(NAME FROM INSTR(NAME, '/') + 1), '`', '``'), '` ENGINE=InnoDB,
 ALGORITHM=COPY;') AS Query
FROM INFORMATION_SCHEMA.INNODB_TABLES
```

```
WHERE SPACE <> 0 AND LEFT(NAME, INSTR((NAME), '/') - 1) NOT IN ('mysql','');
```

Rebuilding a MySQL table to move the table's metadata to the shared tablespace requires additional storage space temporarily to rebuild the table, so the DB instance must have storage space available. During rebuilding, the table is locked and inaccessible to queries. For small tables or tables not frequently accessed, this might not be an issue. For large tables or tables frequently accessed in a heavily concurrent environment, you can rebuild tables on a read replica.

You can create a read replica and migrate table metadata to the shared tablespace on the read replica. While the ALTER TABLE statement blocks access on the read replica, the source DB instance is not affected. The source DB instance will continue to generate its binary logs while the read replica lags during the table rebuilding process. Because the rebuilding requires additional storage space and the replay log file can become large, you should create a read replica with storage allocated that is larger than the source DB instance.

To create a read replica and rebuild InnoDB tables to use the shared tablespace, take the following steps:

1. Make sure that backup retention is enabled on the source DB instance so that binary logging is enabled.
2. Use the AWS Management Console or AWS CLI to create a read replica for the source DB instance. Because the creation of a read replica involves many of the same processes as crash recovery, the creation process can take some time if there is a large number of InnoDB tablespaces. Allocate more storage space on the read replica than is currently used on the source DB instance.
3. When the read replica has been created, create a parameter group with the parameter settings `read_only = 0` and `innodb_file_per_table = 0`. Then associate the parameter group with the read replica.
4. Issue the following SQL statement for all tables that you want migrated on the replica:

   ```
   ALTER TABLE name ENGINE = InnoDB
   ```

5. When all of your `ALTER TABLE` statements have completed on the read replica, verify that the read replica is connected to the source DB instance and that the two instances are in sync.
6. Use the console or CLI to promote the read replica to be the instance. Make sure that the parameter group used for the new standalone DB instance has the `innodb_file_per_table` parameter set to 0. Change the name of the new standalone DB instance, and point any applications to the new standalone DB instance.

Managing the Global Status History

> **Tip**
>
> To analyze database performance, you can also use Performance Insights on Amazon RDS. For more information, see Monitoring DB load with Performance Insights on Amazon RDS.

MySQL maintains many status variables that provide information about its operation. Their value can help you detect locking or memory issues on a DB instance. The values of these status variables are cumulative since last time the DB instance was started. You can reset most status variables to 0 by using the `FLUSH STATUS` command.

To allow for monitoring of these values over time, Amazon RDS provides a set of procedures that will snapshot the values of these status variables over time and write them to a table, along with any changes since the last snapshot. This infrastructure, called Global Status History (GoSH), is installed on all MySQL DB instances starting with versions 5.5.23. GoSH is disabled by default.

To enable GoSH, you first enable the event scheduler from a DB parameter group by setting the parameter `event_scheduler` to `ON`. For MySQL DB instances running MySQL 5.7, also set the parameter `show_compatibility_56` to 1. For information about creating and modifying a DB parameter group, see Parameter groups for Amazon RDS. For information about the side effects of enabling this parameter, see show_compatibility_56 in the *MySQL 5.7 Reference Manual*.

You can then use the procedures in the following table to enable and configure GoSH. First connect to your MySQL DB instance, then issue the appropriate commands as shown following. For more information, see Connecting to a DB instance running the MySQL database engine. For each procedure, run the following command and replace *`procedure-name`*:

```
CALL procedure-name;
```

The following table lists all of the procedures that you can use for *`procedure-name`* in the previous command.

Procedure	Description
`mysql.rds_enable_gsh_collector`	Enables GoSH to take default snapshots at intervals specified by `rds_set_gsh_collector` .

Procedure	Description
`mysql.rds_set_gsh_collector`	Specifies the interval, in minutes, between snapshots. Default value is 5.
`mysql.rds_disable_gsh_collector`	Disables snapshots.
`mysql.rds_collect_global_status_history`	Takes a snapshot on demand.
`mysql.rds_enable_gsh_rotation`	Enables rotation of the contents of the `mysql.rds_global_status_history` table to `mysql.rds_global_status_history_old` at intervals specified by `rds_set_gsh_rotation`.
`mysql.rds_set_gsh_rotation`	Specifies the interval, in days, between table rotations. Default value is 7.
`mysql.rds_disable_gsh_rotation`	Disables table rotation.
`mysql.rds_rotate_global_status_history`	Rotates the contents of the `mysql.rds_global_status_history` table to `mysql.rds_global_status_history_old` on demand.

When GoSH is running, you can query the tables that it writes to. For example, to query the hit ratio of the Innodb buffer pool, you would issue the following query:

```
select a.collection_end, a.collection_start, (( a.variable_Delta-b.variable_delta)/
a.variable_delta)*100 as "HitRatio"
    from mysql.rds_global_status_history as a join mysql.rds_global_status_history as b
 on a.collection_end = b.collection_end
    where a. variable_name = 'Innodb_buffer_pool_read_requests' and b.variable_name =
 'Innodb_buffer_pool_reads'
```

Local time zone for MySQL DB instances

By default, the time zone for a MySQL DB instance is Universal Time Coordinated (UTC). You can set the time zone for your DB instance to the local time zone for your application instead.

To set the local time zone for a DB instance, set the `time_zone` parameter in the parameter group for your DB instance to one of the supported values listed later in this section. When you set the `time_zone` parameter for a parameter group, all DB instances and read replicas that are using that parameter group change to use the new local time zone. For information on setting parameters in a parameter group, see Parameter groups for Amazon RDS.

After you set the local time zone, all new connections to the database reflect the change. If you have any open connections to your database when you change the local time zone, you won't see the local time zone update until after you close the connection and open a new connection.

You can set a different local time zone for a DB instance and one or more of its read replicas. To do this, use a different parameter group for the DB instance and the replica or replicas and set the `time_zone` parameter in each parameter group to a different local time zone.

If you are replicating across AWS Regions, then the source DB instance and the read replica use different parameter groups (parameter groups are unique to an AWS Region). To use the same local time zone for each instance, you must set the `time_zone` parameter in the instance's and read replica's parameter groups.

When you restore a DB instance from a DB snapshot, the local time zone is set to UTC. You can update the time zone to your local time zone after the restore is complete. If you restore a DB instance to a point in time, then the local time zone for the restored DB instance is the time zone setting from the parameter group of the restored DB instance.

The Internet Assigned Numbers Authority (IANA) publishes new time zones at https://www.iana.org/time-zones several times a year. Every time RDS releases a new minor maintenance release of MySQL, it ships with the latest time zone data at the time of the release. When you use the latest RDS for MySQL versions, you have recent time zone data from RDS. To ensure that your DB instance has recent time zone data, we recommend upgrading to a higher DB engine version. Alternatively, you can modify the time zone tables in MariaDB DB instances manually. To do so, you can use SQL commands or run the mysql_tzinfo_to_sql tool in a SQL client. After updating the time zone data manually, reboot your DB instance so that the changes take effect. RDS doesn't modify or reset the time zone data of running DB instances. New time zone data is installed only when you perform a database engine version upgrade.

You can set your local time zone to one of the following values.

Zone	Time zone
Africa/Cairo	Asia/Riyadh
Africa/Casablanca	Asia/Seoul
Africa/Harare	Asia/Shanghai
Africa/Monrovia	Asia/Singapore
Africa/Nairobi	Asia/Taipei
Africa/Tripoli	Asia/Tehran

Known issues and limitations for Amazon RDS for MySQL

Known issues and limitations for working with Amazon RDS for MySQL are as follows.

Topics

InnoDB reserved word

`InnoDB` is a reserved word for RDS for MySQL. You can't use this name for a MySQL database.

Storage-full behavior for Amazon RDS for MySQL

When storage becomes full for a MySQL DB instance, there can be metadata inconsistencies, dictionary mismatches, and orphan tables. To prevent these issues, Amazon RDS automatically stops a DB instance that reaches the `storage-full` state.

A MySQL DB instance reaches the `storage-full` state in the following cases:

- The DB instance has less than 20,000 MiB of storage, and available storage reaches 200 MiB or less.
- The DB instance has more than 102,400 MiB of storage, and available storage reaches 1024 MiB or less.

- The DB instance has between 20,000 MiB and 102,400 MiB of storage, and has less than 1% of storage available.

After Amazon RDS stops a DB instance automatically because it reached the `storage-full` state, you can still modify it. To restart the DB instance, complete at least one of the following:

- Modify the DB instance to enable storage autoscaling.

  For more information about storage autoscaling, see Managing capacity automatically with Amazon RDS storage autoscaling.
- Modify the DB instance to increase its storage capacity.

  For more information about increasing storage capacity, see Increasing DB instance storage capacity.

After you make one of these changes, the DB instance is restarted automatically. For information about modifying a DB instance, see Modifying an Amazon RDS DB instance.

Inconsistent InnoDB buffer pool size

For MySQL 5.7, there is currently a bug in the way that the InnoDB buffer pool size is managed. MySQL 5.7 might adjust the value of the `innodb_buffer_pool_size` parameter to a large value that can result in the InnoDB buffer pool growing too large and using up too much memory. This effect can cause the MySQL database engine to stop running or can prevent it from starting. This issue is more common for DB instance classes that have less memory available.

To resolve this issue, set the value of the `innodb_buffer_pool_size` parameter to a multiple of the product of the `innodb_buffer_pool_instances` parameter value and the `innodb_buffer_pool_chunk_size` parameter value. For example, you might set the `innodb_buffer_pool_size` parameter value to a multiple of eight times the product of the `innodb_buffer_pool_instances` and `innodb_buffer_pool_chunk_size` parameter values, as shown in the following example.

```
innodb_buffer_pool_chunk_size = 536870912
innodb_buffer_pool_instances = 4
innodb_buffer_pool_size = (536870912 * 4) * 8 = 17179869184
```

For details on this MySQL 5.7 bug, see https://bugs.mysql.com/bug.php?id=79379 in the MySQL documentation.

Index merge optimization returns incorrect results

Queries that use index merge optimization might return incorrect results due to a bug in the MySQL query optimizer that was introduced in MySQL 5.5.37. When you issue a query against a table with multiple indexes, the optimizer scans ranges of rows based on the multiple indexes, but does not merge the results together correctly. For more information on the query optimizer bug, see http://bugs.mysql.com/bug.php?id=72745 and http://bugs.mysql.com/bug.php?id=68194 in the MySQL bug database.

For example, consider a query on a table with two indexes where the search arguments reference the indexed columns.

```
SELECT * FROM table1
WHERE indexed_col1 = 'value1' AND indexed_col2 = 'value2';
```

In this case, the search engine will search both indexes. However, due to the bug, the merged results are incorrect.

To resolve this issue, you can do one of the following:

- Set the `optimizer_switch` parameter to `index_merge=off` in the DB parameter group for your MySQL DB instance. For information on setting DB parameter group parameters, see Parameter groups for Amazon RDS.
- Upgrade your MySQL DB instance to MySQL version 5.7 or 8.0. For more information, see Upgrading the MySQL DB engine.
- If you cannot upgrade your instance or change the `optimizer_switch` parameter, you can work around the bug by explicitly identifying an index for the query, for example:

  ```
  SELECT * FROM table1
  USE INDEX covering_index
  WHERE indexed_col1 = 'value1' AND indexed_col2 = 'value2';
  ```

For more information, see Index merge optimization in the MySQL documentation.

MySQL parameter exceptions for Amazon RDS DB instances

Some MySQL parameters require special considerations when used with an Amazon RDS DB instance.

lower_case_table_names

Because Amazon RDS uses a case-sensitive file system, setting the value of the `lower_case_table_names` server parameter to 2 (names stored as given but compared in lowercase) is not supported. The following are the supported values for Amazon RDS for MySQL DB instances:

- 0 (names stored as given and comparisons are case-sensitive) is supported for all RDS for MySQL versions.
- 1 (names stored in lowercase and comparisons are not case-sensitive) is supported for RDS for MySQL version 5.7 and version 8.0.28 and higher 8.0 versions.

Set the `lower_case_table_names` parameter in a custom DB parameter group before creating a DB instance. Then, specify the custom DB parameter group when you create the DB instance.

When a parameter group is associated with a MySQL DB instance with a version lower than 8.0, we recommend that you avoid changing the `lower_case_table_names` parameter in the parameter group. Changing it could cause inconsistencies with point-in-time recovery backups and read replica DB instances.

When a parameter group is associated with a version 8.0 MySQL DB instance, you can't modify the `lower_case_table_names` parameter in the parameter group.

Read replicas should always use the same `lower_case_table_names` parameter value as the source DB instance.

long_query_time

You can set the `long_query_time` parameter to a floating point value so that you can log slow queries to the MySQL slow query log with microsecond resolution. You can set a value such as 0.1 seconds, which would be 100 milliseconds, to help when debugging slow transactions that take less than one second.

MySQL file size limits in Amazon RDS

For MySQL DB instances, the maximum provisioned storage limit constrains the size of a table to a maximum size of 16 TB when using InnoDB file-per-table tablespaces. This limit also constrains the system tablespace to a maximum size of 16 TB. InnoDB file-per-table tablespaces (with tables each in their own tablespace) is set by default for MySQL DB instances.

> **Note**
>
> Some existing DB instances have a lower limit. For example, MySQL DB instances created before April 2014 have a file and table size limit of 2 TB. This 2 TB file size limit also applies to DB instances or read replicas created from DB snapshots taken before April 2014, regardless of when the DB instance was created.

There are advantages and disadvantages to using InnoDB file-per-table tablespaces, depending on your application. To determine the best approach for your application, see File-per-table tablespaces in the MySQL documentation.

We don't recommend allowing tables to grow to the maximum file size. In general, a better practice is to partition data into smaller tables, which can improve performance and recovery times.

One option that you can use for breaking up a large table into smaller tables is partitioning. Partitioning distributes portions of your large table into separate files based on rules that you specify. For example, if you store transactions by date, you can create partitioning rules that distribute older transactions into separate files using partitioning. Then periodically, you can archive the historical transaction data that doesn't need to be readily available to your application. For more information, see Partitioning in the MySQL documentation.

Because there is no single system table or view that provides the size of all the tables and the InnoDB system tablespace, you must query multiple tables to determine the size of the tablespaces.

To determine the size of the InnoDB system tablespace and the data dictionary tablespace

- Use the following SQL command to determine if any of your tablespaces are too large and are candidates for partitioning.

> **Note**
>
> The data dictionary tablespace is specific to MySQL 8.0.

```
select FILE_NAME,TABLESPACE_NAME, ROUND(((TOTAL_EXTENTS*EXTENT_SIZE)
/1024/1024/1024), 2)  as "File Size (GB)" from information_schema.FILES
where tablespace_name in ('mysql','innodb_system');
```

To determine the size of InnoDB user tables outside of the InnoDB system tablespace (for MySQL 5.7 versions)

- Use the following SQL command to determine if any of your tables are too large and are candidates for partitioning.

```
SELECT SPACE,NAME,ROUND((ALLOCATED_SIZE/1024/1024/1024), 2)
as "Tablespace Size (GB)"
FROM information_schema.INNODB_SYS_TABLESPACES ORDER BY 3 DESC;
```

To determine the size of InnoDB user tables outside of the InnoDB system tablespace (for MySQL 8.0 versions)

- Use the following SQL command to determine if any of your tables are too large and are candidates for partitioning.

```
SELECT SPACE,NAME,ROUND((ALLOCATED_SIZE/1024/1024/1024), 2)
as "Tablespace Size (GB)"
FROM information_schema.INNODB_TABLESPACES ORDER BY 3 DESC;
```

To determine the size of non-InnoDB user tables

- Use the following SQL command to determine if any of your non-InnoDB user tables are too large.

```
SELECT TABLE_SCHEMA, TABLE_NAME, round(((DATA_LENGTH + INDEX_LENGTH+DATA_FREE)
/ 1024 / 1024/ 1024), 2) As "Approximate size (GB)" FROM information_schema.TABLES
```

```
WHERE TABLE_SCHEMA NOT IN ('mysql', 'information_schema', 'performance_schema')
and ENGINE<>'InnoDB';
```

To enable InnoDB file-per-table tablespaces

- Set the *innodb_file_per_table* parameter to 1 in the parameter group for the DB instance.

To disable InnoDB file-per-table tablespaces

- Set the *innodb_file_per_table* parameter to `0` in the parameter group for the DB instance.

For information on updating a parameter group, see Parameter groups for Amazon RDS.

When you have enabled or disabled InnoDB file-per-table tablespaces, you can issue an `ALTER TABLE` command to move a table from the global tablespace to its own tablespace, or from its own tablespace to the global tablespace as shown in the following example:

```
ALTER TABLE table_name TABLESPACE=innodb_file_per_table;
```

MySQL Keyring Plugin not supported

Currently, Amazon RDS for MySQL doesn't support the MySQL `keyring_aws` Amazon Web Services Keyring Plugin.

Custom ports

Amazon RDS blocks connections to custom port 33060 for the MySQL engine. Choose a different port for your MySQL engine.

MySQL stored procedure limitations

The mysql.rds_kill and mysql.rds_kill_query stored procedures can't terminate sessions or queries owned by MySQL users with usernames longer than 16 characters on the following RDS for MySQL versions:

- 8.0.32 and lower 8 versions
- 5.7.41 and lower 5.7 versions

GTID-based replication with an external source instance

Amazon RDS supports replication based on global transaction identifiers (GTIDs) from an external MySQL instance into an Amazon RDS for MySQL DB instance that requires setting GTID_PURGED during configuration. However, only RDS for MySQL 8.0.37 and higher versions support this functionality.

MySQL default authentication plugin

RDS for MySQL version 8.0.34 and higher use the `mysql_native_password` plugin. You can't change the `default_authentication_plugin` setting.

Overriding innodb_buffer_pool_size

With micro or small DB instance classes, the default value for the `innodb_buffer_pool_size` parameter might differ from the value returned by running the following command:

```
mysql> SELECT @@innodb_buffer_pool_size;
```

This difference can occur when Amazon RDS needs to override the default value as part of managing the DB instance classes. If necessary, you can override the default value and set it to a value that your DB instance class supports. To determine a valid value, add the memory usage and the total memory available on your DB instance. For more information, see Amazon RDS instance types.

If your DB instance has only 4 GB of memory, you can't set `innodb_buffer_pool_size` to 8 GB but you might be able to set it to 3 GB, depending on how much memory you allocated for other parameters.

If the value that you input is too large, Amazon RDS lowers the value to the following limits:

- Micro DB instance classes: 256 MB
- db.t4g.micro DB instance classes: 128 MB

RDS for MySQL stored procedure reference

These topics describe system stored procedures that are available for Amazon RDS instances running the MySQL DB engine. The master user must run these procedures.

Topics

Collecting and maintaining the Global Status History

Amazon RDS provides a set of procedures that take snapshots of the values of status variables over time and write them to a table, along with any changes since the last snapshot. This infrastructure is called Global Status History. For more information, see Managing the Global Status History.

The following stored procedures manage how the Global Status History is collected and maintained.

Topics

mysql.rds_collect_global_status_history

Takes a snapshot on demand for the Global Status History.

Syntax

```
CALL mysql.rds_collect_global_status_history;
```

mysql.rds_disable_gsh_collector

Turns off snapshots taken by the Global Status History.

Syntax

```
CALL mysql.rds_disable_gsh_collector;
```

mysql.rds_disable_gsh_rotation

Turns off rotation of the `mysql.global_status_history` table.

Syntax

```
CALL mysql.rds_disable_gsh_rotation;
```

mysql.rds_enable_gsh_collector

Turns on the Global Status History to take default snapshots at intervals specified by `rds_set_gsh_collector`.

Syntax

```
CALL mysql.rds_enable_gsh_collector;
```

mysql.rds_enable_gsh_rotation

Turns on rotation of the contents of the `mysql.global_status_history` table to `mysql.global_status_history_old` at intervals specified by `rds_set_gsh_rotation`.

Syntax

```
CALL mysql.rds_enable_gsh_rotation;
```

mysql.rds_rotate_global_status_history

Rotates the contents of the `mysql.global_status_history` table to `mysql.global_status_history_old` on demand.

Syntax

```
CALL mysql.rds_rotate_global_status_history;
```

mysql.rds_set_gsh_collector

Specifies the interval, in minutes, between snapshots taken by the Global Status History.

Syntax

```
CALL mysql.rds_set_gsh_collector(intervalPeriod);
```

Parameters

intervalPeriod

The interval, in minutes, between snapshots. Default value is 5.

mysql.rds_set_gsh_rotation

Specifies the interval, in days, between rotations of the `mysql.global_status_history` table.

Syntax

```
CALL mysql.rds_set_gsh_rotation(intervalPeriod);
```

Parameters

intervalPeriod

The interval, in days, between table rotations. Default value is 7.

Configuring, starting, and stopping binary log (binlog) replication

The following stored procedures control how transactions are replicated from an external database into RDS for MySQL, or from RDS for MySQL to an external database.

Topics

mysql.rds_next_master_log

Changes the source database instance log position to the start of the next binary log on the source database instance. Use this procedure only if you are receiving replication I/O error 1236 on a read replica.

Syntax

```
CALL mysql.rds_next_master_log(
curr_master_log
);
```

Parameters

curr_master_log

The index of the current master log file. For example, if the current file is named `mysql-bin-changelog.012345`, then the index is 12345. To determine the current master log file name, run the `SHOW REPLICA STATUS` command and view the `Master_Log_File` field.

> **Note**
>
> Previous versions of MySQL used `SHOW SLAVE STATUS` instead of `SHOW REPLICA STATUS`. If you are using a MySQL version before 8.0.23, then use `SHOW SLAVE STATUS`.

Usage notes

The master user must run the `mysql.rds_next_master_log` procedure.

> **Warning**
>
> Call `mysql.rds_next_master_log` only if replication fails after a failover of a Multi-AZ DB instance that is the replication source, and the `Last_IO_Errno` field of `SHOW REPLICA STATUS` reports I/O error 1236.
> Calling `mysql.rds_next_master_log` can result in data loss in the read replica if transactions in the source instance were not written to the binary log on disk before the failover event occurred.
> You can reduce the chance of this happening by setting the source instance parameters `sync_binlog` and `innodb_support_xa` to 1, although this might reduce performance. For more information, see Troubleshooting a MySQL read replica problem.

Examples

Assume replication fails on an RDS for MySQL read replica. Running `SHOW REPLICA STATUS\G` on the read replica returns the following result:

```
*************************** 1. row ***************************
             Replica_IO_State:
                  Source_Host: myhost.XXXXXXXXXXXXXX.rr-rrrr-1.rds.amazonaws.com
```

```
                  Source_User: MasterUser
                  Source_Port: 3306
                Connect_Retry: 10
              Source_Log_File: mysql-bin-changelog.012345
          Read_Source_Log_Pos: 1219393
               Relay_Log_File: relaylog.012340
                Relay_Log_Pos: 30223388
        Relay_Source_Log_File: mysql-bin-changelog.012345
           Replica_IO_Running: No
          Replica_SQL_Running: Yes
              Replicate_Do_DB:
          Replicate_Ignore_DB:
           Replicate_Do_Table:
       Replicate_Ignore_Table:
      Replicate_Wild_Do_Table:
  Replicate_Wild_Ignore_Table:
                  Last_Errno: 0
                  Last_Error:
                Skip_Counter: 0
          Exec_Source_Log_Pos: 30223232
              Relay_Log_Space: 5248928866
              Until_Condition: None
               Until_Log_File:
                Until_Log_Pos: 0
           Source_SSL_Allowed: No
           Source_SSL_CA_File:
           Source_SSL_CA_Path:
              Source_SSL_Cert:
            Source_SSL_Cipher:
               Source_SSL_Key:
        Seconds_Behind_Master: NULL
Source_SSL_Verify_Server_Cert: No
                Last_IO_Errno: 1236
                Last_IO_Error: Got fatal error 1236 from master when reading data from
 binary log: 'Client requested master to start replication from impossible position;
 the first event 'mysql-bin-changelog.013406' at 1219393, the last event read from
 '/rdsdbdata/log/binlog/mysql-bin-changelog.012345' at 4, the last byte read from '/
rdsdbdata/log/binlog/mysql-bin-changelog.012345' at 4.'
               Last_SQL_Errno: 0
               Last_SQL_Error:
  Replicate_Ignore_Server_Ids:
             Source_Server_Id: 67285976
```

The `Last_IO_Errno` field shows that the instance is receiving I/O error 1236. The `Master_Log_File` field shows that the file name is `mysql-bin-changelog.012345`, which means that the log file index is `12345`. To resolve the error, you can call `mysql.rds_next_master_log` with the following parameter:

```
CALL mysql.rds_next_master_log(12345);
```

Note

Previous versions of MySQL used `SHOW SLAVE STATUS` instead of `SHOW REPLICA STATUS`. If you are using a MySQL version before 8.0.23, then use `SHOW SLAVE STATUS`.

mysql.rds_reset_external_master

Reconfigures an RDS for MySQL DB instance to no longer be a read replica of an instance of MySQL running external to Amazon RDS.

Important

To run this procedure, `autocommit` must be enabled. To enable it, set the `autocommit` parameter to 1. For information about modifying parameters, see Modifying parameters in a DB parameter group in Amazon RDS.

Syntax

```
CALL mysql.rds_reset_external_master;
```

Usage notes

The master user must run the `mysql.rds_reset_external_master` procedure. This procedure must be run on the MySQL DB instance to be removed as a read replica of a MySQL instance running external to Amazon RDS.

Note

We recommend that you use read replicas to manage replication between two Amazon RDS DB instances when possible. When you do so, we recommend that you use only this and other replication-related stored procedures. These practices enable more complex replication topologies between Amazon RDS DB instances. We offer these stored procedures primarily to enable replication with MySQL instances running external to Amazon RDS. For information about managing replication between Amazon RDS DB instances, see Working with DB instance read replicas.

For more information about using replication to import data from an instance of MySQL running external to Amazon RDS, see Configuring binary log file position replication with an external source instance.

mysql.rds_set_external_master

Configures an RDS for MySQL DB instance to be a read replica of an instance of MySQL running external to Amazon RDS.

Important

To run this procedure, `autocommit` must be enabled. To enable it, set the `autocommit` parameter to 1. For information about modifying parameters, see Modifying parameters in a DB parameter group in Amazon RDS.

Note

You can use the mysql.rds_set_external_master_with_delay stored procedure to configure an external source database instance and delayed replication.

Syntax

```
CALL mysql.rds_set_external_master (
  host_name
```

```
  , host_port
  , replication_user_name
  , replication_user_password
  , mysql_binary_log_file_name
  , mysql_binary_log_file_location
  , ssl_encryption
);
```

Parameters

host_name

The host name or IP address of the MySQL instance running external to Amazon RDS to become the source database instance.

host_port

The port used by the MySQL instance running external to Amazon RDS to be configured as the source database instance. If your network configuration includes Secure Shell (SSH) port replication that converts the port number, specify the port number that is exposed by SSH.

replication_user_name

The ID of a user with `REPLICATION CLIENT` and `REPLICATION SLAVE` permissions on the MySQL instance running external to Amazon RDS. We recommend that you provide an account that is used solely for replication with the external instance.

replication_user_password

The password of the user ID specified in `replication_user_name`.

mysql_binary_log_file_name

The name of the binary log on the source database instance that contains the replication information.

mysql_binary_log_file_location

The location in the `mysql_binary_log_file_name` binary log at which replication starts reading the replication information.

You can determine the binlog file name and location by running `SHOW MASTER STATUS` on the source database instance.

ssl_encryption

A value that specifies whether Secure Socket Layer (SSL) encryption is used on the replication connection. 1 specifies to use SSL encryption, 0 specifies to not use encryption. The default is 0.

> **Note**
>
> The MASTER_SSL_VERIFY_SERVER_CERT option isn't supported. This option is set to 0, which means that the connection is encrypted, but the certificates aren't verified.

Usage notes

The master user must run the `mysql.rds_set_external_master` procedure. This procedure must be run on the MySQL DB instance to be configured as the read replica of a MySQL instance running external to Amazon RDS.

Before you run `mysql.rds_set_external_master`, you must configure the instance of MySQL running external to Amazon RDS to be a source database instance. To connect to the MySQL instance running external to Amazon RDS, you must specify `replication_user_name` and `replication_user_password` values that indicate a replication user that has `REPLICATION CLIENT` and `REPLICATION SLAVE` permissions on the external instance of MySQL.

To configure an external instance of MySQL as a source database instance

1. Using the MySQL client of your choice, connect to the external instance of MySQL and create a user account to be used for replication. The following is an example.

   MySQL 5.7

   ```
   CREATE USER 'repl_user'@'mydomain.com' IDENTIFIED BY 'password';
   ```

   MySQL 8.0

   ```
   CREATE USER 'repl_user'@'mydomain.com' IDENTIFIED WITH mysql_native_password BY
    'password';
   ```

> **Note**
>
> Specify a password other than the prompt shown here as a security best practice.

2. On the external instance of MySQL, grant `REPLICATION CLIENT` and `REPLICATION SLAVE` privileges to your replication user. The following example grants `REPLICATION CLIENT` and `REPLICATION SLAVE` privileges on all databases for the 'repl_user' user for your domain.

   MySQL 5.7

   ```
   GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'mydomain.com'
    IDENTIFIED BY 'password';
   ```

   MySQL 8.0

   ```
   GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'mydomain.com';
   ```

To use encrypted replication, configure source database instance to use SSL connections.

> **Note**
>
> We recommend that you use read replicas to manage replication between two Amazon RDS DB instances when possible. When you do so, we recommend that you use only this and other replication-related stored procedures. These practices enable more complex replication topologies between Amazon RDS DB instances. We offer these stored procedures primarily to enable replication with MySQL instances running external to Amazon RDS. For information about managing replication between Amazon RDS DB instances, see Working with DB instance read replicas.

After calling `mysql.rds_set_external_master` to configure an Amazon RDS DB instance as a read replica, you can call mysql.rds_start_replication on the read replica to start the replication process. You can call mysql.rds_reset_external_master to remove the read replica configuration.

When `mysql.rds_set_external_master` is called, Amazon RDS records the time, user, and an action of `set master` in the `mysql.rds_history` and `mysql.rds_replication_status` tables.

Examples

When run on a MySQL DB instance, the following example configures the DB instance to be a read replica of an instance of MySQL running external to Amazon RDS.

```
call mysql.rds_set_external_master(
  'Externaldb.some.com',
  3306,
  'repl_user',
  'password',
  'mysql-bin-changelog.0777',
  120,
  0);
```

mysql.rds_set_external_master_with_auto_position

Configures an RDS for MySQL DB instance to be a read replica of an instance of MySQL running external to Amazon RDS. This procedure also configures delayed replication and replication based on global transaction identifiers (GTIDs).

> **Important**
>
> To run this procedure, `autocommit` must be enabled. To enable it, set the `autocommit` parameter to 1. For information about modifying parameters, see Modifying parameters in a DB parameter group in Amazon RDS.

Syntax

```
CALL mysql.rds_set_external_master_with_auto_position (
  host_name
  , host_port
  , replication_user_name
  , replication_user_password
  , ssl_encryption
  , delay
);
```

Parameters

host_name

The host name or IP address of the MySQL instance running external to Amazon RDS to become the source database instance.

host_port

The port used by the MySQL instance running external to Amazon RDS to be configured as the source database instance. If your network configuration includes Secure Shell (SSH) port replication that converts the port number, specify the port number that is exposed by SSH.

replication_user_name

The ID of a user with `REPLICATION CLIENT` and `REPLICATION SLAVE` permissions on the MySQL instance running external to Amazon RDS. We recommend that you provide an account that is used solely for replication with the external instance.

replication_user_password

The password of the user ID specified in `replication_user_name`.

ssl_encryption

A value that specifies whether Secure Socket Layer (SSL) encryption is used on the replication connection. 1 specifies to use SSL encryption, 0 specifies to not use encryption. The default is 0.

> **Note**
>
> The `MASTER_SSL_VERIFY_SERVER_CERT` option isn't supported. This option is set to 0, which means that the connection is encrypted, but the certificates aren't verified.

delay

The minimum number of seconds to delay replication from source database instance.

The limit for this parameter is one day (86,400 seconds).

Usage notes

The master user must run the `mysql.rds_set_external_master_with_auto_position` procedure. This procedure must be run on the MySQL DB instance to be configured as the read replica of a MySQL instance running external to Amazon RDS.

This procedure is supported for all RDS for MySQL 5.7 versions, and RDS for MySQL 8.0.26 and higher 8.0 versions.

Before you run `mysql.rds_set_external_master_with_auto_position`, you must configure the instance of MySQL running external to Amazon RDS to be a source database instance. To connect to the MySQL instance running external to Amazon RDS, you must specify values for `replication_user_name` and `replication_user_password`. These values must indicate a replication user that has `REPLICATION CLIENT` and `REPLICATION SLAVE` permissions on the external instance of MySQL.

To configure an external instance of MySQL as a source database instance

1. Using the MySQL client of your choice, connect to the external instance of MySQL and create a user account to be used for replication. The following is an example.

   ```
   CREATE USER 'repl_user'@'mydomain.com' IDENTIFIED BY 'SomePassW0rd'
   ```

2. On the external instance of MySQL, grant `REPLICATION CLIENT` and `REPLICATION SLAVE` privileges to your replication user. The following example grants `REPLICATION CLIENT` and `REPLICATION SLAVE` privileges on all databases for the `'repl_user'` user for your domain.

   ```
   GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'mydomain.com'
   IDENTIFIED BY 'SomePassW0rd'
   ```

For more information, see Configuring binary log file position replication with an external source instance.

> **Note**
>
> We recommend that you use read replicas to manage replication between two Amazon RDS DB instances when possible. When you do so, we recommend that you use only this and other replication-related stored procedures. These practices enable more complex replication topologies between Amazon RDS DB instances. We offer these stored

procedures primarily to enable replication with MySQL instances running external to Amazon RDS. For information about managing replication between Amazon RDS DB instances, see Working with DB instance read replicas.

Before you call `mysql.rds_set_external_master_with_auto_position`, make sure to call the section called "mysql.rds_set_external_source_gtid_purged" to set the `gtid_purged` system variable with a specified GTID range from an external source.

After calling `mysql.rds_set_external_master_with_auto_position` to configure an Amazon RDS DB instance as a read replica, you can call mysql.rds_start_replication on the read replica to start the replication process. You can call mysql.rds_reset_external_master to remove the read replica configuration.

When you call `mysql.rds_set_external_master_with_auto_position`, Amazon RDS records the time, the user, and an action of `set master` in the `mysql.rds_history` and `mysql.rds_replication_status` tables.

For disaster recovery, you can use this procedure with the mysql.rds_start_replication_until or mysql.rds_start_replication_until_gtid stored procedure. To roll forward changes to a delayed read replica to the time just before a disaster, you can run the `mysql.rds_set_external_master_with_auto_position` procedure. After the `mysql.rds_start_replication_until_gtid` procedure stops replication, you can promote the read replica to be the new primary DB instance by using the instructions in Promoting a read replica to be a standalone DB instance.

To use the `mysql.rds_rds_start_replication_until_gtid` procedure, GTID-based replication must be enabled. To skip a specific GTID-based transaction that is known to cause disaster, you can use the mysql.rds_skip_transaction_with_gtid stored procedure. For more information about working with GTID-based replication, see Using GTID-based replication.

Examples

When run on a MySQL DB instance, the following example configures the DB instance to be a read replica of an instance of MySQL running external to Amazon RDS. It sets the minimum replication delay to one hour (3,600 seconds) on the MySQL DB instance. A change from the MySQL source database instance running external to Amazon RDS isn't applied on the MySQL DB instance read replica for at least one hour.

```
call mysql.rds_set_external_master_with_auto_position(
  'Externaldb.some.com',
  3306,
  'repl_user',
  'SomePassW0rd',
  0,
  3600);
```

mysql.rds_set_external_master_with_delay

Configures an RDS for MySQL DB instance to be a read replica of an instance of MySQL running external to Amazon RDS and configures delayed replication.

> **Important**
>
> To run this procedure, `autocommit` must be enabled. To enable it, set the `autocommit` parameter to 1. For information about modifying parameters, see Modifying parameters in a DB parameter group in Amazon RDS.

Syntax

```
CALL mysql.rds_set_external_master_with_delay(
  host_name
  , host_port
  , replication_user_name
  , replication_user_password
  , mysql_binary_log_file_name
  , mysql_binary_log_file_location
  , ssl_encryption
  , delay
);
```

Parameters

host_name

The host name or IP address of the MySQL instance running external to Amazon RDS that will become the source database instance.

host_port

The port used by the MySQL instance running external to Amazon RDS to be configured as the source database instance. If your network configuration includes SSH port replication that converts the port number, specify the port number that is exposed by SSH.

replication_user_name

The ID of a user with `REPLICATION CLIENT` and `REPLICATION SLAVE` permissions on the MySQL instance running external to Amazon RDS. We recommend that you provide an account that is used solely for replication with the external instance.

replication_user_password

The password of the user ID specified in `replication_user_name`.

mysql_binary_log_file_name

The name of the binary log on the source database instance contains the replication information.

mysql_binary_log_file_location

The location in the `mysql_binary_log_file_name` binary log at which replication will start reading the replication information.

You can determine the binlog file name and location by running `SHOW MASTER STATUS` on the source database instance.

ssl_encryption

A value that specifies whether Secure Socket Layer (SSL) encryption is used on the replication connection. 1 specifies to use SSL encryption, 0 specifies to not use encryption. The default is 0.

> **Note**
>
> The `MASTER_SSL_VERIFY_SERVER_CERT` option isn't supported. This option is set to 0, which means that the connection is encrypted, but the certificates aren't verified.

delay

The minimum number of seconds to delay replication from source database instance.

The limit for this parameter is one day (86400 seconds).

Usage notes

The master user must run the `mysql.rds_set_external_master_with_delay` procedure. This procedure must be run on the MySQL DB instance to be configured as the read replica of a MySQL instance running external to Amazon RDS.

Before you run `mysql.rds_set_external_master_with_delay`, you must configure the instance of MySQL running external to Amazon RDS to be a source database instance. To connect to the MySQL instance running external to Amazon RDS, you must specify values for `replication_user_name` and `replication_user_password`. These values must indicate a replication user that has `REPLICATION CLIENT` and `REPLICATION SLAVE` permissions on the external instance of MySQL.

To configure an external instance of MySQL as a source database instance

1. Using the MySQL client of your choice, connect to the external instance of MySQL and create a user account to be used for replication. The following is an example.

   ```
   CREATE USER 'repl_user'@'mydomain.com' IDENTIFIED BY 'SomePassW0rd'
   ```

2. On the external instance of MySQL, grant `REPLICATION CLIENT` and `REPLICATION SLAVE` privileges to your replication user. The following example grants `REPLICATION CLIENT` and `REPLICATION SLAVE` privileges on all databases for the `'repl_user'` user for your domain.

   ```
   GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'mydomain.com'
   IDENTIFIED BY 'SomePassW0rd'
   ```

For more information, see Configuring binary log file position replication with an external source instance.

> **Note**
>
> We recommend that you use read replicas to manage replication between two Amazon RDS DB instances when possible. When you do so, we recommend that you use only this and other replication-related stored procedures. These practices enable more complex replication topologies between Amazon RDS DB instances. We offer these stored

procedures primarily to enable replication with MySQL instances running external to Amazon RDS. For information about managing replication between Amazon RDS DB instances, see Working with DB instance read replicas.

After calling `mysql.rds_set_external_master_with_delay` to configure an Amazon RDS DB instance as a read replica, you can call mysql.rds_start_replication on the read replica to start the replication process. You can call mysql.rds_reset_external_master to remove the read replica configuration.

When you call `mysql.rds_set_external_master_with_delay`, Amazon RDS records the time, the user, and an action of `set master` in the `mysql.rds_history` and `mysql.rds_replication_status` tables.

For disaster recovery, you can use this procedure with the mysql.rds_start_replication_until or mysql.rds_start_replication_until_gtid stored procedure. To roll forward changes to a delayed read replica to the time just before a disaster, you can run the `mysql.rds_set_external_master_with_delay` procedure. After the `mysql.rds_start_replication_until` procedure stops replication, you can promote the read replica to be the new primary DB instance by using the instructions in Promoting a read replica to be a standalone DB instance.

To use the `mysql.rds_rds_start_replication_until_gtid` procedure, GTID-based replication must be enabled. To skip a specific GTID-based transaction that is known to cause disaster, you can use the mysql.rds_skip_transaction_with_gtid stored procedure. For more information about working with GTID-based replication, see Using GTID-based replication.

The `mysql.rds_set_external_master_with_delay` procedure is available in these versions of RDS for MySQL:

- MySQL 8.0.26 and higher 8.0 versions
- All 5.7 versions

Examples

When run on a MySQL DB instance, the following example configures the DB instance to be a read replica of an instance of MySQL running external to Amazon RDS. It sets the minimum replication delay to one hour (3,600 seconds) on the MySQL DB instance. A change from the MySQL source

database instance running external to Amazon RDS isn't applied on the MySQL DB instance read replica for at least one hour.

```
call mysql.rds_set_external_master_with_delay(
  'Externaldb.some.com',
  3306,
  'repl_user',
  'SomePassW0rd',
  'mysql-bin-changelog.000777',
  120,
  0,
  3600);
```

mysql.rds_set_external_source_gtid_purged

Sets the gtid_purged system variable with a specified GTID range from an external source. The `gtid_purged` value is required for configuring GTID-based replication to resume the replication using auto positioning.

> **Important**
>
> To run this procedure, `autocommit` must be enabled. To enable it, set the `autocommit` parameter to 1. For information about modifying parameters, see Modifying parameters in a DB parameter group in Amazon RDS.

Syntax

```
CALL mysql.rds_set_external_source_gtid_purged(
  server_uuid
  , start_pos
  , end_pos
);
```

Parameters

server_uuid

The universally unique identifier (UUID) of the external server from which the GTID range is being imported.

start_pos

The starting position of the GTID range to be set.

end_pos

The ending position of the GTID range to be set.

Usage notes

The mysql.rds_set_external_source_gtid_purged procedure is only available with MySQL 8.0.37 and higher 8.0 versions.

Call mysql.rds_set_external_source_gtid_purged before you call the section called "mysql.rds_set_external_master_with_auto_position" or the section called "mysql.rds_set_external_source_with_auto_position_for_channel".

Before you call mysql.rds_set_external_source_gtid_purged, make sure to stop all active replication channels for the database. To check the status of a channel, use the SHOW REPLICA STATUS MySQL statement. To stop replication on a channel, call the section called "mysql.rds_stop_replication_for_channel".

The GTID range that you specify must be a superset of the existing GTID_PURGED value. This stored procedure checks the following values before it sets the GTID_PURGED value:

- The server_uuid is valid.
- The value of start_pos is greater than 0 and less than the value of end_pos.
- The value of end_pos is greater than or equal to the value of start_pos.

If the GTID set on your external server contains multiple ranges of values, consider calling the procedure multiple times with different GTID set values.

When you call mysql.rds_set_external_source_gtid_purged, Amazon RDS records the time, the user, and an action of set gtid_purged in the mysql.rds_history table.

If you don't set the gtid_purged value appropriately for the backup that you use for replication, this can result in missing or duplicated transactions during the replication process. Perform the following steps to set the correct gtid_purged value.

To set the gtid_purged value on the replica

1. Determine the point in time or the specific backup file to use as the starting point for replication. This could be a logical backup (a mysqldump file) or a physical backup (an Amazon RDS snapshot).
2. Determine the `gtid_executed` value. This value represents the set of all GTIDs that were committed on the server. To retrieve this value, on the source instance, do one of the following:
   - Run the SQL statement `SELECT @@GLOBAL.GTID_EXECUTED;` at the time the backup was taken.
   - If any related options are included in the respective backup utility, extract the value from the backup file. For more information, see the set-gtid-purged option in the MySQL documentation.
3. Determine the `gtid_purged` value to use for the call to `mysql.rds_set_external_source_gtid_purged`. The `gtid_purged` value should include all the GTIDs that were executed on the source instance and are no longer needed for replication. Therefore, the `gtid_purged` value should be a subset of the `gtid_executed` value that you retrieved in the previous step.

   To determine the `gtid_purged` value, identify the GTIDs that aren't included in the backup and are no longer needed for replication. You can do so by analyzing the binary logs or by using a tool such as mysqlbinlog to find the GTIDs that were purged from the binary logs.

   Alternatively, if you have a consistent backup that includes all of the binary logs up to the backup point, you can set the `gtid_purged` value to be the same as the `gtid_executed` value at the backup point.
4. After you determine the appropriate `gtid_purged` value that's consistent with your backup, call the `mysql.rds_set_external_source_gtid_purged` stored procedure on your RDS for MySQL DB instance to set the value.

Examples

When run on a MySQL DB instance, the following example sets the GTID range from an external MySQL server with the UUID `12345678-abcd-1234-efgh-123456789abc`, a starting position of 1, and an ending position of `100`. The resulting GTID value is set to `+12345678-abcd-1234-efgh-123456789abc:1-100`.

```
CALL mysql.rds_set_external_source_gtid_purged('12345678-abcd-1234-efgh-123456789abc',
 1, 100);
```

mysql.rds_set_master_auto_position

Sets the replication mode to be based on either binary log file positions or on global transaction identifiers (GTIDs).

Syntax

```
CALL mysql.rds_set_master_auto_position (
auto_position_mode
);
```

Parameters

auto_position_mode

A value that indicates whether to use log file position replication or GTID-based replication:

- `0` – Use the replication method based on binary log file position. The default is `0`.
- 1 – Use the GTID-based replication method.

Usage notes

The master user must run the `mysql.rds_set_master_auto_position` procedure.

This procedure is supported for all RDS for MySQL 5.7 versions, and RDS for MySQL 8.0.26 and higher 8.0 versions.

mysql.rds_set_source_delay

Sets the minimum number of seconds to delay replication from source database instance to the current read replica. Use this procedure when you are connected to a read replica to delay replication from its source database instance.

Syntax

```
CALL mysql.rds_set_source_delay(
```

```
    delay
);
```

Parameters

delay

The minimum number of seconds to delay replication from the source database instance.

The limit for this parameter is one day (86400 seconds).

Usage notes

The master user must run the `mysql.rds_set_source_delay` procedure.

For disaster recovery, you can use this procedure with the mysql.rds_start_replication_until stored procedure or the mysql.rds_start_replication_until_gtid stored procedure. To roll forward changes to a delayed read replica to the time just before a disaster, you can run the `mysql.rds_set_source_delay` procedure. After the `mysql.rds_start_replication_until` or `mysql.rds_start_replication_until_gtid` procedure stops replication, you can promote the read replica to be the new primary DB instance by using the instructions in Promoting a read replica to be a standalone DB instance.

To use the `mysql.rds_rds_start_replication_until_gtid` procedure, GTID-based replication must be enabled. To skip a specific GTID-based transaction that is known to cause disaster, you can use the mysql.rds_skip_transaction_with_gtid stored procedure. For more information on GTID-based replication, see Using GTID-based replication.

The `mysql.rds_set_source_delay` procedure is available in these versions of RDS for MySQL:

- MySQL 8.0.26 and higher 8.0 versions
- All 5.7 versions

Examples

To delay replication from source database instance to the current read replica for at least one hour (3,600 seconds), you can call `mysql.rds_set_source_delay` with the following parameter:

```
CALL mysql.rds_set_source_delay(3600);
```

mysql.rds_skip_repl_error

Skips and deletes a replication error on a MySQL DB read replica.

Syntax

```
CALL mysql.rds_skip_repl_error;
```

Usage notes

The master user must run the `mysql.rds_skip_repl_error` procedure on a read replica. For more information about this procedure, see Calling the mysql.rds_skip_repl_error procedure.

To determine if there are errors, run the MySQL `SHOW REPLICA STATUS\G` command. If a replication error isn't critical, you can run `mysql.rds_skip_repl_error` to skip the error. If there are multiple errors, `mysql.rds_skip_repl_error` deletes the first error, then warns that others are present. You can then use `SHOW REPLICA STATUS\G` to determine the correct course of action for the next error. For information about the values returned, see SHOW REPLICA STATUS statement in the MySQL documentation.

> **Note**
>
> Previous versions of MySQL used `SHOW SLAVE STATUS` instead of `SHOW REPLICA STATUS`. If you are using a MySQL version before 8.0.23, then use `SHOW SLAVE STATUS`.

For more information about addressing replication errors with Amazon RDS, see Troubleshooting a MySQL read replica problem.

Replication stopped error

When you call the `mysql.rds_skip_repl_error` procedure, you might receive an error message stating that the replica is down or disabled.

This error message appears if you run the procedure on the primary instance instead of the read replica. You must run this procedure on the read replica for the procedure to work.

This error message might also appear if you run the procedure on the read replica, but replication can't be restarted successfully.

If you need to skip a large number of errors, the replication lag can increase beyond the default retention period for binary log (binlog) files. In this case, you might encounter a fatal error due to binlog files being purged before they have been replayed on the read replica. This purge causes replication to stop, and you can no longer call the `mysql.rds_skip_repl_error` command to skip replication errors.

You can mitigate this issue by increasing the number of hours that binlog files are retained on your source database instance. After you have increased the binlog retention time, you can restart replication and call the `mysql.rds_skip_repl_error` command as needed.

To set the binlog retention time, use the mysql.rds_set_configuration procedure and specify a configuration parameter of `'binlog retention hours'` along with the number of hours to retain binlog files on the DB cluster. The following example sets the retention period for binlog files to 48 hours.

```
CALL mysql.rds_set_configuration('binlog retention hours', 48);
```

mysql.rds_start_replication

Initiates replication from an RDS for MySQL DB instance.

> **Note**
>
> You can use the mysql.rds_start_replication_until or mysql.rds_start_replication_until_gtid stored procedure to initiate replication from an RDS for MySQL DB instance and stop replication at the specified binary log file location.

Syntax

```
CALL mysql.rds_start_replication;
```

Usage notes

The master user must run the `mysql.rds_start_replication` procedure.

To import data from an instance of MySQL external to Amazon RDS, call `mysql.rds_start_replication` on the read replica to start the replication process after

you call `mysql.rds_set_external_master` to build the replication configuration. For more information, see Restoring a backup into a MySQL DB instance.

To export data to an instance of MySQL external to Amazon RDS, call `mysql.rds_start_replication` and `mysql.rds_stop_replication` on the read replica to control some replication actions, such as purging binary logs. For more information, see Exporting data from a MySQL DB instance by using replication.

You can also call `mysql.rds_start_replication` on the read replica to restart any replication process that you previously stopped by calling `mysql.rds_stop_replication`. For more information, see Working with DB instance read replicas.

mysql.rds_start_replication_until

Initiates replication from an RDS for MySQL DB instance and stops replication at the specified binary log file location.

Syntax

```
CALL mysql.rds_start_replication_until (
replication_log_file
  , replication_stop_point
);
```

Parameters

replication_log_file

The name of the binary log on the source database instance that contains the replication information.

replication_stop_point

The location in the `replication_log_file` binary log at which replication will stop.

Usage notes

The master user must run the `mysql.rds_start_replication_until` procedure.

The `mysql.rds_start_replication_until` procedure is available in these versions of RDS for MySQL:

- MySQL 8.0.26 and higher 8.0 versions
- All 5.7 versions

You can use this procedure with delayed replication for disaster recovery. If you have delayed replication configured, you can use this procedure to roll forward changes to a delayed read replica to the time just before a disaster. After this procedure stops replication, you can promote the read replica to be the new primary DB instance by using the instructions in Promoting a read replica to be a standalone DB instance.

You can configure delayed replication using the following stored procedures:

- mysql.rds_set_configuration
- mysql.rds_set_external_master_with_delay
- mysql.rds_set_source_delay

The file name specified for the `replication_log_file` parameter must match the source database instance binlog file name.

When the `replication_stop_point` parameter specifies a stop location that is in the past, replication is stopped immediately.

Examples

The following example initiates replication and replicates changes until it reaches location `120` in the `mysql-bin-changelog.000777` binary log file.

```
call mysql.rds_start_replication_until(
  'mysql-bin-changelog.000777',
  120);
```

mysql.rds_stop_replication

Stops replication from a MySQL DB instance.

Syntax

```
CALL mysql.rds_stop_replication;
```

Usage notes

The master user must run the `mysql.rds_stop_replication` procedure.

If you are configuring replication to import data from an instance of MySQL running external to Amazon RDS, you call `mysql.rds_stop_replication` on the read replica to stop the replication process after the import has completed. For more information, see Restoring a backup into a MySQL DB instance.

If you are configuring replication to export data to an instance of MySQL external to Amazon RDS, you call `mysql.rds_start_replication` and `mysql.rds_stop_replication` on the read replica to control some replication actions, such as purging binary logs. For more information, see Exporting data from a MySQL DB instance by using replication.

You can also use `mysql.rds_stop_replication` to stop replication between two Amazon RDS DB instances. You typically stop replication to perform a long running operation on the read replica, such as creating a large index on the read replica. You can restart any replication process that you stopped by calling mysql.rds_start_replication on the read replica. For more information, see Working with DB instance read replicas.

Ending a session or query

The following stored procedures end a session or query.

Topics

mysql.rds_kill

Ends a connection to the MySQL server.

Syntax

```
CALL mysql.rds_kill(processID);
```

Parameters

processID

The identity of the connection thread to be ended.

Usage notes

Each connection to the MySQL server runs in a separate thread. To end a connection, use the `mysql.rds_kill` procedure and pass in the thread ID of that connection. To obtain the thread ID, use the MySQL SHOW PROCESSLIST command.

For information about limitations, see MySQL stored procedure limitations.

Examples

The following example ends a connection with a thread ID of 4243:

```
CALL mysql.rds_kill(4243);
```

mysql.rds_kill_query

Ends a query running against the MySQL server.

Syntax

```
CALL mysql.rds_kill_query(processID);
```

Parameters

processID

The identity of the process or thread that is running the query to be ended.

Usage notes

To stop a query running against the MySQL server, use the `mysql_rds_kill_query` procedure and pass in the connection ID of the thread that is running the query. The procedure then terminates the connection.

To obtain the ID, query the MySQL INFORMATION_SCHEMA PROCESSLIST table or use the MySQL SHOW PROCESSLIST command. The value in the ID column from `SHOW PROCESSLIST` or `SELECT * FROM INFORMATION_SCHEMA.PROCESSLIST` is the *processID*.

For information about limitations, see MySQL stored procedure limitations.

Examples

The following example stops a query with a query thread ID of 230040:

```
CALL mysql.rds_kill_query(230040);
```

Managing active-active clusters

The following stored procedures set up and manage RDS for MySQL active-active clusters. For more information, see the section called "Configuring active-active clusters".

These stored procedures are only available with RDS for MySQL DB instances running version 8.0.35 and higher minor versions.

Topics

- mysql.rds_group_replication_advance_gtid
- mysql.rds_group_replication_create_user
- mysql.rds_group_replication_set_recovery_channel
- mysql.rds_group_replication_start
- mysql.rds_group_replication_stop

mysql.rds_group_replication_advance_gtid

Creates placeholder GTIDs on the current DB instance.

Syntax

```
CALL mysql.rds_group_replication_advance_gtid(
begin_id
, end_id
, server_uuid
);
```

Parameters

begin_id

The start transaction ID to be created.

end_id

The end transaction ID to be created.

begin_id

The `group_replication_group_name` for the transaction to be created. The `group_replication_group_name` is specified as a UUID in the DB parameter group associated with the DB instance.

Usage notes

In an active-active cluster, for a DB instance to join a group, all GTID transactions executed on the new DB instance must exist on the other members in the cluster. In unusual cases, a new DB instance might have more transactions when transactions are executed before joining the instance to group. In this case, you can't remove any existing transactions, but you can use this procedure to create the corresponding placeholder GTIDs on the othe DB instances in the group. Before doing so, verify that the transactions *don't affect the replicated data*.

When you call this procedure, GTID transactions of `server_uuid:begin_id-end_id` are created with empty content. To avoid replication issues, don't use this procedure under any other conditions.

> **Important**
>
> Avoid calling this procedure when the active-active cluster is functioning normally. Don't call this procedure unless you understand the possible consequences of the transactions you are creating. Calling this procedure might result in inconsistent data.

Example

The following example creates placeholder GTIDs on current DB instance.:

```
CALL mysql.rds_group_replication_advance_gtid(5, 6,
 '11111111-2222-3333-4444-555555555555');
```

mysql.rds_group_replication_create_user

Creates the replication user `rdsgrprepladmin` for group replication on the DB instance.

Syntax

```
CALL mysql.rds_group_replication_create_user(
```

```
replication_user_password
);
```

Parameters

replication_user_password

The password of the replication user `rdsgrprepladmin`.

Usage notes

- The password of the replication user `rdsgrprepladmin` must be the same on all of the DB instances in an active-active cluster.
- The `rdsgrprepladmin` user name is reserved for group replication connections. No other user, including the master user, can have this user name.

Example

The following example creates the replication user `rdsgrprepladmin` for group replication on the DB instance:

```
CALL mysql.rds_group_replication_create_user('password');
```

mysql.rds_group_replication_set_recovery_channel

Sets the `group_replication_recovery` channel for an active-active cluster. The procedure uses the reserved `rdsgrprepladmin` user to configure the channel.

Syntax

```
CALL mysql.rds_group_replication_set_recovery_channel(
replication_user_password);
```

Parameters

replication_user_password

The password of the replication user `rdsgrprepladmin`.

Usage notes

The password of the replication user `rdsgrprepladmin` must be the same on all of the DB instances in an active-active cluster. A call to the `mysql.rds_group_replication_create_user` specifies the password.

Example

The following example sets the `group_replication_recovery` channel for an active-active cluster:

```
CALL mysql.rds_group_replication_set_recovery_channel('password');
```

mysql.rds_group_replication_start

Starts group replication on the current DB instance.

Syntax

```
CALL mysql.rds_group_replication_start(
bootstrap
);
```

Parameters

`bootstrap`

A value that specifies whether to initialize a new group or join an existing group. `1` initializes a new group with the current DB instance. `0` joins the current DB instance to an existing group by connecting to the endpoints defined in `group_replication_group_seeds` parameter in the of DB parameter group associated with the DB instance.

Example

The following example initializes a new group with the current DB instance:

```
CALL mysql.rds_group_replication_start(1);
```

mysql.rds_group_replication_stop

Stops group replication on the current DB instance.

Syntax

```
CALL mysql.rds_group_replication_stop();
```

Usage notes

When you stop replication on a DB instance, it doesn't affect any other DB instance in the active-active cluster.

Managing multi-source replication

The following stored procedures set up and manage replication channels on a RDS for MySQL multi-source replica. For more information, see the section called "Configuring multi-source replication".

These stored procedures are only available with RDS for MySQL DB instances running the following engine versions:

- 8.0.35 and higher minor versions
- 5.7.44 and higher minor versions

> **Note**
>
> Although this documentation refers to source DB instances as RDS for MySQL DB instances, these procedures also work for MySQL instances running external to Amazon RDS.

Topics

- mysql.rds_next_source_log_for_channel
- mysql.rds_reset_external_source_for_channel
- mysql.rds_set_external_source_for_channel
- mysql.rds_set_external_source_with_auto_position_for_channel
- mysql.rds_set_external_source_with_delay_for_channel
- mysql.rds_set_source_auto_position_for_channel
- mysql.rds_set_source_delay_for_channel
- mysql.rds_skip_repl_error_for_channel
- mysql.rds_start_replication_for_channel
- mysql.rds_start_replication_until_for_channel
- mysql.rds_start_replication_until_gtid_for_channel
- mysql.rds_stop_replication_for_channel

mysql.rds_next_source_log_for_channel

Changes the source DB instance log position to the start of the next binary log on the source DB instance for the channel. Use this procedure only if you are receiving replication I/O error 1236 on a multi-source replica.

Syntax

```
CALL mysql.rds_next_source_log_for_channel(
curr_master_log,
channel_name
);
```

Parameters

curr_master_log

The index of the current source log file. For example, if the current file is named `mysql-bin-changelog.012345`, then the index is 12345. To determine the current source log file name, run the `SHOW REPLICA STATUS FOR CHANNEL '`*channel_name*`'` command and view the `Source_Log_File` field.

> **Note**
>
> Previous versions of MySQL used `SHOW SLAVE STATUS` instead of `SHOW REPLICA STATUS`. If you are using a MySQL version before 8.0.23, then use `SHOW SLAVE STATUS`.

channel_name

The name of the replication channel on the multi-source replica. Each replication channel receives the binary log events from a single source RDS for MySQL DB instance running on a specific host and port.

Usage notes

The master user must run the `mysql.rds_next_source_log_for_channel` procedure. If there is an IO_Thread error, for example, you can use this procedure to skip all the events in the current

binary log file and resume the replication from the next binary log file for the channel specified in `channel_name`.

Example

Assume replication fails on a channel on a multi-source replica. Running `SHOW REPLICA STATUS FOR CHANNEL 'channel_1'\G` on the multi-source replica returns the following result:

```
mysql> SHOW REPLICA STATUS FOR CHANNEL 'channel_1'\G
*************************** 1. row ***************************
             Replica_IO_State: Waiting for source to send event
                  Source_Host: myhost.XXXXXXXXXXXXXX.rr-rrrr-1.rds.amazonaws.com
                  Source_User: ReplicationUser
                  Source_Port: 3306
                Connect_Retry: 60
              Source_Log_File: mysql-bin-changelog.012345
          Read_Source_Log_Pos: 1219393
               Relay_Log_File: replica-relay-bin.000003
                Relay_Log_Pos: 30223388
        Relay_Source_Log_File: mysql-bin-changelog.012345
           Replica_IO_Running: No
          Replica_SQL_Running: Yes
              Replicate_Do_DB:.
              .
              .
                Last_IO_Errno: 1236
                Last_IO_Error: Got fatal error 1236 from master when reading data from
 binary log: 'Client requested master to start replication from impossible position;
 the first event 'mysql-bin-changelog.013406' at 1219393, the last event read from
 '/rdsdbdata/log/binlog/mysql-bin-changelog.012345' at 4, the last byte read from '/
rdsdbdata/log/binlog/mysql-bin-changelog.012345' at 4.'
               Last_SQL_Errno: 0
               Last_SQL_Error:
               .
               .
                 Channel_name: channel_1
              .
              .
 -- Some fields are omitted in this example output
```

The `Last_IO_Errno` field shows that the instance is receiving I/O error 1236. The `Source_Log_File` field shows that the file name is `mysql-bin-changelog.012345`,

which means that the log file index is 12345. To resolve the error, you can call `mysql.rds_next_source_log_for_channel` with the following parameters:

```
CALL mysql.rds_next_source_log_for_channel(12345,'channel_1');
```

> **Note**
>
> Previous versions of MySQL used `SHOW SLAVE STATUS` instead of `SHOW REPLICA STATUS`. If you are using a MySQL version before 8.0.23, then use `SHOW SLAVE STATUS`.

mysql.rds_reset_external_source_for_channel

Stops the replication process on the specified channel, and removes the channel and associated configurations from the multi-source replica.

> **Important**
>
> To run this procedure, `autocommit` must be enabled. To enable it, set the `autocommit` parameter to 1. For information about modifying parameters, see Modifying parameters in a DB parameter group in Amazon RDS.

Syntax

```
CALL mysql.rds_reset_external_source_for_channel (channel_name);
```

Parameters

channel_name

The name of the replication channel on the multi-source replica. Each replication channel receives the binary log events from a single source RDS for MySQL DB instance running on a specific host and port.

Usage notes

The master user must run the `mysql.rds_reset_external_source_for_channel` procedure. This procedure deletes all relay logs that belong to the channel being removed.

mysql.rds_set_external_source_for_channel

Configures a replication channel on an RDS for MySQL DB instance to replicate the data from another RDS for MySQL DB instance.

> **Important**
>
> To run this procedure, `autocommit` must be enabled. To enable it, set the `autocommit` parameter to 1. For information about modifying parameters, see Modifying parameters in a DB parameter group in Amazon RDS.

> **Note**
>
> You can use the the section called "mysql.rds_set_external_source_with_delay_for_channel" stored procedure instead to configure this channel with delayed replication.

Syntax

```
CALL mysql.rds_set_external_source_for_channel (
  host_name
  , host_port
  , replication_user_name
  , replication_user_password
  , mysql_binary_log_file_name
  , mysql_binary_log_file_location
  , ssl_encryption
  , channel_name
);
```

Parameters

host_name

The host name or IP address of the RDS for MySQL source DB instance.

host_port

The port used by the RDS for MySQL source DB instance. If your network configuration includes Secure Shell (SSH) port replication that converts the port number, specify the port number that is exposed by SSH.

replication_user_name

The ID of a user with `REPLICATION CLIENT` and `REPLICATION SLAVE` permissions on the RDS for MySQL source DB instance. We recommend that you provide an account that is used solely for replication with the source DB instance.

replication_user_password

The password of the user ID specified in `replication_user_name`.

mysql_binary_log_file_name

The name of the binary log on the source DB instance that contains the replication information.

mysql_binary_log_file_location

The location in the `mysql_binary_log_file_name` binary log at which replication starts reading the replication information.

You can determine the binlog file name and location by running `SHOW MASTER STATUS` on the source DB instance.

ssl_encryption

A value that specifies whether Secure Socket Layer (SSL) encryption is used on the replication connection. 1 specifies to use SSL encryption, 0 specifies to not use encryption. The default is 0.

> **Note**
>
> The `MASTER_SSL_VERIFY_SERVER_CERT` option isn't supported. This option is set to 0, which means that the connection is encrypted, but the certificates aren't verified.

channel_name

The name of the replication channel. Each replication channel receives the binary log events from a single source RDS for MySQL DB instance running on a specific host and port.

Usage notes

The master user must run the `mysql.rds_set_external_source_for_channel` procedure. This procedure must be run on the target RDS for MySQL DB instance on which you're creating the replication channel.

Before you run `mysql.rds_set_external_source_for_channel`, configure a replication user on the source DB instance with the privileges required for the multi-source replica. To connect the multi-source replica to the source DB instance, you must specify `replication_user_name` and `replication_user_password` values of a replication user that has `REPLICATION CLIENT` and `REPLICATION SLAVE` permissions on the source DB instance.

To configure a replication user on the source DB instance

1. Using the MySQL client of your choice, connect to the source DB instance and create a user account to be used for replication. The following is an example.

   Important

   As a security best practice, specify a password other than the placeholder value shown in the following examples.

   MySQL 8.0

   ```
   CREATE USER 'repl_user'@'example.com' IDENTIFIED WITH mysql_native_password BY
    'password';
   ```

   MySQL 5.7

   ```
   CREATE USER 'repl_user'@'example.com' IDENTIFIED BY 'password';
   ```

2. On the source DB instance, grant `REPLICATION CLIENT` and `REPLICATION SLAVE` privileges to your replication user. The following example grants `REPLICATION CLIENT` and `REPLICATION SLAVE` privileges on all databases for the 'repl_user' user for your domain.

```
GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'example.com';
```

To use encrypted replication, configure the source DB instance to use SSL connections.

After calling `mysql.rds_set_external_source_for_channel` to configure this replication channel, you can call mysql.rds_start_replication_for_channel on the replica to start the replication process on the channel. You can call the section called "mysql.rds_reset_external_source_for_channel" to stop replication on the channel and remove the channel configuration from the replica.

When you call `mysql.rds_set_external_source_for_channel`, Amazon RDS records the time, user, and an action of `set channel source` in the `mysql.rds_history` table without channel-specific details, and in the `mysql.rds_replication_status` table, with the channel name. This information is recorded only for internal usage and monitoring purposes. To record the complete procedure call for auditing purpose, consider enabling audit logs or general logs, based on the specific requirements of your application.

Examples

When run on a RDS for MySQL DB instance, the following example configures a replication channel named `channel_1` on this DB instance to replicate data from the source specified by host `sourcedb.example.com` and port `3306`.

```
call mysql.rds_set_external_source_for_channel(
  'sourcedb.example.com',
  3306,
  'repl_user',
  'password',
  'mysql-bin-changelog.0777',
  120,
  0,
  'channel_1');
```

mysql.rds_set_external_source_with_auto_position_for_channel

Configures a replication channel on an RDS for MySQL DB instance with an optional replication delay. The replication is based on global transaction identifiers (GTIDs).

> **Important**
>
> To run this procedure, `autocommit` must be enabled. To enable it, set the `autocommit` parameter to 1. For information about modifying parameters, see Modifying parameters in a DB parameter group in Amazon RDS.

Syntax

```
CALL mysql.rds_set_external_source_with_auto_position_for_channel (
  host_name
  , host_port
  , replication_user_name
  , replication_user_password
  , ssl_encryption
  , delay
  , channel_name
);
```

Parameters

host_name

The host name or IP address of the RDS for MySQL source DB instance.

host_port

The port used by the RDS for MySQL source DB instance. If your network configuration includes Secure Shell (SSH) port replication that converts the port number, specify the port number that is exposed by SSH.

replication_user_name

The ID of a user with `REPLICATION CLIENT` and `REPLICATION SLAVE` permissions on the RDS for MySQL source DB instance. We recommend that you provide an account that is used solely for replication with the source DB instance.

replication_user_password

The password of the user ID specified in `replication_user_name`.

ssl_encryption

A value that specifies whether Secure Socket Layer (SSL) encryption is used on the replication connection. 1 specifies to use SSL encryption, 0 specifies to not use encryption. The default is 0.

> **Note**
>
> The `MASTER_SSL_VERIFY_SERVER_CERT` option isn't supported. This option is set to 0, which means that the connection is encrypted, but the certificates aren't verified.

delay

The minimum number of seconds to delay replication from source DB instance.

The limit for this parameter is one day (86,400 seconds).

channel_name

The name of the replication channel. Each replication channel receives the binary log events from a single source RDS for MySQL DB instance running on a specific host and port.

Usage notes

The master user must run the `mysql.rds_set_external_source_with_auto_position_for_channel` procedure. This procedure must be run on the target RDS for MySQL DB instance on which you're creating the replication channel.

Before you run `rds_set_external_source_with_auto_position_for_channel`, configure a replication user on the source DB instance with the privileges required for the multi-source replica. To connect the multi-source replica to the source DB instance, you must specify `replication_user_name` and `replication_user_password` values of a replication user that has `REPLICATION CLIENT` and `REPLICATION SLAVE` permissions on the source DB instance.

To configure a replication user on the source DB instance

1. Using the MySQL client of your choice, connect to the source DB instance and create a user account to be used for replication. The following is an example.

   > **Important**
   >
   > As a security best practice, specify a password other than the placeholder value shown in the following examples.

   MySQL 8.0

   ```
   CREATE USER 'repl_user'@'example.com' IDENTIFIED WITH mysql_native_password BY
    'password';
   ```

   MySQL 5.7

   ```
   CREATE USER 'repl_user'@'example.com' IDENTIFIED BY 'password';
   ```

2. On the source DB instance, grant `REPLICATION CLIENT` and `REPLICATION SLAVE` privileges to your replication user. The following example grants `REPLICATION CLIENT` and `REPLICATION SLAVE` privileges on all databases for the 'repl_user' user for your domain.

   ```
   GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'example.com';
   ```

To use encrypted replication, configure the source DB instance to use SSL connections.

Before you call `mysql.rds_set_external_source_with_auto_position_for_channel`, make sure to call the section called "mysql.rds_set_external_source_gtid_purged" to set the `gtid_purged` system variable with a specified GTID range from an external source.

After calling `mysql.rds_set_external_source_with_auto_position_for_channel` to configure an Amazon RDS DB instance as a read replica on a specific channel, you can call the section called "mysql.rds_start_replication_for_channel" on the read replica to start the replication process on that channel.

After calling `mysql.rds_set_external_source_with_auto_position_for_channel` to configure this replication channel, you can call mysql.rds_start_replication_for_channel on the replica to start the replication process on the channel. You can call the section called "mysql.rds_reset_external_source_for_channel" to stop replication on the channel and remove the channel configuration from the replica.

Examples

When run on a RDS for MySQL DB instance, the following example configures a replication channel named `channel_1` on this DB instance to replicate data from the source specified by host `sourcedb.example.com` and port `3306` It sets the minimum replication delay to one hour (3,600 seconds). This means that a change from the source RDS for MySQL DB instance isn't applied on the multi-source replica for at least one hour.

```
call mysql.rds_set_external_source_with_auto_position_for_channel(
  'sourcedb.example.com',
  3306,
  'repl_user',
  'password',
  0,
  3600,
  'channel_1');
```

mysql.rds_set_external_source_with_delay_for_channel

Configures a replication channel on an RDS for MySQL DB instance with a specified replication delay.

> **Important**
>
> To run this procedure, `autocommit` must be enabled. To enable it, set the `autocommit` parameter to 1. For information about modifying parameters, see Modifying parameters in a DB parameter group in Amazon RDS.

Syntax

```
CALL mysql.rds_set_external_source_with_delay_for_channel (
  host_name
  , host_port
```

```
  , replication_user_name
  , replication_user_password
  , mysql_binary_log_file_name
  , mysql_binary_log_file_location
  , ssl_encryption
  , delay
  , channel_name
);
```

Parameters

host_name

The host name or IP address of the RDS for MySQL source DB instance.

host_port

The port used by the RDS for MySQL source DB instance. If your network configuration includes Secure Shell (SSH) port replication that converts the port number, specify the port number that is exposed by SSH.

replication_user_name

The ID of a user with `REPLICATION CLIENT` and `REPLICATION SLAVE` permissions on the RDS for MySQL source DB instance. We recommend that you provide an account that is used solely for replication with the source DB instance.

replication_user_password

The password of the user ID specified in `replication_user_name`.

mysql_binary_log_file_name

The name of the binary log on the source DB instance contains the replication information.

mysql_binary_log_file_location

The location in the `mysql_binary_log_file_name` binary log at which replication will start reading the replication information.

You can determine the binlog file name and location by running `SHOW MASTER STATUS` on the source database instance.

ssl_encryption

A value that specifies whether Secure Socket Layer (SSL) encryption is used on the replication connection. 1 specifies to use SSL encryption, 0 specifies to not use encryption. The default is 0.

> **Note**
>
> The MASTER_SSL_VERIFY_SERVER_CERT option isn't supported. This option is set to 0, which means that the connection is encrypted, but the certificates aren't verified.

delay

The minimum number of seconds to delay replication from source DB instance.

The limit for this parameter is one day (86400 seconds).

channel_name

The name of the replication channel. Each replication channel receives the binary log events from a single source RDS for MySQL DB instance running on a specific host and port.

Usage notes

The master user must run the mysql.rds_set_external_source_with_delay_for_channel procedure. This procedure must be run on the target RDS for MySQL DB instance on which you're creating the replication channel.

Before you run mysql.rds_set_external_source_with_delay_for_channel, configure a replication user on the source DB instance with the privileges required for the multi-source replica. To connect the multi-source replica to the source DB instance, you must specify replication_user_name and replication_user_password values of a replication user that has REPLICATION CLIENT and REPLICATION SLAVE permissions on the source DB instance.

To configure a replication user on the source DB instance

1. Using the MySQL client of your choice, connect to the source DB instance and create a user account to be used for replication. The following is an example.

   > **Important**
   >
   > As a security best practice, specify a password other than the placeholder value shown in the following examples.

MySQL 8.0

```
CREATE USER 'repl_user'@'example.com' IDENTIFIED WITH mysql_native_password BY
 'password';
```

MySQL 5.7

```
CREATE USER 'repl_user'@'example.com' IDENTIFIED BY 'password';
```

2. On the source DB instance, grant `REPLICATION CLIENT` and `REPLICATION SLAVE` privileges to your replication user. The following example grants `REPLICATION CLIENT` and `REPLICATION SLAVE` privileges on all databases for the 'repl_user' user for your domain.

```
GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'example.com';
```

To use encrypted replication, configure the source DB instance to use SSL connections.

After calling `mysql.rds_set_external_source_with_delay_for_channel` to configure this replication channel, you can call mysql.rds_start_replication_for_channel on the replica to start the replication process on the channel. You can call the section called "mysql.rds_reset_external_source_for_channel" to stop replication on the channel and remove the channel configuration from the replica.

When you call `mysql.rds_set_external_source_with_delay_for_channel`, Amazon RDS records the time, user, and an action of `set channel source` in the `mysql.rds_history` table without channel-specific details, and in the `mysql.rds_replication_status` table, with the channel name. This information is recorded only for internal usage and monitoring purposes. To record the complete procedure call for auditing purpose, consider enabling audit logs or general logs, based on the specific requirements of your application.

Examples

When run on a RDS for MySQL DB instance, the following example configures a replication channel named `channel_1` on this DB instance to replicate data from the source specified by host `sourcedb.example.com` and port `3306` It sets the minimum replication delay to one hour (3,600 seconds). This means that a change from the source RDS for MySQL DB instance isn't applied on the multi-source replica for at least one hour.

```
call mysql.rds_set_external_source_with_delay_for_channel(
  'sourcedb.example.com',
  3306,
  'repl_user',
  'password',
  'mysql-bin-changelog.000777',
  120,
  0,
  3600,
  'channel_1');
```

mysql.rds_set_source_auto_position_for_channel

Sets the replication mode for the specified channel to be based on either binary log file positions or on global transaction identifiers (GTIDs).

Syntax

```
CALL mysql.rds_set_source_auto_position_for_channel (
auto_position_mode
 , channel_name
);
```

Parameters

auto_position_mode

A value that indicates whether to use log file position replication or GTID-based replication:

- 0 – Use the replication method based on binary log file position. The default is 0.
- 1 – Use the GTID-based replication method.

channel_name

The name of the replication channel on the multi-source replica. Each replication channel receives the binary log events from a single source RDS for MySQL DB instance running on a specific host and port.

Usage notes

The master user must run the `mysql.rds_set_source_auto_position_for_channel` procedure. This procedure restarts replication on the specified channel to apply the specified auto position mode.

Examples

The following example sets the auto position mode for channel_1 to use the GTID-based replication method.

```
call mysql.rds_set_source_auto_position_for_channel(1,'channel_1');
```

mysql.rds_set_source_delay_for_channel

Sets the minimum number of seconds to delay replication from the source database instance to the multi-source replica for the specified channel.

Syntax

```
CALL mysql.rds_set_source_delay_for_channel(delay, channel_name);
```

Parameters

delay

The minimum number of seconds to delay replication from the source DB instance.

The limit for this parameter is one day (86400 seconds).

channel_name

The name of the replication channel on the multi-source replica. Each replication channel receives the binary log events from a single source RDS for MySQL DB instance running on a specific host and port.

Usage notes

The master user must run the `mysql.rds_set_source_delay_for_channel` procedure. To use this procedure, first call `mysql.rds_stop_replication_for_channel` to stop the replication. Then, call this procedure to set the replication delay value. When the delay is set, call `mysql.rds_start_replication_for_channel` to restart the replication.

Examples

The following example sets the delay for replication from the source database instance on `channel_1` of the multi-source replica for at least one hour (3,600 seconds).

```
CALL mysql.rds_set_source_delay_for_channel(3600,'channel_1');
```

mysql.rds_skip_repl_error_for_channel

Skips a binary log event and deletes a replication error on a MySQL DB multi-source replica for the specified channel.

Syntax

```
CALL mysql.rds_skip_repl_error_for_channel(channel_name);
```

Parameters

channel_name

The name of the replication channel on the multi-source replica. Each replication channel receives the binary log events from a single source RDS for MySQL DB instance running on a specific host and port.

Usage notes

The master user must run the `mysql.rds_skip_repl_error_for_channel` procedure on a read replica. You can use this procedure in a similar way `mysql.rds_skip_repl_error` is used to skip an error on a read replica. For more information, see Calling the mysql.rds_skip_repl_error procedure.

> **Note**
>
> To skip errors in GTID-based replication, we recommend that you use the procedure the section called “mysql.rds_skip_transaction_with_gtid” instead.

To determine if there are errors, run the MySQL `SHOW REPLICA STATUS FOR CHANNEL '`*channel_name*`'\G` command. If a replication error isn't critical, you can run

`mysql.rds_skip_repl_error_for_channel` to skip the error. If there are multiple errors, `mysql.rds_skip_repl_error_for_channel` deletes the first error on the specified replication channel, then warns that others are present. You can then use `SHOW REPLICA STATUS FOR CHANNEL 'channel_name'\G` to determine the correct course of action for the next error. For information about the values returned, see SHOW REPLICA STATUS statement in the MySQL documentation.

mysql.rds_start_replication_for_channel

Initiates replication from an RDS for MySQL DB instance to a multi-source replica on the specified channel.

> **Note**
>
> You can use the mysql.rds_start_replication_until_for_channel or mysql.rds_start_replication_until_gtid_for_channel stored procedure to initiate replication from an RDS for MySQL DB instance and stop replication at the specified binary log file location.

Syntax

```
CALL mysql.rds_start_replication_for_channel(channel_name);
```

Parameters

channel_name

The name of the replication channel on the multi-source replica. Each replication channel receives the binary log events from a single source RDS for MySQL DB instance running on a specific host and port.

Usage notes

The master user must run the `mysql.rds_start_replication_for_channel` procedure. After you import the data from the source RDS for MySQL DB instance, run this command on the multi-source replica to start replication on the specified channel.

Examples

The following example starts replication on `channel_1` of the multi-source replica.

```
CALL mysql.rds_start_replication_for_channel('channel_1');
```

mysql.rds_start_replication_until_for_channel

Initiates replication from an RDS for MySQL DB instance on the specified channel and stops replication at the specified binary log file location.

Syntax

```
CALL mysql.rds_start_replication_until_for_channel (
replication_log_file
  , replication_stop_point
  , channel_name
);
```

Parameters

replication_log_file

The name of the binary log on the source DB instance contains the replication information.

replication_stop_point

The location in the `replication_log_file` binary log at which replication will stop.

channel_name

The name of the replication channel on the multi-source replica. Each replication channel receives the binary log events from a single source RDS for MySQL DB instance running on a specific host and port.

Usage notes

The master user must run the `mysql.rds_start_replication_until_for_channel` procedure. With this procedure, replication starts and then stops when the specified binlog file

position is reached. For version 8.0, the procedure stops only the SQL_Thread. For version 5.7, the procedure stops both the SQL_Thread and the IO_Thread.

The file name specified for the replication_log_file parameter must match the source DB instance binlog file name.

When the replication_stop_point parameter specifies a stop location that's in the past, replication is stopped immediately.

Examples

The following example initiates replication on channel_1, and replicates changes until it reaches location 120 in the mysql-bin-changelog.000777 binary log file.

```
call mysql.rds_start_replication_until_for_channel(
  'mysql-bin-changelog.000777',
  120,
  'channel_1'
  );
```

mysql.rds_start_replication_until_gtid_for_channel

Initiates replication on the specified channel from an RDS for MySQL DB instance and stops replication at the specified global transaction identifier (GTID).

Syntax

```
CALL mysql.rds_start_replication_until_gtid_for_channel(gtid,channel_name);
```

Parameters

gtid

The GTID after which to stop replication.

channel_name

The name of the replication channel on the multi-source replica. Each replication channel receives the binary log events from a single source RDS for MySQL DB instance running on a specific host and port.

Usage notes

The master user must run the `mysql.rds_start_replication_until_gtid_for_channel` procedure. The procedure starts replication on the specified channel and applies all changes up to the specified GTID value. Then, it stops replication on the channel.

When the `gtid` parameter specifies a transaction that has already been run by the replica, replication is stopped immediately.

Before you run this procedure, you must disable multi-threaded replication by setting the value of `replica_parallel_workers` or `slave_parallel_workers` to `0`.

Examples

The following example initiates replication on `channel_1`, and replicates changes until it reaches GTID `3E11FA47-71CA-11E1-9E33-C80AA9429562:23`.

```
call mysql.rds_start_replication_until_gtid_for_channel('3E11FA47-71CA-11E1-9E33-
C80AA9429562:23','channel_1');
```

mysql.rds_stop_replication_for_channel

Stops replication from a MySQL DB instance on the specified channel.

Syntax

```
CALL mysql.rds_stop_replication_for_channel(channel_name);
```

Parameters

channel_name

The name of the replication channel on the multi-source replica. Each replication channel receives the binary log events from a single source RDS for MySQL DB instance running on a specific host and port.

Usage notes

The master user must run the `mysql.rds_stop_replication_for_channel` procedure.

Examples

The following example stops replication on `channel_1` of the multi-source replica.

```
CALL mysql.rds_stop_replication_for_channel('channel_1');
```

Replicating transactions using GTIDs

The following stored procedures control how transactions are replicated using global transaction identifiers (GTIDs) with RDS for MySQL. For more information about replication based on GTIDs with RDS for MySQL, see Using GTID-based replication.

Topics

mysql.rds_skip_transaction_with_gtid

Skips replication of a transaction with the specified global transaction identifier (GTID) on a MySQL DB instance.

You can use this procedure for disaster recovery when a specific GTID transaction is known to cause a problem. Use this stored procedure to skip the problematic transaction. Examples of problematic transactions include transactions that disable replication, delete important data, or cause the DB instance to become unavailable.

Syntax

```
CALL mysql.rds_skip_transaction_with_gtid (
gtid_to_skip
);
```

Parameters

gtid_to_skip

The GTID of the replication transaction to skip.

Usage notes

The master user must run the `mysql.rds_skip_transaction_with_gtid` procedure.

This procedure is supported for all RDS for MySQL 5.7 versions, and RDS for MySQL 8.0.26 and higher 8.0 versions.

Examples

The following example skips replication of the transaction with the GTID `3E11FA47-71CA-11E1-9E33-C80AA9429562:23`.

```
CALL mysql.rds_skip_transaction_with_gtid('3E11FA47-71CA-11E1-9E33-C80AA9429562:23');
```

mysql.rds_start_replication_until_gtid

Initiates replication from an RDS for MySQL DB instance and stops replication immediately after the specified global transaction identifier (GTID).

Syntax

```
CALL mysql.rds_start_replication_until_gtid(gtid);
```

Parameters

gtid

The GTID after which replication is to stop.

Usage notes

The master user must run the `mysql.rds_start_replication_until_gtid` procedure.

This procedure is supported for all RDS for MySQL 5.7 versions, and RDS for MySQL 8.0.26 and higher 8.0 versions.

You can use this procedure with delayed replication for disaster recovery. If you have delayed replication configured, you can use this procedure to roll forward changes to a delayed read replica to the time just before a disaster. After this procedure stops replication, you can promote the read replica to be the new primary DB instance by using the instructions in Promoting a read replica to be a standalone DB instance.

You can configure delayed replication using the following stored procedures:

- mysql.rds_set_configuration
- mysql.rds_set_external_master_with_delay

- mysql.rds_set_source_delay

When the `gtid` parameter specifies a transaction that has already been run by the replica, replication is stopped immediately.

Examples

The following example initiates replication and replicates changes until it reaches GTID `3E11FA47-71CA-11E1-9E33-C80AA9429562:23`.

```
call mysql.rds_start_replication_until_gtid('3E11FA47-71CA-11E1-9E33-C80AA9429562:23');
```

Rotating the query logs

The following stored procedures rotate MySQL logs to backup tables. For more information, see MySQL database log files.

Topics

mysql.rds_rotate_general_log

Rotates the `mysql.general_log` table to a backup table.

Syntax

```
CALL mysql.rds_rotate_general_log;
```

Usage notes

You can rotate the `mysql.general_log` table to a backup table by calling the `mysql.rds_rotate_general_log` procedure. When log tables are rotated, the current log table is copied to a backup log table and the entries in the current log table are removed. If a backup log table already exists, then it is deleted before the current log table is copied to the backup. You can query the backup log table if needed. The backup log table for the `mysql.general_log` table is named `mysql.general_log_backup`.

You can run this procedure only when the `log_output` parameter is set to `TABLE`.

mysql.rds_rotate_slow_log

Rotates the `mysql.slow_log` table to a backup table.

Syntax

```
CALL mysql.rds_rotate_slow_log;
```

Usage notes

You can rotate the `mysql.slow_log` table to a backup table by calling the `mysql.rds_rotate_slow_log` procedure. When log tables are rotated, the current log table is copied to a backup log table and the entries in the current log table are removed. If a backup log table already exists, then it is deleted before the current log table is copied to the backup.

You can query the backup log table if needed. The backup log table for the `mysql.slow_log` table is named `mysql.slow_log_backup`.

Setting and showing binary log configuration

The following stored procedures set and show configuration parameters, such as for binary log file retention.

Topics

mysql.rds_set_configuration

Specifies the number of hours to retain binary logs or the number of seconds to delay replication.

Syntax

```
CALL mysql.rds_set_configuration(name,value);
```

Parameters

name

The name of the configuration parameter to set.

value

The value of the configuration parameter.

Usage notes

The `mysql.rds_set_configuration` procedure supports the following configuration parameters:

- binlog retention hours
- source delay
- target delay

The configuration parameters are stored permanently and survive any DB instance reboot or failover.

binlog retention hours

The `binlog retention hours` parameter is used to specify the number of hours to retain binary log files. Amazon RDS normally purges a binary log as soon as possible, but the binary log might still be required for replication with a MySQL database external to RDS.

The default value of `binlog retention hours` is `NULL`. For RDS for MySQL, `NULL` means binary logs aren't retained (0 hours).

To specify the number of hours to retain binary logs on a DB instance, use the `mysql.rds_set_configuration` stored procedure and specify a period with enough time for replication to occur, as shown in the following example.

```
call mysql.rds_set_configuration('binlog retention hours', 24);
```

> **Note**
>
> You can't use the value `0` for `binlog retention hours`.

For MySQL DB instances, the maximum `binlog retention hours` value is 168 (7 days).

After you set the retention period, monitor storage usage for the DB instance to make sure that the retained binary logs don't take up too much storage.

For Multi-AZ DB cluster deployments, you can only configure binary log retention from the writer DB instance, and the setting is propagated to all reader DB instances asynchronously. If binary logs on the DB cluster exceed half of the total local storage space, Amazon RDS automatically moves stale logs to the EBS volume. However, the newest logs remain in local storage, so they're subject to be lost if there's a failure that requires a host replacement, or if you scale the database up or down.

source delay

Use the `source delay` parameter in a read replica to specify the number of seconds to delay replication from the read replica to its source DB instance. Amazon RDS normally replicates changes as soon as possible, but you might want some environments to delay replication. For example, when replication is delayed, you can roll forward a delayed read replica to the time just before a disaster. If a table is dropped accidentally, you can use delayed replication to quickly recover it. The default value of `target delay` is `0` (don't delay replication).

When you use this parameter, it runs mysql.rds_set_source_delay and applies CHANGE primary TO MASTER_DELAY = input value. If successful, the procedure saves the `source delay` parameter to the `mysql.rds_configuration` table.

To specify the number of seconds for Amazon RDS to delay replication to a source DB instance, use the `mysql.rds_set_configuration` stored procedure and specify the number of seconds to delay replication. In the following example, the replication is delayed by at least one hour (3,600 seconds).

```
call mysql.rds_set_configuration('source delay', 3600);
```

The procedure then runs `mysql.rds_set_source_delay(3600)`.

The limit for the `source delay` parameter is one day (86400 seconds).

> **Note**
>
> The `source delay` parameter isn't supported for RDS for MySQL version 8.0 or MariaDB versions below 10.2.

target delay

Use the `target delay` parameter to specify the number of seconds to delay replication between a DB instance and any future RDS-managed read replicas created from this instance. This parameter is ignored for non-RDS-managed read replicas. Amazon RDS normally replicates changes as soon as possible, but you might want some environments to delay replication. For example, when replication is delayed, you can roll forward a delayed read replica to the time just before a disaster. If a table is dropped accidentally, you can use delayed replication to recover it quickly. The default value of `target delay` is `0` (don't delay replication).

For disaster recovery, you can use this configuration parameter with the mysql.rds_start_replication_until stored procedure or the mysql.rds_start_replication_until_gtid stored procedure. To roll forward changes to a delayed read replica to the time just before a disaster, you can run the `mysql.rds_set_configuration` procedure with this parameter set. After the `mysql.rds_start_replication_until` or `mysql.rds_start_replication_until_gtid` procedure stops replication, you can promote the read replica to be the new primary DB instance by using the instructions in Promoting a read replica to be a standalone DB instance.

To use the `mysql.rds_rds_start_replication_until_gtid` procedure, GTID-based replication must be enabled. To skip a specific GTID-based transaction that is known to cause disaster, you can use the mysql.rds_skip_transaction_with_gtid stored procedure. For more information about working with GTID-based replication, see Using GTID-based replication.

To specify the number of seconds for Amazon RDS to delay replication to a read replica, use the `mysql.rds_set_configuration` stored procedure and specify the number of seconds to delay replication. The following example specifies that replication is delayed by at least one hour (3,600 seconds).

```
call mysql.rds_set_configuration('target delay', 3600);
```

The limit for the `target delay` parameter is one day (86400 seconds).

> **Note**
>
> The `target delay` parameter isn't supported for RDS for MySQL version 8.0 or MariaDB versions earlier than 10.2.

mysql.rds_show_configuration

The number of hours that binary logs are retained.

Syntax

```
CALL mysql.rds_show_configuration;
```

Usage notes

To verify the number of hours that Amazon RDS retains binary logs, use the `mysql.rds_show_configuration` stored procedure.

Examples

The following example displays the retention period:

```
call mysql.rds_show_configuration;
               name                          value     description
```

```
                binlog retention hours       24        binlog retention hours specifies
the duration in hours before binary logs are automatically deleted.
```

Warming the InnoDB cache

The following stored procedures save, load, or cancel loading the InnoDB buffer pool on RDS for MySQL DB instances. For more information, see InnoDB cache warming for MySQL on Amazon RDS.

Topics

mysql.rds_innodb_buffer_pool_dump_now

Dumps the current state of the buffer pool to disk.

Syntax

```
CALL mysql.rds_innodb_buffer_pool_dump_now();
```

Usage notes

The master user must run the `mysql.rds_innodb_buffer_pool_dump_now` procedure.

mysql.rds_innodb_buffer_pool_load_abort

Cancels a load of the saved buffer pool state while in progress.

Syntax

```
CALL mysql.rds_innodb_buffer_pool_load_abort();
```

Usage notes

The master user must run the `mysql.rds_innodb_buffer_pool_load_abort` procedure.

mysql.rds_innodb_buffer_pool_load_now

Loads the saved state of the buffer pool from disk.

Syntax

```
CALL mysql.rds_innodb_buffer_pool_load_now();
```

Usage notes

The master user must run the `mysql.rds_innodb_buffer_pool_load_now` procedure.

Amazon RDS for Oracle

Amazon RDS supports DB instances that run the following versions and editions of Oracle Database:

- Oracle Database 21c (21.0.0.0)
- Oracle Database 19c (19.0.0.0)

> **Note**
>
> Oracle Database 11g, Oracle Database 12c, and Oracle Database 18c are legacy versions that are no longer supported in Amazon RDS.

Before creating a DB instance, complete the steps in the Setting up your Amazon RDS environment section of this guide. When you create a DB instance using your master account, the account gets DBA privileges, with some limitations. Use this account for administrative tasks such as creating additional database accounts. You can't use SYS, SYSTEM, or other Oracle-supplied administrative accounts.

You can create the following:

- DB instances
- DB snapshots
- Point-in-time restores
- Automated backups
- Manual backups

You can use DB instances running Oracle inside a VPC. You can also add features to your Oracle DB instance by enabling various options. Amazon RDS supports Multi-AZ deployments for Oracle as a high-availability, failover solution.

> **Important**
>
> To deliver a managed service experience, Amazon RDS doesn't provide shell access to DB instances. It also restricts access to certain system procedures and tables that need

advanced privileges. You can access your database using standard SQL clients such as Oracle SQL*Plus. However, you can't access the host directly by using Telnet or Secure Shell (SSH).

Topics

Overview of Oracle on Amazon RDS

You can read the following sections to get an overview of RDS for Oracle.

Topics

- RDS for Oracle limitations

RDS for Oracle features

Amazon RDS for Oracle supports most of the features and capabilities of Oracle Database. Some features might have limited support or restricted privileges. Some features are only available in Enterprise Edition, and some require additional licenses. For more information about Oracle Database features for specific Oracle Database versions, see the *Oracle Database Licensing Information User Manual* for the version you're using.

You can filter new Amazon RDS features on the What's New with Database? page. For **Products**, choose **Amazon RDS**. Then search using keywords such as **`Oracle 2022`**.

> **Note**
>
> The following lists are not exhaustive.

Topics

- New features in RDS for Oracle
- Supported features in RDS for Oracle
- Unsupported features in RDS for Oracle

New features in RDS for Oracle

To see new features in RDS for Oracle, use the following techniques:

- Search Document history for the keyword **`Oracle`**.
- Filter new Amazon RDS features on the What's New with Database? page. For **Products**, choose **Amazon RDS**. Then search for **`Oracle`** ***`YYYY`***, where *YYYY* is a year such as **`2024`**.

Supported features in RDS for Oracle

Amazon RDS for Oracle supports the following Oracle Database features:

- Advanced Compression
- Application Express (APEX)

For more information, see Oracle Application Express (APEX).

- Automatic Memory Management
- Automatic Undo Management
- Automatic Workload Repository (AWR)

  For more information, see Generating performance reports with Automatic Workload Repository (AWR).
- Active Data Guard with Maximum Performance in the same AWS Region or across AWS Regions

  For more information, see Working with read replicas for Amazon RDS for Oracle.
- Blockchain tables (Oracle Database 21c and higher)

  For more information, see Managing Blockchain Tables in the Oracle Database documentation.
- Continuous Query Notification

  For more information, see Using Continuous Query Notification (CQN) in the Oracle documentation.
- Data Redaction
- Continuous Query Notification

  For more information, see Database Change Notification in the Oracle documentation.
- Database In-Memory
- Distributed Queries and Transactions
- Edition-Based Redefinition

  For more information, see Setting the default edition for a DB instance.
- EM Express (12c and higher)

  For more information, see Oracle Enterprise Manager.
- Fine-Grained Auditing
- Flashback Table, Flashback Query, Flashback Transaction Query
- Gradual password rollover for applications (Oracle Database 21c and higher)

  For more information, see Managing Gradual Database Password Rollover for Applications in the Oracle Database documentation.

- HugePages

  For more information, see Turning on HugePages for an RDS for Oracle instance.
- Import/export (legacy and Data Pump) and SQL*Loader

  For more information, see Importing data into Oracle on Amazon RDS.
- Java Virtual Machine (JVM)

  For more information, see Oracle Java virtual machine.
- JavaScript (Oracle Database 21c and higher)

  For more information, see DBMS_MLE in the Oracle Database documentation.
- Label Security

  For more information, see Oracle Label Security.
- Locator

  For more information, see Oracle Locator.
- Materialized Views
- Multitenant

  The Oracle multitenant architecture is supported for all Oracle Database 19c and higher releases. For more information, see Working with CDBs in RDS for Oracle.
- Network encryption

  For more information, see Oracle native network encryption and Oracle Secure Sockets Layer.
- Partitioning
- Real Application Testing

  To use the full capture and replay capabilities, you must use Amazon Elastic File System (Amazon EFS) to access files generated by Oracle Real Application Testing. For more information, see Amazon EFS integration and the blog post Use Oracle Real Application Testing features with Amazon RDS for Oracle.
- Sharding at the application level (but not the Oracle Sharding feature)
- Spatial and Graph

  For more information, see Oracle Spatial.

- Star Query Optimization
- Streams and Advanced Queuing
- Summary Management – Materialized View Query Rewrite
- Text (File and URL data store types are not supported)
- Total Recall
- Transparent Data Encryption (TDE)

  For more information, see Oracle Transparent Data Encryption.
- Unified Auditing, Mixed Mode

  For more information, see Mixed mode auditing in the Oracle documentation.
- XML DB (without the XML DB Protocol Server)

  For more information, see Oracle XML DB.
- Virtual Private Database

Unsupported features in RDS for Oracle

Amazon RDS for Oracle doesn't support the following Oracle Database features:

- Automatic Storage Management (ASM)
- Database Vault
- Flashback Database

> **Note**
>
> For alternative solutions, see the AWS Database Blog entry Alternatives to the Oracle flashback database feature in Amazon RDS for Oracle.

- FTP and SFTP
- Hybrid partitioned tables
- Messaging Gateway
- Oracle Enterprise Manager Cloud Control Management Repository
- Real Application Clusters (Oracle RAC)

- Real Application Security (RAS)
- Unified Auditing, Pure Mode
- Workspace Manager (WMSYS) schema

> **Note**
>
> The preceding list is not exhaustive.

> **Warning**
>
> In general, Amazon RDS doesn't prevent you from creating schemas for unsupported features. However, if you create schemas for Oracle features and components that require SYSDBA privileges, you can damage the data dictionary and affect the availability of your DB instance. Use only supported features and schemas that are available in Adding options to Oracle DB instances.

RDS for Oracle releases

RDS for Oracle for Oracle supports multiple Oracle Database releases.

> **Note**
>
> For information about upgrading your releases, see Upgrading the RDS for Oracle DB engine.

Topics

Oracle Database 21c with Amazon RDS

Amazon RDS supports Oracle Database 21c, which includes Oracle Enterprise Edition and Oracle Standard Edition 2. Oracle Database 21c (21.0.0.0) includes many new features and updates from

the previous version. A key change is that Oracle Database 21c supports only the multitenant architecture: you can no longer create a database as a traditional non-CDB. To learn more about the differences between CDBs and non-CDBs, see Limitations of RDS for Oracle CDBs.

In this section, you can find the features and changes important to using Oracle Database 21c (21.0.0.0) on Amazon RDS. For a complete list of the changes, see the Oracle database 21c documentation. For a complete list of features supported by each Oracle Database 21c edition, see Permitted features, options, and management packs by Oracle database offering in the Oracle documentation.

Amazon RDS parameter changes for Oracle Database 21c (21.0.0.0)

Oracle Database 21c (21.0.0.0) includes several new parameters and parameters with new ranges and new default values.

Topics

- New parameters
- Changes for the compatible parameter
- Removed parameters

New parameters

The following table shows the new Amazon RDS parameters for Oracle Database 21c (21.0.0.0).

Name	Range of values	Default value	Modifiable	Description
blockchain_table_max_no_drop	NONE | 0	NONE	Y	Lets you control the maximum amount of idle time that can be specified when creating a blockchain table.
dbnest_enable	NONE | CDB_RESOURCE_PDB_ALL	NONE	N	Allows you to enable or disable dbNest. DbNest provides operating system resource isolation and management, file system

Name	Range of values	Default value	Modifiable	Description
				isolation, and secure computing for PDBs.
dbnest_pdb_fs_conf	NONE | *pathname*	NONE	N	Specifies the dbNest file system configuration file for a PDB.
diagnostics_control	ERROR | WARNING | IGNORE	IGNORE	Y	Allows you to control and monitor the users who perform potentially unsafe database diagnostic operations.
drcp_dedicated_opt	YES | NO	YES	Y	Enables or disables the use of dedicated optimization with Database Resident Connection Pooling (DRCP).
enable_per_pdb_drcp	true | false	true	N	Controls whether Database Resident Connection Pooling (DRCP) configures one connection pool for the entire CDB or one isolated connection pool for each PDB.
inmemory_deep_vectorization	true | false	true	Y	Enables or disables the deep vectorization framework.
mandatory_user_profile	*profile_name*	N/A	N	Specifies the mandatory user profile for a CDB or PDB.
optimizer_capture_sql_quarantine	true | false	false	Y	Enables or disables the deep vectorization framework.

Name	Range of values	Default value	Modifiable	Description
optimizer_use_sql_quarantine	true | false	false	Y	Enables or disables the automatic creation of SQL Quarantine configurations.
result_cache_execution_threshold	0 to 68719476736	2	Y	Specifies the maximum number of times a PL/SQL function can be executed before its result is stored in the result cache.
result_cache_max_temp_result	0 to 100	5	Y	Specifies the percentage of RESULT_CACHE_MAX_TEMP_SIZE that any single cached query result can consume.
result_cache_max_temp_size	0 to 2199023255552	RESULT_CACHE_SIZE * 10	Y	Specifies the maximum amount of temporary tablespace (in bytes) that can be consumed by the result cache.
sga_min_size	0 to 2199023255552 (maximum value is 50% of sga_target)	0	Y	Indicates a possible minimum value for SGA usage of a pluggable database (PDB).

Name	Range of values	Default value	Modifiable	Description
tablespace_encryption_default_algorithm	GOST256 | SEED128 | ARIA256 | ARIA192 | ARIA128 | 3DES168 | AES256 | AES192 | AES128	AES128	Y	Specifies the default algorithm the database uses when encrypting a tablespace.

Changes for the compatible parameter

The `compatible` parameter has a new maximum value for Oracle Database 21c (21.0.0.0) on Amazon RDS. The following table shows the new default value.

Parameter name	Oracle Database 21c (21.0.0.0) maximum value
compatible	21.0.0

Removed parameters

The following parameters were removed in Oracle Database 21c (21.0.0.0):

- `remote_os_authent`
- `sec_case_sensitive_logon`
- `unified_audit_sga_queue_size`

Oracle Database 19c with Amazon RDS

Amazon RDS supports Oracle Database 19c, which includes Oracle Enterprise Edition and Oracle Standard Edition Two.

Oracle Database 19c (19.0.0.0) includes many new features and updates from the previous version. In this section, you can find the features and changes important to using Oracle Database 19c (19.0.0.0) on Amazon RDS. For a complete list of the changes, see the Oracle database 19c documentation. For a complete list of features supported by each Oracle Database 19c edition, see Permitted features, options, and management packs by Oracle database offering in the Oracle documentation.

Amazon RDS parameter changes for Oracle Database 19c (19.0.0.0)

Oracle Database 19c (19.0.0.0) includes several new parameters and parameters with new ranges and new default values.

Topics

- New parameters
- Changes to the compatible parameter
- Removed parameters

New parameters

The following table shows the new Amazon RDS parameters for Oracle Database 19c (19.0.0.0).

Name	Values	Modifiable	Description
lob_signature_enable	TRUE, FALSE (default)	Y	Enables or disables the LOB locator signature feature.
max_datapump_parallel_per_job	1 to 1024, or AUTO	Y	Specifies the maximum number of parallel processes allowed for each Oracle Data Pump job.

Changes to the compatible parameter

The `compatible` parameter has a new maximum value for Oracle Database 19c (19.0.0.0) on Amazon RDS. The following table shows the new default value.

Parameter name	Oracle Database 19c (19.0.0.0) maximum value
compatible	19.0.0

Removed parameters

The following parameters were removed in Oracle Database 19c (19.0.0.0):

- `exafusion_enabled`
- `max_connections`
- `o7_dictionary_access`

RDS for Oracle licensing options

Amazon RDS for Oracle has two licensing options: License Included (LI) and Bring Your Own License (BYOL). After you create an Oracle DB instance on Amazon RDS, you can change the licensing model by modifying the DB instance. For more information, see Modifying an Amazon RDS DB instance.

> **Important**
>
> Make sure that you have the appropriate Oracle Database license, with Software Update License and Support, for your DB instance class and Oracle Database edition. Also make sure that you have licenses for any separately licensed Oracle Database features.

Topics

- License Included model for SE2
- Bring Your Own License (BYOL) for EE and SE2
- Licensing Oracle Multi-AZ deployments

License Included model for SE2

In the License Included model, you don't need to purchase Oracle Database licenses separately. AWS holds the license for the Oracle database software. The License Included model is only supported on Amazon RDS for Oracle Database Standard Edition 2 (SE2).

In this model, if you have an AWS Support account with case support, contact AWS Support for both Amazon RDS and Oracle Database service requests. Your use of RDS for Oracle the LI option is subject to Section 10.3.1 of the AWS Service Terms.

Bring Your Own License (BYOL) for EE and SE2

In the BYOL model, you can use your existing Oracle Database licenses to deploy databases on Amazon RDS. Amazon RDS supports the BYOL model only for Oracle Database Enterprise Edition (EE) and Oracle Database Standard Edition 2 (SE2).

Make sure that you have the appropriate Oracle Database license (with Software Update License and Support) for the DB instance class and Oracle Database edition you wish to run. You must also follow Oracle's policies for licensing Oracle Database software in the cloud computing environment. For more information on Oracle's licensing policy for Amazon EC2, see Licensing Oracle software in the cloud computing environment.

In this model, you continue to use your active Oracle support account, and you contact Oracle directly for Oracle Database service requests. If you have an AWS Support account with case support, you can contact AWS Support for Amazon RDS issues. Amazon Web Services and Oracle have a multi-vendor support process for cases that require assistance from both organizations.

Integrating with AWS License Manager

To make it easier to monitor Oracle license usage in the BYOL model, AWS License Manager integrates with Amazon RDS for Oracle. License Manager supports tracking of RDS for Oracle engine editions and licensing packs based on virtual cores (vCPUs). You can also use License Manager with AWS Organizations to manage all of your organizational accounts centrally.

The following table shows the product information filters for RDS for Oracle.

Filter	Name	Description
Engine Edition	`oracle-ee`	Oracle Database Enterprise Edition (EE)
	`oracle-se2`	Oracle Database Standard Edition 2 (SE2)
License Pack	`data guard`	See Working with read replicas for Amazon RDS for Oracle (Oracle Active Data Guard)
	`olap`	See Oracle OLAP

Filter	Name	Description
	`ols`	See Oracle Label Security
	`diagnostic pack sqlt`	See Oracle SQLT
	`tuning pack sqlt`	See Oracle SQLT

To track license usage of your Oracle DB instances, you can create a self-managed license using AWS License Manager. In this case, RDS for Oracle resources that match the product information filter are automatically associated with the self-managed license. Discovery of Oracle DB instances can take up to 24 hours. You can also track a license across accounts by using AWS Resource Access Manager.

Console

To create a self-managed license in AWS License Manager to track the license usage of your RDS for Oracle DB instances

1. Go to https://console.aws.amazon.com/license-manager/.
2. Choose **Create self-managed license**.

   For instructions, see Create a self-managed license in the *AWS License Manager User Guide*.

   Add a rule for an **RDS Product Information Filter** in the **Product Information** panel.

   For more information, see ProductInformation in the *AWS License Manager API Reference*.
3. (Cross-account tracking only) Use AWS Resource Access Manager to share your self-managed licenses with any AWS account or through AWS Organizations. For more information, see Sharing your AWS resources.

AWS CLI

To create a self-managed license by using the AWS CLI, call the create-license-configuration command. Use the `--cli-input-json` or `--cli-input-yaml` parameters to pass the parameters to the command.

Example

The following example creates a self-managed license for Oracle Enterprise Edition.

```
aws license-manager create-license-configuration --cli-input-json file://rds-oracle-
ee.json
```

The following is the sample `rds-oracle-ee.json` file used in the example.

```
{
    "Name": "rds-oracle-ee",
    "Description": "RDS Oracle Enterprise Edition",
    "LicenseCountingType": "vCPU",
    "LicenseCountHardLimit": false,
    "ProductInformationList": [
        {
            "ResourceType": "RDS",
            "ProductInformationFilterList": [
                {
                    "ProductInformationFilterName": "Engine Edition",
                    "ProductInformationFilterValue": ["oracle-ee"],
                    "ProductInformationFilterComparator": "EQUALS"
                }
            ]
        }
    ]
}
```

For more information about product information, see Automated discovery of resource inventory in the *AWS License Manager User Guide*.

For more information about the `--cli-input` parameter, see Generating AWS CLI skeleton and input parameters from a JSON or YAML input file in the *AWS CLI User Guide*.

Migrating between Oracle Database editions

If you have an unused BYOL Oracle Database license appropriate for the edition and class of DB instance that you plan to run, you can migrate from Standard Edition 2 (SE2) to Enterprise Edition (EE). You can't migrate from EE to other editions.

To change your Oracle Database edition and retain your data

1. Create a snapshot of the DB instance.

For more information, see Creating a DB snapshot for a Single-AZ DB instance.

2. Restore the snapshot to a new DB instance, and select the Oracle database edition you want to use.

   For more information, see Restoring to a DB instance.

3. (Optional) Delete the old DB instance, unless you want to keep it running and have the appropriate Oracle Database licenses for it.

   For more information, see Deleting a DB instance.

Licensing Oracle Multi-AZ deployments

Amazon RDS supports Multi-AZ deployments for Oracle as a high-availability, failover solution. We recommend Multi-AZ for production workloads. For more information, see Configuring and managing a Multi-AZ deployment.

If you use the Bring Your Own License model, you must have a license for both the primary DB instance and the standby DB instance in a Multi-AZ deployment.

RDS for Oracle users and privileges

When you create an Amazon RDS for Oracle DB instance, the default master user has most of the maximum user permissions on the DB instance. Use the master user account for any administrative tasks, such as creating additional user accounts in your database. Because RDS is a managed service, you aren't allowed to log in as SYS and SYSTEM, and thus don't have SYSDBA privileges.

Topics

- Limitations for Oracle DBA privileges
- How to manage privileges on SYS objects

Limitations for Oracle DBA privileges

In the database, a *role* is a collection of privileges that you can grant to or revoke from a user. An Oracle database uses roles to provide security. For more information, see Configuring Privilege and Role Authorization in the Oracle Database documentation.

The predefined role DBA normally allows all administrative privileges on an Oracle database. When you create a DB instance, your master user account gets DBA privileges (with some limitations). To deliver a managed experience, an RDS for Oracle database doesn't provide the following privileges for the DBA role:

- `ALTER DATABASE`
- `ALTER SYSTEM`
- `CREATE ANY DIRECTORY`
- `DROP ANY DIRECTORY`
- `GRANT ANY PRIVILEGE`
- `GRANT ANY ROLE`

For more RDS for Oracle system privilege and role information, see Master user account privileges.

How to manage privileges on SYS objects

You can manage privileges on SYS objects by using the `rdsadmin.rdsadmin_util` package. For example, if you create the database user `myuser`, you could use the `rdsadmin.rdsadmin_util.grant_sys_object` procedure to grant SELECT privileges on `V_$SQLAREA` to `myuser`. For more information, see the following topics:

- Granting SELECT or EXECUTE privileges to SYS objects
- Revoking SELECT or EXECUTE privileges on SYS objects
- Granting privileges to non-master users

RDS for Oracle DB instance classes

The computation and memory capacity of an RDS for Oracle DB instance is determined by its instance class. The DB instance class you need depends on your processing power and memory requirements.

Supported RDS for Oracle DB instance classes

The supported RDS for Oracle instance classes are a subset of the RDS DB instance classes. For the complete list of RDS instance classes, see DB instance classes.

RDS for Oracle preconfigured DB instance classes

RDS for Oracle also offers instance classes that are preconfigured for workloads that require additional memory, storage, and I/O per vCPU. These instance classes use the following naming convention:

```
db.r5b.instance_size.tpcthreads_per_core.memratio
db.r5.instance_size.tpcthreads_per_core.memratio
```

The following is an example of an instance class that is preconfigured for additional memory:

```
db.r5b.4xlarge.tpc2.mem2x
```

The components of the preceding instance class name are as follows:

- `db.r5b.4xlarge` – The name of the instance class.
- `tpc2` – The threads per core. A value of 2 means that multithreading is turned on. A value of 1 means that multithreading is turned off.
- `mem2x` – The ratio of additional memory to the standard memory for the instance class. In this example, the optimization provides twice as much memory as a standard db.r5.4xlarge DB instance.

Supported edition, instance class, and licensing combinations in RDS for Oracle

If you're using the RDS console, you can find out whether a specific edition, instance class, and license combination is supported by choosing **Create database** and specifying different option. In the AWS CLI, you can run the following command:

```
aws rds describe-orderable-db-instance-options --engine engine-type --license-
model license-type
```

The following table lists all editions, instance classes, and license types supported for RDS for Oracle. For information about the memory attributes of each type, see RDS for Oracle instance types. For information about pricing, see Amazon RDS for Oracle pricing models.

Oracle edition	Oracle Database 19c and higher
Enterprise Edition (EE)	**Standard instance classes**

Oracle edition	Oracle Database 19c and higher
Bring Your Own License (BYOL)	db.m6i.large–db.m6i.32xlarge db.m5d.large–db.m5d.24xlarge db.m5.large–db.m5.24xlarge
	Memory optimized instance classes

Oracle edition	Oracle Database 19c and higher
	db.r6i.8xlarge.tpc2.mem4x
	db.r6i.8xlarge.tpc2.mem3x
	db.r6i.6xlarge.tpc2.mem4x
	db.r6i.4xlarge.tpc2.mem4x
	db.r6i.4xlarge.tpc2.mem3x

	db.r5.large–db.r5.4xlarge
	Burstable performance instance classes
	db.t3.small–db.t3.2xlarge

Note

We encourage all BYOL customers to consult their licensing agreement to assess the impact of Amazon RDS for Oracle deprecations. For more information on the compute capacity of DB instance classes supported by RDS for Oracle, see DB instance classes and Configuring the processor for a DB instance class in RDS for Oracle.

> **Note**
>
> If you have DB snapshots of DB instances that were using deprecated DB instance classes, you can choose a DB instance class that is not deprecated when you restore the DB snapshots. For more information, see Restoring to a DB instance.

Deprecated RDS for Oracle DB instance classes

The following DB instance classes are deprecated for RDS for Oracle:

- db.m1, db.m2, db.m3, db.m4
- db.t1, db.t2
- db.r1, db.r2, db.r3, db.r4

The preceding DB instance classes have been replaced by better performing DB instance classes that are generally available at a lower cost. If you have DB instances that use deprecated DB instance classes, you have the following options:

- Allow Amazon RDS to modify each DB instance automatically to use a comparable non-deprecated DB instance class. For deprecation timelines, see DB instance class types.
- Change the DB instance class yourself by modifying the DB instance. For more information, see Modifying an Amazon RDS DB instance.

If you have DB snapshots of DB instances that were using deprecated DB instance classes, you can choose a DB instance class that is not deprecated when you restore the DB snapshots. For more information, see Restoring to a DB instance.

RDS for Oracle database architecture

The *Oracle multitenant architecture*, also known as the *CDB architecture*, enables an Oracle database to function as a *multitenant container database (CDB)*. A CDB can include customer-created *pluggable databases (PDBs)*. A *non-CDB* is an Oracle database that uses the traditional architecture, which can't contain PDBs. For more information about the multitenant architecture, see *Oracle Multitenant Administrator's Guide*.

For Oracle Database 19c and higher, you can create an RDS for Oracle DB instance that uses the CDB architecture. Your client applications connect at the PDB level rather than the CDB level. RDS for Oracle supports the following configurations of the CDB architecture:

Multi-tenant configuration

This RDS platform feature allows an RDS for Oracle CDB instance to contain between 1–30 tenant databases, depending on the database edition and any required option licenses tenant databases (PDBs). The multi-tenant configuration doesn't support application PDBs or proxy PDBs. You can use RDS APIs to add, modify, and remove tenant databases.

> **Note**
>
> The Amazon RDS feature is called "multi-tenant" rather than "multitenant" because it is a capability of the RDS platform, not just the Oracle DB engine. The term "Oracle multitenant" refers exclusively to the Oracle database architecture, which is compatible with both on-premises and RDS deployments.

Single-tenant configuration

This RDS platform feature limits an RDS for Oracle CDB instance to 1 tenant database (PDB). You can't add more PDBs using RDS APIs. The single-tenant configuration uses the same RDS APIs as the non-CDB architecture. Thus, the experience of working with a CDB in the single-tenant configuration is mostly the same as working with a non-CDB.

You can convert a CDB that uses the single-tenant configuration to the multi-tenant configuration, thus allowing you to add PDBs to your CDB. This architecture change is permanent and irreversible. For more information, see Converting the single-tenant configuration to multi-tenant.

> **Note**
>
> You can't access the CDB itself.

In Oracle Database 21c and higher, all databases are CDBs. In contrast, you can create an Oracle Database 19c DB instance as either a CDB or non-CDB. You can't upgrade a non-CDB to a CDB, but

you convert an Oracle Database 19c non-CDB to a CDB, and then upgrade it. You can't convert a CDB to a non-CDB.

For more information, see the following resources:

- Working with CDBs in RDS for Oracle
- Limitations of RDS for Oracle CDBs
- Creating an Amazon RDS DB instance

RDS for Oracle parameters

DB parameter groups

In Amazon RDS, you manage parameters using DB parameter groups. For more information, see Parameter groups for Amazon RDS. To view the supported initialization parameters for a specific Oracle Database edition and version, run the AWS CLI command `describe-engine-default-parameters`.

For example, to view the supported initialization parameters for the Enterprise Edition of Oracle Database 19c, run the following command.

```
aws rds describe-engine-default-parameters \
    --db-parameter-group-family oracle-ee-19
```

Oracle database initialization parameters

To find documentation for the initialization parameters, see Initialization Parameters in the Oracle Database documentation. The following initialization parameters have special considerations:

- `ARCHIVE_LAG_TARGET`

  This parameter forces a redo log switch after the specified time elapses. In RDS for Oracle, `ARCHIVE_LAG_TARGET` is set to `300` because the recovery point objective (RPO) is 5 minutes. To honor this objective, RDS for Oracle switches the online redo log every 5 minutes and stores it in an Amazon S3 bucket. If the frequency of the log switch causes a performance issue for your RDS for Oracle database, you can scale your DB instance and storage to one with higher IOPS and throughput. Alternatively, if you use RDS Custom for Oracle or deploy an Oracle database on Amazon EC2, you can adjust the setting of the `ARCHIVE_LAG_TARGET` initialization parameter.

RDS for Oracle character sets

RDS for Oracle supports two types of character sets: the DB character set and national character set.

DB character set

The Oracle database character set is used in the CHAR, VARCHAR2, and CLOB data types. The database also uses this character set for metadata such as table names, column names, and SQL statements. The Oracle database character set is typically referred to as the *DB character set*.

You set the character set when you create a DB instance. You can't change the DB character set after you create the database.

Supported DB character sets

The following table lists the Oracle DB character sets that are supported in Amazon RDS. You can use a value from this table with the `--character-set-name` parameter of the AWS CLI create-db-instance command or with the `CharacterSetName` parameter of the Amazon RDS API CreateDBInstance operation.

> **Note**
>
> The character set for a CDB is always AL32UTF8. You can set a different character set for the PDB only.

Value	Description
AL32UTF8	Unicode 5.0 UTF-8 Universal character set (default)
AR8ISO8859P6	ISO 8859-6 Latin/Arabic
AR8MSWIN1256	Microsoft Windows Code Page 1256 8-bit Latin/Arabic
BLT8ISO8859P13	ISO 8859-13 Baltic

Value	Description
BLT8MSWIN1257	Microsoft Windows Code Page 1257 8-bit Baltic
CL8ISO8859P5	ISO 88559-5 Latin/Cyrillic
CL8MSWIN1251	Microsoft Windows Code Page 1251 8-bit Latin/Cyrillic
EE8ISO8859P2	ISO 8859-2 East European
EL8ISO8859P7	ISO 8859-7 Latin/Greek
EE8MSWIN1250	Microsoft Windows Code Page 1250 8-bit East European
EL8MSWIN1253	Microsoft Windows Code Page 1253 8-bit Latin/Greek
IW8ISO8859P8	ISO 8859-8 Latin/Hebrew
IW8MSWIN1255	Microsoft Windows Code Page 1255 8-bit Latin/Hebrew
JA16EUC	EUC 24-bit Japanese
JA16EUCTILDE	Same as JA16EUC except for mapping of wave dash and tilde to and from Unicode
JA16SJIS	Shift-JIS 16-bit Japanese
JA16SJISTILDE	Same as JA16SJIS except for mapping of wave dash and tilde to and from Unicode
KO16MSWIN949	Microsoft Windows Code Page 949 Korean
NE8ISO8859P10	ISO 8859-10 North European
NEE8ISO8859P4	ISO 8859-4 North and Northeast European

Value	Description
TH8TISASCII	Thai Industrial Standard 620-2533-ASCII 8-bit
TR8MSWIN1254	Microsoft Windows Code Page 1254 8-bit Turkish
US7ASCII	ASCII 7-bit American
UTF8	Unicode 3.0 UTF-8 Universal character set, CESU-8 compliant
VN8MSWIN1258	Microsoft Windows Code Page 1258 8-bit Vietnamese
WE8ISO8859P1	Western European 8-bit ISO 8859 Part 1
WE8ISO8859P15	ISO 8859-15 West European
WE8ISO8859P9	ISO 8859-9 West European and Turkish
WE8MSWIN1252	Microsoft Windows Code Page 1252 8-bit West European
ZHS16GBK	GBK 16-bit Simplified Chinese
ZHT16HKSCS	Microsoft Windows Code Page 950 with Hong Kong Supplementary Character Set HKSCS-2001. Character set conversion is based on Unicode 3.0.
ZHT16MSWIN950	Microsoft Windows Code Page 950 Traditional Chinese
ZHT32EUC	EUC 32-bit Traditional Chinese

NLS_LANG environment variable

A *locale* is a set of information addressing linguistic and cultural requirements that corresponds to a given language and country. Setting the NLS_LANG environment variable in your client's

environment is the simplest way to specify locale behavior for Oracle. This variable sets the language and territory used by the client application and the database server. It also indicates the client's character set, which corresponds to the character set for data entered or displayed by a client application. For more information on NLS_LANG and character sets, see What is a character set or code page? in the Oracle documentation.

NLS initialization parameters

You can also set the following National Language Support (NLS) initialization parameters at the instance level for an Oracle DB instance in Amazon RDS:

- NLS_DATE_FORMAT
- NLS_LENGTH_SEMANTICS
- NLS_NCHAR_CONV_EXCP
- NLS_TIME_FORMAT
- NLS_TIME_TZ_FORMAT
- NLS_TIMESTAMP_FORMAT
- NLS_TIMESTAMP_TZ_FORMAT

For information about modifying instance parameters, see Parameter groups for Amazon RDS.

You can set other NLS initialization parameters in your SQL client. For example, the following statement sets the NLS_LANGUAGE initialization parameter to GERMAN in a SQL client that is connected to an Oracle DB instance:

```
ALTER SESSION SET NLS_LANGUAGE=GERMAN;
```

For information about connecting to an Oracle DB instance with a SQL client, see Connecting to your RDS for Oracle DB instance.

National character set

The national character set is used in the NCHAR, NVARCHAR2, and NCLOB data types. The national character set is typically referred to as the *NCHAR character set*. Unlike the DB character set, the NCHAR character set doesn't affect database metadata.

The NCHAR character set supports the following character sets:

- AL16UTF16 (default)
- UTF8

You can specify either value with the `--nchar-character-set-name` parameter of the create-db-instance command (AWS CLI version 2 only). If you use the Amazon RDS API, specify the `NcharCharacterSetName` parameter of CreateDBInstance operation. You can't change the national character set after you create the database.

For more information about Unicode in Oracle databases, see Supporting multilingual databases with unicode in the Oracle documentation.

RDS for Oracle limitations

In the following sections, you can find important limitations of using RDS for Oracle. For limitations specific to CDBs, see Limitations of RDS for Oracle CDBs.

> **Note**
>
> This list is not exhaustive.

Topics

- Oracle file size limits in Amazon RDS
- Public synonyms for Oracle-supplied schemas
- Schemas for unsupported features
- Limitations for Oracle DBA privileges
- Deprecation of TLS 1.0 and 1.1 Transport Layer Security

Oracle file size limits in Amazon RDS

The maximum size of a single file on RDS for Oracle DB instances is 16 TiB (tebibytes). This limit is imposed by the ext4 filesystem used by the instance. Thus, Oracle bigfile data files are limited to 16 TiB. If you try to resize a data file in a bigfile tablespace to a value over the limit, you receive an error such as the following.

```
ORA-01237: cannot extend datafile 6
ORA-01110: data file 6: '/rdsdbdata/db/mydir/datafile/myfile.dbf'
```

```
ORA-27059: could not reduce file size
Linux-x86_64 Error: 27: File too large
Additional information: 2
```

Public synonyms for Oracle-supplied schemas

Don't create or modify public synonyms for Oracle-supplied schemas, including SYS, SYSTEM, and RDSADMIN. Such actions might result in invalidation of core database components and affect the availability of your DB instance.

You can create public synonyms referencing objects in your own schemas.

Schemas for unsupported features

In general, Amazon RDS doesn't prevent you from creating schemas for unsupported features. However, if you create schemas for Oracle features and components that require SYS privileges, you can damage the data dictionary and affect your instance availability. Use only supported features and schemas that are available in Adding options to Oracle DB instances.

Limitations for Oracle DBA privileges

In the database, a *role* is a collection of privileges that you can grant to or revoke from a user. An Oracle database uses roles to provide security.

The predefined role DBA normally allows all administrative privileges on an Oracle database. When you create a DB instance, your master user account gets DBA privileges (with some limitations). To deliver a managed experience, an RDS for Oracle database doesn't provide the following privileges for the DBA role:

- ALTER DATABASE
- ALTER SYSTEM
- CREATE ANY DIRECTORY
- DROP ANY DIRECTORY
- GRANT ANY PRIVILEGE
- GRANT ANY ROLE

Use the master user account for administrative tasks such as creating additional user accounts in the database. You can't use SYS, SYSTEM, and other Oracle-supplied administrative accounts.

Deprecation of TLS 1.0 and 1.1 Transport Layer Security

Transport Layer Security protocol versions 1.0 and 1.1 (TLS 1.0 and TLS 1.1) are deprecated. In accordance with security best practices, Oracle has deprecated the use of TLS 1.0 and TLS 1.1. To meet your security requirements, RDS for Oracle strongly recommends that you use TLS 1.2 instead.

Connecting to your RDS for Oracle DB instance

After Amazon RDS provisions your Oracle DB instance, you can use any standard SQL client application to log in to your DB instance. Because RDS is a managed service, you can't log in as SYS or SYSTEM. For more information, see RDS for Oracle users and privileges.

In this topic, you learn how to use Oracle SQL Developer or SQL*Plus to connect to an RDS for Oracle DB instance. For an example that walks you through the process of creating and connecting to a sample DB instance, see Creating and connecting to an Oracle DB instance.

Topics

Finding the endpoint of your RDS for Oracle DB instance

Each Amazon RDS DB instance has an endpoint, and each endpoint has the DNS name and port number for the DB instance. To connect to your DB instance using a SQL client application, you need the DNS name and port number for your DB instance.

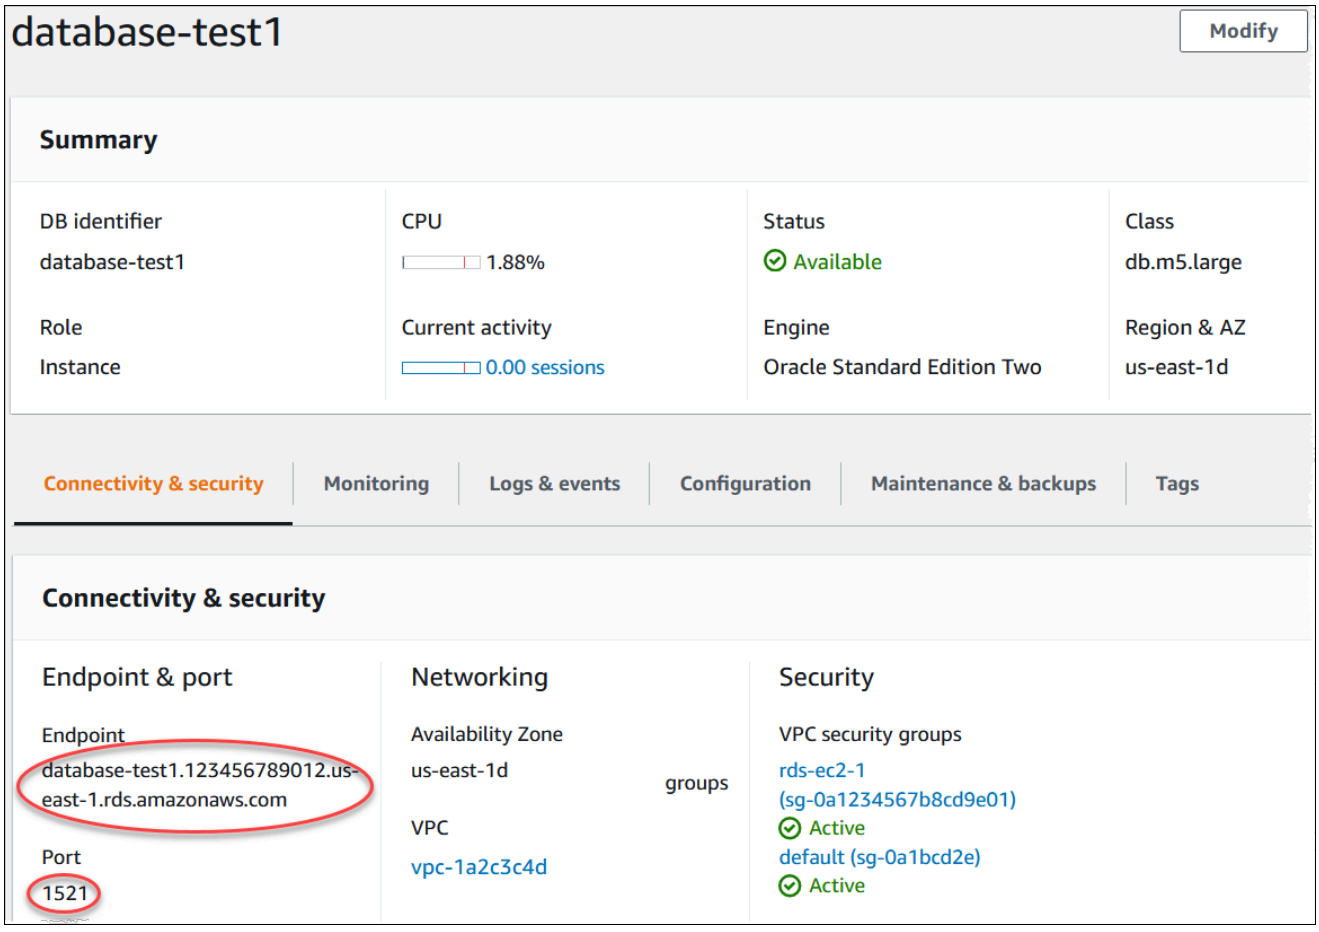
You can find the endpoint for a DB instance using the Amazon RDS console or the AWS CLI.

> **Note**
>
> If you are using Kerberos authentication, see Connecting to Oracle with Kerberos authentication.

Console

To find the endpoint using the console

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the upper-right corner of the console, choose the AWS Region of your DB instance.
3. Find the DNS name and port number for your DB instance.
   a. Choose **Databases** to display a list of your DB instances.
   b. Choose the Oracle DB instance name to display the instance details.
   c. On the **Connectivity & security** tab, copy the endpoint. Also, note the port number. You need both the endpoint and the port number to connect to the DB instance.



AWS CLI

To find the endpoint of an Oracle DB instance by using the AWS CLI, call the describe-db-instances command.

Example To find the endpoint using the AWS CLI

```
aws rds describe-db-instances
```

Search for `Endpoint` in the output to find the DNS name and port number for your DB instance. The `Address` line in the output contains the DNS name. The following is an example of the JSON endpoint output.

```
"Endpoint": {
    "HostedZoneId": "Z1PVIF0B656C1W",
    "Port": 3306,
    "Address": "myinstance.123456789012.us-west-2.rds.amazonaws.com"
},
```

> **Note**
>
> The output might contain information for multiple DB instances.

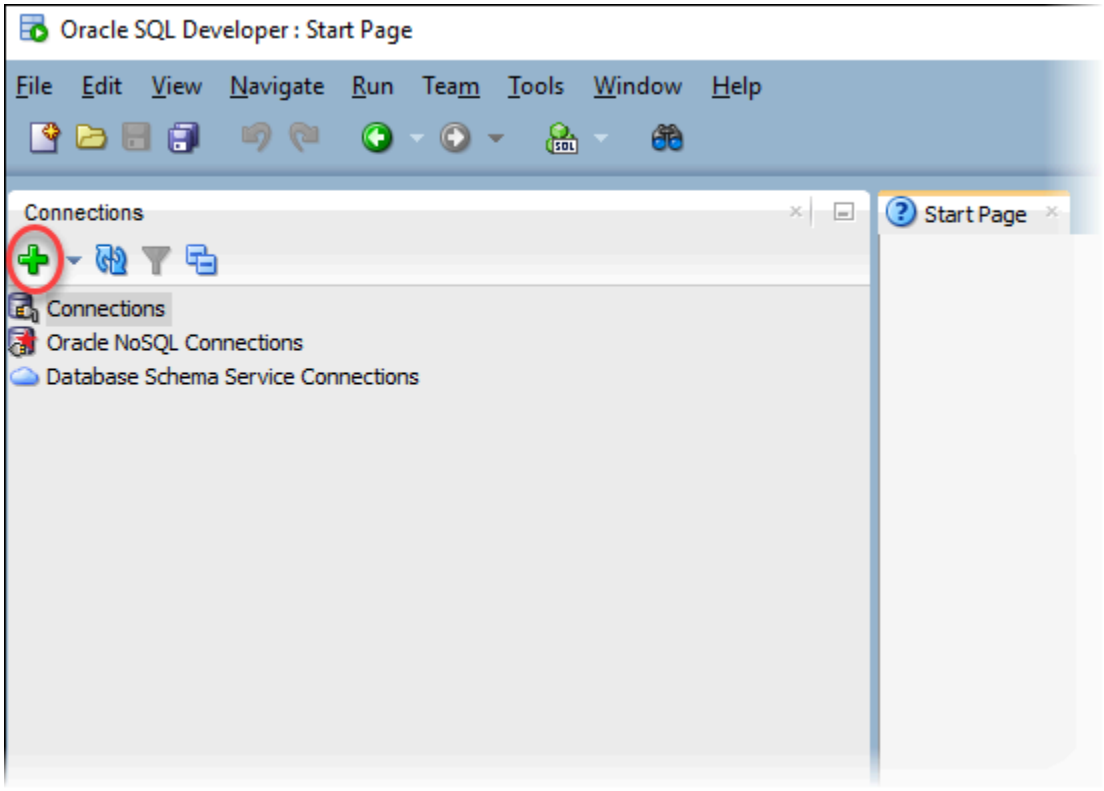
Connecting to your DB instance using Oracle SQL developer

In this procedure, you connect to your DB instance by using Oracle SQL Developer. To download a standalone version of this utility, see the Oracle SQL developer downloads page.

To connect to your DB instance, you need its DNS name and port number. For information about finding the DNS name and port number for a DB instance, see Finding the endpoint of your RDS for Oracle DB instance.

To connect to a DB instance using SQL developer

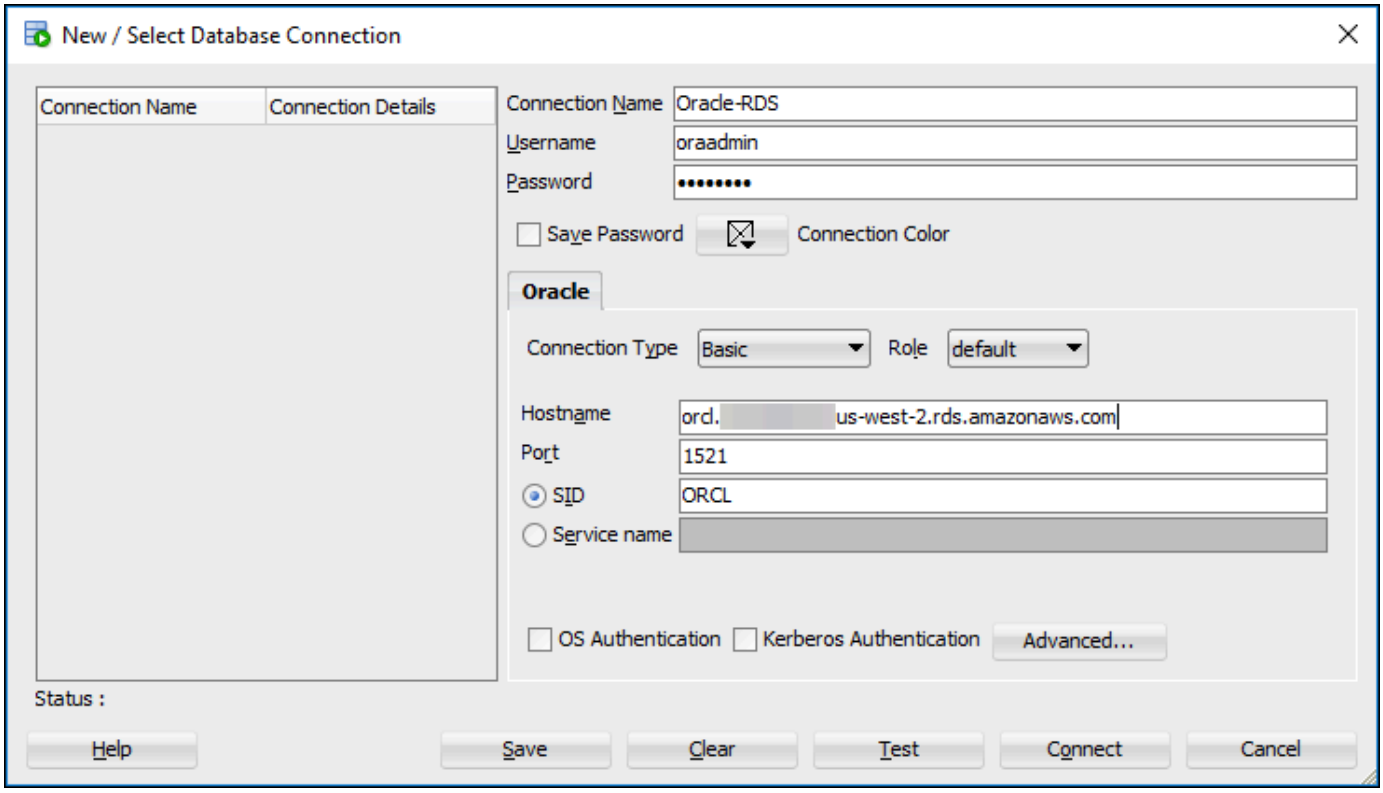
1. Start Oracle SQL Developer.
2. On the **Connections** tab, choose the **add (+)** icon.



3. In the **New/Select Database Connection** dialog box, provide the information for your DB instance:

   - For **Connection Name**, enter a name that describes the connection, such as `Oracle-RDS`.
   - For **Username**, enter the name of the database administrator for the DB instance.
   - For **Password**, enter the password for the database administrator.
   - For **Hostname**, enter the DNS name of the DB instance.
   - For **Port**, enter the port number.
   - For **SID**, enter the DB name. You can find the DB name on the **Configuration** tab of your database details page.

   The completed dialog box should look similar to the following.



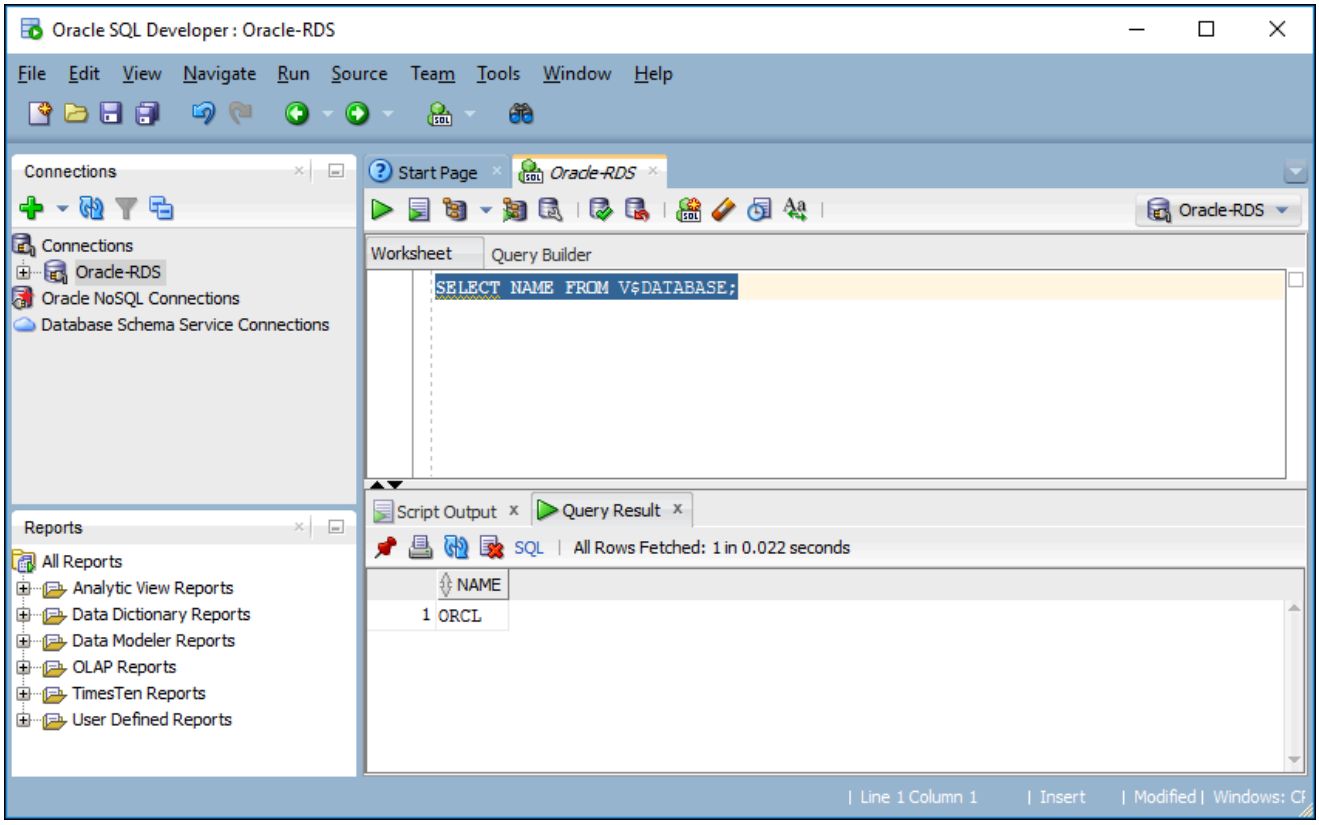
4. Choose **Connect**.
5. You can now start creating your own databases and running queries against your DB instance and databases as usual. To run a test query against your DB instance, do the following:

   a. In the **Worksheet** tab for your connection, enter the following SQL query.

   ```
   SELECT NAME FROM V$DATABASE;
   ```

   b. Choose the **execute** icon to run the query.

   
   SQL Developer returns the database name.



Connecting to your DB instance using SQL*Plus

You can use a utility like SQL*Plus to connect to an Amazon RDS DB instance running Oracle. To download Oracle Instant Client, which includes a standalone version of SQL*Plus, see Oracle Instant Client Downloads.

To connect to your DB instance, you need its DNS name and port number. For information about finding the DNS name and port number for a DB instance, see Finding the endpoint of your RDS for Oracle DB instance.

Example To connect to an Oracle DB instance using SQL*Plus

In the following examples, substitute the user name of your DB instance administrator. Also, substitute the DNS name for your DB instance, and then include the port number and the Oracle SID. The SID value is the name of the DB instance's database that you specified when you created the DB instance, and not the name of the DB instance.

For Linux, macOS, or Unix:

```
sqlplus 'user_name@(DESCRIPTION=(ADDRESS=(PROTOCOL=TCP)(HOST=dns_name)(PORT=port))
(CONNECT_DATA=(SID=database_name)))'
```

For Windows:

```
sqlplus user_name@(DESCRIPTION=(ADDRESS=(PROTOCOL=TCP)(HOST=dns_name)(PORT=port))
(CONNECT_DATA=(SID=database_name)))
```

You should see output similar to the following.

```
SQL*Plus: Release 12.1.0.2.0 Production on Mon Aug 21 09:42:20 2017
```

After you enter the password for the user, the SQL prompt appears.

```
SQL>
```

> **Note**
>
> The shorter format connection string (EZ Connect), such as `sqlplus USER/PASSWORD@longer-than-63-chars-rds-endpoint-here:1521/database-identifier`, might encounter a maximum character limit, so you we recommend that you don't use it to connect.

Considerations for security groups

For you to connect to your DB instance, it must be associated with a security group that contains the necessary IP addresses and network configuration. Your DB instance might use the default security group. If you assigned a default, nonconfigured security group when you created the DB instance, the firewall prevents connections. For information about creating a new security group, see Controlling access with security groups.

After you create the new security group, you modify your DB instance to associate it with the security group. For more information, see Modifying an Amazon RDS DB instance.

You can enhance security by using SSL to encrypt connections to your DB instance. For more information, see Oracle Secure Sockets Layer.

Considerations for process architecture

Server processes handle user connections to an Oracle DB instance. By default, the Oracle DB instance uses dedicated server processes. With dedicated server processes, each server process services only one user process. You can optionally configure shared server processes. With shared server processes, each server process can service multiple user processes.

You might consider using shared server processes when a high number of user sessions are using too much memory on the server. You might also consider shared server processes when sessions connect and disconnect very often, resulting in performance issues. There are also disadvantages to using shared server processes. For example, they can strain CPU resources, and they are more complicated to configure and administer.

For more information about dedicated and shared server processes, see About dedicated and shared server processes in the Oracle documentation. For more information about configuring shared server processes on an RDS for Oracle DB instance, see How do I configure Amazon RDS for Oracle database to work with shared servers? in the Knowledge Center.

Troubleshooting connections to your Oracle DB instance

The following are issues you might encounter when you try to connect to your Oracle DB instance.

Issue	Troubleshooting suggestions
Unable to connect to your DB instance.	For a newly created DB instance, the DB instance has a status of **creating** until it is ready to use. When the state changes to **available**, you can connect to the DB instance. Depending on the DB instance class and the amount of storage, it can take up to 20 minutes before the new DB instance is available.
Unable to connect to your DB instance.	If you can't send or receive communications over the port that you specified when you created the DB instance, you can't connect to the DB instance. Check with your network administrator to verify that the port you specified for your DB instance allows inbound and outbound communication.
Unable to connect to your DB instance.	The access rules enforced by your local firewall and the IP addresses you authorized to access your DB instance in the

Issue	Troubleshooting suggestions
	security group for the DB instance might not match. The problem is most likely the inbound or outbound rules on your firewall. You can add or edit an inbound rule in the security group. For **Source**, choose **My IP**. This allows access to the DB instance from the IP address detected in your browser. For more information, see Amazon VPC and Amazon RDS. For more information about security groups, see Controlling access with security groups. To walk through the process of setting up rules for your security group, see Tutorial: Create a VPC for use with a DB instance (IPv4 only).
Connect failed because target host or object does not exist – Oracle, Error: ORA-12545	Make sure that you specified the server name and port number correctly. For **Server name**, enter the DNS name from the console. For information about finding the DNS name and port number for a DB instance, see Finding the endpoint of your RDS for Oracle DB instance.
Invalid username/ password; logon denied – Oracle, Error: ORA-01017	You were able to reach the DB instance, but the connection was refused. This is usually caused by providing an incorrect user name or password. Verify the user name and password, and then retry.
TNS:listener does not currently know of SID given in connect descriptor - Oracle, ERROR: ORA-12505	Ensure the correct SID is entered. The SID is the same as your DB name. Find the DB name in the **Configuration** tab of the **Databases** page for your instance. You can also find the DB name using the AWS CLI: `aws rds describe-db-instances --query 'DBInstances[*].[DBInstanceIdentifier,DBName]' --output text`

For more information on connection issues, see Can't connect to Amazon RDS DB instance.

Modifying connection properties using sqlnet.ora parameters

The sqlnet.ora file includes parameters that configure Oracle Net features on Oracle database servers and clients. Using the parameters in the sqlnet.ora file, you can modify properties for connections in and out of the database.

For more information about why you might set sqlnet.ora parameters, see Configuring profile parameters in the Oracle documentation.

Setting sqlnet.ora parameters

Amazon RDS for Oracle parameter groups include a subset of sqlnet.ora parameters. You set them in the same way that you set other Oracle parameters. The `sqlnetora.` prefix identifies which parameters are sqlnet.ora parameters. For example, in an Oracle parameter group in Amazon RDS, the `default_sdu_size` sqlnet.ora parameter is `sqlnetora.default_sdu_size`.

For information about managing parameter groups and setting parameter values, see Parameter groups for Amazon RDS.

Supported sqlnet.ora parameters

Amazon RDS supports the following sqlnet.ora parameters. Changes to dynamic sqlnet.ora parameters take effect immediately.

Parameter	Valid values	Static/ Dynamic	Description
`sqlnetora.default_sdu_size`	`512` to `20971`	Dynamic	The session data unit (SDU) size, in bytes. The SDU is the amount of data that is put in a buffer and sent across the network at one time.
`sqlnetora.diag_adr_enabled`	`ON`, `OFF`	Dynamic	A value that enables or disables Automatic Diagnostic Repository (ADR) tracing.

Parameter	Valid values	Static/ Dynamic	Description
			ON specifies that ADR file tracing is used. OFF specifies that non-ADR file tracing is used.
sqlnetora.recv_buf_size	8192 to 26843	Dynamic	The buffer space limit for receive operations of sessions, supported by the TCP/IP, TCP/IP with SSL, and SDP protocols.
sqlnetora.send_buf_size	8192 to 26843	Dynamic	The buffer space limit for send operations of sessions, supported by the TCP/IP, TCP/IP with SSL, and SDP protocols.
sqlnetora.sqlnet.allowed_logon_version_client	8, 10, 11, 12	Dynamic	Minimum authentication protocol version allowed for clients, and servers acting as clients, to establish a connection to Oracle DB instances.
sqlnetora.sqlnet.allowed_logon_version_server	8, 9, 10, 11, 12, 12a	Dynamic	Minimum authentication protocol version allowed to establish a connection to Oracle DB instances.

Parameter	Valid values	Static/ Dynamic	Description
sqlnetora.sqlnet.expire_time	0 to 1440	Dynamic	Time interval, in minutes, to send a check to verify that client-server connections are active.
sqlnetora.sqlnet.inbound_connect_timeout	0 or 10 to 7200	Dynamic	Time, in seconds, for a client to connect with the database server and provide the necessary authentication information.
sqlnetora.sqlnet.outbound_connect_timeout	0 or 10 to 7200	Dynamic	Time, in seconds, for a client to establish an Oracle Net connection to the DB instance.
sqlnetora.sqlnet.recv_timeout	0 or 10 to 7200	Dynamic	Time, in seconds, for a database server to wait for client data after establishing a connection.
sqlnetora.sqlnet.send_timeout	0 or 10 to 7200	Dynamic	Time, in seconds, for a database server to complete a send operation to clients after establishing a connection.
sqlnetora.tcp.connect_timeout	0 or 10 to 7200	Dynamic	Time, in seconds, for a client to establish a TCP connection to the database server.

Parameter	Valid values	Static/ Dynamic	Description
sqlnetora.trace_level_server	0, 4, 10, 16, OFF, USER, ADMIN, SUPPOF	Dynamic	For non-ADR tracing, turns server tracing on at a specified level or turns it off.

The default value for each supported sqlnet.ora parameter is the Oracle Database default for the release.

Viewing sqlnet.ora parameters

You can view sqlnet.ora parameters and their settings using the AWS Management Console, the AWS CLI, or a SQL client.

Viewing sqlnet.ora parameters using the console

For information about viewing parameters in a parameter group, see Parameter groups for Amazon RDS.

In Oracle parameter groups, the `sqlnetora.` prefix identifies which parameters are sqlnet.ora parameters.

Viewing sqlnet.ora parameters using the AWS CLI

To view the sqlnet.ora parameters that were configured in an Oracle parameter group, use the AWS CLI describe-db-parameters command.

To view the all of the sqlnet.ora parameters for an Oracle DB instance, call the AWS CLI download-db-log-file-portion command. Specify the DB instance identifier, the log file name, and the type of output.

Example

The following code lists all of the sqlnet.ora parameters for `mydbinstance`.

For Linux, macOS, or Unix:

```
aws rds download-db-log-file-portion \
    --db-instance-identifier mydbinstance \
    --log-file-name trace/sqlnet-parameters \
    --output text
```

For Windows:

```
aws rds download-db-log-file-portion ^
    --db-instance-identifier mydbinstance ^
    --log-file-name trace/sqlnet-parameters ^
    --output text
```

Viewing sqlnet.ora parameters using a SQL client

After you connect to the Oracle DB instance in a SQL client, the following query lists the sqlnet.ora parameters.

```
SELECT * FROM TABLE
   (rdsadmin.rds_file_util.read_text_file(
        p_directory => 'BDUMP',
        p_filename  => 'sqlnet-parameters'));
```

For information about connecting to an Oracle DB instance in a SQL client, see Connecting to your RDS for Oracle DB instance.

Securing Oracle DB instance connections

Amazon RDS for Oracle supports SSL/TLS encrypted connections and also the Oracle Native Network Encryption (NNE) option to encrypt connections between your application and your Oracle DB instance. For more information about the Oracle Native Network Encryption option, see Oracle native network encryption.

Topics

Using SSL with an RDS for Oracle DB instance

Secure Sockets Layer (SSL) is an industry-standard protocol for securing network connections between client and server. After SSL version 3.0, the name was changed to Transport Layer Security (TLS), but we still often refer to the protocol as SSL. Amazon RDS supports SSL encryption for Oracle DB instances. Using SSL, you can encrypt a connection between your application client and your Oracle DB instance. SSL support is available in all AWS Regions for Oracle.

To enable SSL encryption for an Oracle DB instance, add the Oracle SSL option to the option group associated with the DB instance. Amazon RDS uses a second port, as required by Oracle, for SSL connections. Doing this allows both clear text and SSL-encrypted communication to occur at the same time between a DB instance and an Oracle client. For example, you can use the port with clear text communication to communicate with other resources inside a VPC while using the port with SSL-encrypted communication to communicate with resources outside the VPC.

For more information, see Oracle Secure Sockets Layer.

> **Note**
>
> You can't use both SSL and Oracle native network encryption (NNE) on the same DB instance. Before you can use SSL encryption, you must disable any other connection encryption.

Updating applications to connect to Oracle DB instances using new SSL/TLS certificates

As of January 13, 2023, Amazon RDS has published new Certificate Authority (CA) certificates for connecting to your RDS DB instances using Secure Socket Layer or Transport Layer Security (SSL/TLS). Following, you can find information about updating your applications to use the new certificates.

This topic can help you to determine whether any client applications use SSL/TLS to connect to your DB instances.

Important

When you change the certificate for an Amazon RDS for Oracle DB instance, only the database listener is restarted. The DB instance isn't restarted. Existing database connections are unaffected, but new connections will encounter errors for a brief period while the listener is restarted.

Note

For client applications that use SSL/TLS to connect to your DB instances, you must update your client application trust stores to include the new CA certificates.

After you update your CA certificates in the client application trust stores, you can rotate the certificates on your DB instances. We strongly recommend testing these procedures in a development or staging environment before implementing them in your production environments.

For more information about certificate rotation, see Rotating your SSL/TLS certificate. For more information about downloading certificates, see Using SSL/TLS to encrypt a connection to a DB instance or cluster. For information about using SSL/TLS with Oracle DB instances, see Oracle Secure Sockets Layer.

Topics

Finding out whether applications connect using SSL

If your Oracle DB instance uses an option group with the SSL option added, you might be using SSL. Check this by following the instructions in Listing the options and option settings for an option group. For information about the SSL option, see Oracle Secure Sockets Layer.

Check the listener log to determine whether there are SSL connections. The following is sample output in a listener log.

```
date time * (CONNECT_DATA=(CID=(PROGRAM=program)
(HOST=host)(USER=user))(SID=sid)) *
(ADDRESS=(PROTOCOL=tcps)(HOST=host)(PORT=port)) * establish * ORCL * 0
```

When PROTOCOL has the value `tcps` for an entry, it shows an SSL connection. However, when HOST is `127.0.0.1`, you can ignore the entry. Connections from `127.0.0.1` are a local management agent on the DB instance. These connections aren't external SSL connections. Therefore, you have applications connecting using SSL if you see listener log entries where PROTOCOL is `tcps` and HOST is *not* `127.0.0.1`.

To check the listener log, you can publish the log to Amazon CloudWatch Logs. For more information, see Publishing Oracle logs to Amazon CloudWatch Logs.

Updating your application trust store

You can update the trust store for applications that use SQL*Plus or JDBC for SSL/TLS connections.

Updating your application trust store for SQL*Plus

You can update the trust store for applications that use SQL*Plus for SSL/TLS connections.

> **Note**
>
> When you update the trust store, you can retain older certificates in addition to adding the new certificates.

To update the trust store for SQL*Plus applications

1. Download the new root certificate that works for all AWS Regions and put the file in the `ssl_wallet` directory.

For information about downloading the root certificate, see Using SSL/TLS to encrypt a connection to a DB instance or cluster.

2. Run the following command to update the Oracle wallet.

```
prompt>orapki wallet add -wallet $ORACLE_HOME/ssl_wallet -trusted_cert -cert
      $ORACLE_HOME/ssl_wallet/ssl-cert.pem -auto_login_only
```

Replace the file name with the one that you downloaded.

3. Run the following command to confirm that the wallet was updated successfully.

```
prompt>orapki wallet display -wallet $ORACLE_HOME/ssl_wallet
```

Your output should contain the following.

```
Trusted Certificates:
Subject: CN=Amazon RDS Root 2019 CA,OU=Amazon RDS,O=Amazon Web Services\,
 Inc.,L=Seattle,ST=Washington,C=US
```

Updating your application trust store for JDBC

You can update the trust store for applications that use JDBC for SSL/TLS connections.

For information about downloading the root certificate, see Using SSL/TLS to encrypt a connection to a DB instance or cluster.

For sample scripts that import certificates, see Sample script for importing certificates into your trust store.

Example Java code for establishing SSL connections

The following code example shows how to set up the SSL connection using JDBC.

```
import java.sql.Connection;
import java.sql.DriverManager;
import java.sql.SQLException;
import java.util.Properties;

public class OracleSslConnectionTest {
    private static final String DB_SERVER_NAME = "<dns-name-provided-by-amazon-rds>";
```

```
    private static final Integer SSL_PORT = "<ssl-option-port-configured-in-option-
group>";
    private static final String DB_SID = "<oracle-sid>";
    private static final String DB_USER = "<user name>";
    private static final String DB_PASSWORD = "<password>";
    // This key store has only the prod root ca.
    private static final String KEY_STORE_FILE_PATH = "<file-path-to-keystore>";
    private static final String KEY_STORE_PASS = "<keystore-password>";

    public static void main(String[] args) throws SQLException {
        final Properties properties = new Properties();
        final String connectionString = String.format(
                "jdbc:oracle:thin:@(DESCRIPTION=(ADDRESS=(PROTOCOL=TCPS)(HOST=%s)(PORT=
%d))(CONNECT_DATA=(SID=%s)))",
                DB_SERVER_NAME, SSL_PORT, DB_SID);
        properties.put("user", DB_USER);
        properties.put("password", DB_PASSWORD);
        properties.put("oracle.jdbc.J2EE13Compliant", "true");
        properties.put("javax.net.ssl.trustStore", KEY_STORE_FILE_PATH);
        properties.put("javax.net.ssl.trustStoreType", "JKS");
        properties.put("javax.net.ssl.trustStorePassword", KEY_STORE_PASS);
        final Connection connection = DriverManager.getConnection(connectionString,
 properties);
        // If no exception, that means handshake has passed, and an SSL connection can
 be opened
    }
}
```

Important

After you have determined that your database connections use SSL/TLS and have updated your application trust store, you can update your database to use the rds-ca-rsa2048-g1 certificates. For instructions, see step 3 in Updating your CA certificate by modifying your DB instance or cluster.

Using native network encryption with an RDS for Oracle DB instance

Oracle Database offers two ways to encrypt data over the network: native network encryption (NNE) and Transport Layer Security (TLS). NNE is a proprietary Oracle security feature, whereas TLS is an industry standard. RDS for Oracle supports NNE for all editions of Oracle Database.

NNE has the following advantages over TLS:

- You can control NNE on the client and server using settings in the NNE option:
  - `SQLNET.ALLOW_WEAK_CRYPTO_CLIENTS` and `SQLNET.ALLOW_WEAK_CRYPTO`
  - `SQLNET.CRYPTO_CHECKSUM_CLIENT` and `SQLNET.CRYPTO_CHECKSUM_SERVER`
  - `SQLNET.CRYPTO_CHECKSUM_TYPES_CLIENT` and `SQLNET.CRYPTO_CHECKSUM_TYPES_SERVER`
  - `SQLNET.ENCRYPTION_CLIENT` and `SQLNET.ENCRYPTION_SERVER`
  - `SQLNET.ENCRYPTION_TYPES_CLIENT` and `SQLNET.ENCRYPTION_TYPES_SERVER`
- In most cases, you don't need to configure your client or server. In contrast, TLS requires you to configure both client and server.
- No certificates are required. In TLS, the server requires a certificate (which eventually expires), and the client requires a trusted root certificate for the certificate authority that issued the server's certificate.

To enable NNE encryption for an Oracle DB instance, add the Oracle NNE option to the option group associated with the DB instance. For more information, see Oracle native network encryption.

> **Note**
>
> You can't use both NNE and TLS on the same DB instance.

Configuring Kerberos authentication for Amazon RDS for Oracle

You can use Kerberos authentication to authenticate users when they connect to your Amazon RDS for Oracle DB instance. In this configuration, your DB instance works with AWS Directory Service for Microsoft Active Directory, also called AWS Managed Microsoft AD. When users authenticate with an RDS for Oracle DB instance joined to the trusting domain, authentication requests are forwarded to the directory that you create with AWS Directory Service.

Keeping all of your credentials in the same directory can save you time and effort. You have a centralized place for storing and managing credentials for multiple database instances. A directory can also improve your overall security profile.

Region and version availability

Feature availability and support varies across specific versions of each database engine, and across AWS Regions. For more information on version and Region availability of RDS for Oracle with Kerberos authentication, see Supported Regions and DB engines for Kerberos authentication in Amazon RDS.

> **Note**
>
> Kerberos authentication isn't supported for DB instance classes that are deprecated for RDS for Oracle DB instances. For more information, see RDS for Oracle DB instance classes.

Topics

- Setting up Kerberos authentication for Oracle DB instances
- Managing a DB instance in a domain
- Connecting to Oracle with Kerberos authentication

Setting up Kerberos authentication for Oracle DB instances

Use AWS Directory Service for Microsoft Active Directory, also called AWS Managed Microsoft AD, to set up Kerberos authentication for an Oracle DB instance. To set up Kerberos authentication, complete the following steps:

- Step 1: Create a directory using the AWS Managed Microsoft AD
- Step 2: Create a trust
- Step 3: Configure IAM permissions for Amazon RDS
- Step 4: Create and configure users
- Step 5: Enable cross-VPC traffic between the directory and the DB instance
- Step 6: Create or modify an Oracle DB instance
- Step 7: Create Kerberos authentication Oracle logins
- Step 8: Configure an Oracle client

> **Note**
>
> During the setup, RDS creates an Oracle database user named *managed_service_user*@*example.com* with the `CREATE SESSION` privilege, where *example.com* is your domain name. This user corresponds to the user that Directory Service creates inside your Managed Active Directory. Periodically, RDS uses the credentials provided by the Directory Service to log in to your Oracle database. Afterwards, RDS immediately destroys the ticket cache.

Step 1: Create a directory using the AWS Managed Microsoft AD

AWS Directory Service creates a fully managed Active Directory in the AWS Cloud. When you create an AWS Managed Microsoft AD directory, AWS Directory Service creates two domain controllers and Domain Name System (DNS) servers on your behalf. The directory servers are created in different subnets in a VPC. This redundancy helps make sure that your directory remains accessible even if a failure occurs.

When you create an AWS Managed Microsoft AD directory, AWS Directory Service performs the following tasks on your behalf:

- Sets up an Active Directory within the VPC.
- Creates a directory administrator account with the user name Admin and the specified password. You use this account to manage your directory.

  > **Note**
  >
  > Be sure to save this password. AWS Directory Service doesn't store it. You can reset it, but you can't retrieve it.

- Creates a security group for the directory controllers.

When you launch an AWS Managed Microsoft AD, AWS creates an Organizational Unit (OU) that contains all of your directory's objects. This OU has the NetBIOS name that you typed when you created your directory and is located in the domain root. The domain root is owned and managed by AWS.

The Admin account that was created with your AWS Managed Microsoft AD directory has permissions for the most common administrative activities for your OU:

- Create, update, or delete users
- Add resources to your domain such as file or print servers, and then assign permissions for those resources to users in your OU
- Create additional OUs and containers
- Delegate authority
- Restore deleted objects from the Active Directory Recycle Bin
- Run AD and DNS Windows PowerShell modules on the Active Directory Web Service

The Admin account also has rights to perform the following domain-wide activities:

- Manage DNS configurations (add, remove, or update records, zones, and forwarders)
- View DNS event logs
- View security event logs

To create the directory, use the AWS Management Console, the AWS CLI, or the AWS Directory Service API. Make sure to open the relevant outbound ports on the directory security group so that the directory can communicate with the Oracle DB instance.

To create a directory with AWS Managed Microsoft AD

1. Sign in to the AWS Management Console and open the AWS Directory Service console at https://console.aws.amazon.com/directoryservicev2/.
2. In the navigation pane, choose **Directories** and choose **Set up Directory**.
3. Choose **AWS Managed Microsoft AD**. AWS Managed Microsoft AD is the only option that you can currently use with Amazon RDS.
4. Enter the following information:

   Directory DNS name

   The fully qualified name for the directory, such as **`corp.example.com`**.

   Directory NetBIOS name

   The short name for the directory, such as **`CORP`**.

Directory description

(Optional) A description for the directory.

Admin password

The password for the directory administrator. The directory creation process creates an administrator account with the user name Admin and this password.

The directory administrator password and can't include the word "admin." The password is case-sensitive and must be 8–64 characters in length. It must also contain at least one character from three of the following four categories:

- Lowercase letters (a–z)
- Uppercase letters (A–Z)
- Numbers (0–9)
- Non-alphanumeric characters (~!@#$%^&*_-+=`|\(){}[]:;"'<>,.?/)

Confirm password

The administrator password retyped.

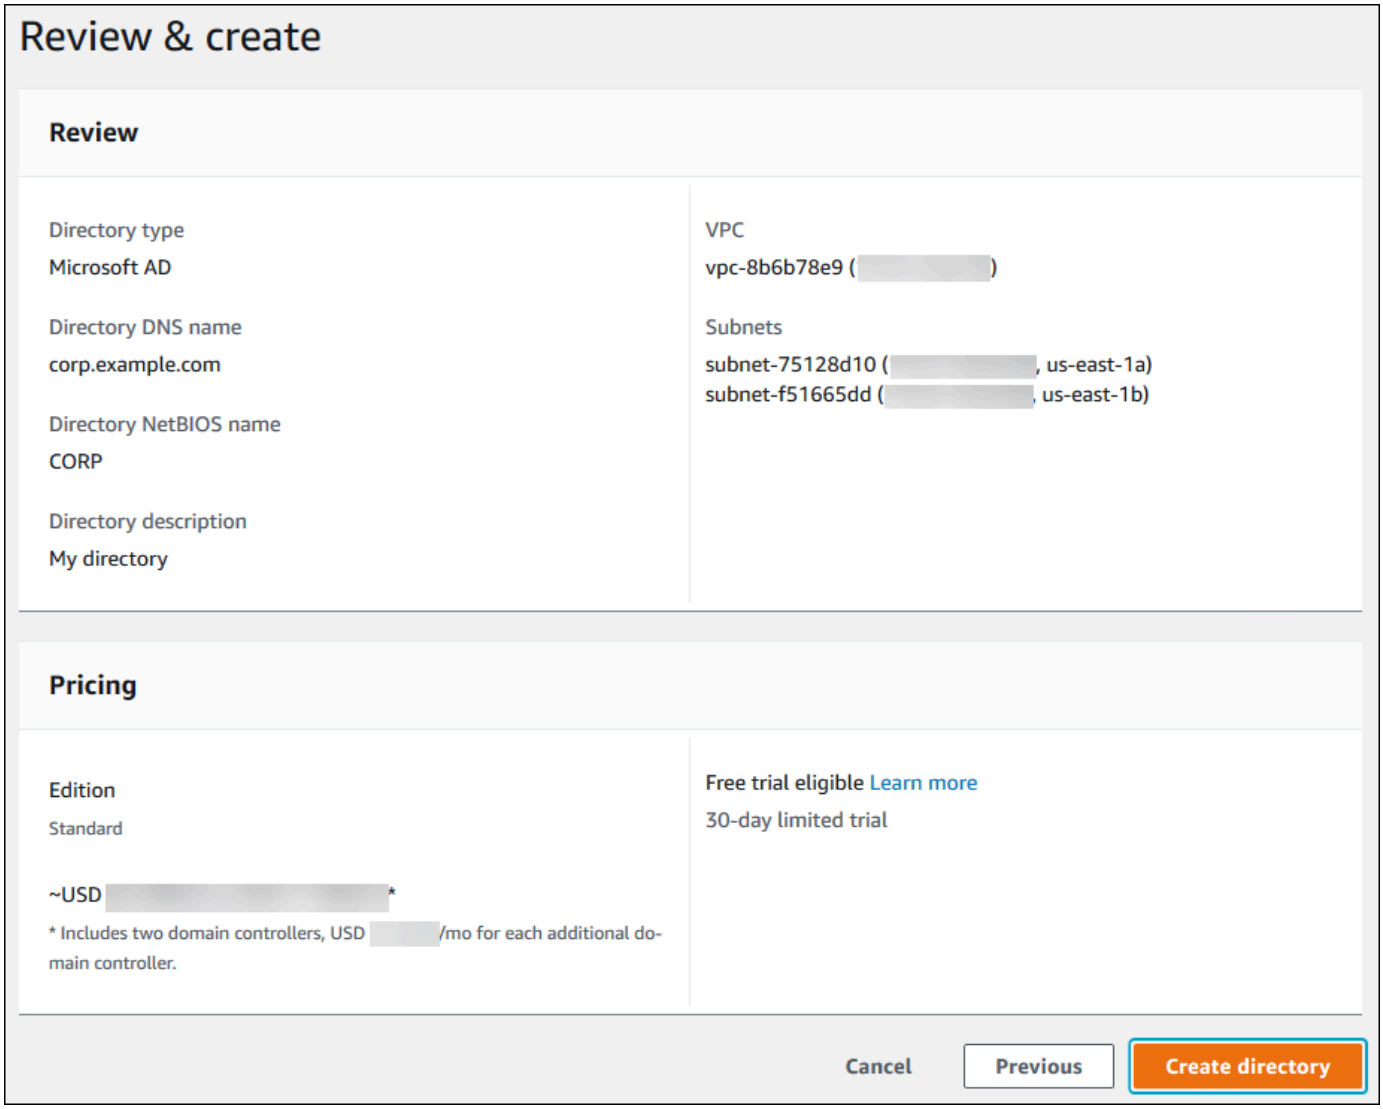
5. Choose **Next**.
6. Enter the following information in the **Networking** section and then choose **Next**:

   VPC

   The VPC for the directory. Create the Oracle DB instance in this same VPC.

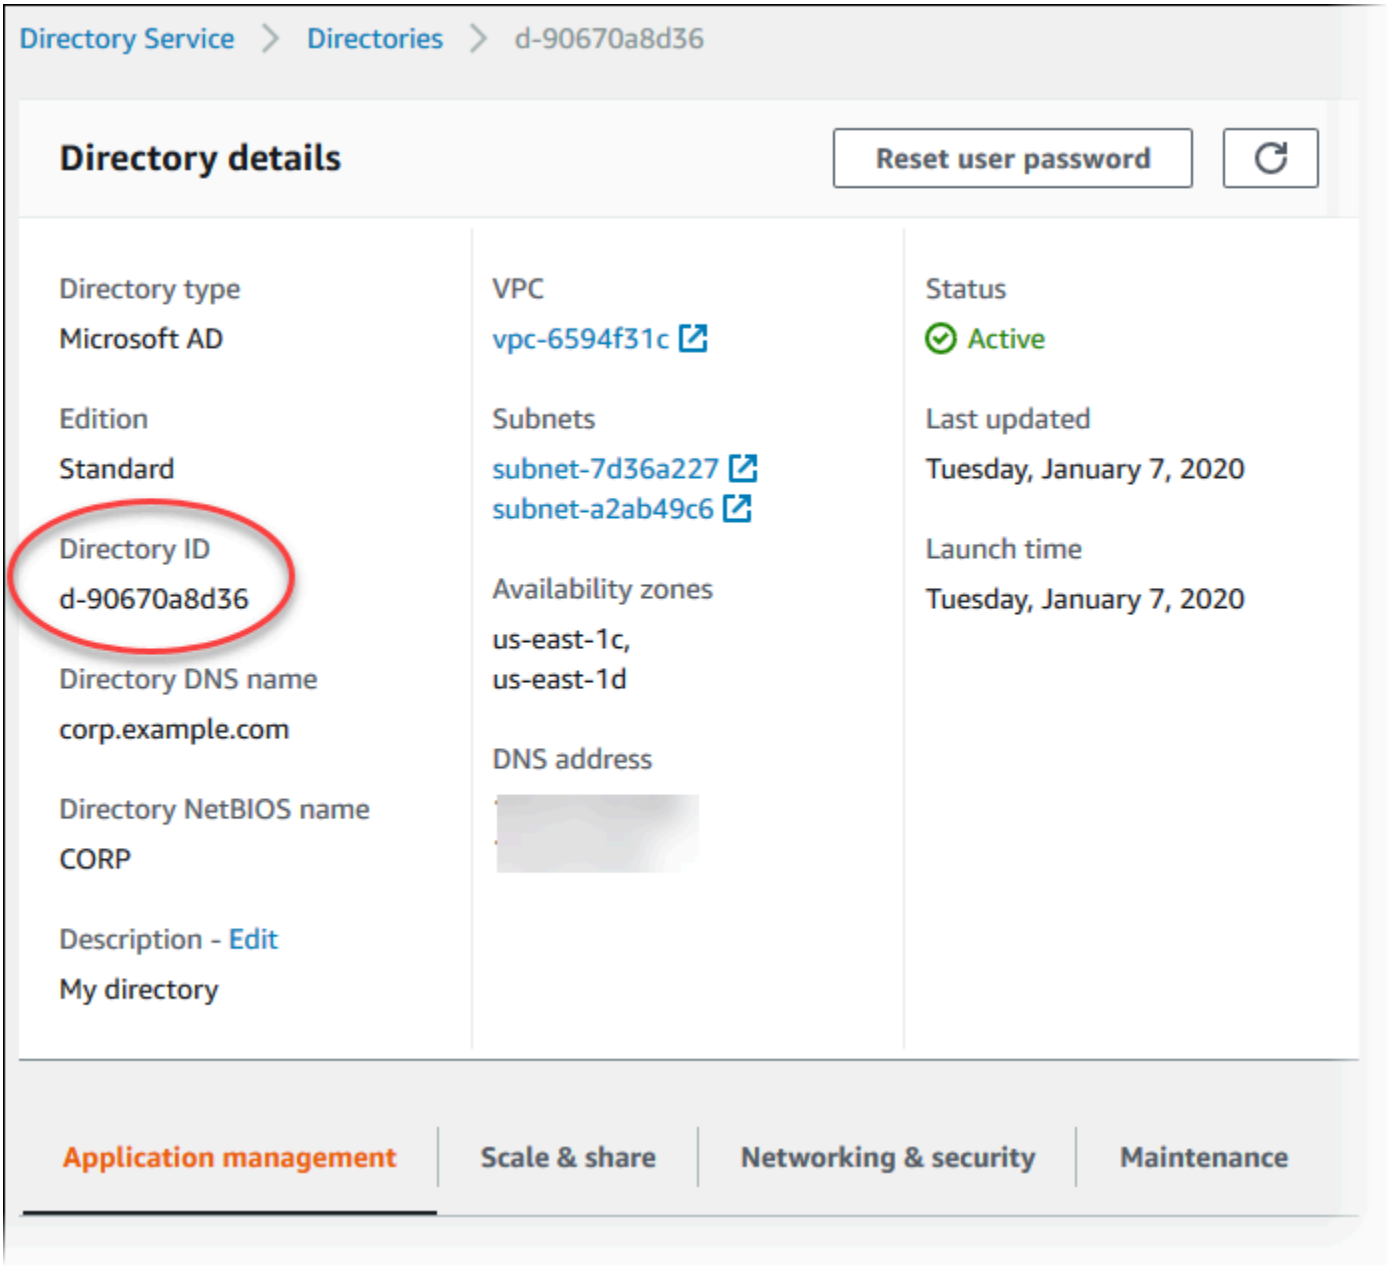
   Subnets

   Subnets for the directory servers. The two subnets must be in different Availability Zones.
7. Review the directory information and make any necessary changes. When the information is correct, choose **Create directory**.



It takes several minutes for the directory to be created. When it has been successfully created, the **Status** value changes to **Active**.

To see information about your directory, choose the directory name in the directory listing. Note the **Directory ID** value because you need this value when you create or modify your Oracle DB instance.



Step 2: Create a trust

If you plan to use AWS Managed Microsoft AD only, move on to Step 3: Configure IAM permissions for Amazon RDS.

To get Kerberos authentication using an on-premises or self-hosted Microsoft Active Directory, create a forest trust or external trust. The trust can be one-way or two-way. For more information about setting up forest trusts using AWS Directory Service, see When to create a trust relationship in the *AWS Directory Service Administration Guide*.

Step 3: Configure IAM permissions for Amazon RDS

To call AWS Directory Service for you, Amazon RDS requires an IAM role that uses the managed IAM policy `AmazonRDSDirectoryServiceAccess`. This role allows Amazon RDS to make calls to the AWS Directory Service.

> **Note**
>
> For the role to allow access, the AWS Security Token Service (AWS STS) endpoint must be activated in the correct AWS Region for your AWS account. AWS STS endpoints are active by default in all AWS Regions, and you can use them without any further actions. For more information, see Activating and deactivating AWS STS in an AWS Region in the *IAM User Guide*.

Creating an IAM role

When you create a DB instance using the AWS Management Console, and the console user has the `iam:CreateRole` permission, the console creates `rds-directoryservice-kerberos-access-role` automatically. Otherwise, you must create the IAM role manually. When you create an IAM role manually, choose `Directory Service`, and attach the AWS managed policy `AmazonRDSDirectoryServiceAccess` to it.

For more information about creating IAM roles for a service, see Creating a role to delegate permissions to an AWS service in the *IAM User Guide*.

> **Note**
>
> The IAM role used for Windows Authentication for RDS for Microsoft SQL Server can't be used for RDS for Oracle.

Creating an IAM trust policy manually

Optionally, you can create resource policies with the required permissions instead of using the managed IAM policy `AmazonRDSDirectoryServiceAccess`. Specify both `directoryservice.rds.amazonaws.com` and `rds.amazonaws.com` as principals.

To limit the permissions that Amazon RDS gives another service for a specific resource, we recommend using the `aws:SourceArn` and `aws:SourceAccount` global condition context keys in

resource policies. The most effective way to protect against the confused deputy problem is to use the `aws:SourceArn` global condition context key with the full ARN of an Amazon RDS resource. For more information, see Preventing cross-service confused deputy problems.

The following example shows how you can use the `aws:SourceArn` and `aws:SourceAccount` global condition context keys in Amazon RDS to prevent the confused deputy problem.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "",
      "Effect": "Allow",
      "Principal": {
        "Service": [
          "directoryservice.rds.amazonaws.com",
          "rds.amazonaws.com"
        ]
      },
      "Action": "sts:AssumeRole",
      "Condition": {
        "ArnLike": {
          "aws:SourceArn": "arn:aws:rds:us-east-1:123456789012:db:mydbinstance"
        },
        "StringEquals": {
          "aws:SourceAccount": "123456789012"
        }
      }
    }
  ]
}
```

For opt-in Regions, you must also include a service principal for that Region in the form of `directoryservice.rds.region_name.amazonaws.com`. For example, in the Africa (Cape Town) Region, use the following trust policy:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "",
      "Effect": "Allow",
```

```
      "Principal": {
        "Service": [
          "directoryservice.rds.amazonaws.com",
          "directoryservice.rds.af-south-1.amazonaws.com",
          "rds.amazonaws.com"
        ]
      },
      "Action": "sts:AssumeRole",
      "Condition": {
        "ArnLike": {
          "aws:SourceArn": "arn:aws:rds:af-south-1:123456789012:db:mydbinstance"
        },
        "StringEquals": {
          "aws:SourceAccount": "123456789012"
        }
      }
    }
  ]
}
```

The role must also have the following IAM policy.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Action": [
        "ds:DescribeDirectories",
        "ds:AuthorizeApplication",
        "ds:UnauthorizeApplication",
        "ds:GetAuthorizedApplicationDetails"
      ],
    "Effect": "Allow",
    "Resource": "*"
    }
  ]
}
```

Step 4: Create and configure users

You can create users with the Active Directory Users and Computers tool, which is one of the Active Directory Domain Services and Active Directory Lightweight Directory Services tools. In this case, *users* are individual people or entities that have access to your directory.

To create users in an AWS Directory Service directory, you must be connected to a Windows-based Amazon EC2 instance that is a member of the AWS Directory Service directory. At the same time, you must be logged in as a user that has privileges to create users. For more information about creating users in your Microsoft Active Directory, see Manage users and groups in AWS Managed Microsoft AD in the *AWS Directory Service Administration Guide*.

Step 5: Enable cross-VPC traffic between the directory and the DB instance

If you plan to locate the directory and the DB instance in the same VPC, skip this step and move on to Step 6: Create or modify an Oracle DB instance.

If you plan to locate the directory and the DB instance in different AWS accounts or VPCs, configure cross-VPC traffic using VPC peering or AWS Transit Gateway. The following procedure enables traffic between VPCs using VPC peering. Follow the instructions in What is VPC peering? in the *Amazon Virtual Private Cloud Peering Guide*.

To enable cross-VPC traffic using VPC peering

1. Set up appropriate VPC routing rules to ensure that network traffic can flow both ways.
2. Ensure that the DB instance's security group can receive inbound traffic from the directory's security group. For more information, see Best practices for AWS Managed Microsoft AD in the *AWS Directory Service Administration Guide*.
3. Ensure that there is no network access control list (ACL) rule to block traffic.

If a different AWS account owns the directory, you must share the directory.

To share the directory between AWS accounts

1. Start sharing the directory with the AWS account that the DB instance will be created in by following the instructions in Tutorial: Sharing your AWS Managed Microsoft AD directory for seamless EC2 Domain-join in the *AWS Directory Service Administration Guide*.
2. Sign in to the AWS Directory Service console using the account for the DB instance, and ensure that the domain has the SHARED status before proceeding.
3. While signed into the AWS Directory Service console using the account for the DB instance, note the **Directory ID** value. You use this directory ID to join the DB instance to the domain.

Step 6: Create or modify an Oracle DB instance

Create or modify an Oracle DB instance for use with your directory. You can use the console, CLI, or RDS API to associate a DB instance with a directory. You can do this in one of the following ways:

- Create a new Oracle DB instance using the console, the create-db-instance CLI command, or the CreateDBInstance RDS API operation.

  For instructions, see Creating an Amazon RDS DB instance.
- Modify an existing Oracle DB instance using the console, the modify-db-instance CLI command, or the ModifyDBInstance RDS API operation.

  For instructions, see Modifying an Amazon RDS DB instance.
- Restore an Oracle DB instance from a DB snapshot using the console, the restore-db-instance-from-db-snapshot CLI command, or the RestoreDBInstanceFromDBSnapshot RDS API operation.

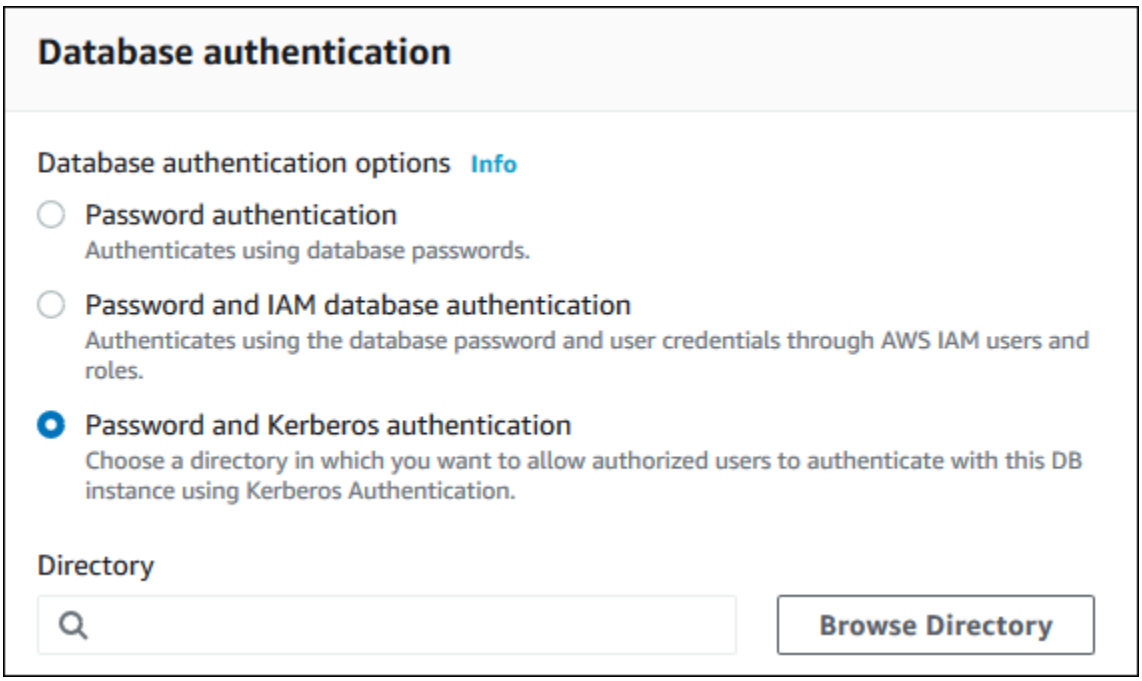
  For instructions, see Restoring to a DB instance.
- Restore an Oracle DB instance to a point-in-time using the console, the restore-db-instance-to-point-in-time CLI command, or the RestoreDBInstanceToPointInTime RDS API operation.

  For instructions, see Restoring a DB instance to a specified time.

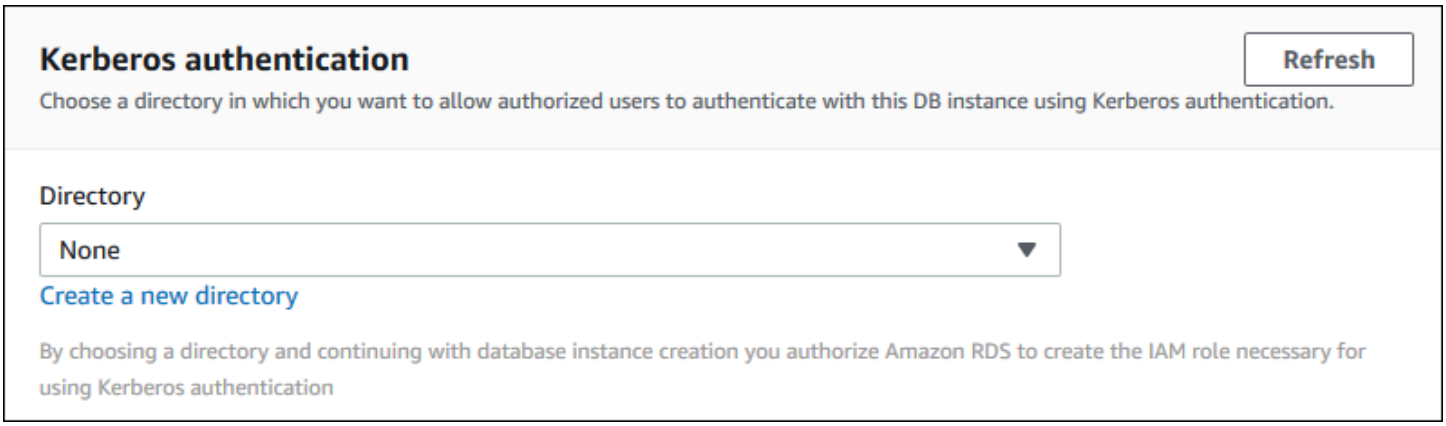
Kerberos authentication is only supported for Oracle DB instances in a VPC. The DB instance can be in the same VPC as the directory, or in a different VPC. When you create or modify the DB instance, do the following:

- Provide the domain identifier (`d-*` identifier) that was generated when you created your directory.
- Provide the name of the IAM role that you created.
- Ensure that the DB instance security group can receive inbound traffic from the directory security group and send outbound traffic to the directory.

When you use the console to create a DB instance, choose **Password and Kerberos authentication** in the **Database authentication** section. Choose **Browse Directory** and then select the directory, or choose **Create a new directory**.



When you use the console to modify or restore a DB instance, choose the directory in the **Kerberos authentication** section, or choose **Create a new directory**.



When you use the AWS CLI, the following parameters are required for the DB instance to be able to use the directory that you created:

- For the `--domain` parameter, use the domain identifier ("d-*" identifier) generated when you created the directory.
- For the `--domain-iam-role-name` parameter, use the role you created that uses the managed IAM policy `AmazonRDSDirectoryServiceAccess`.

For example, the following CLI command modifies a DB instance to use a directory.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier mydbinstance \
    --domain d-ID \
    --domain-iam-role-name role-name
```

For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier mydbinstance ^
    --domain d-ID ^
    --domain-iam-role-name role-name
```

Important

If you modify a DB instance to enable Kerberos authentication, reboot the DB instance after making the change.

Note

MANAGED_SERVICE_USER is a service account whose name is randomly generated by Directory Service for RDS. During the Kerberos authentication setup, RDS for Oracle creates a user with the same name and assigns it the `CREATE SESSION` privilege. The Oracle DB user is identified externally as *MANAGED_SERVICE_USER@EXAMPLE.COM*, where *EXAMPLE.COM* is the name of your domain. Periodically, RDS uses the credentials provided by the Directory Service to log in to your Oracle database. Afterward, RDS immediately destroys the ticket cache.

Step 7: Create Kerberos authentication Oracle logins

Use the Amazon RDS master user credentials to connect to the Oracle DB instance as you do any other DB instance. The DB instance is joined to the AWS Managed Microsoft AD domain. Thus, you can provision Oracle logins and users from the Microsoft Active Directory users and groups in your domain. To manage database permissions, you grant and revoke standard Oracle permissions to these logins.

To allow a Microsoft Active Directory user to authenticate with Oracle

1. Connect to the Oracle DB instance using your Amazon RDS master user credentials.
2. Create an externally authenticated user in Oracle database.

   In the following example, replace *KRBUSER@CORP.EXAMPLE.COM* with the user name and domain name.

   ```
   CREATE USER "KRBUSER@CORP.EXAMPLE.COM" IDENTIFIED EXTERNALLY;
   GRANT CREATE SESSION TO "KRBUSER@CORP.EXAMPLE.COM";
   ```

   Users (both humans and applications) from your domain can now connect to the Oracle DB instance from a domain joined client machine using Kerberos authentication.

Step 8: Configure an Oracle client

To configure an Oracle client, meet the following requirements:

- Create a configuration file named krb5.conf (Linux) or krb5.ini (Windows) to point to the domain. Configure the Oracle client to use this configuration file.
- Verify that traffic can flow between the client host and AWS Directory Service over DNS port 53 over TCP/UDP, Kerberos ports (88 and 464 for managed AWS Directory Service) over TCP, and LDAP port 389 over TCP.
- Verify that traffic can flow between the client host and the DB instance over the database port.

Following is sample content for AWS Managed Microsoft AD.

```
[libdefaults]
 default_realm = EXAMPLE.COM
[realms]
 EXAMPLE.COM = {
  kdc = example.com
  admin_server = example.com
 }
[domain_realm]
 .example.com = CORP.EXAMPLE.COM
 example.com = CORP.EXAMPLE.COM
```

Following is sample content for on-premise Microsoft AD. In your krb5.conf or krb5.ini file, replace *on-prem-ad-server-name* with the name of your on-premises AD server.

```
[libdefaults]
 default_realm = ONPREM.COM
[realms]
 AWSAD.COM = {
  kdc = awsad.com
  admin_server = awsad.com
 }
 ONPREM.COM = {
  kdc = on-prem-ad-server-name
  admin_server = on-prem-ad-server-name
 }
[domain_realm]
 .awsad.com = AWSAD.COM
 awsad.com= AWSAD.COM
 .onprem.com = ONPREM.COM
 onprem.com= ONPREM.COM
```

Note

After you configure your krb5.ini or krb5.conf file, we recommend that you reboot the server.

The following is sample sqlnet.ora content for a SQL*Plus configuration:

```
SQLNET.AUTHENTICATION_SERVICES=(KERBEROS5PRE,KERBEROS5)
SQLNET.KERBEROS5_CONF=path_to_krb5.conf_file
```

For an example of a SQL Developer configuration, see Document 1609359.1 from Oracle Support.

Managing a DB instance in a domain

You can use the console, the CLI, or the RDS API to manage your DB instance and its relationship with your Microsoft Active Directory. For example, you can associate a Microsoft Active Directory to enable Kerberos authentication. You can also disassociate a Microsoft Active Directory to disable Kerberos authentication. You can also move a DB instance to be externally authenticated by one Microsoft Active Directory to another.

For example, using the CLI, you can do the following:

- To reattempt enabling Kerberos authentication for a failed membership, use the modify-db-instance CLI command and specify the current membership's directory ID for the `--domain` option.
- To disable Kerberos authentication on a DB instance, use the modify-db-instance CLI command and specify `none` for the `--domain` option.
- To move a DB instance from one domain to another, use the modify-db-instance CLI command and specify the domain identifier of the new domain for the `--domain` option.

Viewing the status of domain membership

After you create or modify your DB instance, the DB instance becomes a member of the domain. You can view the status of the domain membership for the DB instance in the console or by running the describe-db-instances CLI command. The status of the DB instance can be one of the following:

- `kerberos-enabled` – The DB instance has Kerberos authentication enabled.
- `enabling-kerberos` – AWS is in the process of enabling Kerberos authentication on this DB instance.
- `pending-enable-kerberos` – Enabling Kerberos authentication is pending on this DB instance.
- `pending-maintenance-enable-kerberos` – AWS will attempt to enable Kerberos authentication on the DB instance during the next scheduled maintenance window.
- `pending-disable-kerberos` – Disabling Kerberos authentication is pending on this DB instance.
- `pending-maintenance-disable-kerberos` – AWS will attempt to disable Kerberos authentication on the DB instance during the next scheduled maintenance window.
- `enable-kerberos-failed` – A configuration problem has prevented AWS from enabling Kerberos authentication on the DB instance. Correct the configuration problem before reissuing the command to modify the DB instance.
- `disabling-kerberos` – AWS is in the process of disabling Kerberos authentication on this DB instance.

A request to enable Kerberos authentication can fail because of a network connectivity issue or an incorrect IAM role. If the attempt to enable Kerberos authentication fails when you create or modify a DB instance, make sure that you're using the correct IAM role. Then modify the DB instance to join the domain.

> **Note**
>
> Only Kerberos authentication with Amazon RDS for Oracle sends traffic to the domain's DNS servers. All other DNS requests are treated as outbound network access on your DB instances running Oracle. For more information about outbound network access with Amazon RDS for Oracle, see Setting up a custom DNS server.

Force-rotating Kerberos keys

A secret key is shared between AWS Managed Microsoft AD and Amazon RDS for Oracle DB instance. This key is rotated automatically every 45 days. You can use the following Amazon RDS procedure to force the rotation of this key.

```
SELECT rdsadmin.rdsadmin_kerberos_auth_tasks.rotate_kerberos_keytab AS TASK_ID FROM
 DUAL;
```

> **Note**
>
> In a read replica configuration, this procedure is available only on the source DB instance and not on the read replica.

The SELECT statement returns the ID of the task in a VARCHAR2 data type. You can view the status of an ongoing task in a bdump file. The bdump files are located in the `/rdsdbdata/log/trace` directory. Each bdump file name is in the following format.

```
dbtask-task-id.log
```

You can view the result by displaying the task's output file.

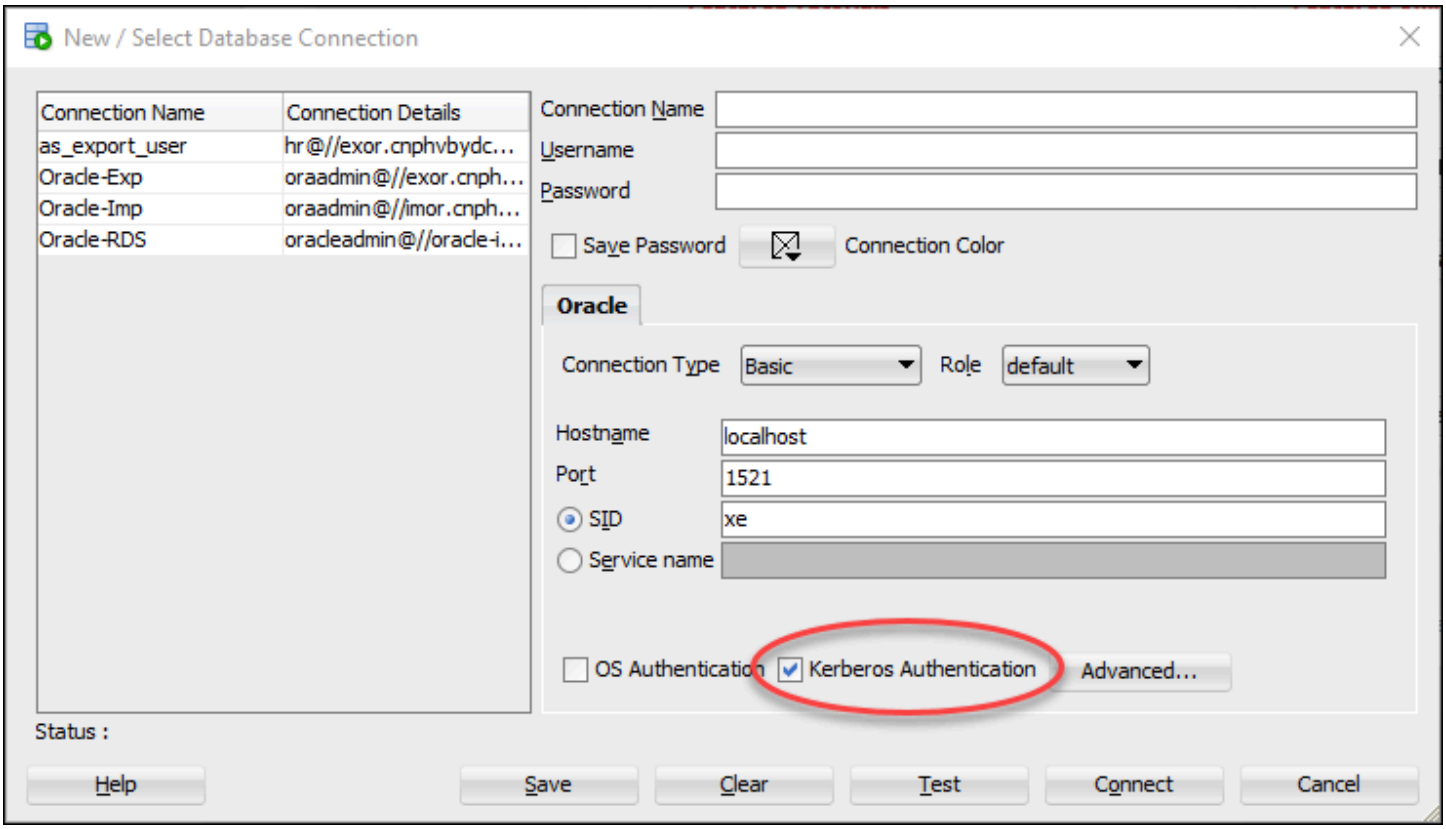
```
SELECT text FROM table(rdsadmin.rds_file_util.read_text_file('BDUMP','dbtask-task-
id.log'));
```

Replace *task-id* with the task ID returned by the procedure.

> **Note**
>
> Tasks are executed asynchronously.

Connecting to Oracle with Kerberos authentication

This section assumes that you have set up your Oracle client as described in Step 8: Configure an Oracle client. To connect to the Oracle DB with Kerberos authentication, log in using the Kerberos authentication type. For example, after launching Oracle SQL Developer, choose **Kerberos Authentication** as the authentication type, as shown in the following example.



To connect to Oracle with Kerberos authentication with SQL*Plus:

1. At a command prompt, run the following command:

```
kinit username
```

Replace *username* with the user name and, at the prompt, enter the password stored in the Microsoft Active Directory for the user.

2. Open SQL*Plus and connect using the DNS name and port number for the Oracle DB instance.

   For more information about connecting to an Oracle DB instance in SQL*Plus, see Connecting to your DB instance using SQL*Plus.

Configuring UTL_HTTP access using certificates and an Oracle wallet

Amazon RDS supports outbound network access on your RDS for Oracle DB instances. To connect your DB instance to the network, you can use the following PL/SQL packages:

`UTL_HTTP`

This package makes HTTP calls from SQL and PL/SQL. You can use it to access data on the Internet over HTTP. For more information, see UTL_HTTP in the Oracle documentation.

`UTL_TCP`

This package provides TCP/IP client-side access functionality in PL/SQL. This package is useful to PL/SQL applications that use Internet protocols and email. For more information, see UTL_TCP in the Oracle documentation.

`UTL_SMTP`

This package provides interfaces to the SMTP commands that enable a client to dispatch emails to an SMTP server. For more information, see UTL_SMTP in the Oracle documentation.

By completing the following tasks, you can configure `UTL_HTTP.REQUEST` to work with websites that require client authentication certificates during the SSL handshake. You can also configure password authentication for `UTL_HTTP` access to websites by modifying the Oracle wallet generation commands and the `DBMS_NETWORK_ACL_ADMIN.APPEND_WALLET_ACE` procedure. For more information, see DBMS_NETWORK_ACL_ADMIN in the Oracle Database documentation.

> **Note**
>
> You can adapt the following tasks for `UTL_SMTP`, which enables you to send emails over SSL/TLS (including Amazon Simple Email Service).

Topics

Considerations when configuring UTL_HTTP access

Before configuring access, consider the following:

- You can use SMTP with the UTL_MAIL option. For more information, see Oracle UTL_MAIL.
- The Domain Name Server (DNS) name of the remote host can be any of the following:
  - Publicly resolvable.
  - The endpoint of an Amazon RDS DB instance.
  - Resolvable through a custom DNS server. For more information, see Setting up a custom DNS server.
  - The private DNS name of an Amazon EC2 instance in the same VPC or a peered VPC. In this case, make sure that the name is resolvable through a custom DNS server. Alternatively, to use the DNS provided by Amazon, you can enable the `enableDnsSupport` attribute in the VPC settings and enable DNS resolution support for the VPC peering connection. For more information, see DNS support in your VPC and Modifying your VPC peering connection.
  - To connect securely to remote SSL/TLS resources, we recommend that you create and upload customized Oracle wallets. By using the Amazon S3 integration with Amazon RDS for Oracle feature, you can download a wallet from Amazon S3 into Oracle DB instances. For information about Amazon S3 integration for Oracle, see Amazon S3 integration.
- You can establish database links between Oracle DB instances over an SSL/TLS endpoint if the Oracle SSL option is configured for each instance. No further configuration is required. For more information, see Oracle Secure Sockets Layer.

Step 1: Get the root certificate for a website

For the RDS for Oracle DB instance to make secure connections to a website, add the root CA certificate. Amazon RDS uses the root certificate to sign the website certificate to the Oracle wallet.

You can get the root certificate in various ways. For example, you can do the following:

1. Use a web server to visit the website secured by the certificate.
2. Download the root certificate that was used for signing.

For AWS services, root certificates typically reside in the Amazon trust services repository.

Step 2: Create an Oracle wallet

Create an Oracle wallet that contains both the web server certificates and the client authentication certificates. The RDS Oracle instance uses the web server certificate to establish a secure connection to the website. The website needs the client certificate to authenticate the Oracle database user.

You might want to configure secure connections without using client certificates for authentication. In this case, you can skip the Java keystore steps in the following procedure.

To create an Oracle wallet

1. Place the root and client certificates in a single directory, and then change into this directory.
2. Convert the .p12 client certificate to the Java keystore.

   > **Note**
   >
   > If you're not using client certificates for authentication, you can skip this step.

   The following example converts the client certificate named *client_certificate.p12* to the Java keystore named *client_keystore.jks*. The keystore is then included in the Oracle wallet. The keystore password is *P12PASSWORD*.

   ```
   orapki wallet pkcs12_to_jks -wallet ./client_certificate.p12 -
   jksKeyStoreLoc ./client_keystore.jks -jksKeyStorepwd P12PASSWORD
   ```

3. Create a directory for your Oracle wallet that is different from the certificate directory.

The following example creates the directory `/tmp/wallet`.

```
mkdir -p /tmp/wallet
```

4. Create an Oracle wallet in your wallet directory.

   The following example sets the Oracle wallet password to *P12PASSWORD*, which is the same password used by the Java keystore in a previous step. Using the same password is convenient, but not necessary. The `-auto_login` parameter turns on the automatic login feature, so that you don't need to specify a password every time you want to access it.

   > **Note**
   >
   > Specify a password other than the prompt shown here as a security best practice.

   ```
   orapki wallet create -wallet /tmp/wallet -pwd P12PASSWORD -auto_login
   ```

5. Add the Java keystore to your Oracle wallet.

   > **Note**
   >
   > If you're not using client certificates for authentication, you can skip this step.

   The following example adds the keystore *client_keystore.jks* to the Oracle wallet named */tmp/wallet*. In this example, you specify the same password for the Java keystore and the Oracle wallet.

   ```
   orapki wallet jks_to_pkcs12 -wallet /tmp/wallet -pwd P12PASSWORD -
   keystore ./client_keystore.jks -jkspwd P12PASSWORD
   ```

6. Add the root certificate for your target website to the Oracle wallet.

   The following example adds a certificate named *Root_CA.cer*.

   ```
   orapki wallet add -wallet /tmp/wallet -trusted_cert -cert ./Root_CA.cer -
   pwd P12PASSWORD
   ```

7. Add any intermediate certificates.

   The following example adds a certificate named *Intermediate.cer*. Repeat this step as many times as need to load all intermediate certificates.

   ```
   orapki wallet add -wallet /tmp/wallet -trusted_cert -cert ./Intermediate.cer -
   pwd P12PASSWORD
   ```

8. Confirm that your newly created Oracle wallet has the required certificates.

   ```
   orapki wallet display -wallet /tmp/wallet -pwd P12PASSWORD
   ```

Step 3: Download your Oracle wallet to your RDS for Oracle instance

In this step, you upload your Oracle wallet to Amazon S3, and then download the wallet from Amazon S3 to your RDS for Oracle instance.

To download your Oracle wallet to your RDS for Oracle DB instance

1. Complete the prerequisites for Amazon S3 integration with Oracle, and add the `S3_INTEGRATION` option to your Oracle DB instance. Ensure that the IAM role for the option has access to the Amazon S3 bucket you are using.

   For more information, see Amazon S3 integration.

2. Log in to your DB instance as the master user, and then create an Oracle directory to hold the Oracle wallet.

   The following example creates an Oracle directory named *WALLET_DIR*.

   ```
   EXEC rdsadmin.rdsadmin_util.create_directory('WALLET_DIR');
   ```

   For more information, see Creating and dropping directories in the main data storage space.

3. Upload the Oracle wallet to your Amazon S3 bucket.

   You can use any supported upload technique.

4. If you're re-uploading an Oracle wallet, delete the existing wallet. Otherwise, skip to the next step.

   The following example removes the existing wallet, which is named *cwallet.sso*.

```
EXEC UTL_FILE.FREMOVE ('WALLET_DIR','cwallet.sso');
```

5. Download the Oracle wallet from your Amazon S3 bucket to the Oracle DB instance.

   The following example downloads the wallet named *cwallet.sso* from the Amazon S3 bucket named *my_s3_bucket* to the DB instance directory named *WALLET_DIR*.

```
SELECT rdsadmin.rdsadmin_s3_tasks.download_from_s3(
      p_bucket_name    =>  'my_s3_bucket',
      p_s3_prefix      =>  'cwallet.sso',
      p_directory_name =>  'WALLET_DIR')
   AS TASK_ID FROM DUAL;
```

6. (Optional) Download a password-protected Oracle wallet.

   Download this wallet only if you want to require a password for every use of the wallet. The following example downloads password-protected wallet *ewallet.p12*.

```
SELECT rdsadmin.rdsadmin_s3_tasks.download_from_s3(
      p_bucket_name    =>  'my_s3_bucket',
      p_s3_prefix      =>  'ewallet.p12',
      p_directory_name =>  'WALLET_DIR')
   AS TASK_ID FROM DUAL;
```

7. Check the status of your DB task.

   Substitute the task ID returned from the preceding steps for *dbtask-1234567890123-4567.log* in the following example.

```
SELECT TEXT FROM
 TABLE(rdsadmin.rds_file_util.read_text_file('BDUMP','dbtask-1234567890123-4567.log'));
```

8. Check the contents of the directory that you're using to store the Oracle wallet.

```
SELECT * FROM TABLE(rdsadmin.rds_file_util.listdir(p_directory => 'WALLET_DIR'));
```

   For more information, see Listing files in a DB instance directory.

Step 4: Grant user permissions for the Oracle wallet

You can either create a new database user or configure an existing user. In either case, you must configure the user to access the Oracle wallet for secure connections and client authentication using certificates.

To grant user permissions for the Oracle wallet

1. Log in your RDS for Oracle DB instance as the master user.
2. If you don't want to configure an existing database user, create a new user. Otherwise, skip to the next step.

   The following example creates a database user named *my-user*.

   ```
   CREATE USER my-user IDENTIFIED BY my-user-pwd;
   GRANT CONNECT TO my-user;
   ```

3. Grant permission to your database user on the directory containing your Oracle wallet.

   The following example grants read access to user *my-user* on directory *WALLET_DIR*.

   ```
   GRANT READ ON DIRECTORY WALLET_DIR TO my-user;
   ```

4. Grant permission to your database user to use the UTL_HTTP package.

   The following PL/SQL program grants UTL_HTTP access to user *my-user*.

   ```
   BEGIN
     rdsadmin.rdsadmin_util.grant_sys_object('UTL_HTTP', UPPER('my-user'));
     END;
   /
   ```

5. Grant permission to your database user to use the UTL_FILE package.

   The following PL/SQL program grants UTL_FILE access to user *my-user*.

   ```
   BEGIN
     rdsadmin.rdsadmin_util.grant_sys_object('UTL_FILE', UPPER('my-user'));
     END;
   /
   ```

Step 5: Configure access to a website from your DB instance

In this step, you configure your Oracle database user so that it can connect to your target website using UTL_HTTP, your uploaded Oracle Wallet, and the client certificate. For more information, see Configuring Access Control to an Oracle Wallet in the Oracle Database documentation.

To configure access to a website from your RDS for Oracle DB instance

1. Log in your RDS for Oracle DB instance as the master user.
2. Create a Host Access Control Entry (ACE) for your user and the target website on a secure port.

   The following example configures *my-user* to access *secret.encrypted-website.com* on secure port 443.

```
BEGIN
  DBMS_NETWORK_ACL_ADMIN.APPEND_HOST_ACE(
    host       => 'secret.encrypted-website.com',
    lower_port => 443,
    upper_port => 443,
    ace        => xs$ace_type(privilege_list => xs$name_list('http'),
                              principal_name => 'my-user',
                              principal_type => xs_acl.ptype_db));
                           -- If the program unit results in PLS-00201, set
                           -- the principal_type parameter to 2 as follows:
                           -- principal_type => 2));
END;
/
```

Important

The preceding program unit can result in the following error: `PLS-00201: identifier 'XS_ACL' must be declared`. If this error is returned, replace the line that assigns a value to `principal_type` with the following line, and then rerun the program unit:

```
principal_type => 2));
```

For more information about constants in the PL/SQL package XS_ACL, see *Real Application Security Administrator's and Developer's Guide* in the Oracle Database documentation.

For more information, see Configuring Access Control for External Network Services in the Oracle Database documentation.

3. (Optional) Create an ACE for your user and target website on the standard port.

   You might need to use the standard port if some web pages are served from the standard web server port (80) instead of the secure port (443).

```
BEGIN
  DBMS_NETWORK_ACL_ADMIN.APPEND_HOST_ACE(
    host       => 'secret.encrypted-website.com',
    lower_port => 80,
    upper_port => 80,
    ace        => xs$ace_type(privilege_list => xs$name_list('http'),
                              principal_name => 'my-user',
                              principal_type => xs_acl.ptype_db));
                           -- If the program unit results in PLS-00201, set
                           -- the principal_type parameter to 2 as follows:
                           -- principal_type => 2));
END;
/
```

4. Confirm that the access control entries exist.

```
SET LINESIZE 150
COLUMN HOST FORMAT A40
COLUMN ACL FORMAT A50

SELECT HOST, LOWER_PORT, UPPER_PORT, ACL
  FROM DBA_NETWORK_ACLS
ORDER BY HOST;
```

5. Grant permission to your database user to use the UTL_HTTP package.

   The following PL/SQL program grants UTL_HTTP access to user *my-user*.

```
BEGIN
  rdsadmin.rdsadmin_util.grant_sys_object('UTL_HTTP', UPPER('my-user'));
  END;
/
```

6. Confirm that related access control lists exist.

```
SET LINESIZE 150
COLUMN ACL FORMAT A50
COLUMN PRINCIPAL FORMAT A20
COLUMN PRIVILEGE FORMAT A10

SELECT ACL, PRINCIPAL, PRIVILEGE, IS_GRANT,
       TO_CHAR(START_DATE, 'DD-MON-YYYY') AS START_DATE,
       TO_CHAR(END_DATE, 'DD-MON-YYYY') AS END_DATE
  FROM DBA_NETWORK_ACL_PRIVILEGES
ORDER BY ACL, PRINCIPAL, PRIVILEGE;
```

7. Grant permission to your database user to use certificates for client authentication and your Oracle wallet for connections.

> **Note**
>
> If you're not using client certificates for authentication, you can skip this step.

```
DECLARE
  l_wallet_path all_directories.directory_path%type;
BEGIN
  SELECT DIRECTORY_PATH
    INTO l_wallet_path
    FROM ALL_DIRECTORIES
   WHERE UPPER(DIRECTORY_NAME)='WALLET_DIR';
  DBMS_NETWORK_ACL_ADMIN.APPEND_WALLET_ACE(
    wallet_path => 'file:/' || l_wallet_path,
    ace         =>  xs$ace_type(privilege_list => xs
$name_list('use_client_certificates'),
                                principal_name => 'my-user',
                                principal_type => xs_acl.ptype_db));
END;
```

```
/
```

Step 6: Test connections from your DB instance to a website

In this step, you configure your database user so that it can connect to the website using UTL_HTTP, your uploaded Oracle Wallet, and the client certificate.

To configure access to a website from your RDS for Oracle DB instance

1. Log in your RDS for Oracle DB instance as a database user with UTL_HTTP permissions.
2. Confirm that a connection to your target website can resolve the host address.

   The following example gets the host address from *secret.encrypted-website.com*.

   ```
   SELECT UTL_INADDR.GET_HOST_ADDRESS(host => 'secret.encrypted-website.com')
     FROM DUAL;
   ```

3. Test a failed connection.

   The following query fails because UTL_HTTP requires the location of the Oracle wallet with the certificates.

   ```
   SELECT UTL_HTTP.REQUEST('secret.encrypted-website.com') FROM DUAL;
   ```

4. Test website access by using UTL_HTTP.SET_WALLET and selecting from DUAL.

   ```
   DECLARE
     l_wallet_path all_directories.directory_path%type;
   BEGIN
     SELECT DIRECTORY_PATH
       INTO l_wallet_path
       FROM ALL_DIRECTORIES
      WHERE UPPER(DIRECTORY_NAME)='WALLET_DIR';
     UTL_HTTP.SET_WALLET('file:/' || l_wallet_path);
   END;
   /

   SELECT UTL_HTTP.REQUEST('secret.encrypted-website.com') FROM DUAL;
   ```

5. (Optional) Test website access by storing your query in a variable and using EXECUTE IMMEDIATE.

```
DECLARE
  l_wallet_path all_directories.directory_path%type;
  v_webpage_sql VARCHAR2(1000);
  v_results     VARCHAR2(32767);
BEGIN
  SELECT DIRECTORY_PATH
    INTO l_wallet_path
    FROM ALL_DIRECTORIES
   WHERE UPPER(DIRECTORY_NAME)='WALLET_DIR';
  v_webpage_sql := 'SELECT UTL_HTTP.REQUEST(''secret.encrypted-website.com'', '''',
 ''file:/' ||l_wallet_path||''') FROM DUAL';
  DBMS_OUTPUT.PUT_LINE(v_webpage_sql);
  EXECUTE IMMEDIATE v_webpage_sql INTO v_results;
  DBMS_OUTPUT.PUT_LINE(v_results);
END;
/
```

6. (Optional) Find the file system location of your Oracle wallet directory.

```
SELECT * FROM TABLE(rdsadmin.rds_file_util.listdir(p_directory => 'WALLET_DIR'));
```

Use the output from the previous command to make an HTTP request. For example, if the directory is *rdsdbdata/userdirs/01*, run the following query.

```
SELECT UTL_HTTP.REQUEST('https://secret.encrypted-website.com/', '',
 'file://rdsdbdata/userdirs/01')
FROM   DUAL;
```

Working with CDBs in RDS for Oracle

In the Oracle multitenant architecture, a container database (CDB) can include customer-created pluggable databases (PDBs). For more information about CDBs, see Introduction to the Multitenant Architecture in the Oracle Database documentation.

Topics

Overview of RDS for Oracle CDBs

You can create an RDS for Oracle DB instance as a container database (CDB) when you run Oracle Database 19c or higher. Starting with Oracle Database 21c, all databases are CDBs. A CDB differs from a non-CDB because it can contain pluggable databases (PDBs), which are called *tenant databases* in RDS for Oracle. A PDB is a portable collection of schemas and objects that appears to an application as a separate database.

You create your initial tenant database (PDB) when you create your CDB instance. In RDS for Oracle, your client application interacts with a PDB rather than the CDB. Your experience with a PDB is mostly identical to your experience with a non-CDB.

Topics

- User accounts and privileges in a CDB
- Parameter group families in a CDB
- Limitations of RDS for Oracle CDBs

Multi-tenant configuration of the CDB architecture

RDS for Oracle supports the *multi-tenant configuration* of the Oracle multitenant architecture, also called the *CDB architecture*. In this configuration, your RDS for Oracle CDB instance can contain 1–30 tenant databases, depending on the database edition and any required option licenses. In Oracle database, a tenant database is a PDB. Your DB instance must use Oracle database release 19.0.0.0.ru-2022-01.rur-2022.r1 or higher.

> **Note**
>
> The Amazon RDS feature is called "multi-tenant" rather than "multitenant" because it is a capability of the RDS platform, not just the Oracle DB engine. The term "Oracle multitenant" refers exclusively to the Oracle database architecture, which is compatible with both on-premises and RDS deployments.

You can configure the following settings:

- Tenant database name
- Tenant database master username
- Tenant database master password
- Tenant database character set
- Tenant database national character set

The tenant database character set can be different from the CDB character set. The same applies to the national character set. After you create your initial tenant database, you can create, modify, or delete tenant databases using RDS APIs. The CDB name defaults to RDSCDB and can't be changed. For more information, see Settings for DB instances and Modifying an RDS for Oracle tenant database.

Single-tenant configuration of the CDB architecture

RDS for Oracle supports a legacy configuration of the Oracle multitenant architecture called the *single-tenant configuration*. In this configuration, an RDS for Oracle CDB instance can contain only one tenant (PDB). You can't create more PDBs later.

Creation and conversion options for CDBs

Oracle Database 21c supports only CDBs, whereas Oracle Database 19c supports both CDBs and non-CDBs. All RDS for Oracle CDB instances support both the multi-tenant and single-tenant configurations.

Creation, conversion, and upgrade options for the Oracle database architecture

The following table shows the different architecture options for creating and upgrading RDS for Oracle databases.

Release	Database creation options	Architecture conversion options	Major version upgrade targets
Oracle Database 21c	CDB architecture only	N/A	N/A
Oracle Database 19c	CDB or non-CDB architecture	Non-CDB to CDB architecture (April 2021 RU or higher)	Oracle Database 21c CDB

As shown in the preceding table, you can't directly upgrade a non-CDB to a CDB in a new major database version. But you can convert an Oracle Database 19c non-CDB to an Oracle Database 19c CDB, and then upgrade the Oracle Database 19c CDB to an Oracle Database 21c CDB. For more information, see Converting an RDS for Oracle non-CDB to a CDB.

Conversion options for CDB architecture configurations

The following table shows the different options for converting the architecture configuration of an RDS for Oracle DB instance.

Current architecture and configuration	Conversion to the single-tenant configuration of the CDB architecture	Conversion to the multi-tenant configuration of the CDB architecture	Conversion to the non-CDB architecture
Non-CDB	Supported	Supported*	N/A
CDB using the single-tenant configuration	N/A	Supported	Not supported
CDB using the multi-tenant configuration	Not supported	N/A	Not supported

* You can't convert a non-CDB to the multi-tenant configuration in a single operation. When you convert a non-CDB to a CDB, the CDB is in the single-tenant configuration. You can then convert the single-tenant to the multi-tenant configuration in a separate operation.

User accounts and privileges in a CDB

In the Oracle multitenant architecture, all user accounts are either *common users* or *local users*. A CDB common user is a database user whose single identity and password are known in the CDB root and in every existing and future PDB. In contrast, a local user exists only in a single PDB.

The RDS master user is a local user account in the PDB, which you name when you create your DB instance. If you create new user accounts, these users will also be local users residing in the PDB. You can't use any user accounts to create new PDBs or modify the state of the existing PDB.

The `rdsadmin` user is a common user account. You can run RDS for Oracle packages that exist in this account, but you can't log in as `rdsadmin`. For more information, see About Common Users and Local Users in the Oracle documentation.

Parameter group families in a CDB

CDBs have their own parameter group families and default parameter values. The CDB parameter group families are as follows:

- oracle-ee-cdb-21

- oracle-se2-cdb-21
- oracle-ee-cdb-19
- oracle-se2-cdb-19

Limitations of RDS for Oracle CDBs

RDS for Oracle supports a subset of features available in an on-premises CDB.

CDB limitations

The following limitations apply to RDS for Oracle at the CDB level:

- You can't connect to a CDB. You always connect to the tenant database (PDB) rather than the CDB. Specify the endpoint for the PDB just as for a non-CDB. The only difference is that you specify *pdb_name* for the database name, where *pdb_name* is the name you chose for your PDB.
- You can't convert a CDB in the multi-tenant configuration to a CDB in the single-tenant conversion. Conversion to the multi-tenant configuration is one-way and irreversible.
- You can't enable or convert to the multi-tenant configuration if your DB instance uses an Oracle database release lower than 19.0.0.0.ru-2022-01.rur-2022.r1.
- You can't use an RDS for Oracle CDB with ORDS 22 and higher. As a workaround, you can either use a lower version of ORDS or use an Oracle Database 19c non-CDB.
- You can enable auditing from within `CDB$ROOT`. You must enable auditing within each PDB individually.

Support for the following features depends on the architecture configuration.

Feature	Supported in single-tenant	Supported in multi-tenant
Oracle Data Guard	Yes	No
Oracle Label Security	No	No
Oracle Enterprise Manager (OEM)	No	No
OEM Agent	No	No

Feature	Supported in single-tenant	Supported in multi-tenant
Database Activity Streams	Yes	No

Tenant database (PDB) limitations

The following limitations apply to tenant databases in the RDS for Oracle multi-tenant configuration:

- You can't defer tenant database operations to the maintenance window. All changes occur immediately.
- You can't add a tenant database to a CDB that uses the single-tenant configuration.
- You can't add or modify multiple tenant databases in a single operation. You can only add or modify them one at a time.
- You can't modify a tenant database to be named `CDB$ROOT` or `PDB$SEED`.
- You can't delete a tenant database if it is the only tenant in the CDB.
- Not all DB instance class types have sufficient resources to support multiple PDBs in an RDS for Oracle CDB instance. An increased PDB count affects the performance and stability of the smaller instance classes and increases the time of most instance-level operations, for example, database upgrades.
- You can't use multiple AWS accounts to create PDBs in the same CDB. PDBs must be owned by the same account as the DB instance that the PDBs are hosted on.
- All PDBs in a CDB use the same endpoint and database listener.
- The following operations aren't supported at the PDB level but are supported at the CDB level:
  - Backup and recovery
  - Database upgrades
  - Maintenance actions
- The following features aren't supported at the PDB level but are supported at the CDB level:
  - Option groups (options are installed on all PDBs on your CDB instance)
  - Parameter groups (all parameters are derived from the parameter group associated with your CDB instance)
- PDB-level operations that are supported in the on-premises CDB architecture but aren't supported in an RDS for Oracle CDB include the following:

> **Note**
>
> The following list is not exhaustive.

- Application PDBs
- Proxy PDBs
- Starting and stopping a PDB
- Unplugging and plugging in PDBs

  To move data into or out of your CDB, use the same techniques as for a non-CDB. For more information about migrating data, see Importing data into Oracle on Amazon RDS.
- Setting options at the PDB level

  The PDB inherits options settings from the CDB option group. For more information about setting options, see Parameter groups for Amazon RDS. For best practices, see Working with DB parameter groups.
- Configuring parameters in a PDB

  The PDB inherits parameter settings from the CDB. For more information about setting option, see Adding options to Oracle DB instances.
- Configuring different listeners for PDBs in the same CDB
- Oracle Flashback features

Configuring an RDS for Oracle CDB

Configuring a CDB is similar to configuring a non-CDB.

Topics

- Creating an RDS for Oracle CDB instance
- Connecting to a PDB in your RDS for Oracle CDB

Creating an RDS for Oracle CDB instance

In RDS for Oracle, creating a CDB is almost identical to creating a non-CDB. The difference is that you choose the Oracle multitenant architecture when creating your DB instance and also choose an architecture configuration: multi-tenant or single-tenant. If you create tags when you create a CDB in the multi-tenant configuration, RDS propagates the tags to the initial tenant database. To create a CDB, use the AWS Management Console, the AWS CLI, or the RDS API.

Console

To create a CDB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the upper-right corner of the Amazon RDS console, choose the AWS Region in which you want to create the CDB instance.
3. In the navigation pane, choose **Databases**.
4. Choose **Create database**.
5. In **Choose a database creation method**, select **Standard Create**.
6. In **Engine options**, choose **Oracle**.
7. For **Database management type**, choose **Amazon RDS**.
8. For **Architecture settings**, choose **Oracle multitenant architecture**.
9. For **Architecture configuration**, do either of the following:
   - Choose **Multi-tenant configuration** and proceed to the next step.
   - Choose **Single-tenant configuration** and skip to Step 11.
10. (Multi-tenant configuration) For **Tenant database settings**, make the following changes:
    - For **Tenant database name**, enter the name of your initial PDB. The PDB name must be different from the CDB name, which defaults to RDSCDB.
    - For **Tenant database master username**, enter the master username of your PDB. You can't use the tenant database master username to log in to the CDB itself.
    - Either enter a password in **Tenant database master password** or choose **Auto generate a password**.
    - For **Tenant database character set**, choose a character set for the PDB. You can choose a tenant database character set that is different from the CDB character set.

The default PDB character set is **AL32UTF8**. If you choose a nondefault PDB character set, CDB creation might be slower.

> **Note**
>
> You can't create multiple tenant databases as part of the CDB creation process. You can only add PDBs to an already existing CDB.

11. (Single-tenant configuration) Choose the settings that you want based on the options listed in Settings for DB instances. Note the following:
    - For **Master username**, enter the name for a local user in your PDB. You can't use the master username to log in to the CDB root.
    - For **Initial database name**, enter the name of your PDB. You can't name the CDB, which has the default name RDSCDB.
12. Choose **Create database**.

AWS CLI

To create a CDB in the multi-tenant configuration, use the create-db-instance command with the following parameters:

- `--db-instance-identifier`
- `--db-instance-class`
- `--engine { oracle-ee-cdb | oracle-se2-cdb }`
- `--master-username`
- `--master-user-password`
- `--multi-tenant` (for the single-tenant configuration, either don't specify `multi-tenant` or specify `--no-multi-tenant`)
- `--allocated-storage`
- `--backup-retention-period`

For information about each setting, see Settings for DB instances.

This following example creates an RDS for Oracle DB instance named *my-cdb-inst* in the multi-tenant configuration. If you specify `--no-multi-tenant` or don't specify `--multi-tenant`, the default CDB configuration is single-tenant. The engine is `oracle-ee-cdb`: a command that specifies `oracle-ee` and `--multi-tenant` fails with an error. The initial tenant database is named *mypdb*.

Example

For Linux, macOS, or Unix:

```
aws rds create-db-instance \
    --engine oracle-ee-cdb \
    --db-instance-identifier my-cdb-inst \
    --multi-tenant \
    --db-name mypdb \
    --allocated-storage 250 \
    --db-instance-class db.t3.large \
    --master-username pdb_admin \
    --master-user-password pdb_admin_password \
    --backup-retention-period 3
```

For Windows:

```
aws rds create-db-instance ^
    --engine oracle-ee-cdb ^
    --db-instance-identifier my-cdb-inst ^
    --multi-tenant ^
    --db-name mypdb ^
    --allocated-storage 250 ^
    --db-instance-class db.t3.large ^
    --master-username pdb_admin ^
    --master-user-password pdb_admin_password ^
    --backup-retention-period 3
```

Note

Specify a password other than the prompt shown here as a security best practice.

This command produces output similar to the following. The database name, character set, national character set, and master user aren't included in the output. You can view this information by using the CLI command `describe-tenant-databases`.

```
{
    "DBInstance": {
        "DBInstanceIdentifier": "my-cdb-inst",
        "DBInstanceClass": "db.t3.large",
        "MultiTenant": true,
        "Engine": "oracle-ee-cdb",
        "DBResourceId": "db-ABCDEFGJIJKLMNOPQRSTUVWXYZ",
        "DBInstanceStatus": "creating",
        "AllocatedStorage": 250,
        "PreferredBackupWindow": "04:59-05:29",
        "BackupRetentionPeriod": 3,
        "DBSecurityGroups": [],
        "VpcSecurityGroups": [
            {
                "VpcSecurityGroupId": "sg-0a1bcd2e",
                "Status": "active"
            }
        ],
        "DBParameterGroups": [
            {
                "DBParameterGroupName": "default.oracle-ee-cdb-19",
                "ParameterApplyStatus": "in-sync"
            }
        ],
        "DBSubnetGroup": {
            "DBSubnetGroupName": "default",
            "DBSubnetGroupDescription": "default",
            "VpcId": "vpc-1234567a",
            "SubnetGroupStatus": "Complete",
            ...
```

RDS API

To create a DB instance by using the Amazon RDS API, call the CreateDBInstance operation.

For information about each setting, see Settings for DB instances.

Connecting to a PDB in your RDS for Oracle CDB

You can use a utility like SQL*Plus to connect to a PDB. To download Oracle Instant Client, which includes a standalone version of SQL*Plus, see Oracle Instant Client Downloads.

To connect SQL*Plus to your PDB, you need the following information:

- PDB name
- Database user name and password
- Endpoint for your DB instance
- Port number

For information about finding the preceding information, see Finding the endpoint of your RDS for Oracle DB instance.

Example To connect to your PDB using SQL*Plus

In the following examples, substitute your master user for *master_user_name*. Also, substitute the endpoint for your DB instance, and then include the port number and the Oracle SID. The SID value is the name of the PDB that you specified when you created your DB instance, and not the DB instance identifier.

For Linux, macOS, or Unix:

```
sqlplus 'master_user_name@(DESCRIPTION=(ADDRESS=(PROTOCOL=TCP)(HOST=endpoint)
(PORT=port))(CONNECT_DATA=(SID=pdb_name)))'
```

For Windows:

```
sqlplus master_user_name@(DESCRIPTION=(ADDRESS=(PROTOCOL=TCP)(HOST=endpoint)
(PORT=port))(CONNECT_DATA=(SID=pdb_name)))
```

You should see output similar to the following.

```
SQL*Plus: Release 19.0.0.0.0 Production on Mon Aug 21 09:42:20 2021
```

After you enter the password for the user, the SQL prompt appears.

```
SQL>
```

Note

The shorter format connection string (Easy connect or EZCONNECT), such as `sqlplus username/password@LONGER-THAN-63-CHARS-RDS-ENDPOINT-HERE:1521/database-identifier`, might encounter a maximum character limit and should not be used to connect.

Backing up and restoring a CDB

You can back up and restore your CDB using either RDS DB snapshots or Recovery Manager (RMAN).

Backing up and restoring a CDB using DB snapshots

DB snapshots work similarly in the CDB and non-CDB architectures. The principal differences are as follows:

- When you restore a DB snapshot of a CDB, you can't rename the CDB. The CDB is named RDSCDB and can't be changed.
- When you restore a DB snapshot of a CDB, you can't rename PDBs. You can modify the PDB name by using the modify-tenant-database command.
- To find tenant databases in a snapshot, use the CLI command describe-db-snapshot-tenant-databases.
- You can't directly interact with the tenant databases in a CDB snapshot that uses the multi-tenant architecture configuration. If you restore the DB snapshot, you restore all its tenant databases.
- RDS for Oracle implicitly copies tags on a tenant database to the tenant database in a DB snapshot. When you restore a tenant database, the tags appear in the restored database.
- If you restore a DB snapshot and specify new tags using the `--tags` parameter, the new tags overwrite all existing tags.
- If you take a DB snapshot of a CDB instance that has tags, and you specify `--copy-tags-to-snapshot`, RDS for Oracle copies tags from the tenant databases to the tenant databases in the snapshot.

For more information, see Oracle Database considerations.

Backing up and restoring a CDB using RMAN

To learn how to back up and restore a CDB or individual tenant database using RMAN, see Performing common RMAN tasks for Oracle DB instances.

Converting an RDS for Oracle non-CDB to a CDB

You can change the architecture of an Oracle database from the non-CDB architecture to the Oracle multitenant architecture, also called the *CDB architecture*, with the `modify-db-instance` command. In most cases, this technique is preferable to creating a new CDB and importing data. The conversion operation incurs downtime.

When you upgrade your database engine version, you can't change the database architecture in the same operation. Therefore, to upgrade an Oracle Database 19c non-CDB to an Oracle Database 21c CDB, you first need to convert the non-CDB to a CDB in one step, and then upgrade the 19c CDB to a 21c CDB in a separate step.

The non-CDB conversion operation has the following requirements:

- You must specify `oracle-ee-cdb` or `oracle-se2-cdb` for the DB engine type. These are the only supported values.
- Your DB engine must use Oracle Database 19c with an April 2021 or later release update (RU).

The operation has the following limitations:

- You can't convert a CDB to a non-CDB. You can only convert a non-CDB to a CDB.
- You can't convert a non-CDB to the multi-tenant configuration in a single `modify-db-instance` call. After you convert a non-CDB to a CDB, your CDB is in the single-tenant configuration. To convert the single-tenant configuration to the multi-tenant configuration, run `modify-db-instance` again. For more information, see Converting the single-tenant configuration to multi-tenant.
- You can't convert a primary or replica database that has Oracle Data Guard enabled. To convert a non-CDB that has read replicas, first delete all read replicas.
- You can't upgrade the DB engine version and convert a non-CDB to a CDB in the same operation.

Before converting your non-CDB, consider the following:

- The considerations for option and parameter groups are the same as for upgrading the DB engine. For more information, see Considerations for Oracle DB upgrades.
- If your DB instance has the `OEMAGENT` option installed, a best practice is to remove this option before you convert your non-CDB. After your non-CDB is converted to a CDB, reinstall the option. For more information, see Oracle Management Agent for Enterprise Manager Cloud Control.

Console

To convert a non-CDB to a CDB

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the upper-right corner of the Amazon RDS console, choose the AWS Region where your DB instance resides.
3. In the navigation pane, choose **Databases**, and then choose the non-CDB instance that you want to convert to a CDB instance.
4. Choose **Modify**.
5. For **Architecture settings**, select **Oracle multitenant architecture**. After conversion, your CDB will be in the single-tenant configuration.
6. (Optional) For **DB parameter group**, choose a new parameter group for your CDB instance. The same parameter group considerations apply when converting a DB instance as when upgrading a DB instance. For more information, see Parameter group considerations.
7. (Optional) For **Option group**, choose a new option group for your CDB instance. The same option group considerations apply when converting a DB instance as when upgrading a DB instance. For more information, see Option group considerations.
8. When all the changes are as you want them, choose **Continue** and check the summary of modifications.
9. (Optional) Choose **Apply immediately** to apply the changes immediately. Choosing this option can cause downtime in some cases. For more information, see Schedule modifications setting.
10. On the confirmation page, review your changes. If they are correct, choose **Modify DB instance**.

    Or choose **Back** to edit your changes or **Cancel** to cancel your changes.

AWS CLI

To convert the non-CDB on your DB instance to a CDB in the single-tenant configuration, set `--engine` to `oracle-ee-cdb` or `oracle-se2-cdb` in the AWS CLI command modify-db-instance. For more information, see Settings for DB instances.

The following example converts the DB instance named *my-non-cdb* and specifies a custom option group and parameter group.

Example

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier my-non-cdb \
    --engine oracle-ee-cdb \
    --option-group-name custom-option-group \
    --db-parameter-group-name custom-parameter-group
```

For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier my-non-cdb ^
    --engine oracle-ee-cdb ^
    --option-group-name custom-option-group ^
    --db-parameter-group-name custom-parameter-group
```

RDS API

To convert a non-CDB to a CDB, specify `Engine` in the RDS API operation ModifyDBInstance.

Converting the single-tenant configuration to multi-tenant

You can modify the architecture of an RDS for Oracle CDB from the single-tenant configuration to the multi-tenant configuration. Before and after the conversion, your CDB contains a single tenant database (PDB).

During the conversion, RDS for Oracle migrates the following metadata to the new tenant database:

- The master username

- The database name
- The character set
- The national character set

Before the conversion, you could view the preceding information by using the `describe-db-instances` command. After the conversion, you view the information by using the `describe-tenant-database` command.

The conversion has the following requirements and limitations:

- After you convert the single-tenant architecture configuration to the multi-tenant configuration, you can't later convert the architecture back to the single-tenant configuration. The operation is irreversible.
- The tags for the DB instance propagate to the initial tenant DB created during the conversion.
- You can't convert a primary or replica database that has Oracle Data Guard enabled.
- You can't upgrade the DB engine version and convert to the multi-tenant configuration in the same operation.
- Your IAM policy must have permission to create a tenant database.

Console

To convert a CDB using the single-tenant configuration to the multi-tenant configuration

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the upper-right corner of the Amazon RDS console, choose the AWS Region where your DB instance resides.
3. In the navigation pane, choose **Databases**, and then choose the non-CDB instance that you want to convert to a CDB instance.
4. Choose **Modify**.
5. For **Architecture settings**, select **Oracle multitenant architecture**.
6. For **Architecture configuration**, select **Multi-tenant configuration**.
7. (Optional) For **DB parameter group**, choose a new parameter group for your CDB instance. The same parameter group considerations apply when converting a DB instance as when upgrading a DB instance.

8. (Optional) For **Option group**, choose a new option group for your CDB instance. The same option group considerations apply when converting a DB instance as when upgrading a DB instance.
9. When all the changes are as you want them, choose **Continue** and check the summary of modifications.
10. Choose **Apply immediately**. This option is required when you switch to a multi-tenant configuration. Note that this option can cause downtime in some cases.
11. On the confirmation page, review your changes. If they are correct, choose **Modify DB instance**.

    Or choose **Back** to edit your changes or **Cancel** to cancel your changes.

AWS CLI

To convert a CDB using the single-tenant configuration to the multi-tenant configuration, specify `--multi-tenant` in the AWS CLI command modify-db-instance.

The following example converts the DB instance named `my-st-cdb` from the single-tenant configuration to the multi-tenant configuration. The `--apply-immediately` option is required.

Example

For Linux, macOS, or Unix:

```
aws rds modify-db-instance --region us-east-1\
    --db-instance-identifier my-st-cdb \
    --multi-tenant \
    --apply-immediately
```

For Windows:

```
aws rds modify-db-instance --region us-east-1 ^
    --db-instance-identifier my-st-cdb ^
    --multi-tenant ^
    --apply-immediately
```

The output looks something like the following.

```
{
```

```
    "DBInstance": {
        "DBInstanceIdentifier": "my-st-cdb",
        "DBInstanceClass": "db.r5.large",
        "MultiTenant": false,
        "Engine": "oracle-ee-cdb",
        "DBResourceId": "db-AB1CDE2FGHIJK34LMNOPRLXTXU",
        "DBInstanceStatus": "modifying",
        "MasterUsername": "admin",
        "DBName": "ORCL",
        ...
        "EngineVersion": "19.0.0.0.ru-2022-01.rur-2022-01.r1",
        "AutoMinorVersionUpgrade": true,
        "ReadReplicaDBInstanceIdentifiers": [],
        "LicenseModel": "bring-your-own-license",
        "OptionGroupMemberships": [
            {
                "OptionGroupName": "default:oracle-ee-cdb-19",
                "Status": "in-sync"
            }
        ],
        ...
        "PendingModifiedValues": {
            "MultiTenant": "true"
        }
    }
}
```

Adding an RDS for Oracle tenant database to your CDB instance

In the RDS for Oracle multi-tenant configuration, a tenant database is a PDB. To add a tenant database, make sure you meet the following prerequisites:

- Your CDB has the multi-tenant configuration enabled. For more information, see Multi-tenant configuration of the CDB architecture.
- You have the necessary IAM permissions to create the tenant database.

You can add a tenant database using the AWS Management Console, the AWS CLI, or the RDS API. You can't add multiple tenant databases in a single operation: you must add them one at a time. If the CDB has backup retention enabled, Amazon RDS backs up the DB instance before and after it adds a new tenant database.

Console

To add a tenant database to your DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the upper-right corner of the Amazon RDS console, choose the AWS Region in which you want to create the tenant database.
3. In the navigation pane, choose **Databases**.
4. Choose the CDB instance to which you want to add a tenant database. Your DB instance must use the multi-tenant configuration of the CDB architecture.
5. Choose **Actions** and then **Add tenant database**.
6. For **Tenant database settings**, do the following:

   - For **Tenant database name**, enter the name of your new PDB.
   - For **Tenant database master username**, enter the name of the master user for your PDB. This master user is different from the master user of the CDB.
   - Either enter a password in **Tenant database master password** or select **Auto generate a password**.
   - For **Tenant database character set**, choose a character set for the PDB. The default is **AL32UTF8**. You can choose a PDB character set that is different from the CDB character set.
   - For **Tenant database national character set**, choose a national character set for the PDB. The default is **AL32UTF8**. The national character set specifies the encoding only for columns that use the NCHAR data type (NCHAR, NVARCHAR2, and NCLOB) and doesn't affect database metadata.

   For more information about the preceding settings, see Settings for DB instances.
7. Choose **Add tenant**.

AWS CLI

To add a tenant database to your CDB with the AWS CLI, use the command create-tenant-database with the following required parameters:

- `--db-instance-identifier`

- `--tenant-db-name`
- `--master-username`
- `--master-user-password`

This following example creates a tenant database named *mypdb2* in the RDS for Oracle CDB instance named *my-cdb-inst*. The PDB character set is UTF-16.

Example

For Linux, macOS, or Unix:

```
aws rds create-tenant-database --region us-east-1 \
    --db-instance-identifier my-cdb-inst \
    --tenant-db-name mypdb2 \
    --master-username mypdb2-admin \
    --master-user-password mypdb2-pwd \
    --character-set-name UTF-16
```

For Windows:

```
aws rds create-tenant-database --region us-east-1 \
    --db-instance-identifier my-cdb-inst ^
    --tenant-db-name mypdb2 ^
    --master-username mypdb2-admin ^
    --master-user-password mypdb2-pwd ^
    --character-set-name UTF-16
```

The output looks similar to the following.

```
...}
    "TenantDatabase" :
         {
            "DbiResourceId" : "db-abc123",
            "TenantDatabaseResourceId" : "tdb-bac567",
            "TenantDatabaseArn" : "arn:aws:rds:us-east-1:123456789012:db:my-cdb-
inst:mypdb2",
            "DBInstanceIdentifier" : "my-cdb-inst",
            "TenantDBName" : "mypdb2",
            "Status" : "creating",
            "MasterUsername" : "mypdb2",
```

```
            "CharacterSetName" : "UTF-16",
            ...
        }
}...
```

Modifying an RDS for Oracle tenant database

You can modify only the PDB name and the master user password of a tenant database in your CDB. Note the following requirements and limitations:

- To modify the settings of a tenant database in your DB instance, the tenant database must exist.
- You can't modify multiple tenant databases in a single operation. You can only modify one tenant database at a time.
- You can't change the name of a tenant database to `CDB$ROOT` or `PDB$SEED`.

You can modify PDBs using the AWS Management Console, the AWS CLI, or the RDS API.

Console

To modify the PDB name or master password of a tenant database

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the upper-right corner of the Amazon RDS console, choose the AWS Region in which you want to create the tenant database.
3. In the navigation pane, choose **Databases**.
4. Choose the tenant database whose database name or master user password you want to modify.
5. Choose **Modify**.
6. For **Tenant database settings**, do any of the following:
   - For **Tenant database name**, enter the new name of your new PDB.
   - For **Tenant database master password**, enter a new password.
7. Choose **Modify tenant**.

AWS CLI

To modify a tenant database using the AWS CLI, call the modify-tenant-database command with the following parameters:

- `--db-instance-identifier` *value*
- `--tenant-db-name` *value*
- `[--new-tenant-db-name` *value*`]`
- `[--master-user-password` *value*`]`

The following example renames tenant database `pdb1` to `pdb-hr` on DB instance `my-cdb-inst`.

Example

For Linux, macOS, or Unix:

```
aws rds modify-tenant-database --region us-east-1 \
    --db-instance-identifier my-cdb-inst \
    --tenant-db-name pdb1 \
    --new-tenant-db-name pdb-hr
```

For Windows:

```
aws rds modify-tenant-database --region us-east-1 ^
    --db-instance-identifier my-cdb-inst ^
    --tenant-db-name pdb1 ^
    --new-tenant-db-name pdb-hr
```

This command produces output similar to the following.

```
{
    "TenantDatabase" : {
        "DbiResourceId" : "db-abc123",
        "TenantDatabaseResourceId" : "tdb-bac567",
        "TenantDatabaseArn" : "arn:aws:rds:us-east-1:123456789012:db:my-cdb-inst:pdb1",
        "DBInstanceIdentifier" : "my-cdb-inst",
        "TenantDBName" : "pdb1",
        "Status" : "modifying",
        "MasterUsername" : "tenant-admin-user"
```

```
        "Port" : "6555",
        "CharacterSetName" : "UTF-16",
        "MaxAllocatedStorage" : "1000",
        "ParameterGroups": [
            {
                "ParameterGroupName": "pdb1-params",
                "ParameterApplyStatus": "in-sync"
            }
        ],
        "OptionGroupMemberships": [
            {
                "OptionGroupName": "pdb1-options",
                "Status": "in-sync"
            }
        ],
        "PendingModifiedValues": {
            "TenantDBName": "pdb-hr"
        }
    }
}
```

Deleting an RDS for Oracle tenant database from your CDB

You can delete a tenant database (PDB) using the AWS Management Console, the AWS CLI, or the RDS API. Consider the following prerequisites and limitations:

- The tenant database and DB instance must exist.
- For the deletion to succeed, one of the following situations must exist:
  - The tenant database and DB instance are available.

    > **Note**
    >
    > You can take a final snapshot, but only if the tenant database and DB instance were in an available state before you issued the `delete-tenant-database` command.

  - The tenant database is being created.
  - The DB instance is modifying the tenant database.
- You can't delete multiple tenant databases in a single operation.
- You can't delete a tenant database if it is the only tenant in the CDB.

Console

To delete a tenant database

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**, and then choose the tenant database that you want to delete.
3. For **Actions**, choose **Delete**.
4. To create a final DB snapshot for the DB instance, choose **Create final snapshot?**.
5. If you chose to create a final snapshot, enter the **Final snapshot name**.
6. Enter **`delete me`** in the box.
7. Choose **Delete**.

AWS CLI

To delete a tenant database using the AWS CLI, call the delete-tenant-database command with the following parameters:

- `--db-instance-identifier` *value*
- `--tenant-db-name` *value*
- `[--skip-final-snapshot | --no-skip-final-snapshot]`
- `[--final-snapshot-identifier` *value*`]`

This following example deletes the tenant database named *pdb-test* from the CDB named *my-cdb-inst*. By default, the operation creates a final snapshot.

Example

For Linux, macOS, or Unix:

```
aws rds delete-tenant-database --region us-east-1 \
    --db-instance-identifier my-cdb-inst \
    --tenant-db-name pdb-test \
    --final-snapshot-identifier final-snap-pdb-test
```

For Windows:

```
aws rds delete-tenant-database --region us-east-1 ^
    --db-instance-identifier my-cdb-inst ^
    --tenant-db-name pdb-test ^
    --final-snapshot-identifier final-snap-pdb-test
```

This command produces output similar to the following.

```
{
    "TenantDatabase" : {
        "DbiResourceId" : "db-abc123",
        "TenantDatabaseResourceId" : "tdb-bac456",
        "TenantDatabaseArn" : "arn:aws:rds:us-east-1:123456789012:db:my-cdb-inst:pdb-
test",
        "DBInstanceIdentifier" : "my-cdb-inst",
        "TenantDBName" : "pdb-test",
        "Status" : "deleting",
        "MasterUsername" : "pdb-test-admin"
        "Port" : "6555",
        "CharacterSetName" : "UTF-16",
        "MaxAllocatedStorage" : "1000",
        "ParameterGroups": [
            {
                "ParameterGroupName": "tenant-1-params",
                "ParameterApplyStatus": "in-sync"
            }
        ],
        "OptionGroupMemberships": [
            {
                "OptionGroupName": "tenant-1-options",
                "Status": "in-sync"
            }
        ]
    }
}
```

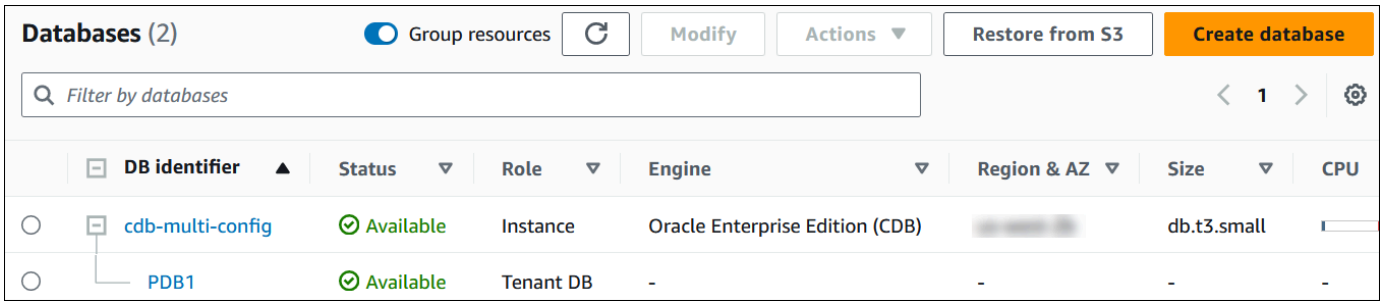
Viewing tenant database details

You can view details about a tenant database in the same way that you can for a non-CDB or CDB.

Console

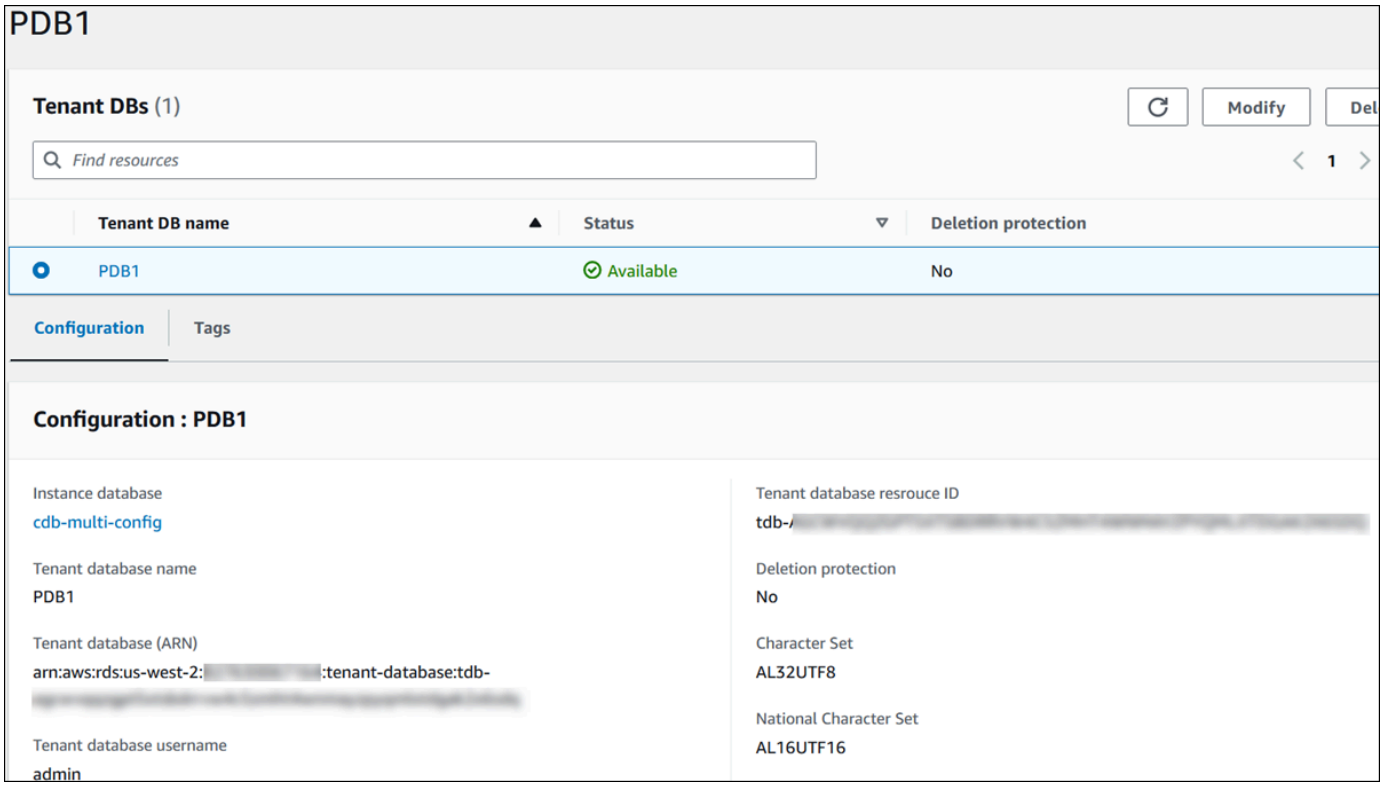
To view details about a tenant database

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the upper-right corner of the Amazon RDS console, choose the AWS Region where your DB instance resides.
3. In the navigation pane, choose **Databases**.



In the preceding image, the sole tenant database (PDB) appears as a child of the DB instance.

4. Choose the name of a tenant database.



AWS CLI

To see details about your PDBs, use the AWS CLI command describe-tenant-databases.

This following example describes all tenant databases in the specified Region.

Example

For Linux, macOS, or Unix:

```
aws rds describe-tenant-databases --region us-east-1
```

For Windows:

```
aws rds describe-tenant-databases --region us-east-1
```

This command produces output similar to the following.

```
    "TenantDatabases" : [
         {
            "DBInstanceIdentifier" : "my-cdb-inst",
            "TenantDBName" : "pdb-test",
            "Status" : "available",
            "MasterUsername" : "pdb-test-admin",
            "DbiResourceId" : "db-abc123",
            "TenantDatabaseResourceId" : "tdb-bac456",
            "TenantDatabaseArn" : "arn:aws:rds:us-east-1:123456789012:db:my-cdb-
inst:pdb-test",
            "CharacterSetName": "AL32UTF8",
            "NcharCharacterSetName": "AL16UTF16",
            "DeletionProtection": false,
            "PendingModifiedValues": {
                 "MasterUserPassword": "****"
            },
            "TagList": []
         },
         {

            "DBInstanceIdentifier" : "my-cdb-inst2",
            "TenantDBName" : "pdb-dev",
            "Status" : "modifying",
            "MasterUsername" : "masterrdsuser"
```

```
            "DbiResourceId" : "db-xyz789",
            "TenantDatabaseResourceId" : "tdb-ghp890",
            "TenantDatabaseArn" : "arn:aws:rds:us-east-1:123456789012:db:my-cdb-
inst2:pdb-dev",
            "CharacterSetName": "AL32UTF8",
            "NcharCharacterSetName": "AL16UTF16",
            "DeletionProtection": false,
            "PendingModifiedValues": {
                 "MasterUserPassword": "****"
            },
            "TagList": []
         },
         ... other truncated data
```

The following example describes the tenant databases on DB instance `my-cdb-inst` in the specified Region.

Example

For Linux, macOS, or Unix:

```
aws rds describe-tenant-databases --region us-east-1 \
    --db-instance-identifier my-cdb-inst
```

For Windows:

```
aws rds describe-tenant-databases --region us-east-1 ^
    --db-instance-identifier my-cdb-inst
```

This command produces output similar to the following.

```
{
    "TenantDatabase": {
        "TenantDatabaseCreateTime": "2023-10-19T23:55:30.046Z",
        "DBInstanceIdentifier": "my-cdb-inst",
        "TenantDBName": "pdb-hr",
        "Status": "creating",
        "MasterUsername": "tenant-admin-user",
        "DbiResourceId": "db-abc123",
        "TenantDatabaseResourceId": "tdb-bac567",
        "TenantDatabaseARN": "arn:aws:rds:us-west-2:579508833180:pdb-hr:tdb-
abcdefghi1jklmno2p3qrst4uvw5xy6zabc7defghi8jklmn90op",
```

```
        "CharacterSetName": "AL32UTF8",
        "NcharCharacterSetName": "AL16UTF16",
        "DeletionProtection": false,
        "PendingModifiedValues": {
            "MasterUserPassword": "****"
        },
        "TagList": [
            {
                "Key": "TEST",
                "Value": "testValue"
            }
        ]
    }
}
```

The following example describes tenant database pdb1 on DB instance `my-cdb-inst` in the US East (N. Virginia) Region.

Example

For Linux, macOS, or Unix:

```
aws rds describe-tenant-databases --region us-east-1 \
--db-instance-identifier my-cdb-inst \
--tenant-db-name pdb1
```

For Windows:

```
aws rds describe-tenant-databases --region us-east-1 ^
--db-instance-identifier my-cdb-inst ^
--tenant-db-name pdb1
```

This command produces output similar to the following.

```
{
    "TenantDatabases" : [
        {
            "DbiResourceId" : "db-abc123",
            "TenantDatabaseResourceId" : "tdb-bac567",
            "TenantDatabaseArn" : "arn:aws:rds:us-east-1:123456789012:db:my-cdb-
inst:pdb1"
            "DBInstanceIdentifier" : "my-cdb-inst",
```

```
            "TenantDBName" : "pdb1",
            "Status" : "ACTIVE",
            "MasterUsername" : "masterawsuser"
            "Port" : "1234",
            "CharacterSetName": "UTF-8",
            "ParameterGroups": [
                {
                    "ParameterGroupName": "tenant-custom-pg",
                    "ParameterApplyStatus": "in-sync"
                }
            ],
            {
            "OptionGroupMemberships": [
                {
                    "OptionGroupName": "tenant-custom-og",
                    "Status": "in-sync"
                }
            ]
        }
    ]
}
```

Upgrading your CDB

You can upgrade a CDB to a different Oracle Database release. For example, you can upgrade an Oracle Database 19c CDB to an Oracle Database 21c CDB. You can't change the database architecture during an upgrade. Thus, you can't upgrade a non-CDB to a CDB or upgrade a CDB to a non-CDB.

The procedure for upgrading a CDB to a CDB is the same as for upgrading a non-CDB to a non-CDB. For more information, see Upgrading the RDS for Oracle DB engine.

Administering your RDS for Oracle DB instance

Following are the common management tasks that you perform with an RDS for Oracle DB instance. Some tasks are the same for all RDS DB instances. Other tasks are specific to RDS for Oracle.

The following tasks are common to all RDS databases, but Oracle Database has special considerations. For example, you connect to an Oracle database using the Oracle clients SQL*Plus and SQL Developer.

Task area	Relevant documentation
Instance classes, storage, and PIOPS If you are creating a production instance, learn how instance classes, storage types, and Provisioned IOPS work in Amazon RDS.	RDS for Oracle DB instance classes Amazon RDS storage types
Multi-AZ deployments A production DB instance should use Multi-AZ deployments. Multi-AZ deployments provide increased availability, data durability, and fault tolerance for DB instances.	Configuring and managing a Multi-AZ deployment
Amazon VPC If your AWS account has a default virtual private cloud (VPC), then your DB instance is automatically created inside the default VPC. If your account doesn't have a default VPC, and you want the DB instance in a VPC, create the VPC and subnet groups before you create the instance.	Working with a DB instance in a VPC
Security groups By default, DB instances use a firewall that prevents access. Make sure that you create a security group with the correct IP addresses and network configuration to access the DB instance.	Controlling access with security groups
Parameter groups	Parameter groups for Amazon RDS

Task area	Relevant documentation
If your DB instance is going to require specific database parameters, create a parameter group before you create the DB instance.	
Option groups If your DB instance requires specific database options, create an option group before you create the DB instance.	Adding options to Oracle DB instances
Connecting to your DB instance After creating a security group and associating it to a DB instance, you can connect to the DB instance using any standard SQL client application such as Oracle SQL*Plus.	Connecting to your RDS for Oracle DB instance
Backup and restore You can configure your DB instance to take automated backups, or take manual snapshots, and then restore instances from the backups or snapshots.	Backing up, restoring, and exporting data
Monitoring You can monitor an Oracle DB instance by using CloudWatch Amazon RDS metrics, events, and enhanced monitoring.	Viewing metrics in the Amazon RDS console Viewing Amazon RDS events
Log files You can access the log files for your Oracle DB instance.	Monitoring Amazon RDS log files

Following, you can find a description for Amazon RDS–specific implementations of common DBA tasks for RDS Oracle. To deliver a managed service experience, Amazon RDS doesn't provide shell access to DB instances. Also, RDS restricts access to certain system procedures and tables that require advanced privileges. In many of the tasks, you run the `rdsadmin` package, which is an Amazon RDS–specific tool that enables you to administer your database.

The following are common DBA tasks for DB instances running Oracle:

- System tasks

Disconnecting a session	Amazon RDS method: `rdsadmin.rdsadmin_util.disconnect` Oracle method: `alter system disconnect session`
Terminating a session	Amazon RDS method: `rdsadmin.rdsadmin_util.kill` Oracle method: `alter system kill session`
Canceling a SQL statement in a session	Amazon RDS method: `rdsadmin.rdsadmin_util.cancel` Oracle method: `alter system cancel sql`
Enabling and disabling restricted sessions	Amazon RDS method: `rdsadmin.rdsadmin_util.restricted_session` Oracle method: `alter system enable restricted session`
Flushing the shared pool	Amazon RDS method: `rdsadmin.rdsadmin_util.flush_shared_pool` Oracle method: `alter system flush shared_pool`
Flushing the buffer cache	Amazon RDS method: `rdsadmin.rdsadmin_util.flush_buffer_cache` Oracle method: `alter system flush buffer_cache`
Granting SELECT or EXECUTE privileges to SYS objects	Amazon RDS method: `rdsadmin.rdsadmin_util.grant_sys_object` Oracle method: `grant`
Revoking SELECT or EXECUTE privileges on SYS objects	Amazon RDS method: `rdsadmin.rdsadmin_util.revoke_sys_object` Oracle method: `revoke`

Managing RDS_X$ views for Oracle DB instances	Amazon RDS method: `rdsadmin.rdsadmin_util.create_sys_x$_view` Oracle method: `CREATE VIEW`
Granting privileges to non-master users	Amazon RDS method: `grant`
Creating custom functions to verify passwords	Amazon RDS method: `rdsadmin.rdsadmin_password_verify.create_verify_function` Amazon RDS method: `rdsadmin.rdsadmin_password_verify.create_passthrough_verify_fcn`
Setting up a custom DNS server	—
Listing allowed system diagnostic events	Amazon RDS method: `rdsadmin.rdsadmin_util.list_allowed_system_events` Oracle method: —
Setting system diagnostic events	Amazon RDS method: `rdsadmin.rdsadmin_util.set_allowed_system_events` Oracle method: `ALTER SYSTEM SET EVENTS 'set_event_clause'`
Listing system diagnostic events that are set	Amazon RDS method: `rdsadmin.rdsadmin_util.list_set_system_events` Oracle method: `ALTER SESSION SET EVENTS 'IMMEDIATE EVENTDUMP(SYSTEM)'`
Unsetting system diagnostic events	Amazon RDS method: `rdsadmin.rdsadmin_util.unset_system_event` Oracle method: `ALTER SYSTEM SET EVENTS 'unset_event_clause'`

- Database tasks

Changing the global name of a database	Amazon RDS method: `rdsadmin.rdsadmin_util.rename_global_name` Oracle method: `alter database rename`
Creating and sizing tablespaces	Amazon RDS method: `create tablespace` Oracle method: `alter database`
Setting the default tablespace	Amazon RDS method: `rdsadmin.rdsadmin_util.alter_default_tablespace` Oracle method: `alter database default tablespace`
Setting the default temporary tablespace	Amazon RDS method: `rdsadmin.rdsadmin_util.alter_default_temp_tablespace` Oracle method: `alter database default temporary tablespace`
Creating a temporary tablespace on the instance store	Amazon RDS method: `rdsadmin.rdsadmin_util.create_inst_store_tmp_tblspace` Oracle method: `create temporary tablespace`
Checkpointing a database	Amazon RDS method: `rdsadmin.rdsadmin_util.checkpoint` Oracle method: `alter system checkpoint`
Setting distributed recovery	Amazon RDS method: `rdsadmin.rdsadmin_util.enable_distr_recovery` Oracle method: `alter system enable distributed recovery`

Setting the database time zone	Amazon RDS method: `rdsadmin.rdsadmin_util.alter_db_time_zone` Oracle method: `alter database set time_zone`
Working with Oracle external tables	—
Generating performance reports with Automatic Workload Repository (AWR)	Amazon RDS method: `rdsadmin.rdsadmin_diagnostic_util` procedures Oracle method: `dbms_workload_repository` package
Adjusting database links for use with DB instances in a VPC	—
Setting the default edition for a DB instance	Amazon RDS method: `rdsadmin.rdsadmin_util.alter_default_edition` Oracle method: `alter database default edition`
Enabling auditing for the SYS.AUD$ table	Amazon RDS method: `rdsadmin.rdsadmin_master_util.audit_all_sys_aud_table` Oracle method: `audit`
Disabling auditing for the SYS.AUD$ table	Amazon RDS method: `rdsadmin.rdsadmin_master_util.noaudit_all_sys_aud_table` Oracle method: `noaudit`
Cleaning up interrupted online index builds	Amazon RDS method: `rdsadmin.rdsadmin_dbms_repair.online_index_clean` Oracle method: `dbms_repair.online_index_clean`

Skipping corrupt blocks	Amazon RDS method: Several `rdsadmin.rdsadmin_dbms_repair` procedures Oracle method: `dbms_repair` package
Resizing tablespaces, data files, and temp files	Amazon RDS method: `rdsadmin.rdsadmin_util.resize_temp_tablespace`, `rdsadmin.rdsadmin_util.resize_tempfile`, or `rdsadmin.rdsadmin_util.autoextend_tempfile` procedures `rdsadmin.rdsadmin_util.resize_datafile` or `rdsadmin.rdsadmin_util.autoextend_datafile` procedure Oracle method: —
Purging the recycle bin	Amazon RDS method: `EXEC rdsadmin.rdsadmin_util.purge_dba_recyclebin` Oracle method: `purge dba_recyclebin`
Setting the default displayed values for full redaction	Amazon RDS method: `EXEC rdsadmin.rdsadmin_util.dbms_redact_upd_full_rdct_val` Oracle method: `exec dbms_redact.UPDATE_FULL_REDACTION_VALUES`

- Log tasks

Setting force logging	Amazon RDS method: `rdsadmin.rdsadmin_util.force_logging` Oracle method: `alter database force logging`

Setting supplemental logging	Amazon RDS method: `rdsadmin.rdsadmin_util.alter_supplemental_logging` Oracle method: `alter database add supplemental log`
Switching online log files	Amazon RDS method: `rdsadmin.rdsadmin_util.switch_logfile` Oracle method: `alter system switch logfile`
Adding online redo logs	Amazon RDS method: `rdsadmin.rdsadmin_util.add_logfile`
Dropping online redo logs	Amazon RDS method: `rdsadmin.rdsadmin_util.drop_logfile`
Resizing online redo logs	—
Retaining archived redo logs	Amazon RDS method: `rdsadmin.rdsadmin_util.set_configuration`

Downloading archived redo logs from Amazon S3	Amazon RDS method: `rdsadmin.rdsadmin_archive_log_download.download_log_with_seqnum` Amazon RDS method: `rdsadmin.rdsadmin_archive_log_download.download_logs_in_seqnum_range`
Accessing online and archived redo logs	Amazon RDS method: `rdsadmin.rdsadmin_master_util.create_archivelog_dir` Amazon RDS method: `rdsadmin.rdsadmin_master_util.create_onlinelog_dir`

- RMAN tasks

Validating database files in RDS for Oracle	Amazon RDS method: `rdsadmin_rman_util. procedure` Oracle method: `RMAN VALIDATE`

Enabling and disabling block change tracking	Amazon RDS method: `rdsadmin_rman_util . procedure` Oracle method: `ALTER DATABASE`
Crosschecking archived redo logs	Amazon RDS method: `rdsadmin_rman_util .crosscheck_archivelog` Oracle method: `RMAN BACKUP`
Backing up archived redo log files	Amazon RDS method: `rdsadmin_rman_util . procedure` Oracle method: `RMAN BACKUP`
Performing a full database backup	Amazon RDS method: `rdsadmin_rman_util .backup_database_full` Oracle method: `RMAN BACKUP`
Performing an incremental database backup	Amazon RDS method: `rdsadmin_rman_util .backup_database_incremental` Oracle method: `RMAN BACKUP`

Backing up a tablespace	Amazon RDS method: `rdsadmin_rman_util.backup_database_tablespace` Oracle method: `RMAN BACKUP`

- Oracle Scheduler tasks

Modifying DBMS_SCHEDULER jobs	Amazon RDS method: `dbms_scheduler.set_attribute` Oracle method: `dbms_scheduler.set_attribute`
Modifying AutoTask maintenance windows	Amazon RDS method: `dbms_scheduler.set_attribute` Oracle method: `dbms_scheduler.set_attribute`
Setting the time zone for Oracle Scheduler jobs	Amazon RDS method: `dbms_scheduler.set_scheduler_attribute` Oracle method: `dbms_scheduler.set_scheduler_attribute`

Turning off Oracle Scheduler jobs owned by SYS	Amazon RDS method: `rdsadmin.rdsadmin_dbms_scheduler.disable` Oracle method: `dbms_scheduler.disable`
Turning on Oracle Scheduler jobs owned by SYS	Amazon RDS method: `rdsadmin.rdsadmin_dbms_scheduler.enable` Oracle method: `dbms_scheduler.enable`
Modifying the Oracle Scheduler repeat interval for jobs of CALENDAR type	Amazon RDS method: `rdsadmin.rdsadmin_dbms_scheduler.set_attribute` Oracle method: `dbms_scheduler.set_attribute`
Modifying the Oracle Scheduler repeat interval for jobs of NAMED type	Amazon RDS method: `rdsadmin.rdsadmin_dbms_scheduler.set_attribute` Oracle method: `dbms_scheduler.set_attribute`

Turning off autocommit for Oracle Scheduler job creation	Amazon RDS method: `rdsadmin.rdsadmin_dbms_scheduler.set_no_commit_flag` Oracle method: `dbms_isched.set_no_commit_flag`

- Diagnostic tasks

Listing incidents	Amazon RDS method: `rdsadmin.rdsadmin_adrci_util.list_adrci_incidents` Oracle method: ADRCI command `show incident`
Listing problems	Amazon RDS method: `rdsadmin.rdsadmin_adrci_util.list_adrci_problem` Oracle method: ADRCI command `show problem`
Creating incident packages	Amazon RDS method: `rdsadmin.rdsadmin_adrci_util.create_adrci_package` Oracle method: ADRCI command `ips create package`

Showing trace files	Amazon RDS method: `rdsadmin.rdsadmin_adrci_util.show_adrci_tracefile` Oracle method: ADRCI command `show tracefile`

- Other tasks

Creating and dropping directories in the main data storage space	Amazon RDS method: `rdsadmin.rdsadmin_util.create_directory` Oracle method: `CREATE DIRECTORY` Amazon RDS method: `rdsadmin.rdsadmin_util.drop_directory` Oracle method: `DROP DIRECTORY`
Listing files in a DB instance directory	Amazon RDS method: `rdsadmin.rds_file_util.listdir` Oracle method: —

Reading files in a DB instance directory	Amazon RDS method: `rdsadmin.rds_file_util.read_text_file` Oracle method: —
Accessing Opatch files	Amazon RDS method: `rdsadmin.rds_file_util.read_text_file` or `rdsadmin.tracefile_listing` Oracle method: `opatch`
Setting parameters for advisor tasks	Amazon RDS method: `rdsadmin.rdsadmin_util.advisor_task_set_parameter` Oracle method: Various stored package procedures
Disabling AUTO_STATS_ADVISOR_TASK	Amazon RDS method: `rdsadmin.rdsadmin_util.advisor_task_drop` Oracle method: —
Re-enabling AUTO_STATS_ADVISOR_TASK	Amazon RDS method: `rdsadmin.rdsadmin_util.dbms_stats_init` Oracle method: —

You can also use Amazon RDS procedures for Amazon S3 integration with Oracle and for running OEM Management Agent database tasks. For more information, see Amazon S3 integration and Administering the Management Agent.

Performing common system tasks for Oracle DB instances

Following, you can find how to perform certain common DBA tasks related to the system on your Amazon RDS DB instances running Oracle. To deliver a managed service experience, Amazon RDS doesn't provide shell access to DB instances, and restricts access to certain system procedures and tables that require advanced privileges.

Topics

Disconnecting a session

To disconnect the current session by ending the dedicated server process, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.disconnect`. The `disconnect` procedure has the following parameters.

Parameter name	Data type	Default	Required	Description
sid	number	—	Yes	The session identifier.
serial	number	—	Yes	The serial number of the session.
method	varchar	'IMMEDIATE'	No	Valid values are 'IMMEDIATE' or 'POST_TRANSACTION'.

The following example disconnects a session.

```
begin
    rdsadmin.rdsadmin_util.disconnect(
        sid    => sid,
        serial => serial_number);
end;
/
```

To get the session identifier and the session serial number, query the V$SESSION view. The following example gets all sessions for the user AWSUSER.

```
SELECT SID, SERIAL#, STATUS FROM V$SESSION WHERE USERNAME = 'AWSUSER';
```

The database must be open to use this method. For more information about disconnecting a session, see ALTER SYSTEM in the Oracle documentation.

Terminating a session

To terminate a session, use the Amazon RDS procedure rdsadmin.rdsadmin_util.kill. The kill procedure has the following parameters.

Parameter name	Data type	Default	Required	Description
sid	number	—	Yes	The session identifier.

Parameter name	Data type	Default	Required	Description
serial	number	—	Yes	The serial number of the session.
method	varchar	null	No	Valid values are 'IMMEDIATE' or 'PROCESS' . If you specify IMMEDIATE , it has the same effect as running the following statement: `ALTER SYSTEM KILL SESSION 'sid,serial#' IMMEDIATE` If you specify PROCESS, you terminate the processes associated with a session. Only specify PROCESS if terminating the session using IMMEDIATE was unsuccessful.

To get the session identifier and the session serial number, query the V$SESSION view. The following example gets all sessions for the user *AWSUSER*.

```
SELECT SID, SERIAL#, STATUS FROM V$SESSION WHERE USERNAME = 'AWSUSER';
```

The following example terminates a session.

```
BEGIN
    rdsadmin.rdsadmin_util.kill(
        sid    => sid,
        serial => serial_number,
        method => 'IMMEDIATE');
```

```
END;
/
```

The following example terminates the processes associated with a session.

```
BEGIN
    rdsadmin.rdsadmin_util.kill(
        sid    => sid,
        serial => serial_number,
        method => 'PROCESS');
END;
/
```

Canceling a SQL statement in a session

To cancel a SQL statement in a session, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.cancel`.

> **Note**
>
> This procedure is supported for Oracle Database 19c (19.0.0) and all higher major and minor versions of RDS for Oracle.

The `cancel` procedure has the following parameters.

Parameter name	Data type	Default	Required	Description
`sid`	number	—	Yes	The session identifier.
`serial`	number	—	Yes	The serial number of the session.
`sql_id`	varchar2	null	No	The SQL identifier of the SQL statement.

The following example cancels a SQL statement in a session.

```
begin
```

```
    rdsadmin.rdsadmin_util.cancel(
        sid    => sid,
        serial => serial_number,
        sql_id => sql_id);
end;
/
```

To get the session identifier, the session serial number, and the SQL identifier of a SQL statement, query the V$SESSION view. The following example gets all sessions and SQL identifiers for the user AWSUSER.

```
select SID, SERIAL#, SQL_ID, STATUS from V$SESSION where USERNAME = 'AWSUSER';
```

Enabling and disabling restricted sessions

To enable and disable restricted sessions, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.restricted_session`. The `restricted_session` procedure has the following parameters.

Parameter name	Data type	Default	Yes	Description
p_enable	boolean	true	No	Set to `true` to enable restricted sessions, `false` to disable restricted sessions.

The following example shows how to enable and disable restricted sessions.

```
/* Verify that the database is currently unrestricted. */

SELECT LOGINS FROM V$INSTANCE;

LOGINS
-------
ALLOWED

/* Enable restricted sessions */

EXEC rdsadmin.rdsadmin_util.restricted_session(p_enable => true);
```

```
/* Verify that the database is now restricted. */

SELECT LOGINS FROM V$INSTANCE;

LOGINS
----------
RESTRICTED

/* Disable restricted sessions */

EXEC rdsadmin.rdsadmin_util.restricted_session(p_enable => false);

/* Verify that the database is now unrestricted again. */

SELECT LOGINS FROM V$INSTANCE;

LOGINS
-------
ALLOWED
```

Flushing the shared pool

To flush the shared pool, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.flush_shared_pool`. The `flush_shared_pool` procedure has no parameters.

The following example flushes the shared pool.

```
EXEC rdsadmin.rdsadmin_util.flush_shared_pool;
```

Flushing the buffer cache

To flush the buffer cache, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.flush_buffer_cache`. The `flush_buffer_cache` procedure has no parameters.

The following example flushes the buffer cache.

```
EXEC rdsadmin.rdsadmin_util.flush_buffer_cache;
```

Flushing the database smart flash cache

To flush the database smart flash cache, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.flush_flash_cache`. The `flush_flash_cache` procedure has no parameters. The following example flushes the database smart flash cache.

```
EXEC rdsadmin.rdsadmin_util.flush_flash_cache;
```

For more information about using the database smart flash cache with RDS for Oracle, see Storing temporary data in an RDS for Oracle instance store.

Granting SELECT or EXECUTE privileges to SYS objects

Usually you transfer privileges by using roles, which can contain many objects. To grant privileges to a single object, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.grant_sys_object`. The procedure grants only privileges that the master user has already been granted through a role or direct grant.

The `grant_sys_object` procedure has the following parameters.

> **Important**
>
> For all parameter values, use uppercase unless you created the user with a case-sensitive identifier. For example, if you run `CREATE USER myuser` or `CREATE USER MYUSER`, the data dictionary stores `MYUSER`. However, if you use double quotes in `CREATE USER "MyUser"`, the data dictionary stores `MyUser`.

Parameter name	Data type	Default	Required	Description
p_obj_name	varchar2	—	Yes	The name of the object to grant privileges for. The object can be a directory, function, package, procedure, sequence, table, or view.

Parameter name	Data type	Default	Required	Description
				Object names must be spelled exactly as they appear in DBA_OBJECTS . Most system objects are defined in uppercase , so we recommend that you try that first.
p_grantee	varchar2	—	Yes	The name of the object to grant privileges to. The object can be a schema or a role.
p_privilege	varchar2	null	Yes	—
p_grant_option	boolean	false	No	Set to true to use the with grant option.

The following example grants select privileges on an object named V_$SESSION to a user named USER1.

```
begin
    rdsadmin.rdsadmin_util.grant_sys_object(
        p_obj_name  => 'V_$SESSION',
        p_grantee   => 'USER1',
        p_privilege => 'SELECT');
end;
/
```

The following example grants select privileges on an object named V_$SESSION to a user named USER1 with the grant option.

```
begin
    rdsadmin.rdsadmin_util.grant_sys_object(
        p_obj_name     => 'V_$SESSION',
        p_grantee      => 'USER1',
        p_privilege    => 'SELECT',
```

```
        p_grant_option => true);
end;
/
```

To be able to grant privileges on an object, your account must have those privileges granted to it directly with the grant option, or via a role granted using `with admin option`. In the most common case, you may want to grant SELECT on a DBA view that has been granted to the SELECT_CATALOG_ROLE role. If that role isn't already directly granted to your user using `with admin option`, then you can't transfer the privilege. If you have the DBA privilege, then you can grant the role directly to another user.

The following example grants the SELECT_CATALOG_ROLE and EXECUTE_CATALOG_ROLE to USER1. Since the `with admin option` is used, USER1 can now grant access to SYS objects that have been granted to SELECT_CATALOG_ROLE.

```
GRANT SELECT_CATALOG_ROLE TO USER1 WITH ADMIN OPTION;
GRANT EXECUTE_CATALOG_ROLE to USER1 WITH ADMIN OPTION;
```

Objects already granted to PUBLIC do not need to be re-granted. If you use the `grant_sys_object` procedure to re-grant access, the procedure call succeeds.

Revoking SELECT or EXECUTE privileges on SYS objects

To revoke privileges on a single object, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.revoke_sys_object`. The procedure only revokes privileges that the master account has already been granted through a role or direct grant.

The `revoke_sys_object` procedure has the following parameters.

Parameter name	Data type	Default	Required	Description
p_obj_name	varchar2	—	Yes	The name of the object to revoke privileges for. The object can be a directory, function, package, procedure, sequence, table, or view. Object names must be spelled exactly as they

Parameter name	Data type	Default	Required	Description
				appear in DBA_OBJECTS . Most system objects are defined in upper case, so we recommend you try that first.
p_revokee	varchar2	—	Yes	The name of the object to revoke privileges for. The object can be a schema or a role.
p_privilege	varchar2	null	Yes	—

The following example revokes select privileges on an object named V_$SESSION from a user named USER1.

```
begin
    rdsadmin.rdsadmin_util.revoke_sys_object(
        p_obj_name  => 'V_$SESSION',
        p_revokee   => 'USER1',
        p_privilege => 'SELECT');
end;
/
```

Managing RDS_X$ views for Oracle DB instances

You might need to access SYS.X$ fixed tables, which are only accessible by SYS. To create SYS.RDS_X$ views on eligible X$ tables, use the procedures in the rdsadmin.rdsadmin_util package. Your master user is automatically granted the privilege SELECT ... WITH GRANT OPTION on the RDS_X$ views.

The rdsadmin.rdsadmin_util procedures are available in the following database engine versions:

- 21.0.0.0.ru-2023-10.rur-2023-10.r1 and higher Oracle Database 21c versions
- 19.0.0.0.ru-2023-10.rur-2023-10.r1 and higher Oracle Database 19c versions

> **Important**
>
> Internally, the `rdsadmin.rdsadmin_util` package creates views on X$ tables. The X$ tables are internal system objects that aren't described in the Oracle Database documentation. We recommend that you test specific views in your non-production database and only create views in your production database under the guidance of Oracle Support.

List X$ fixed tables eligible for use in RDS_X$ views

To list X$ tables that are eligible for use in RDS_X$ views, use the RDS procedure `rdsadmin.rdsadmin_util.list_allowed_sys_x$_views`. This procedure accepts no parameters. The following statements lists all eligible X$ tables (sample output included).

```
SQL> SET SERVEROUTPUT ON
SQL> SELECT * FROM TABLE(rdsadmin.rdsadmin_util.list_allowed_sys_x$_views);

'X$BH'
'X$K2GTE'
'X$KCBWBPD'
'X$KCBWDS'
'X$KGLLK'
'X$KGLOB'
'X$KGLPN'
'X$KSLHOT'
'X$KSMSP'
'X$KSPPCV'
'X$KSPPI'
'X$KSPPSV'
'X$KSQEQ'
'X$KSQRS'
'X$KTUXE'
'X$KQRFP'
```

The list of eligible X$ tables can change over time. To make sure that your list of eligible X$ fixed tables is current, rerun `list_allowed_sys_x$_views` periodically.

Creating SYS.RDS_X$ views

To create an RDS_X$ view on an eligible X$ table, use the RDS procedure `rdsadmin.rdsadmin_util.create_sys_x$_view`. You can only create views for the tables listed in the output of `rdsadmin.rdsadmin_util.list_allowed_sys_x$_views`. The `create_sys_x$_view` procedure accepts the following parameters.

Parameter name	Data type	Default	Required	Description
`p_x$_tbl`	varchar2	Null	Yes	A valid X$ table name. The value must be one of the X$ tables reported by `list_allowed_sys_x$_views` .
`p_force_creation`	Boolean	FALSE	No	A value indicating whether to force creation of an RDS_X$ view that already exists for an X$ table. By default, RDS won't create a view if it already exists. To force creation, set this parameter to TRUE.

The following example creates the SYS.RDS_X$KGLOB view on the table X$KGLOB. The format for the view name is RDS_*X$tablename*.

```
SQL> SET SERVEROUTPUT ON
SQL> EXEC rdsadmin.rdsadmin_util.create_sys_x$_view('X$KGLOB');

PL/SQL procedure successfully completed.
```

The following data dictionary query lists the view SYS.RDS_X$KGLOB and shows its status. Your master user is automatically granted the privilege `SELECT ... WITH GRANT OPTION` on this view.

```
SQL> SET SERVEROUTPUT ON
```

```
SQL> COL OWNER FORMAT A30
SQL> COL OBJECT_NAME FORMAT A30
SQL> COL STATUS FORMAT A30
SQL> SET LINESIZE 200
SQL> SELECT OWNER, OBJECT_NAME, STATUS
FROM DBA_OBJECTS
WHERE OWNER = 'SYS' AND OBJECT_NAME = 'RDS_X$KGLOB';

OWNER                          OBJECT_NAME                    STATUS
------------------------------ ------------------------------
 ------------------------------
SYS                            RDS_X$KGLOB                    VALID
```

Important

X$ tables aren't guaranteed to stay the same before and after an upgrade. RDS for Oracle drops and recreates the RDS_X$ views on X$ tables during an engine upgrade. Then it grants the `SELECT ... WITH GRANT OPTION` privilege to the master user. After an upgrade, grant privileges to database users as needed on the corresponding RDS_X$ views.

Listing SYS.RDS_X$ views

To list existing RDS_X$ views, use the RDS procedure `rdsadmin.rdsadmin_util.list_created_sys_x$_views`. The procedure lists only views that were created by the procedure `create_sys_x$_view`. The following example lists X$ tables that have corresponding RDS_X$ views (sample output included).

```
SQL> SET SERVEROUTPUT ON
SQL> COL XD_TBL_NAME FORMAT A30
SQL> COL STATUS FORMAT A30
SQL> SET LINESIZE 200
SQL> SELECT * FROM TABLE(rdsadmin.rdsadmin_util.list_created_sys_x$_views);

XD_TBL_NAME                    STATUS
------------------------------ ------------------------------
X$BH                           VALID
X$K2GTE                        VALID
X$KCBWBPD                      VALID

3 rows selected.
```

Dropping RDS_X$ views

To drop a SYS.RDS_X$ view, use the RDS procedure `rdsadmin.rdsadmin_util.drop_sys_x$_view`. You can only drop views listed in the output of `rdsadmin.rdsadmin_util.list_allowed_sys_x$_views`. The `drop_sys_x$_view` procedure accepts the following parameter.

Parameter name	Data type	Default	Required	Description
p_x$_tbl	varchar2	Null	Yes	A valid X$ fixed table name. The value must be one of the X$ fixed tables reported by `list_created_sys_x$_views .`

The following example drops the RDS_X$KGLOB view, which was created on the table X$KGLOB.

```
SQL> SET SERVEROUTPUT ON
SQL> EXEC rdsadmin.rdsadmin_util.drop_sys_x$_view('X$KGLOB');

PL/SQL procedure successfully completed.
```

The following example shows that the view SYS.RDS_X$KGLOB has been dropped (sample output included).

```
SQL> SET SERVEROUTPUT ON
SQL> COL OWNER FORMAT A30
SQL> COL OBJECT_NAME FORMAT A30
SQL> COL STATUS FORMAT A30
SQL> SET LINESIZE 200
SQL> SELECT OWNER, OBJECT_NAME, STATUS
FROM DBA_OBJECTS
WHERE OWNER = 'SYS' AND OBJECT_NAME = 'RDS_X$KGLOB';

no rows selected
```

Granting privileges to non-master users

You can grant select privileges for many objects in the SYS schema by using the SELECT_CATALOG_ROLE role. The SELECT_CATALOG_ROLE role gives users SELECT privileges on data dictionary views. The following example grants the role SELECT_CATALOG_ROLE to a user named user1.

```
GRANT SELECT_CATALOG_ROLE TO user1;
```

You can grant EXECUTE privileges for many objects in the SYS schema by using the EXECUTE_CATALOG_ROLE role. The EXECUTE_CATALOG_ROLE role gives users EXECUTE privileges for packages and procedures in the data dictionary. The following example grants the role EXECUTE_CATALOG_ROLE to a user named *user1*.

```
GRANT EXECUTE_CATALOG_ROLE TO user1;
```

The following example gets the permissions that the roles SELECT_CATALOG_ROLE and EXECUTE_CATALOG_ROLE allow.

```
  SELECT *
    FROM ROLE_TAB_PRIVS
   WHERE ROLE IN ('SELECT_CATALOG_ROLE','EXECUTE_CATALOG_ROLE')
ORDER BY ROLE, TABLE_NAME ASC;
```

The following example creates a non-master user named user1, grants the CREATE SESSION privilege, and grants the SELECT privilege on a database named *sh.sales*.

```
CREATE USER user1 IDENTIFIED BY PASSWORD;
GRANT CREATE SESSION TO user1;
GRANT SELECT ON sh.sales TO user1;
```

Creating custom functions to verify passwords

You can create a custom password verification function in the following ways:

- To use standard verification logic, and to store your function in the SYS schema, use the create_verify_function procedure.
- To use custom verification logic, or to avoid storing your function in the SYS schema, use the create_passthrough_verify_fcn procedure.

The create_verify_function procedure

You can create a custom function to verify passwords by using the Amazon RDS procedure `rdsadmin.rdsadmin_password_verify.create_verify_function`. The `create_verify_function` procedure is supported for all versions of RDS for Oracle.

The `create_verify_function` procedure has the following parameters.

Parameter name	Data type	Default	Required	Description
`p_verify_function_name`	varchar2	—	Yes	The name for your custom function. This function is created for you in the SYS schema. You assign this function to user profiles.
`p_min_length`	number	8	No	The minimum number of characters required.
`p_max_length`	number	256	No	The maximum number of characters allowed.
`p_min_letters`	number	1	No	The minimum number of letters required.
`p_min_uppercase`	number	0	No	The minimum number of uppercase letters required.
`p_min_lowercase`	number	0	No	The minimum number of lowercase letters required.
`p_min_digits`	number	1	No	The minimum number of digits required.

Parameter name	Data type	Default	Required	Description
p_min_special	number	0	No	The minimum number of special characters required.
p_min_different_chars	number	3	No	The minimum number of different characters required between the old and new password.
p_disallow_username	boolean	true	No	Set to true to disallow the user name in the password.
p_disallow_reverse	boolean	true	No	Set to true to disallow the reverse of the user name in the password.
p_disallow_db_name	boolean	true	No	Set to true to disallow the database or server name in the password.
p_disallow_simple_strings	boolean	true	No	Set to true to disallow simple strings as the password.
p_disallow_whitespace	boolean	false	No	Set to true to disallow white space characters in the password.
p_disallow_at_sign	boolean	false	No	Set to true to disallow the @ character in the password.

You can create multiple password verification functions.

There are restrictions on the name of your custom function. Your custom function can't have the same name as an existing system object. The name can be no more than 30 characters long. Also, the name must include one of the following strings: PASSWORD, VERIFY, COMPLEXITY, ENFORCE, or STRENGTH.

The following example creates a function named CUSTOM_PASSWORD_FUNCTION. The function requires that a password has at least 12 characters, 2 uppercase characters, 1 digit, and 1 special character, and that the password disallows the @ character.

```
begin
    rdsadmin.rdsadmin_password_verify.create_verify_function(
        p_verify_function_name => 'CUSTOM_PASSWORD_FUNCTION',
        p_min_length           => 12,
        p_min_uppercase        => 2,
        p_min_digits           => 1,
        p_min_special          => 1,
        p_disallow_at_sign     => true);
end;
/
```

To see the text of your verification function, query DBA_SOURCE. The following example gets the text of a custom password function named CUSTOM_PASSWORD_FUNCTION.

```
COL TEXT FORMAT a150

  SELECT TEXT
    FROM DBA_SOURCE
   WHERE OWNER = 'SYS'
     AND NAME = 'CUSTOM_PASSWORD_FUNCTION'
ORDER BY LINE;
```

To associate your verification function with a user profile, use `alter profile`. The following example associates a verification function with the DEFAULT user profile.

```
ALTER PROFILE DEFAULT LIMIT PASSWORD_VERIFY_FUNCTION CUSTOM_PASSWORD_FUNCTION;
```

To see what user profiles are associated with what verification functions, query DBA_PROFILES. The following example gets the profiles that are associated with the custom verification function named CUSTOM_PASSWORD_FUNCTION.

```
SELECT * FROM DBA_PROFILES WHERE RESOURCE_NAME = 'PASSWORD' AND LIMIT =
 'CUSTOM_PASSWORD_FUNCTION';

PROFILE                    RESOURCE_NAME                    RESOURCE  LIMIT
-------------------------  -------------------------------  --------
 ------------------------
DEFAULT                    PASSWORD_VERIFY_FUNCTION         PASSWORD
 CUSTOM_PASSWORD_FUNCTION
```

The following example gets all profiles and the password verification functions that they are associated with.

```
SELECT * FROM DBA_PROFILES WHERE RESOURCE_NAME = 'PASSWORD_VERIFY_FUNCTION';

PROFILE                    RESOURCE_NAME                    RESOURCE  LIMIT
-------------------------  -------------------------------  --------
 ------------------------
DEFAULT                    PASSWORD_VERIFY_FUNCTION         PASSWORD
 CUSTOM_PASSWORD_FUNCTION
RDSADMIN                   PASSWORD_VERIFY_FUNCTION         PASSWORD  NULL
```

The create_passthrough_verify_fcn procedure

The `create_passthrough_verify_fcn` procedure is supported for all versions of RDS for Oracle.

You can create a custom function to verify passwords by using the Amazon RDS procedure `rdsadmin.rdsadmin_password_verify.create_passthrough_verify_fcn`. The `create_passthrough_verify_fcn` procedure has the following parameters.

Parameter name	Data type	Default	Required	Description
`p_verify_function_name`	varchar2	—	Yes	The name for your custom verification function. This is a wrapper function that is created for you in the SYS schema, and

Parameter name	Data type	Default	Required	Description
				it doesn't contain any verification logic. You assign this function to user profiles.
p_target_owner	varchar2	—	Yes	The schema owner for your custom verification function.
p_target_function_name	varchar2	—	Yes	The name of your existing custom function that contains the verification logic. Your custom function must return a boolean. Your function should return `true` if the password is valid and `false` if the password is invalid.

The following example creates a password verification function that uses the logic from the function named PASSWORD_LOGIC_EXTRA_STRONG.

```
begin
    rdsadmin.rdsadmin_password_verify.create_passthrough_verify_fcn(
        p_verify_function_name => 'CUSTOM_PASSWORD_FUNCTION',
        p_target_owner         => 'TEST_USER',
        p_target_function_name => 'PASSWORD_LOGIC_EXTRA_STRONG');
end;
/
```

To associate the verification function with a user profile, use `alter profile`. The following example associates the verification function with the DEFAULT user profile.

```
ALTER PROFILE DEFAULT LIMIT PASSWORD_VERIFY_FUNCTION CUSTOM_PASSWORD_FUNCTION;
```

Setting up a custom DNS server

Amazon RDS supports outbound network access on your DB instances running Oracle. For more information about outbound network access, including prerequisites, see Configuring UTL_HTTP access using certificates and an Oracle wallet.

Amazon RDS Oracle allows Domain Name Service (DNS) resolution from a custom DNS server owned by the customer. You can resolve only fully qualified domain names from your Amazon RDS DB instance through your custom DNS server.

After you set up your custom DNS name server, it takes up to 30 minutes to propagate the changes to your DB instance. After the changes are propagated to your DB instance, all outbound network traffic requiring a DNS lookup queries your DNS server over port 53.

To set up a custom DNS server for your Amazon RDS for Oracle DB instance, do the following:

- From the DHCP options set attached to your virtual private cloud (VPC), set the `domain-name-servers` option to the IP address of your DNS name server. For more information, see DHCP options sets.

  > **Note**
  >
  > The `domain-name-servers` option accepts up to four values, but your Amazon RDS DB instance uses only the first value.

- Ensure that your DNS server can resolve all lookup queries, including public DNS names, Amazon EC2 private DNS names, and customer-specific DNS names. If the outbound network traffic contains any DNS lookups that your DNS server can't handle, your DNS server must have appropriate upstream DNS providers configured.
- Configure your DNS server to produce User Datagram Protocol (UDP) responses of 512 bytes or less.
- Configure your DNS server to produce Transmission Control Protocol (TCP) responses of 1024 bytes or less.
- Configure your DNS server to allow inbound traffic from your Amazon RDS DB instances over port 53. If your DNS server is in an Amazon VPC, the VPC must have a security group that contains inbound rules that permit UDP and TCP traffic on port 53. If your DNS server is not in an Amazon VPC, it must have appropriate firewall allow-listing to permit UDP and TCP inbound traffic on port 53.

For more information, see Security groups for your VPC and Adding and removing rules.

- Configure the VPC of your Amazon RDS DB instance to allow outbound traffic over port 53. Your VPC must have a security group that contains outbound rules that allow UDP and TCP traffic on port 53.

  For more information, see Security groups for your VPC and Adding and removing rules.

- The routing path between the Amazon RDS DB instance and the DNS server has to be configured correctly to allow DNS traffic.
  - If the Amazon RDS DB instance and the DNS server are not in the same VPC, a peering connection has to be set up between them. For more information, see What is VPC peering?

Setting and unsetting system diagnostic events

To set and unset diagnostic events at the session level, you can use the Oracle SQL statement `ALTER SESSION SET EVENTS`. However, to set events at the system level you can't use Oracle SQL. Instead, use the system event procedures in the `rdsadmin.rdsadmin_util` package. The system event procedures are available in the following engine versions:

- All Oracle Database 21c versions
- 19.0.0.0.ru-2020-10.rur-2020-10.r1 and higher Oracle Database 19c versions

  For more information, see Version 19.0.0.0.ru-2020-10.rur-2020-10.r1 in the *Amazon RDS for Oracle Release Notes*

> **Important**
>
> Internally, the `rdsadmin.rdsadmin_util` package sets events by using the `ALTER SYSTEM SET EVENTS` statement. This `ALTER SYSTEM` statement isn't documented in the Oracle Database documentation. Some system diagnostic events can generate large amounts of tracing information, cause contention, or affect database availability. We recommend that you test specific diagnostic events in your nonproduction database, and only set events in your production database under guidance of Oracle Support.

Listing allowed system diagnostic events

To list the system events that you can set, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.list_allowed_system_events`. This procedure accepts no parameters.

The following example lists all system events that you can set.

```
SET SERVEROUTPUT ON
EXEC rdsadmin.rdsadmin_util.list_allowed_system_events;
```

The following sample output lists event numbers and their descriptions. Use the Amazon RDS procedures `set_system_event` to set these events and `unset_system_event` to unset them.

```
604   - error occurred at recursive SQL level
942   - table or view does not exist
1401  - inserted value too large for column
1403  - no data found
1410  - invalid ROWID
1422  - exact fetch returns more than requested number of rows
1426  - numeric overflow
1427  - single-row subquery returns more than one row
1476  - divisor is equal to zero
1483  - invalid length for DATE or NUMBER bind variable
1489  - result of string concatenation is too long
1652  - unable to extend temp segment by  in tablespace
1858  - a non-numeric character was found where a numeric was expected
4031  - unable to allocate  bytes of shared memory ("","","","")
6502  - PL/SQL: numeric or value error
10027 - Specify Deadlock Trace Information to be Dumped
10046 - enable SQL statement timing
10053 - CBO Enable optimizer trace
10173 - Dynamic Sampling time-out error
10442 - enable trace of kst for ORA-01555 diagnostics
12008 - error in materialized view refresh path
12012 - error on auto execute of job
12504 - TNS:listener was not given the SERVICE_NAME in CONNECT_DATA
14400 - inserted partition key does not map to any partition
31693 - Table data object  failed to load/unload and is being skipped due to error:
```

> **Note**
>
> The list of the allowed system events can change over time. To make sure that you have the most recent list of eligible events, use `rdsadmin.rdsadmin_util.list_allowed_system_events`.

Setting system diagnostic events

To set a system event, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.set_system_event`. You can only set events listed in the output of `rdsadmin.rdsadmin_util.list_allowed_system_events`. The `set_system_event` procedure accepts the following parameters.

Parameter name	Data type	Default	Required	Description
`p_event`	number	—	Yes	The system event number. The value must be one of the event numbers reported by `list_allowed_system_events` .
`p_level`	number	—	Yes	The event level. See the Oracle Database documentation or Oracle Support for descriptions of different level values.

The procedure `set_system_event` constructs and runs the required `ALTER SYSTEM SET EVENTS` statements according to the following principles:

- The event type (`context` or `errorstack`) is determined automatically.
- A statement in the form `ALTER SYSTEM SET EVENTS 'event LEVEL event_level'` sets the context events. This notation is equivalent to `ALTER SYSTEM SET EVENTS 'event TRACE NAME CONTEXT FOREVER, LEVEL event_level'`.

- A statement in the form `ALTER SYSTEM SET EVENTS 'event ERRORSTACK (event_level)'` sets the error stack events. This notation is equivalent to `ALTER SYSTEM SET EVENTS 'event TRACE NAME ERRORSTACK LEVEL event_level'`.

The following example sets event 942 at level 3, and event 10442 at level 10. Sample output is included.

```
SQL> SET SERVEROUTPUT ON
SQL> EXEC rdsadmin.rdsadmin_util.set_system_event(942,3);
Setting system event 942 with: alter system set events '942 errorstack (3)'

PL/SQL procedure successfully completed.

SQL> EXEC rdsadmin.rdsadmin_util.set_system_event(10442,10);
Setting system event 10442 with: alter system set events '10442 level 10'

PL/SQL procedure successfully completed.
```

Listing system diagnostic events that are set

To list the system events that are currently set, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.list_set_system_events`. This procedure reports only events set at system level by `set_system_event`.

The following example lists the active system events.

```
SET SERVEROUTPUT ON
EXEC rdsadmin.rdsadmin_util.list_set_system_events;
```

The following sample output shows the list of events, the event type, the level at which the events are currently set, and the time when the event was set.

```
942 errorstack (3) - set at 2020-11-03 11:42:27
10442 level 10 - set at 2020-11-03 11:42:41

PL/SQL procedure successfully completed.
```

Unsetting system diagnostic events

To unset a system event, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.unset_system_event`. You can only unset events listed in the output of `rdsadmin.rdsadmin_util.list_allowed_system_events`. The `unset_system_event` procedure accepts the following parameter.

Parameter name	Data type	Default	Required	Description
`p_event`	number	—	Yes	The system event number. The value must be one of the event numbers reported by `list_allowed_system_events` .

The following example unsets events 942 and 10442. Sample output is included.

```
SQL> SET SERVEROUTPUT ON
SQL> EXEC rdsadmin.rdsadmin_util.unset_system_event(942);
Unsetting system event 942 with: alter system set events '942 off'

PL/SQL procedure successfully completed.

SQL> EXEC rdsadmin.rdsadmin_util.unset_system_event(10442);
Unsetting system event 10442 with: alter system set events '10442 off'

PL/SQL procedure successfully completed.
```

Performing common database tasks for Oracle DB instances

Following, you can find how to perform certain common DBA tasks related to databases on your Amazon RDS DB instances running Oracle. To deliver a managed service experience, Amazon RDS doesn't provide shell access to DB instances. Amazon RDS also restricts access to some system procedures and tables that require advanced privileges.

Topics

- Changing the global name of a database

- Creating and sizing tablespaces
- Setting the default tablespace
- Setting the default temporary tablespace
- Creating a temporary tablespace on the instance store
- Adding a tempfile to the instance store on a read replica
- Dropping tempfiles on a read replica
- Checkpointing a database
- Setting distributed recovery
- Setting the database time zone
- Working with Oracle external tables
- Generating performance reports with Automatic Workload Repository (AWR)
- Adjusting database links for use with DB instances in a VPC
- Setting the default edition for a DB instance
- Enabling auditing for the SYS.AUD$ table
- Disabling auditing for the SYS.AUD$ table
- Cleaning up interrupted online index builds
- Skipping corrupt blocks
- Resizing tablespaces, data files, and temp files
- Purging the recycle bin
- Setting the default displayed values for full redaction

Changing the global name of a database

To change the global name of a database, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.rename_global_name`. The `rename_global_name` procedure has the following parameters.

Parameter name	Data type	Default	Required	Description
`p_new_global_name`	varchar2	—	Yes	The new global name for the database.

The database must be open for the name change to occur. For more information about changing the global name of a database, see ALTER DATABASE in the Oracle documentation.

The following example changes the global name of a database to `new_global_name`.

```
EXEC rdsadmin.rdsadmin_util.rename_global_name(p_new_global_name => 'new_global_name');
```

Creating and sizing tablespaces

Amazon RDS only supports Oracle Managed Files (OMF) for data files, log files, and control files. When you create data files and log files, you can't specify the physical file names.

By default, if you don't specify a data file size, tablespaces are created with the default of `AUTOEXTEND ON`, and no maximum size. In the following example, the tablespace *`users1`* is autoextensible.

```
CREATE TABLESPACE users1;
```

Because of these default settings, tablespaces can grow to consume all allocated storage. We recommend that you specify an appropriate maximum size on permanent and temporary tablespaces, and that you carefully monitor space usage.

The following example creates a tablespace named *`users2`* with a starting size of 1 gigabyte. Because a data file size is specified, but `AUTOEXTEND ON` isn't specified, the tablespace isn't autoextensible.

```
CREATE TABLESPACE users2 DATAFILE SIZE 1G;
```

The following example creates a tablespace named *`users3`* with a starting size of 1 gigabyte, autoextend turned on, and a maximum size of 10 gigabytes.

```
CREATE TABLESPACE users3 DATAFILE SIZE 1G AUTOEXTEND ON MAXSIZE 10G;
```

The following example creates a temporary tablespace named *`temp01`*.

```
CREATE TEMPORARY TABLESPACE temp01;
```

You can resize a bigfile tablespace by using `ALTER TABLESPACE`. You can specify the size in kilobytes (K), megabytes (M), gigabytes (G), or terabytes (T). The following example resizes a bigfile tablespace named *`users_bf`* to 200 MB.

```
ALTER TABLESPACE users_bf RESIZE 200M;
```

The following example adds an additional data file to a smallfile tablespace named *`users_sf`*.

```
ALTER TABLESPACE users_sf ADD DATAFILE SIZE 100000M AUTOEXTEND ON NEXT 250m
 MAXSIZE UNLIMITED;
```

Setting the default tablespace

To set the default tablespace, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.alter_default_tablespace`. The `alter_default_tablespace` procedure has the following parameters.

Parameter name	Data type	Default	Required	Description
`tablespace_name`	varchar	—	Yes	The name of the default tablespace.

The following example sets the default tablespace to *`users2`*:

```
EXEC rdsadmin.rdsadmin_util.alter_default_tablespace(tablespace_name => 'users2');
```

Setting the default temporary tablespace

To set the default temporary tablespace, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.alter_default_temp_tablespace`. The `alter_default_temp_tablespace` procedure has the following parameters.

Parameter name	Data type	Default	Required	Description
`tablespace_name`	varchar	—	Yes	The name of the default temporary tablespace.

The following example sets the default temporary tablespace to *temp01*.

```
EXEC rdsadmin.rdsadmin_util.alter_default_temp_tablespace(tablespace_name => 'temp01');
```

Creating a temporary tablespace on the instance store

To create a temporary tablespace on the instance store, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.create_inst_store_tmp_tblspace`. The `create_inst_store_tmp_tblspace` procedure has the following parameters.

Parameter name	Data type	Default	Required	Description
p_tablespace_name	varchar	—	Yes	The name of the temporary tablespace.

The following example creates the temporary tablespace *temp01* in the instance store.

```
EXEC rdsadmin.rdsadmin_util.create_inst_store_tmp_tblspace(p_tablespace_name =>
 'temp01');
```

> **Important**
>
> When you run `rdsadmin_util.create_inst_store_tmp_tblspace`, the newly created temporary tablespace is not automatically set as the default temporary tablespace. To set it as the default, see Setting the default temporary tablespace.

For more information, see Storing temporary data in an RDS for Oracle instance store.

Adding a tempfile to the instance store on a read replica

When you create a temporary tablespace on a primary DB instance, the read replica doesn't create tempfiles. Assume that an empty temporary tablespace exists on your read replica for either of the following reasons:

- You dropped a tempfile from the tablespace on your read replica. For more information, see Dropping tempfiles on a read replica.

- You created a new temporary tablespace on the primary DB instance. In this case, RDS for Oracle synchronizes the metadata to the read replica.

You can add a tempfile to the empty temporary tablespace, and store the tempfile in the instance store. To create a tempfile in the instance store, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.add_inst_store_tempfile`. You can use this procedure only on a read replica. The procedure has the following parameters.

Parameter name	Data type	Default	Required	Description
`p_tablespace_name`	varchar	—	Yes	The name of the temporary tablespace on your read replica.

In the following example, the empty temporary tablespace *`temp01`* exists on your read replica. Run the following command to create a tempfile for this tablespace, and store it in the instance store.

```
EXEC rdsadmin.rdsadmin_util.add_inst_store_tempfile(p_tablespace_name => 'temp01');
```

For more information, see Storing temporary data in an RDS for Oracle instance store.

Dropping tempfiles on a read replica

You can't drop an existing temporary tablespace on a read replica. You can change the tempfile storage on a read replica from Amazon EBS to the instance store, or from the instance store to Amazon EBS. To achieve these goals, do the following:

1. Drop the current tempfiles in the temporary tablespace on the read replica.
2. Create new tempfiles on different storage.

To drop the tempfiles, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.drop_replica_tempfiles`. You can use this procedure only on read replicas. The `drop_replica_tempfiles` procedure has the following parameters.

Parameter name	Data type	Default	Required	Description
p_tablespace_name	varchar	—	Yes	The name of the temporary tablespace on your read replica.

Assume that a temporary tablespace named *temp01* resides in the instance store on your read replica. Drop all tempfiles in this tablespace by running the following command.

```
EXEC rdsadmin.rdsadmin_util.drop_replica_tempfiles(p_tablespace_name => 'temp01');
```

For more information, see Storing temporary data in an RDS for Oracle instance store.

Checkpointing a database

To checkpoint the database, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.checkpoint`. The `checkpoint` procedure has no parameters.

The following example checkpoints the database.

```
EXEC rdsadmin.rdsadmin_util.checkpoint;
```

Setting distributed recovery

To set distributed recovery, use the Amazon RDS procedures `rdsadmin.rdsadmin_util.enable_distr_recovery` and `disable_distr_recovery`. The procedures have no parameters.

The following example enables distributed recovery.

```
EXEC rdsadmin.rdsadmin_util.enable_distr_recovery;
```

The following example disables distributed recovery.

```
EXEC rdsadmin.rdsadmin_util.disable_distr_recovery;
```

Setting the database time zone

You can set the time zone of your Amazon RDS Oracle database in the following ways:

- The `Timezone` option

  The `Timezone` option changes the time zone at the host level and affects all date columns and values such as SYSDATE. For more information, see Oracle time zone.

- The Amazon RDS procedure `rdsadmin.rdsadmin_util.alter_db_time_zone`

  The `alter_db_time_zone` procedure changes the time zone for only certain data types, and doesn't change SYSDATE. There are additional restrictions on setting the time zone listed in the Oracle documentation.

> **Note**
>
> You can also set the default time zone for Oracle Scheduler. For more information, see Setting the time zone for Oracle Scheduler jobs.

The `alter_db_time_zone` procedure has the following parameters.

Parameter name	Data type	Default	Required	Description
p_new_tz	varchar2	—	Yes	The new time zone as a named region or an absolute offset from Coordinated Universal Time (UTC). Valid offsets range from -12:00 to +14:00.

The following example changes the time zone to UTC plus three hours.

```
EXEC rdsadmin.rdsadmin_util.alter_db_time_zone(p_new_tz => '+3:00');
```

The following example changes the time zone to the Africa/Algiers time zone.

```
EXEC rdsadmin.rdsadmin_util.alter_db_time_zone(p_new_tz => 'Africa/Algiers');
```

After you alter the time zone by using the `alter_db_time_zone` procedure, reboot your DB instance for the change to take effect. For more information, see Rebooting a DB instance. For information about upgrading time zones, see Time zone considerations.

Working with Oracle external tables

Oracle external tables are tables with data that is not in the database. Instead, the data is in external files that the database can access. By using external tables, you can access data without loading it into the database. For more information about external tables, see Managing external tables in the Oracle documentation.

With Amazon RDS, you can store external table files in directory objects. You can create a directory object, or you can use one that is predefined in the Oracle database, such as the DATA_PUMP_DIR directory. For information about creating directory objects, see Creating and dropping directories in the main data storage space. You can query the ALL_DIRECTORIES view to list the directory objects for your Amazon RDS Oracle DB instance.

> **Note**
>
> Directory objects point to the main data storage space (Amazon EBS volume) used by your instance. The space used—along with data files, redo logs, audit, trace, and other files—counts against allocated storage.

You can move an external data file from one Oracle database to another by using the DBMS_FILE_TRANSFER package or the UTL_FILE package. The external data file is moved from a directory on the source database to the specified directory on the destination database. For information about using DBMS_FILE_TRANSFER, see Importing using Oracle Data Pump.

After you move the external data file, you can create an external table with it. The following example creates an external table that uses the `emp_xt_file1.txt` file in the USER_DIR1 directory.

```
CREATE TABLE emp_xt (
  emp_id      NUMBER,
  first_name  VARCHAR2(50),
  last_name   VARCHAR2(50),
  user_name   VARCHAR2(20)
)
ORGANIZATION EXTERNAL (
```

```
  TYPE ORACLE_LOADER
  DEFAULT DIRECTORY USER_DIR1
  ACCESS PARAMETERS (
    RECORDS DELIMITED BY NEWLINE
    FIELDS TERMINATED BY ','
    MISSING FIELD VALUES ARE NULL
    (emp_id,first_name,last_name,user_name)
  )
  LOCATION ('emp_xt_file1.txt')
)
PARALLEL
REJECT LIMIT UNLIMITED;
```

Suppose that you want to move data that is in an Amazon RDS Oracle DB instance into an external data file. In this case, you can populate the external data file by creating an external table and selecting the data from the table in the database. For example, the following SQL statement creates the `orders_xt` external table by querying the `orders` table in the database.

```
CREATE TABLE orders_xt
  ORGANIZATION EXTERNAL
   (
     TYPE ORACLE_DATAPUMP
     DEFAULT DIRECTORY DATA_PUMP_DIR
     LOCATION ('orders_xt.dmp')
   )
   AS SELECT * FROM orders;
```

In this example, the data is populated in the `orders_xt.dmp` file in the DATA_PUMP_DIR directory.

Generating performance reports with Automatic Workload Repository (AWR)

To gather performance data and generate reports, Oracle recommends Automatic Workload Repository (AWR). AWR requires Oracle Database Enterprise Edition and a license for the Diagnostics and Tuning packs. To enable AWR, set the `CONTROL_MANAGEMENT_PACK_ACCESS` initialization parameter to either `DIAGNOSTIC` or `DIAGNOSTIC+TUNING`.

Working with AWR reports in RDS

To generate AWR reports, you can run scripts such as `awrrpt.sql`. These scripts are installed on the database host server. In Amazon RDS, you don't have direct access to the host. However, you can get copies of SQL scripts from another installation of Oracle Database.

You can also use AWR by running procedures in the `SYS.DBMS_WORKLOAD_REPOSITORY` PL/SQL package. You can use this package to manage baselines and snapshots, and also to display ASH and AWR reports. For example, to generate an AWR report in text format run the `DBMS_WORKLOAD_REPOSITORY.AWR_REPORT_TEXT` procedure. However, you can't reach these AWR reports from the AWS Management Console.

When working with AWR, we recommend using the `rdsadmin.rdsadmin_diagnostic_util` procedures. You can use these procedures to generate the following:

- AWR reports
- Active Session History (ASH) reports
- Automatic Database Diagnostic Monitor (ADDM) reports
- Oracle Data Pump Export dump files of AWR data

The `rdsadmin_diagnostic_util` procedures save the reports to the DB instance file system. You can access these reports from the console. You can also access reports using the `rdsadmin.rds_file_util` procedures, and you can access reports that are copied to Amazon S3 using the S3 Integration option. For more information, see Reading files in a DB instance directory and Amazon S3 integration.

You can use the `rdsadmin_diagnostic_util` procedures in the following Amazon RDS for Oracle DB engine versions:

- All Oracle Database 21c versions
- 19.0.0.0.ru-2020-04.rur-2020-04.r1 and higher Oracle Database 19c versions

For a blog that explains how to work with diagnostic reports in a replication scenario, see Generate AWR reports for Amazon RDS for Oracle read replicas.

Common parameters for the diagnostic utility package

You typically use the following parameters when managing AWR and ADDM with the `rdsadmin_diagnostic_util` package.

Parameter	Data type	Defau	Requi	Description
begin_snap_id	NUMBEI	—	Yes	The ID of the beginning snapshot.
end_snap_id	NUMBEI	—	Yes	The ID of the ending snapshot.
dump_directory	VARCHA	BDUMI	No	The directory to write the report or export file to. If you specify a nondefault directory, the user that runs the rdsadmin_diagnostic_util procedures must have write permissions for the directory.
p_tag	VARCHA	—	No	A string that can be used to distinguish between backups to indicate the purpose or usage of backups, such as incremental or daily. You can specify up to 30 characters. Valid characters are a-z, A-Z, 0-9, an underscore (_), a dash (-), and a period (.). The tag is not case-sensitive. RMAN always stores tags in uppercase, regardless of the case used when entering them. Tags don't need to be unique, so multiple backups can have the same tag. If you don't specify a tag, RMAN assigns a default tag automatically using the format TAG*YYYYMMDDTHHMMSS* , where *YYYY* is the year, *MM* is the month, *DD* is the day, *HH* is the hour (in 24-hour format), *MM* is the minutes, and *SS* is the seconds. The date and time indicate when RMAN started the backup. For example, a backup with the default tagTAG20190927T214517 indicates a backup that started on 2019-09-27 at 21:45:17. The p_tag parameter is supported for the following RDS for Oracle DB engine versions:

Parameter	Data type	Defau	Requi	Description
				• Oracle Database 21c (21.0.0) • Oracle Database 19c (19.0.0), using 19.0.0.0.ru-2021-10.rur-2021-10.r1 and higher
report_type	VARCHA	HTML	No	The format of the report. Valid values are TEXT and HTML.
dbid	NUMBEF	—	No	A valid database identifier (DBID) shown in the DBA_HIST_DATABASE_INSTANCE view for Oracle. If this parameter is not specified, RDS uses the current DBID, which is shown in the V$DATABASE.DBID view.

You typically use the following parameters when managing ASH with the rdsadmin_diagnostic_util package.

Parameter	Data type	Defaul	Requir	Description
begin_time	DATE	—	Yes	The beginning time of the ASH analysis.
end_time	DATE	—	Yes	The ending time of the ASH analysis.
slot_width	NUMBER	0	No	The duration of the slots (in seconds) used in the "Top Activity" section of the ASH report. If this parameter isn't specified, the time interval between begin_time and end_time uses no more than 10 slots.
sid	NUMBER	Null	No	The session ID.
sql_id	VARCHAR2	Null	No	The SQL ID.
wait_class	VARCHAR2	Null	No	The wait class name.

Parameter	Data type	Defaul	Requir	Description
service_hash	NUMBER	Null	No	The service name hash.
module_name	VARCHAR2	Null	No	The module name.
action_name	VARCHAR2	Null	No	The action name.
client_id	VARCHAR2	Null	No	The application-specific ID of the database session.
plsql_entry	VARCHAR2	Null	No	The PL/SQL entry point.

Generating an AWR report

To generate an AWR report, use the `rdsadmin.rdsadmin_diagnostic_util.awr_report` procedure.

The following example generates a AWR report for the snapshot range 101–106. The output text file is named `awrrpt_101_106.txt`. You can access this report from the AWS Management Console.

```
EXEC rdsadmin.rdsadmin_diagnostic_util.awr_report(101,106,'TEXT');
```

The following example generates an HTML report for the snapshot range 63–65. The output HTML file is named `awrrpt_63_65.html`. The procedure writes the report to the nondefault database directory named `AWR_RPT_DUMP`.

```
EXEC rdsadmin.rdsadmin_diagnostic_util.awr_report(63,65,'HTML','AWR_RPT_DUMP');
```

Extracting AWR data into a dump file

To extract AWR data into a dump file, use the `rdsadmin.rdsadmin_diagnostic_util.awr_extract` procedure.

The following example extracts the snapshot range 101–106. The output dump file is named `awrextract_101_106.dmp`. You can access this file through the console.

```
EXEC rdsadmin.rdsadmin_diagnostic_util.awr_extract(101,106);
```

The following example extracts the snapshot range 63–65. The output dump file is named `awrextract_63_65.dmp`. The file is stored in the nondefault database directory named `AWR_RPT_DUMP`.

```
EXEC rdsadmin.rdsadmin_diagnostic_util.awr_extract(63,65,'AWR_RPT_DUMP');
```

Generating an ADDM report

To generate an ADDM report, use the `rdsadmin.rdsadmin_diagnostic_util.addm_report` procedure.

The following example generates an ADDM report for the snapshot range 101–106. The output text file is named `addmrpt_101_106.txt`. You can access the report through the console.

```
EXEC rdsadmin.rdsadmin_diagnostic_util.addm_report(101,106);
```

The following example generates an ADDM report for the snapshot range 63–65. The output text file is named `addmrpt_63_65.txt`. The file is stored in the nondefault database directory named `ADDM_RPT_DUMP`.

```
EXEC rdsadmin.rdsadmin_diagnostic_util.addm_report(63,65,'ADDM_RPT_DUMP');
```

Generating an ASH report

To generate an ASH report, use the `rdsadmin.rdsadmin_diagnostic_util.ash_report` procedure.

The following example generates an ASH report that includes the data from 14 minutes ago until the current time. The name of the output file uses the format `ashrpt`*`begin_time`*`end_time`*`.txt`*, where *`begin_time`* and *`end_time`* use the format `YYYYMMDDHH24MISS`. You can access the file through the console.

```
BEGIN
    rdsadmin.rdsadmin_diagnostic_util.ash_report(
```

```
        begin_time     =>     SYSDATE-14/1440,
        end_time       =>     SYSDATE,
        report_type    =>     'TEXT');
END;
/
```

The following example generates an ASH report that includes the data from November 18, 2019, at 6:07 PM through November 18, 2019, at 6:15 PM. The name of the output HTML report is `ashrpt_20190918180700_20190918181500.html`. The report is stored in the nondefault database directory named `AWR_RPT_DUMP`.

```
BEGIN
    rdsadmin.rdsadmin_diagnostic_util.ash_report(
        begin_time     =>    TO_DATE('2019-09-18 18:07:00', 'YYYY-MM-DD HH24:MI:SS'),
        end_time       =>    TO_DATE('2019-09-18 18:15:00', 'YYYY-MM-DD HH24:MI:SS'),
        report_type    =>    'html',
        dump_directory =>    'AWR_RPT_DUMP');
END;
/
```

Accessing AWR reports from the console or CLI

To access AWR reports or export dump files, you can use the AWS Management Console or AWS CLI. For more information, see Downloading a database log file.

Adjusting database links for use with DB instances in a VPC

To use Oracle database links with Amazon RDS DB instances inside the same virtual private cloud (VPC) or peered VPCs, the two DB instances should have a valid route between them. Verify the valid route between the DB instances by using your VPC routing tables and network access control list (ACL).

The security group of each DB instance must allow ingress to and egress from the other DB instance. The inbound and outbound rules can refer to security groups from the same VPC or a peered VPC. For more information, see Updating your security groups to reference peered VPC security groups.

If you have configured a custom DNS server using the DHCP Option Sets in your VPC, your custom DNS server must be able to resolve the name of the database link target. For more information, see Setting up a custom DNS server.

For more information about using database links with Oracle Data Pump, see Importing using Oracle Data Pump.

Setting the default edition for a DB instance

You can redefine database objects in a private environment called an edition. You can use edition-based redefinition to upgrade an application's database objects with minimal downtime.

You can set the default edition of an Amazon RDS Oracle DB instance using the Amazon RDS procedure `rdsadmin.rdsadmin_util.alter_default_edition`.

The following example sets the default edition for the Amazon RDS Oracle DB instance to `RELEASE_V1`.

```
EXEC rdsadmin.rdsadmin_util.alter_default_edition('RELEASE_V1');
```

The following example sets the default edition for the Amazon RDS Oracle DB instance back to the Oracle default.

```
EXEC rdsadmin.rdsadmin_util.alter_default_edition('ORA$BASE');
```

For more information about Oracle edition-based redefinition, see About editions and edition-based redefinition in the Oracle documentation.

Enabling auditing for the SYS.AUD$ table

To enable auditing on the database audit trail table `SYS.AUD$`, use the Amazon RDS procedure `rdsadmin.rdsadmin_master_util.audit_all_sys_aud_table`. The only supported audit property is `ALL`. You can't audit or not audit individual statements or operations.

Enabling auditing is supported for Oracle DB instances running the following versions:

- Oracle Database 21c (21.0.0)
- Oracle Database 19c (19.0.0)

The `audit_all_sys_aud_table` procedure has the following parameters.

Parameter name	Data type	Default	Required	Description
p_by_access	boolean	true	No	Set to true to audit BY ACCESS. Set to false to audit BY SESSION.

The following query returns the current audit configuration for SYS.AUD$ for a database.

```
SELECT * FROM DBA_OBJ_AUDIT_OPTS WHERE OWNER='SYS' AND OBJECT_NAME='AUD$';
```

The following commands enable audit of ALL on SYS.AUD$ BY ACCESS.

```
EXEC rdsadmin.rdsadmin_master_util.audit_all_sys_aud_table;

EXEC rdsadmin.rdsadmin_master_util.audit_all_sys_aud_table(p_by_access => true);
```

The following command enables audit of ALL on SYS.AUD$ BY SESSION.

```
EXEC rdsadmin.rdsadmin_master_util.audit_all_sys_aud_table(p_by_access => false);
```

For more information, see AUDIT (traditional auditing) in the Oracle documentation.

Disabling auditing for the SYS.AUD$ table

To disable auditing on the database audit trail table SYS.AUD$, use the Amazon RDS procedure rdsadmin.rdsadmin_master_util.noaudit_all_sys_aud_table. This procedure takes no parameters.

The following query returns the current audit configuration for SYS.AUD$ for a database:

```
SELECT * FROM DBA_OBJ_AUDIT_OPTS WHERE OWNER='SYS' AND OBJECT_NAME='AUD$';
```

The following command disables audit of ALL on SYS.AUD$.

```
EXEC rdsadmin.rdsadmin_master_util.noaudit_all_sys_aud_table;
```

For more information, see NOAUDIT (traditional auditing) in the Oracle documentation.

Cleaning up interrupted online index builds

To clean up failed online index builds, use the Amazon RDS procedure `rdsadmin.rdsadmin_dbms_repair.online_index_clean`.

The `online_index_clean` procedure has the following parameters.

Parameter name	Data type	Default	Required	Description
`object_id`	binary_integer	`ALL_INDEX_ID`	No	The object ID of the index. Typically, you can use the object ID from the ORA-08104 error text.
`wait_for_lock`	binary_integer	`rdsadmin.rdsadmin_dbms_repair.lock_wait`	No	Specify `rdsadmin.rdsadmin_dbms_repair.lock_wait` , the default, to try to get a lock on the underlying object and retry until an internal limit is reached if the lock fails. Specify `rdsadmin.rdsadmin_dbms_repair.lock_nowait` to try to get a lock on the underlying object but not retry if the lock fails.

The following example cleans up a failed online index build:

```
declare
  is_clean boolean;
begin
```

```
  is_clean := rdsadmin.rdsadmin_dbms_repair.online_index_clean(
    object_id     => 1234567890,
    wait_for_lock => rdsadmin.rdsadmin_dbms_repair.lock_nowait
  );
end;
/
```

For more information, see ONLINE_INDEX_CLEAN function in the Oracle documentation.

Skipping corrupt blocks

To skip corrupt blocks during index and table scans, use the `rdsadmin.rdsadmin_dbms_repair` package.

The following procedures wrap the functionality of the `sys.dbms_repair.admin_table` procedure and take no parameters:

- `rdsadmin.rdsadmin_dbms_repair.create_repair_table`
- `rdsadmin.rdsadmin_dbms_repair.create_orphan_keys_table`
- `rdsadmin.rdsadmin_dbms_repair.drop_repair_table`
- `rdsadmin.rdsadmin_dbms_repair.drop_orphan_keys_table`
- `rdsadmin.rdsadmin_dbms_repair.purge_repair_table`
- `rdsadmin.rdsadmin_dbms_repair.purge_orphan_keys_table`

The following procedures take the same parameters as their counterparts in the `DBMS_REPAIR` package for Oracle databases:

- `rdsadmin.rdsadmin_dbms_repair.check_object`
- `rdsadmin.rdsadmin_dbms_repair.dump_orphan_keys`
- `rdsadmin.rdsadmin_dbms_repair.fix_corrupt_blocks`
- `rdsadmin.rdsadmin_dbms_repair.rebuild_freelists`
- `rdsadmin.rdsadmin_dbms_repair.segment_fix_status`
- `rdsadmin.rdsadmin_dbms_repair.skip_corrupt_blocks`

For more information about handling database corruption, see DBMS_REPAIR in the Oracle documentation.

Example Responding to corrupt blocks

This example shows the basic workflow for responding to corrupt blocks. Your steps will depend on the location and nature of your block corruption.

> **Important**
>
> Before attempting to repair corrupt blocks, review the DBMS_REPAIR documentation carefully.

To skip corrupt blocks during index and table scans

1. Run the following procedures to create repair tables if they don't already exist.

```
EXEC rdsadmin.rdsadmin_dbms_repair.create_repair_table;
EXEC rdsadmin.rdsadmin_dbms_repair.create_orphan_keys_table;
```

2. Run the following procedures to check for existing records and purge them if appropriate.

```
SELECT COUNT(*) FROM SYS.REPAIR_TABLE;
SELECT COUNT(*) FROM SYS.ORPHAN_KEY_TABLE;
SELECT COUNT(*) FROM SYS.DBA_REPAIR_TABLE;
SELECT COUNT(*) FROM SYS.DBA_ORPHAN_KEY_TABLE;

EXEC rdsadmin.rdsadmin_dbms_repair.purge_repair_table;
EXEC rdsadmin.rdsadmin_dbms_repair.purge_orphan_keys_table;
```

3. Run the following procedure to check for corrupt blocks.

```
SET SERVEROUTPUT ON
DECLARE v_num_corrupt INT;
BEGIN
  v_num_corrupt := 0;
  rdsadmin.rdsadmin_dbms_repair.check_object (
    schema_name => '&corruptionOwner',
    object_name => '&corruptionTable',
    corrupt_count =>  v_num_corrupt
  );
  dbms_output.put_line('number corrupt: '||to_char(v_num_corrupt));
END;
/
```

```
COL CORRUPT_DESCRIPTION FORMAT a30
COL REPAIR_DESCRIPTION FORMAT a30

SELECT OBJECT_NAME, BLOCK_ID, CORRUPT_TYPE, MARKED_CORRUPT,
       CORRUPT_DESCRIPTION, REPAIR_DESCRIPTION
FROM   SYS.REPAIR_TABLE;

SELECT SKIP_CORRUPT
FROM   DBA_TABLES
WHERE  OWNER = '&corruptionOwner'
AND    TABLE_NAME = '&corruptionTable';
```

4. Use the `skip_corrupt_blocks` procedure to enable or disable corruption skipping for affected tables. Depending on the situation, you may also need to extract data to a new table, and then drop the table containing the corrupt block.

   Run the following procedure to enable corruption skipping for affected tables.

   ```
   begin
     rdsadmin.rdsadmin_dbms_repair.skip_corrupt_blocks (
       schema_name => '&corruptionOwner',
       object_name => '&corruptionTable',
       object_type => rdsadmin.rdsadmin_dbms_repair.table_object,
       flags => rdsadmin.rdsadmin_dbms_repair.skip_flag);
   end;
   /
   select skip_corrupt from dba_tables where owner = '&corruptionOwner' and table_name
    = '&corruptionTable';
   ```

   Run the following procedure to disable corruption skipping.

   ```
   begin
     rdsadmin.rdsadmin_dbms_repair.skip_corrupt_blocks (
       schema_name => '&corruptionOwner',
       object_name => '&corruptionTable',
       object_type => rdsadmin.rdsadmin_dbms_repair.table_object,
       flags => rdsadmin.rdsadmin_dbms_repair.noskip_flag);
   end;
   /
   ```

```
select skip_corrupt from dba_tables where owner = '&corruptionOwner' and table_name
 = '&corruptionTable';
```

5. When you have completed all repair work, run the following procedures to drop the repair tables.

```
EXEC rdsadmin.rdsadmin_dbms_repair.drop_repair_table;
EXEC rdsadmin.rdsadmin_dbms_repair.drop_orphan_keys_table;
```

Resizing tablespaces, data files, and temp files

By default, Oracle tablespaces are created with auto-extend turned on and no maximum size. Because of these default settings, tablespaces can sometimes grow too large. We recommend that you specify an appropriate maximum size on permanent and temporary tablespaces, and that you carefully monitor space usage.

Resizing permanent tablespaces

To resize a permanent tablespace in an RDS for Oracle DB instance, use any of the following Amazon RDS procedures:

- `rdsadmin.rdsadmin_util.resize_datafile`
- `rdsadmin.rdsadmin_util.autoextend_datafile`

The `resize_datafile` procedure has the following parameters.

Parameter name	Data type	Default	Required	Description
`p_data_file_id`	number	—	Yes	The identifier of the data file to resize.
`p_size`	varchar2	—	Yes	The size of the data file. Specify the size in bytes (the default), kilobytes (K), megabytes (M), or gigabytes (G).

The `autoextend_datafile` procedure has the following parameters.

Parameter name	Data type	Default	Required	Description
`p_data_file_id`	number	—	Yes	The identifier of the data file to resize.
`p_autoextend_state`	varchar2	—	Yes	The state of the autoextension feature. Specify `ON` to extend the data file automatically and `OFF` to turn off autoextension.
`p_next`	varchar2	—	No	The size of the next data file increment. Specify the size in bytes (the default), kilobytes (K), megabytes (M), or gigabytes (G).
`p_maxsize`	varchar2	—	No	The maximum disk space allowed for automatic extension. Specify the size in bytes (the default), kilobytes (K), megabytes (M), or gigabytes (G). You can specify `UNLIMITED` to remove the file size limit.

The following example resizes data file 4 to 500 MB.

```
EXEC rdsadmin.rdsadmin_util.resize_datafile(4,'500M');
```

The following example turns off autoextension for data file 4. It also turns on autoextension for data file 5, with an increment of 128 MB and no maximum size.

```
EXEC rdsadmin.rdsadmin_util.autoextend_datafile(4,'OFF');
EXEC rdsadmin.rdsadmin_util.autoextend_datafile(5,'ON','128M','UNLIMITED');
```

Resizing temporary tablespaces

To resize a temporary tablespaces in an RDS for Oracle DB instance, including a read replica, use any of the following Amazon RDS procedures:

- `rdsadmin.rdsadmin_util.resize_temp_tablespace`
- `rdsadmin.rdsadmin_util.resize_tempfile`
- `rdsadmin.rdsadmin_util.autoextend_tempfile`

The `resize_temp_tablespace` procedure has the following parameters.

Parameter name	Data type	Default	Required	Description
`p_temp_tablespace_name`	varchar2	—	Yes	The name of the temporary tablespace to resize.
`p_size`	varchar2	—	Yes	The size of the tablespace. Specify the size in bytes (the default), kilobytes (K), megabytes (M), or gigabytes (G).

The `resize_tempfile` procedure has the following parameters.

Parameter name	Data type	Default	Required	Description
`p_temp_file_id`	number	—	Yes	The identifier of the temp file to resize.
`p_size`	varchar2	—	Yes	The size of the temp file. Specify the size in bytes (the default), kilobytes

Parameter name	Data type	Default	Required	Description
				(K), megabytes (M), or gigabytes (G).

The `autoextend_tempfile` procedure has the following parameters.

Parameter name	Data type	Default	Required	Description
`p_temp_file_id`	number	—	Yes	The identifier of the temp file to resize.
`p_autoextend_state`	varchar2	—	Yes	The state of the autoextension feature. Specify `ON` to extend the temp file automatic ally and `OFF` to turn off autoextension.
`p_next`	varchar2	—	No	The size of the next temp file increment. Specify the size in bytes (the default), kilobytes (K), megabytes (M), or gigabytes (G).
`p_maxsize`	varchar2	—	No	The maximum disk space allowed for automatic extension. Specify the size in bytes (the default), kilobytes (K), megabytes (M), or gigabytes (G). You can specify `UNLIMITED` to remove the file size limit.

The following examples resize a temporary tablespace named TEMP to the size of 4 GB.

```
EXEC rdsadmin.rdsadmin_util.resize_temp_tablespace('TEMP','4G');
```

```
EXEC rdsadmin.rdsadmin_util.resize_temp_tablespace('TEMP','4096000000');
```

The following example resizes a temporary tablespace based on the temp file with the file identifier 1 to the size of 2 MB.

```
EXEC rdsadmin.rdsadmin_util.resize_tempfile(1,'2M');
```

The following example turns off autoextension for temp file 1. It also sets the maximum autoextension size of temp file 2 to 10 GB, with an increment of 100 MB.

```
EXEC rdsadmin.rdsadmin_util.autoextend_tempfile(1,'OFF');
EXEC rdsadmin.rdsadmin_util.autoextend_tempfile(2,'ON','100M','10G');
```

For more information about read replicas for Oracle DB instances see Working with read replicas for Amazon RDS for Oracle.

Purging the recycle bin

When you drop a table, your Oracle database doesn't immediately remove its storage space. The database renames the table and places it and any associated objects in a recycle bin. Purging the recycle bin removes these items and releases their storage space.

To purge the entire recycle bin, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.purge_dba_recyclebin`. However, this procedure can't purge the recycle bin of SYS and RDSADMIN objects. If you need to purge these objects, contact AWS Support.

The following example purges the entire recycle bin.

```
EXEC rdsadmin.rdsadmin_util.purge_dba_recyclebin;
```

Setting the default displayed values for full redaction

To change the default displayed values for full redaction on your Amazon RDS Oracle instance, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.dbms_redact_upd_full_rdct_val`.

Note that you create a redaction policy with the DBMS_REDACT PL/SQL package, as explained in the Oracle Database documentation. The dbms_redact_upd_full_rdct_val procedure specifies the characters to display for different data types affected by an existing policy.

The dbms_redact_upd_full_rdct_val procedure has the following parameters.

Parameter name	Data type	Default	Required	Description
p_number_val	number	Null	No	Modifies the default value for columns of the NUMBER data type.
p_binfloat_val	binary_float	Null	No	Modifies the default value for columns of the BINARY_FLOAT data type.
p_bindouble_val	binary_double	Null	No	Modifies the default value for columns of the BINARY_DOUBLE data type.
p_char_val	char	Null	No	Modifies the default value for columns of the CHAR data type.
p_varchar_val	varchar2	Null	No	Modifies the default value for columns of the VARCHAR2 data type.
p_nchar_val	nchar	Null	No	Modifies the default value for columns of the NCHAR data type.
p_nvarchar_val	nvarchar2	Null	No	Modifies the default value for columns of the NVARCHAR2 data type.

Parameter name	Data type	Default	Required	Description
p_date_val	date	Null	No	Modifies the default value for columns of the DATE data type.
p_ts_val	timestamp	Null	No	Modifies the default value for columns of the TIMESTAMP data type.
p_tswtz_val	timestamp with time zone	Null	No	Modifies the default value for columns of the TIMESTAMP WITH TIME ZONE data type.
p_blob_val	blob	Null	No	Modifies the default value for columns of the BLOB data type.
p_clob_val	clob	Null	No	Modifies the default value for columns of the CLOB data type.
p_nclob_val	nclob	Null	No	Modifies the default value for columns of the NCLOB data type.

The following example changes the default redacted value to * for the CHAR data type:

```
EXEC rdsadmin.rdsadmin_util.dbms_redact_upd_full_rdct_val(p_char_val => '*');
```

The following example changes the default redacted values for NUMBER, DATE, and CHAR data types:

```
BEGIN
rdsadmin.rdsadmin_util.dbms_redact_upd_full_rdct_val(
    p_number_val=>1,
    p_date_val=>to_date('1900-01-01','YYYY-MM-DD'),
```

```
    p_varchar_val=>'X');
END;
/
```

After you alter the default values for full redaction with the `dbms_redact_upd_full_rdct_val` procedure, reboot your DB instance for the change to take effect. For more information, see Rebooting a DB instance.

Performing common log-related tasks for Oracle DB instances

Following, you can find how to perform certain common DBA tasks related to logging on your Amazon RDS DB instances running Oracle. To deliver a managed service experience, Amazon RDS doesn't provide shell access to DB instances, and restricts access to certain system procedures and tables that require advanced privileges.

For more information, see Oracle database log files.

Topics

- Setting force logging
- Setting supplemental logging
- Switching online log files
- Adding online redo logs
- Dropping online redo logs
- Resizing online redo logs
- Retaining archived redo logs
- Accessing online and archived redo logs
- Downloading archived redo logs from Amazon S3

Setting force logging

In force logging mode, Oracle logs all changes to the database except changes in temporary tablespaces and temporary segments (`NOLOGGING` clauses are ignored). For more information, see Specifying FORCE LOGGING mode in the Oracle documentation.

To set force logging, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.force_logging`. The `force_logging` procedure has the following parameters.

Parameter name	Data type	Default	Yes	Description
p_enable	boolean	true	No	Set to true to put the database in force logging mode, false to remove the database from force logging mode.

The following example puts the database in force logging mode.

```
EXEC rdsadmin.rdsadmin_util.force_logging(p_enable => true);
```

Setting supplemental logging

If you enable supplemental logging, LogMiner has the necessary information to support chained rows and clustered tables. For more information, see Supplemental logging in the Oracle documentation.

Oracle Database doesn't enable supplemental logging by default. To enable and disable supplemental logging, use the Amazon RDS procedure rdsadmin.rdsadmin_util.alter_supplemental_logging. For more information about how Amazon RDS manages the retention of archived redo logs for Oracle DB instances, see Retaining archived redo logs.

The alter_supplemental_logging procedure has the following parameters.

Parameter name	Data type	Default	Required	Description
p_action	varchar2	—	Yes	'ADD' to add supplemental logging, 'DROP' to drop supplemental logging.
p_type	varchar2	null	No	The type of supplemental logging. Valid values are 'ALL', 'FOREIGN KEY', 'PRIMARY

Parameter name	Data type	Default	Required	Description
				KEY', 'UNIQUE', or PROCEDURAL .

The following example enables supplemental logging.

```
begin
    rdsadmin.rdsadmin_util.alter_supplemental_logging(
        p_action => 'ADD');
end;
/
```

The following example enables supplemental logging for all fixed-length maximum size columns.

```
begin
    rdsadmin.rdsadmin_util.alter_supplemental_logging(
        p_action => 'ADD',
        p_type   => 'ALL');
end;
/
```

The following example enables supplemental logging for primary key columns.

```
begin
    rdsadmin.rdsadmin_util.alter_supplemental_logging(
        p_action => 'ADD',
        p_type   => 'PRIMARY KEY');
end;
/
```

Switching online log files

To switch log files, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.switch_logfile`. The `switch_logfile` procedure has no parameters.

The following example switches log files.

```
EXEC rdsadmin.rdsadmin_util.switch_logfile;
```

Adding online redo logs

An Amazon RDS DB instance running Oracle starts with four online redo logs, 128 MB each. To add additional redo logs, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.add_logfile`.

The `add_logfile` procedure has the following parameters.

> **Note**
>
> The parameters are mutually exclusive.

Parameter name	Data type	Default	Required	Description
`bytes`	positive	null	No	The size of the log file in bytes.
`p_size`	varchar2	—	Yes	The size of the log file. You can specify the size in kilobytes (K), megabytes (M), or gigabytes (G).

The following command adds a 100 MB log file.

```
EXEC rdsadmin.rdsadmin_util.add_logfile(p_size => '100M');
```

Dropping online redo logs

To drop redo logs, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.drop_logfile`. The `drop_logfile` procedure has the following parameters.

Parameter name	Data type	Default	Required	Description
`grp`	positive	—	Yes	The group number of the log.

The following example drops the log with group number 3.

```
EXEC rdsadmin.rdsadmin_util.drop_logfile(grp => 3);
```

You can only drop logs that have a status of unused or inactive. The following example gets the statuses of the logs.

```
SELECT GROUP#, STATUS FROM V$LOG;

GROUP#     STATUS
---------- ----------------
1          CURRENT
2          INACTIVE
3          INACTIVE
4          UNUSED
```

Resizing online redo logs

An Amazon RDS DB instance running Oracle starts with four online redo logs, 128 MB each. The following example shows how you can use Amazon RDS procedures to resize your logs from 128 MB each to 512 MB each.

```
/* Query V$LOG to see the logs.          */
/* You start with 4 logs of 128 MB each. */

SELECT GROUP#, BYTES, STATUS FROM V$LOG;

GROUP#     BYTES      STATUS
---------- ---------- ----------------
1          134217728  INACTIVE
2          134217728  CURRENT
3          134217728  INACTIVE
4          134217728  INACTIVE

/* Add four new logs that are each 512 MB */

EXEC rdsadmin.rdsadmin_util.add_logfile(bytes => 536870912);
EXEC rdsadmin.rdsadmin_util.add_logfile(bytes => 536870912);
EXEC rdsadmin.rdsadmin_util.add_logfile(bytes => 536870912);
EXEC rdsadmin.rdsadmin_util.add_logfile(bytes => 536870912);
```

```
/* Query V$LOG to see the logs. */
/* Now there are 8 logs.        */

SELECT GROUP#, BYTES, STATUS FROM V$LOG;

GROUP#     BYTES      STATUS
---------- ---------- ----------------
1          134217728  INACTIVE
2          134217728  CURRENT
3          134217728  INACTIVE
4          134217728  INACTIVE
5          536870912  UNUSED
6          536870912  UNUSED
7          536870912  UNUSED
8          536870912  UNUSED

/* Drop each inactive log using the group number. */

EXEC rdsadmin.rdsadmin_util.drop_logfile(grp => 1);
EXEC rdsadmin.rdsadmin_util.drop_logfile(grp => 3);
EXEC rdsadmin.rdsadmin_util.drop_logfile(grp => 4);

/* Query V$LOG to see the logs. */
/* Now there are 5 logs.        */

select GROUP#, BYTES, STATUS from V$LOG;

GROUP#     BYTES      STATUS
---------- ---------- ----------------
2          134217728  CURRENT
5          536870912  UNUSED
6          536870912  UNUSED
7          536870912  UNUSED
8          536870912  UNUSED

/* Switch logs so that group 2 is no longer current. */

EXEC rdsadmin.rdsadmin_util.switch_logfile;
```

```
/* Query V$LOG to see the logs.        */
/* Now one of the new logs is current. */

SQL>SELECT GROUP#, BYTES, STATUS FROM V$LOG;

GROUP#     BYTES      STATUS
---------- ---------- ----------------
2          134217728  ACTIVE
5          536870912  CURRENT
6          536870912  UNUSED
7          536870912  UNUSED
8          536870912  UNUSED

/* If the status of log 2 is still "ACTIVE", issue a checkpoint to clear it to
 "INACTIVE".  */

EXEC rdsadmin.rdsadmin_util.checkpoint;

/* Query V$LOG to see the logs.            */
/* Now the final original log is inactive. */

select GROUP#, BYTES, STATUS from V$LOG;

GROUP#     BYTES      STATUS
---------- ---------- ----------------
2          134217728  INACTIVE
5          536870912  CURRENT
6          536870912  UNUSED
7          536870912  UNUSED
8          536870912  UNUSED

# Drop the final inactive log.

EXEC rdsadmin.rdsadmin_util.drop_logfile(grp => 2);

/* Query V$LOG to see the logs.    */
/* Now there are four 512 MB logs. */

SELECT GROUP#, BYTES, STATUS FROM V$LOG;
```

```
GROUP#     BYTES      STATUS
---------- ---------- ----------------
5          536870912  CURRENT
6          536870912  UNUSED
7          536870912  UNUSED
8          536870912  UNUSED
```

Retaining archived redo logs

You can retain archived redo logs locally on your DB instance for use with products like Oracle LogMiner (DBMS_LOGMNR). After you have retained the redo logs, you can use LogMiner to analyze the logs. For more information, see Using LogMiner to analyze redo log files in the Oracle documentation.

To retain archived redo logs, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.set_configuration`. The `set_configuration` procedure has the following parameters.

Parameter name	Data type	Default	Required	Description
`name`	varchar	—	Yes	The name of the configuration to update.
`value`	varchar	—	Yes	The value for the configuration.

The following example retains 24 hours of redo logs.

```
begin
    rdsadmin.rdsadmin_util.set_configuration(
        name  => 'archivelog retention hours',
        value => '24');
end;
/
commit;
```

> **Note**
>
> The commit is required for the change to take effect.

To view how long archived redo logs are kept for your DB instance, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.show_configuration`.

The following example shows the log retention time.

```
set serveroutput on
EXEC rdsadmin.rdsadmin_util.show_configuration;
```

The output shows the current setting for `archivelog retention hours`. The following output shows that archived redo logs are kept for 48 hours.

```
NAME:archivelog retention hours
VALUE:48
DESCRIPTION:ArchiveLog expiration specifies the duration in hours before archive/redo
 log files are automatically deleted.
```

Because the archived redo logs are retained on your DB instance, ensure that your DB instance has enough allocated storage for the retained logs. To determine how much space your DB instance has used in the last X hours, you can run the following query, replacing X with the number of hours.

```
SELECT SUM(BLOCKS * BLOCK_SIZE) bytes
  FROM V$ARCHIVED_LOG
 WHERE FIRST_TIME >= SYSDATE-(X/24) AND DEST_ID=1;
```

RDS for Oracle only generates archived redo logs when the backup retention period of your DB instance is greater than zero. By default the backup retention period is greater than zero.

When the archived log retention period expires, RDS for Oracle removes the archived redo logs from your DB instance. To support restoring your DB instance to a point in time, Amazon RDS retains the archived redo logs outside of your DB instance based on the backup retention period. To modify the backup retention period, see Modifying an Amazon RDS DB instance.

Note

In some cases, you might be using JDBC on Linux to download archived redo logs and experience long latency times and connection resets. In such cases, the issues might be caused by the default random number generator setting on your Java client. We recommend setting your JDBC drivers to use a nonblocking random number generator.

Accessing online and archived redo logs

You might want to access your online and archived redo log files for mining with external tools such as GoldenGate, Attunity, Informatica, and others. To access these files, do the following:

1. Create directory objects that provide read-only access to the physical file paths.

   Use `rdsadmin.rdsadmin_master_util.create_archivelog_dir` and `rdsadmin.rdsadmin_master_util.create_onlinelog_dir`.
2. Read the files using PL/SQL.

   You can read the files by using PL/SQL. For more information about reading files from directory objects, see Listing files in a DB instance directory and Reading files in a DB instance directory.

Accessing transaction logs is supported for the following releases:

- Oracle Database 21c
- Oracle Database 19c

The following code creates directories that provide read-only access to your online and archived redo log files:

> **Important**
>
> This code also revokes the `DROP ANY DIRECTORY` privilege.

```
EXEC rdsadmin.rdsadmin_master_util.create_archivelog_dir;
EXEC rdsadmin.rdsadmin_master_util.create_onlinelog_dir;
```

The following code drops the directories for your online and archived redo log files.

```
EXEC rdsadmin.rdsadmin_master_util.drop_archivelog_dir;
EXEC rdsadmin.rdsadmin_master_util.drop_onlinelog_dir;
```

The following code grants and revokes the `DROP ANY DIRECTORY` privilege.

```
EXEC rdsadmin.rdsadmin_master_util.revoke_drop_any_directory;
```

```
EXEC rdsadmin.rdsadmin_master_util.grant_drop_any_directory;
```

Downloading archived redo logs from Amazon S3

You can download archived redo logs on your DB instance using the `rdsadmin.rdsadmin_archive_log_download` package. If archived redo logs are no longer on your DB instance, you might want to download them again from Amazon S3. Then you can mine the logs or use them to recover or replicate your database.

> **Note**
>
> You can't download archived redo logs on read replica instances.

Downloading archived redo logs: basic steps

The availability of your archived redo logs depends on the following retention policies:

- Backup retention policy – Logs inside of this policy are available in Amazon S3. Logs outside of this policy are removed.
- Archived log retention policy – Logs inside of this policy are available on your DB instance. Logs outside of this policy are removed.

If logs aren't on your instance but are protected by your backup retention period, use `rdsadmin.rdsadmin_archive_log_download` to download them again. RDS for Oracle saves the logs to the `/rdsdbdata/log/arch` directory on your DB instance.

To download archived redo logs from Amazon S3

1. Configure your retention period to ensure your downloaded archived redo logs are retained for the duration you need them. Make sure to `COMMIT` your change.

   RDS retains your downloaded logs according to the archived log retention policy, starting from the time the logs were downloaded. To learn how to set the retention policy, see Retaining archived redo logs.
2. Wait up to 5 minutes for the archived log retention policy change to take effect.
3. Download the archived redo logs from Amazon S3 using `rdsadmin.rdsadmin_archive_log_download`.

For more information, see Downloading a single archived redo log and Downloading a series of archived redo logs.

> **Note**
>
> RDS automatically checks the available storage before downloading. If the requested logs consume a high percentage of space, you receive an alert.

4. Confirm that the logs were downloaded from Amazon S3 successfully.

   You can view the status of your download task in a bdump file. The bdump files have the path name `/rdsdbdata/log/trace/dbtask-task-id.log`. In the preceding download step, you run a `SELECT` statement that returns the task ID in a `VARCHAR2` data type. For more information, see similar examples in Monitoring the status of a file transfer.

Downloading a single archived redo log

To download a single archived redo log to the `/rdsdbdata/log/arch` directory, use `rdsadmin.rdsadmin_archive_log_download.download_log_with_seqnum`. This procedure has the following parameter.

Parameter name	Data type	Default	Required	Description
`seqnum`	number	—	Yes	The sequence number of the archived redo log.

The following example downloads the log with sequence number 20.

```
SELECT rdsadmin.rdsadmin_archive_log_download.download_log_with_seqnum(seqnum => 20)
       AS TASK_ID
FROM   DUAL;
```

Downloading a series of archived redo logs

To download a series of archived redo logs to the `/rdsdbdata/log/arch` directory, use `download_logs_in_seqnum_range`. Your download is limited to 300 logs per request. The `download_logs_in_seqnum_range` procedure has the following parameters.

Parameter name	Data type	Default	Required	Description
start_seq	number	—	Yes	The starting sequence number for the series.
end_seq	number	—	Yes	The ending sequence number for the series.

The following example downloads the logs from sequence 50 to 100.

```
SELECT rdsadmin.rdsadmin_archive_log_download.download_logs_in_seqnum_range(start_seq
 => 50, end_seq => 100)
       AS TASK_ID
FROM   DUAL;
```

Performing common RMAN tasks for Oracle DB instances

In the following section, you can find how you can perform Oracle Recovery Manager (RMAN) DBA tasks on your Amazon RDS DB instances running Oracle. To deliver a managed service experience, Amazon RDS doesn't provide shell access to DB instances. It also restricts access to certain system procedures and tables that require advanced privileges.

Use the Amazon RDS package `rdsadmin.rdsadmin_rman_util` to perform RMAN backups of your Amazon RDS for Oracle database to disk. The `rdsadmin.rdsadmin_rman_util` package supports full and incremental database file backups, tablespace backups, and archived redo log backups.

After an RMAN backup has finished, you can copy the backup files off the Amazon RDS for Oracle DB instance host. You might do this for the purpose of restoring to a non-RDS host or for long-term storage of backups. For example, you can copy the backup files to an Amazon S3 bucket. For more information, see using Amazon S3 integration.

The backup files for RMAN backups remain on the Amazon RDS DB instance host until you remove them manually. You can use the `UTL_FILE.FREMOVE` Oracle procedure to remove files from a directory. For more information, see FREMOVE procedure in the Oracle Database documentation.

You can't use the RMAN to restore RDS for Oracle DB instances. However, you can use RMAN to restore a backup to an on-premises or Amazon EC2 instance. For more information, see the blog article Restore an Amazon RDS for Oracle instance to a self-managed instance.

> **Note**
>
> For backing up and restoring to another Amazon RDS for Oracle DB instance, you can continue to use the Amazon RDS backup and restore features. For more information, see Backing up, restoring, and exporting data.

Topics

Prerequisites for RMAN backups

Before backing up your database using the `rdsadmin.rdsadmin_rman_util` package, make sure that you meet the following prerequisites:

- Make sure that your RDS for Oracle database is in `ARCHIVELOG` mode. To enable this mode, set the backup retention period to a non-zero value.
- When backing up archived redo logs or performing a full or incremental backup that includes archived redo logs, and when backing up the database, make sure that redo log retention is set to a nonzero value. Archived redo logs are required to make database files consistent during recovery. For more information, see Retaining archived redo logs.

- Make sure that your DB instance has sufficient free space to hold the backups. When back up your database, you specify an Oracle directory object as a parameter in the procedure call. RMAN places the files in the specified directory. You can use default directories, such as `DATA_PUMP_DIR`, or create a new directory. For more information, see Creating and dropping directories in the main data storage space.

  You can monitor the current free space in an RDS for Oracle instance using the CloudWatch metric `FreeStorageSpace`. We recommend that your free space exceeds the current size of the database, though RMAN backs up only formatted blocks and supports compression.

Common parameters for RMAN procedures

You can use procedures in the Amazon RDS package `rdsadmin.rdsadmin_rman_util` to perform tasks with RMAN. Several parameters are common to the procedures in the package. The package has the following common parameters.

Parameter name	Data type	Valid values	Defau	Requir	Description
`p_directory_name`	varchar	A valid database directory name.	—	Yes	The name of the directory to contain the backup files.
`p_label`	varchar	`a-z`, `A-Z`, `0-9`, `'_'`, `'-'`, `'.'`	—	No	A unique string that is included in the backup file names. **Note** The limit is 30 characters.
`p_owner`	varchar	A valid owner of the directory specified in	—	Yes	The owner of the directory to contain the backup files.

Parameter name	Data type	Valid values	Defau	Requir	Description
		p_directory_name .			

Parameter name	Data type	Valid values	Defau	Requir	Description
p_tag	varchar	a-z, A-Z, 0-9, '_', '-', '.'	NULL	No	A string that can be used to distinguish between backups to indicate the purpose or usage of backups, such as daily, weekly, or incremental-level backups. The limit is 30 characters. The tag is not case-sensitive. Tags are always stored in uppercase, regardless of the case used when entering them. Tags don't need to be unique, so multiple backups can have the same tag. If you don't specify a tag, then RMAN assigns a default tag automatically using the format TAG*YYYYMMDDT HHMMSS* , where *YYYY* is the year, *MM* is the month, *DD* is the day, *HH* is the hour (in 24-hour format), *MM* is the minutes, and *SS* is the seconds. The date and time refer to when RMAN started the backup. For example, a backup might receive a tag TAG20190927T214517 for a backup that started on 2019-09-27 at 21:45:17. The p_tag parameter is supported for the following Amazon RDS for Oracle DB engine versions: • Oracle Database 21c (21.0.0)

Parameter name	Data type	Valid values	Defau	Requir	Description
					• Oracle Database 19c (19.0.0), using 19.0.0.0.ru-2021-10.rur-2021-10.r1 or higher
p_compress	boolean	TRUE, FALSE	FALSE	No	Specify TRUE to enable BASIC backup compression. Specify FALSE to disable BASIC backup compression.
p_include_archive_logs	boolean	TRUE, FALSE	FALSE	No	Specify TRUE to include archived redo logs in the backup. Specify FALSE to exclude archived redo logs from the backup. If you include archived redo logs in the backup, set retention to one hour or greater using the rdsadmin.rdsadmin_util.set_configuration procedure. Also, call the rdsadmin.rdsadmin_rman_util.crosscheck_archivelog procedure immediately before running the backup. Otherwise, the backup might fail due to missing archived redo log files that have been deleted by Amazon RDS management procedures.
p_include_controlfile	boolean	TRUE, FALSE	FALSE	No	Specify TRUE to include the control file in the backup. Specify FALSE to exclude the control file from the backup.

Parameter name	Data type	Valid values	Defau	Requir	Description
p_optimize	boolean	TRUE, FALSE	TRUE	No	Specify TRUE to enable backup optimization, if archived redo logs are included, to reduce backup size. Specify FALSE to disable backup optimization.
p_parallel	number	A valid integer between 1 and 254 for Oracle Database Enterprise Edition (EE) 1 for other Oracle Database editions	1	No	Number of channels.
p_rman_to_dbms_output	boolean	TRUE, FALSE	FALSE	No	When TRUE, the RMAN output is sent to the DBMS_OUTPUT package in addition to a file in the BDUMP directory. In SQL*Plus, use SET SERVEROUTPUT ON to see the output. When FALSE, the RMAN output is only sent to a file in the BDUMP directory.

Parameter name	Data type	Valid values	Defau	Requir	Description
p_section_size_mb	numbe	A valid integer	NULL	No	The section size in megabytes (MB). Validates in parallel by dividing each file into the specified section size. When NULL, the parameter is ignored.
p_validation_type	varchar	'PHYSICAL', 'PHYSICAL+LOGICAL'	'PHYS'	No	The level of corruption detection. Specify 'PHYSICAL' to check for physical corruption. An example of physical corruption is a block with a mismatch in the header and footer. Specify 'PHYSICAL+LOGICAL' to check for logical inconsistencies in addition to physical corruption. An example of logical corruption is a corrupt block.

Validating database files in RDS for Oracle

You can use the Amazon RDS package `rdsadmin.rdsadmin_rman_util` to validate Amazon RDS for Oracle database files, such as data files, tablespaces, control files, and server parameter files (SPFILEs).

For more information about RMAN validation, see Validating database files and backups and VALIDATE in the Oracle documentation.

Topics

- Validating a database
- Validating a tenant database
- Validating a tablespace
- Validating a control file

- Validating an SPFILE
- Validating an Oracle data file

Validating a database

To validate all of the relevant files used by an Oracle database in RDS for Oracle, use the Amazon RDS procedure `rdsadmin.rdsadmin_rman_util.validate_database`.

This procedure uses the following common parameters for RMAN tasks:

- `p_validation_type`
- `p_parallel`
- `p_section_size_mb`
- `p_rman_to_dbms_output`

For more information, see Common parameters for RMAN procedures.

The following example validates the database using the default values for the parameters.

```
EXEC rdsadmin.rdsadmin_rman_util.validate_database;
```

The following example validates the database using the specified values for the parameters.

```
BEGIN
    rdsadmin.rdsadmin_rman_util.validate_database(
        p_validation_type     => 'PHYSICAL+LOGICAL',
        p_parallel            => 4,
        p_section_size_mb     => 10,
        p_rman_to_dbms_output => FALSE);
END;
/
```

When the `p_rman_to_dbms_output` parameter is set to `FALSE`, the RMAN output is written to a file in the `BDUMP` directory.

To view the files in the `BDUMP` directory, run the following `SELECT` statement.

```
SELECT * FROM table(rdsadmin.rds_file_util.listdir('BDUMP')) order by mtime;
```

To view the contents of a file in the BDUMP directory, run the following SELECT statement.

```
SELECT text FROM table(rdsadmin.rds_file_util.read_text_file('BDUMP','rds-rman-validate-nnn.txt'));
```

Replace the file name with the name of the file you want to view.

Validating a tenant database

To validate the data files of the tenant database in a container database (CDB), use the Amazon RDS procedure `rdsadmin.rdsadmin_rman_util.validate_tenant`.

This procedure applies only to the current tenant database and uses the following common parameters for RMAN tasks:

- `p_validation_type`
- `p_parallel`
- `p_section_size_mb`
- `p_rman_to_dbms_output`

For more information, see Common parameters for RMAN procedures. This procedure is supported for the following DB engine versions:

- Oracle Database 21c (21.0.0) CDB
- Oracle Database 19c (19.0.0) CDB

The following example validates the current tenant database using the default values for the parameters.

```
EXEC rdsadmin.rdsadmin_rman_util.validate_tenant;
```

The following example validates the current tenant database using the specified values for the parameters.

```
BEGIN
    rdsadmin.rdsadmin_rman_util.validate_tenant(
        p_validation_type     => 'PHYSICAL+LOGICAL',
```

```
        p_parallel            => 4,
        p_section_size_mb     => 10,
        p_rman_to_dbms_output => FALSE);
END;
/
```

When the p_rman_to_dbms_output parameter is set to FALSE, the RMAN output is written to a file in the BDUMP directory.

To view the files in the BDUMP directory, run the following SELECT statement.

```
SELECT * FROM table(rdsadmin.rds_file_util.listdir('BDUMP')) order by mtime;
```

To view the contents of a file in the BDUMP directory, run the following SELECT statement.

```
SELECT text FROM table(rdsadmin.rds_file_util.read_text_file('BDUMP','rds-rman-
validate-nnn.txt'));
```

Replace the file name with the name of the file you want to view.

Validating a tablespace

To validate the files associated with a tablespace, use the Amazon RDS procedure rdsadmin.rdsadmin_rman_util.validate_tablespace.

This procedure uses the following common parameters for RMAN tasks:

- p_validation_type
- p_parallel
- p_section_size_mb
- p_rman_to_dbms_output

For more information, see Common parameters for RMAN procedures.

This procedure also uses the following additional parameter.

Parameter name	Data type	Valid values	Default	Required	Description
p_tablespace_name	varchar2	A valid tablespace name	—	Yes	The name of the tablespace.

Validating a control file

To validate only the control file used by an Amazon RDS Oracle DB instance, use the Amazon RDS procedure `rdsadmin.rdsadmin_rman_util.validate_current_controlfile`.

This procedure uses the following common parameter for RMAN tasks:

- `p_validation_type`
- `p_rman_to_dbms_output`

For more information, see Common parameters for RMAN procedures.

Validating an SPFILE

To validate only the server parameter file (SPFILE) used by an Amazon RDS Oracle DB instance, use the Amazon RDS procedure `rdsadmin.rdsadmin_rman_util.validate_spfile`.

This procedure uses the following common parameter for RMAN tasks:

- `p_validation_type`
- `p_rman_to_dbms_output`

For more information, see Common parameters for RMAN procedures.

Validating an Oracle data file

To validate a data file, use the Amazon RDS procedure `rdsadmin.rdsadmin_rman_util.validate_datafile`.

This procedure uses the following common parameters for RMAN tasks:

- `p_validation_type`

- p_parallel
- p_section_size_mb
- p_rman_to_dbms_output

For more information, see Common parameters for RMAN procedures.

This procedure also uses the following additional parameters.

Parameter name	Data type	Valid values	Default	Required	Description
p_datafile	varchar2	A valid datafile ID number or a valid datafile name including complete path	—	Yes	The datafile ID number (from v $datafile.file#) or the full datafile name including the path (from v $datafile.name).
p_from_block	number	A valid integer	NULL	No	The number of the block where the validation starts within the data file. When this is NULL, 1 is used.
p_to_block	number	A valid integer	NULL	No	The number of the block where the validation ends within the data file. When this is NULL, the maximum block in the data file is used.

Enabling and disabling block change tracking

Block changing tracking records changed blocks in a tracking file. This technique can improve the performance of RMAN incremental backups. For more information, see Using Block Change Tracking to Improve Incremental Backup Performance in the Oracle Database documentation.

RMAN features aren't supported in a read replica. However, as part of your high availability strategy, you might choose to enable block tracking in a read-only replica using the procedure `rdsadmin.rdsadmin_rman_util.enable_block_change_tracking`. If you promote this read-only replica to a source DB instance, block change tracking is enabled for the new source instance. Thus, your instance can benefit from fast incremental backups.

Block change tracking procedures are supported in Enterprise Edition only for the following DB engine versions:

- Oracle Database 21c (21.0.0)
- Oracle Database 19c (19.0.0)

> **Note**
>
> In a single-tenant CDB, the following operations work, but no customer-visible mechanism can detect the current status of the operations. See also Limitations of RDS for Oracle CDBs.

To enable block change tracking for a DB instance, use the Amazon RDS procedure `rdsadmin.rdsadmin_rman_util.enable_block_change_tracking`. To disable block change tracking, use `disable_block_change_tracking`. These procedures take no parameters.

To determine whether block change tracking is enabled for your DB instance, run the following query.

```
SELECT STATUS, FILENAME FROM V$BLOCK_CHANGE_TRACKING;
```

The following example enables block change tracking for a DB instance.

```
EXEC rdsadmin.rdsadmin_rman_util.enable_block_change_tracking;
```

The following example disables block change tracking for a DB instance.

```
EXEC rdsadmin.rdsadmin_rman_util.disable_block_change_tracking;
```

Crosschecking archived redo logs

You can crosscheck archived redo logs using the Amazon RDS procedure `rdsadmin.rdsadmin_rman_util.crosscheck_archivelog`.

You can use this procedure to crosscheck the archived redo logs registered in the control file and optionally delete the expired logs records. When RMAN makes a backup, it creates a record in the control file. Over time, these records increase the size of the control file. We recommend that you remove expired records periodically.

> **Note**
>
> Standard Amazon RDS backups don't use RMAN and therefore don't create records in the control file.

This procedure uses the common parameter `p_rman_to_dbms_output` for RMAN tasks.

For more information, see Common parameters for RMAN procedures.

This procedure also uses the following additional parameter.

Parameter name	Data type	Valid values	Default	Required	Description
`p_delete_expired`	boolean	`TRUE`, `FALSE`	`TRUE`	No	When `TRUE`, delete expired archived redo log records from the control file. When `FALSE`, retain the expired archived redo log records in the control file.

This procedure is supported for the following Amazon RDS for Oracle DB engine versions:

- Oracle Database 21c (21.0.0)
- Oracle Database 19c (19.0.0)

The following example marks archived redo log records in the control file as expired, but does not delete the records.

```
BEGIN
    rdsadmin.rdsadmin_rman_util.crosscheck_archivelog(
        p_delete_expired      => FALSE,
        p_rman_to_dbms_output => FALSE);
END;
/
```

The following example deletes expired archived redo log records from the control file.

```
BEGIN
    rdsadmin.rdsadmin_rman_util.crosscheck_archivelog(
        p_delete_expired      => TRUE,
        p_rman_to_dbms_output => FALSE);
END;
/
```

Backing up archived redo log files

You can use the Amazon RDS package `rdsadmin.rdsadmin_rman_util` to back up archived redo logs for an Amazon RDS Oracle DB instance.

The procedures for backing up archived redo logs are supported for the following Amazon RDS for Oracle DB engine versions:

- Oracle Database 21c (21.0.0)
- Oracle Database 19c (19.0.0)

Topics

- Backing up all archived redo logs
- Backing up an archived redo log from a date range
- Backing up an archived redo log from an SCN range
- Backing up an archived redo log from a sequence number range

Backing up all archived redo logs

To back up all of the archived redo logs for an Amazon RDS Oracle DB instance, use the Amazon RDS procedure `rdsadmin.rdsadmin_rman_util.backup_archivelog_all`.

This procedure uses the following common parameters for RMAN tasks:

- `p_owner`
- `p_directory_name`
- `p_label`
- `p_parallel`
- `p_compress`
- `p_rman_to_dbms_output`
- `p_tag`

For more information, see Common parameters for RMAN procedures.

The following example backs up all archived redo logs for the DB instance.

```
BEGIN
    rdsadmin.rdsadmin_rman_util.backup_archivelog_all(
        p_owner               => 'SYS',
        p_directory_name      => 'MYDIRECTORY',
        p_parallel            => 4,
        p_tag                 => 'MY_LOG_BACKUP',
        p_rman_to_dbms_output => FALSE);
END;
/
```

Backing up an archived redo log from a date range

To back up specific archived redo logs for an Amazon RDS Oracle DB instance by specifying a date range, use the Amazon RDS procedure `rdsadmin.rdsadmin_rman_util.backup_archivelog_date`. The date range specifies which archived redo logs to back up.

This procedure uses the following common parameters for RMAN tasks:

- p_owner
- p_directory_name
- p_label
- p_parallel
- p_compress
- p_rman_to_dbms_output
- p_tag

For more information, see Common parameters for RMAN procedures.

This procedure also uses the following additional parameters.

Parameter name	Data type	Valid values	Default	Required	Description
p_from_date	date	A date that is between the start_date and next_date of an archived redo log that exists on disk. The value must be less than or equal to the value specified	—	Yes	The starting date for the archived log backups.

Parameter name	Data type	Valid values	Default	Required	Description
		for p_to_date .			
p_to_date	date	A date that is between the start_date and next_date of an archived redo log that exists on disk. The value must be greater than or equal to the value specified for p_from_date .	—	Yes	The ending date for the archived log backups.

The following example backs up archived redo logs in the date range for the DB instance.

```
BEGIN
    rdsadmin.rdsadmin_rman_util.backup_archivelog_date(
        p_owner               => 'SYS',
```

```
        p_directory_name      => 'MYDIRECTORY',
        p_from_date           => '03/01/2019 00:00:00',
        p_to_date             => '03/02/2019 00:00:00',
        p_parallel            => 4,
        p_tag                 => 'MY_LOG_BACKUP',
        p_rman_to_dbms_output => FALSE);
END;
/
```

Backing up an archived redo log from an SCN range

To back up specific archived redo logs for an Amazon RDS Oracle DB instance by specifying a system change number (SCN) range, use the Amazon RDS procedure `rdsadmin.rdsadmin_rman_util.backup_archivelog_scn`. The SCN range specifies which archived redo logs to back up.

This procedure uses the following common parameters for RMAN tasks:

- `p_owner`
- `p_directory_name`
- `p_label`
- `p_parallel`
- `p_compress`
- `p_rman_to_dbms_output`
- `p_tag`

For more information, see Common parameters for RMAN procedures.

This procedure also uses the following additional parameters.

Parameter name	Data type	Valid values	Default	Required	Description
`p_from_scn`	number	An SCN of an archived redo	—	Yes	The starting SCN for the archived log backups.

Parameter name	Data type	Valid values	Default	Required	Description
		log that exists on disk. The value must be less than or equal to the value specified for `p_to_scn`.			
`p_to_scn`	number	An SCN of an archived redo log that exists on disk. The value must be greater than or equal to the value specified for `p_from_scn`.	—	Yes	The ending SCN for the archived log backups.

The following example backs up archived redo logs in the SCN range for the DB instance.

```
BEGIN
    rdsadmin.rdsadmin_rman_util.backup_archivelog_scn(
        p_owner                => 'SYS',
        p_directory_name       => 'MYDIRECTORY',
        p_from_scn             => 1533835,
        p_to_scn               => 1892447,
        p_parallel             => 4,
        p_tag                  => 'MY_LOG_BACKUP',
        p_rman_to_dbms_output => FALSE);
END;
/
```

Backing up an archived redo log from a sequence number range

To back up specific archived redo logs for an Amazon RDS Oracle DB instance by specifying a sequence number range, use the Amazon RDS procedure `rdsadmin.rdsadmin_rman_util.backup_archivelog_sequence`. The sequence number range specifies which archived redo logs to back up.

This procedure uses the following common parameters for RMAN tasks:

- `p_owner`
- `p_directory_name`
- `p_label`
- `p_parallel`
- `p_compress`
- `p_rman_to_dbms_output`
- `p_tag`

For more information, see Common parameters for RMAN procedures.

This procedure also uses the following additional parameters.

Parameter name	Data type	Valid values	Default	Required	Description
`p_from_sequence`	number	A sequence	—	Yes	The starting sequence number

Parameter name	Data type	Valid values	Default	Required	Description
		number an archived redo log that exists on disk. The value must be less than or equal to the value specified for `p_to_sequence`.			for the archived log backups.

Parameter name	Data type	Valid values	Default	Required	Description
p_to_sequence	number	A sequence number of an archived redo log that exists on disk. The value must be greater than or equal to the value specified for p_from_sequence .	—	Yes	The ending sequence number for the archived log backups.

The following example backs up archived redo logs in the sequence number range for the DB instance.

```
BEGIN
    rdsadmin.rdsadmin_rman_util.backup_archivelog_sequence(
        p_owner               => 'SYS',
        p_directory_name      => 'MYDIRECTORY',
        p_from_sequence       => 11160,
        p_to_sequence         => 11160,
        p_parallel            => 4,
        p_tag                 => 'MY_LOG_BACKUP',
        p_rman_to_dbms_output => FALSE);
END;
/
```

Performing a full database backup

You can perform a backup of all blocks of data files included in the backup using Amazon RDS procedure `rdsadmin.rdsadmin_rman_util.backup_database_full`.

This procedure uses the following common parameters for RMAN tasks:

- `p_owner`
- `p_directory_name`
- `p_label`
- `p_parallel`
- `p_section_size_mb`
- `p_include_archive_logs`
- `p_optimize`
- `p_compress`
- `p_rman_to_dbms_output`
- `p_tag`

For more information, see Common parameters for RMAN procedures.

This procedure is supported for the following Amazon RDS for Oracle DB engine versions:

- Oracle Database 21c (21.0.0)
- Oracle Database 19c (19.0.0)

The following example performs a full backup of the DB instance using the specified values for the parameters.

```
BEGIN
    rdsadmin.rdsadmin_rman_util.backup_database_full(
        p_owner               => 'SYS',
        p_directory_name      => 'MYDIRECTORY',
        p_parallel            => 4,
        p_section_size_mb     => 10,
        p_tag                 => 'FULL_DB_BACKUP',
        p_rman_to_dbms_output => FALSE);
```

```
END;
/
```

Performing a full backup of a tenant database

You can perform a backup of all data blocks included a tenant database in a container database (CDB). Use the Amazon RDS procedure `rdsadmin.rdsadmin_rman_util.backup_tenant_full`. This procedure applies only to the current database backup and uses the following common parameters for RMAN tasks:

- `p_owner`
- `p_directory_name`
- `p_label`
- `p_parallel`
- `p_section_size_mb`
- `p_include_archive_logs`
- `p_optimize`
- `p_compress`
- `p_rman_to_dbms_output`
- `p_tag`

For more information, see Common parameters for RMAN procedures.

The `rdsadmin_rman_util.backup_tenant_full` procedure is supported for the following RDS for Oracle DB engine versions:

- Oracle Database 21c (21.0.0) CDB
- Oracle Database 19c (19.0.0) CDB

The following example performs a full backup of the current tenant database using the specified values for the parameters.

```
BEGIN
    rdsadmin.rdsadmin_rman_util.backup_tenant_full(
        p_owner               => 'SYS',
```

```
        p_directory_name      => 'MYDIRECTORY',
        p_parallel            => 4,
        p_section_size_mb     => 10,
        p_tag                 => 'FULL_TENANT_DB_BACKUP',
        p_rman_to_dbms_output => FALSE);
END;
/
```

Performing an incremental database backup

You can perform an incremental backup of your DB instance using the Amazon RDS procedure `rdsadmin.rdsadmin_rman_util.backup_database_incremental`.

For more information about incremental backups, see Incremental backups in the Oracle documentation.

This procedure uses the following common parameters for RMAN tasks:

- `p_owner`
- `p_directory_name`
- `p_label`
- `p_parallel`
- `p_section_size_mb`
- `p_include_archive_logs`
- `p_include_controlfile`
- `p_optimize`
- `p_compress`
- `p_rman_to_dbms_output`
- `p_tag`

For more information, see Common parameters for RMAN procedures.

This procedure is supported for the following Amazon RDS for Oracle DB engine versions:

- Oracle Database 21c (21.0.0)
- Oracle Database 19c (19.0.0)

This procedure also uses the following additional parameter.

Parameter name	Data type	Valid values	Default	Required	Description
p_level	number	0, 1	0	No	Specify 0 to enable a full incremental backup. Specify 1 to enable a non-cumulative incremental backup.

The following example performs an incremental backup of the DB instance using the specified values for the parameters.

```
BEGIN
    rdsadmin.rdsadmin_rman_util.backup_database_incremental(
        p_owner                => 'SYS',
        p_directory_name       => 'MYDIRECTORY',
        p_level                => 1,
        p_parallel             => 4,
        p_section_size_mb      => 10,
        p_tag                  => 'MY_INCREMENTAL_BACKUP',
        p_rman_to_dbms_output => FALSE);
END;
/
```

Performing an incremental backup of a tenant database

You can perform an incremental backup of the current tenant database in your CDB. Use the Amazon RDS procedure `rdsadmin.rdsadmin_rman_util.backup_tenant_incremental`.

For more information about incremental backups, see Incremental backups in the Oracle Database documentation.

This procedure applies only to the current tenant database and uses the following common parameters for RMAN tasks:

- p_owner

- p_directory_name
- p_label
- p_parallel
- p_section_size_mb
- p_include_archive_logs
- p_include_controlfile
- p_optimize
- p_compress
- p_rman_to_dbms_output
- p_tag

For more information, see Common parameters for RMAN procedures.

This procedure is supported for the following Amazon RDS for Oracle DB engine versions:

- Oracle Database 21c (21.0.0) CDB
- Oracle Database 19c (19.0.0) CDB

This procedure also uses the following additional parameter.

Parameter name	Data type	Valid values	Default	Required	Description
p_level	number	0, 1	0	No	Specify 0 to enable a full incremental backup. Specify 1 to enable a non-cumulative incremental backup.

The following example performs an incremental backup of the current tenant database using the specified values for the parameters.

```
BEGIN
    rdsadmin.rdsadmin_rman_util.backup_tenant_incremental(
        p_owner                => 'SYS',
        p_directory_name       => 'MYDIRECTORY',
        p_level                => 1,
        p_parallel             => 4,
        p_section_size_mb      => 10,
        p_tag                  => 'MY_INCREMENTAL_BACKUP',
        p_rman_to_dbms_output => FALSE);
END;
/
```

Backing up a tablespace

You can back up a tablespace using the Amazon RDS procedure `rdsadmin.rdsadmin_rman_util.backup_tablespace`.

This procedure uses the following common parameters for RMAN tasks:

- `p_owner`
- `p_directory_name`
- `p_label`
- `p_parallel`
- `p_section_size_mb`
- `p_include_archive_logs`
- `p_include_controlfile`
- `p_optimize`
- `p_compress`
- `p_rman_to_dbms_output`
- `p_tag`

For more information, see Common parameters for RMAN procedures.

This procedure also uses the following additional parameter.

Parameter name	Data type	Valid values	Default	Required	Description
p_tablespace_name	varchar2	A valid tablespace name.	—	Yes	The name of the tablespace to back up.

This procedure is supported for the following Amazon RDS for Oracle DB engine versions:

- Oracle Database 21c (21.0.0)
- Oracle Database 19c (19.0.0)

The following example performs a tablespace backup using the specified values for the parameters.

```
BEGIN
    rdsadmin.rdsadmin_rman_util.backup_tablespace(
        p_owner               => 'SYS',
        p_directory_name      => 'MYDIRECTORY',
        p_tablespace_name     => 'MYTABLESPACE',
        p_parallel            => 4,
        p_section_size_mb     => 10,
        p_tag                 => 'MYTABLESPACE_BACKUP',
        p_rman_to_dbms_output => FALSE);
END;
/
```

Backing up a control file

You can back up a control file using the Amazon RDS procedure `rdsadmin.rdsadmin_rman_util.backup_current_controlfile`.

This procedure uses the following common parameters for RMAN tasks:

- `p_owner`
- `p_directory_name`
- `p_label`

- p_compress
- p_rman_to_dbms_output
- p_tag

For more information, see Common parameters for RMAN procedures.

This procedure is supported for the following Amazon RDS for Oracle DB engine versions:

- Oracle Database 21c (21.0.0)
- Oracle Database 19c (19.0.0)

The following example backs up a control file using the specified values for the parameters.

```
BEGIN
    rdsadmin.rdsadmin_rman_util.backup_current_controlfile(
        p_owner               => 'SYS',
        p_directory_name      => 'MYDIRECTORY',
        p_tag                 => 'CONTROL_FILE_BACKUP',
        p_rman_to_dbms_output => FALSE);
END;
/
```

Performing block media recovery

You can recovery individual data blocks, known as *block media recovery*, using the Amazon RDS procedures rdsadmin.rdsadmin_rman_util.recover_datafile_block. You can use this overloaded procedure to recover either an individual data block or a range of data blocks.

This procedure uses the following common parameter for RMAN tasks:

- p_rman_to_dbms_output

For more information, see Common parameters for RMAN procedures.

This procedure uses the following additional parameters.

Parameter name	Data type	Valid values	Default	Required	Description
p_datafile	NUMBER	A valid data file ID number.	—	Yes	The data file containing the corrupt blocks. Specify the data file in either of the following ways: • The data file ID number, which is located in V$DATAFILE.FILE# • The full data file name, including the path, located in V$DATAFILE.NAME
p_block	NUMBER	A valid integer.	—	Yes	The number of an individual block to be recovered. The following parameters are mutually exclusive: • p_block • p_from_block and p_to_block
p_from_block	NUMBER	A valid integer.	—	Yes	The first block number in a range of blocks to be recovered. The following parameters are mutually exclusive: • p_block

Parameter name	Data type	Valid values	Default	Required	Description
					• p_from_block and p_to_block
p_to_block	NUMBER	A valid integer.	—	Yes	The last block number in a range of blocks to be recovered. The following parameters are mutually exclusive: • p_block • p_from_block and p_to_block

This procedure is supported for the following Amazon RDS for Oracle DB engine versions:

- Oracle Database 21c (21.0.0)
- Oracle Database 19c (19.0.0)

The following example recovers block 100 in data file 5.

```
BEGIN
    rdsadmin.rdsadmin_rman_util.recover_datafile_block(
        p_datafile            => 5,
        p_block               => 100,
        p_rman_to_dbms_output => TRUE);
END;
/
```

The following example recovers blocks 100 to 150 in data file 5.

```
BEGIN
    rdsadmin.rdsadmin_rman_util.recover_datafile_block(
        p_datafile            => 5,
        p_from_block          => 100,
        p_to_block            => 150,
```

```
        p_rman_to_dbms_output => TRUE);
END;
/
```

Performing common scheduling tasks for Oracle DB instances

Some scheduler jobs owned by SYS can interfere with normal database operations. Oracle Support recommends you disable these jobs or modify the schedule. To perform tasks for Oracle Scheduler jobs owned by SYS, use the Amazon RDS package `rdsadmin.rdsadmin_dbms_scheduler`.

The `rdsadmin.rdsadmin_dbms_scheduler` procedures are supported for the following Amazon RDS for Oracle DB engine versions:

- Oracle Database 21c (21.0.0)
- Oracle Database 19c

Common parameters for Oracle Scheduler procedures

To perform tasks with Oracle Scheduler, use procedures in the Amazon RDS package `rdsadmin.rdsadmin_dbms_scheduler`. Several parameters are common to the procedures in the package. The package has the following common parameters.

Parameter name	Data type	Valid values	Default	Required	Description
name	varchar2	'SYS.BSLN_MAINTAIN_STATS_JOB' ,'SYS.CLEANUP_ONLINE_IND_BUILD'	—	Yes	The name of the job to modify. **Note** Currently, you can only modify SYS.CLEANUP_ONLINE_IND_BUILD and SYS.BSLN_

Parameter name	Data type	Valid values	Default	Required	Description
					MAINTAIN_STATS_JOB jobs.
attribute	varchar2	'REPEAT_INTERVAL' _NAME'	–	Yes	Attribute to modify. To modify the repeat interval for the job, specify 'REPEAT_INTERVAL' . To modify the schedule name for the job, specify 'SCHEDULE_NAME' .
value	varchar2	A valid schedule interval or schedule name, depending on attribute used.	–	Yes	The new value of the attribute.

Modifying DBMS_SCHEDULER jobs

To modify certain components of Oracle Scheduler, use the Oracle procedure dbms_scheduler.set_attribute. For more information, see DBMS_SCHEDULER and SET_ATTRIBUTE procedure in the Oracle documentation.

When working with Amazon RDS DB instances, prepend the schema name SYS to the object name. The following example sets the resource plan attribute for the Monday window object.

```
BEGIN
    DBMS_SCHEDULER.SET_ATTRIBUTE(
        name      => 'SYS.MONDAY_WINDOW',
        attribute => 'RESOURCE_PLAN',
        value     => 'resource_plan_1');
END;
/
```

Modifying AutoTask maintenance windows

Amazon RDS for Oracle instances are created with default settings for maintenance windows. Automated maintenance tasks such as optimizer statistics collection run during these windows. By default, the maintenance windows turn on Oracle Database Resource Manager.

To modify the window, use the `DBMS_SCHEDULER` package. You might need to modify the maintenance window settings for the following reasons:

- You want maintenance jobs to run at a different time, with different settings, or not at all. For example, might want to modify the window duration, or change the repeat time and interval.
- You want to avoid the performance impact of enabling Resource Manager during maintenance. For example, if the default maintenance plan is specified, and if the maintenance window opens while the database is under load, you might see wait events such as `resmgr:cpu quantum`. This wait event is related to Database Resource Manager. You have the following options:
  - Ensure that maintenance windows are active during off-peak times for your DB instance.
  - Disable the default maintenance plan by setting the `resource_plan` attribute to an empty string.
  - Set the `resource_manager_plan` parameter to `FORCE:` in your parameter group. If your instance uses Enterprise Edition, this setting prevents Database Resource Manager plans from activating.

To modify your maintenance window settings

1. Connect to your database using an Oracle SQL client.
2. Query the current configuration for a scheduler window.

The following example queries the configuration for MONDAY_WINDOW.

```
SELECT ENABLED, RESOURCE_PLAN, DURATION, REPEAT_INTERVAL
FROM   DBA_SCHEDULER_WINDOWS
WHERE  WINDOW_NAME='MONDAY_WINDOW';
```

The following output shows that the window is using the default values.

```
ENABLED         RESOURCE_PLAN                  DURATION         REPEAT_INTERVAL
--------------- ------------------------------ ----------------
 ------------------------------
TRUE            DEFAULT_MAINTENANCE_PLAN       +000 04:00:00
 freq=daily;byday=MON;byhour=22
                                                                 ;byminute=0;
 bysecond=0
```

3. Modify the window using the DBMS_SCHEDULER package.

The following example sets the resource plan to null so that the Resource Manager won't run during the maintenance window.

```
BEGIN
  -- disable the window to make changes
  DBMS_SCHEDULER.DISABLE(name=>'"SYS"."MONDAY_WINDOW"',force=>TRUE);

  -- specify the empty string to use no plan
  DBMS_SCHEDULER.SET_ATTRIBUTE(name=>'"SYS"."MONDAY_WINDOW"',
 attribute=>'RESOURCE_PLAN', value=>'');

  -- re-enable the window
  DBMS_SCHEDULER.ENABLE(name=>'"SYS"."MONDAY_WINDOW"');
END;
/
```

The following example sets the maximum duration of the window to 2 hours.

```
BEGIN
  DBMS_SCHEDULER.DISABLE(name=>'"SYS"."MONDAY_WINDOW"',force=>TRUE);
  DBMS_SCHEDULER.SET_ATTRIBUTE(name=>'"SYS"."MONDAY_WINDOW"',
 attribute=>'DURATION', value=>'0 2:00:00');
  DBMS_SCHEDULER.ENABLE(name=>'"SYS"."MONDAY_WINDOW"');
```

```
END;
/
```

The following example sets the repeat interval to every Monday at 10 AM.

```
BEGIN
  DBMS_SCHEDULER.DISABLE(name=>'"SYS"."MONDAY_WINDOW"',force=>TRUE);
  DBMS_SCHEDULER.SET_ATTRIBUTE(name=>'"SYS"."MONDAY_WINDOW"',
 attribute=>'REPEAT_INTERVAL',
 value=>'freq=daily;byday=MON;byhour=10;byminute=0;bysecond=0');
  DBMS_SCHEDULER.ENABLE(name=>'"SYS"."MONDAY_WINDOW"');
END;
/
```

Setting the time zone for Oracle Scheduler jobs

To modify the time zone for Oracle Scheduler, you can use the Oracle procedure `dbms_scheduler.set_scheduler_attribute`. For more information about the `dbms_scheduler` package, see DBMS_SCHEDULER and SET_SCHEDULER_ATTRIBUTE in the Oracle documentation.

To modify the current time zone setting

1. Connect to the database using a client such as SQL Developer. For more information, see Connecting to your DB instance using Oracle SQL developer.
2. Set the default time zone as following, substituting your time zone for *`time_zone_name`*.

```
BEGIN
  DBMS_SCHEDULER.SET_SCHEDULER_ATTRIBUTE(
    attribute => 'default_timezone',
    value => 'time_zone_name'
  );
END;
/
```

In the following example, you change the time zone to Asia/Shanghai.

Start by querying the current time zone, as shown following.

```
SELECT VALUE FROM DBA_SCHEDULER_GLOBAL_ATTRIBUTE WHERE
 ATTRIBUTE_NAME='DEFAULT_TIMEZONE';
```

The output shows that the current time zone is ETC/UTC.

```
VALUE
-------
Etc/UTC
```

Then you set the time zone to Asia/Shanghai.

```
BEGIN
  DBMS_SCHEDULER.SET_SCHEDULER_ATTRIBUTE(
    attribute => 'default_timezone',
    value => 'Asia/Shanghai'
  );
END;
/
```

For more information about changing the system time zone, see Oracle time zone.

Turning off Oracle Scheduler jobs owned by SYS

To disable an Oracle Scheduler job owned by the SYS user, use the `rdsadmin.rdsadmin_dbms_scheduler.disable` procedure.

This procedure uses the `name` common parameter for Oracle Scheduler tasks. For more information, see Common parameters for Oracle Scheduler procedures.

The following example disables the `SYS.CLEANUP_ONLINE_IND_BUILD` Oracle Scheduler job.

```
BEGIN
   rdsadmin.rdsadmin_dbms_scheduler.disable('SYS.CLEANUP_ONLINE_IND_BUILD');
END;
/
```

Turning on Oracle Scheduler jobs owned by SYS

To turn on an Oracle Scheduler job owned by SYS, use the `rdsadmin.rdsadmin_dbms_scheduler.enable` procedure.

This procedure uses the name common parameter for Oracle Scheduler tasks. For more information, see Common parameters for Oracle Scheduler procedures.

The following example enables the SYS.CLEANUP_ONLINE_IND_BUILD Oracle Scheduler job.

```
BEGIN
   rdsadmin.rdsadmin_dbms_scheduler.enable('SYS.CLEANUP_ONLINE_IND_BUILD');
END;
/
```

Modifying the Oracle Scheduler repeat interval for jobs of CALENDAR type

To modify the repeat interval to modify a SYS-owned Oracle Scheduler job of CALENDAR type, use the rdsadmin.rdsadmin_dbms_scheduler.disable procedure.

This procedure uses the following common parameters for Oracle Scheduler tasks:

- name
- attribute
- value

For more information, see Common parameters for Oracle Scheduler procedures.

The following example modifies the repeat interval of the SYS.CLEANUP_ONLINE_IND_BUILD Oracle Scheduler job.

```
BEGIN
     rdsadmin.rdsadmin_dbms_scheduler.set_attribute(
          name      => 'SYS.CLEANUP_ONLINE_IND_BUILD',
          attribute => 'repeat_interval',
          value     => 'freq=daily;byday=FRI,SAT;byhour=20;byminute=0;bysecond=0');
END;
/
```

Modifying the Oracle Scheduler repeat interval for jobs of NAMED type

Some Oracle Scheduler jobs use a schedule name instead of an interval. For this type of jobs, you must create a new named schedule in the master user schema. Use the standard Oracle sys.dbms_scheduler.create_schedule procedure to do this. Also, use the

`rdsadmin.rdsadmin_dbms_scheduler.set_attribute procedure` to assign the new named schedule to the job.

This procedure uses the following common parameter for Oracle Scheduler tasks:

- `name`
- `attribute`
- `value`

For more information, see Common parameters for Oracle Scheduler procedures.

The following example modifies the repeat interval of the `SYS.BSLN_MAINTAIN_STATS_JOB` Oracle Scheduler job.

```
BEGIN
     DBMS_SCHEDULER.CREATE_SCHEDULE (
          schedule_name   => 'rds_master_user.new_schedule',
          start_date      => SYSTIMESTAMP,
          repeat_interval =>
 'freq=daily;byday=MON,TUE,WED,THU,FRI;byhour=0;byminute=0;bysecond=0',
          end_date        => NULL,
          comments        => 'Repeats daily forever');
END;
/

BEGIN
     rdsadmin.rdsadmin_dbms_scheduler.set_attribute (
          name      => 'SYS.BSLN_MAINTAIN_STATS_JOB',
          attribute => 'schedule_name',
          value     => 'rds_master_user.new_schedule');
END;
/
```

Turning off autocommit for Oracle Scheduler job creation

When `DBMS_SCHEDULER.CREATE_JOB` creates Oracle Scheduler jobs, it creates the jobs immediately and commits the changes. You might need to incorporate the creation of Oracle Scheduler jobs in the user transaction to do the following:

- Roll back the Oracle Schedule job when the user transaction is rolled back.

- Create the Oracle Scheduler job when the main user transaction is committed.

You can use the procedure `rdsadmin.rdsadmin_dbms_scheduler.set_no_commit_flag` to turn on this behavior. This procedure takes no parameters. You can use this procedure in the following RDS for Oracle releases:

- 21.0.0.0.ru-2022-07.rur-2022-07.r1 and higher
- 19.0.0.0.ru-2022-07.rur-2022-07.r1 and higher

The following example turns off autocommit for Oracle Scheduler, creates an Oracle Scheduler job, and then rolls back the transaction. Because autocommit is turned off, the database also rolls back the creation of the Oracle Scheduler job.

```
BEGIN
  rdsadmin.rdsadmin_dbms_scheduler.set_no_commit_flag;
  DBMS_SCHEDULER.CREATE_JOB(job_name   => 'EMPTY_JOB',
                            job_type   => 'PLSQL_BLOCK',
                            job_action => 'begin null; end;',
                            auto_drop  => false);
  ROLLBACK;
END;
/

PL/SQL procedure successfully completed.

SELECT * FROM DBA_SCHEDULER_JOBS WHERE JOB_NAME='EMPTY_JOB';

no rows selected
```

Performing common diagnostic tasks for Oracle DB instances

Oracle Database includes a fault diagnosability infrastructure that you can use to investigate database problems. In Oracle terminology, a *problem* is a critical error such as a code bug or data corruption. An *incident* is the occurrence of a problem. If the same error occurs three times, then the infrastructure shows three incidents of this problem. For more information, see Diagnosing and resolving problems in the Oracle Database documentation.

The Automatic Diagnostic Repository Command Interpreter (ADRCI) utility is an Oracle command-line tool that you use to manage diagnostic data. For example, you can use this tool to investigate

problems and package diagnostic data. An *incident package* includes diagnostic data for an incident or all incidents that reference a specific problem. You can upload an incident package, which is implemented as a .zip file, to Oracle Support.

To deliver a managed service experience, Amazon RDS doesn't provide shell access to ADRCI. To perform diagnostic tasks for your Oracle instance, instead use the Amazon RDS package `rdsadmin.rdsadmin_adrci_util`.

By using the functions in `rdsadmin_adrci_util`, you can list and package problems and incidents, and also show trace files. All functions return a task ID. This ID forms part of the name of log file that contains the ADRCI output, as in `dbtask-`*`task_id`*`.log`. The log file resides in the BDUMP directory. You can download the log file by following the procedure described in Downloading a database log file.

Common parameters for diagnostic procedures

To perform diagnostic tasks, use functions in the Amazon RDS package `rdsadmin.rdsadmin_adrci_util`. The package has the following common parameters.

Parameter name	Data type	Valid values	Default	Required	Description
`incident_id`	number	A valid incident ID or null	Null	No	If the value is null, the function shows all incidents. If the value isn't null and represents a valid incident ID, the function shows the specified incident.
`problem_id`	number	A valid problem ID or null	Null	No	If the value is null, the function shows all problems. If the value isn't null and represents a valid problem ID, the

Parameter name	Data type	Valid values	Default	Required	Description
					function shows the specified problem.
`last`	number	A valid integer greater than 0 or null	Null	No	If the value is null, then the function displays at most 50 items. If the value isn't null, the function displays the specified number.

Listing incidents

To list diagnostic incidents for Oracle, use the Amazon RDS function `rdsadmin.rdsadmin_adrci_util.list_adrci_incidents`. You can list incidents in either basic or detailed mode. By default, the function lists the 50 most recent incidents.

This function uses the following common parameters:

- `incident_id`
- `problem_id`
- `last`

If you specify `incident_id` and `problem_id`, then `incident_id` overrides `problem_id`. For more information, see Common parameters for diagnostic procedures.

This function uses the following additional parameter.

Parameter name	Data type	Valid values	Default	Required	Description
`detail`	boolean	`TRUE` or `FALSE`	`FALSE`	No	If `TRUE`, the function lists incidents in detail mode. If

Parameter name	Data type	Valid values	Default	Required	Description
					FALSE, the function lists incidents in basic mode.

To list all incidents, query the `rdsadmin.rdsadmin_adrci_util.list_adrci_incidents` function without any arguments. The query returns the task ID.

```
SQL> SELECT rdsadmin.rdsadmin_adrci_util.list_adrci_incidents AS task_id FROM DUAL;

TASK_ID
------------------
1590786706158-3126
```

Or call the `rdsadmin.rdsadmin_adrci_util.list_adrci_incidents` function without any arguments and store the output in a SQL client variable. You can use the variable in other statements.

```
SQL> VAR task_id VARCHAR2(80);
SQL> EXEC :task_id := rdsadmin.rdsadmin_adrci_util.list_adrci_incidents;

PL/SQL procedure successfully completed.
```

To read the log file, call the Amazon RDS procedure `rdsadmin.rds_file_util.read_text_file`. Supply the task ID as part of the file name. The following output shows three incidents: 53523, 53522, and 53521.

```
SQL> SELECT * FROM TABLE(rdsadmin.rds_file_util.read_text_file('BDUMP',
 'dbtask-'||:task_id||'.log'));

```

To list a particular incident, specify its ID using the `incident_id` parameter. In the following example, you query the log file for incident 53523 only.

```
SQL> EXEC :task_id :=
 rdsadmin.rdsadmin_adrci_util.list_adrci_incidents(incident_id=>53523);

PL/SQL procedure successfully completed.

SQL> SELECT * FROM TABLE(rdsadmin.rds_file_util.read_text_file('BDUMP',
 'dbtask-'||:task_id||'.log'));

Listing problems

To list diagnostic problems for Oracle, use the Amazon RDS function `rdsadmin.rdsadmin_adrci_util.list_adrci_problems`.

By default, the function lists the 50 most recent problems.

This function uses the common parameters `problem_id` and `last`. For more information, see Common parameters for diagnostic procedures.

To get the task ID for all problems, call the `rdsadmin.rdsadmin_adrci_util.list_adrci_problems` function without any arguments, and store the output in a SQL client variable.

```
SQL> EXEC :task_id := rdsadmin.rdsadmin_adrci_util.list_adrci_problems;

PL/SQL procedure successfully completed.
```

To read the log file, call the `rdsadmin.rds_file_util.read_text_file` function, supplying the task ID as part of the file name. In the following output, the log file shows three problems: 1, 2, and 3.

```
SQL> SELECT * FROM TABLE(rdsadmin.rds_file_util.read_text_file('BDUMP',
 'dbtask-'||:task_id||'.log'));

Creating incident packages

You can create incident packages using the Amazon RDS function `rdsadmin.rdsadmin_adrci_util.create_adrci_package`. The output is a .zip file that you can supply to Oracle Support.

This function uses the following common parameters:

- `problem_id`
- `incident_id`

Make sure to specify one of the preceding parameters. If you specify both parameters, `incident_id` overrides `problem_id`. For more information, see Common parameters for diagnostic procedures.

To create a package for a specific incident, call the Amazon RDS function `rdsadmin.rdsadmin_adrci_util.create_adrci_package` with the `incident_id` parameter. The following example creates a package for incident 53523.

```
SQL> EXEC :task_id :=
 rdsadmin.rdsadmin_adrci_util.create_adrci_package(incident_id=>53523);

PL/SQL procedure successfully completed.
```

To read the log file, call the `rdsadmin.rds_file_util.read_text_file`. You can supply the task ID as part of the file name. The output shows that you generated incident package `ORA700EVE_20200529212043_COM_1.zip`.

```
SQL> SELECT * FROM TABLE(rdsadmin.rds_file_util.read_text_file('BDUMP',
 'dbtask-'||:task_id||'.log'));

TEXT
--------------------------------------------------------------------------------
2020-05-29 21:20:43.031 UTC [INFO ] The ADRCI package is being created.

2020-05-29 21:20:47.642 UTC [INFO ] The ADRCI package was successfully created.
2020-05-29 21:20:47.642 UTC [INFO ] The task finished successfully.
```

To package diagnostic data for a particular problem, specify its ID using the `problem_id` parameter. In the following example, you package data for problem 3 only.

```
SQL> EXEC :task_id := rdsadmin.rdsadmin_adrci_util.create_adrci_package(problem_id=>3);

PL/SQL procedure successfully completed.
```

To read the task output, call `rdsadmin.rds_file_util.read_text_file`, supplying the task ID as part of the file name. The output shows that you generated incident package `ORA700EVE_20200529212111_COM_1.zip`.

```
SQL> SELECT * FROM TABLE(rdsadmin.rds_file_util.read_text_file('BDUMP',
 'dbtask-'||:task_id||'.log'));

TEXT
--------------------------------------------------------------------------------
2020-05-29 21:21:11.050 UTC [INFO ] The ADRCI package is being created.
2020-05-29 21:21:15.646 UTC [INFO ] Generated package 2 in file /rdsdbdata/log/trace/
ORA700EVE_20200529212111_COM_1.zip, mode complete
2020-05-29 21:21:15.646 UTC [INFO ] The ADRCI package was successfully created.
2020-05-29 21:21:15.646 UTC [INFO ] The task finished successfully.
```

You can also download the log file. For more information, see Downloading a database log file.

Showing trace files

You can use the Amazon RDS function `rdsadmin.rdsadmin_adrci_util.show_adrci_tracefile` to list trace files under the trace directory and all incident directories under the current ADR home. You can also show the contents of trace files and incident trace files.

This function uses the following parameter.

Parameter name	Data type	Valid values	Default	Required	Description
`filename`	varchar2	A valid trace file name	Null	No	If the value is null, the function shows all trace files. If it isn't null, the function

Parameter name	Data type	Valid values	Default	Required	Description
					shows the specified file.

To show the trace file, call the Amazon RDS function `rdsadmin.rdsadmin_adrci_util.show_adrci_tracefile`.

```
SQL> EXEC :task_id := rdsadmin.rdsadmin_adrci_util.show_adrci_tracefile;

PL/SQL procedure successfully completed.
```

To list the trace file names, call the Amazon RDS procedure `rdsadmin.rds_file_util.read_text_file`, supplying the task ID as part of the file name.

```
SQL> SELECT * FROM TABLE(rdsadmin.rds_file_util.read_text_file('BDUMP',
 'dbtask-'||:task_id||'.log')) WHERE TEXT LIKE '%/alert_%';

TEXT
--------------------------------------------------------------------
     diag/rdbms/orcl_a/ORCL/trace/alert_ORCL.log.2020-05-28
     diag/rdbms/orcl_a/ORCL/trace/alert_ORCL.log.2020-05-27
     diag/rdbms/orcl_a/ORCL/trace/alert_ORCL.log.2020-05-26
     diag/rdbms/orcl_a/ORCL/trace/alert_ORCL.log.2020-05-25
     diag/rdbms/orcl_a/ORCL/trace/alert_ORCL.log.2020-05-24
     diag/rdbms/orcl_a/ORCL/trace/alert_ORCL.log.2020-05-23
     diag/rdbms/orcl_a/ORCL/trace/alert_ORCL.log.2020-05-22
     diag/rdbms/orcl_a/ORCL/trace/alert_ORCL.log.2020-05-21
     diag/rdbms/orcl_a/ORCL/trace/alert_ORCL.log

9 rows selected.
```

In the following example, you generate output for `alert_ORCL.log`.

```
SQL> EXEC :task_id := rdsadmin.rdsadmin_adrci_util.show_adrci_tracefile('diag/rdbms/
orcl_a/ORCL/trace/alert_ORCL.log');

PL/SQL procedure successfully completed.
```

To read the log file, call `rdsadmin.rds_file_util.read_text_file`. Supply the task ID as part of the file name. The output shows the first 10 lines of alert_ORCL.log.

```
SQL> SELECT * FROM TABLE(rdsadmin.rds_file_util.read_text_file('BDUMP',
 'dbtask-'||:task_id||'.log')) WHERE ROWNUM <= 10;

You can also download the log file. For more information, see Downloading a database log file.

Performing miscellaneous tasks for Oracle DB instances

Following, you can find how to perform miscellaneous DBA tasks on your Amazon RDS DB instances running Oracle. To deliver a managed service experience, Amazon RDS doesn't provide shell access to DB instances, and restricts access to certain system procedures and tables that require advanced privileges.

Topics

- Creating and dropping directories in the main data storage space
- Listing files in a DB instance directory
- Reading files in a DB instance directory
- Accessing Opatch files
- Managing advisor tasks
- Transporting tablespaces

Creating and dropping directories in the main data storage space

To create directories, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.create_directory`. You can create up to 10,000 directories, all located in your main data storage space. To drop directories, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.drop_directory`.

The `create_directory` and `drop_directory` procedures have the following required parameter.

Parameter name	Data type	Default	Required	Description
`p_directory_name`	VARCHAR2	—	Yes	The name of the directory.

The following example creates a new directory named `PRODUCT_DESCRIPTIONS`.

```
EXEC rdsadmin.rdsadmin_util.create_directory(p_directory_name =>
 'product_descriptions');
```

The data dictionary stores the directory name in uppercase. You can list the directories by querying `DBA_DIRECTORIES`. The system chooses the actual host pathname automatically. The following example gets the directory path for the directory named `PRODUCT_DESCRIPTIONS`:

```
SELECT DIRECTORY_PATH
  FROM DBA_DIRECTORIES
 WHERE DIRECTORY_NAME='PRODUCT_DESCRIPTIONS';

DIRECTORY_PATH
----------------------------------------
/rdsdbdata/userdirs/01
```

The master user name for the DB instance has read and write privileges in the new directory, and can grant access to other users. `EXECUTE` privileges are not available for directories on a DB instance. Directories are created in your main data storage space and will consume space and I/O bandwidth.

The following example drops the directory named `PRODUCT_DESCRIPTIONS`.

```
EXEC rdsadmin.rdsadmin_util.drop_directory(p_directory_name => 'product_descriptions');
```

Note

You can also drop a directory by using the Oracle SQL command `DROP DIRECTORY`.

Dropping a directory doesn't remove its contents. Because the `rdsadmin.rdsadmin_util.create_directory` procedure can reuse pathnames, files in dropped directories can appear in a newly created directory. Before you drop a directory, we recommend that you use `UTL_FILE.FREMOVE` to remove files from the directory. For more information, see FREMOVE procedure in the Oracle documentation.

Listing files in a DB instance directory

To list the files in a directory, use the Amazon RDS procedure `rdsadmin.rds_file_util.listdir`. This procedure isn't supported on an Oracle replica. The `listdir` procedure has the following parameters.

Parameter name	Data type	Default	Required	Description
`p_directory`	varchar2	—	Yes	The name of the directory to list.

The following example grants read/write privileges on the directory `PRODUCT_DESCRIPTIONS` to user `rdsadmin`, and then lists the files in this directory.

```
GRANT READ,WRITE ON DIRECTORY PRODUCT_DESCRIPTIONS TO rdsadmin;
SELECT * FROM TABLE(rdsadmin.rds_file_util.listdir(p_directory =>
 'PRODUCT_DESCRIPTIONS'));
```

Reading files in a DB instance directory

To read a text file, use the Amazon RDS procedure `rdsadmin.rds_file_util.read_text_file`. The `read_text_file` procedure has the following parameters.

Parameter name	Data type	Default	Required	Description
p_directory	varchar2	—	Yes	The name of the directory that contains the file.
p_filename	varchar2	—	Yes	The name of the file to read.

The following example creates the file rice.txt in the directory PRODUCT_DESCRIPTIONS.

```
declare
  fh sys.utl_file.file_type;
begin
  fh := utl_file.fopen(location=>'PRODUCT_DESCRIPTIONS', filename=>'rice.txt',
 open_mode=>'w');
  utl_file.put(file=>fh, buffer=>'AnyCompany brown rice, 15 lbs');
  utl_file.fclose(file=>fh);
end;
/
```

The following example reads the file rice.txt from the directory PRODUCT_DESCRIPTIONS.

```
SELECT * FROM TABLE
    (rdsadmin.rds_file_util.read_text_file(
        p_directory => 'PRODUCT_DESCRIPTIONS',
        p_filename  => 'rice.txt'));
```

Accessing Opatch files

Opatch is an Oracle utility that enables the application and rollback of patches to Oracle software. The Oracle mechanism for determining which patches have been applied to a database is the opatch lsinventory command. To open service requests for Bring Your Own Licence (BYOL) customers, Oracle Support requests the lsinventory file and sometimes the lsinventory_detail file generated by Opatch.

To deliver a managed service experience, Amazon RDS doesn't provide shell access to Opatch. Instead, the lsinventory-*dbv*.txt in the BDUMP directory contains the patch information

related to your current engine version. When you perform a minor or major upgrade, Amazon RDS updates `lsinventory-dbv.txt` within an hour of applying the patch. To verify the applied patches, read `lsinventory-dbv.txt`. This action is similar to running the `opatch lsinventory` command.

> **Note**
>
> The examples in this section assume that the BDUMP directory is named BDUMP. On a read replica, the BDUMP directory name is different. To learn how to get the BDUMP name by querying `V$DATABASE.DB_UNIQUE_NAME` on a read replica, see Listing files.

The inventory files use the Amazon RDS naming convention `lsinventory-dbv.txt` and `lsinventory_detail-dbv.txt`, where *dbv* is the full name of your DB version. The `lsinventory-dbv.txt` file is available on all DB versions. The corresponding `lsinventory_detail-dbv.txt` is available on 19.0.0.0, ru-2020-01.rur-2020-01.r1 or later.

For example, if your DB version is 19.0.0.0.ru-2021-07.rur-2021-07.r1, then your inventory files have the following names.

```
lsinventory-19.0.0.0.ru-2021-07.rur-2021-07.r1.txt
lsinventory_detail-19.0.0.0.ru-2021-07.rur-2021-07.r1.txt
```

Ensure that you download the files that match the current version of your DB engine.

Console

To download an inventory file using the console

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.
3. Choose the name of the DB instance that has the log file that you want to view.
4. Choose the **Logs & events** tab.
5. Scroll down to the **Logs** section.
6. In the **Logs** section, search for `lsinventory`.
7. Select the file that you want to access, and then choose **Download**.

SQL

To read the `lsinventory-dbv.txt` in a SQL client, you can use a `SELECT` statement. For this technique, use either of the following `rdsadmin` functions: `rdsadmin.rds_file_util.read_text_file` or `rdsadmin.tracefile_listing`.

In the following sample query, replace *dbv* with your Oracle DB version. For example, your DB version might be 19.0.0.0.ru-2020-04.rur-2020-04.r1.

```
SELECT text
FROM   TABLE(rdsadmin.rds_file_util.read_text_file('BDUMP', 'lsinventory-dbv.txt'));
```

PL/SQL

To read the `lsinventory-dbv.txt` in a SQL client, you can write a PL/SQL program. This program uses `utl_file` to read the file, and `dbms_output` to print it. These are Oracle-supplied packages.

In the following sample program, replace *dbv* with your Oracle DB version. For example, your DB version might be 19.0.0.0.ru-2020-04.rur-2020-04.r1.

```
SET SERVEROUTPUT ON
DECLARE
  v_file              SYS.UTL_FILE.FILE_TYPE;
  v_line              VARCHAR2(1000);
  v_oracle_home_type  VARCHAR2(1000);
  c_directory         VARCHAR2(30) := 'BDUMP';
  c_output_file       VARCHAR2(30) := 'lsinventory-dbv.txt';
BEGIN
  v_file := SYS.UTL_FILE.FOPEN(c_directory, c_output_file, 'r');
  LOOP
    BEGIN
      SYS.UTL_FILE.GET_LINE(v_file, v_line,1000);
      DBMS_OUTPUT.PUT_LINE(v_line);
    EXCEPTION
      WHEN no_data_found THEN
        EXIT;
    END;
  END LOOP;
END;
/
```

Or query `rdsadmin.tracefile_listing`, and spool the output to a file. The following example spools the output to `/tmp/tracefile.txt`.

```
SPOOL /tmp/tracefile.txt
SELECT *
FROM   rdsadmin.tracefile_listing
WHERE  FILENAME LIKE 'lsinventory%';
SPOOL OFF;
```

Managing advisor tasks

Oracle Database includes a number of advisors. Each advisor supports automated and manual tasks. You can use procedures in the `rdsadmin.rdsadmin_util` package to manage some advisor tasks.

The advisor task procedures are available in the following engine versions:

- Oracle Database 21c (21.0.0)
- Version 19.0.0.0.ru-2021-01.rur-2021-01.r1 and higher Oracle Database 19c versions

  For more information, see Version 19.0.0.0.ru-2021-01.rur-2021-01.r1 in the *Amazon RDS for Oracle Release Notes*.

Topics

- Setting parameters for advisor tasks
- Disabling AUTO_STATS_ADVISOR_TASK
- Re-enabling AUTO_STATS_ADVISOR_TASK

Setting parameters for advisor tasks

To set parameters for some advisor tasks, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.advisor_task_set_parameter`. The `advisor_task_set_parameter` procedure has the following parameters.

Parameter name	Data type	Default	Require	Description
p_task_name	varchar2	—	Yes	The name of the advisor task whose parameters you want to change. The following values are valid: • AUTO_STATS_ADVISOR_TASK • INDIVIDUAL_STATS_ADVISOR_TASK • SYS_AUTO_SPM_EVOLVE_TASK • SYS_AUTO_SQL_TUNING_TASK

p_parameter	varchar2	—	Yes	The name of the task parameter. To find valid parameters for an advisor task, run the following query. Substitute *p_task_name* with a valid value for p_task_name :
				`COL PARAMETER_NAME FORMAT a30`
				`COL PARAMETER_VALUE FORMAT a30`
				`SELECT PARAMETER_NAME, PARAMETER _VALUE`
				`FROM DBA_ADVISOR_PARAMETERS`
				`WHERE TASK_NAME='  p_task_name '`
				`AND PARAMETER_VALUE != 'UNUSED'`
				`ORDER BY PARAMETER_NAME;`

p_value	varchar2	—	Yes	The value for a task parameter. To find valid values for task parameters, run the following query. Substitute *p_task_name* with a valid value for p_task_name :
				`COL PARAMETER_NAME FORMAT a30`
				`COL PARAMETER_VALUE FORMAT a30`
				`SELECT PARAMETER_NAME, PARAMETER _VALUE`
				`FROM DBA_ADVISOR_PARAMETERS`
				`WHERE TASK_NAME='  p_task_name '`
				`AND PARAMETER_VALUE != 'UNUSED'`

Parameter name	Data type	Default	Require	Description
				ORDER BY PARAMETER_NAME;

The following PL/SQL program sets ACCEPT_PLANS to FALSE for SYS_AUTO_SPM_EVOLVE_TASK. The SQL Plan Management automated task verifies the plans and generates a report of its findings, but does not evolve the plans automatically. You can use a report to identify new SQL plan baselines and accept them manually.

```
BEGIN
  rdsadmin.rdsadmin_util.advisor_task_set_parameter(
    p_task_name => 'SYS_AUTO_SPM_EVOLVE_TASK',
    p_parameter => 'ACCEPT_PLANS',
    p_value     => 'FALSE');
END;
```

The following PL/SQL program sets EXECUTION_DAYS_TO_EXPIRE to 10 for AUTO_STATS_ADVISOR_TASK. The predefined task AUTO_STATS_ADVISOR_TASK runs automatically in the maintenance window once per day. The example sets the retention period for the task execution to 10 days.

```
BEGIN
  rdsadmin.rdsadmin_util.advisor_task_set_parameter(
    p_task_name => 'AUTO_STATS_ADVISOR_TASK',
    p_parameter => 'EXECUTION_DAYS_TO_EXPIRE',
    p_value     => '10');
END;
```

Disabling AUTO_STATS_ADVISOR_TASK

To disable AUTO_STATS_ADVISOR_TASK, use the Amazon RDS procedure rdsadmin.rdsadmin_util.advisor_task_drop. The advisor_task_drop procedure accepts the following parameter.

Parameter name	Data type	Default	Require	Description
p_task_name	varchar2	—	Yes	The name of the advisor task to be disabled. The only valid value is AUTO_STATS_ADVISOR_TASK .

The following command drops AUTO_STATS_ADVISOR_TASK.

```
EXEC rdsadmin.rdsadmin_util.advisor_task_drop('AUTO_STATS_ADVISOR_TASK')
```

You can re-enable AUTO_STATS_ADVISOR_TASK using rdsadmin.rdsadmin_util.dbms_stats_init.

Re-enabling AUTO_STATS_ADVISOR_TASK

To re-enable AUTO_STATS_ADVISOR_TASK, use the Amazon RDS procedure rdsadmin.rdsadmin_util.dbms_stats_init. The dbms_stats_init procedure takes no parameters.

The following command re-enables AUTO_STATS_ADVISOR_TASK.

```
EXEC rdsadmin.rdsadmin_util.dbms_stats_init()
```

Transporting tablespaces

Use the Amazon RDS package rdsadmin.rdsadmin_transport_util to copy a set of tablespaces from an on-premises Oracle database to an RDS for Oracle DB instance. At the physical level, the transportable tablespace feature incrementally copies source data files and metadata files to your target instance. You can transfer the files using either Amazon EFS or Amazon S3. For more information, see Migrating using Oracle transportable tablespaces.

Topics

- Importing transported tablespaces to your DB instance
- Importing transportable tablespace metadata into your DB instance
- Listing orphaned files after a tablespace import

- Deleting orphaned data files after a tablespace import

Importing transported tablespaces to your DB instance

Use the procedure `rdsadmin.rdsadmin_transport_util.import_xtts_tablespaces` to restore tablespaces that you have previously exported from a source DB instance. In the transport phase, you back up your read-only tablespaces, export Data Pump metadata, transfer these files to your target DB instance, and then import the tablespaces. For more information, see Phase 4: Transport the tablespaces.

Syntax

```
FUNCTION import_xtts_tablespaces(
    p_tablespace_list IN CLOB,
    p_directory_name  IN VARCHAR2,
    p_platform_id     IN NUMBER DEFAULT 13,
    p_parallel        IN INTEGER DEFAULT 0) RETURN VARCHAR2;
```

Parameters

Parameter name	Data type	Default	Required	Description
`p_tablespace_list`	`CLOB`	—	Yes	The list of tablespaces to import.
`p_directory_name`	`VARCHAR2`	—	Yes	The directory that contains the tablespace backups.
`p_platform_id`	`NUMBER`	`13`	No	Provide a platform ID that matches the one specified during the backup phase. To find a list of platforms, query `V$TRANSPORTABLE_PLATFORM`. The default platform is Linux x86 64-bit, which is little endian.

Parameter name	Data type	Default	Required	Description
p_parallel	INTEGER	0	No	The degree of parallelism. By default, parallelism is disabled.

Examples

The following example imports the tablespaces *TBS1*, *TBS2*, and *TBS3* from the directory *DATA_PUMP_DIR*. The source platform is AIX-Based Systems (64-bit), which has the platform ID of 6. You can find the platform IDs by querying V$TRANSPORTABLE_PLATFORM.

```
VAR task_id CLOB

BEGIN
  :task_id:=rdsadmin.rdsadmin_transport_util.import_xtts_tablespaces(
        'TBS1,TBS2,TBS3',
        'DATA_PUMP_DIR',
        p_platform_id => 6);
END;
/

PRINT task_id
```

Importing transportable tablespace metadata into your DB instance

Use the procedure rdsadmin.rdsadmin_transport_util.import_xtts_metadata to import transportable tablespace metadata into your RDS for Oracle DB instance. During the operation, the status of the metadata import is shown in the table rdsadmin.rds_xtts_operation_info. For more information, see Step 5: Import tablespace metadata on your target DB instance.

Syntax

```
PROCEDURE import_xtts_metadata(
    p_datapump_metadata_file IN SYS.DBA_DATA_FILES.FILE_NAME%TYPE,
    p_directory_name         IN VARCHAR2,
    p_exclude_stats          IN BOOLEAN DEFAULT FALSE,
    p_remap_tablespace_list  IN CLOB DEFAULT NULL,
    p_remap_user_list        IN CLOB DEFAULT NULL);
```

Parameters

Parameter name	Data type	Default	Required	Description
p_datapump_metadata_file	SYS.DBA_DATA_FILES.FILE_NAME%TYPE	—	Yes	The name of the Oracle Data Pump file that contains the metadata for your transportable tablespaces.
p_directory_name	VARCHAR2	—	Yes	The directory that contains the Data Pump file.
p_exclude_stats	BOOLEAN	FALSE	No	Flag that indicates whether to exclude statistics.
p_remap_tablespace_list	CLOB	NULL	No	A list of tablespaces to be remapped during the metadata import. Use the format *from_tbs*:*to_tbs*. For example, specify users:user_data .
p_remap_user_list	CLOB	NULL	No	A list of user schemas to be remapped during the metadata import. Use the format *from_schema_name* :*to_schema_name* . For example, specify

Parameter name	Data type	Default	Required	Description
				hr:human_resources .

Examples

The example imports the tablespace metadata from the file *xttdump.dmp*, which is located in directory *DATA_PUMP_DIR*.

```
BEGIN
  rdsadmin.rdsadmin_transport_util.import_xtts_metadata('xttdump.dmp','DATA_PUMP_DIR');
END;
/
```

Listing orphaned files after a tablespace import

Use the `rdsadmin.rdsadmin_transport_util.list_xtts_orphan_files` procedure to list data files that were orphaned after a tablespace import. After you identify the data files, you can delete them by calling `rdsadmin.rdsadmin_transport_util.cleanup_incomplete_xtts_import`.

Syntax

```
FUNCTION list_xtts_orphan_files RETURN xtts_orphan_files_list_t PIPELINED;
```

Examples

The following example runs the procedure `rdsadmin.rdsadmin_transport_util.list_xtts_orphan_files`. The output shows two data files that are orphaned.

```
SQL> SELECT * FROM TABLE(rdsadmin.rdsadmin_transport_util.list_xtts_orphan_files);

FILENAME       FILESIZE
-------------- ---------
datafile_7.dbf 104865792
datafile_8.dbf 104865792
```

Deleting orphaned data files after a tablespace import

Use the `rdsadmin.rdsadmin_transport_util.list_xtts_orphan_files` procedure to delete data files that were orphaned after a tablespace import. Running this command generates a log file that uses the name format `rds-xtts-delete_xtts_orphaned_files-`*`YYYY-MM-DD.HH24-MI-SS.FF`*`.log` in the BDUMP directory. Use the procedure `rdsadmin.rdsadmin_transport_util.cleanup_incomplete_xtts_import` to find the orphaned files. You can read the log file by calling the procedure `rdsadmin.rds_file_util.read_text_file`. For more information, see Phase 6: Clean up leftover files.

Syntax

```
PROCEDURE cleanup_incomplete_xtts_import(
    p_directory_name IN VARCHAR2);
```

Parameters

Parameter name	Data type	Default	Required	Description
p_directory_name	VARCHAR2	—	Yes	The directory that contains the orphaned data files.

Examples

The following example deletes the orphaned data files in *DATA_PUMP_DIR*.

```
BEGIN
  rdsadmin.rdsadmin_transport_util.cleanup_incomplete_xtts_import('DATA_PUMP_DIR');
END;
/
```

The following example reads the log file generated by the previous command.

```
SELECT *
FROM TABLE(rdsadmin.rds_file_util.read_text_file(
       p_directory => 'BDUMP',
```

```
       p_filename  => 'rds-xtts-
delete_xtts_orphaned_files-2023-06-01.09-33-11.868894000.log'));

TEXT
--------------------------------------------------------------------------------
orphan transported datafile datafile_7.dbf deleted.
orphan transported datafile datafile_8.dbf deleted.
```

Configuring advanced RDS for Oracle features

RDS for Oracle supports various advanced features, including HugePages, an instance store, and extended data types.

Topics

Storing temporary data in an RDS for Oracle instance store

Use an instance store for the temporary tablespaces and the Database Smart Flash Cache (the flash cache) on supported RDS for Oracle DB instance classes.

Topics

Overview of the RDS for Oracle instance store

An *instance store* provides temporary block-level storage for an RDS for Oracle DB instance. You can use an instance store for temporary storage of information that changes frequently.

An instance store is based on Non-Volatile Memory Express (NVMe) devices that are physically attached to the host computer. The storage is optimized for low latency, random I/O performance, and sequential read throughput.

The size of the instance store varies by DB instance type. For more information about the instance store, see Amazon EC2 instance store in the *Amazon Elastic Compute Cloud User Guide for Linux Instances*.

Topics

Types of data in the RDS for Oracle instance store

You can place the following types of RDS for Oracle temporary data in an instance store:

A temporary tablespace

Oracle Database uses temporary tablespaces to store intermediate query results that don't fit in memory. Larger queries can generate large amounts of intermediate data that needs to be cached temporarily, but doesn't need to persist. In particular, a temporary tablespace is useful for sorts, hash aggregations, and joins. If your RDS for Oracle DB instance uses the Enterprise Edition or Standard Edition 2, you can place a temporary tablespace in an instance store.

The flash cache

The flash cache improves the performance of single-block random reads in the conventional path. A best practice is to size the cache to accommodate most of your active data set. If your RDS for Oracle DB instance uses the Enterprise Edition, you can place the flash cache in an instance store.

By default, an instance store is configured for a temporary tablespace but not for the flash cache. You can't place Oracle data files and database log files in an instance store.

Benefits of the RDS for Oracle instance store

You might consider using an instance store to store temporary files and caches that you can afford to lose. If you want to improve DB performance, or if an increasing workload is causing performance problems for your Amazon EBS storage, consider scaling to an instance class that supports an instance store.

By placing your temporary tablespace and flash cache on an instance store, you get the following benefits:

- Lower read latencies
- Higher throughput
- Reduced load on your Amazon EBS volumes
- Lower storage and snapshot costs because of reduced Amazon EBS load
- Less need to provision high IOPS, possibly lowering your overall cost

By placing your temporary tablespace on the instance store, you deliver an immediate performance boost to queries that use temporary space. When you place the flash cache on the instance store, cached block reads typically have much lower latency than Amazon EBS reads. The flash cache needs to be "warmed up" before it delivers performance benefits. The cache warms up by itself because the database writes blocks to the flash cache as they age out of the database buffer cache.

> **Note**
>
> In some cases, the flash cache causes performance overhead because of cache management. Before you turn on the flash cache in a production environment, we recommend that you analyze your workload and test the cache in a test environment.

Supported instance classes for the RDS for Oracle instance store

Amazon RDS supports the instance store for the following DB instance classes:

- db.m5d
- db.r5d
- db.x2idn
- db.x2iedn

RDS for Oracle supports the preceding DB instance classes for the BYOL licensing model only. For more information, see Supported RDS for Oracle DB instance classes and Bring Your Own License (BYOL) for EE and SE2.

To see the total instance storage for the supported DB instance types, run the following command in the AWS CLI.

Example

```
aws ec2 describe-instance-types \
  --filters "Name=instance-type,Values=*5d.*large*" \
  --query "InstanceTypes[?contains(InstanceType,'m5d')||contains(InstanceType,'r5d')]
[InstanceType, InstanceStorageInfo.TotalSizeInGB]" \
  --output table
```

The preceding command returns the raw device size for the instance store. RDS for Oracle uses a small portion of this space for configuration. The space in the instance store that is available for temporary tablespaces or the flash cache is slightly smaller.

Supported engine versions for the RDS for Oracle instance store

The instance store is supported for the following RDS for Oracle engine versions:

- 21.0.0.0.ru-2022-01.rur-2022-01.r1 or higher Oracle Database 21c versions
- 19.0.0.0.ru-2021-10.rur-2021-10.r1 or higher Oracle Database 19c versions

Supported AWS Regions for the RDS for Oracle instance store

The instance store is available in all AWS Regions where one or more of these instance types are supported. For more information on the db.m5d and db.r5d instance classes, see DB instance classes. For more information on the instance classes supported by Amazon RDS for Oracle, see RDS for Oracle DB instance classes.

Cost of the RDS for Oracle instance store

The cost of the instance store is built into the cost of the instance-store turned on instances. You don't incur additional costs by enabling an instance store on an RDS for Oracle DB instance. For more information about instance-store turned on instances, see Supported instance classes for the RDS for Oracle instance store.

Turning on an RDS for Oracle instance store

To turn on the instance store for RDS for Oracle temporary data, do one of the following:

- Create an RDS for Oracle DB instance using a supported instance class. For more information, see Creating an Amazon RDS DB instance.

- Modify an existing RDS for Oracle DB instance to use a supported instance class. For more information, see Modifying an Amazon RDS DB instance.

Configuring an RDS for Oracle instance store

By default, 100% of instance store space is allocated to the temporary tablespace. To configure the instance store to allocate space to the flash cache and temporary tablespace, set the following parameters in the parameter group for your instance:

db_flash_cache_size={DBInstanceStore*{0,2,4,6,8,10}/10}

This parameter specifies the amount of storage space allocated for the flash cache. This parameter is valid only for Oracle Database Enterprise Edition. The default value is `{DBInstanceStore*0/10}`. If you set a nonzero value for `db_flash_cache_size`, your RDS for Oracle instance enables the flash cache after you restart the instance.

rds.instance_store_temp_size={DBInstanceStore*{0,2,4,6,8,10}/10}

This parameter specifies the amount of storage space allocated for the temporary tablespace. The default value is `{DBInstanceStore*10/10}`. This parameter is modifiable for Oracle Database Enterprise Edition and read-only for Standard Edition 2. If you set a nonzero value for `rds.instance_store_temp_size`, Amazon RDS allocates space in the instance store for the temporary tablespace.

You can set the `db_flash_cache_size` and `rds.instance_store_temp_size` parameters for DB instances that don't use an instance store. In this case, both settings evaluate to `0`, which turns off the feature. In this case, you can use the same parameter group for different instance sizes and for instances that don't use an instance store. If you modify these parameters, make sure to reboot the associated instances so that the changes can take effect.

> **Important**
>
> If you allocate space for a temporary tablespace, Amazon RDS doesn't create the temporary tablespace automatically. To learn how to create the temporary tablespace on the instance store, see Creating a temporary tablespace on the instance store.

The combined value of the preceding parameters must not exceed 10/10, or 100%. The following table illustrates valid and invalid parameter settings.

db_flash_cache_size setting	rds.instance_store_temp_size setting	Explanation
db_flash_cache_size={DBInstanceStore*0/10}	rds.instance_store_temp_size={DBInstanceStore*10/10}	This is a valid configuration for all editions of Oracle Database. Amazon RDS allocates 100% of instance store space to the temporary tablespace. This is the default.
db_flash_cache_size={DBInstanceStore*10/10}	rds.instance_store_temp_size={DBInstanceStore*0/10}	This is a valid configuration for Oracle Database Enterprise Edition only. Amazon RDS allocates 100% of instance store space to the flash cache.
db_flash_cache_size={DBInstanceStore*2/10}	rds.instance_store_temp_size={DBInstanceStore*8/10}	This is a valid configuration for Oracle Database Enterprise Edition only. Amazon RDS allocates 20% of instance store space to

db_flash_cache_size setting	rds.instance_store_temp_size setting	Explanation
		the flash cache, and 80% of instance store space to the temporary tablespace.
db_flash_cache_size={DBInstanceStore*6/10}	rds.instance_store_temp_size={DBInstanceStore*4/10}	This is a valid configuration for Oracle Database Enterprise Edition only. Amazon RDS allocates 60% of instance store space to the flash cache, and 40% of instance store space to the temporary tablespace.

db_flash_cache_size setting	rds.instance_store_temp_size setting	Explanation
db_flash_cache_size={DBInstanceStore*2/10}	rds.instance_store_temp_size={DBInstanceStore*4/10}	This is a valid configuration for Oracle Database Enterprise Edition only. Amazon RDS allocates 20% of instance store space to the flash cache, and 40% of instance store space to the temporary tablespace.
db_flash_cache_size={DBInstanceStore*8/10}	rds.instance_store_temp_size={DBInstanceStore*8/10}	This is an invalid configuration because the combined percentage of instance store space exceeds 100%. In such cases, Amazon RDS fails the attempt.

Considerations when changing the DB instance type

If you change your DB instance type, it can affect the configuration of the flash cache or the temporary tablespace on the instance store. Consider the following modifications and their effects:

You scale up or scale down the DB instance that supports the instance store.

The following values increase or decrease proportionally to the new size of the instance store:

- The new size of the flash cache.
- The space allocated to the temporary tablespaces that reside in the instance store.

For example, the setting `db_flash_cache_size={DBInstanceStore*6/10}` on a db.m5d.4xlarge instance provides around 340 GB of flash cache space. If you scale up the instance type to db.m5d.8xlarge, the flash cache space increases to around 680 GB.

You modify a DB instance that doesn't use an instance store to an instance that does use an instance store.

If `db_flash_cache_size` is set to a value larger than `0`, the flash cache is configured. If `rds.instance_store_temp_size` is set to a value larger than `0`, the instance store space is allocated for use by a temporary tablespace. RDS for Oracle doesn't move tempfiles to the instance store automatically. For information about using the allocated space, see Creating a temporary tablespace on the instance store or Adding a tempfile to the instance store on a read replica.

You modify a DB instance that uses an instance store to an instance that doesn't use an instance store.

In this case, RDS for Oracle removes the flash cache. RDS re-creates the tempfile that is currently located on the instance store on an Amazon EBS volume. The maximum size of the new tempfile is the former size of the `rds.instance_store_temp_size` parameter.

Working with an instance store on an Oracle read replica

Read replicas support the flash cache and temporary tablespaces on an instance store. While the flash cache works the same way as on the primary DB instance, note the following differences for temporary tablespaces:

- You can't create a temporary tablespace on a read replica. If you create a new temporary tablespace on the primary instance, RDS for Oracle replicates the tablespace information without tempfiles. To add a new tempfile, use either of the following techniques:
  - Use the Amazon RDS procedure `rdsadmin.rdsadmin_util.add_inst_store_tempfile`. RDS for Oracle creates a tempfile in the instance store on your read replica, and adds it to the specified temporary tablespace.

- Run the `ALTER TABLESPACE ... ADD TEMPFILE` command. RDS for Oracle places the tempfile on Amazon EBS storage.

> **Note**
>
> The tempfile sizes and storage types can be different on the primary DB instance and the read replica.

- You can manage the default temporary tablespace setting only on the primary DB instance. RDS for Oracle replicates the setting to all read replicas.
- You can configure the temporary tablespace groups only on the primary DB instance. RDS for Oracle replicates the setting to all read replicas.

Configuring a temporary tablespace group on an instance store and Amazon EBS

You can configure a temporary tablespace group to include temporary tablespaces on both an instance store and Amazon EBS. This technique is useful when you want more temporary storage than is allowed by the maximum setting of `rds.instance_store_temp_size`.

When you configure a temporary tablespace group on both an instance store and Amazon EBS, the two tablespaces have significantly different performance characteristics. Oracle Database chooses the tablespace to serve queries based on an internal algorithm. Therefore, similar queries can vary in performance.

Typically, you create a temporary tablespace in the instance store as follows:

1. Create a temporary tablespace in the instance store.
2. Set the new tablespace as the database default temporary tablespace.

If the tablespace size in the instance store is insufficient, you can create additional temporary storage as follows:

1. Assign the temporary tablespace in the instance store to a temporary tablespace group.
2. Create a new temporary tablespace in Amazon EBS if one doesn't exist.
3. Assign the temporary tablespace in Amazon EBS to the same tablespace group that includes the instance store tablespace.
4. Set the tablespace group as the default temporary tablespace.

The following example assumes that the size of the temporary tablespace in the instance store doesn't meet your application requirements. The example creates the temporary tablespace `temp_in_inst_store` in the instance store, assigns it to tablespace group `temp_group`, adds the existing Amazon EBS tablespace named `temp_in_ebs` to this group, and sets this group as the default temporary tablespace.

```
SQL> EXEC rdsadmin.rdsadmin_util.create_inst_store_tmp_tblspace('temp_in_inst_store');

PL/SQL procedure successfully completed.

SQL> ALTER TABLESPACE temp_in_inst_store TABLESPACE GROUP temp_group;

Tablespace altered.

SQL> ALTER TABLESPACE temp_in_ebs TABLESPACE GROUP temp_group;

Tablespace altered.

SQL> EXEC rdsadmin.rdsadmin_util.alter_default_temp_tablespace('temp_group');

PL/SQL procedure successfully completed.

SQL> SELECT * FROM DBA_TABLESPACE_GROUPS;

GROUP_NAME                     TABLESPACE_NAME
------------------------------ ------------------------------
TEMP_GROUP                     TEMP_IN_EBS
TEMP_GROUP                     TEMP_IN_INST_STORE

SQL> SELECT PROPERTY_VALUE FROM DATABASE_PROPERTIES WHERE
 PROPERTY_NAME='DEFAULT_TEMP_TABLESPACE';

PROPERTY_VALUE
--------------
TEMP_GROUP
```

Removing an RDS for Oracle instance store

To remove the instance store, modify your RDS for Oracle DB instance to use an instance type that doesn't support instance store, such as db.m5 or db.r5.

Turning on HugePages for an RDS for Oracle instance

Amazon RDS for Oracle supports Linux kernel HugePages for increased database scalability. HugePages results in smaller page tables and less CPU time spent on memory management, increasing the performance of large database instances. For more information, see Overview of HugePages in the Oracle documentation.

You can use HugePages with all supported versions and editions of RDS for Oracle.

The `use_large_pages` parameter controls whether HugePages are turned on for a DB instance. The possible settings for this parameter are `ONLY`, `FALSE`, and `{DBInstanceClassHugePagesDefault}`. The `use_large_pages` parameter is set to `{DBInstanceClassHugePagesDefault}` in the default DB parameter group for Oracle.

To control whether HugePages are turned on for a DB instance automatically, you can use the `DBInstanceClassHugePagesDefault` formula variable in parameter groups. The value is determined as follows:

- For the DB instance classes mentioned in the table following, `DBInstanceClassHugePagesDefault` always evaluates to `FALSE` by default, and `use_large_pages` evaluates to `FALSE`. You can turn on HugePages manually for these DB instance classes if the DB instance class has at least 14 GiB of memory.
- For DB instance classes not mentioned in the table following, if the DB instance class has less than 14 GiB of memory, `DBInstanceClassHugePagesDefault` always evaluates to `FALSE`. Also, `use_large_pages` evaluates to `FALSE`.
- For DB instance classes not mentioned in the table following, if the instance class has at least 14 GiB of memory and less than 100 GiB of memory, `DBInstanceClassHugePagesDefault` evaluates to `TRUE` by default. Also, `use_large_pages` evaluates to `ONLY`. You can turn off HugePages manually by setting `use_large_pages` to `FALSE`.
- For DB instance classes not mentioned in the table following, if the instance class has at least 100 GiB of memory, `DBInstanceClassHugePagesDefault` always evaluates to `TRUE`. Also, `use_large_pages` evaluates to `ONLY` and HugePages can't be disabled.

HugePages are not turned on by default for the following DB instance classes.

DB instance class family	DB instance classes with HugePages not turned on by default
db.m5	db.m5.large
db.m4	db.m4.large, db.m4.xlarge, db.m4.2xlarge, db.m4.4xlarge, db.m4.10xlarge
db.t3	db.t3.micro, db.t3.small, db.t3.medium, db.t3.large

For more information about DB instance classes, see Hardware specifications for DB instance classes.

To turn on HugePages for new or existing DB instances manually, set the `use_large_pages` parameter to `ONLY`. You can't use HugePages with Oracle Automatic Memory Management (AMM). If you set the parameter `use_large_pages` to `ONLY`, then you must also set both `memory_target` and `memory_max_target` to `0`. For more information about setting DB parameters for your DB instance, see Parameter groups for Amazon RDS.

You can also set the `sga_target`, `sga_max_size`, and `pga_aggregate_target` parameters. When you set system global area (SGA) and program global area (PGA) memory parameters, add the values together. Subtract this total from your available instance memory (`DBInstanceClassMemory`) to determine the free memory beyond the HugePages allocation. You must leave free memory of at least 2 GiB, or 10 percent of the total available instance memory, whichever is smaller.

After you configure your parameters, you must reboot your DB instance for the changes to take effect. For more information, see Rebooting a DB instance.

Note

The Oracle DB instance defers changes to SGA-related initialization parameters until you reboot the instance without failover. In the Amazon RDS console, choose **Reboot** but *do not* choose **Reboot with failover**. In the AWS CLI, call the `reboot-db-instance` command with the `--no-force-failover` parameter. The DB instance does not process the SGA-related parameters during failover or during other maintenance operations that cause the instance to restart.

The following is a sample parameter configuration for HugePages that enables HugePages manually. You should set the values to meet your needs.

```
memory_target            = 0
memory_max_target        = 0
pga_aggregate_target     = {DBInstanceClassMemory*1/8}
sga_target               = {DBInstanceClassMemory*3/4}
sga_max_size             = {DBInstanceClassMemory*3/4}
use_large_pages          = ONLY
```

Assume the following parameters values are set in a parameter group.

```
memory_target            = IF({DBInstanceClassHugePagesDefault}, 0,
 {DBInstanceClassMemory*3/4})
memory_max_target        = IF({DBInstanceClassHugePagesDefault}, 0,
 {DBInstanceClassMemory*3/4})
pga_aggregate_target     = IF({DBInstanceClassHugePagesDefault},
 {DBInstanceClassMemory*1/8}, 0)
sga_target               = IF({DBInstanceClassHugePagesDefault},
 {DBInstanceClassMemory*3/4}, 0)
sga_max_size             = IF({DBInstanceClassHugePagesDefault},
 {DBInstanceClassMemory*3/4}, 0)
use_large_pages          = {DBInstanceClassHugePagesDefault}
```

The parameter group is used by a db.r4 DB instance class with less than 100 GiB of memory. With these parameter settings and `use_large_pages` set to `{DBInstanceClassHugePagesDefault}`, HugePages are turned on for the db.r4 instance.

Consider another example with following parameters values set in a parameter group.

```
memory_target           = IF({DBInstanceClassHugePagesDefault}, 0,
 {DBInstanceClassMemory*3/4})
memory_max_target       = IF({DBInstanceClassHugePagesDefault}, 0,
 {DBInstanceClassMemory*3/4})
pga_aggregate_target    = IF({DBInstanceClassHugePagesDefault},
 {DBInstanceClassMemory*1/8}, 0)
sga_target              = IF({DBInstanceClassHugePagesDefault},
 {DBInstanceClassMemory*3/4}, 0)
sga_max_size            = IF({DBInstanceClassHugePagesDefault},
 {DBInstanceClassMemory*3/4}, 0)
use_large_pages         = FALSE
```

The parameter group is used by a db.r4 DB instance class and a db.r5 DB instance class, both with less than 100 GiB of memory. With these parameter settings, HugePages are turned off on the db.r4 and db.r5 instance.

> **Note**
>
> If this parameter group is used by a db.r4 DB instance class or db.r5 DB instance class with at least 100 GiB of memory, the `FALSE` setting for `use_large_pages` is overridden and set to `ONLY`. In this case, a customer notification regarding the override is sent.

After HugePages are active on your DB instance, you can view HugePages information by enabling enhanced monitoring. For more information, see Monitoring OS metrics with Enhanced Monitoring.

Turning on extended data types in RDS for Oracle

Amazon RDS for Oracle supports extended data types. With extended data types, the maximum size is 32,767 bytes for the `VARCHAR2`, `NVARCHAR2`, and `RAW` data types. To use extended data types, set the `MAX_STRING_SIZE` parameter to `EXTENDED`. For more information, see Extended data types in the Oracle documentation.

If you don't want to use extended data types, keep the `MAX_STRING_SIZE` parameter set to `STANDARD` (the default). In this case, the size limits are 4,000 bytes for the `VARCHAR2` and `NVARCHAR2` data types, and 2,000 bytes for the RAW data type.

You can turn on extended data types on a new or existing DB instance. For new DB instances, DB instance creation time is typically longer when you turn on extended data types. For existing DB instances, the DB instance is unavailable during the conversion process.

Considerations for extended data types

Consider the following when you enable extended data types for your DB instance:

- When you turn on extended data types for a new or existing DB instance, you must reboot the instance for the change to take effect.
- After you turn on extended data types, you can't change the DB instance back to use the standard size for data types. If you set the `MAX_STRING_SIZE` parameter back to `STANDARD` it results in the `incompatible-parameters` status.

- When you restore a DB instance that uses extended data types, you must specify a parameter group with the `MAX_STRING_SIZE` parameter set to `EXTENDED`. During restore, if you specify the default parameter group or any other parameter group with `MAX_STRING_SIZE` set to `STANDARD` it results in the `incompatible-parameters` status.
- When the DB instance status is `incompatible-parameters` because of the `MAX_STRING_SIZE` setting, the DB instance remains unavailable until you set the `MAX_STRING_SIZE` parameter to `EXTENDED` and reboot the DB instance.

Turning on extended data types for a new DB instance

When you create a DB instance with `MAX_STRING_SIZE` set to `EXTENDED`, the instance shows `MAX_STRING_SIZE` set to the default `STANDARD`. Reboot the instance to enable the change.

To turn on extended data types for a new DB instance

1. Set the `MAX_STRING_SIZE` parameter to `EXTENDED` in a parameter group.

   To set the parameter, you can either create a new parameter group or modify an existing parameter group.

   For more information, see Parameter groups for Amazon RDS.
2. Create a new RDS for Oracle DB instance.

   For more information, see Creating an Amazon RDS DB instance.
3. Associate the parameter group with `MAX_STRING_SIZE` set to `EXTENDED` with the DB instance.

   For more information, see Creating an Amazon RDS DB instance.
4. Reboot the DB instance for the parameter change to take effect.

   For more information, see Rebooting a DB instance.

Turning on extended data types for an existing DB instance

When you modify a DB instance to turn on extended data types, RDS converts the data in the database to use the extended sizes. The conversion and downtime occur when you next reboot the database after the parameter change. The DB instance is unavailable during the conversion.

The amount of time it takes to convert the data depends on the DB instance class, the database size, and the time of the last DB snapshot. To reduce downtime, consider taking a snapshot immediately before rebooting. This shortens the time of the backup that occurs during the conversion workflow.

> **Note**
>
> After you turn on extended data types, you can't perform a point-in-time restore to a time during the conversion. You can restore to the time immediately before the conversion or after the conversion.

To turn on extended data types for an existing DB instance

1. Take a snapshot of the database.

   If there are invalid objects in the database, Amazon RDS tries to recompile them. The conversion to extended data types can fail if Amazon RDS can't recompile an invalid object. The snapshot enables you to restore the database if there is a problem with the conversion. Always check for invalid objects before conversion and fix or drop those invalid objects. For production databases, we recommend testing the conversion process on a copy of your DB instance first.

   For more information, see Creating a DB snapshot for a Single-AZ DB instance.
2. Set the `MAX_STRING_SIZE` parameter to `EXTENDED` in a parameter group.

   To set the parameter, you can either create a new parameter group or modify an existing parameter group.

   For more information, see Parameter groups for Amazon RDS.
3. Modify the DB instance to associate it with the parameter group with `MAX_STRING_SIZE` set to `EXTENDED`.

   For more information, see Modifying an Amazon RDS DB instance.
4. Reboot the DB instance for the parameter change to take effect.

   For more information, see Rebooting a DB instance.

Importing data into Oracle on Amazon RDS

How you import data into an Amazon RDS for Oracle DB instance depends on the following:

- The amount of data you have
- The number of database objects in your database
- The variety of database objects in your database

For example, you can use the following tools, depending on your requirements:

- Oracle SQL Developer – Import a simple, 20 MB database.
- Oracle Data Pump – Import complex databases, or databases that are several hundred megabytes or several terabytes in size. For example, you can transport tablespaces from an on-premises database to your RDS for Oracle DB instance. You can use Amazon S3 or Amazon EFS to transfer the data files and metadata. For more information, see Migrating using Oracle transportable tablespaces, Amazon EFS integration, and Amazon S3 integration.
- AWS Database Migration Service (AWS DMS) – Migrate databases without downtime. For more information about AWS DMS, see What is AWS Database Migration Service and the blog post Migrating Oracle databases with near-zero downtime using AWS DMS.

> **Important**
>
> Before you use the preceding migration techniques, we recommend that you back up your database. After you import the data, you can back up your RDS for Oracle DB instances by creating snapshots. Later, you can restore the snapshots. For more information, see Backing up, restoring, and exporting data.

For many database engines, ongoing replication can continue until you are ready to switch over to the target database. You can use AWS DMS to migrate to RDS for Oracle from either the same database engine or a different engine. If you migrate from a different database engine, you can use the AWS Schema Conversion Tool to migrate schema objects that AWS DMS doesn't migrate.

- Migrating using Oracle transportable tablespaces

- Importing using Oracle Data Pump
- Importing using Oracle Export/Import
- Importing using Oracle SQL*Loader
- Migrating with Oracle materialized views

Importing using Oracle SQL Developer

Oracle SQL Developer is a graphical Java tool distributed without cost by Oracle. SQL Developer provides options for migrating data between two Oracle databases, or for migrating data from other databases, such as MySQL, to an Oracle database. This tool is best for migrating small databases.

You can install this tool on your desktop computer (Windows, Linux, or Mac) or on one of your servers. After you install SQL Developer, you can use it to connect to your source and target databases. Use the **Database Copy** command on the Tools menu to copy your data to your RDS for Oracle DB instance.

To download SQL Developer, go to http://www.oracle.com/technetwork/developer-tools/sql-developer.

We recommend that you read the Oracle SQL Developer product documentation before you begin migrating your data. Oracle also has documentation on how to migrate from other databases, including MySQL and SQL Server. For more information, see http://www.oracle.com/technetwork/database/migration in the Oracle documentation.

Migrating using Oracle transportable tablespaces

You can use the Oracle transportable tablespaces feature to copy a set of tablespaces from an on-premises Oracle database to an RDS for Oracle DB instance. At the physical level, you transfer source data files and metadata files to your target DB instance using either Amazon EFS or Amazon S3. The transportable tablespaces feature uses the `rdsadmin.rdsadmin_transport_util` package. For syntax and semantics of this package, see Transporting tablespaces.

For blog posts that explain how to transport tablespaces, see Migrate Oracle Databases to AWS using transportable tablespace and Amazon RDS for Oracle Transportable Tablespaces using RMAN.

Topics

Overview of Oracle transportable tablespaces

A transportable tablespace set consists of data files for the set of tablespaces being transported and an export dump file containing tablespace metadata. In a physical migration solution such as transportable tablespaces, you transfer physical files: data files, configuration files, and Data Pump dump files.

Topics

Advantages and disadvantages of transportable tablespaces

We recommend that you use transportable tablespaces when you need to migrate one or more large tablespaces to RDS with minimum downtime. Transportable tablespaces offer the following advantages over logical migration:

- Downtime is lower than most other Oracle migration solutions.
- Because the transportable tablespace feature copies only physical files, it avoids the data integrity errors and logical corruption that can occur in logical migration.
- No additional license is required.
- You can migrate a set of tablespaces across different platforms and endianness types, for example, from an Oracle Solaris platform to Linux. However, transporting tablespaces to and from Windows servers isn't supported.

> **Note**
>
> Linux is fully tested and supported. Not all UNIX variations have been tested.

If you use transportable tablespaces, you can transport data using either Amazon S3 or Amazon EFS:

- When you use EFS, your backups remain in the EFS file system for the duration of the import. You can remove the files afterward. In this technique, you don't need to provision EBS storage for your DB instance. For this reason, we recommend using Amazon EFS instead of S3. For more information, see Amazon EFS integration.
- When you use S3, you download RMAN backups to EBS storage attached to your DB instance. The files remain in your EBS storage during the import. After the import, you can free up this space, which remains allocated to your DB instance.

The primary disadvantage of transportable tablespaces is that you need relatively advanced knowledge of Oracle Database. For more information, see Transporting Tablespaces Between Databases in the *Oracle Database Administrator's Guide*.

Limitations for transportable tablespaces

Oracle Database limitations for transportable tablespaces apply when you use this feature in RDS for Oracle. For more information, see Limitations on Transportable Tablespaces and General Limitations on Transporting Data in the *Oracle Database Administrator's Guide*. Note the following additional limitations for transportable tablespaces in RDS for Oracle:

- Neither the source or target database can use Standard Edition 2 (SE2). Only Enterprise Edition is supported.
- You can't use an Oracle Database 11g database as a source. The RMAN cross-platform transportable tablespaces feature relies on the RMAN transport mechanism, which Oracle Database 11g doesn't support.
- You can't migrate data from an RDS for Oracle DB instance using transportable tablespaces. You can only use transportable tablespaces to migrate data to an RDS for Oracle DB instance.
- The Windows operating system isn't supported.

- You can't transport tablespaces into a database at a lower release level. The target database must be at the same or later release level as the source database. For example, you can't transport tablespaces from Oracle Database 21c into Oracle Database 19c.
- You can't transport administrative tablespaces such as SYSTEM and SYSAUX.
- You can't transport non-data objects such as PL/SQL packages, Java classes, views, triggers, sequences, users, roles, and temporary tables. To transport non-data objects, create them manually or use Data Pump metadata export and import. For more information, see My Oracle Support Note 1454872.1.
- You can't transport tablespaces that are encrypted or use encrypted columns.
- If you transfer files using Amazon S3, the maximum supported file size is 5 TiB.
- If the source database uses Oracle options such as Spatial, you can't transport tablespaces unless the same options are configured on the target database.
- You can't transport tablespaces into an RDS for Oracle DB instance in an Oracle replica configuration. As a workaround, you can delete all replicas, transport the tablespaces, and then recreate the replicas.

Prerequisites for transportable tablespaces

Before you begin, complete the following tasks:

- Review the requirements for transportable tablespaces described in the following documents in My Oracle Support:
  - Reduce Transportable Tablespace Downtime using Cross Platform Incremental Backup (Doc ID 2471245.1)
  - Transportable Tablespace (TTS) Restrictions and Limitations: Details, Reference, and Version Where Applicable (Doc ID 1454872.1)
  - Primary Note for Transportable Tablespaces (TTS) -- Common Questions and Issues (Doc ID 1166564.1)
- Plan for endianness conversion. If you specify the source platform ID, RDS for Oracle converts the endianness automatically. To learn how to find platform IDs, see Data Guard Support for Heterogeneous Primary and Physical Standbys in Same Data Guard Configuration (Doc ID 413484.1).
- Make sure that the transportable tablespace feature is enabled on your target DB instance. The feature is enabled only if you don't get an ORA-20304 error when you run the following query:

```
SELECT * FROM TABLE(rdsadmin.rdsadmin_transport_util.list_xtts_orphan_files);
```

If the transportable tablespace feature isn't enabled, reboot your DB instance. For more information, see Rebooting a DB instance.

- If you plan to transfer files using Amazon S3, do the following:
  - Make sure that an Amazon S3 bucket is available for file transfers, and that the Amazon S3 bucket is in the same AWS Region as your DB instance. For instructions, see Create a bucket in the *Amazon Simple Storage Service Getting Started Guide*.
  - Prepare the Amazon S3 bucket for Amazon RDS integration by following the instructions in Configuring IAM permissions for RDS for Oracle integration with Amazon S3.
- If you plan to transfer files using Amazon EFS, make sure that you have configured EFS according to the instructions in Amazon EFS integration.
- We strongly recommend that you turn on automatic backups in your target DB instance. Because the metadata import step can potentially fail, it's important to be able to restore your DB instance to its state before the import, thereby avoiding the necessity to back up, transfer, and import your tablespaces again.

Phase 1: Set up your source host

In this step, you copy the transport tablespaces scripts provided by My Oracle Support and set up necessary configuration files. In the following steps, the *source host* is running the database that contains the tablespaces to be transported to your *target instance*.

To set up your source host

1. Log in to your source host as the owner of your Oracle home.
2. Make sure that your `ORACLE_HOME` and `ORACLE_SID` environment variables point to your source database.
3. Log in to your database as an administrator, and verify that the time zone version, DB character set, and national character set are the same as in your target database.

   ```
   SELECT * FROM V$TIMEZONE_FILE;
   SELECT * FROM NLS_DATABASE_PARAMETERS
     WHERE PARAMETER IN ('NLS_CHARACTERSET','NLS_NCHAR_CHARACTERSET');
   ```

4. Set up the transportable tablespace utility as described in Oracle Support note 2471245.1.

The setup includes editing the `xtt.properties` file on your source host. The following sample `xtt.properties` file specifies backups of three tablespaces in the `/dsk1/backups` directory. These are the tablespaces that you intend to transport to your target DB instance. It also specifies the source platform ID to convert the endianness automatically.

> **Note**
>
> For valid platform IDs, see Data Guard Support for Heterogeneous Primary and Physical Standbys in Same Data Guard Configuration (Doc ID 413484.1).

```
#linux system
platformid=13
#list of tablespaces to transport
tablespaces=TBS1,TBS2,TBS3
#location where backup will be generated
src_scratch_location=/dsk1/backups
#RMAN command for performing backup
usermantransport=1
```

Phase 2: Prepare the full tablespace backup

In this phase, you back up your tablespaces for the first time, transfer the backups to your target host, and then restore them using the procedure `rdsadmin.rdsadmin_transport_util.import_xtts_tablespaces`. When this phase is complete, the initial tablespace backups reside on your target DB instance and can be updated with incremental backups.

Topics

- Step 1: Back up the tablespaces on your source host
- Step 2: Transfer the backup files to your target DB instance
- Step 3: Import the tablespaces on your target DB instance

Step 1: Back up the tablespaces on your source host

In this step, you use the `xttdriver.pl` script to make a full backup of your tablespaces. The output of `xttdriver.pl` is stored in the `TMPDIR` environment variable.

To back up your tablespaces

1. If your tablespaces are in read-only mode, log in to your source database as a user with the `ALTER TABLESPACE` privilege, and place your tablespaces in read/write mode. Otherwise, skip to the next step.

   The following example places `tbs1`, `tbs2`, and `tbs3` in read/write mode.

   ```
   ALTER TABLESPACE tbs1 READ WRITE;
   ALTER TABLESPACE tbs2 READ WRITE;
   ALTER TABLESPACE tbs3 READ WRITE;
   ```

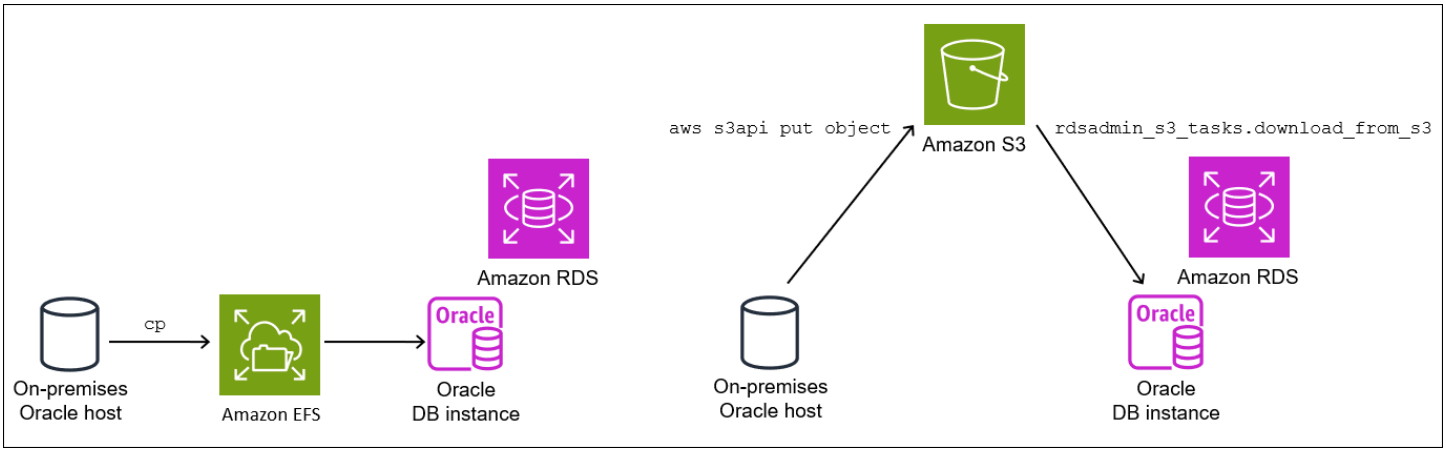
2. Back up your tablespaces using the `xttdriver.pl` script. Optionally, you can specify `--debug` to run the script in debug mode.

   ```
   export TMPDIR=location_of_log_files
   cd location_of_xttdriver.pl
   $ORACLE_HOME/perl/bin/perl xttdriver.pl --backup
   ```

Step 2: Transfer the backup files to your target DB instance

In this step, copy the backup and configuration files from your scratch location to your target DB instance. Choose one of the following options:

- If the source and target hosts share an Amazon EFS file system, use an operating system utility such as `cp` to copy your backup files and the `res.txt` file from your scratch location to a shared directory. Then skip to Step 3: Import the tablespaces on your target DB instance.
- If you need to stage your backups to an Amazon S3 bucket, complete the following steps.



Step 2.2: Upload the backups to your Amazon S3 bucket

Upload your backups and the `res.txt` file from your scratch directory to your Amazon S3 bucket. For more information, see Uploading objects in the *Amazon Simple Storage Service User Guide*.

Step 2.3: Download the backups from your Amazon S3 bucket to your target DB instance

In this step, you use the procedure `rdsadmin.rdsadmin_s3_tasks.download_from_s3` to download your backups to your RDS for Oracle DB instance.

To download your backups from your Amazon S3 bucket

1. Start SQL*Plus or Oracle SQL Developer and log in to your RDS for Oracle DB instance.
2. Download the backups from the Amazon S3 bucket to your target DB instance by using the Amazon RDS procedure `rdsadmin.rdsadmin_s3_tasks.download_from_s3` to d. The following example downloads all of the files from an Amazon S3 bucket named *`amzn-s3-demo-bucket`* to the *`DATA_PUMP_DIR`* directory.

```
EXEC UTL_FILE.FREMOVE ('DATA_PUMP_DIR', 'res.txt');
SELECT rdsadmin.rdsadmin_s3_tasks.download_from_s3(
  p_bucket_name    =>  'amzn-s3-demo-bucket',
  p_directory_name =>  'DATA_PUMP_DIR')
AS TASK_ID FROM DUAL;
```

   The SELECT statement returns the ID of the task in a VARCHAR2 data type. For more information, see Downloading files from an Amazon S3 bucket to an Oracle DB instance.

Step 3: Import the tablespaces on your target DB instance

To restore your tablespaces to your target DB instance, use the procedure `rdsadmin.rdsadmin_transport_util.import_xtts_tablespaces`. This procedure automatically converts the data files to the correct endian format.

If you import from a platform other than Linux, specify the source platform using the parameter `p_platform_id` when you call `import_xtts_tablespaces`. Make sure that the platform ID that you specify matches the one specified in the `xtt.properties` file in Step 2: Export tablespace metadata on your source host.

Import the tablespaces on your target DB instance

1. Start an Oracle SQL client and log in to your target RDS for Oracle DB instance as the master user.
2. Run the procedure `rdsadmin.rdsadmin_transport_util.import_xtts_tablespaces`, specifying the tablespaces to import and the directory containing the backups.

   The following example imports the tablespaces *TBS1*, *TBS2*, and *TBS3* from the directory *DATA_PUMP_DIR*. The source platform is AIX-Based Systems (64-bit), which has the platform ID of 6. You can find the platform IDs by querying `V$TRANSPORTABLE_PLATFORM`.

   ```
   VAR task_id CLOB

   BEGIN
     :task_id:=rdsadmin.rdsadmin_transport_util.import_xtts_tablespaces(
           'TBS1,TBS2,TBS3',
           'DATA_PUMP_DIR',
           p_platform_id => 6);
   END;
   /

   PRINT task_id
   ```

3. (Optional) Monitor progress by querying the table `rdsadmin.rds_xtts_operation_info`. The `xtts_operation_state` column shows the value `EXECUTING`, `COMPLETED`, or `FAILED`.

   ```
   SELECT * FROM rdsadmin.rds_xtts_operation_info;
   ```

> **Note**
>
> For long-running operations, you can also query V$SESSION_LONGOPS, V$RMAN_STATUS, and V$RMAN_OUTPUT.

4. View the log of the completed import by using the task ID from the previous step.

```
SELECT * FROM TABLE(rdsadmin.rds_file_util.read_text_file('BDUMP',
 'dbtask-'||'&task_id'||'.log'));
```

Make sure that the import succeeded before continuing to the next step.

Phase 3: Make and transfer incremental backups

In this phase, you make and transfer incremental backups periodically while the source database is active. This technique reduces the size of your final tablespace backup. If you take multiple incremental backups, you must copy the `res.txt` file after the last incremental backup before you can apply it on the target instance.

The steps are the same as in Phase 2: Prepare the full tablespace backup, except that the import step is optional.

Phase 4: Transport the tablespaces

In this phase, you back up your read-only tablespaces and export Data Pump metadata, transfer these files to your target host, and import both the tablespaces and the metadata.

Topics

- Step 1: Back up your read-only tablespaces
- Step 2: Export tablespace metadata on your source host
- Step 3: (Amazon S3 only) Transfer the backup and export files to your target DB instance
- Step 4: Import the tablespaces on your target DB instance
- Step 5: Import tablespace metadata on your target DB instance

Step 1: Back up your read-only tablespaces

This step is identical to Step 1: Back up the tablespaces on your source host, with one key difference: you place your tablespaces in read-only mode before backing up your tablespaces for the last time.

The following example places `tbs1`, `tbs2`, and `tbs3` in read-only mode.

```
ALTER TABLESPACE tbs1 READ ONLY;
ALTER TABLESPACE tbs2 READ ONLY;
ALTER TABLESPACE tbs3 READ ONLY;
```

Step 2: Export tablespace metadata on your source host

Export your tablespace metadata by running the `expdb` utility on your source host. The following example exports tablespaces *TBS1*, *TBS2*, and *TBS3* to dump file *xttdump.dmp* in directory *DATA_PUMP_DIR*.

```
expdp username/pwd \
dumpfile=xttdump.dmp \
directory=DATA_PUMP_DIR \
statistics=NONE \
transport_tablespaces=TBS1,TBS2,TBS3 \
transport_full_check=y \
logfile=tts_export.log
```

If *DATA_PUMP_DIR* is a shared directory in Amazon EFS, skip to Step 4: Import the tablespaces on your target DB instance.

Step 3: (Amazon S3 only) Transfer the backup and export files to your target DB instance

If you are using Amazon S3 to stage your tablespace backups and Data Pump export file, complete the following steps.

Step 3.1: Upload the backups and dump file from your source host to your Amazon S3 bucket

Upload your backup and dump files from your source host to your Amazon S3 bucket. For more information, see Uploading objects in the *Amazon Simple Storage Service User Guide*.

Step 3.2: Download the backups and dump file from your Amazon S3 bucket to your target DB instance

In this step, you use the procedure `rdsadmin.rdsadmin_s3_tasks.download_from_s3` to download your backups and dump file to your RDS for Oracle DB instance. Follow the steps in Step 2.3: Download the backups from your Amazon S3 bucket to your target DB instance.

Step 4: Import the tablespaces on your target DB instance

Use the procedure `rdsadmin.rdsadmin_transport_util.import_xtts_tablespaces` to restore the tablespaces. For syntax and semantics of this procedure, see Importing transported tablespaces to your DB instance

> **Important**
>
> After you complete your final tablespace import, the next step is importing the Oracle Data Pump metadata. If the import fails, it's important to return your DB instance to its state before the failure. Thus, we recommend that you create a DB snapshot of your DB instance by following the instructions in Creating a DB snapshot for a Single-AZ DB instance. The snapshot will contain all imported tablespaces, so if the import fails, you don't need to repeat the backup and import process.
> If your target DB instance has automatic backups turned on, and Amazon RDS doesn't detect that a valid snapshot was initiated before you import the metadata, RDS attempts to create a snapshot. Depending on your instance activity, this snapshot might or might not succeed. If a valid snapshot isn't detected or a snapshot can't be initiated, the metadata import exits with errors.

Import the tablespaces on your target DB instance

1. Start an Oracle SQL client and log in to your target RDS for Oracle DB instance as the master user.
2. Run the procedure `rdsadmin.rdsadmin_transport_util.import_xtts_tablespaces`, specifying the tablespaces to import and the directory containing the backups.

   The following example imports the tablespaces *TBS1*, *TBS2*, and *TBS3* from the directory *DATA_PUMP_DIR*.

   ```
   BEGIN
   ```

```
 :task_id:=rdsadmin.rdsadmin_transport_util.import_xtts_tablespaces('TBS1,TBS2,TBS3','DATA_
END;
/
PRINT task_id
```

3. (Optional) Monitor progress by querying the table `rdsadmin.rds_xtts_operation_info`. The `xtts_operation_state` column shows the value `EXECUTING`, `COMPLETED`, or `FAILED`.

```
SELECT * FROM rdsadmin.rds_xtts_operation_info;
```

> **Note**
>
> For long-running operations, you can also query `V$SESSION_LONGOPS`, `V$RMAN_STATUS`, and `V$RMAN_OUTPUT`.

4. View the log of the completed import by using the task ID from the previous step.

```
SELECT * FROM TABLE(rdsadmin.rds_file_util.read_text_file('BDUMP',
 'dbtask-'||'&task_id'||'.log'));
```

   Make sure that the import succeeded before continuing to the next step.

5. Take a manual DB snapshot by following the instructions in Creating a DB snapshot for a Single-AZ DB instance.

Step 5: Import tablespace metadata on your target DB instance

In this step, you import the transportable tablespace metadata into your RDS for Oracle DB instance using the procedure `rdsadmin.rdsadmin_transport_util.import_xtts_metadata`. For syntax and semantics of this procedure, see Importing transportable tablespace metadata into your DB instance. During the operation, the status of the import is shown in the table `rdsadmin.rds_xtts_operation_info`.

> **Important**
>
> Before you import metadata, we strongly recommend that you confirm that a DB snapshot was successfully created after you imported your tablespaces. If the import step fails, restore your DB instance, address the import errors, and then attempt the import again.

Import the Data Pump metadata into your RDS for Oracle DB instance

1. Start your Oracle SQL client and log in to your target DB instance as the master user.
2. Create the users that own schemas in your transported tablespaces, if these users don't already exist.

```
CREATE USER tbs_owner IDENTIFIED BY password;
```

3. Import the metadata, specifying the name of the dump file and its directory location.

```
BEGIN

 rdsadmin.rdsadmin_transport_util.import_xtts_metadata('xttdump.dmp','DATA_PUMP_DIR');
END;
/
```

4. (Optional) Query the transportable tablespace history table to see the status of the metadata import.

```
SELECT * FROM rdsadmin.rds_xtts_operation_info;
```

   When the operation completes, your tablespaces are in read-only mode.

5. (Optional) View the log file.

   The following example lists the contents of the BDUMP directory and then queries the import log.

```
SELECT * FROM TABLE(rdsadmin.rds_file_util.listdir(p_directory => 'BDUMP'));

SELECT * FROM TABLE(rdsadmin.rds_file_util.read_text_file(
  p_directory => 'BDUMP',
```

```
  p_filename => 'rds-xtts-
import_xtts_metadata-2023-05-22.01-52-35.560858000.log'));
```

Phase 5: Validate the transported tablespaces

In this optional step, you validate your transported tablespaces using the procedure `rdsadmin.rdsadmin_rman_util.validate_tablespace`, and then place your tablespaces in read/write mode.

To validate the transported data

1. Start SQL*Plus or SQL Developer and log in to your target DB instance as the master user.
2. Validate the tablespaces using the procedure `rdsadmin.rdsadmin_rman_util.validate_tablespace`.

```
SET SERVEROUTPUT ON
BEGIN
    rdsadmin.rdsadmin_rman_util.validate_tablespace(
        p_tablespace_name     => 'TBS1',
        p_validation_type     => 'PHYSICAL+LOGICAL',
        p_rman_to_dbms_output => TRUE);
    rdsadmin.rdsadmin_rman_util.validate_tablespace(
        p_tablespace_name     => 'TBS2',
        p_validation_type     => 'PHYSICAL+LOGICAL',
        p_rman_to_dbms_output => TRUE);
    rdsadmin.rdsadmin_rman_util.validate_tablespace(
        p_tablespace_name     => 'TBS3',
        p_validation_type     => 'PHYSICAL+LOGICAL',
        p_rman_to_dbms_output => TRUE);
END;
/
```

3. Place your tablespaces in read/write mode.

```
ALTER TABLESPACE TBS1 READ WRITE;
ALTER TABLESPACE TBS2 READ WRITE;
ALTER TABLESPACE TBS3 READ WRITE;
```

Phase 6: Clean up leftover files

In this optional step, you remove any unneeded files. Use the `rdsadmin.rdsadmin_transport_util.list_xtts_orphan_files` procedure to list data files that were orphaned after a tablespace import, and then use `rdsadmin.rdsadmin_transport_util.list_xtts_orphan_files` procedure to delete them. For syntax and semantics of these procedures, see Listing orphaned files after a tablespace import and Deleting orphaned data files after a tablespace import.

To clean up leftover files

1. Remove old backups in *DATA_PUMP_DIR* as follows:

   a. List the backup files by running `rdsadmin.rdsadmin_file_util.listdir`.

   ```
   SELECT * FROM TABLE(rdsadmin.rds_file_util.listdir(p_directory =>
    'DATA_PUMP_DIR'));
   ```

   b. Remove the backups one by one by calling `UTL_FILE.FREMOVE`.

   ```
   EXEC UTL_FILE.FREMOVE ('DATA_PUMP_DIR', 'backup_filename');
   ```

2. If you imported tablespaces but didn't import metadata for these tablespaces, you can delete the orphaned data files as follows:

   a. List the orphaned data files that you need to delete. The following example runs the procedure `rdsadmin.rdsadmin_transport_util.list_xtts_orphan_files`.

   ```
   SQL> SELECT * FROM
    TABLE(rdsadmin.rdsadmin_transport_util.list_xtts_orphan_files);

   FILENAME       FILESIZE
   -------------- ---------
   datafile_7.dbf 104865792
   datafile_8.dbf 104865792
   ```

   b. Delete the orphaned files by running the procedure `rdsadmin.rdsadmin_transport_util.cleanup_incomplete_xtts_import`.

   ```
   BEGIN
   ```

```
 rdsadmin.rdsadmin_transport_util.cleanup_incomplete_xtts_import('DATA_PUMP_DIR');
END;
/
```

The cleanup operation generates a log file that uses the name format `rds-xtts-delete_xtts_orphaned_files-YYYY-MM-DD.HH24-MI-SS.FF.log` in the BDUMP directory.

c. Read the log file generated in the previous step. The following example reads log `rds-xtts-delete_xtts_orphaned_files-2023-06-01.09-33-11.868894000.log`.

```
SELECT *
FROM TABLE(rdsadmin.rds_file_util.read_text_file(
       p_directory => 'BDUMP',
       p_filename  => 'rds-xtts-
delete_xtts_orphaned_files-2023-06-01.09-33-11.868894000.log'));

TEXT
--------------------------------------------------------------------------------
orphan transported datafile datafile_7.dbf deleted.
orphan transported datafile datafile_8.dbf deleted.
```

3. If you imported tablespaces and imported metadata for these tablespaces, but you encountered compatibility errors or other Oracle Data Pump issues, clean up the partially transported data files as follows:

a. List the tablespaces that contain partially transported data files by querying DBA_TABLESPACES.

```
SQL> SELECT TABLESPACE_NAME FROM DBA_TABLESPACES WHERE PLUGGED_IN='YES';

TABLESPACE_NAME
--------------------------------------------------------------------------------
TBS_3
```

b. Drop the tablespaces and the partially transported data files.

```
DROP TABLESPACE TBS_3 INCLUDING CONTENTS AND DATAFILES;
```

Importing using Oracle Data Pump

Oracle Data Pump is a utility that allows you to export Oracle data to a dump file and import it into another Oracle database. It is a long-term replacement for the Oracle Export/Import utilities. Oracle Data Pump is the recommended way to move large amounts of data from an Oracle database to an Amazon RDS DB instance.

The examples in this section show one way to import data into an Oracle database, but Oracle Data Pump supports other techniques. For more information, see the Oracle Database documentation.

The examples in this section use the `DBMS_DATAPUMP` package. You can accomplish the same tasks using the Oracle Data Pump command line utilities `impdp` and `expdp`. You can install these utilities on a remote host as part of an Oracle Client installation, including Oracle Instant Client. For more information, see How do I use Oracle Instant Client to run Data Pump Import or Export for my Amazon RDS for Oracle DB instance?

Topics

Overview of Oracle Data Pump

Oracle Data Pump is made up of the following components:

- Command-line clients `expdp` and `impdp`
- The `DBMS_DATAPUMP` PL/SQL package
- The `DBMS_METADATA` PL/SQL package

You can use Oracle Data Pump for the following scenarios:

- Import data from an Oracle database, either on-premises or on an Amazon EC2 instance, to an RDS for Oracle DB instance.
- Import data from an RDS for Oracle DB instance to an Oracle database, either on-premises or on an Amazon EC2 instance.
- Import data between RDS for Oracle DB instances, for example, to migrate data from EC2-Classic to VPC.

To download Oracle Data Pump utilities, see Oracle database software downloads on the Oracle Technology Network website. For compatibility considerations when migrating between versions of Oracle Database, see the Oracle Database documentation.

Oracle Data Pump workflow

Typically, you use Oracle Data Pump in the following stages:

1. Export your data into a dump file on the source database.
2. Upload your dump file to your destination RDS for Oracle DB instance. You can transfer using an Amazon S3 bucket or by using a database link between the two databases.
3. Import the data from your dump file into your RDS for Oracle DB instance.

Oracle Data Pump best practices

When you use Oracle Data Pump to import data into an RDS for Oracle instance, we recommend the following best practices:

- Perform imports in `schema` or `table` mode to import specific schemas and objects.
- Limit the schemas you import to those required by your application.
- Don't import in `full` mode or import schemas for system-maintained components.

  Because RDS for Oracle doesn't allow access to SYS or SYSDBA administrative users, these actions might damage the Oracle data dictionary and affect the stability of your database.
- When loading large amounts of data, do the following:
  1. Transfer the dump file to the target RDS for Oracle DB instance.
  2. Take a DB snapshot of your instance.
  3. Test the import to verify that it succeeds.

  If database components are invalidated, you can delete the DB instance and re-create it from the DB snapshot. The restored DB instance includes any dump files staged on the DB instance when you took the DB snapshot.
- Don't import dump files that were created using the Oracle Data Pump export parameters `TRANSPORT_TABLESPACES`, `TRANSPORTABLE`, or `TRANSPORT_FULL_CHECK`. RDS for Oracle DB instances don't support importing these dump files.
- Don't import dump files that contain Oracle Scheduler objects in SYS, `SYSTEM`, `RDSADMIN`, `RDSSEC`, and `RDS_DATAGUARD`, and belong to the following categories:

- Jobs
- Programs
- Schedules
- Chains
- Rules
- Evaluation contexts
- Rule sets

RDS for Oracle DB instances don't support importing these dump files.

- To exclude unsupported Oracle Scheduler objects, use additional directives during the Data Pump export. If you use DBMS_DATAPUMP, you can add an additional METADATA_FILTER before the DBMS_METADATA.START_JOB:

```
DBMS_DATAPUMP.METADATA_FILTER(
  v_hdnl,
  'EXCLUDE_NAME_EXPR',
  q'[IN (SELECT NAME FROM SYS.OBJ$
         WHERE TYPE# IN (66,67,74,79,59,62,46)
         AND OWNER# IN
           (SELECT USER# FROM SYS.USER$
            WHERE NAME IN ('RDSADMIN','SYS','SYSTEM','RDS_DATAGUARD','RDSSEC')
            )
        )
  ]',
  'PROCOBJ'
);
```

If you use expdp, create a parameter file that contains the exclude directive shown in the following example. Then use PARFILE=*parameter_file* with your expdp command.

```
exclude=procobj:"IN
  (SELECT NAME FROM sys.OBJ$
   WHERE TYPE# IN (66,67,74,79,59,62,46)
   AND OWNER# IN
     (SELECT USER# FROM SYS.USER$
      WHERE NAME IN ('RDSADMIN','SYS','SYSTEM','RDS_DATAGUARD','RDSSEC')
     )
  )"
```

Importing data with Oracle Data Pump and an Amazon S3 bucket

The following import process uses Oracle Data Pump and an Amazon S3 bucket. The steps are as follows:

1. Export data on the source database using the Oracle DBMS_DATAPUMP package.
2. Place the dump file in an Amazon S3 bucket.
3. Download the dump file from the Amazon S3 bucket to the `DATA_PUMP_DIR` directory on the target RDS for Oracle DB instance.
4. Import the data from the copied dump file into the RDS for Oracle DB instance using the package `DBMS_DATAPUMP`.

Topics

Requirements for Importing data with Oracle Data Pump and an Amazon S3 bucket

The process has the following requirements:

- Make sure that an Amazon S3 bucket is available for file transfers, and that the Amazon S3 bucket is in the same AWS Region as the DB instance. For instructions, see Create a bucket in the *Amazon Simple Storage Service Getting Started Guide*.
- The object that you upload into the Amazon S3 bucket must be 5 TB or less. For more information about working with objects in Amazon S3, see Amazon Simple Storage Service User Guide.

> **Note**
>
> If you dump file exceeds 5 TB, you can run the Oracle Data Pump export with the parallel option. This operation spreads the data into multiple dump files so that you do not exceed the 5 TB limit for individual files.

- You must prepare the Amazon S3 bucket for Amazon RDS integration by following the instructions in Configuring IAM permissions for RDS for Oracle integration with Amazon S3.
- You must ensure that you have enough storage space to store the dump file on the source instance and the target DB instance.

> **Note**
>
> This process imports a dump file into the `DATA_PUMP_DIR` directory, a preconfigured directory on all Oracle DB instances. This directory is located on the same storage volume as your data files. When you import the dump file, the existing Oracle data files use more space. Thus, you should make sure that your DB instance can accommodate that additional use of space. The imported dump file is not automatically deleted or purged from the `DATA_PUMP_DIR` directory. To remove the imported dump file, use UTL_FILE.FREMOVE, found on the Oracle website.

Step 1: Grant privileges to the database user on the RDS for Oracle target DB instance

In this step, you create the schemas into which you plan to import data and grant the users necessary privileges.

To create users and grant necessary privileges on the RDS for Oracle target instance

1. Use SQL*Plus or Oracle SQL Developer to log in as the master user to the RDS for Oracle DB instance into which the data will be imported. For information about connecting to a DB instance, see Connecting to your RDS for Oracle DB instance.
2. Create the required tablespaces before you import the data. For more information, see Creating and sizing tablespaces.

3. Create the user account and grant the necessary permissions and roles if the user account into which the data is imported doesn't exist. If you plan to import data into multiple user schemas, create each user account and grant the necessary privileges and roles to it.

   For example, the following SQL statements create a new user and grant the necessary permissions and roles to import the data into the schema owned by this user. Replace *schema_1* with the name of your schema in this step and in the following steps.

   ```
   CREATE USER schema_1 IDENTIFIED BY my_password;
   GRANT CREATE SESSION, RESOURCE TO schema_1;
   ALTER USER schema_1 QUOTA 100M ON users;
   ```

   > **Note**
   >
   > Specify a password other than the prompt shown here as a security best practice.

   The preceding statements grant the new user the `CREATE SESSION` privilege and the `RESOURCE` role. You might need additional privileges and roles depending on the database objects that you import.

Step 2: Export data into a dump file using DBMS_DATAPUMP

To create a dump file, use the `DBMS_DATAPUMP` package.

To export Oracle data into a dump file

1. Use SQL Plus or Oracle SQL Developer to connect to the source RDS for Oracle DB instance with an administrative user. If the source database is an RDS for Oracle DB instance, connect with the Amazon RDS master user.
2. Export the data by calling `DBMS_DATAPUMP` procedures.

   The following script exports the *SCHEMA_1* schema into a dump file named `sample.dmp` in the `DATA_PUMP_DIR` directory. Replace *SCHEMA_1* with the name of the schema that you want to export.

   ```
   DECLARE
     v_hdnl NUMBER;
   ```

```
BEGIN
  v_hdnl := DBMS_DATAPUMP.OPEN(
    operation => 'EXPORT',
    job_mode  => 'SCHEMA',
    job_name  => null
  );
  DBMS_DATAPUMP.ADD_FILE(
    handle    => v_hdnl         ,
    filename  => 'sample.dmp'   ,
    directory => 'DATA_PUMP_DIR',
    filetype  => dbms_datapump.ku$_file_type_dump_file
  );
  DBMS_DATAPUMP.ADD_FILE(
    handle    => v_hdnl,
    filename  => 'sample_exp.log',
    directory => 'DATA_PUMP_DIR' ,
    filetype  => dbms_datapump.ku$_file_type_log_file
  );
  DBMS_DATAPUMP.METADATA_FILTER(v_hdnl,'SCHEMA_EXPR','IN (''SCHEMA_1'')');
  DBMS_DATAPUMP.METADATA_FILTER(
    v_hdnl,
    'EXCLUDE_NAME_EXPR',
    q'[IN (SELECT NAME FROM SYS.OBJ$
           WHERE TYPE# IN (66,67,74,79,59,62,46)
           AND OWNER# IN
             (SELECT USER# FROM SYS.USER$
              WHERE NAME IN ('RDSADMIN','SYS','SYSTEM','RDS_DATAGUARD','RDSSEC')
             )
          )
    ]',
    'PROCOBJ'
  );
  DBMS_DATAPUMP.START_JOB(v_hdnl);
END;
/
```

Note

Data Pump starts jobs asynchronously. For information about monitoring a Data Pump job, see Monitoring job status in the Oracle documentation.

3. (Optional) View the contents of the export log by calling the `rdsadmin.rds_file_util.read_text_file` procedure. For more information, see Reading files in a DB instance directory.

Step 3: Upload the dump file to your Amazon S3 bucket

Use the Amazon RDS procedure `rdsadmin.rdsadmin_s3_tasks.upload_to_s3` to copy the dump file to the Amazon S3 bucket. The following example uploads all of the files from the `DATA_PUMP_DIR` directory to an Amazon S3 bucket named *amzn-s3-demo-bucket*.

```
SELECT rdsadmin.rdsadmin_s3_tasks.upload_to_s3(
  p_bucket_name    =>  'amzn-s3-demo-bucket',
  p_directory_name =>  'DATA_PUMP_DIR')
AS TASK_ID FROM DUAL;
```

The SELECT statement returns the ID of the task in a VARCHAR2 data type. For more information, see Uploading files from your RDS for Oracle DB instance to an Amazon S3 bucket.

Step 4: Download the dump file from your Amazon S3 bucket to your target DB instance

Perform this step using the Amazon RDS procedure `rdsadmin.rdsadmin_s3_tasks.download_from_s3`. When you download a file to a directory, the procedure `download_from_s3` skips the download if an identically named file already exists in the directory. To remove a file from the download directory, use UTL_FILE.FREMOVE, found on the Oracle website.

To download your dump file

1. Start SQL*Plus or Oracle SQL Developer and log in as the master on your Amazon RDS target Oracle DB instance
2. Download the dump file using the Amazon RDS procedure `rdsadmin.rdsadmin_s3_tasks.download_from_s3`.

   The following example downloads all files from an Amazon S3 bucket named *amzn-s3-demo-bucket* to the directory `DATA_PUMP_DIR`.

   ```
   SELECT rdsadmin.rdsadmin_s3_tasks.download_from_s3(
     p_bucket_name    =>  'amzn-s3-demo-bucket',
     p_directory_name =>  'DATA_PUMP_DIR')
   ```

```
AS TASK_ID FROM DUAL;
```

The SELECT statement returns the ID of the task in a VARCHAR2 data type. For more information, see Downloading files from an Amazon S3 bucket to an Oracle DB instance.

Step 5: Import your dump file into your target DB instance using DBMS_DATAPUMP

Use DBMS_DATAPUMP to import the schema into your RDS for Oracle DB instance. Additional options such as METADATA_REMAP might be required.

To import data into your target DB instance

1. Start SQL*Plus or SQL Developer and log in as the master user to your RDS for Oracle DB instance.
2. Import the data by calling DBMS_DATAPUMP procedures.

   The following example imports the *SCHEMA_1* data from `sample_copied.dmp` into your target DB instance.

```
DECLARE
  v_hdnl NUMBER;
BEGIN
  v_hdnl := DBMS_DATAPUMP.OPEN(
    operation => 'IMPORT',
    job_mode  => 'SCHEMA',
    job_name  => null);
  DBMS_DATAPUMP.ADD_FILE(
    handle    => v_hdnl,
    filename  => 'sample_copied.dmp',
    directory => 'DATA_PUMP_DIR',
    filetype  => dbms_datapump.ku$_file_type_dump_file);
  DBMS_DATAPUMP.ADD_FILE(
    handle    => v_hdnl,
    filename  => 'sample_imp.log',
    directory => 'DATA_PUMP_DIR',
    filetype  => dbms_datapump.ku$_file_type_log_file);
  DBMS_DATAPUMP.METADATA_FILTER(v_hdnl,'SCHEMA_EXPR','IN (''SCHEMA_1'')');
  DBMS_DATAPUMP.START_JOB(v_hdnl);
END;
/
```

> **Note**
>
> Data Pump jobs are started asynchronously. For information about monitoring a Data Pump job, see Monitoring job status in the Oracle documentation. You can view the contents of the import log by using the `rdsadmin.rds_file_util.read_text_file` procedure. For more information, see Reading files in a DB instance directory.

3. Verify the data import by listing the schema tables on your target DB instance.

   For example, the following query returns the number of tables for *SCHEMA_1*.

```
SELECT COUNT(*) FROM DBA_TABLES WHERE OWNER='SCHEMA_1';
```

Step 6: Clean up

After the data has been imported, you can delete the files that you don't want to keep.

To remove unneeded files

1. Start SQL*Plus or SQL Developer and log in as the master user to your RDS for Oracle DB instance.
2. List the files in `DATA_PUMP_DIR` using the following command.

```
SELECT * FROM TABLE(rdsadmin.rds_file_util.listdir('DATA_PUMP_DIR')) ORDER BY
 MTIME;
```

3. Delete files in `DATA_PUMP_DIR` that you no longer require, use the following command.

```
EXEC UTL_FILE.FREMOVE('DATA_PUMP_DIR','filename');
```

   For example, the following command deletes the file named `sample_copied.dmp`.

```
EXEC UTL_FILE.FREMOVE('DATA_PUMP_DIR','sample_copied.dmp');
```

Importing data with Oracle Data Pump and a database link

The following import process uses Oracle Data Pump and the Oracle DBMS_FILE_TRANSFER package. The steps are as follows:

1. Connect to a source Oracle database, which can be an on-premises database, Amazon EC2 instance, or an RDS for Oracle DB instance.
2. Export data using the DBMS_DATAPUMP package.
3. Use `DBMS_FILE_TRANSFER.PUT_FILE` to copy the dump file from the Oracle database to the `DATA_PUMP_DIR` directory on the target RDS for Oracle DB instance that is connected using a database link.
4. Import the data from the copied dump file into the RDS for Oracle DB instance using the `DBMS_DATAPUMP` package.

The import process using Oracle Data Pump and the `DBMS_FILE_TRANSFER` package has the following steps.

Topics

Requirements for importing data with Oracle Data Pump and a database link

The process has the following requirements:

- You must have execute privileges on the `DBMS_FILE_TRANSFER` and `DBMS_DATAPUMP` packages.
- You must have write privileges to the `DATA_PUMP_DIR` directory on the source DB instance.
- You must ensure that you have enough storage space to store the dump file on the source instance and the target DB instance.

> **Note**
>
> This process imports a dump file into the DATA_PUMP_DIR directory, a preconfigured directory on all Oracle DB instances. This directory is located on the same storage volume as your data files. When you import the dump file, the existing Oracle data files use more space. Thus, you should make sure that your DB instance can accommodate that additional use of space. The imported dump file is not automatically deleted or purged from the DATA_PUMP_DIR directory. To remove the imported dump file, use UTL_FILE.FREMOVE, found on the Oracle website.

Step 1: Grant privileges to the user on the RDS for Oracle target DB instance

To grant privileges to the user on the RDS for Oracle target DB instance, take the following steps:

1. Use SQL Plus or Oracle SQL Developer to connect to the RDS for Oracle DB instance into which you intend to import the data. Connect as the Amazon RDS master user. For information about connecting to the DB instance, see Connecting to your RDS for Oracle DB instance.
2. Create the required tablespaces before you import the data. For more information, see Creating and sizing tablespaces.
3. If the user account into which the data is imported doesn't exist, create the user account and grant the necessary permissions and roles. If you plan to import data into multiple user schemas, create each user account and grant the necessary privileges and roles to it.

   For example, the following commands create a new user named *schema_1* and grant the necessary permissions and roles to import the data into the schema for this user.

   ```
   CREATE USER schema_1 IDENTIFIED BY my-password;
   GRANT CREATE SESSION, RESOURCE TO schema_1;
   ALTER USER schema_1 QUOTA 100M ON users;
   ```

   > **Note**
   >
   > Specify a password other than the prompt shown here as a security best practice.

The preceding example grants the new user the `CREATE SESSION` privilege and the `RESOURCE` role. Additional privileges and roles might be required depending on the database objects that you import.

> **Note**
>
> Replace *schema_1* with the name of your schema in this step and in the following steps.

Step 2: Grant privileges to the user on the source database

Use SQL*Plus or Oracle SQL Developer to connect to the RDS for Oracle DB instance that contains the data to be imported. If necessary, create a user account and grant the necessary permissions.

> **Note**
>
> If the source database is an Amazon RDS instance, you can skip this step. You use your Amazon RDS master user account to perform the export.

The following commands create a new user and grant the necessary permissions.

```
CREATE USER export_user IDENTIFIED BY my-password;
GRANT CREATE SESSION, CREATE TABLE, CREATE DATABASE LINK TO export_user;
ALTER USER export_user QUOTA 100M ON users;
GRANT READ, WRITE ON DIRECTORY data_pump_dir TO export_user;
GRANT SELECT_CATALOG_ROLE TO export_user;
GRANT EXECUTE ON DBMS_DATAPUMP TO export_user;
GRANT EXECUTE ON DBMS_FILE_TRANSFER TO export_user;
```

> **Note**
>
> Specify a password other than the prompt shown here as a security best practice.

Step 3: Create a dump file using DBMS_DATAPUMP

To create a dump file, do the following:

1. Use SQL*Plus or Oracle SQL Developer to connect to the source Oracle instance with an administrative user or with the user you created in step 2. If the source database is an Amazon RDS for Oracle DB instance, connect with the Amazon RDS master user.
2. Create a dump file using the Oracle Data Pump utility.

   The following script creates a dump file named *sample.dmp* in the DATA_PUMP_DIR directory.

```
DECLARE
  v_hdnl NUMBER;
BEGIN
  v_hdnl := DBMS_DATAPUMP.OPEN(
    operation => 'EXPORT' ,
    job_mode  => 'SCHEMA' ,
    job_name  => null
  );
  DBMS_DATAPUMP.ADD_FILE(
    handle    => v_hdnl,
    filename  => 'sample.dmp'    ,
    directory => 'DATA_PUMP_DIR' ,
    filetype  => dbms_datapump.ku$_file_type_dump_file
  );
  DBMS_DATAPUMP.ADD_FILE(
    handle    => v_hdnl           ,
    filename  => 'sample_exp.log' ,
    directory => 'DATA_PUMP_DIR'  ,
    filetype  => dbms_datapump.ku$_file_type_log_file
  );
  DBMS_DATAPUMP.METADATA_FILTER(
    v_hdnl              ,
    'SCHEMA_EXPR'       ,
    'IN (''SCHEMA_1'')'
  );
  DBMS_DATAPUMP.METADATA_FILTER(
    v_hdnl,
    'EXCLUDE_NAME_EXPR',
    q'[IN (SELECT NAME FROM sys.OBJ$
           WHERE TYPE# IN (66,67,74,79,59,62,46)
           AND OWNER# IN
             (SELECT USER# FROM SYS.USER$
              WHERE NAME IN ('RDSADMIN','SYS','SYSTEM','RDS_DATAGUARD','RDSSEC')
             )
         )
    ]',
```

```
    'PROCOBJ'
  );
  DBMS_DATAPUMP.START_JOB(v_hdnl);
END;
/
```

> **Note**
>
> Data Pump jobs are started asynchronously. For information about monitoring a Data Pump job, see Monitoring job status in the Oracle documentation. You can view the contents of the export log by using the `rdsadmin.rds_file_util.read_text_file` procedure. For more information, see Reading files in a DB instance directory.

Step 4: Create a database link to the target DB instance

Create a database link between your source DB instance and your target DB instance. Your local Oracle instance must have network connectivity to the DB instance in order to create a database link and to transfer your export dump file.

Perform this step connected with the same user account as the previous step.

If you are creating a database link between two DB instances inside the same VPC or peered VPCs, the two DB instances should have a valid route between them. The security group of each DB instance must allow ingress to and egress from the other DB instance. The security group inbound and outbound rules can refer to security groups from the same VPC or a peered VPC. For more information, see Adjusting database links for use with DB instances in a VPC.

The following command creates a database link named `to_rds` that connects to the Amazon RDS master user at the target DB instance.

```
CREATE DATABASE LINK to_rds
  CONNECT TO <master_user_account> IDENTIFIED BY <password>
  USING '(DESCRIPTION=(ADDRESS=(PROTOCOL=TCP)(HOST=<dns or ip address of remote db>)
         (PORT=<listener port>))(CONNECT_DATA=(SID=<remote SID>)))';
```

Step 5: Copy the exported dump file to the target DB instance using DBMS_FILE_TRANSFER

Use DBMS_FILE_TRANSFER to copy the dump file from the source database instance to the target DB instance. The following script copies a dump file named sample.dmp from the source instance to a target database link named *to_rds* (created in the previous step).

```
BEGIN
  DBMS_FILE_TRANSFER.PUT_FILE(
    source_directory_object       => 'DATA_PUMP_DIR',
    source_file_name              => 'sample.dmp',
    destination_directory_object  => 'DATA_PUMP_DIR',
    destination_file_name         => 'sample_copied.dmp',
    destination_database          => 'to_rds' );
END;
/
```

Step 6: Import the data file to the target DB instance using DBMS_DATAPUMP

Use Oracle Data Pump to import the schema in the DB instance. Additional options such as METADATA_REMAP might be required.

Connect to the DB instance with the Amazon RDS master user account to perform the import.

```
DECLARE
  v_hdnl NUMBER;
BEGIN
  v_hdnl := DBMS_DATAPUMP.OPEN(
    operation => 'IMPORT',
    job_mode  => 'SCHEMA',
    job_name  => null);
  DBMS_DATAPUMP.ADD_FILE(
    handle    => v_hdnl,
    filename  => 'sample_copied.dmp',
    directory => 'DATA_PUMP_DIR',
    filetype  => dbms_datapump.ku$_file_type_dump_file );
  DBMS_DATAPUMP.ADD_FILE(
    handle    => v_hdnl,
    filename  => 'sample_imp.log',
    directory => 'DATA_PUMP_DIR',
    filetype  => dbms_datapump.ku$_file_type_log_file);
  DBMS_DATAPUMP.METADATA_FILTER(v_hdnl,'SCHEMA_EXPR','IN (''SCHEMA_1'')');
  DBMS_DATAPUMP.START_JOB(v_hdnl);
```

```
END;
/
```

> **Note**
>
> Data Pump jobs are started asynchronously. For information about monitoring a Data Pump job, see Monitoring job status in the Oracle documentation. You can view the contents of the import log by using the `rdsadmin.rds_file_util.read_text_file` procedure. For more information, see Reading files in a DB instance directory.

You can verify the data import by viewing the user's tables on the DB instance. For example, the following query returns the number of tables for *schema_1*.

```
SELECT COUNT(*) FROM DBA_TABLES WHERE OWNER='SCHEMA_1';
```

Step 7: Clean up

After the data has been imported, you can delete the files that you don't want to keep. You can list the files in `DATA_PUMP_DIR` using the following command.

```
SELECT * FROM TABLE(rdsadmin.rds_file_util.listdir('DATA_PUMP_DIR')) ORDER BY MTIME;
```

To delete files in `DATA_PUMP_DIR` that you no longer require, use the following command.

```
EXEC UTL_FILE.FREMOVE('DATA_PUMP_DIR','<file name>');
```

For example, the following command deletes the file named `"sample_copied.dmp"`.

```
EXEC UTL_FILE.FREMOVE('DATA_PUMP_DIR','sample_copied.dmp');
```

Importing using Oracle Export/Import

You might consider Oracle Export/Import utilities for migrations in the following conditions:

- Your data size is small.
- Data types such as binary float and double aren't required.

The import process creates the necessary schema objects. Thus, you don't need to run a script to create the objects beforehand.

The easiest way to install the Oracle the export and import utilities is to install the Oracle Instant Client. To download the software, go to https://www.oracle.com/database/technologies/instant-client.html. For documentation, see Instant Client for SQL*Loader, Export, and Import in the *Oracle Database Utilities* manual.

To export tables and then import them

1. Export the tables from the source database using the `exp` command.

   The following command exports the tables named `tab1`, `tab2`, and `tab3`. The dump file is `exp_file.dmp`.

   ```
   exp cust_dba@ORCL FILE=exp_file.dmp TABLES=(tab1,tab2,tab3) LOG=exp_file.log
   ```

   The export creates a binary dump file that contains both the schema and data for the specified tables.
2. Import the schema and data into a target database using the `imp` command.

   The following command imports the tables `tab1`, `tab2`, and `tab3` from dump file `exp_file.dmp`.

   ```
   imp cust_dba@targetdb FROMUSER=cust_schema TOUSER=cust_schema \
   TABLES=(tab1,tab2,tab3) FILE=exp_file.dmp LOG=imp_file.log
   ```

Export and Import have other variations that might be better suited to your requirements. See the Oracle Database documentation for full details.

Importing using Oracle SQL*Loader

You might consider Oracle SQL*Loader for large databases that contain a limited number of objects. Because the process of exporting from a source database and loading to a target database is specific to the schema, the following example creates the sample schema objects, exports from a source, and then loads the data into a target database.

The easiest way to install Oracle SQL*Loader is to install the Oracle Instant Client. To download the software, go to https://www.oracle.com/database/technologies/instant-client.html. For

documentation, see Instant Client for SQL*Loader, Export, and Import in the *Oracle Database Utilities* manual.

To import data using Oracle SQL*Loader

1. Create a sample source table using the following SQL statement.

```
CREATE TABLE customer_0 TABLESPACE users
   AS (SELECT ROWNUM id, o.*
       FROM   ALL_OBJECTS o, ALL_OBJECTS x
       WHERE  ROWNUM <= 1000000);
```

2. On the target RDS for Oracle DB instance, create a destination table for loading the data. The clause `WHERE 1=2` ensures that you copy the structure of `ALL_OBJECTS`, but don't copy any rows.

```
CREATE TABLE customer_1 TABLESPACE users
  AS (SELECT 0 AS ID, OWNER, OBJECT_NAME, CREATED
      FROM   ALL_OBJECTS
      WHERE  1=2);
```

3. Export the data from the source database to a text file. The following example uses SQL*Plus. For your data, you will likely need to generate a script that does the export for all the objects in the database.

```
ALTER SESSION SET NLS_DATE_FORMAT = 'YYYY/MM/DD HH24:MI:SS'

SET LINESIZE 800 HEADING OFF FEEDBACK OFF ARRAY 5000 PAGESIZE 0
SPOOL customer_0.out
SET MARKUP HTML PREFORMAT ON
SET COLSEP ','

SELECT id, owner, object_name, created
FROM   customer_0;

SPOOL OFF
```

4. Create a control file to describe the data. You might need to write a script to perform this step.

```
cat << EOF > sqlldr_1.ctl
load data
infile customer_0.out
```

```
into table customer_1
APPEND
fields terminated by "," optionally enclosed by '"'
(
  id           POSITION(01:10)    INTEGER EXTERNAL,
  owner        POSITION(12:41)    CHAR,
  object_name  POSITION(43:72)    CHAR,
  created      POSITION(74:92)    date "YYYY/MM/DD HH24:MI:SS"
)
```

If needed, copy the files generated by the preceding code to a staging area, such as an Amazon EC2 instance.

5. Import the data using SQL*Loader with the appropriate user name and password for the target database.

```
sqlldr cust_dba@targetdb CONTROL=sqlldr_1.ctl BINDSIZE=10485760 READSIZE=10485760
 ROWS=1000
```

Migrating with Oracle materialized views

To migrate large datasets efficiently, you can use Oracle materialized view replication. With replication, you can keep the target tables synchronized with the source tables. Thus, you can switch over to Amazon RDS later, if needed.

Before you can migrate using materialized views, make sure that you meet the following requirements:

- Configure access from the target database to the source database. In the following example, access rules were enabled on the source database to allow the RDS for Oracle target database to connect to the source over SQL*Net.
- Create a database link from the RDS for Oracle DB instance to the source database.

To migrate data using materialized views

1. Create a user account on both source and RDS for Oracle target instances that can authenticate with the same password. The following example creates a user named `dblink_user`.

```
CREATE USER dblink_user IDENTIFIED BY my-password
  DEFAULT TABLESPACE users
  TEMPORARY TABLESPACE temp;

GRANT CREATE SESSION TO dblink_user;

GRANT SELECT ANY TABLE TO dblink_user;

GRANT SELECT ANY DICTIONARY TO dblink_user;
```

> **Note**
>
> Specify a password other than the prompt shown here as a security best practice.

2. Create a database link from the RDS for Oracle target instance to the source instance using your newly created user.

```
CREATE DATABASE LINK remote_site
  CONNECT TO dblink_user IDENTIFIED BY my-password
  USING '(description=(address=(protocol=tcp) (host=my-host)
    (port=my-listener-port)) (connect_data=(sid=my-source-db-sid)))';
```

> **Note**
>
> Specify a password other than the prompt shown here as a security best practice.

3. Test the link:

```
SELECT * FROM V$INSTANCE@remote_site;
```

4. Create a sample table with primary key and materialized view log on the source instance.

```
CREATE TABLE customer_0 TABLESPACE users
  AS (SELECT ROWNUM id, o.*
      FROM   ALL_OBJECTS o, ALL_OBJECTS x
      WHERE  ROWNUM <= 1000000);

ALTER TABLE customer_0 ADD CONSTRAINT pk_customer_0 PRIMARY KEY (id) USING INDEX;
```

```
CREATE MATERIALIZED VIEW LOG ON customer_0;
```

5. On the target RDS for Oracle DB instance, create a materialized view.

```
CREATE MATERIALIZED VIEW customer_0
  BUILD IMMEDIATE REFRESH FAST
  AS (SELECT *
      FROM   cust_dba.customer_0@remote_site);
```

6. On the target RDS for Oracle DB instance, refresh the materialized view.

```
EXEC DBMS_MVIEW.REFRESH('CUSTOMER_0', 'f');
```

7. Drop the materialized view and include the `PRESERVE TABLE` clause to retain the materialized view container table and its contents.

```
DROP MATERIALIZED VIEW customer_0 PRESERVE TABLE;
```

   The retained table has the same name as the dropped materialized view.

Working with read replicas for Amazon RDS for Oracle

To configure replication between Oracle DB instances, you can create replica databases. For an overview of Amazon RDS read replicas, see Overview of Amazon RDS read replicas. For a summary of the differences between Oracle replicas and other DB engines, see Differences among read replicas for DB engines.

Topics

Overview of RDS for Oracle replicas

An *Oracle replica* database is a physical copy of your primary database. An Oracle replica in read-only mode is called a *read replica*. An Oracle replica in mounted mode is called a *mounted replica*. Oracle Database doesn't permit writes in a replica, but you can promote a replica to make it writable. The promoted read replica has the replicated data to the point when the request was made to promote it.

The following video provides a helpful overview of RDS for Oracle disaster recovery.

For more information, see the blog post Managed disaster recovery with Amazon RDS for Oracle cross-Region automated backups - Part 1 and Managed disaster recovery with Amazon RDS for Oracle cross-Region automated backups - Part 2.

Topics

- Archived redo log retention
- Outages during Oracle replication

Read-only and mounted replicas

When creating or modifying an Oracle replica, you can place it in either of the following modes:

Read-only

This is the default. Active Data Guard transmits and applies changes from the source database to all read replica databases.

You can create up to five read replicas from one source DB instance. For general information about read replicas that applies to all DB engines, see Working with DB instance read replicas. For information about Oracle Data Guard, see Oracle Data Guard concepts and administration in the Oracle documentation.

Mounted

In this case, replication uses Oracle Data Guard, but the replica database doesn't accept user connections. The primary use for mounted replicas is cross-Region disaster recovery.

A mounted replica can't serve a read-only workload. The mounted replica deletes archived redo log files after it applies them, regardless of the archived log retention policy.

You can create a combination of mounted and read-only DB replicas for the same source DB instance. You can change a read-only replica to mounted mode, or change a mounted replica to read-only mode. In either case, the Oracle database preserves the archived log retention setting.

Read replicas of CDBs

RDS for Oracle supports Data Guard read replicas for Oracle Database 19c and 21c CDBs in the single-tenant configuration only. You can create, manage, and promote read replicas in a CDB just as you can in a non-CDB. Mounted replicas are also supported. You get the following benefits:

- Managed disaster recovery, high availability, and read-only access to your replicas
- The ability to create read replicas in a different AWS Region.
- Integration with the existing RDS read replica APIs: CreateDBInstanceReadReplica, PromoteReadReplica, and SwitchoverReadReplica

To use this feature, you need an Active Data Guard license and an Oracle Database Enterprise Edition license for both the replica and primary DB instances. There are no additional costs related to using CDB architecture. You pay only for your DB instances.

For more information about the single-tenant and multi-tenant configurations of the CDB architecture, see Overview of RDS for Oracle CDBs.

Archived redo log retention

If a primary DB instance has no cross-Region read replicas, Amazon RDS for Oracle keeps a minimum of two hours of archived redo logs on the source DB instance. This is true regardless of the setting for `archivelog retention hours` in `rdsadmin.rdsadmin_util.set_configuration`.

RDS purges logs from the source DB instance after two hours or after the archive log retention hours setting has passed, whichever is longer. RDS purges logs from the read replica after the archive log retention hours setting has passed only if they have been successfully applied to the database.

In some cases, a primary DB instance might have one or more cross-Region read replicas. If so, Amazon RDS for Oracle keeps the transaction logs on the source DB instance until they have been transmitted and applied to all cross-Region read replicas. For information about `rdsadmin.rdsadmin_util.set_configuration`, see Retaining archived redo logs.

Outages during Oracle replication

When you create a read replica, Amazon RDS takes a DB snapshot of your source DB instance and begins replication. The source DB instance experiences a very brief I/O suspension when the DB snapshot operation begins. The I/O suspension typically lasts about one second. You can avoid the I/O suspension if the source DB instance is a Multi-AZ deployment, because in that case the snapshot is taken from the secondary DB instance.

The DB snapshot becomes the Oracle replica. Amazon RDS sets the necessary parameters and permissions for the source database and replica without service interruption. Similarly, if you delete a replica, no outage occurs.

Requirements and considerations for RDS for Oracle replicas

Before creating an Oracle replica, familiarize yourself with the following requirements and considerations.

Topics

Version and licensing requirements for RDS for Oracle replicas

Before you create an RDS for Oracle replica, consider the following:

- If the replica is in read-only mode, make sure that you have an Active Data Guard license. If you place the replica in mounted mode, you don't need an Active Data Guard license. Only the Oracle DB engine supports mounted replicas.
- Oracle replicas are supported only for Oracle Enterprise Edition (EE).
- Oracle replicas of non-CDBs are supported only for DB instances created using non-CDB instances running Oracle Database 19c.
- Oracle replicas are available for DB instances running only on DB instance classes with two or more vCPUs. A source DB instance can't use the db.t3.small instance class.
- The Oracle DB engine version of the source DB instance and all its replicas must be the same. Amazon RDS upgrades the replicas immediately after upgrading the source DB instance, regardless of a replica's maintenance window. For major version upgrades of cross-Region replicas, Amazon RDS automatically does the following:
  - Generates an option group for the target version.
  - Copies all options and option settings from the original option group to the new option group.
  - Associates the upgraded cross-Region replica with the new option group.

  For more information about upgrading the DB engine version, see Upgrading the RDS for Oracle DB engine.

Option group limitations for RDS for Oracle replicas

Before you create an RDS for Oracle replica, consider the following:

- If your Oracle replica is in the same AWS Region as its source DB instance, the replica can't use a different option group from the source DB instance. Modifications to the source option group or source option group membership propagate to Oracle replicas. These changes are applied to the replicas immediately after they are applied to the source DB instance, regardless of the replica's maintenance window.

  For more information about option groups, see Working with option groups.
- You can't remove an RDS for Oracle cross-Region replica from its dedicated option group, which is automatically created for the replica.
- You can't add the dedicated option group for an RDS for Oracle cross-Region replica to a different DB instance.
- You can only add or remove the following nonreplicated options from a dedicated option group for an RDS for Oracle cross-Region replica:
  - `NATIVE_NETWORK_ENCRYPTION`
  - `OEM`
  - `OEM_AGENT`
  - `SSL`

  To add other options to an RDS for Oracle cross-Region replica, add them to the source DB instance's option group. The option is also installed on all of the source DB instance's replicas. For licensed options, make sure that there are sufficient licenses for the replicas.

  When you promote an RDS for Oracle cross-Region replica, the promoted replica behaves the same as other Oracle DB instances, including the management of its options. You can promote a replica explicitly or implicitly by deleting its source DB instance.

  For more information about option groups, see Working with option groups.
- The `EFS_INTEGRATION` option isn't supported for RDS for Oracle cross-Region replicas.

Backup and restore considerations for RDS for Oracle replicas

Before you create an RDS for Oracle replica, consider the following:

- To create snapshots of RDS for Oracle replicas or turn on automatic backups, make sure to set the backup retention period manually. Automatic backups aren't turned on by default.

- When you restore a replica backup, you restore to the database time, not the time that the backup was taken. The *database time* refers to the latest applied transaction time of the data in the backup. The difference is significant because a replica can lag behind the primary for minutes or hours.

  To find the difference, use the `describe-db-snapshots` command. Compare the `snapshotDatabaseTime`, which is the database time of the replica backup, and the `OriginalSnapshotCreateTime` field, which is the latest applied transaction on the primary database.

Oracle Data Guard requirements and limitations for RDS for Oracle replicas

Before you create an RDS for Oracle replica, note the following requirements and limitations:

- If your primary DB instance uses the single-tenant configuration of the multitenant architecture, consider the following:
  - You must use Oracle Database 19c or higher with the Enterprise Edition.
  - Your primary CDB instance must be in an `ACTIVE` lifecycle.
  - You can't convert a non-CDB primary instance to a CDB instance and convert its replicas in the same operation. Instead, delete the non-CDB replicas, convert the primary DB instance to a CDB, and then create new replicas
- Make sure that a logon trigger on a primary DB instance permits access to the `RDS_DATAGUARD` user and to any user whose `AUTHENTICATED_IDENTITY` value is `RDS_DATAGUARD` or `rdsdb`. Also, the trigger must not set the current schema for the `RDS_DATAGUARD` user.
- To avoid blocking connections from the Data Guard broker process, don't enable restricted sessions. For more information about restricted sessions, see Enabling and disabling restricted sessions.

Miscellaneous considerations for RDS for Oracle replicas

Before you create an RDS for Oracle replica, consider the following:

- If your DB instance is a source for one or more cross-Region replicas, the source DB retains its archived redo log files until they are applied on all cross-Region replicas. The archived redo logs might result in increased storage consumption.

- To avoid disrupting RDS automation, system triggers must permit specific users to log on to the primary and replica database. System triggers include DDL, logon, and database role triggers. We recommend that you add code to your triggers to exclude the users listed in the following sample code:

```
-- Determine who the user is
SELECT SYS_CONTEXT('USERENV','AUTHENTICATED_IDENTITY') INTO CURRENT_USER FROM DUAL;
-- The following users should always be able to login to either the Primary or
 Replica
IF CURRENT_USER IN ('master_user', 'SYS', 'SYSTEM', 'RDS_DATAGUARD', 'rdsdb') THEN
RETURN;
END IF;
```

- Block change tracking is supported for read-only replicas, but not for mounted replicas. You can change a mounted replica to a read-only replica, and then enable block change tracking. For more information, see Enabling and disabling block change tracking.

Preparing to create an Oracle replica

Before you can begin using your replica, perform the following tasks.

Topics

- Enabling automatic backups
- Enabling force logging mode
- Changing your logging configuration
- Setting the MAX_STRING_SIZE parameter
- Planning compute and storage resources

Enabling automatic backups

Before a DB instance can serve as a source DB instance, make sure to enable automatic backups on the source DB instance. To learn how to perform this procedure, see Enabling automated backups.

Enabling force logging mode

We recommend that you enable force logging mode. In force logging mode, the Oracle database writes redo records even when `NOLOGGING` is used with data definition language (DDL) statements.

To enable force logging mode

1. Log in to your Oracle database using a client tool such as SQL Developer.
2. Enable force logging mode by running the following procedure.

```
exec rdsadmin.rdsadmin_util.force_logging(p_enable => true);
```

For more information about this procedure, see Setting force logging.

Changing your logging configuration

For *n* online redo logs of size *m*, RDS automatically creates *n*+1 standby logs of size *m* on the primary DB instance and all replicas. Whenever you change the logging configuration on the primary, the changes propagate automatically to the replicas.

If you change your logging configuration, consider the following guidelines:

- We recommend that you complete the changes before making a DB instance the source for replicas. RDS for Oracle also supports updating the instance after it becomes a source.
- Before you change the logging configuration on the primary DB instance, check that each replica has enough storage to accommodate the new configuration.

You can modify the logging configuration for a DB instance by using the Amazon RDS procedures `rdsadmin.rdsadmin_util.add_logfile` and `rdsadmin.rdsadmin_util.drop_logfile`. For more information, see Adding online redo logs and Dropping online redo logs.

Setting the MAX_STRING_SIZE parameter

Before you create an Oracle replica, ensure that the setting of the `MAX_STRING_SIZE` parameter is the same on the source DB instance and the replica. You can do this by associating them with the same parameter group. If you have different parameter groups for the source and the replica, you can set `MAX_STRING_SIZE` to the same value. For more information about setting this parameter, see Turning on extended data types for a new DB instance.

Planning compute and storage resources

Ensure that the source DB instance and its replicas are sized properly, in terms of compute and storage, to suit their operational load. If a replica reaches compute, network, or storage resource

capacity, the replica stops receiving or applying changes from its source. Amazon RDS for Oracle doesn't intervene to mitigate high replica lag between a source DB instance and its replicas. You can modify the storage and CPU resources of a replica independently from its source and other replicas.

Creating an RDS for Oracle replica in mounted mode

By default, Oracle replicas are read-only. To create a replica in mounted mode, use the console, the AWS CLI, or the RDS API.

Console

To create a mounted replica from a source Oracle DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.
3. Choose the Oracle DB instance that you want to use as the source for a mounted replica.
4. For **Actions**, choose **Create replica**.
5. For **Replica mode**, choose **Mounted**.
6. Choose the settings that you want to use. For **DB instance identifier**, enter a name for the read replica. Adjust other settings as needed.
7. For **Regions**, choose the Region where the mounted replica will be launched.
8. Choose your instance size and storage type. We recommend that you use the same DB instance class and storage type as the source DB instance for the read replica.
9. For **Multi-AZ deployment**, choose **Create a standby instance** to create a standby of your replica in another Availability Zone for failover support for the mounted replica. Creating your mounted replica as a Multi-AZ DB instance is independent of whether the source database is a Multi-AZ DB instance.
10. Choose the other settings that you want to use.
11. Choose **Create replica**.

In the **Databases** page, the mounted replica has the role Replica.

AWS CLI

To create an Oracle replica in mounted mode, set `--replica-mode` to `mounted` in the AWS CLI command create-db-instance-read-replica.

Example

For Linux, macOS, or Unix:

```
aws rds create-db-instance-read-replica \
    --db-instance-identifier myreadreplica \
    --source-db-instance-identifier mydbinstance \
    --replica-mode mounted
```

For Windows:

```
aws rds create-db-instance-read-replica ^
    --db-instance-identifier myreadreplica ^
    --source-db-instance-identifier mydbinstance ^
    --replica-mode mounted
```

To change a read-only replica to a mounted state, set `--replica-mode` to `mounted` in the AWS CLI command modify-db-instance. To place a mounted replica in read-only mode, set `--replica-mode` to `open-read-only`.

RDS API

To create an Oracle replica in mounted mode, specify `ReplicaMode=mounted` in the RDS API operation CreateDBInstanceReadReplica.

Modifying the RDS for Oracle replica mode

To change the replica mode of an existing replica, use the console, AWS CLI, or RDS API. When you change to mounted mode, the replica disconnects all active connections. When you change to read-only mode, Amazon RDS initializes Active Data Guard.

The change operation can take a few minutes. During the operation, the DB instance status changes to **modifying**. For more information about status changes, see Viewing Amazon RDS DB instance status.

Console

To change the replica mode of an Oracle replica from mounted to read-only

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.
3. Choose the mounted replica database.
4. Choose **Modify**.
5. For **Replica mode**, choose **Read-only**.
6. Choose the other settings that you want to change.
7. Choose **Continue**.
8. For **Scheduling of modifications**, choose **Apply immediately**.
9. Choose **Modify DB instance**.

AWS CLI

To change a read replica to mounted mode, set `--replica-mode` to `mounted` in the AWS CLI command modify-db-instance. To change a mounted replica to read-only mode, set `--replica-mode` to `open-read-only`.

Example

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier myreadreplica \
    --replica-mode mode
```

For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier myreadreplica ^
    --replica-mode mode
```

RDS API

To change a read-only replica to mounted mode, set `ReplicaMode=mounted` in ModifyDBInstance. To change a mounted replica to read-only mode, set `ReplicaMode=read-only`.

Working with RDS for Oracle replica backups

You can create and restore backups of an RDS for Oracle replica. Both automatic backups and manual snapshots are supported. For more information, see Backing up, restoring, and exporting data. The following sections describe the key differences between managing backups of a primary and an RDS for Oracle replica.

Turning on RDS for Oracle replica backups

An Oracle replica doesn't have automated backups turned on by default. You turn on automated backups by setting the backup retention period to a positive nonzero value.

Console

To enable automated backups immediately

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**, and then choose the DB instance or Multi-AZ DB cluster that you want to modify.
3. Choose **Modify**.
4. For **Backup retention period**, choose a positive nonzero value, for example 3 days.
5. Choose **Continue**.
6. Choose **Apply immediately**.
7. Choose **Modify DB instance** or **Modify cluster** to save your changes and enable automated backups.

AWS CLI

To enable automated backups, use the AWS CLI `modify-db-instance` or `modify-db-cluster` command.

Include the following parameters:

- `--db-instance-identifier` (or `--db-cluster-identifier` for a Multi-AZ DB cluster)
- `--backup-retention-period`
- `--apply-immediately` or `--no-apply-immediately`

In the following example, we enable automated backups by setting the backup retention period to three days. The changes are applied immediately.

Example

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier mydbinstance  \
    --backup-retention-period 3 \
    --apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier mydbinstance  ^
    --backup-retention-period 3 ^
    --apply-immediately
```

RDS API

To enable automated backups, use the RDS API `ModifyDBInstance` or `ModifyDBCluster` operation with the following required parameters:

- `DBInstanceIdentifier` or `DBClusterIdentifier`
- `BackupRetentionPeriod`

Restoring an RDS for Oracle replica backup

You can restore an Oracle replica backup just as you can restore a backup of the primary instance. For more information, see the following:

- Restoring to a DB instance

- Restoring a DB instance to a specified time

The main consideration when you restore a replica backup is determining the point in time to which you are restoring. The *database time* refers to the latest applied transaction time of the data in the backup. When you restore a replica backup, you restore to the database time, not the time when the backup completed. The difference is significant because an RDS for Oracle replica can lag behind the primary by minutes or hours. Thus, the database time of a replica backup, and thus the point in time to which you restore it, might be much earlier than the backup creation time.

To find the difference between database time and creation time, use the `describe-db-snapshots` command. Compare the `SnapshotDatabaseTime`, which is the database time of the replica backup, and the `OriginalSnapshotCreateTime` field, which is the latest applied transaction on the primary database. The following example shows the difference between the two times:

```
aws rds describe-db-snapshots \
    --db-instance-identifier my-oracle-replica
    --db-snapshot-identifier my-replica-snapshot

{
    "DBSnapshots": [
        {
            "DBSnapshotIdentifier": "my-replica-snapshot",
            "DBInstanceIdentifier": "my-oracle-replica",
            "SnapshotDatabaseTime": "2022-07-26T17:49:44Z",
            ...
            "OriginalSnapshotCreateTime": "2021-07-26T19:49:44Z"
        }
    ]
}
```

Performing an Oracle Data Guard switchover

A *switchover* is a role reversal between a primary database and a standby database. During a switchover, the original primary database transitions to a standby role, while the original standby database transitions to the primary role.

In an Oracle Data Guard environment, a primary database supports one or more standby databases. You can perform a managed, switchover-based role transition from a primary database

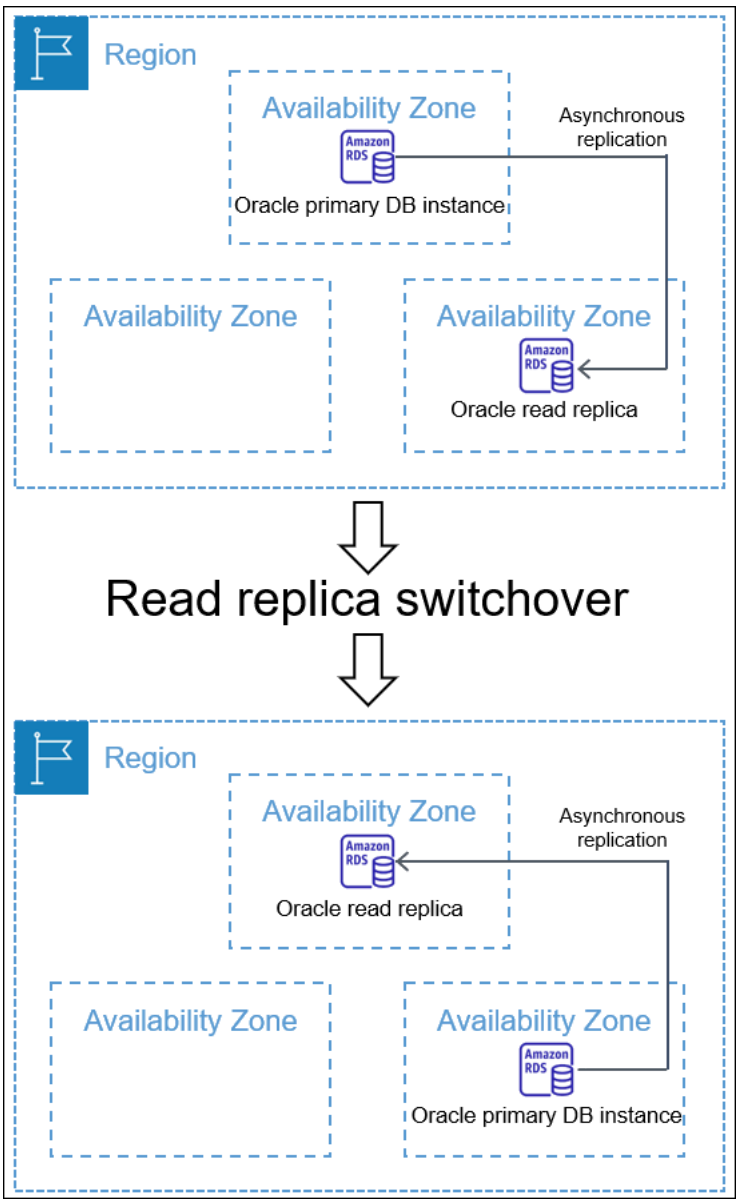
to a standby database. A *switchover* is a role reversal between a primary database and a standby database. During a switchover, the original primary database transitions to a standby role, while the original standby database transitions to the primary role.

Topics

Overview of Oracle Data Guard switchover

Amazon RDS supports a fully managed, switchover-based role transition for Oracle Database replicas. You can only initiate a switchover to a standby database that is mounted or open read-only.

The replicas can reside in separate AWS Regions or in different Availability Zones (AZs) of a single Region. All AWS Regions are supported.



A switchover differs from a read replica promotion. In a switchover, the source and replica DB instances change roles. In a promotion, a read replica becomes a source DB instance, but the source DB instance doesn't become a replica. For more information, see Promoting a read replica to be a standalone DB instance.

Topics

- Benefits of Oracle Data Guard switchover
- Supported Oracle Database versions
- Cost of Oracle Data Guard switchover
- How Oracle Data Guard switchover works

Benefits of Oracle Data Guard switchover

Just as for RDS for Oracle read replicas, a managed switchover relies on Oracle Data Guard. The operation is designed to have zero data loss. Amazon RDS automates the following aspects of the switchover:

- Reverses the roles of your primary database and specified standby database, putting the new standby database in the same state (mounted or read-only) as the original standby
- Ensures data consistency
- Maintains your replication configuration after the transition
- Supports repeated reversals, allowing your new standby database to return to its original primary role

Supported Oracle Database versions

Oracle Data Guard switchover is supported for Oracle Database 19c and higher releases.

Cost of Oracle Data Guard switchover

The Oracle Data Guard switchover feature doesn't incur additional costs. Oracle Database Enterprise Edition includes support for standby databases in mounted mode. To open standby databases in read-only mode, you need the Oracle Active Data Guard option.

How Oracle Data Guard switchover works

Oracle Data Guard switchover is a fully managed operation. You initiate the switchover for a standby database by issuing the CLI command `switchover-read-replica`. Then Amazon RDS modifies the primary and standby roles in your replication configuration.

The *original standby* and *original primary* are the roles that exist before the switchover. The *new standby* and *new primary* are the roles that exist after the switchover. A *bystander replica* is a replica database that serves as a standby database in the Oracle Data Guard environment but is not switching roles.

Topics

Stages of the Oracle Data Guard switchover

To perform the switchover, Amazon RDS must take the following steps:

1. Block new transactions on the original primary database. During the switchover, Amazon RDS interrupts replication for all databases in your Oracle Data Guard configuration. During the switchover, the original primary database can't process write requests.
2. Ship unapplied transactions to the original standby database, and apply them.
3. Restart the new standby database in read-only or mounted mode. The mode depends on the open state of the original standby database before the switchover.
4. Open the new primary database in read/write mode.

After the Oracle Data Guard switchover

Amazon RDS switches the roles of the primary and standby database. You are responsible for reconnecting your application and performing any other desired configuration.

Topics

- Success criteria
- Connection to the new primary database
- Configuration of the new primary database

Success criteria

The Oracle Data Guard switchover is successful when the original standby database does the following:

- Transitions to its role as new primary database
- Completes its reconfiguration

To limit downtime, your new primary database becomes active as soon as possible. Because Amazon RDS configures bystander replicas asynchronously, these replicas might become active after the original primary database.

Connection to the new primary database

Amazon RDS won't propagate your current database connections to the new primary database after the switchover. After the Oracle Data Guard switchover completes, reconnect your application to the new primary database.

Configuration of the new primary database

To perform a switchover to the new primary database, Amazon RDS changes the mode of the original standby database to open. The change in role is the only change to the database. Amazon RDS doesn't set up features such as Multi-AZ replication.

If you perform a switchover to a cross-Region replica with different options, the new primary database keeps its own options. Amazon RDS won't migrate the options on the original primary database. If the original primary database had options such as SSL, NNE, OEM, and OEM_AGENT, Amazon RDS doesn't propagate them to the new primary database.

Requirements for the Oracle Data Guard switchover

Before initiating the Oracle Data Guard switchover, make sure that your replication environment meets the following requirements:

- The original standby database is mounted or open read-only.
- Automatic backups are enabled on the original standby database.
- The original primary database and the original standby database are in an available state.
- The original primary database and the original standby database have no pending maintenance actions.
- The original standby database is in the replicating state.
- You aren't attempting to initiate a switchover when either the primary database or standby database is currently in a switchover lifecycle. If a replica database is reconfiguring after a switchover, Amazon RDS prevents you from initiating another switchover.

  > **Note**
  >
  > A *bystander replica* is a replica in the Oracle Data Guard configuration that isn't the target of the switchover. Bystander replicas can be in any state during the switchover.

- The original standby database has a configuration that is as close as desired to the original primary database. Assume a scenario where the original primary and original standby databases

have different options. After the switchover completes, Amazon RDS doesn't automatically reconfigure the new primary database to have the same options as the original primary database.

- You configure your desired Multi-AZ deployment before initiating a switchover. Amazon RDS doesn't manage Multi-AZ as part of the switchover. The Multi-AZ deployment remains as it is.

  Assume that db_maz is the primary database in a Multi-AZ deployment, and db_saz is a Single-AZ replica. You initiate a switchover from db_maz to db_saz. Afterward, db_maz is a Multi-AZ replica database, and db_saz is a Single-AZ primary database. The new primary database is now unprotected by a Multi-AZ deployment.
- In preparation for a cross-Region switchover, the primary database doesn't use the same option group as a DB instance outside of the replication configuration. For a cross-Region switchover to succeed, the current primary database and its read replicas must be the only DB instances to use the option group of the current primary database. Otherwise, Amazon RDS prevents the switchover.

Initiating the Oracle Data Guard switchover

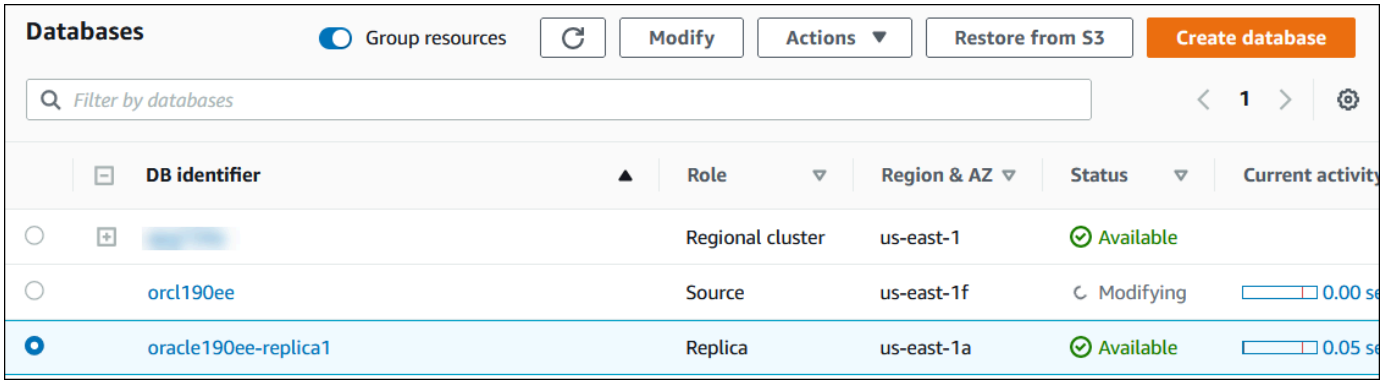
You can switch over an RDS for Oracle read replica to the primary role, and the former primary DB instance to a replica role.

Console

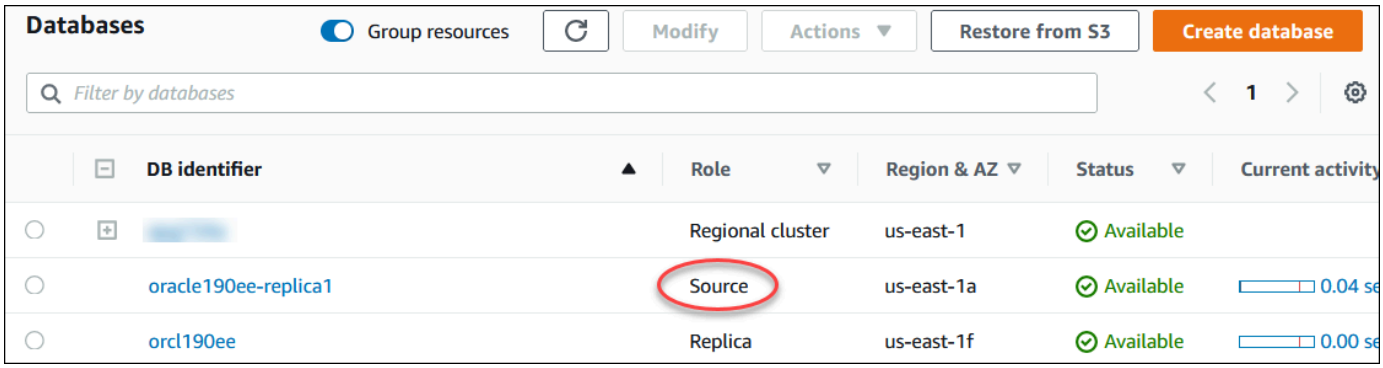
To switch over an Oracle read replica to the primary DB role

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the Amazon RDS console, choose **Databases**.

   The **Databases** pane appears. Each read replica shows **Replica** in the **Role** column.
3. Choose the read replica that you want to switch over to the primary role.
4. For **Actions**, choose **Switch over replica**.
5. Choose **I acknowledge**. Then choose **Switch over replica**.
6. On the **Databases** page, monitor the progress of the switchover.



When the switchover completes, the role of the switchover target changes from **Replica** to **Source**.



AWS CLI

To switch over an Oracle replica to the primary DB role, use the AWS CLI `switchover-read-replica` command. The following examples make the Oracle replica named *`replica-to-be-made-primary`* into the new primary database.

Example

For Linux, macOS, or Unix:

```
aws rds switchover-read-replica \
    --db-instance-identifier replica-to-be-made-primary
```

For Windows:

```
aws rds switchover-read-replica ^
    --db-instance-identifier replica-to-be-made-primary
```

RDS API

To switch over an Oracle replica to the primary DB role, call the Amazon RDS API `SwitchoverReadReplica` operation with the required parameter `DBInstanceIdentifier`. This parameter specifies the name of the Oracle replica that you want to assume the primary DB role.

Monitoring the Oracle Data Guard switchover

To check the status of your instances, use the AWS CLI command `describe-db-instances`. The following command checks the status of the DB instance *`orcl2`*. This database was a standby database before the switchover, but is the new primary database after the switchover.

```
aws rds describe-db-instances \
    --db-instance-identifier orcl2
```

To confirm that the switchover completed successfully, query `V$DATABASE.OPEN_MODE`. Check that the value for the new primary database is `READ WRITE`.

```
SELECT OPEN_MODE FROM V$DATABASE;
```

To look for switchover-related events, use the AWS CLI command `describe-events`. The following example looks for events on the *`orcl2`* instance.

```
aws rds describe-events \
    --source-identifier orcl2 \
    --source-type db-instance
```

Troubleshooting RDS for Oracle replicas

This section describes possible replication problems and solutions.

Topics

- Monitoring Oracle replication lag
- Troubleshooting Oracle replication failure after adding or modifying triggers

Monitoring Oracle replication lag

To monitor replication lag in Amazon CloudWatch, view the Amazon RDS `ReplicaLag` metric. For more information about replication lag time, see Monitoring read replication and Amazon CloudWatch metrics for Amazon RDS.

For a read replica, if the lag time is too long, query the following views:

- `V$ARCHIVED_LOG` – Shows which commits have been applied to the read replica.
- `V$DATAGUARD_STATS` – Shows a detailed breakdown of the components that make up the `ReplicaLag` metric.
- `V$DATAGUARD_STATUS` – Shows the log output from Oracle's internal replication processes.

For a mounted replica, if the lag time is too long, you can't query the `V$` views. Instead, do the following:

- Check the `ReplicaLag` metric in CloudWatch.
- Check the alert log file for the replica in the console. Look for errors in the recovery messages. The messages include the log sequence number, which you can compare to the primary sequence number. For more information, see Oracle database log files.

Troubleshooting Oracle replication failure after adding or modifying triggers

If you add or modify any triggers, and if replication fails afterward, the problem may be the triggers. Ensure that the trigger excludes the following user accounts, which are required by RDS for replication:

- User accounts with administrator privileges
- `SYS`
- `SYSTEM`
- `RDS_DATAGUARD`
- `rdsdb`

For more information, see Miscellaneous considerations for RDS for Oracle replicas.

Adding options to Oracle DB instances

In Amazon RDS, an *option* is an additional feature. Following, you can find a description of options that you can add to Amazon RDS instances running the Oracle DB engine.

Topics

Overview of Oracle DB options

To enable options for your Oracle database, add them to an option group, and then associate the option group with your DB instance. For more information, see Working with option groups.

Topics

- Summary of Oracle Database options
- Options supported for different editions
- Memory requirements for specific options

Summary of Oracle Database options

You can add the following options for Oracle DB instances.

Option	Option ID
Amazon S3 integration	S3_INTEGRATION
Oracle Application Express (APEX)	APEX APEX-DEV
Oracle Enterprise Manager	OEM OEM_AGENT
Oracle Java virtual machine	JVM
Oracle Label Security	OLS
Oracle Locator	LOCATOR
Oracle native network encryption	NATIVE_NETWORK_ENCRYPTION
Oracle OLAP	OLAP
Oracle Secure Sockets Layer	SSL
Oracle Spatial	SPATIAL
Oracle SQLT	SQLT
Oracle Statspack	STATSPACK
Oracle time zone	Timezone

Option	Option ID
Oracle time zone file autoupgrade	TIMEZONE_FILE_AUTOUPGRADE
Oracle Transparent Data Encryption	TDE
Oracle UTL_MAIL	UTL_MAIL
Oracle XML DB	XMLDB

Options supported for different editions

RDS for Oracle prevents you from adding options to an edition if they aren't supported. To find out which RDS options are supported in different Oracle Database editions, use the command `aws rds describe-option-group-options`. The following example lists supported options for Oracle Database 19c Enterprise Edition.

```
aws rds describe-option-group-options \
    --engine-name oracle-ee \
    --major-engine-version 19
```

For more information, see describe-option-group-options in the *AWS CLI Command Reference*.

Memory requirements for specific options

Some options require additional memory to run on your DB instance. For example, Oracle Enterprise Manager Database Control uses about 300 MB of RAM. If you enable this option for a small DB instance, you might encounter performance problems due to memory constraints. You can adjust the Oracle parameters so that the database requires less RAM. Alternatively, you can scale up to a larger DB instance.

Amazon S3 integration

You can transfer files between your RDS for Oracle DB instance and an Amazon S3 bucket. You can use Amazon S3 integration with Oracle Database features such as Oracle Data Pump. For example, you can download Data Pump files from Amazon S3 to your RDS for Oracle DB instance. For more information, see Importing data into Oracle on Amazon RDS.

> **Note**
>
> Your DB instance and your Amazon S3 bucket must be in the same AWS Region.

Topics

Configuring IAM permissions for RDS for Oracle integration with Amazon S3

For RDS for Oracle to integrate with Amazon S3, your DB instance must have access to an Amazon S3 bucket. The Amazon VPC used by your DB instance doesn't need to provide access to the Amazon S3 endpoints.

RDS for Oracle supports transferring files between a DB instance in one account and an Amazon S3 bucket in a different account. Where additional steps are required, they are noted in the following sections.

Topics

Step 1: Create an IAM policy for your Amazon RDS role

In this step, you create an AWS Identity and Access Management (IAM) policy with the permissions required to transfer files between your Amazon S3 bucket and your RDS DB instance. This step assumes that you have already created an S3 bucket.

Before you create the policy, note the following pieces of information:

- The Amazon Resource Name (ARN) for your bucket
- The ARN for your AWS KMS key, if your bucket uses SSE-KMS or SSE-S3 encryption

> **Note**
>
> An RDS for Oracle DB instance can't access Amazon S3 buckets encrypted with SSE-C.

For more information, see Protecting data using server-side encryption in the *Amazon Simple Storage Service User Guide*.

Console

To create an IAM policy to allow Amazon RDS to access your Amazon S3 bucket

1. Open the IAM Management Console.
2. Under **Access management**, choose **Policies**.
3. Choose **Create Policy**.
4. On the **Visual editor** tab, choose **Choose a service**, and then choose **S3**.
5. For **Actions**, choose **Expand all**, and then choose the bucket permissions and object permissions required to transfer files from an Amazon S3 bucket to Amazon RDS. For example, do the following:
   - Expand **List**, and then select **ListBucket**.
   - Expand **Read**, and then select **GetObject**.
   - Expand **Write**, and then select **PutObject** and **DeleteObject**.
   - Expand **Permissions management**, and then select **PutObjectAcl**. This permission is necessary if you plan to upload files to a bucket owned by a different account, and this account needs full control of the bucket contents.

Object permissions are permissions for object operations in Amazon S3. You must grant them for objects in a bucket, not the bucket itself. For more information, see Permissions for object operations.

6. Choose **Resources**, and then do the following:

   a. Choose **Specific**.

   b. For **bucket**, choose **Add ARN**. Enter your bucket ARN. The bucket name is filled in automatically. Then choose **Add**.

   c. If the **object** resource is shown, either choose **Add ARN** to add resources manually or choose **Any**.

   > **Note**
   >
   > You can set **Amazon Resource Name (ARN)** to a more specific ARN value to allow Amazon RDS to access only specific files or folders in an Amazon S3 bucket. For more information about how to define an access policy for Amazon S3, see Managing access permissions to your Amazon S3 resources.

7. (Optional) Choose **Add additional permissions** to add resources to the policy. For example, do the following:

   a. If your bucket is encrypted with a custom KMS key, select **KMS** for the service.

   b. For **Manual actions**, select the following:

      - **Encrypt**
      - **ReEncrypt from** and **ReEncrypt to**
      - **Decrypt**
      - **DescribeKey**
      - **GenerateDataKey**

   c. For **Resources**, choose **Specific**.

   d. For **key**, choose **Add ARN**. Enter the ARN of your custom key as the resource, and then choose **Add**.

For more information, see Protecting Data Using Server-Side Encryption with KMS keys Stored in AWS Key Management Service (SSE-KMS) in the *Amazon Simple Storage Service User Guide*.

e. If you want Amazon RDS to access to access other buckets, add the ARNs for these buckets. Optionally, you can also grant access to all buckets and objects in Amazon S3.

8. Choose **Next: Tags** and then **Next: Review**.
9. For **Name**, enter a name for your IAM policy, for example `rds-s3-integration-policy`. You use this name when you create an IAM role to associate with your DB instance. You can also add an optional **Description** value.
10. Choose **Create policy**.

AWS CLI

Create an AWS Identity and Access Management (IAM) policy that grants Amazon RDS access to an Amazon S3 bucket. After you create the policy, note the ARN of the policy. You need the ARN for a subsequent step.

Include the appropriate actions in the policy based on the type of access required:

- `GetObject` – Required to transfer files from an Amazon S3 bucket to Amazon RDS.
- `ListBucket` – Required to transfer files from an Amazon S3 bucket to Amazon RDS.
- `PutObject` – Required to transfer files from Amazon RDS to an Amazon S3 bucket.

The following AWS CLI command creates an IAM policy named *`rds-s3-integration-policy`* with these options. It grants access to a bucket named *`amzn-s3-demo-bucket`*.

Example

For Linux, macOS, or Unix:

```
aws iam create-policy \
   --policy-name rds-s3-integration-policy \
   --policy-document '{
     "Version": "2012-10-17",
     "Statement": [
       {
```

```
        "Sid": "s3integration",
        "Action": [
          "s3:GetObject",
          "s3:ListBucket",
          "s3:PutObject"
        ],
        "Effect": "Allow",
        "Resource": [
          "arn:aws:s3:::amzn-s3-demo-bucket",
          "arn:aws:s3:::amzn-s3-demo-bucket/*"
        ]
      }
    ]
  }'
```

The following example includes permissions for custom KMS keys.

```
aws iam create-policy \
  --policy-name rds-s3-integration-policy \
  --policy-document '{
    "Version": "2012-10-17",
    "Statement": [
      {
        "Sid": "s3integration",
        "Action": [
          "s3:GetObject",
          "s3:ListBucket",
          "s3:PutObject",
          "kms:Decrypt",
          "kms:Encrypt",
          "kms:ReEncrypt*",
          "kms:GenerateDataKey",
          "kms:DescribeKey",
        ],
        "Effect": "Allow",
        "Resource": [
          "arn:aws:s3:::amzn-s3-demo-bucket",
          "arn:aws:s3:::amzn-s3-demo-bucket/*",
          "arn:aws:kms:::your-kms-arn"
        ]
      }
    ]
  }'
```

For Windows:

```
aws iam create-policy ^
   --policy-name rds-s3-integration-policy ^
   --policy-document '{
     "Version": "2012-10-17",
     "Statement": [
       {
         "Sid": "s3integration",
         "Action": [
           "s3:GetObject",
           "s3:ListBucket",
           "s3:PutObject"
         ],
         "Effect": "Allow",
         "Resource": [
           "arn:aws:s3:::amzn-s3-demo-bucket",
           "arn:aws:s3:::amzn-s3-demo-bucket/*"
         ]
       }
     ]
   }'
```

The following example includes permissions for custom KMS keys.

```
aws iam create-policy ^
   --policy-name rds-s3-integration-policy ^
   --policy-document '{
     "Version": "2012-10-17",
     "Statement": [
       {
         "Sid": "s3integration",
         "Action": [
           "s3:GetObject",
           "s3:ListBucket",
           "s3:PutObject",
           "kms:Decrypt",
           "kms:Encrypt",
           "kms:ReEncrypt",
           "kms:GenerateDataKey",
           "kms:DescribeKey",
         ],
         "Effect": "Allow",
```

```
        "Resource": [
          "arn:aws:s3:::amzn-s3-demo-bucket",
          "arn:aws:s3:::amzn-s3-demo-bucket/*",
          "arn:aws:kms:::your-kms-arn"
        ]
      }
    ]
  }'
```

Step 2: (Optional) Create an IAM policy for your Amazon S3 bucket

This step is necessary only in the following conditions:

- You plan to upload files to an Amazon S3 bucket from one account (account A) and access them from a different account (account B).
- Account B owns the bucket.
- Account B needs full control of objects loaded into the bucket.

If the preceding conditions don't apply to you, skip to Step 3: Create an IAM role for your DB instance and attach your policy.

To create your bucket policy, make sure you have the following:

- The account ID for account A
- The user name for account A
- The ARN value for the Amazon S3 bucket in account B

Console

To create or edit a bucket policy

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the **Buckets** list, choose the name of the bucket that you want to create a bucket policy for or whose bucket policy you want to edit.
3. Choose **Permissions**.
4. Under **Bucket policy**, choose **Edit**. This opens the Edit bucket policy page.

5. On the **Edit bucket policy** page, explore **Policy examples** in the *Amazon S3 User Guide*, choose **Policy generator** to generate a policy automatically, or edit the JSON in the **Policy** section.

   If you choose **Policy generator**, the AWS Policy Generator opens in a new window:

   a. On the **AWS Policy Generator** page, in **Select Type of Policy**, choose **S3 Bucket Policy**.

   b. Add a statement by entering the information in the provided fields, and then choose **Add Statement**. Repeat for as many statements as you would like to add. For more information about these fields, see the IAM JSON policy elements reference in the *IAM User Guide*.

   > **Note**
   >
   > For convenience, the **Edit bucket policy** page displays the **Bucket ARN** (Amazon Resource Name) of the current bucket above the **Policy** text field. You can copy this ARN for use in the statements on the **AWS Policy Generator** page.

   c. After you finish adding statements, choose **Generate Policy**.

   d. Copy the generated policy text, choose **Close**, and return to the **Edit bucket policy** page in the Amazon S3 console.

6. In the **Policy** box, edit the existing policy or paste the bucket policy from the Policy generator. Make sure to resolve security warnings, errors, general warnings, and suggestions before you save your policy.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "Example permissions",
      "Effect": "Allow",
      "Principal": {
        "AWS": "arn:aws:iam::account-A-ID:account-A-user"
      },
      "Action": [
        "s3:PutObject",
        "s3:PutObjectAcl"
      ],
      "Resource": [
        "arn:aws:s3:::amzn-s3-demo-destination-bucket",
        "arn:aws:s3:::amzn-s3-demo-destination-bucket/*"
      ]
```

```
    }
  ]
}
```

7. Choose **Save changes**, which returns you to the Bucket Permissions page.

Step 3: Create an IAM role for your DB instance and attach your policy

This step assumes that you have created the IAM policy in Step 1: Create an IAM policy for your Amazon RDS role. In this step, you create a role for your RDS for Oracle DB instance and then attach your policy to the role.

Console

To create an IAM role to allow Amazon RDS to access an Amazon S3 bucket

1. Open the IAM Management Console.
2. In the navigation pane, choose **Roles**.
3. Choose **Create role**.
4. Choose **AWS service**.
5. For **Use cases for other AWS services:**, choose **RDS** and then **RDS – Add Role to Database**. Then choose **Next**.
6. For **Search** under **Permissions policies**, enter the name of the IAM policy you created in Step 1: Create an IAM policy for your Amazon RDS role, and select the policy when it appears in the list. Then choose **Next**.
7. For **Role name**, enter a name for your IAM role, for example, `rds-s3-integration-role`. You can also add an optional **Description** value.
8. Choose **Create role**.

AWS CLI

To create a role and attach your policy to it

1. Create an IAM role that Amazon RDS can assume on your behalf to access your Amazon S3 buckets.

We recommend using the aws:SourceArn and aws:SourceAccount global condition context keys in resource-based trust relationships to limit the service's permissions to a specific resource. This is the most effective way to protect against the confused deputy problem.

You might use both global condition context keys and have the aws:SourceArn value contain the account ID. In this case, the aws:SourceAccount value and the account in the aws:SourceArn value must use the same account ID when used in the same statement.

- Use aws:SourceArn if you want cross-service access for a single resource.
- Use aws:SourceAccount if you want to allow any resource in that account to be associated with the cross-service use.

In the trust relationship, make sure to use the aws:SourceArn global condition context key with the full Amazon Resource Name (ARN) of the resources accessing the role.

The following AWS CLI command creates the role named *rds-s3-integration-role* for this purpose.

Example

For Linux, macOS, or Unix:

```
aws iam create-role \
   --role-name rds-s3-integration-role \
   --assume-role-policy-document '{
     "Version": "2012-10-17",
     "Statement": [
       {
         "Effect": "Allow",
         "Principal": {
            "Service": "rds.amazonaws.com"
          },
         "Action": "sts:AssumeRole",
         "Condition": {
             "StringEquals": {
                 "aws:SourceAccount": my_account_ID,
                 "aws:SourceArn": "arn:aws:rds:Region:my_account_ID:db:dbname"
             }
         }
       }
```

```
    ]
  }'
```

For Windows:

```
aws iam create-role ^
   --role-name rds-s3-integration-role ^
   --assume-role-policy-document '{
     "Version": "2012-10-17",
     "Statement": [
       {
         "Effect": "Allow",
         "Principal": {
            "Service": "rds.amazonaws.com"
          },
         "Action": "sts:AssumeRole",
         "Condition": {
             "StringEquals": {
                 "aws:SourceAccount": my_account_ID,
                 "aws:SourceArn": "arn:aws:rds:Region:my_account_ID:db:dbname"
             }
         }
       }
     ]
   }'
```

For more information, see Creating a role to delegate permissions to an IAM user in the *IAM User Guide*.

2. After the role is created, note the ARN of the role. You need the ARN for a subsequent step.
3. Attach the policy you created to the role you created.

   The following AWS CLI command attaches the policy to the role named *rds-s3-integration-role*.

   Example

   For Linux, macOS, or Unix:

```
aws iam attach-role-policy \
   --policy-arn your-policy-arn \
```

```
    --role-name rds-s3-integration-role
```

For Windows:

```
aws iam attach-role-policy ^
   --policy-arn your-policy-arn ^
   --role-name rds-s3-integration-role
```

Replace *your-policy-arn* with the policy ARN that you noted in a previous step.

Step 4: Associate your IAM role with your RDS for Oracle DB instance

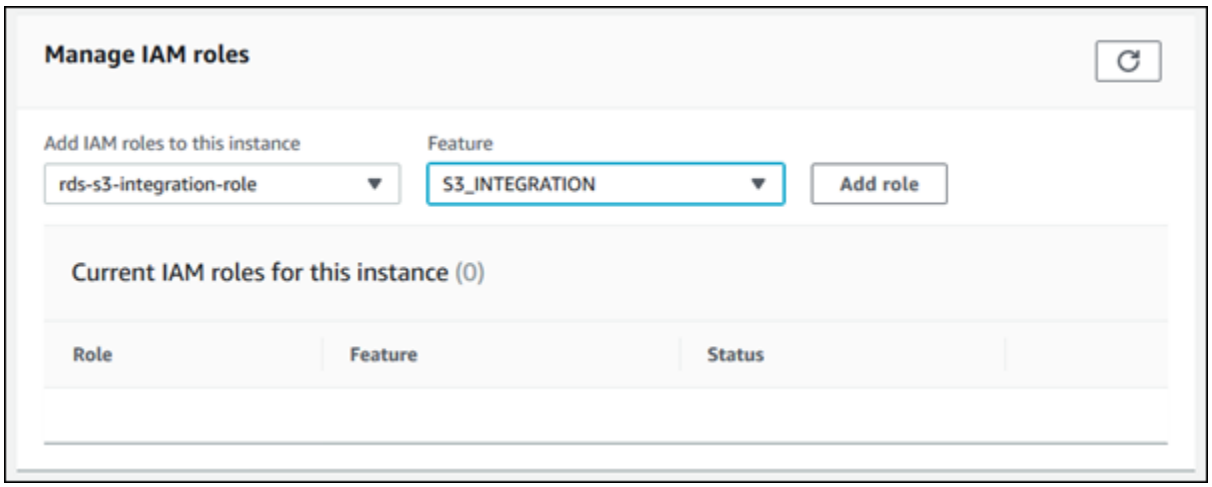
The last step in configuring permissions for Amazon S3 integration is associating your IAM role with your DB instance. Note the following requirements:

- You must have access to an IAM role with the required Amazon S3 permissions policy attached to it.
- You can only associate one IAM role with your RDS for Oracle DB instance at a time.
- Your DB instance must be in the **Available** state.

Console

To associate your IAM role with your RDS for Oracle DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Choose **Databases** from the navigation pane.
3. Choose the RDS for Oracle DB instance name to display its details.
4. On the **Connectivity & security** tab, scroll down to the **Manage IAM roles** section at the bottom of the page.
5. For **Add IAM roles to this instance**, choose the role that you created in Step 3: Create an IAM role for your DB instance and attach your policy.
6. For **Feature**, choose **S3_INTEGRATION**.



7. Choose **Add role**.

AWS CLI

The following AWS CLI command adds the role to an Oracle DB instance named *mydbinstance*.

Example

For Linux, macOS, or Unix:

```
aws rds add-role-to-db-instance \
   --db-instance-identifier mydbinstance \
   --feature-name S3_INTEGRATION \
   --role-arn your-role-arn
```

For Windows:

```
aws rds add-role-to-db-instance ^
   --db-instance-identifier mydbinstance ^
   --feature-name S3_INTEGRATION ^
   --role-arn your-role-arn
```

Replace *your-role-arn* with the role ARN that you noted in a previous step. `S3_INTEGRATION` must be specified for the `--feature-name` option.

Adding the Amazon S3 integration option

To integrate Amazon RDS for Oracle with Amazon S3, your DB instance must be associated with an option group that includes the `S3_INTEGRATION` option.

Console

To configure an option group for Amazon S3 integration

1. Create a new option group or identify an existing option group to which you can add the `S3_INTEGRATION` option.

   For information about creating an option group, see Creating an option group.

2. Add the `S3_INTEGRATION` option to the option group.

   For information about adding an option to an option group, see Adding an option to an option group.

3. Create a new RDS for Oracle DB instance and associate the option group with it, or modify an RDS for Oracle DB instance to associate the option group with it.

   For information about creating a DB instance, see Creating an Amazon RDS DB instance.

   For information about modifying a DB instance, see Modifying an Amazon RDS DB instance.

AWS CLI

To configure an option group for Amazon S3 integration

1. Create a new option group or identify an existing option group to which you can add the `S3_INTEGRATION` option.

   For information about creating an option group, see Creating an option group.

2. Add the `S3_INTEGRATION` option to the option group.

   For example, the following AWS CLI command adds the `S3_INTEGRATION` option to an option group named **`myoptiongroup`**.

   Example

   For Linux, macOS, or Unix:

```
aws rds add-option-to-option-group \
   --option-group-name myoptiongroup \
   --options OptionName=S3_INTEGRATION,OptionVersion=1.0
```

For Windows:

```
aws rds add-option-to-option-group ^
   --option-group-name myoptiongroup ^
   --options OptionName=S3_INTEGRATION,OptionVersion=1.0
```

3. Create a new RDS for Oracle DB instance and associate the option group with it, or modify an RDS for Oracle DB instance to associate the option group with it.

   For information about creating a DB instance, see Creating an Amazon RDS DB instance.

   For information about modifying an RDS for Oracle DB instance, see Modifying an Amazon RDS DB instance.

Transferring files between Amazon RDS for Oracle and an Amazon S3 bucket

To transfer files between an RDS for Oracle DB instance and an Amazon S3 bucket, you can use the Amazon RDS package `rdsadmin_s3_tasks`. You can compress files with GZIP when uploading them, and decompress them when downloading.

Topics

- Requirements and limitations for file transfers
- Uploading files from your RDS for Oracle DB instance to an Amazon S3 bucket
- Downloading files from an Amazon S3 bucket to an Oracle DB instance
- Monitoring the status of a file transfer

Requirements and limitations for file transfers

Before transferring files between your DB instance and an Amazon S3 bucket, note the following:

- The `rdsadmin_s3_tasks` package transfers files located in a single directory. You can't include subdirectories in a transfer.
- The maximum object size in an Amazon S3 bucket is 5 TB.
- Tasks created by `rdsadmin_s3_tasks` run asynchronously.
- You can upload files from the Data Pump directory, such as `DATA_PUMP_DIR`, or any user-created directory. You can't upload files from a directory used by Oracle background processes, such as the `adump`, `bdump`, or `trace` directories.

- The download limit is 2000 files per procedure call for `download_from_s3`. If you need to download more than 2000 files from Amazon S3, split your download into separate actions, with no more than 2000 files per procedure call.
- If a file exists in your download folder, and you attempt to download a file with the same name, `download_from_s3` skips the download. To remove a file from the download directory, use the PL/SQL procedure UTL_FILE.FREMOVE.

Uploading files from your RDS for Oracle DB instance to an Amazon S3 bucket

To upload files from your DB instance to an Amazon S3 bucket, use the procedure `rdsadmin.rdsadmin_s3_tasks.upload_to_s3`. For example, you can upload Oracle Recovery Manager (RMAN) backup files or Oracle Data Pump files. For more information about working with objects, see Amazon Simple Storage Service User Guide. For more information about performing RMAN backups, see Performing common RMAN tasks for Oracle DB instances.

The `rdsadmin.rdsadmin_s3_tasks.upload_to_s3` procedure has the following parameters.

Parameter name	Data type	Default	Required	Description
`p_bucket_name`	VARCHAR2	–	required	The name of the Amazon S3 bucket to upload files to.
`p_directory_name`	VARCHAR2	–	required	The name of the Oracle directory object to upload files from. The directory can be any user-created directory object or the Data Pump directory, such as `DATA_PUMP_DIR` . You can't upload files from a directory used by background processes, such as `adump`, `bdump`, and `trace`.

Parameter name	Data type	Default	Required	Description
				Note You can only upload files from the specified directory. You can't upload files in subdirectories in the specified directory.
`p_s3_prefix`	VARCHAR2	–	required	An Amazon S3 file name prefix that files are uploaded to. An empty prefix uploads all files to the top level in the specified Amazon S3 bucket and doesn't add a prefix to the file names. For example, if the prefix is `folder_1/oradb` , files are uploaded to `folder_1`. In this case, the `oradb` prefix is added to each file.
`p_prefix`	VARCHAR2	–	required	A file name prefix that file names must match to be uploaded. An empty prefix uploads all files in the specified directory.

Parameter name	Data type	Default	Required	Description
p_compression_level	NUMBER	0	optional	The level of GZIP compression. Valid values range from 0 to 9: • 0 – No compression • 1 – Fastest compression • 9 – Highest compression
p_bucket_owner_full_control	VARCHAR2	–	optional	The access control setting for the bucket. The only valid values are null or FULL_CONTROL . This setting is required only if you upload files from one account (account A) into a bucket owned by a different account (account B), and account B needs full control of the files.

The return value for the rdsadmin.rdsadmin_s3_tasks.upload_to_s3 procedure is a task ID.

The following example uploads all of the files in the *DATA_PUMP_DIR* directory to the Amazon S3 bucket named *amzn-s3-demo-bucket*. The files aren't compressed.

```
SELECT rdsadmin.rdsadmin_s3_tasks.upload_to_s3(
      p_bucket_name    =>  'amzn-s3-demo-bucket',
      p_prefix         =>  '',
      p_s3_prefix      =>  '',
      p_directory_name =>  'DATA_PUMP_DIR')
   AS TASK_ID FROM DUAL;
```

The following example uploads all of the files with the prefix *db* in the *DATA_PUMP_DIR* directory to the Amazon S3 bucket named *amzn-s3-demo-bucket*. Amazon RDS applies the highest level of GZIP compression to the files.

```
SELECT rdsadmin.rdsadmin_s3_tasks.upload_to_s3(
      p_bucket_name       =>  'amzn-s3-demo-bucket',
      p_prefix            =>  'db',
      p_s3_prefix         =>  '',
      p_directory_name    =>  'DATA_PUMP_DIR',
      p_compression_level =>  9)
   AS TASK_ID FROM DUAL;
```

The following example uploads all of the files in the *DATA_PUMP_DIR* directory to the Amazon S3 bucket named *amzn-s3-demo-bucket*. The files are uploaded to a `dbfiles` folder. In this example, the GZIP compression level is *1*, which is the fastest level of compression.

```
SELECT rdsadmin.rdsadmin_s3_tasks.upload_to_s3(
      p_bucket_name       =>  'amzn-s3-demo-bucket',
      p_prefix            =>  '',
      p_s3_prefix         =>  'dbfiles/',
      p_directory_name    =>  'DATA_PUMP_DIR',
      p_compression_level =>  1)
   AS TASK_ID FROM DUAL;
```

The following example uploads all of the files in the *DATA_PUMP_DIR* directory to the Amazon S3 bucket named *amzn-s3-demo-bucket*. The files are uploaded to a `dbfiles` folder and `ora` is added to the beginning of each file name. No compression is applied.

```
SELECT rdsadmin.rdsadmin_s3_tasks.upload_to_s3(
      p_bucket_name    =>  'amzn-s3-demo-bucket',
      p_prefix         =>  '',
      p_s3_prefix      =>  'dbfiles/ora',
      p_directory_name =>  'DATA_PUMP_DIR')
   AS TASK_ID FROM DUAL;
```

The following example assumes that the command is run in account A, but account B requires full control of the bucket contents. The command `rdsadmin_s3_tasks.upload_to_s3` transfers all files in the *DATA_PUMP_DIR* directory to the bucket named *s3bucket0wnedByAccountB*. Access control is set to `FULL_CONTROL` so that account B can access the files in the bucket. The GZIP compression level is *6*, which balances speed and file size.

```
SELECT rdsadmin.rdsadmin_s3_tasks.upload_to_s3(
      p_bucket_name               =>  's3bucketOwnedByAccountB',
      p_prefix                    =>  '',
      p_s3_prefix                 =>  '',
      p_directory_name            =>  'DATA_PUMP_DIR',
      p_bucket_owner_full_control =>  'FULL_CONTROL',
      p_compression_level         =>  6)
   AS TASK_ID FROM DUAL;
```

In each example, the SELECT statement returns the ID of the task in a VARCHAR2 data type.

You can view the result by displaying the task's output file.

```
SELECT text FROM table(rdsadmin.rds_file_util.read_text_file('BDUMP','dbtask-task-id.log'));
```

Replace *task-id* with the task ID returned by the procedure.

> **Note**
>
> Tasks are executed asynchronously.

Downloading files from an Amazon S3 bucket to an Oracle DB instance

To download files from an Amazon S3 bucket to an RDS for Oracle instance, use the Amazon RDS procedure `rdsadmin.rdsadmin_s3_tasks.download_from_s3`.

The `download_from_s3` procedure has the following parameters.

Parameter name	Data type	Default	Required	Description
p_bucket_name	VARCHAR	–	Required	The name of the Amazon S3 bucket to download files from.
p_directory_name	VARCHAR	–	Required	The name of the Oracle directory object to download files to. The directory can be any user-created

Parameter name	Data type	Default	Required	Description
				directory object or the Data Pump directory, such as `DATA_PUMP_DIR` .
`p_error_on_zero_downloads`	VARCHAR	FALSE	Optional	A flag that determines whether the task raises an error when no objects in the Amazon S3 bucket match the prefix. If this parameter is not set or set to FALSE (default), the task prints a message that no objects were found, but doesn't raise an exception or fail. If this parameter is TRUE, the task raises an exception and fails. Examples of prefix specifications that can fail match tests are spaces in prefixes, as in `' import/test9.log'` , and case mismatches, as in `test9.log` and `test9.LOG` .

Parameter name	Data type	Default	Required	Description
p_s3_prefix	VARCHAR	–	Required	A file name prefix that file names must match to be downloaded. An empty prefix downloads all of the top level files in the specified Amazon S3 bucket, but not the files in folders in the bucket. The procedure downloads Amazon S3 objects only from the first level folder that matches the prefix. Nested directory structures matching the specified prefix are not downloaded. For example, suppose that an Amazon S3 bucket has the folder structure folder_1/folder_2/folder_3 . You specify the 'folder_1/folder_2/' prefix. In this case, only the files in folder_2 are downloaded, not the files in folder_1 or folder_3. If, instead, you specify the 'folder_1/folder_2' prefix, all files in folder_1 that match the 'folder_2' prefix are downloaded, and no files in folder_2 are downloaded.
p_decompression_format	VARCHAR	–	Optional	The decompression format. Valid values are NONE for no decompression and GZIP for decompression.

The return value for the rdsadmin.rdsadmin_s3_tasks.download_from_s3 procedure is a task ID.

The following example downloads all files in the Amazon S3 bucket named *amzn-s3-demo-bucket* to the *DATA_PUMP_DIR* directory. The files aren't compressed, so no decompression is applied.

```
SELECT rdsadmin.rdsadmin_s3_tasks.download_from_s3(
      p_bucket_name    =>  'amzn-s3-demo-bucket',
      p_directory_name =>  'DATA_PUMP_DIR')
   AS TASK_ID FROM DUAL;
```

The following example downloads all of the files with the prefix *db* in the Amazon S3 bucket named *amzn-s3-demo-bucket* to the *DATA_PUMP_DIR* directory. The files are compressed with GZIP, so decompression is applied. The parameter `p_error_on_zero_downloads` turns on prefix error checking, so if the prefix doesn't match any files in the bucket, the task raises and exception and fails.

```
SELECT rdsadmin.rdsadmin_s3_tasks.download_from_s3(
      p_bucket_name               =>  'amzn-s3-demo-bucket',
      p_s3_prefix                 =>  'db',
      p_directory_name            =>  'DATA_PUMP_DIR',
      p_decompression_format      =>  'GZIP',
      p_error_on_zero_downloads   =>  'TRUE')
   AS TASK_ID FROM DUAL;
```

The following example downloads all of the files in the folder *myfolder/* in the Amazon S3 bucket named *amzn-s3-demo-bucket* to the *DATA_PUMP_DIR* directory. Use the `p_s3_prefix` parameter to specify the Amazon S3 folder. The uploaded files are compressed with GZIP, but aren't decompressed during the download.

```
SELECT rdsadmin.rdsadmin_s3_tasks.download_from_s3(
      p_bucket_name          =>  'amzn-s3-demo-bucket',
      p_s3_prefix            =>  'myfolder/',
      p_directory_name       =>  'DATA_PUMP_DIR',
      p_decompression_format =>  'NONE')
   AS TASK_ID FROM DUAL;
```

The following example downloads the file *mydumpfile.dmp* in the Amazon S3 bucket named *amzn-s3-demo-bucket* to the *DATA_PUMP_DIR* directory. No decompression is applied.

```
SELECT rdsadmin.rdsadmin_s3_tasks.download_from_s3(
```

```
      p_bucket_name    =>  'amzn-s3-demo-bucket',
      p_s3_prefix      =>  'mydumpfile.dmp',
      p_directory_name =>  'DATA_PUMP_DIR')
   AS TASK_ID FROM DUAL;
```

In each example, the SELECT statement returns the ID of the task in a VARCHAR2 data type.

You can view the result by displaying the task's output file.

```
SELECT text FROM table(rdsadmin.rds_file_util.read_text_file('BDUMP','dbtask-task-id.log'));
```

Replace *task-id* with the task ID returned by the procedure.

> **Note**
>
> Tasks are executed asynchronously.
> You can use the UTL_FILE.FREMOVE Oracle procedure to remove files from a directory. For more information, see FREMOVE procedure in the Oracle documentation.

Monitoring the status of a file transfer

File transfer tasks publish Amazon RDS events when they start and when they complete. The event message contains the task ID for the file transfer. For information about viewing events, see Viewing Amazon RDS events.

You can view the status of an ongoing task in a bdump file. The bdump files are located in the /rdsdbdata/log/trace directory. Each bdump file name is in the following format.

```
dbtask-task-id.log
```

Replace *task-id* with the ID of the task that you want to monitor.

> **Note**
>
> Tasks are executed asynchronously.

You can use the `rdsadmin.rds_file_util.read_text_file` stored procedure to view the contents of bdump files. For example, the following query returns the contents of the *dbtask-1234567890123-1234.log* bdump file.

```
SELECT text FROM
 table(rdsadmin.rds_file_util.read_text_file('BDUMP','dbtask-1234567890123-1234.log'));
```

The following sample shows the log file for a failed transfer.

```
TASK_ID

--------------------------------------------------------------------------------------------
1234567890123-1234

TEXT

--------------------------------------------------------------------------------------------
2023-04-17 18:21:33.993 UTC [INFO ] File #1: Uploading the file /rdsdbdata/datapump/
A123B4CDEF567890G1234567890H1234/sample.dmp to Amazon S3 with bucket name amzn-s3-demo-
bucket and key sample.dmp.
2023-04-17 18:21:34.188 UTC [ERROR] RDS doesn't have permission to write to Amazon S3
 bucket name amzn-s3-demo-bucket and key sample.dmp.
2023-04-17 18:21:34.189 UTC [INFO ] The task failed.
```

Troubleshooting Amazon S3 integration

For troubleshooting tips, see the AWS re:Post article How do troubleshoot issues when I integrate Amazon RDS for Oracle with Amazon S3?.

Removing the Amazon S3 integration option

You can remove Amazon S3 integration option from a DB instance.

To remove the Amazon S3 integration option from a DB instance, do one of the following:

- To remove the Amazon S3 integration option from multiple DB instances, remove the `S3_INTEGRATION` option from the option group to which the DB instances belong. This change affects all DB instances that use the option group. For more information, see Removing an option from an option group.
- To remove the Amazon S3 integration option from a single DB instance, modify the instance and specify a different option group that doesn't include the `S3_INTEGRATION` option. You can specify the default (empty) option group or a different custom option group. For more information, see Modifying an Amazon RDS DB instance.

Oracle Application Express (APEX)

Amazon RDS supports Oracle Application Express (APEX) through the use of the APEX and APEX-DEV options. You can deploy Oracle APEX as a runtime environment or as a full development environment for web-based applications. Using Oracle APEX, you can build applications entirely within the web browser. For more information, see Oracle application Express in the Oracle documentation.

Topics

APEX components

Oracle APEX consists of the following main components:

- A *repository* that stores the metadata for APEX applications and components. The repository consists of tables, indexes, and other objects that are installed in your Amazon RDS DB instance.
- A *listener* that manages HTTP communications with Oracle APEX clients. The listener resides on a separate host such as an Amazon EC2 instance, an on-premises server at your company, or your desktop computer. The listener accepts incoming connections from web browsers, forwards them to the Amazon RDS DB instance for processing, and then sends results from the repository back to the browsers.

  RDS for Oracle supports the following types of listeners:

- For APEX version 5.0 and later, use Oracle REST Data Services (ORDS) version 19.1 and higher. We recommend that you use the latest supported version of Oracle APEX and ORDS. This documentation describes older versions for backwards compatibility only.
- For APEX version 4.1.1, you can use Oracle APEX Listener version 1.1.4.
- You can use Oracle HTTP Server and `mod_plsql` listeners.

> **Note**
>
> Amazon RDS doesn't support the Oracle XML DB HTTP server with the embedded PL/SQL gateway as a listener for APEX. In general, Oracle recommends against using the embedded PL/SQL gateway for applications that run on the internet.

For more information about these listener types, see About choosing a web listener in the Oracle documentation.

When you add the Amazon RDS APEX options to your RDS for Oracle DB instance, Amazon RDS installs the Oracle APEX repository only. Install your listener on a separate host.

APEX version requirements

The APEX option uses storage on the DB instance class for your DB instance. Following are the supported versions and approximate storage requirements for Oracle APEX.

APEX version	Storage requirements	Supported Oracle Database versions	Notes
Oracle APEX version 23.2.v1	110 MiB	All	This version includes patch 35895964: PSE BUNDLE FOR APEX 23.2 (PSES ON TOP OF 23.2.0), PATCH_VERSION 6.
Oracle APEX version 23.1.v1	106 MiB	All	This version includes patch 35283657: PSE BUNDLE FOR APEX 23.1 (PSES ON TOP OF 23.1.0), PATCH_VERSION 2.

APEX version	Storage requirements	Supported Oracle Database versions	Notes
Oracle APEX version 22.2.v1	106 MiB	All	This version includes patch 34628174: PSE BUNDLE FOR APEX 22.2 (PSES ON TOP OF 22.2.0), PATCH_VERSION 4.
Oracle APEX version 22.1.v1	124 MiB	All	This version includes patch 34020981: PSE BUNDLE FOR APEX 22.1 (PSES ON TOP OF 22.1.0), PATCH_VERSION 6.
Oracle APEX version 21.2.v1	125 MiB	All	This version includes patch 33420059: PSE BUNDLE FOR APEX 21.2 (PSES ON TOP OF 21.2.0), PATCH_VERSION 8.
Oracle APEX version 21.1.v1	125 MiB	All	This version includes patch 32598392: PSE BUNDLE FOR APEX 21.1, PATCH_VERSION 3.
Oracle APEX version 20.2.v1	148 MiB	All except Oracle Database 21c	This version includes patch 32006852: PSE BUNDLE FOR APEX 20.2, PATCH_VERSION 2020.11.12. You can see the patch number and date by running the following query: `SELECT PATCH_VERSION, PATCH_NUMBER FROM APEX_PATCHES;`
Oracle APEX version 20.1.v1	173 MiB	All except Oracle Database 21c	This version includes patch 30990551: PSE BUNDLE FOR APEX 20.1, PATCH_VERSION 2020.07.15.
Oracle APEX version 19.2.v1	149 MiB	All except Oracle Database 21c	

APEX version	Storage requirements	Supported Oracle Database versions	Notes
Oracle APEX version 19.1.v1	148 MiB	All except Oracle Database 21c	

For downloadable APEX .zip files, see Oracle APEX Prior Release Archives on the Oracle website.

Oracle APEX and ORDS requirements

Note the following requirements for APEX and ORDS:

- Your system must use the Java Runtime Environment (JRE).
- Your Oracle client installation must include the following:
  - SQL*Plus or SQL Developer for administration tasks
  - Oracle Net Services for configuring connections to your RDS for Oracle DB instance

Adding the APEX and APEX-DEV options to your DB instance

To add the `APEX` and `APEX-DEV` options to your RDS for Oracle DB instance, do the following:

1. Create a new option group, or copy or modify an existing option group.
2. Add the `APEX` and `APEX-DEV` options to the option group.
3. Associate the option group with your DB instance.

When you add the Amazon RDS APEX options, a brief outage occurs while your DB instance is automatically restarted.

> **Note**
>
> APEX_MAIL is available when the APEX option is installed. The execute privilege for the APEX_MAIL package is granted to PUBLIC so you don't need the APEX administrative account to use it.

To add the APEX options to a DB instance

1. Determine the option group that you want to use. You can create a new option group or use an existing option group. If you want to use an existing option group, skip to the next step. Otherwise, create a custom DB option group with the following settings:

   a. For **Engine**, choose the Oracle edition that you want to use. The APEX options are supported on all editions.

   b. For **Major engine version**, choose the version of your DB instance.

   For more information, see Creating an option group.

2. Add the options to the option group. If you want to deploy only the Oracle APEX runtime environment, add only the APEX option. To deploy the full development environment, add both the APEX and APEX-DEV options.

   For **Version**, choose the version of APEX that you want to use.

   > **Important**
   >
   > If you add the APEX options to an existing option group that is already attached to one or more DB instances, a brief outage occurs. During this outage, all the DB instances are automatically restarted.

   For more information about adding options, see Adding an option to an option group.

3. Apply the option group to a new or existing DB instance:

   - For a new DB instance, you apply the option group when you launch the instance. For more information, see Creating an Amazon RDS DB instance.

- For an existing DB instance, you apply the option group by modifying the instance and attaching the new option group. When you add the APEX options to an existing DB instance, a brief outage occurs while your DB instance is automatically restarted. For more information, see Modifying an Amazon RDS DB instance.

Unlocking the public user account on your DB instance

After the Amazon RDS APEX options are installed on your DB instance, make sure to do the following:

1. Change the password for the APEX public user account.
2. Unlock the account.

You can do this by using the Oracle SQL*Plus command line utility. Connect to your DB instance as the master user, and issue the following commands. Replace `new_password` with a password of your choice.

```
ALTER USER APEX_PUBLIC_USER IDENTIFIED BY new_password;
ALTER USER APEX_PUBLIC_USER ACCOUNT UNLOCK;
```

Configuring RESTful services for Oracle APEX

To configure RESTful services in APEX (not needed for APEX 4.1.1.V1), use SQL*Plus to connect to your DB instance as the master user. After you do this, run the `rdsadmin.rdsadmin_run_apex_rest_config` stored procedure. When you run the stored procedure, you provide passwords for the following users:

- `APEX_LISTENER`
- `APEX_REST_PUBLIC_USER`

The stored procedure runs the `apex_rest_config.sql` script, which creates new database accounts for these users.

> **Note**
>
> Configuration isn't required for Oracle APEX version 4.1.1.v1. For this Oracle APEX version only, you don't need to run the stored procedure.

The following command runs the stored procedure.

```
EXEC rdsadmin.rdsadmin_run_apex_rest_config('apex_listener_password',
 'apex_rest_public_user_password');
```

Preparing to install ORDS on a separate host

Install ORDS on a separate host such as an Amazon EC2 instance, an on-premises server at your company, or your desktop computer. The examples in this section,assume that your host runs Linux and is named `myapexhost.example.com`.

Before you can install ORDS, you need to create a nonprivileged OS user, and then download and unzip the APEX installation file.

To prepare for ORDS installation

1. Log in to `myapexhost.example.com` as `root`.
2. Create a nonprivileged OS user to own the listener installation. The following command creates a new user named *apexuser*.

   ```
   useradd -d /home/apexuser apexuser
   ```

   The following command assigns a password to the new user.

   ```
   passwd apexuser;
   ```

3. Log in to `myapexhost.example.com` as `apexuser`, and download the APEX installation file from Oracle to your `/home/apexuser` directory:
   - http://www.oracle.com/technetwork/developer-tools/apex/downloads/index.html
   - Oracle application Express prior release archives
4. Unzip the file in the `/home/apexuser` directory.

```
unzip apex_version.zip
```

After you unzip the file, there is an `apex` directory in the `/home/apexuser` directory.

5. While you are still logged into `myapexhost.example.com` as `apexuser`, download the Oracle REST Data Services file from Oracle to your `/home/apexuser` directory: http://www.oracle.com/technetwork/developer-tools/apex-listener/downloads/index.html.

Installing and configuring ORDS 21 and lower

You are now ready to install and configure Oracle Rest Data Services (ORDS) for use with Oracle APEX. For APEX version 5.0 and later, use ORDS versions 19.1 to 21. To learn how to install ORDS 22 and higher, see Installing and configuring ORDS 22 and higher.

Install the listener on a separate host such as an Amazon EC2 instance, an on-premises server at your company, or your desktop computer. For the examples in this section, we assume that the name of your host is `myapexhost.example.com`, and that your host is running Linux.

To install and configure ORDS 21 and lower for use with Oracle APEX

1. Go to Oracle REST data services, and examine the Readme. Make sure that you have the required version of Java installed.
2. Create a new directory for your ORDS installation.

```
mkdir /home/apexuser/ORDS
cd /home/apexuser/ORDS
```

3. Download the file `ords.version.number.zip` from Oracle REST data services.
4. Unzip the file into the `/home/apexuser/ORDS` directory.
5. If you're installing ORDS in a multitenant database, add the following line to the file `/home/apexuser/ORDS/params/ords_params.properties`:

```
pdb.disable.lockdown=false
```

6. Grant the master user the required privileges to install ORDS.

After the Amazon RDS APEX option is installed, give the master user the required privileges to install the ORDS schema. You can do this by connecting to the database and running the following commands. Replace *MASTER_USER* with the uppercase name of your master user.

> **Important**
>
> When you enter the user name, use uppercase unless you created the user with a case-sensitive identifier. For example, if you run `CREATE USER myuser` or `CREATE USER MYUSER`, the data dictionary stores `MYUSER`. However, if you use double quotes in `CREATE USER "MyUser"`, the data dictionary stores `MyUser`. For more information, see Granting SELECT or EXECUTE privileges to SYS objects.

```
exec rdsadmin.rdsadmin_util.grant_sys_object('DBA_OBJECTS', 'MASTER_USER',
 'SELECT', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('DBA_ROLE_PRIVS', 'MASTER_USER',
 'SELECT', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('DBA_TAB_COLUMNS', 'MASTER_USER',
 'SELECT', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('USER_CONS_COLUMNS', 'MASTER_USER',
 'SELECT', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('USER_CONSTRAINTS', 'MASTER_USER',
 'SELECT', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('USER_OBJECTS', 'MASTER_USER',
 'SELECT', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('USER_PROCEDURES', 'MASTER_USER',
 'SELECT', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('USER_TAB_COLUMNS', 'MASTER_USER',
 'SELECT', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('USER_TABLES', 'MASTER_USER',
 'SELECT', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('USER_VIEWS', 'MASTER_USER', 'SELECT',
 true);
exec rdsadmin.rdsadmin_util.grant_sys_object('WPIUTL', 'MASTER_USER', 'EXECUTE',
 true);
exec rdsadmin.rdsadmin_util.grant_sys_object('DBMS_SESSION', 'MASTER_USER',
 'EXECUTE', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('DBMS_UTILITY', 'MASTER_USER',
 'EXECUTE', true);
```

> **Note**
>
> These commands apply to ORDS version 19.1 and later.

7. Install the ORDS schema using the downloaded ords.war file.

```
java -jar ords.war install advanced
```

The program prompts you for the following information. The default values are in brackets. For more information, see Introduction to Oracle REST data services in the Oracle documentation.

- Enter the location to store configuration data:

  Enter */home/apexuser/ORDS*. This is the location of the ORDS configuration files.

- Specify the database connection type to use. Enter number for [1] Basic [2] TNS [3] Custom URL [1]:

  Choose the desired connection type.

- Enter the name of the database server [localhost]: *DB_instance_endpoint*

  Choose the default or enter the correct value.

- Enter the database listener port [1521]: *DB_instance_port*

  Choose the default or enter the correct value.

- Enter 1 to specify the database service name, or 2 to specify the database SID [1]:

  Choose 2 to specify the database SID.

- Database SID [xe]

  Choose the default or enter the correct value.

- Enter 1 if you want to verify/install Oracle REST Data Services schema or 2 to skip this step [1]:

  Choose 1. This step creates the Oracle REST Data Services proxy user named ORDS_PUBLIC_USER.

- Enter the database password for ORDS_PUBLIC_USER:

Enter the password, and then confirm it.

- Requires to login with administrator privileges to verify Oracle REST Data Services schema.

  Enter the administrator user name: *master_user*

  Enter the database password for *master_user*: *master_user_password*

  Confirm the password: *master_user_password*

  > **Note**
  >
  > Specify a password other than the prompt shown here as a security best practice.

- Enter the default tablespace for ORDS_METADATA [SYSAUX].

  Enter the temporary tablespace for ORDS_METADATA [TEMP].

  Enter the default tablespace for ORDS_PUBLIC_USER [USERS].

  Enter the temporary tablespace for ORDS_PUBLIC_USER [TEMP].

- Enter 1 if you want to use PL/SQL Gateway or 2 to skip this step. If you're using Oracle Application Express or migrating from mod_plsql, you must enter 1 [1].

  Choose the default.

- Enter the PL/SQL Gateway database user name [APEX_PUBLIC_USER]

  Choose the default.

- Enter the database password for APEX_PUBLIC_USER:

  Enter the password, and then confirm it.

- Enter 1 to specify passwords for Application Express RESTful Services database users (APEX_LISTENER, APEX_REST_PUBLIC_USER) or 2 to skip this step [1]:

  Choose 2 for APEX 4.1.1.V1; choose 1 for all other APEX versions.

- [Not needed for APEX 4.1.1.v1] Database password for APEX_LISTENER

  Enter the password (if required), and then confirm it.

- [Not needed for APEX 4.1.1.v1] Database password for APEX_REST_PUBLIC_USER

Enter the password (if required), and then confirm it.

- Enter a number to select a feature to enable:

  Enter 1 to enable all features: SQL Developer Web, REST Enabled SQL, and Database API.

- Enter 1 if you wish to start in standalone mode or 2 to exit [1]:

  Enter 1.

- Enter the APEX static resources location:

  If you unzipped APEX installation files into `/home/apexuser`, enter `/home/apexuser/apex/images`. Otherwise, enter *`unzip_path`*`/apex/images`, where *`unzip_path`* is the directory where you unzipped the file.

- Enter 1 if using HTTP or 2 if using HTTPS [1]:

  If you enter 1, specify the HTTP port. If you enter 2, specify the HTTPS port and the SSL host name. The HTTPS option prompts you to specify how you will provide the certificate:

  - Enter 1 to use the self-signed certificate.
  - Enter 2 to provide your own certificate. If you enter 2, specify the path for the SSL certificate and the path for the SSL certificate private key.

8. Set a password for the APEX `admin` user. To do this, use SQL*Plus to connect to your DB instance as the master user, and then run the following commands.

```
EXEC rdsadmin.rdsadmin_util.grant_apex_admin_role;
grant APEX_ADMINISTRATOR_ROLE to master;
@/home/apexuser/apex/apxchpwd.sql
```

   Replace *`master`* with your master user name. When the `apxchpwd.sql` script prompts you, enter a new `admin` password.

9. Start the ORDS listener. Run the following code.

```
java -jar ords.war
```

   The first time you start ORDS, you are prompted to provide the location of the APEX Static resources. This images folder is located in the `/apex/images` directory in the installation directory for APEX.

10. Return to the APEX administration window in your browser and choose **Administration**. Next, choose **Application Express Internal Administration**. When you are prompted for credentials, enter the following information:

    - **User name** – `admin`
    - **Password** – the password you set using the `apxchpwd.sql` script

    Choose **Login**, and then set a new password for the `admin` user.

Your listener is now ready for use.

Installing and configuring ORDS 22 and higher

You are now ready to install and configure Oracle Rest Data Services (ORDS) for use with Oracle APEX. For the examples in this section, we assume that the name of your separate host is `myapexhost.example.com`, and that your host is running Linux. The instructions for ORDS 22 differ from the instructions for previous releases.

To install and configure ORDS 22 and higher for use with Oracle APEX

1. Go to Oracle REST data services, and examine the Readme for the ORDS version that you plan to download. Make sure that you have the required version of Java installed.
2. Create a new directory for your ORDS installation.

   ```
   mkdir /home/apexuser/ORDS
   cd /home/apexuser/ORDS
   ```

3. Download the file `ords.version.number.zip` or `ords-latest.zip` from Oracle REST data services.
4. Unzip the file into the `/home/apexuser/ORDS` directory.
5. Grant the master user the required privileges to install ORDS.

   After the Amazon RDS APEX option is installed, give the master user the required privileges to install the ORDS schema. You can do this by logging in to the database and running the following commands. Replace *MASTER_USER* with the uppercase name of your master user.

Important

When you enter the user name, use uppercase unless you created the user with a case-sensitive identifier. For example, if you run `CREATE USER myuser` or `CREATE USER MYUSER`, the data dictionary stores `MYUSER`. However, if you use double quotes in `CREATE USER "MyUser"`, the data dictionary stores `MyUser`. For more information, see Granting SELECT or EXECUTE privileges to SYS objects.

```
exec rdsadmin.rdsadmin_util.grant_sys_object('DBA_OBJECTS', 'MASTER_USER',
 'SELECT', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('DBA_ROLE_PRIVS', 'MASTER_USER',
 'SELECT', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('DBA_TAB_COLUMNS', 'MASTER_USER',
 'SELECT', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('USER_CONS_COLUMNS', 'MASTER_USER',
 'SELECT', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('USER_CONSTRAINTS', 'MASTER_USER',
 'SELECT', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('USER_OBJECTS', 'MASTER_USER',
 'SELECT', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('USER_PROCEDURES', 'MASTER_USER',
 'SELECT', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('USER_TAB_COLUMNS', 'MASTER_USER',
 'SELECT', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('USER_TABLES', 'MASTER_USER',
 'SELECT', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('USER_VIEWS', 'MASTER_USER', 'SELECT',
 true);
exec rdsadmin.rdsadmin_util.grant_sys_object('WPIUTL', 'MASTER_USER', 'EXECUTE',
 true);
exec rdsadmin.rdsadmin_util.grant_sys_object('DBMS_SESSION', 'MASTER_USER',
 'EXECUTE', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('DBMS_UTILITY', 'MASTER_USER',
 'EXECUTE', true);

exec rdsadmin.rdsadmin_util.grant_sys_object('DBMS_LOB', 'MASTER_USER', 'EXECUTE',
 true);
exec rdsadmin.rdsadmin_util.grant_sys_object('DBMS_ASSERT', 'MASTER_USER',
 'EXECUTE', true);
```

```
exec rdsadmin.rdsadmin_util.grant_sys_object('DBMS_OUTPUT', 'MASTER_USER',
 'EXECUTE', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('DBMS_SCHEDULER', 'MASTER_USER',
 'EXECUTE', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('HTP', 'MASTER_USER', 'EXECUTE',
 true);
exec rdsadmin.rdsadmin_util.grant_sys_object('OWA', 'MASTER_USER', 'EXECUTE',
 true);
exec rdsadmin.rdsadmin_util.grant_sys_object('WPG_DOCLOAD', 'MASTER_USER',
 'EXECUTE', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('DBMS_CRYPTO', 'MASTER_USER',
 'EXECUTE', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('DBMS_METADATA', 'MASTER_USER',
 'EXECUTE', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('DBMS_SQL', 'MASTER_USER', 'EXECUTE',
 true);
exec rdsadmin.rdsadmin_util.grant_sys_object('UTL_SMTP', 'MASTER_USER', 'EXECUTE',
 true);
exec rdsadmin.rdsadmin_util.grant_sys_object('DBMS_NETWORK_ACL_ADMIN',
 'MASTER_USER', 'EXECUTE', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('SESSION_PRIVS', 'MASTER_USER',
 'SELECT', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('DBA_USERS', 'MASTER_USER', 'SELECT',
 true);
exec rdsadmin.rdsadmin_util.grant_sys_object('DBA_NETWORK_ACL_PRIVILEGES',
 'MASTER_USER', 'SELECT', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('DBA_NETWORK_ACLS', 'MASTER_USER',
 'SELECT', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('DBA_REGISTRY', 'MASTER_USER',
 'SELECT', true);
```

Note

The preceding commands apply to ORDS 22 and later.

6. Install the ORDS schema using the downloaded `ords` script. Specify directories to contain configuration files and log files. Oracle Corporation recommends not placing these directories inside the directory that contains the ORDS product software.

```
mkdir -p /home/apexuser/ords_config /home/apexuser/ords_logs

/home/apexuser/ORDS/bin/ords \
```

```
  --config /home/apexuser/ords_config \
  install --interactive --log-folder /home/apexuser/ords_logs
```

For DB instances running the container database (CDB) architecture, use ORDS 23.2 and higher and pass the `--pdb-skip-disable-lockdown` argument when installing ORDS.

```
/home/apexuser/ORDS/bin/ords \
  --config /home/apexuser/ords_config \
  install --interactive --log-folder /home/apexuser/ords_logs --pdb-skip-disable-
lockdown
```

The program prompts you for the following information. The default values are in brackets. For more information, see Introduction to Oracle REST data services in the Oracle documentation.

- `Choose the type of installation:`

  Choose **2** to install ORDS schemas in the database and create a database connection pool in the local ORDS configuration files.

- `Specify the database connection type to use. Enter number for [1] Basic [2] TNS [3] Custom URL:`

  Choose the desired connection type. This example assumes that you choose **1**.

- `Enter the name of the database server [localhost]:` ***`DB_instance_endpoint`***

  Choose the default or enter the correct value.

- `Enter the database listener port [1521]:` ***`DB_instance_port`***

  Choose the default **1521** or enter the correct value.

- `Enter the database service name [orcl]:`

  Enter the database name used by your RDS for Oracle DB instance.

- `Provide database user name with administrator privileges`

  Enter the master user name for your RDS for Oracle DB instance.

- `Enter the database password for [username]:`

  Enter the master user password for your RDS for Oracle DB instance.

- `Enter the default tablespace for ORDS_METADATA and ORDS_PUBLIC_USER [SYSAUX]:`
- `Enter the temporary tablespace for ORDS_METADATA [TEMP]. Enter the default tablespace for ORDS_PUBLIC_USER [USERS]. Enter the temporary tablespace for ORDS_PUBLIC_USER [TEMP].`
- `Enter a number to select additional feature(s) to enable [1]:`
- `Enter a number to configure and start ORDS in standalone mode [1]:`

  Choose **2** to skip starting ORDS immediately in standalone mode.
- `Enter a number to select the protocol [1] HTTP`
- `Enter the HTTP port [8080]:`
- `Enter the APEX static resources location:`

  Enter the path to APEX installation files (`/home/apexuser/apex/images`).

7. Set a password for the APEX `admin` user. To do this, use SQL*Plus to connect to your DB instance as the master user, and then run the following commands.

```
EXEC rdsadmin.rdsadmin_util.grant_apex_admin_role;
grant APEX_ADMINISTRATOR_ROLE to master;
@/home/apexuser/apex/apxchpwd.sql
```

   Replace *`master`* with your master user name. When the `apxchpwd.sql` script prompts you, enter a new `admin` password.

8. Run ORDS in standalone mode using the `ords` script with the `serve` command. For production deployments, consider using supported Java EE application servers such as Apache Tomcat or Oracle WebLogic Server. For more information, see Deploying and Monitoring Oracle REST Data Services in the Oracle Database documentation.

```
/home/apexuser/ORDS/bin/ords \
  --config /home/apexuser/ords_config serve \
  --port 8193 \
  --apex-images /home/apexuser/apex/images
```

   If ORDS is running but unable to access the APEX installation, you might see the following error, particularly on non-CDB instances.

```
The procedure named apex_admin could not be accessed, it may not be declared,
 or the user executing this request may not have been granted execute privilege
 on the procedure, or a function specified by security.requestValidationFunction
 configuration property has prevented access.
```

To fix this error, change the request validation function used by ORDS by running the `ords` script with the `config` command. By default, ORDS uses the `ords_util.authorize_plsql_gateway` procedure, which is only supported on CDB instances. For non-CDB instances, you can change this procedure to the `wwv_flow_epg_include_modules.authorize` package. See the Oracle Database documentation and Oracle Support for best practices on configuring the proper request validation function for your use case.

9. Return to the APEX administration window in your browser and choose **Administration**. Next, choose **Application Express Internal Administration**. When you are prompted for credentials, enter the following information:

   - **User name** – `admin`
   - **Password** – the password you set using the `apxchpwd.sql` script

   Choose **Login**, and then set a new password for the `admin` user.

Your listener is now ready for use.

Setting up Oracle APEX listener

> **Note**
>
> Oracle APEX Listener is deprecated.

Amazon RDS for Oracle continues to support APEX version 4.1.1 and Oracle APEX Listener version 1.1.4. We recommend that you use the latest supported versions of Oracle APEX and ORDS.

Install Oracle APEX Listener on a separate host such as an Amazon EC2 instance, an on-premises server at your company, or your desktop computer. We assume that the name of your host is `myapexhost.example.com`, and that your host is running Linux.

Preparing to install Oracle APEX listener

Before you can install Oracle APEX Listener, you need to create a nonprivileged OS user, and then download and unzip the APEX installation file.

To prepare for Oracle APEX listener installation

1. Log in to `myapexhost.example.com` as `root`.
2. Create a nonprivileged OS user to own the listener installation. The following command creates a new user named *apexuser*.

   ```
   useradd -d /home/apexuser apexuser
   ```

   The following command assigns a password to the new user.

   ```
   passwd apexuser;
   ```

3. Log in to `myapexhost.example.com` as `apexuser`, and download the APEX installation file from Oracle to your `/home/apexuser` directory:

   - http://www.oracle.com/technetwork/developer-tools/apex/downloads/index.html
   - Oracle application Express prior release archives

4. Unzip the file in the `/home/apexuser` directory.

   ```
   unzip apex_<version>.zip
   ```

   After you unzip the file, there is an `apex` directory in the `/home/apexuser` directory.

5. While you are still logged into `myapexhost.example.com` as `apexuser`, download the Oracle APEX Listener file from Oracle to your `/home/apexuser` directory.

Installing and configuring Oracle APEX listener

Before you can use APEX, you need to download the apex.war file, use Java to install Oracle APEX Listener, and then start the listener.

To install and configure Oracle APEX listener

1. Create a new directory based on Oracle APEX Listener and open the listener file.

Run the following code:

```
mkdir /home/apexuser/apexlistener
cd /home/apexuser/apexlistener
unzip ../apex_listener.version.zip
```

2. Run the following code.

```
java -Dapex.home=./apex -Dapex.images=/home/apexuser/apex/images -Dapex.erase -
jar ./apex.war
```

3. Enter information for the program prompts following:

   - The APEX Listener Administrator user name. The default is *adminlistener*.
   - A password for the APEX Listener Administrator.
   - The APEX Listener Manager user name. The default is *managerlistener*.
   - A password for the APEX Listener Administrator.

   The program prints a URL that you need to complete the configuration, as follows.

```
INFO: Please complete configuration at: http://localhost:8080/apex/
listenerConfigure
Database is not yet configured
```

4. Leave Oracle APEX Listener running so that you can use Oracle Application Express. When you have finished this configuration procedure, you can run the listener in the background.
5. From your web browser, go to the URL provided by the APEX Listener program. The Oracle Application Express Listener administration window appears. Enter the following information:

   - **Username** – APEX_PUBLIC_USER
   - **Password** – the password for *APEX_PUBLIC_USER*. This password is the one that you specified earlier when you configured the APEX repository. For more information, see Unlocking the public user account on your DB instance.
   - **Connection type** – Basic
   - **Hostname** – the endpoint of your Amazon RDS DB instance, such as `mydb.f9rbfa893tft.us-east-1.rds.amazonaws.com`.
   - **Port** – 1521

- **SID** – the name of the database on your Amazon RDS DB instance, such as `mydb`.

6. Choose **Apply**. The APEX administration window appears.
7. Set a password for the APEX `admin` user. To do this, use SQL*Plus to connect to your DB instance as the master user, and then run the following commands.

```
EXEC rdsadmin.rdsadmin_util.grant_apex_admin_role;
grant APEX_ADMINISTRATOR_ROLE to master;
@/home/apexuser/apex/apxchpwd.sql
```

   Replace *`master`* with your master user name. When the `apxchpwd.sql` script prompts you, enter a new `admin` password.
8. Return to the APEX administration window in your browser and choose **Administration**. Next, choose **Application Express Internal Administration**. When you are prompted for credentials, enter the following information:

   - **User name** – `admin`
   - **Password** – the password you set using the `apxchpwd.sql` script

   Choose **Login**, and then set a new password for the `admin` user.

Your listener is now ready for use.

Upgrading the APEX version

> **Important**
>
> Back up your DB instance before you upgrade APEX. For more information, see Creating a DB snapshot for a Single-AZ DB instance and Testing an Oracle DB upgrade.

To upgrade APEX with your DB instance, do the following:

- Create a new option group for the upgraded version of your DB instance.
- Add the upgraded versions of APEX and APEX-DEV to the new option group. Be sure to include any other options that your DB instance uses. For more information, see Option group considerations.

- When you upgrade your DB instance, specify the new option group for your upgraded DB instance.

After you upgrade your version of APEX, the APEX schema for the previous version might still exist in your database. If you don't need it anymore, you can drop the old APEX schema from your database after you upgrade.

If you upgrade the APEX version and RESTful services were not configured in the previous APEX version, we recommend that you configure RESTful services. For more information, see Configuring RESTful services for Oracle APEX.

In some cases when you plan to do a major version upgrade of your DB instance, you might find that you're using an APEX version that isn't compatible with your target database version. In these cases, you can upgrade your version of APEX before you upgrade your DB instance. Upgrading APEX first can reduce the amount of time that it takes to upgrade your DB instance.

> **Note**
>
> After upgrading APEX, install and configure a listener for use with the upgraded version. For instructions, see Setting up Oracle APEX listener.

Removing the APEX option

You can remove the Amazon RDS APEX options from a DB instance. To remove the APEX options from a DB instance, do one of the following:

- To remove the APEX options from multiple DB instances, remove the APEX options from the option group they belong to. This change affects all DB instances that use the option group. When you remove the APEX options from an option group that is attached to multiple DB instances, a brief outage occurs while all the DB instances are restarted.

  For more information, see Removing an option from an option group.
- To remove the APEX options from a single DB instance, modify the DB instance and specify a different option group that doesn't include the APEX options. You can specify the default (empty) option group, or a different custom option group. When you remove the APEX options, a brief outage occurs while your DB instance is automatically restarted.

  For more information, see Modifying an Amazon RDS DB instance.

When you remove the APEX options from a DB instance, the APEX schema is removed from your database.

Amazon EFS integration

Amazon Elastic File System (Amazon EFS) provides serverless, fully elastic file storage so that you can share file data without provisioning or managing storage capacity and performance. With Amazon EFS, you can create a file system and then mount it in your VPC through the NFS versions 4.0 and 4.1 (NFSv4) protocol. Then you can use the EFS file system like any other POSIX-compliant file system. For general information, see What is Amazon Elastic File System? and the AWS blog Integrate Amazon RDS for Oracle with Amazon EFS.

Topics

Overview of Amazon EFS integration

With Amazon EFS, you can transfer files between your RDS for Oracle DB instance and an EFS file system. For example, you can use EFS to support the following use cases:

- Share a file system between applications and multiple database servers.
- Create a shared directory for migration-related files, including transportable tablespace data files. For more information, see Migrating using Oracle transportable tablespaces.
- Store and share archived redo log files without allocating additional storage space on the server.
- Use Oracle Database utilities such as `UTL_FILE` to read and write files.

Advantages to Amazon EFS integration

When you choose an EFS file system over alternative data transfer solutions, you get the following benefits:

- You can transfer Oracle Data Pump files between Amazon EFS and your RDS for Oracle DB instance. You don't need to copy these files locally because Data Pump imports directly from the EFS file system. For more information, see Importing data into Oracle on Amazon RDS.
- Data migration is faster than using a database link.
- You avoid allocating storage space on your RDS for Oracle DB instance to hold the files.
- An EFS file systems can automatically scale storage without requiring you to provision it.
- Amazon EFS integration has no minimum fees or setup costs. You pay only for what you use.
- Amazon EFS integration supports two forms of encryption: encryption of data in transit and encryption at rest. Encryption of data in transit is enabled by default using TLS version 1.2. You can enable encryption of data at rest when creating an Amazon EFS file system. For more information, see Encrypting data at rest in the *Amazon Elastic File System User Guide*.

Requirements for Amazon EFS integration

Make sure that you meet the following requirements:

- Your database must run database version 19.0.0.0.ru-2022-07.rur-2022-07.r1 or higher.
- Your DB instance and your EFS file system must be in the same AWS Region, VPC, and AWS account. RDS for Oracle doesn't support cross-account and cross-Region access for EFS.
- Your VPC must have both **DNS Resolution** and **DNS Hostnames** enabled. For more information, see DNS attributes in your VPC in the *Amazon Virtual Private Cloud User Guide*.
- Your EFS file system must use the Standard or Standard-IA storage class.
- If you use a DNS name in the `mount` command, make sure your VPC configured to use the DNS server provided by Amazon. Custom DNS servers aren't supported.
- You must use non-RDS solutions to back up your EFS file system. RDS for Oracle doesn't support automated backups or manual DB snapshots of an EFS file system. For more information, see Backing up your Amazon EFS file systems.

Configuring network permissions for RDS for Oracle integration with Amazon EFS

For RDS for Oracle to integrate with Amazon EFS, make sure that your DB instance has network access to an EFS file system. For more information, see Controlling network access to Amazon EFS file systems for NFS clients in the *Amazon Elastic File System User Guide*.

Topics

- Controlling network access with security groups
- Controlling network access with file system policies

Controlling network access with security groups

You can control your DB instance access to EFS file systems using network layer security mechanisms such as VPC security groups. To allow access to an EFS file system for your DB instance, make sure that your EFS file system meets the following requirements:

- An EFS mount target exists in every Availability Zone used by an RDS for Oracle DB instance.

  An *EFS mount target* provides an IP address for an NFSv4 endpoint at which you can mount an EFS file system. You mount your file system using its DNS name, which resolves to the IP address of the EFS mount target in the used by the Availability Zone of your DB instance.

  You can configure DB instances in different AZs to use the same EFS file system. For Multi-AZ, you need a mount point for each AZ in your deployment. You might need to move a DB instance to a different AZ. For these reasons, we recommend that you create an EFS mount point in each AZ in your VPC. By default, when you create a new EFS file system using the console, RDS creates mount targets for all AZs.
- A security group is attached to the mount target.
- The security group has an inbound rule to allow the network subnet or security group of the RDS for Oracle DB instance on TCP/2049 (Type NFS).

For more information, see Creating Amazon EFS file systems and Creating and managing EFS mount targets and security groups in the *Amazon Elastic File System User Guide*.

Controlling network access with file system policies

Amazon EFS integration with RDS for Oracle works with the default (empty) EFS file system policy. The default policy doesn't use IAM to authenticate. Instead, it grants full access to any anonymous client that can connect to the file system using a mount target. The default policy is in effect whenever a user-configured file system policy isn't in effect, including at file system creation. For more information, see Default EFS file system policy in the *Amazon Elastic File System User Guide*.

To strengthen access to your EFS file system for all clients, including RDS for Oracle, you can configure IAM permissions. In this approach, you create a file system policy. For more information, see Creating file system policies in the *Amazon Elastic File System User Guide*.

Configuring IAM permissions for RDS for Oracle integration with Amazon EFS

By default, Amazon EFS integration feature doesn't use an IAM role: the `USE_IAM_ROLE` option setting is `FALSE`. To integrate RDS for Oracle with Amazon EFS and an IAM role, your DB instance must have IAM permissions to access an Amazon EFS file system.

Topics

Step 1: Create an IAM role for your DB instance and attach your policy

In this step, you create a role for your RDS for Oracle DB instance to allow Amazon RDS to access your EFS file system.

Console

To create an IAM role to allow Amazon RDS access to an EFS file system

1. Open the IAM Management Console.
2. In the navigation pane, choose **Roles**.
3. Choose **Create role**.
4. For **AWS service**, choose **RDS**.
5. For **Select your use case**, choose **RDS – Add Role to Database**.
6. Choose **Next**.
7. Don't add any permissions policies. Choose **Next**.
8. Set **Role name** to a name for your IAM role, for example `rds-efs-integration-role`. You can also add an optional **Description** value.
9. Choose **Create role**.

AWS CLI

To limit the service's permissions to a specific resource, we recommend using the `aws:SourceArn` and `aws:SourceAccount` global condition context keys in resource-based trust relationships. This is the most effective way to protect against the confused deputy problem.

You might use both global condition context keys and have the `aws:SourceArn` value contain the account ID. In this case, the `aws:SourceAccount` value and the account in the `aws:SourceArn` value must use the same account ID when used in the same statement.

- Use `aws:SourceArn` if you want cross-service access for a single resource.
- Use `aws:SourceAccount` if you want to allow any resource in that account to be associated with the cross-service use.

In the trust relationship, make sure to use the `aws:SourceArn` global condition context key with the full Amazon Resource Name (ARN) of the resources accessing the role.

The following AWS CLI command creates the role named *`rds-efs-integration-role`* for this purpose.

Example

For Linux, macOS, or Unix:

```
aws iam create-role \
   --role-name rds-efs-integration-role \
   --assume-role-policy-document '{
     "Version": "2012-10-17",
     "Statement": [
       {
         "Effect": "Allow",
         "Principal": {
            "Service": "rds.amazonaws.com"
          },
         "Action": "sts:AssumeRole",
         "Condition": {
             "StringEquals": {
                 "aws:SourceAccount": my_account_ID,
                 "aws:SourceArn": "arn:aws:rds:Region:my_account_ID:db:dbname"
             }
         }
       }
     ]
   }'
```

For Windows:

```
aws iam create-role ^
   --role-name rds-efs-integration-role ^
   --assume-role-policy-document '{
     "Version": "2012-10-17",
     "Statement": [
       {
         "Effect": "Allow",
         "Principal": {
            "Service": "rds.amazonaws.com"
          },
         "Action": "sts:AssumeRole",
         "Condition": {
             "StringEquals": {
                 "aws:SourceAccount": my_account_ID,
                 "aws:SourceArn": "arn:aws:rds:Region:my_account_ID:db:dbname"
             }
         }
       }
     ]
   }'
```

For more information, see Creating a role to delegate permissions to an IAM user in the *IAM User Guide*.

Step 2: Create a file system policy for your Amazon EFS file system

In this step, you create a file system policy for your EFS file system.

To create or edit an EFS file system policy

1. Open the EFS Management Console.
2. Choose **File Systems**.
3. On the **File systems** page, choose the file system that you want to edit or create a file system policy for. The details page for that file system is displayed.
4. Choose the **File system policy** tab.

   If the policy is empty, then the default EFS file system policy is in use. For more information, see Default EFS file system policy in the *Amazon Elastic File System User Guide*.
5. Choose **Edit**. The **File system policy** page appears.
6. In **Policy editor**, enter a policy such as the following, and then choose **Save**.

```
{
    "Version": "2012-10-17",
    "Id": "ExamplePolicy01",
    "Statement": [
        {
            "Sid": "ExampleStatement01",
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws:iam::123456789012:role/rds-efs-integration-role"
            },
            "Action": [
                "elasticfilesystem:ClientMount",
                "elasticfilesystem:ClientWrite",
                "elasticfilesystem:ClientRootAccess"
            ],
            "Resource": "arn:aws:elasticfilesystem:us-east-1:123456789012:file-
system/fs-1234567890abcdef0"
        }
    ]
}
```

Step 3: Associate your IAM role with your RDS for Oracle DB instance

In this step, you associate your IAM role with your DB instance. Be aware of the following requirements:

- You must have access to an IAM role with the required Amazon EFS permissions policy attached to it.
- You can associate only one IAM role with your RDS for Oracle DB instance at a time.
- The status of your instance must be **Available**.

For more information, see Identity and access management for Amazon EFS in the *Amazon Elastic File System User Guide*.

Console

To associate your IAM role with your RDS for Oracle DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Choose **Databases**.
3. If your database instance is unavailable, choose **Actions** and then **Start**. When the instance status shows **Started**, go to the next step.
4. Choose the Oracle DB instance name to display its details.
5. On the **Connectivity & security** tab, scroll down to the **Manage IAM roles** section at the bottom of the page.
6. Choose the role to add in the **Add IAM roles to this instance** section.
7. For **Feature**, choose **EFS_INTEGRATION**.
8. Choose **Add role**.

AWS CLI

The following AWS CLI command adds the role to an Oracle DB instance named *mydbinstance*.

Example

For Linux, macOS, or Unix:

```
aws rds add-role-to-db-instance \
   --db-instance-identifier mydbinstance \
   --feature-name EFS_INTEGRATION \
   --role-arn your-role-arn
```

For Windows:

```
aws rds add-role-to-db-instance ^
   --db-instance-identifier mydbinstance ^
   --feature-name EFS_INTEGRATION ^
   --role-arn your-role-arn
```

Replace *your-role-arn* with the role ARN that you noted in a previous step. `EFS_INTEGRATION` must be specified for the `--feature-name` option.

Adding the EFS_INTEGRATION option

To integrate Amazon RDS for Oracle with Amazon EFS, your DB instance must be associated with an option group that includes the `EFS_INTEGRATION` option.

Multiple Oracle DB instances that belong to the same option group share the same EFS file system. Different DB instances can access the same data, but access can be divided by using different Oracle directories. For more information see Transferring files between RDS for Oracle and an Amazon EFS file system.

Console

To configure an option group for Amazon EFS integration

1. Create a new option group or identify an existing option group to which you can add the `EFS_INTEGRATION` option.

   For information about creating an option group, see Creating an option group.
2. Add the `EFS_INTEGRATION` option to the option group. You need to specify the `EFS_ID` file system ID and set the `USE_IAM_ROLE` flag.

   For more information, see Adding an option to an option group.
3. Associate the option group with your DB instance in either of the following ways:

   - Create a new Oracle DB instance and associate the option group with it. For information about creating a DB instance, see Creating an Amazon RDS DB instance.
   - Modify an Oracle DB instance to associate the option group with it. For information about modifying an Oracle DB instance, see Modifying an Amazon RDS DB instance.

AWS CLI

To configure an option group for EFS integration

1. Create a new option group or identify an existing option group to which you can add the `EFS_INTEGRATION` option.

   For information about creating an option group, see Creating an option group.
2. Add the `EFS_INTEGRATION` option to the option group.

For example, the following AWS CLI command adds the `EFS_INTEGRATION` option to an option group named **`myoptiongroup`**.

Example

For Linux, macOS, or Unix:

```
aws rds add-option-to-option-group \
   --option-group-name myoptiongroup \
   --options "OptionName=EFS_INTEGRATION,OptionSettings=\
   [{Name=EFS_ID,Value=fs-1234567890abcdef0},{Name=USE_IAM_ROLE,Value=TRUE}]"
```

For Windows:

```
aws rds add-option-to-option-group ^
   --option-group-name myoptiongroup ^
   --options "OptionName=EFS_INTEGRATION,OptionSettings=^
   [{Name=EFS_ID,Value=fs-1234567890abcdef0},{Name=USE_IAM_ROLE,Value=TRUE}]"
```

3. Associate the option group with your DB instance in either of the following ways:

- Create a new Oracle DB instance and associate the option group with it. For information about creating a DB instance, see Creating an Amazon RDS DB instance.
- Modify an Oracle DB instance to associate the option group with it. For information about modifying an Oracle DB instance, see Modifying an Amazon RDS DB instance.

Configuring Amazon EFS file system permissions

By default, only the root user (UID `0`) has read, write, and execute permissions for a newly created EFS file system. For other users to modify the file system, the root user must explicitly grant them access. The user for the RDS for Oracle DB instance is in the `others` category. For more information, see Working with users, groups, and permissions at the Network File System (NFS) Level in the *Amazon Elastic File System User Guide*.

To allow your RDS for Oracle DB instance to read and write files on an EFS file system, do the following:

- Mount an EFS file system locally on your Amazon EC2 or on-premises instance.
- Configure fine grain permissions.

For example, to grant `other` users permissions to write to the EFS file system root, run `chmod 777` on this directory. For more information, see Example Amazon EFS file system use cases and permissions in the *Amazon Elastic File System User Guide*.

Transferring files between RDS for Oracle and an Amazon EFS file system

To transfer files between an RDS for Oracle instance and an Amazon EFS file system, create at least one Oracle directory and configure EFS file system permissions to control DB instance access.

Topics

- Creating an Oracle directory
- Transferring data to and from an EFS file system: examples

Creating an Oracle directory

To create an Oracle directory, use the procedure `rdsadmin.rdsadmin_util.create_directory_efs`. The procedure has the following parameters.

Parameter name	Data type	Defaul	Requir	Description
`p_directory_name`	VARCHAR2	–	Yes	The name of the Oracle directory.
`p_path_on_efs`	VARCHAR2	–	Yes	The path on the EFS file system. The prefix of the path name uses the pattern `/rdsefs-`*`fsid`*`/`, where *`fsid`* is a placeholder for your EFS file system ID. For example, if your EFS file system is named `fs-1234567890abcdef0` , and you create a subdirectory on this file system named `mydir`, you could specify the following value: `/rdsefs-fs-1234567890abcdef0/mydir`

Assume that you create a subdirectory named `/datapump1` on the EFS file system `fs-1234567890abcdef0`. The following example creates an Oracle directory `DATA_PUMP_DIR_EFS` that points to the `/datapump1` directory on the EFS file system. The file system path value for the `p_path_on_efs` parameter is prefixed with the string `/rdsefs-`.

```
BEGIN
  rdsadmin.rdsadmin_util.create_directory_efs(
    p_directory_name => 'DATA_PUMP_DIR_EFS',
    p_path_on_efs    => '/rdsefs-fs-1234567890abcdef0/datapump1');
END;
/
```

Transferring data to and from an EFS file system: examples

The following example uses Oracle Data Pump to export the table named `MY_TABLE` to file `datapump.dmp`. This file resides on an EFS file system.

```
DECLARE
  v_hdnl NUMBER;
BEGIN
  v_hdnl := DBMS_DATAPUMP.OPEN(operation => 'EXPORT', job_mode => 'TABLE',
 job_name=>null);
  DBMS_DATAPUMP.ADD_FILE(
    handle    => v_hdnl,
    filename  => 'datapump.dmp',
    directory => 'DATA_PUMP_DIR_EFS',
    filetype  => dbms_datapump.ku$_file_type_dump_file);
  DBMS_DATAPUMP.ADD_FILE(
    handle    => v_hdnl,
    filename  => 'datapump-exp.log',
    directory => 'DATA_PUMP_DIR_EFS',
    filetype  => dbms_datapump.ku$_file_type_log_file);
  DBMS_DATAPUMP.METADATA_FILTER(v_hdnl,'NAME_EXPR','IN (''MY_TABLE'')');
  DBMS_DATAPUMP.START_JOB(v_hdnl);
END;
/
```

The following example uses Oracle Data Pump to import the table named `MY_TABLE` from file `datapump.dmp`. This file resides on an EFS file system.

```
DECLARE
```

```
  v_hdnl NUMBER;
BEGIN
  v_hdnl := DBMS_DATAPUMP.OPEN(
    operation => 'IMPORT',
    job_mode  => 'TABLE',
    job_name  => null);
  DBMS_DATAPUMP.ADD_FILE(
    handle    => v_hdnl,
    filename  => 'datapump.dmp',
    directory => 'DATA_PUMP_DIR_EFS',
    filetype  => dbms_datapump.ku$_file_type_dump_file );
  DBMS_DATAPUMP.ADD_FILE(
    handle    => v_hdnl,
    filename  => 'datapump-imp.log',
    directory => 'DATA_PUMP_DIR_EFS',
    filetype  => dbms_datapump.ku$_file_type_log_file);
  DBMS_DATAPUMP.METADATA_FILTER(v_hdnl,'NAME_EXPR','IN (''MY_TABLE'')');
  DBMS_DATAPUMP.START_JOB(v_hdnl);
END;
/
```

For more information, see Importing data into Oracle on Amazon RDS.

Removing the EFS_INTEGRATION option

The steps for removing the `EFS_INTEGRATION` option depend on whether you're removing the option from multiple DB instances or a single instance.

Number of DB instances	Action	Related information
Multiple	Remove the `EFS_INTEGRATION` option from the option group to which the DB instances belong. This change affects all instances that use the option group.	Removing an option from an option group
Single	Modify the DB instance and specify a different option group that doesn't include the `EFS_INTEGRATION` option. You can specify the default (empty) option group or a different custom option group.	Modifying an Amazon RDS DB instance

After you remove the EFS_INTEGRATION option, you can optionally delete the EFS file system that was connected to your DB instances.

Troubleshooting Amazon EFS integration

Your RDS for Oracle DB instance monitors the connectivity to an Amazon EFS file system. When monitoring detects an issue, it might try to correct the issue and publish an event in the RDS console. For more information, see Viewing Amazon RDS events.

Use the information in this section to help you diagnose and fix common issues when you work with Amazon EFS integration.

Notification	Description	Action
`The EFS for RDS Oracle instance` *instance_name* `isn't available on the primary host. NFS port 2049 of your EFS isn't reachable.`	The DB instance can't communicate with the EFS file system.	Make sure of the following: • The EFS file system exists. • The security group that is attached to the EFS mount target has an inbound rule to allow the security group or network subnet of the RDS for Oracle DB instance on TCP/2049 (Type NFS).
`The EFS isn't reachable.`	An error occurred during the installation of the `EFS_INTEGRATION` option.	Make sure of the following: • The EFS file system exists. • The security group that is attached to the EFS mount target has an inbound rule to allow the security group or network subnet of the RDS for Oracle DB instance on TCP/2049 (Type NFS). • The `enableDnsSupport` attribute is turned on for your VPC.

Notification	Description	Action
		• You are using the Amazon provided DNS server in your VPC. Amazon EFS integrati on doesn't work with a custom DHCP DNS.
`The associated role with your DB instance wasn't found.`	An error occurred during the installation of the `EFS_INTEGRATION` option.	Make sure that you associated an IAM role with your RDS for Oracle DB instance.
`The associated role with your DB instance wasn't found.`	An error occurred during the installation of the `EFS_INTEGRATION` option. RDS for Oracle was restored from a DB snapshot with the `USE_IAM_ROLE` option setting of `TRUE`.	Make sure that you associated an IAM role with your RDS for Oracle DB instance.
`The associated role with your DB instance wasn't found.`	An error occurred during the installation of the `EFS_INTEGRATION` option. RDS for Oracle was created from an all-in-one CloudForm ation template with the `USE_IAM_ROLE` option setting of `TRUE`.	As a workaround, complete the following steps: 1. Create a DB instance with the IAM role and default option group. 2. On a subsequent stack update, add the custom option group with the `EFS_INTEGRATION` option.
`PLS-00302: component 'CREATE_DIRECTORY_ EFS' must be declared`	This error can occur when you're using a version of RDS for Oracle that doesn't support Amazon EFS.	Make sure that you are using RDS for Oracle DB instance version 19.0.0.0.ru-2022-0 7.rur-2022-07.r1 or higher.

Notification	Description	Action
`Read access of your EFS is denied. Check your file system policy.`	Your DB instance can't read the EFS file system.	Make sure that your EFS file system allows read access through the IAM role or on the EFS file system level.
N/A	Your DB instance can't write to the EFS file system.	Take the following steps: 1. Make sure that your EFS file system is mounted on an Amazon EC2 instance. 2. Give the `others` group write access to your RDS user. The simplest technique is to run the `chmod 777` command on the top directory of the EFS file system.

Oracle Java virtual machine

Amazon RDS supports Oracle Java Virtual Machine (JVM) through the use of the `JVM` option. Oracle Java provides a SQL schema and functions that facilitate Oracle Java features in an Oracle database. For more information, see Introduction to Java in Oracle database in the Oracle documentation. You can use Oracle JVM with all versions of Oracle Database 21c (21.0.0) and Oracle Database 19c (19.0.0).

Considerations for Oracle JVM

Java implementation in Amazon RDS has a limited set of permissions. The master user is granted the `RDS_JAVA_ADMIN` role, which grants a subset of the privileges granted by the `JAVA_ADMIN` role. To list the privileges granted to the `RDS_JAVA_ADMIN` role, run the following query on your DB instance:

```
SELECT * FROM dba_java_policy
   WHERE grantee IN ('RDS_JAVA_ADMIN', 'PUBLIC')
   AND enabled = 'ENABLED'
   ORDER BY type_name, name, grantee;
```

Prerequisites for Oracle JVM

The following are prerequisites for using Oracle Java:

- Your DB instance must be of a large enough class. Oracle Java isn't supported for the db.t3.micro or db.t3.small DB instance classes. For more information, see DB instance classes.
- Your DB instance must have **Auto Minor Version Upgrade** enabled. This option enables your DB instance to receive minor DB engine version upgrades automatically when they become available. Amazon RDS uses this option to update your DB instance to the latest Oracle Patch Set Update (PSU) or Release Update (RU). For more information, see Modifying an Amazon RDS DB instance.

Best practices for Oracle JVM

The following are best practices for using Oracle Java:

- For maximum security, use the `JVM` option with Secure Sockets Layer (SSL). For more information, see Oracle Secure Sockets Layer.

- Configure your DB instance to restrict network access. For more information, see Scenarios for accessing a DB instance in a VPC and Working with a DB instance in a VPC.
- Update the configuration of your HTTPS endpoints to support TLSv1.2 if you meet the following conditions:
  - You use Oracle Java Virtual Machine (JVM) to connect an HTTPS endpoint over TLSv1 or TLSv1.1 protocols.
  - Your endpoint doesn't support the TLSv1.2 protocol.
  - You haven't applied the April 2021 release update to your Oracle DB.

  By updating your endpoint configuration, you ensure that the connectivity of the JVM to the HTTPS endpoint will continue to work. For more information about TLS changes in the Oracle JRE and JDK, see Oracle JRE and JDK Cryptographic Roadmap.

Adding the Oracle JVM option

The following is the general process for adding the `JVM` option to a DB instance:

1. Create a new option group, or copy or modify an existing option group.
2. Add the option to the option group.
3. Associate the option group with the DB instance.

There is a brief outage while the `JVM` option is added. After you add the option, you don't need to restart your DB instance. As soon as the option group is active, Oracle Java is available.

> **Note**
>
> During this outage, password verification functions are disabled briefly. You can also expect to see events related to password verification functions during the outage. Password verification functions are enabled again before the Oracle DB instance is available.

To add the JVM option to a DB instance

1. Determine the option group that you want to use. You can create a new option group or use an existing option group. If you want to use an existing option group, skip to the next step. Otherwise, create a custom DB option group with the following settings:

- For **Engine**, choose the DB engine used by the DB instance (**oracle-ee**, **oracle-se**, **oracle-se1**, or **oracle-se2**).
- For **Major engine version**, choose the version of your DB instance.

For more information, see Creating an option group.

2. Add the **JVM** option to the option group. For more information about adding options, see Adding an option to an option group.
3. Apply the option group to a new or existing DB instance:

   - For a new DB instance, apply the option group when you launch the instance. For more information, see Creating an Amazon RDS DB instance.
   - For an existing DB instance, apply the option group by modifying the instance and attaching the new option group. For more information, see Modifying an Amazon RDS DB instance.
4. Grant the required permissions to users.

   The Amazon RDS master user has the permissions to use the `JVM` option by default. If other users require these permissions, connect to the DB instance as the master user in a SQL client and grant the permissions to the users.

   The following example grants the permissions to use the `JVM` option to the `test_proc` user.

```
create user test_proc identified by password;
CALL dbms_java.grant_permission('TEST_PROC',
 'oracle.aurora.security.JServerPermission', 'LoadClassInPackage.*', '');
```

> **Note**
>
> Specify a password other than the prompt shown here as a security best practice.

   After the user is granted the permissions, the following query should return output.

```
select * from dba_java_policy where grantee='TEST_PROC';
```

> **Note**
>
> The Oracle user name is case-sensitive, and it usually has all uppercase characters.

Removing the Oracle JVM option

You can remove the `JVM` option from a DB instance. There is a brief outage while the option is removed. After you remove the `JVM` option, you don't need to restart your DB instance.

> **Warning**
>
> Removing the `JVM` option can result in data loss if the DB instance is using data types that were enabled as part of the option. Back up your data before proceeding. For more information, see Backing up, restoring, and exporting data.

To remove the `JVM` option from a DB instance, do one of the following:

- Remove the `JVM` option from the option group it belongs to. This change affects all DB instances that use the option group. For more information, see Removing an option from an option group.
- Modify the DB instance and specify a different option group that doesn't include the `JVM` option. This change affects a single DB instance. You can specify the default (empty) option group, or a different custom option group. For more information, see Modifying an Amazon RDS DB instance.

Oracle Enterprise Manager

Amazon RDS supports Oracle Enterprise Manager (OEM). OEM is the Oracle product line for integrated management of enterprise information technology.

Amazon RDS supports OEM on Oracle Database 19c non-CDBs or CDBs. The following table describes the supported OEM options.

Option	Option ID	Supported OEM releases
OEM Database Express	`OEM`	OEM Database Express 19c
OEM Management Agent	`OEM_AGENT`	OEM Cloud Control for 13c

Note

You can use OEM Database or OEM Management Agent, but not both.

Oracle Enterprise Manager Database Express

Amazon RDS supports Oracle Enterprise Manager Database Express (EM Express) through the use of the OEM option. Amazon RDS supports EM Express for Oracle Database 19c using the CDB or non-CDB architecture.

EM Express is a web-based database management tool included in your database and is only available when it is open. It supports key performance management and basic database administration functions. For more information, see Introduction to Oracle Enterprise Manager Database Express in the Oracle Database documentation.

> **Note**
>
> EM Express isn't supported on the db.t3.small DB instance class. For more information about DB instance classes, see RDS for Oracle DB instance classes.

OEM option settings

Amazon RDS supports the following settings for the OEM option.

Option setting	Valid values	Description
Port	An integer value	The port on the RDS for Oracle DB instance that listens for EM Express. The default is 5500.
Security Groups	—	A security group that has access to **Port**.

Step 1: Adding the OEM option

The general process for adding the OEM option to a DB instance is the following:

1. Create a new option group, or copy or modify an existing option group.
2. Add the option to the option group.
3. Associate the option group with your DB instance.

When you add the OEM option, a brief outage occurs while your DB instance is automatically restarted.

To add the OEM option to a DB instance

1. Determine the option group you want to use. You can create a new option group or use an existing option group. If you want to use an existing option group, skip to the next step. Otherwise, create a custom DB option group with the following settings:

   a. For **Engine** choose the oracle edition for your DB instance.

   b. For **Major engine version** choose the version of your DB instance.

   For more information, see Creating an option group.

2. Add the OEM option to the option group, and configure the option settings. For more information about adding options, see Adding an option to an option group. For more information about each setting, see OEM option settings.

   > **Note**
   >
   > If you add the OEM option to an existing option group that is already attached to one or more DB instances, a brief outage occurs while all the DB instances are automatically restarted.

3. Apply the option group to a new or existing DB instance:

   - For a new DB instance, apply the option group when you launch the instance. For more information, see Creating an Amazon RDS DB instance.
   - For an existing DB instance, apply the option group by modifying the instance and attaching the new option group. When you add the OEM option, a brief outage occurs while your DB instance is automatically restarted. For more information, see Modifying an Amazon RDS DB instance.

> **Note**
>
> You can also use the AWS CLI to add the OEM option. For examples, see Adding an option to an option group.

Step 2: (CDB only) Unlocking the DBSNMP user account

If your DB instance uses the CDB architecture, you must log in to EM Express as DBSNMP. in a CDB, DBSNMP is a common user. By default, this account is locked. If your DB instance doesn't use the CDB architecture, skip this step.

To unlock the DBSNMP user account in a CDB instance

1. In SQL*Plus or another Oracle SQL application, log in to your DB instance as your master user.
2. Run the following stored procedure to unlock the DBSNMP account:

   ```
   EXEC rdsadmin.rdsadmin_util.reset_oem_agent_password('new_password');
   ```

   If you receive an error stating that the procedure doesn't exist, reboot your CDB instance to install it automatically. For more information, see Rebooting a DB instance.

Step 3: Accessing EM Express through your browser

When you access EM Express from your web browser, a login window appears that prompts you for a user name and password.

To access EM Express through your browser

1. Identify the endpoint and EM Express port for your Amazon RDS DB instance. For information about finding the endpoint for your Amazon RDS DB instance, see Finding the endpoint of your RDS for Oracle DB instance.
2. Enter a URL in your browser locator bar using the following format.

   ```
   https://endpoint.rds.amazonaws.com:port/em
   ```

   For example, if the endpoint for your Amazon RDS DB instance is `mydb.a1bcde234fgh.us-east-1.rds.amazonaws.com`, and your EM Express port is 1158, then use the following URL to access EM Express.

   ```
   https://mydb.f9rbfa893tft.us-east-1.rds.amazonaws.com:1158/em
   ```

3. When prompted for your login details, do one of the following actions, depending on your database architecture:

Your database is a non-CDB.

Type the master user name and master password for your DB instance.

Your database is a CDB.

Enter `DBSNMP` for the user and the `DBSNMP` password. Leave the `Container` field empty.

Modifying OEM Database settings

After you enable OEM Database, you can modify the Security Groups setting for the option.

You can't modify the OEM port number after you have associated the option group with a DB instance. To change the OEM port number for a DB instance, do the following:

1. Create a new option group.
2. Add the OEM option with the new port number to the new option group.
3. Remove the existing option group from the DB instance.
4. Add the new option group to the DB instance.

For more information about how to modify option settings, see Modifying an option setting. For more information about each setting, see OEM option settings.

Running OEM Database Express tasks

You can use Amazon RDS procedures to run certain OEM Database Express tasks. By running these procedures, you can do the tasks listed following.

> **Note**
>
> OEM Database Express tasks run asynchronously.

Tasks

- Switching the website front end for OEM Database Express to Adobe Flash
- Switching the website front end for OEM Database Express to Oracle JET

Switching the website front end for OEM Database Express to Adobe Flash

> **Note**
>
> This task is available only for Oracle Database 19c non-CDBs.

Starting with Oracle Database 19c, Oracle has deprecated the former OEM Database Express user interface, which was based on Adobe Flash. Instead, OEM Database Express now uses an interface built with Oracle JET. If you experience difficulties with the new interface, you can switch back to the deprecated Flash-based interface. Difficulties you might experience with the new interface include being stuck on a `Loading` screen after logging in to OEM Database Express. You might also miss certain features that were present in the Flash-based version of OEM Database Express.

To switch the OEM Database Express website front end to Adobe Flash, run the Amazon RDS procedure `rdsadmin.rdsadmin_oem_tasks.em_express_frontend_to_flash`. This procedure is equivalent to the `execemx emx` SQL command.

Security best practices discourage the use of Adobe Flash. Although you can revert to the Flash-based OEM Database Express, we recommend the use of the JET-based OEM Database Express websites if possible. If you revert to using Adobe Flash and want to switch back to using Oracle JET, use the `rdsadmin.rdsadmin_oem_tasks.em_express_frontend_to_jet` procedure. After an Oracle database upgrade, a newer version of Oracle JET might resolve JET-related issues in OEM Database Express. For more information about switching to Oracle JET, see Switching the website front end for OEM Database Express to Oracle JET.

> **Note**
>
> Running this task from the source DB instance for a read replica also causes the read replica to switch its OEM Database Express website front ends to Adobe Flash.

The following procedure invocation creates a task to switch the OEM Database Express website to Adobe Flash and returns the ID of the task.

```
SELECT rdsadmin.rdsadmin_oem_tasks.em_express_frontend_to_flash() as TASK_ID from DUAL;
```

You can view the result by displaying the task's output file.

```
SELECT text FROM table(rdsadmin.rds_file_util.read_text_file('BDUMP','dbtask-task-id.log'));
```

Replace *task-id* with the task ID returned by the procedure. For more information about the Amazon RDS procedure `rdsadmin.rds_file_util.read_text_file`, see Reading files in a DB instance directory

You can also view the contents of the task's output file in the AWS Management Console by searching the log entries in the **Logs & events** section for the `task-id`.

Switching the website front end for OEM Database Express to Oracle JET

> **Note**
>
> This task is available only for Oracle Database 19c non-CDBs.

To switch the OEM Database Express website front end to Oracle JET, run the Amazon RDS procedure `rdsadmin.rdsadmin_oem_tasks.em_express_frontend_to_jet`. This procedure is equivalent to the `execemx omx` SQL command.

By default, the OEM Database Express websites for Oracle DB instances running 19c or later use Oracle JET. If you used the `rdsadmin.rdsadmin_oem_tasks.em_express_frontend_to_flash` procedure to switch the OEM Database Express website front end to Adobe Flash, you can switch back to Oracle JET. To do this, use the `rdsadmin.rdsadmin_oem_tasks.em_express_frontend_to_jet` procedure. For more information about switching to Adobe Flash, see Switching the website front end for OEM Database Express to Adobe Flash.

> **Note**
>
> Running this task from the source DB instance for a read replica also causes the read replica to switch its OEM Database Express website front ends to Oracle JET.

The following procedure invocation creates a task to switch the OEM Database Express website to Oracle JET and returns the ID of the task.

```
SELECT rdsadmin.rdsadmin_oem_tasks.em_express_frontend_to_jet() as TASK_ID from DUAL;
```

You can view the result by displaying the task's output file.

```
SELECT text FROM table(rdsadmin.rds_file_util.read_text_file('BDUMP','dbtask-task-id.log'));
```

Replace *task-id* with the task ID returned by the procedure. For more information about the Amazon RDS procedure `rdsadmin.rds_file_util.read_text_file`, see Reading files in a DB instance directory

You can also view the contents of the task's output file in the AWS Management Console by searching the log entries in the **Logs & events** section for the `task-id`.

Removing the OEM Database option

You can remove the OEM option from a DB instance. When you remove the OEM option, a brief outage occurs while your instance is automatically restarted. Therefore, after you remove the OEM option, you don't need to restart your DB instance.

To remove the OEM option from a DB instance, do one of the following:

- Remove the OEM option from the option group it belongs to. This change affects all DB instances that use the option group. For more information, see Removing an option from an option group.
- Modify the DB instance and specify a different option group that doesn't include the OEM option. This change affects a single DB instance. You can specify the default (empty) option group, or a different custom option group. For more information, see Modifying an Amazon RDS DB instance.

Oracle Management Agent for Enterprise Manager Cloud Control

Oracle Enterprise Manager (OEM) Management Agent is a software component that monitors targets running on hosts and communicates that information to the middle-tier Oracle Management Service (OMS). Amazon RDS supports Management Agent through the use of the `OEM_AGENT` option.

For more information, see Overview of Oracle Enterprise Manager cloud control 12c and Overview of Oracle Enterprise Manager cloud control 13c in the Oracle documentation.

Topics

Requirements for Management Agent

Following are general requirements for using Management Agent:

- Your DB instance must run Oracle Database 19c (19.0.0.0). You can use either the CDB or non-CDB architecture.
- You must use an Oracle Management Service (OMS) that is configured to connect to your DB instance. Note the following OMS requirements:
  - Management Agent version 13.5.0.0.v1 requires OMS version 13.5.0.0 or later.
  - Management Agent version 13.4.0.9.v1 requires OMS version 13.4.0.9 or later and patch 32198287.
- In most cases, you must configure your VPC to allow connections from OMS to your DB instance. If you aren't familiar with Amazon Virtual Private Cloud (Amazon VPC), we recommend that

you complete the steps in Tutorial: Create a VPC for use with a DB instance (IPv4 only) before continuing.

- You can use Management Agent with Oracle Enterprise Manager Cloud Control for 12c and 13c. Ensure that you have sufficient storage space for your OEM release:
  - At least 8.5 GiB for OEM 13c Release 5
  - At least 8.5 GiB for OEM 13c Release 4
  - At least 8.5 GiB for OEM 13c Release 3
  - At least 5.5 GiB for OEM 13c Release 2
  - At least 4.5 GiB OEM 13c Release 1
  - At least 2.5 GiB for OEM 12c
- If you're using Management Agent versions `OEM_AGENT 13.2.0.0.v3` and `13.3.0.0.v2`, and if you want to use TCPS connectivity, follow the instructions in Configuring third party CA certificates for communication with target databases in the Oracle documentation. Also, update the JDK on your OMS by following the instructions in the Oracle document with the Oracle Doc ID 2241358.1. This step ensures that OMS supports all the cipher suites that the database supports.

> **Note**
>
> TCPS connectivity between the Management Agent and the DB instance is supported for Management Agent `OEM_AGENT 13.2.0.0.v3`, `13.3.0.0.v2`, `13.4.0.9.v1`, and higher versions.

OMS host communication prerequisites

Make sure that your OMS host and your Amazon RDS DB instance can communicate. Do the following:

- To connect from the Management Agent to your OMS, if your OMS is behind a firewall, add the IP addresses of your DB instances to your OMS.

  Make sure the firewall for the OMS allows traffic from both the DB listener port (default 1521) and the OEM Agent port (default 3872), originating from the IP address of the DB instance.
- To connect from your OMS to the Management Agent, if your OMS has a publicly resolvable host name, add the OMS address to a security group. Your security group must have inbound

rules that allow access to the DB listener port and the Management Agent port. For an example of creating a security and adding inbound rules, see Tutorial: Create a VPC for use with a DB instance (IPv4 only).

- To connect from your OMS to the Management Agent, if your OMS doesn't have a publicly resolvable host name, use one of the following:
  - If your OMS is hosted on an Amazon Elastic Compute Cloud (Amazon EC2) instance in a private VPC, you can set up VPC peering to connect from OMS to Management Agent. For more information, see A DB instance in a VPC accessed by an EC2 instance in a different VPC.
  - If your OMS is hosted on-premises, you can set up a VPN connection to allow access from OMS to Management Agent. For more information, see A DB instance in a VPC accessed by a client application through the internet or VPN connections.

Limitations for Management Agent

Following are some limitations to using Management Agent:

- You can't provide custom Oracle Management Agent images.
- Administrative tasks such as job execution and database patching, that require host credentials, aren't supported.
- Host metrics and the process list aren't guaranteed to reflect the actual system state. Thus, you shouldn't use OEM to monitor the root file system or mount point file system. For more information about monitoring the operating system, see Monitoring OS metrics with Enhanced Monitoring.
- Autodiscovery isn't supported. You must manually add database targets.
- OMS module availability depends on your database edition. For example, the database performance diagnosis and tuning module is only available for Oracle Database Enterprise Edition.
- Management Agent consumes additional memory and computing resources. If you experience performance problems after enabling the `OEM_AGENT` option, we recommend that you scale up to a larger DB instance class. For more information, see DB instance classes and Modifying an Amazon RDS DB instance.
- The user running the `OEM_AGENT` on the Amazon RDS host doesn't have operating system access to the alert log. Thus, you can't collect metrics for `DB Alert Log` and `DB Alert Log Error Status` in OEM.

Option settings for Management Agent

Amazon RDS supports the following settings for the Management Agent option.

Option setting	Require	Valid values	Description
Version (AGENT_VERSION)	Yes	13.5.0.0.v1 13.4.0.9.v1 13.3.0.0.v2 13.3.0.0.v1 13.2.0.0.v3 13.2.0.0.v2 13.2.0.0.v1 13.1.0.0.v1	The version of the Management Agent software. The minimum supported version is 13.1.0.0.v1 . The AWS CLI option name is OptionVersion . **Note** In the AWS GovCloud (US) Regions, 13.1 versions aren't available.
Port (AGENT_PORT)	Yes	An integer value	The port on the DB instance that listens for the OMS host. The default is 3872. Your OMS host must belong to a security group that has access to this port. The AWS CLI option name is Port.

Option setting	Require	Valid values	Description
Security Groups	Yes	Existing security groups	A security group that has access to **Port**. Your OMS host must belong to this security group. The AWS CLI option name is `VpcSecurityGroupMemberships` or `DBSecurityGroupMemberships` .
OMS_HOST	Yes	A string value, for example *my.example.oms*	The publicly accessible host name or IP address of the OMS. The AWS CLI option name is `OMS_HOST`.
OMS_PORT	Yes	An integer value	The HTTPS upload port on the OMS Host that listens for the Management Agent. To determine the HTTPS upload port, connect to the OMS host, and run the following command (which requires the SYSMAN password): `emctl status oms -details` The AWS CLI option name is `OMS_PORT`.

Option setting	Require	Valid values	Description
AGENT_REGISTRATION_PASSWORD	Yes	A string value	The password that the Management Agent uses to authenticate itself with the OMS. We recommend that you create a persistent password in your OMS before enabling the `OEM_AGENT` option. With a persistent password you can share a single Management Agent option group among multiple Amazon RDS databases. The AWS CLI option name is `AGENT_REGISTRATION_PASSWORD` .
ALLOW_TLS_ONLY	No	`true`, `false` (default)	A value that configures the OEM Agent to support only the `TLSv1` protocol while the agent listens as a server. This setting is no longer supported. Management Agent versions 13.1.0.0.v1 and higher support Transport Layer Security (TLS) by default.
MINIMUM_TLS_VERSION	No	`TLSv1` (default), `TLSv1.2`	A value that specifies the minimum TLS version supported by the OEM Agent while the agent listens as a server. Desupported agent versions only support the `TLSv1` setting.
TLS_CIPHER_SUITE	No	See Option settings for Management Agent.	A value that specifies the TLS cipher suite used by the OEM Agent while the agent listens as a server.

The following table lists the TLS cipher suites that the Management Agent option supports.

Cipher suite	Agent version supported	FedRAMP compliant
TLS_RSA_WITH_AES_128_CBC_SHA	All	No
TLS_RSA_WITH_AES_128_CBC_SHA256	13.1.0.0.v1 and higher	No
TLS_RSA_WITH_AES_256_CBC_SHA	13.2.0.0.v3 and higher	No
TLS_RSA_WITH_AES_256_CBC_SHA256	13.2.0.0.v3 and higher	No
TLS_ECDHE_RSA_WITH_AES_128_CBC_SHA	13.2.0.0.v3 and higher	Yes
TLS_ECDHE_RSA_WITH_AES_256_CBC_SHA	13.2.0.0.v3 and higher	Yes
TLS_ECDHE_RSA_WITH_AES_128_CBC_SHA256	13.2.0.0.v3 and higher	Yes
TLS_ECDHE_RSA_WITH_AES_256_CBC_SHA384	13.2.0.0.v3 and higher	Yes

Step1: Adding the Management Agent option to your DB instance

To add the Management Agent option to your DB instance, do the following:

1. Create a new option group, or copy or modify an existing option group.
2. Add the option to the option group.
3. Associate the option group with the DB instance.

If you encounter errors, check My Oracle Support documents for information about resolving specific problems.

After you add the Management Agent option, you don't need to restart your DB instance. As soon as the option group is active, the OEM Agent is active.

If your OMS host is using an untrusted third-party certificate, Amazon RDS returns the following error.

```
You successfully installed the OEM_AGENT option. Your OMS host is using an untrusted
 third party certificate.
Configure your OMS host with the trusted certificates from your third party.
```

If this error is returned, the Management Agent option isn't enabled until the problem is corrected. For information about correcting the problem, see the My Oracle Support document 2202569.1.

Console

To add the Management Agent option to your DB instance

1. Determine the option group you want to use. You can create a new option group or use an existing option group. If you want to use an existing option group, skip to the next step. Otherwise, create a custom DB option group with the following settings:

   a. For **Engine** choose the oracle edition for your DB instance.

   b. For **Major engine version** choose the version of your DB instance.

   For more information, see Creating an option group.
2. Add the **OEM_AGENT** option to the option group, and configure the option settings. For more information about adding options, see Adding an option to an option group. For more information about each setting, see Option settings for Management Agent.
3. Apply the option group to a new or existing DB instance:

   - For a new DB instance, you apply the option group when you launch the instance. For more information, see Creating an Amazon RDS DB instance.
   - For an existing DB instance, you apply the option group by modifying the instance and attaching the new option group. For more information, see Modifying an Amazon RDS DB instance.

AWS CLI

The following example uses the AWS CLI add-option-to-option-group command to add the `OEM_AGENT` option to an option group called `myoptiongroup`.

For Linux, macOS, or Unix:

```
aws rds add-option-to-option-group \
    --option-group-name "myoptiongroup" \
    --options
 OptionName=OEM_AGENT,OptionVersion=13.1.0.0.v1,Port=3872,VpcSecurityGroupMemberships=sg-123456
{Name=OMS_PORT,Value=4903},{Name=AGENT_REGISTRATION_PASSWORD,Value=password}] \
    --apply-immediately
```

For Windows:

```
aws rds add-option-to-option-group ^
    --option-group-name "myoptiongroup" ^
    --options
 OptionName=OEM_AGENT,OptionVersion=13.1.0.0.v1,Port=3872,VpcSecurityGroupMemberships=sg-123456
{Name=OMS_PORT,Value=4903},{Name=AGENT_REGISTRATION_PASSWORD,Value=password}] ^
    --apply-immediately
```

Step 2: Unlocking the DBSNMP user account

The Management Agent uses the DBSNMP user account to connect to the database and report issues to Oracle Enterprise Manager. In a CDB, DBSNMP is a common user. This user account is necessary for both the Management Agent and OEM Database Express. By default, this account is locked. The procedure for unlocking this account differs depending on whether your database uses the non-CDB or CDB architecture.

To unlock the DBSNMP user account

1. In SQL*Plus or another Oracle SQL application, log in to your DB instance as your master user.
2. Do either of the following actions, depending on the database architecture:

   Your database is a non-CDB.

   Run the following SQL statement:

   ```
   ALTER USER dbsnmp IDENTIFIED BY new_password ACCOUNT UNLOCK;
   ```

   Your database is a CDB.

   Run the following stored procedure to unlock the DBSNMP account:

```
EXEC rdsadmin.rdsadmin_util.reset_oem_agent_password('new_password');
```

If you receive an error stating that the procedure doesn't exist, reboot your CDB instance to install it automatically. For more information, see Rebooting a DB instance.

Step 3: Adding your targets to the Management Agent console

To add a DB instance as a target, make sure you know the endpoint and port. For information about finding the endpoint for your Amazon RDS DB instance, see Finding the endpoint of your RDS for Oracle DB instance. If your database uses the CDB architecture, then add the CDB$ROOT container separately as a target.

To add targets to the Management Agent console

1. In your OMS console, choose **Setup**, **Add Target**, **Add Targets Manually**.
2. Choose **Add Targets Declaratively by Specifying Target Monitoring Properties**.
3. For **Target Type**, choose **Database Instance**.
4. For **Monitoring Agent**, choose the agent with the identifier that is the same as your RDS DB instance identifier.
5. Choose **Add Manually**.
6. Enter the endpoint for your Amazon RDS DB instance, or choose it from the host name list. Make sure that the specified host name matches the endpoint of the Amazon RDS DB instance.
7. Specify the following database properties:
   - For **Target name**, enter a name.
   - For **Database system name**, enter a name.
   - For **Monitor username**, enter **dbsnmp**.
   - For **Monitor password**, enter the password from Step 2: Unlocking the DBSNMP user account.
   - For **Role**, enter **normal**.
   - For **Oracle home path**, enter **/oracle**.
   - For **Listener Machine name**, the agent identifier already appears.
   - For **Port**, enter the database port. The RDS default port is 1521.

- For **Database name**, enter the name of your database. If your database is a CDB, this name is RDSCDB.

8. Choose **Test Connection**.
9. Choose **Next**. The target database appears in your list of monitored resources.

Administering the Management Agent

You can use Amazon RDS procedures to run certain EMCTL commands on the Management Agent. By running these procedures, you can do the tasks listed following.

> **Note**
>
> Tasks are executed asynchronously.

Tasks

- Getting the status of the Management Agent
- Restarting the Management Agent
- Listing the targets monitored by the Management Agent
- Listing the collection threads monitored by the Management Agent
- Clearing the Management Agent state
- Making the Management Agent upload its OMS
- Pinging the OMS
- Viewing the status of an ongoing task

Getting the status of the Management Agent

To get the status of the Management Agent, run the Amazon RDS procedure `rdsadmin.rdsadmin_oem_agent_tasks.get_status_oem_agent`. This procedure is equivalent to the `emctl status agent` command.

The following procedure creates a task to get the Management Agent's status and returns the ID of the task.

```
SELECT rdsadmin.rdsadmin_oem_agent_tasks.get_status_oem_agent() as TASK_ID from DUAL;
```

To view the result by displaying the task's output file, see Viewing the status of an ongoing task.

Restarting the Management Agent

To restart the Management Agent, run the Amazon RDS procedure `rdsadmin.rdsadmin_oem_agent_tasks.restart_oem_agent`. This procedure is equivalent to running the `emctl stop agent` and `emctl start agent` commands.

The following procedure creates a task to restart the Management Agent and returns the ID of the task.

```
SELECT rdsadmin.rdsadmin_oem_agent_tasks.restart_oem_agent as TASK_ID from DUAL;
```

To view the result by displaying the task's output file, see Viewing the status of an ongoing task.

Listing the targets monitored by the Management Agent

To list the targets monitored by the Management Agent, run the Amazon RDS procedure `rdsadmin.rdsadmin_oem_agent_tasks.list_targets_oem_agent`. This procedure is equivalent to running the `emctl config agent listtargets` command.

The following procedure creates a task to list the targets monitored by the Management Agent and returns the ID of the task.

```
SELECT rdsadmin.rdsadmin_oem_agent_tasks.list_targets_oem_agent as TASK_ID from DUAL;
```

To view the result by displaying the task's output file, see Viewing the status of an ongoing task.

Listing the collection threads monitored by the Management Agent

To list of all the running, ready, and scheduled collection threads monitored by the Management Agent, run the Amazon RDS procedure `rdsadmin.rdsadmin_oem_agent_tasks.list_clxn_threads_oem_agent`. This procedure is equivalent to the `emctl status agent scheduler` command.

The following procedure creates a task to list the collection threads and returns the ID of the task.

```
SELECT rdsadmin.rdsadmin_oem_agent_tasks.list_clxn_threads_oem_agent() as TASK_ID from
 DUAL;
```

To view the result by displaying the task's output file, see Viewing the status of an ongoing task.

Clearing the Management Agent state

To clear the Management Agent's state, run the Amazon RDS procedure `rdsadmin.rdsadmin_oem_agent_tasks.clearstate_oem_agent`. This procedure is equivalent to running the `emctl clearstate agent` command.

The following procedure creates a task that clears the Management Agent's state and returns the ID of the task.

```
SELECT rdsadmin.rdsadmin_oem_agent_tasks.clearstate_oem_agent() as TASK_ID from DUAL;
```

To view the result by displaying the task's output file, see Viewing the status of an ongoing task.

Making the Management Agent upload its OMS

To make the Management Agent upload the Oracle Management Server (OMS) associated with it, run the Amazon RDS procedure `rdsadmin.rdsadmin_oem_agent_tasks.upload_oem_agent`. This procedure is equivalent to running the `emclt upload agent` command.

The following procedure creates a task that makes the Management Agent upload its associated OMS and return the ID of the task.

```
SELECT rdsadmin.rdsadmin_oem_agent_tasks.upload_oem_agent() as TASK_ID from DUAL;
```

To view the result by displaying the task's output file, see Viewing the status of an ongoing task.

Pinging the OMS

To ping the Management Agent's OMS, run the Amazon RDS procedure `rdsadmin.rdsadmin_oem_agent_tasks.ping_oms_oem_agent`. This procedure is equivalent to running the `emctl pingOMS` command.

The following procedure creates a task that pings the Management Agent's OMS and returns the ID of the task.

```
SELECT rdsadmin.rdsadmin_oem_agent_tasks.ping_oms_oem_agent() as TASK_ID from DUAL;
```

To view the result by displaying the task's output file, see Viewing the status of an ongoing task.

Viewing the status of an ongoing task

You can view the status of an ongoing task in a bdump file. The bdump files are located in the `/rdsdbdata/log/trace` directory. Each bdump file name is in the following format.

```
dbtask-task-id.log
```

When you want to monitor a task, replace *`task-id`* with the ID of the task that you want to monitor.

To view the contents of bdump files, run the Amazon RDS procedure `rdsadmin.rds_file_util.read_text_file`. The following query returns the contents of the `dbtask-1546988886389-2444.log` bdump file.

```
SELECT text FROM
 table(rdsadmin.rds_file_util.read_text_file('BDUMP','dbtask-1546988886389-2444.log'));
```

For more information about the Amazon RDS procedure `rdsadmin.rds_file_util.read_text_file`, see Reading files in a DB instance directory.

Removing the Management Agent option

You can remove the OEM Agent from a DB instance. After you remove the OEM Agent, you don't need to restart your DB instance.

To remove the OEM Agent from a DB instance, do one of the following:

- Remove the OEM Agent option from the option group it belongs to. This change affects all DB instances that use the option group. For more information, see Removing an option from an option group.
- Modify the DB instance and specify a different option group that doesn't include the OEM Agent option. This change affects a single DB instance. You can specify the default (empty) option group, or a different custom option group. For more information, see Modifying an Amazon RDS DB instance.

Oracle Label Security

Amazon RDS supports Oracle Label Security for the Enterprise Edition of Oracle Database through the use of the OLS option.

Most database security controls access at the object level. Oracle Label Security provides fine-grained control of access to individual table rows. For example, you can use Label Security to enforce regulatory compliance with a policy-based administration model. You can use Label Security policies to control access to sensitive data, and restrict access to only users with the appropriate clearance level. For more information, see Introduction to Oracle Label Security in the Oracle documentation.

Topics

Requirements for Oracle Label Security

Familiarize yourself with the following requirements for Oracle Label Security:

- Your DB instance must use the Bring Your Own License model. For more information, see RDS for Oracle licensing options.
- You must have a valid license for Oracle Enterprise Edition with Software Update License and Support.
- Your Oracle license must include the Label Security option.

Considerations when using Oracle Label Security

To use Oracle Label Security, you create policies that control access to specific rows in your tables. For more information, see Creating an Oracle Label Security policy in the Oracle documentation.

Consider the following:

- Oracle Label Security is a permanent and persistent option. Because the option is permanent, you can't remove it from an option group. If you add Oracle Label Security to an option group

and associate it with your DB instance, you can later associate a different option group with your DB instance, but this group must also contain the Oracle Label Security option.

- When you work with Label Security, you perform all actions as the LBAC_DBA role. The master user for your DB instance is granted the LBAC_DBA role. You can grant the LBAC_DBA role to other users so that they can administer Label Security policies.
- Make sure to grant access to the OLS_ENFORCEMENT package to any new users who require access to Oracle Label Security. To grant access to the OLS_ENFORCEMENT package, connect to the DB instance as the master user and run the following SQL statement:

```
GRANT ALL ON LBACSYS.OLS_ENFORCEMENT TO username;
```

- You can configure Label Security through Oracle Enterprise Manager (OEM) Cloud Control. Amazon RDS supports OEM Cloud Control through the Management Agent option. For more information, see Oracle Management Agent for Enterprise Manager Cloud Control.

Adding the Oracle Label Security option

The general process for adding the Oracle Label Security option to a DB instance is the following:

1. Create a new option group, or copy or modify an existing option group.
2. Add the option to the option group.

> **Important**
>
> Oracle Label Security is a permanent and persistent option.

3. Associate the option group with the DB instance.

After you add the Label Security option, as soon as the option group is active, Label Security is active.

To add the label security option to a DB instance

1. Determine the option group you want to use. You can create a new option group or use an existing option group. If you want to use an existing option group, skip to the next step. Otherwise, create a custom DB option group with the following settings:

   a. For **Engine**, choose **oracle-ee**.

b. For **Major engine version**, choose the version of your DB instance.

For more information, see Creating an option group.

2. Add the **OLS** option to the option group. For more information about adding options, see Adding an option to an option group.

> **Important**
>
> If you add Label Security to an existing option group that is already attached to one or more DB instances, all the DB instances are restarted.

3. Apply the option group to a new or existing DB instance:

- For a new DB instance, you apply the option group when you launch the instance. For more information, see Creating an Amazon RDS DB instance.
- For an existing DB instance, you apply the option group by modifying the instance and attaching the new option group. When you add the Label Security option to an existing DB instance, a brief outage occurs while your DB instance is automatically restarted. For more information, see Modifying an Amazon RDS DB instance.

Troubleshooting

The following are issues you might encounter when you use Oracle Label Security.

Issue	Troubleshooting suggestions
When you try to create a policy, you see an error message similar to the following : `insufficient authorization for the SYSDBA package`.	A known issue with Oracle's Label Security feature prevents users with usernames of 16 or 24 characters from running Label Security commands. You can create a new user with a different number of characters, grant LBAC_DBA to the new user, log in as the new user, and run the OLS commands as the new user. For additional information, contact Oracle Support.

Oracle Locator

Amazon RDS supports Oracle Locator through the use of the LOCATOR option. Oracle Locator provides capabilities that are typically required to support internet and wireless service-based applications and partner-based GIS solutions. Oracle Locator is a limited subset of Oracle Spatial. For more information, see Oracle Locator in the Oracle documentation.

> **Important**
>
> If you use Oracle Locator, Amazon RDS automatically updates your DB instance to the latest Oracle PSU if there are security vulnerabilities with a Common Vulnerability Scoring System (CVSS) score of 9+ or other announced security vulnerabilities.

Supported database releases for Oracle Locator

RDS for Oracle supports Oracle Locator for Oracle Database 19c. Oracle Locator isn't supported for Oracle Database 21c, but its functionality is available in the Oracle Spatial option. Formerly, the Spatial option required additional licenses. Oracle Locator represented a subset of Oracle Spatial features and didn't require additional licenses. In 2019, Oracle announced that all Oracle Spatial features were included in the Enterprise Edition and Standard Edition 2 licenses without additional cost. Consequently, the Oracle Spatial option no longer required additional licensing. For more information, see Machine Learning, Spatial and Graph - No License Required! in the Oracle Database Insider blog.

Prerequisites for Oracle Locator

The following are prerequisites for using Oracle Locator:

- Your DB instance must be of sufficient class. Oracle Locator is not supported for the db.t3.micro or db.t3.small DB instance classes. For more information, see RDS for Oracle DB instance classes.
- Your DB instance must have **Auto Minor Version Upgrade** enabled. This option enables your DB instance to receive minor DB engine version upgrades automatically when they become available and is required for any options that install the Oracle Java Virtual Machine (JVM). Amazon RDS uses this option to update your DB instance to the latest Oracle Patch Set Update (PSU) or Release Update (RU). For more information, see Modifying an Amazon RDS DB instance.

Best practices for Oracle Locator

The following are best practices for using Oracle Locator:

- For maximum security, use the LOCATOR option with Secure Sockets Layer (SSL). For more information, see Oracle Secure Sockets Layer.
- Configure your DB instance to restrict access to your DB instance. For more information, see Scenarios for accessing a DB instance in a VPC and Working with a DB instance in a VPC.

Adding the Oracle Locator option

The following is the general process for adding the LOCATOR option to a DB instance:

1. Create a new option group, or copy or modify an existing option group.
2. Add the option to the option group.
3. Associate the option group with the DB instance.

If Oracle Java Virtual Machine (JVM) is *not* installed on the DB instance, there is a brief outage while the LOCATOR option is added. There is no outage if Oracle Java Virtual Machine (JVM) is already installed on the DB instance. After you add the option, you don't need to restart your DB instance. As soon as the option group is active, Oracle Locator is available.

> **Note**
>
> During this outage, password verification functions are disabled briefly. You can also expect to see events related to password verification functions during the outage. Password verification functions are enabled again before the Oracle DB instance is available.

To add the LOCATOR option to a DB instance

1. Determine the option group that you want to use. You can create a new option group or use an existing option group. If you want to use an existing option group, skip to the next step. Otherwise, create a custom DB option group with the following settings:
   a. For **Engine**, choose the oracle edition for your DB instance.
   b. For **Major engine version**, choose the version of your DB instance.

For more information, see Creating an option group.

2. Add the **LOCATOR** option to the option group. For more information about adding options, see Adding an option to an option group.
3. Apply the option group to a new or existing DB instance:

   - For a new DB instance, you apply the option group when you launch the instance. For more information, see Creating an Amazon RDS DB instance.
   - For an existing DB instance, you apply the option group by modifying the instance and attaching the new option group. For more information, see Modifying an Amazon RDS DB instance.

Using Oracle Locator

After you enable the Oracle Locator option, you can begin using it. You should only use Oracle Locator features. Don't use any Oracle Spatial features unless you have a license for Oracle Spatial.

For a list of features that are supported for Oracle Locator, see Features Included with Locator in the Oracle documentation.

For a list of features that are not supported for Oracle Locator, see Features Not Included with Locator in the Oracle documentation.

Removing the Oracle Locator option

After you drop all objects that use data types provided by the `LOCATOR` option, you can remove the option from a DB instance. If Oracle Java Virtual Machine (JVM) is *not* installed on the DB instance, there is a brief outage while the `LOCATOR` option is removed. There is no outage if Oracle Java Virtual Machine (JVM) is already installed on the DB instance. After you remove the `LOCATOR` option, you don't need to restart your DB instance.

To drop the `LOCATOR` option

1. Back up your data.

> **Warning**
>
> If the instance uses data types that were enabled as part of the option, and if you remove the LOCATOR option, you can lose data. For more information, see Backing up, restoring, and exporting data.

2. Check whether any existing objects reference data types or features of the LOCATOR option.

   If LOCATOR options exist, the instance can get stuck when applying the new option group that doesn't have the LOCATOR option. You can identify the objects by using the following queries:

```
SELECT OWNER, SEGMENT_NAME, TABLESPACE_NAME, BYTES/1024/1024 mbytes
FROM   DBA_SEGMENTS
WHERE  SEGMENT_TYPE LIKE '%TABLE%'
AND    (OWNER, SEGMENT_NAME) IN
       (SELECT DISTINCT OWNER, TABLE_NAME
        FROM   DBA_TAB_COLUMNS
        WHERE  DATA_TYPE='SDO_GEOMETRY'
        AND    OWNER <> 'MDSYS')
ORDER BY 1,2,3,4;

SELECT OWNER, TABLE_NAME, COLUMN_NAME
FROM   DBA_TAB_COLUMNS
WHERE  DATA_TYPE = 'SDO_GEOMETRY'
AND    OWNER <> 'MDSYS'
ORDER BY 1,2,3;
```

3. Drop any objects that reference data types or features of the LOCATOR option.
4. Do one of the following:

   - Remove the LOCATOR option from the option group it belongs to. This change affects all DB instances that use the option group. For more information, see Removing an option from an option group.
   - Modify the DB instance and specify a different option group that doesn't include the LOCATOR option. This change affects a single DB instance. You can specify the default (empty) option group, or a different custom option group. For more information, see Modifying an Amazon RDS DB instance.

Oracle native network encryption

Amazon RDS supports Oracle native network encryption (NNE). With the `NATIVE_NETWORK_ENCRYPTION` option, you can encrypt data as it moves to and from a DB instance. Amazon RDS supports NNE for all editions of Oracle Database.

A detailed discussion of Oracle native network encryption is beyond the scope of this guide, but you should understand the strengths and weaknesses of each algorithm and key before you decide on a solution for your deployment. For information about the algorithms and keys that are available through Oracle native network encryption, see Configuring network data encryption in the Oracle documentation. For more information about AWS security, see the AWS security center.

> **Note**
>
> You can use Native Network Encryption or Secure Sockets Layer, but not both. For more information, see Oracle Secure Sockets Layer.

NATIVE_NETWORK_ENCRYPTION option settings

You can specify encryption requirements on both the server and the client. The DB instance can act as a client when, for example, it uses a database link to connect to another database. You might want to avoid forcing encryption on the server side. For example, you might not want to force all client communications to use encryption because the server requires it. In this case, you can force encryption on the client side using the `SQLNET.*CLIENT` options.

Amazon RDS supports the following settings for the `NATIVE_NETWORK_ENCRYPTION` option.

> **Note**
>
> When you use commas to separate values for an option setting, don't put a space after the comma.

Option setting	Valid values	Default values	Description
`SQLNET.ALLOW_WEAK_CRYPTO_CLIENTS`	`TRUE`, `FALSE`	`TRUE`	The behavior of the server when a client using a non-secure cipher

Option setting	Valid values	Default values	Description
			attempts to connect to the database. If TRUE, clients can connect even if they aren't patched with the July 2021 PSU. If the setting is FALSE, clients can connect to the database only when they are patched with the July 2021 PSU. Before you set SQLNET.ALLOW_WEAK_CRYPTO_CLIENTS to FALSE, make sure that the following conditions are met: • SQLNET.ENCRYPTION_TYPES_SERVER and SQLNET.ENCRYPTION_TYPES_CLIENT have one matching encryption method that is not DES, 3DES, or RC4 (all key lengths). • SQLNET.CHECKSUM_TYPES_SERVER and SQLNET.CHECKSUM_TYPES_CLIENT have one matching secure checksumming method that is not MD5. • The client is patched with the July 2021 PSU. If the client isn't patched, the client loses the connection and receives the ORA-12269 error.

Option setting	Valid values	Default values	Description
SQLNET.ALLOW_WEAK_CRYPTO	TRUE, FALSE	TRUE	The behavior of the server when a client using a non-secure cipher attempts to connect to the database. The following ciphers are considered not secure: • DES encryption method (all key lengths) • 3DES encryption method (all key lengths) • RC4 encryption method (all key lengths) • MD5 checksumming method If the setting is TRUE, clients can connect when they use the preceding non-secure ciphers. If the setting is FALSE, the database prevents clients from connecting when they use the preceding non-secure ciphers. Before you set SQLNET.ALLOW_WEAK_CRYPTO to FALSE, make sure that the following conditions are met: • SQLNET.ENCRYPTION_TYPES_SERVER and SQLNET.ENCRYPTION_TYPES_CLIENT have one matching encryption method that is not DES, 3DES, or RC4 (all key lengths).

Option setting	Valid values	Default values	Description
			• SQLNET.CHECKSUM_TYPES_SERVER and SQLNET.CHECKSUM_TYPES_CLIENT have one matching secure checksumming method that is not MD5. • The client is patched with the July 2021 PSU. If the client isn't patched, the client loses the connection and receives the ORA-12269 error.
SQLNET.CRYPTO_CHECKSUM_CLIENT	Accepted Rejected Requested , Required	Requested	The data integrity behavior when a DB instance connects to the client, or a server acting as a client. When a DB instance uses a database link, it acts as a client. Requested indicates that the client doesn't require the DB instance to perform a checksum.
SQLNET.CRYPTO_CHECKSUM_SERVER	Accepted Rejected Requested , Required	Requested	The data integrity behavior when a client, or a server acting as a client, connects to the DB instance. When a DB instance uses a database link, it acts as a client. Requested indicates that the DB instance doesn't require the client to perform a checksum.

Option setting	Valid values	Default values	Description
SQLNET.CRYPTO_CHECKSUM_TYPES_CLIENT	SHA256, SHA384, SHA512, SHA1, MD5	SHA256, SHA384, SHA512	A list of checksum algorithms. You can specify either one value or a comma-separated list of values. If you use a comma, don't insert a space after the comma; otherwise, you receive an InvalidParameterValue error. This parameter and SQLNET.CRYPTO_CHECKSUM_TYPES_SERVER must have a common cipher.
SQLNET.CRYPTO_CHECKSUM_TYPES_SERVER	SHA256, SHA384, SHA512, SHA1, MD5	SHA256, SHA384, SHA512, SHA1, MD5	A list of checksum algorithms. You can specify either one value or a comma-separated list of values. If you use a comma, don't insert a space after the comma; otherwise, you receive an InvalidParameterValue error. This parameter and SQLNET.CRYPTO_CHECKSUM_TYPES_CLIENT must have a common cipher.
SQLNET.ENCRYPTION_CLIENT	Accepted Rejected Requested , Required	Requested	The encryption behavior of the client when a client, or a server acting as a client, connects to the DB instance. When a DB instance uses a database link, it acts as a client. Requested indicates that the client does not require traffic from the server to be encrypted.

Option setting	Valid values	Default values	Description
SQLNET.ENCRYPTION_SERVER	Accepted Rejected Requested , Required	Requested	The encryption behavior of the server when a client, or a server acting as a client, connects to the DB instance. When a DB instance uses a database link, it acts as a client. Requested indicates that the DB instance does not require traffic from the client to be encrypted.

Option setting	Valid values	Default values	Description
SQLNET.ENCRYPTION_TYPES_CLIENT	RC4_256, AES256, AES192, 3DES168, RC4_128, AES128, 3DES112, RC4_56, DES, RC4_40, DES40	RC4_256, AES256, AES192, 3DES168, RC4_128, AES128, 3DES112, RC4_56, DES, RC4_40, DES40	A list of encryption algorithms used by the client. The client attempts to decrypt the server input by trying each algorithm in order, proceeding until an algorithm succeeds or the end of the list is reached. Amazon RDS uses the following default list from Oracle. RDS starts with RC4_256 and proceeds down the list in order. You can change the order or limit the algorithms that the DB instance will accept. 1. RC4_256: RSA RC4 (256-bit key size) 2. AES256: AES (256-bit key size) 3. AES192: AES (192-bit key size) 4. 3DES168: 3-key Triple-DES (112-bit effective key size) 5. RC4_128: RSA RC4 (128-bit key size) 6. AES128: AES (128-bit key size) 7. 3DES112: 2-key Triple-DES (80-bit effective key size) 8. RC4_56: RSA RC4 (56-bit key size) 9. DES: Standard DES (56-bit key size) 10. RC4_40: RSA RC4 (40-bit key size) 11. DES40: DES40 (40-bit key size) You can specify either one value or a comma-separated list of values. If you a comma, don't insert a space after

Option setting	Valid values	Default values	Description
			the comma; otherwise, you receive an `InvalidParameterValue` error. This parameter and `SQLNET.SQLNET.ENCRYPTION_TYPES_SERVER` must have a common cipher.

Option setting	Valid values	Default values	Description
SQLNET.ENCRYPTION_TYPES_SERVER	RC4_256, AES256, AES192, 3DES168, RC4_128, AES128, 3DES112, RC4_56, DES, RC4_40, DES40	RC4_256, AES256, AES192, 3DES168, RC4_128, AES128, 3DES112, RC4_56, DES, RC4_40, DES40	A list of encryption algorithms used by the DB instance. The DB instance uses each algorithm, in order, to attempt to decrypt the client input until an algorithm succeeds or until the end of the list is reached. Amazon RDS uses the following default list from Oracle. You can change the order or limit the algorithms that the client will accept. 1. RC4_256: RSA RC4 (256-bit key size) 2. AES256: AES (256-bit key size) 3. AES192: AES (192-bit key size) 4. 3DES168: 3-key Triple-DES (112-bit effective key size) 5. RC4_128: RSA RC4 (128-bit key size) 6. AES128: AES (128-bit key size) 7. 3DES112: 2-key Triple-DES (80-bit effective key size) 8. RC4_56: RSA RC4 (56-bit key size) 9. DES: Standard DES (56-bit key size) 10RC4_40: RSA RC4 (40-bit key size) 11DES40: DES40 (40-bit key size) You can specify either one value or a comma-separated list of values. If you a comma, don't insert a space after the comma; otherwise, you receive an InvalidParameterValue error.

Option setting	Valid values	Default values	Description
			This parameter and SQLNET.SQLNET.ENCRYPTION_TYPES_SERVER must have a common cipher.

Adding the NATIVE_NETWORK_ENCRYPTION option

The general process for adding the NATIVE_NETWORK_ENCRYPTION option to a DB instance is the following:

1. Create a new option group, or copy or modify an existing option group.
2. Add the option to the option group.
3. Associate the option group with the DB instance.

When the option group is active, NNE is active.

To add the NATIVE_NETWORK_ENCRYPTION option to a DB instance using the AWS Management Console

1. For **Engine**, choose the Oracle edition that you want to use. NNE is supported on all editions.
2. For **Major engine version**, choose the version of your DB instance.

   For more information, see Creating an option group.
3. Add the **NATIVE_NETWORK_ENCRYPTION** option to the option group. For more information about adding options, see Adding an option to an option group.

   > **Note**
   >
   > After you add the **NATIVE_NETWORK_ENCRYPTION** option, you don't need to restart your DB instances. As soon as the option group is active, NNE is active.

4. Apply the option group to a new or existing DB instance:

- For a new DB instance, you apply the option group when you launch the instance. For more information, see Creating an Amazon RDS DB instance.
- For an existing DB instance, you apply the option group by modifying the instance and attaching the new option group. After you add the **NATIVE_NETWORK_ENCRYPTION** option, you don't need to restart your DB instance. As soon as the option group is active, NNE is active. For more information, see Modifying an Amazon RDS DB instance.

Setting NNE values in the sqlnet.ora

With Oracle native network encryption, you can set network encryption on the server side and client side. The client is the computer used to connect to the DB instance. You can specify the following client settings in the sqlnet.ora:

- `SQLNET.ALLOW_WEAK_CRYPTO`
- `SQLNET.ALLOW_WEAK_CRYPTO_CLIENTS`
- `SQLNET.CRYPTO_CHECKSUM_CLIENT`
- `SQLNET.CRYPTO_CHECKSUM_TYPES_CLIENT`
- `SQLNET.ENCRYPTION_CLIENT`
- `SQLNET.ENCRYPTION_TYPES_CLIENT`

For information, see Configuring network data encryption and integrity for Oracle servers and clients in the Oracle documentation.

Sometimes, the DB instance rejects a connection request from an application. For example, a rejection can occur when the encryption algorithms on the client and on the server don't match. To test Oracle native network encryption, add the following lines to the sqlnet.ora file on the client:

```
DIAG_ADR_ENABLED=off
TRACE_DIRECTORY_CLIENT=/tmp
TRACE_FILE_CLIENT=nettrace
TRACE_LEVEL_CLIENT=16
```

When a connection is attempted, the preceding lines generate a trace file on the client called `/tmp/nettrace*`. The trace file contains information about the connection. For more information about connection-related issues when you are using Oracle Native Network Encryption, see About negotiating encryption and integrity in the Oracle Database documentation.

Modifying NATIVE_NETWORK_ENCRYPTION option settings

After you enable the NATIVE_NETWORK_ENCRYPTION option, you can modify its settings. Currently, you can modify NATIVE_NETWORK_ENCRYPTION option settings only with the AWS CLI or RDS API. You can't use the console. The following example modifies two settings in the option.

```
aws rds add-option-to-option-group \
    --option-group-name my-option-group \
    --options
 "OptionName=NATIVE_NETWORK_ENCRYPTION,OptionSettings=[{Name=SQLNET.CRYPTO_CHECKSUM_TYPES_SERVE
{Name=SQLNET.CRYPTO_CHECKSUM_TYPES_SERVER,Value=SHA256}]" \
    --apply-immediately
```

To learn how to modify option settings using the CLI, see AWS CLI. For more information about each setting, see NATIVE_NETWORK_ENCRYPTION option settings.

Topics

- Modifying CRYPTO_CHECKSUM_* values
- Modifying ALLOW_WEAK_CRYPTO* settings

Modifying CRYPTO_CHECKSUM_* values

If you modify **NATIVE_NETWORK_ENCRYPTION** option settings, make sure that the following option settings have at least one common cipher:

- SQLNET.CRYPTO_CHECKSUM_TYPES_SERVER
- SQLNET.CRYPTO_CHECKSUM_TYPES_CLIENT

The following example shows a scenario in which you modify SQLNET.CRYPTO_CHECKSUM_TYPES_SERVER. The configuration is valid because the CRYPTO_CHECKSUM_TYPES_CLIENT and CRYPTO_CHECKSUM_TYPES_SERVER both use SHA256.

Option setting	Values before modification	Values after modification
SQLNET.CRYPTO_CHECKSUM_TYPES_CLIENT	**SHA256**, SHA384, SHA512	No change

Option setting	Values before modification	Values after modification
SQLNET.CRYPTO_CHECKSUM_TYPES_SERVER	**SHA256**, SHA384, SHA512, SHA1, MD5	SHA1,MD5, **SHA256**

For another example, assume that you want to modify SQLNET.CRYPTO_CHECKSUM_TYPES_SERVER from its default setting to SHA1,MD5. In this case, make sure you set SQLNET.CRYPTO_CHECKSUM_TYPES_CLIENT to SHA1 or MD5. These algorithms aren't included in the default values for SQLNET.CRYPTO_CHECKSUM_TYPES_CLIENT.

Modifying ALLOW_WEAK_CRYPTO* settings

To set the SQLNET.ALLOW_WEAK_CRYPTO* options from the default value to FALSE, make sure that the following conditions are met:

- SQLNET.ENCRYPTION_TYPES_SERVER and SQLNET.ENCRYPTION_TYPES_CLIENT have one matching secure encryption method. A method is considered secure if it's not DES, 3DES, or RC4 (all key lengths).
- SQLNET.CHECKSUM_TYPES_SERVER and SQLNET.CHECKSUM_TYPES_CLIENT have one matching secure checksumming method. A method is considered secure if it's not MD5.
- The client is patched with the July 2021 PSU. If the client isn't patched, the client loses the connection and receives the ORA-12269 error.

The following example shows sample NNE settings. Assume that you want to set SQLNET.ENCRYPTION_TYPES_SERVER and SQLNET.ENCRYPTION_TYPES_CLIENT to FALSE, thereby blocking non-secure connections. The checksum option settings meet the prerequisites because they both have SHA256. However, SQLNET.ENCRYPTION_TYPES_CLIENT and SQLNET.ENCRYPTION_TYPES_SERVER use the DES, 3DES, and RC4 encryption methods, which are non-secure. Therefore, to set the SQLNET.ALLOW_WEAK_CRYPTO* options to FALSE, first set SQLNET.ENCRYPTION_TYPES_SERVER and SQLNET.ENCRYPTION_TYPES_CLIENT to a secure encryption method such as AES256.

Option setting	Values
SQLNET.CRYPTO_CHECKSUM_TYPES_CLIENT	SHA256, SHA384, SHA512
SQLNET.CRYPTO_CHECKSUM_TYPES_SERVER	SHA1,MD5,SHA256
SQLNET.ENCRYPTION_TYPES_CLIENT	RC4_256, 3DES168, DES40
SQLNET.ENCRYPTION_TYPES_SERVER	RC4_256, 3DES168, DES40

Removing the NATIVE_NETWORK_ENCRYPTION option

You can remove NNE from a DB instance.

To remove the NATIVE_NETWORK_ENCRYPTION option from a DB instance, do one of the following:

- To remove the option from multiple DB instances, remove the NATIVE_NETWORK_ENCRYPTION option from the option group they belong to. This change affects all DB instances that use the option group. After you remove the NATIVE_NETWORK_ENCRYPTION option, you don't need to restart your DB instances. For more information, see Removing an option from an option group.
- To remove the option from a single DB instance, modify the DB instance and specify a different option group that doesn't include the NATIVE_NETWORK_ENCRYPTION option. You can specify the default (empty) option group, or a different custom option group. After you remove the NATIVE_NETWORK_ENCRYPTION option, you don't need to restart your DB instance. For more information, see Modifying an Amazon RDS DB instance.

Oracle OLAP

Amazon RDS supports Oracle OLAP through the use of the OLAP option. This option provides Online Analytical Processing (OLAP) for Oracle DB instances. You can use Oracle OLAP to analyze large amounts of data by creating dimensional objects and cubes in accordance with the OLAP standard. For more information, see the Oracle documentation.

> **Important**
>
> If you use Oracle OLAP, Amazon RDS automatically updates your DB instance to the latest Oracle PSU if there are security vulnerabilities with a Common Vulnerability Scoring System (CVSS) score of 9+ or other announced security vulnerabilities.

Amazon RDS supports Oracle OLAP for the Enterprise Edition of Oracle Database 19c and higher.

Prerequisites for Oracle OLAP

The following are prerequisites for using Oracle OLAP:

- You must have an Oracle OLAP license from Oracle. For more information, see Licensing Information in the Oracle documentation.
- Your DB instance must be of a sufficient instance class. Oracle OLAP isn't supported for the db.t3.micro or db.t3.small DB instance classes. For more information, see RDS for Oracle DB instance classes.
- Your DB instance must have **Auto Minor Version Upgrade** enabled. This option enables your DB instance to receive minor DB engine version upgrades automatically when they become available and is required for any options that install the Oracle Java Virtual Machine (JVM). Amazon RDS uses this option to update your DB instance to the latest Oracle Patch Set Update (PSU) or Release Update (RU). For more information, see Modifying an Amazon RDS DB instance.
- Your DB instance must not have a user named OLAPSYS. If it does, the OLAP option installation fails.

Best practices for Oracle OLAP

The following are best practices for using Oracle OLAP:

- For maximum security, use the OLAP option with Secure Sockets Layer (SSL). For more information, see Oracle Secure Sockets Layer.
- Configure your DB instance to restrict access to your DB instance. For more information, see Scenarios for accessing a DB instance in a VPC and Working with a DB instance in a VPC.

Adding the Oracle OLAP option

The following is the general process for adding the OLAP option to a DB instance:

1. Create a new option group, or copy or modify an existing option group.
2. Add the option to the option group.
3. Associate the option group with the DB instance.

If Oracle Java Virtual Machine (JVM) is *not* installed on the DB instance, there is a brief outage while the OLAP option is added. There is no outage if Oracle Java Virtual Machine (JVM) is already installed on the DB instance. After you add the option, you don't need to restart your DB instance. As soon as the option group is active, Oracle OLAP is available.

To add the OLAP option to a DB instance

1. Determine the option group that you want to use. You can create a new option group or use an existing option group. If you want to use an existing option group, skip to the next step. Otherwise, create a custom DB option group with the following settings:

   - For **Engine**, choose the Oracle edition for your DB instance.
   - For **Major engine version**, choose the version of your DB instance.

   For more information, see Creating an option group.
2. Add the **OLAP** option to the option group. For more information about adding options, see Adding an option to an option group.
3. Apply the option group to a new or existing DB instance:

   - For a new DB instance, apply the option group when you launch the instance. For more information, see Creating an Amazon RDS DB instance.
   - For an existing DB instance, apply the option group by modifying the instance and attaching the new option group. For more information, see Modifying an Amazon RDS DB instance.

Using Oracle OLAP

After you enable the Oracle OLAP option, you can begin using it. For a list of features that are supported for Oracle OLAP, see the Oracle documentation.

Removing the Oracle OLAP option

After you drop all objects that use data types provided by the OLAP option, you can remove the option from a DB instance. If Oracle Java Virtual Machine (JVM) is *not* installed on the DB instance, there is a brief outage while the OLAP option is removed. There is no outage if Oracle Java Virtual Machine (JVM) is already installed on the DB instance. After you remove the OLAP option, you don't need to restart your DB instance.

To drop the OLAP option

1. Back up your data.

   > **Warning**
   >
   > If the instance uses data types that were enabled as part of the option, and if you remove the OLAP option, you can lose data. For more information, see Backing up, restoring, and exporting data.

2. Check whether any existing objects reference data types or features of the OLAP option.
3. Drop any objects that reference data types or features of the OLAP option.
4. Do one of the following:

   - Remove the OLAP option from the option group it belongs to. This change affects all DB instances that use the option group. For more information, see Removing an option from an option group.
   - Modify the DB instance and specify a different option group that doesn't include the OLAP option. This change affects a single DB instance. You can specify the default (empty) option group, or a different custom option group. For more information, see Modifying an Amazon RDS DB instance.

Oracle Secure Sockets Layer

To enable SSL encryption for an RDS for Oracle DB instance, add the Oracle SSL option to the option group associated with the DB instance. Amazon RDS uses a second port, as required by Oracle, for SSL connections. This approach allows both clear text and SSL-encrypted communication to occur at the same time between a DB instance and SQL*Plus. For example, you can use the port with clear text communication to communicate with other resources inside a VPC while using the port with SSL-encrypted communication to communicate with resources outside the VPC.

> **Note**
>
> You can use either SSL or Native Network Encryption (NNE) on the same RDS for Oracle DB instance, but not both. If you use SSL encryption, make sure to turn off any other connection encryption. For more information, see Oracle native network encryption.

SSL/TLS and NNE are no longer part of Oracle Advanced Security. In RDS for Oracle, you can use SSL encryption with all licensed editions of the following database versions:

- Oracle Database 21c (21.0.0)
- Oracle Database 19c (19.0.0)

TLS versions for the Oracle SSL option

Amazon RDS for Oracle supports Transport Layer Security (TLS) versions 1.0 and 1.2. When you add a new Oracle SSL option, set `SQLNET.SSL_VERSION` explicitly to a valid value. The following values are allowed for this option setting:

- `"1.0"` – Clients can connect to the DB instance using TLS version 1.0 only. For existing Oracle SSL options, `SQLNET.SSL_VERSION` is set to `"1.0"` automatically. You can change the setting if necessary.
- `"1.2"` – Clients can connect to the DB instance using TLS 1.2 only.
- `"1.2 or 1.0"` – Clients can connect to the DB instance using either TLS 1.2 or 1.0.

Cipher suites for the Oracle SSL option

Amazon RDS for Oracle supports multiple SSL cipher suites. By default, the Oracle SSL option is configured to use the `SSL_RSA_WITH_AES_256_CBC_SHA` cipher suite. To specify a different cipher suite to use over SSL connections, use the `SQLNET.CIPHER_SUITE` option setting.

You can specify multiple values for `SQLNET.CIPHER_SUITE`. This technique is useful if you have database links between your DB instances and decide to update your cipher suites.

The following table summarizes SSL support for RDS for Oracle in all editions of Oracle Database 19c and 21c.

Cipher suite (SQLNET.CIPHER_SUITE)	TLS version support (SQLNET.SSL_VERSION)	FIPS support	FedRAMP compliant
SSL_RSA_WITH_AES_256_CBC_SHA (default)	1.0 and 1.2	Yes	No
SSL_RSA_WITH_AES_256_CBC_SHA256	1.2	Yes	No
SSL_RSA_WITH_AES_256_GCM_SHA384	1.2	Yes	No
TLS_ECDHE_RSA_WITH_AES_256_GCM_SHA384	1.2	Yes	Yes
TLS_ECDHE_RSA_WITH_AES_128_GCM_SHA256	1.2	Yes	Yes
TLS_ECDHE_RSA_WITH_AES_256_CBC_SHA384	1.2	Yes	Yes
TLS_ECDHE_RSA_WITH_AES_128_CBC_SHA256	1.2	Yes	Yes
TLS_ECDHE_RSA_WITH_AES_256_CBC_SHA	1.2	Yes	Yes
TLS_ECDHE_RSA_WITH_AES_128_CBC_SHA	1.2	Yes	Yes

FIPS support

RDS for Oracle allows you to use the Federal Information Processing Standard (FIPS) standard for 140-2. FIPS 140-2 is a United States government standard that defines cryptographic module security requirements. You turn on the FIPS standard by setting `FIPS.SSLFIPS_140` to `TRUE` for the Oracle SSL option. When FIPS 140-2 is configured for SSL, the cryptographic libraries encrypt data between the client and the RDS for Oracle DB instance.

Clients must use the cipher suite that is FIPS-compliant. When establishing a connection, the client and RDS for Oracle DB instance negotiate which cipher suite to use when transmitting messages back and forth. The table in Cipher suites for the Oracle SSL option shows the FIPS-compliant SSL cipher suites for each TLS version. For more information, see Oracle database FIPS 140-2 settings in the Oracle Database documentation.

Adding the SSL option

To use SSL, your RDS for Oracle DB instance must be associated with an option group that includes the SSL option.

Console

To add the SSL option to an option group

1. Create a new option group or identify an existing option group to which you can add the SSL option.

   For information about creating an option group, see Creating an option group.
2. Add the SSL option to the option group.

   If you want to use only FIPS-verified cipher suites for SSL connections, set the option `FIPS.SSLFIPS_140` to `TRUE`. For information about the FIPS standard, see FIPS support.

   For information about adding an option to an option group, see Adding an option to an option group.
3. Create a new RDS for Oracle DB instance and associate the option group with it, or modify an RDS for Oracle DB instance to associate the option group with it.

   For information about creating an DB instance, see Creating an Amazon RDS DB instance.

   For information about modifying an DB instance, see Modifying an Amazon RDS DB instance.

AWS CLI

To add the SSL option to an option group

1. Create a new option group or identify an existing option group to which you can add the SSL option.

   For information about creating an option group, see Creating an option group.

2. Add the SSL option to the option group.

   Specify the following option settings:

   - `Port` – The SSL port number
   - `VpcSecurityGroupMemberships` – The VPC security group for which the option is enabled
   - `SQLNET.SSL_VERSION` – The TLS version that client can use to connect to the DB instance

   For example, the following AWS CLI command adds the SSL option to an option group named `ora-option-group`.

   Example

   For Linux, macOS, or Unix:

```
aws rds add-option-to-option-group --option-group-name ora-option-group \
  --options
 'OptionName=SSL,Port=2484,VpcSecurityGroupMemberships="sg-68184619",OptionSettings=[{Name=
```

   For Windows:

```
aws rds add-option-to-option-group --option-group-name ora-option-group ^
  --options
 'OptionName=SSL,Port=2484,VpcSecurityGroupMemberships="sg-68184619",OptionSettings=[{Name=
```

3. Create a new RDS for Oracle DB instance and associate the option group with it, or modify an RDS for Oracle DB instance to associate the option group with it.

   For information about creating an DB instance, see Creating an Amazon RDS DB instance.

For information about modifying an DB instance, see Modifying an Amazon RDS DB instance.

Configuring SQL*Plus to use SSL with an RDS for Oracle DB instance

Before you can connect to an RDS for Oracle DB instance that uses the Oracle SSL option, you must configure SQL*Plus before connecting.

> **Note**
>
> To allow access to the DB instance from the appropriate clients, ensure that your security groups are configured correctly. For more information, see Controlling access with security groups. Also, these instructions are for SQL*Plus and other clients that directly use an Oracle home. For JDBC connections, see Setting up an SSL connection over JDBC.

To configure SQL*Plus to use SSL to connect to an RDS for Oracle DB instance

1. Set the `ORACLE_HOME` environment variable to the location of your Oracle home directory.

   The path to your Oracle home directory depends on your installation. The following example sets the `ORACLE_HOME` environment variable.

   ```
   prompt>export ORACLE_HOME=/home/user/app/user/product/19.0.0/dbhome_1
   ```

   For information about setting Oracle environment variables, see SQL*Plus environment variables in the Oracle documentation, and also see the Oracle installation guide for your operating system.
2. Append `$ORACLE_HOME/lib` to the `LD_LIBRARY_PATH` environment variable.

   The following is an example that sets the LD_LIBRARY_PATH environment variable.

   ```
   prompt>export LD_LIBRARY_PATH=$LD_LIBRARY_PATH:$ORACLE_HOME/lib
   ```
3. Create a directory for the Oracle wallet at `$ORACLE_HOME/ssl_wallet`.

   The following is an example that creates the Oracle wallet directory.

   ```
   prompt>mkdir $ORACLE_HOME/ssl_wallet
   ```

4. Download the certificate bundle .pem file that works for all AWS Regions and put the file in the ssl_wallet directory. For information, see Using SSL/TLS to encrypt a connection to a DB instance or cluster.

5. In the `$ORACLE_HOME/network/admin` directory, modify or create the `tnsnames.ora` file and include the following entry.

```
net_service_name =
  (DESCRIPTION =
    (ADDRESS_LIST =
      (ADDRESS =
        (PROTOCOL = TCPS)
        (HOST = endpoint)
        (PORT = ssl_port_number)
      )
    )
    (CONNECT_DATA =
      (SID = database_name)
    )
    (SECURITY =
      (SSL_SERVER_CERT_DN =
 "C=US,ST=Washington,L=Seattle,O=Amazon.com,OU=RDS,CN=endpoint")
    )
  )
```

6. In the same directory, modify or create the sqlnet.ora file and include the following parameters.

> **Note**
>
> To communicate with entities over a TLS secured connection, Oracle requires a wallet with the necessary certificates for authentication. You can use Oracle's ORAPKI utility to create and maintain Oracle wallets, as shown in step 7. For more information, see Setting up Oracle wallet using ORAPKI in the Oracle documentation.

```
WALLET_LOCATION = (SOURCE = (METHOD = FILE) (METHOD_DATA = (DIRECTORY =
 $ORACLE_HOME/ssl_wallet)))
SSL_CLIENT_AUTHENTICATION = FALSE
SSL_VERSION = 1.0
SSL_CIPHER_SUITES = (SSL_RSA_WITH_AES_256_CBC_SHA)
```

```
SSL_SERVER_DN_MATCH = ON
```

> **Note**
>
> You can set SSL_VERSION to a higher value if your DB instance supports it.

7. Run the following command to create the Oracle wallet.

```
prompt>orapki wallet create -wallet $ORACLE_HOME/ssl_wallet -auto_login_only
```

8. Extract each certificate in the .pem bundle file into a separate .pem file using an OS utility.
9. Add each certificate to your wallet using separate `orapki` commands, replacing *`certificate-pem-file`* with the absolute file name of the .pem file.

```
prompt>orapki wallet add -wallet $ORACLE_HOME/ssl_wallet -trusted_cert -cert
      certificate-pem-file -auto_login_only
```

For more information, see Rotating your SSL/TLS certificate.

Connecting to an RDS for Oracle DB instance using SSL

After you configure SQL*Plus to use SSL as described previously, you can connect to the RDS for Oracle DB instance with the SSL option. Optionally, you can first export the TNS_ADMIN value that points to the directory that contains the tnsnames.ora and sqlnet.ora files. Doing so ensures that SQL*Plus can find these files consistently. The following example exports the TNS_ADMIN value.

```
export TNS_ADMIN = ${ORACLE_HOME}/network/admin
```

Connect to the DB instance. For example, you can connect using SQL*Plus and a *`<net_service_name>`* in a tnsnames.ora file.

```
sqlplus mydbuser@net_service_name
```

You can also connect to the DB instance using SQL*Plus without using a tnsnames.ora file by using the following command.

```
sqlplus 'mydbuser@(DESCRIPTION = (ADDRESS = (PROTOCOL = TCPS)(HOST = endpoint) (PORT
 = ssl_port_number))(CONNECT_DATA = (SID = database_name)))'
```

You can also connect to the RDS for Oracle DB instance without using SSL. For example, the following command connects to the DB instance through the clear text port without SSL encryption.

```
sqlplus 'mydbuser@(DESCRIPTION = (ADDRESS = (PROTOCOL = TCP)(HOST = endpoint) (PORT
 = port_number))(CONNECT_DATA = (SID = database_name)))'
```

If you want to close Transmission Control Protocol (TCP) port access, create a security group with no IP address ingresses and add it to the instance. This addition closes connections over the TCP port, while still allowing connections over the SSL port that are specified from IP addresses within the range permitted by the SSL option security group.

Setting up an SSL connection over JDBC

To use an SSL connection over JDBC, you must create a keystore, trust the Amazon RDS root CA certificate, and use the code snippet specified following.

To create the keystore in JKS format, you can use the following command. For more information about creating the keystore, see the Creating a keystore in the Oracle documentation. For reference information, see keytool in the *Java Platform, Standard Edition Tools Reference*.

```
keytool -genkey -alias client -validity 365 -keyalg RSA -keystore clientkeystore

```

Take the following steps to trust the Amazon RDS root CA certificate.

To trust the Amazon RDS root CA certificate

1. Download the certificate bundle .pem file that works for all AWS Regions and put the file in the ssl_wallet directory.

   For information about downloading certificates, see Using SSL/TLS to encrypt a connection to a DB instance or cluster.
2. Extract each certificate in the .pem file into a separate file using an OS utility.
3. Convert each certificate to .der format using a separate `openssl` command, replacing *`certificate-pem-file`* with the name of the certificate .pem file (without the .pem extension).

```
openssl x509 -outform der -in certificate-pem-file.pem -out certificate-pem-
file.der
```

4. Import each certificate into the keystore using the following command.

```
keytool -import -alias rds-root -keystore clientkeystore.jks -file certificate-pem-
file.der
```

   For more information, see Rotating your SSL/TLS certificate.

5. Confirm that the key store was created successfully.

```
keytool -list -v -keystore clientkeystore.jks
```

   Enter the keystore password when you are prompted for it.

The following code example shows how to set up the SSL connection using JDBC.

```
import java.sql.Connection;
import java.sql.DriverManager;
import java.sql.SQLException;
import java.util.Properties;

public class OracleSslConnectionTest {
    private static final String DB_SERVER_NAME = "dns-name-provided-by-amazon-rds";
    private static final Integer SSL_PORT = "ssl-option-port-configured-in-option-
group";
    private static final String DB_SID = "oracle-sid";
    private static final String DB_USER = "user-name";
    private static final String DB_PASSWORD = "password";
    // This key store has only the prod root ca.
    private static final String KEY_STORE_FILE_PATH = "file-path-to-keystore";
    private static final String KEY_STORE_PASS = "keystore-password";

    public static void main(String[] args) throws SQLException {
        final Properties properties = new Properties();
        final String connectionString = String.format(
                "jdbc:oracle:thin:@(DESCRIPTION=(ADDRESS=(PROTOCOL=TCPS)(HOST=%s)(PORT=
%d))(CONNECT_DATA=(SID=%s)))",
                DB_SERVER_NAME, SSL_PORT, DB_SID);
```

```
        properties.put("user", DB_USER);
        properties.put("password", DB_PASSWORD);
        properties.put("oracle.jdbc.J2EE13Compliant", "true");
        properties.put("javax.net.ssl.trustStore", KEY_STORE_FILE_PATH);
        properties.put("javax.net.ssl.trustStoreType", "JKS");
        properties.put("javax.net.ssl.trustStorePassword", KEY_STORE_PASS);
        final Connection connection = DriverManager.getConnection(connectionString,
 properties);
        // If no exception, that means handshake has passed, and an SSL connection can
 be opened
    }
}
```

Note

Specify a password other than the prompt shown here as a security best practice.

Enforcing a DN match with an SSL connection

You can use the Oracle parameter SSL_SERVER_DN_MATCH to enforce that the distinguished name (DN) for the database server matches its service name. If you enforce the match verifications, then SSL ensures that the certificate is from the server. If you don't enforce the match verification, then SSL performs the check but allows the connection, regardless if there is a match. If you do not enforce the match, you allow the server to potentially fake its identity.

To enforce DN matching, add the DN match property and use the connection string specified below.

Add the property to the client connection to enforce DN matching.

```
properties.put("oracle.net.ssl_server_dn_match", "TRUE");
```

Use the following connection string to enforce DN matching when using SSL.

```
final String connectionString = String.format(
    "jdbc:oracle:thin:@(DESCRIPTION=(ADDRESS=(PROTOCOL=TCPS)(HOST=%s)(PORT=%d))" +
    "(CONNECT_DATA=(SID=%s))" +
    "(SECURITY = (SSL_SERVER_CERT_DN =
\"C=US,ST=Washington,L=Seattle,O=Amazon.com,OU=RDS,CN=%s\")))",
```

```
    DB_SERVER_NAME, SSL_PORT, DB_SID, DB_SERVER_NAME);
```

Troubleshooting SSL connections

You might query your database and receive the `ORA-28860` error.

```
ORA-28860: Fatal SSL error
28860. 00000 - "Fatal SSL error"
*Cause: An error occurred during the SSL connection to the peer. It is likely that this
 side sent data which the peer rejected.
*Action: Enable tracing to determine the exact cause of this error.
```

This error occurs when the client attempts to connect using a version of TLS that the server doesn't support. To avoid this error, edit the sqlnet.ora and set `SSL_VERSION` to the correct TLS version. For more information, see Oracle Support Document 2748438.1 in My Oracle Support.

Oracle Spatial

Amazon RDS supports Oracle Spatial through the use of the `SPATIAL` option. Oracle Spatial provides a SQL schema and functions that facilitate the storage, retrieval, update, and query of collections of spatial data in an Oracle database. For more information, see Spatial Concepts in the Oracle documentation.

Important

If you use Oracle Spatial, Amazon RDS automatically updates your DB instance to the latest Oracle PSU when any of the following exist:

- Security vulnerabilities with a Common Vulnerability Scoring System (CVSS) score of 9+
- Other announced security vulnerabilities

Amazon RDS supports Oracle Spatial only in Oracle Enterprise Edition (EE) and Oracle Standard Edition 2 (SE2). The following table shows the versions of the DB engine that support EE and SE2.

Oracle database version	Enterprise Edition	Standard Edition 2
21.0.0.0, all versions	Yes	Yes
19.0.0.0, all versions	Yes	Yes

Note

In Oracle Database 19c, Spatial patch bundles are separate from the database Patch Set Updates (PSUs) and Release Updates (RUs). RDS for Oracle doesn't support applying Spatial batch bundles.

Prerequisites for Oracle Spatial

The following are prerequisites for using Oracle Spatial:

- Make sure that your DB instance is of a sufficient instance class. Oracle Spatial isn't supported for the db.t3.micro or db.t3.small DB instance classes. For more information, see RDS for Oracle DB instance classes.
- Make sure that your DB instance has **Auto Minor Version Upgrade** enabled. This option enables your DB instance to receive minor DB engine version upgrades automatically when they become available and is required for any options that install the Oracle Java Virtual Machine (JVM). Amazon RDS uses this option to update your DB instance to the latest Oracle Patch Set Update (PSU) or Release Update (RU). For more information, see Modifying an Amazon RDS DB instance.

Best practices for Oracle Spatial

The following are best practices for using Oracle Spatial:

- For maximum security, use the `SPATIAL` option with Secure Sockets Layer (SSL). For more information, see Oracle Secure Sockets Layer.
- Configure your DB instance to restrict access to your DB instance. For more information, see Scenarios for accessing a DB instance in a VPC and Working with a DB instance in a VPC.

Adding the Oracle Spatial option

The following is the general process for adding the `SPATIAL` option to a DB instance:

1. Create a new option group, or copy or modify an existing option group.
2. Add the option to the option group.
3. Associate the option group with the DB instance.

If Oracle Java Virtual Machine (JVM) is *not* installed on the DB instance, there is a brief outage while the `SPATIAL` option is added. There is no outage if Oracle Java Virtual Machine (JVM) is already installed on the DB instance. After you add the option, you don't need to restart your DB instance. As soon as the option group is active, Oracle Spatial is available.

> **Note**
>
> During this outage, password verification functions are disabled briefly. You can also expect to see events related to password verification functions during the outage. Password verification functions are enabled again before the Oracle DB instance is available.

To add the SPATIAL option to a DB instance

1. Determine the option group that you want to use. You can create a new option group or use an existing option group. If you want to use an existing option group, skip to the next step. Otherwise, create a custom DB option group with the following settings:

   a. For **Engine**, choose the Oracle edition for your DB instance.

   b. For **Major engine version**, choose the version of your DB instance.

   For more information, see Creating an option group.
2. Add the **SPATIAL** option to the option group. For more information about adding options, see Adding an option to an option group.
3. Apply the option group to a new or existing DB instance:

   - For a new DB instance, you apply the option group when you launch the instance. For more information, see Creating an Amazon RDS DB instance.
   - For an existing DB instance, you apply the option group by modifying the instance and attaching the new option group. For more information, see Modifying an Amazon RDS DB instance.

Removing the Oracle Spatial option

After you drop all objects that use data types provided by the SPATIAL option, you can drop the option from a DB instance. If Oracle Java Virtual Machine (JVM) is *not* installed on the DB instance, there is a brief outage while the SPATIAL option is removed. There is no outage if Oracle Java Virtual Machine (JVM) is already installed on the DB instance. After you remove the SPATIAL option, you don't need to restart your DB instance.

To drop the SPATIAL option

1. Back up your data.

   Warning

   If the instance uses data types that were enabled as part of the option, and if you remove the SPATIAL option, you can lose data. For more information, see Backing up, restoring, and exporting data.

2. Check whether any existing objects reference data types or features of the SPATIAL option.

   If SPATIAL options exist, the instance can get stuck when applying the new option group that doesn't have the SPATIAL option. You can identify the objects by using the following queries:

```
SELECT OWNER, SEGMENT_NAME, TABLESPACE_NAME, BYTES/1024/1024 mbytes
FROM   DBA_SEGMENTS
WHERE  SEGMENT_TYPE LIKE '%TABLE%'
AND    (OWNER, SEGMENT_NAME) IN
       (SELECT DISTINCT OWNER, TABLE_NAME
        FROM   DBA_TAB_COLUMNS
        WHERE  DATA_TYPE='SDO_GEOMETRY'
        AND    OWNER <> 'MDSYS')
ORDER BY 1,2,3,4;

SELECT OWNER, TABLE_NAME, COLUMN_NAME
FROM   DBA_TAB_COLUMNS
WHERE  DATA_TYPE = 'SDO_GEOMETRY'
AND    OWNER <> 'MDSYS'
ORDER BY 1,2,3;
```

3. Drop any objects that reference data types or features of the SPATIAL option.
4. Do one of the following:

   - Remove the SPATIAL option from the option group it belongs to. This change affects all DB instances that use the option group. For more information, see Removing an option from an option group.
   - Modify the DB instance and specify a different option group that doesn't include the SPATIAL option. This change affects a single DB instance. You can specify the default (empty) option group, or a different custom option group. For more information, see Modifying an Amazon RDS DB instance.

Oracle SQLT

Amazon RDS supports Oracle SQLTXPLAIN (SQLT) through the use of the SQLT option. You can use SQLT with any edition of Oracle Database 19c and higher.

The Oracle `EXPLAIN PLAN` statement can determine the execution plan of a SQL statement. It can verify whether the Oracle optimizer chooses a certain execution plan, such as a nested loops join. It also helps you understand the optimizer's decisions, such as why it chose a nested loops join over a hash join. So `EXPLAIN PLAN` helps you understand the statement's performance.

SQLT is an Oracle utility that produces a report. The report includes object statistics, object metadata, optimizer-related initialization parameters, and other information that a database administrator can use to tune a SQL statement for optimal performance. SQLT produces an HTML report with hyperlinks to all of the sections in the report.

Unlike Automatic Workload Repository or Statspack reports, SQLT works on individual SQL statements. SQLT is a collection of SQL, PL/SQL, and SQL*Plus files that collect, store, and display performance data.

Following are the supported Oracle versions for each SQLT version.

SQLT version	Oracle Database 21c	Oracle Database 19c
2018-07-25.v1	Supported	Supported
2018-03-31.v1	Not supported	Not supported
2016-04-29.v1	Not supported	Not supported

To download SQLT and access instructions for using it:

- Log in to your My Oracle Support account, and open the following documents:
- To download SQLT: Document 215187.1
- For SQLT usage instructions: Document 1614107.1
- For frequently asked questions about SQLT: Document 1454160.1
- For information about reading SQLT output: Document 1456176.1
- For interpreting the Main report: Document 1922234.1

Amazon RDS doesn't support the following SQLT methods:

- XPLORE
- XHUME

Prerequisites for SQLT

The following are prerequisites for using SQLT:

- You must remove users and roles that are required by SQLT, if they exist.

  The SQLT option creates the following users and roles on a DB instance:

  - SQLTXPLAIN user
  - SQLTXADMIN user
  - SQLT_USER_ROLE role

  If your DB instance has any of these users or roles, log in to the DB instance using a SQL client, and drop them using the following statements:

```
DROP USER SQLTXPLAIN CASCADE;
DROP USER SQLTXADMIN CASCADE;
DROP ROLE SQLT_USER_ROLE CASCADE;
```

- You must remove tablespaces that are required by SQLT, if they exist.

  The SQLT option creates the following tablespaces on a DB instance:

  - RDS_SQLT_TS
  - RDS_TEMP_SQLT_TS

  If your DB instance has these tablespaces, log in to the DB instance using a SQL client, and drop them.

SQLT option settings

SQLT can work with licensed features that are provided by the Oracle Tuning Pack and the Oracle Diagnostics Pack. The Oracle Tuning Pack includes the SQL Tuning Advisor, and the Oracle

Diagnostics Pack includes the Automatic Workload Repository. The SQLT settings enable or disable access to these features from SQLT.

Amazon RDS supports the following settings for the SQLT option.

Option setting	Valid values	Default value	Description
LICENSE_PACK	T, D, N	N	The Oracle Management Packs that you want to access with SQLT. Enter one of the following values: • T indicates that you have a license for the Oracle Tuning Pack and the Oracle Diagnostics Pack, and you want to access the SQL Tuning Advisor and Automatic Workload Repository from SQLT. • D indicates that you have a license for the Oracle Diagnostics Pack, and you want to access the Automatic Workload Repository from SQLT. • N indicates that you don't have a license for the Oracle Tuning Pack and the Oracle Diagnostics Pack, or that you have a license for one or both of them, but you don't want SQLT to access them. **Note** Amazon RDS does not provide licenses for these Oracle Management Packs. If you indicate that you want to use a pack that is not included in

Option setting	Valid values	Default value	Description
			your DB instance, you can use SQLT with the DB instance. However, SQLT can't access the pack, and the SQLT report doesn't include the data for the pack. For example, if you specify T, but the DB instance doesn't include the Oracle Tuning Pack, SQLT works on the DB instance, but the report it generates doesn't contain data related to the Oracle Tuning Pack.
VERSION	2016-04-29.v1 2018-03-31.v1 2018-07-25.v1	2016-04-29.v1	The version of SQLT that you want to install. **Note** For Oracle Database 19c and 21c, the only supported version is 2018-07-25.v1 . This version is the default for these releases.

Adding the SQLT option

The following is the general process for adding the SQLT option to a DB instance:

1. Create a new option group, or copy or modify an existing option group.
2. Add the SQLT option to the option group.
3. Associate the option group with the DB instance.

After you add the SQLT option, as soon as the option group is active, SQLT is active.

To add the SQLT option to a DB instance

1. Determine the option group that you want to use. You can create a new option group or use an existing option group. If you want to use an existing option group, skip to the next step. Otherwise, create a custom DB option group with the following settings:

   a. For **Engine**, choose the Oracle edition that you want to use. The SQLT option is supported on all editions.

   b. For **Major engine version**, choose the version of your DB instance.

   For more information, see Creating an option group.
2. Add the **SQLT** option to the option group. For more information about adding options, see Adding an option to an option group.
3. Apply the option group to a new or existing DB instance:

   - For a new DB instance, you apply the option group when you launch the instance. For more information, see Creating an Amazon RDS DB instance.
   - For an existing DB instance, you apply the option group by modifying the instance and attaching the new option group. For more information, see Modifying an Amazon RDS DB instance.
4. (Optional) Verify the SQLT installation on each DB instance with the SQLT option.

   a. Use a SQL client to connect to the DB instance as the master user.

   For information about connecting to an Oracle DB instance using a SQL client, see Connecting to your RDS for Oracle DB instance.

   b. Run the following query:

```
SELECT sqltxplain.sqlt$a.get_param('tool_version') sqlt_version FROM DUAL;
```

   The query returns the current version of the SQLT option on Amazon RDS. `12.1.160429` is an example of a version of SQLT that is available on Amazon RDS.

5. Change the passwords of the users that are created by the SQLT option.

   a. Use a SQL client to connect to the DB instance as the master user.

   b. Run the following SQL statement to change the password for the SQLTXADMIN user:

```
ALTER USER SQLTXADMIN IDENTIFIED BY new_password ACCOUNT UNLOCK;
```

> **Note**
>
> Specify a password other than the prompt shown here as a security best practice.

   c. Run the following SQL statement to change the password for the SQLTXPLAIN user:

```
ALTER USER SQLTXPLAIN IDENTIFIED BY new_password ACCOUNT UNLOCK;
```

> **Note**
>
> Specify a password other than the prompt shown here as a security best practice.

> **Note**
>
> Upgrading SQLT requires uninstalling an older version of SQLT and then installing the new version. So, all SQLT metadata can be lost when you upgrade SQLT. A major version upgrade of a database also uninstalls and re-installs SQLT. An example of a major version upgrade is an upgrade from Oracle Database 19c to Oracle Database 21c.

Using SQLT

SQLT works with the Oracle SQL*Plus utility.

To use SQLT

1. Download the SQLT .zip file from Document 215187.1 on the My Oracle Support site.

   > **Note**
   >
   > You can't download SQLT 12.1.160429 from the My Oracle Support site. Oracle has deprecated this older version.

2. Unzip the SQLT .zip file.
3. From a command prompt, change to the `sqlt/run` directory on your file system.
4. From the command prompt, open SQL*Plus, and connect to the DB instance as the master user.

   For information about connecting to a DB instance using SQL*Plus, see Connecting to your RDS for Oracle DB instance.
5. Get the SQL ID of a SQL statement:

   ```
   SELECT SQL_ID FROM V$SQL WHERE SQL_TEXT='sql_statement';
   ```

   Your output is similar to the following:

   ```
   SQL_ID
   -------------
   chvsmttqjzjkn
   ```
6. Analyze a SQL statement with SQLT:

   ```
   START sqltxtract.sql sql_id sqltxplain_user_password
   ```

   For example, for the SQL ID `chvsmttqjzjkn`, enter the following:

```
START sqltxtract.sql chvsmttqjzjkn sqltxplain_user_password
```

SQLT generates the HTML report and related resources as a .zip file in the directory from which the SQLT command was run.

7. (Optional) To enable application users to diagnose SQL statements with SQLT, grant SQLT_USER_ROLE to each application user with the following statement:

```
GRANT SQLT_USER_ROLE TO application_user_name;
```

> **Note**
>
> Oracle does not recommend running SQLT with the SYS user or with users that have the DBA role. It is a best practice to run SQLT diagnostics using the application user's account, by granting SQLT_USER_ROLE to the application user.

Upgrading the SQLT option

With Amazon RDS for Oracle, you can upgrade the SQLT option from your existing version to a higher version. To upgrade the SQLT option, complete steps 1–3 in Using SQLT for the new version of SQLT. Also, if you granted privileges for the previous version of SQLT in step 7 of that section, grant the privileges again for the new SQLT version.

Upgrading the SQLT option results in the loss of the older SQLT version's metadata. The older SQLT version's schema and related objects are dropped, and the newer version of SQLT is installed. For more information about the changes in the latest SQLT version, see Document 1614201.1 on the My Oracle Support site.

> **Note**
>
> Version downgrades are not supported.

Modifying SQLT settings

After you enable SQLT, you can modify the `LICENSE_PACK` and `VERSION` settings for the option.

For more information about how to modify option settings, see Modifying an option setting. For more information about each setting, see SQLT option settings.

Removing the SQLT option

You can remove SQLT from a DB instance.

To remove SQLT from a DB instance, do one of the following:

- To remove SQLT from multiple DB instances, remove the SQLT option from the option group to which the DB instances belong. This change affects all DB instances that use the option group. For more information, see Removing an option from an option group.
- To remove SQLT from a single DB instance, modify the DB instance and specify a different option group that doesn't include the SQLT option. You can specify the default (empty) option group or a different custom option group. For more information, see Modifying an Amazon RDS DB instance.

Oracle Statspack

The Oracle Statspack option installs and enables the Oracle Statspack performance statistics feature. Oracle Statspack is a collection of SQL, PL/SQL, and SQL*Plus scripts that collect, store, and display performance data. For information about using Oracle Statspack, see Oracle Statspack in the Oracle documentation.

> **Note**
>
> Oracle Statspack is no longer supported by Oracle and has been replaced by the more advanced Automatic Workload Repository (AWR). AWR is available only for Oracle Enterprise Edition customers who have purchased the Diagnostics Pack. You can use Oracle Statspack with any Oracle DB engine on Amazon RDS. You can't run Oracle Statspack on Amazon RDS read replicas.

Setting up Oracle Statspack

To run Statspack scripts, you must add the Statspack option.

To set up Oracle Statspack

1. In a SQL client, log in to the Oracle DB with an administrative account.
2. Do either of the following actions, depending on whether Statspack is installed:
   - If Statspack is installed, and the PERFSTAT account is associated with Statspack, skip to Step 4.
   - If Statspack is not installed, and the PERFSTAT account exists, drop the account as follows:

     ```
     DROP USER PERFSTAT CASCADE;
     ```

     Otherwise, attempting to add the Statspack option generates an error and RDS-Event-0058.
3. Add the Statspack option to an option group. See Adding an option to an option group.

   Amazon RDS automatically installs the Statspack scripts on the DB instance and then sets up the PERFSTAT account.

4. Reset the password using the following SQL statement, replacing *pwd* with your new password:

```
ALTER USER PERFSTAT IDENTIFIED BY pwd ACCOUNT UNLOCK;
```

   You can log in using the PERFSTAT user account and run the Statspack scripts.

5. Grant the CREATE JOB privilege to the PERFSTAT account using the following statement:

```
GRANT CREATE JOB TO PERFSTAT;
```

6. Ensure that idle wait events in the PERFSTAT.STATS$IDLE_EVENT table are populated.

   Because of Oracle Bug 28523746, the idle wait events in PERFSTAT.STATS$IDLE_EVENT may not be populated. To ensure all idle events are available, run the following statement:

```
INSERT INTO PERFSTAT.STATS$IDLE_EVENT (EVENT)
SELECT NAME FROM V$EVENT_NAME WHERE WAIT_CLASS='Idle'
MINUS
SELECT EVENT FROM PERFSTAT.STATS$IDLE_EVENT;
COMMIT;
```

Generating Statspack reports

A Statspack report compares two snapshots.

To generate Statspack reports

1. In a SQL client, log in to the Oracle DB with the PERFSTAT account.
2. Create a snapshot using either of the following techniques:
   - Create a Statspack snapshot manually.
   - Create a job that takes a Statspack snapshot after a given time interval. For example, the following job creates a Statspack snapshot every hour:

```
VARIABLE jn NUMBER;
exec dbms_job.submit(:jn, 'statspack.snap;',SYSDATE,'TRUNC(SYSDATE
+1/24,''HH24'')');
COMMIT;
```

3. View the snapshots using the following query:

```
SELECT SNAP_ID, SNAP_TIME FROM STATS$SNAPSHOT ORDER BY 1;
```

4. Run the Amazon RDS procedure `rdsadmin.rds_run_spreport`, replacing *begin_snap* and *end_snap* with the snapshot IDs:

```
exec rdsadmin.rds_run_spreport(begin_snap,end_snap);
```

For example, the following command creates a report based on the interval between Statspack snapshots 1 and 2:

```
exec rdsadmin.rds_run_spreport(1,2);
```

The file name of the Statspack report includes the number of the two snapshots. For example, a report file created using Statspack snapshots 1 and 2 would be named `ORCL_spreport_1_2.lst`.

5. Monitor the output for errors.

Oracle Statspack performs checks before running the report. Therefore, you could also see error messages in the command output. For example, you might try to generate a report based on an invalid range, where the beginning Statspack snapshot value is larger than the ending value. In this case, the output shows the error message, but the DB engine does not generate an error file.

```
exec rdsadmin.rds_run_spreport(2,1);
*
ERROR at line 1:
ORA-20000: Invalid snapshot IDs. Find valid ones in perfstat.stats$snapshot.
```

If you use an invalid number a Statspack snapshot, the output shows an error. For example, if you try to generate a report for snapshots 1 and 50, but snapshot 50 doesn't exist, the output shows an error.

```
exec rdsadmin.rds_run_spreport(1,50);
*
ERROR at line 1:
ORA-20000: Could not find both snapshot IDs
```

6. (Optional)

   To retrieve the report, call the trace file procedures, as explained in Working with Oracle trace files.

   Alternatively, download the Statspack report from the RDS console. Go to the **Log** section of the DB instance details and choose **Download**. The following example shows `trace/ORCL_spreport_1_2.lst`

   If an error occurs while generating a report, the DB engine uses the same naming conventions as for a report but with an extension of `.err`. For example, if an error occurred while creating a report using Statspack snapshots 1 and 7, the report file would be named `ORCL_spreport_1_7.err`. You can download the error report using the same techniques as for a standard Snapshot report.

Removing Statspack snapshots

To remove a range of Oracle Statspack snapshots, use the following command:

```
exec statspack.purge(begin snap, end snap);
```

Oracle time zone

To change the system time zone used by your Oracle DB instance, use the time zone option. For example, you might change the time zone of a DB instance to be compatible with an on-premises environment, or a legacy application. The time zone option changes the time zone at the host level. Changing the time zone impacts all date columns and values, including `SYSDATE` and `SYSTIMESTAMP`.

The time zone option differs from the `rdsadmin_util.alter_db_time_zone` command. The `alter_db_time_zone` command changes the time zone only for certain data types. The time zone option changes the time zone for all date columns and values. For more information about `alter_db_time_zone`, see Setting the database time zone. For more information about upgrade considerations, see Time zone considerations.

Restrictions for setting the time zone

The time zone option is a permanent and persistent option. Therefore, you can't do the following:

- Remove the option from an option group after you add the time zone option.
- Remove the option group from a DB instance after you add the group.
- Modify the time zone setting of the option to a different time zone.

Recommendations for setting the time zone

Before you add the time zone option to your production database, we strongly recommend that you do the following:

- Take a snapshot of your DB instance. If you accidentally set the time zone incorrectly, you must recover your DB instance to its previous time zone setting. For more information, see Creating a DB snapshot for a Single-AZ DB instance.
- Add the time zone option to a test DB instance. Adding the time zone option can cause problems with tables that use the system date to add dates or times. We recommend that you analyze your data and applications on the test instance. This way you can assess the impact of changing the time zone on your production instance.

Time zone option settings

Amazon RDS supports the following settings for the time zone option.

Option setting	Valid values	Description
TIME_ZONE	One of the available time zones. For the full list, see Available time zones.	The new time zone for your DB instance.

Adding the time zone option

Complete the following steps to add the time zone option to your DB instance:

1. (Recommended) Take a snapshot of your DB instance.
2. Do one of the following tasks:
   - Create a new option group from scratch. For more information, see Creating an option group.
   - Copy an existing option group using the AWS CLI or API. For more information, see Copying an option group.
   - Reuse an existing non-default option group. A best practice is to use an option group that isn't currently associated with any DB instances or snapshots.
3. Add the new option to the option group from the preceding step.
4. If the option group that is currently associated with your DB instance has options enabled, add these options to your new option group. This strategy prevents the existing options from being uninstalled while enabling the new option.
5. Add the new option group to your DB instance.

When you add the time zone option, a brief outage occurs while your DB instance is automatically restarted.

Console

To add the time zone option to an option group and associate it with a DB instance

1. In the RDS console, choose **Option groups.**
2. Choose the name of the option group to which you want to add the option.
3. Choose **Add option**.
4. For **Option name**, choose **Timezone**, and then configure the option settings.

5. Associate the option group with a new or existing DB instance:

   - For a new DB instance, apply the option group when you launch the instance. For more information, see Creating an Amazon RDS DB instance.
   - For an existing DB instance, apply the option group by modifying the instance and attaching the new option group. When you add the new option to an existing DB instance, a brief outage occurs while your DB instance is automatically restarted. For more information, see Modifying an Amazon RDS DB instance.

AWS CLI

The following example uses the AWS CLI add-option-to-option-group command to add the `Timezone` option and the `TIME_ZONE` option setting to an option group called `myoptiongroup`. The time zone is set to `Africa/Cairo`.

For Linux, macOS, or Unix:

```
aws rds add-option-to-option-group \
    --option-group-name "myoptiongroup" \
    --options "OptionName=Timezone,OptionSettings=[{Name=TIME_ZONE,Value=Africa/
Cairo}]" \
    --apply-immediately
```

For Windows:

```
aws rds add-option-to-option-group ^
    --option-group-name "myoptiongroup" ^
    --options "OptionName=Timezone,OptionSettings=[{Name=TIME_ZONE,Value=Africa/
Cairo}]" ^
    --apply-immediately
```

Modifying time zone settings

The time zone option is a permanent and persistent option. You can't remove the option from an option group after you add it. You can't remove the option group from a DB instance after you add it. You can't modify the time zone setting of the option to a different time zone. If you set the time zone incorrectly, restore a snapshot of your DB instance from before you added the time zone option.

Removing the time zone option

The time zone option is a permanent and persistent option. You can't remove the option from an option group after you add it. You can't remove the option group from a DB instance after you add it. To remove the time zone option, restore a snapshot of your DB instance from before you added the time zone option.

Available time zones

You can use the following values for the time zone option.

Zone	Time zone
Africa	Africa/Cairo, Africa/Casablanca, Africa/Harare, Africa/Lagos, Africa/Luanda, Africa/Monrovia, Africa/Nairobi, Africa/Tripoli, Africa/Windhoek
America	America/Araguaina, America/Argentina/Buenos_Aires, America/Asuncion, America/Bogota, America/Caracas, America/Chicago, America/Chihuahua, America/Cuiaba, America/Denver, America/Detroit, America/Fortaleza, America/Godthab, America/Guatemala, America/Halifax, America/Lima, America/Los_Angeles, America/Manaus, America/Matamoros, America/Mexico_City, America/Monterrey, America/Montevideo, America/New_York, America/Phoenix, America/Santiago, America/Sao_Paulo, America/Tijuana, America/Toronto
Asia	Asia/Amman, Asia/Ashgabat, Asia/Baghdad, Asia/Baku, Asia/Bangkok, Asia/Beirut, Asia/Calcutta, Asia/Damascus, Asia/Dhaka, Asia/Hong_Kong, Asia/Irkutsk, Asia/Jakarta, Asia/Jerusalem, Asia/Kabul, Asia/Karachi, Asia/Kathmandu, Asia/Kolkata, Asia/Krasnoyarsk, Asia/Magadan, Asia/Manila, Asia/Muscat, Asia/Novosibirsk, Asia/Rangoon, Asia/Riyadh, Asia/Seoul, Asia/Shanghai, Asia/Singapore, Asia/Taipei, Asia/Tehran, Asia/Tokyo, Asia/Ulaanbaatar, Asia/Vladivostok, Asia/Yakutsk, Asia/Yerevan
Atlantic	Atlantic/Azores, Atlantic/Cape_Verde
Australia	Australia/Adelaide, Australia/Brisbane, Australia/Darwin, Australia/Eucla, Australia/Hobart, Australia/Lord_Howe, Australia/Perth, Australia/Sydney
Brazil	Brazil/DeNoronha, Brazil/East

Zone	Time zone
Canada	Canada/Newfoundland, Canada/Saskatchewan
Etc	Etc/GMT-3
Europe	Europe/Amsterdam, Europe/Athens, Europe/Berlin, Europe/Dublin, Europe/Helsinki, Europe/Kaliningrad, Europe/London, Europe/Madrid, Europe/Moscow, Europe/Paris, Europe/Prague, Europe/Rome, Europe/Sarajevo
Pacific	Pacific/Apia, Pacific/Auckland, Pacific/Chatham, Pacific/Fiji, Pacific/Guam, Pacific/Honolulu, Pacific/Kiritimati, Pacific/Marquesas, Pacific/Samoa, Pacific/Tongatapu, Pacific/Wake
US	US/Alaska, US/Central, US/East-Indiana, US/Eastern, US/Pacific
UTC	UTC

Oracle time zone file autoupgrade

With the `TIMEZONE_FILE_AUTOUPGRADE` option, you can upgrade the current time zone file to the latest version on your RDS for Oracle DB instance.

Topics

Overview of Oracle time zone files

An Oracle Database *time zone file* stores the following information:

- Offset from Coordinated Universal Time (UTC)
- Transition times for Daylight Saving Time (DST)
- Abbreviations for standard time and DST

Oracle Database supplies multiple versions of time zone files. When you create an Oracle database in an on-premises environment, you choose the time zone file version. For more information , see Choosing a Time Zone File in the *Oracle Database Globalization Support Guide*.

If the rules change for DST, Oracle publishes new time zone files. Oracle releases these new time zone files independently of the schedule for quarterly Release Updates (RUs) and Release Update Revisions (RURs). The time zone files reside on the database host in the directory `$ORACLE_HOME/oracore/zoneinfo/`. The time zone file names use the format DSTv*`version`*, as in DSTv35.

How the time zone file affects data transfer

In Oracle Database, the `TIMESTAMP WITH TIME ZONE` data type stores time stamp and time zone data. Data with the `TIMESTAMP WITH TIME ZONE` data type uses the rules in the associated time zone file version. Thus, existing `TIMESTAMP WITH TIME ZONE` data is affected when you update the time zone file.

Problems can occur when you transfer data between databases that use different versions of the time zone file. For example, if you import data from a source database with a higher time zone file version than the target database, the database issues the `ORA-39405` error. Previously, you had to work around this error by using either of the following techniques:

- Create an RDS for Oracle DB instance with the desired time zone file, export data from your source database, and then import it into the new database.
- Use AWS DMS or logical replication to migrate your data.

Automatic updates using the TIMEZONE_FILE_AUTOUPGRADE option

When the option group attached to your RDS for Oracle DB instance includes the `TIMEZONE_FILE_AUTOUPGRADE` option, RDS updates your time zone files automatically. By ensuring that your Oracle databases use the same time zone file version, you avoid time-consuming manual techniques when you move data between different environments. The `TIMEZONE_FILE_AUTOUPGRADE` option is supported for both container databases (CDBs) and non-CDBs.

When you add the `TIMEZONE_FILE_AUTOUPGRADE` option to your option group, you can choose whether to add the option immediately or during the maintenance window. After your DB instance applies the new option, RDS checks whether it can install a newer DSTv*`version`* file. The target DSTv*`version`* depends on the following:

- The minor engine version that your DB instance is currently running
- The minor engine version to which you want to upgrade your DB instance

For example, your current time zone file version might be DSTv33. When RDS applies the update to your option group, it might determine that DSTv34 is currently available on your DB instance file system. RDS will then update your time zone file to DSTv34 automatically.

To find the available DST versions in the supported RDS release updates, look at the patches in Release notes for Amazon Relational Database Service (Amazon RDS) for Oracle. For example, version 19.0.0.0.ru-2022-10.rur-2022-10.r1 lists patch 34533061: RDBMS - DSTV39 UPDATE - TZDATA2022C.

Strategies for updating your time zone file

Upgrading your DB engine and adding the TIMEZONE_FILE_AUTOUPGRADE option to an option group are separate operations. Adding the TIMEZONE_FILE_AUTOUPGRADE option initiates the update of your time zone file if a more current one is available. You run the following commands (only relevant options are shown) either immediately or at the next maintenance window:

- Upgrade your DB engine only using the following RDS CLI command:

```
modify-db-instance --engine-version name ...
```

- Add the TIMEZONE_FILE_AUTOUPGRADE option only using the following CLI command:

```
add-option-to-option-group --option-group-name name --options
 OptionName=TIMEZONE_FILE_AUTOUPGRADE ...
```

- Upgrade your DB engine and add a new option group to your instance using the following CLI command:

```
modify-db-instance --engine-version name --option-group-name name ...
```

Your update strategy depends on whether you want to upgrade your database and time zone file together or perform just one of these operations. Keep in mind that if you update your option group and then upgrade your DB engine in separate API operations, it's possible for a time zone file update to be currently in progress when you upgrade your DB engine.

The examples in this section assume the following:

- You have not yet added TIMEZONE_FILE_AUTOUPGRADE to the option group currently associated with your DB instance.
- Your DB instance uses database version 19.0.0.0.ru-2019-07.rur-2019-07.r1 and time zone file DSTv33.
- Your DB instance file system includes file DSTv34.
- Release update 19.0.0.0.ru-2022-10.rur-2022-10.r1 includes DSTv35.

To update your time zone file, you can use the following strategies.

Topics

- Update the time zone file without upgrading the engine
- Upgrade the time zone file and DB engine version
- Upgrade your DB engine version without updating the time zone file

Update the time zone file without upgrading the engine

In this scenario, your database is using DSTv33, but DSTv34 is available on your DB instance file system. You want to update the time zone file used by your DB instance from DSTv33 to DSTv34, but you don't want to upgrade your engine to a new minor version, which includes DSTv35.

In an `add-option-to-option-group` command, add `TIMEZONE_FILE_AUTOUPGRADE` to the option group used by your DB instance. Specify whether to add the option immediately or defer it to the maintenance window. After applying the `TIMEZONE_FILE_AUTOUPGRADE` option, RDS does the following:

1. Checks for a new DST version.
2. Determines that DSTv34 is available on the file system.
3. Updates the time zone file immediately.

Upgrade the time zone file and DB engine version

In this scenario, your database is using DSTv33, but DSTv34 is available on your DB instance file system. You want to upgrade your DB engine to minor version 19.0.0.0.ru-2022-10.rur-2022-10.r1, which includes DSTv35, and update your time zone file to DSTv35 during the engine upgrade. Thus, your goal is to skip DSTv34 and update your time zone files directly to DSTv35.

To upgrade the engine and time zone file together, run `modify-db-instance` with the `--option-group-name` and `--engine-version` options. You can run the command immediately or defer it to maintenance window. `In --option-group-name`, specify an option group that includes the `TIMEZONE_FILE_AUTOUPGRADE` option. For example:

```
aws rds modify-db-instance
    --db-instance-identifier my-instance \
    --engine-version new-version \
    ----option-group-name og-with-timezone-file-autoupgrade \
    --apply-immediately
```

RDS begins upgrading your engine to 19.0.0.0.ru-2022-10.rur-2022-10.r1. After applying the TIMEZONE_FILE_AUTOUPGRADE option, RDS checks for a new DST version, sees that DSTv35 is available in 19.0.0.0.ru-2022-10.rur-2022-10.r1, and immediately starts the update to DSTv35.

To upgrade your engine immediately and then upgrade your a timezone file, perform the operations in sequence:

1. Upgrade your DB engine only using the following CLI command:

```
aws rds modify-db-instance \
    --db-instance-identifier my-instance \
    --engine-version new-version \
    --apply-immediately
```

2. Add the TIMEZONE_FILE_AUTOUPGRADE option to the option group attached to your instance using the following CLI command:

```
aws rds add-option-to-option-group \
    --option-group-name og-in-use-by-your-instance \
    --options OptionName=TIMEZONE_FILE_AUTOUPGRADE \
    --apply-immediately
```

Upgrade your DB engine version without updating the time zone file

In this scenario, your database is using DSTv33, but DSTv34 is available on your DB instance file system. You want to upgrade your DB engine to version 19.0.0.0.ru-2022-10.rur-2022-10.r1, which includes DSTv35, but retain time zone file DSTv33. You might choose this strategy for the following reasons:

- Your data doesn't use the TIMESTAMP WITH TIME ZONE data type.
- Your data uses the TIMESTAMP WITH TIME ZONE data type, but your data is not affected by the time zone changes.
- You want to postpone updating the time zone file because you can't tolerate the extra downtime.

Your strategy depends on which of the following possibilities are true:

- Your DB instance isn't associated with an option group that includes `TIMEZONE_FILE_AUTOUPGRADE`. In your `modify-db-instance` command, don't specify a new option group so that RDS doesn't update your time zone file.
- Your DB instance is currently associated with an option group that includes `TIMEZONE_FILE_AUTOUPGRADE`. Within a single `modify-db-instance` command, associate your DB instance with an option group that doesn't include `TIMEZONE_FILE_AUTOUPGRADE` and upgrade your DB engine to 19.0.0.0.ru-2022-10.rur-2022-10.r1.

Downtime during the time zone file update

When RDS updates your time zone file, existing data that uses `TIMESTAMP WITH TIME ZONE` might change. In this case, your primary consideration is downtime.

> **Warning**
>
> If you add the `TIMEZONE_FILE_AUTOUPGRADE` option, your engine upgrade might have prolonged downtime. Updating time zone data for a large database might take hours or even days.

The length of the time zone file update depends on factors such as the following:

- The amount of `TIMESTAMP WITH TIME ZONE` data in your database
- The DB instance configuration
- The DB instance class
- The storage configuration
- The database configuration
- The database parameter settings

Additional downtime can occur when you do the following:

- Add the option to the option group when the DB instance uses an outdated time zone file
- Upgrade the Oracle database engine when the new engine version contains a new version of the time zone file

Note

During the time zone file update, RDS for Oracle calls `PURGE DBA_RECYCLEBIN`.

Preparing to update the time zone file

A time zone file upgrade has two separate phases: prepare and upgrade. While not required, we strongly recommend that you perform the prepare step. In this step, you find out which data will be affected by running the PL/SQL procedure `DBMS_DST.FIND_AFFECTED_TABLES`. For more information about the prepare window, see Upgrading the Time Zone File and Timestamp with Time Zone Data in the Oracle Database documentation.

To prepare to update the time zone file

1. Connect to your Oracle database using a SQL client.
2. Determine the current timezone file version used.

```
SELECT * FROM V$TIMEZONE_FILE;
```

3. Determine the latest timezone file version available on your DB instance.

```
SELECT DBMS_DST.GET_LATEST_TIMEZONE_VERSION FROM DUAL;
```

4. Determine the total size of tables that have columns of type `TIMESTAMP WITH LOCAL TIME ZONE` or `TIMESTAMP WITH TIME ZONE`.

```
SELECT SUM(BYTES)/1024/1024/1024 "Total_size_w_TSTZ_columns_GB"
FROM   DBA_SEGMENTS
WHERE  SEGMENT_TYPE LIKE 'TABLE%'
AND    (OWNER, SEGMENT_NAME) IN
         (SELECT OWNER, TABLE_NAME
          FROM   DBA_TAB_COLUMNS
          WHERE  DATA_TYPE LIKE 'TIMESTAMP%TIME ZONE');
```

5. Determine the names and sizes of segments that have columns of type `TIMESTAMP WITH LOCAL TIME ZONE` or `TIMESTAMP WITH TIME ZONE`.

```
SELECT OWNER, SEGMENT_NAME, SUM(BYTES)/1024/1024/1024
 "SEGMENT_SIZE_W_TSTZ_COLUMNS_GB"
```

```
FROM   DBA_SEGMENTS
WHERE  SEGMENT_TYPE LIKE 'TABLE%'
AND    (OWNER, SEGMENT_NAME) IN
         (SELECT OWNER, TABLE_NAME
          FROM   DBA_TAB_COLUMNS
          WHERE  DATA_TYPE LIKE 'TIMESTAMP%TIME ZONE')
GROUP BY OWNER, SEGMENT_NAME;
```

6. Run the prepare step.

   - The procedure DBMS_DST.CREATE_AFFECTED_TABLE creates a table to store any affected data. You pass the name of this table to the DBMS_DST.FIND_AFFECTED_TABLES procedure. For more information, see CREATE_AFFECTED_TABLE Procedure in the Oracle Database documentation.
   - This procedure CREATE_ERROR_TABLE creates a table to log errors. For more information, see CREATE_ERROR_TABLE Procedure in the Oracle Database documentation.

   The following example creates the affected data and error tables, and finds all affected tables.

```
EXEC DBMS_DST.CREATE_ERROR_TABLE('my_error_table')
EXEC DBMS_DST.CREATE_AFFECTED_TABLE('my_affected_table')

EXEC DBMS_DST.BEGIN_PREPARE(new_version);
EXEC DBMS_DST.FIND_AFFECTED_TABLES('my_affected_table', TRUE, 'my_error_table');
EXEC DBMS_DST.END_PREPARE;

SELECT * FROM my_affected_table;
SELECT * FROM my_error_table;
```

7. Query the affected and error tables.

```
SELECT * FROM my_affected_table;
SELECT * FROM my_error_table;
```

Adding the time zone file autoupgrade option

When you add the option to an option group, the option group is in one of the following states:

- An existing option group is currently attached to at least one DB instance. When you add the option, all DB instances that use this option group automatically restart. This causes a brief outage.
- An existing option group is not attached to any DB instance. You plan to add the option and then associate the existing option group with existing DB instances or with a new DB instance.
- You create a new option group and add the option. You plan to associate the new option group with existing DB instances or with a new DB instance.

Console

To add the time zone file autoupgrade option to a DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Option groups**.
3. Determine the option group you want to use. You can create a new option group or use an existing option group. If you want to use an existing option group, skip to the next step. Otherwise, create a custom DB option group with the following settings:

   a. For **Engine** choose the Oracle Database edition for your DB instance.

   b. For **Major engine version** choose the version of your DB instance.

   For more information, see Creating an option group.
4. Choose the option group that you want to modify, and then choose **Add option**.
5. In the **Add option** window, do the following:

   a. Choose **TIMEZONE_FILE_AUTOUPGRADE**.

   b. To enable the option on all associated DB instances as soon as you add it, for **Apply Immediately**, choose **Yes**. If you choose **No** (the default), the option is enabled for each associated DB instance during its next maintenance window.
6. When the settings are as you want them, choose **Add option**.

AWS CLI

The following example uses the AWS CLI add-option-to-option-group command to add the `TIMEZONE_FILE_AUTOUPGRADE` option to an option group called `myoptiongroup`.

For Linux, macOS, or Unix:

```
aws rds add-option-to-option-group \
    --option-group-name "myoptiongroup" \
    --options "OptionName=TIMEZONE_FILE_AUTOUPGRADE" \
    --apply-immediately
```

For Windows:

```
aws rds add-option-to-option-group ^
    --option-group-name "myoptiongroup" ^
    --options "OptionName=TIMEZONE_FILE_AUTOUPGRADE" ^
    --apply-immediately
```

Checking your data after the update of the time zone file

We recommend that you check your data after you update the time zone file. During the prepare step, RDS for Oracle automatically creates the following tables:

- `rdsadmin.rds_dst_affected_tables` – Lists the tables that contain data affected by the update
- `rdsadmin.rds_dst_error_table` – Lists the errors generated during the update

These tables are independent of any tables that you create in the prepare window. To see the results of the update, query the tables as follows.

```
SELECT * FROM rdsadmin.rds_dst_affected_tables;
SELECT * FROM rdsadmin.rds_dst_error_table;
```

For more information about the schema for the affected data and error tables, see FIND_AFFECTED_TABLES Procedure in the Oracle documentation.

Oracle Transparent Data Encryption

Amazon RDS supports Oracle Transparent Data Encryption (TDE), a feature of the Oracle Advanced Security option available in Oracle Enterprise Edition. This feature automatically encrypts data before it is written to storage and automatically decrypts data when the data is read from storage. This option is only supported for the Bring Your Own License (BYOL) model.

TDE is useful in scenarios where you need to encrypt sensitive data in case data files and backups are obtained by a third party. TDE is also useful when you need to comply with security-related regulations.

A detailed explanation about TDE in Oracle Database is beyond the scope of this guide. For information, see the following Oracle Database resources:

- Introduction to Transparent Data Encryption in the Oracle Database documentation
- Oracle advanced security in the Oracle Database documentation
- Oracle advanced security Transparent Data Encryption best practices, which is an Oracle whitepaper

For more information about using TDE with RDS for Oracle, see the following blogs:

- Oracle Database Encryption Options on Amazon RDS
- Migrate a cross-account TDE-enabled Amazon RDS for Oracle DB instance with reduced downtime using AWS DMS

TDE encryption modes

Oracle Transparent Data Encryption supports two encryption modes: TDE tablespace encryption and TDE column encryption. TDE tablespace encryption is used to encrypt entire application tables. TDE column encryption is used to encrypt individual data elements that contain sensitive data. You can also apply a hybrid encryption solution that uses both TDE tablespace and column encryption.

> **Note**
>
> Amazon RDS manages the Oracle Wallet and TDE master key for the DB instance. You do not need to set the encryption key using the command `ALTER SYSTEM set encryption key`.

After you enable the TDE option, you can check the status of the Oracle Wallet by using the following command:

```
SELECT * FROM v$encryption_wallet;
```

To create an encrypted tablespace, use the following command:

```
CREATE TABLESPACE encrypt_ts ENCRYPTION DEFAULT STORAGE (ENCRYPT);
```

To specify the encryption algorithm, use the following command:

```
CREATE TABLESPACE encrypt_ts ENCRYPTION USING 'AES256' DEFAULT STORAGE (ENCRYPT);
```

The previous statements for encrypting a tablespace are the same as you would use on an on-premises Oracle database.

Restrictions for the TDE option

The TDE option is permanent and persistent. After you associate your DB instance with an option group that has the TDE option enabled, you can't do the following actions:

- Disable the TDE option in the currently associated option group.
- Associate your DB instance with a different option group that doesn't include the TDE option.
- Share a DB snapshot that uses the TDE option. For more information about sharing DB snapshots, see Sharing a DB snapshot.

For more information about persistent and permanent options, see Persistent and permanent options.

Determining whether your DB instance is using TDE

You might want to determine whether your DB instance is associated with an option group that has the TDE option enabled. To view the option group that a DB instance is associated with, use the RDS console, the describe-db-instance AWS CLI command, or the API operation DescribeDBInstances.

Adding the TDE option

To add the TDE option to your DB instance, complete the following steps:

1. (Recommended) Take a snapshot of your DB instance.
2. Do one of the following tasks:
   - Create a new option group from scratch. For more information, see Creating an option group.
   - Copy an existing option group using the AWS CLI or API. For more information, see Copying an option group.
   - Reuse an existing non-default option group. A best practice is to use an option group that isn't currently associated with any DB instances or snapshots.
3. Add the new option to the option group from the preceding step.
4. If the option group that is currently associated with your DB instance has options enabled, add these options to your new option group. This strategy prevents the existing options from being uninstalled while enabling the new option.
5. Add the new option group to your DB instance.

Console

To add the TDE option to an option group and associate it with your DB instance

1. In the RDS console, choose **Option groups.**
2. Choose the name of the option group to which you want to add the option.
3. Choose **Add option**.
4. For **Option name**, choose **TDE**, and then configure the option settings.
5. Choose **Add option**.

> **Important**
>
> If you add the **TDE** option to an option group that is currently attached to one or more DB instances, a brief outage occurs while all the DB instances are automatically restarted.

   For more information about adding options, see Adding an option to an option group.
6. Associate the option group with a new or existing DB instance:
   - For a new DB instance, apply the option group when you launch the instance. For more information, see Creating an Amazon RDS DB instance.

- For an existing DB instance, apply the option group by modifying the instance and attaching the new option group. When you add the new option to an existing DB instance, a brief outage occurs while your DB instance is automatically restarted. For more information, see Modifying an Amazon RDS DB instance.

AWS CLI

In the following example, you use the AWS CLI add-option-to-option-group command to add the TDE option to an option group called `myoptiongroup`. For more information, see Getting started: Flink 1.13.2 .

For Linux, macOS, or Unix:

```
aws rds add-option-to-option-group \
    --option-group-name "myoptiongroup" \
    --options "OptionName=TDE" \
    --apply-immediately
```

For Windows:

```
aws rds add-option-to-option-group ^
    --option-group-name "myoptiongroup" ^
    --options "OptionName=TDE" ^
    --apply-immediately
```

Copying your data to a DB instance that doesn't include the TDE option

You can't remove the TDE option from a DB instance or associate it with an option group that doesn't include the TDE option. To migrate your data to an instance that doesn't include the TDE option, do the following:

1. Decrypt the data on your DB instance.
2. Copy the data to a new DB instance that is not associated with an option group that has TDE enabled.
3. Delete your original DB instance.

You can use the same name for the new instance as the previous DB instance.

Considerations when using TDE with Oracle Data Pump

You can use Oracle Data Pump to import or export encrypted dump files. Amazon RDS supports the password encryption mode (`ENCRYPTION_MODE=PASSWORD`) for Oracle Data Pump. Amazon RDS does not support transparent encryption mode (`ENCRYPTION_MODE=TRANSPARENT`) for Oracle Data Pump. For more information, see Importing using Oracle Data Pump.

Oracle UTL_MAIL

Amazon RDS supports Oracle UTL_MAIL through the use of the UTL_MAIL option and SMTP servers. You can send email directly from your database by using the UTL_MAIL package. Amazon RDS supports UTL_MAIL for the following versions of Oracle:

- Oracle Database 21c (21.0.0.0), all versions
- Oracle Database 19c (19.0.0.0), all versions

The following are some limitations to using UTL_MAIL:

- UTL_MAIL does not support Transport Layer Security (TLS) and therefore emails are not encrypted.

  To connect securely to remote SSL/TLS resources by creating and uploading custom Oracle wallets, follow the instructions in Configuring UTL_HTTP access using certificates and an Oracle wallet.

  The specific certificates that are required for your wallet vary by service. For AWS services, these can typically be found in the Amazon trust services repository.
- UTL_MAIL does not support authentication with SMTP servers.
- You can only send a single attachment in an email.
- You can't send attachments larger than 32 K.
- You can only use ASCII and Extended Binary Coded Decimal Interchange Code (EBCDIC) character encodings.
- SMTP port (25) is throttled based on the elastic network interface owner's policies.

When you enable UTL_MAIL, only the master user for your DB instance is granted the execute privilege. If necessary, the master user can grant the execute privilege to other users so that they can use UTL_MAIL.

Important

We recommend that you enable Oracle's built-in auditing feature to track the use of UTL_MAIL procedures.

Prerequisites for Oracle UTL_MAIL

The following are prerequisites for using Oracle UTL_MAIL:

- One or more SMTP servers, and the corresponding IP addresses or public or private Domain Name Server (DNS) names. For more information about private DNS names resolved through a custom DNS server, see Setting up a custom DNS server.

Adding the Oracle UTL_MAIL option

The general process for adding the Oracle UTL_MAIL option to a DB instance is the following:

1. Create a new option group, or copy or modify an existing option group.
2. Add the option to the option group.
3. Associate the option group with the DB instance.

After you add the UTL_MAIL option, as soon as the option group is active, UTL_MAIL is active.

To add the UTL_MAIL option to a DB instance

1. Determine the option group you want to use. You can create a new option group or use an existing option group. If you want to use an existing option group, skip to the next step. Otherwise, create a custom DB option group with the following settings:

   a. For **Engine**, choose the edition of Oracle you want to use.

   b. For **Major engine version**, choose the version of your DB instance.

   For more information, see Creating an option group.
2. Add the **UTL_MAIL** option to the option group. For more information about adding options, see Adding an option to an option group.
3. Apply the option group to a new or existing DB instance:

   - For a new DB instance, you apply the option group when you launch the instance. For more information, see Creating an Amazon RDS DB instance.
   - For an existing DB instance, you apply the option group by modifying the instance and attaching the new option group. For more information, see Modifying an Amazon RDS DB instance.

Using Oracle UTL_MAIL

After you enable the UTL_MAIL option, you must configure the SMTP server before you can begin using it.

You configure the SMTP server by setting the SMTP_OUT_SERVER parameter to a valid IP address or public DNS name. For the SMTP_OUT_SERVER parameter, you can specify a comma-separated list of the addresses of multiple servers. If the first server is unavailable, UTL_MAIL tries the next server, and so on.

You can set the default SMTP_OUT_SERVER for a DB instance by using a DB parameter group. You can set the SMTP_OUT_SERVER parameter for a session by running the following code on your database on your DB instance.

```
ALTER SESSION SET smtp_out_server = mailserver.domain.com:25;
```

After the UTL_MAIL option is enabled, and your SMTP_OUT_SERVER is configured, you can send mail by using the SEND procedure. For more information, see UTL_MAIL in the Oracle documentation.

Removing the Oracle UTL_MAIL option

You can remove Oracle UTL_MAIL from a DB instance.

To remove UTL_MAIL from a DB instance, do one of the following:

- To remove UTL_MAIL from multiple DB instances, remove the UTL_MAIL option from the option group they belong to. This change affects all DB instances that use the option group. For more information, see Removing an option from an option group.
- To remove UTL_MAIL from a single DB instance, modify the DB instance and specify a different option group that doesn't include the UTL_MAIL option. You can specify the default (empty) option group, or a different custom option group. For more information, see Modifying an Amazon RDS DB instance.

Troubleshooting

The following are issues you might encounter when you use UTL_MAIL with Amazon RDS.

- Throttling. SMTP port (25) is throttled based on the elastic network interface owner's policies. If you can successfully send email by using UTL_MAIL, and you see the error `ORA-29278: SMTP transient error: 421 Service not available`, you are possibly being throttled. If you experience throttling with email delivery, we recommend that you implement a backoff algorithm. For more information about backoff algorithms, see Error retries and exponential backoff in AWS and How to handle a "throttling – Maximum sending rate exceeded" error.

  You can request that this throttle be removed. For more information, see How do I remove the throttle on port 25 from my EC2 instance?.

Oracle XML DB

Oracle XML DB adds native XML support to your DB instance. With XML DB, you can store and retrieve structured or unstructured XML and relational data. The XML DB protocol server isn't supported on RDS for Oracle.

XML DB is preinstalled on Oracle Database 12c and higher. Thus, you don't need to use an option group to explicitly install XML DB as an additional feature.

To learn how to configure and use XML DB, see Oracle XML DB Developer's Guide in the Oracle Database documentation.

Upgrading the RDS for Oracle DB engine

When Amazon RDS supports a new version of Oracle Database, you can upgrade your DB instances to the new version. For information about which Oracle versions are available on Amazon RDS, see *Amazon RDS for Oracle Release Notes*.

> **Important**
>
> RDS for Oracle Databases 11g, 12c, and 18c are no longer supported. If you maintain Oracle Database 11g, 12c, or 18c snapshots, you can upgrade them to a later release. For more information, see Upgrading an Oracle DB snapshot.

Topics

Overview of RDS for Oracle engine upgrades

Before upgrading your RDS for Oracle DB instance, familiarize yourself with the following concepts.

Topics

Major and minor version upgrades

Major versions are major releases of Oracle Database that occur every 1-2 years. Examples of major releases are Oracle Database 19c and Oracle Database 21c.

Minor versions, which are also called Release Updates (RUs), are typically released by Oracle every quarter. Minor versions contain small feature enhancements and bug fixes. Examples of minor versions are 21.0.0.0.ru-2023-10.rur-2023-10.r1 and 19.0.0.0.ru-2023-10.rur-2023-10.r1. For more information, see Release notes for Amazon Relational Database Service (Amazon RDS) for Oracle.

RDS for Oracle supports the following upgrades to a DB instance.

Upgrade type	Application compatibility	Upgrade methods	Sample upgrade path
Major version	A major version upgrade can introduce changes that aren't compatible with existing applications.	Manual only	From Oracle Database 19c to Oracle Database 21c
Minor version	A minor version upgrade includes only changes that are backward-compatible with existing applications.	Automatic or manual	From 21.0.0.0.ru-2023-07.rur-2022-07.r1 to 21.0.0.0.ru-2023-10.rur-2022-10.r1

Important

When you upgrade your DB engine, an outage occurs. The duration of the outage depends on your engine version and DB instance size.
Make sure that you thoroughly test any upgrade to verify that your applications work correctly before applying the upgrade to your production databases. For more information, see Testing an Oracle DB upgrade.

Expected support dates for RDS for Oracle major releases

RDS for Oracle major versions remain available at least until the end of support date for the corresponding Oracle Database release version. You can use the following dates to plan your testing and upgrade cycles. These dates represent the earliest date that an upgrade to a newer version might be required. If Amazon extends support for an RDS for Oracle version for longer than originally stated, we plan to update this table to reflect the later date.

Oracle Database major release version	Expected date for upgrading to a newer version
Oracle Database 19c	April 30, 2026 with BYOL Premier Support (fees waived for Extended Support) April 30, 2027 with BYOL Extended Support (extra cost) or an Unlimited License Agreement April 30, 2027 with License Included (LI)
Oracle Database 21c	April 30, 2025 (not available for Extended Support)

Before we ask you to upgrade to a newer major version, we remind you at least 12 months in advance. We detail the upgrade process, including the timing of important milestones, the impact on your DB instances, and recommended actions. You should thoroughly test your applications with new RDS for Oracle versions before you upgrade to a major version.

After this advance notification period, an automatic upgrade to the subsequent major version might be applied to any RDS for Oracle DB instance still running the older version. If so, the upgrade is started during scheduled maintenance windows.

For more information, see Release Schedule of Current Database Releases in My Oracle Support.

Oracle engine version management

With DB engine version management, you control when and how the database engine is patched and upgraded. You get the flexibility to maintain compatibility with database engine patch versions. You can also test new patch versions of RDS for Oracle to ensure they work with your application before deploying them in production. In addition, you upgrade the versions on your own terms and timelines.

> **Note**
>
> Amazon RDS periodically aggregates official Oracle database patches using an Amazon RDS-specific DB engine version. To see a list of which Oracle patches are contained in an Amazon RDS Oracle-specific engine version, go to *Amazon RDS for Oracle Release Notes*.

Automatic snapshots during engine upgrades

During upgrades of an Oracle DB instance, snapshots offer protection against upgrade issues. If the backup retention period for your DB instance is greater than 0, Amazon RDS takes the following DB snapshots during the upgrade:

1. A snapshot of the DB instance before any upgrade changes have been made. If the upgrade fails, you can restore this snapshot to create a DB instance running the old version.
2. A snapshot of the DB instance after the upgrade completes.

> **Note**
>
> To change your backup retention period, see Modifying an Amazon RDS DB instance.

After an upgrade, you can't revert to the previous engine version. However, you can create a new Oracle DB instance by restoring the pre-upgrade snapshot.

Oracle upgrades in a Multi-AZ deployment

If your DB instance is in a Multi-AZ deployment, Amazon RDS upgrades both the primary and standby replicas. If no operating system updates are required, the primary and standby upgrades occur simultaneously. The instances are not available until the upgrade completes.

If operating system updates are required in a Multi-AZ deployment, Amazon RDS applies the updates when you request the database upgrade. Amazon RDS performs the following steps:

1. Updates the operating system on the current standby DB instance.
2. Fails over the primary DB instance to the standby DB instance.
3. Upgrades the database version on the new primary DB instance, which was formerly the standby instance. The primary database is unavailable during the upgrade.

4. Updates the operating system on the new standby DB instance, which was formerly the primary DB instance.
5. Upgrades the database version on the new standby DB instance.
6. Fails over the new primary DB instance back to the original primary DB instance, and the new standby DB instance back to the original standby DB instance. Thus, Amazon RDS returns the replication configuration to its original state.

Oracle upgrades of read replicas

The Oracle DB engine version of the source DB instance and all of its read replicas must be the same. Amazon RDS performs the upgrade in the following stages:

1. Upgrades the source DB instance. The read replicas are available during this stage.
2. Upgrades the read replicas in parallel, regardless of the replica maintenance windows. The source DB is available during this stage.

For major version upgrades of cross-Region read replicas, Amazon RDS performs additional actions:

- Generates an option group for the target version automatically
- Copies all options and option settings from the original option group to the new option group
- Associates the upgraded cross-Region read replica with the new option group

Oracle major version upgrades

To perform a major version upgrade, modify the DB instance manually. Major version upgrades don't occur automatically.

> **Important**
>
> Make sure that you thoroughly test any upgrade to verify that your applications work correctly before applying the upgrade to your production databases. For more information, see Testing an Oracle DB upgrade.

Topics

Supported versions for major upgrades

Amazon RDS supports the following major version upgrades.

Current version	Upgrade supported
19.0.0.0 using the CDB architecture	21.0.0.0

A major version upgrade of Oracle Database must upgrade to a Release Update (RU) that was released in the same month or later. Major version downgrades aren't supported for any Oracle Database versions.

Supported instance classes for major upgrades

Your current Oracle DB instance might run on a DB instance class that isn't supported for the version to which you are upgrading. In this case, before you upgrade, migrate the DB instance to a supported DB instance class. For more information about the supported DB instance classes for each version and edition of Amazon RDS for Oracle, see DB instance classes.

Gathering statistics before major upgrades

Before you perform a major version upgrade, Oracle recommends that you gather optimizer statistics on the DB instance that you are upgrading. This action can reduce DB instance downtime during the upgrade.

To gather optimizer statistics, connect to the DB instance as the master user, and run the `DBMS_STATS.GATHER_DICTIONARY_STATS` procedure, as in the following example.

```
EXEC DBMS_STATS.GATHER_DICTIONARY_STATS;
```

For more information, see GATHER_DICTIONARY_STATS Procedure in the Oracle documentation.

Allowing major upgrades

A major engine version upgrade might be incompatible with your application. The upgrade is irreversible. If you specify a major version for the EngineVersion parameter that is different from the current major version, you must allow major version upgrades.

If you upgrade a major version using the CLI command modify-db-instance, specify `--allow-major-version-upgrade`. This setting isn't persistent, so you must specify `--allow-major-version-upgrade` whenever you perform a major upgrade. This parameter has no impact on upgrades of minor engine versions. For more information, see Upgrading a DB instance engine version.

If you upgrade a major version using the console, you don't need to choose an option to allow the upgrade. Instead, the console displays a warning that major upgrades are irreversible.

Oracle minor version upgrades

A minor version upgrade applies an Oracle Database Patch Set Update (PSU) or Release Update (RU) to a major engine version. For example, if your DB instance runs major version Oracle Database 21c and minor version 21.0.0.0.ru-2022-07.rur-2022-07.r1, you can upgrade your upgrade to minor version 21.0.0.0.ru-2022-10.rur-2022-10.r1. Typically, a new minor version is available every quarter.

> **Note**
>
> RDS for Oracle doesn't support minor version downgrades.

You can upgrade your DB engine to a minor version manually or automatically. To learn how to upgrade manually, see Manually upgrading the engine version. To learn how to configure automatic upgrades, see Automatically upgrading the minor engine version. Whether you upgrade manually or automatically, a minor version upgrade entails downtime. Keep this in mind when planning your upgrades.

> **Important**
>
> Make sure that you thoroughly test any upgrade to verify that your applications work correctly before applying the upgrade to your production databases. For more information, see Testing an Oracle DB upgrade.

Topics

Turning on automatic minor version upgrades for Oracle

In an automatic minor version upgrade, RDS applies the latest available minor version to your Oracle database without manual intervention. An Amazon RDS for Oracle DB instance schedules your upgrade during the next maintenance window in the following circumstances:

- Your DB instance has the **Auto minor version upgrade** option turned on.
- Your DB instance isn't already running the latest minor DB engine version.
- Your DB instance doesn't already have a pending upgrade scheduled.

To learn how to turn on automatic upgrades, see Automatically upgrading the minor engine version.

Before an automatic minor version upgrade for Oracle is scheduled

RDS publishes an advance notice before it begins scheduling automatic upgrades. You can find the notification in the **Maintenance & backups** tab of the database details page. The message has the following format:

```
An automatic minor version upgrade to engine version will become available
 on availability-date and will be applied during a subsequent maintenance window.
```

The *availability-date* in the preceding message is the date when RDS starts scheduling upgrades for DB instances in your AWS Region. It is not the date on which the upgrade of your DB instance is scheduled to occur.

You can also get the upgrade availability date by using the `describe-pending-maintenance-actions` command in the AWS CLI, as shown in the following example:

```
aws rds describe-pending-maintenance-actions
```

```
{
    "PendingMaintenanceActions": [
        {
            "ResourceIdentifier": "arn:aws:rds:us-east-1:123456789012:db:orclinst1",
            "PendingMaintenanceActionDetails": [
                {
                    "Action": "db-upgrade",
                    "Description": "Automatic minor version upgrade to
 21.0.0.0.ru-2022-10.rur-2022-10.r1",
                    "CurrentApplyDate": "2022-12-02T08:10:00Z",
                    "OptInStatus": "next-maintenance"
                }
            ]
        }, ...
```

The following table describes your options for each type of pending maintenance action message.

Pending maintenance action message	When message appears	Eligible to be applied at the next maintenance window?	Eligible to be applied immediately?	Eligible to have the opt-in undone?
An automatic minor version upgrade to *engine-version* will become available on *availability-date* and should be applied during a subsequent maintenance window.	4-6 weeks before automatic upgrades are scheduled.	Yes	Yes	Yes
Automatic minor version upgrade to *engine-version*	On or after *availability-date*. RDS automatically applies this upgrade in the next maintenance	Yes	Yes	No

Pending maintenance action message	When message appears	Eligible to be applied at the next maintenance window?	Eligible to be applied immediately?	Eligible to have the opt-in undone?
	window of the DB instance.			

For more information about describe-pending-maintenance-actions, see the *AWS CLI Command Reference*.

When RDS schedules automatic minor version upgrades for Oracle

When the availability date for automatic upgrades arrives, RDS begins scheduling upgrades. For most AWS Regions, RDS schedules your upgrade to the latest quarterly RU approximately four to six weeks after the availability date. The scheduled date varies depending on the AWS Region and other factors. For more information about RUs and RURs, see *Amazon RDS for Oracle Release Notes*.

When RDS schedules the upgrade, the following notification appears in the **Maintenance & backups** tab of the database details page:

```
Automatic minor version upgrade to engine-version
```

The preceding message indicates that RDS has scheduled your DB engine to be upgraded in the next maintenance window.

Managing an automatic minor version upgrade for Oracle

When a new minor version becomes available, you can upgrade your DB instance to this version manually. The following example upgrades the DB instance named `orclinst1` immediately:

```
aws rds apply-pending-maintenance-action \
    --resource-identifier arn:aws:rds:us-east-1:123456789012:db:orclinst1 \
    --apply-action db-upgrade \
    --opt-in-type immediate
```

To opt out of an automatic minor version upgrade that hasn't been scheduled yet, set `opt-in-type` to `undo-opt-in`, as in the following example:

```
aws rds apply-pending-maintenance-action \
    --resource-identifier arn:aws:rds:us-east-1:123456789012:db:orclinst1 \
    --apply-action db-upgrade \
    --opt-in-type undo-opt-in
```

If RDS has already scheduled an upgrade for your DB instance, you can't use `apply-pending-maintenance-action` to cancel it. But you can modify your DB instance and turn off the automatic minor upgrade feature, which then unschedules the upgrade.

To learn how to turn off automatic minor version upgrades, see Automatically upgrading the minor engine version. For more information about apply-pending-maintenance-action, see the *AWS CLI Command Reference*.

Considerations for Oracle DB upgrades

Before you upgrade your Oracle instance, review the following information.

Topics

- Oracle Multitenant considerations
- Option group considerations
- Parameter group considerations
- Time zone considerations

Oracle Multitenant considerations

The following table describes the Oracle Database architectures supported in different releases.

Oracle Database release	RDS support status	Architecture
Oracle Database 21c	Supported	CDB only
Oracle Database 19c	Supported	CDB or non-CDB

The following table describes supported and unsupported upgrade paths.

Upgrade path	Supported?
CDB to CDB	Yes
Non-CDB to CDB	No, but you can convert a non-CDB to a CDB and then upgrade it
CDB to non-CDB	No

For more information about Oracle Multitenant in RDS for Oracle, see Single-tenant configuration of the CDB architecture.

Option group considerations

If your DB instance uses a custom option group, sometimes Amazon RDS can't automatically assign a new option group. For example, this situation occurs when you upgrade to a new major version. In such cases, specify a new option group when you upgrade. We recommend that you create a new option group, and add the same options to it as in your existing custom option group.

For more information, see Creating an option group or Copying an option group.

If your DB instance uses a custom option group that contains the APEX option, you can sometimes reduce the upgrade time. To do this, upgrade your version of APEX at the same time as your DB instance. For more information, see Upgrading the APEX version.

Parameter group considerations

If your DB instance uses a custom parameter group, sometimes Amazon RDS can't automatically assign your DB instance a new parameter group. For example, this situation occurs when you upgrade to a new major version. In such cases, make sure to specify a new parameter group when you upgrade. We recommend that you create a new parameter group, and configure the parameters as in your existing custom parameter group.

For more information, see Creating a DB parameter group in Amazon RDS or Copying a DB parameter group in Amazon RDS.

Time zone considerations

You can use the time zone option to change the *system time zone* used by your Oracle DB instance. For example, you might change the time zone of a DB instance to be compatible with an on-

premises environment, or a legacy application. The time zone option changes the time zone at the host level. Amazon RDS for Oracle updates the system time zone automatically throughout the year. For more information about the system time zone, see Oracle time zone.

When you create an Oracle DB instance, the database automatically sets the *database time zone*. The database time zone is also known as the Daylight Saving Time (DST) time zone. The database time zone is distinct from the system time zone.

Between Oracle Database releases, patch sets or individual patches may include new DST versions. These patches reflect the changes in transition rules for various time zone regions. For example, a government might change when DST takes effect. Changes to DST rules may affect existing data of the `TIMESTAMP WITH TIME ZONE` data type.

If you upgrade an RDS for Oracle DB instance, Amazon RDS doesn't upgrade the database time zone file automatically. To upgrade the time zone file automatically, you can include the `TIMEZONE_FILE_AUTOUPGRADE` option in the option group associated with your DB instance during or after the engine version upgrade. For more information, see Oracle time zone file autoupgrade.

Alternatively, to upgrade the database time zone file manually, create a new Oracle DB instance that has the desired DST patch. However, we recommend that you upgrade the database time zone file using the `TIMEZONE_FILE_AUTOUPGRADE` option.

After upgrading the time zone file, migrate the data from your current instance to the new instance. You can migrate data using several techniques, including the following:

- AWS Database Migration Service
- Oracle GoldenGate
- Oracle Data Pump
- Original Export/Import (desupported for general use)

> **Note**
>
> When you migrate data using Oracle Data Pump, the utility raises the error ORA-39405 when the target time zone version is lower than the source time zone version.

For more information, see TIMESTAMP WITH TIMEZONE restrictions in the Oracle documentation.

Testing an Oracle DB upgrade

Before you upgrade your DB instance to a major version, thoroughly test your database and all applications that access the database for compatibility with the new version. We recommend that you use the following procedure.

To test a major version upgrade

1. Review the Oracle upgrade documentation for the new version of the database engine to see if there are compatibility issues that might affect your database or applications. For more information, see Database Upgrade Guide in the Oracle documentation.
2. If your DB instance uses a custom option group, create a new option group compatible with the new version you are upgrading to. For more information, see Option group considerations.
3. If your DB instance uses a custom parameter group, create a new parameter group compatible with the new version you are upgrading to. For more information, see Parameter group considerations.
4. Create a DB snapshot of the DB instance to be upgraded. For more information, see Creating a DB snapshot for a Single-AZ DB instance.
5. Restore the DB snapshot to create a new test DB instance. For more information, see Restoring to a DB instance.
6. Modify this new test DB instance to upgrade it to the new version, by using one of the following methods:
   - Console
   - AWS CLI
   - RDS API
7. Perform testing:
   - Run as many of your quality assurance tests against the upgraded DB instance as needed to ensure that your database and application work correctly with the new version.
   - Implement any new tests needed to evaluate the impact of any compatibility issues that you identified in step 1.
   - Test all stored procedures, functions, and triggers.
   - Direct test versions of your applications to the upgraded DB instance. Verify that the applications work correctly with the new version.

- Evaluate the storage used by the upgraded instance to determine if the upgrade requires additional storage. You might need to choose a larger instance class to support the new version in production. For more information, see DB instance classes.

8. If all tests pass, upgrade your production DB instance. We recommend that you confirm that the DB instance working correctly before allowing write operations to the DB instance.

Upgrading the version of an RDS for Oracle DB instance

To manually upgrade the DB engine version of an RDS for Oracle DB instance,use the AWS Management Console, the AWS CLI, or the RDS API. For general information about database upgrades in RDS, see Upgrading the version of an RDS for Oracle DB instance. To get valid upgrade targets, use the AWS CLI describe-db-engine-versions command.

Console

To upgrade the engine version of an RDS for Oracle DB instance by using the console

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**, and then choose the DB instance that you want to upgrade.
3. Choose **Modify**.
4. For **DB engine version**, choose a higher database version.
5. Choose **Continue** and check the summary of modifications. Make sure that you understand the implications of a database version upgrade. You can't convert an upgraded DB instance back to the previous version. Make sure you have tested both your database and your application with the new version before continuing.
6. Decide when to schedule your DB instance upgrade. To apply the changes immediately, choose **Apply immediately**. Choosing this option can cause an outage in some cases. For more information, see Schedule modifications setting.
7. On the confirmation page, review your changes. If they are correct, choose **Modify DB instance** to save your changes.

   Alternatively, choose **Back** to edit your changes, or choose **Cancel** to cancel your changes.

AWS CLI

To upgrade the engine version of an RDS for Oracle DB instance, you can use the CLI modify-db-instance command. Specify the following parameters:

- `--db-instance-identifier` – the name of the RDS for Oracle DB instance.
- `--engine-version` – the version number of the database engine to upgrade to.

  For information about valid engine versions, use the AWS CLI describe-db-engine-versions command.
- `--allow-major-version-upgrade` – to upgrade the DB engine version.
- `--no-apply-immediately` – to apply changes during the next maintenance window. To apply changes immediately, use `--apply-immediately`.

Example

The following example upgrades a CDB instance named `myorainst` from its current version of `19.0.0.0.ru-2024-01.rur-2024-01.r1` to version `21.0.0.0.ru-2024-04.rur-2024-04.r1`.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier myorainst \
    --engine-version 21.0.0.0.ru-2024-04.rur-2024-04.r1 \
    --allow-major-version-upgrade \
    --no-apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier myorainst ^
    --engine-version 21.0.0.0.ru-2024-04.rur-2024-04.r1 ^
    --allow-major-version-upgrade ^
    --no-apply-immediately
```

RDS API

To upgrade an RDS for Oracle DB instance, use the ModifyDBInstance action. Specify the following parameters:

- `DBInstanceIdentifier` – the name of the DB instance, for example *`myorainst`*.
- `EngineVersion` – the version number of the database engine to upgrade to. For information about valid engine versions, use the DescribeDBEngineVersions operation.
- `AllowMajorVersionUpgrade` – whether to allow a major version upgrade. To do so, set the value to `true`.
- `ApplyImmediately` – whether to apply changes immediately or during the next maintenance window. To apply changes immediately, set the value to `true`. To apply changes during the next maintenance window, set the value to `false`.

Upgrading an Oracle DB snapshot

Upgrading your Oracle DB snapshots in Amazon RDS ensures that your database remains secure, compatible, and fully supported. As older Oracle versions reach the end of patch support, you can upgrade any manual DB snapshots tied to these versions to avoid potential vulnerabilities or service limitations. For more information, see Oracle engine version management.

Amazon RDS supports upgrading snapshots in all AWS Regions.

Console

To upgrade an Oracle DB snapshot

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Snapshots**, and then select the DB snapshot that you want to upgrade.
3. For **Actions**, choose **Upgrade snapshot**. The **Upgrade snapshot** page appears.
4. Choose the **New engine version** to upgrade the snapshot to.
5. (Optional) For **Option group**, choose the option group for the upgraded DB snapshot. The same option group considerations apply when upgrading a DB snapshot as when upgrading a DB instance. For more information, see Option group considerations.
6. Choose **Save changes** to save your changes.

   During the upgrade process, all snapshot actions are disabled for this DB snapshot. Also, the DB snapshot status changes from **available** to **upgrading**, and then changes to **active** upon completion. If the DB snapshot can't be upgraded because of snapshot corruption issues, the status changes to **unavailable**. You can't recover the snapshot from this state.

> **Note**
>
> If the DB snapshot upgrade fails, the snapshot is rolled back to the original state with the original version.

AWS CLI

To upgrade an Oracle DB snapshot by using the AWS CLI, call the modify-db-snapshot command with the following parameters:

- `--db-snapshot-identifier` – The name of the DB snapshot.
- `--engine-version` – The version to upgrade the snapshot to.

You might also need to include the following parameter. The same option group considerations apply when upgrading a DB snapshot as when upgrading a DB instance. For more information, see Option group considerations.

- `--option-group-name` – The option group for the upgraded DB snapshot.

Example

The following example upgrades a DB snapshot.

For Linux, macOS, or Unix:

```
aws rds modify-db-snapshot \
    --db-snapshot-identifier mydbsnapshot \
    --engine-version 19.0.0.0.ru-2020-10.rur-2020-10.r1 \
    --option-group-name default:oracle-se2-19
```

For Windows:

```
aws rds modify-db-snapshot ^
    --db-snapshot-identifier mydbsnapshot ^
    --engine-version 19.0.0.0.ru-2020-10.rur-2020-10.r1 ^
    --option-group-name default:oracle-se2-19
```

RDS API

To upgrade an Oracle DB snapshot by using the Amazon RDS API, call the ModifyDBSnapshot operation with the following parameters:

- `DBSnapshotIdentifier` – The name of the DB snapshot.
- `EngineVersion` – The version to upgrade the snapshot to.

You might also need to include the `OptionGroupName` parameter. The same option group considerations apply when upgrading a DB snapshot as when upgrading a DB instance. For more information, see Option group considerations.

Using third-party software with your RDS for Oracle DB instance

You can host an RDS for Oracle DB instance that supports tools and third-party software.

Topics

Using Oracle GoldenGate with Amazon RDS for Oracle

Oracle GoldenGate collects, replicates, and manages transactional data between databases. It is a log-based change data capture (CDC) and replication software package used with databases for online transaction processing (OLTP) systems. Oracle GoldenGate creates trail files that contain the most recent changed data from the source database. It then pushes these files to the server, where a process converts the trail file into standard SQL to be applied to the target database.

Oracle GoldenGate with RDS for Oracle supports the following features:

- Active-Active database replication
- Disaster recovery
- Data protection
- In-Region and cross-Region replication
- Zero-downtime migration and upgrades
- Data replication between an RDS for Oracle DB instance and a non-Oracle database

> **Note**
>
> For a list of supported databases, see Oracle Fusion Middleware Supported System Configurations in the Oracle documentation.

You can use Oracle GoldenGate with RDS for Oracle to upgrade to major versions of Oracle Database. For example, you can use Oracle GoldenGate to upgrade from an Oracle Database 11g on-premises database to Oracle Database 19c on an Amazon RDS DB instance.

Topics

Supported versions and licensing options for Oracle GoldenGate

You can use Standard Edition 2 (SE2) or Enterprise Edition (EE) of RDS for Oracle with Oracle GoldenGate version 12c and higher. You can use the following Oracle GoldenGate features:

- Oracle GoldenGate Remote Capture (extract) is supported.
- Capture (extract) is supported on RDS for Oracle DB instances that use the traditional non-CDB database architecture. Oracle GoldenGate Remote PDB capture is supported on Oracle Database 21c container databases (CDBs).
- Oracle GoldenGate Remote Delivery (replicat) is supported on RDS for Oracle DB instances that use either the non-CDB or CDB architectures. Remote Delivery supports Integrated Replicat, Parallel Replicat, Coordinated Replicat, and classic Replicat.
- RDS for Oracle supports the Classic and Microservices architectures of Oracle GoldenGate.
- Oracle GoldenGate DDL and Sequence value replication is supported when using Integrated capture mode.

You are responsible for managing Oracle GoldenGate licensing (BYOL) for use with Amazon RDS in all AWS Regions. For more information, see RDS for Oracle licensing options.

Requirements and limitations for Oracle GoldenGate

When you're working with Oracle GoldenGate and RDS for Oracle, consider the following requirements and limitations:

- You're responsible for setting up and managing Oracle GoldenGate for use with RDS for Oracle.
- You're responsible for setting up an Oracle GoldenGate version that is certified with the source and the target databases. For more information, see Oracle Fusion Middleware Supported System Configurations in the Oracle documentation.
- You can use Oracle GoldenGate on many different AWS environments for many different use cases. If you have a support-related issue relating to Oracle GoldenGate, contact Oracle Support Services.
- You can use Oracle GoldenGate on RDS for Oracle DB instances that use Oracle Transparent Data Encryption (TDE). To maintain the integrity of replicated data, configure encryption on the Oracle GoldenGate hub using Amazon EBS encrypted volumes or trail file encryption. Also configure encryption for data sent between the Oracle GoldenGate hub and the source and

target database instances. RDS for Oracle DB instances support encryption with Oracle Secure Sockets Layer or Oracle native network encryption.

Oracle GoldenGate architecture

The Oracle GoldenGate architecture for use with Amazon RDS consists of the following decoupled modules:

Source database

Your source database can be either an on-premises Oracle database, an Oracle database on an Amazon EC2 instance, or an Oracle database on an Amazon RDS DB instance.

Oracle GoldenGate hub

An Oracle GoldenGate hub moves transaction information from the source database to the target database. Your hub can be either of the following:

- An Amazon EC2 instance with Oracle Database and Oracle GoldenGate installed
- An on-premises Oracle installation

You can have more than one Amazon EC2 hub. We recommend that you use two hubs if you use Oracle GoldenGate for cross-Region replication.

Target database

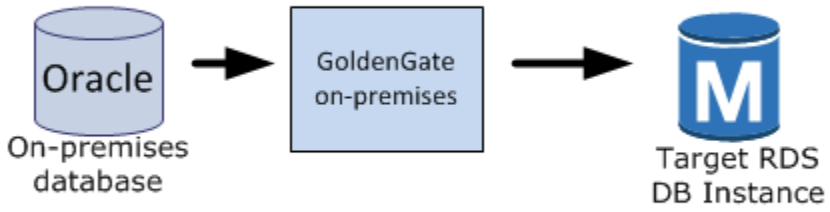
Your target database can be on either an Amazon RDS DB instance, an Amazon EC2 instance, or an on-premises location.

The following sections describe common scenarios for Oracle GoldenGate on Amazon RDS.

Topics

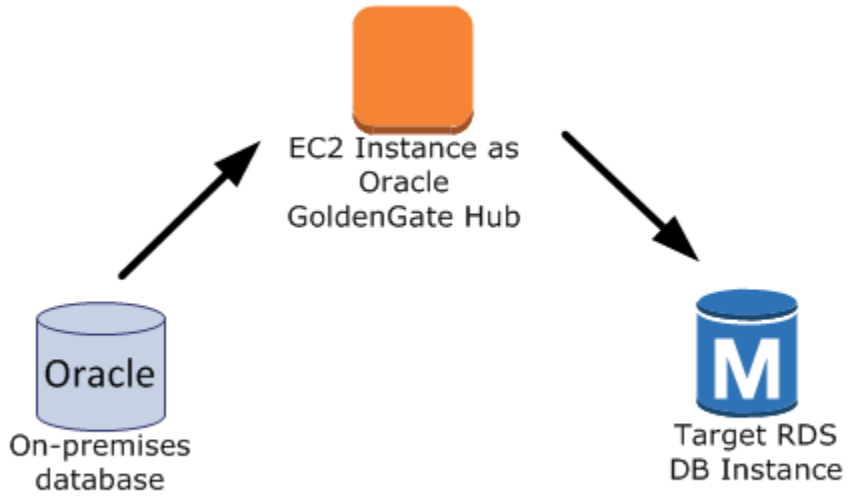
On-premises source database and Oracle GoldenGate hub

In this scenario, an on-premises Oracle source database and on-premises Oracle GoldenGate hub provides data to a target Amazon RDS DB instance.



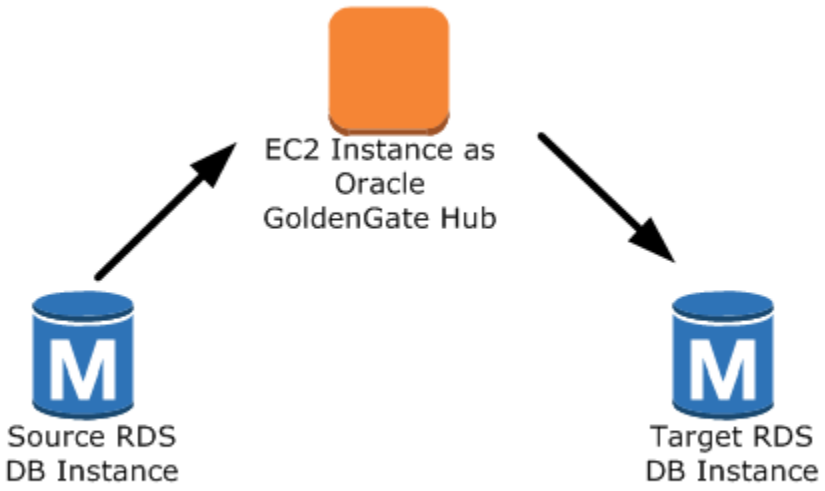
On-premises source database and Amazon EC2 hub

In this scenario, an on-premises Oracle database acts as the source database. It's connected to an Amazon EC2 instance hub. This hub provides data to a target RDS for Oracle DB instance.



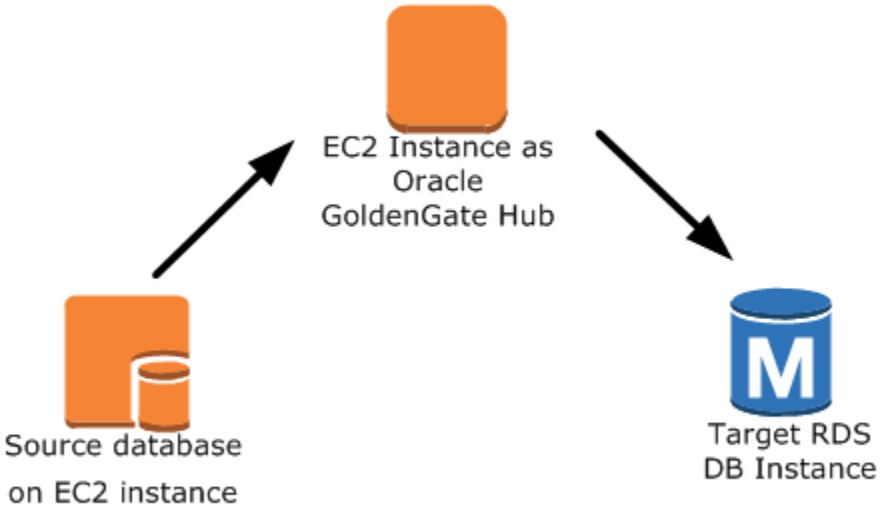
Amazon RDS source database and Amazon EC2 hub

In this scenario, an RDS for Oracle DB instance acts as the source database. It's connected to an Amazon EC2 instance hub. This hub provides data to a target RDS for Oracle DB instance.



Amazon EC2 source database and Amazon EC2 hub

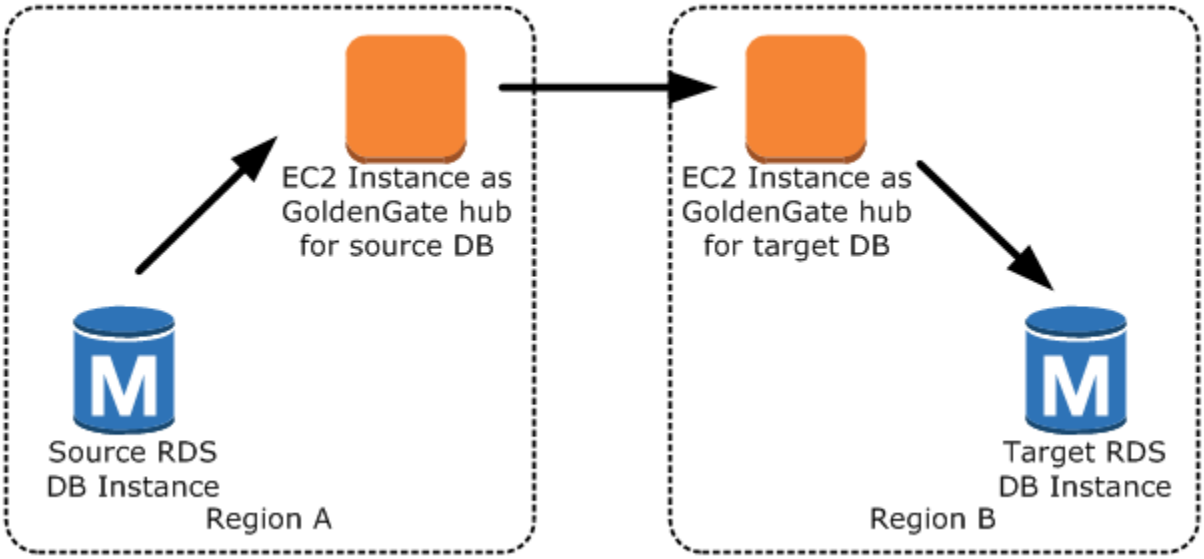
In this scenario, an Oracle database on an Amazon EC2 instance acts as the source database. It's connected to an Amazon EC2 instance hub. This hub provides data to a target RDS for Oracle DB instance.



Amazon EC2 hubs in different AWS Regions

In this scenario, an Oracle database on an Amazon RDS DB instance is connected to an Amazon EC2 instance hub in the same AWS Region. The hub is connected to an Amazon EC2 instance hub in a

different AWS Region. This second hub provides data to the target RDS for Oracle DB instance in the same AWS Region as the second Amazon EC2 instance hub.



> **Note**
>
> Any issues that affect running Oracle GoldenGate on an on-premises environment also affect running Oracle GoldenGate on AWS. We strongly recommend that you monitor the Oracle GoldenGate hub to ensure that `EXTRACT` and `REPLICAT` are resumed if a failover occurs. Because the Oracle GoldenGate hub is run on an Amazon EC2 instance, Amazon RDS does not manage the Oracle GoldenGate hub and cannot ensure that it is running.

Setting up Oracle GoldenGate

To set up Oracle GoldenGate using Amazon RDS, configure the hub on an Amazon EC2 instance, and then configure the source and target databases. The following sections give an example of how to set up Oracle GoldenGate for use with Amazon RDS for Oracle.

Topics

- Setting up an Oracle GoldenGate hub on Amazon EC2
- Setting up a source database for use with Oracle GoldenGate on Amazon RDS
- Setting up a target database for use with Oracle GoldenGate on Amazon RDS

Setting up an Oracle GoldenGate hub on Amazon EC2

To create an Oracle GoldenGate hub on an Amazon EC2 instance, you first create an Amazon EC2 instance with a full client installation of Oracle RDBMS. The Amazon EC2 instance must also have Oracle GoldenGate software installed. The Oracle GoldenGate software versions depend on the source and target database versions. For more information about installing Oracle GoldenGate, see the Oracle GoldenGate documentation.

The Amazon EC2 instance that serves as the Oracle GoldenGate hub stores and processes the transaction information from the source database into trail files. To support this process, make sure that you meet the following requirements:

- You have allocated enough storage for the trail files.
- The Amazon EC2 instance has enough processing power to manage the amount of data.
- The EC2 instance has enough memory to store the transaction information before it's written to the trail file.

To set up an Oracle GoldenGate classic architecture hub on an Amazon EC2 instance

1. Create subdirectories in the Oracle GoldenGate directory.

   In the Amazon EC2 command line shell, start `ggsci`, the Oracle GoldenGate command interpreter. The `CREATE SUBDIRS` command creates subdirectories under the `/gg` directory for parameter, report, and checkpoint files.

   ```
   prompt$ cd /gg
   prompt$ ./ggsci

   GGSCI> CREATE SUBDIRS
   ```

2. Configure the `mgr.prm` file.

   The following example adds lines to the `$GGHOME/dirprm/mgr.prm` file.

   ```
   PORT 8199
   PurgeOldExtracts ./dirdat/*, UseCheckpoints, MINKEEPDAYS 5
   ```

3. Start the manager.

   The following example starts `ggsci` and runs the `start mgr` command.

```
GGSCI> start mgr
```

The Oracle GoldenGate hub is now ready for use.

Setting up a source database for use with Oracle GoldenGate on Amazon RDS

Complete the following tasks to set up a source database for use with Oracle GoldenGate.

Setup steps

- Step 1: Turn on supplemental logging on the source database
- Step 2: Set the ENABLE_GOLDENGATE_REPLICATION initialization parameter to true
- Step 3: Set the log retention period on the source database
- Step 4: Create an Oracle GoldenGate user account on the source database
- Step 5: Grant user account privileges on the source database
- Step 6: Add a TNS alias for the source database

Step 1: Turn on supplemental logging on the source database

To turn on the minimum database-level supplemental logging, run the following PL/SQL procedure:

```
EXEC rdsadmin.rdsadmin_util.alter_supplemental_logging(p_action => 'ADD')
```

Step 2: Set the ENABLE_GOLDENGATE_REPLICATION initialization parameter to true

When you set the `ENABLE_GOLDENGATE_REPLICATION` initialization parameter to `true`, it allows database services to support logical replication. If your source database is on an Amazon RDS DB instance, make sure that you have a parameter group assigned to the DB instance with the `ENABLE_GOLDENGATE_REPLICATION` initialization parameter set to `true`. For more information about the `ENABLE_GOLDENGATE_REPLICATION` initialization parameter, see the Oracle Database documentation.

Step 3: Set the log retention period on the source database

Make sure that you configure the source database to retain archived redo logs. Consider the following guidelines:

- Specify the duration for log retention in hours. The minimum value is one hour.
- Set the duration to exceed any potential downtime of the source DB instance, any potential period of communication, and any potential period of networking issues for the source instance. Such a duration lets Oracle GoldenGate recover logs from the source instance as needed.
- Ensure that you have sufficient storage on your instance for the files.

For example, set the retention period for archived redo logs to 24 hours.

```
EXEC rdsadmin.rdsadmin_util.set_configuration('archivelog retention hours',24)
```

If you don't have log retention enabled, or if the retention value is too small, you receive an error message similar to the following.

```
2022-03-06 06:17:27  ERROR   OGG-00446  error 2 (No such file or directory)
opening redo log /rdsdbdata/db/GGTEST3_A/onlinelog/o1_mf_2_9k4bp1n6_.log for sequence
 1306
Not able to establish initial position for begin time 2022-03-06 06:16:55.
```

Because your DB instance retains your archived redo logs, make sure that you have sufficient space for the files. To see how much space you have used in the last *num_hours* hours, run the following query, replacing *num_hours* with the number of hours.

```
SELECT SUM(BLOCKS * BLOCK_SIZE) BYTES FROM V$ARCHIVED_LOG
   WHERE NEXT_TIME>=SYSDATE-num_hours/24 AND DEST_ID=1;
```

Step 4: Create an Oracle GoldenGate user account on the source database

Oracle GoldenGate runs as a database user and requires the appropriate database privileges to access the redo and archived redo logs for the source database. To provide these, create a user account on the source database. For more information about the permissions for an Oracle GoldenGate user account, see the Oracle documentation.

The following statements create a user account named oggadm1.

```
CREATE TABLESPACE administrator;
CREATE USER oggadm1  IDENTIFIED BY "password"
   DEFAULT TABLESPACE ADMINISTRATOR TEMPORARY TABLESPACE TEMP;
```

```
ALTER USER oggadm1 QUOTA UNLIMITED ON administrator;
```

> **Note**
>
> Specify a password other than the prompt shown here as a security best practice.

Step 5: Grant user account privileges on the source database

In this task, you grant necessary account privileges for database users on your source database.

To grant account privileges on the source database

1. Grant the necessary privileges to the Oracle GoldenGate user account using the SQL command `grant` and the `rdsadmin.rdsadmin_util` procedure `grant_sys_object`. The following statements grant privileges to a user named oggadm1.

   ```
   GRANT CREATE SESSION, ALTER SESSION TO oggadm1;
   GRANT RESOURCE TO oggadm1;
   GRANT SELECT ANY DICTIONARY TO oggadm1;
   GRANT FLASHBACK ANY TABLE TO oggadm1;
   GRANT SELECT ANY TABLE TO oggadm1;
   GRANT SELECT_CATALOG_ROLE TO rds_master_user_name WITH ADMIN OPTION;
   EXEC rdsadmin.rdsadmin_util.grant_sys_object ('DBA_CLUSTERS', 'OGGADM1');
   GRANT EXECUTE ON DBMS_FLASHBACK TO oggadm1;
   GRANT SELECT ON SYS.V_$DATABASE TO oggadm1;
   GRANT ALTER ANY TABLE TO oggadm1;
   ```

2. Grant the privileges needed by a user account to be an Oracle GoldenGate administrator. Run the following PL/SQL program.

   ```
   EXEC rdsadmin.rdsadmin_dbms_goldengate_auth.grant_admin_privilege (
       grantee                 => 'OGGADM1',
       privilege_type          => 'capture',
       grant_select_privileges => true,
       do_grants               => TRUE);
   ```

   To revoke privileges, use the procedure `revoke_admin_privilege` in the same package.

Step 6: Add a TNS alias for the source database

Add the following entry to `$ORACLE_HOME/network/admin/tnsnames.ora` in the Oracle home to be used by the EXTRACT process. For more information on the `tnsnames.ora` file, see the Oracle documentation.

```
OGGSOURCE=
   (DESCRIPTION=
        (ENABLE=BROKEN)
        (ADDRESS_LIST=
            (ADDRESS=(PROTOCOL=TCP)(HOST=goldengate-source.abcdef12345.us-
west-2.rds.amazonaws.com)(PORT=8200)))
        (CONNECT_DATA=(SERVICE_NAME=ORCL))
    )
```

Setting up a target database for use with Oracle GoldenGate on Amazon RDS

In this task, you set up a target DB instance for use with Oracle GoldenGate.

Setup steps

- Step 1: Set the ENABLE_GOLDENGATE_REPLICATION initialization parameter to true
- Step 2: Create an Oracle GoldenGate user account on the target database
- Step 3: Grant account privileges on the target database
- Step 4: Add a TNS alias for the target database

Step 1: Set the ENABLE_GOLDENGATE_REPLICATION initialization parameter to true

When you set the `ENABLE_GOLDENGATE_REPLICATION` initialization parameter is to `true`, it allows database services to support logical replication. If your source database is on an Amazon RDS DB instance, make sure that you have a parameter group assigned to the DB instance with the `ENABLE_GOLDENGATE_REPLICATION` initialization parameter set to `true`. For more information about the `ENABLE_GOLDENGATE_REPLICATION` initialization parameter, see the Oracle Database documentation.

Step 2: Create an Oracle GoldenGate user account on the target database

Oracle GoldenGate runs as a database user and requires the appropriate database privileges. To make sure it has these privileges, create a user account on the target database.

The following statement creates a user named `oggadm1`.

```
CREATE TABLESPSACE administrator;
CREATE USER oggadm1  IDENTIFIED BY "password"
   DEFAULT TABLESPACE administrator
   TEMPORARY TABLESPACE temp;
ALTER USER oggadm1 QUOTA UNLIMITED ON administrator;
```

> **Note**
>
> Specify a password other than the prompt shown here as a security best practice.

Step 3: Grant account privileges on the target database

In this task, you grant necessary account privileges for database users on your target database.

To grant account privileges on the target database

1. Grant necessary privileges to the Oracle GoldenGate user account on the target database. In the following example, you grant privileges to `oggadm1`.

```
GRANT CREATE SESSION        TO oggadm1;
GRANT ALTER SESSION         TO oggadm1;
GRANT CREATE CLUSTER        TO oggadm1;
GRANT CREATE INDEXTYPE      TO oggadm1;
GRANT CREATE OPERATOR       TO oggadm1;
GRANT CREATE PROCEDURE      TO oggadm1;
GRANT CREATE SEQUENCE       TO oggadm1;
GRANT CREATE TABLE          TO oggadm1;
GRANT CREATE TRIGGER        TO oggadm1;
GRANT CREATE TYPE           TO oggadm1;
GRANT SELECT ANY DICTIONARY TO oggadm1;
GRANT CREATE ANY TABLE      TO oggadm1;
GRANT ALTER ANY TABLE       TO oggadm1;
GRANT LOCK ANY TABLE        TO oggadm1;
GRANT SELECT ANY TABLE      TO oggadm1;
GRANT INSERT ANY TABLE      TO oggadm1;
GRANT UPDATE ANY TABLE      TO oggadm1;
GRANT DELETE ANY TABLE      TO oggadm1;
```

2. Grant the privileges needed by a user account to be an Oracle GoldenGate administrator. Run the following PL/SQL program.

```
EXEC rdsadmin.rdsadmin_dbms_goldengate_auth.grant_admin_privilege (
    grantee                 => 'OGGADM1',
    privilege_type          => 'apply',
    grant_select_privileges => true,
    do_grants               => TRUE);
```

To revoke privileges, use the procedure `revoke_admin_privilege` in the same package.

Step 4: Add a TNS alias for the target database

Add the following entry to `$ORACLE_HOME/network/admin/tnsnames.ora` in the Oracle home to be used by the `REPLICAT` process. For Oracle Multitenant databases, make sure that the TNS alias points to the service name of the PDB. For more information on the `tnsnames.ora` file, see the Oracle documentation.

```
OGGTARGET=
    (DESCRIPTION=
        (ENABLE=BROKEN)
        (ADDRESS_LIST=
            (ADDRESS=(PROTOCOL=TCP)(HOST=goldengate-target.abcdef12345.us-
west-2.rds.amazonaws.com)(PORT=8200)))
        (CONNECT_DATA=(SERVICE_NAME=ORCL))
    )
```

Working with the EXTRACT and REPLICAT utilities of Oracle GoldenGate

The Oracle GoldenGate utilities `EXTRACT` and `REPLICAT` work together to keep the source and target databases in sync via incremental transaction replication using trail files. All changes that occur on the source database are automatically detected by `EXTRACT`, then formatted and transferred to trail files on the Oracle GoldenGate on-premises or Amazon EC2 instance hub. After initial load is completed, the data is read from these files and replicated to the target database by the `REPLICAT` utility.

Running the Oracle GoldenGate EXTRACT utility

The `EXTRACT` utility retrieves, converts, and outputs data from the source database to trail files. The basic process is as follows:

1. `EXTRACT` queues transaction details to memory or to temporary disk storage.

2. The source database commits the transaction.
3. EXTRACT writes the transaction details to a trail file.
4. The trail file routes these details to the Oracle GoldenGate on-premises or the Amazon EC2 instance hub and then to the target database.

The following steps start the EXTRACT utility, capture the data from EXAMPLE.TABLE in source database OGGSOURCE, and create the trail files.

To run the EXTRACT utility

1. Configure the EXTRACT parameter file on the Oracle GoldenGate hub (on-premises or Amazon EC2 instance). The following listing shows an example EXTRACT parameter file named $GGHOME/dirprm/eabc.prm.

```
EXTRACT EABC

USERID oggadm1@OGGSOURCE, PASSWORD "my-password"
EXTTRAIL /path/to/goldengate/dirdat/ab

IGNOREREPLICATES
GETAPPLOPS
TRANLOGOPTIONS EXCLUDEUSER OGGADM1

TABLE EXAMPLE.TABLE;
```

2. On the Oracle GoldenGate hub, log in to the source database and launch the Oracle GoldenGate command line interface ggsci. The following example shows the format for logging in.

```
dblogin oggadm1@OGGSOURCE
```

3. Add transaction data to turn on supplemental logging for the database table.

```
add trandata EXAMPLE.TABLE
```

4. Using the ggsci command line, enable the EXTRACT utility using the following commands.

```
add extract EABC tranlog, INTEGRATED tranlog, begin now
add exttrail /path/to/goldengate/dirdat/ab
   extract EABC,
```

```
   MEGABYTES 100
```

5. Register the EXTRACT utility with the database so that the archive logs are not deleted. This task allows you to recover old, uncommitted transactions if necessary. To register the EXTRACT utility with the database, use the following command.

```
register EXTRACT EABC, DATABASE
```

6. Start the EXTRACT utility with the following command.

```
start EABC
```

Running the Oracle GoldenGate REPLICAT utility

The REPLICAT utility "pushes" transaction information in the trail files to the target database.

The following steps enable and start the REPLICAT utility so that it can replicate the captured data to the table EXAMPLE.TABLE in target database OGGTARGET.

To run the REPLICATE utility

1. Configure the REPLICAT parameter file on the Oracle GoldenGate hub (on-premises or EC2 instance). The following listing shows an example REPLICAT parameter file named $GGHOME/dirprm/rabc.prm.

```
REPLICAT RABC

USERID oggadm1@OGGTARGET, password "my-password"

ASSUMETARGETDEFS
MAP EXAMPLE.TABLE, TARGET EXAMPLE.TABLE;
```

> **Note**
>
> Specify a password other than the prompt shown here as a security best practice.

2. Log in to the target database and launch the Oracle GoldenGate command line interface (ggsci). The following example shows the format for logging in.

```
dblogin userid oggadm1@OGGTARGET
```

3. Using the `ggsci` command line, add a checkpoint table. The user indicated should be the Oracle GoldenGate user account, not the target table schema owner. The following example creates a checkpoint table named `gg_checkpoint`.

```
add checkpointtable oggadm1.oggchkpt
```

4. To enable the `REPLICAT` utility, use the following command.

```
add replicat RABC EXTTRAIL /path/to/goldengate/dirdat/ab CHECKPOINTTABLE
 oggadm1.oggchkpt
```

5. Start the `REPLICAT` utility by using the following command.

```
start RABC
```

Monitoring Oracle GoldenGate

When you use Oracle GoldenGate for replication, make sure that the Oracle GoldenGate process is up and running and the source and target databases are synchronized. You can use the following monitoring tools:

- Amazon CloudWatch is a monitoring service that is used in this pattern to monitor GoldenGate error logs.
- Amazon SNS is a message notification service that is used in this pattern to send email notifications.

For detailed instructions, see Monitor Oracle GoldenGate logs by using Amazon CloudWatch.

Troubleshooting Oracle GoldenGate

This section explains the most common issues when using Oracle GoldenGate with Amazon RDS for Oracle.

Topics

- Error opening an online redo log

- Oracle GoldenGate appears to be properly configured but replication is not working
- Integrated REPLICAT slow due to query on SYS."_DBA_APPLY_CDR_INFO"

Error opening an online redo log

Make sure that you configure your databases to retain archived redo logs. Consider the following guidelines:

- Specify the duration for log retention in hours. The minimum value is one hour.
- Set the duration to exceed any potential downtime of the source DB instance, any potential period of communication, and any potential period of networking issues for the source DB instance. Such a duration lets Oracle GoldenGate recover logs from the source DB instance as needed.
- Ensure that you have sufficient storage on your instance for the files.

If you don't have log retention enabled, or if the retention value is too small, you receive an error message similar to the following.

```
2022-03-06 06:17:27  ERROR   OGG-00446  error 2 (No such file or directory)
opening redo log /rdsdbdata/db/GGTEST3_A/onlinelog/o1_mf_2_9k4bp1n6_.log for sequence
 1306
Not able to establish initial position for begin time 2022-03-06 06:16:55.
```

Oracle GoldenGate appears to be properly configured but replication is not working

For pre-existing tables, you must specify the SCN that Oracle GoldenGate works from.

To fix this issue

1. Log in to the source database and launch the Oracle GoldenGate command line interface (`ggsci`). The following example shows the format for logging in.

   ```
   dblogin userid oggadm1@OGGSOURCE
   ```

2. Using the `ggsci` command line, set up the start SCN for the EXTRACT process. The following example sets the SCN to 223274 for the EXTRACT.

   ```
   ALTER EXTRACT EABC SCN 223274
   ```

```
start EABC
```

3. Log in to the target database. The following example shows the format for logging in.

```
dblogin userid oggadm1@OGGTARGET
```

4. Using the `ggsci` command line, set up the start SCN for the `REPLICAT` process. The following example sets the SCN to 223274 for the `REPLICAT`.

```
start RABC atcsn 223274
```

Integrated REPLICAT slow due to query on SYS."_DBA_APPLY_CDR_INFO"

Oracle GoldenGate Conflict Detection and Resolution (CDR) provides basic conflict resolution routines. For example, CDR can resolve a unique conflict for an `INSERT` statement.

When CDR resolves a collision, it can insert records into the exception table `_DBA_APPLY_CDR_INFO` temporarily. Integrated `REPLICAT` deletes these records later. In a rare scenario, the integrated `REPLICAT` can process a large number of collisions, but a new integrated `REPLICAT` does not replace it. Instead of being removed, the existing rows in `_DBA_APPLY_CDR_INFO` are orphaned. Any new integrated `REPLICAT` processes slow down because they are querying orphaned rows in `_DBA_APPLY_CDR_INFO`.

To remove all rows from `_DBA_APPLY_CDR_INFO`, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.truncate_apply$_cdr_info`. This procedure is released as part of the October 2020 release and patch update. The procedure is available in the following database versions:

- Version 21.0.0.0.ru-2022-01.rur-2022-01.r1 and higher
- Version 19.0.0.0.ru-2020-10.rur-2020-10.r1 and higher

The following example truncates the table `_DBA_APPLY_CDR_INFO`.

```
SET SERVEROUTPUT ON SIZE 2000
EXEC rdsadmin.rdsadmin_util.truncate_apply$_cdr_info;
```

Using the Oracle Repository Creation Utility on RDS for Oracle

You can use Amazon RDS to host an RDS for Oracle DB instance that holds the schemas to support your Oracle Fusion Middleware components. Before you can use Fusion Middleware components, create and populate schemas for them in your database. You create and populate the schemas by using the Oracle Repository Creation Utility (RCU).

Supported versions and licensing options for RCU

Amazon RDS supports Oracle Repository Creation Utility (RCU) version 12c only. You can use the RCU in the following configurations:

- RCU 12c with Oracle Database 21c
- RCU 12c with Oracle Database 19c

Before you can use RCU, make sure that you do the following:

- Obtain a license for Oracle Fusion Middleware.
- Follow the Oracle licensing guidelines for the Oracle database that hosts the repository. For more information, see Oracle Fusion Middleware Licensing Information User Manual in the Oracle documentation.

Fusion MiddleWare supports repositories on Oracle Database Enterprise Edition and Standard Edition 2. Oracle recommends Enterprise Edition for production installations that require partitioning and installations that require online index rebuild.

Before you create your RDS for Oracle instance, confirm the Oracle database version that you need to support the components that you want to deploy. To find the requirements for the Fusion Middleware components and versions you want to deploy, use the Certification Matrix. For more information, see Oracle Fusion Middleware Supported System Configurations in the Oracle documentation.

Amazon RDS supports Oracle database version upgrades as needed. For more information, see Upgrading a DB instance engine version.

Requirements and limitations for RCU

To use RCU, you need an Amazon VPC. Your Amazon RDS DB instance must be available only to your Fusion Middleware components, and not to the public Internet. Thus, host your Amazon RDS

DB instance in a private subnet, which provides greater security. You also need an RDS for Oracle DB instance. For more information, see Creating and connecting to an Oracle DB instance.

You can store the schemas for any Fusion Middleware components in your Amazon RDS DB instance. The following schemas have been verified to install correctly:

- Analytics (ACTIVITIES)
- Audit Services (IAU)
- Audit Services Append (IAU_APPEND)
- Audit Services Viewer (IAU_VIEWER)
- Discussions (DISCUSSIONS)
- Metadata Services (MDS)
- Oracle Business Intelligence (BIPLATFORM)
- Oracle Platform Security Services (OPSS)
- Portal and Services (WEBCENTER)
- Portlet Producers (PORTLET)
- Service Table (STB)
- SOA Infrastructure (SOAINFRA)
- User Messaging Service (UCSUMS)
- WebLogic Services (WLS)

Guidelines for using RCU

The following are some recommendations for working with your DB instance in this scenario:

- We recommend that you use Multi-AZ for production workloads. For more information about working with multiple Availability Zones, see Regions, Availability Zones, and Local Zones.
- For additional security, Oracle recommends that you use Transparent Data Encryption (TDE) to encrypt your data at rest. If you have an Enterprise Edition license that includes the Advanced Security Option, you can enable encryption at rest by using the TDE option. For more information, see Oracle Transparent Data Encryption.

  Amazon RDS also provides an encryption at rest option for all database editions. For more information, see Encrypting Amazon RDS resources.

- Configure your VPC Security Groups to allow communication between your application servers and your Amazon RDS DB instance. The application servers that host the Fusion Middleware components can be on Amazon EC2 or on-premises.

Running RCU

To create and populate the schemas to support your Fusion Middleware components, use the Oracle Repository Creation Utility (RCU). You can run RCU in different ways.

Topics

Running RCU using the command line in one step

If you don't need to edit any of your schemas before populating them, you can run RCU in a single step. Otherwise, see the following section for running RCU in multiple steps.

You can run the RCU in silent mode by using the command-line parameter `-silent`. When you run RCU in silent mode, you can avoid entering passwords on the command line by creating a text file containing the passwords. Create a text file with the password for dbUser on the first line, and the password for each component on subsequent lines. You specify the name of the password file as the last parameter to the RCU command.

Example

The following example creates and populates schemas for the SOA Infrastructure component (and its dependencies) in a single step.

For Linux, macOS, or Unix:

```
export ORACLE_HOME=/u01/app/oracle/product/12.2.1.0/fmw
export JAVA_HOME=/usr/java/jdk1.8.0_65
${ORACLE_HOME}/oracle_common/bin/rcu \
-silent \
-createRepository \
-connectString ${dbhost}:${dbport}:${dbname} \
-dbUser ${dbuser} \
```

```
-dbRole Normal \
-honorOMF \
-schemaPrefix ${SCHEMA_PREFIX} \
-component MDS \
-component STB \
-component OPSS \
-component IAU \
-component IAU_APPEND \
-component IAU_VIEWER \
-component UCSUMS \
-component WLS \
-component SOAINFRA \
-f < /tmp/passwordfile.txt
```

For more information, see Running Repository Creation Utility from the command line in the Oracle documentation.

Running RCU using the command line in multiple steps

To manually edit your schema scripts, run RCU in multiple steps:

1. Run RCU in **Prepare Scripts for System Load** mode by using the `-generateScript` command-line parameter to create the scripts for your schemas.
2. Manually edit and run the generated script `script_systemLoad.sql`.
3. Run RCU again in **Perform Product Load** mode by using the `-dataLoad` command-line parameter to populate the schemas.
4. Run the generated cleanup script `script_postDataLoad.sql`.

To run RCU in silent mode, specify the command-line parameter `-silent`. When you run RCU in silent mode, you can avoid typing passwords on the command line by creating a text file containing the passwords. Create a text file with the password for `dbUser` on the first line, and the password for each component on subsequent lines. Specify the name of the password file as the last parameter to the RCU command.

Example

The following example creates schema scripts for the SOA Infrastructure component and its dependencies.

For Linux, macOS, or Unix:

```
export ORACLE_HOME=/u01/app/oracle/product/12.2.1.0/fmw
export JAVA_HOME=/usr/java/jdk1.8.0_65
${ORACLE_HOME}/oracle_common/bin/rcu \
-silent \
-generateScript \
-connectString ${dbhost}:${dbport}:${dbname} \
-dbUser ${dbuser} \
-dbRole Normal \
-honorOMF \
[-encryptTablespace true] \
-schemaPrefix ${SCHEMA_PREFIX} \
-component MDS \
-component STB \
-component OPSS \
-component IAU \
-component IAU_APPEND \
-component IAU_VIEWER \
-component UCSUMS \
-component WLS \
-component SOAINFRA \
-scriptLocation /tmp/rcuscripts \
-f < /tmp/passwordfile.txt
```

Now you can edit the generated script, connect to your Oracle DB instance, and run the script. The generated script is named `script_systemLoad.sql`. For information about connecting to your Oracle DB instance, see Step 3: Connect your SQL client to an Oracle DB instance.

The following example populates the schemas for the SOA Infrastructure component (and its dependencies).

For Linux, macOS, or Unix:

```
export JAVA_HOME=/usr/java/jdk1.8.0_65
${ORACLE_HOME}/oracle_common/bin/rcu \
-silent \
-dataLoad \
-connectString ${dbhost}:${dbport}:${dbname} \
-dbUser ${dbuser} \
-dbRole Normal \
-honorOMF \
-schemaPrefix ${SCHEMA_PREFIX} \
-component MDS \
```

```
-component STB \
-component OPSS \
-component IAU \
-component IAU_APPEND \
-component IAU_VIEWER \
-component UCSUMS \
-component WLS \
-component SOAINFRA \
-f < /tmp/passwordfile.txt
```

To finish, you connect to your Oracle DB instance, and run the clean-up script. The script is named `script_postDataLoad.sql`.

For more information, see Running Repository Creation Utility from the command line in the Oracle documentation.

Running RCU in interactive mode

To use the RCU graphical user interface, run RCU in interactive mode. Include the `-interactive` parameter and omit the `-silent` parameter. For more information, see Understanding Repository Creation Utility screens in the Oracle documentation.

Example

The following example starts RCU in interactive mode and pre-populates the connection information.

For Linux, macOS, or Unix:

```
export ORACLE_HOME=/u01/app/oracle/product/12.2.1.0/fmw
export JAVA_HOME=/usr/java/jdk1.8.0_65
${ORACLE_HOME}/oracle_common/bin/rcu \
-interactive \
-createRepository \
-connectString ${dbhost}:${dbport}:${dbname} \
-dbUser ${dbuser} \
-dbRole Normal
```

Troubleshooting RCU

Be mindful of the following issues.

Topics

- Oracle Managed Files (OMF)
- Object privileges
- Enterprise Scheduler Service

Oracle Managed Files (OMF)

Amazon RDS uses OMF data files to simplify storage management. You can customize tablespace attributes, such as size and extent management. However, if you specify a data file name when you run RCU, the tablespace code fails with `ORA-20900`. You can use RCU with OMF in the following ways:

- In RCU 12.2.1.0 and later, use the `-honorOMF` command-line parameter.
- In RCU 12.1.0.3 and later, use multiple steps and edit the generated script. For more information, see Running RCU using the command line in multiple steps.

Object privileges

Because Amazon RDS is a managed service, you don't have full `SYSDBA` access to your RDS for Oracle DB instance. However, RCU 12c supports users with lower privileges. In most cases, the master user privilege is sufficient to create repositories.

The master account can directly grant privileges that it has already been granted `WITH GRANT OPTION`. In some cases, when you attempt to grant SYS object privileges, the RCU might fail with `ORA-01031`. You can retry and run the `rdsadmin_util.grant_sys_object` stored procedure, as shown in the following example:

```
BEGIN
  rdsadmin.rdsadmin_util.grant_sys_object('GV_$SESSION','MY_DBA','SELECT');
END;
/
```

If you attempt to grant SYS privileges on the object `SCHEMA_VERSION_REGISTRY`, the operation might fail with `ORA-20199: Error in rdsadmin_util.grant_sys_object`. You can qualify the table `SCHEMA_VERSION_REGISTRY$` and the view `SCHEMA_VERSION_REGISTRY` with the schema owner name, which is `SYSTEM`, and retry the operation. Or, you can create a synonym. Log in as the master user and run the following statements:

```
CREATE OR REPLACE VIEW SYSTEM.SCHEMA_VERSION_REGISTRY
  AS SELECT * FROM SYSTEM.SCHEMA_VERSION_REGISTRY$;
CREATE OR REPLACE PUBLIC SYNONYM SCHEMA_VERSION_REGISTRY FOR
 SYSTEM.SCHEMA_VERSION_REGISTRY;
CREATE OR REPLACE PUBLIC SYNONYM SCHEMA_VERSION_REGISTRY$ FOR SCHEMA_VERSION_REGISTRY;
```

Enterprise Scheduler Service

When you use the RCU to drop an Enterprise Scheduler Service repository, the RCU might fail with `Error: Component drop check failed`.

Configuring Oracle Connection Manager on an Amazon EC2 instance

Oracle Connection Manager (CMAN) is a proxy server that forwards connection requests to database servers or other proxy servers. You can use CMAN to configure the following:

Access control

You can create rules that filter out user-specified client requests and accept others.

Session multiplexing

You can funnel multiple client sessions through a network connection to a shared server destination.

Typically, CMAN resides on a host separate from the database server and client hosts. For more information, see Configuring Oracle Connection Manager in the Oracle Database documentation.

Topics

Supported versions and licensing options for CMAN

CMAN supports the Enterprise Edition of all versions of Oracle Database that Amazon RDS supports. For more information, see RDS for Oracle releases.

You can install Oracle Connection Manager on a separate host from the host where Oracle Database is installed. You don't need a separate license for the host that runs CMAN.

Requirements and limitations for CMAN

To provide a fully managed experience, Amazon RDS restricts access to the operating system. You can't modify database parameters that require operating system access. Thus, Amazon RDS doesn't support features of CMAN that require you to log in to the operating system.

Configuring CMAN

When you configure CMAN, you perform most of the work outside of your RDS for Oracle database.

Topics

Step 1: Configure CMAN on an Amazon EC2 instance in the same VPC as the RDS for Oracle instance

To learn how to set up CMAN, follow the detailed instructions in the blog post Configuring and using Oracle Connection Manager on Amazon EC2 for Amazon RDS for Oracle.

Step 2: Configure database parameters for CMAN

For CMAN features such as Traffic Director Mode and session multiplexing, set `REMOTE_LISTENER` parameter to the address of CMAN instance in a DB parameter group. Consider the following scenario:

- The CMAN instance resides on a host with IP address `10.0.159.100` and uses port `1521`.
- The databases `orcla`, `orclb`, and `orclc` reside on separate RDS for Oracle DB instances.

The following table shows how to set the `REMOTE_LISTENER` value. The `LOCAL_LISTENER` value is set automatically by Amazon RDS.

DB instance name	DB instance IP	Local listener value (set automatically)	Remote listener value (set by user)
`orcla`	`10.0.159.200`	`( address= (protocol=tcp) (host=10.0.159.200) (port=1521) )`	`10.0.159.100:1521`
`orclb`	`10.0.159.300`	`( address= (protocol=tcp) (host=10.0.159.300)`	`10.0.159.100:1521`

DB instance name	DB instance IP	Local listener value (set automatically)	Remote listener value (set by user)
		(port=1521))	
orclc	10.0.159.400	(address= (protocol=tcp) (host=10.0.159.400) (port=1521))	10.0.159.100:1521

Step 3: Associate your DB instance with the parameter group

Create or modify your DB instance to use the parameter group that you configured in Step 2: Configure database parameters for CMAN. For more information, see Associating a DB parameter group with a DB instance in Amazon RDS.

Installing a Siebel database on Oracle on Amazon RDS

You can use Amazon RDS to host a Siebel Database on an Oracle DB instance. The Siebel Database is part of the Siebel Customer Relationship Management (CRM) application architecture. For an illustration, see Generic architecture of Siebel business application.

Use the following topic to help set up a Siebel Database on an Oracle DB instance on Amazon RDS. You can also find out how to use Amazon Web Services to support the other components required by the Siebel CRM application architecture.

> **Note**
>
> To install a Siebel Database on Oracle on Amazon RDS, you need to use the master user account. You don't need SYSDBA privilege; master user privilege is sufficient. For more information, see Master user account privileges.

Licensing and versions

To install a Siebel Database on Amazon RDS, you must use your own Oracle Database license, and your own Siebel license. You must have the appropriate Oracle Database license (with Software Update License and Support) for the DB instance class and Oracle Database edition. For more information, see RDS for Oracle licensing options.

Oracle Database Enterprise Edition is the only edition certified by Siebel for this scenario. Amazon RDS supports Siebel CRM version 15.0 or 16.0.

Amazon RDS supports database version upgrades. For more information, see Upgrading a DB instance engine version.

Before you begin

Before you begin, you need an Amazon VPC. Because your Amazon RDS DB instance needs to be available only to your Siebel Enterprise Server, and not to the public Internet, your Amazon RDS DB instance is hosted in a private subnet, providing greater security. For information about how to create an Amazon VPC for use with Siebel CRM, see Creating and connecting to an Oracle DB instance.

Before you begin, you also need an Oracle DB instance. For information about how to create an Oracle DB instance for use with Siebel CRM, see Creating an Amazon RDS DB instance.

Installing and configuring a Siebel database

After you create your Oracle DB instance, you can install your Siebel Database. You install the database by creating table owner and administrator accounts, installing stored procedures and functions, and then running the Siebel Database Configuration Wizard. For more information, see Installing the Siebel database on the RDBMS.

To run the Siebel Database Configuration Wizard, you need to use the master user account. You don't need SYSDBA privilege; master user privilege is sufficient. For more information, see Master user account privileges.

Using other Amazon RDS features with a Siebel database

After you create your Oracle DB instance, you can use additional Amazon RDS features to help you customize your Siebel Database.

Collecting statistics with the Oracle Statspack option

You can add features to your DB instance through the use of options in DB option groups. When you created your Oracle DB instance, you used the default DB option group. If you want to add features to your database, you can create a new option group for your DB instance.

If you want to collect performance statistics on your Siebel Database, you can add the Oracle Statspack feature. For more information, see Oracle Statspack.

Some option changes are applied immediately, and some option changes are applied during the next maintenance window for the DB instance. For more information, see Working with option groups. After you create a customized option group, modify your DB instance to attach it. For more information, see Modifying an Amazon RDS DB instance.

Performance tuning with parameters

You manage your DB engine configuration through the use of parameters in a DB parameter group. When you created your Oracle DB instance, you used the default DB parameter group. If you want to customize your database configuration, you can create a new parameter group for your DB instance.

When you change a parameter, depending on the type of the parameter, the changes are applied either immediately or after you manually reboot the DB instance. For more information, see Parameter groups for Amazon RDS. After you create a customized parameter group, modify your DB instance to attach it. For more information, see Modifying an Amazon RDS DB instance.

To optimize your Oracle DB instance for Siebel CRM, you can customize certain parameters. The following table shows some recommended parameter settings. For more information about performance tuning Siebel CRM, see Siebel CRM Performance Tuning Guide.

Parameter name	Default value	Guidance for optimal Siebel CRM performance
_always_semi_join	CHOOSE	OFF
_b_tree_bitmap_plans	TRUE	FALSE
_like_with_bind_as_equality	FALSE	TRUE
_no_or_expansion	FALSE	FALSE
_optimizer_join_sel_sanity_check	TRUE	TRUE
_optimizer_max_permutations	2000	100
_optimizer_sortmerge_join_enabled	TRUE	FALSE
_partition_view_enabled	TRUE	FALSE

Parameter name	Default value	Guidance for optimal Siebel CRM performance
`open_cursors`	`300`	At least **`2000`**.

Creating snapshots

After you create your Siebel Database, you can copy the database by using the snapshot features of Amazon RDS. For more information, see Creating a DB snapshot for a Single-AZ DB instance and Restoring to a DB instance.

Support for other Siebel CRM components

In addition to your Siebel Database, you can also use Amazon Web Services to support the other components of your Siebel CRM application architecture. You can find more information about the support provided by Amazon AWS for additional Siebel CRM components in the following table.

Siebel CRM component	Amazon AWS Support
Siebel Enterprise (with one or more Siebel Servers)	You can host your Siebel Servers on Amazon Elastic Compute Cloud (Amazon EC2) instances. You can use Amazon EC2 to launch as many or as few virtual servers as you need. Using Amazon EC2, you can scale up or down easily to handle changes in requirements. For more information, see What is Amazon EC2? You can put your servers in the same VPC with your DB instance and use the VPC security group to access the database. For more information, see Working with a DB instance in a VPC.
Web Servers (with Siebel Web Server Extensions)	You can install multiple Web Servers on multiple EC2 instances. You can then use Elastic Load Balancing to distribute incoming traffic among the instances. For more information, see What is Elastic Load Balancing?

Siebel CRM component	Amazon AWS Support
Siebel Gateway Name Server	You can host your Siebel Gateway Name Server on an EC2 instance. You can then put your server in the same VPC with the DB instance and use the VPC security group to access the database. For more information, see Working with a DB instance in a VPC.

Oracle Database engine release notes

Updates to your Amazon RDS for Oracle DB instances keep them current. If you apply updates, you can be confident that your DB instance is running a version of the database software that has been tested by both Oracle and Amazon. We don't support applying one-off patches to individual RDS for Oracle DB instances.

You can specify any currently supported Oracle Database version when you create a new DB instance. You can specify the major version, such as Oracle Database 19c, and any supported minor version for the specified major version. If no version is specified, Amazon RDS defaults to a supported version, typically the most recent version. If a major version is specified but a minor version is not, Amazon RDS defaults to a recent release of the major version that you have specified. To see a list of supported versions and defaults for newly created DB instances, use the `describe-db-engine-versions` AWS CLI command.

For details about the Oracle Database versions that Amazon RDS supports, see the *Amazon RDS for Oracle Release Notes*.

Amazon RDS for PostgreSQL

Amazon RDS supports DB instances running several versions of PostgreSQL. For a list of available versions, see Available PostgreSQL database versions.

> **Note**
>
> Deprecation of PostgreSQL 9.6 is scheduled for April 26, 2022. For more information, see Deprecation of PostgreSQL version 9.6.

You can create DB instances and DB snapshots, point-in-time restores and backups. DB instances running PostgreSQL support Multi-AZ deployments, read replicas, Provisioned IOPS, and can be created inside a virtual private cloud (VPC). You can also use Secure Socket Layer (SSL) to connect to a DB instance running PostgreSQL.

Before creating a DB instance, make sure to complete the steps in Setting up your Amazon RDS environment.

You can use any standard SQL client application to run commands for the instance from your client computer. Such applications include pgAdmin, a popular Open Source administration and development tool for PostgreSQL, or psql, a command line utility that is part of a PostgreSQL installation. To deliver a managed service experience, Amazon RDS doesn't provide host access to DB instances. Also, it restricts access to certain system procedures and tables that require advanced privileges. Amazon RDS supports access to databases on a DB instance using any standard SQL client application. Amazon RDS doesn't allow direct host access to a DB instance by using Telnet or Secure Shell (SSH).

Amazon RDS for PostgreSQL is compliant with many industry standards. For example, you can use Amazon RDS for PostgreSQL databases to build HIPAA-compliant applications and to store healthcare-related information. This includes storage for protected health information (PHI) under a completed Business Associate Agreement (BAA) with AWS. Amazon RDS for PostgreSQL also meets Federal Risk and Authorization Management Program (FedRAMP) security requirements. Amazon RDS for PostgreSQL has received a FedRAMP Joint Authorization Board (JAB) Provisional Authority to Operate (P-ATO) at the FedRAMP HIGH Baseline within the AWS GovCloud (US) Regions. For more information on supported compliance standards, see AWS cloud compliance.

To import PostgreSQL data into a DB instance, follow the information in the Importing data into PostgreSQL on Amazon RDS section.

Topics

Common management tasks for Amazon RDS for PostgreSQL

The following are the common management tasks you perform with an Amazon RDS for PostgreSQL DB instance, with links to relevant documentation for each task.

Task area	Relevant documentation
Setting up Amazon RDS for first-time use Before you can create your DB instance, make sure to complete a few prerequisites. For example, DB instances are created by default with a firewall that prevents access to it. So you need to create a security group with the correct IP addresses and network configuration to access the DB instance.	Setting up your Amazon RDS environment
Understanding Amazon RDS DB instances If you are creating a DB instance for production purposes, you should understand how instance classes, storage types, and Provisioned IOPS work in Amazon RDS.	DB instance classes Amazon RDS storage types Provisioned IOPS SSD storage
Finding available PostgreSQL versions Amazon RDS supports several versions of PostgreSQL.	Available PostgreSQL database versions
Setting up high availability and failover support A production DB instance should use Multi-AZ deploymen ts. Multi-AZ deployments provide increased availability, data durability, and fault tolerance for DB instances.	Configuring and managing a Multi-AZ deployment
Understanding the Amazon Virtual Private Cloud (VPC) network If your AWS account has a default VPC, then your DB instance is automatically created inside the default VPC. In some cases, your account might not have a default VPC, and you might want the DB instance in a VPC. In these cases, create the VPC and subnet groups before you create the DB instance.	Working with a DB instance in a VPC
Importing data into Amazon RDS PostgreSQL You can use several different tools to import data into your PostgreSQL DB instance on Amazon RDS.	Importing data into PostgreSQL on Amazon RDS

Task area	Relevant documentation
Setting up read-only read replicas (primary and standbys) RDS for PostgreSQL supports read replicas in both the same AWS Region and in a different AWS Region from the primary instance.	Working with DB instance read replicas Working with read replicas for Amazon RDS for PostgreSQL Creating a read replica in a different AWS Region
Understanding security groups By default, DB instances are created with a firewall that prevents access to them. To provide access through that firewall, you edit the inbound rules for the VPC security group associated with the VPC hosting the DB instance.	Controlling access with security groups
Setting up parameter groups and features To change the default parameters for your DB instance, create a custom DB parameter group and change settings to that. If you do this before creating your DB instance, you can choose your custom DB parameter group when you create the instance.	Parameter groups for Amazon RDS
Connecting to your PostgreSQL DB instance After creating a security group and associating it to a DB instance, you can connect to the DB instance using any standard SQL client application such as `psql` or `pgAdmin`.	Connecting to a DB instance running the PostgreSQL database engine Using SSL with a PostgreSQL DB instance
Backing up and restoring your DB instance You can configure your DB instance to take automated backups, or take manual snapshots, and then restore instances from the backups or snapshots.	Backing up, restoring, and exporting data

Task area	Relevant documentation
Monitoring the activity and performance of your DB instance You can monitor a PostgreSQL DB instance by using CloudWatch Amazon RDS metrics, events, and enhanced monitoring.	Viewing metrics in the Amazon RDS console Viewing Amazon RDS events
Upgrading the PostgreSQL database version You can do both major and minor version upgrades for your PostgreSQL DB instance.	Upgrading the PostgreSQL DB engine for Amazon RDS Choosing a major version upgrade for PostgreSQL
Working with log files You can access the log files for your PostgreSQL DB instance.	RDS for PostgreSQL database log files
Understanding the best practices for PostgreSQL DB instances Find some of the best practices for working with PostgreSQL on Amazon RDS.	Best practices for working with PostgreSQL

Following is a list of other sections in this guide that can help you understand and use important features of RDS for PostgreSQL:

- Understanding PostgreSQL roles and permissions
- Controlling user access to the PostgreSQL database
- Working with parameters on your RDS for PostgreSQL DB instance
- Understanding logging mechanisms supported by RDS for PostgreSQL
- Working with the PostgreSQL autovacuum on Amazon RDS for PostgreSQL
- Using a custom DNS server for outbound network access

Working with the Database Preview environment

The PostgreSQL community continuously releases new PostgreSQL version and extensions, including beta versions. This gives PostgreSQL users the opportunity to try out a new PostgreSQL version early. To learn more about the PostgreSQL community beta release process, see Beta Information in the PostgreSQL documentation. Similarly, Amazon RDS makes certain PostgreSQL beta versions available as Preview releases. This allows you to create DB instances using the Preview version and test out its features in the Database Preview Environment.

RDS for PostgreSQL DB instances in the Database Preview Environment are functionally similar to other RDS for PostgreSQL instances. However, you can't use a Preview version for production.

Keep in mind the following important limitations:

- All DB instances are deleted 60 days after you create them, along with any backups and snapshots.
- You can only create a DB instance in a virtual private cloud (VPC) based on the Amazon VPC service.
- You can only use General Purpose SSD and Provisioned IOPS SSD storage.
- You can't get help from AWS Support with DB instances. Instead, you can post your questions to the AWS-managed Q&A community, AWS re:Post.
- You can't copy a snapshot of a DB instance to a production environment.

The following options are supported by the Preview.

- You can create DB instances using M6i, R6i, M6g, M5, T3, R6g, and R5 instance types only. For more information about RDS instance classes, see DB instance classes.
- You can use both single-AZ and multi-AZ deployments.
- You can use standard PostgreSQL dump and load functions to export databases from or import databases to the Database Preview Environment.

Features not supported in the Database Preview environment

The following features aren't available in the Database Preview environment:

- Cross-Region snapshot copy

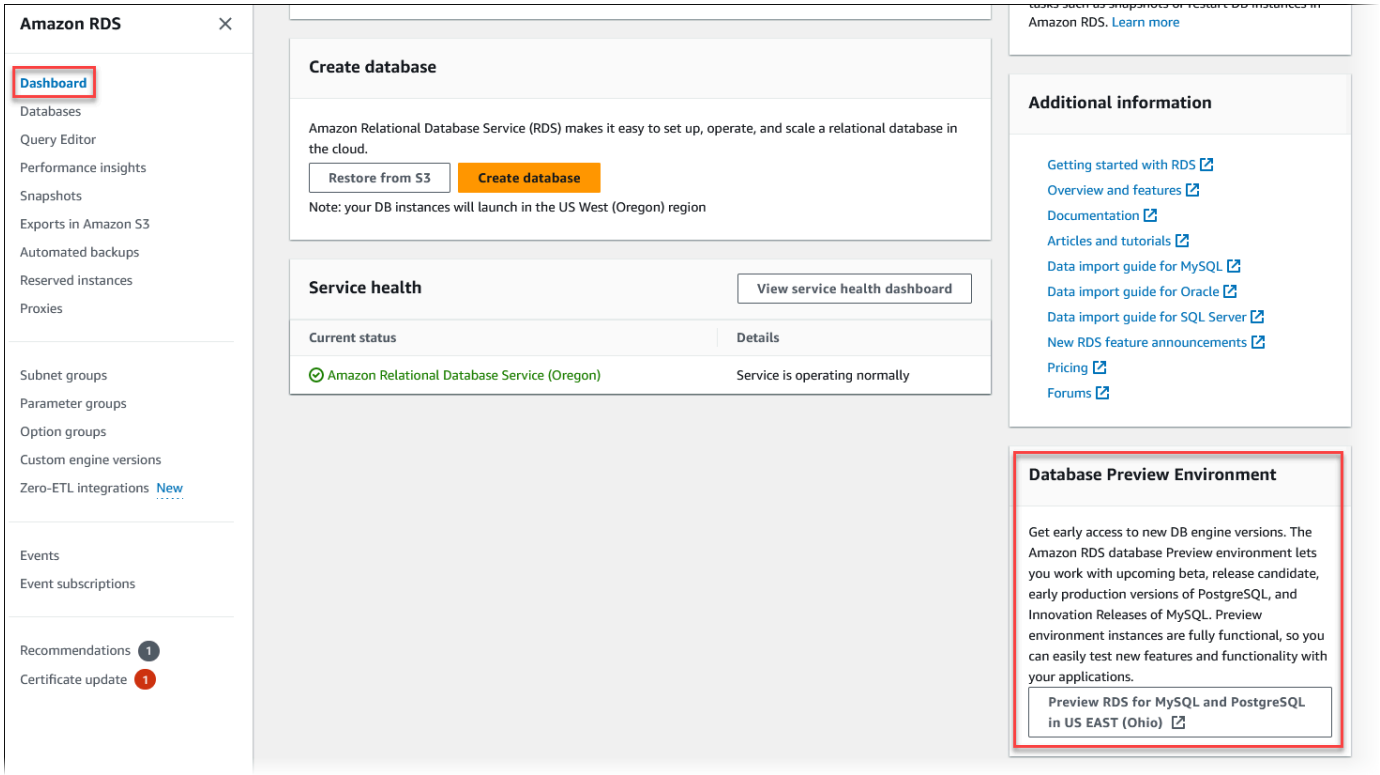
- Cross-Region read replicas

Creating a new DB instance in the Database Preview environment

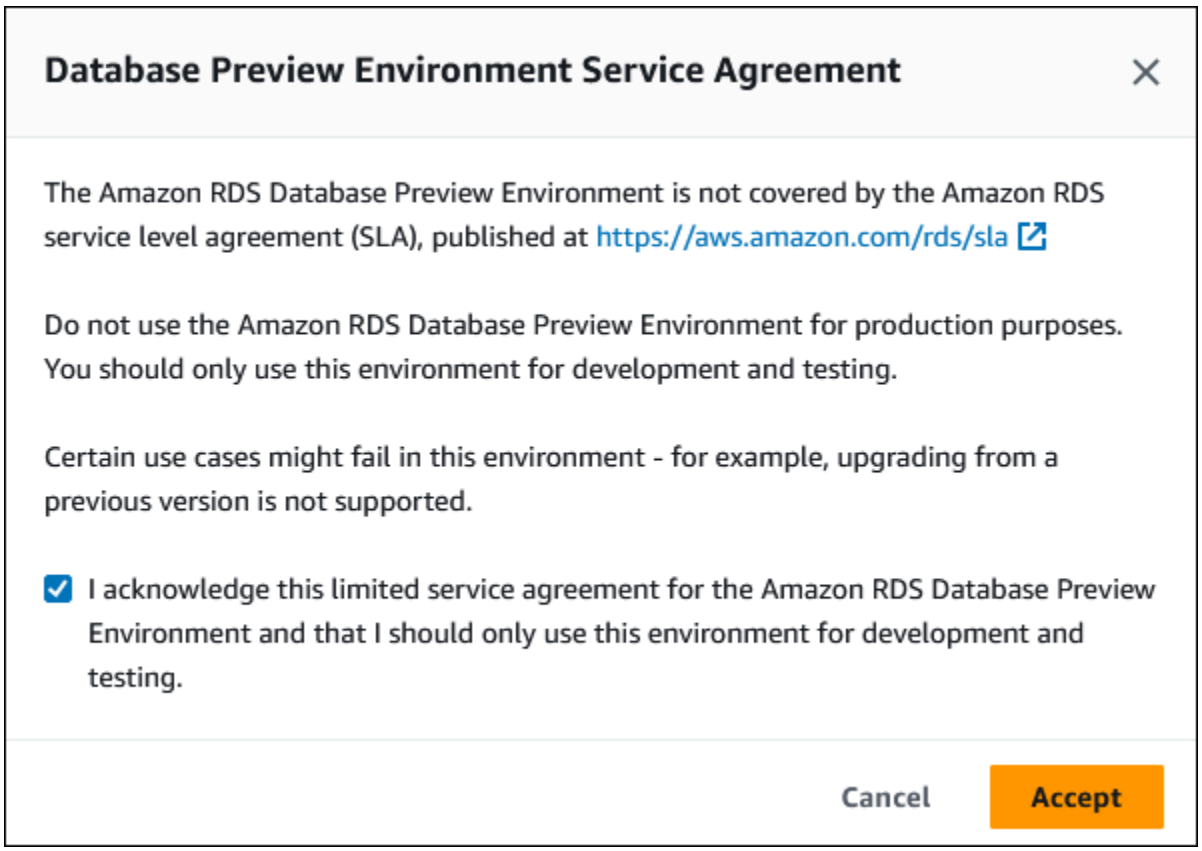
Use the following procedure to create a DB instance in the preview environment.

To create a DB instance in the Database Preview environment

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Choose **Dashboard** from the navigation pane.
3. In the Dashboard page, locate the **Database Preview Environment** section on the Dashboard page, as shown in the following image.



You can navigate directly to the Database Preview environment. Before you can proceed, you must acknowledge and accept the limitations.



4. To create the RDS for PostgreSQL DB instance, follow the same process as that for creating any Amazon RDS DB instance. For more information, see the Console procedure in Creating a DB instance.

To create an instance in the Database Preview Environment using the RDS API or the AWS CLI, use the following endpoint.

```
rds-preview.us-east-2.amazonaws.com
```

PostgreSQL version 17 in the Database Preview environment

> **Note**
>
> This is preview documentation for Amazon RDS PostgreSQL version 17. It is subject to change.

PostgreSQL version 17 RC1 is now available in the Amazon RDS Database Preview environment. PostgreSQL version 17 RC1 contains several improvements that are described in the following PostgreSQL documentation, PostgreSQL 17 RC1 Released!

For information on the Database Preview Environment, see the section called " The Database Preview environment". To access the Preview Environment from the console, select https://console.aws.amazon.com/rds-preview/.

Available PostgreSQL database versions

Amazon RDS supports DB instances running several editions of PostgreSQL. You can specify any currently available PostgreSQL version when creating a new DB instance. You can specify the major version (such as PostgreSQL 14), and any available minor version for the specified major version. If no version is specified, Amazon RDS defaults to an available version, typically the most recent version. If a major version is specified but a minor version is not, Amazon RDS defaults to a recent release of the major version you have specified.

To see a list of available versions, as well as defaults for newly created DB instances, use the `describe-db-engine-versions` AWS CLI command. For example, to display the default PostgreSQL engine version, use the following command:

```
aws rds describe-db-engine-versions --default-only --engine postgres
```

For details about the PostgreSQL versions that are supported on Amazon RDS, see the *Amazon RDS for PostgreSQL Release Notes*.

If you aren't ready to manually upgrade to a new major engine version before the RDS end of standard support date, Amazon RDS will automatically enroll your databases in Amazon RDS Extended Support after the RDS end of standard support date. Then, you can continue to run RDS for PostgreSQL version 11 and higher. For more information, see Using Amazon RDS Extended Support and Amazon RDS pricing.

Deprecation of PostgreSQL version 10

On April 17, 2023, Amazon RDS plans to deprecate PostgreSQL 10 using the following schedule. We recommend that you take action and upgrade your PostgreSQL databases running on major version 10 to a later version, such as PostgreSQL version 14. To upgrade your RDS for PostgreSQL major version 10 DB instance from a PostgreSQL version older than 10.19, we recommend that you first upgrade to version 10.19 and then upgrade to version 14. For more information, see Upgrading the PostgreSQL DB engine for Amazon RDS.

Action or recommendation	Dates
The PostgreSQL community plans to deprecate PostgreSQL 10 and won't provide any security patches after this date.	November 10, 2022

Action or recommendation	Dates
Start upgrading RDS for PostgreSQL 10 DB instances to a later major version, such as PostgreSQL 14. Although you can continue to restore PostgreSQL 10 snapshots and create read replicas with version 10, be aware of the other critical dates in this deprecation schedule and their impact.	Until February 14, 2023
After this date, you can't create new Amazon RDS instances with PostgreSQL major version 10 from either the AWS Management Console or the AWS CLI.	February 14, 2023
After this date, Amazon RDS automatically upgrades PostgreSQL 10 instances to version 14. If you restore a PostgreSQL 10 database snapshot, Amazon RDS automatically upgrades the restored database to PostgreSQL 14.	April 17, 2023

For more information about RDS for PostgreSQL version 10 deprecation, see [Announcement]: RDS for PostgreSQL 10 deprecation in AWS re:Post.

Deprecation of PostgreSQL version 9.6

On March 31, 2022, Amazon RDS plans to deprecate PostgreSQL 9.6 using the following schedule. This extends the previously announced date of January 18, 2022 to April 26, 2022. You should upgrade all your PostgreSQL 9.6 DB instances to PostgreSQL 12 or higher as soon as possible. We recommend that you first upgrade to minor version 9.6.20 or higher and then upgrade directly to PostgreSQL 12 rather than upgrading to an intermediate major version. For more information, see Upgrading the PostgreSQL DB engine for Amazon RDS.

Action or recommendation	Dates
The PostgreSQL community discontinued support for PostgreSQL 9.6, and will no longer provide bug fixes or security patches for this version.	November 11, 2021
Start upgrading RDS for PostgreSQL 9.6 DB instances to PostgreSQL 12 or higher as soon as possible. Although you can continue to restore PostgreSQL 9.6 snapshots and create read replicas with version 9.6, be aware of the other critical dates in this deprecation schedule and their impact.	Until March 31, 2022
After this date, you can't create new Amazon RDS instances with PostgreSQL major version 9.6 from either the AWS Management Console or the AWS CLI.	March 31, 2022
After this date, Amazon RDS automatically upgrades PostgreSQL 9.6 instances to version 12. If you restore a PostgreSQL 9.6 database snapshot, Amazon RDS automatically upgrades the restored database to PostgreSQL 12.	April 26, 2022

Deprecated versions for Amazon RDS for PostgreSQL

RDS for PostgreSQL 9.5 is deprecated as of March, 2021. For more information about RDS for PostgreSQL 9.5 deprecation, see Upgrading from Amazon RDS for PostgreSQL version 9.5.

To learn more about deprecation policy for RDS for PostgreSQL, see Amazon RDS FAQs. For more information about PostgreSQL versions, see Versioning Policy in the PostgreSQL documentation.

Supported PostgreSQL extension versions

RDS for PostgreSQL supports many PostgreSQL extensions. The PostgreSQL community sometimes refers to these as modules. Extensions expand on the functionality provided by the PostgreSQL engine. You can find a list of extensions supported by Amazon RDS in the default DB parameter group for that PostgreSQL version. You can also see the current extensions list using `psql` by showing the `rds.extensions` parameter as in the following example.

```
SHOW rds.extensions;
```

> **Note**
>
> Parameters added in a minor version release might display inaccurately when using the `rds.extensions` parameter in `psql`.

As of RDS for PostgreSQL 13, certain extensions can be installed by database users other than the `rds_superuser`. These are known as *trusted extensions*. To learn more, see PostgreSQL trusted extensions.

Certain versions of RDS for PostgreSQL support the `rds.allowed_extensions` parameter. This parameter lets an `rds_superuser` limit the extensions that can be installed in the RDS for PostgreSQL DB instance. For more information, see Restricting installation of PostgreSQL extensions.

For lists of PostgreSQL extensions and versions that are supported by each available RDS for PostgreSQL version, see PostgreSQL extensions supported on Amazon RDS in *Amazon RDS for PostgreSQL Release Notes*.

Restricting installation of PostgreSQL extensions

You can restrict which extensions can be installed on a PostgreSQL DB instance. By default, this parameter isn't set, so any supported extension can be added if the user has permissions to do so. To do so, set the `rds.allowed_extensions` parameter to a string of comma-separated extension names. By adding a list of extensions to this parameter, you explicitly identify the extensions that your RDS for PostgreSQL DB instance can use. Only these extensions can then be installed in the PostgreSQL DB instance.

The default string for the `rds.allowed_extensions` parameter is '*', which means that any extension available for the engine version can be installed. Changing the `rds.allowed_extensions` parameter does not require a database restart because it's a dynamic parameter.

The PostgreSQL DB instance engine must be one of the following versions for you to use the `rds.allowed_extensions` parameter:

- All PostgreSQL 16 versions
- PostgreSQL 15 and all higher versions
- PostgreSQL 14 and all higher versions
- PostgreSQL 13.3 and higher minor versions
- PostgreSQL 12.7 and higher minor versions

To see which extension installations are allowed, use the following psql command.

```
postgres=> SHOW rds.allowed_extensions;
 rds.allowed_extensions
------------------------
 *
```

If an extension was installed prior to it being left out of the list in the `rds.allowed_extensions` parameter, the extension can still be used normally, and commands such as `ALTER EXTENSION` and `DROP EXTENSION` will continue to work. However, after an extension is restricted, `CREATE EXTENSION` commands for the restricted extension will fail.

Installation of extension dependencies with `CREATE EXTENSION CASCADE` are also restricted. The extension and its dependencies must be specified in `rds.allowed_extensions`. If an extension dependency installation fails, the entire `CREATE EXTENSION CASCADE` statement will fail.

If an extension is not included with the `rds.allowed_extensions` parameter, you will see an error such as the following if you try to install it.

```
ERROR: permission denied to create extension "extension-name"
HINT: This extension is not specified in "rds.allowed_extensions".
```

PostgreSQL trusted extensions

To install most PostgreSQL extensions requires `rds_superuser` privileges. PostgreSQL 13 introduced trusted extensions, which reduce the need to grant `rds_superuser` privileges to regular users. With this feature, users can install many extensions if they have the CREATE privilege on the current database instead of requiring the `rds_superuser` role. For more information, see the SQL CREATE EXTENSION command in the PostgreSQL documentation.

The following lists the extensions that can be installed by a user who has the CREATE privilege on the current database and do not require the `rds_superuser` role:

- bool_plperl
- btree_gin
- btree_gist
- citext
- cube
- dict_int
- fuzzystrmatch
- hstore
- intarray
- isn
- jsonb_plperl
- ltree
- pg_trgm
- pgcrypto
- plperl
- plpgsql
- pltcl
- tablefunc
- tsm_system_rows
- tsm_system_time
- unaccent
- uuid-ossp

For lists of PostgreSQL extensions and versions that are supported by each available RDS for PostgreSQL version, see PostgreSQL extensions supported on Amazon RDS in *Amazon RDS for PostgreSQL Release Notes*.

Working with PostgreSQL features supported by Amazon RDS for PostgreSQL

Amazon RDS for PostgreSQL supports many of the most common PostgreSQL features. For example, PostgreSQL has an autovacuum feature that performs routine maintenance on the database. The autovacuum feature is active by default. Although you can turn off this feature, we highly recommend that you keep it on. Understanding this feature and what you can do to make sure it works as it should is a basic task of any DBA. For more information about the autovacuum, see Working with the PostgreSQL autovacuum on Amazon RDS for PostgreSQL. To learn more about other common DBA tasks, Common DBA tasks for Amazon RDS for PostgreSQL.

RDS for PostgreSQL also supports extensions that add important functionality to the DB instance. For example, you can use the PostGIS extension to work with spatial data, or use the pg_cron extension to schedule maintenance from within the instance. For more information about PostgreSQL extensions, see Using PostgreSQL extensions with Amazon RDS for PostgreSQL.

Foreign data wrappers are a specific type of extension designed to let your RDS for PostgreSQL DB instance work with other commercial databases or data types. For more information about foreign data wrappers supported by RDS for PostgreSQL, see Working with the supported foreign data wrappers for Amazon RDS for PostgreSQL.

Following, you can find information about some other features supported by RDS for PostgreSQL.

Topics

Custom data types and enumerations with RDS for PostgreSQL

PostgreSQL supports creating custom data types and working with enumerations. For more information about creating and working with enumerations and other data types, see Enumerated types in the PostgreSQL documentation.

The following is an example of creating a type as an enumeration and then inserting values into a table.

```
CREATE TYPE rainbow AS ENUM ('red', 'orange', 'yellow', 'green', 'blue', 'purple');
CREATE TYPE
CREATE TABLE t1 (colors rainbow);
CREATE TABLE
INSERT INTO t1 VALUES ('red'), ( 'orange');
INSERT 0 2
SELECT * from t1;
colors
--------
red
orange
(2 rows)
postgres=> ALTER TYPE rainbow RENAME VALUE 'red' TO 'crimson';
ALTER TYPE
postgres=> SELECT * from t1;
colors
---------
crimson
orange
(2 rows)
```

Event triggers for RDS for PostgreSQL

All current PostgreSQL versions support event triggers, and so do all available versions of RDS for PostgreSQL. You can use the main user account (default, `postgres`) to create, modify, rename, and delete event triggers. Event triggers are at the DB instance level, so they can apply to all databases on an instance.

For example, the following code creates an event trigger that prints the current user at the end of every data definition language (DDL) command.

```
CREATE OR REPLACE FUNCTION raise_notice_func()
```

```
    RETURNS event_trigger
    LANGUAGE plpgsql AS
$$
BEGIN
    RAISE NOTICE 'In trigger function: %', current_user;
END;
$$;

CREATE EVENT TRIGGER event_trigger_1
    ON ddl_command_end
EXECUTE PROCEDURE raise_notice_func();
```

For more information about PostgreSQL event triggers, see Event triggers in the PostgreSQL documentation.

There are several limitations to using PostgreSQL event triggers on Amazon RDS. These include the following:

- You can't create event triggers on read replicas. You can, however, create event triggers on a read replica source. The event triggers are then copied to the read replica. The event triggers on the read replica don't fire on the read replica when changes are pushed from the source. However, if the read replica is promoted, the existing event triggers fire when database operations occur.
- To perform a major version upgrade to a PostgreSQL DB instance that uses event triggers, make sure to delete the event triggers before you upgrade the instance.

Huge pages for RDS for PostgreSQL

Huge pages are a memory management feature that reduces overhead when a DB instance is working with large contiguous chunks of memory, such as that used by shared buffers. This PostgreSQL feature is supported by all currently available RDS for PostgreSQL versions. You allocate huge pages for your application by using calls to `mmap` or `SYSV` shared memory. RDS for PostgreSQL supports both 4-KB and 2-MB page sizes.

You can turn huge pages on or off by changing the value of the `huge_pages` parameter. The feature is turned on by default for all the DB instance classes other than micro, small, and medium DB instance classes.

RDS for PostgreSQL uses huge pages based on the available shared memory. If the DB instance can't use huge pages due to shared memory constraints, Amazon RDS prevents the DB instance

from starting. In this case, Amazon RDS sets the status of the DB instance to an incompatible parameters state. If this occurs, you can set the `huge_pages` parameter to `off` to allow Amazon RDS to start the DB instance.

The `shared_buffers` parameter is key to setting the shared memory pool that is required for using huge pages. The default value for the `shared_buffers` parameter uses a database parameters macro. This macro sets a percentage of the total 8 KB pages available for the DB instance's memory. When you use huge pages, those pages are located with the huge pages. Amazon RDS puts a DB instance into an incompatible parameters state if the shared memory parameters are set to require more than 90 percent of the DB instance memory.

To learn more about PostgreSQL memory management, see Resource Consumption in the PostgreSQL documentation.

Performing logical replication for Amazon RDS for PostgreSQL

Starting with version 10.4, RDS for PostgreSQL supports the publication and subscription SQL syntax that was introduced in PostgreSQL 10. To learn more, see Logical replication in the PostgreSQL documentation.

> **Note**
>
> In addition to the native PostgreSQL logical replication feature introduced in PostgreSQL 10, RDS for PostgreSQL also supports the `pglogical` extension. For more information, see Using pglogical to synchronize data across instances.

Following, you can find information about setting up logical replication for an RDS for PostgreSQL DB instance.

Topics

- Understanding logical replication and logical decoding
- Working with logical replication slots

Understanding logical replication and logical decoding

RDS for PostgreSQL supports the streaming of write-ahead log (WAL) changes using PostgreSQL's logical replication slots. It also supports using logical decoding. You can set up logical replication

slots on your instance and stream database changes through these slots to a client such as `pg_recvlogical`. You create logical replication slots at the database level, and they support replication connections to a single database.

The most common clients for PostgreSQL logical replication are AWS Database Migration Service or a custom-managed host on an Amazon EC2 instance. The logical replication slot has no information about the receiver of the stream. Also, there's no requirement that the target be a replica database. If you set up a logical replication slot and don't read from the slot, data can be written and quickly fill up your DB instance's storage.

You turn on PostgreSQL logical replication and logical decoding for Amazon RDS with a parameter, a replication connection type, and a security role. The client for logical decoding can be any client that can establish a replication connection to a database on a PostgreSQL DB instance.

To turn on logical decoding for an RDS for PostgreSQL DB instance

1. Make sure that the user account that you're using has these roles:
   - The `rds_superuser` role so you can turn on logical replication
   - The `rds_replication` role to grant permissions to manage logical slots and to stream data using logical slots
2. Set the `rds.logical_replication` static parameter to 1. As part of applying this parameter, also set the parameters `wal_level`, `max_wal_senders`, `max_replication_slots`, and `max_connections`. These parameter changes can increase WAL generation, so set the `rds.logical_replication` parameter only when you are using logical slots.
3. Reboot the DB instance for the static `rds.logical_replication` parameter to take effect.
4. Create a logical replication slot as explained in the next section. This process requires that you specify a decoding plugin. Currently, RDS for PostgreSQL supports the test_decoding and wal2json output plugins that ship with PostgreSQL.

For more information on PostgreSQL logical decoding, see the PostgreSQL documentation.

Working with logical replication slots

You can use SQL commands to work with logical slots. For example, the following command creates a logical slot named `test_slot` using the default PostgreSQL output plugin `test_decoding`.

```
SELECT * FROM pg_create_logical_replication_slot('test_slot', 'test_decoding');
slot_name    | xlog_position
-----------------+---------------
regression_slot | 0/16B1970
(1 row)
```

To list logical slots, use the following command.

```
SELECT * FROM pg_replication_slots;
```

To drop a logical slot, use the following command.

```
SELECT pg_drop_replication_slot('test_slot');
pg_drop_replication_slot
-----------------------
(1 row)
```

For more examples on working with logical replication slots, see Logical decoding examples in the PostgreSQL documentation.

After you create the logical replication slot, you can start streaming. The following example shows how logical decoding is controlled over the streaming replication protocol. This example uses the program pg_recvlogical, which is included in the PostgreSQL distribution. Doing this requires that client authentication is set up to allow replication connections.

```
pg_recvlogical -d postgres --slot test_slot -U postgres
    --host -instance-name.111122223333.aws-region.rds.amazonaws.com
    -f -  --start
```

To see the contents of the `pg_replication_origin_status` view, query the `pg_show_replication_origin_status` function.

```
SELECT * FROM pg_show_replication_origin_status();
local_id | external_id | remote_lsn | local_lsn
----------+-------------+------------+-----------
(0 rows)
```

RAM disk for the stats_temp_directory

You can use the RDS for PostgreSQL parameter `rds.pg_stat_ramdisk_size` to specify the system memory allocated to a RAM disk for storing the PostgreSQL `stats_temp_directory`. The RAM disk parameter is only available in RDS for PostgreSQL version 14 and lower versions.

Under certain workloads, setting this parameter can improve performance and decrease I/O requirements. For more information about the `stats_temp_directory`, see the PostgreSQL documentation..

To set up a RAM disk for your `stats_temp_directory`, set the `rds.pg_stat_ramdisk_size` parameter to an integer literal value in the parameter group used by your DB instance. This parameter denotes MB, so you must use an integer value. Expressions, formulas, and functions aren't valid for the `rds.pg_stat_ramdisk_size` parameter. Be sure to reboot the DB instance so that the change takes effect. For information about setting parameters, see Parameter groups for Amazon RDS.

For example, the following AWS CLI command sets the RAM disk parameter to 256 MB.

```
aws rds modify-db-parameter-group \
    --db-parameter-group-name pg-95-ramdisk-testing \
    --parameters "ParameterName=rds.pg_stat_ramdisk_size, ParameterValue=256,
 ApplyMethod=pending-reboot"
```

After you reboot, run the following command to see the status of the `stats_temp_directory`.

```
postgres=> SHOW stats_temp_directory;
```

The command should return the following.

```
stats_temp_directory
----------------------------
/rdsdbramdisk/pg_stat_tmp
(1 row)
```

Tablespaces for RDS for PostgreSQL

RDS for PostgreSQL supports tablespaces for compatibility. Because all storage is on a single logical volume, you can't use tablespaces for I/O splitting or isolation. Our benchmarks and experience indicate that a single logical volume is the best setup for most use cases.

To create and use tablespaces with your RDS for PostgreSQL DB instance requires the `rds_superuser` role. Your RDS for PostgreSQL DB instance's main user account (default name, `postgres`) is a member of this role. For more information, see Understanding PostgreSQL roles and permissions.

If you specify a file name when you create a tablespace, the path prefix is `/rdsdbdata/db/base/tablespace`. The following example places tablespace files in `/rdsdbdata/db/base/tablespace/data`. This example assumes that a `dbadmin` user (role) exists and that it's been granted the `rds_superuser` role needed to work with tablespaces.

```
postgres=> CREATE TABLESPACE act_data
  OWNER dbadmin
  LOCATION '/data';
CREATE TABLESPACE
```

To learn more about PostgreSQL tablespaces, see Tablespaces in the PostgreSQL documentation.

RDS for PostgreSQL collations for EBCDIC and other mainframe migrations

RDS for PostgreSQL versions 10 and higher include ICU version 60.2, which is based on Unicode 10.0 and includes collations from the Unicode Common Locale Data Repository, CLDR 32. These software internationalization libraries ensure that character encodings are presented in a consistent way, regardless of operating system or platform. For more information about Unicode CLDR-32, see the CLDR 32 Release Note on the Unicode CLDR website. You can learn more about the internationalization components for Unicode (ICU) at the ICU Technical Committee (ICU-TC) website. For information about ICU-60, see Download ICU 60.

Starting with version 14.3, RDS for PostgreSQL also includes collations that help with data integration and conversion from EBCDIC-based systems. The extended binary coded decimal interchange code or *EBCDIC* encoding is commonly used by mainframe operating systems. These Amazon RDS-provided collations are narrowly defined to sort only those Unicode characters that directly map to EBCDIC code pages. The characters are sorted in EBCDIC code-point order to allow for data validation after conversion. These collations don't include denormalized forms, nor do they include Unicode characters that don't directly map to a character on the source EBCDIC code page.

The character mappings between EBCDIC code pages and Unicode code points are based on tables published by IBM. The complete set is available from IBM as a compressed file for download. RDS

for PostgreSQL used these mappings with tools provided by the ICU to create the collations listed in the tables in this section. The collation names include a language and country as required by the ICU. However, EBCDIC code pages don't specify languages, and some EBCDIC code pages cover multiple countries. That means that the language and country portion of the collation names in the table are arbitrary, and they don't need to match the current locale. In other words, the code page number is the most important part of the collation name in this table. You can use any of the collations listed in the following tables in any RDS for PostgreSQL database.

- Unicode to EBCDIC collations table – Some mainframe data migration tools internally use LATIN1 or LATIN9 to encode and process data. Such tools use round-trip schemes to preserve data integrity and support reverse conversion. The collations in this table can be used by tools that process data using LATIN1 encoding, which doesn't require special handling.
- Unicode to LATIN9 collations table – You can use these collations in any RDS for PostgreSQL database.

In the following table, you find collations available in RDS for PostgreSQL that map EBCDIC code pages to Unicode code points. We recommend that you use the collations in this table for application development that requires sorting based on the ordering of IBM code pages.

PostgreSQL collation name	Description of code-page mapping and sort order
da-DK-cp277-x-icu	Unicode characters that directly map to IBM EBCDIC Code Page 277 (per conversion tables) are sorted in IBM CP 277 code point order
de-DE-cp273-x-icu	Unicode characters that directly map to IBM EBCDIC Code Page 273 (per conversion tables) are sorted in IBM CP 273 code point order
en-GB-cp285-x-icu	Unicode characters that directly map to IBM EBCDIC Code Page 285 (per conversion tables) are sorted in IBM CP 285 code point order

PostgreSQL collation name	Description of code-page mapping and sort order
en-US-cp037-x-icu	Unicode characters that directly map to IBM EBCDIC Code Page 037 (per conversion tables) are sorted in IBM CP 37 code point order
es-ES-cp284-x-icu	Unicode characters that directly map to IBM EBCDIC Code Page 284 (per conversion tables) are sorted in IBM CP 284 code point order
fi-FI-cp278-x-icu	Unicode characters that directly map to IBM EBCDIC Code Page 278 (per conversion tables) are sorted in IBM CP 278 code point order
fr-FR-cp297-x-icu	Unicode characters that directly map to IBM EBCDIC Code Page 297 (per conversion tables) are sorted in IBM CP 297 code point order
it-IT-cp280-x-icu	Unicode characters that directly map to IBM EBCDIC Code Page 280 (per conversion tables) are sorted in IBM CP 280 code point order
nl-BE-cp500-x-icu	Unicode characters that directly map to IBM EBCDIC Code Page 500 (per conversion tables) are sorted in IBM CP 500 code point order

Amazon RDS provides a set of additional collations that sort Unicode code points that map to LATIN9 characters using the tables published by IBM, in the order of the original code points according to the EBCDIC code page of the source data.

PostgreSQL collation name	Description of code-page mapping and sort order
da-DK-cp1142m-x-icu	Unicode characters that map to LATIN9 characters originally converted from IBM EBCDIC Code Page 1142 (per conversion

PostgreSQL collation name	Description of code-page mapping and sort order
	tables) are sorted in IBM CP 1142 code point order
de-DE-cp1141m-x-icu	Unicode characters that map to LATIN9 characters originally converted from IBM EBCDIC Code Page 1141 (per conversion tables) are sorted in IBM CP 1141 code point order
en-GB-cp1146m-x-icu	Unicode characters that map to LATIN9 characters originally converted from IBM EBCDIC Code Page 1146 (per conversion tables) are sorted in IBM CP 1146 code point order
en-US-cp1140m-x-icu	Unicode characters that map to LATIN9 characters originally converted from IBM EBCDIC Code Page 1140 (per conversion tables) are sorted in IBM CP 1140 code point order
es-ES-cp1145m-x-icu	Unicode characters that map to LATIN9 characters originally converted from IBM EBCDIC Code Page 1145 (per conversion tables) are sorted in IBM CP 1145 code point order
fi-FI-cp1143m-x-icu	Unicode characters that map to LATIN9 characters originally converted from IBM EBCDIC Code Page 1143 (per conversion tables) are sorted in IBM CP 1143 code point order

PostgreSQL collation name	Description of code-page mapping and sort order
fr-FR-cp1147m-x-icu	Unicode characters that map to LATIN9 characters originally converted from IBM EBCDIC Code Page 1147 (per conversion tables) are sorted in IBM CP 1147 code point order
it-IT-cp1144m-x-icu	Unicode characters that map to LATIN9 characters originally converted from IBM EBCDIC Code Page 1144 (per conversion tables) are sorted in IBM CP 1144 code point order
nl-BE-cp1148m-x-icu	Unicode characters that map to LATIN9 characters originally converted from IBM EBCDIC Code Page 1148 (per conversion tables) are sorted in IBM CP 1148 code point order

In the following, you can find an example of using an RDS for PostgreSQL collation.

```
db1=> SELECT pg_import_system_collations('pg_catalog');
 pg_import_system_collations
-----------------------------
                          36
db1=> SELECT '¤' < 'a' col1;
 col1
------
 t
db1=> SELECT '¤' < 'a' COLLATE "da-DK-cp277-x-icu" col1;
 col1
------
 f
```

We recommend that you use the collations in the Unicode to EBCDIC collations table and in the Unicode to LATIN9 collations table for application development that requires sorting based on the

ordering of IBM code pages. The following collations (suffixed with the letter “b”) are also visible in `pg_collation`, but are intended for use by mainframe data integration and migration tools at AWS that map code pages with specific code point shifts and require special handling in collation. In other words, the following collations aren't recommended for use.

- da-DK-277b-x-icu
- da-DK-1142b-x-icu
- de-DE-cp273b-x-icu
- de-DE-cp1141b-x-icu
- en-GB-cp1146b-x-icu
- en-GB-cp285b-x-icu
- en-US-cp037b-x-icu
- en-US-cp1140b-x-icu
- es-ES-cp1145b-x-icu
- es-ES-cp284b-x-icu
- fi-FI-cp1143b-x-icu
- fr-FR-cp1147b-x-icu

For more information about managing collations in PostgreSQL, see Collation Support in the PostgreSQL documentation.

Connecting to a DB instance running the PostgreSQL database engine

After Amazon RDS provisions your DB instance, you can use any standard SQL client application to connect to the instance. Before you can connect, the DB instance must be available and accessible. Whether you can connect to the instance from outside the VPC depends on how you created the Amazon RDS DB instance:

- If you created your DB instance as *public*, devices and Amazon EC2 instances outside the VPC can connect to your database.
- If you created your DB instance as *private*, only Amazon EC2 instances and devices inside the Amazon VPC can connect to your database.

To check whether your DB instance is public or private, use the AWS Management Console to view the **Connectivity & security** tab for your instance. Under **Security**, you can find the "Publicly accessible" value, with No for private, Yes for public.

To learn more about different Amazon RDS and Amazon VPC configurations and how they affect accessibility, see Scenarios for accessing a DB instance in a VPC.

Contents

Installing the psql client

To connect to your DB instance from an EC2 instance, you can install a PostgreSQL client on the EC2 instance. To install the psql client on Amazon Linux 2023, run the following command:

```
sudo dnf install postgresql15
```

To install the psql client on Amazon Linux 2, run the following command:

```
sudo amazon-linux-extras install postgresql14
```

To install the psql client on Ubuntu, run the following command:

```
sudo apt-get install -y postgresql14
```

Finding the connection information for an RDS for PostgreSQL DB instance

If the DB instance is available and accessible, you can connect by providing the following information to the SQL client application:

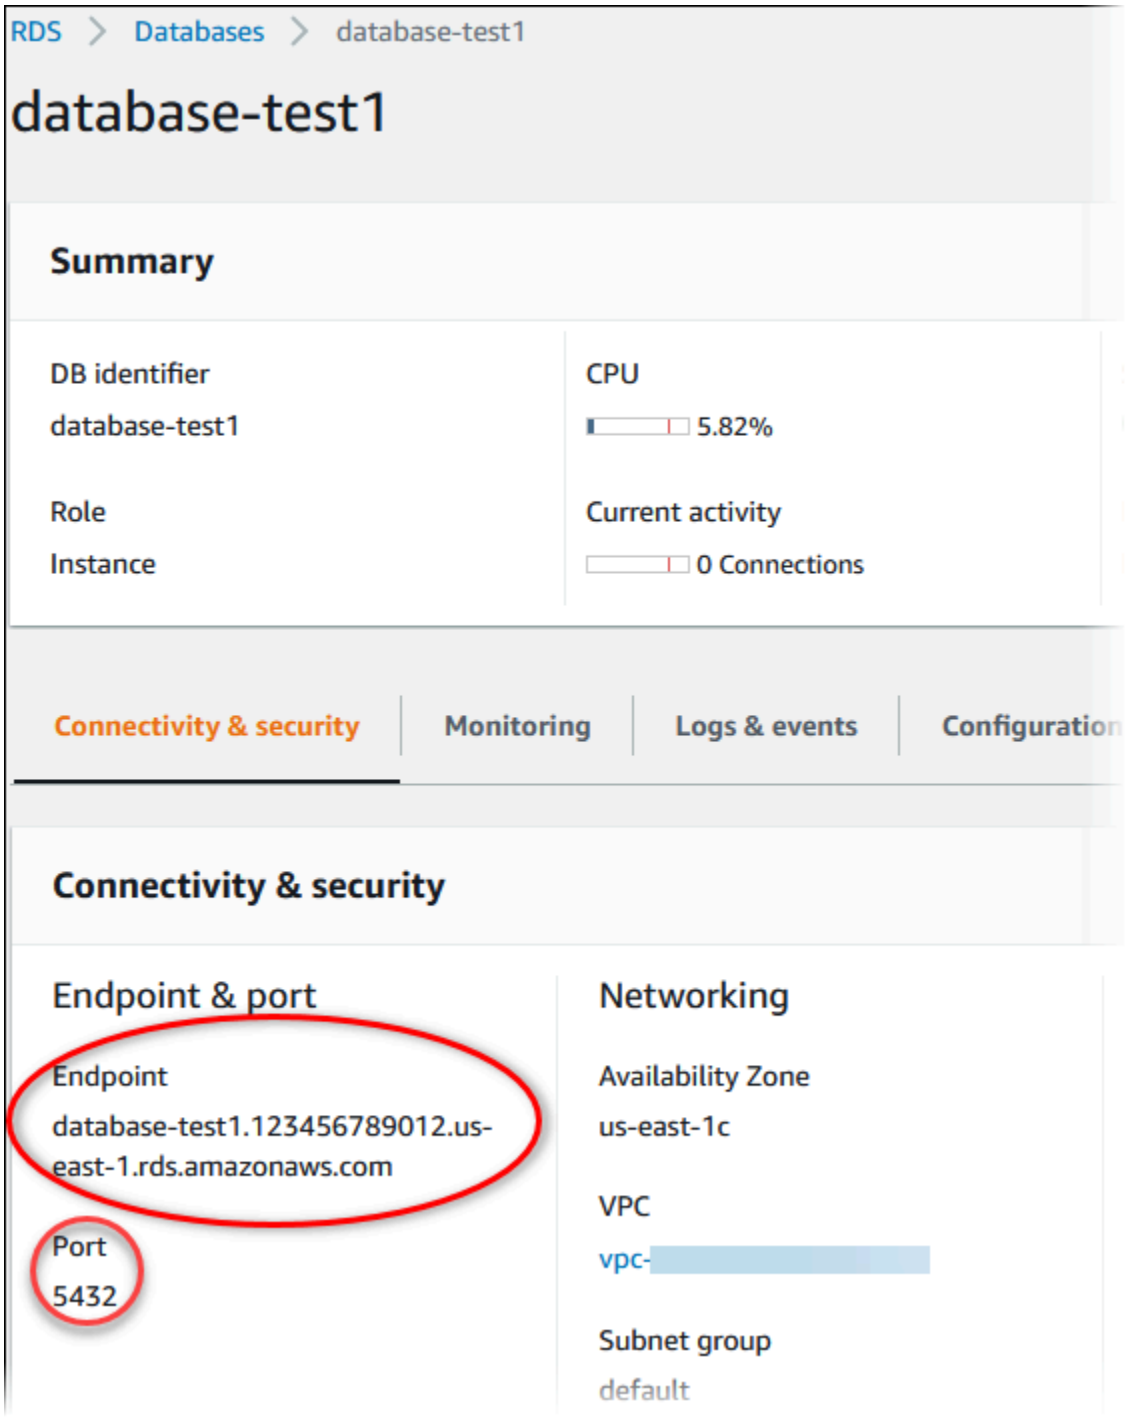
- The DB instance endpoint, which serves as the host name (DNS name) for the instance.
- The port on which the DB instance is listening. For PostgreSQL, the default port is 5432.
- The user name and password for the DB instance. The default 'master username' for PostgreSQL is `postgres`.
- The name and password of the database (DB name).

You can obtain these details by using the AWS Management Console, the AWS CLI describe-db-instances command, or the Amazon RDS API DescribeDBInstances operation.

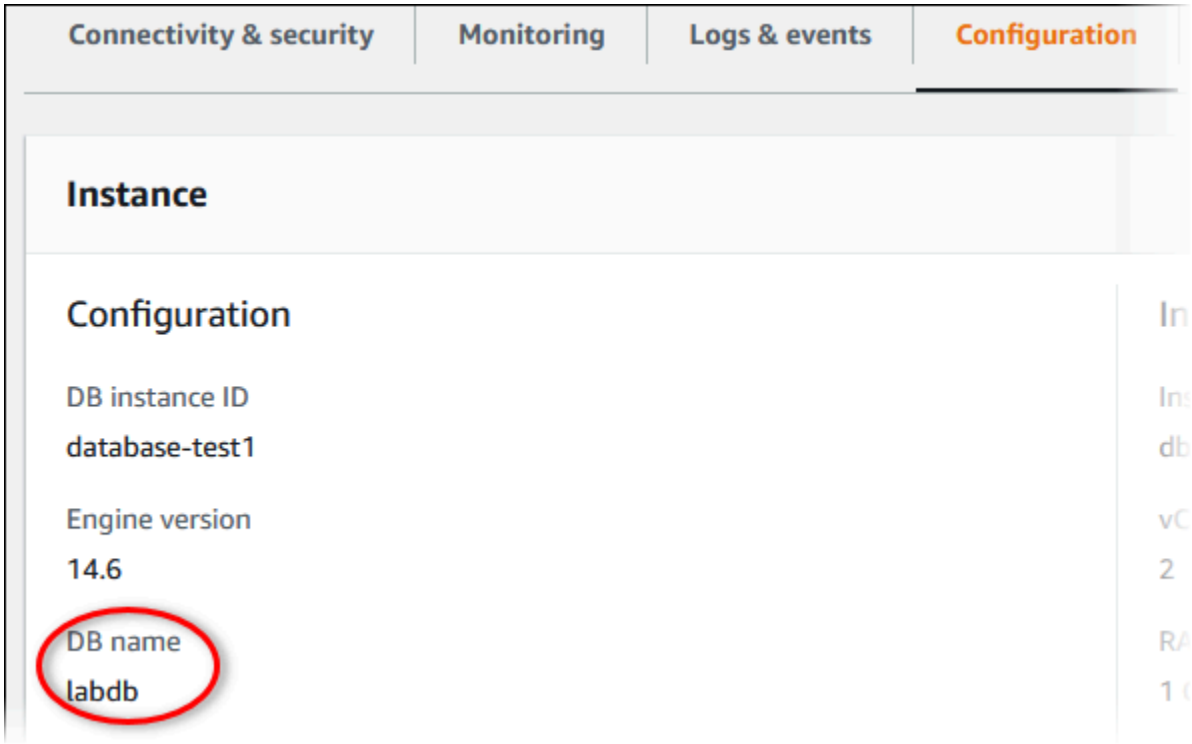
To find the endpoint, port number, and DB name using the AWS Management Console

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Open the RDS console and then choose **Databases** to display a list of your DB instances.
3. Choose the PostgreSQL DB instance name to display its details.

4. On the **Connectivity & security** tab, copy the endpoint. Also, note the port number. You need both the endpoint and the port number to connect to the DB instance.



5. On the **Configuration** tab, note the DB name. If you created a database when you created the RDS for PostgreSQL instance, you see the name listed under DB name. If you didn't create a database, the DB name displays a dash (-).



Following are two ways to connect to a PostgreSQL DB instance. The first example uses pgAdmin, a popular open-source administration and development tool for PostgreSQL. The second example uses psql, a command line utility that is part of a PostgreSQL installation.

Using pgAdmin to connect to a RDS for PostgreSQL DB instance

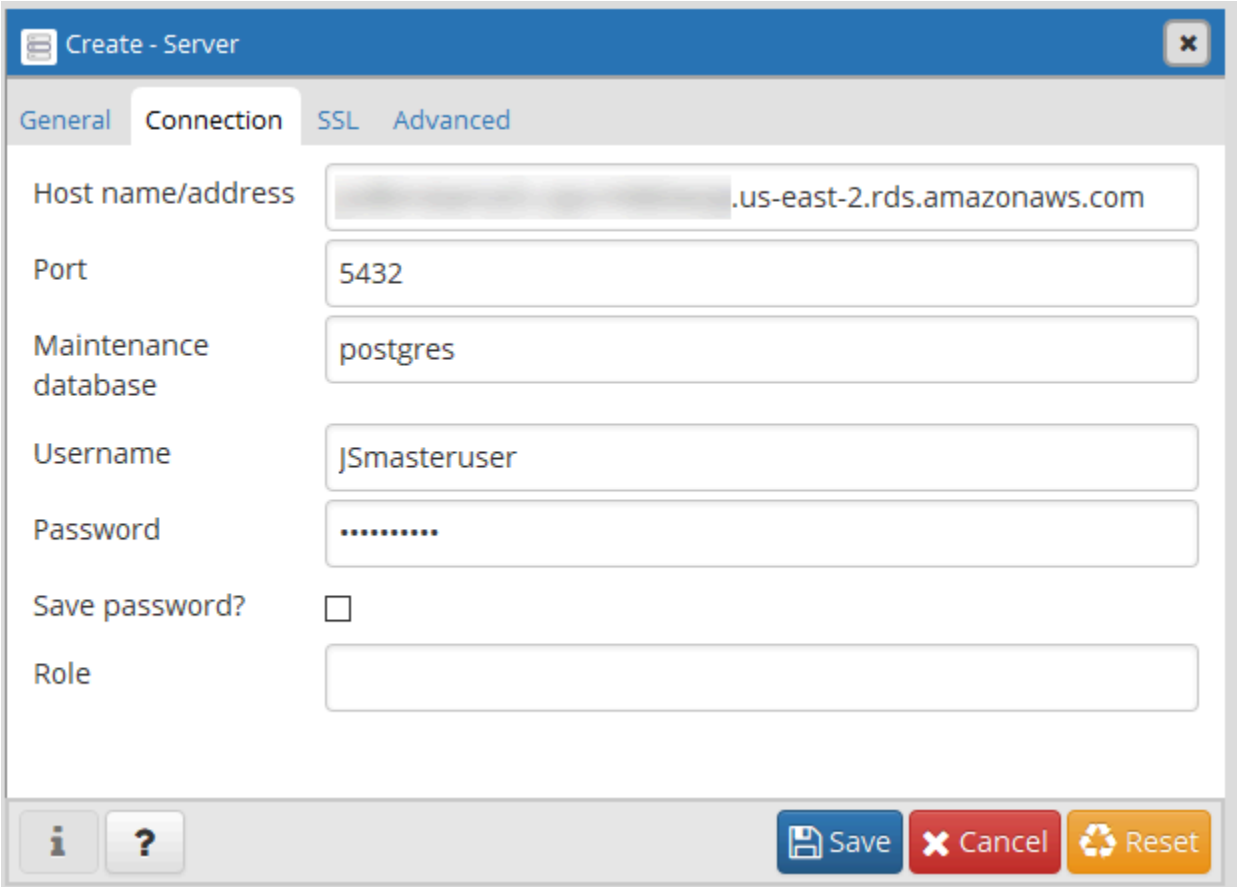
You can use the open-source tool pgAdmin to connect to your RDS for PostgreSQL DB instance. You can download and install pgAdmin from http://www.pgadmin.org/ without having a local instance of PostgreSQL on your client computer.

To connect to your RDS for PostgreSQL DB instance using pgAdmin

1. Launch the pgAdmin application on your client computer.
2. On the **Dashboard** tab, choose **Add New Server**.
3. In the **Create - Server** dialog box, type a name on the **General** tab to identify the server in pgAdmin.
4. On the **Connection** tab, type the following information from your DB instance:

   - For **Host**, type the endpoint, for example `mypostgresql.c6c8dntfzzhgv0.us-east-2.rds.amazonaws.com`.

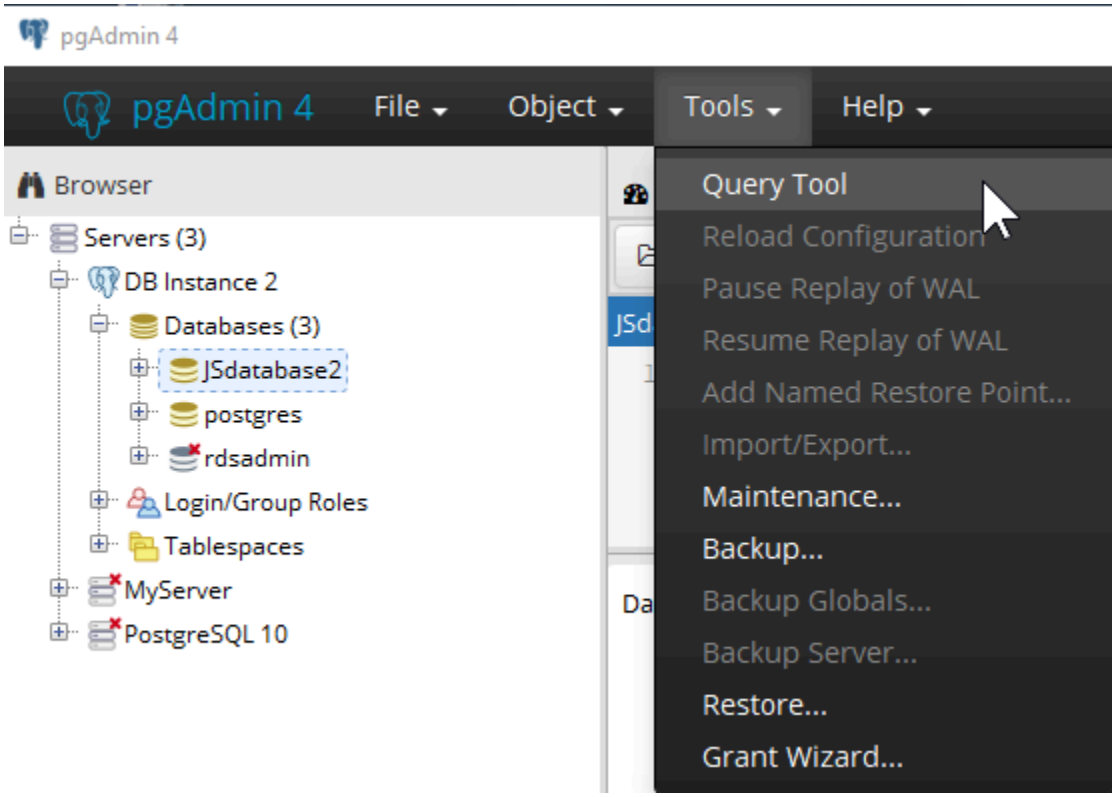
- For **Port**, type the assigned port.
- For **Username**, type the user name that you entered when you created the DB instance (if you changed the 'master username' from the default, `postgres`).
- For **Password**, type the password that you entered when you created the DB instance.



5. Choose **Save**.

   If you have any problems connecting, see [Troubleshooting connections to your RDS for PostgreSQL instance].

6. To access a database in the pgAdmin browser, expand **Servers**, the DB instance, and **Databases**. Choose the DB instance's database name.



7. To open a panel where you can enter SQL commands, choose **Tools**, **Query Tool**.

Using psql to connect to your RDS for PostgreSQL DB instance

You can use a local instance of the psql command line utility to connect to a RDS for PostgreSQL DB instance. You need either PostgreSQL or the psql client installed on your client computer.

You can download the PostgreSQL client from the PostgreSQL website. Follow the instructions specific to your operating system version to install psql.

To connect to your RDS for PostgreSQL DB instance using psql, you need to provide host (DNS) information, access credentials, and the name of the database.

Use one of the following formats to connect to your RDS for PostgreSQL DB instance. When you connect, you're prompted for a password. For batch jobs or scripts, use the `--no-password` option. This option is set for the entire session.

> **Note**
>
> A connection attempt with `--no-password` fails when the server requires password authentication and a password is not available from other sources. For more information, see the psql documentation.

If this is the first time you are connecting to this DB instance, or if you didn't yet create a database for this RDS for PostgreSQL instance, you can connect to the **postgres** database using the 'master username' and password.

For Unix, use the following format.

```
psql \
   --host=<DB instance endpoint> \
   --port=<port> \
   --username=<master username> \
   --password \
   --dbname=<database name>
```

For Windows, use the following format.

```
psql ^
   --host=<DB instance endpoint> ^
   --port=<port> ^
   --username=<master username> ^
   --password ^
   --dbname=<database name>
```

For example, the following command connects to a database called `mypgdb` on a PostgreSQL DB instance called `mypostgresql` using fictitious credentials.

```
psql --host=mypostgresql.c6c8mwvfdgv0.us-west-2.rds.amazonaws.com --port=5432 --
username=awsuser --password --dbname=mypgdb
```

Connecting to RDS for PostgreSQL with the Amazon Web Services (AWS) JDBC Driver

The Amazon Web Services (AWS) JDBC Driver is designed as an advanced JDBC wrapper. This wrapper is complementary to and extends the functionality of an existing JDBC driver. The driver is drop-in compatible with the community pgJDBC driver.

To install the AWS JDBC Driver, append the AWS JDBC Driver .jar file (located in the application CLASSPATH), and keep references to the respective community driver. Update the respective connection URL prefix as follows:

- `jdbc:postgresql://` to `jdbc:aws-wrapper:postgresql://`

For more information about the AWS JDBC Driver and complete instructions for using it, see the Amazon Web Services (AWS) JDBC Driver GitHub repository.

Connecting to RDS for PostgreSQL with the Amazon Web Services (AWS) Python Driver

The Amazon Web Services (AWS) Python Driver is designed as an advanced Python wrapper. This wrapper is complementary to and extends the functionality of the open-source Psycopg driver. The AWS Python Driver supports Python versions 3.8 and higher. You can install the `aws-advanced-python-wrapper` package using the `pip` command, along with the `psycopg` open-source packages.

For more information about the AWS Python Driver and complete instructions for using it, see the Amazon Web Services (AWS) Python Driver GitHub repository.

Troubleshooting connections to your RDS for PostgreSQL instance

Topics

Error – FATAL: database *name* does not exist

If when trying to connect you receive an error like `FATAL: database name does not exist`, try using the default database name **postgres** for the `--dbname` option.

Error – Could not connect to server: Connection timed out

If you can't connect to the DB instance, the most common error is `Could not connect to server: Connection timed out.` If you receive this error, check the following:

- Check that the host name used is the DB instance endpoint and that the port number used is correct.
- Make sure that the DB instance's public accessibility is set to **Yes** to allow external connections. To modify the **Public access** setting, see Modifying an Amazon RDS DB instance.
- Make sure that the user connecting to the database has CONNECT access to it. You can use the following query to provide connect access to the database.

  ```
  GRANT CONNECT ON DATABASE database name TO username;
  ```

- Check that the security group assigned to the DB instance has rules to allow access through any firewall your connection might go through. For example, if the DB instance was created using the default port of 5432, your company might have firewall rules blocking connections to that port from external company devices.

  To fix this, modify the DB instance to use a different port. Also, make sure that the security group applied to the DB instance allows connections to the new port. To modify the **Database port** setting, see Modifying an Amazon RDS DB instance.
- See also Errors with security group access rules.

Errors with security group access rules

By far the most common connection problem is with the security group's access rules assigned to the DB instance. If you used the default security group when you created the DB instance, the security group likely didn't have access rules that allow you to access the instance.

For the connection to work, the security group you assigned to the DB instance at its creation must allow access to the DB instance. For example, if the DB instance was created in a VPC, it must have a VPC security group that authorizes connections. Check if the DB instance was created using a

security group that doesn't authorize connections from the device or Amazon EC2 instance where the application is running.

You can add or edit an inbound rule in the security group. For **Source**, choosing **My IP** allows access to the DB instance from the IP address detected in your browser. For more information, see Provide access to your DB instance in your VPC by creating a security group.

Alternatively, if the DB instance was created outside of a VPC, it must have a database security group that authorizes those connections.

For more information about Amazon RDS security groups, see Controlling access with security groups.

Securing connections to RDS for PostgreSQL with SSL/TLS

RDS for PostgreSQL supports Secure Socket Layer (SSL) encryption for PostgreSQL DB instances. Using SSL, you can encrypt a PostgreSQL connection between your applications and your PostgreSQL DB instances. You can also force all connections to your PostgreSQL DB instance to use SSL. RDS for PostgreSQL also supports Transport Layer Security (TLS), the successor protocol to SSL.

To learn more about Amazon RDS and data protection, including encrypting connections using SSL/TLS, see Data protection in Amazon RDS.

Topics

Using SSL with a PostgreSQL DB instance

Amazon RDS supports Secure Socket Layer (SSL) encryption for PostgreSQL DB instances. Using SSL, you can encrypt a PostgreSQL connection between your applications and your PostgreSQL DB instances. By default, RDS for PostgreSQL uses and expects all clients to connect using SSL/TLS, but you can also require it. RDS for PostgreSQL supports Transport Layer Security (TLS) versions 1.1, 1.2, and 1.3.

For general information about SSL support and PostgreSQL databases, see SSL support in the PostgreSQL documentation. For information about using an SSL connection over JDBC, see Configuring the client in the PostgreSQL documentation.

SSL support is available in all AWS Regions for PostgreSQL. Amazon RDS creates an SSL certificate for your PostgreSQL DB instance when the instance is created. If you enable SSL certificate verification, then the SSL certificate includes the DB instance endpoint as the Common Name (CN) for the SSL certificate to guard against spoofing attacks.

Topics

- SSL cipher suites in RDS for PostgreSQL

Connecting to a PostgreSQL DB instance over SSL

To connect to a PostgreSQL DB instance over SSL

1. Download the certificate.

   For information about downloading certificates, see Using SSL/TLS to encrypt a connection to a DB instance or cluster.

2. Connect to your PostgreSQL DB instance over SSL.

   When you connect using SSL, your client can choose whether to verify the certificate chain. If your connection parameters specify `sslmode=verify-ca` or `sslmode=verify-full`, then your client requires the RDS CA certificates to be in their trust store or referenced in the connection URL. This requirement is to verify the certificate chain that signs your database certificate.

   When a client, such as psql or JDBC, is configured with SSL support, the client first tries to connect to the database with SSL by default. If the client can't connect with SSL, it reverts to connecting without SSL. The default `sslmode` mode used is different between libpq-based clients (such as psql) and JDBC. The libpq-based clients default to `prefer`, and JDBC clients default to `verify-full`.

   Use the `sslrootcert` parameter to reference the certificate, for example `sslrootcert=rds-ssl-ca-cert.pem`.

The following is an example of using `psql` to connect to a PostgreSQL DB instance using SSL with certificate verification.

```
$ psql "host=db-name.555555555555.ap-southeast-1.rds.amazonaws.com
    port=5432 dbname=testDB user=testuser sslrootcert=rds-ca-rsa2048-g1.pem
 sslmode=verify-full"
```

Requiring an SSL connection to a PostgreSQL DB instance

You can require that connections to your PostgreSQL DB instance use SSL by using the `rds.force_ssl` parameter. The `rds.force_ssl` parameter default value is 1 (on) for RDS for

PostgreSQL version 15 and later. For all other RDS for PostgreSQL major versions 14 and older, the default value of this parameter is 0 (off). You can set the `rds.force_ssl` parameter to 1 (on) to require SSL/TLS for connections to your DB cluster. You can set the `rds.force_ssl` parameter to 1 (on) to require SSL for connections to your DB instance.

To change the value of this parameter, you need to create a custom DB parameter group. You then change the value for `rds.force_ssl` in your custom DB parameter group to 1 to turn on this feature. If you prepare the custom DB parameter group before creating your RDS for PostgreSQL DB instance you can choose it (instead of a default parameter group) during the creation process. If you do this after your RDS for PostgreSQL DB instance is already running, you need to reboot the instance so that your instance uses the custom parameter group. For more information, see Parameter groups for Amazon RDS.

When the `rds.force_ssl` feature is active on your DB instance, connection attempts that aren't using SSL are rejected with the following message:

```
$ psql -h db-name.555555555555.ap-southeast-1.rds.amazonaws.com port=5432 dbname=testDB
 user=testuser
psql: error: FATAL: no pg_hba.conf entry for host "w.x.y.z", user "testuser", database
 "testDB", SSL off
```

Determining the SSL connection status

The encrypted status of your connection is shown in the logon banner when you connect to the DB instance:

```
Password for user master:
psql (10.3)
SSL connection (cipher: DHE-RSA-AES256-SHA, bits: 256)
Type "help" for help.
postgres=>
```

You can also load the `sslinfo` extension and then call the `ssl_is_used()` function to determine if SSL is being used. The function returns `t` if the connection is using SSL, otherwise it returns `f`.

```
postgres=> CREATE EXTENSION sslinfo;
CREATE EXTENSION
postgres=> SELECT ssl_is_used();
ssl_is_used
```

```
---------
t
(1 row)
```

For more detailed information, you can use the following query to get information from pg_settings:

```
SELECT name as "Parameter name", setting as value, short_desc FROM pg_settings WHERE
 name LIKE '%ssl%';
             Parameter name             |                  value                  |
                  short_desc
----------------------------------------+-----------------------------------------
+-------------------------------------------------------
 ssl                                    | on                                      |
 Enables SSL connections.
 ssl_ca_file                            | /rdsdbdata/rds-metadata/ca-cert.pem     |
 Location of the SSL certificate authority file.
 ssl_cert_file                          | /rdsdbdata/rds-metadata/server-cert.pem |
 Location of the SSL server certificate file.
 ssl_ciphers                            | HIGH:!aNULL:!3DES                       |
 Sets the list of allowed SSL ciphers.
 ssl_crl_file                           |                                         |
 Location of the SSL certificate revocation list file.
 ssl_dh_params_file                     |                                         |
 Location of the SSL DH parameters file.
 ssl_ecdh_curve                         | prime256v1                              |
 Sets the curve to use for ECDH.
 ssl_key_file                           | /rdsdbdata/rds-metadata/server-key.pem  |
 Location of the SSL server private key file.
 ssl_library                            | OpenSSL                                 |
 Name of the SSL library.
 ssl_max_protocol_version               |                                         |
 Sets the maximum SSL/TLS protocol version to use.
 ssl_min_protocol_version               | TLSv1.2                                 |
 Sets the minimum SSL/TLS protocol version to use.
 ssl_passphrase_command                 |                                         |
 Command to obtain passphrases for SSL.
 ssl_passphrase_command_supports_reload | off                                     |
 Also use ssl_passphrase_command during server reload.
 ssl_prefer_server_ciphers              | on                                      |
 Give priority to server ciphersuite order.
(14 rows)
```

You can also collect all the information about your RDS for PostgreSQL DB instance's SSL usage by process, client, and application by using the following query:

```
SELECT datname as "Database name", usename as "User name", ssl, client_addr,
 application_name, backend_type
   FROM pg_stat_ssl
   JOIN pg_stat_activity
   ON pg_stat_ssl.pid = pg_stat_activity.pid
   ORDER BY ssl;
 Database name | User name | ssl |  client_addr   |    application_name    |
 backend_type
---------------+-----------+-----+----------------+------------------------
+------------------------------
               |           | f   |                |                        | autovacuum
 launcher
               | rdsadmin  | f   |                |                        | logical
 replication launcher
               |           | f   |                |                        | background
 writer
               |           | f   |                |                        |
 checkpointer
               |           | f   |                |                        | walwriter
 rdsadmin      | rdsadmin  | t   | 127.0.0.1      |                        | client
 backend
 rdsadmin      | rdsadmin  | t   | 127.0.0.1      | PostgreSQL JDBC Driver | client
 backend
 postgres      | postgres  | t   | 204.246.162.36 | psql                   | client
 backend
(8 rows)
```

To identify the cipher used for your SSL connection, you can query as follows:

```
postgres=> SELECT ssl_cipher();
ssl_cipher
--------------------
DHE-RSA-AES256-SHA
(1 row)
```

To learn more about the `sslmode` option, see Database connection control functions in the *PostgreSQL documentation*.

SSL cipher suites in RDS for PostgreSQL

The PostgreSQL configuration parameter ssl_ciphers specifies the categories of cipher suites that are allowed for SSL connections. The following table lists the default cipher suites used in RDS for PostgreSQL.

PostgreSQL engine version	Cipher suites
16	`HIGH:!aNULL:!3DES`
15	`HIGH:!aNULL:!3DES`
14	`HIGH:!aNULL:!3DES`
13	`HIGH:!aNULL:!3DES`
12	`HIGH:!aNULL:!3DES`
11.4 and higher minor versions	`HIGH:MEDIUM:+3DES:!aNULL:!RC4`
11.1, 11.2	`HIGH:MEDIUM:+3DES:!aNULL`
10.9 and higher minor versions	`HIGH:MEDIUM:+3DES:!aNULL:!RC4`
10.7 and lower minor versions	`HIGH:MEDIUM:+3DES:!aNULL`

Updating applications to connect to PostgreSQL DB instances using new SSL/TLS certificates

Certificates used for Secure Socket Layer or Transport Layer Security (SSL/TLS) typically have a set lifetime. When service providers update their Certificate Authority (CA) certificates, clients must update their applications to use the new certificates. Following, you can find information about how to determine if your client applications use SSL/TLS to connect to your Amazon RDS for PostgreSQL DB instance. You also find information about how to check if those applications verify the server certificate when they connect.

> **Note**
>
> A client application that's configured to verify the server certificate before SSL/TLS connection must have a valid CA certificate in the client's trust store. Update the client trust store when necessary for new certificates.

After you update your CA certificates in the client application trust stores, you can rotate the certificates on your DB instances. We strongly recommend testing these procedures in a nonproduction environment before implementing them in your production environments.

For more information about certificate rotation, see Rotating your SSL/TLS certificate. For more information about downloading certificates, see Using SSL/TLS to encrypt a connection to a DB instance or cluster. For information about using SSL/TLS with PostgreSQL DB instances, see Using SSL with a PostgreSQL DB instance.

Topics

- Determining whether applications are connecting to PostgreSQL DB instances using SSL
- Determining whether a client requires certificate verification in order to connect
- Updating your application trust store
- Using SSL/TLS connections for different types of applications

Determining whether applications are connecting to PostgreSQL DB instances using SSL

Check the DB instance configuration for the value of the `rds.force_ssl` parameter. By default, the `rds.force_ssl` parameter is set to `0` (off) for DB instances using PostgreSQL versions before version 15. By default, `rds.force_ssl` is set to `1` (on) for DB instances using PostgreSQL version 15 and later major versions. If the `rds.force_ssl` parameter is set to `1` (on), clients are required to use SSL/TLS for connections. For more information about parameter groups, see Parameter groups for Amazon RDS.

If you are using RDS PostgreSQL version 9.5 or later major version and `rds.force_ssl` is not set to `1` (on), query the `pg_stat_ssl` view to check connections using SSL. For example, the following query returns only SSL connections and information about the clients using SSL.

```
SELECT datname, usename, ssl, client_addr
```

```
  FROM pg_stat_ssl INNER JOIN pg_stat_activity ON pg_stat_ssl.pid =
 pg_stat_activity.pid
  WHERE ssl is true and usename<>'rdsadmin';
```

Only rows using SSL/TLS connections are displayed with information about the connection. The following is sample output.

```
 datname  | usename | ssl | client_addr
----------+---------+-----+-------------
 benchdb  | pgadmin | t   | 53.95.6.13
 postgres | pgadmin | t   | 53.95.6.13
(2 rows)
```

This query displays only the current connections at the time of the query. The absence of results doesn't indicate that no applications are using SSL connections. Other SSL connections might be established at a different time.

Determining whether a client requires certificate verification in order to connect

When a client, such as psql or JDBC, is configured with SSL support, the client first tries to connect to the database with SSL by default. If the client can't connect with SSL, it reverts to connecting without SSL. The default `sslmode` mode used for both libpq-based clients (such as psql) and JDBC is set to `prefer`. The certificate on the server is verified only when `sslrootcert` is provided with `sslmode` set to `verify-ca` or `verify-full`. An error is thrown if the certificate is invalid.

Use PGSSLROOTCERT to verify the certificate with the PGSSLMODE environment variable, with PGSSLMODE set to `verify-ca` or `verify-full`.

```
PGSSLMODE=verify-full PGSSLROOTCERT=/fullpath/ssl-cert.pem psql -h
 pgdbidentifier.cxxxxxxxx.us-east-2.rds.amazonaws.com -U masteruser -d postgres
```

Use the `sslrootcert` argument to verify the certificate with `sslmode` in connection string format, with `sslmode` set to `verify-ca` or `verify-full` to verify the certificate.

```
psql "host=pgdbidentifier.cxxxxxxxx.us-east-2.rds.amazonaws.com sslmode=verify-full
 sslrootcert=/full/path/ssl-cert.pem user=masteruser dbname=postgres"
```

For example, in the preceding case, if you are using an invalid root certificate, then you see an error similar to the following on your client.

```
psql: SSL error: certificate verify failed
```

Updating your application trust store

For information about updating the trust store for PostgreSQL applications, see Secure TCP/IP connections with SSL in the PostgreSQL documentation.

For information about downloading the root certificate, see Using SSL/TLS to encrypt a connection to a DB instance or cluster.

For sample scripts that import certificates, see Sample script for importing certificates into your trust store.

> **Note**
>
> When you update the trust store, you can retain older certificates in addition to adding the new certificates.

Using SSL/TLS connections for different types of applications

The following provides information about using SSL/TLS connections for different types of applications:

- **psql**

  The client is invoked from the command line by specifying options either as a connection string or as environment variables. For SSL/TLS connections, the relevant options are `sslmode` (environment variable `PGSSLMODE`), `sslrootcert` (environment variable `PGSSLROOTCERT`).

  For the complete list of options, see Parameter key words in the PostgreSQL documentation. For the complete list of environment variables, see Environment variables in the PostgreSQL documentation.

- **pgAdmin**

  This browser-based client is a more user-friendly interface for connecting to a PostgreSQL database.

  For information about configuring connections, see the pgAdmin documentation.

- **JDBC**

  JDBC enables database connections with Java applications.

  For general information about connecting to a PostgreSQL database with JDBC, see Connecting to the database in the PostgreSQL JDBC driver documentation. For information about connecting with SSL/TLS, see Configuring the client in the PostgreSQL JDBC driver documentation.

- **Python**

  A popular Python library for connecting to PostgreSQL databases is `psycopg2`.

  For information about using `psycopg2`, see the psycopg2 documentation. For a short tutorial on how to connect to a PostgreSQL database, see Psycopg2 tutorial. You can find information about the options the connect command accepts in The psycopg2 module content.

> **Important**
>
> After you have determined that your database connections use SSL/TLS and have updated your application trust store, you can update your database to use the rds-ca-rsa2048-g1 certificates. For instructions, see step 3 in Updating your CA certificate by modifying your DB instance or cluster.

Using Kerberos authentication with Amazon RDS for PostgreSQL

You can use Kerberos to authenticate users when they connect to your DB instance running PostgreSQL. To do so, configure your DB instance to use AWS Directory Service for Microsoft Active Directory for Kerberos authentication. AWS Directory Service for Microsoft Active Directory is also called AWS Managed Microsoft AD. It's a feature available with AWS Directory Service. To learn more, see What is AWS Directory Service? in the *AWS Directory Service Administration Guide*.

To start, create an AWS Managed Microsoft AD directory to store user credentials. Then, provide to your PostgreSQL DB instance the Active Directory's domain and other information. When users authenticate with the PostgreSQL DB instance, authentication requests are forwarded to the AWS Managed Microsoft AD directory.

Keeping all of your credentials in the same directory can save you time and effort. You have a centralized location for storing and managing credentials for multiple DB instances. Using a directory can also improve your overall security profile.

In addition, you can access credentials from your own on-premises Microsoft Active Directory. To do so, create a trusting domain relationship so that the AWS Managed Microsoft AD directory trusts your on-premises Microsoft Active Directory. In this way, your users can access your PostgreSQL instances with the same Windows single sign-on (SSO) experience as when they access workloads in your on-premises network.

A database can use password authentication or password authentication with either Kerberos or AWS Identity and Access Management (IAM) authentication. For more information about IAM authentication, see IAM database authentication for MariaDB, MySQL, and PostgreSQL.

Topics

Region and version availability

Feature availability and support varies across specific versions of each database engine, and across AWS Regions. For more information on version and Region availability of RDS for PostgreSQL with Kerberos authentication, see Supported Regions and DB engines for Kerberos authentication in Amazon RDS.

Overview of Kerberos authentication for PostgreSQL DB instances

To set up Kerberos authentication for a PostgreSQL DB instance, take the following steps, described in more detail later:

1. Use AWS Managed Microsoft AD to create an AWS Managed Microsoft AD directory. You can use the AWS Management Console, the AWS CLI, or the AWS Directory Service API to create the directory. Make sure to open the relevant outbound ports on the directory security group so that the directory can communicate with the instance.
2. Create a role that provides Amazon RDS access to make calls to your AWS Managed Microsoft AD directory. To do so, create an AWS Identity and Access Management (IAM) role that uses the managed IAM policy `AmazonRDSDirectoryServiceAccess`.

   For the IAM role to allow access, the AWS Security Token Service (AWS STS) endpoint must be activated in the correct AWS Region for your AWS account. AWS STS endpoints are active by default in all AWS Regions, and you can use them without any further actions. For more information, see Activating and deactivating AWS STS in an AWS Region in the *IAM User Guide*.
3. Create and configure users in the AWS Managed Microsoft AD directory using the Microsoft Active Directory tools. For more information about creating users in your Active Directory, see Manage users and groups in AWS Managed Microsoft AD in the *AWS Directory Service Administration Guide*.
4. If you plan to locate the directory and the DB instance in different AWS accounts or virtual private clouds (VPCs), configure VPC peering. For more information, see What is VPC peering? in the *Amazon VPC Peering Guide*.
5. Create or modify a PostgreSQL DB instance either from the console, CLI, or RDS API using one of the following methods:
   - Creating an Amazon RDS DB instance
   - Modifying an Amazon RDS DB instance
   - Restoring to a DB instance

- Restoring a DB instance to a specified time

You can locate the instance in the same Amazon Virtual Private Cloud (VPC) as the directory or in a different AWS account or VPC. When you create or modify the PostgreSQL DB instance, do the following:

- Provide the domain identifier (`d-*` identifier) that was generated when you created your directory.
- Provide the name of the IAM role that you created.
- Ensure that the DB instance security group can receive inbound traffic from the directory security group.

6. Use the RDS master user credentials to connect to the PostgreSQL DB instance. Create the user in PostgreSQL to be identified externally. Externally identified users can log in to the PostgreSQL DB instance using Kerberos authentication.

Setting up Kerberos authentication for PostgreSQL DB instances

You use AWS Directory Service for Microsoft Active Directory (AWS Managed Microsoft AD) to set up Kerberos authentication for a PostgreSQL DB instance. To set up Kerberos authentication, take the following steps.

Topics

- Step 1: Create a directory using AWS Managed Microsoft AD
- Step 2: (Optional) Create a trust relationship between your on-premises Active Directory and AWS Directory Service
- Step 3: Create an IAM role for Amazon RDS to access the AWS Directory Service
- Step 4: Create and configure users
- Step 5: Enable cross-VPC traffic between the directory and the DB instance
- Step 6: Create or modify a PostgreSQL DB instance
- Step 7: Create PostgreSQL users for your Kerberos principals
- Step 8: Configure a PostgreSQL client

Step 1: Create a directory using AWS Managed Microsoft AD

AWS Directory Service creates a fully managed Active Directory in the AWS Cloud. When you create an AWS Managed Microsoft AD directory, AWS Directory Service creates two domain controllers and DNS servers for you. The directory servers are created in different subnets in a VPC. This redundancy helps make sure that your directory remains accessible even if a failure occurs.

When you create an AWS Managed Microsoft AD directory, AWS Directory Service performs the following tasks on your behalf:

- Sets up an Active Directory within your VPC.
- Creates a directory administrator account with the user name `Admin` and the specified password. You use this account to manage your directory.

  > **Important**
  >
  > Make sure to save this password. AWS Directory Service doesn't store this password, and it can't be retrieved or reset.

- Creates a security group for the directory controllers. The security group must permit communication with the PostgreSQL DB instance.

When you launch AWS Directory Service for Microsoft Active Directory, AWS creates an Organizational Unit (OU) that contains all of your directory's objects. This OU, which has the NetBIOS name that you entered when you created your directory, is located in the domain root. The domain root is owned and managed by AWS.

The `Admin` account that was created with your AWS Managed Microsoft AD directory has permissions for the most common administrative activities for your OU:

- Create, update, or delete users
- Add resources to your domain such as file or print servers, and then assign permissions for those resources to users in your OU
- Create additional OUs and containers
- Delegate authority
- Restore deleted objects from the Active Directory Recycle Bin

- Run Active Directory and Domain Name Service (DNS) modules for Windows PowerShell on the Active Directory Web Service

The `Admin` account also has rights to perform the following domain-wide activities:

- Manage DNS configurations (add, remove, or update records, zones, and forwarders)
- View DNS event logs
- View security event logs

To create a directory with AWS Managed Microsoft AD

1. In the AWS Directory Service console navigation pane, choose **Directories**, and then choose **Set up directory**.
2. Choose **AWS Managed Microsoft AD**. AWS Managed Microsoft AD is the only option currently supported for use with Amazon RDS.
3. Choose **Next**.
4. On the **Enter directory information** page, provide the following information:

   Edition

   Choose the edition that meets your requirements.

   Directory DNS name

   The fully qualified name for the directory, such as **`corp.example.com`**.

   Directory NetBIOS name

   An optional short name for the directory, such as `CORP`.

   Directory description

   An optional description for the directory.

   Admin password

   The password for the directory administrator. The directory creation process creates an administrator account with the user name `Admin` and this password.

The directory administrator password can't include the word "admin." The password is case-sensitive and must be 8–64 characters in length. It must also contain at least one character from three of the following four categories:

- Lowercase letters (a–z)
- Uppercase letters (A–Z)
- Numbers (0–9)
- Nonalphanumeric characters (~!@#$%^&*_-+=`|\(){}[]:;"'<>,.?/)

Confirm password

Retype the administrator password.

> **Important**
>
> Make sure that you save this password. AWS Directory Service doesn't store this password, and it can't be retrieved or reset.

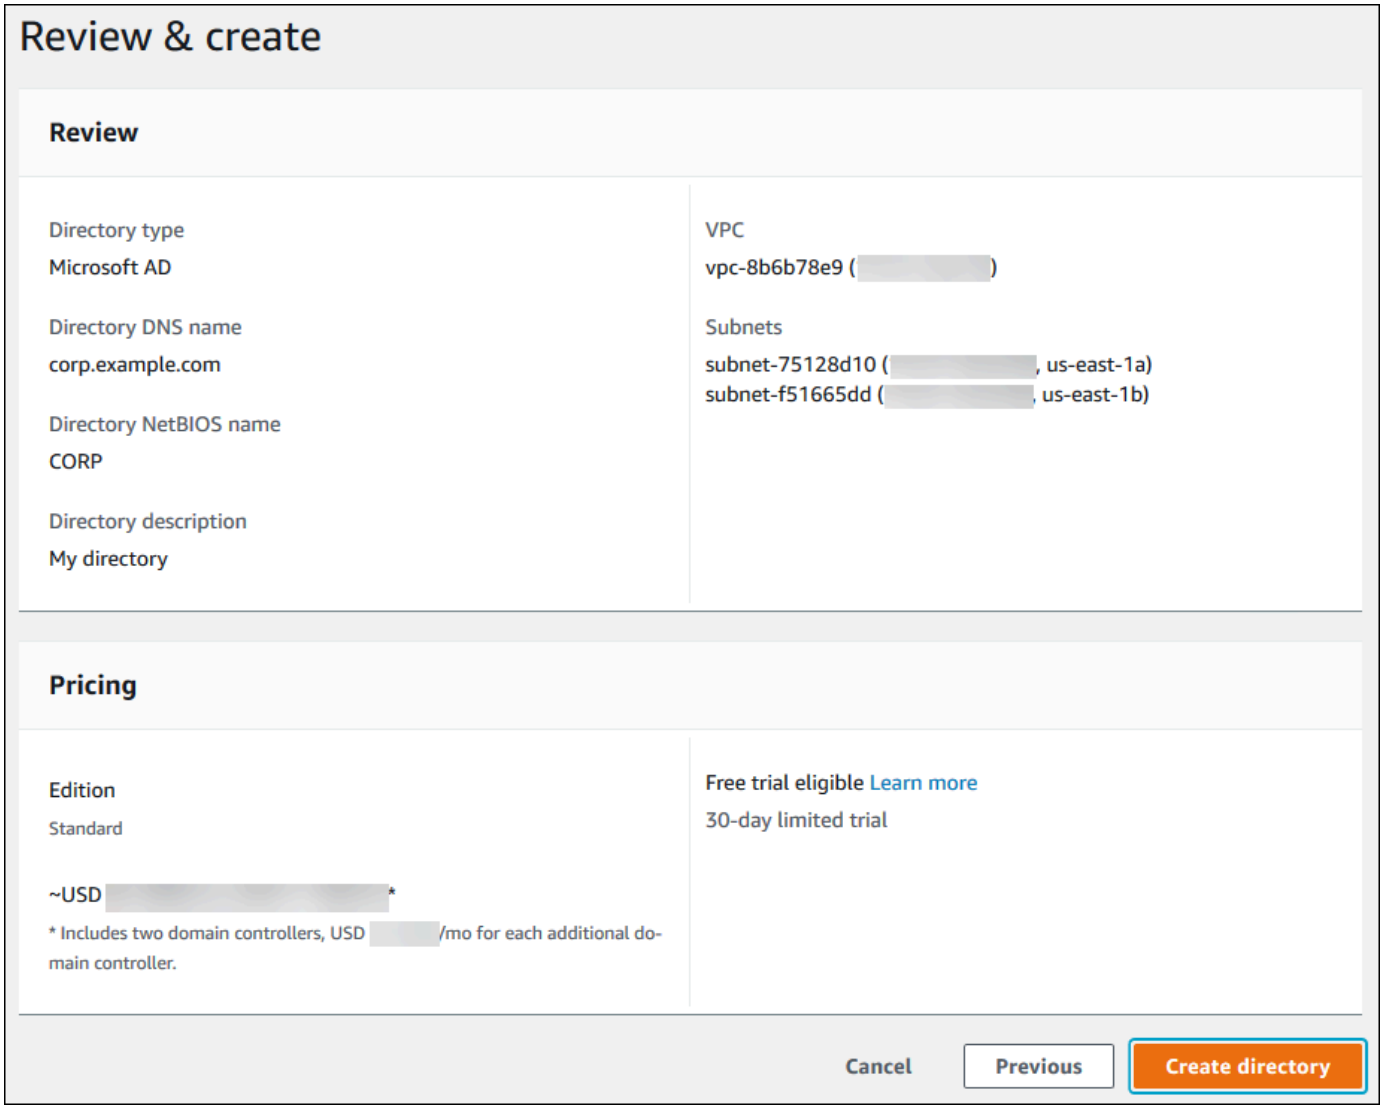
5. Choose **Next**.
6. On the **Choose VPC and subnets** page, provide the following information:

   VPC

   Choose the VPC for the directory. You can create the PostgreSQL DB instance in this same VPC or in a different VPC.

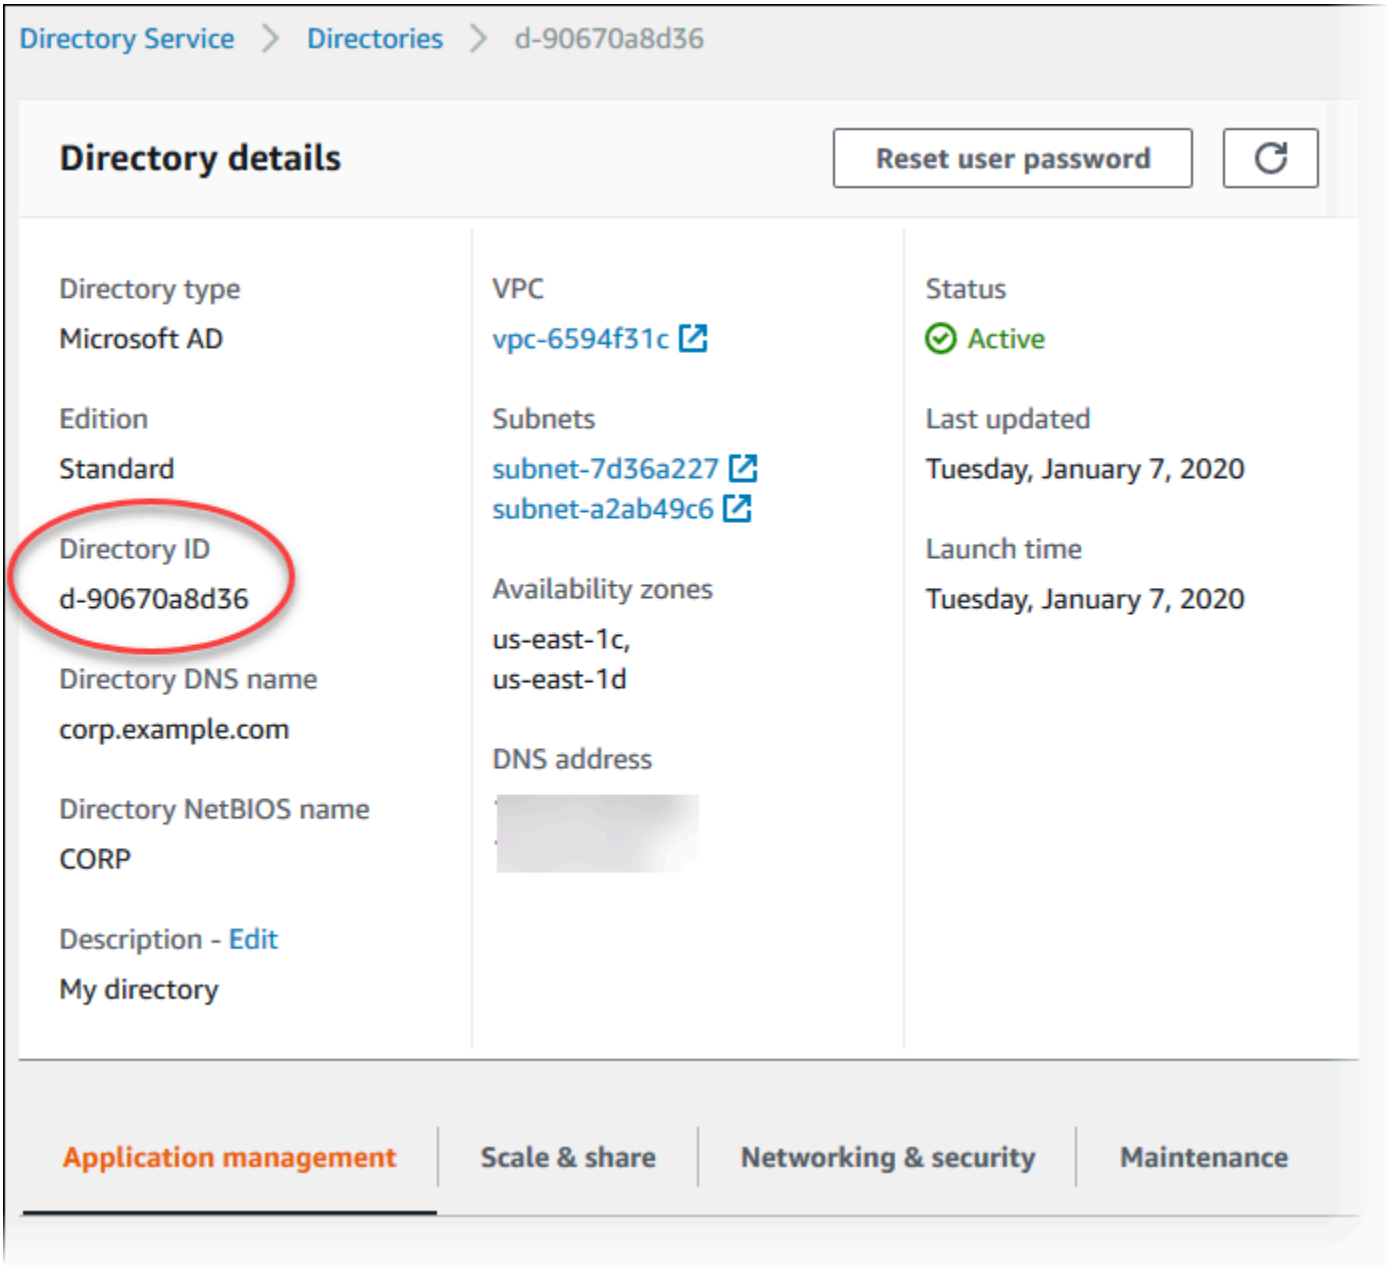
   Subnets

   Choose the subnets for the directory servers. The two subnets must be in different Availability Zones.
7. Choose **Next**.
8. Review the directory information. If changes are needed, choose **Previous** and make the changes. When the information is correct, choose **Create directory**.



It takes several minutes for the directory to be created. When it has been successfully created, the **Status** value changes to **Active**.

To see information about your directory, choose the directory ID in the directory listing. Make a note of the **Directory ID** value. You need this value when you create or modify your PostgreSQL DB instance.



Step 2: (Optional) Create a trust relationship between your on-premises Active Directory and AWS Directory Service

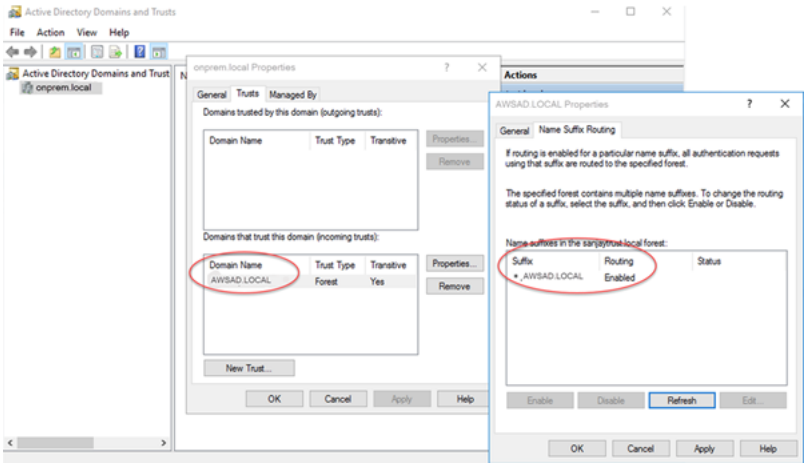
If you don't plan to use your own on-premises Microsoft Active Directory, skip to Step 3: Create an IAM role for Amazon RDS to access the AWS Directory Service.

To get Kerberos authentication using your on-premises Active Directory, you need to create a trusting domain relationship using a forest trust between your on-premises Microsoft Active Directory and the AWS Managed Microsoft AD directory (created in Step 1: Create a directory using AWS Managed Microsoft AD). The trust can be one-way, where the AWS Managed Microsoft

AD directory trusts the on-premises Microsoft Active Directory. The trust can also be two-way, where both Active Directories trust each other. For more information about setting up trusts using AWS Directory Service, see When to create a trust relationship in the *AWS Directory Service Administration Guide*.

> **Note**
>
> If you use an on-premises Microsoft Active Directory, Windows clients connect using the domain name of the AWS Directory Service in the endpoint rather than rds.amazonaws.com. To learn more, see Connecting to PostgreSQL with Kerberos authentication.

Make sure that your on-premises Microsoft Active Directory domain name includes a DNS suffix routing that corresponds to the newly created trust relationship. The following screenshot shows an example.



Step 3: Create an IAM role for Amazon RDS to access the AWS Directory Service

For Amazon RDS to call AWS Directory Service for you, your AWS account needs an IAM role that uses the managed IAM policy `AmazonRDSDirectoryServiceAccess`. This role allows Amazon RDS to make calls to AWS Directory Service.

When you create a DB instance using the AWS Management Console and your console user account has the `iam:CreateRole` permission, the console creates the needed IAM role automatically. In this case, the role name is `rds-directoryservice-kerberos-access-role`. Otherwise, you must create the IAM role manually. When you create this IAM role, choose `Directory Service`, and attach the AWS managed policy `AmazonRDSDirectoryServiceAccess` to it.

For more information about creating IAM roles for a service, see Creating a role to delegate permissions to an AWS service in the *IAM User Guide*.

> **Note**
>
> The IAM role used for Windows Authentication for RDS for Microsoft SQL Server can't be used for Amazon RDS for PostgreSQL.

As an alternative to using the `AmazonRDSDirectoryServiceAccess` managed policy, you can create policies with the required permissions. In this case, the IAM role must have the following IAM trust policy.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "",
      "Effect": "Allow",
      "Principal": {
        "Service": [
          "directoryservice.rds.amazonaws.com",
          "rds.amazonaws.com"
        ]
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
```

The role must also have the following IAM role policy.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Action": [
        "ds:DescribeDirectories",
        "ds:AuthorizeApplication",
        "ds:UnauthorizeApplication",
        "ds:GetAuthorizedApplicationDetails"
```

```
      ],
    "Effect": "Allow",
    "Resource": "*"
    }
  ]
}
```

Step 4: Create and configure users

You can create users by using the Active Directory Users and Computers tool. This is one of the Active Directory Domain Services and Active Directory Lightweight Directory Services tools. For more information, see Add Users and Computers to the Active Directory domain in the Microsoft documentation. In this case, users are individuals or other entities, such as their computers that are part of the domain and whose identities are being maintained in the directory.

To create users in an AWS Directory Service directory, you must be connected to a Windows-based Amazon EC2 instance that's a member of the AWS Directory Service directory. At the same time, you must be logged in as a user that has privileges to create users. For more information, see Create a user in the *AWS Directory Service Administration Guide*.

Step 5: Enable cross-VPC traffic between the directory and the DB instance

If you plan to locate the directory and the DB instance in the same VPC, skip this step and move on to Step 6: Create or modify a PostgreSQL DB instance.

If you plan to locate the directory and the DB instance in different VPCs, configure cross-VPC traffic using VPC peering or AWS Transit Gateway.

The following procedure enables traffic between VPCs using VPC peering. Follow the instructions in What is VPC peering? in the *Amazon Virtual Private Cloud Peering Guide*.

To enable cross-VPC traffic using VPC peering

1. Set up appropriate VPC routing rules to ensure that network traffic can flow both ways.
2. Ensure that the DB instance security group can receive inbound traffic from the directory security group.
3. Ensure that there is no network access control list (ACL) rule to block traffic.

If a different AWS account owns the directory, you must share the directory.

To share the directory between AWS accounts

1. Start sharing the directory with the AWS account that the DB instance will be created in by following the instructions in Tutorial: Sharing your AWS Managed Microsoft AD directory for seamless EC2 Domain-join in the *AWS Directory Service Administration Guide*.
2. Sign in to the AWS Directory Service console using the account for the DB instance, and ensure that the domain has the SHARED status before proceeding.
3. While signed into the AWS Directory Service console using the account for the DB instance, note the **Directory ID** value. You use this directory ID to join the DB instance to the domain.

Step 6: Create or modify a PostgreSQL DB instance

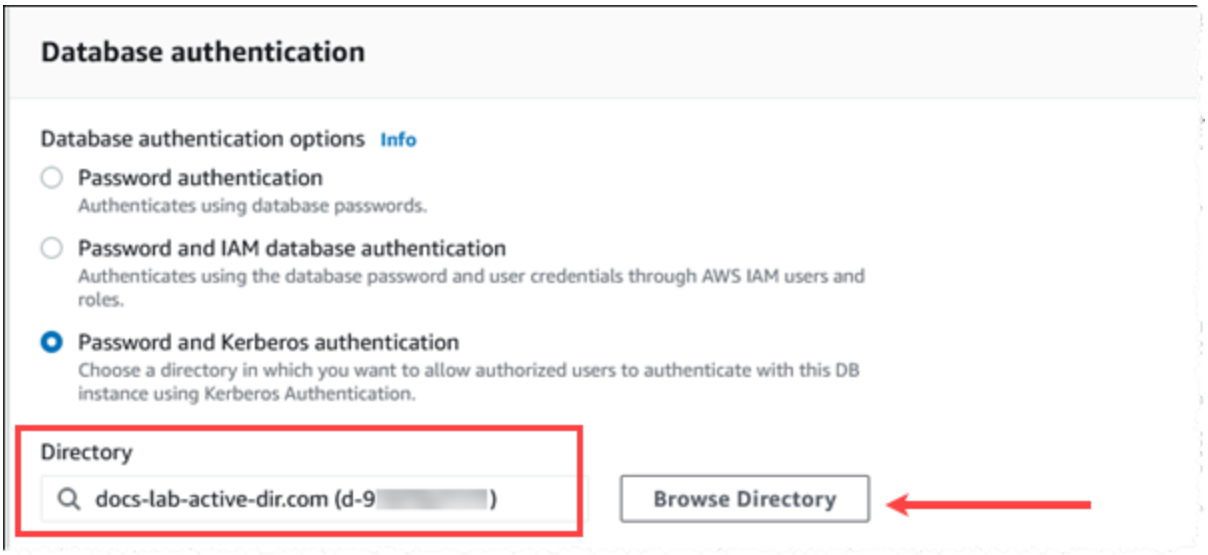
Create or modify a PostgreSQL DB instance for use with your directory. You can use the console, CLI, or RDS API to associate a DB instance with a directory. You can do this in one of the following ways:

- Create a new PostgreSQL DB instance using the console, the create-db-instance CLI command, or the CreateDBInstance RDS API operation. For instructions, see Creating an Amazon RDS DB instance.
- Modify an existing PostgreSQL DB instance using the console, the modify-db-instance CLI command, or the ModifyDBInstance RDS API operation. For instructions, see Modifying an Amazon RDS DB instance.
- Restore a PostgreSQL DB instance from a DB snapshot using the console, the restore-db-instance-from-db-snapshot CLI command, or the RestoreDBInstanceFromDBSnapshot RDS API operation. For instructions, see Restoring to a DB instance.
- Restore a PostgreSQL DB instance to a point-in-time using the console, the restore-db-instance-to-point-in-time CLI command, or the RestoreDBInstanceToPointInTime RDS API operation. For instructions, see Restoring a DB instance to a specified time.

Kerberos authentication is only supported for PostgreSQL DB instances in a VPC. The DB instance can be in the same VPC as the directory, or in a different VPC. The DB instance must use a security group that allows ingress and egress within the directory's VPC so the DB instance can communicate with the directory.

Console

When you use the console to create, modify, or restore a DB instance, choose **Password and Kerberos authentication** in the **Database authentication** section. Then choose **Browse Directory**. Select the directory or choose **Create a new directory** to use the Directory Service.



AWS CLI

When you use the AWS CLI, the following parameters are required for the DB instance to be able to use the directory that you created:

- For the `--domain` parameter, use the domain identifier ("d-*" identifier) generated when you created the directory.
- For the `--domain-iam-role-name` parameter, use the role you created that uses the managed IAM policy `AmazonRDSDirectoryServiceAccess`.

For example, the following CLI command modifies a DB instance to use a directory.

```
aws rds modify-db-instance --db-instance-identifier mydbinstance --domain d-Directory-ID --domain-iam-role-name role-name
```

> **Important**
>
> If you modify a DB instance to enable Kerberos authentication, reboot the DB instance after making the change.

Step 7: Create PostgreSQL users for your Kerberos principals

At this point, your RDS for PostgreSQL DB instance is joined to the AWS Managed Microsoft AD domain. The users that you created in the directory in Step 4: Create and configure users need to be set up as PostgreSQL database users and granted privileges to login to the database. You do that by signing in as the database user with `rds_superuser` privileges. For example, if you accepted the defaults when you created your RDS for PostgreSQL DB instance, you use `postgres`, as shown in the following steps.

To create PostgreSQL database users for Kerberos principals

1. Use `psql` to connect to your RDS for PostgreSQL DB instance endpoint using `psql`. The following example uses the default `postgres` account for the `rds_superuser` role.

   ```
   psql --host=cluster-instance-1.111122223333.aws-region.rds.amazonaws.com --
   port=5432 --username=postgres --password
   ```

2. Create a database user name for each Kerberos principal (Active Directory username) that you want to have access to the database. Use the canonical username (identity) as defined in the Active Directory instance, that is, a lower-case `alias` (username in Active Directory) and the upper-case name of the Active Directory domain for that user name. The Active Directory user name is an externally authenticated user, so use quotes around the name as shown following.

   ```
   postgres=> CREATE USER "username@CORP.EXAMPLE.COM" WITH LOGIN;
   CREATE ROLE
   ```

3. Grant the `rds_ad` role to the database user.

   ```
   postgres=> GRANT rds_ad TO "username@CORP.EXAMPLE.COM";
   GRANT ROLE
   ```

After you finish creating all the PostgreSQL users for your Active Directory user identities, users can access the RDS for PostgreSQL DB instance by using their Kerberos credentials.

It's required that the database users who authenticate using Kerberos are doing so from client machines that are members of the Active Directory domain.

Database users that have been granted the `rds_ad` role can't also have the `rds_iam` role. This also applies to nested memberships. For more information, see IAM database authentication for MariaDB, MySQL, and PostgreSQL.

Step 8: Configure a PostgreSQL client

To configure a PostgreSQL client, take the following steps:

- Create a krb5.conf file (or equivalent) to point to the domain.
- Verify that traffic can flow between the client host and AWS Directory Service. Use a network utility such as Netcat for the following:
  - Verify traffic over DNS for port 53.
  - Verify traffic over TCP/UDP for port 53 and for Kerberos, which includes ports 88 and 464 for AWS Directory Service.
- Verify that traffic can flow between the client host and the DB instance over the database port. For example, use psql to connect and access the database.

The following is sample krb5.conf content for AWS Managed Microsoft AD.

```
[libdefaults]
 default_realm = EXAMPLE.COM
[realms]
 EXAMPLE.COM = {
  kdc = example.com
  admin_server = example.com
 }
[domain_realm]
 .example.com = EXAMPLE.COM
 example.com = EXAMPLE.COM
```

The following is sample krb5.conf content for an on-premises Microsoft Active Directory.

```
[libdefaults]
 default_realm = EXAMPLE.COM
[realms]
 EXAMPLE.COM = {
  kdc = example.com
  admin_server = example.com
 }
 ONPREM.COM = {
```

```
  kdc = onprem.com
  admin_server = onprem.com
 }
[domain_realm]
 .example.com = EXAMPLE.COM
 example.com = EXAMPLE.COM
 .onprem.com = ONPREM.COM
 onprem.com = ONPREM.COM
 .rds.amazonaws.com = EXAMPLE.COM
 .amazonaws.com.cn = EXAMPLE.COM
 .amazon.com = EXAMPLE.COM
```

Managing an RDS for PostgreSQL DB instance in an Active Directory domain

You can use the console, the CLI, or the RDS API to manage your DB instance and its relationship with your Microsoft Active Directory. For example, you can associate an Active Directory to enable Kerberos authentication. You can also remove the association for an Active Directory to disable Kerberos authentication. You can also move a DB instance to be externally authenticated by one Microsoft Active Directory to another.

For example, using the CLI, you can do the following:

- To reattempt enabling Kerberos authentication for a failed membership, use the modify-db-instance CLI command. Specify the current membership's directory ID for the `--domain` option.
- To disable Kerberos authentication on a DB instance, use the modify-db-instance CLI command. Specify `none` for the `--domain` option.
- To move a DB instance from one domain to another, use the modify-db-instance CLI command. Specify the domain identifier of the new domain for the `--domain` option.

Understanding Domain membership

After you create or modify your DB instance, it becomes a member of the domain. You can view the status of the domain membership in the console or by running the describe-db-instances CLI command. The status of the DB instance can be one of the following:

- `kerberos-enabled` – The DB instance has Kerberos authentication enabled.
- `enabling-kerberos` – AWS is in the process of enabling Kerberos authentication on this DB instance.

- `pending-enable-kerberos` – Enabling Kerberos authentication is pending on this DB instance.
- `pending-maintenance-enable-kerberos` – AWS will attempt to enable Kerberos authentication on the DB instance during the next scheduled maintenance window.
- `pending-disable-kerberos` – Disabling Kerberos authentication is pending on this DB instance.
- `pending-maintenance-disable-kerberos` – AWS will attempt to disable Kerberos authentication on the DB instance during the next scheduled maintenance window.
- `enable-kerberos-failed` – A configuration problem prevented AWS from enabling Kerberos authentication on the DB instance. Correct the configuration problem before reissuing the command to modify the DB instance.
- `disabling-kerberos` – AWS is in the process of disabling Kerberos authentication on this DB instance.

A request to enable Kerberos authentication can fail because of a network connectivity issue or an incorrect IAM role. In some cases, the attempt to enable Kerberos authentication might fail when you create or modify a DB instance. If so, make sure that you are using the correct IAM role, then modify the DB instance to join the domain.

> **Note**
>
> Only Kerberos authentication with RDS for PostgreSQL sends traffic to the domain's DNS servers. All other DNS requests are treated as outbound network access on your DB instances running PostgreSQL. For more information about outbound network access with RDS for PostgreSQL, see Using a custom DNS server for outbound network access.

Connecting to PostgreSQL with Kerberos authentication

You can connect to PostgreSQL with Kerberos authentication with the pgAdmin interface or with a command-line interface such as psql. For more information about connecting, see Connecting to a DB instance running the PostgreSQL database engine . For information about obtaining the endpoint, port number, and other details needed for connection, see Step 3: Connect to a PostgreSQL DB instance.

pgAdmin

To use pgAdmin to connect to PostgreSQL with Kerberos authentication, take the following steps:

1. Launch the pgAdmin application on your client computer.
2. On the **Dashboard** tab, choose **Add New Server**.
3. In the **Create - Server** dialog box, enter a name on the **General** tab to identify the server in pgAdmin.
4. On the **Connection** tab, enter the following information from your RDS for PostgreSQL database.
   - For **Host**, enter the endpoint for the RDS for PostgreSQL DB instance. An endpoint looks similar to the following:

     ```
     RDS-DB-instance.111122223333.aws-region.rds.amazonaws.com
     ```

     To connect to an on-premises Microsoft Active Directory from a Windows client, you use the domain name of the AWS Managed Active Directory instead of `rds.amazonaws.com` in the host endpoint. For example, suppose that the domain name for the AWS Managed Active Directory is `corp.example.com`. Then for **Host**, the endpoint would be specified as follows:

     ```
     RDS-DB-instance.111122223333.aws-region.corp.example.com
     ```
   - For **Port**, enter the assigned port.
   - For **Maintenance database**, enter the name of the initial database to which the client will connect.
   - For **Username**, enter the user name that you entered for Kerberos authentication in Step 7: Create PostgreSQL users for your Kerberos principals .
5. Choose **Save**.

Psql

To use psql to connect to PostgreSQL with Kerberos authentication, take the following steps:

1. At a command prompt, run the following command.

   ```
   kinit username
   ```

Replace *username* with the user name. At the prompt, enter the password stored in the Microsoft Active Directory for the user.

2. If the PostgreSQL DB instance is using a publicly accessible VPC, put IP address for your DB instance endpoint in your `/etc/hosts` file on the EC2 client. For example, the following commands obtain the IP address and then put it in the `/etc/hosts` file.

```
% dig +short PostgreSQL-endpoint.AWS-Region.rds.amazonaws.com
;; Truncated, retrying in TCP mode.
ec2-34-210-197-118.AWS-Region.compute.amazonaws.com.
34.210.197.118

% echo " 34.210.197.118  PostgreSQL-endpoint.AWS-Region.rds.amazonaws.com" >> /etc/
hosts
```

   If you're using an on-premises Microsoft Active Directory from a Windows client, then you need to connect using a specialized endpoint. Instead of using the Amazon domain `rds.amazonaws.com` in the host endpoint, use the domain name of the AWS Managed Active Directory.

   For example, suppose that the domain name for your AWS Managed Active Directory is `corp.example.com`. Then use the format *PostgreSQL-endpoint.AWS-Region.corp.example.com* for the endpoint and put it in the `/etc/hosts` file.

```
% echo " 34.210.197.118  PostgreSQL-endpoint.AWS-Region.corp.example.com" >> /etc/
hosts
```

3. Use the following psql command to log in to a PostgreSQL DB instance that is integrated with Active Directory.

```
psql -U username@CORP.EXAMPLE.COM -p 5432 -h PostgreSQL-endpoint.AWS-
Region.rds.amazonaws.com postgres
```

   To log in to the PostgreSQL DB cluster from a Windows client using an on-premises Active Directory, use the following psql command with the domain name from the previous step (`corp.example.com`):

```
psql -U username@CORP.EXAMPLE.COM -p 5432 -h PostgreSQL-endpoint.AWS-
Region.corp.example.com postgres
```

Using a custom DNS server for outbound network access

RDS for PostgreSQL supports outbound network access on your DB instances and allows Domain Name Service (DNS) resolution from a custom DNS server owned by the customer. You can resolve only fully qualified domain names from your RDS for PostgreSQL DB instance through your custom DNS server.

Topics

Turning on custom DNS resolution

To turn on DNS resolution in your customer VPC, first associate a custom DB parameter group to your RDS for PostgreSQL instance. Then turn on the `rds.custom_dns_resolution` parameter by setting it to 1, and then restart the DB instance for the changes to take place.

Turning off custom DNS resolution

To turn off DNS resolution in your customer VPC, first turn off the `rds.custom_dns_resolution` parameter of your custom DB parameter group by setting it to 0. Then restart the DB instance for the changes to take place.

Setting up a custom DNS server

After you set up your custom DNS name server, it takes up to 30 minutes to propagate the changes to your DB instance. After the changes are propagated to your DB instance, all outbound network traffic requiring a DNS lookup queries your DNS server over port 53.

> **Note**
>
> If you don't set up a custom DNS server and `rds.custom_dns_resolution` is set to 1, hosts are resolved using an Amazon Route 53 private zone. For more information, see Working with private hosted zones.

To set up a custom DNS server for your RDS for PostgreSQL DB instance

1. From the Dynamic Host Configuration Protocol (DHCP) options set attached to your VPC, set the `domain-name-servers` option to the IP address of your DNS name server. For more information, see DHCP options sets.

   > **Note**
   >
   > The `domain-name-servers` option accepts up to four values, but your Amazon RDS DB instance uses only the first value.

2. Ensure that your DNS server can resolve all lookup queries, including public DNS names, Amazon EC2 private DNS names, and customer-specific DNS names. If the outbound network traffic contains any DNS lookups that your DNS server can't handle, your DNS server must have appropriate upstream DNS providers configured.
3. Configure your DNS server to produce User Datagram Protocol (UDP) responses of 512 bytes or less.
4. Configure your DNS server to produce Transmission Control Protocol (TCP) responses of 1,024 bytes or less.
5. Configure your DNS server to allow inbound traffic from your Amazon RDS DB instances over port 53. If your DNS server is in an Amazon VPC, the VPC must have a security group that contains inbound rules that allow UDP and TCP traffic on port 53. If your DNS server is not in an Amazon VPC, it must have appropriate firewall settings to allow UDP and TCP inbound traffic on port 53.

   For more information, see Security groups for your VPC and Adding and removing rules.
6. Configure the VPC of your Amazon RDS DB instance to allow outbound traffic over port 53. Your VPC must have a security group that contains outbound rules that allow UDP and TCP traffic on port 53.

   For more information, see Security groups for your VPC and Adding and removing rules in the *Amazon VPC User Guide*.
7. Make sure that the routing path between the Amazon RDS DB instance and the DNS server is configured correctly to allow DNS traffic.

Also, if the Amazon RDS DB instance and the DNS server are not in the same VPC, make sure that a peering connection is set up between them. For more information, see What is VPC peering? in *Amazon VPC Peering Guide*.

Upgrading the PostgreSQL DB engine for Amazon RDS

There are two types of upgrades that you can manage for your PostgreSQL database:

- Operating system updates – Occasionally, Amazon RDS might need to update the underlying operating system of your database to apply security fixes or OS changes. You can decide when Amazon RDS applies OS updates by using the RDS console, AWS Command Line Interface (AWS CLI), or RDS API. For more information about OS updates, see Applying updates for a DB instance.
- Database engine upgrades – When Amazon RDS supports a new version of a database engine, you can upgrade your databases to the new version.

A *database* in this context is an RDS for PostgreSQL DB instance or Multi-AZ DB cluster.

There are two kinds of engine upgrades for PostgreSQL databases: major version upgrades and minor version upgrades.

Major version upgrades

Major version upgrades can contain database changes that are not backward-compatible with existing applications. As a result, you must manually perform major version upgrades of your databases. You can initiate a major version upgrade by modifying your DB instance or Multi-AZ DB cluster. Before you perform a major version upgrade, we recommend that you follow the steps described in Choosing a major version upgrade for PostgreSQL.

If you're upgrading a DB instance that has in-Region read replicas, Amazon RDS upgrades the replicas along with the primary DB instance.

Amazon RDS doesn't upgrade Multi-AZ DB cluster read replicas. If you perform a major version upgrade of a Multi-AZ DB cluster, then the replication state of its read replicas changes to **terminated**. You must manually delete and recreate the read replicas after the upgrade completes.

> **Tip**
>
> You can minimize the downtime required for a major version upgrade by using a blue/green deployment. For more information, see *Using Blue/Green Deployments for database updates*.

Minor version upgrades

In contrast, *minor version upgrades* include only changes that are backward-compatible with existing applications. You can initiate a minor version upgrade manually by modifying your database. Or, you can enable the **Auto minor version upgrade** option when creating or modifying a database. Doing so means that Amazon RDS automatically upgrades your database after testing and approving the new version. If your PostgreSQL database uses read replicas, you must first upgrade all of the read replicas before upgrading the source instance or cluster.

If your database is a Multi-AZ DB instance deployment, Amazon RDS simultaneously upgrades the primary and any standby instances. Therefore, your database might not be available until the upgrade completes. If your database is a Multi-AZ DB cluster deployment, Amazon RDS upgrades the reader DB instances one at a time. Then, one of the reader DB instances switches to be the new writer DB instance. Amazon RDS then upgrades the old writer instance (which is now a reader instance).

> **Note**
>
> The downtime for a minor version upgrade of a Multi-AZ DB *instance* deployment can last for several minutes. Multi-AZ DB clusters typically reduce the downtime of minor version upgrades to approximately 35 seconds. When used with RDS Proxy, you can further reduce downtime to one second or less. For more information, see *Using RDS Proxy*. Alternately, you can use an open source database proxy such as ProxySQL,PgBouncer, or the AWS JDBC Driver for MySQL,

For more information, see Automatic minor version upgrades for PostgreSQL. For information about manually performing a minor version upgrade, see Manually upgrading the engine version.

For more information about database engine versions and the policy for deprecating database engine versions, see Database Engine Versions in the Amazon RDS FAQs.

Overview of upgrading PostgreSQL

To safely upgrade your databases, Amazon RDS uses the `pg_upgrade` utility described in the PostgreSQL documentation,

When you use the AWS Management Console to upgrade a database, it shows the valid upgrade targets for the database. You can also use the following AWS CLI command to identify the valid upgrade targets for a database:

For Linux, macOS, or Unix:

```
aws rds describe-db-engine-versions \
  --engine postgres \
  --engine-version version-number \
  --query "DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}" --
output text
```

For Windows:

```
aws rds describe-db-engine-versions ^
  --engine postgres ^
  --engine-version version-number ^
  --query "DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}" --
output text
```

For example, to identify the valid upgrade targets for a PostgreSQL version 12.13 database, run the following AWS CLI command:

For Linux, macOS, or Unix:

```
aws rds describe-db-engine-versions \
  --engine postgres \
  --engine-version 12.13 \
```

```
  --query "DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}" --
output text
```

For Windows:

```
aws rds describe-db-engine-versions ^
  --engine postgres ^
  --engine-version 12.13 ^
  --query "DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}" --
output text
```

If your backup retention period is greater than 0, Amazon RDS takes two DB snapshots during the upgrade process. The first DB snapshot is of the database before any upgrade changes have been made. If the upgrade fails for your databases, you can restore this snapshot to create a database running the old version. The second DB snapshot is taken after the upgrade completes.

> **Note**
>
> Amazon RDS takes DB snapshots during the upgrade process only if you have set the backup retention period for your database to a number greater than 0. To change the backup retention period for a DB instance, see the section called “Modifying a DB instance”. You can't configure a custom backup retention period for a Multi-AZ DB cluster.

When you perform a major version upgrade of a DB instance, any in-Region read replicas are also automatically upgraded. After the upgrade workflow starts, the read replicas wait for the `pg_upgrade` to complete successfully on the primary DB instance. Then the primary DB instance upgrade waits for the read replica upgrades to complete. You experience an outage until the upgrade is complete. When you perform a major version upgrade of a Multi-AZ DB cluster, the replication state of its read replicas changes to **terminated**.

After an upgrade is complete, you can't revert to the previous version of the DB engine. If you want to return to the previous version, restore the DB snapshot that was taken before the upgrade to create a new database.

PostgreSQL version numbers

The version numbering sequence for the PostgreSQL database engine is as follows:

- For PostgreSQL versions 10 and later, the engine version number is in the form *major.minor*. The major version number is the integer part of the version number. The minor version number is the fractional part of the version number.

  A major version upgrade increases the integer part of the version number, such as upgrading from 10.*minor* to 11.*minor*.
- For PostgreSQL versions earlier than 10, the engine version number is in the form *major.major.minor*. The major engine version number is both the integer and the first fractional part of the version number. For example, 9.6 is a major version. The minor version number is the third part of the version number. For example, for version 9.6.12, the 12 is the minor version number.

  A major version upgrade increases the major part of the version number. For example, an upgrade from *9.6*.12 to 11.14 is a major version upgrade, where *9.6* and *11* are the major version numbers.

For information about RDS Extended Support version numbering, see Amazon RDS Extended Support version naming.

RDS version number

RDS version numbers use the *major.minor.patch* naming scheme. An RDS patch version includes important bug fixes added to a minor version after its release. For information about RDS Extended Support version numbering, see Amazon RDS Extended Support version naming.

To identify the Amazon RDS version number of your database, you must first create the `rds_tools` extension by using the following command:

```
CREATE EXTENSION rds_tools;
```

Starting with the release of PostgreSQL version 15.2-R2, you can find out the RDS version number of your RDS for PostgreSQL database with the following SQL query:

```
postgres=> SELECT rds_tools.rds_version();
```

For example, querying an RDS for PostgreSQL 15.2 database returns the following:

```
rds_version
---------------
```

```
 15.2.R2
(1 row)
```

Choosing a major version upgrade for PostgreSQL

Major version upgrades can contain changes that are not backward-compatible with previous versions of the database. New functionality can cause your existing applications to stop working correctly. For this reason, Amazon RDS doesn't apply major version upgrades automatically. To perform a major version upgrade, you modify your database manually. Make sure that you thoroughly test any upgrade to verify that your applications work correctly before applying the upgrade to your production databases. When you do a PostgreSQL major version upgrade, we recommend that you follow the steps described in How to perform a major version upgrade.

When you upgrade a PostgreSQL Single-AZ DB instance or Multi-AZ DB instance deployment to its next major version, any read replicas associated with the database are also upgraded to that next major version. In some cases, you can skip to a higher major version when upgrading. If your upgrade skips a major version, the read replicas are also upgraded to that target major version. Upgrades to version 11 that skip other major versions have certain limitations. You can find the details in the steps described in How to perform a major version upgrade.

Most PostgreSQL extensions aren't upgraded during a PostgreSQL engine upgrade. These must be upgraded separately. For more information, see Upgrading PostgreSQL extensions.

You can find out which major versions are available for your RDS for PostgreSQL database by running the following AWS CLI query:

```
aws rds describe-db-engine-versions --engine postgres  --engine-version your-version
 --query "DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}" --
output text
```

The following table summarizes the results of this query for all available versions. An asterisk (*) on the version number means that version is no longer supported. If your current version is unsupported, we recommend that you upgrade to the newest minor version upgrade target or to one of the other available upgrade targets for that version.

Current source version	Newest major version upgrade target	Other available upgrade targets
16.3	none	16.4

Current source version	Newest major version upgrade target	Other available upgrade targets
16.2	none	16.4, 16.3
16.1	none	16.4, 16.3, 16.2
15.8	16.4	none

* This version is no longer supported.

How to perform a major version upgrade

We recommend the following process when performing a major version upgrade on an Amazon RDS for PostgreSQL database:

1. **Have a version-compatible parameter group ready** – If you are using a custom parameter group, you have two options. You can specify a default parameter group for the new DB engine version. Or you can create your own custom parameter group for the new DB engine version. For more information, see the section called “Parameter groups” and the section called “DB cluster parameter groups”.
2. **Check for unsupported database classes** – Check that your database's instance class is compatible with the PostgreSQL version you are upgrading to. For more information, see Supported DB engines for DB instance classes.
3. **Check for unsupported usage:**

- **Prepared transactions** – Commit or roll back all open prepared transactions before attempting an upgrade.

  You can use the following query to verify that there are no open prepared transactions on your database.

```
SELECT count(*) FROM pg_catalog.pg_prepared_xacts;
```

- **Reg* data types** – Remove all uses of the *reg** data types before attempting an upgrade. Except for `regtype` and `regclass`, you can't upgrade the *reg** data types. The `pg_upgrade` utility can't persist this data type, which is used by Amazon RDS to do the upgrade.

  To verify that there are no uses of unsupported *reg** data types, use the following query for each database.

```
SELECT count(*) FROM pg_catalog.pg_class c, pg_catalog.pg_namespace n,
 pg_catalog.pg_attribute a
  WHERE c.oid = a.attrelid
      AND NOT a.attisdropped
      AND a.atttypid IN ('pg_catalog.regproc'::pg_catalog.regtype,
                         'pg_catalog.regprocedure'::pg_catalog.regtype,
                         'pg_catalog.regoper'::pg_catalog.regtype,
                         'pg_catalog.regoperator'::pg_catalog.regtype,
                         'pg_catalog.regconfig'::pg_catalog.regtype,
                         'pg_catalog.regdictionary'::pg_catalog.regtype)
      AND c.relnamespace = n.oid
      AND n.nspname NOT IN ('pg_catalog', 'information_schema');
```

4. **Handle logical replication slots** – An upgrade can't occur if the database has any logical replication slots. Logical replication slots are typically used for AWS DMS migration and for replicating tables from the database to data lakes, BI tools, and other targets. Before upgrading, make sure that you know the purpose of any logical replication slots that are in use, and confirm that it's okay to delete them. If the logical replication slots are still being used, you shouldn't delete them, and you can't proceed with the upgrade.

   If the logical replication slots aren't needed, you can delete them using the following SQL:

```
SELECT * FROM pg_replication_slots;
```

```
SELECT pg_drop_replication_slot(slot_name);
```

Logical replication setups that use the `pglogical` extension also need to have slots dropped for a successful major version upgrade. For information about how to identify and drop slots created using the `pglogical` extension, see Managing logical replication slots for RDS for PostgreSQL.

5. **Handle read replicas** – An upgrade of a Single-AZ DB instance or Multi-AZ DB instance deployment also upgrades the in-Region read replicas along with the primary DB instance. Amazon RDS doesn't upgrade Multi-AZ DB cluster read replicas.

   You can't upgrade read replicas separately. If you could, it could lead to situations where the primary and replica databases have different PostgreSQL major versions. However, read replica upgrades might increase downtime on the primary DB instance. To prevent a read replica upgrade, promote the replica to a standalone instance or delete it before starting the upgrade process.

   The upgrade process recreates the read replica's parameter group based on the read replica's current parameter group. You can apply a custom parameter group to a read replica only after the upgrade completes by modifying the read replica. For more information about read replicas, see Working with read replicas for Amazon RDS for PostgreSQL.

6. **Perform a backup** – We recommend that you perform a backup before performing the major version upgrade so that you have a known restore point for your database. If your backup retention period is greater than 0, the upgrade process creates DB snapshots of your database before and after upgrading. To change your backup retention period, see Modifying an Amazon RDS DB instance and the section called “Modifying a Multi-AZ DB cluster”.

   To perform a backup manually, see the section called “Creating a DB snapshot for a Single-AZ DB instance” and the section called “Creating a Multi-AZ DB cluster snapshot”.

7. **Upgrade certain extensions before a major version upgrade** – If you plan to skip a major version with the upgrade, you need to update certain extensions *before* performing the major version upgrade. For example, upgrading from versions 9.5.x or 9.6.x to version 11.x skips a major version. The extensions to update include PostGIS and related extensions for processing spatial data.

   - `address_standardizer`
   - `address_standardizer_data_us`
   - `postgis_raster`

- `postgis_tiger_geocoder`
- `postgis_topology`

Run the following command for each extension that you're using:

```
ALTER EXTENSION PostgreSQL-extension UPDATE TO 'new-version';
```

For more information, see Upgrading PostgreSQL extensions. To learn more about upgrading PostGIS, see Step 6: Upgrade the PostGIS extension.

8. **Drop certain extensions before the major version upgrade** – An upgrade that skips a major version to version 11.x doesn't support updating the `pgRouting` extension. Upgrading from versions 9.4.x, 9.5.x, or 9.6.x to versions 11.x skips a major version. It's safe to drop the `pgRouting` extension and then reinstall it to a compatible version after the upgrade. For the extension versions you can update to, see Supported PostgreSQL extension versions.

   The `tsearch2` and `chkpass` extensions are no longer supported for PostgreSQL versions 11 or later. If you are upgrading to version 11.x, drop the `tsearch2`, and `chkpass` extensions before the upgrade.

9. **Drop unknown data types** – Drop `unknown` data types depending on the target version.

   PostgreSQL version 10 stopped supporting the `unknown` data type. If a version 9.6 database uses the `unknown` data type, an upgrade to a version 10 shows an error message such as the following:

   ```
   Database instance is in a state that cannot be upgraded: PreUpgrade checks failed:
   The instance could not be upgraded because the 'unknown' data type is used in user
    tables.
   Please remove all usages of the 'unknown' data type and try again."
   ```

   To find the `unknown` data type in your database so you can remove the offending column or change it to a supported data type, use the following SQL:

   ```
   SELECT DISTINCT data_type FROM information_schema.columns WHERE data_type ILIKE
    'unknown';
   ```

10. **Perform an upgrade dry run** – We highly recommend testing a major version upgrade on a duplicate of your production database before attempting the upgrade on your production database. You can monitor the execution plans on the duplicate test database for any possible

execution plan regressions and to evaluate its performance. To create a duplicate test instance, you can either restore your database from a recent snapshot or do a point-in-time restore of your database to its latest restorable time.

For more information, see the section called "Restoring from a snapshot" or the section called "Point-in-time recovery". For Multi-AZ DB clusters, see the section called "Restoring from a snapshot to a Multi-AZ DB cluster" or the section called "Restoring a Multi-AZ DB cluster to a specified time".

For details on performing the upgrade, see the section called "Manually upgrading the engine version".

In upgrading a version 9.6 database to version 10, be aware that PostgreSQL 10 enables parallel queries by default. You can test the impact of parallelism *before* the upgrade by changing the `max_parallel_workers_per_gather` parameter on your test database to 2.

> **Note**
>
> The default value for `max_parallel_workers_per_gather` parameter in the `default.postgresql10` DB parameter group is 2.

For more information, see Parallel Query in the PostgreSQL documentation. To disable parallelism on version 10, set the `max_parallel_workers_per_gather` parameter to 0.

During the major version upgrade, the `public` and `template1` databases and the `public` schema in every database are temporarily renamed. These objects appear in the logs with their original name and a random string appended. The string is appended so that custom settings such as `locale` and `owner` are preserved during the major version upgrade. After the upgrade completes, the objects are renamed back to their original names.

> **Note**
>
> During the major version upgrade process, you can't do a point-in-time restore of your DB instance or Multi-AZ DB cluster. After Amazon RDS performs the upgrade, it takes an automatic backup of the database. You can perform a point-in-time restore to times before the upgrade began and after the automatic backup of your database has completed.

11 **If an upgrade fails with precheck procedure errors, resolve the issues** – During the major version upgrade process, Amazon RDS for PostgreSQL first runs a precheck procedure to identify any issues that might cause the upgrade to fail. The precheck procedure checks all potential incompatible conditions across all databases in the instance.

If the precheck encounters an issue, it creates a log event indicating the upgrade precheck failed. The precheck process details are in an upgrade log named `pg_upgrade_precheck.log` for all the databases of a database. Amazon RDS appends a timestamp to the file name. For more information about viewing logs, see Monitoring Amazon RDS log files.

If a read replica upgrade fails at precheck, replication on the failed read replica is broken and the read replica is put in the terminated state. Delete the read replica and recreate a new read replica based on the upgraded primary DB instance.

Resolve all of the issues identified in the precheck log and then retry the major version upgrade. The following is an example of a precheck log.

```
-----------------------------------------------------------------------
Upgrade could not be run on Wed Apr 4 18:30:52 2018
-----------------------------------------------------------------------
The instance could not be upgraded from 9.6.11 to 10.6 for the following reasons.
Please take appropriate action on databases that have usage incompatible with the
 requested major engine version upgrade and try the upgrade again.

* There are uncommitted prepared transactions. Please commit or rollback all prepared
 transactions.* One or more role names start with 'pg_'. Rename all role names that
 start with 'pg_'.

* The following issues in the database 'my"million$"db' need to be corrected before
 upgrading:** The ["line","reg*"] data types are used in user tables. Remove all
 usage of these data types.
** The database name contains characters that are not supported by RDS for
 PostgreSQL. Rename the database.
** The database has extensions installed that are not supported on the target
 database version. Drop the following extensions from your database: ["tsearch2"].

* The following issues in the database 'mydb' need to be corrected before
 upgrading:** The database has views or materialized views that depend on
 'pg_stat_activity'. Drop the views.
```

12. **If a read replica upgrade fails while upgrading the database, resolve the issue** – A failed read replica is placed in the `incompatible-restore` state and replication is terminated on the database. Delete the read replica and recreate a new read replica based on the upgraded primary DB instance.

    > **Note**
    >
    > Amazon RDS doesn't upgrade read replicas for Multi-AZ DB clusters. If you perform a major version upgrade on a Multi-AZ DB cluster, then the replication state of its read replicas changes to **terminated**.

    A read replica upgrade might fail for the following reasons:

    - It was unable to catch up with the primary DB instance even after a wait time.
    - It was in a terminal or incompatible lifecycle state such as storage-full, incompatible-restore, and so on.
    - When the primary DB instance upgrade started, there was a separate minor version upgrade running on the read replica.
    - The read replica used incompatible parameters.
    - The read replica was unable to communicate with the primary DB instance to synchronize the data folder.

13. **Upgrade your production database** – When the dry-run major version upgrade is successful, you should be able to upgrade your production database with confidence. For more information, see Manually upgrading the engine version.

14. Run the `ANALYZE` operation to refresh the `pg_statistic` table. You should do this for every database on all your PostgreSQL databases. Optimizer statistics aren't transferred during a major version upgrade, so you need to regenerate all statistics to avoid performance issues. Run the command without any parameters to generate statistics for all regular tables in the current database, as follows:

    ```
    ANALYZE VERBOSE;
    ```

    The `VERBOSE` flag is optional, but using it shows you the progress. For more information, see ANALYZE in the PostgreSQL documentation.

> **Note**
>
> Run ANALYZE on your system after the upgrade to avoid performance issues.

After the major version upgrade is complete, we recommend the following:

- A PostgreSQL upgrade doesn't upgrade any PostgreSQL extensions. To upgrade extensions, see Upgrading PostgreSQL extensions.
- Optionally, use Amazon RDS to view two logs that the `pg_upgrade` utility produces. These are `pg_upgrade_internal.log` and `pg_upgrade_server.log`. Amazon RDS appends a timestamp to the file name for these logs. You can view these logs as you can any other log. For more information, see Monitoring Amazon RDS log files.

  You can also upload the upgrade logs to Amazon CloudWatch Logs. For more information, see Publishing PostgreSQL logs to Amazon CloudWatch Logs.
- To verify that everything works as expected, test your application on the upgraded database with a similar workload. After the upgrade is verified, you can delete this test instance.

Automatic minor version upgrades for PostgreSQL

If you enable the **Auto minor version upgrade** option when creating or modifying a DB instance or Multi-AZ DB cluster, you can have your database automatically upgraded.

For each RDS for PostgreSQL major version, one minor version is designated by RDS as the automatic upgrade version. After a minor version has been tested and approved by Amazon RDS, the minor version upgrade occurs automatically during your maintenance window. RDS doesn't automatically set newer released minor versions as the automatic upgrade version. Before RDS designates a newer automatic upgrade version, several criteria are considered, such as the following:

- Known security issues
- Bugs in the PostgreSQL community version
- Overall fleet stability since the minor version was released

You can use the following AWS CLI command to determine the current automatic minor upgrade target version for a specified PostgreSQL minor version in a specific AWS Region.

For Linux, macOS, or Unix:

```
aws rds describe-db-engine-versions \
--engine postgres \
--engine-version minor-version \
--region region \
--query "DBEngineVersions[*].ValidUpgradeTarget[*].
{AutoUpgrade:AutoUpgrade,EngineVersion:EngineVersion}" \
--output text
```

For Windows:

```
aws rds describe-db-engine-versions ^
--engine postgres ^
--engine-version minor-version ^
--region region ^
--query "DBEngineVersions[*].ValidUpgradeTarget[*].
{AutoUpgrade:AutoUpgrade,EngineVersion:EngineVersion}" ^
--output text
```

For example, the following AWS CLI command determines the automatic minor upgrade target for PostgreSQL minor version 12.13 in the US East (Ohio) AWS Region (us-east-2).

For Linux, macOS, or Unix:

```
aws rds describe-db-engine-versions \
--engine postgres \
--engine-version 12.13 \
--region us-east-2 \
--query "DBEngineVersions[*].ValidUpgradeTarget[*].
{AutoUpgrade:AutoUpgrade,EngineVersion:EngineVersion}" \
--output table
```

For Windows:

```
aws rds describe-db-engine-versions ^
--engine postgres ^
```

```
--engine-version 12.13 ^
--region us-east-2 ^
--query "DBEngineVersions[*].ValidUpgradeTarget[*].
{AutoUpgrade:AutoUpgrade,EngineVersion:EngineVersion}" ^
--output table
```

Your output is similar to the following.

```
---------------------------------
|    DescribeDBEngineVersions    |
+--------------+-----------------+
|  AutoUpgrade |  EngineVersion  |
+--------------+-----------------+
|  True        |  12.14          |
|  False       |  12.15          |
|  False       |  13.9           |
|  False       |  13.10          |
|  False       |  13.11          |
|  False       |  14.6           |
+--------------+-----------------+
```

In this example, the `AutoUpgrade` value is `True` for PostgreSQL version 12.14. So, the automatic minor upgrade target is PostgreSQL version 12.14, which is highlighted in the output.

A PostgreSQL database is automatically upgraded during your maintenance window if the following criteria are met:

- The database has the **Auto minor version upgrade** option enabled.
- The database is running a minor DB engine version that is less than the current automatic upgrade minor version.

For more information, see Automatically upgrading the minor engine version.

> **Note**
>
> A PostgreSQL upgrade doesn't upgrade PostgreSQL extensions. To upgrade extensions, see Upgrading PostgreSQL extensions.

Upgrading PostgreSQL extensions

A PostgreSQL engine upgrade doesn't upgrade most PostgreSQL extensions. To update an extension after a version upgrade, use the `ALTER EXTENSION UPDATE` command.

> **Note**
>
> For information about updating the PostGIS extension, see Managing spatial data with the PostGIS extension (Step 6: Upgrade the PostGIS extension).
> To update the `pg_repack` extension, drop the extension and then create the new version in the upgraded database. For more information, see pg_repack installation in the `pg_repack` documentation.

To upgrade an extension, use the following command.

```
ALTER EXTENSION extension_name UPDATE TO 'new_version';
```

For the list of supported versions of PostgreSQL extensions, see Supported PostgreSQL extension versions.

To list your currently installed extensions, use the PostgreSQL pg_extension catalog in the following command.

```
SELECT * FROM pg_extension;
```

To view a list of the specific extension versions that are available for your installation, use the PostgreSQL pg_available_extension_versions view in the following command.

```
SELECT * FROM pg_available_extension_versions;
```

Upgrading a PostgreSQL DB snapshot engine version

With Amazon RDS, you can create a storage volume DB snapshot of your PostgreSQL DB instance. When you create a DB snapshot, the snapshot is based on the engine version used by your Amazon RDS instance. In addition to upgrading the DB engine version of your DB instance, you can also upgrade the engine version for your DB snapshots.

After restoring a DB snapshot upgraded to a new engine version, make sure to test that the upgrade was successful. For more information about a major version upgrade, see Upgrading the PostgreSQL DB engine for Amazon RDS. To learn how to restore a DB snapshot, see Restoring to a DB instance.

You can upgrade manual DB snapshots that are either encrypted or not encrypted.

For the list of engine versions that are available for upgrading a DB snapshot, see Upgrading the PostgreSQL DB engine for Amazon RDS.

> **Note**
>
> You can't upgrade automated DB snapshots that are created during the automated backup process.

Console

To upgrade a DB snapshot

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Snapshots**.
3. Choose the snapshot that you want to upgrade.
4. For **Actions**, choose **Upgrade snapshot**. The **Upgrade snapshot** page appears.
5. Choose the **New engine version** to upgrade to.
6. Choose **Save changes** to upgrade the snapshot.

   During the upgrade process, all snapshot actions are disabled for this DB snapshot. Also, the DB snapshot status changes from **available** to **upgrading**, and then changes to **active** upon

completion. If the DB snapshot can't be upgraded because of snapshot corruption issues, the status changes to **unavailable**. You can't recover the snapshot from this state.

> **Note**
>
> If the DB snapshot upgrade fails, the snapshot is rolled back to the original state with the original version.

AWS CLI

To upgrade a DB snapshot to a new database engine version, use the AWS CLI modify-db-snapshot command.

Parameters

- `--db-snapshot-identifier` – The identifier of the DB snapshot to upgrade. The identifier must be a unique Amazon Resource Name (ARN). For more information, see Amazon Resource Names (ARNs) in Amazon RDS.
- `--engine-version` – The engine version to upgrade the DB snapshot to.

Example

For Linux, macOS, or Unix:

```
aws rds modify-db-snapshot \
    --db-snapshot-identifier my_db_snapshot \
    --engine-version new_version
```

For Windows:

```
aws rds modify-db-snapshot ^
    --db-snapshot-identifier my_db_snapshot ^
    --engine-version new_version
```

RDS API

To upgrade a DB snapshot to a new database engine version, call the Amazon RDS API ModifyDBSnapshot operation.

- `DBSnapshotIdentifier` – The identifier of the DB snapshot to upgrade. The identifier must be a unique Amazon Resource Name (ARN). For more information, see Amazon Resource Names (ARNs) in Amazon RDS.
- `EngineVersion` – The engine version to upgrade the DB snapshot to.

Working with read replicas for Amazon RDS for PostgreSQL

You can scale reads for your Amazon RDS for PostgreSQL DB instances by adding read replicas to the instances. As with other Amazon RDS database engines, RDS for PostgreSQL uses native replication mechanisms of PostgreSQL to keep read replicas up to date with changes on the source DB. For general information about read replicas and Amazon RDS, see Working with DB instance read replicas.

Following, you can find information specific to working with read replicas with RDS for PostgreSQL.

Logical decoding on a read replica

RDS for PostgreSQL supports logical replication from standbys with PostgreSQL 16.1. This allows you to create logical decoding from a read-only standby that reduces the load on the primary DB instance. You can achieve higher-availability for your applications that need to synchronize data across multiple systems. This feature boosts the performance of your data warehouse and data analytics.

Also, replication slots on a given standby persist the promotion of that standby to a primary. This means that in the event of a primary DB instance failover or the promotion of a standby to be the new primary, the replication slots will persist and the former standby subscribers will not be affected.

To create logical decoding on a read replica

1. **Turn on logical replication** – To create logical decoding on a standby, you must turn on logical replication on your source DB instance and its physical replica. For more information, see Read replica configuration with PostgreSQL.

   - **To turn on logical replication for a newly created RDS for PostgreSQL DB instance** – Create a new DB custom parameter group and set the static parameter `rds.logical_replication` to 1. Then, associate this DB parameter group with the Source DB instance and its physical read replica. For more information, see Associating a DB parameter group with a DB instance in Amazon RDS.
   - **To turn on logical replication for an existing RDS for PostgreSQL DB instance** – Modify the DB custom parameter group of the source DB instance and its physical read replica to set the static parameter `rds.logical_replication` to 1. For more information, see Modifying parameters in a DB parameter group in Amazon RDS.

> **Note**
>
> You must reboot the DB instance to apply these parameter changes.

You can use the following query to verify the values for `wal_level` and `rds.logical_replication` on the source DB instance and its physical read replica.

```
Postgres=>SELECT name,setting FROM pg_settings WHERE name IN
 ('wal_level','rds.logical_replication');

 name                    | setting
-------------------------+---------
 rds.logical_replication | on
 wal_level               | logical
(2 rows)
```

2. **Create a table in the source database** – Connect to the database in your source DB instance. For more information, see Connecting to a DB instance running the PostgreSQL database engine.

   Use the following queries to create table in your source database and to insert values:

```
Postgres=>CREATE TABLE LR_test (a int PRIMARY KEY);
CREATE TABLE
```

```
Postgres=>INSERT INTO LR_test VALUES (generate_series(1,10000));
INSERT 0 10000
```

3. **Create a publication for the source table** – Use the following query to create a publication for the table on the source DB instance.

```
Postgres=>CREATE PUBLICATION testpub FOR TABLE LR_test;
CREATE PUBLICATION
```

   Use a SELECT query to verify the details of the publication that was created on both the source DB instance and the physical read replica instance.

```
Postgres=>SELECT * from pg_publication;

oid    | pubname | pubowner | puballtables | pubinsert | pubupdate | pubdelete |
 pubtruncate | pubviaroot
-------+---------+----------+--------------+-----------+-----------+-----------
+-------------+------------
 16429 | testpub |    16413 | f            | t         | t         | t         | t
          | f
(1 row)
```

4. **Create a subscription from logical replica instance** – Create another RDS for PostgreSQL DB instance as the logical replica instance. Make sure that VPC is setup correctly to ensure that this logical replica instance can access the physical read replica instance. For more information, see Amazon VPC and Amazon RDS. If your source DB instance is idle, connectivity issues might occur and the primary doesn't send the data to standby.

```
Postgres=>CREATE SUBSCRIPTION testsub CONNECTION 'host=Physical replica host name
 port=port
                dbname=source_db_name user=user password=password
 PUBLICATION testpub;
NOTICE:  created replication slot "testsub" on publisher
CREATE SUBSCRIPTION
```

```
Postgres=>CREATE TABLE LR_test (a int PRIMARY KEY);
CREATE TABLE
```

Use a SELECT query to verify the details of the subscription on the logical replica instance.

```
Postgres=>SELECT oid,subname,subenabled,subslotname,subpublications FROM
 pg_subscription;

oid    | subname | subenabled | subslotname | subpublications
-------+---------+------------+-------------+-----------------
 16429 | testsub | t          | testsub     | {testpub}
(1 row)
postgres=> select count(*) from LR_test;
 count
-------
 10000
(1 row)
```

5. **Inspect logical replication slot state** – You can only see the physical replication slot on your source DB instance.

```
Postgres=>select slot_name, slot_type, confirmed_flush_lsn from
 pg_replication_slots;

slot_name                                    | slot_type | confirmed_flush_lsn
---------------------------------------------+-----------+---------------------
 rds_us_west_2_db_dhqfsmo5wbbjqrn3m6b6ivdhu4 | physical  |
(1 row)
```

However, on your read replica instance, you can see the logical replication slot and the `confirmed_flush_lsn` value changes as the application actively consumes logical changes.

```
Postgres=>select slot_name, slot_type, confirmed_flush_lsn from
 pg_replication_slots;

slot_name | slot_type | confirmed_flush_lsn
-----------+-----------+---------------------
 testsub   | logical   | 0/500002F0
(1 row)
```

```
Postgres=>select slot_name, slot_type, confirmed_flush_lsn from
 pg_replication_slots;

slot_name | slot_type | confirmed_flush_lsn
-----------+-----------+---------------------
 testsub   | logical   | 0/5413F5C0
(1 row)
```

Read replica limitations with PostgreSQL

The following are limitations for PostgreSQL read replicas:

> **Note**
>
> A read replica for RDS for PostgreSQL Multi-AZ and Single-AZ DB instance running PostgreSQL version 12 and earlier, reboots automatically to apply the password rotation

during the 60 to 90 days maintenance window. If the connection from replica to source breaks before the scheduled reboot, the instance will still be rebooted for the replication to resume.

- PostgreSQL read replicas are read-only. Although a read replica isn't a writeable DB instance, you can promote it to become a standalone RDS for PostgreSQL DB instance. However, the process isn't reversible.
- You can't create a read replica from another read replica if your RDS for PostgreSQL DB instance is running a PostgreSQL version earlier than 14.1. RDS for PostgreSQL supports cascading read replicas on RDS for PostgreSQL version 14.1 and higher releases only. For more information, see Using cascading read replicas with RDS for PostgreSQL.
- If you promote a PostgreSQL read replica, it becomes a writable DB instance. It stops receiving write-ahead log (WAL) files from a source DB instance, and it's no longer a read-only instance. You can create new read replicas from the promoted DB instance as you do for any RDS for PostgreSQL DB instance. For more information, see Promoting a read replica to be a standalone DB instance.
- If you promote a PostgreSQL read replica from within a replication chain (a series of cascading read replicas), any existing downstream read replicas continue receiving WAL files from the promoted instance automatically. For more information, see Using cascading read replicas with RDS for PostgreSQL.
- If no user transactions are running on the source DB instance, the associated PostgreSQL read replica reports a replication lag of up to five minutes. The replica lag is calculated as `currentTime - lastCommitedTransactionTimestamp`, which means that when no transactions are being processed, the value of replica lag increases for a period of time until the write-ahead log (WAL) segment switches. By default RDS for PostgreSQL switches the WAL segment every 5 minutes, which results in a transaction record and a decrease in the reported lag.
- You can't turn on automated backups for PostgreSQL read replicas for RDS for PostgreSQL versions earlier than 14.1. Automated backups for read replicas are supported for RDS for PostgreSQL 14.1 and higher versions only. For RDS for PostgreSQL 13 and earlier versions, create a snapshot from a read replica if you want a backup of it.
- Point-in-time recovery (PITR) isn't supported for read replicas. You can use PITR with a primary (writer) instance only, not a read replica. To learn more, see Restoring a DB instance to a specified time.

Read replica configuration with PostgreSQL

RDS for PostgreSQL uses PostgreSQL native streaming replication to create a read-only copy of a source DB instance. This read replica DB instance is an asynchronously created physical replica of the source DB instance. It's created by a special connection that transmits write ahead log (WAL) data from the source DB instance to the read replica. For more information, see Streaming Replication in the PostgreSQL documentation.

PostgreSQL asynchronously streams database changes to this secure connection as they're made on the source DB instance. You can encrypt communications from your client applications to the source DB instance or any read replicas by setting the `ssl` parameter to `1`. For more information, see Using SSL with a PostgreSQL DB instance .

PostgreSQL uses a *replication* role to perform streaming replication. The role is privileged, but you can't use it to modify any data. PostgreSQL uses a single process for handling replication.

You can create a PostgreSQL read replica without affecting operations or users of the source DB instance. Amazon RDS sets the necessary parameters and permissions for you, on the source DB instance and the read replica, without affecting the service. A snapshot is taken of the source DB instance, and this snapshot is used to create the read replica. If you delete the read replica at some point in the future, no outage occurs.

You can create up to 15 read replicas from one source DB instance within the same Region. As of RDS for PostgreSQL 14.1, you can also create up to three levels of read replica in a chain (cascade) from a source DB instance. For more information, see Using cascading read replicas with RDS for PostgreSQL. In all cases, the source DB instance needs to have automated backups configured. You do this by setting the backup retention period on your DB instance to any value other than 0. For more information, see Creating a read replica.

You can create read replicas for your RDS for PostgreSQL DB instance in the same AWS Region as your source DB instance. This is known as *in-Region* replication. You can also create read replicas in different AWS Regions than the source DB instance. This is known as *cross-Region* replication. For more information about setting up cross-Region read replicas, see Creating a read replica in a different AWS Region. The various mechanisms supporting the replication process for in-Region and cross-Region differ slightly depending on the RDS for PostgreSQL version as explained in How streaming replication works for different RDS for PostgreSQL versions.

For replication to operate effectively, each read replica should have the same amount of compute and storage resources as the source DB instance. If you scale the source DB instance, be sure to also scale the read replicas.

Amazon RDS overrides any incompatible parameters on a read replica if they prevent the read replica from starting. For example, suppose that the `max_connections` parameter value is higher on the source DB instance than on the read replica. In that case, Amazon RDS updates the parameter on the read replica to be the same value as that on the source DB instance.

RDS for PostgreSQL read replicas have access to external databases that are available through foreign data wrappers (FDWs) on the source DB instance. For example, suppose that your RDS for PostgreSQL DB instance is using the `mysql_fdw` wrapper to access data from RDS for MySQL. If so, your read replicas can also access that data. Other supported FDWs include `oracle_fdw`, `postgres_fdw`, and `tds_fdw`. For more information, see Working with the supported foreign data wrappers for Amazon RDS for PostgreSQL.

Using RDS for PostgreSQL read replicas with Multi-AZ configurations

You can create a read replica from a single-AZ or Multi-AZ DB instance. You can use Multi-AZ deployments to improve the durability and availability of critical data, with a standby replica. A *standby replica* is a dedicated read replica that can assume the workload if the source DB fails over. You can't use your standby replica to serve read traffic. However, you can create read replicas from high-traffic Multi-AZ DB instances to offload read-only queries. To learn more about Multi-AZ deployments, see Multi-AZ DB instance deployments.

If the source DB instance of a Multi-AZ deployment fails over to a standby, the associated read replicas switch to using the standby (now primary) as their replication source. The read replicas might need to restart, depending on the RDS for PostgreSQL version, as follows:

- **PostgreSQL 13 and higher versions** – Restarting isn't required. The read replicas are automatically synchronized with the new primary. However, in some cases your client application might cache Domain Name Service (DNS) details for your read replicas. If so, set the time-to-live (TTL) value to less than 30 seconds. Doing this prevents the read replica from holding on to a stale IP address (and thus, prevents it from synchronizing with the new primary). To learn more about this and other best practices, see Amazon RDS basic operational guidelines.
- **PostgreSQL 12 and all earlier versions** – The read replicas restart automatically after a fail over to the standby replica because the standby (now primary) has a different IP address and a different instance name. Restarting synchronizes the read replica with the new primary.

To learn more about failover, see Failover process for Amazon RDS. To learn more about how read replicas work in a Multi-AZ deployment, see Working with DB instance read replicas.

To provide failover support for a read replica, you can create the read replica as a Multi-AZ DB instance so that Amazon RDS creates a standby of your replica in another Availability Zone (AZ). Creating your read replica as a Multi-AZ DB instance is independent of whether the source database is a Multi-AZ DB instance.

Using cascading read replicas with RDS for PostgreSQL

As of version 14.1, RDS for PostgreSQL supports cascading read replicas. With *cascading read replicas*, you can scale reads without adding overhead to your source RDS for PostgreSQL DB instance. Updates to the WAL log aren't sent by the source DB instance to each read replica. Instead, each read replica in a cascading series sends WAL log updates to the next read replica in the series. This reduces the burden on the source DB instance.

With cascading read replicas, your RDS for PostgreSQL DB instance sends WAL data to the first read replica in the chain. That read replica then sends WAL data to the second replica in the chain, and so on. The end result is that all read replicas in the chain have the changes from the RDS for PostgreSQL DB instance, but without the overhead solely on the source DB instance.

You can create a series of up to three read replicas in a chain from a source RDS for PostgreSQL DB instance. For example, suppose that you have an RDS for PostgreSQL 14.1 DB instance, `rpg-db-main`. You can do the following:

- Starting with `rpg-db-main`, create the first read replica in the chain, `read-replica-1`.
- Next, from `read-replica-1`, create the next read replica in the chain, `read-replica-2`.
- Finally, from `read-replica-2`, create the third read replica in the chain, `read-replica-3`.

You can't create another read replica beyond this third cascading read replica in the series for `rpg-db-main`. A complete series of instances from an RDS for PostgreSQL source DB instance through to the end of a series of cascading read replicas can consist of at most four DB instances.

For cascading read replicas to work, turn on automatic backups on your RDS for PostgreSQL. Create the read replica first and then turn on automatic backups on the RDS for PostgreSQL DB instance. The process is the same as for other Amazon RDS DB engines. For more information, see Creating a read replica.

As with any read replica, you can promote a read replica that's part of a cascade. Promoting a read replica from within a chain of read replicas removes that replica from the chain. For example, suppose that you want to move some of the workload off of your `rpg-db-main` DB instance to a new instance for use by the accounting department only. Assuming the chain of three read replicas from the example, you decide to promote `read-replica-2`. The chain is affected as follows:

- Promoting `read-replica-2` removes it from the replication chain.
  - It is now a full read/write DB instance.
  - It continues replicating to `read-replica-3`, just as it was doing before promotion.
- Your `rpg-db-main` continues replicating to `read-replica-1`.

For more information about promoting read replicas, see Promoting a read replica to be a standalone DB instance.

> **Note**
>
> For cascading read replicas, RDS for PostgreSQL supports 15 read replicas for each source DB instance at first level of replication, and 5 read replicas for each source DB instance at the second and third level of replication.

Creating cross-Region cascading read replicas with RDS for PostgreSQL

RDS for PostgreSQL supports cross-Region cascading read replicas. You can create a cross-Region replica from the source DB instance, and then create same-Region replicas from it. You can also create a same-Region replica from the source DB instance, and then create cross-Region replicas from it.

Create a cross-Region replica and then create same-Region replicas

You can use an RDS for PostgreSQL DB instance with version 14.1 or higher, `rpg-db-main`, to do the following:

1. Start with `rpg-db-main` (US-EAST-1), create the first cross-Region read replica in the chain, `read-replica-1` (US-WEST-2).
2. Using the first cross-Region `read-replica-1` (US-WEST-2), create the second read replica in the chain, `read-replica-2` (US-WEST-2).

3. Using `read-replica-2`, create the third read replica in the chain, `read-replica-3` (US-WEST-2).

Create a same-Region replica and then create cross-Region replicas

You can use an RDS for PostgreSQL DB instance with version 14.1 or higher, `rpg-db-main`, to do the following:

1. Starting with `rpg-db-main` (US-EAST-1), create the first read replica in the chain, `read-replica-1` (US-EAST-1).
2. Using `read-replica-1` (US-EAST-1), create the first cross-Region read replica in the chain, `read-replica-2` (US-WEST-2).
3. Using `read-replica-2` (US-WEST-2), create the third read replica in the chain, `read-replica-3` (US-WEST-2).

Limitations in creating cross-Region read replicas

- A cross-Region cascading chain of database replicas can span a maximum of two Regions, with a maximum of four levels. The four levels include the database source and three read replicas.

Advantages of using cascading read replicas

- Improved read scalability – By distributing read queries across multiple replicas, cascading replication helps balance the load. This improves performance, especially in read-heavy applications, by reducing the strain on the writer database.
- Geographical distribution – Cascading replicas can be located in different geographic locations. This reduces latency for users located far from the primary database and provides a local read replica, enhancing performance and user experience.
- High availability and disaster recovery – In the event of a primary server failure, replicas can be promoted to primary, ensuring continuity. cascading replication further enhances this by providing multiple layers of failover options, improving the overall resilience of the system.
- Flexibility and modular growth – As the system grows, new replicas can be added at different levels without major reconfiguration of the primary database. This modular approach allows for scalable and manageable growth of the replication setup.

For more information about the advantages of using replication, see About replication in Cloud SQL.

Best practice for using cross-Region read replicas

- Before promoting a replica, create additional replicas. This will save time, and provide efficient handling of the workload.

How streaming replication works for different RDS for PostgreSQL versions

As discussed in Read replica configuration with PostgreSQL, RDS for PostgreSQL uses PostgreSQL's native streaming replication protocol to send WAL data from the source DB instance. It sends source WAL data to read replicas for both in-Region and cross-Region read replicas. With version 9.4, PostgreSQL introduced physical replication slots as a supporting mechanism for the replication process.

A *physical replication slot* prevents a source DB instance from removing WAL data before it's consumed by all read replicas. Each read replica has its own physical slot on the source DB instance. The slot keeps track of the oldest WAL (by logical sequence number, LSN) that might be needed by the replica. After all slots and DB connections have progressed beyond a given WAL (LSN), that LSN becomes a candidate for removal at the next checkpoint.

Amazon RDS uses Amazon S3 to archive WAL data. For in-Region read replicas, you can use this archived data to recover the read replica when necessary. An example of when you might do so is if the connection between source DB and read replica is interrupted for any reason.

In the following table, you can find a summary of differences between PostgreSQL versions and the supporting mechanisms for in-Region and cross-Region used by RDS for PostgreSQL.

Version	In-Region	Cross-Region
PostgreSQL 14.1 and higher versions	• Replication slots • Amazon S3 archive	• Replication slots
PostgreSQL 13 and lower versions	• Amazon S3 archive	• Replication slots

For more information, see Monitoring and tuning the replication process.

Understanding the parameters that control PostgreSQL replication

The following parameters affect the replication process and determine how well read replicas stay up to date with the source DB instance:

max_wal_senders

The `max_wal_senders` parameter specifies the maximum number of connections that the source DB instance can support at the same time over the streaming replication protocol. The default for RDS for PostgreSQL 13 and higher releases is 20. This parameter should be set to slightly higher than the actual number of read replicas. If this parameter is set too low for the number of read replicas, replication stops.

For more information, see max_wal_senders in the PostgreSQL documentation.

wal_keep_segments

The `wal_keep_segments` parameter specifies the number of write-ahead log (WAL) files that the source DB instance keeps in the `pg_wal` directory. The default setting is 32.

If `wal_keep_segments` isn't set to a large enough value for your deployment, a read replica can fall so far behind that streaming replication stops. If that happens, Amazon RDS generates a replication error and begins recovery on the read replica. It does so by replaying the source DB instance's archived WAL data from Amazon S3. This recovery process continues until the read replica has caught up enough to continue streaming replication. You can see this process in action as captured by the PostgreSQL log in Example: How a read replica recovers from replication interruptions.

> **Note**
>
> In PostgreSQL version 13, the `wal_keep_segments` parameter is named `wal_keep_size`. It serves the same purpose as `wal_keep_segments`, but its default value is in megabytes (MB) (2048 MB) rather than the number of files. For more information, see wal_keep_segments and wal_keep_size in the PostgreSQL documentation.

max_slot_wal_keep_size

The `max_slot_wal_keep_size` parameter controls the quantity of WAL data that the RDS for PostgreSQL DB instance retains in the `pg_wal` directory to serve slots. This parameter is used for configurations that use replication slots. The default value for this parameter is `-1`, meaning that there's no limit to how much WAL data is kept on the source DB instance. For information about monitoring your replication slots, see Monitoring replication slots for your RDS for PostgreSQL DB instance.

For more information about this parameter, see max_slot_wal_keep_size in the PostgreSQL documentation.

Whenever the stream that provides WAL data to a read replica is interrupted, PostgreSQL switches into recovery mode. It restores the read replica by using archived WAL data from Amazon S3 or by using the WAL data associated with the replication slot. When this process is complete, PostgreSQL re-establishes streaming replication.

Example: How a read replica recovers from replication interruptions

In the following example, you find the log details that demonstrate the recovery process for a read replica. The example is from an RDS for PostgreSQL DB instance running PostgreSQL version 12.9 in the same AWS Region as the source DB, so replication slots aren't used. The recovery process is the same for other RDS for PostgreSQL DB instances running PostgreSQL earlier than version 14.1 with in-Region read replicas.

When the read replica lost contact with the source DB instance, Amazon RDS records the issue in the log as `FATAL: could not receive data from WAL stream` message, along with the `ERROR: requested WAL segment ... has already been removed`. As shown in the bold line, Amazon RDS recovers the replica by replaying an archived WAL file.

```
2014-11-07 19:01:10 UTC::@:[23180]:DEBUG:  switched WAL source from archive to stream
 after failure
2014-11-07 19:01:10 UTC::@:[11575]:LOG: started streaming WAL from primary at 1A/
D3000000 on timeline 1
2014-11-07 19:01:10 UTC::@:[11575]:FATAL: could not receive data from WAL stream:
ERROR:  requested WAL segment 000000010000001A000000D3 has already been removed
2014-11-07 19:01:10 UTC::@:[23180]:DEBUG: could not restore file "00000002.history"
 from archive: return code 0
2014-11-07 19:01:15 UTC::@:[23180]:DEBUG: switched WAL source from stream to archive
 after failure recovering 000000010000001A000000D3
```

```
2014-11-07 19:01:16 UTC::@:[23180]:LOG:  restored log file "000000010000001A000000D3"
 from archive
```

When Amazon RDS replays enough archived WAL data on the replica to catch up, streaming to the read replica begins again. When streaming resumes, Amazon RDS writes an entry to the log file similar to the following.

```
2014-11-07 19:41:36 UTC::@:[24714]:LOG:started streaming WAL from primary at 1B/
B6000000 on timeline 1
```

Setting the parameters that control shared memory

The parameters you set determine the size of shared memory for tracking transaction IDs, locks, and prepared transactions. **The shared memory structure of a standby instance must be equal or greater than that of a primary instance.** This ensures that the former doesn't run out of shared memory during recovery. If the parameter values on the replica are less than the parameter values on the primary, Amazon RDS will automatically adjust the replica parameters and restart the engine.

The parameters affected are:

- max_connections
- max_worker_processes
- max_wal_senders
- max_prepared_transactions
- max_locks_per_transaction

To avoid RDS reboots of replicas due to insufficient memory, we recommend applying the parameter changes as a rolling reboot to each replica. You must apply the following rules, when you set the parameters:

- **Increasing the parameter values:**
  - You should always increase the parameter values of all the read replicas first, and perform a rolling reboot of all replicas. Then, apply the parameter changes on the primary instance and reboot.
- **Decreasing the parameter values:**

- You should first decrease the parameter values of the primary instance and perform a reboot. Then, apply the parameter changes to all the associated read replicas and perform a rolling reboot.

Monitoring and tuning the replication process

We strongly recommend that you routinely monitor your RDS for PostgreSQL DB instance and read replicas. You need to ensure that your read replicas are keeping up with changes on the source DB instance. Amazon RDS transparently recovers your read replicas when interruptions to the replication process occur. However, it's best to avoid needing to recover at all. Recovering using replication slots is faster than using the Amazon S3 archive, but any recovery process can affect read performance.

To determine how well your read replicas are keeping up with the source DB instance, you can do the following:

- **Check the amount of `ReplicaLag` between source DB instance and replicas.** *Replica lag* is the amount of time, in seconds, that a read replica lags behind its source DB instance. This metric reports the result of the following query.

  ```
  SELECT extract(epoch from now() - pg_last_xact_replay_timestamp()) AS "ReplicaLag";
  ```

  Replica lag is an indication of how well a read replica is keeping up with the source DB instance. It's the amount of latency between the source DB instance and a specific read instance. A high value for replica lag can indicate a mismatch between the DB instance classes or storage types (or both) used by the source DB instance and its read replicas. The DB instance class and storage types for DB source instance and all read replicas should be the same.

  Replica lag can also be the result of intermittent connection issues. You can monitor replication lag in Amazon CloudWatch by viewing the Amazon RDS `ReplicaLag` metric. To learn more about `ReplicaLag` and other metrics for Amazon RDS, see Amazon CloudWatch metrics for Amazon RDS.
- **Check the PostgreSQL log for information you can use to adjust your settings.** At every checkpoint, the PostgreSQL log captures the number of recycled transaction log files, as shown in the following example.

```
2014-11-07 19:59:35 UTC::@:[26820]:LOG:  checkpoint complete: wrote 376 buffers
 (0.2%);
0 transaction log file(s) added, 0 removed, 1 recycled; write=35.681 s, sync=0.013 s,
 total=35.703 s;
sync files=10, longest=0.013 s, average=0.001 s
```

You can use this information to figure out how many transaction files are being recycled in a given time period. You can then change the setting for `wal_keep_segments` if necessary. For example, suppose that the PostgreSQL log at `checkpoint complete` shows `35 recycled` for a 5-minute interval. In this case, the `wal_keep_segments` default value of 32 isn't sufficient to keep pace with the streaming activity, so you should increase the value of this parameter.

- **Use Amazon CloudWatch to monitor metrics that can predict replication issues.** Rather than analyzing the PostgreSQL log directly, you can use Amazon CloudWatch to check metrics that have been collected. For example, you can check the value of the `TransactionLogsGeneration` metric to see how much WAL data is being generated by the source DB instance. In some cases, the workload on your DB instance might generate a large amount of WAL data. If so, you might need to change the DB instance class for your source DB instance and read replicas. Using an instance class with high (10 Gbps) network performance can reduce replica lag.

Monitoring replication slots for your RDS for PostgreSQL DB instance

All versions of RDS for PostgreSQL use replication slots for cross-Region read replicas. RDS for PostgreSQL 14.1 and higher versions use replication slots for in-Region read replicas. In-region read replicas also use Amazon S3 to archive WAL data. In other words, if your DB instance and read replicas are running PostgreSQL 14.1 or higher, replication slots and Amazon S3 archives are both available for recovering the read replica. Recovering a read replica using its replication slot is faster than recovering from Amazon S3 archive. So, we recommend that you monitor the replication slots and related metrics.

You can view the replication slots on your RDS for PostgreSQL DB instances by querying the `pg_replication_slots` view, as follows.

```
postgres=> SELECT * FROM pg_replication_slots;
slot_name                 | plugin | slot_type | datoid | database | temporary |
 active | active_pid | xmin | catalog_xmin | restart_lsn | confirmed_flush_lsn |
 wal_status | safe_wal_size | two_phase
```

```
-------------------------+--------+----------+--------+----------+-----------
+--------+------------+------+-------------+-------------+--------------------
+------------+--------------+-----------
rds_us_west_1_db_555555555 |        | physical  |        |          | f         | t
  |      13194 |      |              | 23/D8000060 |                    | reserved   |
               | f
(1 row)
```

The `wal_status` of `reserved` value means that the amount of WAL data held by the slot is within the bounds of the `max_wal_size` parameter. In other words, the replication slot is properly sized. Other possible status values are as follows:

- `extended` – The slot exceeds the `max_wal_size` setting, but the WAL data is retained.
- `unreserved` – The slot no longer has the all required WAL data. Some of it will be removed at the next checkpoint.
- `lost` – Some required WAL data has been removed. The slot is no longer usable.

The `unreserved` and `lost` states of the `wal_status` are seen only when `max_slot_wal_keep_size` is non-negative.

The `pg_replication_slots` view shows you the current state of your replication slots. To assess the performance of your replication slots, you can use Amazon CloudWatch and monitor the following metrics:

- **`OldestReplicationSlotLag`** – Lists the slot that has the most lag, that is the one that's furthest behind the primary. This lag can be associated with the read replica but also the connection.
- **`TransactionLogsDiskUsage`** – Shows how much storage is being used for WAL data. When a read replica lags significantly, the value of this metric can increase substantially.

To learn more about using Amazon CloudWatch and its metrics for RDS for PostgreSQL, see Monitoring Amazon RDS metrics with Amazon CloudWatch. For more information about monitoring streaming replication on your RDS for PostgreSQL DB instances, see Best practices for Amazon RDS PostgreSQL replication on the *AWS Database Blog*.

Troubleshooting for RDS for PostgreSQL read replica

Following, you can find troubleshooting ideas for some common RDS for PostgreSQL read replica issues.

Terminate the query that causes the read replica lag

Transactions either in active or idle in transaction state that are running for a long time in the database might interfere with the WAL replication process, thereby increasing the replication lag. Therefore, be sure to monitor the runtime of these transactions with the PostgreSQL `pg_stat_activity` view.

Run a query on the primary instance similar to the following to find the process ID (PID) of the query that's running for a long time:

```
SELECT datname, pid,usename, client_addr, backend_start,
xact_start, current_timestamp - xact_start AS xact_runtime, state,
backend_xmin FROM pg_stat_activity WHERE state='active';
```

```
SELECT now() - state_change as idle_in_transaction_duration, now() - xact_start as
 xact_duration,*
FROM  pg_stat_activity
WHERE state  = 'idle in transaction'
AND   xact_start is not null
ORDER BY 1 DESC;
```

After identifying the PID of the query, you can choose to end the query.

Run a query on the primary instance similar to the following to terminate the query that's running for a long time:

```
SELECT pg_terminate_backend(PID);
```

Improving query performance for RDS for PostgreSQL with Amazon RDS Optimized Reads

You can achieve faster query processing for RDS for PostgreSQL with Amazon RDS Optimized Reads. An RDS for PostgreSQL DB instance or Multi-AZ DB cluster that uses RDS Optimized Reads can achieve up to 50% faster query processing compared to one that doesn't use it.

Topics

Overview of RDS Optimized Reads in PostgreSQL

Optimized Reads is available by default on RDS for PostgreSQL versions 15.2 and higher, 14.7 and higher, and 13.10 and higher.

When you use an RDS for PostgreSQL DB instance or Multi-AZ DB cluster that has RDS Optimized Reads turned on, it achieves up to 50% faster query performance using the local Non-Volatile Memory Express (NVMe) based solid state drive (SSD) block-level storage. You can achieve faster query processing by placing the temporary tables that are generated by PostgreSQL on the local storage, which reduces the traffic to Elastic Block Storage (EBS) over the network.

In PostgreSQL, temporary objects are assigned to a temporary namespace that drops automatically at the end of the session. The temporary namespace while dropping removes any objects that are session-dependent, including schema-qualified objects, such as tables, functions, operators, or even extensions.

In RDS for PostgreSQL, the `temp_tablespaces` parameter is configured for this temporary work area where the temporary objects are stored.

The following queries return the name of the tablespace and its location.

```
postgres=> show temp_tablespaces;
temp_tablespaces
---------------------
rds_temp_tablespace
(1 row)
```

The `rds_temp_tablespace` is a tablespace configured by RDS that points to the NVMe local storage. You can always switch back to Amazon EBS storage by modifying this parameter in the `Parameter group` using the AWS Management Console to point to any tablespace other than `rds_temp_tablespace`. For more information, see Modifying parameters in a DB parameter group. You can also use the SET command to modify the value of the `temp_tablespaces` parameter to `pg_default` at the session level using SET command. Modifying the parameter redirects the temporary work area to Amazon EBS. Switching back to Amazon EBS helps when the local storage for your RDS instance or cluster isn't sufficient to perform a specific SQL operation.

```
postgres=> SET temp_tablespaces TO 'pg_default';
SET
```

```
postgres=> show temp_tablespaces;

 temp_tablespaces
------------------
 pg_default
```

Use cases for RDS Optimized Reads

The following are some use cases that can benefit from Optimized Reads:

- Analytical queries that include Common Table Expressions (CTEs), derived tables, and grouping operations.
- Read replicas that handle the unoptimized queries for an application.
- On-demand or dynamic reporting queries with complex operations such as GROUP BY and ORDER BY that can't always use appropriate indexes.
- Other workloads that use internal temporary tables.
- `CREATE INDEX` or `REINDEX` operations for sorting.

Best practices for RDS Optimized Reads

Use the following best practices for RDS Optimized Reads:

- Add retry logic for read-only queries in case they fail because the instance store is full during the execution.
- Monitor the storage space available on the instance store with the CloudWatch metric `FreeLocalStorage`. If the instance store is reaching its limit because of the workload on the DB instance or Multi-AZ DB cluster, modify it to use a larger DB instance class.

Using RDS Optimized Reads

When you provision an RDS for PostgreSQL DB instance with one of the NVMe based DB instance classes in a Single-AZ DB instance deployment, Multi-AZ DB instance deployment, or Multi-AZ DB cluster deployment, the DB instance automatically uses RDS Optimized Reads.

For more information about Multi-AZ deployment, see Configuring and managing a Multi-AZ deployment.

To turn on RDS Optimized Reads, do one of the following:

- Create an RDS for PostgreSQL DB instance or Multi-AZ DB cluster using one of the NVMe based DB instance classes. For more information, see Creating an Amazon RDS DB instance.
- Modify an existing RDS for PostgreSQL DB instance or Multi-AZ DB cluster to use one of the NVMe based DB instance classes. For more information, see Modifying an Amazon RDS DB instance.

RDS Optimized Reads is available in all AWS Regions where one or more of the DB instance classes with local NVMe SSD storage are supported. For more information, see DB instance classes.

To switch back to a non-optimized reads RDS instance, modify the DB instance class of your RDS instance or cluster to the similar instance class that only supports EBS storage for your database workloads. For example, if the current DB instance class is db.r6gd.4xlarge, choose db.r6g.4xlarge to switch back. For more information, see Modifying an Amazon RDS DB instance.

Monitoring DB instances that use RDS Optimized Reads

You can monitor DB instances that use RDS Optimized Reads using the following CloudWatch metrics:

- `FreeLocalStorage`
- `ReadIOPSLocalStorage`
- `ReadLatencyLocalStorage`
- `ReadThroughputLocalStorage`
- `WriteIOPSLocalStorage`
- `WriteLatencyLocalStorage`
- `WriteThroughputLocalStorage`

These metrics provide data about available instance store storage, IOPS, and throughput. For more information about these metrics, see Amazon CloudWatch instance-level metrics for Amazon RDS.

To monitor current usage of your local storage, log in to your database using the following query:

```
SELECT
    spcname AS "Name",
    pg_catalog.pg_size_pretty(pg_catalog.pg_tablespace_size(oid)) AS "size"
FROM
    pg_catalog.pg_tablespace
WHERE
    spcname IN ('rds_temp_tablespace');
```

For more information about the temporary files and their usage, see Managing temporary files with PostgreSQL.

Limitations for RDS Optimized Reads in PostgreSQL

The following limitation apply to RDS Optimized Reads in PostgreSQL:

- Transactions can fail when the instance store is full.

Importing data into PostgreSQL on Amazon RDS

Suppose that you have an existing PostgreSQL deployment that you want to move to Amazon RDS. The complexity of your task depends on the size of your database and the types of database objects that you're transferring. For example, consider a database that contains datasets on the order of gigabytes, along with stored procedures and triggers. Such a database is going to be more complicated than a simple database with only a few megabytes of test data and no triggers or stored procedures.

We recommend that you use native PostgreSQL database migration tools under the following conditions:

- You have a homogeneous migration, where you are migrating from a database with the same database engine as the target database.
- You are migrating an entire database.
- The native tools allow you to migrate your system with minimal downtime.

In most other cases, performing a database migration using AWS Database Migration Service (AWS DMS) is the best approach. AWS DMS can migrate databases without downtime and, for many database engines, continue ongoing replication until you are ready to switch over to the target database. You can migrate to either the same database engine or a different database engine using AWS DMS. If you are migrating to a different database engine than your source database, you can use the AWS Schema Conversion Tool (AWS SCT). You use AWS SCT to migrate schema objects that are not migrated by AWS DMS. For more information about AWS DMS, see What is AWS Database Migration Service?

Modify your DB parameter group to include the following settings *for your import only*. You should test the parameter settings to find the most efficient settings for your DB instance size. You also need to revert back to production values for these parameters after your import completes.

Modify your DB instance settings to the following:

- Disable DB instance backups (set backup_retention to 0).
- Disable Multi-AZ.

Modify your DB parameter group to include the following settings. You should only use these settings when importing data. You should test the parameter settings to find the most efficient

settings for your DB instance size. You also need to revert back to production values for these parameters after your import completes.

Parameter	Recommended value when importing	Description
maintenance_work_mem	524288, 1048576, 2097152, or 4194304 (in KB). These settings are comparable to 512 MB, 1 GB, 2 GB, and 4 GB.	The value for this setting depends on the size of your host. This parameter is used during CREATE INDEX statements and each parallel command can use this much memory. Calculate the best value so that you don't set this value so high that you run out of memory.
max_wal_size	256 (for version 9.6), 4096 (for versions 10 and higher)	Maximum size to let the WAL grow during automatic checkpoints. Increasing this parameter can increase the amount of time needed for crash recovery. This parameter replaces checkpoint_segments for PostgreSQL 9.6 and later. For PostgreSQL version 9.6, this value is in 16 MB units. For later versions, the value is in 1 MB units. For example, in version 9.6, 128 means 128 chunks that are each 16 MB in size. In version 12.4, 2048 means 2048 chunks that are each 1 MB in size.
checkpoint_timeout	1800	The value for this setting allows for less frequent WAL rotation.
synchronous_commit	Off	Disable this setting to speed up writes. Turning this parameter off can increase the risk of data loss in the event of a server crash (do not turn off FSYNC).
wal_buffers	8192	This is value is in 8 KB units. This again helps your WAL generation speed

Parameter	Recommended value when importing	Description
`autovacuum`	0	Disable the PostgreSQL auto vacuum parameter while you are loading data so that it doesn't use resources

Use the `pg_dump -Fc` (compressed) or `pg_restore -j` (parallel) commands with these settings.

> **Note**
>
> The PostgreSQL command `pg_dumpall` requires super_user permissions that are not granted when you create a DB instance, so it cannot be used for importing data.

Topics

- Importing a PostgreSQL database from an Amazon EC2 instance
- Using the \copy command to import data to a table on a PostgreSQL DB instance
- Importing data from Amazon S3 into an RDS for PostgreSQL DB instance
- Transporting PostgreSQL databases between DB instances

Importing a PostgreSQL database from an Amazon EC2 instance

If you have data in a PostgreSQL server on an Amazon EC2 instance and want to move it to a PostgreSQL DB instance, you can use the following process. The following list shows the steps to take. Each step is discussed in more detail in the following sections.

1. Create a file using pg_dump that contains the data to be loaded
2. Create the target DB instance
3. Use *psql* to create the database on the DB instance and load the data
4. Create a DB snapshot of the DB instance

Step 1: Create a file using pg_dump that contains the data to load

The pg_dump utility uses the COPY command to create a schema and data dump of a PostgreSQL database. The dump script generated by pg_dump loads data into a database with the same name and recreates the tables, indexes, and foreign keys. You can use the pg_restore command and the -d parameter to restore the data to a database with a different name.

Before you create the data dump, you should query the tables to be dumped to get a row count so you can confirm the count on the target DB instance.

The following command creates a dump file called mydb2dump.sql for a database called mydb2.

```
prompt>pg_dump dbname=mydb2 -f mydb2dump.sql
```

Step 2: Create the target DB instance

Create the target PostgreSQL DB instance using either the Amazon RDS console, AWS CLI, or API. Create the instance with the backup retention setting set to 0 and disable Multi-AZ. Doing so allows faster data import. You must create a database on the instance before you can dump the data. The database can have the same name as the database that is contained the dumped data. Alternatively, you can create a database with a different name. In this case, you use the pg_restore command and the -d parameter to restore the data into the newly named database.

For example, the following commands can be used to dump, restore, and rename a database.

```
pg_dump -Fc -v -h [endpoint of instance] -U [master username] [database]
 > [database].dump
createdb [new database name]
pg_restore -v -h [endpoint of instance] -U [master username] -d [new database
 name] [database].dump
```

Step 3: Use psql to create the database on the DB instance and load data

You can use the same connection you used to run the pg_dump command to connect to the target DB instance and recreate the database. Using *psql*, you can use the master user name and master password to create the database on the DB instance

The following example uses *psql* and a dump file named mydb2dump.sql to create a database called mydb2 on a PostgreSQL DB instance called mypginstance:

For Linux, macOS, or Unix:

```
psql \
   -f mydb2dump.sql \
   --host mypginstance.555555555555.aws-region.rds.amazonaws.com \
   --port 8199 \
   --username myawsuser \
   --password password \
   --dbname mydb2
```

For Windows:

```
psql ^
   -f mydb2dump.sql ^
   --host mypginstance.555555555555.aws-region.rds.amazonaws.com ^
   --port 8199 ^
   --username myawsuser ^
   --password password ^
   --dbname mydb2
```

> **Note**
>
> Specify a password other than the prompt shown here as a security best practice.

Step 4: Create a DB snapshot of the DB instance

Once you have verified that the data was loaded into your DB instance, we recommend that you create a DB snapshot of the target PostgreSQL DB instance. DB snapshots are complete backups of your DB instance that can be used to restore your DB instance to a known state. A DB snapshot taken immediately after the load protects you from having to load the data again in case of a mishap. You can also use such a snapshot to seed new DB instances. For information about creating a DB snapshot, see Creating a DB snapshot for a Single-AZ DB instance.

Using the \copy command to import data to a table on a PostgreSQL DB instance

The PostgreSQL `\copy` command is a meta-command available from the `psql` interactive client tool. You can use `\copy` to import data into a table on your RDS for PostgreSQL DB instance. To

use the \copy command, you need to first create the table structure on the target DB instance so that \copy has a destination for the data being copied.

You can use \copy to load data from a comma-separated values (CSV) file, such as one that's been exported and saved to your client workstation.

To import the CSV data to the target RDS for PostgreSQL DB instance, first connect to the target DB instance using psql.

```
psql --host=db-instance.111122223333.aws-region.rds.amazonaws.com --port=5432 --
username=postgres --password --dbname=target-db
```

You then run \copy command with the following parameters to identify the target for the data and its format.

- target_table – The name of the table that should receive the data being copied from the CSV file.
- column_list – Column specifications for the table.
- 'filename' – The complete path to the CSV file on your local workstation.

```
 \copy target_table from '/path/to/local/filename.csv' WITH DELIMITER ',' CSV;
```

If your CSV file has column heading information, you can use this version of the command and parameters.

```
\copy target_table (column-1, column-2, column-3, ...)
    from '/path/to/local/filename.csv' WITH DELIMITER ',' CSV HEADER;
```

If the \copy command fails, PostgreSQL outputs error messages.

Creating a new DB instance in the Database Preview environment using psql command with the \copy meta-command as shown in the following examples. This example uses *source-table* as the source table name, *source-table.csv* as the .csv file, and *target-db* as the target database:

For Linux, macOS, or Unix:

```
$psql target-db \
    -U <admin user> \
```

```
    -p <port> \
    -h <DB instance name> \
    -c "\copy source-table from 'source-table.csv' with DELIMITER ','"
```

For Windows:

```
$psql target-db ^
    -U <admin user> ^
    -p <port> ^
    -h <DB instance name> ^
    -c "\copy source-table from 'source-table.csv' with DELIMITER ','"
```

For complete details about the `\copy` command, see the psql page in the PostgreSQL documentation, in the *Meta-Commands* section.

Importing data from Amazon S3 into an RDS for PostgreSQL DB instance

You can import data that's been stored using Amazon Simple Storage Service into a table on an RDS for PostgreSQL DB instance. To do this, you first install the RDS for PostgreSQL `aws_s3` extension. This extension provides the functions that you use to import data from an Amazon S3 bucket. A *bucket* is an Amazon S3 container for objects and files. The data can be in a comma-separate value (CSV) file, a text file, or a compressed (gzip) file. Following, you can learn how to install the extension and how to import data from Amazon S3 into a table.

Your database must be running PostgreSQL version 10.7 or higher to import from Amazon S3 into RDS for PostgreSQL.

If you don't have data stored on Amazon S3, you need to first create a bucket and store the data. For more information, see the following topics in the *Amazon Simple Storage Service User Guide*.

- Create a bucket
- Add an object to a bucket

Cross-account import from Amazon S3 is supported. For more information, see Granting cross-account permissions in the *Amazon Simple Storage Service User Guide*.

You can use the customer managed key for encryption while importing data from S3. For more information, see KMS keys stored in AWS KMS in the *Amazon Simple Storage Service User Guide*.

> **Note**
>
> Importing data from Amazon S3 isn't supported for Aurora Serverless v1. It is supported for Aurora Serverless v2.

Topics

Installing the aws_s3 extension

Before you can use Amazon S3 with your RDS for PostgreSQL DB instance, you need to install the `aws_s3` extension. This extension provides functions for importing data from an Amazon S3. It also provides functions for exporting data from an RDS for PostgreSQL DB instance to an Amazon S3 bucket. For more information, see Exporting data from an RDS for PostgreSQL DB instance to Amazon S3. The `aws_s3` extension depends on some of the helper functions in the `aws_commons` extension, which is installed automatically when needed.

To install the `aws_s3` extension

1. Use psql (or pgAdmin) to connect to the RDS for PostgreSQL DB instance as a user that has `rds_superuser` privileges. If you kept the default name during the setup process, you connect as `postgres`.

   ```
   psql --host=111122223333.aws-region.rds.amazonaws.com --port=5432 --
   username=postgres --password
   ```

2. To install the extension, run the following command.

   ```
   postgres=> CREATE EXTENSION aws_s3 CASCADE;
   NOTICE: installing required extension "aws_commons"
   CREATE EXTENSION
   ```

3. To verify that the extension is installed, you can use the psql `\dx` metacommand.

```
postgres=> \dx
       List of installed extensions
    Name     | Version |   Schema   |                Description
-------------+---------+------------+-------------------------------------------
 aws_commons | 1.2     | public     | Common data types across AWS services
 aws_s3      | 1.1     | public     | AWS S3 extension for importing data from S3
 plpgsql     | 1.0     | pg_catalog | PL/pgSQL procedural language
(3 rows)
```

The functions for importing data from Amazon S3 and exporting data to Amazon S3 are now available to use.

Overview of importing data from Amazon S3 data

To import S3 data into Amazon RDS

First, gather the details that you need to supply to the function. These include the name of the table on your RDS for PostgreSQL DB instance, and the bucket name, file path, file type, and AWS Region where the Amazon S3 data is stored. For more information, see View an object in the *Amazon Simple Storage Service User Guide*.

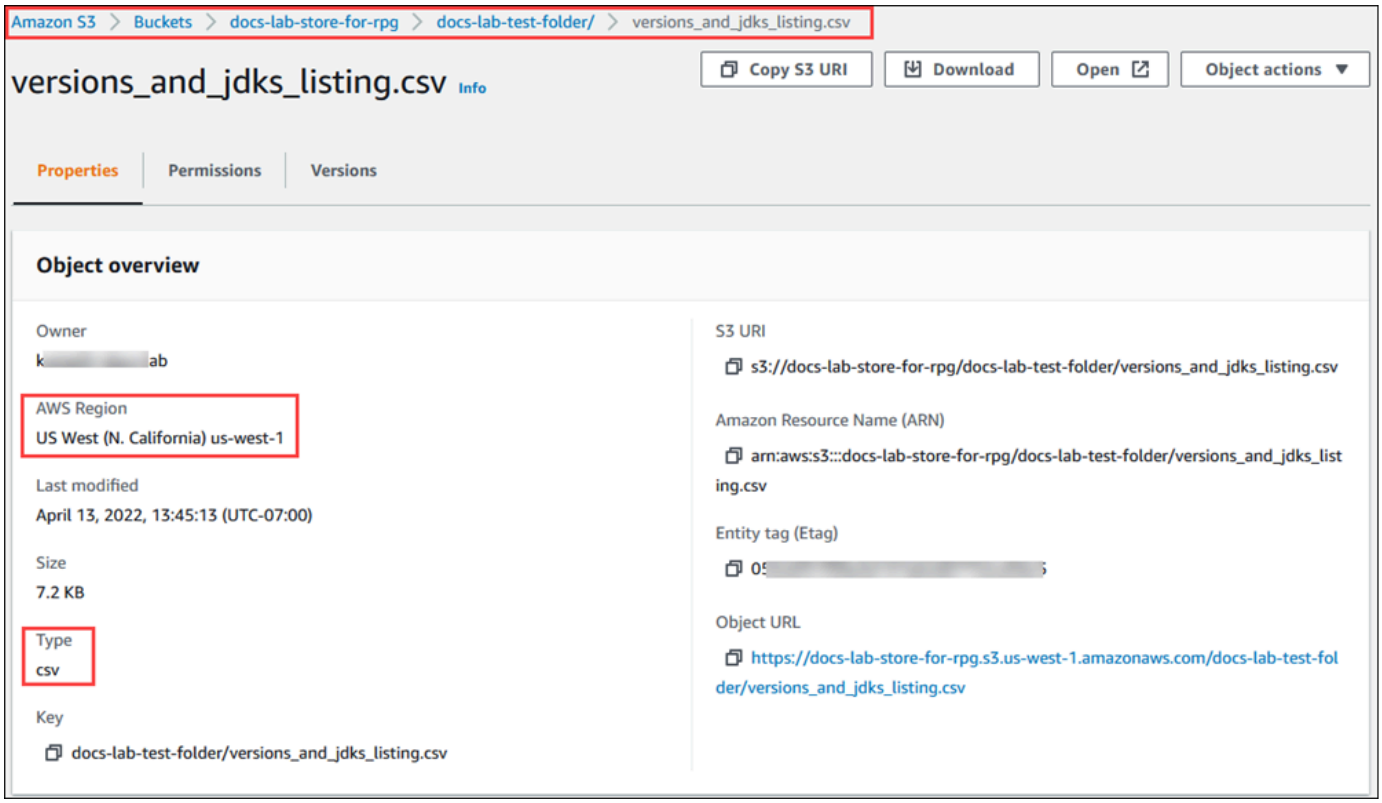
> **Note**
>
> Multi part data import from Amazon S3 isn't currently supported.

1. Get the name of the table into which the `aws_s3.table_import_from_s3` function is to import the data. As an example, the following command creates a table `t1` that can be used in later steps.

   ```
   postgres=> CREATE TABLE t1
       (col1 varchar(80),
       col2 varchar(80),
       col3 varchar(80));
   ```

2. Get the details about the Amazon S3 bucket and the data to import. To do this, open the Amazon S3 console at https://console.aws.amazon.com/s3/, and choose **Buckets**. Find the bucket containing your data in the list. Choose the bucket, open its Object overview page, and then choose Properties.

Make a note of the bucket name, path, the AWS Region, and file type. You need the Amazon Resource Name (ARN) later, to set up access to Amazon S3 through an IAM role. For more more information, see Setting up access to an Amazon S3 bucket. The image following shows an example.



3. You can verify the path to the data on the Amazon S3 bucket by using the AWS CLI command `aws s3 cp`. If the information is correct, this command downloads a copy of the Amazon S3 file.

```
aws s3 cp s3://amzn-s3-demo-bucket/sample_file_path ./
```

4. Set up permissions on your RDS for PostgreSQL DB instance to allow access to the file on the Amazon S3 bucket. To do so, you use either an AWS Identity and Access Management (IAM) role or security credentials. For more information, see Setting up access to an Amazon S3 bucket.

5. Supply the path and other Amazon S3 object details gathered (see step 2) to the `create_s3_uri` function to construct an Amazon S3 URI object. To learn more about this function, see aws_commons.create_s3_uri. The following is an example of constructing this object during a psql session.

```
postgres=> SELECT aws_commons.create_s3_uri(
   'docs-lab-store-for-rpg',
   'versions_and_jdks_listing.csv',
   'us-west-1'
) AS s3_uri \gset
```

In the next step, you pass this object (`aws_commons._s3_uri_1`) to the `aws_s3.table_import_from_s3` function to import the data to the table.

6. Invoke the `aws_s3.table_import_from_s3` function to import the data from Amazon S3 into your table. For reference information, see aws_s3.table_import_from_s3. For examples, see Importing data from Amazon S3 to your RDS for PostgreSQL DB instance.

Setting up access to an Amazon S3 bucket

To import data from an Amazon S3 file, give the RDS for PostgreSQL DB instance permission to access the Amazon S3 bucket containing the file. You provide access to an Amazon S3 bucket in one of two ways, as described in the following topics.

Topics

- Using an IAM role to access an Amazon S3 bucket
- Using security credentials to access an Amazon S3 bucket
- Troubleshooting access to Amazon S3

Using an IAM role to access an Amazon S3 bucket

Before you load data from an Amazon S3 file, give your RDS for PostgreSQL DB instance permission to access the Amazon S3 bucket the file is in. This way, you don't have to manage additional credential information or provide it in the aws_s3.table_import_from_s3 function call.

To do this, create an IAM policy that provides access to the Amazon S3 bucket. Create an IAM role and attach the policy to the role. Then assign the IAM role to your DB instance.

> **Note**
>
> You can't associate an IAM role with an Aurora Serverless v1 DB cluster, so the following steps don't apply.

To give an RDS for PostgreSQL DB instance access to Amazon S3 through an IAM role

1. Create an IAM policy.

   This policy provides the bucket and object permissions that allow your RDS for PostgreSQL DB instance to access Amazon S3.

   Include in the policy the following required actions to allow the transfer of files from an Amazon S3 bucket to Amazon RDS:

   - `s3:GetObject`
   - `s3:ListBucket`

   Include in the policy the following resources to identify the Amazon S3 bucket and objects in the bucket. This shows the Amazon Resource Name (ARN) format for accessing Amazon S3.

   - arn:aws:s3:::*amzn-s3-demo-bucket*
   - arn:aws:s3:::*amzn-s3-demo-bucket*/*

   For more information on creating an IAM policy for RDS for PostgreSQL, see Creating and using an IAM policy for IAM database access. See also Tutorial: Create and attach your first customer managed policy in the *IAM User Guide*.

   The following AWS CLI command creates an IAM policy named `rds-s3-import-policy` with these options. It grants access to a bucket named *amzn-s3-demo-bucket*.

   > **Note**
   >
   > Make a note of the Amazon Resource Name (ARN) of the policy returned by this command. You need the ARN in a subsequent step when you attach the policy to an IAM role.

   Example

   For Linux, macOS, or Unix:

   ```
   aws iam create-policy \
   ```

```
   --policy-name rds-s3-import-policy \
   --policy-document '{
     "Version": "2012-10-17",
     "Statement": [
       {
         "Sid": "s3import",
         "Action": [
           "s3:GetObject",
           "s3:ListBucket"
         ],
         "Effect": "Allow",
         "Resource": [
           "arn:aws:s3:::amzn-s3-demo-bucket",
           "arn:aws:s3:::amzn-s3-demo-bucket/*"
         ]
       }
     ]
   }'
```

For Windows:

```
aws iam create-policy ^
   --policy-name rds-s3-import-policy ^
   --policy-document '{
     "Version": "2012-10-17",
     "Statement": [
       {
         "Sid": "s3import",
         "Action": [
           "s3:GetObject",
           "s3:ListBucket"
         ],
         "Effect": "Allow",
         "Resource": [
           "arn:aws:s3:::amzn-s3-demo-bucket",
           "arn:aws:s3:::amzn-s3-demo-bucket/*"
         ]
       }
     ]
   }'
```

2. Create an IAM role.

You do this so Amazon RDS can assume this IAM role to access your Amazon S3 buckets. For more information, see Creating a role to delegate permissions to an IAM user in the *IAM User Guide*.

We recommend using the `aws:SourceArn` and `aws:SourceAccount` global condition context keys in resource-based policies to limit the service's permissions to a specific resource. This is the most effective way to protect against the confused deputy problem.

If you use both global condition context keys and the `aws:SourceArn` value contains the account ID, the `aws:SourceAccount` value and the account in the `aws:SourceArn` value must use the same account ID when used in the same policy statement.

- Use `aws:SourceArn` if you want cross-service access for a single resource.
- Use `aws:SourceAccount` if you want to allow any resource in that account to be associated with the cross-service use.

In the policy, be sure to use the `aws:SourceArn` global condition context key with the full ARN of the resource. The following example shows how to do so using the AWS CLI command to create a role named `rds-s3-import-role`.

Example

For Linux, macOS, or Unix:

```
aws iam create-role \
   --role-name rds-s3-import-role \
   --assume-role-policy-document '{
     "Version": "2012-10-17",
     "Statement": [
       {
         "Effect": "Allow",
         "Principal": {
            "Service": "rds.amazonaws.com"
          },
         "Action": "sts:AssumeRole",
         "Condition": {
             "StringEquals": {
                "aws:SourceAccount": "111122223333",
                "aws:SourceArn": "arn:aws:rds:us-east-1:111122223333:db:dbname"
                }
```

```
            }
        }
      ]
   }'
```

For Windows:

```
aws iam create-role ^
   --role-name rds-s3-import-role ^
   --assume-role-policy-document '{
     "Version": "2012-10-17",
     "Statement": [
       {
         "Effect": "Allow",
         "Principal": {
            "Service": "rds.amazonaws.com"
          },
         "Action": "sts:AssumeRole",
         "Condition": {
             "StringEquals": {
                "aws:SourceAccount": "111122223333",
                "aws:SourceArn": "arn:aws:rds:us-east-1:111122223333:db:dbname"
                }
             }
       }
     ]
   }'
```

3. Attach the IAM policy that you created to the IAM role that you created.

   The following AWS CLI command attaches the policy created in the previous step to the role named `rds-s3-import-role` Replace *`your-policy-arn`* with the policy ARN that you noted in an earlier step.

   Example

   For Linux, macOS, or Unix:

```
aws iam attach-role-policy \
   --policy-arn your-policy-arn \
   --role-name rds-s3-import-role
```

For Windows:

```
aws iam attach-role-policy ^
   --policy-arn your-policy-arn ^
   --role-name rds-s3-import-role
```

4. Add the IAM role to the DB instance.

   You do so by using the AWS Management Console or AWS CLI, as described following.

Console

To add an IAM role for a PostgreSQL DB instance using the console

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Choose the PostgreSQL DB instance name to display its details.
3. On the **Connectivity & security** tab, in the **Manage IAM roles** section, choose the role to add under **Add IAM roles to this instance** .
4. Under **Feature**, choose **s3Import**.
5. Choose **Add role**.

AWS CLI

To add an IAM role for a PostgreSQL DB instance using the CLI

- Use the following command to add the role to the PostgreSQL DB instance named `my-db-instance`. Replace *`your-role-arn`* with the role ARN that you noted in a previous step. Use `s3Import` for the value of the `--feature-name` option.

  Example

  For Linux, macOS, or Unix:

```
aws rds add-role-to-db-instance \
   --db-instance-identifier my-db-instance \
   --feature-name s3Import \
   --role-arn your-role-arn   \
```

```
   --region your-region
```

For Windows:

```
aws rds add-role-to-db-instance ^
   --db-instance-identifier my-db-instance ^
   --feature-name s3Import ^
   --role-arn your-role-arn ^
   --region your-region
```

RDS API

To add an IAM role for a PostgreSQL DB instance using the Amazon RDS API, call the AddRoleToDBInstance operation.

Using security credentials to access an Amazon S3 bucket

If you prefer, you can use security credentials to provide access to an Amazon S3 bucket instead of providing access with an IAM role. You do so by specifying the `credentials` parameter in the aws_s3.table_import_from_s3 function call.

The `credentials` parameter is a structure of type `aws_commons._aws_credentials_1`, which contains AWS credentials. Use the aws_commons.create_aws_credentials function to set the access key and secret key in an `aws_commons._aws_credentials_1` structure, as shown following.

```
postgres=> SELECT aws_commons.create_aws_credentials(
   'sample_access_key', 'sample_secret_key', '')
AS creds \gset
```

After creating the `aws_commons._aws_credentials_1` structure, use the aws_s3.table_import_from_s3 function with the `credentials` parameter to import the data, as shown following.

```
postgres=> SELECT aws_s3.table_import_from_s3(
   't', '', '(format csv)',
   :'s3_uri',
   :'creds'
);
```

Or you can include the aws_commons.create_aws_credentials function call inline within the aws_s3.table_import_from_s3 function call.

```
postgres=> SELECT aws_s3.table_import_from_s3(
   't', '', '(format csv)',
   :'s3_uri',
   aws_commons.create_aws_credentials('sample_access_key', 'sample_secret_key', '')
);
```

Troubleshooting access to Amazon S3

If you encounter connection problems when attempting to import data from Amazon S3, see the following for recommendations:

- Troubleshooting Amazon RDS identity and access
- Troubleshooting Amazon S3 in the *Amazon Simple Storage Service User Guide*
- Troubleshooting Amazon S3 and IAM in the *IAM User Guide*

Importing data from Amazon S3 to your RDS for PostgreSQL DB instance

You import data from your Amazon S3 bucket by using the table_import_from_s3 function of the aws_s3 extension. For reference information, see aws_s3.table_import_from_s3.

> **Note**
>
> The following examples use the IAM role method to allow access to the Amazon S3 bucket. Thus, the aws_s3.table_import_from_s3 function calls don't include credential parameters.

The following shows a typical example.

```
postgres=> SELECT aws_s3.table_import_from_s3(
   't1',
   '',
   '(format csv)',
   :'s3_uri'
);
```

The parameters are the following:

- `t1` – The name for the table in the PostgreSQL DB instance to copy the data into.
- `''` – An optional list of columns in the database table. You can use this parameter to indicate which columns of the S3 data go in which table columns. If no columns are specified, all the columns are copied to the table. For an example of using a column list, see Importing an Amazon S3 file that uses a custom delimiter.
- `(format csv)` – PostgreSQL COPY arguments. The copy process uses the arguments and format of the PostgreSQL COPY command to import the data. Choices for format include comma-separated value (CSV) as shown in this example, text, and binary. The default is text.
- `s3_uri` – A structure that contains the information identifying the Amazon S3 file. For an example of using the aws_commons.create_s3_uri function to create an `s3_uri` structure, see Overview of importing data from Amazon S3 data.

For more information about this function, see aws_s3.table_import_from_s3.

The `aws_s3.table_import_from_s3` function returns text. To specify other kinds of files for import from an Amazon S3 bucket, see one of the following examples.

> **Note**
>
> Importing 0 bytes file will cause an error.

Topics

- Importing an Amazon S3 file that uses a custom delimiter
- Importing an Amazon S3 compressed (gzip) file
- Importing an encoded Amazon S3 file

Importing an Amazon S3 file that uses a custom delimiter

The following example shows how to import a file that uses a custom delimiter. It also shows how to control where to put the data in the database table using the `column_list` parameter of the aws_s3.table_import_from_s3 function.

For this example, assume that the following information is organized into pipe-delimited columns in the Amazon S3 file.

```
1|foo1|bar1|elephant1
2|foo2|bar2|elephant2
3|foo3|bar3|elephant3
4|foo4|bar4|elephant4
...
```

To import a file that uses a custom delimiter

1. Create a table in the database for the imported data.

   ```
   postgres=> CREATE TABLE test (a text, b text, c text, d text, e text);
   ```

2. Use the following form of the aws_s3.table_import_from_s3 function to import data from the Amazon S3 file.

   You can include the aws_commons.create_s3_uri function call inline within the `aws_s3.table_import_from_s3` function call to specify the file.

   ```
   postgres=> SELECT aws_s3.table_import_from_s3(
      'test',
      'a,b,d,e',
      'DELIMITER ''|''',
      aws_commons.create_s3_uri('amzn-s3-demo-bucket', 'pipeDelimitedSampleFile', 'us-
   east-2')
   );
   ```

The data is now in the table in the following columns.

```
postgres=> SELECT * FROM test;
a | b | c | d | e
---+------+---+---+------+-----------
1 | foo1 | | bar1 | elephant1
2 | foo2 | | bar2 | elephant2
3 | foo3 | | bar3 | elephant3
4 | foo4 | | bar4 | elephant4
```

Importing an Amazon S3 compressed (gzip) file

The following example shows how to import a file from Amazon S3 that is compressed with gzip. The file that you import needs to have the following Amazon S3 metadata:

- Key: `Content-Encoding`
- Value: `gzip`

If you upload the file using the AWS Management Console, the metadata is typically applied by the system. For information about uploading files to Amazon S3 using the AWS Management Console, the AWS CLI, or the API, see Uploading objects in the *Amazon Simple Storage Service User Guide*.

For more information about Amazon S3 metadata and details about system-provided metadata, see Editing object metadata in the Amazon S3 console in the *Amazon Simple Storage Service User Guide*.

Import the gzip file into your RDS for PostgreSQL DB instance as shown following.

```
postgres=> CREATE TABLE test_gzip(id int, a text, b text, c text, d text);
postgres=> SELECT aws_s3.table_import_from_s3(
 'test_gzip', '', '(format csv)',
 'amzn-s3-demo-bucket', 'test-data.gz', 'us-east-2'
);
```

Importing an encoded Amazon S3 file

The following example shows how to import a file from Amazon S3 that has Windows-1252 encoding.

```
postgres=> SELECT aws_s3.table_import_from_s3(
 'test_table', '', 'encoding ''WIN1252''',
 aws_commons.create_s3_uri('amzn-s3-demo-bucket', 'SampleFile', 'us-east-2')
);
```

Function reference

Functions

- aws_s3.table_import_from_s3
- aws_commons.create_s3_uri
- aws_commons.create_aws_credentials

aws_s3.table_import_from_s3

Imports Amazon S3 data into an Amazon RDS table. The `aws_s3` extension provides the `aws_s3.table_import_from_s3` function. The return value is text.

Syntax

The required parameters are `table_name`, `column_list` and `options`. These identify the database table and specify how the data is copied into the table.

You can also use the following parameters:

- The `s3_info` parameter specifies the Amazon S3 file to import. When you use this parameter, access to Amazon S3 is provided by an IAM role for the PostgreSQL DB instance.

```
aws_s3.table_import_from_s3 (
   table_name text,
   column_list text,
   options text,
   s3_info aws_commons._s3_uri_1
)
```

- The `credentials` parameter specifies the credentials to access Amazon S3. When you use this parameter, you don't use an IAM role.

```
aws_s3.table_import_from_s3 (
   table_name text,
   column_list text,
   options text,
   s3_info aws_commons._s3_uri_1,
   credentials aws_commons._aws_credentials_1
)
```

Parameters

table_name

A required text string containing the name of the PostgreSQL database table to import the data into.

column_list

A required text string containing an optional list of the PostgreSQL database table columns in which to copy the data. If the string is empty, all columns of the table are used. For an example, see Importing an Amazon S3 file that uses a custom delimiter.

options

A required text string containing arguments for the PostgreSQL COPY command. These arguments specify how the data is to be copied into the PostgreSQL table. For more details, see the PostgreSQL COPY documentation.

s3_info

An `aws_commons._s3_uri_1` composite type containing the following information about the S3 object:

- `bucket` – The name of the Amazon S3 bucket containing the file.
- `file_path` – The Amazon S3 file name including the path of the file.
- `region` – The AWS Region that the file is in. For a listing of AWS Region names and associated values, see Regions, Availability Zones, and Local Zones.

credentials

An `aws_commons._aws_credentials_1` composite type containing the following credentials to use for the import operation:

- Access key
- Secret key
- Session token

For information about creating an `aws_commons._aws_credentials_1` composite structure, see aws_commons.create_aws_credentials.

Alternate syntax

To help with testing, you can use an expanded set of parameters instead of the `s3_info` and `credentials` parameters. Following are additional syntax variations for the `aws_s3.table_import_from_s3` function:

- Instead of using the `s3_info` parameter to identify an Amazon S3 file, use the combination of the `bucket`, `file_path`, and `region` parameters. With this form of the function, access to Amazon S3 is provided by an IAM role on the PostgreSQL DB instance.

```
aws_s3.table_import_from_s3 (
   table_name text,
   column_list text,
   options text,
   bucket text,
   file_path text,
   region text
)
```

- Instead of using the `credentials` parameter to specify Amazon S3 access, use the combination of the `access_key`, `session_key`, and `session_token` parameters.

```
aws_s3.table_import_from_s3 (
   table_name text,
   column_list text,
   options text,
   bucket text,
   file_path text,
   region text,
   access_key text,
   secret_key text,
   session_token text
)
```

Alternate parameters

bucket

A text string containing the name of the Amazon S3 bucket that contains the file.

file_path

A text string containing the Amazon S3 file name including the path of the file.

region

A text string identifying the AWS Region location of the file. For a listing of AWS Region names and associated values, see Regions, Availability Zones, and Local Zones.

access_key

A text string containing the access key to use for the import operation. The default is NULL.

secret_key

A text string containing the secret key to use for the import operation. The default is NULL.

session_token

(Optional) A text string containing the session key to use for the import operation. The default is NULL.

aws_commons.create_s3_uri

Creates an `aws_commons._s3_uri_1` structure to hold Amazon S3 file information. Use the results of the `aws_commons.create_s3_uri` function in the `s3_info` parameter of the aws_s3.table_import_from_s3 function.

Syntax

```
aws_commons.create_s3_uri(
   bucket text,
   file_path text,
   region text
)
```

Parameters

bucket

A required text string containing the Amazon S3 bucket name for the file.

file_path

A required text string containing the Amazon S3 file name including the path of the file.

region

A required text string containing the AWS Region that the file is in. For a listing of AWS Region names and associated values, see Regions, Availability Zones, and Local Zones.

aws_commons.create_aws_credentials

Sets an access key and secret key in an `aws_commons._aws_credentials_1` structure. Use the results of the `aws_commons.create_aws_credentials` function in the `credentials` parameter of the aws_s3.table_import_from_s3 function.

Syntax

```
aws_commons.create_aws_credentials(
   access_key text,
   secret_key text,
   session_token text
)
```

Parameters

access_key

A required text string containing the access key to use for importing an Amazon S3 file. The default is NULL.

secret_key

A required text string containing the secret key to use for importing an Amazon S3 file. The default is NULL.

session_token

An optional text string containing the session token to use for importing an Amazon S3 file. The default is NULL. If you provide an optional `session_token`, you can use temporary credentials.

Transporting PostgreSQL databases between DB instances

By using PostgreSQL transportable databases for Amazon RDS, you can move a PostgreSQL database between two DB instances. This is a very fast way to migrate large databases between different DB instances. To use this approach, your DB instances must both run the same major version of PostgreSQL.

This capability requires that you install the `pg_transport` extension on both the source and the destination DB instance. The `pg_transport` extension provides a physical transport mechanism

that moves the database files with minimal processing. This mechanism moves data much faster than traditional dump and load processes, with less downtime.

> **Note**
>
> PostgreSQL transportable databases are available in RDS for PostgreSQL 11.5 and higher, and RDS for PostgreSQL version 10.10 and higher.

To transport a PostgreSQL DB instance from one RDS for PostgreSQL DB instance to another, you first set up the source and destination instances as detailed in Setting up a DB instance for transport. You can then transport the database by using the function described in Transporting a PostgreSQL database.

Topics

Limitations for using PostgreSQL transportable databases

Transportable databases have the following limitations:

- **Read replicas** – You can't use transportable databases on read replicas or parent instances of read replicas.
- **Unsupported column types** – You can't use the `reg` data types in any database tables that you plan to transport with this method. These types depend on system catalog object IDs (OIDs), which often change during transport.
- **Tablespaces** – All source database objects must be in the default `pg_default` tablespace.
- **Compatibility** – Both the source and destination DB instances must run the same major version of PostgreSQL.
- **Extensions** – The source DB instance can have only the `pg_transport` installed.

- **Roles and ACLs** – The source database's access privileges and ownership information aren't carried over to the destination database. All database objects are created and owned by the local destination user of the transport.
- **Concurrent transports** – A single DB instance can support up to 32 concurrent transports, including both imports and exports, if worker processes have been configured properly.
- **RDS for PostgreSQL DB instances only** – PostgreSQL transportable databases are supported on RDS for PostgreSQL DB instances only. You can't use it with on-premises databases or databases running on Amazon EC2.

Setting up to transport a PostgreSQL database

Before you begin, make sure that your RDS for PostgreSQL DB instances meet the following requirements:

- The RDS for PostgreSQL DB instances for source and destination must run the same version of PostgreSQL.
- The destination DB can't have a database of the same name as the source DB that you want to transport.
- The account you use to run the transport needs `rds_superuser` privileges on both the source DB and the destination DB.
- The security group for the source DB instance must allow inbound access from the destination DB instance. This might already be the case if your source and destination DB instances are located in the VPC. For more information about security groups, see Controlling access with security groups.

Transporting databases from a source DB instance to a destination DB instance requires several changes to the DB parameter group associated with each instance. That means that you must create a custom DB parameter group for the source DB instance and create a custom DB parameter group for the destination DB instance.

> **Note**
>
> If your DB instances are already configured using custom DB parameter groups, you can start with step 2 in the following procedure.

To configure the custom DB group parameters for transporting databases

For the following steps, use an account that has `rds_superuser` privileges.

1. If the source and destination DB instances use a default DB parameter group, you need to create a custom DB parameter group using the appropriate version for your instances. You do this so you can change values for several parameters. For more information, see Parameter groups for Amazon RDS.
2. In the custom DB parameter group, change values for the following parameters:

   - `shared_preload_libraries` – Add `pg_transport` to the list of libraries.
   - `pg_transport.num_workers` – The default value is 3. Increase or reduce this value as needed for your database. For a 200 GB database, we recommend no larger than 8. Keep in mind that if you increase the default value for this parameter, you should also increase the value of `max_worker_processes`.
   - `pg_transport.work_mem` – The default value is either 128 MB or 256 MB, depending on the PostgreSQL version. The default setting can typically be left unchanged.
   - `max_worker_processes` – The value of this parameter needs to be set using the following calculation:

     ```
     (3 * pg_transport.num_workers) + 9
     ```

     This value is required on the destination to handle various background worker processes involved in the transport. To learn more about `max_worker_processes`, see Resource Consumption in the PostgreSQL documentation.

   For more information about `pg_transport` parameters, see Transportable databases parameter reference .
3. Reboot the source RDS for PostgreSQL DB instance and the destination instance so that the settings for the parameters take effect.
4. Connect to your RDS for PostgreSQL source DB instance.

   ```
   psql --host=source-instance.111122223333.aws-region.rds.amazonaws.com --port=5432
    --username=postgres --password
   ```
5. Remove extraneous extensions from the public schema of the DB instance. Only the `pg_transport` extension is allowed during the actual transport operation.

6. Install the pg_transport extension as follows:

```
postgres=> CREATE EXTENSION pg_transport;
CREATE EXTENSION
```

7. Connect to your RDS for PostgreSQL destination DB instance. Remove any extraneous extensions, and then install the pg_transport extension.

```
postgres=> CREATE EXTENSION pg_transport;
CREATE EXTENSION
```

Transporting a PostgreSQL database to the destination from the source

After you complete the process described in Setting up to transport a PostgreSQL database, you can start the transport. To do so, run the transport.import_from_server function on the destination DB instance. In the syntax following you can find the function parameters.

```
SELECT transport.import_from_server(
   'source-db-instance-endpoint',
    source-db-instance-port,
   'source-db-instance-user',
   'source-user-password',
   'source-database-name',
   'destination-user-password',
   false);
```

The false value shown in the example tells the function that this is not a dry run. To test your transport setup, you can specify true for the dry_run option when you call the function, as shown following:

```
postgres=> SELECT transport.import_from_server(
    'docs-lab-source-db.666666666666aws-region.rds.amazonaws.com', 5432,
    'postgres', '********', 'labdb', '******', true);
INFO:  Starting dry-run of import of database "labdb".
INFO:  Created connections to remote database       (took 0.03 seconds).
INFO:  Checked remote cluster compatibility         (took 0.05 seconds).
INFO:  Dry-run complete                          (took 0.08 seconds total).
 import_from_server
--------------------
```

```
(1 row)
```

The INFO lines are output because the `pg_transport.timing` parameter is set to its default value, `true`. Set the `dry_run` to `false` when you run the command and the source database is imported to the destination, as shown following:

```
INFO:  Starting import of database "labdb".
INFO:  Created connections to remote database        (took 0.02 seconds).
INFO:  Marked remote database as read only           (took 0.13 seconds).
INFO:  Checked remote cluster compatibility          (took 0.03 seconds).
INFO:  Signaled creation of PITR blackout window     (took 2.01 seconds).
INFO:  Applied remote database schema pre-data       (took 0.50 seconds).
INFO:  Created connections to local cluster          (took 0.01 seconds).
INFO:  Locked down destination database              (took 0.00 seconds).
INFO:  Completed transfer of database files          (took 0.24 seconds).
INFO:  Completed clean up                            (took 1.02 seconds).
INFO:  Physical transport complete              (took 3.97 seconds total).
import_from_server
--------------------
(1 row)
```

This function requires that you provide database user passwords. Thus, we recommend that you change the passwords of the user roles you used after transport is complete. Or, you can use SQL bind variables to create temporary user roles. Use these temporary roles for the transport and then discard the roles afterwards.

If your transport isn't successful, you might see an error message similar to the following:

```
pg_transport.num_workers=8 25% of files transported failed to download file data
```

The "failed to download file data" error message indicates that the number of worker processes isn't set correctly for the size of the database. You might need to increase or decrease the value set for `pg_transport.num_workers`. Each failure reports the percentage of completion, so you can see the impact of your changes. For example, changing the setting from 8 to 4 in one case resulted in the following:

```
pg_transport.num_workers=4 75% of files transported failed to download file data
```

Keep in mind that the `max_worker_processes` parameter is also taken into account during the transport process. In other words, you might need to modify both `pg_transport.num_workers`

and `max_worker_processes` to successfully transport the database. The example shown finally worked when the `pg_transport.num_workers` was set to 2:

```
pg_transport.num_workers=2 100% of files transported
```

For more information about the `transport.import_from_server` function and its parameters, see Transportable databases function reference.

What happens during database transport

The PostgreSQL transportable databases feature uses a pull model to import the database from the source DB instance to the destination. The `transport.import_from_server` function creates the in-transit database on the destination DB instance. The in-transit database is inaccessible on the destination DB instance for the duration of the transport.

When transport begins, all current sessions on the source database are ended. Any databases other than the source database on the source DB instance aren't affected by the transport.

The source database is put into a special read-only mode. While it's in this mode, you can connect to the source database and run read-only queries. However, write-enabled queries and some other types of commands are blocked. Only the specific source database that is being transported is affected by these restrictions.

During transport, you can't restore the destination DB instance to a point in time. This is because the transport isn't transactional and doesn't use the PostgreSQL write-ahead log to record changes. If the destination DB instance has automatic backups enabled, a backup is automatically taken after transport completes. Point-in-time restores are available for times *after* the backup finishes.

If the transport fails, the `pg_transport` extension attempts to undo all changes to the source and destination DB instances. This includes removing the destination's partially transported database. Depending on the type of failure, the source database might continue to reject write-enabled queries. If this happens, use the following command to allow write-enabled queries.

```
ALTER DATABASE db-name SET default_transaction_read_only = false;
```

Transportable databases function reference

The `transport.import_from_server` function transports a PostgreSQL database by importing it from a source DB instance to a destination DB instance. It does this by using a physical database connection transport mechanism.

Before starting the transport, this function verifies that the source and the destination DB instances are the same version and are compatible for the migration. It also confirms that the destination DB instance has enough space for the source.

Syntax

```
transport.import_from_server(
   host text,
   port int,
   username text,
   password text,
   database text,
   local_password text,
   dry_run bool
)
```

Return Value

None.

Parameters

You can find descriptions of the `transport.import_from_server` function parameters in the following table.

Parameter	Description
`host`	The endpoint of the source DB instance.
`port`	An integer representing the port of the source DB instance. PostgreSQL DB instances often use port 5432.
`username`	The user of the source DB instance. This user must be a member of the `rds_superuser` role.

Parameter	Description
password	The user password of the source DB instance.
database	The name of the database in the source DB instance to transport.
local_password	The local password of the current user for the destination DB instance. This user must be a member of the rds_superuser role.
dry_run	An optional Boolean value specifying whether to perform a dry run. The default is false, which means the transport proceeds. To confirm compatibility between the source and destination DB instances without performing the actual transport, set dry_run to true.

Example

For an example, see Transporting a PostgreSQL database to the destination from the source.

Transportable databases parameter reference

Several parameters control the behavior of the pg_transport extension. Following, you can find descriptions of these parameters.

pg_transport.num_workers

The number of workers to use for the transport process. The default is 3. Valid values are 1–32. Even the largest database transports typically require fewer than 8 workers. The value of this setting on the destination DB instance is used by both destination and source during transport.

pg_transport.timing

Specifies whether to report timing information during the transport. The default is true, meaning that timing information is reported. We recommend that you leave this parameter set to true so you can monitor progress. For example output, see Transporting a PostgreSQL database to the destination from the source.

pg_transport.work_mem

The maximum amount of memory to allocate for each worker. The default is 131072 kilobytes (KB) or 262144 KB (256 MB), depending on the PostgreSQL version. The minimum value is 64

megabytes (65536 KB). Valid values are in kilobytes (KBs) as binary base-2 units, where 1 KB = 1024 bytes.

The transport might use less memory than is specified in this parameter. Even large database transports typically require less than 256 MB (262144 KB) of memory per worker.

Exporting data from an RDS for PostgreSQL DB instance to Amazon S3

You can query data from an RDS for PostgreSQL DB instance and export it directly into files stored in an Amazon S3 bucket. To do this, you first install the RDS for PostgreSQL `aws_s3` extension. This extension provides you with the functions that you use to export the results of queries to Amazon S3. Following, you can find out how to install the extension and how to export data to Amazon S3.

> **Note**
>
> Cross-account export to Amazon S3 isn't supported.

All currently available versions of RDS for PostgreSQL support exporting data to Amazon Simple Storage Service. For detailed version information, see Amazon RDS for PostgreSQL updates in the *Amazon RDS for PostgreSQL Release Notes*.

If you don't have a bucket set up for your export, see the following topics the *Amazon Simple Storage Service User Guide*.

- Setting up Amazon S3
- Create a bucket

By default, the data exported from RDS for PostgreSQL to Amazon S3 uses server-side encryption with an AWS managed key. If you are using bucket encryption, the Amazon S3 bucket must be encrypted with an AWS Key Management Service (AWS KMS) key (SSE-KMS). Currently, buckets encrypted with Amazon S3 managed keys (SSE-S3) are not supported.

> **Note**
>
> You can save DB snapshot data to Amazon S3 using the AWS Management Console, AWS CLI, or Amazon RDS API. For more information, see Exporting DB snapshot data to Amazon S3.

Topics

Installing the aws_s3 extension

Before you can use Amazon Simple Storage Service with your RDS for PostgreSQL DB instance, you need to install the aws_s3 extension. This extension provides functions for exporting data from an RDS for PostgreSQL DB instance to an Amazon S3 bucket. It also provides functions for importing data from an Amazon S3. For more information, see Importing data from Amazon S3 into an RDS for PostgreSQL DB instance. The aws_s3 extension depends on some of the helper functions in the aws_commons extension, which is installed automatically when needed.

To install the aws_s3 extension

1. Use psql (or pgAdmin) to connect to the RDS for PostgreSQL DB instance as a user that has rds_superuser privileges. If you kept the default name during the setup process, you connect as postgres.

```
psql --host=111122223333.aws-region.rds.amazonaws.com --port=5432 --
username=postgres --password
```

2. To install the extension, run the following command.

```
postgres=> CREATE EXTENSION aws_s3 CASCADE;
NOTICE: installing required extension "aws_commons"
CREATE EXTENSION
```

3. To verify that the extension is installed, you can use the psql \dx metacommand.

```
postgres=> \dx
       List of installed extensions
    Name     | Version |   Schema   |                Description
-------------+---------+------------+-------------------------------------------
```

```
 aws_commons | 1.2     | public     | Common data types across AWS services
 aws_s3      | 1.1     | public     | AWS S3 extension for importing data from S3
 plpgsql     | 1.0     | pg_catalog | PL/pgSQL procedural language
(3 rows)
```

The functions for importing data from Amazon S3 and exporting data to Amazon S3 are now available to use.

Verify that your RDS for PostgreSQL version supports exports to Amazon S3

You can verify that your RDS for PostgreSQL version supports export to Amazon S3 by using the `describe-db-engine-versions` command. The following example verifies support for version 10.14.

```
aws rds describe-db-engine-versions --region us-east-1
--engine postgres --engine-version 10.14 | grep s3Export
```

If the output includes the string `"s3Export"`, then the engine supports Amazon S3 exports. Otherwise, the engine doesn't support them.

Overview of exporting data to Amazon S3

To export data stored in an RDS for PostgreSQL database to an Amazon S3 bucket, use the following procedure.

To export RDS for PostgreSQL data to S3

1. Identify an Amazon S3 file path to use for exporting data. For details about this process, see Specifying the Amazon S3 file path to export to.
2. Provide permission to access the Amazon S3 bucket.

   To export data to an Amazon S3 file, give the RDS for PostgreSQL DB instance permission to access the Amazon S3 bucket that the export will use for storage. Doing this includes the following steps:

   1. Create an IAM policy that provides access to an Amazon S3 bucket that you want to export to.
   2. Create an IAM role.
   3. Attach the policy you created to the role you created.

4. Add this IAM role to your DB instance.

   For details about this process, see Setting up access to an Amazon S3 bucket.

3. Identify a database query to get the data. Export the query data by calling the `aws_s3.query_export_to_s3` function.

   After you complete the preceding preparation tasks, use the aws_s3.query_export_to_s3 function to export query results to Amazon S3. For details about this process, see Exporting query data using the aws_s3.query_export_to_s3 function.

Specifying the Amazon S3 file path to export to

Specify the following information to identify the location in Amazon S3 where you want to export data to:

- Bucket name – A *bucket* is a container for Amazon S3 objects or files.

  For more information on storing data with Amazon S3, see Create a bucket and View an object in the *Amazon Simple Storage Service User Guide*.

- File path – The file path identifies where the export is stored in the Amazon S3 bucket. The file path consists of the following:
  - An optional path prefix that identifies a virtual folder path.
  - A file prefix that identifies one or more files to be stored. Larger exports are stored in multiple files, each with a maximum size of approximately 6 GB. The additional file names have the same file prefix but with `_part`*XX* appended. The *XX* represents 2, then 3, and so on.

  For example, a file path with an `exports` folder and a `query-1-export` file prefix is `/exports/query-1-export`.

- AWS Region (optional) – The AWS Region where the Amazon S3 bucket is located. If you don't specify an AWS Region value, then Amazon RDS saves your files into Amazon S3 in the same AWS Region as the exporting DB instance.

> **Note**
>
> Currently, the AWS Region must be the same as the region of the exporting DB instance.

For a listing of AWS Region names and associated values, see Regions, Availability Zones, and Local Zones.

To hold the Amazon S3 file information about where the export is to be stored, you can use the aws_commons.create_s3_uri function to create an `aws_commons._s3_uri_1` composite structure as follows.

```
psql=> SELECT aws_commons.create_s3_uri(
   'amzn-s3-demo-bucket',
   'sample-filepath',
   'us-west-2'
) AS s3_uri_1 \gset
```

You later provide this `s3_uri_1` value as a parameter in the call to the aws_s3.query_export_to_s3 function. For examples, see Exporting query data using the aws_s3.query_export_to_s3 function.

Setting up access to an Amazon S3 bucket

To export data to Amazon S3, give your PostgreSQL DB instance permission to access the Amazon S3 bucket that the files are to go in.

To do this, use the following procedure.

To give a PostgreSQL DB instance access to Amazon S3 through an IAM role

1. Create an IAM policy.

   This policy provides the bucket and object permissions that allow your PostgreSQL DB instance to access Amazon S3.

   As part of creating this policy, take the following steps:

   a. Include in the policy the following required actions to allow the transfer of files from your PostgreSQL DB instance to an Amazon S3 bucket:

      - `s3:PutObject`
      - `s3:AbortMultipartUpload`

b. Include the Amazon Resource Name (ARN) that identifies the Amazon S3 bucket and objects in the bucket. The ARN format for accessing Amazon S3 is: `arn:aws:s3:::amzn-s3-demo-bucket/*`

For more information on creating an IAM policy for Amazon RDS for PostgreSQL, see Creating and using an IAM policy for IAM database access. See also Tutorial: Create and attach your first customer managed policy in the *IAM User Guide*.

The following AWS CLI command creates an IAM policy named `rds-s3-export-policy` with these options. It grants access to a bucket named *amzn-s3-demo-bucket*.

> **Warning**
>
> We recommend that you set up your database within a private VPC that has endpoint policies configured for accessing specific buckets. For more information, see Using endpoint policies for Amazon S3 in the Amazon VPC User Guide.
> We strongly recommend that you do not create a policy with all-resource access. This access can pose a threat for data security. If you create a policy that gives `S3:PutObject` access to all resources using `"Resource":"*"`, then a user with export privileges can export data to all buckets in your account. In addition, the user can export data to *any publicly writable bucket within your AWS Region*.

After you create the policy, note the Amazon Resource Name (ARN) of the policy. You need the ARN for a subsequent step when you attach the policy to an IAM role.

```
aws iam create-policy  --policy-name rds-s3-export-policy  --policy-document '{
     "Version": "2012-10-17",
     "Statement": [
       {
         "Sid": "s3export",
         "Action": [
           "s3:PutObject*",
           "s3:ListBucket",
           "s3:GetObject*",
           "s3:DeleteObject*",
           "s3:GetBucketLocation",
           "s3:AbortMultipartUpload"
         ],
```

```
        "Effect": "Allow",
        "Resource": [
          "arn:aws:s3:::amzn-s3-demo-bucket/*"
        ]
      }
    ]
  }'
```

2. Create an IAM role.

   You do this so Amazon RDS can assume this IAM role on your behalf to access your Amazon S3 buckets. For more information, see Creating a role to delegate permissions to an IAM user in the *IAM User Guide*.

   We recommend using the `aws:SourceArn` and `aws:SourceAccount` global condition context keys in resource-based policies to limit the service's permissions to a specific resource. This is the most effective way to protect against the confused deputy problem.

   If you use both global condition context keys and the `aws:SourceArn` value contains the account ID, the `aws:SourceAccount` value and the account in the `aws:SourceArn` value must use the same account ID when used in the same policy statement.

   - Use `aws:SourceArn` if you want cross-service access for a single resource.
   - Use `aws:SourceAccount` if you want to allow any resource in that account to be associated with the cross-service use.

   In the policy, be sure to use the `aws:SourceArn` global condition context key with the full ARN of the resource. The following example shows how to do so using the AWS CLI command to create a role named `rds-s3-export-role`.

   Example

   For Linux, macOS, or Unix:

```
aws iam create-role  \
    --role-name rds-s3-export-role  \
    --assume-role-policy-document '{
     "Version": "2012-10-17",
     "Statement": [
       {
         "Effect": "Allow",
```

```
         "Principal": {
            "Service": "rds.amazonaws.com"
          },
         "Action": "sts:AssumeRole",
         "Condition": {
             "StringEquals": {
                "aws:SourceAccount": "111122223333",
                "aws:SourceArn": "arn:aws:rds:us-east-1:111122223333:db:dbname"
                }
             }
       }
     ]
   }'
```

For Windows:

```
aws iam create-role  ^
    --role-name rds-s3-export-role  ^
    --assume-role-policy-document '{
     "Version": "2012-10-17",
     "Statement": [
       {
         "Effect": "Allow",
         "Principal": {
            "Service": "rds.amazonaws.com"
          },
         "Action": "sts:AssumeRole",
         "Condition": {
             "StringEquals": {
                "aws:SourceAccount": "111122223333",
                "aws:SourceArn": "arn:aws:rds:us-east-1:111122223333:db:dbname"
                }
             }
       }
     ]
   }'
```

3. Attach the IAM policy that you created to the IAM role that you created.

   The following AWS CLI command attaches the policy created earlier to the role named `rds-s3-export-role`. Replace *your-policy-arn* with the policy ARN that you noted in an earlier step.

```
aws iam attach-role-policy  --policy-arn your-policy-arn  --role-name rds-s3-
export-role
```

4. Add the IAM role to the DB instance. You do so by using the AWS Management Console or AWS CLI, as described following.

Console

To add an IAM role for a PostgreSQL DB instance using the console

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Choose the PostgreSQL DB instance name to display its details.
3. On the **Connectivity & security** tab, in the **Manage IAM roles** section, choose the role to add under **Add IAM roles to this instance**.
4. Under **Feature**, choose **s3Export**.
5. Choose **Add role**.

AWS CLI

To add an IAM role for a PostgreSQL DB instance using the CLI

- Use the following command to add the role to the PostgreSQL DB instance named `my-db-instance`. Replace *`your-role-arn`* with the role ARN that you noted in a previous step. Use `s3Export` for the value of the `--feature-name` option.

  Example

  For Linux, macOS, or Unix:

```
aws rds add-role-to-db-instance \
   --db-instance-identifier my-db-instance \
   --feature-name s3Export \
   --role-arn your-role-arn   \
   --region your-region
```

  For Windows:

```
aws rds add-role-to-db-instance ^
   --db-instance-identifier my-db-instance ^
   --feature-name s3Export ^
   --role-arn your-role-arn ^
   --region your-region
```

Exporting query data using the aws_s3.query_export_to_s3 function

Export your PostgreSQL data to Amazon S3 by calling the aws_s3.query_export_to_s3 function.

Topics

Prerequisites

Before you use the `aws_s3.query_export_to_s3` function, be sure to complete the following prerequisites:

- Install the required PostgreSQL extensions as described in Overview of exporting data to Amazon S3.
- Determine where to export your data to Amazon S3 as described in Specifying the Amazon S3 file path to export to.
- Make sure that the DB instance has export access to Amazon S3 as described in Setting up access to an Amazon S3 bucket.

The examples following use a database table called `sample_table`. These examples export the data into a bucket called *amzn-s3-demo-bucket*. The example table and data are created with the following SQL statements in psql.

```
psql=> CREATE TABLE sample_table (bid bigint PRIMARY KEY, name varchar(80));
psql=> INSERT INTO sample_table (bid,name) VALUES (1, 'Monday'), (2,'Tuesday'), (3,
 'Wednesday');
```

Calling aws_s3.query_export_to_s3

The following shows the basic ways of calling the aws_s3.query_export_to_s3 function.

These examples use the variable `s3_uri_1` to identify a structure that contains the information identifying the Amazon S3 file. Use the aws_commons.create_s3_uri function to create the structure.

```
psql=> SELECT aws_commons.create_s3_uri(
   'amzn-s3-demo-bucket',
   'sample-filepath',
   'us-west-2'
) AS s3_uri_1 \gset
```

Although the parameters vary for the following two `aws_s3.query_export_to_s3` function calls, the results are the same for these examples. All rows of the `sample_table` table are exported into a bucket called *amzn-s3-demo-bucket*.

```
psql=> SELECT * FROM aws_s3.query_export_to_s3('SELECT * FROM
 sample_table', :'s3_uri_1');

psql=> SELECT * FROM aws_s3.query_export_to_s3('SELECT * FROM
 sample_table', :'s3_uri_1', options :='format text');
```

The parameters are described as follows:

- `'SELECT * FROM sample_table'` – The first parameter is a required text string containing an SQL query. The PostgreSQL engine runs this query. The results of the query are copied to the S3 bucket identified in other parameters.
- `:'s3_uri_1'` – This parameter is a structure that identifies the Amazon S3 file. This example uses a variable to identify the previously created structure. You can instead create the structure by including the `aws_commons.create_s3_uri` function call inline within the `aws_s3.query_export_to_s3` function call as follows.

  ```
  SELECT * from aws_s3.query_export_to_s3('select * from sample_table',
     aws_commons.create_s3_uri('amzn-s3-demo-bucket', 'sample-filepath', 'us-west-2')
  );
  ```

- `options :='format text'` – The `options` parameter is an optional text string containing PostgreSQL COPY arguments. The copy process uses the arguments and format of the PostgreSQL COPY command.

If the file specified doesn't exist in the Amazon S3 bucket, it's created. If the file already exists, it's overwritten. The syntax for accessing the exported data in Amazon S3 is the following.

```
s3-region://bucket-name[/path-prefix]/file-prefix
```

Larger exports are stored in multiple files, each with a maximum size of approximately 6 GB. The additional file names have the same file prefix but with `_part`*XX* appended. The *XX* represents 2, then 3, and so on. For example, suppose that you specify the path where you store data files as the following.

```
s3-us-west-2://amzn-s3-demo-bucket/my-prefix
```

If the export has to create three data files, the Amazon S3 bucket contains the following data files.

```
s3-us-west-2://amzn-s3-demo-bucket/my-prefix
s3-us-west-2://amzn-s3-demo-bucket/my-prefix_part2
s3-us-west-2://amzn-s3-demo-bucket/my-prefix_part3
```

For the full reference for this function and additional ways to call it, see aws_s3.query_export_to_s3. For more about accessing files in Amazon S3, see View an object in the *Amazon Simple Storage Service User Guide*.

Exporting to a CSV file that uses a custom delimiter

The following example shows how to call the aws_s3.query_export_to_s3 function to export data to a file that uses a custom delimiter. The example uses arguments of the PostgreSQL COPY command to specify the comma-separated value (CSV) format and a colon (:) delimiter.

```
SELECT * from aws_s3.query_export_to_s3('select * from basic_test', :'s3_uri_1',
 options :='format csv, delimiter $$:$$');
```

Exporting to a binary file with encoding

The following example shows how to call the aws_s3.query_export_to_s3 function to export data to a binary file that has Windows-1253 encoding.

```
SELECT * from aws_s3.query_export_to_s3('select * from basic_test', :'s3_uri_1',
 options :='format binary, encoding WIN1253');
```

Function reference

Functions

- aws_s3.query_export_to_s3
- aws_commons.create_s3_uri

aws_s3.query_export_to_s3

Exports a PostgreSQL query result to an Amazon S3 bucket. The `aws_s3` extension provides the `aws_s3.query_export_to_s3` function.

The two required parameters are `query` and `s3_info`. These define the query to be exported and identify the Amazon S3 bucket to export to. An optional parameter called `options` provides for defining various export parameters. For examples of using the `aws_s3.query_export_to_s3` function, see Exporting query data using the aws_s3.query_export_to_s3 function.

Syntax

```
aws_s3.query_export_to_s3(
    query text,
    s3_info aws_commons._s3_uri_1,
    options text,
    kms_key text
)
```

Input parameters

query

A required text string containing an SQL query that the PostgreSQL engine runs. The results of this query are copied to an S3 bucket identified in the `s3_info` parameter.

s3_info

An `aws_commons._s3_uri_1` composite type containing the following information about the S3 object:

- `bucket` – The name of the Amazon S3 bucket to contain the file.

- `file_path` – The Amazon S3 file name and path.
- `region` – The AWS Region that the bucket is in. For a listing of AWS Region names and associated values, see Regions, Availability Zones, and Local Zones.

  Currently, this value must be the same AWS Region as that of the exporting DB instance. The default is the AWS Region of the exporting DB instance.

To create an `aws_commons._s3_uri_1` composite structure, see the aws_commons.create_s3_uri function.

options

An optional text string containing arguments for the PostgreSQL `COPY` command. These arguments specify how the data is to be copied when exported. For more details, see the PostgreSQL COPY documentation.

Alternate input parameters

To help with testing, you can use an expanded set of parameters instead of the `s3_info` parameter. Following are additional syntax variations for the `aws_s3.query_export_to_s3` function.

Instead of using the `s3_info` parameter to identify an Amazon S3 file, use the combination of the `bucket`, `file_path`, and `region` parameters.

```
aws_s3.query_export_to_s3(
    query text,
    bucket text,
    file_path text,
    region text,
    options text,
)
```

query

A required text string containing an SQL query that the PostgreSQL engine runs. The results of this query are copied to an S3 bucket identified in the `s3_info` parameter.

bucket

A required text string containing the name of the Amazon S3 bucket that contains the file.

file_path

A required text string containing the Amazon S3 file name including the path of the file.

region

An optional text string containing the AWS Region that the bucket is in. For a listing of AWS Region names and associated values, see Regions, Availability Zones, and Local Zones.

Currently, this value must be the same AWS Region as that of the exporting DB instance. The default is the AWS Region of the exporting DB instance.

options

An optional text string containing arguments for the PostgreSQL `COPY` command. These arguments specify how the data is to be copied when exported. For more details, see the PostgreSQL COPY documentation.

Output parameters

```
aws_s3.query_export_to_s3(
    OUT rows_uploaded bigint,
    OUT files_uploaded bigint,
    OUT bytes_uploaded bigint
)
```

rows_uploaded

The number of table rows that were successfully uploaded to Amazon S3 for the given query.

files_uploaded

The number of files uploaded to Amazon S3. Files are created in sizes of approximately 6 GB. Each additional file created has `_part`*XX* appended to the name. The *XX* represents 2, then 3, and so on as needed.

bytes_uploaded

The total number of bytes uploaded to Amazon S3.

Examples

```
psql=> SELECT * from aws_s3.query_export_to_s3('select * from sample_table', 'amzn-s3-demo-bucket', 'sample-filepath');
psql=> SELECT * from aws_s3.query_export_to_s3('select * from sample_table', 'amzn-s3-demo-bucket', 'sample-filepath','us-west-2');
psql=> SELECT * from aws_s3.query_export_to_s3('select * from sample_table', 'amzn-s3-demo-bucket', 'sample-filepath','us-west-2','format text');
```

aws_commons.create_s3_uri

Creates an `aws_commons._s3_uri_1` structure to hold Amazon S3 file information. You use the results of the `aws_commons.create_s3_uri` function in the `s3_info` parameter of the aws_s3.query_export_to_s3 function. For an example of using the `aws_commons.create_s3_uri` function, see Specifying the Amazon S3 file path to export to.

Syntax

```
aws_commons.create_s3_uri(
   bucket text,
   file_path text,
   region text
)
```

Input parameters

bucket

A required text string containing the Amazon S3 bucket name for the file.

file_path

A required text string containing the Amazon S3 file name including the path of the file.

region

A required text string containing the AWS Region that the file is in. For a listing of AWS Region names and associated values, see Regions, Availability Zones, and Local Zones.

Troubleshooting access to Amazon S3

If you encounter connection problems when attempting to export data to Amazon S3, first confirm that the outbound access rules for the VPC security group associated with your DB instance permit network connectivity. Specifically, the security group must have a rule that allows the DB instance to send TCP traffic to port 443 and to any IPv4 addresses (0.0.0.0/0). For more information, see Provide access to your DB instance in your VPC by creating a security group.

Invoking an AWS Lambda function from an RDS for PostgreSQL DB instance

AWS Lambda is an event-driven compute service that lets you run code without provisioning or managing servers. It's available for use with many AWS services, including RDS for PostgreSQL. For example, you can use Lambda functions to process event notifications from a database, or to load data from files whenever a new file is uploaded to Amazon S3. To learn more about Lambda, see What is AWS Lambda? in the *AWS Lambda Developer Guide.*

> **Note**
>
> Invoking an AWS Lambda function is supported in these RDS for PostgreSQL versions:
>
> - All PostgreSQL 16 versions
> - All PostgreSQL 15 versions
> - PostgreSQL 14.1 and higher minor versions
> - PostgreSQL 13.2 and higher minor versions
> - PostgreSQL 12.6 and higher minor versions

Setting up RDS for PostgreSQL to work with Lambda functions is a multi-step process involving AWS Lambda, IAM, your VPC, and your RDS for PostgreSQL DB instance. Following, you can find summaries of the necessary steps.

For more information about Lambda functions, see Getting started with Lambda and AWS Lambda foundations in the *AWS Lambda Developer Guide*.

Topics

- Examples: Invoking Lambda functions from your RDS for PostgreSQL DB instance
- Lambda function error messages
- AWS Lambda function and parameter reference

Step 1: Configure your RDS for PostgreSQL DB instance for outbound connections to AWS Lambda

Lambda functions always run inside an Amazon VPC that's owned by the AWS Lambda service. Lambda applies network access and security rules to this VPC and it maintains and monitors the VPC automatically. Your RDS for PostgreSQL DB instance sends network traffic to the Lambda service's VPC. How you configure this depends on whether your DB instance is public or private.

- **Public RDS for PostgreSQL DB instance** – A DB instance is public if it's located in a public subnet on your VPC, and if the instance's "PubliclyAccessible" property is `true`. To find the value of this property, you can use the describe-db-instances AWS CLI command. Or, you can use the AWS Management Console to open the **Connectivity & security** tab and check that **Publicly accessible** is **Yes**. To verify that the instance is in the public subnet of your VPC, you can use the AWS Management Console or the AWS CLI.

  To set up access to Lambda, you use the AWS Management Console or the AWS CLI to create an outbound rule on your VPC's security group. The outbound rule specifies that TCP can use port 443 to send packets to any IPv4 addresses (0.0.0.0/0).
- **Private RDS for PostgreSQL DB instance** – In this case, the instance's "PubliclyAccessible" property is `false` or it's in a private subnet. To allow the instance to work with Lambda, you can use a Network Address Translation) NAT gateway. For more information, see NAT gateways. Or, you can configure your VPC with a VPC endpoint for Lambda. For more information, see VPC endpoints in the *Amazon VPC User Guide*. The endpoint responds to calls made by your RDS for PostgreSQL DB instance to your Lambda functions. The VPC endpoint uses its own private DNS resolution. RDS for PostgreSQL can't use the Lambda VPC endpoint until you change the value of the `rds.custom_dns_resolution` from its default value of 0 (not enabled) to 1. To do so:
  - Create a custom DB parameter group.
  - Change the value of the `rds.custom_dns_resolution` parameter from its default of `0` to `1`.
  - Modify your DB instance to use your custom DB parameter group.
  - Reboot the instance to have the modified parameter take effect.

Your VPC can now interact with the AWS Lambda VPC at the network level. Next, you configure the permissions using IAM.

Step 2: Configure IAM for your RDS for PostgreSQL DB instance and AWS Lambda

Invoking Lambda functions from your RDS for PostgreSQL DB instance requires certain privileges. To configure the necessary privileges, we recommend that you create an IAM policy that allows invoking Lambda functions, assign that policy to a role, and then apply the role to your DB instance. This approach gives the DB instance privileges to invoke the specified Lambda function on your behalf. The following steps show you how to do this using the AWS CLI.

To configure IAM permissions for using your Amazon RDS instance with Lambda

1. Use the create-policy AWS CLI command to create an IAM policy that allows your RDS for PostgreSQL DB instance to invoke the specified Lambda function. (The statement ID (Sid) is an optional description for your policy statement and has no effect on usage.) This policy gives your DB instance the minimum permissions needed to invoke the specified Lambda function.

   ```
   aws iam create-policy  --policy-name rds-lambda-policy --policy-document '{
       "Version": "2012-10-17",
       "Statement": [
           {
           "Sid": "AllowAccessToExampleFunction",
           "Effect": "Allow",
           "Action": "lambda:InvokeFunction",
           "Resource": "arn:aws:lambda:aws-region:444455556666:function:my-function"
           }
       ]
   }'
   ```

   Alternatively, you can use the predefined `AWSLambdaRole` policy that allows you to invoke any of your Lambda functions. For more information, see Identity-based IAM policies for Lambda

2. Use the create-role AWS CLI command to create an IAM role that the policy can assume at runtime.

   ```
   aws iam create-role  --role-name rds-lambda-role --assume-role-policy-document '{
       "Version": "2012-10-17",
       "Statement": [
           {
   ```

```
        "Effect": "Allow",
        "Principal": {
            "Service": "rds.amazonaws.com"
        },
        "Action": "sts:AssumeRole"
        }
    ]
}'
```

3. Apply the policy to the role by using the attach-role-policy AWS CLI command.

```
aws iam attach-role-policy \
    --policy-arn arn:aws:iam::444455556666:policy/rds-lambda-policy \
    --role-name rds-lambda-role --region aws-region
```

4. Apply the role to your RDS for PostgreSQL DB instance by using the add-role-to-db-instance AWS CLI command. This last step allows your DB instance's database users to invoke Lambda functions.

```
aws rds add-role-to-db-instance \
       --db-instance-identifier my-instance-name \
       --feature-name Lambda \
       --role-arn  arn:aws:iam::444455556666:role/rds-lambda-role   \
       --region aws-region
```

With the VPC and the IAM configurations complete, you can now install the `aws_lambda` extension. (Note that you can install the extension at any time, but until you set up the correct VPC support and IAM privileges, the `aws_lambda` extension adds nothing to your RDS for PostgreSQL DB instance's capabilities.)

Step 3: Install the `aws_lambda` extension for an RDS for PostgreSQL DB instance

To use AWS Lambda with your RDS for PostgreSQL DB instance, add the `aws_lambda` PostgreSQL extension to your RDS for PostgreSQL DB instance. This extension provides your RDS for PostgreSQL DB instance with the ability to call Lambda functions from PostgreSQL.

To install the aws_lambda extension in your RDS for PostgreSQL DB instance

Use the PostgreSQL psql command-line or the pgAdmin tool to connect to your RDS for PostgreSQL DB instance.

1. Connect to your RDS for PostgreSQL DB instance as a user with rds_superuser privileges. The default postgres user is shown in the example.

```
psql -h instance.444455556666.aws-region.rds.amazonaws.com -U postgres -p 5432
```

2. Install the aws_lambda extension. The aws_commons extension is also required. It provides helper functions to aws_lambda and many other Aurora extensions for PostgreSQL. If it's not already on your RDS for PostgreSQLDB instance, it's installed with aws_lambda as shown following.

```
CREATE EXTENSION IF NOT EXISTS aws_lambda CASCADE;
NOTICE:  installing required extension "aws_commons"
CREATE EXTENSION
```

The aws_lambda extension is installed in your DB instance. You can now create convenience structures for invoking your Lambda functions.

Step 4: Use Lambda helper functions with your RDS for PostgreSQL DB instance (Optional)

You can use the helper functions in the aws_commons extension to prepare entities that you can more easily invoke from PostgreSQL. To do this, you need to have the following information about your Lambda functions:

- **Function name** – The name, Amazon Resource Name (ARN), version, or alias of the Lambda function. The IAM policy created in Step 2: Configure IAM for your instance and Lambda requires the ARN, so we recommend that you use your function's ARN.
- **AWS Region** – (Optional) The AWS Region where the Lambda function is located if it's not in the same Region as your RDS for PostgreSQL DB instance.

To hold the Lambda function name information, you use the aws_commons.create_lambda_function_arn function. This helper function creates an

`aws_commons._lambda_function_arn_1` composite structure with the details needed by the invoke function. Following, you can find three alternative approaches to setting up this composite structure.

```
SELECT aws_commons.create_lambda_function_arn(
   'my-function',
   'aws-region'
) AS aws_lambda_arn_1 \gset
```

```
SELECT aws_commons.create_lambda_function_arn(
   '111122223333:function:my-function',
   'aws-region'
) AS lambda_partial_arn_1 \gset
```

```
SELECT aws_commons.create_lambda_function_arn(
   'arn:aws:lambda:aws-region:111122223333:function:my-function'
) AS lambda_arn_1 \gset
```

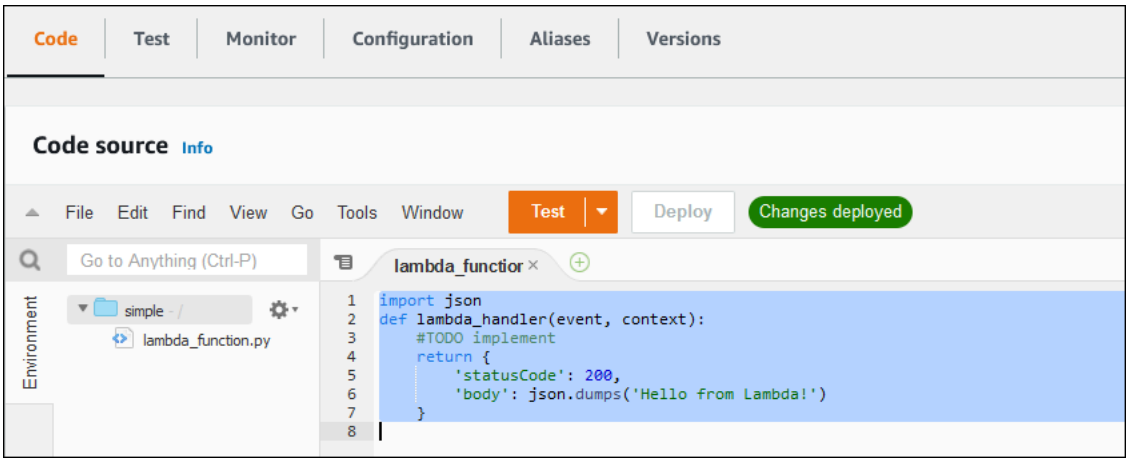
Any of these values can be used in calls to the aws_lambda.invoke function. For examples, see Step 5: Invoke a Lambda function from your RDS for PostgreSQL DB instance.

Step 5: Invoke a Lambda function from your RDS for PostgreSQL DB instance

The `aws_lambda.invoke` function behaves synchronously or asynchronously, depending on the `invocation_type`. The two alternatives for this parameter are `RequestResponse` (the default) and `Event`, as follows.

- **`RequestResponse`** – This invocation type is *synchronous*. It's the default behavior when the call is made without specifying an invocation type. The response payload includes the results of the `aws_lambda.invoke` function. Use this invocation type when your workflow requires receiving results from the Lambda function before proceeding.
- **`Event`** – This invocation type is *asynchronous*. The response doesn't include a payload containing results. Use this invocation type when your workflow doesn't need a result from the Lambda function to continue processing.

As a simple test of your setup, you can connect to your DB instance using `psql` and invoke an example function from the command line. Suppose that you have one of the basic functions set up on your Lambda service, such as the simple Python function shown in the following screenshot.



To invoke an example function

1. Connect to your DB instance using `psql` or pgAdmin.

   ```
   psql -h instance.444455556666.aws-region.rds.amazonaws.com -U postgres -p 5432
   ```

2. Invoke the function using its ARN.

   ```
   SELECT * from
    aws_lambda.invoke(aws_commons.create_lambda_function_arn('arn:aws:lambda:aws-
   region:444455556666:function:simple', 'us-west-1'), '{"body": "Hello from
    Postgres!"}'::json );
   ```

   The response looks as follows.

   ```
   status_code |                         payload                         |
    executed_version | log_result
   -------------+---------------------------------------------------------
   +------------------+------------
            200 | {"statusCode": 200, "body": "\"Hello from Lambda!\""} | $LATEST
        |
   (1 row)
   ```

If your invocation attempt doesn't succeed, see Lambda function error messages .

Step 6: Grant other users permission to invoke Lambda functions

At this point in the procedures, only you as `rds_superuser` can invoke your Lambda functions. To allow other users to invoke any functions that you create, you need to grant them permission.

To grant others permission to invoke Lambda functions

1. Connect to your DB instance using `psql` or pgAdmin.

```
psql -h instance.444455556666.aws-region.rds.amazonaws.com -U postgres -p 5432
```

2. Run the following SQL commands:

```
postgres=>  GRANT USAGE ON SCHEMA aws_lambda TO db_username;
GRANT EXECUTE ON ALL FUNCTIONS IN SCHEMA aws_lambda TO db_username;
```

Examples: Invoking Lambda functions from your RDS for PostgreSQL DB instance

Following, you can find several examples of calling the aws_lambda.invoke function. Most of the examples use the composite structure `aws_lambda_arn_1` that you create in Step 4: Use Lambda helper functions with your RDS for PostgreSQL DB instance (Optional) to simplify passing the function details. For an example of asynchronous invocation, see Example: Asynchronous (Event) invocation of Lambda functions. All the other examples listed use synchronous invocation.

To learn more about Lambda invocation types, see Invoking Lambda functions in the *AWS Lambda Developer Guide*. For more information about `aws_lambda_arn_1`, see aws_commons.create_lambda_function_arn.

Examples list

- Example: Synchronous (RequestResponse) invocation of Lambda functions
- Example: Asynchronous (Event) invocation of Lambda functions
- Example: Capturing the Lambda execution log in a function response
- Example: Including client context in a Lambda function
- Example: Invoking a specific version of a Lambda function

Example: Synchronous (RequestResponse) invocation of Lambda functions

Following are two examples of a synchronous Lambda function invocation. The results of these `aws_lambda.invoke` function calls are the same.

```
SELECT * FROM aws_lambda.invoke('aws_lambda_arn_1', '{"body": "Hello from
 Postgres!"}'::json);
```

```
SELECT * FROM aws_lambda.invoke('aws_lambda_arn_1', '{"body": "Hello from
 Postgres!"}'::json, 'RequestResponse');
```

The parameters are described as follows:

- `:'aws_lambda_arn_1'` – This parameter identifies the composite structure created in Step 4: Use Lambda helper functions with your RDS for PostgreSQL DB instance (Optional), with the `aws_commons.create_lambda_function_arn` helper function. You can also create this structure inline within your `aws_lambda.invoke` call as follows.

  ```
  SELECT * FROM aws_lambda.invoke(aws_commons.create_lambda_function_arn('my-function',
   'aws-region'),
  '{"body": "Hello from Postgres!"}'::json
  );
  ```

- `'{"body": "Hello from PostgreSQL!"}'::json` – The JSON payload to pass to the Lambda function.
- `'RequestResponse'` – The Lambda invocation type.

Example: Asynchronous (Event) invocation of Lambda functions

Following is an example of an asynchronous Lambda function invocation. The `Event` invocation type schedules the Lambda function invocation with the specified input payload and returns immediately. Use the `Event` invocation type in certain workflows that don't depend on the results of the Lambda function.

```
SELECT * FROM aws_lambda.invoke('aws_lambda_arn_1', '{"body": "Hello from
 Postgres!"}'::json, 'Event');
```

Example: Capturing the Lambda execution log in a function response

You can include the last 4 KB of the execution log in the function response by using the `log_type` parameter in your `aws_lambda.invoke` function call. By default, this parameter is set to None, but you can specify `Tail` to capture the results of the Lambda execution log in the response, as shown following.

```
SELECT *, select convert_from(decode(log_result, 'base64'), 'utf-8') as log FROM
 aws_lambda.invoke(:'aws_lambda_arn_1', '{"body": "Hello from Postgres!"}'::json,
 'RequestResponse', 'Tail');
```

Set the aws_lambda.invoke function's `log_type` parameter to `Tail` to include the execution log in the response. The default value for the `log_type` parameter is None.

The `log_result` that's returned is a `base64` encoded string. You can decode the contents using a combination of the `decode` and `convert_from` PostgreSQL functions.

For more information about `log_type`, see aws_lambda.invoke.

Example: Including client context in a Lambda function

The `aws_lambda.invoke` function has a `context` parameter that you can use to pass information separate from the payload, as shown following.

```
SELECT *, convert_from(decode(log_result, 'base64'), 'utf-8') as log FROM
 aws_lambda.invoke(:'aws_lambda_arn_1', '{"body": "Hello from Postgres!"}'::json,
 'RequestResponse', 'Tail');
```

To include client context, use a JSON object for the aws_lambda.invoke function's `context` parameter.

For more information about the `context` parameter, see the aws_lambda.invoke reference.

Example: Invoking a specific version of a Lambda function

You can specify a particular version of a Lambda function by including the `qualifier` parameter with the `aws_lambda.invoke` call. Following, you can find an example that does this using '*`custom_version`*' as an alias for the version.

```
SELECT * FROM aws_lambda.invoke('aws_lambda_arn_1', '{"body": "Hello from
 Postgres!"}'::json, 'RequestResponse', 'None', NULL, 'custom_version');
```

You can also supply a Lambda function qualifier with the function name details instead, as follows.

```
SELECT * FROM aws_lambda.invoke(aws_commons.create_lambda_function_arn('my-
function:custom_version', 'us-west-2'),
'{"body": "Hello from Postgres!"}'::json);
```

For more information about `qualifier` and other parameters, see the aws_lambda.invoke reference.

Lambda function error messages

In the following list you can find information about error messages, with possible causes and solutions.

- **VPC configuration issues**

  VPC configuration issues can raise the following error messages when trying to connect:

  ```
  ERROR:  invoke API failed
  DETAIL: AWS Lambda client returned 'Unable to connect to endpoint'.
  CONTEXT:  SQL function "invoke" statement 1
  ```

  A common cause for this error is improperly configured VPC security group. Make sure you have an outbound rule for TCP open on port 443 of your VPC security group so that your VPC can connect to the Lambda VPC.

  If your DB instance is private, check the private DNS setup for your VPC. Make sure that you set the `rds.custom_dns_resolution` parameter to 1 and setup AWS PrivateLink as outlined in Step 1: Configure your RDS for PostgreSQL DB instance for outbound connections to AWS Lambda. For more information, see Interface VPC endpoints (AWS PrivateLink).

- **Lack of permissions needed to invoke Lambda functions**

  If you see either of the following error messages, the user (role) invoking the function doesn't have proper permissions.

  ```
  ERROR:  permission denied for schema aws_lambda
  ```

  ```
  ERROR:  permission denied for function invoke
  ```

A user (role) must be given specific grants to invoke Lambda functions. For more information, see Step 6: Grant other users permission to invoke Lambda functions.

- **Improper handling of errors in your Lambda functions**

  If a Lambda function throws an exception during request processing, `aws_lambda.invoke` fails with a PostgreSQL error such as the following.

```
SELECT * FROM aws_lambda.invoke('aws_lambda_arn_1', '{"body": "Hello from
 Postgres!"}'::json);
ERROR:  lambda invocation failed
DETAIL:  "arn:aws:lambda:us-west-2:555555555555:function:my-function" returned error
 "Unhandled", details: "<Error details string>".
```

  Be sure to handle errors in your Lambda functions or in your PostgreSQL application.

AWS Lambda function and parameter reference

Following is the reference for the functions and parameters to use for invoking Lambda with RDS for PostgreSQL.

Functions and parameters

- aws_lambda.invoke
- aws_commons.create_lambda_function_arn
- aws_lambda parameters

aws_lambda.invoke

Runs a Lambda function for an RDS for PostgreSQL DB instance.

For more details about invoking Lambda functions, see also Invoke in the *AWS Lambda Developer Guide.*

Syntax

JSON

```
aws_lambda.invoke(
```

```
IN function_name TEXT,
IN payload JSON,
IN region TEXT DEFAULT NULL,
IN invocation_type TEXT DEFAULT 'RequestResponse',
IN log_type TEXT DEFAULT 'None',
IN context JSON DEFAULT NULL,
IN qualifier VARCHAR(128) DEFAULT NULL,
OUT status_code INT,
OUT payload JSON,
OUT executed_version TEXT,
OUT log_result TEXT)
```

```
aws_lambda.invoke(
IN function_name aws_commons._lambda_function_arn_1,
IN payload JSON,
IN invocation_type TEXT DEFAULT 'RequestResponse',
IN log_type TEXT DEFAULT 'None',
IN context JSON DEFAULT NULL,
IN qualifier VARCHAR(128) DEFAULT NULL,
OUT status_code INT,
OUT payload JSON,
OUT executed_version TEXT,
OUT log_result TEXT)
```

JSONB

```
aws_lambda.invoke(
IN function_name TEXT,
IN payload JSONB,
IN region TEXT DEFAULT NULL,
IN invocation_type TEXT DEFAULT 'RequestResponse',
IN log_type TEXT DEFAULT 'None',
IN context JSONB DEFAULT NULL,
IN qualifier VARCHAR(128) DEFAULT NULL,
OUT status_code INT,
OUT payload JSONB,
OUT executed_version TEXT,
OUT log_result TEXT)
```

```
aws_lambda.invoke(
IN function_name aws_commons._lambda_function_arn_1,
IN payload JSONB,
```

```
IN invocation_type TEXT DEFAULT 'RequestResponse',
IN log_type TEXT DEFAULT 'None',
IN context JSONB DEFAULT NULL,
IN qualifier VARCHAR(128) DEFAULT NULL,
OUT status_code INT,
OUT payload JSONB,
OUT executed_version TEXT,
OUT log_result TEXT
)
```

Input parameters

function_name

The identifying name of the Lambda function. The value can be the function name, an ARN, or a partial ARN. For a listing of possible formats, see Lambda function name formats in the *AWS Lambda Developer Guide.*

payload

The input for the Lambda function. The format can be JSON or JSONB. For more information, see JSON Types in the PostgreSQL documentation.

region

(Optional) The Lambda Region for the function. By default, RDS resolves the AWS Region from the full ARN in the `function_name` or it uses the RDS for PostgreSQL DB instance Region. If this Region value conflicts with the one provided in the `function_name` ARN, an error is raised.

invocation_type

The invocation type of the Lambda function. The value is case-sensitive. Possible values include the following:

- `RequestResponse` – The default. This type of invocation for a Lambda function is synchronous and returns a response payload in the result. Use the `RequestResponse` invocation type when your workflow depends on receiving the Lambda function result immediately.
- `Event` – This type of invocation for a Lambda function is asynchronous and returns immediately without a returned payload. Use the `Event` invocation type when you don't need results of the Lambda function before your workflow moves on.
- `DryRun` – This type of invocation tests access without running the Lambda function.

log_type

The type of Lambda log to return in the `log_result` output parameter. The value is case-sensitive. Possible values include the following:

- Tail – The returned `log_result` output parameter will include the last 4 KB of the execution log.
- None – No Lambda log information is returned.

context

Client context in JSON or JSONB format. Fields to use include than `custom` and `env`.

qualifier

A qualifier that identifies a Lambda function's version to be invoked. If this value conflicts with one provided in the `function_name` ARN, an error is raised.

Output parameters

status_code

An HTTP status response code. For more information, see Lambda Invoke response elements in the *AWS Lambda Developer Guide.*

payload

The information returned from the Lambda function that ran. The format is in JSON or JSONB.

executed_version

The version of the Lambda function that ran.

log_result

The execution log information returned if the `log_type` value is `Tail` when the Lambda function was invoked. The result contains the last 4 KB of the execution log encoded in Base64.

aws_commons.create_lambda_function_arn

Creates an `aws_commons._lambda_function_arn_1` structure to hold Lambda function name information. You can use the results of the `aws_commons.create_lambda_function_arn` function in the `function_name` parameter of the aws_lambda.invoke aws_lambda.invoke function.

Syntax

```
aws_commons.create_lambda_function_arn(
    function_name TEXT,
    region TEXT DEFAULT NULL
    )
    RETURNS aws_commons._lambda_function_arn_1
```

Input parameters

function_name

A required text string containing the Lambda function name. The value can be a function name, a partial ARN, or a full ARN.

region

An optional text string containing the AWS Region that the Lambda function is in. For a listing of Region names and associated values, see Regions, Availability Zones, and Local Zones.

aws_lambda parameters

In this table, you can find parameters associated with the `aws_lambda` function.

Parameter	Description
`aws_lambda.connect_timeout_ms`	This is a dynamic parameter and it sets the maximum wait time while connecting to AWS Lambda. The default values is `1000`. Allowed values for this parameter are 1 - 900000.
`aws_lambda.request_timeout_ms`	This is a dynamic parameter and it sets the maximum wait time while waiting for response from AWS Lambda. The default values is `3000`. Allowed values for this parameter are 1 - 900000.
`aws_lambda.endpoint_override`	Specifies the endpoint that can be used to connect to AWS Lambda. An empty string selects the default AWS Lambda endpoint for the region. You must restart the database for this static parameter change to take effect.

Common DBA tasks for Amazon RDS for PostgreSQL

Database administrators (DBAs) perform a variety of tasks when administering an Amazon RDS for PostgreSQL DB instance. If you're a DBA already familiar with PostgreSQL, you need to be aware of some of the important differences between running PostgreSQL on your hardware and RDS for PostgreSQL. For example, because it's a managed service, Amazon RDS doesn't allow shell access to your DB instances. That means that you don't have direct access to `pg_hba.conf` and other configuration files. For RDS for PostgreSQL, changes that are typically made to the PostgreSQL configuration file of an on-premises instance are made to a custom DB parameter group associated with the RDS for PostgreSQL DB instance. For more information, see Parameter groups for Amazon RDS.

You also can't access log files in the same way that you do with an on-premises PostgreSQL instance. To learn more about logging, see RDS for PostgreSQL database log files.

As another example, you don't have access to the PostgreSQL `superuser` account. On RDS for PostgreSQL, the `rds_superuser` role is the most highly privileged role, and it's granted to `postgres` at set up time. Whether you're familiar with using PostgreSQL on-premises or completely new to RDS for PostgreSQL, we recommend that you understand the `rds_superuser` role, and how to work with roles, users, groups, and permissions. For more information, see Understanding PostgreSQL roles and permissions.

Following are some common DBA tasks for RDS for PostgreSQL.

Topics

- Collations supported in RDS for PostgreSQL
- Understanding PostgreSQL roles and permissions
- Working with the PostgreSQL autovacuum on Amazon RDS for PostgreSQL
- Working with logging mechanisms supported by RDS for PostgreSQL
- Managing temporary files with PostgreSQL
- Using pgBadger for log analysis with PostgreSQL
- Using PGSnapper for monitoring PostgreSQL
- Working with parameters on your RDS for PostgreSQL DB instance

Collations supported in RDS for PostgreSQL

Collations are set of rules that determine how character strings stored in the database are sorted and compared. Collations play a fundamental role in the computer system and are included as part of the operating system. Collations change over time when new characters are added to languages or when ordering rules change.

Collation libraries define specific rules and algorithms for a collation. The most popular collation libraries used within PostgreSQL are GNU C (glibc) and Internationalization components for Unicode (ICU). By default, RDS for PostgreSQL uses the glibc collation that includes unicode character sort orders for multi-byte character sequences.

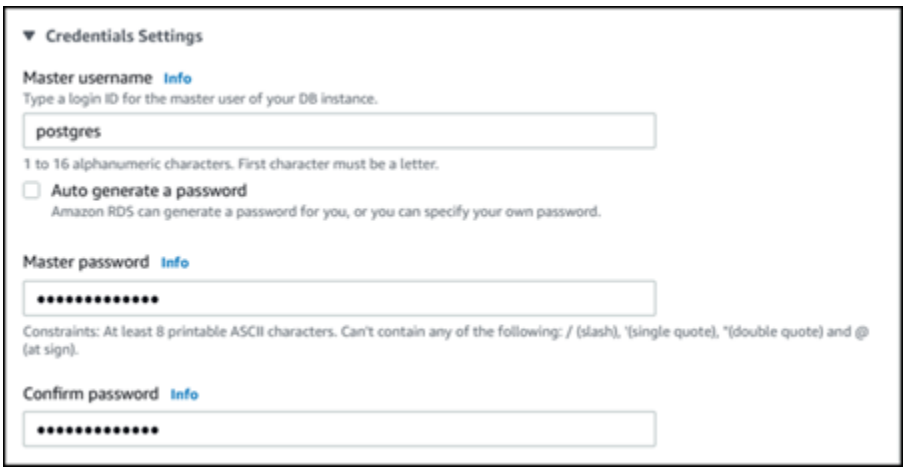
When you create a new DB instance in RDS for PostgreSQL , it checks the operating system for the available collation. The PostgreSQL parameters of the `CREATE DATABASE` command `LC_COLLATE` and `LC_CTYPE` are used to specify a collation, which stands as the default collation in that database. Alternatively, you can also use the `LOCALE` parameter in `CREATE DATABASE` to set these parameters. This determines the default collation for character strings in the database and the rules for classifying characters as letters, numbers, or symbols. You can also choose a collation to use on a column, index, or on a query.

RDS for PostgreSQL depends on the glibc library in the operating system for collation support. RDS for PostgreSQL instance is periodically updated with the latest versions of the operating system. These updates sometimes include a newer version of the glibc library. Rarely, newer versions of glibc change the sort order or collation of some characters, which can cause the data to sort differently or produce invalid index entries. If you discover sort order issues for collation during an update, you might need to rebuild the indexes.

To reduce the possible impacts of the glibc updates, RDS for PostgreSQL now includes an independent default collation library. This collation library is available in RDS for PostgreSQL 14.6, 13.9, 12.13, 11.18, 10.23 and newer minor version releases. It is compatible with glibc 2.26-59.amzn2, and provides sort order stability to prevent incorrect query results.

Understanding PostgreSQL roles and permissions

When you create an RDS for PostgreSQL DB instance using the AWS Management Console, an administrator account is created at the same time. By default, its name is `postgres`, as shown in the following screenshot:



You can choose another name rather than accept the default (`postgres`). If you do, the name you choose must start with a letter and be between 1 and 16 alphanumeric characters. For simplicity's sake, we refer to this main user account by its default value (`postgres`) throughout this guide.

If you use the `create-db-instance` AWS CLI rather than the AWS Management Console, you create the name by passing it with the `master-username` parameter in the command. For more information, see Creating an Amazon RDS DB instance.

Whether you use the AWS Management Console, the AWS CLI, or the Amazon RDS API, and whether you use the default `postgres` name or choose a different name, this first database user account is a member of the `rds_superuser` group and has `rds_superuser` privileges.

Topics

- Understanding the rds_superuser role
- Controlling user access to the PostgreSQL database
- Delegating and controlling user password management
- Using SCRAM for PostgreSQL password encryption

Understanding the rds_superuser role

In PostgreSQL, a *role* can define a user, a group, or a set of specific permissions granted to a group or user for various objects in the database. PostgreSQL commands to `CREATE USER` and `CREATE GROUP` have been replaced by the more general, `CREATE ROLE` with specific properties to distinguish database users. A database user can be thought of as a role with the LOGIN privilege.

> **Note**
>
> The `CREATE USER` and `CREATE GROUP` commands can still be used. For more information, see Database Roles in the PostgreSQL documentation.

The `postgres` user is the most highly privileged database user on your RDS for PostgreSQL DB instance. It has the characteristics defined by the following `CREATE ROLE` statement.

```
CREATE ROLE postgres WITH LOGIN NOSUPERUSER INHERIT CREATEDB CREATEROLE NOREPLICATION
 VALID UNTIL 'infinity'
```

The properties `NOSUPERUSER`, `NOREPLICATION`, `INHERIT`, and `VALID UNTIL 'infinity'` are the default options for CREATE ROLE, unless otherwise specified.

By default, `postgres` has privileges granted to the `rds_superuser` role, and permissions to create roles and databases. The `rds_superuser` role allows the `postgres` user to do the following:

- Add extensions that are available for use with Amazon RDS. For more information, see Working with PostgreSQL features supported by Amazon RDS for PostgreSQL
- Create roles for users and grant privileges to users. For more information, see CREATE ROLE and GRANT in the PostgreSQL documentation.
- Create databases. For more information, see CREATE DATABASE in the PostgreSQL documentation.
- Grant `rds_superuser` privileges to user roles that don't have these privileges, and revoke privileges as needed. We recommend that you grant this role only to those users who perform superuser tasks. In other words, you can grant this role to database administrators (DBAs) or system administrators.
- Grant (and revoke) the `rds_replication` role to database users that don't have the `rds_superuser` role.
- Grant (and revoke) the `rds_password` role to database users that don't have the `rds_superuser` role.
- Obtain status information about all database connections by using the `pg_stat_activity` view. When needed, `rds_superuser` can stop any connections by using `pg_terminate_backend` or `pg_cancel_backend`.

In the `CREATE ROLE postgres...` statement, you can see that the `postgres` user role specifically disallows PostgreSQL `superuser` permissions. RDS for PostgreSQL is a managed service, so you can't access the host OS, and you can't connect using the PostgreSQL `superuser` account. Many of the tasks that require `superuser` access on a stand-alone PostgreSQL are managed automatically by Amazon RDS.

For more information about granting privileges, see GRANT in the PostgreSQL documentation.

The `rds_superuser` role is one of several *predefined* roles in an RDS for PostgreSQL DB instance.

> **Note**
>
> In PostgreSQL 13 and earlier releases, *predefined* roles are known as *default* roles.

In the following list, you find some of the other predefined roles that are created automatically for a new RDS for PostgreSQL DB instance. Predefined roles and their privileges can't be changed. You can't drop, rename, or modify privileges for these predefined roles. Attempting to do so results in an error.

- **rds_password** – A role that can change passwords and set up password constraints for database users. The `rds_superuser` role is granted with this role by default, and can grant the role to database users. For more information, see Controlling user access to the PostgreSQL database.
  - For RDS for PostgreSQL versions older than 14, `rds_password` role can change passwords and set up password constraints for database users and users with `rds_superuser` role. From RDS for PostgreSQL version 14 and later, `rds_password` role can change passwords and set up password constraints only for database users. Only users with `rds_superuser` role can perform these actions on other users with `rds_superuser` role.
- **rdsadmin** – A role that's created to handle many of the management tasks that the administrator with `superuser` privileges would perform on a standalone PostgreSQL database. This role is used internally by RDS for PostgreSQL for many management tasks.
- **rdstopmgr** – A role that's used internally by Amazon RDS to support Multi-AZ deployments.

To see all predefined roles, you can connect to your RDS for PostgreSQL DB instance and use the `psql \du` metacommand. The output looks as follows:

```
List of roles
```

```
  Role name   |      Attributes                    |      Member of
--------------+------------------------------------+----------------------------------
postgres      | Create role, Create DB            +| {rds_superuser}
              | Password valid until infinity      |
rds_superuser | Cannot login                       | {pg_monitor,pg_signal_backend,
              |                                   +|   rds_replication,rds_password}
...
```

In the output, you can see that `rds_superuser` isn't a database user role (it can't login), but it has the privileges of many other roles. You can also see that database user `postgres` is a member of the `rds_superuser` role. As mentioned previously, `postgres` is the default value in the Amazon RDS console's **Create database** page. If you chose another name, that name is shown in the list of roles instead.

Controlling user access to the PostgreSQL database

New databases in PostgreSQL are always created with a default set of privileges in the database's `public` schema that allow all database users and roles to create objects. These privileges allow database users to connect to the database, for example, and create temporary tables while connected.

To better control user access to the databases instances that you create on your RDS for PostgreSQL DB instance, we recommend that you revoke these default `public` privileges. After doing so, you then grant specific privileges for database users on a more granular basis, as shown in the following procedure.

To set up roles and privileges for a new database instance

Suppose you're setting up a database on a newly created RDS for PostgreSQL DB instance for use by several researchers, all of whom need read-write access to the database.

1. Use `psql` (or pgAdmin) to connect to your RDS for PostgreSQL DB instance:

   ```
   psql --host=your-db-instance.666666666666.aws-region.rds.amazonaws.com --port=5432
    --username=postgres --password
   ```

   When prompted, enter your password. The `psql` client connects and displays the default administrative connection database, `postgres=>`, as the prompt.

2. To prevent database users from creating objects in the `public` schema, do the following:

```
postgres=> REVOKE CREATE ON SCHEMA public FROM PUBLIC;
REVOKE
```

3. Next, you create a new database instance:

```
postgres=> CREATE DATABASE lab_db;
CREATE DATABASE
```

4. Revoke all privileges from the PUBLIC schema on this new database.

```
postgres=> REVOKE ALL ON DATABASE lab_db FROM public;
REVOKE
```

5. Create a role for database users.

```
postgres=> CREATE ROLE lab_tech;
CREATE ROLE
```

6. Give database users that have this role the ability to connect to the database.

```
postgres=> GRANT CONNECT ON DATABASE lab_db TO lab_tech;
GRANT
```

7. Grant all users with the `lab_tech` role all privileges on this database.

```
postgres=> GRANT ALL PRIVILEGES ON DATABASE lab_db TO lab_tech;
GRANT
```

8. Create database users, as follows:

```
postgres=> CREATE ROLE lab_user1 LOGIN PASSWORD 'change_me';
CREATE ROLE
postgres=> CREATE ROLE lab_user2 LOGIN PASSWORD 'change_me';
CREATE ROLE
```

9. Grant these two users the privileges associated with the lab_tech role:

```
postgres=> GRANT lab_tech TO lab_user1;
GRANT ROLE
postgres=> GRANT lab_tech TO lab_user2;
GRANT ROLE
```

At this point, `lab_user1` and `lab_user2` can connect to the `lab_db` database. This example doesn't follow best practices for enterprise usage, which might include creating multiple database instances, different schemas, and granting limited permissions. For more complete information and additional scenarios, see Managing PostgreSQL Users and Roles.

For more information about privileges in PostgreSQL databases, see the GRANT command in the PostgreSQL documentation.

Delegating and controlling user password management

As a DBA, you might want to delegate the management of user passwords. Or, you might want to prevent database users from changing their passwords or reconfiguring password constraints, such as password lifetime. To ensure that only the database users that you choose can change password settings, you can turn on the restricted password management feature. When you activate this feature, only those database users that have been granted the `rds_password` role can manage passwords.

> **Note**
>
> To use restricted password management, your RDS for PostgreSQL DB instance must be running PostgreSQL 10.6 or higher.

By default, this feature is `off`, as shown in the following:

```
postgres=> SHOW rds.restrict_password_commands;
  rds.restrict_password_commands
--------------------------------
 off
(1 row)
```

To turn on this feature, you use a custom parameter group and change the setting for `rds.restrict_password_commands` to 1. Be sure to reboot your RDS for PostgreSQL DB instance so that the setting takes effect.

With this feature active, `rds_password` privileges are needed for the following SQL commands:

```
CREATE ROLE myrole WITH PASSWORD 'mypassword';
CREATE ROLE myrole WITH PASSWORD 'mypassword' VALID UNTIL '2023-01-01';
ALTER ROLE myrole WITH PASSWORD 'mypassword' VALID UNTIL '2023-01-01';
```

```
ALTER ROLE myrole WITH PASSWORD 'mypassword';
ALTER ROLE myrole VALID UNTIL '2023-01-01';
ALTER ROLE myrole RENAME TO myrole2;
```

Renaming a role (`ALTER ROLE myrole RENAME TO newname`) is also restricted if the password uses the MD5 hashing algorithm.

With this feature active, attempting any of these SQL commands without the `rds_password` role permissions generates the following error:

```
ERROR: must be a member of rds_password to alter passwords
```

We recommend that you grant the `rds_password` to only a few roles that you use solely for password management. If you grant `rds_password` privileges to database users that don't have `rds_superuser` privileges, you need to also grant them the `CREATEROLE` attribute.

Make sure that you verify password requirements such as expiration and needed complexity on the client side. If you use your own client-side utility for password related changes, the utility needs to be a member of `rds_password` and have `CREATE ROLE` privileges.

Using SCRAM for PostgreSQL password encryption

The *Salted Challenge Response Authentication Mechanism (SCRAM)* is an alternative to PostgreSQL's default message digest (MD5) algorithm for encrypting passwords. The SCRAM authentication mechanism is considered more secure than MD5. To learn more about these two different approaches to securing passwords, see Password Authentication in the PostgreSQL documentation.

We recommend that you use SCRAM rather than MD5 as the password encryption scheme for your RDS for PostgreSQL DB instance. It's a cryptographic challenge-response mechanism that uses the scram-sha-256 algorithm for password authentication and encryption.

You might need to update libraries for your client applications to support SCRAM. For example, JDBC versions before 42.2.0 don't support SCRAM. For more information, see PostgreSQL JDBC Driver in the PostgreSQL JDBC Driver documentation. For a list of other PostgreSQL drivers and SCRAM support, see List of drivers in the PostgreSQL documentation.

> **Note**
>
> RDS for PostgreSQL version 13.1 and higher support scram-sha-256. These versions also let you configure your DB instance to require SCRAM, as discussed in the following procedures.

Setting up RDS for PostgreSQL DB instance to require SCRAM

you can require the RDS for PostgreSQL DB instance to accept only passwords that use the scram-sha-256 algorithm.

> **Important**
>
> For existing RDS Proxies with PostgreSQL databases, if you modify the database authentication to use SCRAM only, the proxy becomes unavailable for up to 60 seconds. To avoid the issue, do one of the following:
>
> - Ensure that the database allows both SCRAM and MD5 authentication.
> - To use only SCRAM authentication, create a new proxy, migrate your application traffic to the new proxy, then delete the proxy previously associated with the database.

Before making changes to your system, be sure you understand the complete process, as follows:

- Get information about all roles and password encryption for all database users.
- Double-check the parameter settings for your RDS for PostgreSQL DB instance for the parameters that control password encryption.
- If your RDS for PostgreSQL DB instance uses a default parameter group, you need to create a custom DB parameter group and apply it to your RDS for PostgreSQL DB instance so that you can modify parameters when needed. If your RDS for PostgreSQL DB instance uses a custom parameter group, you can modify the necessary parameters later in the process, as needed.
- Change the `password_encryption` parameter to `scram-sha-256`.
- Notify all database users that they need to update their passwords. Do the same for your `postgres` account. The new passwords are encrypted and stored using the scram-sha-256 algorithm.
- Verify that all passwords are encrypted using as the type of encryption.
- If all passwords use scram-sha-256, you can change the `rds.accepted_password_auth_method` parameter from `md5+scram` to `scram-sha-256`.

> **Warning**
>
> After you change `rds.accepted_password_auth_method` to scram-sha-256 alone, any users (roles) with `md5`–encrypted passwords can't connect.

Getting ready to require SCRAM for your RDS for PostgreSQL DB instance

Before making any changes to your RDS for PostgreSQL DB instance, check all existing database user accounts. Also, check the type of encryption used for passwords. You can do these tasks by using the `rds_tools` extension. This extension is supported on RDS for PostgreSQL 13.1 and higher releases.

To get a list of database users (roles) and password encryption methods

1. Use `psql` to connect to your RDS for PostgreSQL DB instance, as shown in the following.

```
psql --host=db-name.111122223333.aws-region.rds.amazonaws.com --port=5432 --
username=postgres --password
```

2. Install the `rds_tools` extension.

```
postgres=> CREATE EXTENSION rds_tools;
CREATE EXTENSION
```

3. Get a listing of roles and encryption.

```
postgres=> SELECT * FROM
      rds_tools.role_password_encryption_type();
```

   You see output similar to the following.

```
       rolname        | encryption_type
----------------------+-----------------
 pg_monitor           |
 pg_read_all_settings |
 pg_read_all_stats    |
 pg_stat_scan_tables  |
 pg_signal_backend    |
 lab_tester           | md5
 user_465             | md5
```

```
 postgres             | md5
(8 rows)
```

Creating a custom DB parameter group

> **Note**
>
> If your RDS for PostgreSQL DB instance already uses a custom parameter group, you don't need to create a new one.

For an overview of parameter groups for Amazon RDS, see Working with parameters on your RDS for PostgreSQL DB instance.

The password encryption type used for passwords is set in one parameter, `password_encryption`. The encryption that the RDS for PostgreSQL DB instance allows is set in another parameter, `rds.accepted_password_auth_method`. Changing either of these from the default values requires that you create a custom DB parameter group and apply it to your instance.

You can also use the AWS Management Console or the RDS API to create a custom DB parameter group. For more information, see

You can now associate the custom parameter group with your DB instance.

To create a custom DB parameter group

1. Use the `create-db-parameter-group` CLI command to create the custom DB parameter group. This example uses `postgres13` as the source for this custom parameter group.

   For Linux, macOS, or Unix:

   ```
   aws rds create-db-parameter-group --db-parameter-group-name 'docs-lab-scram-passwords' \
     --db-parameter-group-family postgres13  --description 'Custom parameter group for SCRAM'
   ```

   For Windows:

   ```
   aws rds create-db-parameter-group --db-parameter-group-name "docs-lab-scram-passwords" ^
   ```

```
 --db-parameter-group-family postgres13  --description "Custom DB parameter group
for SCRAM"
```

2. Use the modify-db-instance CLI command to apply this custom parameter group to your RDS for PostgreSQL DB cluster.

   For Linux, macOS, or Unix:

   ```
   aws rds modify-db-instance --db-instance-identifier 'your-instance-name' \
           --db-parameter-group-name "docs-lab-scram-passwords
   ```

   For Windows:

   ```
   aws rds modify-db-instance --db-instance-identifier "your-instance-name" ^
           --db-parameter-group-name "docs-lab-scram-passwords
   ```

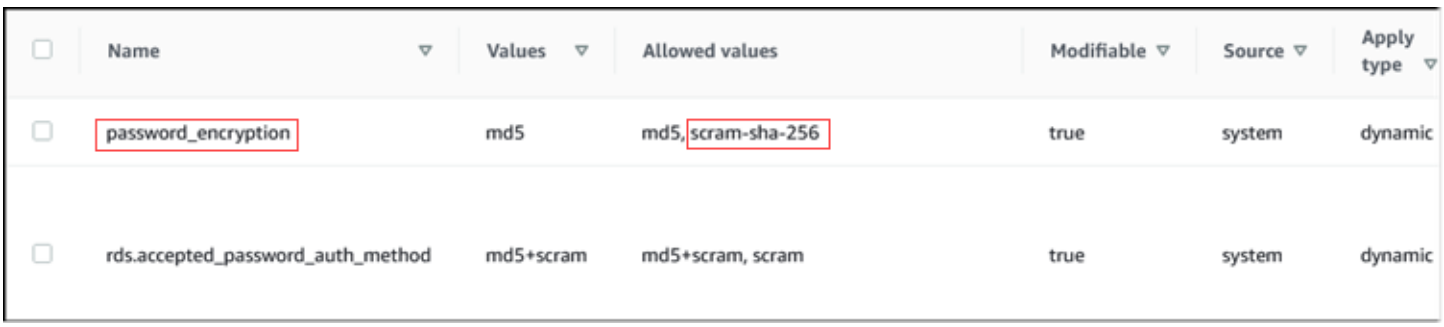
   To resynchronize your RDS for PostgreSQL DB instance with your custom DB parameter group, you need to reboot the primary and all other instances of the cluster. To minimize impact to your users, schedule this to occur during your regular maintenance window.

Configuring password encryption to use SCRAM

The password encryption mechanism used by an RDS for PostgreSQL DB instance is set in the DB parameter group in the `password_encryption` parameter. Allowed values are unset, `md5`, or `scram-sha-256`. The default value depends on the RDS for PostgreSQL version, as follows:

- RDS for PostgreSQL 14 and above – Default is `scram-sha-256`
- RDS for PostgreSQL 13 – Default is `md5`

With a custom DB parameter group attached to your RDS for PostgreSQL DB instance, you can modify values for the password encryption parameter.



Name	Values	Allowed values	Modifiable	Source	Apply type
password_encryption	md5	md5, scram-sha-256	true	system	dynamic
rds.accepted_password_auth_method	md5+scram	md5+scram, scram	true	system	dynamic

To change password encryption setting to scram-sha-256

- Change the value of password encryption to scram-sha-256, as shown following. The change can be applied immediately because the parameter is dynamic, so a restart isn't required for the change to take effect.

  For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group --db-parameter-group-name \
  'docs-lab-scram-passwords' --parameters
 'ParameterName=password_encryption,ParameterValue=scram-
sha-256,ApplyMethod=immediate'
```

  For Windows:

```
aws rds modify-db-parameter-group --db-parameter-group-name ^
  "docs-lab-scram-passwords" --parameters
 "ParameterName=password_encryption,ParameterValue=scram-
sha-256,ApplyMethod=immediate"
```

Migrating passwords for user roles to SCRAM

You can migrate passwords for user roles to SCRAM as described following.

To migrate database user (role) passwords from MD5 to SCRAM

1. Log in as the administrator user (default user name, `postgres`) as shown following.

```
psql --host=db-name.111122223333.aws-region.rds.amazonaws.com --port=5432 --
username=postgres --password
```

2. Check the setting of the `password_encryption` parameter on your RDS for PostgreSQL DB instance by using the following command.

```
postgres=> SHOW password_encryption;
 password_encryption
---------------------
 md5
 (1 row)
```

3. Change the value of this parameter to scram-sha-256. This is a dynamic parameter, so you don't need to reboot the instance after making this change. Check the value again to make sure that it's now set to `scram-sha-256`, as follows.

```
postgres=> SHOW password_encryption;
 password_encryption
---------------------
 scram-sha-256
 (1 row)
```

4. Notify all database users to change their passwords. Be sure to also change your own password for account `postgres` (the database user with `rds_superuser` privileges).

```
labdb=> ALTER ROLE postgres WITH LOGIN PASSWORD 'change_me';
ALTER ROLE
```

5. Repeat the process for all databases on your RDS for PostgreSQL DB instance.

Changing parameter to require SCRAM

This is the final step in the process. After you make the change in the following procedure, any user accounts (roles) that still use `md5` encryption for passwords can't log in to the RDS for PostgreSQL DB instance.

The `rds.accepted_password_auth_method` specifies the encryption method that the RDS for PostgreSQL DB instance accepts for a user password during the login process. The default value is `md5+scram`, meaning that either method is accepted. In the following image, you can find the default setting for this parameter.

Name	Values	Allowed values	Modifiable	Source	Apply type
password_encryption	scram-sha-256	md5, scram-sha-256	true	system	dynamic
rds.accepted_password_auth_method	md5+scram	md5+scram, scram	true	system	dynamic

The allowed values for this parameter are `md5+scram` or `scram` alone. Changing this parameter value to `scram` makes this a requirement.

To change the parameter value to require SCRAM authentication for passwords

1. Verify that all database user passwords for all databases on your RDS for PostgreSQL DB instance use `scram-sha-256` for password encryption. To do so, query `rds_tools` for the role (user) and encryption type, as follows.

```
postgres=> SELECT * FROM rds_tools.role_password_encryption_type();
  rolname        | encryption_type
  ---------------------+----------------
  pg_monitor           |
  pg_read_all_settings |
  pg_read_all_stats    |
  pg_stat_scan_tables  |
  pg_signal_backend    |
  lab_tester           | scram-sha-256
  user_465             | scram-sha-256
  postgres             | scram-sha-256
  ( rows)
```

2. Repeat the query across all DB instances in your RDS for PostgreSQL DB instance.

   If all passwords use scram-sha-256, you can proceed.

3. Change the value of the accepted password authentication to scram-sha-256, as follows.

   For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group --db-parameter-group-name 'docs-lab-scram-
passwords' \
  --parameters
 'ParameterName=rds.accepted_password_auth_method,ParameterValue=scram,ApplyMethod=immediat
```

   For Windows:

```
aws rds modify-db-parameter-group --db-parameter-group-name "docs-lab-scram-
passwords" ^
  --parameters
 "ParameterName=rds.accepted_password_auth_method,ParameterValue=scram,ApplyMethod=immediat
```

Working with the PostgreSQL autovacuum on Amazon RDS for PostgreSQL

We strongly recommend that you use the autovacuum feature to maintain the health of your PostgreSQL DB instance. Autovacuum automates the start of the VACUUM and the ANALYZE commands. It checks for tables with a large number of inserted, updated, or deleted tuples. After this check, it reclaims storage by removing obsolete data or tuples from the PostgreSQL database.

By default, autovacuum is turned on for the Amazon RDS for PostgreSQL DB instances that you create using any of the default PostgreSQL DB parameter groups. These include `default.postgres10`, `default.postgres11`, and so on. All default PostgreSQL DB parameter groups have an `rds.adaptive_autovacuum` parameter that's set to 1, thus activating the feature. Other configuration parameters associated with the autovacuum feature are also set by default. Because these defaults are somewhat generic, you can benefit from tuning some of the parameters associated with the autovacuum feature for your specific workload.

Following, you can find more information about the autovacuum and how to tune some of its parameters on your RDS for PostgreSQL DB instance. For high-level information, see Best practices for working with PostgreSQL.

Topics

Allocating memory for autovacuum

One of the most important parameters influencing autovacuum performance is the maintenance_work_mem parameter. This parameter determines how much memory that you allocate for autovacuum to use to scan a database table and to hold all the row IDs that are going to be vacuumed. If you set the value of the `maintenance_work_mem` parameter too low, the vacuum process might have to scan the table multiple times to complete its work. Such multiple scans can have a negative impact on performance.

When doing calculations to determine the `maintenance_work_mem` parameter value, keep in mind two things:

- The default unit is kilobytes (KB) for this parameter.
- The `maintenance_work_mem` parameter works in conjunction with the `autovacuum_max_workers` parameter. If you have many small tables, allocate more `autovacuum_max_workers` and less `maintenance_work_mem`. If you have large tables (say, larger than 100 GB), allocate more memory and fewer worker processes. You need to have enough memory allocated to succeed on your biggest table. Each `autovacuum_max_workers` can use the memory that you allocate. Thus, make sure that the combination of worker processes and memory equal the total memory that you want to allocate.

In general terms, for large hosts set the `maintenance_work_mem` parameter to a value between one and two gigabytes (between 1,048,576 and 2,097,152 KB). For extremely large hosts, set the parameter to a value between two and four gigabytes (between 2,097,152 and 4,194,304 KB). The value that you set for this parameter depends on the workload. Amazon RDS has updated its default for this parameter to be kilobytes calculated as follows.

`GREATEST({DBInstanceClassMemory/63963136*1024},65536)`.

Reducing the likelihood of transaction ID wraparound

In some cases, parameter group settings related to autovacuum might not be aggressive enough to prevent transaction ID wraparound. To address this, RDS for PostgreSQL provides a mechanism that adapts the autovacuum parameter values automatically. *Adaptive autovacuum parameter tuning* is a feature for RDS for PostgreSQL. A detailed explanation of TransactionID wraparound is found in the PostgreSQL documentation.

Adaptive autovacuum parameter tuning is turned on by default for RDS for PostgreSQL instances with the dynamic parameter `rds.adaptive_autovacuum` set to ON. We strongly recommend

that you keep this turned on. However, to turn off adaptive autovacuum parameter tuning, set the `rds.adaptive_autovacuum` parameter to 0 or OFF.

Transaction ID wraparound is still possible even when Amazon RDS tunes the autovacuum parameters. We encourage you to implement an Amazon CloudWatch alarm for transaction ID wraparound. For more information, see the post Implement an early warning system for transaction ID wraparound in RDS for PostgreSQL on the AWS Database Blog.

With adaptive autovacuum parameter tuning turned on, Amazon RDS begins adjusting autovacuum parameters when the CloudWatch metric `MaximumUsedTransactionIDs` reaches the value of the `autovacuum_freeze_max_age` parameter or 500,000,000, whichever is greater.

Amazon RDS continues to adjust parameters for autovacuum if a table continues to trend toward transaction ID wraparound. Each of these adjustments dedicates more resources to autovacuum to avoid wraparound. Amazon RDS updates the following autovacuum-related parameters:

- autovacuum_vacuum_cost_delay
- autovacuum_vacuum_cost_limit
- autovacuum_work_mem
- autovacuum_naptime

RDS modifies these parameters only if the new value makes autovacuum more aggressive. The parameters are modified in memory on the DB instance. The values in the parameter group aren't changed. To view the current in-memory settings, use the PostgreSQL SHOW SQL command.

When Amazon RDS modifies any of these autovacuum parameters, it generates an event for the affected DB instance. This event is visible on the AWS Management Console and through the Amazon RDS API. After the `MaximumUsedTransactionIDs` CloudWatch metric returns below the threshold, Amazon RDS resets the autovacuum-related parameters in memory back to the values specified in the parameter group. It then generates another event corresponding to this change.

Determining if the tables in your database need vacuuming

You can use the following query to show the number of unvacuumed transactions in a database. The `datfrozenxid` column of a database's `pg_database` row is a lower bound on the normal transaction IDs appearing in that database. This column is the minimum of the per-table `relfrozenxid` values within the database.

```
SELECT datname, age(datfrozenxid) FROM pg_database ORDER BY age(datfrozenxid) desc
 limit 20;
```

For example, the results of running the preceding query might be the following.

```
datname    | age
mydb       | 1771757888
template0  | 1721757888
template1  | 1721757888
rdsadmin   | 1694008527
postgres   | 1693881061
(5 rows)
```

When the age of a database reaches 2 billion transaction IDs, transaction ID (XID) wraparound occurs and the database becomes read-only. You can use this query to produce a metric and run a few times a day. By default, autovacuum is set to keep the age of transactions to no more than 200,000,000 (autovacuum_freeze_max_age).

A sample monitoring strategy might look like this:

- Set the autovacuum_freeze_max_age value to 200 million transactions.
- If a table reaches 500 million unvacuumed transactions, that triggers a low-severity alarm. This isn't an unreasonable value, but it can indicate that autovacuum isn't keeping up.
- If a table ages to 1 billion, this should be treated as an alarm to take action on. In general, you want to keep ages closer to autovacuum_freeze_max_age for performance reasons. We recommend that you investigate using the recommendations that follow.
- If a table reaches 1.5 billion unvacuumed transactions, that triggers a high-severity alarm. Depending on how quickly your database uses transaction IDs, this alarm can indicate that the system is running out of time to run autovacuum. In this case, we recommend that you resolve this immediately.

If a table is constantly breaching these thresholds, modify your autovacuum parameters further. By default, using VACUUM manually (which has cost-based delays disabled) is more aggressive than using the default autovacuum, but it is also more intrusive to the system as a whole.

We recommend the following:

- Be aware and turn on a monitoring mechanism so that you are aware of the age of your oldest transactions.

  For information on creating a process that warns you about transaction ID wraparound, see the AWS Database Blog post Implement an early warning system for transaction ID wraparound in Amazon RDS for PostgreSQL.
- For busier tables, perform a manual vacuum freeze regularly during a maintenance window, in addition to relying on autovacuum. For information on performing a manual vacuum freeze, see Performing a manual vacuum freeze.

Determining which tables are currently eligible for autovacuum

Often, it is one or two tables in need of vacuuming. Tables whose `relfrozenxid` value is greater than the number of transactions in `autovacuum_freeze_max_age` are always targeted by autovacuum. Otherwise, if the number of tuples made obsolete since the last VACUUM exceeds the vacuum threshold, the table is vacuumed.

The autovacuum threshold is defined as:

```
Vacuum-threshold = vacuum-base-threshold + vacuum-scale-factor * number-of-tuples
```

where the `vacuum base threshold` is `autovacuum_vacuum_threshold`, the `vacuum scale factor` is `autovacuum_vacuum_scale_factor`, and the `number of tuples` is `pg_class.reltuples`.

While you are connected to your database, run the following query to see a list of tables that autovacuum sees as eligible for vacuuming.

```
WITH vbt AS (SELECT setting AS autovacuum_vacuum_threshold FROM
pg_settings WHERE name = 'autovacuum_vacuum_threshold'),
vsf AS (SELECT setting AS autovacuum_vacuum_scale_factor FROM
pg_settings WHERE name = 'autovacuum_vacuum_scale_factor'),
fma AS (SELECT setting AS autovacuum_freeze_max_age FROM pg_settings WHERE name =
 'autovacuum_freeze_max_age'),
sto AS (select opt_oid, split_part(setting, '=', 1) as param,
split_part(setting, '=', 2) as value from (select oid opt_oid, unnest(reloptions)
 setting from pg_class) opt)
SELECT '"'||ns.nspname||'"."'||c.relname||'"' as relation,
pg_size_pretty(pg_table_size(c.oid)) as table_size,
```

```
age(relfrozenxid) as xid_age,
coalesce(cfma.value::float, autovacuum_freeze_max_age::float)
 autovacuum_freeze_max_age,
(coalesce(cvbt.value::float, autovacuum_vacuum_threshold::float) +
coalesce(cvsf.value::float,autovacuum_vacuum_scale_factor::float) * c.reltuples)
AS autovacuum_vacuum_tuples, n_dead_tup as dead_tuples FROM
pg_class c join pg_namespace ns on ns.oid = c.relnamespace
join pg_stat_all_tables stat on stat.relid = c.oid join vbt on (1=1) join vsf on (1=1)
 join fma on (1=1)
left join sto cvbt on cvbt.param = 'autovacuum_vacuum_threshold' and c.oid =
 cvbt.opt_oid
left join sto cvsf on cvsf.param = 'autovacuum_vacuum_scale_factor' and c.oid =
 cvsf.opt_oid
left join sto cfma on cfma.param = 'autovacuum_freeze_max_age' and c.oid = cfma.opt_oid
WHERE c.relkind = 'r' and nspname <> 'pg_catalog'
AND (age(relfrozenxid) >= coalesce(cfma.value::float, autovacuum_freeze_max_age::float)
OR coalesce(cvbt.value::float, autovacuum_vacuum_threshold::float) +
coalesce(cvsf.value::float,autovacuum_vacuum_scale_factor::float) *
c.reltuples <= n_dead_tup)
ORDER BY age(relfrozenxid) DESC LIMIT 50;
```

Determining if autovacuum is currently running and for how long

If you need to manually vacuum a table, make sure to determine if autovacuum is currently running. If it is, you might need to adjust parameters to make it run more efficiently, or turn off autovacuum temporarily so that you can manually run VACUUM.

Use the following query to determine if autovacuum is running, how long it has been running, and if it is waiting on another session.

```
SELECT datname, usename, pid, state, wait_event, current_timestamp - xact_start AS
 xact_runtime, query
FROM pg_stat_activity
WHERE upper(query) LIKE '%VACUUM%'
ORDER BY xact_start;
```

After running the query, you should see output similar to the following.

```
 datname | usename  |  pid  | state  | wait_event |      xact_runtime       | query
 --------+----------+-------+--------+------------+-------------------------
+-----------------------------------------------------------------------------------------
```

```
mydb    | rdsadmin | 16473 | active |            | 33 days 16:32:11.600656 |
autovacuum: VACUUM ANALYZE public.mytable1 (to prevent wraparound)
mydb    | rdsadmin | 22553 | active |            | 14 days 09:15:34.073141 |
autovacuum: VACUUM ANALYZE public.mytable2 (to prevent wraparound)
mydb    | rdsadmin | 41909 | active |            | 3 days 02:43:54.203349  |
autovacuum: VACUUM ANALYZE public.mytable3
mydb    | rdsadmin |   618 | active |            | 00:00:00                |
SELECT datname, usename, pid, state, wait_event, current_timestamp - xact_start AS
xact_runtime, query+
        |          |       |        |            |                         | FROM
pg_stat_activity
          +
        |          |       |        |            |                         | WHERE
query like '%VACUUM%'
         +
        |          |       |        |            |                         | ORDER BY
xact_start;
      +
```

Several issues can cause a long-running autovacuum session (that is, multiple days long). The most common issue is that your `maintenance_work_mem` parameter value is set too low for the size of the table or rate of updates.

We recommend that you use the following formula to set the `maintenance_work_mem` parameter value.

```
GREATEST({DBInstanceClassMemory/63963136*1024},65536)
```

Short running autovacuum sessions can also indicate problems:

- It can indicate that there aren't enough `autovacuum_max_workers` for your workload. In this case, you need to indicate the number of workers.
- It can indicate that there is an index corruption (autovacuum crashes and restarts on the same relation but makes no progress). In this case, run a manual `vacuum freeze verbose` *`table`* to see the exact cause.

Performing a manual vacuum freeze

You might want to perform a manual vacuum on a table that has a vacuum process already running. This is useful if you have identified a table with an age approaching 2 billion transactions (or above any threshold you are monitoring).

The following steps are guidelines, with several variations to the process. For example, during testing, suppose that you find that the `maintenance_work_mem` parameter value is set too small and that you need to take immediate action on a table. However, perhaps you don't want to bounce the instance at the moment. Using the queries in previous sections, you determine which table is the problem and notice a long running autovacuum session. You know that you need to change the `maintenance_work_mem` parameter setting, but you also need to take immediate action and vacuum the table in question. The following procedure shows what to do in this situation.

To manually perform a vacuum freeze

1. Open two sessions to the database containing the table you want to vacuum. For the second session, use "screen" or another utility that maintains the session if your connection is dropped.
2. In session one, get the process ID (PID) of the autovacuum session running on the table.

   Run the following query to get the PID of the autovacuum session.

   ```
   SELECT datname, usename, pid, current_timestamp - xact_start
   AS xact_runtime, query
   FROM pg_stat_activity WHERE upper(query) LIKE '%VACUUM%' ORDER BY
   xact_start;
   ```

3. In session two, calculate the amount of memory that you need for this operation. In this example, we determine that we can afford to use up to 2 GB of memory for this operation, so we set `maintenance_work_mem` for the current session to 2 GB.

   ```
   SET maintenance_work_mem='2 GB';
   SET
   ```

4. In session two, issue a `vacuum freeze verbose` command for the table. The verbose setting is useful because, although there is no progress report for this in PostgreSQL currently, you can see activity.

```
\timing on
Timing is on.
vacuum freeze verbose pgbench_branches;
```

```
INFO:  vacuuming "public.pgbench_branches"
INFO:  index "pgbench_branches_pkey" now contains 50 row versions in 2 pages
DETAIL:  0 index row versions were removed.
0 index pages have been deleted, 0 are currently reusable.
CPU 0.00s/0.00u sec elapsed 0.00 sec.
INFO:  index "pgbench_branches_test_index" now contains 50 row versions in 2 pages
DETAIL:  0 index row versions were removed.
0 index pages have been deleted, 0 are currently reusable.
CPU 0.00s/0.00u sec elapsed 0.00 sec.
INFO:  "pgbench_branches": found 0 removable, 50 nonremovable row versions
     in 43 out of 43 pages
DETAIL:  0 dead row versions cannot be removed yet.
There were 9347 unused item pointers.
0 pages are entirely empty.
CPU 0.00s/0.00u sec elapsed 0.00 sec.
VACUUM
Time: 2.765 ms
```

5. In session one, if autovacuum was blocking the vacuum session, you see in `pg_stat_activity` that waiting is "T" for your vacuum session. In this case, you need to end the autovacuum process as follows.

   ```
   SELECT pg_terminate_backend('the_pid');
   ```

   At this point, your session begins. It's important to note that autovacuum restarts immediately because this table is probably the highest on its list of work.

6. Initiate your `vacuum freeze verbose` command in session two, and then end the autovacuum process in session one.

Reindexing a table when autovacuum is running

If an index has become corrupt, autovacuum continues to process the table and fails. If you attempt a manual vacuum in this situation, you receive an error message like the following.

```
postgres=>  vacuum freeze pgbench_branches;
```

```
ERROR: index "pgbench_branches_test_index" contains unexpected
   zero page at block 30521
HINT: Please REINDEX it.
```

When the index is corrupted and autovacuum is attempting to run on the table, you contend with an already running autovacuum session. When you issue a REINDEX command, you take out an exclusive lock on the table. Write operations are blocked, and also read operations that use that specific index.

To reindex a table when autovacuum is running on the table

1. Open two sessions to the database containing the table that you want to vacuum. For the second session, use "screen" or another utility that maintains the session if your connection is dropped.
2. In session one, get the PID of the autovacuum session running on the table.

   Run the following query to get the PID of the autovacuum session.

   ```
   SELECT datname, usename, pid, current_timestamp - xact_start
   AS xact_runtime, query
   FROM pg_stat_activity WHERE upper(query) like '%VACUUM%' ORDER BY
   xact_start;
   ```

3. In session two, issue the reindex command.

   ```
   \timing on
   Timing is on.
   reindex index pgbench_branches_test_index;
   REINDEX
     Time: 9.966 ms
   ```

4. In session one, if autovacuum was blocking the process, you see in `pg_stat_activity` that waiting is "T" for your vacuum session. In this case, you end the autovacuum process.

   ```
   SELECT pg_terminate_backend('the_pid');
   ```

   At this point, your session begins. It's important to note that autovacuum restarts immediately because this table is probably the highest on its list of work.

5. Initiate your command in session two, and then end the autovacuum process in session 1.

Managing autovacuum with large indexes

As part of its operation, *autovacuum* performs several vacuum phases while running on a table. Before the table is cleaned up, all of its indexes are first vacuumed. When removing multiple large indexes, this phase consumes a significant amount of time and resources. Therefore, as a best practice, be sure to control the number of indexes on a table and eliminate unused indexes.

For this process, first check the overall index size. Then, determine if there are potentially unused indexes that can be removed as shown in the following examples.

To check the size of the table and its indexes

```
postgres=> select pg_size_pretty(pg_relation_size('pgbench_accounts'));
pg_size_pretty
6404 MB
(1 row)
```

```
postgres=> select pg_size_pretty(pg_indexes_size('pgbench_accounts'));
pg_size_pretty
11 GB
(1 row)
```

In this example, the size of indexes is larger than the table. This difference can cause performance issues as the indexes are bloated or unused, which impacts the autovacuum as well as insert operations.

To check for unused indexes

Using the `pg_stat_user_indexes` view, you can check how frequently an index is used with the `idx_scan` column. In the following example, the unused indexes have the `idx_scan` value of `0`.

```
postgres=> select * from pg_stat_user_indexes where relname = 'pgbench_accounts' order
 by idx_scan desc;

relid  | indexrelid | schemaname | relname          | indexrelname          | idx_scan
 | idx_tup_read | idx_tup_fetch
-------+------------+------------+------------------+-----------------------+----------
+--------------+---------------
16433  | 16454      | public     | pgbench_accounts | index_f               | 6
 | 6            | 0
```

```
16433  | 16450      | public     | pgbench_accounts | index_b               | 3
 | 199999       | 0
16433  | 16447      | public     | pgbench_accounts | pgbench_accounts_pkey | 0
 | 0            | 0
16433  | 16452      | public     | pgbench_accounts | index_d               | 0
 | 0            | 0
16433  | 16453      | public     | pgbench_accounts | index_e               | 0
 | 0            | 0
16433  | 16451      | public     | pgbench_accounts | index_c               | 0
 | 0            | 0
16433  | 16449      | public     | pgbench_accounts | index_a               | 0
 | 0            | 0
(7 rows)
```

```
postgres=> select schemaname, relname, indexrelname, idx_scan from pg_stat_user_indexes
 where relname = 'pgbench_accounts' order by idx_scan desc;

schemaname  | relname          | indexrelname          | idx_scan
------------+------------------+-----------------------+----------
public      | pgbench_accounts | index_f               | 6
public      | pgbench_accounts | index_b               | 3
public      | pgbench_accounts | pgbench_accounts_pkey | 0
public      | pgbench_accounts | index_d               | 0
public      | pgbench_accounts | index_e               | 0
public      | pgbench_accounts | index_c               | 0
public      | pgbench_accounts | index_a               | 0
(7 rows)
```

Note

These statistics are incremental from the time that the statistics are reset. Suppose you have an index that is only used at the end of a business quarter or just for a specific report. It's possible that this index hasn't been used since the statistics were reset. For more information, see Statistics Functions. Indexes that are used to enforce uniqueness won't have scans performed and shouldn't be identified as unused indexes. To identify the unused indexes, you should have in-depth knowledge of the application and its queries.

To check when the stats were last reset for a database, use `pg_stat_database`

```
postgres=> select datname, stats_reset from pg_stat_database where datname =
 'postgres';

datname   | stats_reset
----------+-------------------------------
postgres  | 2022-11-17 08:58:11.427224+00
(1 row)
```

Vacuuming a table as quickly as possible

RDS for PostgreSQL 12 and higher

If you have too many indexes in a large table, your DB instance could be nearing transaction ID wraparound (XID), which is when the XID counter wraps around to zero. Left unchecked, this situation could result in data loss. However, you can quickly vacuum the table without cleaning up the indexes. In RDS for PostgreSQL 12 and higher, you can use VACUUM with the INDEX_CLEANUP clause.

```
postgres=> VACUUM (INDEX_CLEANUP FALSE, VERBOSE TRUE) pgbench_accounts;

INFO: vacuuming "public.pgbench_accounts"
INFO: table "pgbench_accounts": found 0 removable, 8 nonremovable row versions in 1 out
 of 819673 pages
DETAIL: 0 dead row versions cannot be removed yet, oldest xmin: 7517
Skipped 0 pages due to buffer pins, 0 frozen pages.
CPU: user: 0.01 s, system: 0.00 s, elapsed: 0.01 s.
```

If an autovacuum session is already running, you must terminate it to begin the manual VACUUM. For information on performing a manual vacuum freeze, see Performing a manual vacuum freeze

> **Note**
>
> Skipping index cleanup regularly might cause index bloat, which impacts the overall scan performance. As a best practice, use the preceding procedure only to prevent transaction ID wraparound.

RDS for PostgreSQL 11 and older

However, in RDS for PostgreSQL 11 and lower versions, the only way to allow vacuum to complete faster is to reduce the number of indexes on a table. Dropping an index can affect query plans. We recommend that you drop unused indexes first, then drop the indexes when XID wraparound is very near. After the vacuum process completes, you can recreate these indexes.

Other parameters that affect autovacuum

The following query shows the values of some of the parameters that directly affect autovacuum and its behavior. The autovacuum parameters are described fully in the PostgreSQL documentation.

```
SELECT name, setting, unit, short_desc
FROM pg_settings
WHERE name IN (
'autovacuum_max_workers',
'autovacuum_analyze_scale_factor',
'autovacuum_naptime',
'autovacuum_analyze_threshold',
'autovacuum_analyze_scale_factor',
'autovacuum_vacuum_threshold',
'autovacuum_vacuum_scale_factor',
'autovacuum_vacuum_threshold',
'autovacuum_vacuum_cost_delay',
'autovacuum_vacuum_cost_limit',
'vacuum_cost_limit',
'autovacuum_freeze_max_age',
'maintenance_work_mem',
'vacuum_freeze_min_age');
```

While these all affect autovacuum, some of the most important ones are:

- maintenance_work_mem
- autovacuum_freeze_max_age
- autovacuum_max_workers
- autovacuum_vacuum_cost_delay
- autovacuum_vacuum_cost_limit

Setting table-level autovacuum parameters

You can set autovacuum-related storage parameters at a table level, which can be better than altering the behavior of the entire database. For large tables, you might need to set aggressive settings and you might not want to make autovacuum behave that way for all tables.

The following query shows which tables currently have table-level options in place.

```
SELECT relname, reloptions
FROM pg_class
WHERE reloptions IS NOT null;
```

An example where this might be useful is on tables that are much larger than the rest of your tables. Suppose that you have one 300-GB table and 30 other tables less than 1 GB. In this case, you might set some specific parameters for your large table so you don't alter the behavior of your entire system.

```
ALTER TABLE mytable set (autovacuum_vacuum_cost_delay=0);
```

Doing this turns off the cost-based autovacuum delay for this table at the expense of more resource usage on your system. Normally, autovacuum pauses for `autovacuum_vacuum_cost_delay` each time `autovacuum_cost_limit` is reached. For more details, see the PostgreSQL documentation about cost-based vacuuming.

Logging autovacuum and vacuum activities

Information about autovacuum activities is sent to the `postgresql.log` based on the level specified in the `rds.force_autovacuum_logging_level` parameter. Following are the values allowed for this parameter and the PostgreSQL versions for which that value is the default setting:

- `disabled` (PostgreSQL 10, PostgreSQL 9.6)
- `debug5`, `debug4`, `debug3`, `debug2`, `debug1`
- `info` (PostgreSQL 12, PostgreSQL 11)
- `notice`
- `warning` (PostgreSQL 13 and above)
- `error`, `log`, `fatal`, `panic`

The `rds.force_autovacuum_logging_level` works with the `log_autovacuum_min_duration` parameter. The `log_autovacuum_min_duration` parameter's value is the threshold (in milliseconds) above which autovacuum actions get logged. A setting of `-1` logs nothing, while a setting of 0 logs all actions. As with `rds.force_autovacuum_logging_level`, default values for `log_autovacuum_min_duration` are version dependent, as follows:

- `10000 ms` – PostgreSQL 14, PostgreSQL 13, PostgreSQL 12, and PostgreSQL 11
- `(empty)` – No default value for PostgreSQL 10 and PostgreSQL 9.6

We recommend that you set `rds.force_autovacuum_logging_level` to `WARNING`. We also recommend that you set `log_autovacuum_min_duration` to a value from 1000 to 5000. A setting of 5000 logs activity that takes longer than 5,000 milliseconds. Any setting other than -1 also logs messages if the autovacuum action is skipped because of a conflicting lock or concurrently dropped relations. For more information, see Automatic Vacuuming in the PostgreSQL documentation.

To troubleshoot issues, you can change the `rds.force_autovacuum_logging_level` parameter to one of the debug levels, from `debug1` up to `debug5` for the most verbose information. We recommend that you use debug settings for short periods of time and for troubleshooting purposes only. To learn more, see When to log in the PostgreSQL documentation.

> **Note**
>
> PostgreSQL allows the `rds_superuser` account to view autovacuum sessions in `pg_stat_activity`. For example, you can identify and end an autovacuum session that is blocking a command from running, or running slower than a manually issued vacuum command.

Understanding the behavior of autovacuum with invalid databases

A new value `-2` is introduced into the `datconnlimit` column in the `pg_database` catalog to indicate databases that have been interrupted in the middle of the DROP DATABASE operation as invalid.

This new value is available from the following RDS for PostgreSQL versions:

- 15.4 and all higher versions
- 14.9 and higher versions
- 13.12 and higher versions
- 12.16 and higher versions
- 11.21 and higher versions

Invalid databases do not affect autovacuum's ability to freeze functionality for valid databases. Autovacuum ignores invalid databases. Consequently, regular vacuum operations will continue to function properly and efficiently for all valid databases in your PostgreSQL environment.

Topics

Monitoring transaction ID

The `age(datfrozenxid)` function is commonly used to monitor the transaction ID (XID) age of databases to prevent transaction ID wraparound.

Since invalid databases are excluded from autovacuum, their transaction ID (XID) counter can reach the maximum value of `2 billion`, wrap around to `- 2 billion`, and continue this cycle indefinitely. A typical query to monitor Transaction ID wraparound might look like:

```
SELECT max(age(datfrozenxid)) FROM pg_database;
```

However, with the introduction of the -2 value for `datconnlimit`, invalid databases can skew the results of this query. Since these databases are not valid and should not be part of regular maintenance checks, they can cause false positives, leading you to believe that the `age(datfrozenxid)` is higher than it actually is.

Adjusting the monitoring query

To ensure accurate monitoring, you should adjust your monitoring query to exclude invalid databases. Follow this recommended query:

```
SELECT
    max(age(datfrozenxid))
FROM
    pg_database
WHERE
    datconnlimit <> -2;
```

This query ensures that only valid databases are considered in the `age(datfrozenxid)` calculation, providing a true reflection of the transaction ID age across your PostgreSQL environment.

Resolving invalid database issue

When attempting to connect to an invalid database, you may encounter an error message similar to the following:

```
postgres=> \c db1
connection to server at "mydb.xxxxxxxxxx.us-west-2.rds.amazonaws.com" (xx.xx.xx.xxx),
 port xxxx failed: FATAL:  cannot connect to invalid database "db1"
HINT:  Use DROP DATABASE to drop invalid databases.
Previous connection kept
```

Additionally, if the `log_min_messages` parameter is set to DEBUG2 or higher, you may notice the following log entries indicating that the autovacuum process is skipping the invalid database:

```
2024-07-30 05:59:00 UTC::@:[32000]:DEBUG:  autovacuum: skipping invalid database "db6"
2024-07-30 05:59:00 UTC::@:[32000]:DEBUG:  autovacuum: skipping invalid database "db1"
```

To resolve the issue, follow the `HINT` provided during the connection attempt. Connect to any valid database using your RDS master account or a database account with the `rds_superuser` role, and drop invalid database(s).

```
SELECT
```

```
    'DROP DATABASE ' || quote_ident(datname) || ';'
FROM
    pg_database
WHERE
    datconnlimit = -2 \gexec
```

Working with logging mechanisms supported by RDS for PostgreSQL

There are several parameters, extensions, and other configurable items that you can set to log activities that occur on your PostgreSQL DB instance. These include the following:

- The `log_statement` parameter can be used to log user activity in your PostgreSQL database. To learn more about RDS for PostgreSQL logging and how to monitor the logs, see RDS for PostgreSQL database log files.
- The `rds.force_admin_logging_level` parameter logs actions by the Amazon RDS internal user (rdsadmin) in the databases on the DB instance. It writes the output to the PostgreSQL error log. Allowed values are `disabled`, `debug5`, `debug4`, `debug3`, `debug2`, `debug1`, `info`, `notice`, `warning`, `error`, log, `fatal`, and `panic`. The default value is `disabled`.
- The `rds.force_autovacuum_logging_level` parameter can be set to capture various autovacuum operations in the PostgreSQL error log. For more information, see Logging autovacuum and vacuum activities.
- The PostgreSQL Audit (pgAudit) extension can be installed and configured to capture activities at the session level or at the object level. For more information, see Using pgAudit to log database activity.
- The `log_fdw` extension makes it possible for you to access the database engine log using SQL. For more information, see Using the log_fdw extension to access the DB log using SQL.
- The `pg_stat_statements` library is specified as the default for the `shared_preload_libraries` parameter in RDS for PostgreSQL version 10 and higher. It's this library that you can use to analyze running queries. Be sure that `pg_stat_statements` is set in your DB parameter group. For more information about monitoring your RDS for PostgreSQL DB instance using the information that this library provides, see SQL statistics for RDS PostgreSQL.
- The `log_hostname` parameter captures to the log the hostname of each client connection. For RDS for PostgreSQL version 12 and higher versions, this parameter is set to `off` by default. If you turn it on, be sure to monitor session connection times. When turned on, the service uses the domain name system (DNS) reverse lookup request to get the hostname of the client that's making the connection and add it to the PostgreSQL log. This has a noticeable impact

during session connection. We recommend that you turn on this parameter for troubleshooting purposes only.

In general terms, the point of logging is so that the DBA can monitor, tune performance, and troubleshoot. Many of the logs are uploaded automatically to Amazon CloudWatch or Performance Insights. Here, they're sorted and grouped to provide complete metrics for your DB instance. To learn more about Amazon RDS monitoring and metrics, see Monitoring metrics in an Amazon RDS instance.

Managing temporary files with PostgreSQL

In PostgreSQL, a complex query might perform several sort or hash operations at the same time, with each operation using instance memory to store results up to the value specified in the `work_mem` parameter. When the instance memory is not sufficient, temporary files are created to store the results. These are written to disk to complete the query execution. Later, these files are automatically removed after the query completes. In RDS for PostgreSQL, these files are stored in Amazon EBS on the data volume. For more information, see Amazon RDS DB instance storage. You can monitor the `FreeStorageSpace` metric published in CloudWatch to make sure that your DB instance has enough free storage space. For more information, see `FreeStorageSpace` .

We recommend using Amazon RDS Optimized Read instances for the workloads involving multiple concurrent queries that increase the usage of temporary files. These instances use local Non-Volatile Memory Express (NVMe) based solid state drive (SSD) block-level storage to place the temporary files. For more information, see Amazon RDS Optimized Reads.

You can use the following parameters and functions to manage the temporary files in your instance.

- **`temp_file_limit`** – This parameter cancels any query exceeding the size of temp_files in KB. This limit prevents any query from running endlessly and consuming disk space with temporary files. You can estimate the value using the results from the `log_temp_files` parameter. As a best practice, examine the workload behavior and set the limit according to the estimation. The following example shows how a query is canceled when it exceeds the limit.

```
postgres=>select * from pgbench_accounts, pg_class, big_table;
```

```
ERROR: temporary file size exceeds temp_file_limit (64kB)
```

- **log_temp_files** – This parameter sends messages to the postgresql.log when the temporary files of a session are removed. This parameter produces logs after a query successfully completes. Therefore, it might not help in troubleshooting active, long-running queries.

  The following example shows that when the query successfully completes, the entries are logged in the postgresql.log file while the temporary files are cleaned up.

```
2023-02-06 23:48:35 UTC:205.251.233.182(12456):adminuser@postgres:[31236]:LOG:
 temporary file: path "base/pgsql_tmp/pgsql_tmp31236.5", size 140353536
2023-02-06 23:48:35 UTC:205.251.233.182(12456):adminuser@postgres:[31236]:STATEMENT:
  select a.aid from pgbench_accounts a, pgbench_accounts b where a.bid=b.bid order by
 a.bid limit 10;
2023-02-06 23:48:35 UTC:205.251.233.182(12456):adminuser@postgres:[31236]:LOG:
 temporary file: path "base/pgsql_tmp/pgsql_tmp31236.4", size 180428800
2023-02-06 23:48:35 UTC:205.251.233.182(12456):adminuser@postgres:[31236]:STATEMENT:
  select a.aid from pgbench_accounts a, pgbench_accounts b where a.bid=b.bid order by
 a.bid limit 10;
```

- **pg_ls_tmpdir** – This function that is available from RDS for PostgreSQL 13 and above provides visibility into the current temporary file usage. The completed query doesn't appear in the results of the function. In the following example, you can view the results of this function.

```
postgres=>select * from pg_ls_tmpdir();
```

```
      name       |    size    |      modification
-----------------+------------+------------------------
 pgsql_tmp8355.1 | 1072250880 | 2023-02-06 22:54:56+00
 pgsql_tmp8351.0 | 1072250880 | 2023-02-06 22:54:43+00
 pgsql_tmp8327.0 | 1072250880 | 2023-02-06 22:54:56+00
 pgsql_tmp8351.1 |  703168512 | 2023-02-06 22:54:56+00
 pgsql_tmp8355.0 | 1072250880 | 2023-02-06 22:54:00+00
 pgsql_tmp8328.1 |  835031040 | 2023-02-06 22:54:56+00
 pgsql_tmp8328.0 | 1072250880 | 2023-02-06 22:54:40+00
(7 rows)
```

```
postgres=>select query from pg_stat_activity where pid = 8355;

query
------------------------------------------------------------------------------------------
select a.aid from pgbench_accounts a, pgbench_accounts b where a.bid=b.bid order by
 a.bid
(1 row)
```

The file name includes the processing ID (PID) of the session that generated the temporary file. A more advanced query, such as in the following example, performs a sum of the temporary files for each PID.

```
postgres=>select replace(left(name, strpos(name, '.')-1),'pgsql_tmp','') as pid,
 count(*), sum(size) from pg_ls_tmpdir() group by pid;
```

```
 pid  | count |   sum
------+-------------------
 8355 |     2 | 2144501760
 8351 |     2 | 2090770432
 8327 |     1 | 1072250880
 8328 |     2 | 2144501760
(4 rows)
```

- **pg_stat_statements** – If you activate the pg_stat_statements parameter, then you can view the average temporary file usage per call. You can identify the query_id of the query and use it to examine the temporary file usage as shown in the following example.

```
postgres=>select queryid from pg_stat_statements where query like 'select a.aid from
 pgbench%';
```

```
       queryid
----------------------
 -7170349228837045701
(1 row)
```

```
postgres=>select queryid, substr(query,1,25), calls, temp_blks_read/calls
 temp_blks_read_per_call, temp_blks_written/calls temp_blks_written_per_call from
 pg_stat_statements where queryid = -7170349228837045701;
```

```
       queryid        |          substr           | calls | temp_blks_read_per_call |
 temp_blks_written_per_call
----------------------+---------------------------+-------+-------------------------
+---------------------------
 -7170349228837045701 | select a.aid from pgbench |    50 |                  239226 |
                      388678
(1 row)
```

- **`Performance Insights`** – In the Performance Insights dashboard, you can view temporary file usage by turning on the metrics **temp_bytes** and **temp_files**. Then, you can see the average of both of these metrics and see how they correspond to the query workload. The view within Performance Insights doesn't show specifically the queries that are generating the temporary files. However, when you combine Performance Insights with the query shown for `pg_ls_tmpdir`, you can troubleshoot, analyze, and determine the changes in your query workload.

  For more information about how to analyze metrics and queries with Performance Insights, see Analyzing metrics with the Performance Insights dashboard.

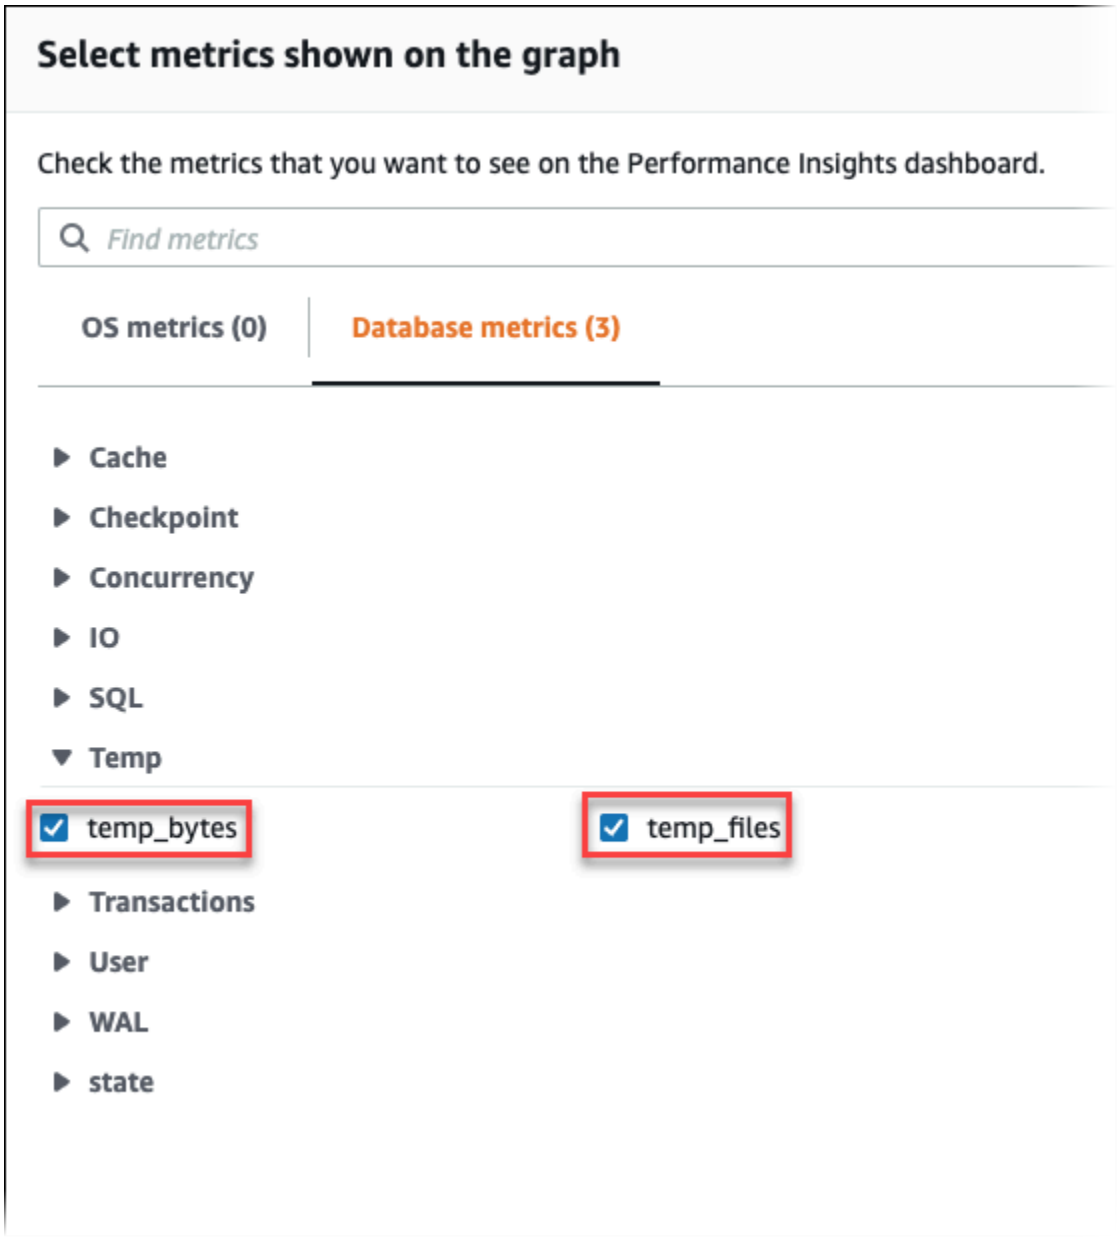
  For an example of viewing temporary file usage with Performance Insights, see Viewing temporary file usage with Performance Insights

Viewing temporary file usage with Performance Insights

You can use Performance Insights to view temporary file usage by turning on the metrics **temp_bytes** and **temp_files**. The view in Performance Insights doesn't show the specific queries that generate temporary files, however, when you combine Performance Insights with the query shown for `pg_ls_tmpdir`, you can troubleshoot, analyze, and determine the changes in your query workload.

1. In the Performance Insights dashboard, choose **Manage Metrics**.

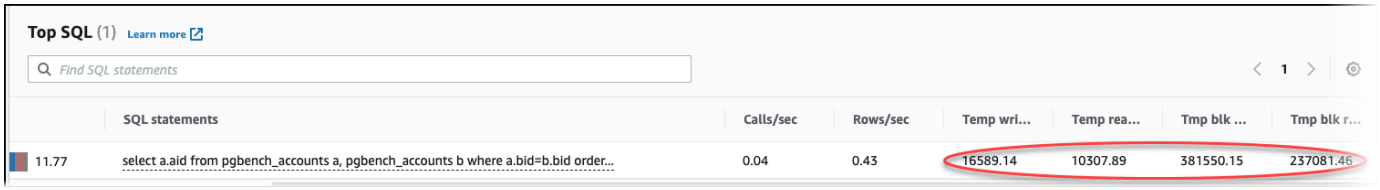
2. Choose **Database metrics**, and select the **temp_bytes** and **temp_files** metrics as shown in the following image.



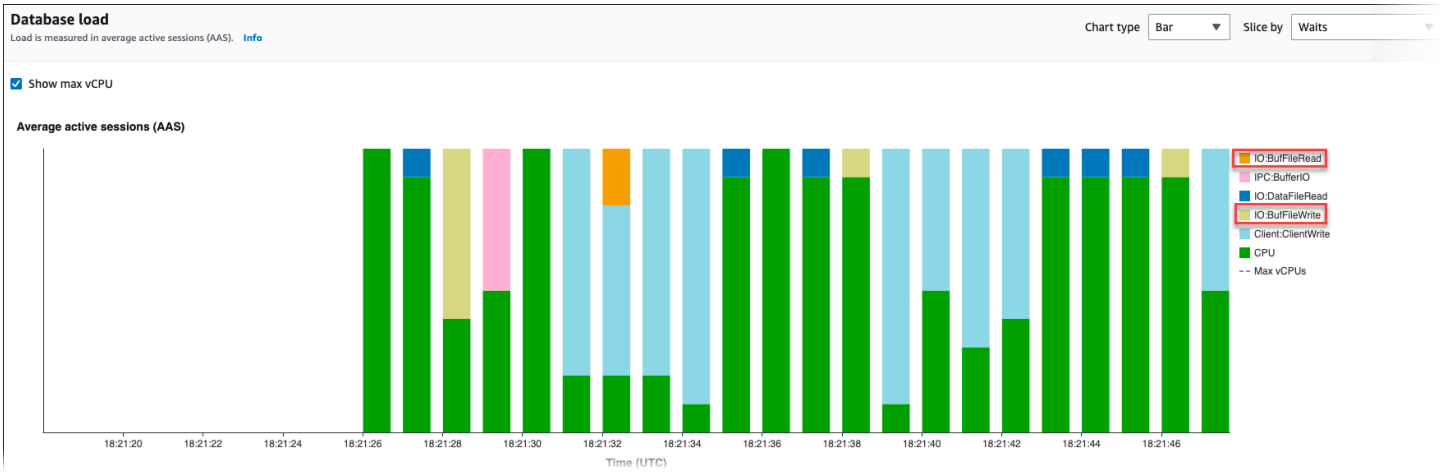
3. In the **Top SQL** tab, choose the **Preferences** icon.
4. In the **Preferences** window, turn on the following statistics to appear in the **Top SQL**tab and choose **Continue**.

   - Temp writes/sec
   - Temp reads/sec
   - Tmp blk write/call
   - Tmp blk read/call

5. The temporary file is broken out when combined with the query shown for `pg_ls_tmpdir`, as shown in the following example.



The `IO:BufFileRead` and `IO:BufFileWrite` events occur when the top queries in your workload often create temporary files. You can use Performance Insights to identify top queries waiting on `IO:BufFileRead` and `IO:BufFileWrite` by reviewing Average Active Session (AAS) in Database Load and Top SQL sections.



For more information on how to analyze top queries and load by wait event with Performance Insights, see Overview of the Top SQL tab. You should identify and tune the queries that cause increase in temporary file usage and related wait events. For more information on these wait events and remediation, see IO:BufFileRead and IO:BufFileWrite.

> **Note**
>
> The `work_mem` parameter controls when the sort operation runs out of memory and results are written into temporary files. We recommend that you don't change the setting of this parameter higher than the default value because it would permit every database session to consume more memory. Also, a single session that performs complex joins and sorts can perform parallel operations in which each operation consumes memory.

As a best practice, when you have a large report with multiple joins and sorts, set this parameter at the session level by using the `SET work_mem` command. Then the change is only applied to the current session and doesn't change the value globally.

Using pgBadger for log analysis with PostgreSQL

You can use a log analyzer such as pgBadger to analyze PostgreSQL logs. The pgBadger documentation states that the %l pattern (the log line for the session or process) should be a part of the prefix. However, if you provide the current RDS `log_line_prefix` as a parameter to pgBadger it should still produce a report.

For example, the following command correctly formats an Amazon RDS for PostgreSQL log file dated 2014-02-04 using pgBadger.

```
./pgbadger -f stderr -p '%t:%r:%u@%d:[%p]:' postgresql.log.2014-02-04-00
```

Using PGSnapper for monitoring PostgreSQL

You can use PGSnapper to assist with periodic collection of Amazon RDS for PostgreSQL performance-related statistics and metrics. For more information, see Monitor Amazon RDS for PostgreSQL performance using PGSnapper.

Working with parameters on your RDS for PostgreSQL DB instance

In some cases, you might create an RDS for PostgreSQL DB instance without specifying a custom parameter group. If so, your DB instance is created using the default parameter group for the version of PostgreSQL that you choose. For example, suppose that you create an RDS for PostgreSQL DB instance using PostgreSQL 13.3. In this case, the DB instance is created using the values in the parameter group for PostgreSQL 13 releases, `default.postgres13`.

You can also create your own custom DB parameter group. You need to do this if you want to modify any settings for the RDS for PostgreSQL DB instance from their default values. To learn how, see Parameter groups for Amazon RDS.

You can track the settings on your RDS for PostgreSQL DB instance in several different ways. You can use the AWS Management Console, the AWS CLI, or the Amazon RDS API. You can also query the values from the PostgreSQL `pg_settings` table of your instance, as shown following.

```
SELECT name, setting, boot_val, reset_val, unit
 FROM pg_settings
 ORDER BY name;
```

To learn more about the values returned from this query, see pg_settings in the PostgreSQL documentation.

Be especially careful when changing the settings for max_connections and shared_buffers on your RDS for PostgreSQL DB instance. For example, suppose that you modify settings for max_connections or shared_buffers and you use values that are too high for your actual workload. In this case, your RDS for PostgreSQL DB instance won't start. If this happens, you see an error such as the following in the postgres.log.

```
2018-09-18 21:13:15 UTC::@:[8097]:FATAL:  could not map anonymous shared memory: Cannot
 allocate memory
2018-09-18 21:13:15 UTC::@:[8097]:HINT:  This error usually means that PostgreSQL's
 request for a shared memory segment
exceeded available memory or swap space. To reduce the request size (currently
 3514134274048 bytes), reduce
PostgreSQL's shared memory usage, perhaps by reducing shared_buffers or
 max_connections.
```

However, you can't change any values of the settings contained in the default RDS for PostgreSQL DB parameter groups. To change settings for any parameters, first create a custom DB parameter group. Then change the settings in that custom group, and then apply the custom parameter group to your RDS for PostgreSQL DB instance. To learn more, see Parameter groups for Amazon RDS.

There are two types of parameters in RDS for PostgreSQL.

- **Static parameters** – Static parameters require that the RDS for PostgreSQL DB instance be rebooted after a change so that the new value can take effect.
- **Dynamic parameters** – Dynamic parameters don't require a reboot after changing their settings.

Note

If your RDS for PostgreSQL DB instance is using your own custom DB parameter group, you can change the values of dynamic parameters on the running DB instance. You can do this by using the AWS Management Console, the AWS CLI, or the Amazon RDS API.

If you have privileges to do so, you can also change parameter values by using the `ALTER DATABASE`, `ALTER ROLE`, and `SET` commands.

RDS for PostgreSQL DB instance parameter list

The following table lists some (but not all) parameters available in an RDS for PostgreSQL DB instance. To view all available parameters, you use the describe-db-parameters AWS CLI command. For example, to get the list of all parameters available in the default parameter group for RDS for PostgreSQL version 13, run the following.

```
aws rds describe-db-parameters --db-parameter-group-name default.postgres13
```

You can also use the Console. Choose **Parameter groups** from the Amazon RDS menu, and then choose the parameter group from those available in your AWS Region.

Parameter name	Apply_Type	Description
application_name	Dynamic	Sets the application name to be reported in statistics and logs.
archive_command	Dynamic	Sets the shell command that will be called to archive a WAL file.
array_nulls	Dynamic	Enables input of NULL elements in arrays.
authentication_timeout	Dynamic	Sets the maximum allowed time to complete client authentication.
autovacuum	Dynamic	Starts the autovacuum subprocess.
autovacuum_analyze_scale_factor	Dynamic	Number of tuple inserts, updates, or deletes before analyze as a fraction of reltuples.
autovacuum_analyze_threshold	Dynamic	Minimum number of tuple inserts, updates, or deletes before analyze.
autovacuum_freeze_max_age	Static	Age at which to autovacuum a table to prevent transaction ID wraparound.
autovacuum_naptime	Dynamic	Time to sleep between autovacuum runs.

Parameter name	Apply_Type	Description
autovacuum_max_workers	Static	Sets the maximum number of simultaneously running autovacuum worker processes.
autovacuum_vacuum_cost_delay	Dynamic	Vacuum cost delay, in milliseconds, for autovacuum.
autovacuum_vacuum_cost_limit	Dynamic	Vacuum cost amount available before napping, for autovacuum.
autovacuum_vacuum_scale_factor	Dynamic	Number of tuple updates or deletes before vacuum as a fraction of reltuples.
autovacuum_vacuum_threshold	Dynamic	Minimum number of tuple updates or deletes before vacuum.
backslash_quote	Dynamic	Sets whether a backslash (\) is allowed in string literals.
bgwriter_delay	Dynamic	Background writer sleep time between rounds.
bgwriter_lru_maxpages	Dynamic	Background writer maximum number of LRU pages to flush per round.
bgwriter_lru_multiplier	Dynamic	Multiple of the average buffer usage to free per round.
bytea_output	Dynamic	Sets the output format for bytes.
check_function_bodies	Dynamic	Checks function bodies during CREATE FUNCTION.
checkpoint_completion_target	Dynamic	Time spent flushing dirty buffers during checkpoint, as a fraction of the checkpoint interval.

Parameter name	Apply_Type	Description
checkpoint_segments	Dynamic	Sets the maximum distance in log segments between automatic write-ahead log (WAL) checkpoints.
checkpoint_timeout	Dynamic	Sets the maximum time between automatic WAL checkpoints.
checkpoint_warning	Dynamic	Enables warnings if checkpoint segments are filled more frequently than this.
client_connection_check_interval	Dynamic	Sets the time interval between checks for disconnection while running queries.
client_encoding	Dynamic	Sets the client's character set encoding.
client_min_messages	Dynamic	Sets the message levels that are sent to the client.
commit_delay	Dynamic	Sets the delay in microseconds between transaction commit and flushing WAL to disk.
commit_siblings	Dynamic	Sets the minimum concurrent open transactions before performing commit_delay.
constraint_exclusion	Dynamic	Enables the planner to use constraints to optimize queries.
cpu_index_tuple_cost	Dynamic	Sets the planner's estimate of the cost of processing each index entry during an index scan.
cpu_operator_cost	Dynamic	Sets the planner's estimate of the cost of processing each operator or function call.
cpu_tuple_cost	Dynamic	Sets the planner's estimate of the cost of processing each tuple (row).
cursor_tuple_fraction	Dynamic	Sets the planner's estimate of the fraction of a cursor's rows that will be retrieved.

Parameter name	Apply_Type	Description
datestyle	Dynamic	Sets the display format for date and time values.
deadlock_timeout	Dynamic	Sets the time to wait on a lock before checking for deadlock.
debug_pretty_print	Dynamic	Indents parse and plan tree displays.
debug_print_parse	Dynamic	Logs each query's parse tree.
debug_print_plan	Dynamic	Logs each query's execution plan.
debug_print_rewritten	Dynamic	Logs each query's rewritten parse tree.
default_statistics_target	Dynamic	Sets the default statistics target.
default_tablespace	Dynamic	Sets the default tablespace to create tables and indexes in.
default_transaction_deferrable	Dynamic	Sets the default deferrable status of new transactions.
default_transaction_isolation	Dynamic	Sets the transaction isolation level of each new transaction.
default_transaction_read_only	Dynamic	Sets the default read-only status of new transactions.
default_with_oids	Dynamic	Creates new tables with object IDs (OIDs) by default.
effective_cache_size	Dynamic	Sets the planner's assumption about the size of the disk cache.
effective_io_concurrency	Dynamic	Number of simultaneous requests that can be handled efficiently by the disk subsystem.

Parameter name	Apply_Type	Description
enable_bitmapscan	Dynamic	Enables the planner's use of bitmap-scan plans.
enable_hashagg	Dynamic	Enables the planner's use of hashed aggregation plans.
enable_hashjoin	Dynamic	Enables the planner's use of hash join plans.
enable_indexscan	Dynamic	Enables the planner's use of index-scan plans.
enable_material	Dynamic	Enables the planner's use of materialization.
enable_mergejoin	Dynamic	Enables the planner's use of merge join plans.
enable_nestloop	Dynamic	Enables the planner's use of nested-loop join plans.
enable_seqscan	Dynamic	Enables the planner's use of sequential-scan plans.
enable_sort	Dynamic	Enables the planner's use of explicit sort steps.
enable_tidscan	Dynamic	Enables the planner's use of TID scan plans.
escape_string_warning	Dynamic	Warns about backslash (\) escapes in ordinary string literals.
extra_float_digits	Dynamic	Sets the number of digits displayed for floating-point values.
from_collapse_limit	Dynamic	Sets the FROM-list size beyond which subqueries are not collapsed.
fsync	Dynamic	Forces synchronization of updates to disk.
full_page_writes	Dynamic	Writes full pages to WAL when first modified after a checkpoint.
geqo	Dynamic	Enables genetic query optimization.

Parameter name	Apply_Type	Description
geqo_effort	Dynamic	GEQO: effort is used to set the default for other GEQO parameters.
geqo_generations	Dynamic	GEQO: number of iterations of the algorithm.
geqo_pool_size	Dynamic	GEQO: number of individuals in the population.
geqo_seed	Dynamic	GEQO: seed for random path selection.
geqo_selection_bias	Dynamic	GEQO: selective pressure within the population.
geqo_threshold	Dynamic	Sets the threshold of FROM items beyond which GEQO is used.
gin_fuzzy_search_limit	Dynamic	Sets the maximum allowed result for exact search by GIN.
hot_standby_feedback	Dynamic	Determines whether a hot standby sends feedback messages to the primary or upstream standby.
intervalstyle	Dynamic	Sets the display format for interval values.
join_collapse_limit	Dynamic	Sets the FROM-list size beyond which JOIN constructs are not flattened.
lc_messages	Dynamic	Sets the language in which messages are displayed.
lc_monetary	Dynamic	Sets the locale for formatting monetary amounts.
lc_numeric	Dynamic	Sets the locale for formatting numbers.
lc_time	Dynamic	Sets the locale for formatting date and time values.

Parameter name	Apply_Type	Description
log_autovacuum_min_duration	Dynamic	Sets the minimum running time above which autovacuum actions will be logged.
log_checkpoints	Dynamic	Logs each checkpoint.
log_connections	Dynamic	Logs each successful connection.
log_disconnections	Dynamic	Logs end of a session, including duration.
log_duration	Dynamic	Logs the duration of each completed SQL statement.
log_error_verbosity	Dynamic	Sets the verbosity of logged messages.
log_executor_stats	Dynamic	Writes executor performance statistics to the server log.
log_filename	Dynamic	Sets the file name pattern for log files.
log_file_mode	Dynamic	Sets file permissions for log files. Default value is 0644.
log_hostname	Dynamic	Logs the host name in the connection logs. As of PostgreSQL 12 and later versions, this parameter is 'off' by default. When turned on, the connection uses DNS reverse-lookup to get the hostname that gets captured to the connection logs. If you turn on this parameter, you should monitor the impact that it has on the time it takes to establish connections.
log_line_prefix	Dynamic	Controls information prefixed to each log line.
log_lock_waits	Dynamic	Logs long lock waits.
log_min_duration_statement	Dynamic	Sets the minimum running time above which statements will be logged.

Parameter name	Apply_Type	Description
log_min_error_statement	Dynamic	Causes all statements generating an error at or above this level to be logged.
log_min_messages	Dynamic	Sets the message levels that are logged.
log_parser_stats	Dynamic	Writes parser performance statistics to the server log.
log_planner_stats	Dynamic	Writes planner performance statistics to the server log.
log_rotation_age	Dynamic	Automatic log file rotation will occur after N minutes.
log_rotation_size	Dynamic	Automatic log file rotation will occur after N kilobytes.
log_statement	Dynamic	Sets the type of statements logged.
log_statement_stats	Dynamic	Writes cumulative performance statistics to the server log.
log_temp_files	Dynamic	Logs the use of temporary files larger than this number of kilobytes.
log_timezone	Dynamic	Sets the time zone to use in log messages.
log_truncate_on_rotation	Dynamic	Truncate existing log files of same name during log rotation.
logging_collector	Static	Start a subprocess to capture stderr output and/or csvlogs into log files.
maintenance_work_mem	Dynamic	Sets the maximum memory to be used for maintenance operations.

Parameter name	Apply_Type	Description
max_connections	Static	Sets the maximum number of concurrent connections.
max_files_per_process	Static	Sets the maximum number of simultaneously open files for each server process.
max_locks_per_transaction	Static	Sets the maximum number of locks per transaction.
max_pred_locks_per_transaction	Static	Sets the maximum number of predicate locks per transaction.
max_prepared_transactions	Static	Sets the maximum number of simultaneously prepared transactions.
max_stack_depth	Dynamic	Sets the maximum stack depth, in kilobytes.
max_standby_archive_delay	Dynamic	Sets the maximum delay before canceling queries when a hot standby server is processing archived WAL data.
max_standby_streaming_delay	Dynamic	Sets the maximum delay before canceling queries when a hot standby server is processing streamed WAL data.
max_wal_size	Dynamic	Sets the WAL size (MB) that triggers a checkpoint. For all versions after RDS for PostgreSQL 10, the default is at least 1 GB (1024 MB). For example, `max_wal_size` setting for RDS for PostgreSQL 14 is 2 GB (2048 MB). Use the `SHOW max_wal_size;` command on your RDS for PostgreSQL DB instance to see its current value.

Parameter name	Apply_Type	Description
min_wal_size	Dynamic	Sets the minimum size to shrink the WAL to. For PostgreSQL version 9.6 and earlier, min_wal_size is in units of 16 MB. For PostgreSQL version 10 and later, min_wal_size is in units of 1 MB.
quote_all_identifiers	Dynamic	Adds quotes (") to all identifiers when generating SQL fragments.
random_page_cost	Dynamic	Sets the planner's estimate of the cost of a non-sequentially fetched disk page. This parameter has no value unless query plan management (QPM) is turned on. When QPM is on, the default value for this parameter 4.
rds.adaptive_autovacuum	Dynamic	Automatically tunes the autovacuum parameters whenever the transaction ID thresholds are exceeded.
rds.force_ssl	Dynamic	Requires the use of SSL connections. The default value is set to 1 (on) for RDS for PostgreSQL version 15. All other RDS for PostgreSQL major version 14 and older have the default value set to 0 (off).
rds.local_volume_spill_enabled	Static	Enables writing logical spill files to the local volume.
rds.log_retention_period	Dynamic	Sets log retention such that Amazon RDS deletes PostgreSQL logs that are older than *n* minutes.
rds.rds_superuser_reserved_connections	Static	Sets the number of connection slots reserved for rds_superusers. This parameter is only available in versions 15 and earlier. For more information, see the PostgreSQL documentation reserved_connections.

Parameter name	Apply_Type	Description
rds.restrict_password_commands	Static	Restricts who can manage passwords to users with the rds_password role. Set this parameter to 1 to enable password restriction. The default is 0.
search_path	Dynamic	Sets the schema search order for names that are not schema-qualified.
seq_page_cost	Dynamic	Sets the planner's estimate of the cost of a sequentially fetched disk page.
session_replication_role	Dynamic	Sets the sessions behavior for triggers and rewrite rules.
shared_buffers	Static	Sets the number of shared memory buffers used by the server.
shared_preload_libraries	Static	Lists the shared libraries to preload into the RDS for PostgreSQL DB instance. Supported values include auto_explain, orafce, pgaudit, pglogical, pg_bigm, pg_cron, pg_hint_plan, pg_prewarm, pg_similarity, pg_stat_statements, pg_tle, pg_transport, plprofiler, and plrust.
ssl	Dynamic	Enables SSL connections.
sql_inheritance	Dynamic	Causes subtables to be included by default in various commands.
ssl_renegotiation_limit	Dynamic	Sets the amount of traffic to send and receive before renegotiating the encryption keys.
standard_conforming_strings	Dynamic	Causes ... strings to treat backslashes literally.

Parameter name	Apply_Type	Description
statement_timeout	Dynamic	Sets the maximum allowed duration of any statement.
synchronize_seqscans	Dynamic	Enables synchronized sequential scans.
synchronous_commit	Dynamic	Sets the current transactions synchronization level.
tcp_keepalives_count	Dynamic	Maximum number of TCP keepalive retransmits.
tcp_keepalives_idle	Dynamic	Time between issuing TCP keepalives.
tcp_keepalives_interval	Dynamic	Time between TCP keepalive retransmits.
temp_buffers	Dynamic	Sets the maximum number of temporary buffers used by each session.
temp_file_limit	Dynamic	Sets the maximum size in KB to which the temporary files can grow.
temp_tablespaces	Dynamic	Sets the tablespaces to use for temporary tables and sort files.

Parameter name	Apply_Type	Description
timezone	Dynamic	Sets the time zone for displaying and interpreting time stamps. The Internet Assigned Numbers Authority (IANA) publishes new time zones at https://www.iana.org/time-zones several times a year. Every time RDS releases a new minor maintenance release of PostgreSQL, it ships with the latest time zone data at the time of the release. When you use the latest RDS for PostgreSQL versions, you have recent time zone data from RDS. To ensure that your DB instance has recent time zone data, we recommend upgrading to a higher DB engine version. You can't modify the time zone tables in PostgreSQL DB instances manually. RDS doesn't modify or reset the time zone data of running DB instances. New time zone data is installed only when you perform a database engine version upgrade.
track_activities	Dynamic	Collects information about running commands.
track_activity_query_size	Static	Sets the size reserved for pg_stat_activity.current_query, in bytes.
track_counts	Dynamic	Collects statistics on database activity.
track_functions	Dynamic	Collects function-level statistics on database activity.
track_io_timing	Dynamic	Collects timing statistics on database I/O activity.
transaction_deferrable	Dynamic	Indicates whether to defer a read-only serializable transaction until it can be started with no possible serialization failures.

Parameter name	Apply_Type	Description
transaction_isolation	Dynamic	Sets the current transactions isolation level.
transaction_read_only	Dynamic	Sets the current transactions read-only status.
transform_null_equals	Dynamic	Treats expr=NULL as expr IS NULL.
update_process_title	Dynamic	Updates the process title to show the active SQL command.
vacuum_cost_delay	Dynamic	Vacuum cost delay in milliseconds.
vacuum_cost_limit	Dynamic	Vacuum cost amount available before napping.
vacuum_cost_page_dirty	Dynamic	Vacuum cost for a page dirtied by vacuum.
vacuum_cost_page_hit	Dynamic	Vacuum cost for a page found in the buffer cache.
vacuum_cost_page_miss	Dynamic	Vacuum cost for a page not found in the buffer cache.
vacuum_defer_cleanup_age	Dynamic	Number of transactions by which vacuum and hot cleanup should be deferred, if any.
vacuum_freeze_min_age	Dynamic	Minimum age at which vacuum should freeze a table row.
vacuum_freeze_table_age	Dynamic	Age at which vacuum should scan a whole table to freeze tuples.
wal_buffers	Static	Sets the number of disk-page buffers in shared memory for WAL.
wal_writer_delay	Dynamic	WAL writer sleep time between WAL flushes.

Parameter name	Apply_Type	Description
work_mem	Dynamic	Sets the maximum memory to be used for query workspaces.
xmlbinary	Dynamic	Sets how binary values are to be encoded in XML.
xmloption	Dynamic	Sets whether XML data in implicit parsing and serialization operations is to be considered as documents or content fragments.

Amazon RDS uses the default PostgreSQL units for all parameters. The following table shows the PostgreSQL default unit for each parameter.

Parameter name	Unit
archive_timeout	s
authentication_timeout	s
autovacuum_naptime	s
autovacuum_vacuum_cost_delay	ms
bgwriter_delay	ms
checkpoint_timeout	s
checkpoint_warning	s
deadlock_timeout	ms
effective_cache_size	8 KB
lock_timeout	ms
log_autovacuum_min_duration	ms

Parameter name	Unit
log_min_duration_statement	ms
log_rotation_age	minutes
log_rotation_size	KB
log_temp_files	KB
maintenance_work_mem	KB
max_stack_depth	KB
max_standby_archive_delay	ms
max_standby_streaming_delay	ms
post_auth_delay	s
pre_auth_delay	s
segment_size	8 KB
shared_buffers	8 KB
statement_timeout	ms
ssl_renegotiation_limit	KB
tcp_keepalives_idle	s
tcp_keepalives_interval	s
temp_file_limit	KB
work_mem	KB
temp_buffers	8 KB
vacuum_cost_delay	ms

Parameter name	Unit
wal_buffers	8 KB
wal_receiver_timeout	ms
wal_segment_size	B
wal_sender_timeout	ms
wal_writer_delay	ms
wal_receiver_status_interval	s

Tuning with wait events for RDS for PostgreSQL

Wait events are an important tuning tool for RDS for PostgreSQL. When you can find out why sessions are waiting for resources and what they are doing, you're better able to reduce bottlenecks. You can use the information in this section to find possible causes and corrective actions. This section also discusses basic PostgreSQL tuning concepts.

The wait events in this section are specific to RDS for PostgreSQL.

Topics

Essential concepts for RDS for PostgreSQL tuning

Before you tune your RDS for PostgreSQL database, make sure to learn what wait events are and why they occur. Also review the basic memory and disk architecture of RDS for PostgreSQL. For a helpful architecture diagram, see the PostgreSQL wikibook.

Topics

RDS for PostgreSQL wait events

A *wait event* is an indication that the session is waiting for a resource. For example, the wait event `Client:ClientRead` occurs when RDS for PostgreSQL is waiting to receive data from the client. Sessions typically wait for resources such as the following.

- Single-threaded access to a buffer, for example, when a session is attempting to modify a buffer
- A row that is currently locked by another session
- A data file read
- A log file write

For example, to satisfy a query, the session might perform a full table scan. If the data isn't already in memory, the session waits for the disk I/O to complete. When the buffers are read into memory, the session might need to wait because other sessions are accessing the same buffers. The database records the waits by using a predefined wait event. These events are grouped into categories.

By itself, a single wait event doesn't indicate a performance problem. For example, if requested data isn't in memory, reading data from disk is necessary. If one session locks a row for an update, another session waits for the row to be unlocked so that it can update it. A commit requires waiting for the write to a log file to complete. Waits are integral to the normal functioning of a database.

On the other hand, large numbers of wait events typically show a performance problem. In such cases, you can use wait event data to determine where sessions are spending time. For example, if a report that typically runs in minutes now takes hours to run, you can identify the wait events that

contribute the most to total wait time. If you can determine the causes of the top wait events, you can sometimes make changes that improve performance. For example, if your session is waiting on a row that has been locked by another session, you can end the locking session.

RDS for PostgreSQL memory

RDS for PostgreSQL memory is divided into shared and local.

Topics

- Shared memory in RDS for PostgreSQL
- Local memory in RDS for PostgreSQL

Shared memory in RDS for PostgreSQL

RDS for PostgreSQL allocates shared memory when the instance starts. Shared memory is divided into multiple subareas. Following, you can find a description of the most important ones.

Topics

- Shared buffers
- Write ahead log (WAL) buffers

Shared buffers

The *shared buffer pool* is an RDS for PostgreSQL memory area that holds all pages that are or were being used by application connections. A *page* is the memory version of a disk block. The shared buffer pool caches the data blocks read from disk. The pool reduces the need to reread data from disk, making the database operate more efficiently.

Every table and index is stored as an array of pages of a fixed size. Each block contains multiple tuples, which correspond to rows. A tuple can be stored in any page.

The shared buffer pool has finite memory. If a new request requires a page that isn't in memory, and no more memory exists, RDS for PostgreSQL evicts a less frequently used page to accommodate the request. The eviction policy is implemented by a clock sweep algorithm.

The `shared_buffers` parameter determines how much memory the server dedicates to caching data.

Write ahead log (WAL) buffers

A *write-ahead log (WAL) buffer* holds transaction data that RDS for PostgreSQL later writes to persistent storage. Using the WAL mechanism, RDS for PostgreSQL can do the following:

- Recover data after a failure
- Reduce disk I/O by avoiding frequent writes to disk

When a client changes data, RDS for PostgreSQL writes the changes to the WAL buffer. When the client issues a `COMMIT`, the WAL writer process writes transaction data to the WAL file.

The `wal_level` parameter determines how much information is written to the WAL.

Local memory in RDS for PostgreSQL

Every backend process allocates local memory for query processing.

Topics

- Work memory area
- Maintenance work memory area
- Temporary buffer area

Work memory area

The *work memory area* holds temporary data for queries that performs sorts and hashes. For example, a query with an `ORDER BY` clause performs a sort. Queries use hash tables in hash joins and aggregations.

The `work_mem` parameter the amount of memory to be used by internal sort operations and hash tables before writing to temporary disk files. The default value is 4 MB. Multiple sessions can run simultaneously, and each session can run maintenance operations in parallel. For this reason, the total work memory used can be multiples of the `work_mem` setting.

Maintenance work memory area

The *maintenance work memory area* caches data for maintenance operations. These operations include vacuuming, creating an index, and adding foreign keys.

The `maintenance_work_mem` parameter specifies the maximum amount of memory to be used by maintenance operations. The default value is 64 MB. A database session can only run one maintenance operation at a time.

Temporary buffer area

The *temporary buffer area* caches temporary tables for each database session.

Each session allocates temporary buffers as needed up to the limit you specify. When the session ends, the server clears the buffers.

The `temp_buffers` parameter sets the maximum number of temporary buffers used by each session. Before the first use of temporary tables within a session, you can change the `temp_buffers` value.

RDS for PostgreSQL processes

RDS for PostgreSQL uses multiple processes.

Topics

- Postmaster process
- Backend processes
- Background processes

Postmaster process

The *postmaster process* is the first process started when you start RDS for PostgreSQL. The postmaster process has the following primary responsibilities:

- Fork and monitor background processes
- Receive authentication requests from client processes, and authenticate them before allowing the database to service requests

Backend processes

If the postmaster authenticates a client request, the postmaster forks a new backend process, also called a postgres process. One client process connects to exactly one backend process. The client process and the backend process communicate directly without intervention by the postmaster process.

Background processes

The postmaster process forks several processes that perform different backend tasks. Some of the more important include the following:

- WAL writer

  RDS for PostgreSQL writes data in the WAL (write ahead logging) buffer to the log files. The principle of write ahead logging is that the database can't write changes to the data files until after the database writes log records describing those changes to disk. The WAL mechanism reduces disk I/O, and allows RDS for PostgreSQL to use the logs to recover the database after a failure.

- Background writer

  This process periodically write dirty (modified) pages from the memory buffers to the data files. A page becomes dirty when a backend process modifies it in memory.

- Autovacuum daemon

  The daemon consists of the following:

  - The autovacuum launcher
  - The autovacuum worker processes

  When autovacuum is turned on, it checks for tables that have had a large number of inserted, updated, or deleted tuples. The daemon has the following responsibilities:

  - Recover or reuse disk space occupied by updated or deleted rows
  - Update statistics used by the planner
  - Protect against loss of old data because of transaction ID wraparound

  The autovacuum feature automates the execution of `VACUUM` and `ANALYZE` commands. `VACUUM` has the following variants: standard and full. Standard vacuum runs in parallel with other database operations. `VACUUM FULL` requires an exclusive lock on the table it is working on. Thus, it can't run in parallel with operations that access the same table. `VACUUM` creates a substantial amount of I/O traffic, which can cause poor performance for other active sessions.

RDS for PostgreSQL wait events

The following table lists the wait events for RDS for PostgreSQL that most commonly indicate performance problems, and summarizes the most common causes and corrective actions..

Wait event	Definition
Client:ClientRead	This event occurs when RDS for PostgreSQL is waiting to receive data from the client.
Client:ClientWrite	This event occurs when RDS for PostgreSQL is waiting to write data to the client.
CPU	This event occurs when a thread is active in CPU or is waiting for CPU.
IO:BufFileRead and IO:BufFileWrite	These events occur when RDS for PostgreSQL creates temporary files.
IO:DataFileRead	This event occurs when a connection waits on a backend process to read a required page from storage because the page isn't available in shared memory.
IO:WALWrite	This event occurs when RDS for PostgreSQL is waiting for the write-ahead log (WAL) buffers to be written to a WAL file.
Lock:advisory	This event occurs when a PostgreSQL application uses a lock to coordinate activity across multiple sessions.
Lock:extend	This event occurs when a backend process is waiting to lock a relation to extend it while another process has a lock on that relation for the same purpose.

Wait event	Definition
Lock:Relation	This event occurs when a query is waiting to acquire a lock on a table or view that's currently locked by another transaction.
Lock:transactionid	This event occurs when a transaction is waiting for a row-level lock.
Lock:tuple	This event occurs when a backend process is waiting to acquire a lock on a tuple.
LWLock:BufferMapping (LWLock:buffer_mapping)	This event occurs when a session is waiting to associate a data block with a buffer in the shared buffer pool.
LWLock:BufferIO (IPC:BufferIO)	This event occurs when RDS for PostgreSQL is waiting for other processes to finish their input/output (I/O) operations when concurrently trying to access a page.
LWLock:buffer_content (BufferContent)	This event occurs when a session is waiting to read or write a data page in memory while another session has that page locked for writing.
LWLock:lock_manager (LWLock:lockmanager)	This event occurs when the RDS for PostgreSQL engine maintains the shared lock's memory area to allocate, check, and deallocate a lock when a fast path lock isn't possible.
Timeout:PgSleep	This event occurs when a server process has called the `pg_sleep` function and is waiting for the sleep timeout to expire.
Timeout:VacuumDelay	This event indicates that the vacuum process is sleeping because the estimated cost limit has been reached.

Client:ClientRead

The `Client:ClientRead` event occurs when RDS for PostgreSQL is waiting to receive data from the client.

Topics

Supported engine versions

This wait event information is supported for RDS for PostgreSQL version 10 and higher.

Context

An RDS for PostgreSQL DB instance is waiting to receive data from the client. The RDS for PostgreSQL DB instance must receive the data from the client before it can send more data to the client. The time that the instance waits before receiving data from the client is a `Client:ClientRead` event.

Likely causes of increased waits

Common causes for the `Client:ClientRead` event to appear in top waits include the following:

Increased network latency

There might be increased network latency between the RDS for PostgreSQL DB instance and client. Higher network latency increases the time required for DB instance to receive data from the client.

Increased load on the client

There might be CPU pressure or network saturation on the client. An increase in load on the client can delay transmission of data from the client to the RDS for PostgreSQL DB instance.

Excessive network round trips

A large number of network round trips between the RDS for PostgreSQL DB instance and the client can delay transmission of data from the client to the RDS for PostgreSQL DB instance.

Large copy operation

During a copy operation, the data is transferred from the client's file system to the RDS for PostgreSQL DB instance. Sending a large amount of data to the DB instance can delay transmission of data from the client to the DB instance.

Idle client connection

When a client connects to the RDS for PostgreSQL DB instance in an `idle in transaction` state, the DB instance might wait for the client to send more data or issue a command. A connection in this state can lead to an increase in `Client:ClientRead` events.

PgBouncer used for connection pooling

PgBouncer has a low-level network configuration setting called `pkt_buf`, which is set to 4,096 by default. If the workload is sending query packets larger than 4,096 bytes through PgBouncer, we recommend increasing the `pkt_buf` setting to 8,192. If the new setting doesn't decrease the number of `Client:ClientRead` events, we recommend increasing the `pkt_buf` setting to larger values, such as 16,384 or 32,768. If the query text is large, the larger setting can be particularly helpful.

Actions

We recommend different actions depending on the causes of your wait event.

Topics

- Place the clients in the same Availability Zone and VPC subnet as the instance
- Scale your client
- Use current generation instances
- Increase network bandwidth
- Monitor maximums for network performance
- Monitor for transactions in the "idle in transaction" state

Place the clients in the same Availability Zone and VPC subnet as the instance

To reduce network latency and increase network throughput, place clients in the same Availability Zone and virtual private cloud (VPC) subnet as the RDS for PostgreSQL DB instance. Make sure that the clients are as geographically close to the DB instance as possible.

Scale your client

Using Amazon CloudWatch or other host metrics, determine if your client is currently constrained by CPU or network bandwidth, or both. If the client is constrained, scale your client accordingly.

Use current generation instances

In some cases, you might not be using a DB instance class that supports jumbo frames. If you're running your application on Amazon EC2, consider using a current generation instance for the client. Also, configure the maximum transmission unit (MTU) on the client operating system. This technique might reduce the number of network round trips and increase network throughput. For more information, see Jumbo frames (9001 MTU) in the *Amazon EC2 User Guide*.

For information about DB instance classes, see DB instance classes. To determine the DB instance class that is equivalent to an Amazon EC2 instance type, place `db.` before the Amazon EC2 instance type name. For example, the `r5.8xlarge` Amazon EC2 instance is equivalent to the `db.r5.8xlarge` DB instance class.

Increase network bandwidth

Use `NetworkReceiveThroughput` and `NetworkTransmitThroughput` Amazon CloudWatch metrics to monitor incoming and outgoing network traffic on the DB instance. These metrics can help you to determine if network bandwidth is sufficient for your workload.

If your network bandwidth isn't enough, increase it. If the AWS client or your DB instance is reaching the network bandwidth limits, the only way to increase the bandwidth is to increase your DB instance size. For more information, see DB instance class types.

For more information about CloudWatch metrics, see Amazon CloudWatch metrics for Amazon RDS.

Monitor maximums for network performance

If you are using Amazon EC2 clients, Amazon EC2 provides maximums for network performance metrics, including aggregate inbound and outbound network bandwidth. It also provides connection tracking to ensure that packets are returned as expected and link-local services access for services such as the Domain Name System (DNS). To monitor these maximums, use a current enhanced networking driver and monitor network performance for your client.

For more information, see Monitor network performance for your Amazon EC2 instance in the *Amazon EC2 User Guide* and Monitor network performance for your Amazon EC2 instance in the *Amazon EC2 User Guide*.

Monitor for transactions in the "idle in transaction" state

Check whether you have an increasing number of `idle in transaction` connections. To do this, monitor the `state` column in the `pg_stat_activity` table. You might be able to identify the connection source by running a query similar to the following.

```
select client_addr, state, count(1) from pg_stat_activity
where state like 'idle in transaction%'
group by 1,2
order by 3 desc
```

Client:ClientWrite

The `Client:ClientWrite` event occurs when RDS for PostgreSQL is waiting to write data to the client.

Topics

Supported engine versions

This wait event information is supported for RDS for PostgreSQL version 10 and higher.

Context

A client process must read all of the data received from an RDS for PostgreSQL DB cluster before the cluster can send more data. The time that the cluster waits before sending more data to the client is a `Client:ClientWrite` event.

Reduced network throughput between the RDS for PostgreSQL DB instance and the client can cause this event. CPU pressure and network saturation on the client can also cause this event. *CPU pressure* is when the CPU is fully utilized and there are tasks waiting for CPU time. *Network saturation* is when the network between the database and client is carrying more data than it can handle.

Likely causes of increased waits

Common causes for the `Client:ClientWrite` event to appear in top waits include the following:

Increased network latency

There might be increased network latency between the RDS for PostgreSQL DB instance and client. Higher network latency increases the time required for the client to receive the data.

Increased load on the client

There might be CPU pressure or network saturation on the client. An increase in load on the client delays the reception of data from the RDS for PostgreSQL DB instance.

Large volume of data sent to the client

The RDS for PostgreSQL DB instance might be sending a large amount of data to the client. A client might not be able to receive the data as fast as the cluster is sending it. Activities such as a copy of a large table can result in an increase in `Client:ClientWrite` events.

Actions

We recommend different actions depending on the causes of your wait event.

Topics

- Place the clients in the same Availability Zone and VPC subnet as the cluster
- Use current generation instances
- Reduce the amount of data sent to the client
- Scale your client

Place the clients in the same Availability Zone and VPC subnet as the cluster

To reduce network latency and increase network throughput, place clients in the same Availability Zone and virtual private cloud (VPC) subnet as the RDS for PostgreSQL DB instance.

Use current generation instances

In some cases, you might not be using a DB instance class that supports jumbo frames. If you're running your application on Amazon EC2, consider using a current generation instance for the client. Also, configure the maximum transmission unit (MTU) on the client operating system. This

technique might reduce the number of network round trips and increase network throughput. For more information, see Jumbo frames (9001 MTU) in the *Amazon EC2 User Guide*.

For information about DB instance classes, see DB instance classes. To determine the DB instance class that is equivalent to an Amazon EC2 instance type, place `db.` before the Amazon EC2 instance type name. For example, the `r5.8xlarge` Amazon EC2 instance is equivalent to the `db.r5.8xlarge` DB instance class.

Reduce the amount of data sent to the client

When possible, adjust your application to reduce the amount of data that the RDS for PostgreSQL DB instance sends to the client. Making such adjustments relieves CPU and network contention on the client.

Scale your client

Using Amazon CloudWatch or other host metrics, determine if your client is currently constrained by CPU or network bandwidth, or both. If the client is constrained, scale your client accordingly.

CPU

This event occurs when a thread is active in CPU or is waiting for CPU.

Topics

- Supported engine versions
- Context
- Likely causes of increased waits
- Actions

Supported engine versions

This wait event information is relevant for all all versions of RDS for PostgreSQL.

Context

The *central processing unit (CPU)* is the component of a computer that runs instructions. For example, CPU instructions perform arithmetic operations and exchange data in memory. If a query increases the number of instructions that it performs through the database engine, the time

spent running the query increases. *CPU scheduling* is giving CPU time to a process. Scheduling is orchestrated by the kernel of the operating system.

Topics

How to tell when this wait occurs

This CPU wait event indicates that a backend process is active in CPU or is waiting for CPU. You know that it's occurring when a query shows the following information:

- The `pg_stat_activity.state` column has the value `active`.
- The `wait_event_type` and `wait_event` columns in `pg_stat_activity` are both `null`.

To see the backend processes that are using or waiting on CPU, run the following query.

```
SELECT *
FROM   pg_stat_activity
WHERE  state = 'active'
AND    wait_event_type IS NULL
AND    wait_event IS NULL;
```

DBLoadCPU metric

The Performance Insights metric for CPU is `DBLoadCPU`. The value for `DBLoadCPU` can differ from the value for the Amazon CloudWatch metric `CPUUtilization`. The latter metric is collected from the HyperVisor for a database instance.

os.cpuUtilization metrics

Performance Insights operating-system metrics provide detailed information about CPU utilization. For example, you can display the following metrics:

- `os.cpuUtilization.nice.avg`
- `os.cpuUtilization.total.avg`

- `os.cpuUtilization.wait.avg`
- `os.cpuUtilization.idle.avg`

Performance Insights reports the CPU usage by the database engine as `os.cpuUtilization.nice.avg`.

Likely cause of CPU scheduling

The operating system (OS) kernel handles scheduling for the CPU. When the CPU is *active*, a process might need to wait to get scheduled. The CPU is active while it's performing computations. It's also active while it has an idle thread that it's not running, that is, an idle thread that's waiting on memory I/O. This type of I/O dominates the typical database workload.

Processes are likely to wait to get scheduled on a CPU when the following conditions are met:

- The CloudWatch `CPUUtilization` metric is near 100 percent.
- The average load is greater than the number of vCPUs, indicating a heavy load. You can find the `loadAverageMinute` metric in the OS metrics section in Performance Insights.

Likely causes of increased waits

When the CPU wait event occurs more than normal, possibly indicating a performance problem, typical causes include the following.

Topics

Likely causes of sudden spikes

The most likely causes of sudden spikes are as follows:

- Your application has opened too many simultaneous connections to the database. This scenario is known as a "connection storm."
- Your application workload changed in any of the following ways:
  - New queries

- An increase in the size of your dataset
- Index maintenance or creation
- New functions
- New operators
- An increase in parallel query execution

- Your query execution plans have changed. In some cases, a change can cause an increase in buffers. For example, the query is now using a sequential scan when it previously used an index. In this case, the queries need more CPU to accomplish the same goal.

Likely causes of long-term high frequency

The most likely causes of events that recur over a long period:

- Too many backend processes are running concurrently on CPU. These processes can be parallel workers.
- Queries are performing suboptimally because they need a large number of buffers.

Corner cases

If none of the likely causes turn out to be actual causes, the following situations might be occurring:

- The CPU is swapping processes in and out.
- The CPU might be managing page table entries if the *huge pages* feature has been turned off. This memory management feature is turned on by default for all DB instance classes other than micro, small, and medium DB instance classes. For more information, see Huge pages for RDS for PostgreSQL .

Actions

If the CPU wait event dominates database activity, it doesn't necessarily indicate a performance problem. Respond to this event only when performance degrades.

Topics

- Investigate whether the database is causing the CPU increase
- Determine whether the number of connections increased

- Respond to workload changes

Investigate whether the database is causing the CPU increase

Examine the `os.cpuUtilization.nice.avg` metric in Performance Insights. If this value is far less than the CPU usage, nondatabase processes are the main contributor to CPU.

Determine whether the number of connections increased

Examine the `DatabaseConnections` metric in Amazon CloudWatch. Your action depends on whether the number increased or decreased during the period of increased CPU wait events.

The connections increased

If the number of connections went up, compare the number of backend processes consuming CPU to the number of vCPUs. The following scenarios are possible:

- The number of backend processes consuming CPU is less than the number of vCPUs.

  In this case, the number of connections isn't an issue. However, you might still try to reduce CPU utilization.
- The number of backend processes consuming CPU is greater than the number of vCPUs.

  In this case, consider the following options:
  - Decrease the number of backend processes connected to your database. For example, implement a connection pooling solution such as RDS Proxy. To learn more, see Using Amazon RDS Proxy.
  - Upgrade your instance size to get a higher number of vCPUs.
  - Redirect some read-only workloads to reader nodes, if applicable.

The connections didn't increase

Examine the `blks_hit` metrics in Performance Insights. Look for a correlation between an increase in `blks_hit` and CPU usage. The following scenarios are possible:

- CPU usage and `blks_hit` are correlated.

  In this case, find the top SQL statements that are linked to the CPU usage, and look for plan changes. You can use either of the following techniques:

- Explain the plans manually and compare them to the expected execution plan.
- Look for an increase in block hits per second and local block hits per second. In the **Top SQL** section of Performance Insights dashboard, choose **Preferences**.

- CPU usage and `blks_hit` aren't correlated.

  In this case, determine whether any of the following occurs:

  - The application is rapidly connecting to and disconnecting from the database.

    Diagnose this behavior by turning on `log_connections` and `log_disconnections`, then analyzing the PostgreSQL logs. Consider using the `pgbadger` log analyzer. For more information, see https://github.com/darold/pgbadger.

  - The OS is overloaded.

    In this case, Performance Insights shows that backend processes are consuming CPU for a longer time than usual. Look for evidence in the Performance Insights `os.cpuUtilization` metrics or the CloudWatch `CPUUtilization` metric. If the operating system is overloaded, look at Enhanced Monitoring metrics to diagnose further. Specifically, look at the process list and the percentage of CPU consumed by each process.

  - Top SQL statements are consuming too much CPU.

    Examine statements that are linked to the CPU usage to see whether they can use less CPU. Run an `EXPLAIN` command, and focus on the plan nodes that have the most impact. Consider using a PostgreSQL execution plan visualizer. To try out this tool, see http://explain.dalibo.com/.

Respond to workload changes

If your workload has changed, look for the following types of changes:

New queries

Check whether the new queries are expected. If so, ensure that their execution plans and the number of executions per second are expected.

An increase in the size of the data set

Determine whether partitioning, if it's not already implemented, might help. This strategy might reduce the number of pages that a query needs to retrieve.

Index maintenance or creation

Check whether the schedule for the maintenance is expected. A best practice is to schedule maintenance activities outside of peak activities.

New functions

Check whether these functions perform as expected during testing. Specifically, check whether the number of executions per second is expected.

New operators

Check whether they perform as expected during the testing.

An increase in running parallel queries

Determine whether any of the following situations has occurred:

- The relations or indexes involved have suddenly grown in size so that they differ significantly from `min_parallel_table_scan_size` or `min_parallel_index_scan_size`.
- Recent changes have been made to `parallel_setup_cost` or `parallel_tuple_cost`.
- Recent changes have been made to `max_parallel_workers` or `max_parallel_workers_per_gather`.

IO:BufFileRead and IO:BufFileWrite

The `IO:BufFileRead` and `IO:BufFileWrite` events occur when RDS for PostgreSQL creates temporary files. When operations require more memory than the working memory parameters currently define, they write temporary data to persistent storage. This operation is sometimes called "spilling to disk."

Topics

Supported engine versions

This wait event information is supported for all versions of RDS for PostgreSQL.

Context

`IO:BufFileRead` and `IO:BufFileWrite` relate to the work memory area and maintenance work memory area. For more information about these local memory areas, see Resource Consumption in the PostgreSQL documentation.

The default value for `work_mem` is 4 MB. If one session performs operations in parallel, each worker handling the parallelism uses 4 MB of memory. For this reason, set `work_mem` carefully. If you increase the value too much, a database running many sessions might consume too much memory. If you set the value too low, RDS for PostgreSQL creates temporary files in local storage. The disk I/O for these temporary files can reduce performance.

If you observe the following sequence of events, your database might be generating temporary files:

1. Sudden and sharp decreases in availability
2. Fast recovery for the free space

You might also see a "chainsaw" pattern. This pattern can indicate that your database is creating small files constantly.

Likely causes of increased waits

In general, these wait events are caused by operations that consume more memory than the `work_mem` or `maintenance_work_mem` parameters allocate. To compensate, the operations write to temporary files. Common causes for the `IO:BufFileRead` and `IO:BufFileWrite` events include the following:

Queries that need more memory than exists in the work memory area

Queries with the following characteristics use the work memory area:

- Hash joins
- `ORDER BY` clause
- `GROUP BY` clause
- `DISTINCT`
- Window functions
- `CREATE TABLE AS SELECT`
- Materialized view refresh

Statements that need more memory than exists in the maintenance work memory area

The following statements use the maintenance work memory area:

- `CREATE INDEX`
- `CLUSTER`

Actions

We recommend different actions depending on the causes of your wait event.

Topics

- Identify the problem
- Examine your join queries
- Examine your ORDER BY and GROUP BY queries
- Avoid using the DISTINCT operation
- Consider using window functions instead of GROUP BY functions
- Investigate materialized views and CTAS statements
- Use pg_repack when you rebuild indexes
- Increase maintenance_work_mem when you cluster tables
- Tune memory to prevent IO:BufFileRead and IO:BufFileWrite

Identify the problem

Assume a situation in which Performance Insights isn't turned on and you suspect that `IO:BufFileRead` and `IO:BufFileWrite` are occurring more frequently than is normal. To identify the source of the problem, you can set the `log_temp_files` parameter to log all queries that generate more than your specified threshold KB of temporary files. By default, `log_temp_files` is set to `-1`, which turns off this logging feature. If you set this parameter to `0`, RDS for PostgreSQL logs all temporary files. If you set it to is `1024`, RDS for PostgreSQL logs all queries that produce temporary files larger than 1 MB. For more information about `log_temp_files`, see Error Reporting and Logging in the PostgreSQL documentation.

Examine your join queries

It's likely that your query uses joins. For example, the following query joins four tables.

```
SELECT *
       FROM "order"
 INNER JOIN order_item
       ON (order.id = order_item.order_id)
 INNER JOIN customer
       ON (customer.id = order.customer_id)
 INNER JOIN customer_address
       ON (customer_address.customer_id = customer.id AND
           order.customer_address_id = customer_address.id)
 WHERE customer.id = 1234567890;
```

A possible cause of spikes in temporary file usage is a problem in the query itself. For example, a broken clause might not filter the joins properly. Consider the second inner join in the following example.

```
SELECT *
       FROM "order"
 INNER JOIN order_item
       ON (order.id = order_item.order_id)
 INNER JOIN customer
       ON (customer.id = customer.id)
 INNER JOIN customer_address
       ON (customer_address.customer_id = customer.id AND
           order.customer_address_id = customer_address.id)
 WHERE customer.id = 1234567890;
```

The preceding query mistakenly joins `customer.id` to `customer.id`, generating a Cartesian product between every customer and every order. This type of accidental join generates large temporary files. Depending on the size of the tables, a Cartesian query can even fill up storage. Your application might have Cartesian joins when the following conditions are met:

- You see large, sharp decreases in storage availability, followed by fast recovery.
- No indexes are being created.
- No `CREATE TABLE FROM SELECT` statements are being issued.
- No materialized views are being refreshed.

To see whether the tables are being joined using the proper keys, inspect your query and object-relational mapping directives. Bear in mind that certain queries of your application are not called all the time, and some queries are dynamically generated.

Examine your ORDER BY and GROUP BY queries

In some cases, an ORDER BY clause can result in excessive temporary files. Consider the following guidelines:

- Only include columns in an ORDER BY clause when they need to be ordered. This guideline is especially important for queries that return thousands of rows and specify many columns in the ORDER BY clause.
- Considering creating indexes to accelerate ORDER BY clauses when they match columns that have the same ascending or descending order. Partial indexes are preferable because they are smaller. Smaller indexes are read and traversed more quickly.
- If you create indexes for columns that can accept null values, consider whether you want the null values stored at the end or at the beginning of the indexes.

  If possible, reduce the number of rows that need to be ordered by filtering the result set. If you use WITH clause statements or subqueries, remember that an inner query generates a result set and passes it to the outside query. The more rows that a query can filter out, the less ordering the query needs to do.
- If you don't need to obtain the full result set, use the LIMIT clause. For example, if you only want the top five rows, a query using the LIMIT clause doesn't keep generating results. In this way, the query requires less memory and temporary files.

A query that uses a GROUP BY clause can also require temporary files. GROUP BY queries summarize values by using functions such as the following:

- COUNT
- AVG
- MIN
- MAX
- SUM
- STDDEV

To tune GROUP BY queries, follow the recommendations for ORDER BY queries.

Avoid using the DISTINCT operation

If possible, avoid using the `DISTINCT` operation to remove duplicated rows. The more unnecessary and duplicated rows that your query returns, the more expensive the `DISTINCT` operation becomes. If possible, add filters in the `WHERE` clause even if you use the same filters for different tables. Filtering the query and joining correctly improves your performance and reduces resource use. It also prevents incorrect reports and results.

If you need to use `DISTINCT` for multiple rows of a same table, consider creating a composite index. Grouping multiple columns in an index can improve the time to evaluate distinct rows. Also, if you use RDS for PostgreSQL version 10 or higher, you can correlate statistics among multiple columns by using the `CREATE STATISTICS` command.

Consider using window functions instead of GROUP BY functions

Using `GROUP BY`, you change the result set, and then retrieve the aggregated result. Using window functions, you aggregate data without changing the result set. A window function uses the `OVER` clause to perform calculations across the sets defined by the query, correlating one row with another. You can use all the `GROUP BY` functions in window functions, but also use functions such as the following:

- `RANK`
- `ARRAY_AGG`
- `ROW_NUMBER`
- `LAG`
- `LEAD`

To minimize the number of temporary files generated by a window function, remove duplications for the same result set when you need two distinct aggregations. Consider the following query.

```
SELECT sum(salary) OVER (PARTITION BY dept ORDER BY salary DESC) as sum_salary
     , avg(salary) OVER (PARTITION BY dept ORDER BY salary ASC) as avg_salary
  FROM empsalary;
```

You can rewrite the query with the `WINDOW` clause as follows.

```
SELECT sum(salary) OVER w as sum_salary
```

```
        , avg(salary) OVER w as_avg_salary
    FROM empsalary
WINDOW w AS (PARTITION BY dept ORDER BY salary DESC);
```

By default, the RDS for PostgreSQL execution planner consolidates similar nodes so that it doesn't duplicate operations. However, by using an explicit declaration for the window block, you can maintain the query more easily. You might also improve performance by preventing duplication.

Investigate materialized views and CTAS statements

When a materialized view refreshes, it runs a query. This query can contain an operation such as `GROUP BY`, `ORDER BY`, or `DISTINCT`. During a refresh, you might observe large numbers of temporary files and the wait events `IO:BufFileWrite` and `IO:BufFileRead`. Similarly, when you create a table based on a `SELECT` statement, the `CREATE TABLE` statement runs a query. To reduce the temporary files needed, optimize the query.

Use pg_repack when you rebuild indexes

When you create an index, the engine orders the result set. As tables grow in size, and as values in the indexed column become more diverse, the temporary files require more space. In most cases, you can't prevent the creation of temporary files for large tables without modifying the maintenance work memory area. For more information about `maintenance_work_mem`, see https://www.postgresql.org/docs/current/runtime-config-resource.html in the PostgreSQL documentation.

A possible workaround when recreating a large index is to use the pg_repack extension. For more information, see Reorganize tables in PostgreSQL databases with minimal locks in the pg_repack documentation. For information about setting up the extension in your RDS for PostgreSQL DB instance, see Reducing bloat in tables and indexes with the pg_repack extension.

Increase maintenance_work_mem when you cluster tables

The `CLUSTER` command clusters the table specified by *table_name* based on an existing index specified by *index_name*. RDS for PostgreSQL physically recreates the table to match the order of a given index.

When magnetic storage was prevalent, clustering was common because storage throughput was limited. Now that SSD-based storage is common, clustering is less popular. However, if you cluster tables, you can still increase performance slightly depending on the table size, index, query, and so on.

If you run the CLUSTER command and observe the wait events `IO:BufFileWrite` and `IO:BufFileRead`, tune `maintenance_work_mem`. Increase the memory size to a fairly large amount. A high value means that the engine can use more memory for the clustering operation.

Tune memory to prevent IO:BufFileRead and IO:BufFileWrite

In some situations, you need to tune memory. Your goal is to balance memory across the following areas of consumption using the appropriate parameters, as follows.

- The `work_mem` value
- The memory remaining after discounting the `shared_buffers` value
- The maximum connections opened and in use, which is limited by `max_connections`

For more information about tuning memory, see Resource Consumption in the PostgreSQL documentation.

Increase the size of the work memory area

In some situations, your only option is to increase the memory used by your session. If your queries are correctly written and are using the correct keys for joins, consider increasing the `work_mem` value.

To find out how many temporary files a query generates, set `log_temp_files` to `0`. If you increase the `work_mem` value to the maximum value identified in the logs, you prevent the query from generating temporary files. However, `work_mem` sets the maximum per plan node for each connection or parallel worker. If the database has 5,000 connections, and if each one uses 256 MiB memory, the engine needs 1.2 TiB of RAM. Thus, your instance might run out of memory.

Reserve sufficient memory for the shared buffer pool

Your database uses memory areas such as the shared buffer pool, not just the work memory area. Consider the requirements of these additional memory areas before you increase `work_mem`.

For example, assume that your RDS for PostgreSQL instance class is db.r5.2xlarge. This class has 64 GiB of memory. By default, 25 percent of the memory is reserved for the shared buffer pool. After you subtract the amount allocated to the shared memory area, 16,384 MB remains. Don't allocate the remaining memory exclusively to the work memory area because the operating system and the engine also require memory.

The memory that you can allocate to `work_mem` depends on the instance class. If you use a larger instance class, more memory is available. However, in the preceding example, you can't use more than 16 GiB. Otherwise, your instance becomes unavailable when it runs out of memory. To recover the instance from the unavailable state, the RDS for PostgreSQL automation services automatically restart.

Manage the number of connections

Suppose that your database instance has 5,000 simultaneous connections. Each connection uses at least 4 MiB of `work_mem`. The high memory consumption of the connections is likely to degrade performance. In response, you have the following options:

- Upgrade to a larger instance class.
- Decrease the number of simultaneous database connections by using a connection proxy or pooler.

For proxies, consider Amazon RDS Proxy, pgBouncer, or a connection pooler based on your application. This solution alleviates the CPU load. It also reduces the risk when all connections require the work memory area. When fewer database connections exist, you can increase the value of `work_mem`. In this way, you reduce the occurrence of the `IO:BufFileRead` and `IO:BufFileWrite` wait events. Also, the queries waiting for the work memory area speed up significantly.

IO:DataFileRead

The `IO:DataFileRead` event occurs when a connection waits on a backend process to read a required page from storage because the page isn't available in shared memory.

Topics

Supported engine versions

This wait event information is supported for all versions of RDS for PostgreSQL.

Context

All queries and data manipulation (DML) operations access pages in the buffer pool. Statements that can induce reads include SELECT, UPDATE, and DELETE. For example, an UPDATE can read pages from tables or indexes. If the page being requested or updated isn't in the shared buffer pool, this read can lead to the IO:DataFileRead event.

Because the shared buffer pool is finite, it can fill up. In this case, requests for pages that aren't in memory force the database to read blocks from disk. If the IO:DataFileRead event occurs frequently, your shared buffer pool might be too small to accommodate your workload. This problem is acute for SELECT queries that read a large number of rows that don't fit in the buffer pool. For more information about the buffer pool, see Resource Consumption in the PostgreSQL documentation.

Likely causes of increased waits

Common causes for the IO:DataFileRead event include the following:

Connection spikes

You might find multiple connections generating the same number of IO:DataFileRead wait events. In this case, a spike (sudden and large increase) in IO:DataFileRead events can occur.

SELECT and DML statements performing sequential scans

Your application might be performing a new operation. Or an existing operation might change because of a new execution plan. In such cases, look for tables (particularly large tables) that have a greater seq_scan value. Find them by querying pg_stat_user_tables. To track queries that are generating more read operations, use the extension pg_stat_statements.

CTAS and CREATE INDEX for large data sets

A *CTAS* is a CREATE TABLE AS SELECT statement. If you run a CTAS using a large data set as a source, or create an index on a large table, the IO:DataFileRead event can occur. When you create an index, the database might need to read the entire object using a sequential scan. A CTAS generates IO:DataFile reads when pages aren't in memory.

Multiple vacuum workers running at the same time

Vacuum workers can be triggered manually or automatically. We recommend adopting an aggressive vacuum strategy. However, when a table has many updated or deleted rows,

the IO:DataFileRead waits increase. After space is reclaimed, the vacuum time spent on IO:DataFileRead decreases.

Ingesting large amounts of data

When your application ingests large amounts of data, ANALYZE operations might occur more often. The ANALYZE process can be triggered by an autovacuum launcher or invoked manually.

The ANALYZE operation reads a subset of the table. The number of pages that must be scanned is calculated by multiplying 30 by the default_statistics_target value. For more information, see the PostgreSQL documentation. The default_statistics_target parameter accepts values between 1 and 10,000, where the default is 100.

Resource starvation

If instance network bandwidth or CPU are consumed, the IO:DataFileRead event might occur more frequently.

Actions

We recommend different actions depending on the causes of your wait event.

Topics

- Check predicate filters for queries that generate waits
- Minimize the effect of maintenance operations
- Respond to high numbers of connections

Check predicate filters for queries that generate waits

Assume that you identify specific queries that are generating IO:DataFileRead wait events. You might identify them using the following techniques:

- Performance Insights
- Catalog views such as the one provided by the extension pg_stat_statements
- The catalog view pg_stat_all_tables, if it periodically shows an increased number of physical reads
- The pg_statio_all_tables view, if it shows that _read counters are increasing

We recommend that you determine which filters are used in the predicate (WHERE clause) of these queries. Follow these guidelines:

- Run the EXPLAIN command. In the output, identify which types of scans are used. A sequential scan doesn't necessarily indicate a problem. Queries that use sequential scans naturally produce more IO:DataFileRead events when compared to queries that use filters.

  Find out whether the column listed in the WHERE clause is indexed. If not, consider creating an index for this column. This approach avoids the sequential scans and reduces the IO:DataFileRead events. If a query has restrictive filters and still produces sequential scans, evaluate whether the proper indexes are being used.
- Find out whether the query is accessing a very large table. In some cases, partitioning a table can improve performance, allowing the query to only read necessary partitions.
- Examine the cardinality (total number of rows) from your join operations. Note how restrictive the values are that you're passing in the filters for your WHERE clause. If possible, tune your query to reduce the number of rows that are passed in each step of the plan.

Minimize the effect of maintenance operations

Maintenance operations such as VACUUM and ANALYZE are important. We recommend that you don't turn them off because you find IO:DataFileRead wait events related to these maintenance operations. The following approaches can minimize the effect of these operations:

- Run maintenance operations manually during off-peak hours. This technique prevents the database from reaching the threshold for automatic operations.
- For very large tables, consider partitioning the table. This technique reduces the overhead of maintenance operations. The database only accesses the partitions that require maintenance.
- When you ingest large amounts of data, consider disabling the autoanalyze feature.

The autovacuum feature is automatically triggered for a table when the following formula is true.

```
pg_stat_user_tables.n_dead_tup > (pg_class.reltuples x autovacuum_vacuum_scale_factor)
 + autovacuum_vacuum_threshold
```

The view pg_stat_user_tables and catalog pg_class have multiple rows. One row can correspond to one row in your table. This formula assumes that the reltuples are for a specific table. The parameters autovacuum_vacuum_scale_factor (0.20 by default) and

`autovacuum_vacuum_threshold` (50 tuples by default) are usually set globally for the whole instance. However, you can set different values for a specific table.

Topics

- Find tables consuming space unnecessarily
- Find indexes consuming space unnecessarily
- Find tables that are eligible to be autovacuumed

Find tables consuming space unnecessarily

To find tables consuming space unnecessarily, you can use functions from the PostgreSQL `pgstattuple` extension. This extension (module) is available by default on all RDS for PostgreSQL DB instances and can be instantiated on the instance with the following command.

```
CREATE EXTENSION pgstattuple;
```

For more information about this extension, see pgstattuple in the PostgreSQL documentation.

You can check for table and index bloat in your application. For more information, see Diagnosing table and index bloat.

Find indexes consuming space unnecessarily

To find bloated indexes and estimate the amount of space consumed unnecessarily on the tables for which you have read privileges, you can run the following query.

```
-- WARNING: rows with is_na = 't' are known to have bad statistics ("name" type is not
 supported).
-- This query is compatible with PostgreSQL 8.2 and later.

SELECT current_database(), nspname AS schemaname, tblname, idxname,
 bs*(relpages)::bigint AS real_size,
  bs*(relpages-est_pages)::bigint AS extra_size,
  100 * (relpages-est_pages)::float / relpages AS extra_ratio,
  fillfactor, bs*(relpages-est_pages_ff) AS bloat_size,
  100 * (relpages-est_pages_ff)::float / relpages AS bloat_ratio,
  is_na
  -- , 100-(sub.pst).avg_leaf_density, est_pages, index_tuple_hdr_bm,
  -- maxalign, pagehdr, nulldatawidth, nulldatahdrwidth, sub.reltuples, sub.relpages
  -- (DEBUG INFO)
FROM (
```

```
  SELECT coalesce(1 +
       ceil(reltuples/floor((bs-pageopqdata-pagehdr)/(4+nulldatahdrwidth)::float)), 0
       -- ItemIdData size + computed avg size of a tuple (nulldatahdrwidth)
    ) AS est_pages,
    coalesce(1 +
       ceil(reltuples/floor((bs-pageopqdata-pagehdr)*fillfactor/
(100*(4+nulldatahdrwidth)::float))), 0
    ) AS est_pages_ff,

 pg_catalog.pg_get_indexdef(a.attrelid, a.attnum, TRUE))
         -- stats from tbl
         OR  (s.tablename = i.idxname AND s.attname = a.attname))
         -- stats from functional cols
       JOIN pg_type AS t ON a.atttypid = t.oid
     WHERE a.attnum > 0
     GROUP BY 1, 2, 3, 4, 5, 6, 7, 8, 9
   ) AS s1
  ) AS s2
   JOIN pg_am am ON s2.relam = am.oid WHERE am.amname = 'btree'
) AS sub
-- WHERE NOT is_na
ORDER BY 2,3,4;
```

Find tables that are eligible to be autovacuumed

To find tables that are eligible to be autovacuumed, run the following query.

```
--This query shows tables that need vacuuming and are eligible candidates.
--The following query lists all tables that are due to be processed by autovacuum.
-- During normal operation, this query should return very little.

```

Respond to high numbers of connections

When you monitor Amazon CloudWatch, you might find that the `DatabaseConnections` metric spikes. This increase indicates an increased number of connections to your database. We recommend the following approach:

- Limit the number of connections that the application can open with each instance. If your application has an embedded connection pool feature, set a reasonable number of connections. Base the number on what the vCPUs in your instance can parallelize effectively.

  If your application doesn't use a connection pool feature, considering using Amazon RDS Proxy or an alternative. This approach lets your application open multiple connections with the load balancer. The balancer can then open a restricted number of connections with the database. As fewer connections are running in parallel, your DB instance performs less context switching in the kernel. Queries should progress faster, leading to fewer wait events. For more information, see Using Amazon RDS Proxy.
- Whenever possible, take advantage of read replicas for RDS for PostgreSQL. When your application runs a read-only operation, send these requests to the read replica(s). This technique reduces the I/O pressure on the primary (writer) node.
- Consider scaling up your DB instance. A higher-capacity instance class gives more memory, which gives RDS for PostgreSQL a larger shared buffer pool to hold pages. The larger size also gives the DB instance more vCPUs to handle connections. More vCPUs are particularly helpful when the operations that are generating `IO:DataFileRead` wait events are writes.

IO:WALWrite

Topics

- Supported engine versions
- Context
- Likely causes of increased waits

- Actions

Supported engine versions

This wait event information is supported for all versions of RDS for PostgreSQL 10 and higher.

Context

Activity in the database that's generating write-ahead log data fills up the WAL buffers first and then writes to disk, asynchronously. The wait event `IO:WALWrite` is generated when the SQL session is waiting for the WAL data to complete writing to disk so that it can release the transaction's COMMIT call.

Likely causes of increased waits

If this wait event occurs often, you should review your workload and the type of updates that your workload performs and their frequency. In particular, look for the following types of activity.

Heavy DML activity

Changing data in database tables doesn't happen instantaneously. An insert to one table might need to wait for an insert or an update to the same table from another client. The data manipulation language (DML) statements for changing data values (INSERT, UPDATE, DELETE, COMMIT, ROLLBACK TRANSACTION) can result in contention that causes the write-ahead logfile to be waiting for the buffers to be flushed. This situation is captured in the following Amazon RDS Performance Insights metrics that indicate heavy DML activity.

- `tup_inserted`
- `tup_updated`
- `tup_deleted`
- `xact_rollback`
- `xact_commit`

For more information about these metrics, see Performance Insights counters for Amazon RDS for PostgreSQL.

Frequent checkpoint activity

Frequent checkpoints contribute to larger WAL size. In RDS for PostgreSQL, full page writes are always "on." Full page writes help protect against data loss. However, when checkpointing occurs too frequently, the system can suffer overall performance issues. This is especially true on systems with heavy DML activity. In some cases, you might find error messages in your `postgresql.log` stating that “checkpoints are occurring too frequently."

We recommend that when tuning checkpoints, you carefully balance performance against expected time need to recover in the event of an abnormal shutdown.

Actions

We recommend the following actions to reduce the numbers of this wait event.

Topics

- Reduce the number of commits
- Monitor your checkpoints
- Scale up IO
- Dedicated log volume (DLV)

Reduce the number of commits

To reduce the number of commits, you can combine statements into transaction blocks. Use Amazon RDS Performance Insights to examine the type of queries being run. You can also move large maintenance operations to off-peak hours. For example, create indexes or use `pg_repack` operations during non-production hours.

Monitor your checkpoints

There are two parameters that you can monitor to see how frequently your RDS for PostgreSQL DB instance is writing to the WAL file for checkpoints.

- `log_checkpoints` – This parameter is set to "on" by default. It causes a message to get sent to the PostgreSQL log for each checkpoint. These log messages include the number of buffers written, the time spent writing them, and the number of WAL files added, removed, or recycled for the given checkpoint.

For more information about this parameter, see Error Reporting and Logging in the PostgreSQL documentation.

- `checkpoint_warning` – This parameter sets a threshold value (in seconds) for checkpoint frequency above which a warning is generated. By default, this parameter isn't set in RDS for PostgreSQL. You can set the value of this parameter to get a warning when the database changes in your RDS for PostgreSQL DB instance are written at a rate for which the WAL files are not sized to handle. For example, say you set this parameter to 30. If your RDS for PostgreSQL instance needs to write changes more often than every 30 seconds, the warning that "checkpoints are occurring too frequently" is sent to the PostgreSQL log. This can indicate that your `max_wal_size` value should be increased.

  For more information, see Write Ahead Log in the PostgreSQL documentation.

Scale up IO

This type of input/output (IO) wait event can remediated by scaling the input/output operations per second (IOPs) to provide faster IO. Scaling IO is preferable to scaling CPU, because scaling CPU can result in even more IO contention because the increased CPU can handle more work and thus make the IO bottleneck even worse. In general, we recommend that you consider tuning your workload before performing scaling operations.

Dedicated log volume (DLV)

You can use a dedicated log volume (DLV) for a DB instance that uses Provisioned IOPS (PIOPS) storage by using the Amazon RDS console, AWS CLI, or Amazon RDS API. A DLV moves PostgreSQL database transaction logs to a storage volume that's separate from the volume containing the database tables. For more information, see Dedicated log volume (DLV).

Lock:advisory

The `Lock:advisory` event occurs when a PostgreSQL application uses a lock to coordinate activity across multiple sessions.

Topics

- Relevant engine versions
- Context
- Causes

- Actions

Relevant engine versions

This wait event information is relevant for RDS for PostgreSQL versions 9.6 and higher.

Context

PostgreSQL advisory locks are application-level, cooperative locks explicitly locked and unlocked by the user's application code. An application can use PostgreSQL advisory locks to coordinate activity across multiple sessions. Unlike regular, object- or row-level locks, the application has full control over the lifetime of the lock. For more information, see Advisory Locks in the PostgreSQL documentation.

Advisory locks can be released before a transaction ends or be held by a session across transactions. This isn't true for implicit, system-enforced locks, such as an access-exclusive lock on a table acquired by a `CREATE INDEX` statement.

For a description of the functions used to acquire (lock) and release (unlock) advisory locks, see Advisory Lock Functions in the PostgreSQL documentation.

Advisory locks are implemented on top of the regular PostgreSQL locking system and are visible in the `pg_locks` system view.

Causes

This lock type is exclusively controlled by an application explicitly using it. Advisory locks that are acquired for each row as part of a query can cause a spike in locks or a long-term buildup.

These effects happen when the query is run in a way that acquires locks on more rows than are returned by the query. The application must eventually release every lock, but if locks are acquired on rows that aren't returned, the application can't find all of the locks.

The following example is from Advisory Locks in the PostgreSQL documentation.

```
SELECT pg_advisory_lock(id) FROM foo WHERE id > 12345 LIMIT 100;
```

In this example, the `LIMIT` clause can only stop the query's output after the rows have already been internally selected and their ID values locked. This can happen suddenly when a growing

data volume causes the planner to choose a different execution plan that wasn't tested during development. The buildup in this case happens because the application explicitly calls `pg_advisory_unlock` for every ID value that was locked. However, in this case it can't find the set of locks acquired on rows that weren't returned. Because the locks are acquired on the session level, they aren't released automatically at the end of the transaction.

Another possible cause for spikes in blocked lock attempts is unintended conflicts. In these conflicts, unrelated parts of the application share the same lock ID space by mistake.

Actions

Review application usage of advisory locks and detail where and when in the application flow each type of advisory lock is acquired and released.

Determine whether a session is acquiring too many locks or a long-running session isn't releasing locks early enough, leading to a slow buildup of locks. You can correct a slow buildup of session-level locks by ending the session using `pg_terminate_backend(pid)`.

A client waiting for an advisory lock appears in `pg_stat_activity` with `wait_event_type=Lock` and `wait_event=advisory`. You can obtain specific lock values by querying the `pg_locks` system view for the same `pid`, looking for `locktype=advisory` and `granted=f`.

You can then identify the blocking session by querying `pg_locks` for the same advisory lock having `granted=t`, as shown in the following example.

```
SELECT blocked_locks.pid AS blocked_pid,
         blocking_locks.pid AS blocking_pid,
         blocked_activity.usename AS blocked_user,
         blocking_activity.usename AS blocking_user,
         now() - blocked_activity.xact_start AS blocked_transaction_duration,
         now() - blocking_activity.xact_start AS blocking_transaction_duration,
         concat(blocked_activity.wait_event_type,':',blocked_activity.wait_event) AS
 blocked_wait_event,
         concat(blocking_activity.wait_event_type,':',blocking_activity.wait_event) AS
 blocking_wait_event,
         blocked_activity.state AS blocked_state,
         blocking_activity.state AS blocking_state,
         blocked_locks.locktype AS blocked_locktype,
         blocking_locks.locktype AS blocking_locktype,
         blocked_activity.query AS blocked_statement,
```

```
         blocking_activity.query AS blocking_statement
   FROM pg_catalog.pg_locks blocked_locks
   JOIN pg_catalog.pg_stat_activity blocked_activity ON blocked_activity.pid =
blocked_locks.pid
   JOIN pg_catalog.pg_locks blocking_locks
       ON blocking_locks.locktype = blocked_locks.locktype
       AND blocking_locks.DATABASE IS NOT DISTINCT FROM blocked_locks.DATABASE
       AND blocking_locks.relation IS NOT DISTINCT FROM blocked_locks.relation
       AND blocking_locks.page IS NOT DISTINCT FROM blocked_locks.page
       AND blocking_locks.tuple IS NOT DISTINCT FROM blocked_locks.tuple
       AND blocking_locks.virtualxid IS NOT DISTINCT FROM blocked_locks.virtualxid
       AND blocking_locks.transactionid IS NOT DISTINCT FROM
blocked_locks.transactionid
       AND blocking_locks.classid IS NOT DISTINCT FROM blocked_locks.classid
       AND blocking_locks.objid IS NOT DISTINCT FROM blocked_locks.objid
       AND blocking_locks.objsubid IS NOT DISTINCT FROM blocked_locks.objsubid
       AND blocking_locks.pid != blocked_locks.pid
   JOIN pg_catalog.pg_stat_activity blocking_activity ON blocking_activity.pid =
blocking_locks.pid
   WHERE NOT blocked_locks.GRANTED;
```

All of the advisory lock API functions have two sets of arguments, either one `bigint` argument or two `integer` arguments:

- For the API functions with one `bigint` argument, the upper 32 bits are in `pg_locks.classid` and the lower 32 bits are in `pg_locks.objid`.
- For the API functions with two `integer` arguments, the first argument is `pg_locks.classid` and the second argument is `pg_locks.objid`.

The `pg_locks.objsubid` value indicates which API form was used: 1 means one `bigint` argument; 2 means two `integer` arguments.

Lock:extend

The `Lock:extend` event occurs when a backend process is waiting to lock a relation to extend it while another process has a lock on that relation for the same purpose.

Topics

- Supported engine versions
- Context

Supported engine versions

This wait event information is supported for all versions of RDS for PostgreSQL.

Context

The event `Lock:extend` indicates that a backend process is waiting to extend a relation that another backend process holds a lock on while it's extending that relation. Because only one process at a time can extend a relation, the system generates a `Lock:extend` wait event. `INSERT`, `COPY`, and `UPDATE` operations can generate this event.

Likely causes of increased waits

When the `Lock:extend` event appears more than normal, possibly indicating a performance problem, typical causes include the following:

Surge in concurrent inserts or updates to the same table

There might be an increase in the number of concurrent sessions with queries that insert into or update the same table.

Insufficient network bandwidth

The network bandwidth on the DB instance might be insufficient for the storage communication needs of the current workload. This can contribute to storage latency that causes an increase in `Lock:extend` events.

Actions

We recommend different actions depending on the causes of your wait event.

Topics

Reduce concurrent inserts and updates to the same relation

First, determine whether there's an increase in `tup_inserted` and `tup_updated` metrics and an accompanying increase in this wait event. If so, check which relations are in high contention for insert and update operations. To determine this, query the `pg_stat_all_tables` view for the values in `n_tup_ins` and `n_tup_upd` fields. For information about the `pg_stat_all_tables` view, see pg_stat_all_tables in the PostgreSQL documentation.

To get more information about blocking and blocked queries, query `pg_stat_activity` as in the following example:

```
SELECT
    blocked.pid,
    blocked.usename,
    blocked.query,
    blocking.pid AS blocking_id,
    blocking.query AS blocking_query,
    blocking.wait_event AS blocking_wait_event,
    blocking.wait_event_type AS blocking_wait_event_type
FROM pg_stat_activity AS blocked
JOIN pg_stat_activity AS blocking ON blocking.pid = ANY(pg_blocking_pids(blocked.pid))
where
blocked.wait_event = 'extend'
and blocked.wait_event_type = 'Lock';

   pid  | usename  |            query             | blocking_id |
            blocking_query                          | blocking_wait_event |
 blocking_wait_event_type
  ------+----------+------------------------------+-------------
+-------------------------------------------------------------------
+---------------------+--------------------------
   7143 |  myuser  | insert into tab1 values (1); |        4600 | INSERT INTO tab1 (a)
 SELECT s FROM generate_series(1,1000000) s; | DataFileExtend      | IO
```

After you identify relations that contribute to increase `Lock:extend` events, use the following techniques to reduce the contention:

- Find out whether you can use partitioning to reduce contention for the same table. Separating inserted or updated tuples into different partitions can reduce contention. For information about partitioning, see Managing PostgreSQL partitions with the pg_partman extension.

- If the wait event is mainly due to update activity, consider reducing the relation's fillfactor value. This can reduce requests for new blocks during the update. The fillfactor is a storage parameter for a table that determines the maximum amount of space for packing a table page. It's expressed as a percentage of the total space for a page. For more information about the fillfactor parameter, see CREATE TABLE in the PostgreSQL documentation.

> **Important**
>
> We highly recommend that you test your system if you change the fillfactor because changing this value can negatively impact performance, depending on your workload.

Increase network bandwidth

To see whether there's an increase in write latency, check the `WriteLatency` metric in CloudWatch. If there is, use the `WriteThroughput` and `ReadThroughput` Amazon CloudWatch metrics to monitor the storage related traffic on the DB instance. These metrics can help you to determine if network bandwidth is sufficient for the storage activity of your workload.

If your network bandwidth isn't enough, increase it. If your DB instance is reaching the network bandwidth limits, the only way to increase the bandwidth is to increase your DB instance size.

For more information about CloudWatch metrics, see Amazon CloudWatch instance-level metrics for Amazon RDS. For information about network performance for each DB instance class, see Amazon CloudWatch instance-level metrics for Amazon RDS.

Lock:Relation

The `Lock:Relation` event occurs when a query is waiting to acquire a lock on a table or view (relation) that's currently locked by another transaction.

Topics

- Supported engine versions
- Context
- Likely causes of increased waits
- Actions

Supported engine versions

This wait event information is supported for all versions of RDS for PostgreSQL.

Context

Most PostgreSQL commands implicitly use locks to control concurrent access to data in tables. You can also use these locks explicitly in your application code with the `LOCK` command. Many lock modes aren't compatible with each other, and they can block transactions when they're trying to access the same object. When this happens, RDS for PostgreSQL generates a `Lock:Relation` event. Some common examples are the following:

- Exclusive locks such as `ACCESS EXCLUSIVE` can block all concurrent access. Data definition language (DDL) operations such as `DROP TABLE`, `TRUNCATE`, `VACUUM FULL`, and `CLUSTER` acquire `ACCESS EXCLUSIVE` locks implicitly. `ACCESS EXCLUSIVE` is also the default lock mode for `LOCK TABLE` statements that don't specify a mode explicitly.
- Using `CREATE INDEX (without CONCURRENT)` on a table conflicts with data manipulation language (DML) statements `UPDATE`, `DELETE`, and `INSERT`, which acquire `ROW EXCLUSIVE` locks.

For more information about table-level locks and conflicting lock modes, see Explicit Locking in the PostgreSQL documentation.

Blocking queries and transactions typically unblock in one of the following ways:

- Blocking query – The application can cancel the query or the user can end the process. The engine can also force the query to end because of a session's statement-timeout or a deadlock detection mechanism.
- Blocking transaction – A transaction stops blocking when it runs a `ROLLBACK` or `COMMIT` statement. Rollbacks also happen automatically when sessions are disconnected by a client or by network issues, or are ended. Sessions can be ended when the database engine is shut down, when the system is out of memory, and so forth.

Likely causes of increased waits

When the `Lock:Relation` event occurs more frequently than normal, it can indicate a performance issue. Typical causes include the following:

Increased concurrent sessions with conflicting table locks

There might be an increase in the number of concurrent sessions with queries that lock the same table with conflicting locking modes.

Maintenance operations

Health maintenance operations such as `VACUUM` and `ANALYZE` can significantly increase the number of conflicting locks. `VACUUM FULL` acquires an `ACCESS EXCLUSIVE` lock, and `ANALYSE` acquires a `SHARE UPDATE EXCLUSIVE` lock. Both types of locks can cause a `Lock:Relation` wait event. Application data maintenance operations such as refreshing a materialized view can also increase blocked queries and transactions.

Locks on reader instances

There might be a conflict between the relation locks held by the writer and readers. Currently, only `ACCESS EXCLUSIVE` relation locks are replicated to reader instances. However, the `ACCESS EXCLUSIVE` relation lock will conflict with any `ACCESS SHARE` relation locks held by the reader. This can cause an increase in lock relation wait events on the reader.

Actions

We recommend different actions depending on the causes of your wait event.

Topics

- Reduce the impact of blocking SQL statements
- Minimize the effect of maintenance operations

Reduce the impact of blocking SQL statements

To reduce the impact of blocking SQL statements, modify your application code where possible. Following are two common techniques for reducing blocks:

- Use the `NOWAIT` option – Some SQL commands, such as `SELECT` and `LOCK` statements, support this option. The `NOWAIT` directive cancels the lock-requesting query if the lock can't be acquired immediately. This technique can help prevent a blocking session from causing a pile-up of blocked sessions behind it.

  For example: Assume that transaction A is waiting on a lock held by transaction B. Now, if B requests a lock on a table that’s locked by transaction C, transaction A might be blocked until

transaction C completes. But if transaction B uses a `NOWAIT` when it requests the lock on C, it can fail fast and ensure that transaction A doesn't have to wait indefinitely.

- Use `SET lock_timeout` – Set a `lock_timeout` value to limit the time a SQL statement waits to acquire a lock on a relation. If the lock isn't acquired within the timeout specified, the transaction requesting the lock is cancelled. Set this value at the session level.

Minimize the effect of maintenance operations

Maintenance operations such as `VACUUM` and `ANALYZE` are important. We recommend that you don't turn them off because you find `Lock:Relation` wait events related to these maintenance operations. The following approaches can minimize the effect of these operations:

- Run maintenance operations manually during off-peak hours.
- To reduce `Lock:Relation` waits caused by autovacuum tasks, perform any needed autovacuum tuning. For information about tuning autovacuum, see Working with PostgreSQL autovacuum on Amazon RDS in the *Amazon RDS User Guide*.

Lock:transactionid

The `Lock:transactionid` event occurs when a transaction is waiting for a row-level lock.

Topics

Supported engine versions

This wait event information is supported for all versions of RDS for PostgreSQL.

Context

The event `Lock:transactionid` occurs when a transaction is trying to acquire a row-level lock that has already been granted to a transaction that is running at the same time. The session that

shows the `Lock:transactionid` wait event is blocked because of this lock. After the blocking transaction ends in either a `COMMIT` or `ROLLBACK` statement, the blocked transaction can proceed.

The multiversion concurrency control semantics of RDS for PostgreSQL guarantee that readers don't block writers and writers don't block readers. For row-level conflicts to occur, blocking and blocked transactions must issue conflicting statements of the following types:

- `UPDATE`
- `SELECT … FOR UPDATE`
- `SELECT … FOR KEY SHARE`

The statement `SELECT … FOR KEY SHARE` is a special case. The database uses the clause `FOR KEY SHARE` to optimize the performance of referential integrity. A row-level lock on a row can block `INSERT`, `UPDATE`, and `DELETE` commands on other tables that reference the row.

Likely causes of increased waits

When this event appears more than normal, the cause is typically `UPDATE`, `SELECT … FOR UPDATE`, or `SELECT … FOR KEY SHARE` statements combined with the following conditions.

Topics

High concurrency

RDS for PostgreSQL can use granular row-level locking semantics. The probability of row-level conflicts increases when the following conditions are met:

- A highly concurrent workload contends for the same rows.
- Concurrency increases.

Idle in transaction

Sometimes the `pg_stat_activity.state` column shows the value `idle in transaction`. This value appears for sessions that have started a transaction, but haven't yet issued a `COMMIT`

or ROLLBACK. If the pg_stat_activity.state value isn't active, the query shown in pg_stat_activity is the most recent one to finish running. The blocking session isn't actively processing a query because an open transaction is holding a lock.

If an idle transaction acquired a row-level lock, it might be preventing other sessions from acquiring it. This condition leads to frequent occurrence of the wait event Lock:transactionid. To diagnose the issue, examine the output from pg_stat_activity and pg_locks.

Long-running transactions

Transactions that run for a long time get locks for a long time. These long-held locks can block other transactions from running.

Actions

Row-locking is a conflict among UPDATE, SELECT … FOR UPDATE, or SELECT … FOR KEY SHARE statements. Before attempting a solution, find out when these statements are running on the same row. Use this information to choose a strategy described in the following sections.

Topics

- Respond to high concurrency
- Respond to idle transactions
- Respond to long-running transactions

Respond to high concurrency

If concurrency is the issue, try one of the following techniques:

- Lower the concurrency in the application. For example, decrease the number of active sessions.
- Implement a connection pool. To learn how to pool connections with RDS Proxy, see Using Amazon RDS Proxy.
- Design the application or data model to avoid contending UPDATE and SELECT … FOR UPDATE statements. You can also decrease the number of foreign keys accessed by SELECT … FOR KEY SHARE statements.

Respond to idle transactions

If pg_stat_activity.state shows idle in transaction, use the following strategies:

- Turn on autocommit wherever possible. This approach prevents transactions from blocking other transactions while waiting for a `COMMIT` or `ROLLBACK`.
- Search for code paths that are missing `COMMIT`, `ROLLBACK`, or `END`.
- Make sure that the exception handling logic in your application always has a path to a valid `end of transaction`.
- Make sure that your application processes query results after ending the transaction with `COMMIT` or `ROLLBACK`.

Respond to long-running transactions

If long-running transactions are causing the frequent occurrence of `Lock:transactionid`, try the following strategies:

- Keep row locks out of long-running transactions.
- Limit the length of queries by implementing autocommit whenever possible.

Lock:tuple

The `Lock:tuple` event occurs when a backend process is waiting to acquire a lock on a tuple.

Topics

Supported engine versions

This wait event information is supported for all versions of RDS for PostgreSQL.

Context

The event `Lock:tuple` indicates that a backend is waiting to acquire a lock on a tuple while another backend holds a conflicting lock on the same tuple. The following table illustrates a scenario in which sessions generate the `Lock:tuple` event.

Time	Session 1	Session 2	Session 3
t1	Starts a transaction.		
t2	Updates row 1.		
t3		Updates row 1. The session acquires an exclusive lock on the tuple and then waits for session 1 to release the lock by committing or rolling back.	
t4			Updates row 1. The session waits for session 2 to release the exclusive lock on the tuple.

Or you can simulate this wait event by using the benchmarking tool pgbench. Configure a high number of concurrent sessions to update the same row in a table with a custom SQL file.

To learn more about conflicting lock modes, see Explicit Locking in the PostgreSQL documentation. To learn more about pgbench, see pgbench in the PostgreSQL documentation.

Likely causes of increased waits

When this event appears more than normal, possibly indicating a performance problem, typical causes include the following:

- A high number of concurrent sessions are trying to acquire a conflicting lock for the same tuple by running `UPDATE` or `DELETE` statements.
- Highly concurrent sessions are running a `SELECT` statement using the `FOR UPDATE` or `FOR NO KEY UPDATE` lock modes.
- Various factors drive application or connection pools to open more sessions to execute the same operations. As new sessions are trying to modify the same rows, DB load can spike, and `Lock:tuple` can appear.

For more information, see Row-Level Locks in the PostgreSQL documentation.

Actions

We recommend different actions depending on the causes of your wait event.

Topics

- Investigate your application logic
- Find the blocker session
- Reduce concurrency when it is high
- Troubleshoot bottlenecks

Investigate your application logic

Find out whether a blocker session has been in the `idle in transaction` state for long time. If so, consider ending the blocker session as a short-term solution. You can use the `pg_terminate_backend` function. For more information about this function, see Server Signaling Functions in the PostgreSQL documentation.

For a long-term solution, do the following:

- Adjust the application logic.
- Use the `idle_in_transaction_session_timeout` parameter. This parameter ends any session with an open transaction that has been idle for longer than the specified amount of time. For more information, see Client Connection Defaults in the PostgreSQL documentation.
- Use autocommit as much as possible. For more information, see SET AUTOCOMMIT in the PostgreSQL documentation.

Find the blocker session

While the `Lock:tuple` wait event is occurring, identify the blocker and blocked session by finding out which locks depend on one another. For more information, see Lock dependency information in the PostgreSQL wiki.

The following example queries all sessions, filtering on `tuple` and ordering by `wait_time`.

```
SELECT blocked_locks.pid AS blocked_pid,
         blocking_locks.pid AS blocking_pid,
         blocked_activity.usename AS blocked_user,
```

```
        blocking_activity.usename AS blocking_user,
        now() - blocked_activity.xact_start AS blocked_transaction_duration,
        now() - blocking_activity.xact_start AS blocking_transaction_duration,
        concat(blocked_activity.wait_event_type,':',blocked_activity.wait_event) AS
blocked_wait_event,
        concat(blocking_activity.wait_event_type,':',blocking_activity.wait_event) AS
blocking_wait_event,
        blocked_activity.state AS blocked_state,
        blocking_activity.state AS blocking_state,
        blocked_locks.locktype AS blocked_locktype,
        blocking_locks.locktype AS blocking_locktype,

       AND blocking_locks.objsubid IS NOT DISTINCT FROM blocked_locks.objsubid
       AND blocking_locks.pid != blocked_locks.pid
   JOIN pg_catalog.pg_stat_activity blocking_activity ON blocking_activity.pid =
blocking_locks.pid
   WHERE NOT blocked_locks.GRANTED;
```

Reduce concurrency when it is high

The `Lock:tuple` event might occur constantly, especially in a busy workload time. In this situation, consider reducing the high concurrency for very busy rows. Often, just a few rows control a queue or the Boolean logic, which makes these rows very busy.

You can reduce concurrency by using different approaches based in the business requirement, application logic, and workload type. For example, you can do the following:

- Redesign your table and data logic to reduce high concurrency.

- Change the application logic to reduce high concurrency at the row level.
- Leverage and redesign queries with row-level locks.
- Use the `NOWAIT` clause with retry operations.
- Consider using optimistic and hybrid-locking logic concurrency control.
- Consider changing the database isolation level.

Troubleshoot bottlenecks

The `Lock:tuple` can occur with bottlenecks such as CPU starvation or maximum usage of Amazon EBS bandwidth. To reduce bottlenecks, consider the following approaches:

- Scale up your instance class type.
- Optimize resource-intensive queries.
- Change the application logic.
- Archive data that is rarely accessed.

LWLock:BufferMapping (LWLock:buffer_mapping)

This event occurs when a session is waiting to associate a data block with a buffer in the shared buffer pool.

> **Note**
>
> This event is named `LWLock:BufferMapping` for RDS for PostgreSQL version 13 and higher versions. For RDS for PostgreSQL version 12 and older versions, this event is named `LWLock:buffer_mapping`.

Topics

Supported engine versions

This wait event information is relevant for RDS for PostgreSQL version 9.6 and higher.

Context

The *shared buffer pool* is a PostgreSQL memory area that holds all pages that are or were being used by processes. When a process needs a page, it reads the page into the shared buffer pool. The `shared_buffers` parameter sets the shared buffer size and reserves a memory area to store the table and index pages. If you change this parameter, make sure to restart the database. .

The `LWLock:buffer_mapping` wait event occurs in the following scenarios:

- A process searches the buffer table for a page and acquires a shared buffer mapping lock.
- A process loads a page into the buffer pool and acquires an exclusive buffer mapping lock.
- A process removes a page from the pool and acquires an exclusive buffer mapping lock.

Causes

When this event appears more than normal, possibly indicating a performance problem, the database is paging in and out of the shared buffer pool. Typical causes include the following:

- Large queries
- Bloated indexes and tables
- Full table scans
- A shared pool size that is smaller than the working set

Actions

We recommend different actions depending on the causes of your wait event.

Topics

- Monitor buffer-related metrics
- Assess your indexing strategy
- Reduce the number of buffers that must be allocated quickly

Monitor buffer-related metrics

When `LWLock:buffer_mapping` waits spike, investigate the buffer hit ratio. You can use these metrics to get a better understanding of what is happening in the buffer cache. Examine the following metrics:

`blks_hit`

This Performance Insights counter metric indicates the number of blocks that were retrieved from the shared buffer pool. After the `LWLock:buffer_mapping` wait event appears, you might observe a spike in `blks_hit`.

`blks_read`

This Performance Insights counter metric indicates the number of blocks that required I/O to be read into the shared buffer pool. You might observe a spike in `blks_read` in the lead-up to the `LWLock:buffer_mapping` wait event.

Assess your indexing strategy

To confirm that your indexing strategy is not degrading performance, check the following:

Index bloat

Ensure that index and table bloat aren't leading to unnecessary pages being read into the shared buffer. If your tables contain unused rows, consider archiving the data and removing the rows from the tables. You can then rebuild the indexes for the resized tables.

Indexes for frequently used queries

To determine whether you have the optimal indexes, monitor DB engine metrics in Performance Insights. The `tup_returned` metric shows the number of rows read. The `tup_fetched` metric shows the number of rows returned to the client. If `tup_returned` is significantly larger than `tup_fetched`, the data might not be properly indexed. Also, your table statistics might not be current.

Reduce the number of buffers that must be allocated quickly

To reduce the `LWLock:buffer_mapping` wait events, try to reduce the number of buffers that must be allocated quickly. One strategy is to perform smaller batch operations. You might be able to achieve smaller batches by partitioning your tables.

LWLock:BufferIO (IPC:BufferIO)

The `LWLock:BufferIO` event occurs when RDS for PostgreSQL is waiting for other processes to finish their input/output (I/O) operations when concurrently trying to access a page. Its purpose is for the same page to be read into the shared buffer.

Topics

Relevant engine versions

This wait event information is relevant for all RDS for PostgreSQL versions. For RDS for PostgreSQL 12 and earlier versions this wait event is named as lwlock:buffer_io whereas in RDS for PostgreSQL 13 version it is named as lwlock:bufferio. From RDS for PostgreSQL 14 version BufferIO wait event moved from `LWLock` to `IPC` wait event type (IPC:BufferIO).

Context

Each shared buffer has an I/O lock that is associated with the `LWLock:BufferIO` wait event, each time a block (or a page) has to be retrieved outside the shared buffer pool.

This lock is used to handle multiple sessions that all require access to the same block. This block has to be read from outside the shared buffer pool, defined by the `shared_buffers` parameter.

As soon as the page is read inside the shared buffer pool, the `LWLock:BufferIO` lock is released.

> **Note**
>
> The `LWLock:BufferIO` wait event precedes the IO:DataFileRead wait event. The `IO:DataFileRead` wait event occurs while data is being read from storage.

For more information on lightweight locks, see Locking Overview.

Causes

Common causes for the `LWLock:BufferIO` event to appear in top waits include the following:

- Multiple backends or connections trying to access the same page that's also pending an I/O operation
- The ratio between the size of the shared buffer pool (defined by the `shared_buffers` parameter) and the number of buffers needed by the current workload
- The size of the shared buffer pool not being well balanced with the number of pages being evicted by other operations
- Large or bloated indexes that require the engine to read more pages than necessary into the shared buffer pool
- Lack of indexes that forces the DB engine to read more pages from the tables than necessary
- Checkpoints occurring too frequently or needing to flush too many modified pages
- Sudden spikes for database connections trying to perform operations on the same page

Actions

We recommend different actions depending on the causes of your wait event:

- Observe Amazon CloudWatch metrics for correlation between sharp decreases in the `BufferCacheHitRatio` and `LWLock:BufferIO` wait events. This effect can mean that you have a small shared buffers setting. You might need to increase it or scale up your DB instance class. You can split your workload into more reader nodes.
- Tune `max_wal_size` and `checkpoint_timeout` based on your workload peak time if you see `LWLock:BufferIO` coinciding with `BufferCacheHitRatio` metric dips. Then identify which query might be causing it.
- Verify whether you have unused indexes, then remove them.
- Use partitioned tables (which also have partitioned indexes). Doing this helps to keep index reordering low and reduces its impact.
- Avoid indexing columns unnecessarily.
- Prevent sudden database connection spikes by using a connection pool.
- Restrict the maximum number of connections to the database as a best practice.

LWLock:buffer_content (BufferContent)

The `LWLock:buffer_content` event occurs when a session is waiting to read or write a data page in memory while another session has that page locked for writing. In RDS for PostgreSQL 13 and higher, this wait event is called `BufferContent`.

Topics

Supported engine versions

This wait event information is supported for all versions of RDS for PostgreSQL.

Context

To read or manipulate data, PostgreSQL accesses it through shared memory buffers. To read from the buffer, a process gets a lightweight lock (LWLock) on the buffer content in shared mode. To write to the buffer, it gets that lock in exclusive mode. Shared locks allow other processes to concurrently acquire shared locks on that content. Exclusive locks prevent other processes from getting any type of lock on it.

The `LWLock:buffer_content` (`BufferContent`) event indicates that multiple processes are attempting to get a lock on contents of a specific buffer.

Likely causes of increased waits

When the `LWLock:buffer_content` (`BufferContent`) event appears more than normal, possibly indicating a performance problem, typical causes include the following:

Increased concurrent updates to the same data

There might be an increase in the number of concurrent sessions with queries that update the same buffer content. This contention can be more pronounced on tables with a lot of indexes.

Workload data is not in memory

When data that the active workload is processing is not in memory, these wait events can increase. This effect is because processes holding locks can keep them longer while they perform disk I/O operations.

Excessive use of foreign key constraints

Foreign key constraints can increase the amount of time a process holds onto a buffer content lock. This effect is because read operations require a shared buffer content lock on the referenced key while that key is being updated.

Actions

We recommend different actions depending on the causes of your wait event. You might identify `LWLock:buffer_content` (`BufferContent`) events by using Amazon RDS Performance Insights or by querying the view `pg_stat_activity`.

Topics

- Improve in-memory efficiency
- Reduce usage of foreign key constraints
- Remove unused indexes
- Increase the cache size when using sequences

Improve in-memory efficiency

To increase the chance that active workload data is in memory, partition tables or scale up your instance class. For information about DB instance classes, see DB instance classes.

Reduce usage of foreign key constraints

Investigate workloads experiencing high numbers of `LWLock:buffer_content` (`BufferContent`) wait events for usage of foreign key constraints. Remove unnecessary foreign key constraints.

Remove unused indexes

For workloads experiencing high numbers of `LWLock:buffer_content` (`BufferContent`) wait events, identify unused indexes and remove them.

Increase the cache size when using sequences

If your tables uses sequences, increase the cache size to remove contention on sequence pages and index pages. Each sequence is a single page in shared memory. The pre-defined cache is per connection. This might not be enough to handle the workload when many concurrent sessions are getting a sequence value.

LWLock:lock_manager (LWLock:lockmanager)

This event occurs when the RDS for PostgreSQL engine maintains the shared lock's memory area to allocate, check, and deallocate a lock when a fast path lock isn't possible.

Topics

Supported engine versions

This wait event information is relevant for RDS for PostgreSQL version 9.6 and higher.
For RDS for PostgreSQL releases older than version 13, the name of this wait event is `LWLock:lock_manager`. For RDS for PostgreSQL version 13 and higher, the name of this wait event is `LWLock:lockmanager`.

Context

When you issue a SQL statement, RDS for PostgreSQL records locks to protect the structure, data, and integrity of your database during concurrent operations. The engine can achieve this goal using a fast path lock or a path lock that isn't fast. A path lock that isn't fast is more expensive and creates more overhead than a fast path lock.

Fast path locking

To reduce the overhead of locks that are taken and released frequently, but that rarely conflict, backend processes can use fast path locking. The database uses this mechanism for locks that meet the following criteria:

- They use the DEFAULT lock method.
- They represent a lock on a database relation rather than a shared relation.
- They are weak locks that are unlikely to conflict.
- The engine can quickly verify that no conflicting locks can possibly exist.

The engine can't use fast path locking when either of the following conditions is true:

- The lock doesn't meet the preceding criteria.
- No more slots are available for the backend process.

To tune your queries for fast-path lockcing, you can use the following query.

```
SELECT count(*), pid, mode, fastpath
  FROM pg_locks
 WHERE fastpath IS NOT NULL
 GROUP BY 4,3,2
 ORDER BY pid, mode;
 count | pid  |      mode       | fastpath
-------+------+-----------------+----------
16 | 9185 | AccessShareLock | t
336 | 9185 | AccessShareLock | f
1 | 9185 | ExclusiveLock   | t
```

The following query shows only the total across the database.

```
SELECT count(*), mode, fastpath
  FROM pg_locks
 WHERE fastpath IS NOT NULL
 GROUP BY 3,2
 ORDER BY mode,1;
count |      mode       | fastpath
-------+-----------------+----------
16 | AccessShareLock | t
337 | AccessShareLock | f
1 | ExclusiveLock   | t
(3 rows)
```

For more information about fast path locking, see fast path in the PostgreSQL lock manager README and pg-locks in the PostgreSQL documentation.

Example of a scaling problem for the lock manager

In this example, a table named `purchases` stores five years of data, partitioned by day. Each partition has two indexes. The following sequence of events occurs:

1. You query many days worth of data, which requires the database to read many partitions.
2. The database creates a lock entry for each partition. If partition indexes are part of the optimizer access path, the database creates a lock entry for them, too.
3. When the number of requested locks entries for the same backend process is higher than 16, which is the value of `FP_LOCK_SLOTS_PER_BACKEND`, the lock manager uses the non–fast path lock method.

Modern applications might have hundreds of sessions. If concurrent sessions are querying the parent without proper partition pruning, the database might create hundreds or even thousands of non–fast path locks. Typically, when this concurrency is higher than the number of vCPUs, the `LWLock:lock_manager` wait event appears.

> **Note**
>
> The `LWLock:lock_manager` wait event isn't related to the number of partitions or indexes in a database schema. Instead, it's related to the number of non–fast path locks that the database must control.

Likely causes of increased waits

When the `LWLock:lock_manager` wait event occurs more than normal, possibly indicating a performance problem, the most likely causes of sudden spikes are as follows:

- Concurrent active sessions are running queries that don't use fast path locks. These sessions also exceed the maximum vCPU.
- A large number of concurrent active sessions are accessing a heavily partitioned table. Each partition has multiple indexes.
- The database is experiencing a connection storm. By default, some applications and connection pool software create more connections when the database is slow. This practice makes the problem worse. Tune your connection pool software so that connection storms don't occur.
- A large number of sessions query a parent table without pruning partitions.

- A data definition language (DDL), data manipulation language (DML), or a maintenance command exclusively locks either a busy relation or tuples that are frequently accessed or modified.

Actions

If the CPU wait event occurs, it doesn't necessarily indicate a performance problem. Respond to this event only when performance degrades and this wait event is dominating DB load.

Topics

- Use partition pruning
- Remove unnecessary indexes
- Tune your queries for fast path locking
- Tune for other wait events
- Reduce hardware bottlenecks
- Use a connection pooler
- Upgrade your RDS for PostgreSQL version

Use partition pruning

Partition pruning is a query optimization strategy for declaratively partitioned tables that excludes unneeded partitions from table scans, thereby improving performance. Partition pruning is turned on by default. If it is turned off, turn it on as follows.

```
SET enable_partition_pruning = on;
```

Queries can take advantage of partition pruning when their `WHERE` clause contains the column used for the partitioning. For more information, see Partition Pruning in the PostgreSQL documentation.

Remove unnecessary indexes

Your database might contain unused or rarely used indexes. If so, consider deleting them. Do either of the following:

- Learn how to find unnecessary indexes by reading Unused Indexes in the PostgreSQL wiki.

- Run PG Collector. This SQL script gathers database information and presents it in a consolidated HTML report. Check the "Unused indexes" section. For more information, see pg-collector in the AWS Labs GitHub repository.

Tune your queries for fast path locking

To find out whether your queries use fast path locking, query the `fastpath` column in the `pg_locks` table. If your queries aren't using fast path locking, try to reduce number of relations per query to fewer than 16.

Tune for other wait events

If `LWLock:lock_manager` is first or second in the list of top waits, check whether the following wait events also appear in the list:

- `Lock:Relation`
- `Lock:transactionid`
- `Lock:tuple`

If the preceding events appear high in the list, consider tuning these wait events first. These events can be a driver for `LWLock:lock_manager`.

Reduce hardware bottlenecks

You might have a hardware bottleneck, such as CPU starvation or maximum usage of your Amazon EBS bandwidth. In these cases, consider reducing the hardware bottlenecks. Consider the following actions:

- Scale up your instance class.
- Optimize queries that consume large amounts of CPU and memory.
- Change your application logic.
- Archive your data.

For more information about CPU, memory, and EBS network bandwidth, see Amazon RDS Instance Types.

Use a connection pooler

If your total number of active connections exceeds the maximum vCPU, more OS processes require CPU than your instance type can support. In this case, consider using or tuning a connection pool. For more information about the vCPUs for your instance type, see Amazon RDS Instance Types.

For more information about connection pooling, see the following resources:

- Using Amazon RDS Proxy
- pgbouncer
- Connection Pools and Data Sources in the *PostgreSQL Documentation*

Upgrade your RDS for PostgreSQL version

If your current version of RDS for PostgreSQL is lower than 12, upgrade to version 12 or higher. PostgreSQL versions 12 and later have an improved partition mechanism. For more information about version 12, see PostgreSQL 12.0 Release Notes. For more information about upgrading RDS for PostgreSQL, see Upgrading the PostgreSQL DB engine for Amazon RDS.

Timeout:PgSleep

The `Timeout:PgSleep` event occurs when a server process has called the `pg_sleep` function and is waiting for the sleep timeout to expire.

Topics

- Supported engine versions
- Likely causes of increased waits
- Actions

Supported engine versions

This wait event information is supported for all versions of RDS for PostgreSQL.

Likely causes of increased waits

This wait event occurs when an application, stored function, or user issues a SQL statement that calls one of the following functions:

- pg_sleep
- pg_sleep_for
- pg_sleep_until

The preceding functions delay execution until the specified number of seconds have elapsed. For example, SELECT pg_sleep(1) pauses for 1 second. For more information, see Delaying Execution in the PostgreSQL documentation.

Actions

Identify the statement that was running the pg_sleep function. Determine if the use of the function is appropriate.

Timeout:VacuumDelay

The Timeout:VacuumDelay event indicates that the cost limit for vacuum I/O has been exceeded and that the vacuum process has been put to sleep. Vacuum operations stop for the duration specified in the respective cost delay parameter and then it resumes its work. For the manual vacuum command, the delay is specified in the vacuum_cost_delay parameter. For the autovacuum daemon, the delay is specified in the autovacuum_vacuum_cost_delay parameter.

Topics

Supported engine versions

This wait event information is supported for all versions of RDS for PostgreSQL.

Context

PostgreSQL has both an autovacuum daemon and a manual vacuum command. The autovacuum process is "on" by default for RDS for PostgreSQL DB instances. The manual vacuum command is used on an as-needed basis, for example, to purge tables of dead tuples or generate new statistics.

When vacuuming is underway, PostgreSQL uses an internal counter to keep track of estimated costs as the system performs various I/O operations. When the counter reaches the value specified by the cost limit parameter, the process performing the operation sleeps for the brief duration specified in the cost delay parameter. It then resets the counter and continues operations.

The vacuum process has parameters that can be used to regulate resource consumption. The autovacuum and the manual vacuum command have their own parameters for setting the cost limit value. They also have their own parameters to specify a cost delay, an amount of time to put the vacuum to sleep when the limit is reached. In this way, the cost delay parameter works as a throttling mechanism for resource consumption. In the following lists, you can find description of these parameters.

Parameters that affect throttling of the autovacuum daemon

- `autovacuum_vacuum_cost_limit` – Specifies the cost limit value to use in automatic vacuum operations. Increasing the setting for this parameter allows the vacuum process to use more resources and decreases the `Timeout:VacuumDelay` wait event.
- `autovacuum_vacuum_cost_delay` – Specifies the cost delay value to use in automatic vacuum operations. The default value is 2 milliseconds. Setting the delay parameter to 0 turns off the throttling mechanism and thus, the `Timeout:VacuumDelay` wait event won't appear.

For more information, see Automatic Vacuuming in the PostgreSQL documentation.

Parameters that affect throttling of the manual vacuum process

- `vacuum_cost_limit` – The threshold at which the vacuuming process is put to sleep. By default, the limit is 200. This number represents the accumulated cost estimates for extra I/O needed by various resources. Increasing this value reduces the number of the `Timeout:VacuumDelay` wait event.
- `vacuum_cost_delay` – The amount of time that the vacuum process sleeps when the vacuum cost limit has been reached. The default setting is 0, which means that this feature is off. You can set this to an integer value to specify the number of milliseconds to turn on this feature, but we recommend that you leave it at its default setting.

For more information about the `vacuum_cost_delay` parameter, see Resource Consumption in the PostgreSQL documentation.

To learn more about how to configure and use the autovacuum with RDS for PostgreSQL, see Working with the PostgreSQL autovacuum on Amazon RDS for PostgreSQL.

Likely causes of increased waits

The `Timeout:VacuumDelay` is affected by the balance between the cost limit parameter settings (`vacuum_cost_limit`, `autovacuum_vacuum_cost_limit`) and the cost delay parameters (`vacuum_cost_delay`, `autovacuum_vacuum_cost_delay`) that control the vacuum's sleep duration. Raising a cost limit parameter value allows more resources to be used by the vacuum before being put to sleep. That results in fewer `Timeout:VacuumDelay` wait events. Increasing either of the delay parameters causes the `Timeout:VacuumDelay` wait event to occur more frequently and for longer periods of time.

The `autovacuum_max_workers` parameter setting can also increase numbers of the `Timeout:VacuumDelay`. Each additional autovacuum worker process contributes to the internal counter mechanism, and thus the limit can be reached more quickly than with a single autovacuum worker process. As the cost limit is reached more quickly, the cost delay is put to effect more frequently, resulting in more `Timeout:VacuumDelay` wait events. For more information, see autovacuum_max_workers in the PostgreSQL documentation.

Large objects, such as 500GB or larger, also raise this wait event because it can take some time for the vacuum to complete processing large objects.

Actions

If the vacuum operations complete as expected, no remediation is needed. In other words, this wait event doesn't necessarily indicate a problem. It indicates that the vacuum is being put to sleep for the period of time specified in the delay parameter so that resources can be applied to other processes that need to complete.

If you want vacuum operations to complete faster, you can lower the delay parameters. This shortens the time that the vacuum sleeps.

Tuning RDS for PostgreSQL with Amazon DevOps Guru proactive insights

DevOps Guru proactive insights detects conditions on your RDS for PostgreSQL DB instances that can cause problems, and lets you know about them before they occur. Proactive insights can alert you to a long running idle in transaction connection. For more information about troubleshooting long running idle in transaction connections, see Database has long running idle in transaction connection

DevOps Guru can do the following:

- Prevent many common database issues by cross-checking your database configuration against common recommended settings.
- Alert you to critical issues in your fleet that, if left unchecked, can lead to larger problems later.
- Alert you to newly discovered problems.

Every proactive insight contains an analysis of the cause of the problem and recommendations for corrective actions.

For more information about Amazon DevOps Guru for Amazon RDS, see Analyzing performance anomalies with Amazon DevOps Guru for Amazon RDS.

Database has long running idle in transaction connection

A connection to the database has been in the `idle in transaction` state for more than 1800 seconds.

Topics

Supported engine versions

This insight information is supported for all versions of RDS for PostgreSQL.

Context

A transaction in the `idle in transaction` state can hold locks that block other queries. It can also prevent `VACUUM` (including autovacuum) from cleaning up dead rows, leading to index or table bloat or transaction ID wraparound.

Likely causes for this issue

A transaction initiated in an interactive session with BEGIN or START TRANSACTION hasn't ended by using a COMMIT, ROLLBACK, or END command. This causes the transaction to move to `idle in transaction` state.

Actions

You can find idle transactions by querying `pg_stat_activity`.

In your SQL client, run the following query to list all connections in `idle in transaction` state and to order them by duration:

```
SELECT now() - state_change as idle_in_transaction_duration, now() - xact_start as
 xact_duration,*
FROM  pg_stat_activity
WHERE state  = 'idle in transaction'
AND   xact_start is not null
ORDER BY 1 DESC;
```

We recommend different actions depending on the causes of your insight.

Topics

- End transaction
- Terminate the connection
- Configure the idle_in_transaction_session_timeout parameter
- Check the AUTOCOMMIT status
- Check the transaction logic in your application code

End transaction

When you initiate a transaction in an interactive session with BEGIN or START TRANSACTION, it moves to `idle in transaction` state. It remains in this state until you end the transaction by issuing a COMMIT, ROLLBACK, END command or disconnect the connection completely to roll back the transaction.

Terminate the connection

Terminate the connection with an idle transaction using the following query:

```
SELECT pg_terminate_backend(pid);
```

pid is the process ID of the connection.

Configure the idle_in_transaction_session_timeout parameter

Configure the `idle_in_transaction_session_timeout` parameter in the parameter group. The advantage of configuring this parameter is that it does not require a manual intervention to terminate the long idle in transaction. For more information on this parameter, see the PostgreSQL documentation.

The following message will be reported in the PostgreSQL log file after the connection is terminated, when a transaction is in the idle_in_transaction state for longer than the specified time.

```
FATAL: terminating connection due to idle in transaction timeout
```

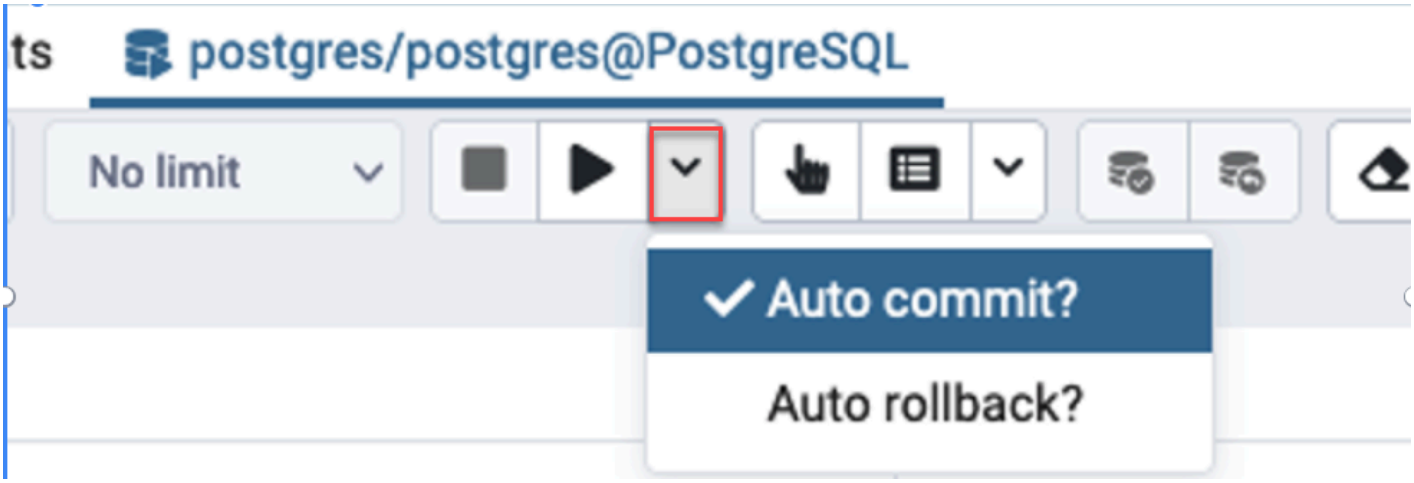
Check the AUTOCOMMIT status

AUTOCOMMIT is turned on by default. But if it is accidentally turned off in the client ensure that you turn it back on.

- In your psql client, run the following command:

  ```
  postgres=> \set AUTOCOMMIT on
  ```

- In pgadmin, turn it on by choosing the AUTOCOMMIT option from the down arrow.



Check the transaction logic in your application code

Investigate your application logic for possible problems. Consider the following actions:

- Check if the JDBC auto commit is set true in your application. Also, consider using explicit `COMMIT` commands in your code.
- Check your error handling logic to see whether it closes a transaction after errors.
- Check whether your application is taking long to process the rows returned by a query while the transaction is open. If so, consider coding the application to close the transaction before processing the rows.
- Check whether a transaction contains many long-running operations. If so, divide a single transaction into multiple transactions.

Relevant metrics

The following PI metrics are related to this insight:

- idle_in_transaction_count - Number of sessions in `idle in transaction` state.
- idle_in_transaction_max_time - The duration of the longest running transaction in the `idle in transaction` state.

Using PostgreSQL extensions with Amazon RDS for PostgreSQL

You can extend the functionality of PostgreSQL by installing a variety of extensions and modules. For example, to work with spatial data you can install and use the PostGIS extension. For more information, see Managing spatial data with the PostGIS extension. As another example, if you want to improve data entry for very large tables, you can consider partitioning your data by using the `pg_partman` extension. To learn more, see Managing PostgreSQL partitions with the pg_partman extension.

> **Note**
>
> As of RDS for PostgreSQL 14.5, RDS for PostgreSQL supports Trusted Language Extensions for PostgreSQL. This feature is implemented as the extension `pg_tle`, which you can add to your RDS for PostgreSQL DB instance. By using this extension, developers can create their own PostgreSQL extensions in a safe environment that simplifies the setup and configuration requirements. For more information, see Working with Trusted Language Extensions for PostgreSQL.

In some cases, rather than installing an extension, you might add a specific module to the list of `shared_preload_libraries` in your RDS for PostgreSQL DB instance's custom DB parameter group. Typically, the default DB cluster parameter group loads only the `pg_stat_statements`, but several other modules are available to add to the list. For example, you can add scheduling capability by adding the `pg_cron` module, as detailed in Scheduling maintenance with the PostgreSQL pg_cron extension. As another example, you can log query execution plans by loading the `auto_explain` module. To learn more, see Logging execution plans of queries in the AWS knowledge center.

Depending on your version of RDS for PostgreSQL, installing an extension might require `rds_superuser` permissions, as follows:

- For RDS for PostgreSQL versions 12 and earlier versions, installing extensions requires `rds_superuser` privileges.
- For RDS for PostgreSQL version 13 and higher versions, users (roles) with create permissions on a given database instance can install and use any *trusted extensions*. For a list of trusted extensions, see PostgreSQL trusted extensions.

You can also specify precisely which extensions can be installed on your RDS for PostgreSQL DB instance, by listing them in the `rds.allowed_extensions` parameter. For more information, see Restricting installation of PostgreSQL extensions.

To learn more about the `rds_superuser` role, see Understanding PostgreSQL roles and permissions.

Topics

Using functions from the orafce extension

The orafce extension provides functions and operators that emulate a subset of functions and packages from an Oracle database. The orafce extension makes it easier for you to port an Oracle application to PostgreSQL. RDS for PostgreSQL versions 9.6.6 and higher support this extension. For more information about orafce, see orafce on GitHub.

> **Note**
>
> RDS for PostgreSQL doesn't support the `utl_file` package that is part of the orafce extension. This is because the `utl_file` schema functions provide read and write operations on operating-system text files, which requires superuser access to the underlying host. As a managed service, RDS for PostgreSQL doesn't provide host access.

To use the orafce extension

1. Connect to the DB instance with the primary user name that you used to create the DB instance.

   If you want to turn on orafce for a different database in the same DB instance, use the /c dbname psql command. Using this command, you change from the primary database after initiating the connection.
2. Turn on the orafce extension with the CREATE EXTENSION statement.

   ```
   CREATE EXTENSION orafce;
   ```
3. Transfer ownership of the oracle schema to the rds_superuser role with the ALTER SCHEMA statement.

   ```
   ALTER SCHEMA oracle OWNER TO rds_superuser;
   ```

   If you want to see the list of owners for the oracle schema, use the \dn psql command.

Using Amazon RDS delegated extension support for PostgreSQL

Using Amazon RDS delegated extension support for PostgreSQL, you can delegate the extension management to a user who need not be an `rds_superuser`. With this delegated extension support, a new role called `rds_extension` is created and you must assign this to a user to manage other extensions. This role can create, update, and drop extensions.

You can specify the extensions that can be installed on your RDS DB instance, by listing them in the `rds.allowed_extensions` parameter. For more information, see Using PostgreSQL extensions with Amazon RDS for PostgreSQL.

You can restrict the list of extensions available that can be managed by the user with the `rds_extension` role using `rds.allowed_delegated_extensions` parameter.

The delegated extension support is available in the following versions:

- All higher versions
- 16.4 and higher 16 versions
- 15.8 and higher 15 versions
- 14.13 and higher 14 versions
- 13.16 and higher 13 versions
- 12.20 and higher 12 versions

Topics

Turning on delegate extension support to a user

You must perform the following to enable delegate extension support to a user:

1. **Grant `rds_extension` role to a user** – Connect to the database as `rds_superuser` and execute the following command:

```
Postgres => grant rds_extension to user_name;
```

2. **Set the list of extensions available for delegated users to manage** – The `rds.allowed_delegated_extensions` allows you to specify a subset of the available extensions using `rds.allowed_extensions` in the DB cluster parameter. You can perform this at one of the following levels:

   - In the cluster or the instance parameter group, through the AWS Management Console or API. For more information, see Parameter groups for Amazon RDS.
   - Use the following command at the database level:

```
alter database database_name set rds.allowed_delegated_extensions =
 'extension_name_1,
                   extension_name_2,...extension_name_n';
```

   - Use the following command at the user level:

```
alter user user_name set rds.allowed_delegated_extensions = 'extension_name_1,
                   extension_name_2,...extension_name_n';
```

> **Note**
>
> You need not restart the database after changing the `rds.allowed_delegated_extensions` dynamic parameter.

3. **Allow access to the delegated user to objects created during the extension creation process** – Certain extensions create objects that require additional permissions to be granted before the user with `rds_extension` role can access them. The `rds_superuser` must grant the delegated user access to those objects. One of the options is to use an event trigger to automatically grant permission to the delegated user. For more information, refer to the event trigger example in Turning off the support for the delegated extension.

Configuration used in RDS delegated extension support for PostgreSQL

Configuration Name	Description	Default Value	Notes	Who can modify or grant permission
rds.allowed_delegated_extensions	This parameter limits the extensions a rds_extension role can manage in a database. It must be a subset of rds.allowed_extensions.	empty string	• By default, this parameter is empty string, which means that no extensions have been delegated to users with rds_extension . • Any supported extension can be added if the user has permission to do so. To do this, set the rds.allowed_delegated_extensions parameter to a string of comma-separated extension names. By adding a list of extensions to this parameter, you explicitly identify the extensions that	rds_superuser

Configuration Name	Description	Default Value	Notes	Who can modify or grant permission
			the user with the `rds_extension` role can install. • When set to `*`, it means that all extensions listed in `rds_allowed_extensions` are delegated to users with `rds_extension` role. To learn more about setting up this parameter, see Turning on delegate extension support to a user.	

Configuration Name	Description	Default Value	Notes	Who can modify or grant permission
rds.allowed_extensions	This parameter lets the customer limit the extensions that can be installed in the RDS DB instance. For more information, see Restricting installation of PostgreSQL extensions	"*"	By default, this parameter is set to "*", which means that all extensions supported on RDS for PostgreSQL and Aurora PostgreSQL are allowed to be created by users with necessary privileges. Empty means no extensions can be installed in the RDS DB instance.	administrator

Configuration Name	Description	Default Value	Notes	Who can modify or grant permission
rds-delegated_extension_allow_drascac	This parameter controls the ability for user with rds_extension to drop the extension using a cascade option.	off	By default, rds-delegated_extension_allow_drop_cascade is set to off. This means that users with rds_extension are not allowed to drop an extension using the cascade option. To grant that ability, the rds.delegated_extension_allow_drop_cascade parameter should be set to on.	rds_superuser

Turning off the support for the delegated extension

Turning off partially

The delegated users can't create new extensions but can still update existing extensions.

- Reset rds.allowed_delegated_extensions to the default value in the DB cluster parameter group.
- Use the following command at the database level:

```
alter database database_name reset rds.allowed_delegated_extensions;
```

- Use the following command at the user level:

```
alter user user_name reset rds.allowed_delegated_extensions;
```

Turning off fully

Revoking `rds_extension` role from a user will revert the user to standard permissions. The user can no longer create, update, or drop extensions.

```
postgres => revoke rds_extension from user_name;
```

Example of event trigger

If you want to allow a delegated user with `rds_extension` to use extensions that require setting permissions on their objects created by the extension creation, you can customize the below example of an event trigger and add only the extensions for which you want the delegated users to have access to the full functionality. This event trigger can be created on template1 (the default template), therefore all database created from template1 will have that event trigger. When a delegated user installs the extension, this trigger will automatically grant ownership on the objects created by the extension.

```
CREATE OR REPLACE FUNCTION create_ext()

  RETURNS event_trigger AS $$

DECLARE

  schemaname TEXT;
  databaseowner TEXT;

  r RECORD;

BEGIN

  IF tg_tag = 'CREATE EXTENSION' and current_user != 'rds_superuser' THEN
    RAISE NOTICE 'SECURITY INVOKER';
```

```
    RAISE NOTICE 'user: %', current_user;
    FOR r IN SELECT * FROM pg_event_trigger_ddl_commands()
    LOOP
        CONTINUE WHEN r.command_tag != 'CREATE EXTENSION' OR r.object_type !=
'extension';

        schemaname = (
            SELECT n.nspname
            FROM pg_catalog.pg_extension AS e
            INNER JOIN pg_catalog.pg_namespace AS n
            ON e.extnamespace = n.oid
            WHERE e.oid = r.objid
        );

        databaseowner = (
            SELECT pg_catalog.pg_get_userbyid(d.datdba)
            FROM pg_catalog.pg_database d
            WHERE d.datname = current_database()
        );
        RAISE NOTICE 'Record for event trigger %, objid: %,tag: %, current_user: %,
schema: %, database_owenr: %', r.object_identity, r.objid, tg_tag, current_user,
schemaname, databaseowner;
        IF r.object_identity = 'address_standardizer_data_us' THEN
            EXECUTE format('GRANT SELECT, UPDATE, INSERT, DELETE ON TABLE %I.us_gaz TO
%I WITH GRANT OPTION;', schemaname, databaseowner);
            EXECUTE format('GRANT SELECT, UPDATE, INSERT, DELETE ON TABLE %I.us_lex TO
%I WITH GRANT OPTION;', schemaname, databaseowner);
            EXECUTE format('GRANT SELECT, UPDATE, INSERT, DELETE ON TABLE %I.us_rules
TO %I WITH GRANT OPTION;', schemaname, databaseowner);
        ELSIF r.object_identity = 'dict_int' THEN
            EXECUTE format('ALTER TEXT SEARCH DICTIONARY %I.intdict OWNER TO %I;',
schemaname, databaseowner);
        ELSIF r.object_identity = 'pg_partman' THEN
            EXECUTE format('GRANT SELECT, UPDATE, INSERT, DELETE ON TABLE
%I.part_config TO %I WITH GRANT OPTION;', schemaname, databaseowner);
            EXECUTE format('GRANT SELECT, UPDATE, INSERT, DELETE ON TABLE
%I.part_config_sub TO %I WITH GRANT OPTION;', schemaname, databaseowner);
            EXECUTE format('GRANT SELECT, UPDATE, INSERT, DELETE ON TABLE
%I.custom_time_partitions TO %I WITH GRANT OPTION;', schemaname, databaseowner);
        ELSIF r.object_identity = 'postgis_topology' THEN
            EXECUTE format('GRANT SELECT, UPDATE, INSERT, DELETE ON ALL TABLES IN
SCHEMA topology TO %I WITH GRANT OPTION;', databaseowner);
            EXECUTE format('GRANT USAGE, SELECT ON ALL SEQUENCES IN SCHEMA topology TO
%I WITH GRANT OPTION;', databaseowner);
```

```
            EXECUTE format('GRANT EXECUTE ON ALL FUNCTIONS IN SCHEMA topology TO %I
 WITH GRANT OPTION;', databaseowner);
            EXECUTE format('GRANT USAGE ON SCHEMA topology TO %I WITH GRANT OPTION;',
 databaseowner);
        END IF;
    END LOOP;
  END IF;
END;
$$ LANGUAGE plpgsql SECURITY DEFINER;

CREATE EVENT TRIGGER log_create_ext ON ddl_command_end EXECUTE PROCEDURE create_ext();
```

Benefits of using Amazon RDS delegated extension support

By using Amazon RDS delegated extension support for PostgreSQL, you securely delegate the extension management to users who do not have the `rds_superuser` role. This feature provides the following benefits:

- You can easily delegate extension management to users of your choice.
- This doesn't require `rds_superuser` role.
- Provides ability to support different set of extensions for different databases in the same DB cluster.

Limitation of Amazon RDS delegated extension support for PostgreSQL

- Objects created during the extension creation process may require additional privileges for the extension to function properly.
- Some extensions can't be managed by the delegated extension user by default, including the following: `log_fdw`, `pg_cron`, `pg_tle`, `pgactive`, `pglogical`, `postgis_raster`, `postgis_tiger_geocoder`, `postgis_topology`.

Permissions required for certain extensions

In order to create, use, or update the following extensions, the delegated user should have the necessary privileges on the following functions, tables, and schema.

Exte s that need owne or perm ns	Function	Tables	Schema	Text Search Dictionary	Comment
addr tand er_da s	none	us_gaz, us_lex, us_lex, I.us_rule s	none	none	none

Security Considerations

Keep in mind that a user with `rds_extension` role will be able to manage extensions on all databases they have the connect privilege on. If the intention is to have a delegated user manage extension on a single database, a good practice is to revoke all privileges from public on each database, then explicitly grant the connect privilege for that specific database to the delegate user.

There are several extensions that can allow a user to access information from multiple database. Ensure the users you grant `rds_extension` has cross database capabilities before adding these extensions to `rds.allowed_delegated_extensions`. For example, `postgres_fdw` and `dblink` provide functionality to query across databases on the same instance or remote instances. `log_fdw` reads the postgres engine log files, which are for all databases in the instance, potentially containing slow queries or error messages from multiple databases. `pg_cron` enables running scheduled background jobs on the DB instance and can configure jobs to run in a different database.

Drop extension cascade disabled

The ability to drop the extension with cascade option by a user with the `rds_extension` role is controlled by `rds.delegated_extension_allow_drop_cascade` parameter. By default, `rds-delegated_extension_allow_drop_cascade` is set to `off`. This means that users with the `rds_extension` role are not allowed to drop an extension using the cascade option as shown in the below query.

```
DROP EXTENSION CASCADE;
```

As this will automatically drop objects that depend on the extension, and in turn all objects that depend on those objects. Attempting to use the cascade option will result in an error.

To grant that ability, the `rds.delegated_extension_allow_drop_cascade` parameter should be set to on.

Changing the `rds.delegated_extension_allow_drop_cascade` dynamic parameter doesn't require a database restart. You can do this at one of the following levels:

- In the cluster or the instance parameter group, through the AWS Management Console or API.
- Using the following command at the database level:

```
alter database database_name set rds.delegated_extension_allow_drop_cascade = 'on';
```

- Using the following command at the user level:

```
alter role tenant_user set rds.delegated_extension_allow_drop_cascade = 'on';
```

Example extensions that can be added using delegated extension support

- rds_tools

```
extension_test_db=> create extension rds_tools;
CREATE EXTENSION
extension_test_db=> SELECT * from rds_tools.role_password_encryption_type() where
 rolname = 'pg_read_server_files';
ERROR: permission denied for function role_password_encryption_type
```

- amcheck

```
extension_test_db=> CREATE TABLE amcheck_test (id int);
CREATE TABLE
extension_test_db=> INSERT INTO amcheck_test VALUES (generate_series(1,100000));
INSERT 0 100000
extension_test_db=> CREATE INDEX amcheck_test_btree_idx ON amcheck_test USING btree
 (id);
CREATE INDEX
extension_test_db=> create extension amcheck;
CREATE EXTENSION
extension_test_db=> SELECT bt_index_check('amcheck_test_btree_idx'::regclass);
ERROR: permission denied for function bt_index_check
extension_test_db=> SELECT bt_index_parent_check('amcheck_test_btree_idx'::regclass);
ERROR: permission denied for function bt_index_parent_check
```

- pg_freespacemap

```
extension_test_db=> create extension pg_freespacemap;
CREATE EXTENSION
extension_test_db=> SELECT * FROM pg_freespace('pg_authid');
ERROR: permission denied for function pg_freespace
extension_test_db=> SELECT * FROM pg_freespace('pg_authid',0);
ERROR: permission denied for function pg_freespace
```

- pg_visibility

```
extension_test_db=> create extension pg_visibility;
CREATE EXTENSION
extension_test_db=> select * from pg_visibility('pg_database'::regclass);
ERROR: permission denied for function pg_visibility
```

- postgres_fdw

```
extension_test_db=> create extension postgres_fdw;
CREATE EXTENSION
extension_test_db=> create server myserver foreign data wrapper postgres_fdw options
 (host 'foo', dbname 'foodb', port '5432');
ERROR: permission denied for foreign-data wrapper postgres_fdw
```

Managing PostgreSQL partitions with the pg_partman extension

PostgreSQL table partitioning provides a framework for high-performance handling of data input and reporting. Use partitioning for databases that require very fast input of large amounts of data. Partitioning also provides for faster queries of large tables. Partitioning helps maintain data without impacting the database instance because it requires less I/O resources.

By using partitioning, you can split data into custom-sized chunks for processing. For example, you can partition time-series data for ranges such as hourly, daily, weekly, monthly, quarterly, yearly, custom, or any combination of these. For a time-series data example, if you partition the table by hour, each partition contains one hour of data. If you partition the time-series table by day, the partitions holds one day's worth of data, and so on. The partition key controls the size of a partition.

When you use an `INSERT` or `UPDATE` SQL command on a partitioned table, the database engine routes the data to the appropriate partition. PostgreSQL table partitions that store the data are child tables of the main table.

During database query reads, the PostgreSQL optimizer examines the `WHERE` clause of the query and, if possible, directs the database scan to only the relevant partitions.

Starting with version 10, PostgreSQL uses declarative partitioning to implement table partitioning. This is also known as native PostgreSQL partitioning. Before PostgreSQL version 10, you used triggers to implement partitions.

PostgreSQL table partitioning provides the following features:

- Creation of new partitions at any time.
- Variable partition ranges.
- Detachable and reattachable partitions using data definition language (DDL) statements.

  For example, detachable partitions are useful for removing historical data from the main partition but keeping historical data for analysis.
- New partitions inherit the parent database table properties, including the following:
  - Indexes
  - Primary keys, which must include the partition key column
  - Foreign keys
  - Check constraints

- References
- Creating indexes for the full table or each specific partition.

You can't alter the schema for an individual partition. However, you can alter the parent table (such as adding a new column), which propagates to partitions.

Topics

Overview of the PostgreSQL pg_partman extension

You can use the PostgreSQL `pg_partman` extension to automate the creation and maintenance of table partitions. For more general information, see PG Partition Manager in the `pg_partman` documentation.

> **Note**
>
> The `pg_partman` extension is supported on RDS for PostgreSQL versions 12.5 and higher.

Instead of having to manually create each partition, you configure `pg_partman` with the following settings:

- Table to be partitioned
- Partition type
- Partition key
- Partition granularity
- Partition precreation and management options

After you create a PostgreSQL partitioned table, you register it with `pg_partman` by calling the `create_parent` function. Doing this creates the necessary partitions based on the parameters you pass to the function.

The pg_partman extension also provides the run_maintenance_proc function, which you can call on a scheduled basis to automatically manage partitions. To ensure that the proper partitions are created as needed, schedule this function to run periodically (such as hourly). You can also ensure that partitions are automatically dropped.

Enabling the pg_partman extension

If you have multiple databases inside the same PostgreSQL DB instance for which you want to manage partitions, enable the pg_partman extension separately for each database. To enable the pg_partman extension for a specific database, create the partition maintenance schema and then create the pg_partman extension as follows.

```
CREATE SCHEMA partman;
CREATE EXTENSION pg_partman WITH SCHEMA partman;
```

> **Note**
>
> To create the pg_partman extension, make sure that you have rds_superuser privileges.

If you receive an error such as the following, grant the rds_superuser privileges to the account or use your superuser account.

```
ERROR: permission denied to create extension "pg_partman"
HINT: Must be superuser to create this extension.
```

To grant rds_superuser privileges, connect with your superuser account and run the following command.

```
GRANT rds_superuser TO user-or-role;
```

For the examples that show using the pg_partman extension, we use the following sample database table and partition. This database uses a partitioned table based on a timestamp. A schema data_mart contains a table named events with a column named created_at. The following settings are included in the events table:

- Primary keys event_id and created_at, which must have the column used to guide the partition.

- A check constraint `ck_valid_operation` to enforce values for an `operation` table column.
- Two foreign keys, where one (`fk_orga_membership`) points to the external table `organization` and the other (`fk_parent_event_id`) is a self-referenced foreign key.
- Two indexes, where one (`idx_org_id`) is for the foreign key and the other (`idx_event_type`) is for the event type.

The following DDL statements create these objects, which are automatically included on each partition.

```
CREATE SCHEMA data_mart;
CREATE TABLE data_mart.organization ( org_id BIGSERIAL,
        org_name TEXT,
        CONSTRAINT pk_organization PRIMARY KEY (org_id)
    );

CREATE TABLE data_mart.events(
        event_id        BIGSERIAL,
        operation       CHAR(1),
        value           FLOAT(24),
        parent_event_id BIGINT,
        event_type      VARCHAR(25),
        org_id          BIGSERIAL,
        created_at      timestamp,
        CONSTRAINT pk_data_mart_event PRIMARY KEY (event_id, created_at),
        CONSTRAINT ck_valid_operation CHECK (operation = 'C' OR operation = 'D'),
        CONSTRAINT fk_orga_membership
            FOREIGN KEY(org_id)
            REFERENCES data_mart.organization (org_id),
        CONSTRAINT fk_parent_event_id
            FOREIGN KEY(parent_event_id, created_at)
            REFERENCES data_mart.events (event_id,created_at)
    ) PARTITION BY RANGE (created_at);

CREATE INDEX idx_org_id     ON  data_mart.events(org_id);
CREATE INDEX idx_event_type ON  data_mart.events(event_type);
```

Configuring partitions using the create_parent function

After you enable the `pg_partman` extension, use the `create_parent` function to configure partitions inside the partition maintenance schema. The following example uses the `events` table

example created in Enabling the pg_partman extension. Call the `create_parent` function as follows.

```
SELECT partman.create_parent( p_parent_table => 'data_mart.events',
 p_control => 'created_at',
 p_type => 'native',
 p_interval=> 'daily',
 p_premake => 30);
```

The parameters are as follows:

- `p_parent_table` – The parent partitioned table. This table must already exist and be fully qualified, including the schema.
- `p_control` – The column on which the partitioning is to be based. The data type must be an integer or time-based.
- `p_type` – The type is either `'native'` or `'partman'`. You typically use the `native` type for its performance improvements and flexibility. The `partman` type relies on inheritance.
- `p_interval` – The time interval or integer range for each partition. Example values include `daily`, hourly, and so on.
- `p_premake` – The number of partitions to create in advance to support new inserts.

For a complete description of the `create_parent` function, see Creation Functions in the `pg_partman` documentation.

Configuring partition maintenance using the run_maintenance_proc function

You can run partition maintenance operations to automatically create new partitions, detach partitions, or remove old partitions. Partition maintenance relies on the `run_maintenance_proc` function of the `pg_partman` extension and the `pg_cron` extension, which initiates an internal scheduler. The `pg_cron` scheduler automatically executes SQL statements, functions, and procedures defined in your databases.

The following example uses the `events` table example created in Enabling the pg_partman extension to set partition maintenance operations to run automatically. As a prerequisite, add `pg_cron` to the `shared_preload_libraries` parameter in the DB instance's parameter group.

```
CREATE EXTENSION pg_cron;
```

```
UPDATE partman.part_config
SET infinite_time_partitions = true,
    retention = '3 months',
    retention_keep_table=true
WHERE parent_table = 'data_mart.events';
SELECT cron.schedule('@hourly', $$CALL partman.run_maintenance_proc()$$);
```

Following, you can find a step-by-step explanation of the preceding example:

1. Modify the parameter group associated with your DB instance and add `pg_cron` to the `shared_preload_libraries` parameter value. This change requires a DB instance restart for it to take effect. For more information, see Modifying parameters in a DB parameter group in Amazon RDS.
2. Run the command `CREATE EXTENSION pg_cron;` using an account that has the `rds_superuser` permissions. Doing this enables the `pg_cron` extension. For more information, see Scheduling maintenance with the PostgreSQL pg_cron extension.
3. Run the command `UPDATE partman.part_config` to adjust the `pg_partman` settings for the `data_mart.events` table.
4. Run the command `SET ...` to configure the `data_mart.events` table, with these clauses:
   a. `infinite_time_partitions = true,` – Configures the table to be able to automatically create new partitions without any limit.
   b. `retention = '3 months',` – Configures the table to have a maximum retention of three months.
   c. `retention_keep_table=true` – Configures the table so that when the retention period is due, the table isn't deleted automatically. Instead, partitions that are older than the retention period are only detached from the parent table.
5. Run the command `SELECT cron.schedule...` to make a `pg_cron` function call. This call defines how often the scheduler runs the `pg_partman` maintenance procedure, `partman.run_maintenance_proc`. For this example, the procedure runs every hour.

For a complete description of the `run_maintenance_proc` function, see Maintenance Functions in the `pg_partman` documentation.

Using pgAudit to log database activity

Financial institutions, government agencies, and many industries need to keep *audit logs* to meet regulatory requirements. By using the PostgreSQL Audit extension (pgAudit) with your RDS for PostgreSQL DB instance, you can capture the detailed records that are typically needed by auditors or to meet regulatory requirements. For example, you can set up the pgAudit extension to track changes made to specific databases and tables, to record the user who made the change, and many other details.

The pgAudit extension builds on the functionality of the native PostgreSQL logging infrastructure by extending the log messages with more detail. In other words, you use the same approach to view your audit log as you do to view any log messages. For more information about PostgreSQL logging, see RDS for PostgreSQL database log files.

The pgAudit extension redacts sensitive data such as cleartext passwords from the logs. If your RDS for PostgreSQL DB instance is configured to log data manipulation language (DML) statements as detailed in Turning on query logging for your RDS for PostgreSQL DB instance, you can avoid the cleartext password issue by using the PostgreSQL Audit extension.

You can configure auditing on your database instances with a great degree of specificity. You can audit all databases and all users. Or, you can choose to audit only certain databases, users, and other objects. You can also explicitly exclude certain users and databases from being audited. For more information, see Excluding users or databases from audit logging.

Given the amount of detail that can be captured, we recommend that if you do use pgAudit, you monitor your storage consumption.

The pgAudit extension is supported on all available RDS for PostgreSQL versions. For a list of pgAudit versions supported by available RDS for PostgreSQL versions, see Extension versions for Amazon RDS for PostgreSQL in the *Amazon RDS for PostgreSQL Release Notes.*

Topics

Setting up the pgAudit extension

To set up the pgAudit extension on your RDS for PostgreSQL DB instance , you first add pgAudit to the shared libraries on the custom DB parameter group for your RDS for PostgreSQL DB instance. For information about creating a custom DB parameter group, see Parameter groups for Amazon RDS. Next, you install the pgAudit extension. Finally, you specify the databases and objects that you want to audit. The procedures in this section show you how. You can use the AWS Management Console or the AWS CLI.

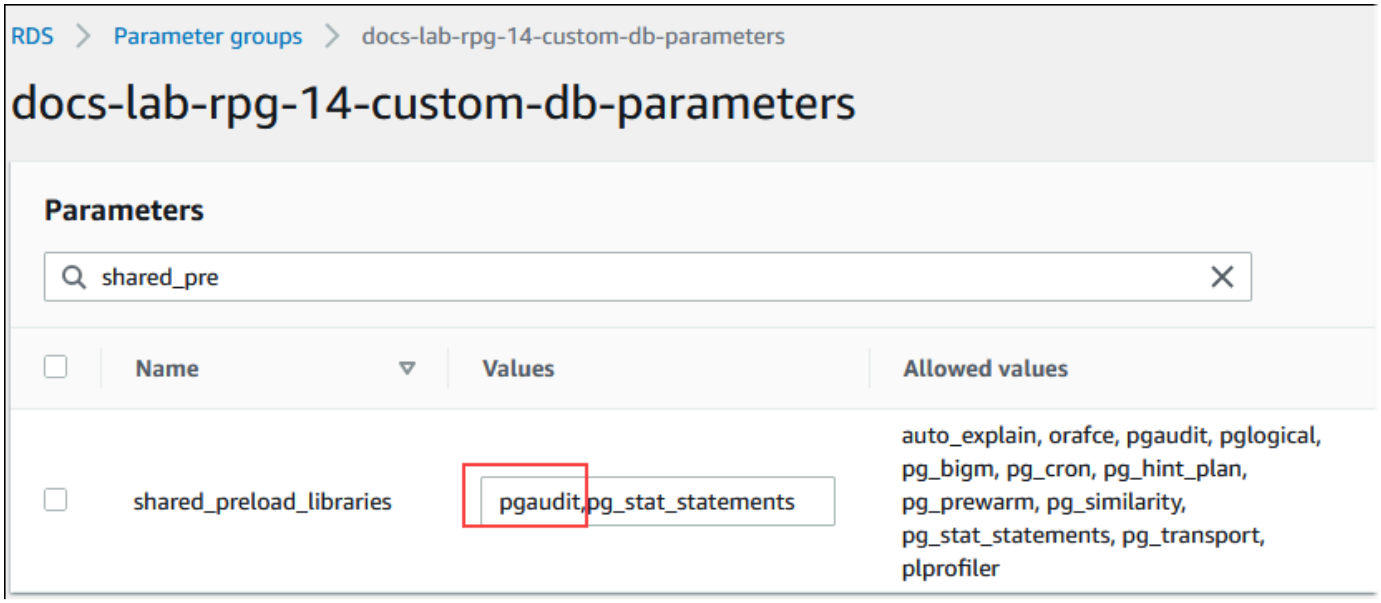
You must have permissions as the `rds_superuser` role to perform all these tasks.

The steps following assume that your RDS for PostgreSQL DB instance is associated with a custom DB parameter group.

Console

To set up the pgAudit extension

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose your RDS for PostgreSQL DB instance.
3. Open the **Configuration** tab for your RDS for PostgreSQL DB instance. Among the Instance details, find the **Parameter group** link.
4. Choose the link to open the custom parameters associated with your RDS for PostgreSQL DB instance.
5. In the **Parameters** search field, type `shared_pre` to find the `shared_preload_libraries` parameter.
6. Choose **Edit parameters** to access the property values.
7. Add `pgaudit` to the list in the **Values** field. Use a comma to separate items in the list of values.



8. Reboot the RDS for PostgreSQL DB instance so that your change to the `shared_preload_libraries` parameter takes effect.
9. When the instance is available, verify that pgAudit has been initialized. Use `psql` to connect to the RDS for PostgreSQL DB instance, and then run the following command.

```
SHOW shared_preload_libraries;
shared_preload_libraries
--------------------------
rdsutils,pgaudit
(1 row)
```

10. With pgAudit initialized, you can now create the extension. You need to create the extension after initializing the library because the `pgaudit` extension installs event triggers for auditing data definition language (DDL) statements.

```
CREATE EXTENSION pgaudit;
```

11. Close the `psql` session.

```
labdb=> \q
```

12. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.

13. Find the `pgaudit.log` parameter in the list and set to the appropriate value for your use case. For example, setting the `pgaudit.log` parameter to `write` as shown in the following image captures inserts, updates, deletes, and some other types changes to the log.

You can also choose one of the following values for the `pgaudit.log` parameter.

- none – This is the default. No database changes are logged.
- all – Logs everything (read, write, function, role, ddl, misc).
- ddl – Logs all data definition language (DDL) statements that aren't included in the `ROLE` class.
- function – Logs function calls and `DO` blocks.
- misc – Logs miscellaneous commands, such as `DISCARD`, `FETCH`, `CHECKPOINT`, `VACUUM`, and `SET`.
- read – Logs `SELECT` and `COPY` when the source is a relation (such as a table) or a query.
- role – Logs statements related to roles and privileges, such as `GRANT`, `REVOKE`, `CREATE ROLE`, `ALTER ROLE`, and `DROP ROLE`.
- write – Logs `INSERT`, `UPDATE`, `DELETE`, `TRUNCATE`, and `COPY` when the destination is a relation (table).

14. Choose **Save changes**.
15. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
16. Choose your RDS for PostgreSQL DB instance from the Databases list.

AWS CLI

To setup pgAudit

To setup pgAudit using the AWS CLI, you call the modify-db-parameter-group operation to modify the audit log parameters in your custom parameter group, as shown in the following procedure.

1. Use the following AWS CLI command to add `pgaudit` to the `shared_preload_libraries` parameter.

```
aws rds modify-db-parameter-group \
   --db-parameter-group-name custom-param-group-name \
   --parameters
 "ParameterName=shared_preload_libraries,ParameterValue=pgaudit,ApplyMethod=pending-
reboot" \
   --region aws-region
```

2. Use the following AWS CLI command to reboot the RDS for PostgreSQL DB instance so that the pgaudit library is initialized.

```
aws rds reboot-db-instance \
    --db-instance-identifier your-instance \
    --region aws-region
```

3. When the instance is available, you can verify that `pgaudit` has been initialized. Use `psql` to connect to the RDS for PostgreSQL DB instance, and then run the following command.

```
SHOW shared_preload_libraries;
shared_preload_libraries
--------------------------
rdsutils,pgaudit
(1 row)
```

   With pgAudit initialized, you can now create the extension.

```
CREATE EXTENSION pgaudit;
```

4. Close the `psql` session so that you can use the AWS CLI.

```
labdb=> \q
```

5. Use the following AWS CLI command to specify the classes of statement that want logged by session audit logging. The example sets the `pgaudit.log` parameter to `write`, which captures inserts, updates, and deletes to the log.

```
aws rds modify-db-parameter-group \
   --db-parameter-group-name custom-param-group-name \
   --parameters
 "ParameterName=pgaudit.log,ParameterValue=write,ApplyMethod=pending-reboot" \
   --region aws-region
```

You can also choose one of the following values for the `pgaudit.log` parameter.

- none – This is the default. No database changes are logged.
- all – Logs everything (read, write, function, role, ddl, misc).
- ddl – Logs all data definition language (DDL) statements that aren't included in the `ROLE` class.
- function – Logs function calls and `DO` blocks.
- misc – Logs miscellaneous commands, such as `DISCARD`, `FETCH`, `CHECKPOINT`, `VACUUM`, and `SET`.
- read – Logs `SELECT` and `COPY` when the source is a relation (such as a table) or a query.
- role – Logs statements related to roles and privileges, such as `GRANT`, `REVOKE`, `CREATE ROLE`, `ALTER ROLE`, and `DROP ROLE`.
- write – Logs `INSERT`, `UPDATE`, `DELETE`, `TRUNCATE`, and `COPY` when the destination is a relation (table).

Reboot the RDS for PostgreSQL DB instance using the following AWS CLI command.

```
aws rds reboot-db-instance \
    --db-instance-identifier your-instance \
    --region aws-region
```

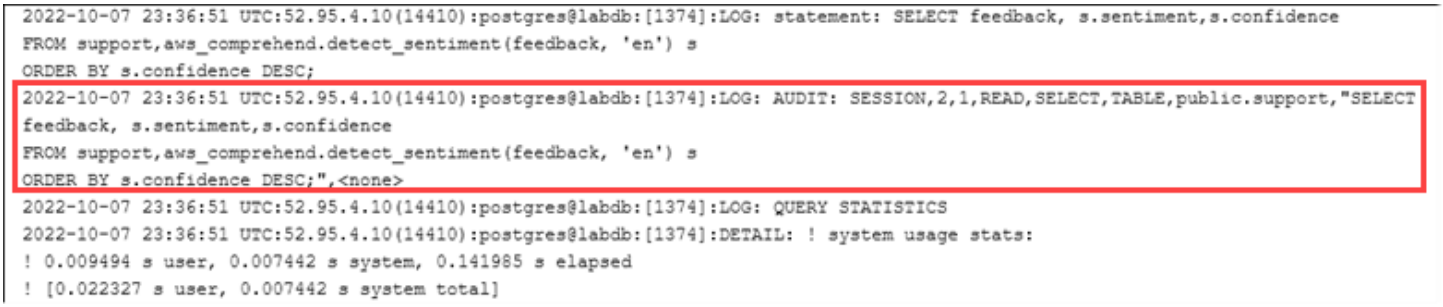
Auditing database objects

With pgAudit set up on your RDS for PostgreSQL DB instance and configured for your requirements, more detailed information is captured in the PostgreSQL log. For example, while the default PostgreSQL logging configuration identifies the date and time that a change was made in

a database table, with the pgAudit extension the log entry can include the schema, user who made the change, and other details depending on how the extension parameters are configured. You can set up auditing to track changes in the following ways.

- For each session, by user. For the session level, you can capture the fully qualified command text.
- For each object, by user and by database.

The object auditing capability is activated when you create the `rds_pgaudit` role on your system and then add this role to the `pgaudit.role` parameter in your custom parameter parameter group. By default, the `pgaudit.role` parameter is unset and the only allowable value is `rds_pgaudit`. The following steps assume that `pgaudit` has been initialized and that you have created the `pgaudit` extension by following the procedure in Setting up the pgAudit extension.



```
2022-10-07 23:36:51 UTC:52.95.4.10(14410):postgres@labdb:[1374]:LOG: statement: SELECT feedback, s.sentiment,s.confidence
FROM support,aws_comprehend.detect_sentiment(feedback, 'en') s
ORDER BY s.confidence DESC;
2022-10-07 23:36:51 UTC:52.95.4.10(14410):postgres@labdb:[1374]:LOG: AUDIT: SESSION,2,1,READ,SELECT,TABLE,public.support,"SELECT
feedback, s.sentiment,s.confidence
FROM support,aws_comprehend.detect_sentiment(feedback, 'en') s
ORDER BY s.confidence DESC;",<none>
2022-10-07 23:36:51 UTC:52.95.4.10(14410):postgres@labdb:[1374]:LOG: QUERY STATISTICS
2022-10-07 23:36:51 UTC:52.95.4.10(14410):postgres@labdb:[1374]:DETAIL: ! system usage stats:
! 0.009494 s user, 0.007442 s system, 0.141985 s elapsed
! [0.022327 s user, 0.007442 s system total]
```

As shown in this example, the "LOG: AUDIT: SESSION" line provides information about the table and its schema, among other details.

To set up object auditing

1. Use `psql` to connect to the RDS for PostgreSQL DB instance.

   ```
   psql --host=your-instance-name.aws-region.rds.amazonaws.com --port=5432 --
   username=postgrespostgres --password --dbname=labdb
   ```

2. Create a database role named `rds_pgaudit` using the following command.

   ```
   labdb=> CREATE ROLE rds_pgaudit;
   CREATE ROLE
   labdb=>
   ```

3. Close the `psql` session.

   ```
   labdb=> \q
   ```

In the next few steps, use the AWS CLI to modify the audit log parameters in your custom parameter group.

4. Use the following AWS CLI command to set the `pgaudit.role` parameter to `rds_pgaudit`. By default, this parameter is empty, and `rds_pgaudit` is the only allowable value.

```
aws rds modify-db-parameter-group \
   --db-parameter-group-name custom-param-group-name \
   --parameters
 "ParameterName=pgaudit.role,ParameterValue=rds_pgaudit,ApplyMethod=pending-reboot"
 \
   --region aws-region
```

5. Use the following AWS CLI command to reboot the RDS for PostgreSQL DB instance so that your changes to the parameters take effect.

```
aws rds reboot-db-instance \
    --db-instance-identifier your-instance \
    --region aws-region
```

6. Run the following command to confirm that the `pgaudit.role` is set to `rds_pgaudit`.

```
SHOW pgaudit.role;
pgaudit.role
------------------
rds_pgaudit
```

To test pgAudit logging, you can run several example commands that you want to audit. For example, you might run the following commands.

```
CREATE TABLE t1 (id int);
GRANT SELECT ON t1 TO rds_pgaudit;
SELECT * FROM t1;
id
----
(0 rows)
```

The database logs should contain an entry similar to the following.

```
...
```

```
2017-06-12 19:09:49 UTC:...:rds_test@postgres:[11701]:LOG: AUDIT:
OBJECT,1,1,READ,SELECT,TABLE,public.t1,select * from t1;
...
```

For information on viewing the logs, see Monitoring Amazon RDS log files.

To learn more about the pgAudit extension, see pgAudit on GitHub.

Excluding users or databases from audit logging

As discussed in RDS for PostgreSQL database log files, PostgreSQL logs consume storage space. Using the pgAudit extension adds to the volume of data gathered in your logs to varying degrees, depending on the changes that you track. You might not need to audit every user or database in your RDS for PostgreSQL DB instance.

To minimize impacts to your storage and to avoid needlessly capturing audit records, you can exclude users and databases from being audited. You can also change logging within a given session. The following examples show you how.

> **Note**
>
> Parameter settings at the session level take precedence over the settings in the custom DB parameter group for the RDS for PostgreSQL DB instance. If you don't want database users to bypass your audit logging configuration settings, be sure to change their permissions.

Suppose that your RDS for PostgreSQL DB instance is configured to audit the same level of activity for all users and databases. You then decide that you don't want to audit the user `myuser`. You can turn off auditing for `myuser` with the following SQL command.

```
ALTER USER myuser SET pgaudit.log TO 'NONE';
```

Then, you can use the following query to check the `user_specific_settings` column for `pgaudit.log` to confirm that the parameter is set to `NONE`.

```
SELECT
    usename AS user_name,
    useconfig AS user_specific_settings
FROM
    pg_user
WHERE
```

```
    usename = 'myuser';
```

You see output such as the following.

```
 user_name | user_specific_settings
-----------+-----------------------
 myuser    | {pgaudit.log=NONE}
(1 row)
```

You can turn off logging for a given user in the midst of their session with the database with the following command.

```
ALTER USER myuser IN DATABASE mydatabase SET pgaudit.log TO 'none';
```

Use the following query to check the settings column for pgaudit.log for a specific user and database combination.

```
SELECT
    usename AS "user_name",
    datname AS "database_name",
    pg_catalog.array_to_string(setconfig, E'\n') AS "settings"
FROM
    pg_catalog.pg_db_role_setting s
    LEFT JOIN pg_catalog.pg_database d ON d.oid = setdatabase
    LEFT JOIN pg_catalog.pg_user r ON r.usesysid = setrole
WHERE
    usename = 'myuser'
    AND datname = 'mydatabase'
ORDER BY
    1,
    2;
```

You see output similar to the following.

```
  user_name | database_name |     settings
-----------+---------------+------------------
 myuser    | mydatabase    | pgaudit.log=none
(1 row)
```

After turning off auditing for `myuser`, you decide that you don't want to track changes to `mydatabase`. You turn off auditing for that specific database by using the following command.

```
ALTER DATABASE mydatabase SET pgaudit.log to 'NONE';
```

Then, use the following query to check the database_specific_settings column to confirm that pgaudit.log is set to NONE.

```
SELECT
a.datname AS database_name,
b.setconfig AS database_specific_settings
FROM
pg_database a
FULL JOIN pg_db_role_setting b ON a.oid = b.setdatabase
WHERE
a.datname = 'mydatabase';
```

You see output such as the following.

```
 database_name | database_specific_settings
---------------+----------------------------
 mydatabase    | {pgaudit.log=NONE}
(1 row)
```

To return settings to the default setting for myuser, use the following command:

```
ALTER USER myuser RESET pgaudit.log;
```

To return settings to their default setting for a database, use the following command.

```
ALTER DATABASE mydatabase RESET pgaudit.log;
```

To reset user and database to the default setting, use the following command.

```
ALTER USER myuser IN DATABASE mydatabase RESET pgaudit.log;
```

You can also capture specific events to the log by setting the `pgaudit.log` to one of the other allowed values for the `pgaudit.log` parameter. For more information, see List of allowable settings for the `pgaudit.log` parameter.

```
ALTER USER myuser SET pgaudit.log TO 'read';
ALTER DATABASE mydatabase SET pgaudit.log TO 'function';
```

```
ALTER USER myuser IN DATABASE mydatabase SET pgaudit.log TO 'read,function'
```

Reference for the pgAudit extension

You can specify the level of detail that you want for your audit log by changing one or more of the parameters listed in this section.

Controlling pgAudit behavior

You can control the audit logging by changing one or more of the parameters listed in the following table.

Parameter	Description
`pgaudit.log`	Specifies the statement classes that will be logged by session audit logging. Allowable values include ddl, function, misc, read, role, write, none, all. For more information, see List of allowable settings for the `pgaudit.log` parameter.
`pgaudit.log_catalog`	When turned on (set to 1), adds statements to audit trail if all relations in a statement are in pg_catalog.
`pgaudit.log_level`	Specifies the log level to use for log entries. Allowed values: debug5, debug4, debug3, debug2, debug1, info, notice, warning, log
`pgaudit.log_parameter`	When turned on (set to 1), parameters passed with the statement are captured in the audit log.
`pgaudit.log_relation`	When turned on (set to 1), the audit log for the session creates a separate log entry for each relation (TABLE, VIEW, and so on) referenced in a SELECT or DML statement.
`pgaudit.log_statement_once`	Specifies whether logging will include the statement text and parameters with the first log entry for a statement/substatement combination or with every entry.
`pgaudit.role`	Specifies the master role to use for object audit logging. The only allowable entry is `rds_pgaudit` .

List of allowable settings for the `pgaudit.log` parameter

Value	Description
none	This is the default. No database changes are logged.
all	Logs everything (read, write, function, role, ddl, misc).
ddl	Logs all data definition language (DDL) statements that aren't included in the `ROLE` class.
function	Logs function calls and `DO` blocks.
misc	Logs miscellaneous commands, such as `DISCARD`, `FETCH`, `CHECKPOINT`, `VACUUM`, and `SET`.
read	Logs `SELECT` and `COPY` when the source is a relation (such as a table) or a query.
role	Logs statements related to roles and privileges, such as `GRANT`, `REVOKE`, `CREATE ROLE`, `ALTER ROLE`, and `DROP ROLE`.
write	Logs `INSERT`, `UPDATE`, `DELETE`, `TRUNCATE`, and `COPY` when the destination is a relation (table).

To log multiple event types with session auditing, use a comma-separated list. To log all event types, set `pgaudit.log` to `ALL`. Reboot your DB instance to apply the changes.

With object auditing, you can refine audit logging to work with specific relations. For example, you can specify that you want audit logging for `READ` operations on one or more tables.

Scheduling maintenance with the PostgreSQL pg_cron extension

You can use the PostgreSQL `pg_cron` extension to schedule maintenance commands within a PostgreSQL database. For more information about the extension, see What is pg_cron? in the pg_cron documentation.

The `pg_cron` extension is supported on RDS for PostgreSQL engine versions 12.5 and higher.

To learn more about using `pg_cron`, see Schedule jobs with pg_cron on your RDS for PostgreSQL or your Aurora PostgreSQL-Compatible Edition databases.

Topics

Setting up the pg_cron extension

Set up the `pg_cron` extension as follows:

1. Modify the custom parameter group associated with your PostgreSQL DB instance by adding `pg_cron` to the `shared_preload_libraries` parameter value.
   - If your RDS for PostgreSQL DB instance uses the `rds.allowed_extensions` parameter to explicitly list extensions that can be installed, you need to add the `pg_cron` extension to the list. Only certain versions of RDS for PostgreSQL support the `rds.allowed_extensions` parameter. By default, all available extensions are allowed. For more information, see Restricting installation of PostgreSQL extensions.

   Restart the PostgreSQL DB instance to have changes to the parameter group take effect. To learn more about working with parameter groups, see Modifying parameters in a DB parameter group in Amazon RDS.
2. After the PostgreSQL DB instance has restarted, run the following command using an account that has `rds_superuser` permissions. For example, if you used the default settings when you created your RDS for PostgreSQL DB instance, connect as user `postgres` and create the extension.

```
CREATE EXTENSION pg_cron;
```

The pg_cron scheduler is set in the default PostgreSQL database named postgres. The pg_cron objects are created in this postgres database and all scheduling actions run in this database.

3. You can use the default settings, or you can schedule jobs to run in other databases within your PostgreSQL DB instance. To schedule jobs for other databases within your PostgreSQL DB instance, see the example in Scheduling a cron job for a database other than the default database.

Granting database users permissions to use pg_cron

Installing the pg_cron extension requires the rds_superuser privileges. However, permissions to use the pg_cron can be granted (by a member of the rds_superuser group/role) to other database users, so that they can schedule their own jobs. We recommend that you grant permissions to the cron schema only as needed if it improves operations in your production environment.

To grant a database user permission in the cron schema, run the following command:

```
postgres=> GRANT USAGE ON SCHEMA cron TO db-user;
```

This gives *db-user* permission to access the cron schema to schedule cron jobs for the objects that they have permissions to access. If the database user doesn't have permissions, the job fails after posting the error message to the postgresql.log file, as shown in the following:

```
2020-12-08 16:41:00 UTC::@:[30647]:ERROR: permission denied for table table-name
2020-12-08 16:41:00 UTC::@:[27071]:LOG: background worker "pg_cron" (PID 30647) exited
 with exit code 1
```

In other words, make sure that database users that are granted permissions on the cron schema also have permissions on the objects (tables, schemas, and so on) that they plan to schedule.

The details of the cron job and its success or failure are also captured in the cron.job_run_details table. For more information, see Tables for scheduling jobs and capturing status .

Scheduling pg_cron jobs

The following sections show how you can schedule various management tasks using pg_cron jobs.

> **Note**
>
> When you create pg_cron jobs, check that the max_worker_processes setting is larger than the number of cron.max_running_jobs. A pg_cron job fails if it runs out of background worker processes. The default number of pg_cron jobs is 5. For more information, see Parameters for managing the pg_cron extension.

Topics

- Vacuuming a table
- Purging the pg_cron history table
- Logging errors to the postgresql.log file only
- Scheduling a cron job for a database other than the default database

Vacuuming a table

Autovacuum handles vacuum maintenance for most cases. However, you might want to schedule a vacuum of a specific table at a time of your choosing.

See also, Working with the PostgreSQL autovacuum on Amazon RDS for PostgreSQL.

Following is an example of using the cron.schedule function to set up a job to use VACUUM FREEZE on a specific table every day at 22:00 (GMT).

```
SELECT cron.schedule('manual vacuum', '0 22 * * *', 'VACUUM FREEZE pgbench_accounts');
 schedule
----------
1
(1 row)
```

After the preceding example runs, you can check the history in the cron.job_run_details table as follows.

```
postgres=> SELECT * FROM cron.job_run_details;
```

```
jobid  | runid | job_pid | database | username | command                          |
 status    | return_message | start_time                    | end_time
-------+-------+---------+----------+----------+-------------------------------
+-----------+---------------+------------------------------
+-------------------------------
 1     | 1     | 3395    | postgres | adminuser| vacuum freeze pgbench_accounts
 | succeeded | VACUUM         | 2020-12-04 21:10:00.050386+00 | 2020-12-04
 21:10:00.072028+00
(1 row)
```

Following is a query of the `cron.job_run_details` table to see the failed jobs.

```
postgres=> SELECT * FROM cron.job_run_details WHERE status = 'failed';
jobid | runid | job_pid | database | username | command                        | status
 | return_message                                | start_time                    |
 end_time
------+-------+---------+----------+----------+--------------------------------+--------
+-----------------------------------------------+------------------------------
+-------------------------------
 5    | 4     | 30339   | postgres | adminuser| vacuum freeze pgbench_account | failed
 | ERROR: relation "pgbench_account" does not exist | 2020-12-04 21:48:00.015145+00 |
 2020-12-04 21:48:00.029567+00
(1 row)
```

For more information, see Tables for scheduling jobs and capturing status .

Purging the pg_cron history table

The `cron.job_run_details` table contains a history of cron jobs that can become very large over time. We recommend that you schedule a job that purges this table. For example, keeping a week's worth of entries might be sufficient for troubleshooting purposes.

The following example uses the cron.schedule function to schedule a job that runs every day at midnight to purge the `cron.job_run_details` table. The job keeps only the last seven days. Use your `rds_superuser` account to schedule the job such as the following.

```
SELECT cron.schedule('0 0 * * *', $$DELETE
    FROM cron.job_run_details
    WHERE end_time < now() - interval '7 days'$$);
```

For more information, see Tables for scheduling jobs and capturing status .

Logging errors to the postgresql.log file only

To prevent writing to the `cron.job_run_details` table, modify the parameter group associated with the PostgreSQL DB instance and set the `cron.log_run` parameter to off. The `pg_cron` extension no longer writes to the table and captures errors to the `postgresql.log` file only. For more information, see Modifying parameters in a DB parameter group in Amazon RDS.

Use the following command to check the value of the `cron.log_run` parameter.

```
postgres=> SHOW cron.log_run;
```

For more information, see Parameters for managing the pg_cron extension.

Scheduling a cron job for a database other than the default database

The metadata for `pg_cron` is all held in the PostgreSQL default database named `postgres`. Because background workers are used for running the maintenance cron jobs, you can schedule a job in any of your databases within the PostgreSQL DB instance:

1. In the cron database, schedule the job as you normally do using the cron.schedule.

   ```
   postgres=> SELECT cron.schedule('database1 manual vacuum', '29 03 * * *', 'vacuum
    freeze test_table');
   ```

2. As a user with the `rds_superuser` role, update the database column for the job that you just created so that it runs in another database within your PostgreSQL DB instance.

   ```
   postgres=> UPDATE cron.job SET database = 'database1' WHERE jobid = 106;
   ```

3. Verify by querying the `cron.job` table.

   ```
   postgres=> SELECT * FROM cron.job;
   jobid | schedule    | command                        | nodename  | nodeport |
    database | username  | active | jobname
   ------+-------------+--------------------------------+-----------+----------
   +----------+-----------+--------+-------------------------
   106   | 29 03 * * * | vacuum freeze test_table       | localhost | 8192     |
    database1| adminuser | t      | database1 manual vacuum
     1   | 59 23 * * * | vacuum freeze pgbench_accounts | localhost | 8192     |
    postgres | adminuser | t      | manual vacuum
   (2 rows)
   ```

> **Note**
>
> In some situations, you might add a cron job that you intend to run on a different database. In such cases, the job might try to run in the default database (`postgres`) before you update the correct database column. If the user name has permissions, the job successfully runs in the default database.

Reference for the pg_cron extension

You can use the following parameters, functions, and tables with the `pg_cron` extension. For more information, see What is pg_cron? in the pg_cron documentation.

Topics

- Parameters for managing the pg_cron extension
- Function reference: cron.schedule
- Function reference: cron.unschedule
- Tables for scheduling jobs and capturing status

Parameters for managing the pg_cron extension

Following is a list of parameters that control the `pg_cron` extension behavior.

Parameter	Description
cron.database_name	The database in which `pg_cron` metadata is kept.
`cron.host`	The hostname to connect to PostgreSQL. You can't modify this value.
`cron.log_run`	Log every job that runs in the `job_run_details` table. Values are `on` or `off`. For more information, see Tables for scheduling jobs and capturing status .

Parameter	Description
`cron.log_statement`	Log all cron statements before running them. Values are on or `off`.
`cron.max_running_jobs`	The maximum number of jobs that can run concurrently.
`cron.use_background_workers`	Use background workers instead of client sessions. You can't modify this value.

Use the following SQL command to display these parameters and their values.

```
postgres=> SELECT name, setting, short_desc FROM pg_settings WHERE name LIKE 'cron.%'
 ORDER BY name;
```

Function reference: cron.schedule

This function schedules a cron job. The job is initially scheduled in the default `postgres` database. The function returns a `bigint` value representing the job identifier. To schedule jobs to run in other databases within your PostgreSQL DB instance, see the example in Scheduling a cron job for a database other than the default database.

The function has two syntax formats.

Syntax

```
cron.schedule (job_name,
    schedule,
    command
);

cron.schedule (schedule,
    command
);
```

Parameters

Parameter	Description
job_name	The name of the cron job.
schedule	Text indicating the schedule for the cron job. The format is the standard cron format.
command	Text of the command to run.

Examples

```
postgres=> SELECT cron.schedule ('test','0 10 * * *', 'VACUUM pgbench_history');
 schedule
----------
      145
(1 row)

postgres=> SELECT cron.schedule ('0 15 * * *', 'VACUUM pgbench_accounts');
 schedule
----------
      146
(1 row)
```

Function reference: cron.unschedule

This function deletes a cron job. You can specify either the `job_name` or the `job_id`. A policy makes sure that you are the owner to remove the schedule for the job. The function returns a Boolean indicating success or failure.

The function has the following syntax formats.

Syntax

```
cron.unschedule (job_id);

cron.unschedule (job_name);
```

Parameters

Parameter	Description
`job_id`	A job identifier that was returned from the `cron.schedule` function when the cron job was scheduled.
`job_name`	The name of a cron job that was scheduled with the `cron.schedule` function.

Examples

```
postgres=> SELECT cron.unschedule(108);
 unschedule
------------
 t
(1 row)

postgres=> SELECT cron.unschedule('test');
 unschedule
------------
 t
(1 row)
```

Tables for scheduling jobs and capturing status

The following tables are used to schedule the cron jobs and record how the jobs completed.

Table	Description
`cron.job`	Contains the metadata about each scheduled job. Most interactions with this table should be done by using the `cron.schedule` and `cron.unschedule` functions.

Table	Description
	Important We recommend that you don't give update or insert privileges directly to this table. Doing so would allow the user to update the `username` column to run as `rds-superuser` .
`cron.job_run_details`	Contains historic information about past scheduled jobs that ran. This is useful to investigate the status, return messages, and start and end time from the job that ran. **Note** To prevent this table from growing indefinitely, purge it on a regular basis. For an example, see Purging the pg_cron history table.

Using pglogical to synchronize data across instances

All currently available RDS for PostgreSQL versions support the `pglogical` extension. The pglogical extension predates the functionally similar logical replication feature that was introduced by PostgreSQL in version 10. For more information, see Performing logical replication for Amazon RDS for PostgreSQL.

The `pglogical` extension supports logical replication between two or more RDS for PostgreSQL DB instances. It also supports replication between different PostgreSQL versions, and between databases running on RDS for PostgreSQL DB instances and Aurora PostgreSQL DB clusters. The `pglogical` extension uses a publish-subscribe model to replicate changes to tables and other objects, such as sequences, from a publisher to a subscriber. It relies on a replication slot to ensure that changes are synchronized from a publisher node to a subscriber node, defined as follows.

- The *publisher node* is the RDS for PostgreSQL DB instance that's the source of data to be replicated to other nodes. The publisher node defines the tables to be replicated in a publication set.
- The *subscriber node* is the RDS for PostgreSQL DB instance that receives WAL updates from the publisher. The subscriber creates a subscription to connect to the publisher and get the decoded WAL data. When the subscriber creates the subscription, the replication slot is created on the publisher node.

Following, you can find information about setting up the `pglogical` extension.

Topics

Requirements and limitations for the pglogical extension

All currently available releases of RDS for PostgreSQL support the `pglogical` extension.

Both the publisher node and the subscriber node must be set up for logical replication.

The tables that you want to replicate from a publisher to a subscriber must have the same names and the same schema. These tables must also contain the same columns, and the columns must use the same data types. Both publisher and subscriber tables must have the same primary keys. We recommend that you use only the PRIMARY KEY as the unique constraint.

The tables on the subscriber node can have more permissive constraints than those on the publisher node for CHECK constraints and NOT NULL constraints.

The `pglogical` extension provides features such as two-way replication that aren't supported by the logical replication feature built into PostgreSQL (version 10 and higher). For more information, see PostgreSQL bi-directional replication using pglogical.

Setting up the pglogical extension

To set up the `pglogical` extension on your RDS for PostgreSQL DB instance , you add `pglogical` to the shared libraries on the custom DB parameter group for your RDS for PostgreSQL DB instance. You also need to set the value of the `rds.logical_replication` parameter to `1`, to turn on logical decoding. Finally, you create the extension in the database. You can use the AWS Management Console or the AWS CLI for these tasks.

You must have permissions as the `rds_superuser` role to perform these tasks.

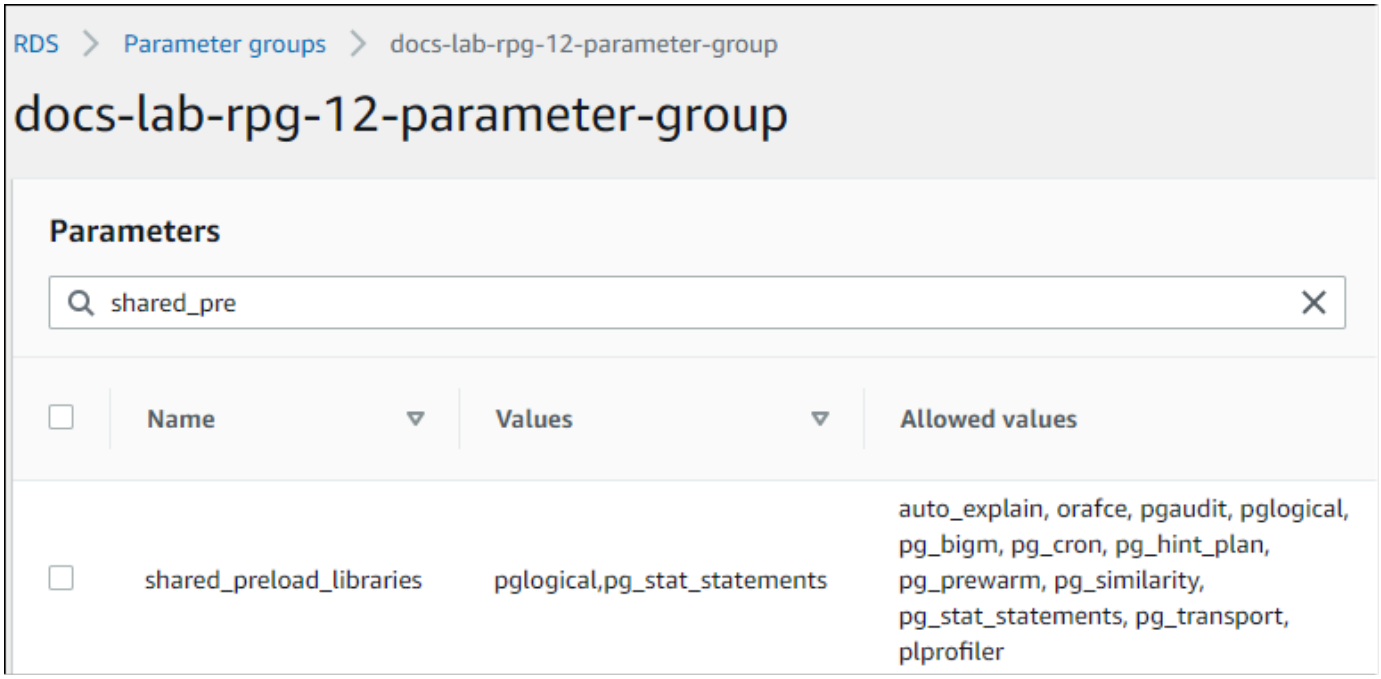
The steps following assume that your RDS for PostgreSQL DB instance is associated with a custom DB parameter group. For information about creating a custom DB parameter group, see Parameter groups for Amazon RDS.

Console

To set up the pglogical extension

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose your RDS for PostgreSQL DB instance.
3. Open the **Configuration** tab for your RDS for PostgreSQL DB instance. Among the Instance details, find the **Parameter group** link.
4. Choose the link to open the custom parameters associated with your RDS for PostgreSQL DB instance.

5. In the **Parameters** search field, type `shared_pre` to find the `shared_preload_libraries` parameter.
6. Choose **Edit parameters** to access the property values.
7. Add `pglogical` to the list in the **Values** field. Use a comma to separate items in the list of values.



8. Find the `rds.logical_replication` parameter and set it to 1, to turn on logical replication.
9. Reboot the RDS for PostgreSQL DB instance so that your changes take effect.
10. When the instance is available, you can use `psql` (or pgAdmin) to connect to the RDS for PostgreSQL DB instance.

```
psql --host=111122223333.aws-region.rds.amazonaws.com --port=5432 --
username=postgres --password --dbname=labdb
```

11. To verify that pglogical is initialized, run the following command.

```
SHOW shared_preload_libraries;
shared_preload_libraries
--------------------------
rdsutils,pglogical
(1 row)
```

12. Verify the setting that enables logical decoding, as follows.

```
SHOW wal_level;
wal_level
-----------
 logical
(1 row)
```

13. Create the extension, as follows.

```
CREATE EXTENSION pglogical;
EXTENSION CREATED
```

14. Choose **Save changes**.
15. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
16. Choose your RDS for PostgreSQL DB instance from the Databases list to select it, and then choose **Reboot** from the Actions menu.

AWS CLI

To setup the pglogical extension

To setup pglogical using the AWS CLI, you call the modify-db-parameter-group operation to modify certain parameters in your custom parameter group as shown in the following procedure.

1. Use the following AWS CLI command to add `pglogical` to the `shared_preload_libraries` parameter.

```
aws rds modify-db-parameter-group \
   --db-parameter-group-name custom-param-group-name \
   --parameters
 "ParameterName=shared_preload_libraries,ParameterValue=pglogical,ApplyMethod=pending-
reboot" \
   --region aws-region
```

2. Use the following AWS CLI command to set `rds.logical_replication` to 1 to turn on the logical decoding capability for the RDS for PostgreSQL DB instance.

```
aws rds modify-db-parameter-group \
   --db-parameter-group-name custom-param-group-name \
```

```
   --parameters
 "ParameterName=rds.logical_replication,ParameterValue=1,ApplyMethod=pending-
reboot" \
   --region aws-region
```

3. Use the following AWS CLI command to reboot the RDS for PostgreSQL DB instance so that the pglogical library is initialized.

```
aws rds reboot-db-instance \
    --db-instance-identifier your-instance \
    --region aws-region
```

4. When the instance is available, use `psql` to connect to the RDS for PostgreSQL DB instance.

```
psql --host=111122223333.aws-region.rds.amazonaws.com --port=5432 --
username=postgres --password --dbname=labdb
```

5. Create the extension, as follows.

```
CREATE EXTENSION pglogical;
EXTENSION CREATED
```

6. Reboot the RDS for PostgreSQL DB instance using the following AWS CLI command.

```
aws rds reboot-db-instance \
    --db-instance-identifier your-instance \
    --region aws-region
```

Setting up logical replication for RDS for PostgreSQL DB instance

The following procedure shows you how to start logical replication between two RDS for PostgreSQL DB instances. The steps assume that both the source (publisher) and the target (subscriber) have the `pglogical` extension set up as detailed in Setting up the pglogical extension.

To create the publisher node and define the tables to replicate

These steps assume that your RDS for PostgreSQL DB instance has a database that has one or more tables that you want to replicate to another node. You need to recreate the table structure from the publisher on the subscriber, so first, get the table structure if necessary. You can do

that by using the psql1 metacommand \d *tablename* and then creating the same table on the subscriber instance. The following procedure creates an example table on the publisher (source) for demonstration purposes.

1. Use psql to connect to the instance that has the table you want to use as a source for subscribers.

   ```
   psql --host=source-instance.aws-region.rds.amazonaws.com --port=5432 --
   username=postgres --password --dbname=labdb
   ```

   If you don't have an existing table that you want to replicate, you can create a sample table as follows.

   a. Create an example table using the following SQL statement.

      ```
      CREATE TABLE docs_lab_table (a int PRIMARY KEY);
      ```

   b. Populate the table with generated data by using the following SQL statement.

      ```
      INSERT INTO docs_lab_table VALUES (generate_series(1,5000));
      INSERT 0 5000
      ```

   c. Verify that data exists in the table by using the following SQL statement.

      ```
      SELECT count(*) FROM docs_lab_table;
      ```

2. Identify this RDS for PostgreSQL DB instance as the publisher node, as follows.

   ```
   SELECT pglogical.create_node(
       node_name := 'docs_lab_provider',
       dsn := 'host=source-instance.aws-region.rds.amazonaws.com port=5432
    dbname=labdb');
    create_node
   -------------
      3410995529
   (1 row)
   ```

3. Add the table that you want to replicate to the default replication set. For more information about replication sets, see Replication sets in the pglogical documentation.

```
SELECT pglogical.replication_set_add_table('default', 'docs_lab_table', 'true',
 NULL, NULL);
 replication_set_add_table
  --------------------------
  t
  (1 row)
```

The publisher node setup is complete. You can now set up the subscriber node to receive the updates from the publisher.

To set up the subscriber node and create a subscription to receive updates

These steps assume that the RDS for PostgreSQL DB instance has been set up with the `pglogical` extension. For more information, see Setting up the pglogical extension.

1. Use `psql` to connect to the instance that you want to receive updates from the publisher.

```
psql --host=target-instance.aws-region.rds.amazonaws.com --port=5432 --
username=postgres --password --dbname=labdb
```

2. On the subscriber RDS for PostgreSQL DB instance,create the same table that exists on the publisher. For this example, the table is `docs_lab_table`. You can create the table as follows.

```
CREATE TABLE docs_lab_table (a int PRIMARY KEY);
```

3. Verify that this table is empty.

```
SELECT count(*) FROM docs_lab_table;
 count
-------
  0
(1 row)
```

4. Identify this RDS for PostgreSQL DB instance as the subscriber node, as follows.

```
SELECT pglogical.create_node(
    node_name := 'docs_lab_target',
    dsn := 'host=target-instance.aws-region.rds.amazonaws.com port=5432
 sslmode=require dbname=labdb user=postgres password=********');
 create_node
```

```
-------------
   2182738256
(1 row)
```

5. Create the subscription.

```
SELECT pglogical.create_subscription(
   subscription_name := 'docs_lab_subscription',
   provider_dsn := 'host=source-instance.aws-region.rds.amazonaws.com port=5432
 sslmode=require dbname=labdb user=postgres password=*******',
   replication_sets := ARRAY['default'],
   synchronize_data := true,
   forward_origins := '{}' );
 create_subscription
---------------------
1038357190
(1 row)
```

When you complete this step, the data from the table on the publisher is created in the table on the subscriber. You can verify that this has occurred by using the following SQL query.

```
SELECT count(*) FROM docs_lab_table;
 count
-------
  5000
(1 row)
```

From this point forward, changes made to the table on the publisher are replicated to the table on the subscriber.

Reestablishing logical replication after a major upgrade

Before you can perform a major version upgrade of an RDS for PostgreSQL DB instance that's set up as a publisher node for logical replication, you must drop all replication slots, even those that aren't active. We recommend that you temporarily divert database transactions from the publisher node, drop the replication slots, upgrade the RDS for PostgreSQL DB instance, and then re-establish and restart replication.

The replication slots are hosted on the publisher node only. The RDS for PostgreSQL subscriber node in a logical replication scenario has no slots to drops, but it can't be upgraded to a major

version while it's designated as a subscriber node with a subscription to the publisher. Before upgrading the RDS for PostgreSQL subscriber node, drop the subscription and the node. For more information, see Managing logical replication slots for RDS for PostgreSQL.

Determining that logical replication has been disrupted

You can determine that the replication process has been disrupted by querying either the publisher node or the subscriber node, as follows.

To check the publisher node

- Use `psql` to connect to the publisher node, and then query the `pg_replication_slots` function. Note the value in the active column. Normally, this will return `t` (true), showing that replication is active. If the query returns `f` (false), it's an indication that replication to the subscriber has stopped.

```
SELECT slot_name,plugin,slot_type,active FROM pg_replication_slots;
                    slot_name              |      plugin      | slot_type | active
-------------------------------------------+------------------+-----------+--------
 pgl_labdb_docs_labcb4fa94_docs_lab3de412c | pglogical_output | logical   | f
(1 row)
```

To check the subscriber node

On the subscriber node, you can check the status of replication in three different ways.

- Look through the PostgreSQL logs on the subscriber node to find failure messages. The log identifies failure with messages that include exit code 1, as shown following.

```
2022-07-06 16:17:03 UTC::@:[7361]:LOG: background worker "pglogical apply
 16404:2880255011" (PID 14610) exited with exit code 1
2022-07-06 16:19:44 UTC::@:[7361]:LOG: background worker "pglogical apply
 16404:2880255011" (PID 21783) exited with exit code 1
```

- Query the `pg_replication_origin` function. Connect to the database on the subscriber node using `psql` and query the `pg_replication_origin` function, as follows.

```
SELECT * FROM pg_replication_origin;
 roident | roname
---------+--------
```

```
(0 rows)
```

The empty result set means that replication has been disrupted. Normally, you see output such as the following.

```
 roident |                      roname
---------+---------------------------------------------------
       1 | pgl_labdb_docs_labcb4fa94_docs_lab3de412c
(1 row)
```

- Query the `pglogical.show_subscription_status` function as shown in the following example.

```
SELECT subscription_name,status,slot_name FROM pglogical.show_subscription_status();
     subscription_name | status |              slot_name
-------+----------------+--------+-----------------------------------
 docs_lab_subscription | down   | pgl_labdb_docs_labcb4fa94_docs_lab3de412c
(1 row)
```

This output shows that replication has been disrupted. Its status is down. Normally, the output shows the status as `replicating`.

If your logical replication process has been disrupted, you can re-establish replication by following these steps.

To reestablish logical replication between publisher and subscriber nodes

To re-establish replication, you first disconnect the subscriber from the publisher node and then re-establish the subscription, as outlined in these steps.

1. Connect to the subscriber node using `psql` as follows.

```
psql --host=222222222222.aws-region.rds.amazonaws.com --port=5432 --
username=postgres --password --dbname=labdb
```

2. Deactivate the subscription by using the `pglogical.alter_subscription_disable` function.

```
SELECT pglogical.alter_subscription_disable('docs_lab_subscription',true);
 alter_subscription_disable
```

```
----------------------------
 t
(1 row)
```

3. Get the publisher node's identifier by querying the `pg_replication_origin`, as follows.

```
SELECT * FROM pg_replication_origin;
 roident |               roname
---------+--------------------------------------
       1 | pgl_labdb_docs_labcb4fa94_docs_lab3de412c
(1 row)
```

4. Use the response from the previous step with the `pg_replication_origin_create` command to assign the identifier that can be used by the subscription when re-established.

```
SELECT pg_replication_origin_create('pgl_labdb_docs_labcb4fa94_docs_lab3de412c');
  pg_replication_origin_create
------------------------------
                             1
(1 row)
```

5. Turn on the subscription by passing its name with a status of `true`, as shown in the following example.

```
SELECT pglogical.alter_subscription_enable('docs_lab_subscription',true);
  alter_subscription_enable
---------------------------
 t
(1 row)
```

Check the status of the node. Its status should be `replicating` as shown in this example.

```
SELECT subscription_name,status,slot_name
  FROM pglogical.show_subscription_status();
            subscription_name |   status    |              slot_name
------------------------------+-------------+-------------------------------------
 docs_lab_subscription         | replicating |
 pgl_labdb_docs_lab98f517b_docs_lab3de412c
(1 row)
```

Check the status of the subscriber's replication slot on the publisher node. The slot's `active` column should return `t` (true), indicating that replication has been re-established.

```
SELECT slot_name,plugin,slot_type,active
  FROM pg_replication_slots;
                    slot_name              |      plugin      | slot_type | active
-------------------------------------------+------------------+-----------+--------
 pgl_labdb_docs_lab98f517b_docs_lab3de412c | pglogical_output | logical   | t
(1 row)
```

Managing logical replication slots for RDS for PostgreSQL

Before you can perform a major version upgrade on an RDS for PostgreSQL DB instance that's serving as a publisher node in a logical replication scenario, you must drop the replication slots on the instance. The major version upgrade pre-check process notifies you that the upgrade can't proceed until the slots are dropped.

To drop slots from your RDS for PostgreSQL DB instance, first drop the subscription and then drop the slot.

To identify replication slots that were created using the `pglogical` extension, log in to each database and get the name of the nodes. When you query the subscriber node, you get both the publisher and the subscriber nodes in the output, as shown in this example.

```
SELECT * FROM pglogical.node;
node_id   |     node_name
------------+------------------
 2182738256 | docs_lab_target
 3410995529 | docs_lab_provider
(2 rows)
```

You can get the details about the subscription with the following query.

```
SELECT sub_name,sub_slot_name,sub_target
  FROM pglogical.subscription;
 sub_name |         sub_slot_name          | sub_target
----------+--------------------------------+------------
  docs_lab_subscription     | pgl_labdb_docs_labcb4fa94_docs_lab3de412c | 2182738256
(1 row)
```

You can now drop the subscription, as follows.

```
SELECT pglogical.drop_subscription(subscription_name := 'docs_lab_subscription');
 drop_subscription
-------------------
                 1
(1 row)
```

After dropping the subscription, you can delete the node.

```
SELECT pglogical.drop_node(node_name := 'docs-lab-subscriber');
 drop_node
-----------
 t
(1 row)
```

You can verify that the node no longer exists, as follows.

```
SELECT * FROM pglogical.node;
 node_id | node_name
---------+-----------
(0 rows)
```

Parameter reference for the pglogical extension

In the table you can find parameters associated with the `pglogical` extension. Parameters such as `pglogical.conflict_log_level` and `pglogical.conflict_resolution` are used to handle update conflicts. Conflicts can emerge when changes are made locally to the same tables that are subscribed to changes from the publisher. Conflicts can also occur during various scenarios, such as two-way replication or when multiple subscribers are replicating from the same publisher. For more information, see PostgreSQL bi-directional replication using pglogical.

Parameter	Description
pglogical.batch_inserts	Batch inserts if possible. Not set by default. Change to '1' to turn on, '0' to turn off.
pglogical.conflict_log_level	Sets the log level to use for logging resolved conflicts. Supported string values are debug5, debug4, debug3, debug2, debug1, info, notice, warning, error, log, fatal, panic.

Parameter	Description
pglogical.conflict_resolution	Sets method to use to resolve conflicts when conflicts are resolvable. Supported string values are error, apply_remote, keep_local, last_update_wins, first_update_wins.
pglogical.extra_connection_options	Connection options to add to all peer node connections.
pglogical.synchronous_commit	pglogical specific synchronous commit value
pglogical.use_spi	Use SPI (server programming interface) instead of low-level API to apply changes. Set to '1' to turn on, '0' to turn off. For more information about SPI, see Server Programming Interface in the PostgreSQL documentation.

Using pgactive to support active-active replication

The `pgactive` extension uses active-active replication to support and coordinate write operations on multiple RDS for PostgreSQL databases. Amazon RDS for PostgreSQL supports the `pgactive` extension on the following versions:

- RDS for PostgreSQL 16.1 and higher 16 versions
- RDS for PostgreSQL 15.4-R2 and higher 15 versions
- RDS for PostgreSQL 14.10 and higher 14 versions
- RDS for PostgreSQL 13.13 and higher 13 versions
- RDS for PostgreSQL 12.17 and higher 12 versions
- RDS for PostgreSQL 11.22

> **Note**
>
> When there are write operations on more than one database in a replication configuration, conflicts are possible. For more information, see Handling conflicts in active-active replication

Topics

Initializing the pgactive extension capability

To initialize the `pgactive` extension capability on your RDS for PostgreSQL DB instance, set the value of the `rds.enable_pgactive` parameter to `1` and then create the extension in the

database. Doing so automatically turns on the parameters `rds.logical_replication` and `track_commit_timestamp` and sets the value of `wal_level` to `logical`.

You must have permissions as the `rds_superuser` role to perform these tasks.

You can use the AWS Management Console or the AWS CLI to create the required RDS for PostgreSQL DB instances. The steps following assume that your RDS for PostgreSQL DB instance is associated with a custom DB parameter group. For information about creating a custom DB parameter group, see Parameter groups for Amazon RDS.

Console

To initialize the pgactive extension capability

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose your RDS for PostgreSQL DB instance.
3. Open the **Configuration** tab for your RDS for PostgreSQL DB instance. In the instance details, find the **DB instance parameter group** link.
4. Choose the link to open the custom parameters associated with your RDS for PostgreSQL DB instance.
5. Find the `rds.enable_pgactive` parameter, and set it to `1` to initialize the `pgactive` capability.
6. Choose **Save changes**.
7. In the navigation pane of the Amazon RDS console, choose **Databases**.
8. Select your RDS for PostgreSQL DB instance, and then choose **Reboot** from the **Actions** menu.
9. Confirm the DB instance reboot so that your changes take effect.
10. When the DB instance is available, you can use `psql` or any other PostgreSQL client to connect to the RDS for PostgreSQL DB instance.

    The following example assumes that your RDS for PostgreSQL DB instance has a default database named *`postgres`*.

    ```
    psql --host=mydb.111122223333.aws-region.rds.amazonaws.com --port=5432 --
    username=master username --password --dbname=postgres
    ```

11. To verify that pgactive is initialized, run the following command.

```
postgres=>SELECT setting ~ 'pgactive'
FROM pg_catalog.pg_settings
WHERE name = 'shared_preload_libraries';
```

If `pgactive` is in `shared_preload_libraries`, the preceding command will return the following:

```
?column?
----------
 t
```

12. Create the extension, as follows.

```
postgres=> CREATE EXTENSION pgactive;
```

AWS CLI

To initialize the pgactive extension capability

To initialize the `pgactive` using the AWS CLI, call the modify-db-parameter-group operation to modify certain parameters in your custom parameter group as shown in the following procedure.

1. Use the following AWS CLI command to set `rds.enable_pgactive` to 1 to initialize the `pgactive` capability for the RDS for PostgreSQL DB instance.

```
postgres=>aws rds modify-db-parameter-group \
   --db-parameter-group-name custom-param-group-name \
   --parameters
 "ParameterName=rds.enable_pgactive,ParameterValue=1,ApplyMethod=pending-reboot" \
   --region aws-region
```

2. Use the following AWS CLI command to reboot the RDS for PostgreSQL DB instance so that the `pgactive` library is initialized.

```
aws rds reboot-db-instance \
    --db-instance-identifier your-instance \
    --region aws-region
```

3. When the instance is available, use `psql` to connect to the RDS for PostgreSQL DB instance.

```
psql --host=mydb.111122223333.aws-region.rds.amazonaws.com --port=5432 --
username=master user --password --dbname=postgres
```

4. Create the extension, as follows.

```
postgres=> CREATE EXTENSION pgactive;
```

Setting up active-active replication for RDS for PostgreSQL DB instances

The following procedure shows you how to start active-active replication between two RDS for PostgreSQL DB instances running PostgreSQL 15.4 or higher in the same region. To run the multi-region high availability example, you need to deploy Amazon RDS for PostgreSQL instances in two different regions and set up VPC Peering. For more information, see VPC peering.

> **Note**
>
> Sending traffic between multiple regions may incur additional costs.

These steps assume that the RDS for PostgreSQL DB instance has been setup with the `pgactive` extension. For more information, see Initializing the pgactive extension capability.

To configure the first RDS for PostgreSQL DB instance with the `pgactive` extension

The following example illustrates how the `pgactive` group is created, along with other steps required to create the `pgactive` extension on the RDS for PostgreSQL DB instance.

1. Use `psql` or another client tool to connect to your first RDS for PostgreSQL DB instance.

```
psql --host=firstinstance.111122223333.aws-region.rds.amazonaws.com --port=5432 --
username=master username --password --dbname=postgres
```

2. Create a database on the RDS for PostgreSQL instance using the following command:

```
postgres=> CREATE DATABASE app;
```

3. Switch connection to the new database using the following command:

```
\c app
```

4. To check if the `shared_preload_libraries` parameter contains `pgactive`, run the following command:

```
app=>SELECT setting ~ 'pgactive' FROM pg_catalog.pg_settings WHERE name =
 'shared_preload_libraries';
```

```
 ?column?
----------
 t
```

5. Create and populate a sample table using the following SQL statements:

   a. Create an example table using the following SQL statement.

```
app=> CREATE SCHEMA inventory;
CREATE TABLE inventory.products (
id int PRIMARY KEY, product_name text NOT NULL,
created_at timestamptz NOT NULL DEFAULT CURRENT_TIMESTAMP);
```

   b. Populate the table with some sample data by using the following SQL statement.

```
app=> INSERT INTO inventory.products (id, product_name)
VALUES (1, 'soap'), (2, 'shampoo'), (3, 'conditioner');
```

   c. Verify that data exists in the table by using the following SQL statement.

```
 app=>SELECT count(*) FROM inventory.products;

 count
-------
 3
```

6. Create `pgactive` extension on the existing database.

```
app=> CREATE EXTENSION pgactive;
```

7. Create and initialize the pgactive group using the following commands:

```
app=> SELECT pgactive.pgactive_create_group(
    node_name := 'node1-app',
    node_dsn := 'dbname=app host=firstinstance.111122223333.aws-
region.rds.amazonaws.com user=master username password=PASSWORD');
```

node1-app is the name that you assign to uniquely identify a node in the pgactive group.

> **Note**
>
> To perform this step successfully on a DB instance that is publicly accessible, you must turn on the rds.custom_dns_resolution parameter by setting it to 1.

8. To check if the DB instance is ready, use the following command:

```
app=> SELECT pgactive.pgactive_wait_for_node_ready();
```

If the command succeeds, you can see the following output:

```
pgactive_wait_for_node_ready
-----------------------------
(1 row)
```

To configure the second RDS for PostgreSQL instance and join it to the pgactive group

The following example illustrates how you can join an RDS for PostgreSQL DB instance to the pgactive group, along with other steps that are required to create the pgactive extension on the DB instance.

These steps assume that another RDS for PostgreSQL DB instances has been set up with the pgactive extension. For more information, see Initializing the pgactive extension capability.

1. Use psql to connect to the instance that you want to receive updates from the publisher.

```
psql --host=secondinstance.111122223333.aws-region.rds.amazonaws.com --port=5432 --
username=master username --password --dbname=postgres
```

2. Create a database on the second RDS for PostgreSQL DB instance using the following command:

```
postgres=> CREATE DATABASE app;
```

3. Switch connection to the new database using the following command:

```
\c app
```

4. Create the `pgactive` extension on the existing database.

```
app=> CREATE EXTENSION pgactive;
```

5. Join the RDS for PostgreSQL second DB instance to the `pgactive` group as follows.

```
app=> SELECT pgactive.pgactive_join_group(
node_name := 'node2-app',
node_dsn := 'dbname=app host=secondinstance.111122223333.aws-
region.rds.amazonaws.com user=master username password=PASSWORD',
join_using_dsn := 'dbname=app host=firstinstance.111122223333.aws-
region.rds.amazonaws.com user=postgres password=PASSWORD');
```

node2-app is the name that you assign to uniquely identify a node in the `pgactive` group.

6. To check if the DB instance is ready, use the following command:

```
app=> SELECT pgactive.pgactive_wait_for_node_ready();
```

If the command succeeds, you can see the following output:

```

pgactive_wait_for_node_ready
-----------------------------
(1 row)
```

If the first RDS for PostgreSQL database is relatively large, you can see `pgactive.pgactive_wait_for_node_ready()` emitting the progress report of the restore operation. The output looks similar to the following:

```
NOTICE:  restoring database 'app', 6% of 7483 MB complete
```

```
NOTICE:  restoring database 'app', 42% of 7483 MB complete
NOTICE:  restoring database 'app', 77% of 7483 MB complete
NOTICE:  restoring database 'app', 98% of 7483 MB complete
NOTICE:  successfully restored database 'app' from node node1-app in
 00:04:12.274956
 pgactive_wait_for_node_ready
------------------------------
(1 row)
```

From this point forward, `pgactive` synchronizes the data between the two DB instances.

7. You can use the following command to verify if the database of the second DB instance has the data:

```
app=> SELECT count(*) FROM inventory.products;
```

If the data is successfully synchronized, you'll see the following output:

```
 count
-------
 3
```

8. Run the following command to insert new values:

```
app=> INSERT INTO inventory.products (id, product_name) VALUES ('lotion');
```

9. Connect to the database of the first DB instance and run the following query:

```
app=> SELECT count(*) FROM inventory.products;
```

If the active-active replication is initialized, the output is similar to the following:

```
count
-------
 4
```

To detach and remove a DB instance from the `pgactive` group

You can detach and remove a DB instance from the `pgactive` group using these steps:

1. You can detach the second DB instance from the first DB instance using the following command:

```
app=> SELECT * FROM pgactive.pgactive_detach_nodes(ARRAY['node2-app']);
```

2. Remove the pgactive extension from the second DB instance using the following command:

```
app=> SELECT * FROM pgactive.pgactive_remove();
```

   To forcefully remove the extension:

```
app=> SELECT * FROM pgactive.pgactive_remove(true);
```

3. Drop the extension using the following command:

```
app=> DROP EXTENSION pgactive;
```

Handling conflicts in active-active replication

The pgactive extension works per database and not per cluster. Each DB instance that uses pgactive is an independent instance and can accept data changes from any source. When a change is sent to a DB instance, PostgreSQL commits it locally and then uses pgactive to replicate the change asynchronously to other DB instances. When two PostgreSQL DB instances update the same record at nearly the same time, a conflict can occur.

The pgactive extension provides mechanisms for conflict detection and automatic resolution. It tracks the time stamp when the transaction was committed on both the DB instances and automatically applies the change with the latest time stamp. The pgactive extension also logs when a conflict occurs in the pgactive.pgactive_conflict_history table.

The pgactive.pgactive_conflict_history will keep growing. You may want to define a purging policy. This can be done by deleting some records on a regular basis or defining a partitioning scheme for this relation (and later detach, drop, truncate partitions of interest). To implement the purging policy on a regular basis, one option is to use the pg_cron extension. See the following information of an example for the pg_cron history table, Scheduling maintenance with the PostgreSQL pg_cron extension.

Handling sequences in active-active replication

An RDS for PostgreSQL DB instance with the `pgactive` extension uses two different sequence mechanisms to generate unique values.

Global Sequences

To use a global sequence, create a local sequence with the `CREATE SEQUENCE` statement. Use `pgactive.pgactive_snowflake_id_nextval(seqname)` instead of `usingnextval(seqname)` to get the next unique value of the sequence.

The following example creates a global sequence:

```
postgres=> CREATE TABLE gstest (
      id bigint primary key,
      parrot text
    );
```

```
postgres=>CREATE SEQUENCE gstest_id_seq OWNED BY gstest.id;
```

```
postgres=> ALTER TABLE gstest \
      ALTER COLUMN id SET DEFAULT \
      pgactive.pgactive_snowflake_id_nextval('gstest_id_seq');
```

Partitioned sequences

In split-step or partitioned sequences, a normal PostgreSQL sequence is used on each node. Each sequence increments by the same amount and starts at different offsets. For example, with step 100, the node 1 generates sequence as 101, 201, 301, and so on and the node 2 generates sequence as 102, 202, 302, and so on. This scheme works well even if the nodes can't communicate for extended periods, but requires that the designer specify a maximum number of nodes when establishing the schema and requires per-node configuration. Mistakes can easily lead to overlapping sequences.

It is relatively simple to configure this approach with `pgactive` by creating the desired sequence on a node as follows:

```

CREATE TABLE some_table (generated_value bigint primary key);
```

```
postgres=> CREATE SEQUENCE some_seq INCREMENT 100 OWNED BY some_table.generated_value;
```

```
postgres=> ALTER TABLE some_table ALTER COLUMN generated_value SET DEFAULT
 nextval('some_seq');
```

Then call `setval` on each node to give a different offset starting value as follows.

```
postgres=>
-- On node 1
SELECT setval('some_seq', 1);

-- On node 2
SELECT setval('some_seq', 2);
```

Parameter reference for the pgactive extension

You can use the following query to view all the parameters associated with `pgactive` extension.

```
postgres=> SELECT * FROM pg_settings WHERE name LIKE 'pgactive.%';
```

Measuring replication lag among pgactive members

You can use the following query to view the replication lag among the `pgactive` members. Run this query on every `pgactive` node to get the full picture.

```
      postgres=# SELECT *, (last_applied_xact_at - last_applied_xact_committs) AS lag
 FROM pgactive.pgactive_node_slots;
-{ RECORD 1 ]---------------
+-------------------------------------------------------------
node_name                   | node2-app
slot_name                   | pgactive_5_7332551165694385385_0_5__
slot_restart_lsn            | 0/1A898A8
slot_confirmed_lsn          | 0/1A898E0
walsender_active            | t
walsender_pid               | 69022
sent_lsn                    | 0/1A898E0
write_lsn                   | 0/1A898E0
flush_lsn                   | 0/1A898E0
```

```
replay_lsn                  | 0/1A898E0
last_sent_xact_id           | 746
last_sent_xact_committs     | 2024-02-06 18:04:22.430376+00
last_sent_xact_at           | 2024-02-06 18:04:22.431359+00
last_applied_xact_id        | 746
last_applied_xact_committs  | 2024-02-06 18:04:22.430376+00
last_applied_xact_at        | 2024-02-06 18:04:52.452465+00
lag                         | 00:00:30.022089
```

Limitations for the pgactive extension

- All tables require a Primary Key, otherwise Update's and Delete's aren't allowed. The values in the Primary Key column shouldn't be updated.
- Sequences may have gaps and sometimes might not follow an order. Sequences are not replicated. For more information, see Handling sequences in active-active replication.
- DDL and large objects are not replicated.
- Secondary unique indexes can cause data divergence.
- Collation needs to be identical on all node in the group.
- Load balancing across nodes is an anti-pattern.
- Large transactions can cause replication lag.

Reducing bloat in tables and indexes with the pg_repack extension

You can use the pg_repack extension to remove bloat from tables and indexes as an alternative to VACUUM FULL. This extension is supported on RDS for PostgreSQL versions 9.6.3 and higher. For more information on the pg_repack extension and the full table repack, see the GitHub project documentation.

Unlike VACUUM FULL, the pg_repack extension requires an exclusive lock (AccessExclusiveLock) only for a short period of time during the table rebuild operation in the following cases:

- Initial creation of log table – A log table is created to record changes that occur during initial copy of the data, as shown in the following example:

```
postgres=>\dt+ repack.log_*
List of relations
-[ RECORD 1 ]-+----------
Schema        | repack
Name          | log_16490
Type          | table
Owner         | postgres
Persistence   | permanent
Access method | heap
Size          | 65 MB
Description   |
```

- Final swap-and-drop phase.

For the rest of the rebuild operation, it only needs an ACCESS SHARE lock on the original table to copy rows from it to the new table. This helps the INSERT, UPDATE, and DELETE operations to proceed as usual.

Recommendations

The following recommendations apply when you remove bloat from the tables and indexes using the pg_repack extension:

- Perform repack during non-business hours or over a maintenance window to minimize its impact on performance of other database activities.
- Closely monitor blocking sessions during the rebuild activity and ensure that there is no activity on the original table that could potentially block pg_repack, specifically during the final swap-

and-drop phase when it needs an exclusive lock on the original table. For more information, see Identifying what is blocking a query.

When you see a blocking session, you can terminate it using the following command after careful consideration. This helps in the continuation of pg_repack to finish the rebuild:

```
SELECT pg_terminate_backend(pid);
```

- While applying the accrued changes from the pg_repack's log table on systems with a very high transaction rate, the apply process might not be able to keep up with the rate of changes. In such cases, pg_repack would not be able to complete the apply process. For more information, see Monitoring the new table during the repack. If indexes are severely bloated, an alternative solution is to perform an index only repack. This also helps VACUUM's index cleanup cycles to finish faster.

  You can skip the index cleanup phase using manual VACUUM from PostgreSQL version 12, and it is skipped automatically during emergency autovacuum from PostgreSQL version 14. This helps VACUUM complete faster without removing the index bloat and is only meant for emergency situations such as preventing wraparound VACUUM. For more information, see Avoiding bloat in indexes in the Amazon Aurora User Guide.

Pre-requisites

- The table must have PRIMARY KEY or not-null UNIQUE constraint.
- The extension version must be the same for both the client and the server.
- Ensure that the RDS instance has more FreeStorageSpace than the total size of the table without the bloat. As an example, consider the total size of the table including TOAST and indexes as 2TB, and total bloat in the table as 1TB. The required FreeStorageSpace must be more than value returned by the following calculation:

  2TB (Table size) - 1TB (Table bloat) = 1TB

  You can use the following query to check the total size of the table and use pgstattuple to derive bloat. For more information, see Diagnosing table and index bloat in the Amazon Aurora User Guide

```
SELECT pg_size_pretty(pg_total_relation_size('table_name')) AS total_table_size;
```

This space is reclaimed after the completion of the activity.

- Ensure that the RDS instance has enough compute and IO capacity to handle the repack operation. You might consider to scale up the instance class for optimal balance of performance.

To use the pg_repack extension

1. Install the pg_repack extension on your RDS for PostgreSQL DB instance by running the following command.

```
CREATE EXTENSION pg_repack;
```

2. Run the following commands to grant write access to temporary log tables created by pg_repack.

```
ALTER DEFAULT PRIVILEGES IN SCHEMA repack GRANT INSERT ON TABLES TO PUBLIC;
ALTER DEFAULT PRIVILEGES IN SCHEMA repack GRANT USAGE, SELECT ON SEQUENCES TO
 PUBLIC;
```

3. Connect to the database using the pg_repack client utility. Use an account that has rds_superuser privileges. As an example, assume that rds_test role has rds_superuser privileges. The following syntax performs pg_repack for full tables including all the table indexes in the postgres database.

```
pg_repack -h db-instance-name.111122223333.aws-region.rds.amazonaws.com -U rds_test
 -k postgres
```

> **Note**
>
> You must connect using the -k option. The -a option is not supported.

The response from the pg_repack client provides information on the tables on the DB instance that are repacked.

```
INFO: repacking table "pgbench_tellers"
INFO: repacking table "pgbench_accounts"
INFO: repacking table "pgbench_branches"
```

4. The following syntax repacks a single table `orders` including indexes in `postgres` database.

```
pg_repack -h db-instance-name.111122223333.aws-region.rds.amazonaws.com -U rds_test
 --table orders -k postgres
```

The following syntax repacks only indexes for `orders` table in `postgres` database.

```
pg_repack -h db-instance-name.111122223333.aws-region.rds.amazonaws.com -U rds_test
 --table orders --only-indexes -k postgres
```

Monitoring the new table during the repack

- The size of the database is increased by the total size of the table minus bloat, until swap-and-drop phase of repack. You can monitor the growth rate of the database size, calculate the speed of the repack, and roughly estimate the time it takes to complete initial data transfer.

  As an example, consider the total size of the table as 2TB, the size of the database as 4TB, and total bloat in the table as 1TB. The database total size value returned by the calculation at the end of the repack operation is the following:

  `2TB (Table size) + 4 TB (Database size) - 1TB (Table bloat) = 5TB`

  You can roughly estimate the speed of the repack operation by sampling the growth rate in bytes between two points in time. If the growth rate is 1GB per minute, it can take 1000 minutes or 16.6 hours approximately to complete the initial table build operation. In addition to the initial table build, `pg_repack` also needs to apply accrued changes. The time it takes depends on the rate of applying ongoing changes plus accrued changes.

  > **Note**
  >
  > You can use `pgstattuple` extension to calculate the bloat in the table. For more information, see pgstattuple .

- The number of rows in the `pg_repack's` log table, under the repack schema represents the volume of changes pending to be applied to the new table after the initial load.

You can check the pg_repack's log table in pg_stat_all_tables to monitor the changes applied to the new table. pg_stat_all_tables.n_live_tup indicates the number of records that are pending to be applied to the new table. For more information, see pg_stat_all_tables.

```
postgres=>SELECT relname,n_live_tup FROM pg_stat_all_tables WHERE schemaname =
 'repack' AND relname ILIKE '%log%';

-[ RECORD 1 ]---------
relname    | log_16490
n_live_tup | 2000000
```

- You can use the pg_stat_statements extension to find out the time taken by each step in the repack operation. This is helpful in preparation for applying the same repack operation in a production environment. You may adjust the LIMIT clause for extending the output further.

```
postgres=>SELECT
     SUBSTR(query, 1, 100) query,
     round((round(total_exec_time::numeric, 6) / 1000 / 60),4)
 total_exec_time_in_minutes
 FROM
     pg_stat_statements
 WHERE
     query ILIKE '%repack%'
 ORDER BY
     total_exec_time DESC LIMIT 5;

 query                                                                |
 total_exec_time_in_minutes
----------------------------------------------------------------------
+---------------------------
 CREATE UNIQUE INDEX index_16493 ON repack.table_16490 USING btree (a) |
        6.8627
 INSERT INTO repack.table_16490 SELECT a FROM ONLY public.t1           |
        6.4150
 SELECT repack.repack_apply($1, $2, $3, $4, $5, $6)                    |
        0.5395
 SELECT repack.repack_drop($1, $2)                                     |
        0.0004
 SELECT repack.repack_swap($1)                                         |
        0.0004
(5 rows)
```

Repacking is completely an out-of-place operation so the original table is not impacted and we do not anticipate any unexpected challenges that require recovery of the original table. If repack fails unexpectedly, you must inspect the cause of the error and resolve it.

After the issue is resolved, drop and recreate the `pg_repack` extension in the database where the table exists, and retry the `pg_repack` step. In addition, the availability of compute resources and concurrent accessibility of the table plays a crucial role in the timely completion of the repack operation.

Upgrading and using the PLV8 extension

PLV8 is a trusted Javascript language extension for PostgreSQL. You can use it for stored procedures, triggers, and other procedural code that's callable from SQL. This language extension is supported by all current releases of PostgreSQL.

If you use PLV8 and upgrade PostgreSQL to a new PLV8 version, you immediately take advantage of the new extension. Take the following steps to synchronize your catalog metadata with the new version of PLV8. These steps are optional, but we highly recommend that you complete them to avoid metadata mismatch warnings.

The upgrade process drops all your existing PLV8 functions. Thus, we recommend that you create a snapshot of your RDS for PostgreSQL DB instance before upgrading. For more information, see Creating a DB snapshot for a Single-AZ DB instance.

To synchronize your catalog metadata with a new version of PLV8

1. Verify that you need to update. To do this, run the following command while connected to your instance.

   ```
   SELECT * FROM pg_available_extensions WHERE name IN ('plv8','plls','plcoffee');
   ```

   If your results contain values for an installed version that is a lower number than the default version, continue with this procedure to update your extensions. For example, the following result set indicates that you should update.

   ```
   name    | default_version | installed_version |                      comment
   --------+-----------------+-------------------
   +-----------------------------------------------
   plls    | 2.1.0           | 1.5.3             | PL/LiveScript (v8) trusted
    procedural language
   plcoffee| 2.1.0           | 1.5.3             | PL/CoffeeScript (v8) trusted
    procedural language
   plv8    | 2.1.0           | 1.5.3             | PL/JavaScript (v8) trusted
    procedural language
   (3 rows)
   ```

2. Create a snapshot of your RDS for PostgreSQL DB instance if you haven't done so yet. You can continue with the following steps while the snapshot is being created.

3. Get a count of the number of PLV8 functions in your DB instance so you can validate that they are all in place after the upgrade. For example, the following SQL query returns the number of functions written in plv8, plcoffee, and plls.

```
SELECT proname, nspname, lanname
FROM pg_proc p, pg_language l, pg_namespace n
WHERE p.prolang = l.oid
AND n.oid = p.pronamespace
AND lanname IN ('plv8','plcoffee','plls');
```

4. Use pg_dump to create a schema-only dump file. For example, create a file on your client machine in the `/tmp` directory.

```
./pg_dump -Fc --schema-only -U master postgres >/tmp/test.dmp
```

   This example uses the following options:

   - `-Fc` – Custom format
   - --schema-only – Dump only the commands necessary to create schema (functions in this case)
   - `-U` – The RDS master user name
   - `database` – The database name for our DB instance

   For more information on pg_dump, see pg_dump in the PostgreSQL documentation.

5. Extract the "CREATE FUNCTION" DDL statement that is present in the dump file. The following example uses the `grep` command to extract the DDL statement that creates the functions and save them to a file. You use this in subsequent steps to recreate the functions.

```
./pg_restore -l /tmp/test.dmp | grep FUNCTION > /tmp/function_list/
```

   For more information on pg_restore, see pg_restore in the PostgreSQL documentation.

6. Drop the functions and extensions. The following example drops any PLV8 based objects. The cascade option ensures that any dependent are dropped.

```
DROP EXTENSION plv8 CASCADE;
```

If your PostgreSQL instance contains objects based on plcoffee or plls, repeat this step for those extensions.

7. Create the extensions. The following example creates the plv8, plcoffee, and plls extensions.

```
CREATE EXTENSION plv8;
CREATE EXTENSION plcoffee;
CREATE EXTENSION plls;
```

8. Create the functions using the dump file and "driver" file.

   The following example recreates the functions that you extracted previously.

```
./pg_restore -U master -d postgres -Fc -L /tmp/function_list /tmp/test.dmp
```

9. Verify that all your functions have been recreated by using the following query.

```
SELECT * FROM pg_available_extensions WHERE name IN ('plv8','plls','plcoffee');
```

   The PLV8 version 2 adds the following extra row to your result set:

```
    proname    |  nspname   | lanname
---------------+------------+----------
 plv8_version  | pg_catalog | plv8
```

Using PL/Rust to write PostgreSQL functions in the Rust language

PL/Rust is a trusted Rust language extension for PostgreSQL. You can use it for stored procedures, functions, and other procedural code that's callable from SQL. The PL/Rust language extension is available in the following versions:

- RDS for PostgreSQL 16.1 and higher 16 versions
- RDS for PostgreSQL 15.2-R2 and higher 15 versions
- RDS for PostgreSQL 14.9 and higher 14 versions
- RDS for PostgreSQL 13.12 and higher 13 versions

For more information, see PL/Rust on GitHub.

Topics

Setting up PL/Rust

To install the plrust extension on your DB instance, add plrust to the `shared_preload_libraries` parameter in the DB parameter group associated with your DB instance. With the plrust extension installed, you can create functions.

To modify the `shared_preload_libraries` parameter, your DB instance must be associated with a custom parameter group. For information about creating a custom DB parameter group, see Parameter groups for Amazon RDS.

You can install the plrust extension using the AWS Management Console or the AWS CLI.

The following steps assume that your DB instance is associated with a custom DB parameter group.

Console

Install the plrust extension in the `shared_preload_libraries` parameter

Complete the following steps using an account that is a member of the `rds_superuser` group (role).

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.
3. Choose the name of your DB instance to display its details.
4. Open the **Configuration** tab for your DB instance and find the DB instance parameter group link.
5. Choose the link to open the custom parameters associated with your DB instance.
6. In the **Parameters** search field, type `shared_pre` to find the **`shared_preload_libraries`** parameter.
7. Choose **Edit parameters** to access the property values.

8. Add plrust to the list in the **Values** field. Use a comma to separate items in the list of values.
9. Reboot the DB instance so that your change to the `shared_preload_libraries` parameter takes effect. The initial reboot may require additional time to complete.
10. When the instance is available, verify that plrust has been initialized. Use `psql` to connect to the DB instance, and then run the following command.

```
SHOW shared_preload_libraries;
```

Your output should look similar to the following:

```
shared_preload_libraries
-------------------------
rdsutils,plrust
(1 row)
```

AWS CLI

Install the plrust extension in the shared_preload_libraries parameter

Complete the following steps using an account that is a member of the `rds_superuser` group (role).

1. Use the modify-db-parameter-group AWS CLI command to add plrust to the `shared_preload_libraries` parameter.

```
aws rds modify-db-parameter-group \
   --db-parameter-group-name custom-param-group-name \
   --parameters
 "ParameterName=shared_preload_libraries,ParameterValue=plrust,ApplyMethod=pending-
reboot" \
   --region aws-region
```

2. Use the reboot-db-instance AWS CLI command to reboot the DB instance and initialize the plrust library. The initial reboot may require additional time to complete.

```
aws rds reboot-db-instance \
    --db-instance-identifier your-instance \
    --region aws-region
```

3. When the instance is available, you can verify that plrust has been initialized. Use `psql` to connect to the DB instance, and then run the following command.

```
SHOW shared_preload_libraries;
```

Your output should look similar to the following:

```
shared_preload_libraries
--------------------------
rdsutils,plrust
(1 row)
```

Creating functions with PL/Rust

PL/Rust will compile the function as a dynamic library, load it, and execute it.

The following Rust function filters multiples out of an array.

```
postgres=> CREATE LANGUAGE plrust;
CREATE EXTENSION
```

```
CREATE OR REPLACE FUNCTION filter_multiples(a BIGINT[], multiple BIGINT) RETURNS
 BIGINT[]
    IMMUTABLE STRICT
    LANGUAGE PLRUST AS
$$
    Ok(Some(a.into_iter().filter(|x| x.unwrap() % multiple != 0).collect()))
$$;

WITH gen_values AS (
SELECT ARRAY(SELECT * FROM generate_series(1,100)) as arr)
SELECT filter_multiples(arr, 3)
from gen_values;
```

Using crates with PL/Rust

In RDS for PostgreSQL versions 16.3-R2 and higher, 15.7-R2 and higher 15 versions, 14.12-R2 and higher 14 versions, and 13.15-R2 and higher 13 versions, PL/Rust supports additional crates:

- `url`

- `regex`
- `serde`
- `serde_json`

In RDS for PostgreSQL versions 15.5-R2 and higher, 14.10-R2 and higher 14 versions, and 13.13-R2 and higher 13 versions, PL/Rust supports two additional crates:

- `croaring-rs`
- `num-bigint`

Starting with Amazon RDS for PostgreSQL versions 15.4, 14.9, and 13.12, PL/Rust supports the following crates:

- `aes`
- `ctr`
- `rand`

Only the default features are supported for these crates. New RDS for PostgreSQL versions might contain updated versions of crates, and older versions of crates may no longer be supported.

Follow the best practices for performing a major version upgrade to test whether your PL/Rust functions are compatible with the new major version. For more information, see the blog Best practices for upgrading Amazon RDS to major and minor versions of PostgreSQL and Upgrading the PostgreSQL DB engine for Amazon RDS in the Amazon RDS User Guide.

Examples of using dependencies when creating a PL/Rust function are available at Use dependencies.

PL/Rust limitations

By default, database users can't use PL/Rust. To provide access to PL/Rust, connect as a user with rds_superuser privilege, and run the following command:

```
postgres=> GRANT USAGE ON LANGUAGE PLRUST TO user;
```

Managing spatial data with the PostGIS extension

PostGIS is an extension to PostgreSQL for storing and managing spatial information. To learn more about PostGIS, see PostGIS.net.

Starting with version 10.5, PostgreSQL supports the libprotobuf 1.3.0 library used by PostGIS for working with map box vector tile data.

Setting up the PostGIS extension requires `rds_superuser` privileges. We recommend that you create a user (role) to manage the PostGIS extension and your spatial data. The PostGIS extension and its related components add thousands of functions to PostgreSQL. Consider creating the PostGIS extension in its own schema if that makes sense for your use case. The following example shows how to install the extension in its own database, but this isn't required.

Topics

Step 1: Create a user (role) to manage the PostGIS extension

First, connect to your RDS for PostgreSQL DB instance as a user that has `rds_superuser` privileges. If you kept the default name when you set up your instance, you connect as `postgres`.

```
psql --host=111122223333.aws-region.rds.amazonaws.com --port=5432 --username=postgres
 --password
```

Create a separate role (user) to administer the PostGIS extension.

```
postgres=>  CREATE ROLE gis_admin LOGIN PASSWORD 'change_me';
```

```
CREATE ROLE
```

Grant this role `rds_superuser` privileges, to allow the role to install the extension.

```
postgres=> GRANT rds_superuser TO gis_admin;
GRANT
```

Create a database to use for your PostGIS artifacts. This step is optional. Or you can create a schema in your user database for the PostGIS extensions, but this also isn't required.

```
postgres=> CREATE DATABASE lab_gis;
CREATE DATABASE
```

Give the `gis_admin` all privileges on the `lab_gis` database.

```
postgres=> GRANT ALL PRIVILEGES ON DATABASE lab_gis TO gis_admin;
GRANT
```

Exit the session and reconnect to your RDS for PostgreSQL DB instance as `gis_admin`.

```
postgres=> psql --host=111122223333.aws-region.rds.amazonaws.com --port=5432 --
username=gis_admin --password --dbname=lab_gis
Password for user gis_admin:...
lab_gis=>
```

Continue setting up the extension as detailed in the next steps.

Step 2: Load the PostGIS extensions

The PostGIS extension includes several related extensions that work together to provide geospatial functionality. Depending on your use case, you might not need all the extensions created in this step.

Use `CREATE EXTENSION` statements to load the PostGIS extensions.

```
CREATE EXTENSION postgis;
CREATE EXTENSION
CREATE EXTENSION postgis_raster;
CREATE EXTENSION
CREATE EXTENSION fuzzystrmatch;
```

```
CREATE EXTENSION
CREATE EXTENSION postgis_tiger_geocoder;
CREATE EXTENSION
CREATE EXTENSION postgis_topology;
CREATE EXTENSION
CREATE EXTENSION address_standardizer_data_us;
CREATE EXTENSION
```

You can verify the results by running the SQL query shown in the following example, which lists the extensions and their owners.

```
SELECT n.nspname AS "Name",
  pg_catalog.pg_get_userbyid(n.nspowner) AS "Owner"
  FROM pg_catalog.pg_namespace n
  WHERE n.nspname !~ '^pg_' AND n.nspname <> 'information_schema'
  ORDER BY 1;
List of schemas
     Name     |   Owner
--------------+-----------
 public       | postgres
 tiger        | rdsadmin
 tiger_data   | rdsadmin
 topology     | rdsadmin
(4 rows)
```

Step 3: Transfer ownership of the extension schemas

Use the ALTER SCHEMA statements to transfer ownership of the schemas to the `gis_admin` role.

```
ALTER SCHEMA tiger OWNER TO gis_admin;
ALTER SCHEMA
ALTER SCHEMA tiger_data OWNER TO gis_admin;
ALTER SCHEMA
ALTER SCHEMA topology OWNER TO gis_admin;
ALTER SCHEMA
```

You can confirm the ownership change by running the following SQL query. Or you can use the \dn metacommand from the psql command line.

```
SELECT n.nspname AS "Name",
```

```
  pg_catalog.pg_get_userbyid(n.nspowner) AS "Owner"
  FROM pg_catalog.pg_namespace n
  WHERE n.nspname !~ '^pg_' AND n.nspname <> 'information_schema'
  ORDER BY 1;

       List of schemas
     Name     |     Owner
--------------+---------------
 public       | postgres
 tiger        | gis_admin
 tiger_data   | gis_admin
 topology     | gis_admin
(4 rows)
```

Step 4: Transfer ownership of the PostGIS tables

> **Note**
>
> Do not change ownership of the PostGIS functions. Proper operation and future upgrades of PostGIS require these functions to retain original ownership. For more information about PostGIS permissions, see PostgreSQL Security.

Use the following function to transfer ownership of the PostGIS tables to the `gis_admin` role. Run the following statement from the psql prompt to create the function.

```
CREATE FUNCTION exec(text) returns text language plpgsql volatile AS $f$ BEGIN EXECUTE
 $1; RETURN $1; END; $f$;
CREATE FUNCTION
```

Next, run the following query to run the `exec` function that in turn runs the statements and alters the permissions.

```
SELECT exec('ALTER TABLE ' || quote_ident(s.nspname) || '.' || quote_ident(s.relname)
 || ' OWNER TO gis_admin;')
  FROM (
    SELECT nspname, relname
    FROM pg_class c JOIN pg_namespace n ON (c.relnamespace = n.oid)
    WHERE nspname in ('tiger','topology') AND
    relkind IN ('r','S','v') ORDER BY relkind = 'S')
```

```
s;
```

Step 5: Test the extensions

To avoid needing to specify the schema name, add the `tiger` schema to your search path using the following command.

```
SET search_path=public,tiger;
SET
```

Test the `tiger` schema by using the following SELECT statement.

```
SELECT address, streetname, streettypeabbrev, zip
 FROM normalize_address('1 Devonshire Place, Boston, MA 02109') AS na;
address | streetname | streettypeabbrev |  zip
---------+------------+------------------+-------
       1 | Devonshire | Pl               | 02109
(1 row)
```

To learn more about this extension, see Tiger Geocoder in the PostGIS documentation.

Test access to the `topology` schema by using the following `SELECT` statement. This calls the `createtopology` function to register a new topology object (my_new_topo) with the specified spatial reference identifier (26986) and default tolerance (0.5). To learn more, see CreateTopology in the PostGIS documentation.

```
SELECT topology.createtopology('my_new_topo',26986,0.5);
 createtopology
----------------
              1
(1 row)
```

Step 6: Upgrade the PostGIS extension

Each new release of PostgreSQL supports one or more versions of the PostGIS extension compatible with that release. Upgrading the PostgreSQL engine to a new version doesn't automatically upgrade the PostGIS extension. Before upgrading the PostgreSQL engine, you typically upgrade PostGIS to the newest available version for the current PostgreSQL version. For details, see PostGIS extension versions.

After the PostgreSQL engine upgrade, you then upgrade the PostGIS extension again, to the version supported for the newly upgraded PostgreSQL engine version. For more information about upgrading the PostgreSQL engine, see How to perform a major version upgrade.

You can check for available PostGIS extension version updates on your RDS for PostgreSQL DB instance at any time. To do so, run the following command. This function is available with PostGIS 2.5.0 and higher versions.

```
SELECT postGIS_extensions_upgrade();
```

If your application doesn't support the latest PostGIS version, you can install an older version of PostGIS that's available in your major version as follows.

```
CREATE EXTENSION postgis VERSION "2.5.5";
```

If you want to upgrade to a specific PostGIS version from an older version, you can also use the following command.

```
ALTER EXTENSION postgis UPDATE TO "2.5.5";
```

Depending on the version that you're upgrading from, you might need to use this function again. The result of the first run of the function determines if an additional upgrade function is needed. For example, this is the case for upgrading from PostGIS 2 to PostGIS 3. For more information, see Upgrading PostGIS 2 to PostGIS 3.

If you upgraded this extension to prepare for a major version upgrade of the PostgreSQL engine, you can continue with other preliminary tasks. For more information, see How to perform a major version upgrade.

PostGIS extension versions

We recommend that you install the versions of all extensions such as PostGIS as listed in Extension versions for Amazon RDS for PostgreSQL in the *Amazon RDS for PostgreSQL Release Notes.* To get a list of versions that are available in your release, use the following command.

```
SELECT * FROM pg_available_extension_versions WHERE name='postgis';
```

You can find version information in the following sections in the *Amazon RDS for PostgreSQL Release Notes*:

- PostgreSQL version 16 extensions supported on Amazon RDS
- PostgreSQL version 15 extensions supported on Amazon RDS
- PostgreSQL version 14 extensions supported on Amazon RDS
- PostgreSQL version 13 extensions supported on Amazon RDS
- PostgreSQL version 12 extensions supported on Amazon RDS
- PostgreSQL version 11 extensions supported on Amazon RDS
- PostgreSQL version 10 extensions supported on Amazon RDS
- PostgreSQL version 9.6.x extensions supported on Amazon RDS

Upgrading PostGIS 2 to PostGIS 3

Starting with version 3.0, the PostGIS raster functionality is now a separate extension, `postgis_raster`. This extension has its own installation and upgrade path. This removes dozens of functions, data types, and other artifacts required for raster image processing from the core `postgis` extension. That means that if your use case doesn't require raster processing, you don't need to install the `postgis_raster` extension.

In the following upgrade example, the first upgrade command extracts raster functionality into the `postgis_raster` extension. A second upgrade command is then required to upgrade `postgis_raster` to the new version.

To upgrade from PostGIS 2 to PostGIS 3

1. Identify the default version of PostGIS that's available to the PostgreSQL version on your RDS for PostgreSQL DB instance. To do so, run the following query.

```
SELECT * FROM pg_available_extensions
    WHERE default_version > installed_version;
  name   | default_version | installed_version |                          comment
---------+-----------------+-------------------
+------------------------------------------------------------
 postgis | 3.1.4           | 2.3.7             | PostGIS geometry and geography
 spatial types and functions
(1 row)
```

2. Identify the versions of PostGIS installed in each database on your RDS for PostgreSQL DB instance. In other words, query each user database as follows.

```
SELECT
    e.extname AS "Name",
    e.extversion AS "Version",
    n.nspname AS "Schema",
    c.description AS "Description"
FROM
    pg_catalog.pg_extension e
    LEFT JOIN pg_catalog.pg_namespace n ON n.oid = e.extnamespace
    LEFT JOIN pg_catalog.pg_description c ON c.objoid = e.oid
    AND c.classoid = 'pg_catalog.pg_extension'::pg_catalog.regclass
WHERE
    e.extname LIKE '%postgis%'
ORDER BY
    1;
  Name   | Version | Schema |                            Description
---------+---------+--------
+------------------------------------------------------------------------
 postgis | 2.3.7   | public | PostGIS geometry, geography, and raster spatial types
 and functions
(1 row)
```

This mismatch between the default version (PostGIS 3.1.4) and the installed version (PostGIS 2.3.7) means that you need to upgrade the PostGIS extension.

```
ALTER EXTENSION postgis UPDATE;
ALTER EXTENSION
WARNING: unpackaging raster
WARNING: PostGIS Raster functionality has been unpackaged
```

3. Run the following query to verify that the raster functionality is now in its own package.

```
SELECT
    probin,
    count(*)
FROM
    pg_proc
WHERE
    probin LIKE '%postgis%'
GROUP BY
    probin;
          probin          | count
```

```
--------------------------+-------
 $libdir/rtpostgis-2.3    | 107
 $libdir/postgis-3        | 487
(2 rows)
```

The output shows that there's still a difference between versions. The PostGIS functions are version 3 (postgis-3), while the raster functions (rtpostgis) are version 2 (rtpostgis-2.3). To complete the upgrade, you run the upgrade command again, as follows.

```
postgres=> SELECT postgis_extensions_upgrade();
```

You can safely ignore the warning messages. Run the following query again to verify that the upgrade is complete. The upgrade is complete when PostGIS and all related extensions aren't marked as needing upgrade.

```
SELECT postgis_full_version();
```

4. Use the following query to see the completed upgrade process and the separately packaged extensions, and verify that their versions match.

```
SELECT
    e.extname AS "Name",
    e.extversion AS "Version",
    n.nspname AS "Schema",
    c.description AS "Description"
FROM
    pg_catalog.pg_extension e
    LEFT JOIN pg_catalog.pg_namespace n ON n.oid = e.extnamespace
    LEFT JOIN pg_catalog.pg_description c ON c.objoid = e.oid
        AND c.classoid = 'pg_catalog.pg_extension'::pg_catalog.regclass
WHERE
    e.extname LIKE '%postgis%'
ORDER BY
    1;
      Name      | Version | Schema |                            Description
----------------+---------+--------
+------------------------------------------------------------------------
 postgis        | 3.1.5   | public | PostGIS geometry, geography, and raster
 spatial types and functions
 postgis_raster | 3.1.5   | public | PostGIS raster types and functions
(2 rows)
```

The output shows that the PostGIS 2 extension was upgraded to PostGIS 3, and both `postgis` and the now separate `postgis_raster` extension are version 3.1.5.

After this upgrade completes, if you don't plan to use the raster functionality, you can drop the extension as follows.

```
DROP EXTENSION postgis_raster;
```

Working with the supported foreign data wrappers for Amazon RDS for PostgreSQL

A foreign data wrapper (FDW) is a specific type of extension that provides access to external data. For example, the `oracle_fdw` extension allows your RDS for PostgreSQL DB cluster to work with Oracle databases. As another example, by using the PostgreSQL native `postgres_fdw` extension you can access data stored in PostgreSQL DB instances external to your RDS for PostgreSQL DB instance.

Following, you can find information about several supported PostgreSQL foreign data wrappers.

Topics

Using the log_fdw extension to access the DB log using SQL

RDS for PostgreSQL DB instance supports the `log_fdw` extension, which you can use to access your database engine log using a SQL interface. The `log_fdw` extension provides two functions that make it easy to create foreign tables for database logs:

- `list_postgres_log_files` – Lists the files in the database log directory and the file size in bytes.
- `create_foreign_table_for_log_file(table_name text, server_name text, log_file_name text)` – Builds a foreign table for the specified file in the current database.

All functions created by `log_fdw` are owned by `rds_superuser`. Members of the `rds_superuser` role can grant access to these functions to other database users.

By default, the log files are generated by Amazon RDS in `stderr` (standard error) format, as specified in `log_destination` parameter. There are only two options for this parameter, `stderr` and `csvlog` (comma-separated values, CSV). If you add the `csvlog` option to the parameter, Amazon RDS generates both `stderr` and `csvlog` logs. This can affect the storage capacity on

your DB cluster, so you need to be aware of the other parameters that affect log handling. For more information, see Setting the log destination (`stderr, csvlog`).

One benefit of generating `csvlog` logs is that the `log_fdw` extension lets you build foreign tables with the data neatly split into several columns. To do this, your instance needs to be associated with a custom DB parameter group so that you can change the setting for `log_destination`. For more information about how to do so, see Working with parameters on your RDS for PostgreSQL DB instance.

The following example assumes that the `log_destination` parameter includes `cvslog`.

To use the log_fdw extension

1. Install the `log_fdw` extension.

```
postgres=> CREATE EXTENSION log_fdw;
CREATE EXTENSION
```

2. Create the log server as a foreign data wrapper.

```
postgres=> CREATE SERVER log_server FOREIGN DATA WRAPPER log_fdw;
CREATE SERVER
```

3. Select all from a list of log files.

```
postgres=> SELECT * FROM list_postgres_log_files() ORDER BY 1;
```

   A sample response is as follows.

```
          file_name           | file_size_bytes
------------------------------+-----------------
 postgresql.log.2023-08-09-22.csv |            1111
 postgresql.log.2023-08-09-23.csv |            1172
 postgresql.log.2023-08-10-00.csv |            1744
 postgresql.log.2023-08-10-01.csv |            1102
(4 rows)
```

4. Create a table with a single 'log_entry' column for the selected file.

```
postgres=> SELECT create_foreign_table_for_log_file('my_postgres_error_log',
     'log_server', 'postgresql.log.2023-08-09-22.csv');
```

The response provides no detail other than that the table now exists.

```
----------------------------------
(1 row)
```

5. Select a sample of the log file. The following code retrieves the log time and error message description.

```
postgres=> SELECT log_time, message FROM my_postgres_error_log ORDER BY 1;
```

A sample response is as follows.

```
            log_time             |                                 message
---------------------------------
+------------------------------------------------------------------------------
Tue Aug 09 15:45:18.172 2023 PDT | ending log output to stderr
Tue Aug 09 15:45:18.175 2023 PDT | database system was interrupted; last known up
 at 2023-08-09 22:43:34 UTC
Tue Aug 09 15:45:18.223 2023 PDT | checkpoint record is at 0/90002E0
Tue Aug 09 15:45:18.223 2023 PDT | redo record is at 0/90002A8; shutdown FALSE
Tue Aug 09 15:45:18.223 2023 PDT | next transaction ID: 0/1879; next OID: 24578
Tue Aug 09 15:45:18.223 2023 PDT | next MultiXactId: 1; next MultiXactOffset: 0
Tue Aug 09 15:45:18.223 2023 PDT | oldest unfrozen transaction ID: 1822, in
 database 1
(7 rows)
```

Using the postgres_fdw extension to access external data

You can access data in a table on a remote database server with the postgres_fdw extension. If you set up a remote connection from your PostgreSQL DB instance, access is also available to your read replica.

To use postgres_fdw to access a remote database server

1. Install the postgres_fdw extension.

```
CREATE EXTENSION postgres_fdw;
```

2. Create a foreign data server using CREATE SERVER.

```
CREATE SERVER foreign_server
FOREIGN DATA WRAPPER postgres_fdw
OPTIONS (host 'xxx.xx.xxx.xx', port '5432', dbname 'foreign_db');
```

3. Create a user mapping to identify the role to be used on the remote server.

```
CREATE USER MAPPING FOR local_user
SERVER foreign_server
OPTIONS (user 'foreign_user', password 'password');
```

4. Create a table that maps to the table on the remote server.

```
CREATE FOREIGN TABLE foreign_table (
        id integer NOT NULL,
        data text)
SERVER foreign_server
OPTIONS (schema_name 'some_schema', table_name 'some_table');
```

Working with MySQL databases by using the mysql_fdw extension

To access a MySQL-compatible database from your RDS for PostgreSQL DB instance, you can install and use the `mysql_fdw` extension. This foreign data wrapper lets you work with RDS for MySQL, Aurora MySQL, MariaDB, and other MySQL-compatible databases. The connection from RDS for PostgreSQL DB instance to the MySQL database is encrypted on a best-effort basis, depending on the client and server configurations. However, you can enforce encryption if you like. For more information, see Using encryption in transit with the extension.

The `mysql_fdw` extension is supported on Amazon RDS for PostgreSQL version 14.2, 13.6, and higher releases. It supports selects, inserts, updates, and deletes from an RDS for PostgreSQL DB to tables on a MySQL-compatible database instance.

Topics

- Setting up your RDS for PostgreSQL DB to use the mysql_fdw extension
- Example: Working with an RDS for MySQL database from RDS for PostgreSQL
- Using encryption in transit with the extension

Setting up your RDS for PostgreSQL DB to use the mysql_fdw extension

Setting up the `mysql_fdw` extension on your RDS for PostgreSQL DB instance involves loading the extension in your DB instance and then creating the connection point to the MySQL DB instance. For that task, you need to have the following details about the MySQL DB instance:

- Hostname or endpoint. For an RDS for MySQL DB instance, you can find the endpoint by using the Console. Choose the Connectivity & security tab and look in the "Endpoint and port" section.
- Port number. The default port number for MySQL is 3306.
- Name of the database. The DB identifier.

You also need to provide access on the security group or the access control list (ACL) for the MySQL port, 3306. Both the RDS for PostgreSQL DB instance and the RDS for MySQL DB instance need access to port 3306. If access isn't configured correctly, when you try to connect to MySQL-compatible table you see an error message similar to the following:

```
ERROR: failed to connect to MySQL: Can't connect to MySQL server on 'hostname.aws-
region.rds.amazonaws.com:3306' (110)
```

In the following procedure, you (as the `rds_superuser` account) create the foreign server. You then grant access to the foreign server to specific users. These users then create their own mappings to the appropriate MySQL user accounts to work with the MySQL DB instance.

To use mysql_fdw to access a MySQL database server

1. Connect to your PostgreSQL DB instance using an account that has the `rds_superuser` role. If you accepted the defaults when you created your RDS for PostgreSQL DB instance , the user name is `postgres`, and you can connect using the `psql` command line tool as follows:

   ```
   psql --host=your-DB-instance.aws-region.rds.amazonaws.com --port=5432 --
   username=postgres --password
   ```

2. Install the `mysql_fdw` extension as follows:

   ```
   postgres=> CREATE EXTENSION mysql_fdw;
   CREATE EXTENSION
   ```

After the extension is installed on your RDS for PostgreSQL DB instance , you set up the foreign server that provides the connection to a MySQL database.

To create the foreign server

Perform these tasks on the RDS for PostgreSQL DB instance . The steps assume that you're connected as a user with `rds_superuser` privileges, such as `postgres`.

1. Create a foreign server in the RDS for PostgreSQL DB instance :

```
postgres=> CREATE SERVER mysql-db FOREIGN DATA WRAPPER mysql_fdw OPTIONS (host 'db-name.111122223333.aws-region.rds.amazonaws.com', port '3306');
CREATE SERVER
```

2. Grant the appropriate users access to the foreign server. These should be non-administrator users, that is, users without the `rds_superuser` role.

```
postgres=> GRANT USAGE ON FOREIGN SERVER mysql-db to user1;
GRANT
```

PostgreSQL users create and manage their own connections to the MySQL database through the foreign server.

Example: Working with an RDS for MySQL database from RDS for PostgreSQL

Suppose that you have a simple table on an RDS for PostgreSQL DB instance . Your RDS for PostgreSQL users want to query (`SELECT`), `INSERT`, `UPDATE`, and `DELETE` items on that table. Assume that the `mysql_fdw` extension was created on your RDS for PostgreSQL DB instance, as detailed in the preceding procedure. After you connect to the RDS for PostgreSQL DB instance as a user that has `rds_superuser` privileges, you can proceed with the following steps.

1. On the RDS for PostgreSQL DB instance, create a foreign server:

```
test=> CREATE SERVER mysqldb FOREIGN DATA WRAPPER mysql_fdw OPTIONS (host 'your-DB.aws-region.rds.amazonaws.com', port '3306');
CREATE SERVER
```

2. Grant usage to a user who doesn't have `rds_superuser` permissions, for example, `user1`:

```
test=> GRANT USAGE ON FOREIGN SERVER mysqldb TO user1;
```

```
GRANT
```

3. Connect as *user1*, and then create a mapping to the MySQL user:

```
test=> CREATE USER MAPPING FOR user1 SERVER mysqldb OPTIONS (username 'myuser',
 password 'mypassword');
CREATE USER MAPPING
```

4. Create a foreign table linked to the MySQL table:

```
test=> CREATE FOREIGN TABLE mytab (a int, b text) SERVER mysqldb OPTIONS (dbname
 'test', table_name '');
CREATE FOREIGN TABLE
```

5. Run a simple query against the foreign table:

```
test=> SELECT * FROM mytab;
a |   b
---+-------
1 | apple
(1 row)
```

6. You can add, change, and remove data from the MySQL table. For example:

```
test=> INSERT INTO mytab values (2, 'mango');
INSERT 0 1
```

   Run the SELECT query again to see the results:

```
test=> SELECT * FROM mytab ORDER BY 1;
 a |   b
---+-------
1 | apple
2 | mango
(2 rows)
```

Using encryption in transit with the extension

The connection to MySQL from RDS for PostgreSQL uses encryption in transit (TLS/SSL) by default. However, the connection falls back to non-encrypted when the client and server configuration

differ. You can enforce encryption for all outgoing connections by specifying the `REQUIRE SSL` option on the RDS for MySQL user accounts. This same approach also works for MariaDB and Aurora MySQL user accounts.

For MySQL user accounts configured to `REQUIRE SSL`, the connection attempt fails if a secure connection can't be established.

To enforce encryption for existing MySQL database user accounts, you can use the `ALTER USER` command. The syntax varies, depending on the MySQL version, as shown in the following table. For more information, see ALTER USER in *MySQL Reference Manual*.

MySQL 5.7, MySQL 8.0	MySQL 5.6
`ALTER USER 'user'@'%' REQUIRE SSL;`	`GRANT USAGE ON *.* to 'user'@'%' REQUIRE SSL;`

For more information about the `mysql_fdw` extension, see the mysql_fdw documentation.

Working with Oracle databases by using the oracle_fdw extension

To access an Oracle database from your RDS for PostgreSQL DB instance you can install and use the `oracle_fdw` extension. This extension is a foreign data wrapper for Oracle databases. To learn more about this extension, see the oracle_fdw documentation.

The `oracle_fdw` extension is supported on RDS for PostgreSQL 12.7, 13.3, and higher versions.

Topics

- Turning on the oracle_fdw extension
- Example: Using a foreign server linked to an Amazon RDS for Oracle database
- Working with encryption in transit
- Understanding the pg_user_mappings view and permissions

Turning on the oracle_fdw extension

To use the oracle_fdw extension, perform the following procedure.

To turn on the oracle_fdw extension

- Run the following command using an account that has `rds_superuser` permissions.

```
CREATE EXTENSION oracle_fdw;
```

Example: Using a foreign server linked to an Amazon RDS for Oracle database

The following example shows the use of a foreign server linked to an Amazon RDS for Oracle database.

To create a foreign server linked to an RDS for Oracle database

1. Note the following on the RDS for Oracle DB instance:
   - Endpoint
   - Port
   - Database name
2. Create a foreign server.

```
test=> CREATE SERVER oradb FOREIGN DATA WRAPPER oracle_fdw OPTIONS (dbserver
 '//endpoint:port/DB_name');
CREATE SERVER
```

3. Grant usage to a user who doesn't have `rds_superuser` privileges, for example `user1`.

```
test=> GRANT USAGE ON FOREIGN SERVER oradb TO user1;
GRANT
```

4. Connect as `user1`, and create a mapping to an Oracle user.

```
test=> CREATE USER MAPPING FOR user1 SERVER oradb OPTIONS (user 'oracleuser',
 password 'mypassword');
CREATE USER MAPPING
```

5. Create a foreign table linked to an Oracle table.

```
test=> CREATE FOREIGN TABLE mytab (a int) SERVER oradb OPTIONS (table 'MYTABLE');
CREATE FOREIGN TABLE
```

6. Query the foreign table.

```
test=>  SELECT * FROM mytab;
a
---
1
(1 row)
```

If the query reports the following error, check your security group and access control list (ACL) to make sure that both instances can communicate.

```
ERROR: connection for foreign table "mytab" cannot be established
DETAIL: ORA-12170: TNS:Connect timeout occurred
```

Working with encryption in transit

PostgreSQL-to-Oracle encryption in transit is based on a combination of client and server configuration parameters. For an example using Oracle 21c, see About the Values for Negotiating Encryption and Integrity in the Oracle documentation. The client used for oracle_fdw on Amazon RDS is configured with ACCEPTED, meaning that the encryption depends on the Oracle database server configuration.

If your database is on RDS for Oracle, see Oracle native network encryption to configure the encryption.

Understanding the pg_user_mappings view and permissions

The PostgreSQL catalog `pg_user_mapping` stores the mapping from an RDS for PostgreSQL user to the user on a foreign data (remote) server. Access to the catalog is restricted, but you use the `pg_user_mappings` view to see the mappings. In the following, you can find an example that shows how permissions apply with an example Oracle database, but this information applies more generally to any foreign data wrapper.

In the following output, you can find roles and permissions mapped to three different example users. Users `rdssu1` and `rdssu2` are members of the `rds_superuser` role, and `user1` isn't. The example uses the `psql` metacommand `\du` to list existing roles.

```
test=>  \du
```

```
                                                                  List of roles
    Role name    |                          Attributes                           |
                 Member of
-----------------+-------------------------------------------------------------
+-----------------------------------------------------------
 rdssu1          |                                                               |
 {rds_superuser}
 rdssu2          |                                                               |
 {rds_superuser}
 user1           |                                                               | {}
```

All users, including users that have `rds_superuser` privileges, are allowed to view their own user mappings (`umoptions`) in the `pg_user_mappings` table. As shown in the following example, when `rdssu1` tries to obtain all user mappings, an error is raised even though `rdssu1rds_superuser` privileges:

```
test=> SELECT * FROM pg_user_mapping;
ERROR: permission denied for table pg_user_mapping
```

Following are some examples.

```
test=> SET SESSION AUTHORIZATION rdssu1;
SET
test=> SELECT * FROM pg_user_mappings;
 umid  | srvid | srvname | umuser | usename    |            umoptions
-------+-------+---------+--------+------------+---------------------------------
 16414 | 16411 | oradb   |  16412 | user1      |
 16423 | 16411 | oradb   |  16421 | rdssu1     | {user=oracleuser,password=mypwd}
 16424 | 16411 | oradb   |  16422 | rdssu2     |
 (3 rows)

test=> SET SESSION AUTHORIZATION rdssu2;
SET
test=> SELECT * FROM pg_user_mappings;
 umid  | srvid | srvname | umuser | usename    |            umoptions
-------+-------+---------+--------+------------+---------------------------------
 16414 | 16411 | oradb   |  16412 | user1      |
 16423 | 16411 | oradb   |  16421 | rdssu1     |
 16424 | 16411 | oradb   |  16422 | rdssu2     | {user=oracleuser,password=mypwd}
 (3 rows)

test=> SET SESSION AUTHORIZATION user1;
```

```
SET
test=> SELECT * FROM pg_user_mappings;
 umid  | srvid | srvname | umuser | usename    |           umoptions
-------+-------+---------+--------+------------+-------------------------------
 16414 | 16411 | oradb   |  16412 | user1      | {user=oracleuser,password=mypwd}
 16423 | 16411 | oradb   |  16421 | rdssu1     |
 16424 | 16411 | oradb   |  16422 | rdssu2     |
 (3 rows)
```

Because of implementation differences between `information_schema._pg_user_mappings` and `pg_catalog.pg_user_mappings`, a manually created `rds_superuser` requires additional permissions to view passwords in `pg_catalog.pg_user_mappings`.

No additional permissions are required for an `rds_superuser` to view passwords in `information_schema._pg_user_mappings`.

Users who don't have the `rds_superuser` role can view passwords in `pg_user_mappings` only under the following conditions:

- The current user is the user being mapped and owns the server or holds the USAGE privilege on it.
- The current user is the server owner and the mapping is for `PUBLIC`.

Working with SQL Server databases by using the tds_fdw extension

You can use the PostgreSQL `tds_fdw` extension to access databases that support the tabular data stream (TDS) protocol, such as Sybase and Microsoft SQL Server databases. This foreign data wrapper lets you connect from your RDS for PostgreSQL DB instance to databases that use the TDS protocol, including Amazon RDS for Microsoft SQL Server. For more information, see tds-fdw/tds_fdw documentation on GitHub.

The `tds_fdw` extension is supported on Amazon RDS for PostgreSQL version 14.2, 13.6, and higher releases.

Setting up your Aurora PostgreSQL DB to use the tds_fdw extension

In the following procedures, you can find an example of setting up and using the `tds_fdw` with an RDS for PostgreSQL DB instance. Before you can connect to a SQL Server database using `tds_fdw`, you need to get the following details for the instance:

- Hostname or endpoint. For an RDS for SQL Server DB instance, you can find the endpoint by using the Console. Choose the Connectivity & security tab and look in the "Endpoint and port" section.
- Port number. The default port number for Microsoft SQL Server is 1433.
- Name of the database. The DB identifier.

You also need to provide access on the security group or the access control list (ACL) for the SQL Server port, 1433. Both the RDS for PostgreSQL DB instance and the RDS for SQL Server DB instance need access to port 1433. If access isn't configured correctly, when you try to query the Microsoft SQL Server you see the following error message:

```
ERROR: DB-Library error: DB #: 20009, DB Msg: Unable to connect:
Adaptive Server is unavailable or does not exist (mssql2019.aws-
region.rds.amazonaws.com), OS #: 0, OS Msg: Success, Level: 9
```

To use tds_fdw to connect to a SQL Server database

1. Connect to your PostgreSQL DB instance using an account that has the `rds_superuser` role:

   ```
   psql --host=your-DB-instance.aws-region.rds.amazonaws.com --port=5432 --
   username=test --password
   ```

2. Install the `tds_fdw` extension:

   ```
   test=> CREATE EXTENSION tds_fdw;
   CREATE EXTENSION
   ```

After the extension is installed on your RDS for PostgreSQL DB instance, you set up the foreign server.

To create the foreign server

Perform these tasks on the RDS for PostgreSQL DB instance using an account that has `rds_superuser` privileges.

1. Create a foreign server in the RDS for PostgreSQL DB instance:

```
test=> CREATE SERVER sqlserverdb FOREIGN DATA WRAPPER tds_fdw OPTIONS
 (servername 'mssql2019.aws-region.rds.amazonaws.com', port '1433', database
 'tds_fdw_testing');
CREATE SERVER
```

To access non-ASCII data on the SQLServer side, create a server link with the character_set option in the RDS for PostgreSQL DB instance:

```
test=> CREATE SERVER sqlserverdb FOREIGN DATA WRAPPER tds_fdw OPTIONS (servername
 'mssql2019.aws-region.rds.amazonaws.com', port '1433', database 'tds_fdw_testing',
 character_set 'UTF-8');
CREATE SERVER
```

2. Grant permissions to a user who doesn't have `rds_superuser` role privileges, for example, `user1`:

```
test=> GRANT USAGE ON FOREIGN SERVER sqlserverdb TO user1;
```

3. Connect as user1 and create a mapping to a SQL Server user:

```
test=> CREATE USER MAPPING FOR user1 SERVER sqlserverdb OPTIONS (username
 'sqlserveruser', password 'password');
CREATE USER MAPPING
```

4. Create a foreign table linked to a SQL Server table:

```
test=> CREATE FOREIGN TABLE mytab (a int) SERVER sqlserverdb OPTIONS (table
 'MYTABLE');
CREATE FOREIGN TABLE
```

5. Query the foreign table:

```
test=> SELECT * FROM mytab;
 a
---
 1
(1 row)
```

Using encryption in transit for the connection

The connection from RDS for PostgreSQL to SQL Server uses encryption in transit (TLS/SSL) depending on the SQL Server database configuration. If the SQL Server isn't configured for encryption, the RDS for PostgreSQL client making the request to the SQL Server database falls back to unencrypted.

You can enforce encryption for the connection to RDS for SQL Server DB instances by setting the `rds.force_ssl` parameter. To learn how, see Forcing connections to your DB instance to use SSL. For more information about SSL/TLS configuration for RDS for SQL Server, see Using SSL with a Microsoft SQL Server DB instance.

Working with Trusted Language Extensions for PostgreSQL

Trusted Language Extensions for PostgreSQL is an open source development kit for building PostgreSQL extensions. It allows you to build high performance PostgreSQL extensions and safely run them on your RDS for PostgreSQL DB instance. By using Trusted Language Extensions (TLE) for PostgreSQL, you can create PostgreSQL extensions that follow the documented approach for extending PostgreSQL functionality. For more information, see Packaging Related Objects into an Extension in the PostgreSQL documentation.

One key benefit of TLE is that you can use it in environments that don't provide access to the file system underlying the PostgreSQL instance. Previously, installing a new extension required access to the file system. TLE removes this constraint. It provides a development environment for creating new extensions for any PostgreSQL database, including those running on your RDS for PostgreSQL DB instances.

TLE is designed to prevent access to unsafe resources for the extensions that you create using TLE. Its runtime environment limits the impact of any extension defect to a single database connection. TLE also gives database administrators fine-grained control over who can install extensions, and it provides a permissions model for running them.

TLE is supported on the following RDS for PostgreSQL versions:

- Version 16.1 and higher 16 versions
- Version 15.2 and higher 15 versions
- Version 14.5 and higher 14 versions
- Version 13.12 and higher 13 versions

The Trusted Language Extensions development environment and runtime are packaged as the `pg_tle` PostgreSQL extension, version 1.0.1. It supports creating extensions in JavaScript, Perl, Tcl, PL/pgSQL, and SQL. You install the `pg_tle` extension in your RDS for PostgreSQL DB instance in the same way that you install other PostgreSQL extensions. After the `pg_tle` is set up, developers can use it to create new PostgreSQL extensions, known as *TLE extensions*.

In the following topics, you can find information about how to set up Trusted Language Extensions and how to get started creating your own TLE extensions.

Topics

Terminology

To help you better understand Trusted Language Extensions, view the following glossary for terms used in this topic.

Trusted Language Extensions for PostgreSQL

Trusted Language Extensions for PostgreSQL is the official name of the open source development kit that's packaged as the `pg_tle` extension. It's available for use on any PostgreSQL system. For more information, see aws/pg_tle on GitHub.

Trusted Language Extensions

Trusted Language Extensions is the short name for Trusted Language Extensions for PostgreSQL. This shortened name and its abbreviation (TLE) are also used in this documentation.

trusted language

A *trusted language* is a programming or scripting language that has specific security attributes. For example, trusted languages typically restrict access to the file system, and they limit use of specified networking properties. The TLE development kit is designed to support trusted languages. PostgreSQL supports several different languages that are used to create trusted or untrusted extensions. For an example, see Trusted and Untrusted PL/Perl in the

PostgreSQL documentation. When you create an extension using Trusted Language Extensions, the extension inherently uses trusted language mechanisms.

TLE extension

A *TLE extension* is a PostgreSQL extension that's been created by using the Trusted Language Extensions (TLE) development kit.

Requirements for using Trusted Language Extensions for PostgreSQL

The following are requirements for setting up and using the TLE development kit.

- **RDS for PostgreSQL versions** – Trusted Language Extensions is supported on RDS for PostgreSQL versions 13.12 and higher 13 versions, 14.5 and higher 14 versions, and 15.2 and higher versions only.
  - If you need to upgrade your RDS for PostgreSQL instance, see Upgrading the PostgreSQL DB engine for Amazon RDS.
  - If you don't yet have an Amazon RDS DB instance running PostgreSQL, you can create one. For more information, see RDS for PostgreSQL DB instance, see Creating and connecting to a PostgreSQL DB instance.
- **Requires `rds_superuser` privileges** – To set up and configure the `pg_tle` extension, your database user role must have the permissions of the `rds_superuser` role. By default, this role is granted to the `postgres` user that creates the RDS for PostgreSQL DB instance.
- **Requires a custom DB parameter group** – Your RDS for PostgreSQL DB instance must be configured with a custom DB parameter group.
  - If your RDS for PostgreSQL DB instance isn't configured with a custom DB parameter group, you should create one and associate it with your RDS for PostgreSQL DB instance. For a short summary of steps, see Creating and applying a custom DB parameter group.
  - If your RDS for PostgreSQL DB instance is already configured using a custom DB parameter group, you can set up Trusted Language Extensions. For details, see Setting up Trusted Language Extensions in your RDS for PostgreSQL DB instance.

Creating and applying a custom DB parameter group

Use the following steps to create a custom DB parameter group and configure your RDS for PostgreSQL DB instance to use it.

Console

To create a custom DB parameter group and use it with your RDS for PostgreSQL DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Choose Parameter groups from the Amazon RDS menu.
3. Choose **Create parameter group**.
4. In the **Parameter group details** page, enter the following information.
   - For **Parameter group family**, choose postgres14.
   - For **Type**, choose DB Parameter Group.
   - For **Group name**, give your parameter group a meaningful name in the context of your operations.
   - For **Description**, enter a useful description so that others on your team can easily find it.
5. Choose **Create**. Your custom DB parameter group is created in your AWS Region. You can now modify your RDS for PostgreSQL DB instance to use it by following the next steps.
6. Choose **Databases** from the Amazon RDS menu.
7. Choose the RDS for PostgreSQL DB instance that you want to use with TLE from among those listed, and then choose **Modify.**
8. In the Modify DB instance settings page, find **Database options** in the Additional configuration section and choose your custom DB parameter group from the selector.
9. Choose **Continue** to save the change.
10. Choose **Apply immediately** so that you can continue setting up the RDS for PostgreSQL DB instance to use TLE.

To continue setting up your system for Trusted Language Extensions, see Setting up Trusted Language Extensions in your RDS for PostgreSQL DB instance.

For more information working with DB parameter groups, see DB parameter groups for Amazon RDS DB instances.

AWS CLI

You can avoid specifying the `--region` argument when you use CLI commands by configuring your AWS CLI with your default AWS Region. For more information, see Configuration basics in the *AWS Command Line Interface User Guide*.

To create a custom DB parameter group and use it with your RDS for PostgreSQL DB instance

1. Use the create-db-parameter-group AWS CLI command to create a custom DB parameter group based on postgres14 for your AWS Region.

   For Linux, macOS, or Unix:

   ```
   aws rds create-db-parameter-group \
     --region aws-region \
     --db-parameter-group-name custom-params-for-pg-tle \
     --db-parameter-group-family postgres14 \
     --description "My custom DB parameter group for Trusted Language Extensions"
   ```

   For Windows:

   ```
   aws rds create-db-parameter-group ^
     --region aws-region ^
     --db-parameter-group-name custom-params-for-pg-tle ^
     --db-parameter-group-family postgres14 ^
     --description "My custom DB parameter group for Trusted Language Extensions"
   ```

   Your custom DB parameter group is available in your AWS Region, so you can modify RDS for PostgreSQL DB instance to use it.

2. Use the modify-db-instance AWS CLI command to apply your custom DB parameter group to your RDS for PostgreSQL DB instance. This command immediately reboots the active instance.

   For Linux, macOS, or Unix:

   ```
   aws rds modify-db-instance \
     --region aws-region \
     --db-instance-identifier your-instance-name \
     --db-parameter-group-name custom-params-for-pg-tle \
     --apply-immediately
   ```

For Windows:

```
aws rds modify-db-instance ^
  --region aws-region ^
  --db-instance-identifier your-instance-name ^
  --db-parameter-group-name custom-params-for-pg-tle ^
  --apply-immediately
```

To continue setting up your system for Trusted Language Extensions, see Setting up Trusted Language Extensions in your RDS for PostgreSQL DB instance.

For more information, see Parameter groups for Amazon RDS.

Setting up Trusted Language Extensions in your RDS for PostgreSQL DB instance

The following steps assume that your RDS for PostgreSQL DB instance is associated with a custom DB parameter group. You can use the AWS Management Console or the AWS CLI for these steps.

When you set up Trusted Language Extensions in your RDS for PostgreSQL DB instance, you install it in a specific database for use by the database users who have permissions on that database.

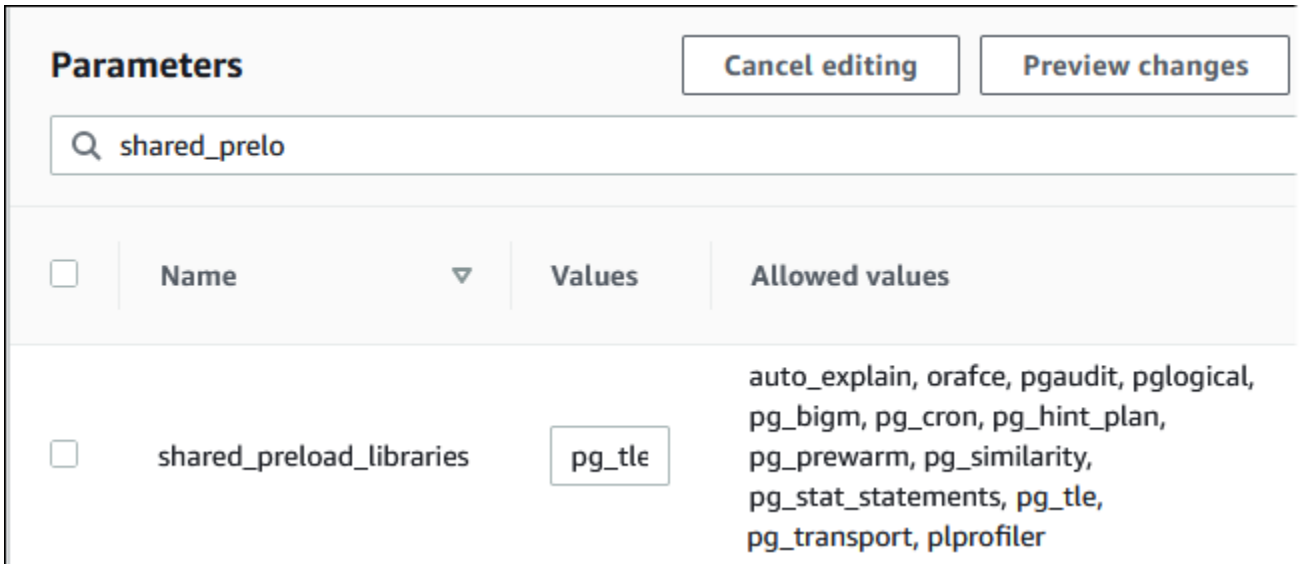
Console

To set up Trusted Language Extensions

Perform the following steps using an account that's a member of the `rds_superuser` group (role).

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose your RDS for PostgreSQL DB instance.
3. Open the **Configuration** tab for your RDS for PostgreSQL DB instance. Among the Instance details, find the **Parameter group** link.
4. Choose the link to open the custom parameters associated with your RDS for PostgreSQL DB instance.
5. In the **Parameters** search field, type `shared_pre` to find the `shared_preload_libraries` parameter.

6. Choose **Edit parameters** to access the property values.
7. Add `pg_tle` to the list in the **Values** field. Use a comma to separate items in the list of values.



8. Reboot the RDS for PostgreSQL DB instance so that your change to the `shared_preload_libraries` parameter takes effect.
9. When the instance is available, verify that `pg_tle` has been initialized. Use `psql` to connect to the RDS for PostgreSQL DB instance, and then run the following command.

```
SHOW shared_preload_libraries;
shared_preload_libraries
--------------------------
rdsutils,pg_tle
(1 row)
```

10. With the `pg_tle` extension initialized, you can now create the extension.

```
CREATE EXTENSION pg_tle;
```

You can verify that the extension is installed by using the following `psql` metacommand.

```
labdb=> \dx
                          List of installed extensions
  Name   | Version |   Schema   |                Description
---------+---------+------------+-------------------------------------------
 pg_tle  | 1.0.1   | pgtle      | Trusted-Language Extensions for PostgreSQL
 plpgsql | 1.0     | pg_catalog | PL/pgSQL procedural language
```

11. Grant the `pgtle_admin` role to the primary user name that you created for your RDS for PostgreSQL DB instance when you set it up. If you accepted the default, it's `postgres`.

```
labdb=> GRANT pgtle_admin TO postgres;
GRANT ROLE
```

You can verify that the grant has occurred by using the `psql` metacommand as shown in the following example. Only the `pgtle_admin` and `postgres` roles are shown in the output. For more information, see Understanding the rds_superuser role.

```
labdb=> \du
                          List of roles
    Role name    |           Attributes            |               Member of
-----------------+---------------------------------
+-----------------------------------
pgtle_admin     | Cannot login                     | {}
postgres        | Create role, Create DB          +| {rds_superuser,pgtle_admin}
                | Password valid until infinity    |...
```

12. Close the `psql` session using the `\q` metacommand.

```
\q
```

To get started creating TLE extensions, see Example: Creating a trusted language extension using SQL.

AWS CLI

You can avoid specifying the `--region` argument when you use CLI commands by configuring your AWS CLI with your default AWS Region. For more information, see Configuration basics in the *AWS Command Line Interface User Guide*.

To set up Trusted Language Extensions

1. Use the modify-db-parameter-group AWS CLI command to add `pg_tle` to the `shared_preload_libraries` parameter.

```
aws rds modify-db-parameter-group \
   --db-parameter-group-name custom-param-group-name \
```

```
   --parameters
 "ParameterName=shared_preload_libraries,ParameterValue=pg_tle,ApplyMethod=pending-
reboot" \
   --region aws-region
```

2. Use the reboot-db-instance AWS CLI command to reboot the RDS for PostgreSQL DB instance and initialize the `pg_tle` library.

```
aws rds reboot-db-instance \
    --db-instance-identifier your-instance \
    --region aws-region
```

3. When the instance is available, you can verify that `pg_tle` has been initialized. Use `psql` to connect to the RDS for PostgreSQL DB instance, and then run the following command.

```
SHOW shared_preload_libraries;
shared_preload_libraries
--------------------------
rdsutils,pg_tle
(1 row)
```

   With `pg_tle` initialized, you can now create the extension.

```
CREATE EXTENSION pg_tle;
```

4. Grant the `pgtle_admin` role to the primary user name that you created for your RDS for PostgreSQL DB instance when you set it up. If you accepted the default, it's `postgres`.

```
GRANT pgtle_admin TO postgres;
GRANT ROLE
```

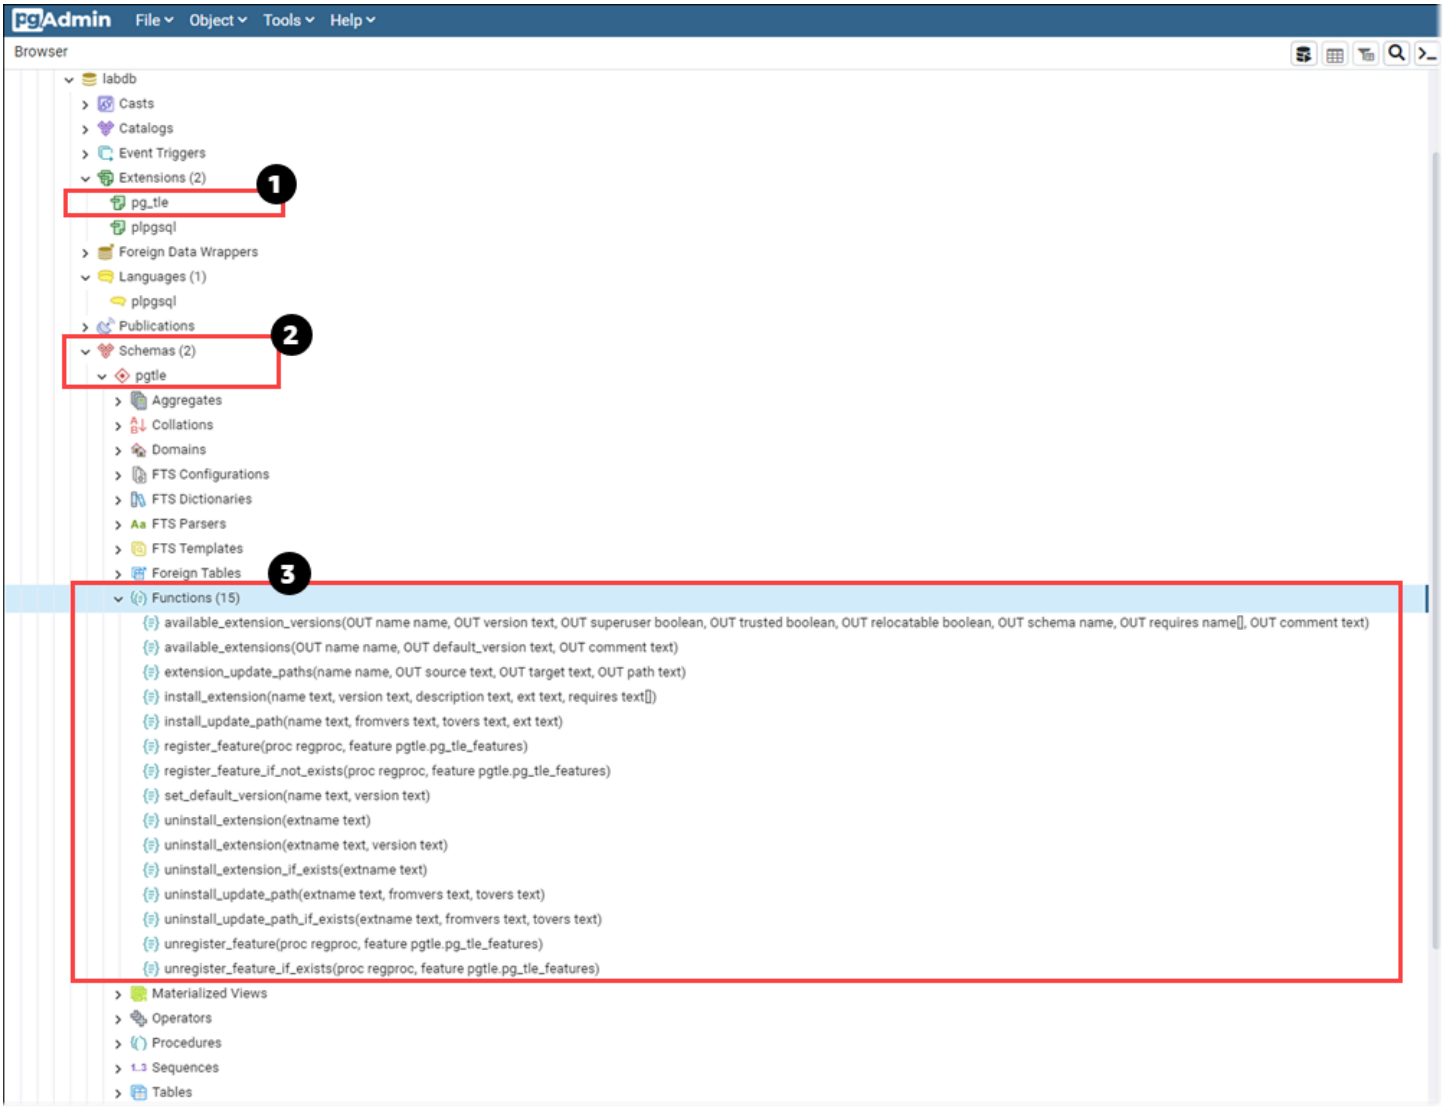
5. Close the `psql` session as follows.

```
labdb=> \q
```

To get started creating TLE extensions, see Example: Creating a trusted language extension using SQL.

Overview of Trusted Language Extensions for PostgreSQL

Trusted Language Extensions for PostgreSQL is a PostgreSQL extension that you install in your RDS for PostgreSQL DB instance in the same way that you set up other PostgreSQL extensions. In the following image of an example database in the pgAdmin client tool, you can view some of the components that comprise the `pg_tle` extension.



You can see the following details.

1. The Trusted Language Extensions (TLE) for PostgreSQL development kit is packaged as the `pg_tle` extension. As such, `pg_tle` is added to the available extensions for the database in which it's installed.
2. TLE has its own schema, `pgtle`. This schema contains helper functions (3) for installing and managing the extensions that you create.

3. TLE provides over a dozen helper functions for installing, registering, and managing your extensions. To learn more about these functions, see Function reference for Trusted Language Extensions for PostgreSQL.

Other components of the `pg_tle` extension include the following:

- **The `pgtle_admin` role** – The `pgtle_admin` role is created when the `pg_tle` extension is installed. This role is privileged and should be treated as such. We strongly recommend that you follow the principle of *least privilege* when granting the `pgtle_admin` role to database users. In other words, grant the `pgtle_admin` role only to database users that are allowed to create, install, and manage new TLE extensions, such as `postgres`.
- **The `pgtle.feature_info` table** – The `pgtle.feature_info` table is a protected table that contains information about your TLEs, hooks, and the custom stored procedures and functions that they use. If you have `pgtle_admin` privileges, you use the following Trusted Language Extensions functions to add and update that information in the table.
  - pgtle.register_feature
  - pgtle.register_feature_if_not_exists
  - pgtle.unregister_feature
  - pgtle.unregister_feature_if_exists

Creating TLE extensions for RDS for PostgreSQL

You can install any extensions that you create with TLE in any RDS for PostgreSQL DB instance that has the `pg_tle` extension installed. The `pg_tle` extension is scoped to the PostgreSQL database in which it's installed. The extensions that you create using TLE are scoped to the same database.

Use the various `pgtle` functions to install the code that makes up your TLE extension. The following Trusted Language Extensions functions all require the `pgtle_admin` role.

- pgtle.install_extension
- pgtle.install_update_path
- pgtle.register_feature
- pgtle.register_feature_if_not_exists
- pgtle.set_default_version
- pgtle.uninstall_extension(name)

- pgtle.uninstall_extension(name, version)
- pgtle.uninstall_extension_if_exists
- pgtle.uninstall_update_path
- pgtle.uninstall_update_path_if_exists
- pgtle.unregister_feature
- pgtle.unregister_feature_if_exists

Example: Creating a trusted language extension using SQL

The following example shows you how to create a TLE extension named `pg_distance` that contains a few SQL functions for calculating distances using different formulas. In the listing, you can find the function for calculating the Manhattan distance and the function for calculating the Euclidean distance. For more information about the difference between these formulas, see Taxicab geometry and Euclidean geometry in Wikipedia.

You can use this example in your own RDS for PostgreSQL DB instance if you have the `pg_tle` extension set up as detailed in Setting up Trusted Language Extensions in your RDS for PostgreSQL DB instance.

> **Note**
>
> You need to have the privileges of the `pgtle_admin` role to follow this procedure.

To create the example TLE extension

The following steps use an example database named `labdb`. This database is owned by the `postgres` primary user. The `postgres` role also has the permissions of the `pgtle_admin` role.

1. Use `psql` to connect to RDS for PostgreSQL DB instance.

```
psql --host=db-instance-123456789012.aws-region.rds.amazonaws.com
--port=5432 --username=postgres --password --dbname=labdb
```

2. Create a TLE extension named `pg_distance` by copying the following code and pasting it into your `psql` session console.

```
SELECT pgtle.install_extension
```

```
(
 'pg_distance',
 '0.1',
  'Distance functions for two points',
$_pg_tle_$
    CREATE FUNCTION dist(x1 float8, y1 float8, x2 float8, y2 float8, norm int)
    RETURNS float8
    AS $$
      SELECT (abs(x2 - x1) ^ norm + abs(y2 - y1) ^ norm) ^ (1::float8 / norm);
    $$ LANGUAGE SQL;

    CREATE FUNCTION manhattan_dist(x1 float8, y1 float8, x2 float8, y2 float8)
    RETURNS float8
    AS $$
      SELECT dist(x1, y1, x2, y2, 1);
    $$ LANGUAGE SQL;

    CREATE FUNCTION euclidean_dist(x1 float8, y1 float8, x2 float8, y2 float8)
    RETURNS float8
    AS $$
      SELECT dist(x1, y1, x2, y2, 2);
    $$ LANGUAGE SQL;
$_pg_tle_$
);
```

You see the output, such as the following.

```
install_extension
---------------
 t
(1 row)
```

The artifacts that make up the `pg_distance` extension are now installed in your database. These artifacts include the control file and the code for the extension, which are items that need to be present so that the extension can be created using the `CREATE EXTENSION` command. In other words, you still need to create the extension to make its functions available to database users.

3. To create the extension, use the `CREATE EXTENSION` command as you do for any other extension. As with other extensions, the database user needs to have the `CREATE` permissions in the database.

```
CREATE EXTENSION pg_distance;
```

4. To test the pg_distance TLE extension, you can use it to calculate the Manhattan distance between four points.

```
labdb=> SELECT manhattan_dist(1, 1, 5, 5);
8
```

To calculate the Euclidean distance between the same set of points, you can use the following.

```
labdb=> SELECT euclidean_dist(1, 1, 5, 5);
5.656854249492381
```

The pg_distance extension loads the functions in the database and makes them available to any users with permissions on the database.

Modifying your TLE extension

To improve query performance for the functions packaged in this TLE extension, add the following two PostgreSQL attributes to their specifications.

- IMMUTABLE – The IMMUTABLE attribute ensures that the query optimizer can use optimizations to improve query response times. For more information, see Function Volatility Categories in the PostgreSQL documentation.
- PARALLEL SAFE – The PARALLEL SAFE attribute is another attribute that allows PostgreSQL to run the function in parallel mode. For more information, see CREATE FUNCTION in the PostgreSQL documentation.

In the following example, you can see how the pgtle.install_update_path function is used to add these attributes to each function to create a version 0.2 of the pg_distance TLE extension. For more information about this function, see pgtle.install_update_path. You need to have the pgtle_admin role to perform this task.

To update an existing TLE extension and specify the default version

1. Connect to RDS for PostgreSQL DB instance using psql or another client tool, such as pgAdmin.

```
psql --host=db-instance-123456789012.aws-region.rds.amazonaws.com
--port=5432 --username=postgres --password --dbname=labdb
```

2. Modify the existing TLE extension by copying the following code and pasting it into your `psql` session console.

```
SELECT pgtle.install_update_path
(
 'pg_distance',
 '0.1',
 '0.2',
$_pg_tle_$
    CREATE OR REPLACE FUNCTION dist(x1 float8, y1 float8, x2 float8, y2 float8,
 norm int)
    RETURNS float8
    AS $$
      SELECT (abs(x2 - x1) ^ norm + abs(y2 - y1) ^ norm) ^ (1::float8 / norm);
    $$ LANGUAGE SQL IMMUTABLE PARALLEL SAFE;

    CREATE OR REPLACE FUNCTION manhattan_dist(x1 float8, y1 float8, x2 float8, y2
 float8)
    RETURNS float8
    AS $$
      SELECT dist(x1, y1, x2, y2, 1);
    $$ LANGUAGE SQL IMMUTABLE PARALLEL SAFE;

    CREATE OR REPLACE FUNCTION euclidean_dist(x1 float8, y1 float8, x2 float8, y2
 float8)
    RETURNS float8
    AS $$
      SELECT dist(x1, y1, x2, y2, 2);
    $$ LANGUAGE SQL IMMUTABLE PARALLEL SAFE;
$_pg_tle_$
);
```

You see a response similar to the following.

```
install_update_path
---------------------
 t
(1 row)
```

You can make this version of the extension the default version, so that database users don't have to specify a version when they create or update the extension in their database.

3. To specify that the modified version (version 0.2) of your TLE extension is the default version, use the `pgtle.set_default_version` function as shown in the following example.

```
SELECT pgtle.set_default_version('pg_distance', '0.2');
```

For more information about this function, see pgtle.set_default_version.

4. With the code in place, you can update the installed TLE extension in the usual way, by using `ALTER EXTENSION ... UPDATE` command, as shown here:

```
ALTER EXTENSION pg_distance UPDATE;
```

Dropping your TLE extensions from a database

You can drop your TLE extensions by using the `DROP EXTENSION` command in the same way that you do for other PostgreSQL extensions. Dropping the extension doesn't remove the installation files that make up the extension, which allows users to re-create the extension. To remove the extension and its installation files, do the following two-step process.

To drop the TLE extension and remove its installation files

1. Use `psql` or another client tool to connect to the RDS for PostgreSQL DB instance.

```
psql --host=.111122223333.aws-region.rds.amazonaws.com --port=5432 --
username=postgres --password --dbname=dbname
```

2. Drop the extension as you would any PostgreSQL extension.

```
DROP EXTENSION your-TLE-extension
```

For example, if you create the `pg_distance` extension as detailed in Example: Creating a trusted language extension using SQL, you can drop the extension as follows.

```
DROP EXTENSION pg_distance;
```

You see output confirming that the extension has been dropped, as follows.

```
DROP EXTENSION
```

At this point, the extension is no longer active in the database. However, its installation files and control file are still available in the database, so database users can create the extension again if they like.

- If you want to leave the extension files intact so that database users can create your TLE extension, you can stop here.
- If you want to remove all files that make up the extension, continue to the next step.

3. To remove all installation files for your extension, use the `pgtle.uninstall_extension` function. This function removes all the code and control files for your extension.

```
SELECT pgtle.uninstall_extension('your-tle-extension-name');
```

For example, to remove all `pg_distance` installation files, use the following command.

```
SELECT pgtle.uninstall_extension('pg_distance');
 uninstall_extension
---------------------
 t
(1 row)
```

Uninstalling Trusted Language Extensions for PostgreSQL

If you no longer want to create your own TLE extensions using TLE, you can drop the `pg_tle` extension and remove all artifacts. This action includes dropping any TLE extensions in the database and dropping the `pgtle` schema.

To drop the `pg_tle` extension and its schema from a database

1. Use `psql` or another client tool to connect to the RDS for PostgreSQL DB instance.

```
psql --host=.111122223333.aws-region.rds.amazonaws.com --port=5432 --
username=postgres --password --dbname=dbname
```

2. Drop the pg_tle extension from the database. If the database has your own TLE extensions still running in the database, you need to also drop those extensions. To do so, you can use the CASCADE keyword, as shown in the following.

```
DROP EXTENSION pg_tle CASCADE;
```

   If the pg_tle extension isn't still active in the database, you don't need to use the CASCADE keyword.

3. Drop the pgtle schema. This action removes all the management functions from the database.

```
DROP SCHEMA pgtle CASCADE;
```

   The command returns the following when the process completes.

```
DROP SCHEMA
```

   The pg_tle extension, its schema and functions, and all artifacts are removed. To create new extensions using TLE, go through the setup process again. For more information, see Setting up Trusted Language Extensions in your RDS for PostgreSQL DB instance.

Using PostgreSQL hooks with your TLE extensions

A *hook* is a callback mechanism available in PostgreSQL that allows developers to call custom functions or other routines during regular database operations. The TLE development kit supports PostgreSQL hooks so that you can integrate custom functions with PostgreSQL behavior at runtime. For example, you can use a hook to associate the authentication process with your own custom code, or to modify the query planning and execution process for your specific needs.

Your TLE extensions can use hooks. If a hook is global in scope, it applies across all databases. Therefore, if your TLE extension uses a global hook, then you need to create your TLE extension in all databases that your users can access.

When you use the pg_tle extension to build your own Trusted Language Extensions, you can use the available hooks from a SQL API to build out the functions of your extension. You should register any hooks with pg_tle. For some hooks, you might also need to set various configuration parameters. For example, the passcode check hook can be set to on, off, or require. For more

information about specific requirements for available pg_tle hooks, see Hooks reference for Trusted Language Extensions for PostgreSQL.

Example: Creating an extension that uses a PostgreSQL hook

The example discussed in this section uses a PostgreSQL hook to check the password provided during specific SQL operations and prevents database users from setting their passwords to any of those contained in the password_check.bad_passwords table. The table contains the top-ten most commonly used, but easily breakable choices for passwords.

To set up this example in your RDS for PostgreSQL DB instance, you must have already installed Trusted Language Extensions. For details, see Setting up Trusted Language Extensions in your RDS for PostgreSQL DB instance.

To set up the password-check hook example

1. Use psql to connect to RDS for PostgreSQL DB instance.

```
psql --host=db-instance-123456789012.aws-region.rds.amazonaws.com
--port=5432 --username=postgres --password --dbname=labdb
```

2. Copy the code from the Password-check hook code listing and paste it into your database.

```
SELECT pgtle.install_extension (
  'my_password_check_rules',
  '1.0',
  'Do not let users use the 10 most commonly used passwords',
$_pgtle_$
  CREATE SCHEMA password_check;
  REVOKE ALL ON SCHEMA password_check FROM PUBLIC;
  GRANT USAGE ON SCHEMA password_check TO PUBLIC;

  CREATE TABLE password_check.bad_passwords (plaintext) AS
  VALUES
    ('123456'),
    ('password'),
    ('12345678'),
    ('qwerty'),
    ('123456789'),
    ('12345'),
    ('1234'),
    ('111111'),
```

```
    ('1234567'),
    ('dragon');
  CREATE UNIQUE INDEX ON password_check.bad_passwords (plaintext);

  CREATE FUNCTION password_check.passcheck_hook(username text, password text,
 password_type pgtle.password_types, valid_until timestamptz, valid_null boolean)
  RETURNS void AS $$
    DECLARE
      invalid bool := false;
    BEGIN
      IF password_type = 'PASSWORD_TYPE_MD5' THEN
        SELECT EXISTS(
          SELECT 1
          FROM password_check.bad_passwords bp
          WHERE ('md5' || md5(bp.plaintext || username)) = password
        ) INTO invalid;
        IF invalid THEN
          RAISE EXCEPTION 'Cannot use passwords from the common password
 dictionary';
        END IF;
      ELSIF password_type = 'PASSWORD_TYPE_PLAINTEXT' THEN
        SELECT EXISTS(
          SELECT 1
          FROM password_check.bad_passwords bp
          WHERE bp.plaintext = password
        ) INTO invalid;
        IF invalid THEN
          RAISE EXCEPTION 'Cannot use passwords from the common common password
 dictionary';
        END IF;
      END IF;
    END
  $$ LANGUAGE plpgsql SECURITY DEFINER;

  GRANT EXECUTE ON FUNCTION password_check.passcheck_hook TO PUBLIC;

  SELECT pgtle.register_feature('password_check.passcheck_hook', 'passcheck');
$_pgtle_$
);
```

When the extension has been loaded into your database, you see the output such as the following.

```
 install_extension
-------------------
 t
(1 row)
```

3. While still connected to the database, you can now create the extension.

```
CREATE EXTENSION my_password_check_rules;
```

4. You can confirm that the extension has been created in the database by using the following `psql` metacommand.

```
\dx
                        List of installed extensions
          Name           | Version |   Schema   |
 Description
------------------------+---------+------------
+-------------------------------------------------------------
 my_password_check_rules | 1.0     | public     | Prevent use of any of the top-ten
 most common bad passwords
 pg_tle                  | 1.0.1   | pgtle      | Trusted-Language Extensions for
 PostgreSQL
 plpgsql                 | 1.0     | pg_catalog | PL/pgSQL procedural language
(3 rows)
```

5. Open another terminal session to work with the AWS CLI. You need to modify your custom DB parameter group to turn on the password-check hook. To do so, use the modify-db-parameter-group CLI command as shown in the following example.

```
aws rds modify-db-parameter-group \
    --region aws-region \
    --db-parameter-group-name your-custom-parameter-group \
    --parameters
 "ParameterName=pgtle.enable_password_check,ParameterValue=on,ApplyMethod=immediate"
```

When the parameter is successfully turned on, you see the output such as the following.

```
(
    "DBParameterGroupName": "docs-lab-parameters-for-tle"
}
```

It might take a few minutes for the change to the parameter group setting to take effect. This parameter is dynamic, however, so you don't need to restart the RDS for PostgreSQL DB instance for the setting to take effect.

6. Open the `psql` session and query the database to verify that the password_check hook has been turned on.

```
labdb=> SHOW pgtle.enable_password_check;
pgtle.enable_password_check
----------------------------
on
(1 row)
```

The password-check hook is now active. You can test it by creating a new role and using one of the bad passwords, as shown in the following example.

```
CREATE ROLE test_role PASSWORD 'password';
ERROR:  Cannot use passwords from the common password dictionary
CONTEXT:  PL/pgSQL function
 password_check.passcheck_hook(text,text,pgtle.password_types,timestamp with time
 zone,boolean) line 21 at RAISE
SQL statement "SELECT password_check.passcheck_hook(
    $1::pg_catalog.text,
    $2::pg_catalog.text,
    $3::pgtle.password_types,
    $4::pg_catalog.timestamptz,
    $5::pg_catalog.bool)"
```

The output has been formatted for readability.

The following example shows that `pgsql` interactive metacommand `\password` behavior is also affected by the password_check hook.

```
postgres=> SET password_encryption TO 'md5';
SET
postgres=> \password
Enter new password for user "postgres":*****
Enter it again:*****
ERROR:  Cannot use passwords from the common password dictionary
```

```
CONTEXT:  PL/pgSQL function
 password_check.passcheck_hook(text,text,pgtle.password_types,timestamp with time
 zone,boolean) line 12 at RAISE
SQL statement "SELECT password_check.passcheck_hook($1::pg_catalog.text,
 $2::pg_catalog.text, $3::pgtle.password_types, $4::pg_catalog.timestamptz,
 $5::pg_catalog.bool)"
```

You can drop this TLE extension and uninstall its source files if you want. For more information, see Dropping your TLE extensions from a database.

Password-check hook code listing

The example code shown here defines the specification for the `my_password_check_rules` TLE extension. When you copy this code and paste it into your database, the code for the `my_password_check_rules` extension is loaded into the database, and the `password_check` hook is registered for use by the extension.

```
SELECT pgtle.install_extension (
  'my_password_check_rules',
  '1.0',
  'Do not let users use the 10 most commonly used passwords',
$_pgtle_$
  CREATE SCHEMA password_check;
  REVOKE ALL ON SCHEMA password_check FROM PUBLIC;
  GRANT USAGE ON SCHEMA password_check TO PUBLIC;

  CREATE TABLE password_check.bad_passwords (plaintext) AS
  VALUES
    ('123456'),
    ('password'),
    ('12345678'),
    ('qwerty'),
    ('123456789'),
    ('12345'),
    ('1234'),
    ('111111'),
    ('1234567'),
    ('dragon');
  CREATE UNIQUE INDEX ON password_check.bad_passwords (plaintext);

  CREATE FUNCTION password_check.passcheck_hook(username text, password text,
 password_type pgtle.password_types, valid_until timestamptz, valid_null boolean)
  RETURNS void AS $$
```

```
    DECLARE
      invalid bool := false;
    BEGIN
      IF password_type = 'PASSWORD_TYPE_MD5' THEN
        SELECT EXISTS(
          SELECT 1
          FROM password_check.bad_passwords bp
          WHERE ('md5' || md5(bp.plaintext || username)) = password
        ) INTO invalid;
        IF invalid THEN
          RAISE EXCEPTION 'Cannot use passwords from the common password dictionary';
        END IF;
      ELSIF password_type = 'PASSWORD_TYPE_PLAINTEXT' THEN
        SELECT EXISTS(
          SELECT 1
          FROM password_check.bad_passwords bp
          WHERE bp.plaintext = password
        ) INTO invalid;
        IF invalid THEN
          RAISE EXCEPTION 'Cannot use passwords from the common common password
 dictionary';
        END IF;
      END IF;
    END
  $$ LANGUAGE plpgsql SECURITY DEFINER;

  GRANT EXECUTE ON FUNCTION password_check.passcheck_hook TO PUBLIC;

  SELECT pgtle.register_feature('password_check.passcheck_hook', 'passcheck');
$_pgtle_$
);
```

Using Custom Data Types in TLE

PostgreSQL supports commands to register new base types (also known as scalar types) for efficiently handling complex data structures in your database. A base type allows you to customize how the data is stored internally, and how to convert it to and from an external textual representation. These custom data types are helpful when extending PostgreSQL to support functional domains where a built-in type such as number or text can't provide sufficient search semantics.

RDS for PostgreSQL enables you to create custom data types in your trusted language extension and define functions that support SQL and index operations for these new data types. Custom data types are available for the following versions:

- RDS for PostgreSQL 15.4 and higher 15 versions
- RDS for PostgreSQL 14.9 and higher 14 versions
- RDS for PostgreSQL 13.12 and higher 13 versions

For more information, see Trusted Language Base types.

Function reference for Trusted Language Extensions for PostgreSQL

View the following reference documentation about functions available in Trusted Language Extensions for PostgreSQL. Use these functions to install, register, update, and manage your *TLE extensions*, that is, the PostgreSQL extensions that you develop using the Trusted Language Extensions development kit.

Functions

- pgtle.available_extensions
- pgtle.available_extension_versions
- pgtle.extension_update_paths
- pgtle.install_extension
- pgtle.install_update_path
- pgtle.register_feature
- pgtle.register_feature_if_not_exists
- pgtle.set_default_version
- pgtle.uninstall_extension(name)
- pgtle.uninstall_extension(name, version)
- pgtle.uninstall_extension_if_exists
- pgtle.uninstall_update_path
- pgtle.uninstall_update_path_if_exists
- pgtle.unregister_feature
- pgtle.unregister_feature_if_exists

pgtle.available_extensions

The `pgtle.available_extensions` function is a set-returning function. It returns all available TLE extensions in the database. Each returned row contains information about a single TLE extension.

Function prototype

```
pgtle.available_extensions()
```

Role

None.

Arguments

None.

Output

- `name` – The name of the TLE extension.
- `default_version` – The version of the TLE extension to use when `CREATE EXTENSION` is called without a version specified.
- `description` – A more detailed description about the TLE extension.

Usage example

```
SELECT * FROM pgtle.available_extensions();
```

pgtle.available_extension_versions

The `available_extension_versions` function is a set-returning function. It returns a list of all available TLE extensions and their versions. Each row contains information about a specific version of the given TLE extension, including whether it requires a specific role.

Function prototype

```
pgtle.available_extension_versions()
```

Role

None.

Arguments

None.

Output

- `name` – The name of the TLE extension.
- `version` – The version of the TLE extension.
- `superuser` – This value is always `false` for your TLE extensions. The permissions needed to create the TLE extension or update it are the same as for creating other objects in the given database.
- `trusted` – This value is always `false` for a TLE extension.
- `relocatable` – This value is always `false` for a TLE extension.
- `schema` – Specifies the name of the schema in which the TLE extension is installed.
- `requires` – An array containing the names of other extensions needed by this TLE extension.
- `description` – A detailed description of the TLE extension.

For more information about output values, see Packaging Related Objects into an Extension > Extension Files in the PostgreSQL documentation.

Usage example

```
SELECT * FROM pgtle.available_extension_versions();
```

pgtle.extension_update_paths

The `extension_update_paths` function is a set-returning function. It returns a list of all the possible update paths for a TLE extension. Each row includes the available upgrades or downgrades for that TLE extension.

Function prototype

```
pgtle.extension_update_paths(name)
```

Role

None.

Arguments

name – The name of the TLE extension from which to get upgrade paths.

Output

- source – The source version for an update.
- target – The target version for an update.
- path – The upgrade path used to update a TLE extension from source version to target version, for example, 0.1--0.2.

Usage example

```
SELECT * FROM pgtle.extension_update_paths('your-TLE');
```

pgtle.install_extension

The install_extension function lets you install the artifacts that make up your TLE extension in the database, after which it can be created using the CREATE EXTENSION command.

Function prototype

```
pgtle.install_extension(name text, version text, description text, ext text, requires
 text[] DEFAULT NULL::text[])
```

Role

None.

Arguments

- name – The name of the TLE extension. This value is used when calling CREATE EXTENSION.
- version – The version of the TLE extension.
- description – A detailed description about the TLE extension. This description is displayed in the comment field in pgtle.available_extensions().
- ext – The contents of the TLE extension. This value contains objects such as functions.

- `requires` – An optional parameter that specifies dependencies for this TLE extension. The `pg_tle` extension is automatically added as a dependency.

Many of these arguments are the same as those that are included in an extension control file for installing a PostgreSQL extension on the file system of a PostgreSQL instance. For more information, see the Extension Files in Packaging Related Objects into an Extension in the PostgreSQL documentation.

Output

This functions returns `OK` on success and `NULL` on error.

- `OK` – The TLE extension has been successfully installed in the database.
- `NULL` – The TLE extension hasn't been successfully installed in the database.

Usage example

```
SELECT pgtle.install_extension(
 'pg_tle_test',
 '0.1',
 'My first pg_tle extension',
$_pgtle_$
  CREATE FUNCTION my_test()
  RETURNS INT
  AS $$
    SELECT 42;
  $$ LANGUAGE SQL IMMUTABLE;
$_pgtle_$
);
```

pgtle.install_update_path

The `install_update_path` function provides an update path between two different versions of a TLE extension. This function allows users of your TLE extension to update its version by using the `ALTER EXTENSION ... UPDATE` syntax.

Function prototype

```
pgtle.install_update_path(name text, fromvers text, tovers text, ext text)
```

Role

`pgtle_admin`

Arguments

- `name` – The name of the TLE extension. This value is used when calling `CREATE EXTENSION`.
- `fromvers` – The source version of the TLE extension for the upgrade.
- `tovers` – The destination version of the TLE extension for the upgrade.
- `ext` – The contents of the update. This value contains objects such as functions.

Output

None.

Usage example

```
SELECT pgtle.install_update_path('pg_tle_test', '0.1', '0.2',
  $_pgtle_$
    CREATE OR REPLACE FUNCTION my_test()
    RETURNS INT
    AS $$
      SELECT 21;
    $$ LANGUAGE SQL IMMUTABLE;
  $_pgtle_$
);
```

pgtle.register_feature

The `register_feature` function adds the specified internal PostgreSQL feature to the `pgtle.feature_info` table. PostgreSQL hooks are an example of an internal PostgreSQL feature. The Trusted Language Extensions development kit supports the use of PostgreSQL hooks. Currently, this function supports the following feature.

- `passcheck` – Registers the password-check hook with your procedure or function that customizes PostgreSQL's password-check behavior.

Function prototype

```
pgtle.register_feature(proc regproc, feature pg_tle_feature)
```

Role

pgtle_admin

Arguments

- proc – The name of a stored procedure or function to use for the feature.
- feature – The name of the pg_tle feature (such as passcheck) to register with the function.

Output

None.

Usage example

```
SELECT pgtle.register_feature('pw_hook', 'passcheck');
```

pgtle.register_feature_if_not_exists

The pgtle.register_feature_if_not_exists function adds the specified PostgreSQL feature to the pgtle.feature_info table and identifies the TLE extension or other procedure or function that uses the feature. For more information about hooks and Trusted Language Extensions, see Using PostgreSQL hooks with your TLE extensions.

Function prototype

```
pgtle.register_feature_if_not_exists(proc regproc, feature pg_tle_feature)
```

Role

pgtle_admin

Arguments

- proc – The name of a stored procedure or function that contains the logic (code) to use as a feature for your TLE extension. For example, the pw_hook code.

- `feature` – The name of the PostgreSQL feature to register for the TLE function. Currently, the only available feature is the `passcheck` hook. For more information, see Password-check hook (passcheck).

Output

Returns `true` after registering the feature for the specified extension. Returns `false` if the feature is already registered.

Usage example

```
SELECT pgtle.register_feature_if_not_exists('pw_hook', 'passcheck');
```

pgtle.set_default_version

The `set_default_version` function lets you specify a `default_version` for your TLE extension. You can use this function to define an upgrade path and designate the version as the default for your TLE extension. When database users specify your TLE extension in the `CREATE EXTENSION` and `ALTER EXTENSION ... UPDATE` commands, that version of your TLE extension is created in the database for that user.

This function returns `true` on success. If the TLE extension specified in the `name` argument doesn't exist, the function returns an error. Similarly, if the `version` of the TLE extension doesn't exist, it returns an error.

Function prototype

```
pgtle.set_default_version(name text, version text)
```

Role

`pgtle_admin`

Arguments

- `name` – The name of the TLE extension. This value is used when calling `CREATE EXTENSION`.
- `version` – The version of the TLE extension to set the default.

Output

- `true` – When setting default version succeeds, the function returns `true`.
- ERROR – Returns an error message if a TLE extension with the specified name or version doesn't exist.

Usage example

```
SELECT * FROM pgtle.set_default_version('my-extension', '1.1');
```

pgtle.uninstall_extension(name)

The `uninstall_extension` function removes all versions of a TLE extension from a database. This function prevents future calls of `CREATE EXTENSION` from installing the TLE extension. If the TLE extension doesn't exist in the database, an error is raised.

The `uninstall_extension` function won't drop a TLE extension that's currently active in the database. To remove a TLE extension that's currently active, you need to explicitly call `DROP EXTENSION` to remove it.

Function prototype

```
pgtle.uninstall_extension(extname text)
```

Role

`pgtle_admin`

Arguments

- `extname` – The name of the TLE extension to uninstall. This name is the same as the one used with `CREATE EXTENSION` to load the TLE extension for use in a given database.

Output

None.

Usage example

```
SELECT * FROM pgtle.uninstall_extension('pg_tle_test');
```

pgtle.uninstall_extension(name, version)

The `uninstall_extension(name, version)` function removes the specified version of the TLE extension from the database. This function prevents `CREATE EXTENSION` and `ALTER EXTENSION` from installing or updating a TLE extension to the specified version. This function also removes all update paths for the specified version of the TLE extension. This function won't uninstall the TLE extension if it's currently active in the database. You must explicitly call `DROP EXTENSION` to remove the TLE extension. To uninstall all versions of a TLE extension, see pgtle.uninstall_extension(name).

Function prototype

```
pgtle.uninstall_extension(extname text, version text)
```

Role

`pgtle_admin`

Arguments

- `extname` – The name of the TLE extension. This value is used when calling `CREATE EXTENSION`.
- `version` – The version of the TLE extension to uninstall from the database.

Output

None.

Usage example

```
SELECT * FROM pgtle.uninstall_extension('pg_tle_test', '0.2');
```

pgtle.uninstall_extension_if_exists

The `uninstall_extension_if_exists` function removes all versions of a TLE extension from a given database. If the TLE extension doesn't exist, the function returns silently (no error message is raised). If the specified extension is currently active within a database, this function doesn't drop it. You must explicitly call `DROP EXTENSION` to remove the TLE extension before using this function to uninstall its artifacts.

Function prototype

```
pgtle.uninstall_extension_if_exists(extname text)
```

Role

pgtle_admin

Arguments

- extname – The name of the TLE extension. This value is used when calling CREATE EXTENSION.

Output

The uninstall_extension_if_exists function returns true after uninstalling the specified extension. If the specified extension doesn't exist, the function returns false.

- true – Returns true after uninstalling the TLE extension.
- false – Returns false when the TLE extension doesn't exist in the database.

Usage example

```
SELECT * FROM pgtle.uninstall_extension_if_exists('pg_tle_test');
```

pgtle.uninstall_update_path

The uninstall_update_path function removes the specific update path from a TLE extension. This prevents ALTER EXTENSION ... UPDATE TO from using this as an update path.

If the TLE extension is currently being used by one of the versions on this update path, it remains in the database.

If the update path specified doesn't exist, this function raises an error.

Function prototype

```
pgtle.uninstall_update_path(extname text, fromvers text, tovers text)
```

Role

pgtle_admin

Arguments

- `extname` – The name of the TLE extension. This value is used when calling `CREATE EXTENSION`.
- `fromvers` – The source version of the TLE extension used on the update path.
- `tovers` – The destination version of the TLE extension used on the update path.

Output

None.

Usage example

```
SELECT * FROM pgtle.uninstall_update_path('pg_tle_test', '0.1', '0.2');
```

pgtle.uninstall_update_path_if_exists

The `uninstall_update_path_if_exists` function is similar to `uninstall_update_path` in that it removes the specified update path from a TLE extension. However, if the update path doesn't exist, this function doesn't raise an error message. Instead, the function returns `false`.

Function prototype

```
pgtle.uninstall_update_path_if_exists(extname text, fromvers text, tovers text)
```

Role

`pgtle_admin`

Arguments

- `extname` – The name of the TLE extension. This value is used when calling `CREATE EXTENSION`.
- `fromvers` – The source version of the TLE extension used on the update path.
- `tovers` – The destination version of the TLE extension used on the update path.

Output

- `true` – The function has successfully updated the path for the TLE extension.
- `false` – The function wasn't able to update the path for the TLE extension.

Usage example

```
SELECT * FROM pgtle.uninstall_update_path_if_exists('pg_tle_test', '0.1', '0.2');
```

pgtle.unregister_feature

The `unregister_feature` function provides a way to remove functions that were registered to use `pg_tle` features, such as hooks. For information about registering a feature, see pgtle.register_feature.

Function prototype

```
pgtle.unregister_feature(proc regproc, feature pg_tle_features)
```

Role

`pgtle_admin`

Arguments

- `proc` – The name of a stored function to register with a `pg_tle` feature.
- `feature` – The name of the `pg_tle` feature to register with the function. For example, `passcheck` is a feature that can be registered for use by the trusted language extensions that you develop. For more information, see Password-check hook (passcheck).

Output

None.

Usage example

```
SELECT * FROM pgtle.unregister_feature('pw_hook', 'passcheck');
```

pgtle.unregister_feature_if_exists

The `unregister_feature` function provides a way to remove functions that were registered to use `pg_tle` features, such as hooks. For more information, see Using PostgreSQL hooks with your TLE extensions. Returns `true` after successfully unregistering the feature. Returns `false` if the feature wasn't registered.

For information about registering pg_tle features for your TLE extensions, see pgtle.register_feature.

Function prototype

```
pgtle.unregister_feature_if_exists('proc regproc', 'feature pg_tle_features')
```

Role

pgtle_admin

Arguments

- proc – The name of the stored function that was registered to include a pg_tle feature.
- feature – The name of the pg_tle feature that was registered with the trusted language extension.

Output

Returns true or false, as follows.

- true – The function has successfully unregistered the feature from extension.
- false – The function wasn't able to unregister the feature from the TLE extension.

Usage example

```
SELECT * FROM pgtle.unregister_feature_if_exists('pw_hook', 'passcheck');
```

Hooks reference for Trusted Language Extensions for PostgreSQL

Trusted Language Extensions for PostgreSQL supports PostgreSQL hooks. A *hook* is an internal callback mechanism available to developers for extending PostgreSQL's core functionality. By using hooks, developers can implement their own functions or procedures for use during various database operations, thereby modifying PostgreSQL's behavior in some way. For example, you can use a passcheck hook to customize how PostgreSQL handles the passwords supplied when creating or changing passwords for users (roles).

View the following documentation to learn about the passcheck hook available for your TLE extensions.

Password-check hook (passcheck)

The `passcheck` hook is used to customize PostgreSQL behavior during the password-checking process for the following SQL commands and `psql` metacommand.

- `CREATE ROLE username ...PASSWORD` – For more information, see CREATE ROLE in the PostgreSQL documentation.
- `ALTER ROLE username...PASSWORD` – For more information, see ALTER ROLE in the PostgreSQL documentation.
- `\password username` – This interactive `psql` metacommand securely changes the password for the specified user by hashing the password before transparently using the `ALTER ROLE ... PASSWORD` syntax. The metacommand is a secure wrapper for the `ALTER ROLE ... PASSWORD` command, thus the hook applies to the behavior of the `psql` metacommand.

For an example, see Password-check hook code listing.

Contents

Function prototype

```
passcheck_hook(username text, password text, password_type pgtle.password_types,
 valid_until timestamptz, valid_null boolean)
```

Arguments

A `passcheck` hook function takes the following arguments.

- `username` – The name (as text) of the role (username) that's setting a password.
- `password` – The plaintext or hashed password. The password entered should match the type specified in `password_type`.
- `password_type` – Specify the `pgtle.password_type` format of the password. This format can be one of the following options.

- PASSWORD_TYPE_PLAINTEXT – A plaintext password.
- PASSWORD_TYPE_MD5 – A password that's been hashed using MD5 (message digest 5) algorithm.
- PASSWORD_TYPE_SCRAM_SHA_256 – A password that's been hashed using SCRAM-SHA-256 algorithm.

- valid_until – Specify the time when the password becomes invalid. This argument is optional. If you use this argument, specify the time as a timestamptz value.
- valid_null – If this Boolean is set to true, the valid_until option is set to NULL.

Configuration

The function pgtle.enable_password_check controls whether the passcheck hook is active. The passcheck hook has three possible settings.

- off – Turns off the passcheck password-check hook. This is the default value.
- on – Turns on the passcode password-check hook so that passwords are checked against the table.
- require – Requires a password check hook to be defined.

Usage notes

To turn the passcheck hook on or off, you need to modify the custom DB parameter group for your RDS for PostgreSQL DB instance.

For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group \
    --region aws-region \
    --db-parameter-group-name your-custom-parameter-group \
    --parameters
 "ParameterName=pgtle.enable_password_check,ParameterValue=on,ApplyMethod=immediate"
```

For Windows:

```
aws rds modify-db-parameter-group ^
    --region aws-region ^
    --db-parameter-group-name your-custom-parameter-group ^
```

```
    --parameters
 "ParameterName=pgtle.enable_password_check,ParameterValue=on,ApplyMethod=immediate"
```

Code examples for Amazon RDS using AWS SDKs

The following code examples show how to use Amazon RDS with an AWS software development kit (SDK).

Basics are code examples that show you how to perform the essential operations within a service.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Scenarios are code examples that show you how to accomplish specific tasks by calling multiple functions within a service or combined with other AWS services.

For a complete list of AWS SDK developer guides and code examples, see Using this service with an AWS SDK. This topic also includes information about getting started and details about previous SDK versions.

Get started

Hello Amazon RDS

The following code examples show how to get started using Amazon RDS.

.NET

AWS SDK for .NET

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
using System;
using System.Threading.Tasks;
using Amazon.RDS;
using Amazon.RDS.Model;

namespace RDSActions;

public static class HelloRds
```

```
{
    static async Task Main(string[] args)
    {
        var rdsClient = new AmazonRDSClient();

        Console.WriteLine($"Hello Amazon RDS! Following are some of your DB
 instances:");
        Console.WriteLine();

        // You can use await and any of the async methods to get a response.
        // Let's get the first twenty DB instances.
        var response = await rdsClient.DescribeDBInstancesAsync(
            new DescribeDBInstancesRequest()
            {
                MaxRecords = 20 // Must be between 20 and 100.
            });

        foreach (var instance in response.DBInstances)
        {
            Console.WriteLine($"\tDB name: {instance.DBName}");
            Console.WriteLine($"\tArn: {instance.DBInstanceArn}");
            Console.WriteLine($"\tIdentifier: {instance.DBInstanceIdentifier}");
            Console.WriteLine();
        }
    }
}
```

- For API details, see DescribeDBInstances in *AWS SDK for .NET API Reference*.

C++

SDK for C++

> **Note**
>

For a complete list of AWS SDK developer guides and code examples, see Using this service with an AWS SDK. This topic also includes information about getting started and details about previous SDK versions.

Learn the basics of Amazon RDS with an AWS SDK

The following code examples show how to:

- Create a custom DB parameter group and set parameter values.
- Create a DB instance that's configured to use the parameter group. The DB instance also contains a database.

- Take a snapshot of the instance.
- Delete the instance and parameter group.

.NET

AWS SDK for .NET

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

Run an interactive scenario at a command prompt.

```
/// <summary>
/// Scenario for RDS DB instance example.
/// </summary>
public class RDSInstanceScenario
{
    /*
    Before running this .NET code example, set up your development environment,
 including your credentials.

    This .NET example performs the following tasks:
    1.  Returns a list of the available DB engine families using the
 DescribeDBEngineVersionsAsync method.
    2.  Selects an engine family and creates a custom DB parameter group using
 the CreateDBParameterGroupAsync method.
    3.  Gets the parameter groups using the DescribeDBParameterGroupsAsync
 method.
    4.  Gets parameters in the group using the DescribeDBParameters method.
    5.  Parses and displays parameters in the group.
    6.  Modifies both the auto_increment_offset and auto_increment_increment
 parameters
        using the ModifyDBParameterGroupAsync method.
    7.  Gets and displays the updated parameters using the DescribeDBParameters
 method with a source of "user".
    8.  Gets a list of allowed engine versions using the
 DescribeDBEngineVersionsAsync method.
```

```
   9.  Displays and selects from a list of micro instance classes available for
the selected engine and version.
   10. Creates an RDS DB instance that contains a MySql database and uses the
parameter group
       using the CreateDBInstanceAsync method.
   11. Waits for DB instance to be ready using the DescribeDBInstancesAsync
method.
   12. Prints out the connection endpoint string for the new DB instance.
   13. Creates a snapshot of the DB instance using the CreateDBSnapshotAsync
method.
   14. Waits for DB snapshot to be ready using the DescribeDBSnapshots method.
   15. Deletes the DB instance using the DeleteDBInstanceAsync method.
   16. Waits for DB instance to be deleted using the DescribeDbInstances method.
   17. Deletes the parameter group using the DeleteDBParameterGroupAsync.

Go

SDK for Go V2

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

Run an interactive scenario at a command prompt.

```
// GetStartedInstances is an interactive example that shows you how to use the
 AWS SDK for Go
// with Amazon Relation Database Service (Amazon RDS) to do the following:
//
//  1. Create a custom DB parameter group and set parameter values.
//  2. Create a DB instance that is configured to use the parameter group. The DB
 instance
//     also contains a database.
```

```
//  3. Take a snapshot of the DB instance.
//  4. Delete the DB instance and parameter group.

/**
 * Before running this Java (v2) code example, set up your development
 * environment, including your credentials.
 *
 * For more information, see the following documentation topic:
 *
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-
started.html
 *
 * This example requires an AWS Secrets Manager secret that contains the
 * database credentials. If you do not create a
 * secret, this example will not work. For details, see:
 *
 * https://docs.aws.amazon.com/secretsmanager/latest/userguide/integrating_how-
services-use-secrets_RS.html
 *
 * This Java example performs these tasks:
 *
 * 1. Returns a list of the available DB engines.
 * 2. Selects an engine family and create a custom DB parameter group.
 * 3. Gets the parameter groups.
 * 4. Gets parameters in the group.
```

```
 * 5. Modifies the auto_increment_offset parameter.
 * 6. Gets and displays the updated parameters.
 * 7. Gets a list of allowed engine versions.
 * 8. Gets a list of micro instance classes available for the selected engine.
 * 9. Creates an RDS database instance that contains a MySql database and uses
 * the parameter group.
 * 10. Waits for the DB instance to be ready and prints out the connection
 * endpoint value.
 * 11. Creates a snapshot of the DB instance.
 * 12. Waits for an RDS DB snapshot to be ready.
 * 13. Deletes the RDS DB instance.
 * 14. Deletes the parameter group.

Kotlin

SDK for Kotlin

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
/**
Before running this code example, set up your development environment, including
 your credentials.

For more information, see the following documentation topic:
```

```
https://docs.aws.amazon.com/sdk-for-kotlin/latest/developer-guide/setup.html

This example requires an AWS Secrets Manager secret that contains the database
 credentials. If you do not create a
secret, this example will not work. For more details, see:

https://docs.aws.amazon.com/secretsmanager/latest/userguide/integrating_how-
services-use-secrets_RS.html

This example performs the following tasks:

1. Returns a list of the available DB engines by invoking the
 DescribeDbEngineVersions method.
2. Selects an engine family and create a custom DB parameter group by invoking
 the createDBParameterGroup method.
3. Gets the parameter groups by invoking the DescribeDbParameterGroups method.
4. Gets parameters in the group by invoking the DescribeDbParameters method.
5. Modifies both the auto_increment_offset and auto_increment_increment
 parameters by invoking the modifyDbParameterGroup method.
6. Gets and displays the updated parameters.
7. Gets a list of allowed engine versions by invoking the
 describeDbEngineVersions method.
8. Gets a list of micro instance classes available for the selected engine.
9. Creates an Amazon Relational Database Service (Amazon RDS) database instance
 that contains a MySQL database and uses the parameter group.
10. Waits for DB instance to be ready and prints out the connection endpoint
 value.
11. Creates a snapshot of the DB instance.
12. Waits for the DB snapshot to be ready.
13. Deletes the DB instance.
14. Deletes the parameter group.
 */

Actions for Amazon RDS using AWS SDKs

The following code examples demonstrate how to perform individual Amazon RDS actions with AWS SDKs. Each example includes a link to GitHub, where you can find instructions for setting up and running the code.

These excerpts call the Amazon RDS API and are code excerpts from larger programs that must be run in context. You can see actions in context in Scenarios for Amazon RDS using AWS SDKs .

The following examples include only the most commonly used actions. For a complete list, see the Amazon Relational Database Service API Reference.

Examples

- Use CreateDBInstance with an AWS SDK or CLI
- Use CreateDBParameterGroup with an AWS SDK or CLI
- Use CreateDBSnapshot with an AWS SDK or CLI
- Use DeleteDBInstance with an AWS SDK or CLI
- Use DeleteDBParameterGroup with an AWS SDK or CLI
- Use DescribeAccountAttributes with an AWS SDK or CLI
- Use DescribeDBEngineVersions with an AWS SDK or CLI
- Use DescribeDBInstances with an AWS SDK or CLI
- Use DescribeDBParameterGroups with an AWS SDK or CLI
- Use DescribeDBParameters with an AWS SDK or CLI
- Use DescribeDBSnapshots with an AWS SDK or CLI
- Use DescribeOrderableDBInstanceOptions with an AWS SDK or CLI
- Use GenerateRDSAuthToken with an AWS SDK or CLI
- Use ModifyDBInstance with an AWS SDK or CLI
- Use ModifyDBParameterGroup with an AWS SDK or CLI
- Use RebootDBInstance with an AWS SDK or CLI

Use `CreateDBInstance` with an AWS SDK or CLI

The following code examples show how to use `CreateDBInstance`.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code example:

```
    Aws::Client::ClientConfiguration clientConfig;
    // Optional: Set to the AWS Region (overrides config file).
    // clientConfig.region = "us-east-1";

Aws::RDS::RDSClient client(clientConfig);

    Aws::RDS::Model::CreateDBInstanceRequest request;
    request.SetDBName(DB_NAME);
    request.SetDBInstanceIdentifier(DB_INSTANCE_IDENTIFIER);
    request.SetDBParameterGroupName(PARAMETER_GROUP_NAME);
```

```
        request.SetEngine(engineVersion.GetEngine());
        request.SetEngineVersion(engineVersion.GetEngineVersion());
        request.SetDBInstanceClass(dbInstanceClass);
        request.SetStorageType(DB_STORAGE_TYPE);
        request.SetAllocatedStorage(DB_ALLOCATED_STORAGE);
        request.SetMasterUsername(administratorName);
        request.SetMasterUserPassword(administratorPassword);

        Aws::RDS::Model::CreateDBInstanceOutcome outcome =
                client.CreateDBInstance(request);

        if (outcome.IsSuccess()) {
            std::cout << "The DB instance creation has started."
                      << std::endl;
        }
        else {
            std::cerr << "Error with RDS::CreateDBInstance. "
                      << outcome.GetError().GetMessage()
                      << std::endl;
            cleanUpResources(PARAMETER_GROUP_NAME, "", client);
            return false;
        }
```

- For API details, see CreateDBInstance in *AWS SDK for C++ API Reference*.

CLI

AWS CLI

To create a DB instance

The following `create-db-instance` example uses the required options to launch a new DB instance.

```
aws rds create-db-instance \
    --db-instance-identifier test-mysql-instance \
    --db-instance-class db.t3.micro \
    --engine mysql \
    --master-username admin \
    --master-user-password secret99 \
    --allocated-storage 20
```

Output:

```
{
    "DBInstance": {
        "DBInstanceIdentifier": "test-mysql-instance",
        "DBInstanceClass": "db.t3.micro",
        "Engine": "mysql",

CLI

AWS CLI

To create a DB parameter group

The following `create-db-parameter-group` example creates a DB parameter group.

```
aws rds create-db-parameter-group \
    --db-parameter-group-name mydbparametergroup \
    --db-parameter-group-family MySQL5.6 \
    --description "My new parameter group"
```

Output:

```
{
    "DBParameterGroup": {
        "DBParameterGroupName": "mydbparametergroup",
        "DBParameterGroupFamily": "mysql5.6",
        "Description": "My new parameter group",
        "DBParameterGroupArn": "arn:aws:rds:us-
east-1:123456789012:pg:mydbparametergroup"
    }
```

```
}
```

For more information, see Creating a DB Parameter Group in the *Amazon RDS User Guide*.

- For API details, see CreateDBParameterGroup in *AWS CLI Command Reference*.

CLI

AWS CLI

To delete a DB instance

The following `delete-db-instance` example deletes the specified DB instance after creating a final DB snapshot named `test-instance-final-snap`.

```
aws rds delete-db-instance \
    --db-instance-identifier test-instance \
    --final-db-snapshot-identifier test-instance-final-snap
```

Output:

```
{
    "DBInstance": {
        "DBInstanceIdentifier": "test-instance",
        "DBInstanceStatus": "deleting",
        ...some output truncated...
    }
}
```

- For API details, see DeleteDBInstance in *AWS CLI Command Reference*.

> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
    /// <summary>
```

```
    /// Delete a DB parameter group. The group cannot be a default DB parameter
group
    /// or be associated with any DB instances.
    /// </summary>
    /// <param name="name">Name of the DB parameter group.</param>
    /// <returns>True if successful.</returns>
    public async Task<bool> DeleteDBParameterGroup(string name)
    {
        var response = await _amazonRDS.DeleteDBParameterGroupAsync(
            new DeleteDBParameterGroupRequest()
            {
                DBParameterGroupName = name,
            });
        return response.HttpStatusCode == HttpStatusCode.OK;
    }
```

- For API details, see DeleteDBParameterGroup in *AWS SDK for .NET API Reference*.

C++

SDK for C++

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
        Aws::Client::ClientConfiguration clientConfig;
        // Optional: Set to the AWS Region (overrides config file).
        // clientConfig.region = "us-east-1";

    Aws::RDS::RDSClient client(clientConfig);

        Aws::RDS::Model::DeleteDBParameterGroupRequest request;
        request.SetDBParameterGroupName(parameterGroupName);

        Aws::RDS::Model::DeleteDBParameterGroupOutcome outcome =
                client.DeleteDBParameterGroup(request);
```

```
        if (outcome.IsSuccess()) {
            std::cout << "The DB parameter group was successfully deleted."
                      << std::endl;
        }
        else {
            std::cerr << "Error with RDS::DeleteDBParameterGroup. "
                      << outcome.GetError().GetMessage()
                      << std::endl;
            result = false;
        }
```

- For API details, see DeleteDBParameterGroup in *AWS SDK for C++ API Reference*.

CLI

AWS CLI

To delete a DB parameter group

The following command example deletes a DB parameter group.

```
aws rds delete-db-parameter-group \
    --db-parameter-group-name mydbparametergroup
```

This command produces no output.

For more information, see Working with DB Parameter Groups in the *Amazon RDS User Guide*.

- For API details, see DeleteDBParameterGroup in *AWS CLI Command Reference*.

CLI

AWS CLI

To describe the DB engine versions for the MySQL DB engine

The following `describe-db-engine-versions` example displays details about each of the DB engine versions for the specified DB engine.

```
aws rds describe-db-engine-versions \
```

```
    --engine mysql
```

Output:

```
{
    "DBEngineVersions": [
        {
            "Engine": "mysql",
            "EngineVersion": "5.5.46",
            "DBParameterGroupFamily": "mysql5.5",
            "DBEngineDescription": "MySQL Community Edition",
            "DBEngineVersionDescription": "MySQL 5.5.46",
            "ValidUpgradeTarget": [
                {
                    "Engine": "mysql",
                    "EngineVersion": "5.5.53",
                    "Description": "MySQL 5.5.53",
                    "AutoUpgrade": false,
                    "IsMajorVersionUpgrade": false
                },
                {
                    "Engine": "mysql",
                    "EngineVersion": "5.5.54",
                    "Description": "MySQL 5.5.54",
                    "AutoUpgrade": false,
                    "IsMajorVersionUpgrade": false
                },
                {

CLI

AWS CLI

Example 1: To describe a DB snapshot for a DB instance

The following `describe-db-snapshots` example retrieves the details of a DB snapshot for a DB instance.

```
aws rds describe-db-snapshots \
    --db-snapshot-identifier mydbsnapshot
```

Output:

```
{
    "DBSnapshots": [
        {
            "DBSnapshotIdentifier": "mydbsnapshot",
            "DBInstanceIdentifier": "mysqldb",
            "SnapshotCreateTime": "2018-02-08T22:28:08.598Z",
            "Engine": "mysql",
            "AllocatedStorage": 20,
            "Status": "available",
            "Port": 3306,
            "AvailabilityZone": "us-east-1f",
            "VpcId": "vpc-6594f31c",
            "InstanceCreateTime": "2018-02-08T22:24:55.973Z",
            "MasterUsername": "mysqladmin",
            "EngineVersion": "5.6.37",
            "LicenseModel": "general-public-license",
            "SnapshotType": "manual",
            "OptionGroupName": "default:mysql-5-6",
            "PercentProgress": 100,
            "StorageType": "gp2",
```

```
            "Encrypted": false,
            "DBSnapshotArn": "arn:aws:rds:us-
east-1:123456789012:snapshot:mydbsnapshot",
            "IAMDatabaseAuthenticationEnabled": false,
            "ProcessorFeatures": [],
            "DbiResourceId": "db-AKIAIOSFODNN7EXAMPLE"
        }
    ]
}
```

For more information, see Creating a DB Snapshot in the *Amazon RDS User Guide*.

Example 2: To find the number of manual snapshots taken

The following `describe-db-snapshots` example uses the `length` operator in the `--query` option to return the number of manual snapshots that have been taken in a particular AWS Region.

```
aws rds describe-db-snapshots \
    --snapshot-type manual \
    --query "length(*[].{DBSnapshots:SnapshotType})" \
    --region eu-central-1
```

Output:

```
35
```

For more information, see Creating a DB Snapshot in the *Amazon RDS User Guide*.

- For API details, see DescribeDBSnapshots in *AWS CLI Command Reference*.

Use `GenerateRDSAuthToken` with an AWS SDK or CLI

The following code example shows how to use `GenerateRDSAuthToken`.

Java

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

Use the RdsUtilities class to generate an authentication token.

```
public class GenerateRDSAuthToken {
    public static void main(String[] args) {
        final String usage = """

                Usage:
                    <dbInstanceIdentifier> <masterUsername>

                Where:
                    dbInstanceIdentifier - The database instance identifier.\s
                    masterUsername - The master user name.\s
                """;
```

```
        if (args.length != 2) {
            System.out.println(usage);
            System.exit(1);
        }

        String dbInstanceIdentifier = args[0];
        String masterUsername = args[1];
        Region region = Region.US_WEST_2;
        RdsClient rdsClient = RdsClient.builder()
                .region(region)
                .build();

        String token = getAuthToken(rdsClient, dbInstanceIdentifier,
 masterUsername);
        System.out.println("The token response is " + token);
    }

    public static String getAuthToken(RdsClient rdsClient, String
 dbInstanceIdentifier, String masterUsername) {

        RdsUtilities utilities = rdsClient.utilities();
        try {
            GenerateAuthenticationTokenRequest tokenRequest =
 GenerateAuthenticationTokenRequest.builder()
                    .credentialsProvider(ProfileCredentialsProvider.create())
                    .username(masterUsername)
                    .port(3306)
                    .hostname(dbInstanceIdentifier)
                    .build();

            return utilities.generateAuthenticationToken(tokenRequest);

        } catch (RdsException e) {
            System.out.println(e.getLocalizedMessage());
            System.exit(1);
        }
        return "";
    }
}
```

- For API details, see GenerateRDSAuthToken in *AWS SDK for Java 2.x API Reference*.

Use `ModifyDBInstance` with an AWS SDK or CLI

The following code examples show how to use `ModifyDBInstance`.

CLI

AWS CLI

Example 1: To modify a DB instance

The following `modify-db-instance` example associates an option group and a parameter group with a compatible Microsoft SQL Server DB instance. The `--apply-immediately` parameter causes the option and parameter groups to be associated immediately, instead of waiting until the next maintenance window.

```
aws rds modify-db-instance \
    --db-instance-identifier database-2 \
    --option-group-name test-se-2017 \
    --db-parameter-group-name test-sqlserver-se-2017 \
    --apply-immediately
```

Output:

```
{
    "DBInstance": {
        "DBInstanceIdentifier": "database-2",
        "DBInstanceClass": "db.r4.large",
        "Engine": "sqlserver-se",
        "DBInstanceStatus": "available",

        ...output omitted...

        "DBParameterGroups": [
            {
                "DBParameterGroupName": "test-sqlserver-se-2017",
                "ParameterApplyStatus": "applying"
            }
```

```
        ],
        "AvailabilityZone": "us-west-2d",

        ...output omitted...

        "MultiAZ": true,
        "EngineVersion": "14.00.3281.6.v1",
        "AutoMinorVersionUpgrade": false,
        "ReadReplicaDBInstanceIdentifiers": [],
        "LicenseModel": "license-included",
        "OptionGroupMemberships": [
            {
                "OptionGroupName": "test-se-2017",
                "Status": "pending-apply"
            }
        ],
        "CharacterSetName": "SQL_Latin1_General_CP1_CI_AS",
        "SecondaryAvailabilityZone": "us-west-2c",
        "PubliclyAccessible": true,
        "StorageType": "gp2",

        ...output omitted...

        "DeletionProtection": false,
        "AssociatedRoles": [],
        "MaxAllocatedStorage": 1000
    }
}
```

For more information, see Modifying an Amazon RDS DB Instance in the *Amazon RDS User Guide*.

Example 2: To associate VPC security group with a DB instance

The following `modify-db-instance` example associates a specific VPC security group and removes DB security groups from a DB instance:

```
aws rds modify-db-instance \
    --db-instance-identifier dbName \
    --vpc-security-group-ids sg-ID
```

Output:

```
{
"DBInstance": {
    "DBInstanceIdentifier": "dbName",
    "DBInstanceClass": "db.t3.micro",
    "Engine": "mysql",
    "DBInstanceStatus": "available",
    "MasterUsername": "admin",
    "Endpoint": {
        "Address": "dbName.abcdefghijk.us-west-2.rds.amazonaws.com",
        "Port": 3306,
        "HostedZoneId": "ABCDEFGHIJK1234"
    },
    "AllocatedStorage": 20,
    "InstanceCreateTime": "2024-02-15T00:37:58.793000+00:00",
    "PreferredBackupWindow": "11:57-12:27",
    "BackupRetentionPeriod": 7,
    "DBSecurityGroups": [],
    "VpcSecurityGroups": [
        {
            "VpcSecurityGroupId": "sg-ID",
            "Status": "active"
        }
    ],
    ... output omitted ...
    "MultiAZ": false,
    "EngineVersion": "8.0.35",
    "AutoMinorVersionUpgrade": true,
    "ReadReplicaDBInstanceIdentifiers": [],
    "LicenseModel": "general-public-license",

    ... output ommited ...
    }
}
```

For more information, see Controlling access with security groups in the *Amazon RDS User Guide*.

- For API details, see ModifyDBInstance in *AWS CLI Command Reference*.

C++

SDK for C++

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
    Aws::Client::ClientConfiguration clientConfig;
    // Optional: Set to the AWS Region (overrides config file).
    // clientConfig.region = "us-east-1";

Aws::RDS::RDSClient client(clientConfig);

    Aws::RDS::Model::ModifyDBParameterGroupRequest request;
    request.SetDBParameterGroupName(PARAMETER_GROUP_NAME);
    request.SetParameters(updateParameters);

    Aws::RDS::Model::ModifyDBParameterGroupOutcome outcome =
            client.ModifyDBParameterGroup(request);

    if (outcome.IsSuccess()) {
        std::cout << "The DB parameter group was successfully modified."
                  << std::endl;
    }
    else {
        std::cerr << "Error with RDS::ModifyDBParameterGroup. "
                  << outcome.GetError().GetMessage()
                  << std::endl;
    }
```

- For API details, see ModifyDBParameterGroup in *AWS SDK for C++ API Reference*.

CLI

AWS CLI

To modify a DB parameter group

The following `modify-db-parameter-group` example changes the value of the `clr enabled` parameter in a DB parameter group. The `--apply-immediately` parameter causes the DB parameter group to be modified immediately, instead of waiting until the next maintenance window.

```
aws rds modify-db-parameter-group \
    --db-parameter-group-name test-sqlserver-se-2017 \
    --parameters "ParameterName='clr
 enabled',ParameterValue=1,ApplyMethod=immediate"
```

Output:

```
{
    "DBParameterGroupName": "test-sqlserver-se-2017"
}
```

For more information, see Modifying Parameters in a DB Parameter Group in the *Amazon RDS User Guide*.

- For API details, see ModifyDBParameterGroup in *AWS CLI Command Reference*.

                    .dbInstanceIdentifier(dbInstanceIdentifier)
                    .build();

            RebootDbInstanceResponse instanceResponse =
 rdsClient.rebootDBInstance(rebootDbInstanceRequest);
            System.out.print("The database " +
 instanceResponse.dbInstance().dbInstanceArn() + " was rebooted");

        } catch (RdsException e) {
            System.out.println(e.getLocalizedMessage());
            System.exit(1);
        }
    }
}
```

- For API details, see RebootDBInstance in *AWS SDK for Java 2.x API Reference*.

For a complete list of AWS SDK developer guides and code examples, see Using this service with an AWS SDK. This topic also includes information about getting started and details about previous SDK versions.

Scenarios for Amazon RDS using AWS SDKs

The following code examples show you how to implement common scenarios in Amazon RDS with AWS SDKs. These scenarios show you how to accomplish specific tasks by calling multiple functions

within Amazon RDS or combined with other AWS services. Each scenario includes a link to the complete source code, where you can find instructions on how to set up and run the code.

Scenarios target an intermediate level of experience to help you understand service actions in context.

Examples

- Create an Aurora Serverless work item tracker

Create an Aurora Serverless work item tracker

The following code examples show how to create a web application that tracks work items in an Amazon Aurora Serverless database and uses Amazon Simple Email Service (Amazon SES) to send reports.

.NET

AWS SDK for .NET

Shows how to use the AWS SDK for .NET to create a web application that tracks work items in an Amazon Aurora database and emails reports by using Amazon Simple Email Service (Amazon SES). This example uses a front end built with React.js to interact with a RESTful .NET backend.

- Integrate a React web application with AWS services.
- List, add, update, and delete items in an Aurora table.
- Send an email report of filtered work items using Amazon SES.
- Deploy and manage example resources with the included AWS CloudFormation script.

For complete source code and instructions on how to set up and run, see the full example on GitHub.

Services used in this example

- Aurora
- Amazon RDS
- Amazon RDS Data Service
- Amazon SES

C++

SDK for C++

Shows how to create a web application that tracks and reports on work items stored in an Amazon Aurora Serverless database.

For complete source code and instructions on how to set up a C++ REST API that queries Amazon Aurora Serverless data and for use by a React application, see the full example on GitHub.

Services used in this example

- Aurora
- Amazon RDS
- Amazon RDS Data Service
- Amazon SES

Java

SDK for Java 2.x

Shows how to create a web application that tracks and reports on work items stored in an Amazon RDS database.

For complete source code and instructions on how to set up a Spring REST API that queries Amazon Aurora Serverless data and for use by a React application, see the full example on GitHub.

For complete source code and instructions on how to set up and run an example that uses the JDBC API, see the full example on GitHub.

Services used in this example

- Aurora
- Amazon RDS
- Amazon RDS Data Service
- Amazon SES

JavaScript

SDK for JavaScript (v3)

Shows how to use the AWS SDK for JavaScript (v3) to create a web application that tracks work items in an Amazon Aurora database and emails reports by using Amazon Simple Email Service (Amazon SES). This example uses a front end built with React.js to interact with an Express Node.js backend.

- Integrate a React.js web application with AWS services.
- List, add, and update items in an Aurora table.
- Send an email report of filtered work items by using Amazon SES.
- Deploy and manage example resources with the included AWS CloudFormation script.

For complete source code and instructions on how to set up and run, see the full example on GitHub.

Services used in this example

- Aurora
- Amazon RDS
- Amazon RDS Data Service
- Amazon SES

Kotlin

SDK for Kotlin

Shows how to create a web application that tracks and reports on work items stored in an Amazon RDS database.

For complete source code and instructions on how to set up a Spring REST API that queries Amazon Aurora Serverless data and for use by a React application, see the full example on GitHub.

Services used in this example

- Aurora
- Amazon RDS
- Amazon RDS Data Service

- Amazon SES

PHP

SDK for PHP

Shows how to use the AWS SDK for PHP to create a web application that tracks work items in an Amazon RDS database and emails reports by using Amazon Simple Email Service (Amazon SES). This example uses a front end built with React.js to interact with a RESTful PHP backend.

- Integrate a React.js web application with AWS services.
- List, add, update, and delete items in an Amazon RDS table.
- Send an email report of filtered work items using Amazon SES.
- Deploy and manage example resources with the included AWS CloudFormation script.

For complete source code and instructions on how to set up and run, see the full example on GitHub.

Services used in this example

- Aurora
- Amazon RDS
- Amazon RDS Data Service
- Amazon SES

Python

SDK for Python (Boto3)

Shows how to use the AWS SDK for Python (Boto3) to create a REST service that tracks work items in an Amazon Aurora Serverless database and emails reports by using Amazon Simple Email Service (Amazon SES). This example uses the Flask web framework to handle HTTP routing and integrates with a React webpage to present a fully functional web application.

- Build a Flask REST service that integrates with AWS services.
- Read, write, and update work items that are stored in an Aurora Serverless database.
- Create an AWS Secrets Manager secret that contains database credentials and use it to authenticate calls to the database.

- Use Amazon SES to send email reports of work items.

For complete source code and instructions on how to set up and run, see the full example on GitHub.

Services used in this example

- Aurora
- Amazon RDS
- Amazon RDS Data Service
- Amazon SES

For a complete list of AWS SDK developer guides and code examples, see Using this service with an AWS SDK. This topic also includes information about getting started and details about previous SDK versions.

Serverless examples for Amazon RDS using AWS SDKs

The following code examples show how to use Amazon RDS with AWS SDKs.

Examples

- Connecting to an Amazon RDS database in a Lambda function

Connecting to an Amazon RDS database in a Lambda function

The following code examples show how to implement a Lambda function that connects to an RDS database. The function makes a simple database request and returns the result.

Go

SDK for Go V2

Connecting to an Amazon RDS database in a Lambda function using Go.

```
/*
Golang v2 code here.
*/

package main

import (
 "context"
 "database/sql"
 "encoding/json"
 "fmt"
 "os"

 "github.com/aws/aws-lambda-go/lambda"
 "github.com/aws/aws-sdk-go-v2/config"
 "github.com/aws/aws-sdk-go-v2/feature/rds/auth"
 _ "github.com/go-sql-driver/mysql"
)

type MyEvent struct {
 Name string `json:"name"`
}

func HandleRequest(event *MyEvent) (map[string]interface{}, error) {

 var dbName string = os.Getenv("DatabaseName")
 var dbUser string = os.Getenv("DatabaseUser")
 var dbHost string = os.Getenv("DBHost") // Add hostname without https
 var dbPort int = os.Getenv("Port")      // Add port number
 var dbEndpoint string = fmt.Sprintf("%s:%d", dbHost, dbPort)
 var region string = os.Getenv("AWS_REGION")

 cfg, err := config.LoadDefaultConfig(context.TODO())
 if err != nil {
  panic("configuration error: " + err.Error())
 }

 authenticationToken, err := auth.BuildAuthToken(
  context.TODO(), dbEndpoint, region, dbUser, cfg.Credentials)
 if err != nil {
  panic("failed to create authentication token: " + err.Error())
 }
```

```
 dsn := fmt.Sprintf("%s:%s@tcp(%s)/%s?tls=true&allowCleartextPasswords=true",
  dbUser, authenticationToken, dbEndpoint, dbName,
 )

 db, err := sql.Open("mysql", dsn)
 if err != nil {
  panic(err)
 }

 defer db.Close()

 var sum int
 err = db.QueryRow("SELECT ?+? AS sum", 3, 2).Scan(&sum)
 if err != nil {
  panic(err)
 }
 s := fmt.Sprint(sum)
 message := fmt.Sprintf("The selected sum is: %s", s)

 messageBytes, err := json.Marshal(message)
 if err != nil {
  return nil, err
 }

 messageString := string(messageBytes)
 return map[string]interface{}{
  "statusCode": 200,
  "headers":    map[string]string{"Content-Type": "application/json"},
  "body":       messageString,
 }, nil
}

func main() {
 lambda.Start(HandleRequest)
}
```

        .time(SystemTime::now())
        .settings(signing_settings)
        .build()?;

    let url = format!(
        "https://{db_hostname}:{port}/?Action=connect&DBUser={db_user}",
        db_hostname = db_hostname,
        port = port,
        db_user = db_username
    );

    let signable_request =
        SignableRequest::new("GET", &url, std::iter::empty(),
 SignableBody::Bytes(&[]))
            .expect("signable request");

    let (signing_instructions, _signature) =
        sign(signable_request, &signing_params.into())?.into_parts();

    let mut url = url::Url::parse(&url).unwrap();
    for (name, value) in signing_instructions.params() {
        url.query_pairs_mut().append_pair(name, &value);
    }

    let response = url.to_string().split_off("https://".len());

    Ok(response)
}

#[tokio::main]

        .await?;

    println!("Result: {:?}", result);

    Ok(json!({
        "statusCode": 200,
        "content-type": "text/plain",
        "body": format!("The selected sum is: {result}")
    }))
}
```

For a complete list of AWS SDK developer guides and code examples, see Using this service with an AWS SDK. This topic also includes information about getting started and details about previous SDK versions.

Security in Amazon RDS

Cloud security at AWS is the highest priority. As an AWS customer, you benefit from a data center and network architecture that are built to meet the requirements of the most security-sensitive organizations.

Security is a shared responsibility between AWS and you. The shared responsibility model describes this as security *of* the cloud and security *in* the cloud:

- **Security of the cloud** – AWS is responsible for protecting the infrastructure that runs AWS services in the AWS Cloud. AWS also provides you with services that you can use securely. Third-party auditors regularly test and verify the effectiveness of our security as part of the AWS compliance programs. To learn about the compliance programs that apply to Amazon RDS, see AWS services in scope by compliance program.
- **Security in the cloud** – Your responsibility is determined by the AWS service that you use. You are also responsible for other factors including the sensitivity of your data, your organization's requirements, and applicable laws and regulations.

This documentation helps you understand how to apply the shared responsibility model when using Amazon RDS. The following topics show you how to configure Amazon RDS to meet your security and compliance objectives. You also learn how to use other AWS services that help you monitor and secure your Amazon RDS resources.

You can manage access to your Amazon RDS resources and your databases on a DB instance. The method you use to manage access depends on what type of task the user needs to perform with Amazon RDS:

- Run your DB instance in a virtual private cloud (VPC) based on the Amazon VPC service for the greatest possible network access control. For more information about creating a DB instance in a VPC, see Amazon VPC and Amazon RDS.
- Use AWS Identity and Access Management (IAM) policies to assign permissions that determine who is allowed to manage Amazon RDS resources. For example, you can use IAM to determine who is allowed to create, describe, modify, and delete DB instances, tag resources, or modify security groups.

- Use security groups to control what IP addresses or Amazon EC2 instances can connect to your databases on a DB instance. When you first create a DB instance, its firewall prevents any database access except through rules specified by an associated security group.
- Use Secure Socket Layer (SSL) or Transport Layer Security (TLS) connections with DB instances running the Db2, MySQL, MariaDB, PostgreSQL, Oracle, or Microsoft SQL Server database engines. For more information on using SSL/TLS with a DB instance, see Using SSL/TLS to encrypt a connection to a DB instance or cluster.
- Use Amazon RDS encryption to secure your DB instances and snapshots at rest. Amazon RDS encryption uses the industry standard AES-256 encryption algorithm to encrypt your data on the server that hosts your DB instance. For more information, see Encrypting Amazon RDS resources.
- Use network encryption and transparent data encryption with Oracle DB instances; for more information, see Oracle native network encryption and Oracle Transparent Data Encryption
- Use the security features of your DB engine to control who can log in to the databases on a DB instance. These features work just as if the database was on your local network.

> **Note**
>
> You have to configure security only for your use cases. You don't have to configure security access for processes that Amazon RDS manages. These include creating backups, replicating data between a primary DB instance and a read replica, and other processes.

For more information on managing access to Amazon RDS resources and your databases on a DB instance, see the following topics.

Database authentication with Amazon RDS

Amazon RDS supports several ways to authenticate database users.

Password, Kerberos, and IAM database authentication use different methods of authenticating to the database. Therefore, a specific user can log in to a database using only one authentication method.

For PostgreSQL, use only one of the following role settings for a user of a specific database:

- To use IAM database authentication, assign the `rds_iam` role to the user.
- To use Kerberos authentication, assign the `rds_ad` role to the user.
- To use password authentication, don't assign either the `rds_iam` or `rds_ad` roles to the user.

Don't assign both the `rds_iam` and `rds_ad` roles to a user of a PostgreSQL database either directly or indirectly by nested grant access. If the `rds_iam` role is added to the master user, IAM authentication takes precedence over password authentication so the master user has to log in as an IAM user.

> **Important**
>
> We strongly recommend that you do not use the master user directly in your applications. Instead, adhere to the best practice of using a database user created with the minimal privileges required for your application.

Topics

- Password authentication

- IAM database authentication
- Kerberos authentication

Password authentication

With *password authentication,* your database performs all administration of user accounts. You create users with SQL statements such as `CREATE USER`, with the appropriate clause required by the DB engine for specifying passwords. For example, in MySQL the statement is `CREATE USER` *`name`* `IDENTIFIED BY` *`password`*, while in PostgreSQL, the statement is `CREATE USER` *`name`* `WITH PASSWORD` *`password`*.

With password authentication, your database controls and authenticates user accounts. If a DB engine has strong password management features, they can enhance security. Database authentication might be easier to administer using password authentication when you have small user communities. Because clear text passwords are generated in this case, integrating with AWS Secrets Manager can enhance security.

For information about using Secrets Manager with Amazon RDS, see Creating a basic secret and Rotating secrets for supported Amazon RDS databases in the *AWS Secrets Manager User Guide*. For information about programmatically retrieving your secrets in your custom applications, see Retrieving the secret value in the *AWS Secrets Manager User Guide*.

IAM database authentication

You can authenticate to your DB instance using AWS Identity and Access Management (IAM) database authentication. With this authentication method, you don't need to use a password when you connect to a DB instance. Instead, you use an authentication token.

For more information about IAM database authentication, including information about availability for specific DB engines, see IAM database authentication for MariaDB, MySQL, and PostgreSQL.

Kerberos authentication

Amazon RDS supports external authentication of database users using Kerberos and Microsoft Active Directory. Kerberos is a network authentication protocol that uses tickets and symmetric-key cryptography to eliminate the need to transmit passwords over the network. Kerberos has been built into Active Directory and is designed to authenticate users to network resources, such as databases.

Amazon RDS support for Kerberos and Active Directory provides the benefits of single sign-on and centralized authentication of database users. You can keep your user credentials in Active Directory. Active Directory provides a centralized place for storing and managing credentials for multiple DB instances.

To use credentials from your self-managed Active Directory, you need to setup a trust relationship to the AWS Directory Service for Microsoft Active Directory that the DB instance is joined to.

RDS for PostgreSQL and RDS for MySQL support one-way and two-way forest trust relationships with forest-wide authentication or selective authentication.

In some scenarios, you can configure Kerberos authentication over an external trust relationship. This requires your self-managed Active Directory to have additional settings. This includes but is not limited to Kerberos Forest Search Order.

Microsoft SQL Server and PostgreSQL DB instances support one-way and two-way forest trust relationships. Oracle DB instances support one-way and two-way external and forest trust relationships. For more information, see When to create a trust relationship in the *AWS Directory Service Administration Guide*.

For information about Kerberos authentication with a specific DB engine, see the following:

- Working with AWS Managed Active Directory with RDS for SQL Server
- Using Kerberos authentication for MySQL
- Configuring Kerberos authentication for Amazon RDS for Oracle
- Using Kerberos authentication with Amazon RDS for PostgreSQL
- Using Kerberos authentication for Amazon RDS for Db2.

> **Note**
>
> Currently, Kerberos authentication isn't supported for MariaDB DB instances.

Password management with Amazon RDS and AWS Secrets Manager

Amazon RDS integrates with Secrets Manager to manage master user passwords for your DB instances and Multi-AZ DB clusters.

Topics

Limitations for Secrets Manager integration with Amazon RDS

Managing master user passwords with Secrets Manager isn't supported for the following features:

- Creating a read replica when the source DB or DB cluster manages credentials with Secrets Manager. This applies to all DB engines except RDS for SQL Server.
- Amazon RDS Blue/Green Deployments
- Amazon RDS Custom
- Oracle Data Guard switchover
- RDS for Oracle with CDB

Overview of managing master user passwords with AWS Secrets Manager

With AWS Secrets Manager, you can replace hard-coded credentials in your code, including database passwords, with an API call to Secrets Manager to retrieve the secret programmatically. For more information about Secrets Manager, see the AWS Secrets Manager User Guide.

When you store database secrets in Secrets Manager, your AWS account incurs charges. For information about pricing, see AWS Secrets Manager Pricing.

You can specify that RDS manages the master user password in Secrets Manager for an Amazon RDS DB instance or Multi-AZ DB cluster when you perform one of the following operations:

- Create the DB instance
- Create the Multi-AZ DB cluster
- Modify the DB instance
- Modify the Multi-AZ DB cluster
- Restore the DB instance from Amazon S3

When you specify that RDS manages the master user password in Secrets Manager, RDS generates the password and stores it in Secrets Manager. You can interact directly with the secret to retrieve the credentials for the master user. You can also specify a customer managed key to encrypt the secret, or use the KMS key that is provided by Secrets Manager.

RDS manages the settings for the secret and rotates the secret every seven days by default. You can modify some of the settings, such as the rotation schedule. If you delete a DB instance that manages a secret in Secrets Manager, the secret and its associated metadata are also deleted.

To connect to a DB instance or Multi-AZ DB cluster with the credentials in a secret, you can retrieve the secret from Secrets Manager. For more information, see Retrieve secrets from AWS Secrets Manager and Connect to a SQL database with credentials in an AWS Secrets Manager secret in the *AWS Secrets Manager User Guide*.

Benefits of managing master user passwords with Secrets Manager

Managing RDS master user passwords with Secrets Manager provides the following benefits:

- RDS automatically generates database credentials.

- RDS automatically stores and manages database credentials in AWS Secrets Manager.
- RDS rotates database credentials regularly, without requiring application changes.
- Secrets Manager secures database credentials from human access and plain text view.
- Secrets Manager allows retrieval of database credentials in secrets for database connections.
- Secrets Manager allows fine-grained control of access to database credentials in secrets using IAM.
- You can optionally separate database encryption from credentials encryption with different KMS keys.
- You can eliminate manual management and rotation of database credentials.
- You can monitor database credentials easily with AWS CloudTrail and Amazon CloudWatch.

For more information about the benefits of Secrets Manager, see the AWS Secrets Manager User Guide.

Permissions required for Secrets Manager integration

Users must have the required permissions to perform operations related to Secrets Manager integration. You can create IAM policies that grant permissions to perform specific API operations on the specified resources they need. You can then attach those policies to the IAM permission sets or roles that require those permissions. For more information, see Identity and access management for Amazon RDS.

For create, modify, or restore operations, the user who specifies that Amazon RDS manages the master user password in Secrets Manager must have permissions to perform the following operations:

- `kms:DescribeKey`
- `secretsmanager:CreateSecret`
- `secretsmanager:TagResource`

For create, modify, or restore operations, the user who specifies the customer managed key to encrypt the secret in Secrets Manager must have permissions to perform the following operations:

- `kms:Decrypt`
- `kms:GenerateDataKey`

- `kms:CreateGrant`

For modify operations, the user who rotates the master user password in Secrets Manager must have permissions to perform the following operation:

- `secretsmanager:RotateSecret`

Enforcing RDS management of the master user password in AWS Secrets Manager

You can use IAM condition keys to enforce RDS management of the master user password in AWS Secrets Manager. The following policy doesn't allow users to create or restore DB instances or DB clusters unless the master user password is managed by RDS in Secrets Manager.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Deny",
            "Action": ["rds:CreateDBInstance", "rds:CreateDBCluster",
 "rds:RestoreDBInstanceFromS3", "rds:RestoreDBClusterFromS3"],
            "Resource": "*",
            "Condition": {
                "Bool": {
                    "rds:ManageMasterUserPassword": false
                }
            }
        }
    ]
}
```

Note

This policy enforces password management in AWS Secrets Manager at creation. However, you can still disable Secrets Manager integration and manually set a master password by modifying the instance.

To prevent this, include `rds:ModifyDBInstance`, `rds:ModifyDBCluster` in the action block of the policy. Be aware, this prevents the user from applying any further modifications to existing instances that don't have Secrets Manager integration enabled.

For more information about using condition keys in IAM policies, see Policy condition keys for Amazon RDS and Example policies: Using condition keys.

Managing the master user password for a DB instance with Secrets Manager

You can configure RDS management of the master user password in Secrets Manager when you perform the following actions:

- Creating an Amazon RDS DB instance
- Modifying an Amazon RDS DB instance
- Restoring a backup into a MySQL DB instance

You can use the RDS console, the AWS CLI, or the RDS API to perform these actions.

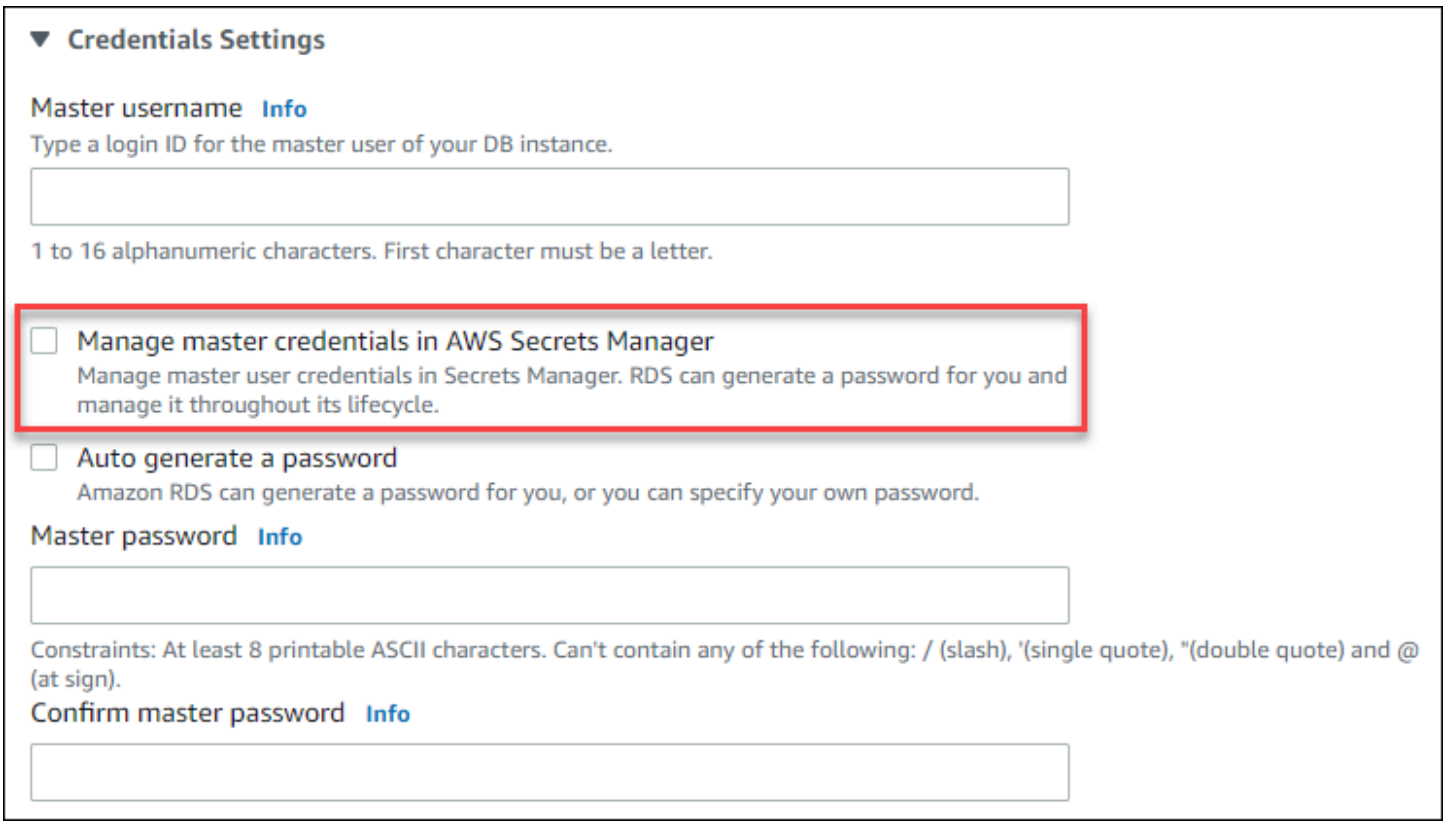
Console

Follow the instructions for creating or modifying a DB instance with the RDS console:

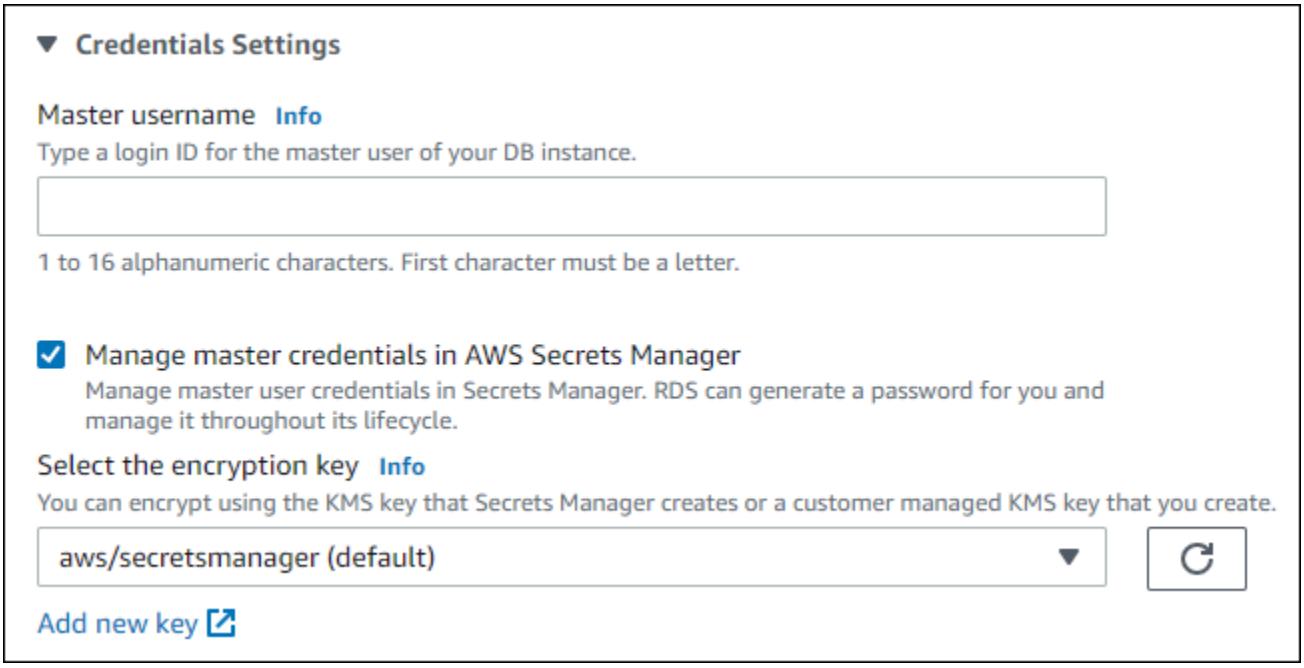
- Creating a DB instance
- Modifying an Amazon RDS DB instance
- Importing data from Amazon S3 to a new MySQL DB instance

When you use the RDS console to perform one of these operations, you can specify that the master user password is managed by RDS in Secrets Manager. To do so when you are creating or restoring a DB instance, select **Manage master credentials in AWS Secrets Manager** in **Credential settings**. When you are modifying a DB instance, select **Manage master credentials in AWS Secrets Manager** in **Settings**.

The following image is an example of the **Manage master credentials in AWS Secrets Manager** setting when you are creating or restoring a DB instance.



When you select this option, RDS generates the master user password and manages it throughout its lifecycle in Secrets Manager.



You can choose to encrypt the secret with a KMS key that Secrets Manager provides or with a customer managed key that you create. After RDS is managing the database credentials for a DB instance, you can't change the KMS key that is used to encrypt the secret.

You can choose other settings to meet your requirements. For more information about the available settings when you are creating a DB instance, see Settings for DB instances. For more information about the available settings when you are modifying a DB instance, see Settings for DB instances.

AWS CLI

To manage the master user password with RDS in Secrets Manager, specify the `--manage-master-user-password` option in one of the following AWS CLI commands:

- create-db-instance
- modify-db-instance
- restore-db-instance-from-s3

When you specify the `--manage-master-user-password` option in these commands, RDS generates the master user password and manages it throughout its lifecycle in Secrets Manager.

To encrypt the secret, you can specify a customer managed key or use the default KMS key that is provided by Secrets Manager. Use the `--master-user-secret-kms-key-id` option to specify a customer managed key. The AWS KMS key identifier is the key ARN, key ID, alias ARN, or alias name for the KMS key. To use a KMS key in a different AWS account, specify the key ARN or alias ARN. After RDS is managing the database credentials for a DB instance, you can't change the KMS key that is used to encrypt the secret.

You can choose other settings to meet your requirements. For more information about the available settings when you are creating a DB instance, see Settings for DB instances. For more information about the available settings when you are modifying a DB instance, see Settings for DB instances.

This example creates a DB instance and specifies that RDS manages the master user password in Secrets Manager. The secret is encrypted using the KMS key that is provided by Secrets Manager.

Example

For Linux, macOS, or Unix:

```
aws rds create-db-instance \
    --db-instance-identifier mydbinstance \
    --engine mysql \
    --engine-version 8.0.30 \
    --db-instance-class db.r5b.large \
    --allocated-storage 200 \
    --manage-master-user-password
```

For Windows:

```
aws rds create-db-instance ^
    --db-instance-identifier mydbinstance ^
    --engine mysql ^
    --engine-version 8.0.30 ^
    --db-instance-class db.r5b.large ^
    --allocated-storage 200 ^
    --manage-master-user-password
```

RDS API

To specify that RDS manages the master user password in Secrets Manager, set the `ManageMasterUserPassword` parameter to `true` in one of the following RDS API operations:

- CreateDBInstance
- ModifyDBInstance
- RestoreDBInstanceFromS3

When you set the `ManageMasterUserPassword` parameter to `true` in one of these operations, RDS generates the master user password and manages it throughout its lifecycle in Secrets Manager.

To encrypt the secret, you can specify a customer managed key or use the default KMS key that is provided by Secrets Manager. Use the `MasterUserSecretKmsKeyId` parameter to specify a customer managed key. The AWS KMS key identifier is the key ARN, key ID, alias ARN, or alias name for the KMS key. To use a KMS key in a different AWS account, specify the key ARN or alias ARN. After RDS is managing the database credentials for a DB instance, you can't change the KMS key that is used to encrypt the secret.

Managing the master user password for a Multi-AZ DB cluster with Secrets Manager

You can configure RDS management of the master user password in Secrets Manager when you perform the following actions:

- Creating a Multi-AZ DB cluster
- Modifying a Multi-AZ DB cluster

You can use the RDS console, the AWS CLI, or the RDS API to perform these actions.

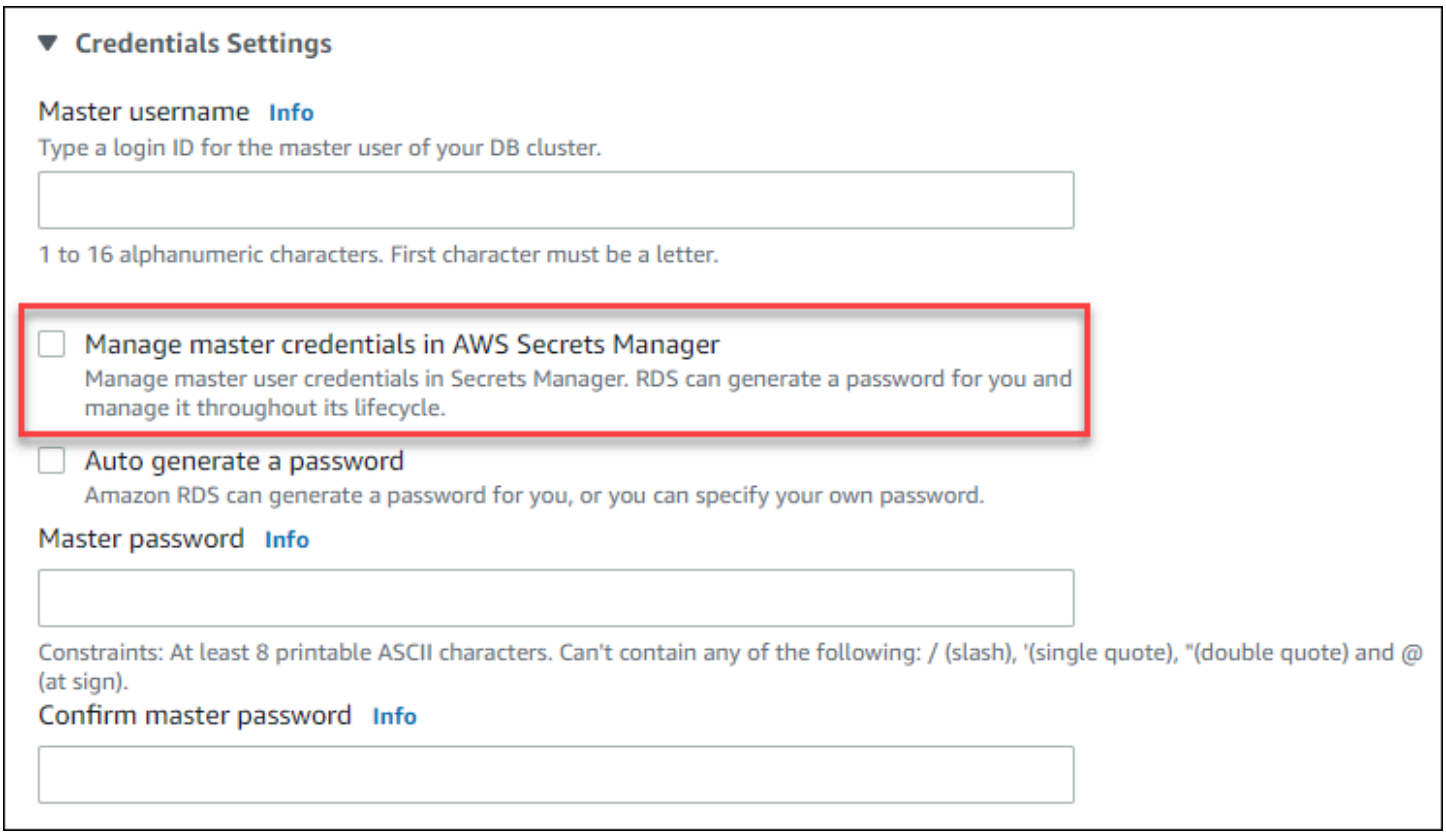
Console

Follow the instructions for creating or modifying a Multi-AZ DB cluster with the RDS console:

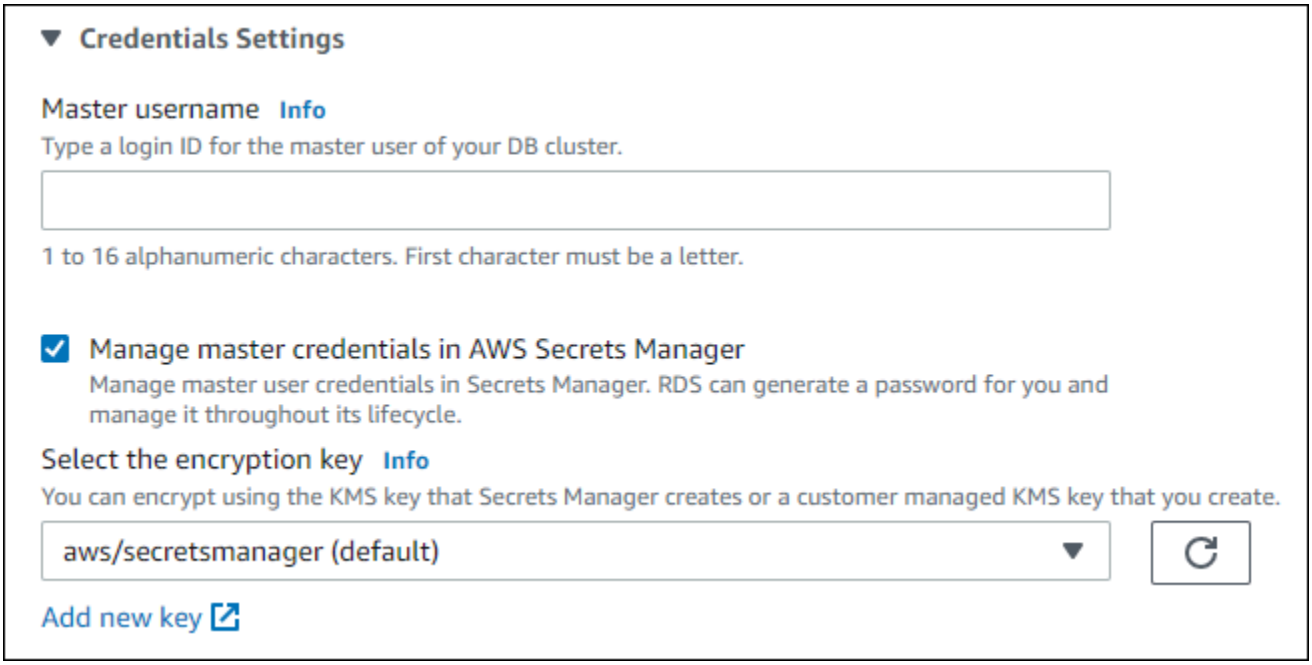
- Creating a DB cluster
- Modifying a Multi-AZ DB cluster

When you use the RDS console to perform one of these operations, you can specify that the master user password is managed by RDS in Secrets Manager. To do so when you are creating a DB cluster, select **Manage master credentials in AWS Secrets Manager** in **Credential settings**. When you are modifying a DB cluster, select **Manage master credentials in AWS Secrets Manager** in **Settings**.

The following image is an example of the **Manage master credentials in AWS Secrets Manager** setting when you are creating a DB cluster.



When you select this option, RDS generates the master user password and manages it throughout its lifecycle in Secrets Manager.



You can choose to encrypt the secret with a KMS key that Secrets Manager provides or with a customer managed key that you create. After RDS is managing the database credentials for a DB cluster, you can't change the KMS key that is used to encrypt the secret.

You can choose other settings to meet your requirements.

For more information about the available settings when you are creating a Multi-AZ DB cluster, see Settings for creating Multi-AZ DB clusters. For more information about the available settings when you are modifying a Multi-AZ DB cluster, see Settings for modifying Multi-AZ DB clusters.

AWS CLI

To specify that RDS manages the master user password in Secrets Manager, specify the `--manage-master-user-password` option in one of the following commands:

- create-db-cluster
- modify-db-cluster

When you specify the `--manage-master-user-password` option in these commands, RDS generates the master user password and manages it throughout its lifecycle in Secrets Manager.

To encrypt the secret, you can specify a customer managed key or use the default KMS key that is provided by Secrets Manager. Use the `--master-user-secret-kms-key-id` option to specify a customer managed key. The AWS KMS key identifier is the key ARN, key ID, alias ARN, or alias name for the KMS key. To use a KMS key in a different AWS account, specify the key ARN or alias ARN. After RDS is managing the database credentials for a DB cluster, you can't change the KMS key that is used to encrypt the secret.

You can choose other settings to meet your requirements.

For more information about the available settings when you are creating a Multi-AZ DB cluster, see Settings for creating Multi-AZ DB clusters. For more information about the available settings when you are modifying a Multi-AZ DB cluster, see Settings for modifying Multi-AZ DB clusters.

This example creates a Multi-AZ DB cluster and specifies that RDS manages the password in Secrets Manager. The secret is encrypted using the KMS key that is provided by Secrets Manager.

Example

For Linux, macOS, or Unix:

```
aws rds create-db-cluster \
   --db-cluster-identifier mysql-multi-az-db-cluster \
   --engine mysql \
   --engine-version 8.0.28  \
   --backup-retention-period 1  \
   --allocated-storage 4000 \
   --storage-type io1 \
   --iops 10000 \
   --db-cluster-instance-class db.r6gd.xlarge \
   --manage-master-user-password
```

For Windows:

```
aws rds create-db-cluster ^
   --db-cluster-identifier mysql-multi-az-db-cluster ^
   --engine mysql ^
   --engine-version 8.0.28 ^
   --backup-retention-period 1 ^
   --allocated-storage 4000 ^
   --storage-type io1 ^
   --iops 10000 ^
   --db-cluster-instance-class db.r6gd.xlarge ^
   --manage-master-user-password
```

RDS API

To specify that RDS manages the master user password in Secrets Manager, set the `ManageMasterUserPassword` parameter to `true` in one of the following operations:

- CreateDBCluster
- ModifyDBCluster

When you set the `ManageMasterUserPassword` parameter to `true` in one of these operations, RDS generates the master user password and manages it throughout its lifecycle in Secrets Manager.

To encrypt the secret, you can specify a customer managed key or use the default KMS key that is provided by Secrets Manager. Use the `MasterUserSecretKmsKeyId` parameter to specify a customer managed key. The AWS KMS key identifier is the key ARN, key ID, alias ARN, or alias name for the KMS key. To use a KMS key in a different AWS account, specify the key ARN or alias ARN.

After RDS is managing the database credentials for a DB cluster, you can't change the KMS key that is used to encrypt the secret.

Rotating the master user password secret for a DB instance

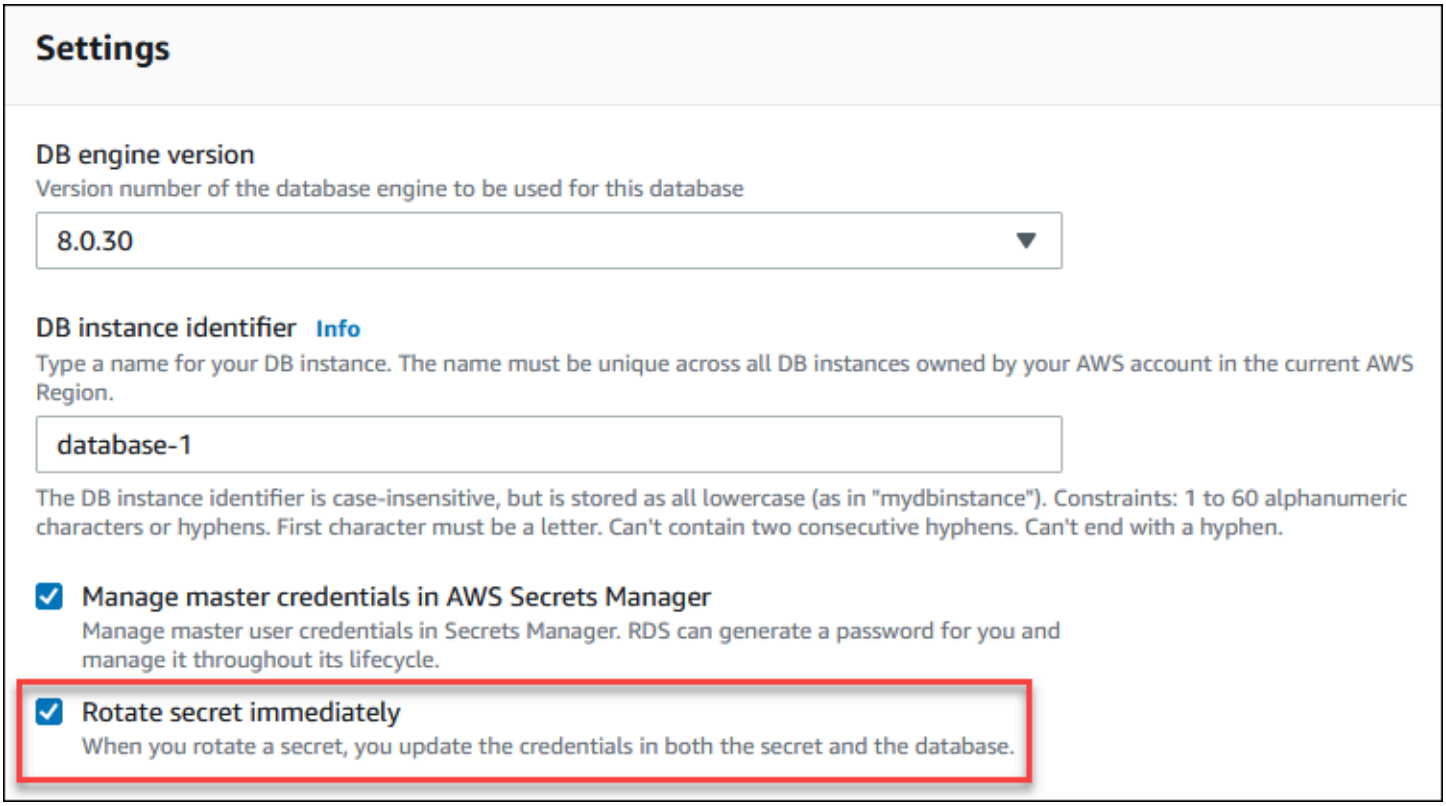
When RDS rotates a master user password secret, Secrets Manager generates a new secret version for the existing secret. The new version of the secret contains the new master user password. Amazon RDS changes the master user password for the DB instance to match the password for the new secret version.

You can rotate a secret immediately instead of waiting for a scheduled rotation. To rotate a master user password secret in Secrets Manager, modify the DB instance. For information about modifying a DB instance, see Modifying an Amazon RDS DB instance.

You can rotate a master user password secret immediately with the RDS console, the AWS CLI, or the RDS API. The new password is always 28 characters long and contains atleast one upper and lowercase character, one number, and one punctuation.

Console

To rotate a master user password secret using the RDS console, modify the DB instance and select **Rotate secret immediately** in **Settings**.



Follow the instructions for modifying a DB instance with the RDS console in Modifying an Amazon RDS DB instance. You must choose **Apply immediately** on the confirmation page.

AWS CLI

To rotate a master user password secret using the AWS CLI, use the modify-db-instance command and specify the `--rotate-master-user-password` option. You must specify the `--apply-immediately` option when you rotate the master password.

This example rotates a master user password secret.

Example

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier mydbinstance \
    --rotate-master-user-password \
    --apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier mydbinstance ^
    --rotate-master-user-password ^
    --apply-immediately
```

RDS API

You can rotate a master user password secret using the ModifyDBInstance operation and setting the `RotateMasterUserPassword` parameter to `true`. You must set the `ApplyImmediately` parameter to `true` when you rotate the master password.

Rotating the master user password secret for a Multi-AZ DB cluster

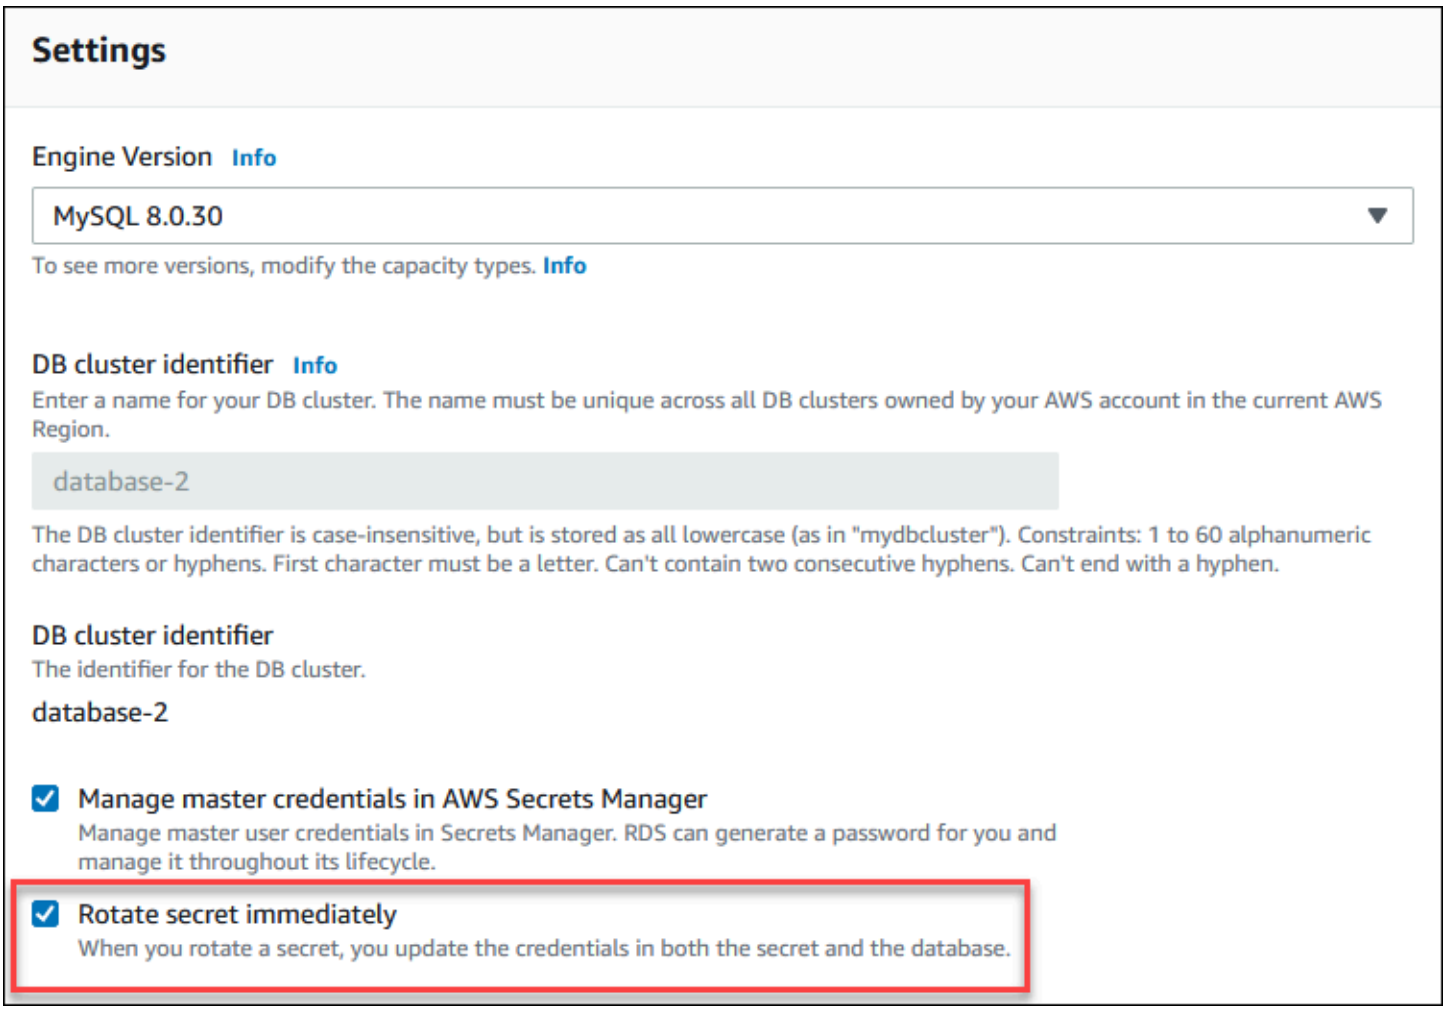
When RDS rotates a master user password secret, Secrets Manager generates a new secret version for the existing secret. The new version of the secret contains the new master user password. Amazon RDS changes the master user password for the Multi-AZ DB cluster to match the password for the new secret version.

You can rotate a secret immediately instead of waiting for a scheduled rotation. To rotate a master user password secret in Secrets Manager, modify the Multi-AZ DB cluster. For information about modifying a Multi-AZ DB cluster, see Modifying a Multi-AZ DB cluster.

You can rotate a master user password secret immediately with the RDS console, the AWS CLI, or the RDS API. The new password is always 28 characters long and contains atleast one upper and lowercase character, one number, and one punctuation.

Console

To rotate a master user password secret using the RDS console, modify the Multi-AZ DB cluster and select **Rotate secret immediately** in **Settings**.



Follow the instructions for modifying a Multi-AZ DB cluster with the RDS console in Modifying a Multi-AZ DB cluster. You must choose **Apply immediately** on the confirmation page.

AWS CLI

To rotate a master user password secret using the AWS CLI, use the modify-db-cluster command and specify the `--rotate-master-user-password` option. You must specify the `--apply-immediately` option when you rotate the master password.

This example rotates a master user password secret.

Example

For Linux, macOS, or Unix:

```
aws rds modify-db-cluster \
    --db-cluster-identifier mydbcluster \
    --rotate-master-user-password \
    --apply-immediately
```

For Windows:

```
aws rds modify-db-cluster ^
    --db-cluster-identifier mydbcluster ^
    --rotate-master-user-password ^
    --apply-immediately
```

RDS API

You can rotate a master user password secret using the ModifyDBCluster operation and setting the `RotateMasterUserPassword` parameter to `true`. You must set the `ApplyImmediately` parameter to `true` when you rotate the master password.

Viewing the details about a secret for a DB instance

You can retrieve your secrets using the console (https://console.aws.amazon.com/secretsmanager/) or the AWS CLI (get-secret-value Secrets Manager command).

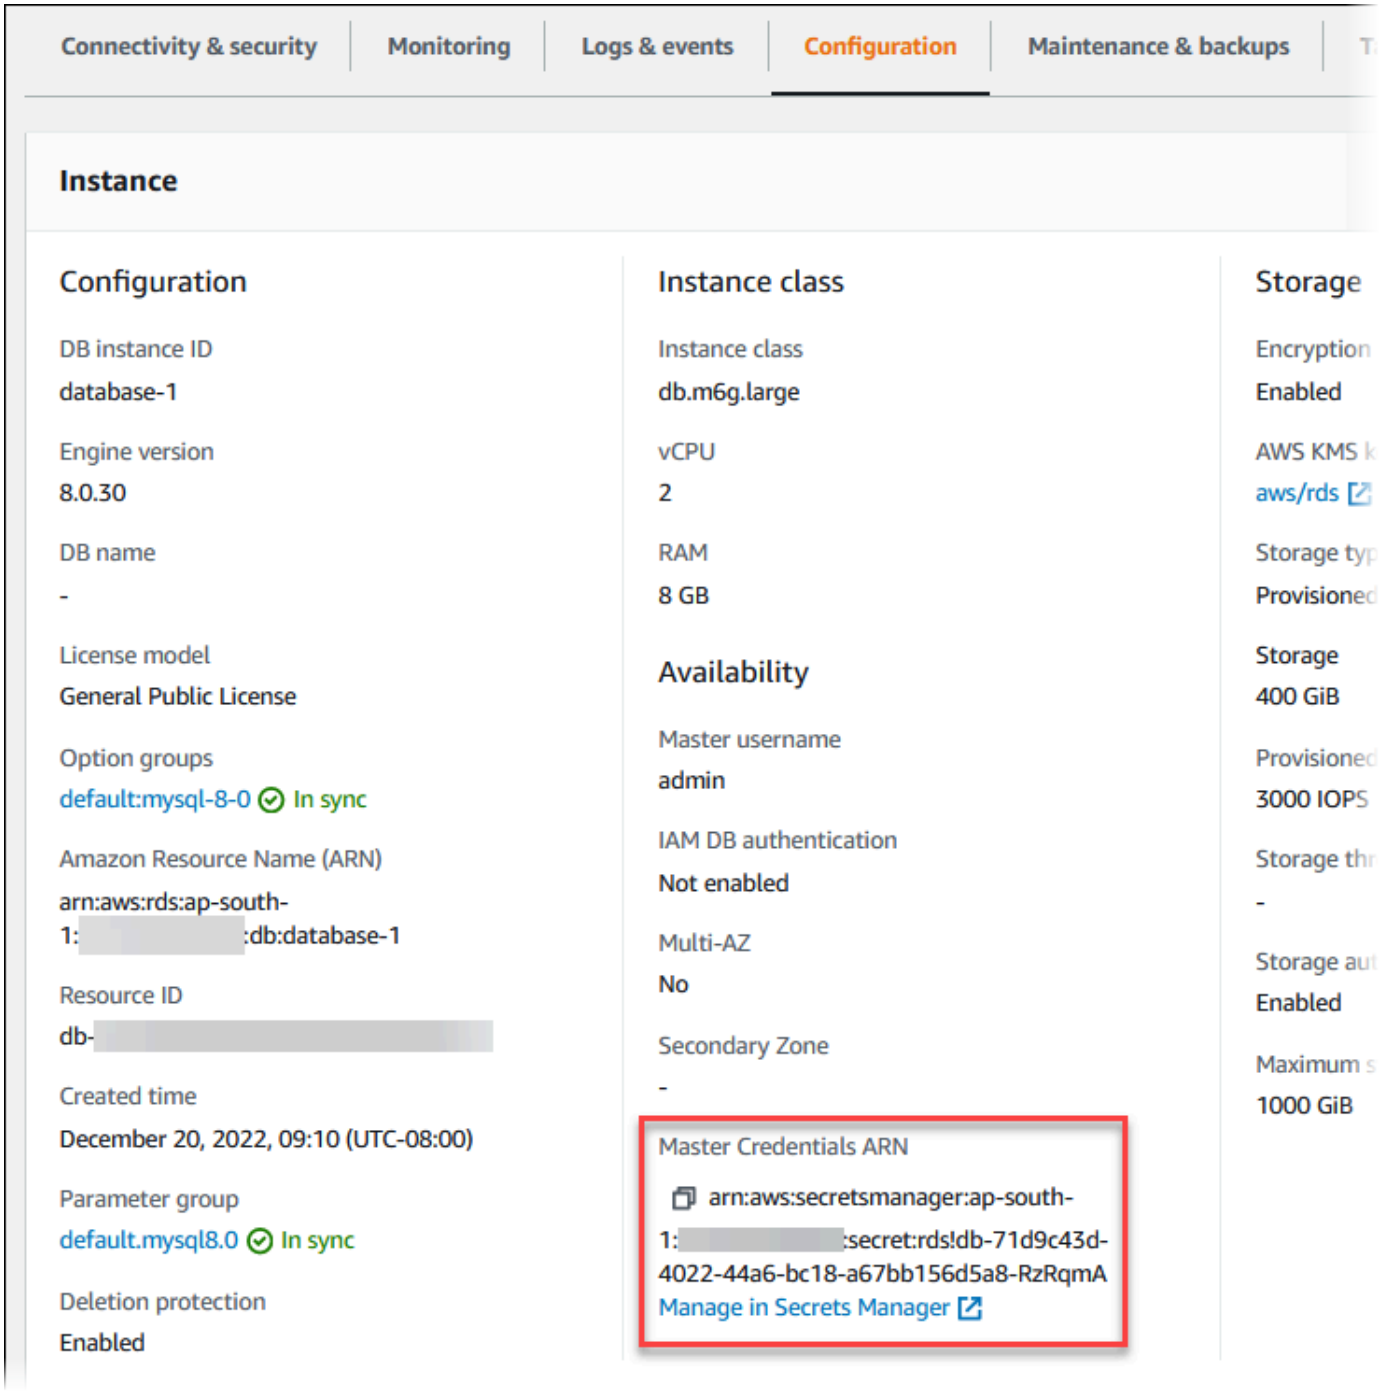
You can find the Amazon Resource Name (ARN) of a secret managed by RDS in Secrets Manager with the RDS console, the AWS CLI, or the RDS API.

Console

To view the details about a secret managed by RDS in Secrets Manager

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.
3. Choose the name of the DB instance to show its details.
4. Choose the **Configuration** tab.

   In **Master Credentials ARN**, you can view the secret ARN.



You can follow the **Manage in Secrets Manager** link to view and manage the secret in the Secrets Manager console.

AWS CLI

You can use the describe-db-instances RDS CLI command to find the following information about a secret managed by RDS in Secrets Manager:

- `SecretArn` – The ARN of the secret
- `SecretStatus` – The status of the secret

  The possible status values include the following:

  - `creating` – The secret is being created.
  - `active` – The secret is available for normal use and rotation.
  - `rotating` – The secret is being rotated.
  - `impaired` – The secret can be used to access database credentials, but it can't be rotated. A secret might have this status if, for example, permissions are changed so that RDS can no longer access the secret or the KMS key for the secret.

    When a secret has this status, you can correct the condition that caused the status. If you correct the condition that caused status, the status remains `impaired` until the next rotation. Alternatively, you can modify the DB instance to turn off automatic management of database credentials, and then modify the DB instance again to turn on automatic management of database credentials. To modify the DB instance, use the `--manage-master-user-password` option in the modify-db-instance command.
- `KmsKeyId` – The ARN of the KMS key that is used to encrypt the secret

Specify the `--db-instance-identifier` option to show output for a specific DB instance. This example shows the output for a secret that is used by a DB instance.

Example

```
aws rds describe-db-instances --db-instance-identifier mydbinstance
```

Following is sample output for a secret:

```
"MasterUserSecret": {
                "SecretArn": "arn:aws:secretsmanager:eu-west-1:123456789012:secret:rds!
db-033d7456-2c96-450d-9d48-f5de3025e51c-xmJRDx",
                "SecretStatus": "active",
                "KmsKeyId": "arn:aws:kms:eu-
west-1:123456789012:key/0987dcba-09fe-87dc-65ba-ab0987654321"
            }
```

When you have the secret ARN, you can view details about the secret using the get-secret-value Secrets Manager CLI command.

This example shows the details for the secret in the previous sample output.

Example

For Linux, macOS, or Unix:

```
aws secretsmanager get-secret-value \
    --secret-id 'arn:aws:secretsmanager:eu-west-1:123456789012:secret:rds!
db-033d7456-2c96-450d-9d48-f5de3025e51c-xmJRDx'
```

For Windows:

```
aws secretsmanager get-secret-value ^
    --secret-id 'arn:aws:secretsmanager:eu-west-1:123456789012:secret:rds!
db-033d7456-2c96-450d-9d48-f5de3025e51c-xmJRDx'
```

RDS API

You can view the ARN, status, and KMS key for a secret managed by RDS in Secrets Manager by using the DescribeDBInstances operation and setting the `DBInstanceIdentifier` parameter to a DB instance identifier. Details about the secret are included in the output.

When you have the secret ARN, you can view details about the secret using the GetSecretValue Secrets Manager operation.

Viewing the details about a secret for a Multi-AZ DB cluster

You can retrieve your secrets using the console (https://console.aws.amazon.com/secretsmanager/) or the AWS CLI (get-secret-value Secrets Manager command).

You can find the Amazon Resource Name (ARN) of a secret managed by RDS in Secrets Manager with the RDS console, the AWS CLI, or the RDS API.

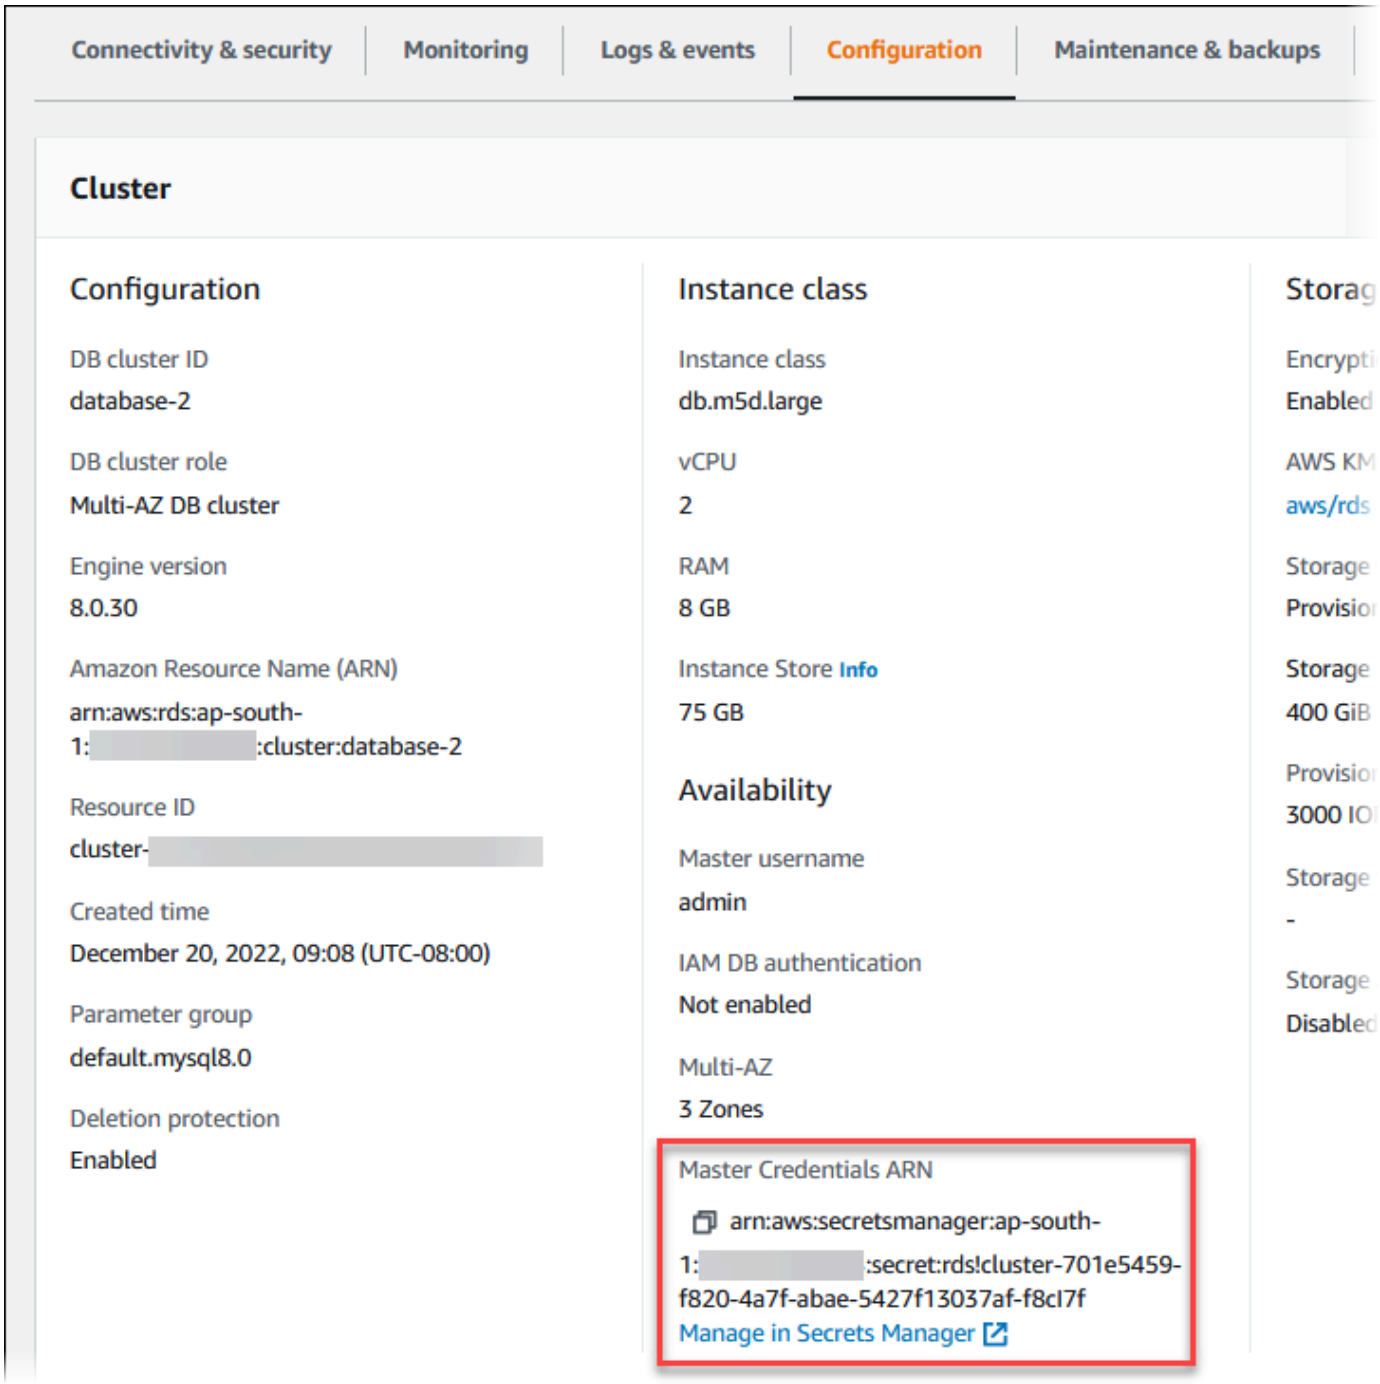
Console

To view the details about a secret managed by RDS in Secrets Manager

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.

2. In the navigation pane, choose **Databases**.
3. Choose the name of the Multi-AZ DB cluster to show its details.
4. Choose the **Configuration** tab.

   In **Master Credentials ARN**, you can view the secret ARN.



You can follow the **Manage in Secrets Manager** link to view and manage the secret in the Secrets Manager console.

AWS CLI

You can use the RDS AWS CLI describe-db-clusters command to find the following information about a secret managed by RDS in Secrets Manager:

- `SecretArn` – The ARN of the secret
- `SecretStatus` – The status of the secret

  The possible status values include the following:

  - `creating` – The secret is being created.
  - `active` – The secret is available for normal use and rotation.
  - `rotating` – The secret is being rotated.
  - `impaired` – The secret can be used to access database credentials, but it can't be rotated. A secret might have this status if, for example, permissions are changed so that RDS can no longer access the secret or the KMS key for the secret.

    When a secret has this status, you can correct the condition that caused the status. If you correct the condition that caused status, the status remains `impaired` until the next rotation. Alternatively, you can modify the DB cluster to turn off automatic management of database credentials, and then modify the DB cluster again to turn on automatic management of database credentials. To modify the DB cluster, use the `--manage-master-user-password` option in the modify-db-cluster command.
- `KmsKeyId` – The ARN of the KMS key that is used to encrypt the secret

Specify the `--db-cluster-identifier` option to show output for a specific DB cluster. This example shows the output for a secret that is used by a DB cluster.

Example

```
aws rds describe-db-clusters --db-cluster-identifier mydbcluster
```

The following sample shows the output for a secret:

```
"MasterUserSecret": {
                "SecretArn": "arn:aws:secretsmanager:eu-west-1:123456789012:secret:rds!
cluster-033d7456-2c96-450d-9d48-f5de3025e51c-xmJRDx",
                "SecretStatus": "active",
                "KmsKeyId": "arn:aws:kms:eu-
west-1:123456789012:key/0987dcba-09fe-87dc-65ba-ab0987654321"
            }
```

When you have the secret ARN, you can view details about the secret using the get-secret-value Secrets Manager CLI command.

This example shows the details for the secret in the previous sample output.

Example

For Linux, macOS, or Unix:

```
aws secretsmanager get-secret-value \
    --secret-id 'arn:aws:secretsmanager:eu-west-1:123456789012:secret:rds!
cluster-033d7456-2c96-450d-9d48-f5de3025e51c-xmJRDx'
```

For Windows:

```
aws secretsmanager get-secret-value ^
    --secret-id 'arn:aws:secretsmanager:eu-west-1:123456789012:secret:rds!
cluster-033d7456-2c96-450d-9d48-f5de3025e51c-xmJRDx'
```

RDS API

You can view the ARN, status, and KMS key for a secret managed by RDS in Secrets Manager using the DescribeDBClusters RDS operation and setting the `DBClusterIdentifier` parameter to a DB cluster identifier. Details about the secret are included in the output.

When you have the secret ARN, you can view details about the secret using the GetSecretValue Secrets Manager operation.

Region and version availability

Feature availability and support varies across specific versions of each database engine and across AWS Regions. For more information about version and Region availability with Secrets Manager

integration with Amazon RDS, see Supported Regions and DB engines for the Secrets Manager integration with Amazon RDS.

Data protection in Amazon RDS

The AWS shared responsibility model applies to data protection in Amazon Relational Database Service. As described in this model, AWS is responsible for protecting the global infrastructure that runs all of the AWS Cloud. You are responsible for maintaining control over your content that is hosted on this infrastructure. You are also responsible for the security configuration and management tasks for the AWS services that you use. For more information about data privacy, see the Data Privacy FAQ. For information about data protection in Europe, see the AWS Shared Responsibility Model and GDPR blog post on the *AWS Security Blog*.

For data protection purposes, we recommend that you protect AWS account credentials and set up individual users with AWS IAM Identity Center or AWS Identity and Access Management (IAM). That way, each user is given only the permissions necessary to fulfill their job duties. We also recommend that you secure your data in the following ways:

- Use multi-factor authentication (MFA) with each account.
- Use SSL/TLS to communicate with AWS resources. We require TLS 1.2 and recommend TLS 1.3.
- Set up API and user activity logging with AWS CloudTrail. For information about using CloudTrail trails to capture AWS activities, see Working with CloudTrail trails in the *AWS CloudTrail User Guide*.
- Use AWS encryption solutions, along with all default security controls within AWS services.
- Use advanced managed security services such as Amazon Macie, which assists in discovering and securing sensitive data that is stored in Amazon S3.
- If you require FIPS 140-3 validated cryptographic modules when accessing AWS through a command line interface or an API, use a FIPS endpoint. For more information about the available FIPS endpoints, see Federal Information Processing Standard (FIPS) 140-3.

We strongly recommend that you never put confidential or sensitive information, such as your customers' email addresses, into tags or free-form text fields such as a **Name** field. This includes when you work with Amazon RDS or other AWS services using the console, API, AWS CLI, or AWS SDKs. Any data that you enter into tags or free-form text fields used for names may be used for billing or diagnostic logs. If you provide a URL to an external server, we strongly recommend that you do not include credentials information in the URL to validate your request to that server.

Topics

Protecting data using encryption

You can enable encryption for database resources. You can also encrypt connections to DB instances.

Topics

Encrypting Amazon RDS resources

Amazon RDS can encrypt your Amazon RDS DB instances. Data that is encrypted at rest includes the underlying storage for DB instances, its automated backups, read replicas, and snapshots.

Amazon RDS encrypted DB instances use the industry standard AES-256 encryption algorithm to encrypt your data on the server that hosts your Amazon RDS DB instances. After your data is encrypted, Amazon RDS handles authentication of access and decryption of your data transparently with a minimal impact on performance. You don't need to modify your database client applications to use encryption.

> **Note**
>
> For encrypted and unencrypted DB instances, data that is in transit between the source and the read replicas is encrypted, even when replicating across AWS Regions.

Topics

- Determining whether encryption is turned on for a DB instance
- Availability of Amazon RDS encryption
- Encryption in transit
- Limitations of Amazon RDS encrypted DB instances

Overview of encrypting Amazon RDS resources

Amazon RDS encrypted DB instances provide an additional layer of data protection by securing your data from unauthorized access to the underlying storage. You can use Amazon RDS encryption to increase data protection of your applications deployed in the cloud, and to fulfill compliance requirements for encryption at rest.

For an Amazon RDS encrypted DB instance, all logs, backups, and snapshots are encrypted. Amazon RDS uses an AWS Key Management Service key to encrypt these resources. For more information about KMS keys, see AWS KMS keys in the *AWS Key Management Service Developer Guide* and AWS KMS key management. If you copy an encrypted snapshot, you can use a different KMS key to encrypt the target snapshot than the one that was used to encrypt the source snapshot.

A read replica of an Amazon RDS encrypted instance must be encrypted using the same KMS key as the primary DB instance when both are in the same AWS Region. If the primary DB instance and read replica are in different AWS Regions, you encrypt the read replica using the KMS key for that AWS Region.

You can use an AWS managed key, or you can create customer managed keys. To manage the customer managed keys used for encrypting and decrypting your Amazon RDS resources, you use the AWS Key Management Service (AWS KMS). AWS KMS combines secure, highly available hardware and software to provide a key management system scaled for the cloud. Using AWS KMS, you can create customer managed keys and define the policies that control how these customer managed keys can be used. AWS KMS supports CloudTrail, so you can audit KMS key usage to verify that customer managed keys are being used appropriately. You can use your customer managed keys with Amazon Aurora and supported AWS services such as Amazon S3, Amazon EBS, and Amazon Redshift. For a list of services that are integrated with AWS KMS, see AWS Service Integration.

Amazon RDS also supports encrypting an Oracle or SQL Server DB instance with Transparent Data Encryption (TDE). TDE can be used with RDS encryption at rest, although using TDE and RDS encryption at rest simultaneously might slightly affect the performance of your database. You

must manage different keys for each encryption method. For more information on TDE, see Oracle Transparent Data Encryption or Support for Transparent Data Encryption in SQL Server.

Encrypting a DB instance

To encrypt a new DB instance, choose **Enable encryption** on the Amazon RDS console. For information on creating a DB instance, see Creating an Amazon RDS DB instance.

If you use the create-db-instance AWS CLI command to create an encrypted DB instance, set the `--storage-encrypted` parameter. If you use the CreateDBInstance API operation, set the `StorageEncrypted` parameter to true.

When you create an encrypted DB instance, you can choose a customer managed key or the AWS managed key for Amazon RDS to encrypt your DB instance. If you don't specify the key identifier for a customer managed key, Amazon RDS uses the AWS managed key for your new DB instance. Amazon RDS creates an AWS managed key for Amazon RDS for your AWS account. Your AWS account has a different AWS managed key for Amazon RDS for each AWS Region.

For more information about KMS keys, see AWS KMS keys in the *AWS Key Management Service Developer Guide*.

Once you have created an encrypted DB instance, you can't change the KMS key used by that DB instance. Therefore, be sure to determine your KMS key requirements before you create your encrypted DB instance.

If you use the AWS CLI `create-db-instance` command to create an encrypted DB instance with a customer managed key, set the `--kms-key-id` parameter to any key identifier for the KMS key. If you use the Amazon RDS API `CreateDBInstance` operation, set the `KmsKeyId` parameter to any key identifier for the KMS key. To use a customer managed key in a different AWS account, specify the key ARN or alias ARN.

Important

Amazon RDS can lose access to the KMS key for a DB instance when you disable the KMS key. In these cases, the encrypted DB instance shortly goes into `inaccessible-encryption-credentials-recoverable` state. The DB instance remains in this state for seven days, during which the instance is stopped. API calls made to the DB instance during this time might not succeed. To recover the DB instance, enable the KMS key and restart this DB instance. Enable the KMS key from the AWS Management Console. Restart

the DB instance using the AWS CLI command start-db-instance or AWS Management Console.
If the DB instance isn't recovered within seven days, it goes into the terminal `inaccessible-encryption-credentials` state. In this state, the DB instance is not usable anymore and you can only restore the DB instance from a backup. We strongly recommend that you always turn on backups for encrypted DB instances to guard against the loss of encrypted data in your databases.
During the creation of a DB instance, Amazon RDS checks if the calling principal has access to the KMS key and generates a grant from the KMS key that it uses for the entire lifetime of the DB instance. Revoking the calling principal's access to the KMS key does not affect a running database. When using KMS keys in cross-account scenarios, such as copying a snapshot to another account, the KMS key needs to be shared with the other account. If you create a DB instance from the snapshot without specifying a different KMS key, the new instance uses the KMS key from the source account. Revoking access to the key after you create the DB instance does not affect the instance. However, disabling the key impacts all DB instances encrypted with that key. To prevent this, specify a different key during the snapshot copy operation.

Determining whether encryption is turned on for a DB instance

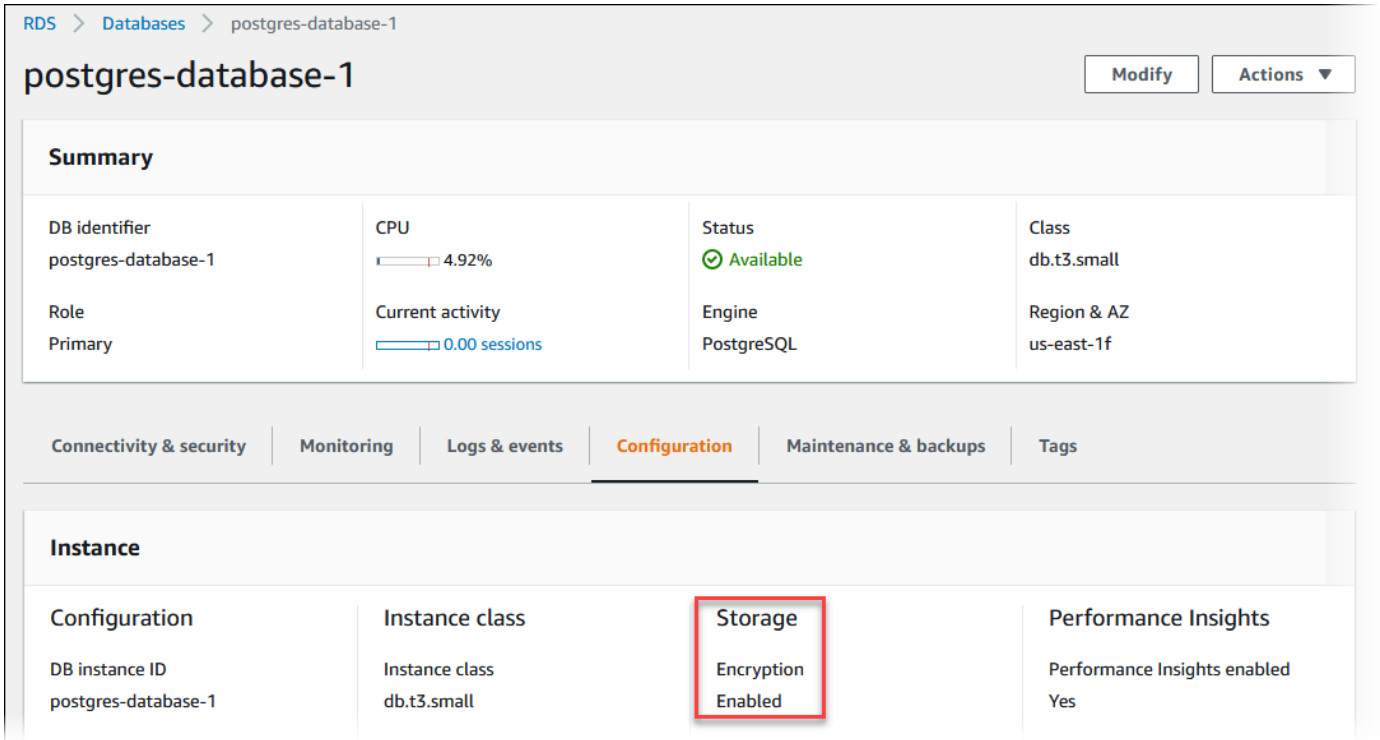
You can use the AWS Management Console, AWS CLI, or RDS API to determine whether encryption at rest is turned on for a DB instance.

Console

To determine whether encryption at rest is turned on for a DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.
3. Choose the name of the DB instance that you want to check to view its details.
4. Choose the **Configuration** tab, and check the **Encryption** value under **Storage**.

   It shows either **Enabled** or **Not enabled**.



AWS CLI

To determine whether encryption at rest is turned on for a DB instance by using the AWS CLI, call the describe-db-instances command with the following option:

- `--db-instance-identifier` – The name of the DB instance.

The following example uses a query to return either TRUE or FALSE regarding encryption at rest for the mydb DB instance.

Example

```
aws rds describe-db-instances --db-instance-identifier mydb --query "*[].
{StorageEncrypted:StorageEncrypted}" --output text
```

RDS API

To determine whether encryption at rest is turned on for a DB instance by using the Amazon RDS API, call the DescribeDBInstances operation with the following parameter:

- `DBInstanceIdentifier` – The name of the DB instance.

Availability of Amazon RDS encryption

Amazon RDS encryption is currently available for all database engines and storage types, except for SQL Server Express Edition.

Amazon RDS encryption is available for most DB instance classes. The following table lists DB instance classes that *don't support* Amazon RDS encryption:

Instance type	Instance class
General purpose (M1)	db.m1.small db.m1.medium db.m1.large db.m1.xlarge
Memory optimized (M2)	db.m2.xlarge db.m2.2xlarge db.m2.4xlarge
Burstable (T2)	db.t2.micro

Encryption in transit

AWS provides secure and private connectivity between DB instances of all types. In addition, some instance types use the offload capabilities of the underlying Nitro System hardware to automatically encrypt in-transit traffic between instances. This encryption uses Authenticated Encryption with Associated Data (AEAD) algorithms, with 256-bit encryption. There is no impact on network performance. To support this additional in-transit traffic encryption between instances, the following requirements must be met:

- The instances use the following instance types:
  - **General purpose**: M6i, M6id, M6in, M6idn, M7g
  - **Memory optimized**: R6i, R6id, R6in, R6idn, R7g, X2idn, X2iedn, X2iezn
- The instances are in the same AWS Region.

- The instances are in the same VPC or peered VPCs, and the traffic does not pass through a virtual network device or service, such as a load balancer or a transit gateway.

For more information about the underlying EC2 instances and the associated encryption, see Encryption in transit in the Amazon EC2 User Guide.

Limitations of Amazon RDS encrypted DB instances

The following limitations exist for Amazon RDS encrypted DB instances:

- You can only encrypt an Amazon RDS DB instance when you create it, not after the DB instance is created.

  However, because you can encrypt a copy of an unencrypted snapshot, you can effectively add encryption to an unencrypted DB instance. That is, you can create a snapshot of your DB instance, and then create an encrypted copy of that snapshot. You can then restore a DB instance from the encrypted snapshot, and thus you have an encrypted copy of your original DB instance. For more information, see Copying a DB snapshot.
- You can't turn off encryption on an encrypted DB instance.
- You can't create an encrypted snapshot of an unencrypted DB instance.
- A snapshot of an encrypted DB instance must be encrypted using the same KMS key as the DB instance.
- You can't have an encrypted read replica of an unencrypted DB instance or an unencrypted read replica of an encrypted DB instance.
- Encrypted read replicas must be encrypted with the same KMS key as the source DB instance when both are in the same AWS Region.
- You can't restore an unencrypted backup or snapshot to an encrypted DB instance.
- To copy an encrypted snapshot from one AWS Region to another, you must specify the KMS key in the destination AWS Region. This is because KMS keys are specific to the AWS Region that they are created in.

  The source snapshot remains encrypted throughout the copy process. Amazon RDS uses envelope encryption to protect data during the copy process. For more information about envelope encryption, see Envelope encryption in the *AWS Key Management Service Developer Guide*.

- You can't unencrypt an encrypted DB instance. However, you can export data from an encrypted DB instance and import the data into an unencrypted DB instance.

AWS KMS key management

Amazon RDS automatically integrates with AWS Key Management Service (AWS KMS) for key management. Amazon RDS uses envelope encryption. For more information about envelope encryption, see Envelope encryption in the *AWS Key Management Service Developer Guide*.

You can use two types of AWS KMS keys to encrypt your DB instances.

- If you want full control over a KMS key, you must create a *customer managed key*. For more information about customer managed keys, see Customer managed keys in the *AWS Key Management Service Developer Guide*.

  You can't share a snapshot that has been encrypted using the AWS managed key of the AWS account that shared the snapshot.
- *AWS managed keys* are KMS keys in your account that are created, managed, and used on your behalf by an AWS service that is integrated with AWS KMS. By default, the RDS AWS managed key (`aws/rds`) is used for encryption. You can't manage, rotate, or delete the RDS AWS managed key. For more information about AWS managed keys, see AWS managed keys in the *AWS Key Management Service Developer Guide*.

To manage KMS keys used for Amazon RDS encrypted DB instances, use the AWS Key Management Service (AWS KMS) in the AWS KMS console, the AWS CLI, or the AWS KMS API. To view audit logs of every action taken with an AWS managed or customer managed key, use AWS CloudTrail. For more information about key rotation, see Rotating AWS KMS keys.

Authorizing use of a customer managed key

When RDS uses a customer managed key in cryptographic operations, it acts on behalf of the user who is creating or changing the RDS resource.

To create an RDS resource using a customer managed key, a user must have permissions to call the following operations on the customer managed key:

- `kms:CreateGrant`
- `kms:DescribeKey`

You can specify these required permissions in a key policy, or in an IAM policy if the key policy allows it.

> **Tip**
>
> To follow the principle of least privilege, do not allow full access to `kms:CreateGrant`. Instead, use the kms:ViaService condition key to allow the user to create grants on the KMS key only when the grant is created on the user's behalf by an AWS service.

You can make the IAM policy stricter in various ways. For example, if you want to allow the customer managed key to be used only for requests that originate in RDS, use the kms:ViaService condition key with the `rds.<region>.amazonaws.com` value. Also, you can use the keys or values in the Amazon RDS encryption context as a condition for using the customer managed key for encryption.

For more information, see Allowing users in other accounts to use a KMS key in the *AWS Key Management Service Developer Guide* and Key policies in AWS KMS.

Amazon RDS encryption context

When RDS uses your KMS key, or when Amazon EBS uses the KMS key on behalf of RDS, the service specifies an encryption context. The encryption context is additional authenticated data (AAD) that AWS KMS uses to ensure data integrity. When an encryption context is specified for an encryption operation, the service must specify the same encryption context for the decryption operation. Otherwise, decryption fails. The encryption context is also written to your AWS CloudTrail logs to help you understand why a given KMS key was used. Your CloudTrail logs might contain many entries describing the use of a KMS key, but the encryption context in each log entry can help you determine the reason for that particular use.

At minimum, Amazon RDS always uses the DB instance ID for the encryption context, as in the following JSON-formatted example:

```
{ "aws:rds:db-id": "db-CQYSMDPBRZ7BPMH7Y3RTDG5QY" }
```

This encryption context can help you identify the DB instance for which your KMS key was used.

When your KMS key is used for a specific DB instance and a specific Amazon EBS volume, both the DB instance ID and the Amazon EBS volume ID are used for the encryption context, as in the following JSON-formatted example:

```
{
  "aws:rds:db-id": "db-BRG7VYS3SVIFQW7234EJQOM5RQ",
  "aws:ebs:id": "vol-ad8c6542"
}
```

Using SSL/TLS to encrypt a connection to a DB instance or cluster

You can use Secure Socket Layer (SSL) or Transport Layer Security (TLS) from your application to encrypt a connection to a database running Db2, MariaDB, Microsoft SQL Server, MySQL, Oracle, or PostgreSQL.

SSL/TLS connections provide a layer of security by encrypting data that moves between your client and DB instance or cluster. Optionally, your SSL/TLS connection can perform server identity verification by validating the server certificate installed on your database. To require server identity verification, follow this general process:

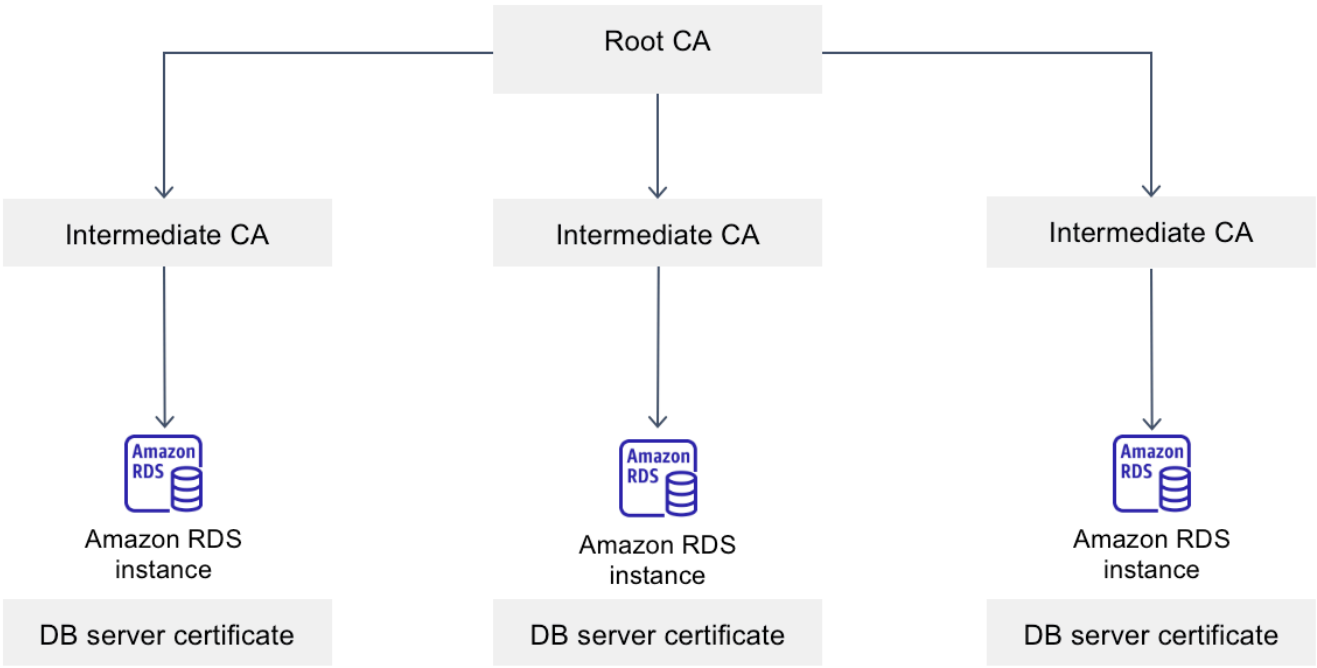
1. Choose the **certificate authority (CA)** that signs the **DB server certificate,** for your database. For more information about certificate authorities, see Certificate authorities.
2. Download a certificate bundle to use when you are connecting to the database. To download a certificate bundle, see Certificate bundles by AWS Region.

   > **Note**
   >
   > All certificates are only available for download using SSL/TLS connections.

3. Connect to the database using your DB engine's process for implementing SSL/TLS connections. Each DB engine has its own process for implementing SSL/TLS. To learn how to implement SSL/TLS for your database, follow the link that corresponds to your DB engine:
   - Using SSL/TLS with an Amazon RDS for Db2 DB instance
   - Using SSL/TLS with a MariaDB DB instance
   - Using SSL with a Microsoft SQL Server DB instance
   - Using SSL/TLS with a MySQL DB instance
   - Using SSL with an RDS for Oracle DB instance
   - Using SSL with a PostgreSQL DB instance

Certificate authorities

The **certificate authority (CA)** is the certificate that identifies the root CA at the top of the certificate chain. The CA signs the **DB server certificate,** which is installed on each DB instance. The DB server certificate identifies the DB instance as a trusted server.



Amazon RDS provides the following CAs to sign the DB server certificate for a database.

Certificate authority (CA)	Description	Common name (CN)
rds-ca-2019	Uses a certificate authority with RSA 2048 private key algorithm and SHA256 signing algorithm. This CA expires in 2024 and doesn't support automatic server certificate rotation. If you are using this CA and want to keep the same standard, we recommend that you switch to the rds-ca-rsa2048-g1 CA.	Amazon RDS *region-id entifier* CA 2019

Certificate authority (CA)	Description	Common name (CN)
rds-ca-rsa2048-g1	Uses a certificate authority with RSA 2048 private key algorithm and SHA256 signing algorithm in most AWS Regions. In the AWS GovCloud (US) Regions, this CA uses a certificate authority with RSA 2048 private key algorithm and SHA384 signing algorithm. This CA remains valid for longer than the rds-ca-2019 CA. This CA supports automatic server certificate rotation.	Amazon RDS *region-id entifier* RSA2048 G1
rds-ca-rsa4096-g1	Uses a certificate authority with RSA 4096 private key algorithm and SHA384 signing algorithm. This CA supports automatic server certificate rotation.	Amazon RDS *region-id entifier* RSA4096 G1
rds-ca-ecc384-g1	Uses a certificate authority with ECC 384 private key algorithm and SHA384 signing algorithm. This CA supports automatic server certificate rotation.	Amazon RDS *region-id entifier* ECC384 G1

Note

If you are using the AWS CLI, you can see the validities of the certificate authorities listed above by using describe-certificates.

These CA certificates are included in the regional and global certificate bundle. When you use the rds-ca-rsa2048-g1, rds-ca-rsa4096-g1, or rds-ca-ecc384-g1 CA with a database, RDS manages the DB server certificate on the database. RDS rotates the DB server certificate automatically before it expires.

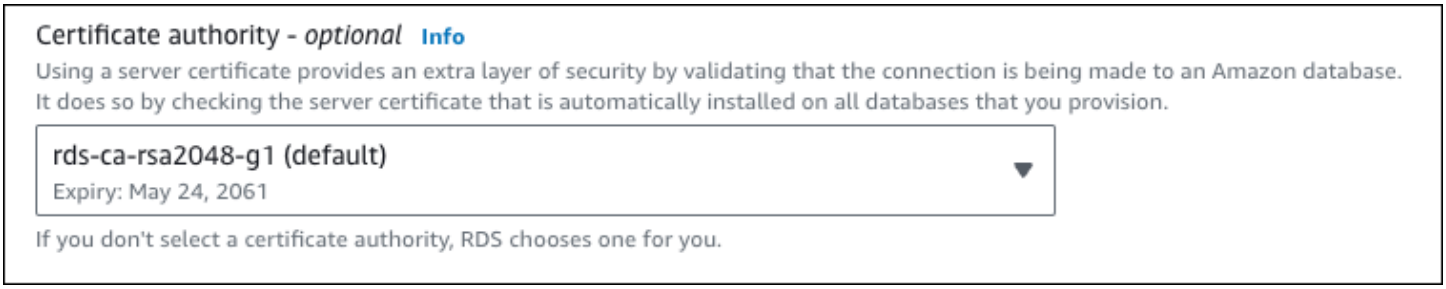
Setting the CA for your database

You can set the CA for a database when you perform the following tasks:

- Create a DB instance or Multi-AZ DB cluster – You can set the CA when you create a DB instance or cluster. For instructions, see the section called "Creating a DB instance" or the section called "Creating a Multi-AZ DB cluster".
- Modify a DB instance or Multi-AZ DB cluster – You can set the CA for a DB instance or cluster by modifying it. For instructions, see the section called "Modifying a DB instance" or the section called "Modifying a Multi-AZ DB cluster".

> **Note**
>
> The default CA is set to rds-ca-rsa2048-g1. You can override the default CA for your AWS account by using the modify-certificates command.

The available CAs depend on the DB engine and DB engine version. When you use the AWS Management Console, you can choose the CA using the **Certificate authority** setting, as shown in the following image.



The console only shows the CAs that are available for the DB engine and DB engine version. If you're using the AWS CLI, you can set the CA for a DB instance using the create-db-instance or modify-db-instance command. You can set the CA for a Multi-AZ DB cluster using the create-db-cluster or modify-db-cluster command.

If you're using the AWS CLI, you can see the available CAs for your account by using the describe-certificates command. This command also shows the expiration date for each CA in `ValidTill` in the output. You can find the CAs that are available for a specific DB engine and DB engine version using the describe-db-engine-versions command.

The following example shows the CAs available for the default RDS for PostgreSQL DB engine version.

```
aws rds describe-db-engine-versions --default-only --engine postgres
```

Your output is similar to the following. The available CAs are listed in `SupportedCACertificateIdentifiers`. The output also shows whether the DB engine version supports rotating the certificate without restart in `SupportsCertificateRotationWithoutRestart`.

```
{
    "DBEngineVersions": [
        {
            "Engine": "postgres",
            "MajorEngineVersion": "13",
            "EngineVersion": "13.4",
            "DBParameterGroupFamily": "postgres13",
            "DBEngineDescription": "PostgreSQL",
            "DBEngineVersionDescription": "PostgreSQL 13.4-R1",
            "ValidUpgradeTarget": [],
            "SupportsLogExportsToCloudwatchLogs": false,
            "SupportsReadReplica": true,
            "SupportedFeatureNames": [
                "Lambda"
            ],
            "Status": "available",
            "SupportsParallelQuery": false,
            "SupportsGlobalDatabases": false,
            "SupportsBabelfish": false,
            "SupportsCertificateRotationWithoutRestart": true,
            "SupportedCACertificateIdentifiers": [
                "rds-ca-2019",
                "rds-ca-rsa2048-g1",
                "rds-ca-ecc384-g1",
                "rds-ca-rsa4096-g1"
            ]
        }
    ]
}
```

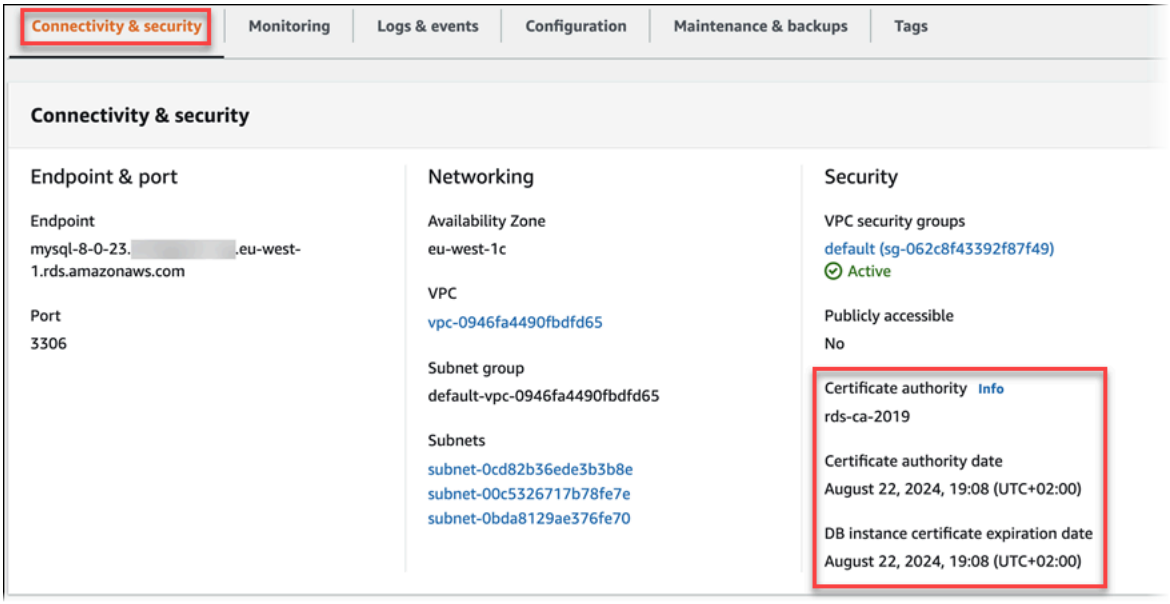
DB server certificate validities

The validity of DB server certificate depends on the DB engine and DB engine version. If the DB engine version supports rotating the certificate without restart, the validity of the DB server certificate is 1 year. Otherwise the validity is 3 years.

For more information about DB server certificate rotation, see Automatic server certificate rotation.

Viewing the CA for your DB instance

You can view the details about the CA for a database by viewing the **Connectivity & security** tab in the console, as in the following image.



If you're using the AWS CLI, you can view the details about the CA for a DB instance by using the describe-db-instances command. You can view the details about the CA for a Multi-AZ DB cluster by using the describe-db-clusters command.

Download certificate bundles for Amazon RDS

When you connect to your database with SSL or TLS, the database instance requires a trust certificate from Amazon RDS. Select the appropriate link in the following table to download the bundle that corresponds with the AWS Region where you host your database.

Certificate bundles by AWS Region

The certificate bundles for all AWS Regions and GovCloud (US) Regions contain the following certificates:

- `rds-ca-2019` intermediate and root certificates.
- `rds-ca-rsa2048-g1`, `rds-ca-rsa4096-g1`, and `rds-ca-ecc384-g1` root CA certificates. Your application trust store only needs to register the root CA certificate.

> **Note**
>
> Amazon RDS Proxy uses certificates from the AWS Certificate Manager (ACM). If you're using RDS Proxy, you don't need to download Amazon RDS certificates or update applications that use RDS Proxy connections. For more information, see Using TLS/SSL with RDS Proxy.

To download a certificate bundle for an AWS Region, select the link for the AWS Region that hosts your database in the following table.

AWS Region	Certificate bundle (PEM)	Certificate bundle (PKCS7)
Any commercial AWS Region	global-bundle.pem	global-bundle.p7b
US East (N. Virginia)	us-east-1-bundle.pem	us-east-1-bundle.p7b
US East (Ohio)	us-east-2-bundle.pem	us-east-2-bundle.p7b
US West (N. California)	us-west-1-bundle.pem	us-west-1-bundle.p7b
US West (Oregon)	us-west-2-bundle.pem	us-west-2-bundle.p7b
Africa (Cape Town)	af-south-1-bundle.pem	af-south-1-bundle.p7b
Asia Pacific (Hong Kong)	ap-east-1-bundle.pem	ap-east-1-bundle.p7b
Asia Pacific (Hyderabad)	ap-south-2-bundle.pem	ap-south-2-bundle.p7b
Asia Pacific (Jakarta)	ap-southeast-3-bundle.pem	ap-southeast-3-bundle.p7b
Asia Pacific (Malaysia)	ap-southeast-5-bundle.pem	ap-southeast-5-bundle.p7b
Asia Pacific (Melbourne)	ap-southeast-4-bundle.pem	ap-southeast-4-bundle.p7b

AWS Region	Certificate bundle (PEM)	Certificate bundle (PKCS7)
Asia Pacific (Mumbai)	ap-south-1-bundle.pem	ap-south-1-bundle.p7b
Asia Pacific (Osaka)	ap-northeast-3-bundle.pem	ap-northeast-3-bundle.p7b
Asia Pacific (Tokyo)	ap-northeast-1-bundle.pem	ap-northeast-1-bundle.p7b
Asia Pacific (Seoul)	ap-northeast-2-bundle.pem	ap-northeast-2-bundle.p7b
Asia Pacific (Singapore)	ap-southeast-1-bundle.pem	ap-southeast-1-bundle.p7b
Asia Pacific (Sydney)	ap-southeast-2-bundle.pem	ap-southeast-2-bundle.p7b
Canada (Central)	ca-central-1-bundle.pem	ca-central-1-bundle.p7b
Canada West (Calgary)	ca-west-1-bundle.pem	ca-west-1-bundle.p7b
Europe (Frankfurt)	eu-central-1-bundle.pem	eu-central-1-bundle.p7b
Europe (Ireland)	eu-west-1-bundle.pem	eu-west-1-bundle.p7b
Europe (London)	eu-west-2-bundle.pem	eu-west-2-bundle.p7b
Europe (Milan)	eu-south-1-bundle.pem	eu-south-1-bundle.p7b
Europe (Paris)	eu-west-3-bundle.pem	eu-west-3-bundle.p7b
Europe (Spain)	eu-south-2-bundle.pem	eu-south-2-bundle.p7b
Europe (Stockholm)	eu-north-1-bundle.pem	eu-north-1-bundle.p7b
Europe (Zurich)	eu-central-2-bundle.pem	eu-central-2-bundle.p7b
Israel (Tel Aviv)	il-central-1-bundle.pem	il-central-1-bundle.p7b
Middle East (Bahrain)	me-south-1-bundle.pem	me-south-1-bundle.p7b
Middle East (UAE)	me-central-1-bundle.pem	me-central-1-bundle.p7b
South America (São Paulo)	sa-east-1-bundle.pem	sa-east-1-bundle.p7b

AWS Region	Certificate bundle (PEM)	Certificate bundle (PKCS7)
Any AWS GovCloud (US) Regions	global-bundle.pem	global-bundle.p7b
AWS GovCloud (US-East)	us-gov-east-1-bundle.pem	us-gov-east-1-bundle.p7b
AWS GovCloud (US-West)	us-gov-west-1-bundle.pem	us-gov-west-1-bundle.p7b

Viewing the contents of your CA certificate

To check the contents of your CA certificate bundle, use the following command:

```
keytool -printcert -v -file global-bundle.pem
```

Rotating your SSL/TLS certificate

Amazon RDS Certificate Authority certificates rds-ca-2019 are set to expire in August, 2024. If you use or plan to use Secure Sockets Layer (SSL) or Transport Layer Security (TLS) with certificate verification to connect to your RDS DB instances or Multi-AZ DB clusters, consider using one of the new CA certificates rds-ca-rsa2048-g1, rds-ca-rsa4096-g1 or rds-ca-ecc384-g1. If you currently do not use SSL/TLS with certificate verification, you might still have an expired CA certificate and must update them to a new CA certificate if you plan to use SSL/TLS with certificate verification to connect to your RDS databases.

Amazon RDS provides new CA certificates as an AWS security best practice. For information about the new certificates and the supported AWS Regions, see Using SSL/TLS to encrypt a connection to a DB instance or cluster.

To update the CA certificate for your database, use the following methods:

- Updating your CA certificate by modifying your DB instance or cluster
- Updating your CA certificate by applying maintenance

Before you update your DB instances or Multi-AZ DB clusters to use the new CA certificate, make sure that you update your clients or applications connecting to your RDS databases.

Considerations for rotating certificates

Consider the following situations before rotating your certificate:

- Amazon RDS Proxy uses certificates from the AWS Certificate Manager (ACM). If you're using RDS Proxy, when you rotate your SSL/TLS certificate, you don't need to update applications that use RDS Proxy connections. For more information, see Using TLS/SSL with RDS Proxy.
- If you're using a Go version 1.15 application with a DB instance or Multi-AZ DB cluster that was created or updated to the rds-ca-2019 certificate prior to July 28, 2020, you must update the certificate again. Update the certificate to rds-ca-rsa2048-g1, rds-ca-rsa4096-g1, or rds-ca-ecc384-g1 depending on your engine.

  Use the `modify-db-instance` command for a DB instance, or the `modify-db-cluster` command for a Multi-AZ DB cluster, using the new CA certificate identifier. You can find the CAs that are available for a specific DB engine and DB engine version using the `describe-db-engine-versions` command.

  If you created your database or updated its certificate after July 28, 2020, no action is required. For more information, see Go GitHub issue #39568.

Updating your CA certificate by modifying your DB instance or cluster

The following example updates your CA certificate from *rds-ca-2019* to *rds-ca-rsa2048-g1*. You can choose a different certificate. For more information, see Certificate authorities.

Update your application trust store to reduce any down time associated with updating your CA certificate. For more information about restarts associated with CA certificate rotation, see Automatic server certificate rotation.

To update your CA certificate by modifying your DB instance or cluster

1. Download the new SSL/TLS certificate as described in Using SSL/TLS to encrypt a connection to a DB instance or cluster.
2. Update your applications to use the new SSL/TLS certificate.

   The methods for updating applications for new SSL/TLS certificates depend on your specific applications. Work with your application developers to update the SSL/TLS certificates for your applications.

For information about checking for SSL/TLS connections and updating applications for each DB engine, see the following topics:

- Updating applications to connect to MariaDB instances using new SSL/TLS certificates
- Updating applications to connect to Microsoft SQL Server DB instances using new SSL/TLS certificates
- Updating applications to connect to MySQL DB instances using new SSL/TLS certificates
- Updating applications to connect to Oracle DB instances using new SSL/TLS certificates
- Updating applications to connect to PostgreSQL DB instances using new SSL/TLS certificates

For a sample script that updates a trust store for a Linux operating system, see Sample script for importing certificates into your trust store.

> **Note**
>
> The certificate bundle contains certificates for both the old and new CA, so you can upgrade your application safely and maintain connectivity during the transition period. If you are using the AWS Database Migration Service to migrate a database to a DB instance or cluster, we recommend using the certificate bundle to ensure connectivity during the migration.

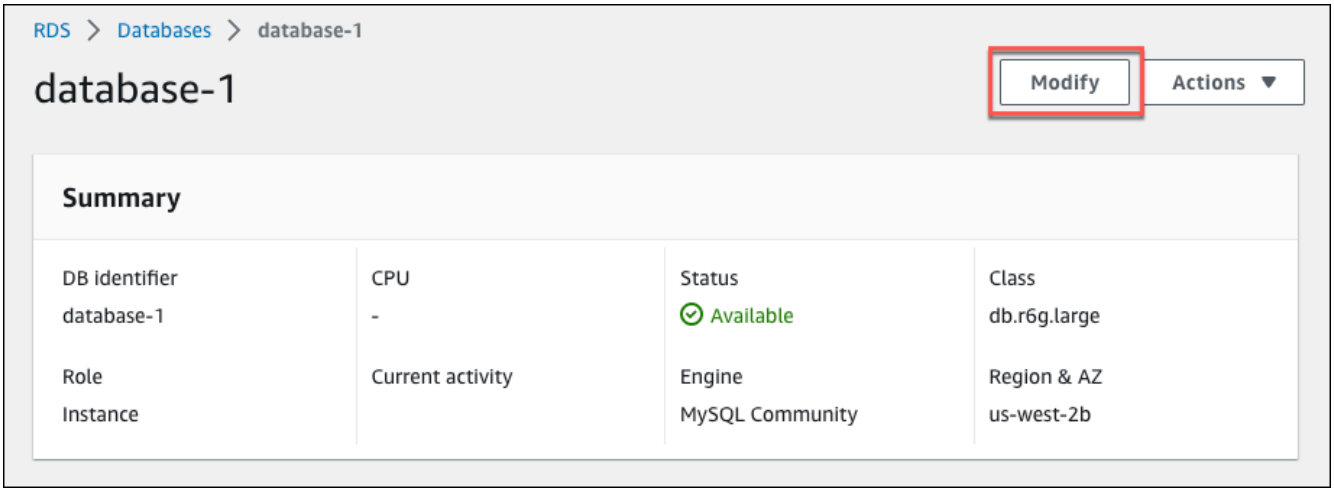
3. Modify the DB instance or Multi-AZ DB cluster to change the CA from **rds-ca-2019** to **rds-ca-rsa2048-g1**. To check if your database requires a restart to update the CA certificates, use the describe-db-engine-versions command and check the `SupportsCertificateRotationWithoutRestart` flag.

> **Important**
>
> If you are experiencing connectivity issues after certificate expiry, use the apply immediately option by specifying **Apply immediately** in the console or by specifying the `--apply-immediately` option using the AWS CLI. By default, this operation is scheduled to run during your next maintenance window.
> To set an override for your instance CA that's different from the default RDS CA, use the modify-certificates CLI command.

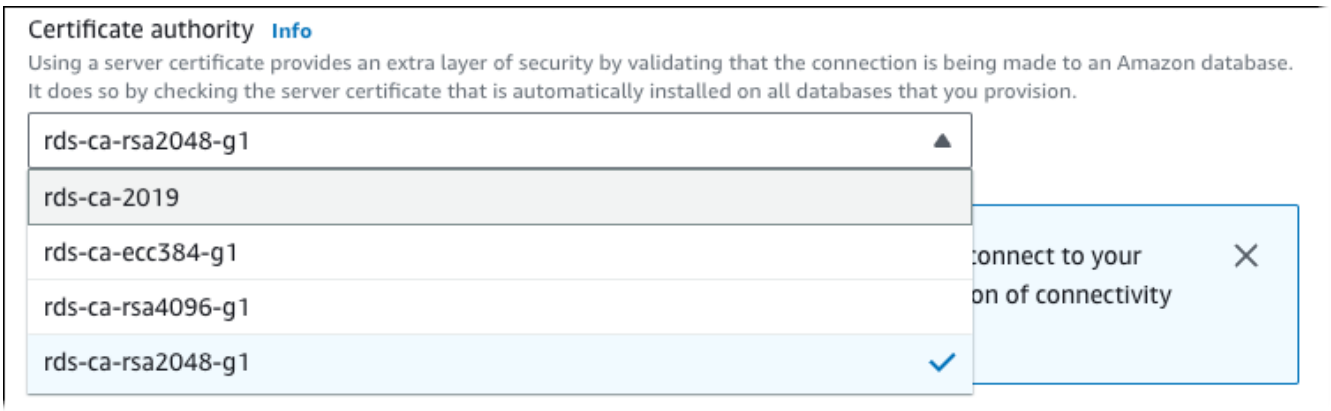
You can use the AWS Management Console or the AWS CLI to change the CA certificate from **rds-ca-2019** to **rds-ca-rsa2048-g1** for a DB instance or Multi-AZ DB cluster.

Console

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**, and then choose the DB instance or Multi-AZ DB cluster that you want to modify.
3. Choose **Modify**.



4. In the **Connectivity** section, choose **rds-ca-rsa2048-g1**.



5. Choose **Continue** and check the summary of modifications.
6. To apply the changes immediately, choose **Apply immediately**.
7. On the confirmation page, review your changes. If they are correct, choose **Modify DB Instance** or **Modify cluster** to save your changes.

> **Important**
>
> When you schedule this operation, make sure that you have updated your client-side trust store beforehand.

Or choose **Back** to edit your changes or **Cancel** to cancel your changes.

AWS CLI

To use the AWS CLI to change the CA from **rds-ca-2019** to **rds-ca-rsa2048-g1** for a DB instance or Multi-AZ DB cluster, call the modify-db-instance or modify-db-cluster command. Specify the DB instance or cluster identifier and the `--ca-certificate-identifier` option.

Use the `--apply-immediately` parameter to apply the update immediately. By default, this operation is scheduled to run during your next maintenance window.

> **Important**
>
> When you schedule this operation, make sure that you have updated your client-side trust store beforehand.

Example

DB instance

The following example modifies `mydbinstance` by setting the CA certificate to `rds-ca-rsa2048-g1`.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier mydbinstance \
    --ca-certificate-identifier rds-ca-rsa2048-g1
```

For Windows:

```
aws rds modify-db-instance ^
```

```
    --db-instance-identifier mydbinstance ^
    --ca-certificate-identifier rds-ca-rsa2048-g1
```

> **Note**
>
> If your instance requires reboot, you can use the modify-db-instance CLI command and specify the `--no-certificate-rotation-restart` option.

Example

Multi-AZ DB cluster

The following example modifies `mydbcluster` by setting the CA certificate to `rds-ca-rsa2048-g1`.

For Linux, macOS, or Unix:

```
aws rds modify-db-cluster \
    --db-cluster-identifier mydbcluster \
    --ca-certificate-identifier rds-ca-rsa2048-g1
```

For Windows:

```
aws rds modify-db-cluster ^
    --db-cluster-identifier mydbcluster ^
    --ca-certificate-identifier rds-ca-rsa2048-g1
```

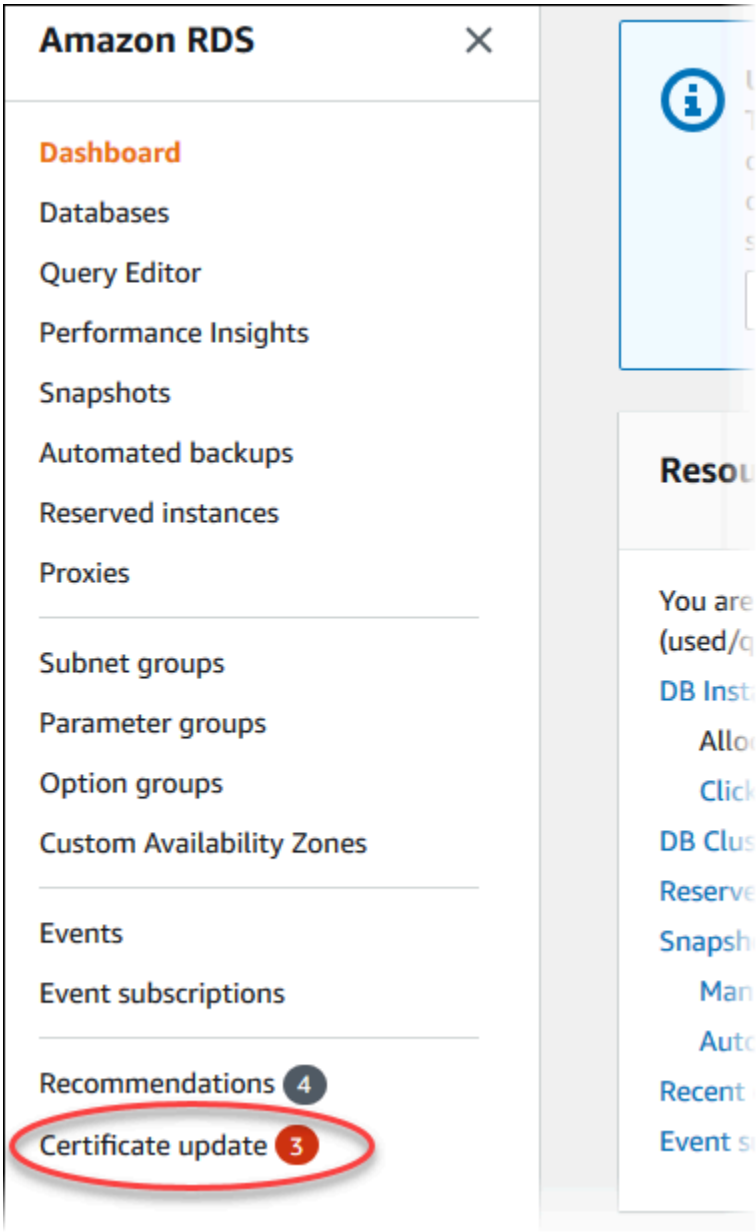
Updating your CA certificate by applying maintenance

Perform the following steps to update your CA certificate by applying maintenance.

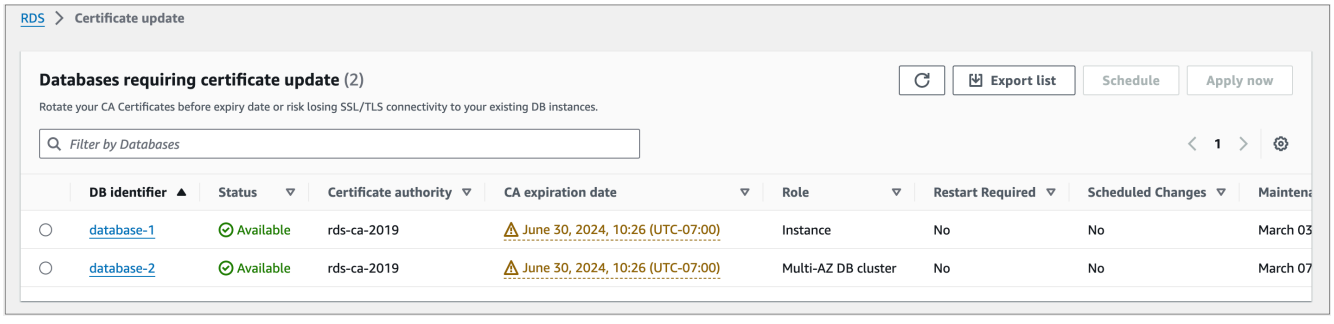
Console

To update your CA certificate by applying maintenance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Certificate update**.



The **Databases requiring certificate update** page appears.



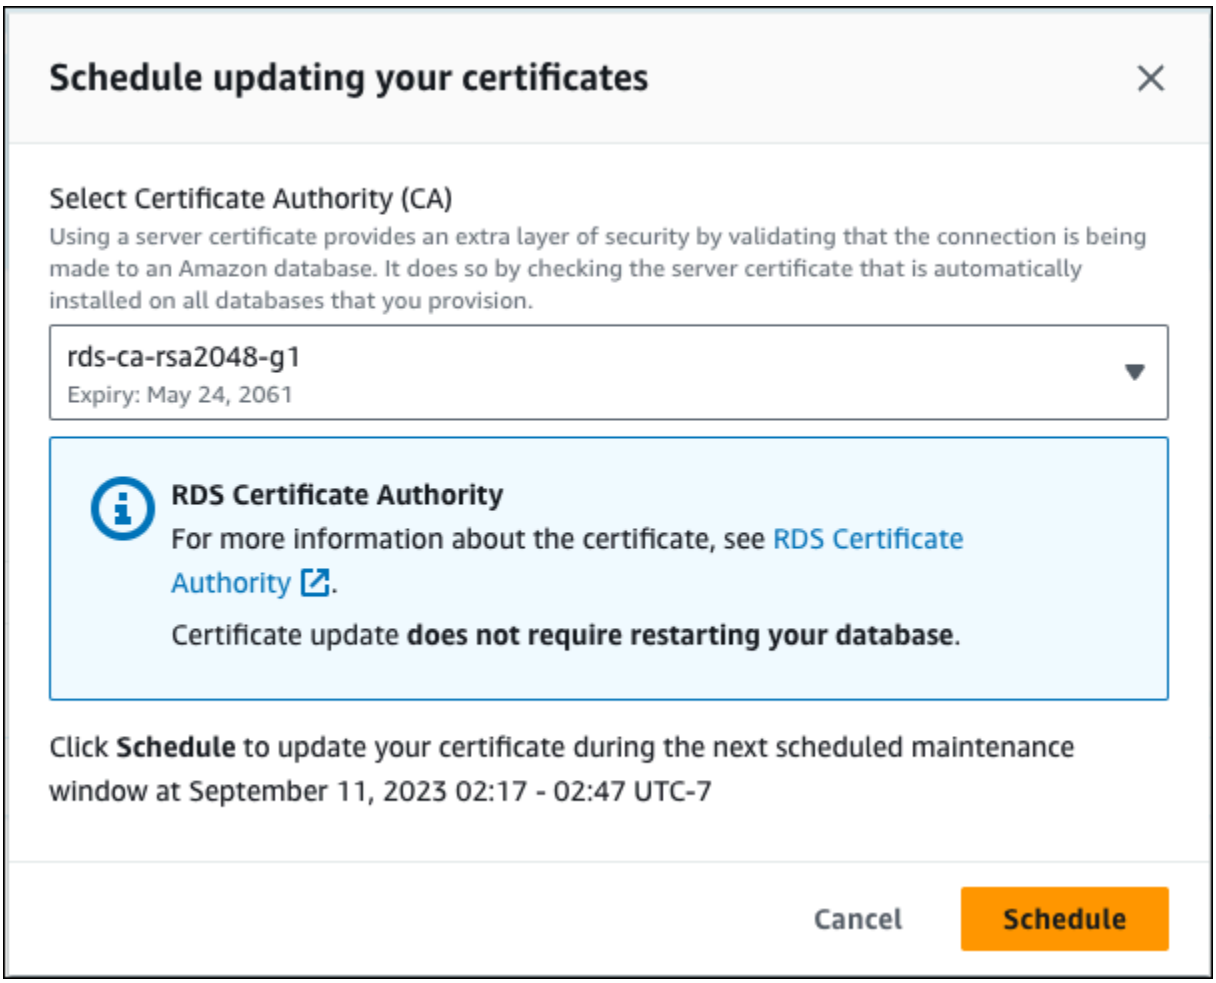
> **Note**
>
> This page only shows the DB instances and clusters for the current AWS Region. If you have databases in more than one AWS Region, check this page in each AWS Region to see all DB instances with old SSL/TLS certificates.

3. Choose the DB instance or Multi-AZ DB cluster that you want to update.

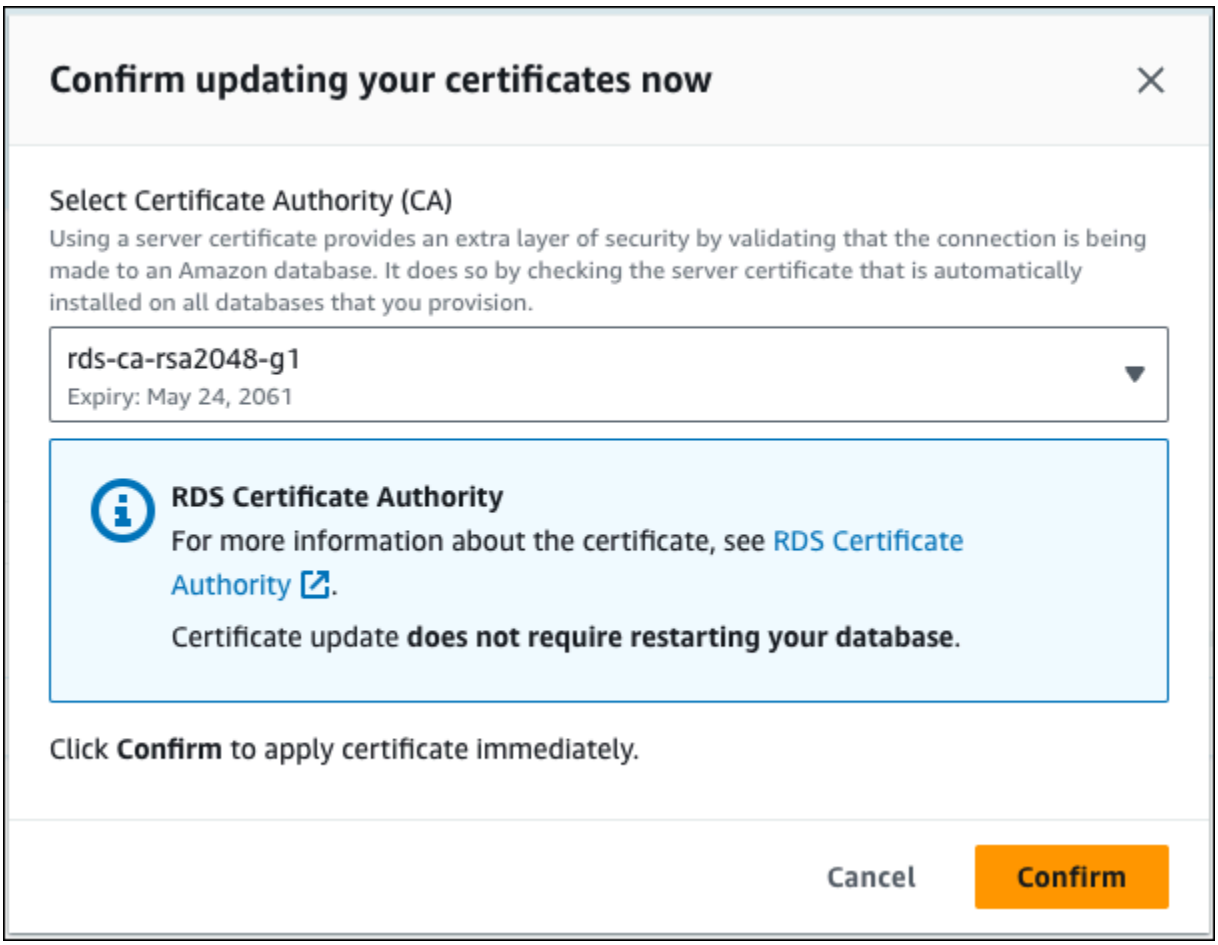
   You can schedule the certificate rotation for your next maintenance window by choosing **Schedule**. Apply the rotation immediately by choosing **Apply now**.

   > **Important**
   >
   > If you experience connectivity issues after certificate expiry, use the **Apply now** option.

4. a. If you choose **Schedule**, you are prompted to confirm the CA certificate rotation. This prompt also states the scheduled window for your update.



b. If you choose **Apply now**, you are prompted to confirm the CA certificate rotation.



> **Important**
>
> Before scheduling the CA certificate rotation on your database, update any client applications that use SSL/TLS and the server certificate to connect. These updates are specific to your DB engine. After you have updated these client applications, you can confirm the CA certificate rotation.

To continue, choose the check box, and then choose **Confirm**.

5. Repeat steps 3 and 4 for each DB instance and cluster that you want to update.

Automatic server certificate rotation

If your root CA supports automatic server certificate rotation, RDS automatically handles the rotation of the DB server certificate. RDS uses the same root CA for this automatic rotation, so you don't need to download a new CA bundle. See Certificate authorities.

The rotation and validity of your DB server certificate depend on your DB engine:

- If your DB engine supports rotation without restart, RDS automatically rotates the DB server certificate without requiring any action from you. RDS attempts to rotate your DB server certificate in your preferred maintenance window at the DB server certificate half life. The new DB server certificate is valid for 12 months.
- If your DB engine doesn't support rotation without restart, RDS notifies you about a maintenance event at least 6 months before the DB server certificate expires. The new DB server certificate is valid for 36 months.

Use the describe-db-engine-versions command and inspect the `SupportsCertificateRotationWithoutRestart` flag to identify whether the DB engine version supports rotating the certificate without restart. For more information, see Setting the CA for your database.

Sample script for importing certificates into your trust store

The following are sample shell scripts that import the certificate bundle into a trust store.

Each sample shell script uses keytool, which is part of the Java Development Kit (JDK). For information about installing the JDK, see JDK Installation Guide.

Linux

The following is a sample shell script that imports the certificate bundle into a trust store on a Linux operating system.

```
mydir=tmp/certs
if [ ! -e "${mydir}" ]
then
mkdir -p "${mydir}"
fi
```

```
truststore=${mydir}/rds-truststore.jks
storepassword=changeit

curl -sS "https://truststore.pki.rds.amazonaws.com/global/global-bundle.pem" >
 ${mydir}/global-bundle.pem
awk 'split_after == 1 {n++;split_after=0} /-----END CERTIFICATE-----/
 {split_after=1}{print > "rds-ca-" n+1 ".pem"}' < ${mydir}/global-bundle.pem

for CERT in rds-ca-*; do
  alias=$(openssl x509 -noout -text -in $CERT | perl -ne 'next unless /Subject:/;
 s/.*(CN=|CN = )//; print')
  echo "Importing $alias"
  keytool -import -file ${CERT} -alias "${alias}" -storepass ${storepassword} -
keystore ${truststore} -noprompt
  rm $CERT
done

rm ${mydir}/global-bundle.pem

echo "Trust store content is: "

keytool -list -v -keystore "$truststore" -storepass ${storepassword} | grep Alias |
 cut -d " " -f3- | while read alias
do
   expiry=`keytool -list -v -keystore "$truststore" -storepass ${storepassword} -
alias "${alias}" | grep Valid | perl -ne 'if(/until: (.*?)\n/) { print "$1\n"; }'`
   echo " Certificate ${alias} expires in '$expiry'"
done
```

macOS

The following is a sample shell script that imports the certificate bundle into a trust store on macOS.

```
mydir=tmp/certs
if [ ! -e "${mydir}" ]
then
mkdir -p "${mydir}"
fi

truststore=${mydir}/rds-truststore.jks
```

```
storepassword=changeit

curl -sS "https://truststore.pki.rds.amazonaws.com/global/global-bundle.pem" >
 ${mydir}/global-bundle.pem
split -p "-----BEGIN CERTIFICATE-----" ${mydir}/global-bundle.pem rds-ca-

for CERT in rds-ca-*; do
  alias=$(openssl x509 -noout -text -in $CERT | perl -ne 'next unless /Subject:/;
 s/.*(CN=|CN = )//; print')
  echo "Importing $alias"
  keytool -import -file ${CERT} -alias "${alias}" -storepass ${storepassword} -
keystore ${truststore} -noprompt
  rm $CERT
done

rm ${mydir}/global-bundle.pem

echo "Trust store content is: "

keytool -list -v -keystore "$truststore" -storepass ${storepassword} | grep Alias |
 cut -d " " -f3- | while read alias
do
   expiry=`keytool -list -v -keystore "$truststore" -storepass ${storepassword} -
alias "${alias}" | grep Valid | perl -ne 'if(/until: (.*?)\n/) { print "$1\n"; }'`
   echo " Certificate ${alias} expires in '$expiry'"
done
```

Internetwork traffic privacy

Connections are protected both between Amazon RDS and on-premises applications and between Amazon RDS and other AWS resources within the same AWS Region.

Traffic between service and on-premises clients and applications

You have two connectivity options between your private network and AWS:

- An AWS Site-to-Site VPN connection. For more information, see What is AWS Site-to-Site VPN?
- An AWS Direct Connect connection. For more information, see What is AWS Direct Connect?

You get access to Amazon RDS through the network by using AWS-published API operations. Clients must support the following:

- Transport Layer Security (TLS). We require TLS 1.2 and recommend TLS 1.3.
- Cipher suites with perfect forward secrecy (PFS) such as DHE (Ephemeral Diffie-Hellman) or ECDHE (Elliptic Curve Ephemeral Diffie-Hellman). Most modern systems such as Java 7 and later support these modes.

Additionally, requests must be signed by using an access key ID and a secret access key that is associated with an IAM principal. Or you can use the AWS Security Token Service (AWS STS) to generate temporary security credentials to sign requests.

Identity and access management for Amazon RDS

AWS Identity and Access Management (IAM) is an AWS service that helps an administrator securely control access to AWS resources. IAM administrators control who can be *authenticated* (signed in) and *authorized* (have permissions) to use Amazon RDS resources. IAM is an AWS service that you can use with no additional charge.

Topics

Audience

How you use AWS Identity and Access Management (IAM) differs, depending on the work you do in Amazon RDS.

Service user – If you use the Amazon RDS service to do your job, then your administrator provides you with the credentials and permissions that you need. As you use more Amazon RDS features to do your work, you might need additional permissions. Understanding how access is managed can help you request the right permissions from your administrator. If you cannot access a feature in Amazon RDS, see Troubleshooting Amazon RDS identity and access.

Service administrator – If you're in charge of Amazon RDS resources at your company, you probably have full access to Amazon RDS. It's your job to determine which Amazon RDS features and resources your employees should access. You must then submit requests to your administrator to change the permissions of your service users. Review the information on this page to understand

the basic concepts of IAM. To learn more about how your company can use IAM with Amazon RDS, see How Amazon RDS works with IAM.

Administrator – If you're an administrator, you might want to learn details about how you can write policies to manage access to Amazon RDS. To view example Amazon RDS identity-based policies that you can use in IAM, see Identity-based policy examples for Amazon RDS.

Authenticating with identities

Authentication is how you sign in to AWS using your identity credentials. You must be *authenticated* (signed in to AWS) as the AWS account root user, as an IAM user, or by assuming an IAM role.

You can sign in to AWS as a federated identity by using credentials provided through an identity source. AWS IAM Identity Center (IAM Identity Center) users, your company's single sign-on authentication, and your Google or Facebook credentials are examples of federated identities. When you sign in as a federated identity, your administrator previously set up identity federation using IAM roles. When you access AWS by using federation, you are indirectly assuming a role.

Depending on the type of user you are, you can sign in to the AWS Management Console or the AWS access portal. For more information about signing in to AWS, see How to sign in to your AWS account in the *AWS Sign-In User Guide*.

If you access AWS programmatically, AWS provides a software development kit (SDK) and a command line interface (CLI) to cryptographically sign your requests by using your credentials. If you don't use AWS tools, you must sign requests yourself. For more information about using the recommended method to sign requests yourself, see Signing AWS API requests in the *IAM User Guide*.

Regardless of the authentication method that you use, you might be required to provide additional security information. For example, AWS recommends that you use multi-factor authentication (MFA) to increase the security of your account. To learn more, see Multi-factor authentication in the *AWS IAM Identity Center User Guide* and Using multi-factor authentication (MFA) in AWS in the *IAM User Guide*.

AWS account root user

When you create an AWS account, you begin with one sign-in identity that has complete access to all AWS services and resources in the account. This identity is called the AWS account *root user* and is accessed by signing in with the email address and password that you used to create the account.

We strongly recommend that you don't use the root user for your everyday tasks. Safeguard your root user credentials and use them to perform the tasks that only the root user can perform. For the complete list of tasks that require you to sign in as the root user, see Tasks that require root user credentials in the *IAM User Guide*.

Federated identity

As a best practice, require human users, including users that require administrator access, to use federation with an identity provider to access AWS services by using temporary credentials.

A *federated identity* is a user from your enterprise user directory, a web identity provider, the AWS Directory Service, the Identity Center directory, or any user that accesses AWS services by using credentials provided through an identity source. When federated identities access AWS accounts, they assume roles, and the roles provide temporary credentials.

For centralized access management, we recommend that you use AWS IAM Identity Center. You can create users and groups in IAM Identity Center, or you can connect and synchronize to a set of users and groups in your own identity source for use across all your AWS accounts and applications. For information about IAM Identity Center, see What is IAM Identity Center? in the *AWS IAM Identity Center User Guide*.

IAM users and groups

An *IAM user* is an identity within your AWS account that has specific permissions for a single person or application. Where possible, we recommend relying on temporary credentials instead of creating IAM users who have long-term credentials such as passwords and access keys. However, if you have specific use cases that require long-term credentials with IAM users, we recommend that you rotate access keys. For more information, see Rotate access keys regularly for use cases that require long-term credentials in the *IAM User Guide*.

An *IAM group* is an identity that specifies a collection of IAM users. You can't sign in as a group. You can use groups to specify permissions for multiple users at a time. Groups make permissions easier to manage for large sets of users. For example, you could have a group named *IAMAdmins* and give that group permissions to administer IAM resources.

Users are different from roles. A user is uniquely associated with one person or application, but a role is intended to be assumable by anyone who needs it. Users have permanent long-term credentials, but roles provide temporary credentials. To learn more, see When to create an IAM user (instead of a role) in the *IAM User Guide*.

You can authenticate to your DB instance using IAM database authentication.

IAM database authentication works with the following DB engines:

- RDS for MariaDB
- RDS for MySQL
- RDS for PostgreSQL

For more information about authenticating to your DB instance using IAM, see IAM database authentication for MariaDB, MySQL, and PostgreSQL.

IAM roles

An *IAM role* is an identity within your AWS account that has specific permissions. It is similar to a user, but is not associated with a specific person. You can temporarily assume an IAM role in the AWS Management Console by switching roles. You can assume a role by calling an AWS CLI or AWS API operation or by using a custom URL. For more information about methods for using roles, see Using IAM roles in the *IAM User Guide*.

IAM roles with temporary credentials are useful in the following situations:

- **Temporary user permissions** – A user can assume an IAM role to temporarily take on different permissions for a specific task.
- **Federated user access** – To assign permissions to a federated identity, you create a role and define permissions for the role. When a federated identity authenticates, the identity is associated with the role and is granted the permissions that are defined by the role. For information about roles for federation, see Creating a role for a third-party Identity Provider in the *IAM User Guide*. If you use IAM Identity Center, you configure a permission set. To control what your identities can access after they authenticate, IAM Identity Center correlates the permission set to a role in IAM. For information about permissions sets, see Permission sets in the *AWS IAM Identity Center User Guide*.
- **Cross-account access** – You can use an IAM role to allow someone (a trusted principal) in a different account to access resources in your account. Roles are the primary way to grant cross-account access. However, with some AWS services, you can attach a policy directly to a resource (instead of using a role as a proxy). To learn the difference between roles and resource-based policies for cross-account access, see How IAM roles differ from resource-based policies in the *IAM User Guide*.

- **Cross-service access** – Some AWS services use features in other AWS services. For example, when you make a call in a service, it's common for that service to run applications in Amazon EC2 or store objects in Amazon S3. A service might do this using the calling principal's permissions, using a service role, or using a service-linked role.
  - **Forward access sessions** – When you use an IAM user or role to perform actions in AWS, you are considered a principal. When you use some services, you might perform an action that then initiates another action in a different service. FAS uses the permissions of the principal calling an AWS service, combined with the requesting AWS service to make requests to downstream services. FAS requests are only made when a service receives a request that requires interactions with other AWS services or resources to complete. In this case, you must have permissions to perform both actions. For policy details when making FAS requests, see Forward access sessions.
  - **Service role** – A service role is an IAM role that a service assumes to perform actions on your behalf. An IAM administrator can create, modify, and delete a service role from within IAM. For more information, see Creating a role to delegate permissions to an AWS service in the *IAM User Guide*.
  - **Service-linked role** – A service-linked role is a type of service role that is linked to an AWS service. The service can assume the role to perform an action on your behalf. Service-linked roles appear in your AWS account and are owned by the service. An IAM administrator can view, but not edit the permissions for service-linked roles.
- **Applications running on Amazon EC2** – You can use an IAM role to manage temporary credentials for applications that are running on an EC2 instance and making AWS CLI or AWS API requests. This is preferable to storing access keys within the EC2 instance. To assign an AWS role to an EC2 instance and make it available to all of its applications, you create an instance profile that is attached to the instance. An instance profile contains the role and enables programs that are running on the EC2 instance to get temporary credentials. For more information, see Using an IAM role to grant permissions to applications running on Amazon EC2 instances in the *IAM User Guide*.

To learn whether to use IAM roles, see When to create an IAM role (instead of a user) in the *IAM User Guide*.

Managing access using policies

You control access in AWS by creating policies and attaching them to IAM identities or AWS resources. A policy is an object in AWS that, when associated with an identity or resource, defines

their permissions. AWS evaluates these policies when an entity (root user, user, or IAM role) makes a request. Permissions in the policies determine whether the request is allowed or denied. Most policies are stored in AWS as JSON documents. For more information about the structure and contents of JSON policy documents, see Overview of JSON policies in the *IAM User Guide*.

An administrator can use policies to specify who has access to AWS resources, and what actions they can perform on those resources. Every IAM entity (permission set or role) starts with no permissions. In other words, by default, users can do nothing, not even change their own password. To give a user permission to do something, an administrator must attach a permissions policy to a user. Or the administrator can add the user to a group that has the intended permissions. When an administrator gives permissions to a group, all users in that group are granted those permissions.

IAM policies define permissions for an action regardless of the method that you use to perform the operation. For example, suppose that you have a policy that allows the `iam:GetRole` action. A user with that policy can get role information from the AWS Management Console, the AWS CLI, or the AWS API.

Identity-based policies

Identity-based policies are JSON permissions policy documents that you can attach to an identity, such as a permission set or role. These policies control what actions that identity can perform, on which resources, and under what conditions. To learn how to create an identity-based policy, see Creating IAM policies in the *IAM User Guide*.

Identity-based policies can be further categorized as *inline policies* or *managed policies*. Inline policies are embedded directly into a single permission set or role. Managed policies are standalone policies that you can attach to multiple permission sets and roles in your AWS account. Managed policies include AWS managed policies and customer managed policies. To learn how to choose between a managed policy or an inline policy, see Choosing between managed policies and inline policies in the *IAM User Guide*.

For information about AWS managed policies that are specific to Amazon RDS, see AWS managed policies for Amazon RDS.

Other policy types

AWS supports additional, less-common policy types. These policy types can set the maximum permissions granted to you by the more common policy types.

- **Permissions boundaries** – A permissions boundary is an advanced feature in which you set the maximum permissions that an identity-based policy can grant to an IAM entity (permission set or role). You can set a permissions boundary for an entity. The resulting permissions are the intersection of entity's identity-based policies and its permissions boundaries. Resource-based policies that specify the permission set or role in the `Principal` field are not limited by the permissions boundary. An explicit deny in any of these policies overrides the allow. For more information about permissions boundaries, see Permissions boundaries for IAM entities in the *IAM User Guide*.
- **Service control policies (SCPs)** – SCPs are JSON policies that specify the maximum permissions for an organization or organizational unit (OU) in AWS Organizations. AWS Organizations is a service for grouping and centrally managing multiple AWS accounts that your business owns. If you enable all features in an organization, then you can apply service control policies (SCPs) to any or all of your accounts. The SCP limits permissions for entities in member accounts, including each AWS account root user. For more information about Organizations and SCPs, see How SCPs work in the *AWS Organizations User Guide*.
- **Session policies** – Session policies are advanced policies that you pass as a parameter when you programmatically create a temporary session for a role or federated user. The resulting session's permissions are the intersection of the permission sets or role's identity-based policies and the session policies. Permissions can also come from a resource-based policy. An explicit deny in any of these policies overrides the allow. For more information, see Session policies in the *IAM User Guide*.

Multiple policy types

When multiple types of policies apply to a request, the resulting permissions are more complicated to understand. To learn how AWS determines whether to allow a request when multiple policy types are involved, see Policy evaluation logic in the *IAM User Guide*.

How Amazon RDS works with IAM

Before you use IAM to manage access to Amazon RDS, you should understand what IAM features are available to use with Amazon RDS.

The following table lists IAM features you can use with Amazon RDS:

IAM feature	Amazon RDS support
Identity-based policies	Yes
Resource-based policies	No
Policy actions	Yes
Policy resources	Yes
Policy condition keys (service-specific)	Yes
ACLs	No
Attribute-based access control (ABAC) (tags in policies)	Yes
Temporary credentials	Yes
Forward access sessions	Yes
Service roles	Yes
Service-linked roles	Yes

To get a high-level view of how Amazon RDS and other AWS services work with IAM, see AWS services that work with IAM in the *IAM User Guide*.

Topics

- Amazon RDS identity-based policies
- Resource-based policies within Amazon RDS
- Policy actions for Amazon RDS
- Policy resources for Amazon RDS
- Policy condition keys for Amazon RDS
- Access control lists (ACLs) in Amazon RDS
- Attribute-based access control (ABAC) in policies with Amazon RDS tags
- Using temporary credentials with Amazon RDS

- Forward access sessions for Amazon RDS
- Service roles for Amazon RDS
- Service-linked roles for Amazon RDS

Amazon RDS identity-based policies

Supports identity-based policies: Yes.

Identity-based policies are JSON permissions policy documents that you can attach to an identity, such as an IAM user, group of users, or role. These policies control what actions users and roles can perform, on which resources, and under what conditions. To learn how to create an identity-based policy, see Creating IAM policies in the *IAM User Guide*.

With IAM identity-based policies, you can specify allowed or denied actions and resources as well as the conditions under which actions are allowed or denied. You can't specify the principal in an identity-based policy because it applies to the user or role to which it is attached. To learn about all of the elements that you can use in a JSON policy, see IAM JSON policy elements reference in the *IAM User Guide*.

Identity-based policy examples for Amazon RDS

To view examples of Amazon RDS identity-based policies, see Identity-based policy examples for Amazon RDS.

Resource-based policies within Amazon RDS

Supports resource-based policies: No.

Resource-based policies are JSON policy documents that you attach to a resource. Examples of resource-based policies are IAM *role trust policies* and Amazon S3 *bucket policies*. In services that support resource-based policies, service administrators can use them to control access to a specific resource. For the resource where the policy is attached, the policy defines what actions a specified principal can perform on that resource and under what conditions. You must specify a principal in a resource-based policy. Principals can include accounts, users, roles, federated users, or AWS services.

To enable cross-account access, you can specify an entire account or IAM entities in another account as the principal in a resource-based policy. Adding a cross-account principal to a resource-

based policy is only half of establishing the trust relationship. When the principal and the resource are in different AWS accounts, an IAM administrator in the trusted account must also grant the principal entity (user or role) permission to access the resource. They grant permission by attaching an identity-based policy to the entity. However, if a resource-based policy grants access to a principal in the same account, no additional identity-based policy is required. For more information, see Cross account resource access in IAM in the *IAM User Guide*.

Policy actions for Amazon RDS

Supports policy actions: Yes.

Administrators can use AWS JSON policies to specify who has access to what. That is, which **principal** can perform **actions** on what **resources**, and under what **conditions**.

The `Action` element of a JSON policy describes the actions that you can use to allow or deny access in a policy. Policy actions usually have the same name as the associated AWS API operation. There are some exceptions, such as *permission-only actions* that don't have a matching API operation. There are also some operations that require multiple actions in a policy. These additional actions are called *dependent actions*.

Include actions in a policy to grant permissions to perform the associated operation.

Policy actions in Amazon RDS use the following prefix before the action: `rds:`. For example, to grant someone permission to describe DB instances with the Amazon RDS `DescribeDBInstances` API operation, you include the `rds:DescribeDBInstances` action in their policy. Policy statements must include either an `Action` or `NotAction` element. Amazon RDS defines its own set of actions that describe tasks that you can perform with this service.

To specify multiple actions in a single statement, separate them with commas as follows.

```
"Action": [
      "rds:action1",
      "rds:action2"
```

You can specify multiple actions using wildcards (*). For example, to specify all actions that begin with the word `Describe`, include the following action.

```
"Action": "rds:Describe*"
```

To see a list of Amazon RDS actions, see Actions Defined by Amazon RDS in the *Service Authorization Reference*.

Policy resources for Amazon RDS

Supports policy resources: Yes.

Administrators can use AWS JSON policies to specify who has access to what. That is, which **principal** can perform **actions** on what **resources**, and under what **conditions**.

The `Resource` JSON policy element specifies the object or objects to which the action applies. Statements must include either a `Resource` or a `NotResource` element. As a best practice, specify a resource using its Amazon Resource Name (ARN). You can do this for actions that support a specific resource type, known as *resource-level permissions*.

For actions that don't support resource-level permissions, such as listing operations, use a wildcard (*) to indicate that the statement applies to all resources.

```
"Resource": "*"
```

The DB instance resource has the following Amazon Resource Name (ARN).

```
arn:${Partition}:rds:${Region}:${Account}:{ResourceType}/${Resource}
```

For more information about the format of ARNs, see Amazon Resource Names (ARNs) and AWS service namespaces.

For example, to specify the `dbtest` DB instance in your statement, use the following ARN.

```
"Resource": "arn:aws:rds:us-west-2:123456789012:db:dbtest"
```

To specify all DB instances that belong to a specific account, use the wildcard (*).

```
"Resource": "arn:aws:rds:us-east-1:123456789012:db:*"
```

Some RDS API operations, such as those for creating resources, can't be performed on a specific resource. In those cases, use the wildcard (*).

```
"Resource": "*"
```

Many Amazon RDS API operations involve multiple resources. For example, `CreateDBInstance` creates a DB instance. You can specify that an user must use a specific security group and parameter group when creating a DB instance. To specify multiple resources in a single statement, separate the ARNs with commas.

```
"Resource": [
      "resource1",
      "resource2"
```

To see a list of Amazon RDS resource types and their ARNs, see Resources Defined by Amazon RDS in the *Service Authorization Reference*. To learn with which actions you can specify the ARN of each resource, see Actions Defined by Amazon RDS.

Policy condition keys for Amazon RDS

Supports service-specific policy condition keys: Yes.

Administrators can use AWS JSON policies to specify who has access to what. That is, which **principal** can perform **actions** on what **resources**, and under what **conditions**.

The `Condition` element (or `Condition` *block*) lets you specify conditions in which a statement is in effect. The `Condition` element is optional. You can create conditional expressions that use condition operators, such as equals or less than, to match the condition in the policy with values in the request.

If you specify multiple `Condition` elements in a statement, or multiple keys in a single `Condition` element, AWS evaluates them using a logical `AND` operation. If you specify multiple values for a single condition key, AWS evaluates the condition using a logical `OR` operation. All of the conditions must be met before the statement's permissions are granted.

You can also use placeholder variables when you specify conditions. For example, you can grant an IAM user permission to access a resource only if it is tagged with their IAM user name. For more information, see IAM policy elements: variables and tags in the *IAM User Guide*.

AWS supports global condition keys and service-specific condition keys. To see all AWS global condition keys, see AWS global condition context keys in the *IAM User Guide*.

Amazon RDS defines its own set of condition keys and also supports using some global condition keys. To see all AWS global condition keys, see AWS global condition context keys in the *IAM User Guide*.

All RDS API operations support the `aws:RequestedRegion` condition key.

To see a list of Amazon RDS condition keys, see Condition Keys for Amazon RDS in the *Service Authorization Reference*. To learn with which actions and resources you can use a condition key, see Actions Defined by Amazon RDS.

Access control lists (ACLs) in Amazon RDS

Supports access control lists (ACLs): No

Access control lists (ACLs) control which principals (account members, users, or roles) have permissions to access a resource. ACLs are similar to resource-based policies, although they do not use the JSON policy document format.

Attribute-based access control (ABAC) in policies with Amazon RDS tags

Supports attribute-based access control (ABAC) tags in policies: Yes

Attribute-based access control (ABAC) is an authorization strategy that defines permissions based on attributes. In AWS, these attributes are called *tags*. You can attach tags to IAM entities (users or roles) and to many AWS resources. Tagging entities and resources is the first step of ABAC. Then you design ABAC policies to allow operations when the principal's tag matches the tag on the resource that they are trying to access.

ABAC is helpful in environments that are growing rapidly and helps with situations where policy management becomes cumbersome.

To control access based on tags, you provide tag information in the condition element of a policy using the `aws:ResourceTag/key-name`, `aws:RequestTag/key-name`, or `aws:TagKeys` condition keys.

If a service supports all three condition keys for every resource type, then the value is **Yes** for the service. If a service supports all three condition keys for only some resource types, then the value is **Partial**.

For more information about ABAC, see What is ABAC? in the *IAM User Guide*. To view a tutorial with steps for setting up ABAC, see Use attribute-based access control (ABAC) in the *IAM User Guide*.

For more information about tagging Amazon RDS resources, see Specifying conditions: Using custom tags. To view an example identity-based policy for limiting access to a resource based on the tags on that resource, see Grant permission for actions on a resource with a specific tag with two different values.

Using temporary credentials with Amazon RDS

Supports temporary credentials: Yes.

Some AWS services don't work when you sign in using temporary credentials. For additional information, including which AWS services work with temporary credentials, see AWS services that work with IAM in the *IAM User Guide*.

You are using temporary credentials if you sign in to the AWS Management Console using any method except a user name and password. For example, when you access AWS using your company's single sign-on (SSO) link, that process automatically creates temporary credentials. You also automatically create temporary credentials when you sign in to the console as a user and then switch roles. For more information about switching roles, see Switching to a role (console) in the *IAM User Guide*.

You can manually create temporary credentials using the AWS CLI or AWS API. You can then use those temporary credentials to access AWS. AWS recommends that you dynamically generate temporary credentials instead of using long-term access keys. For more information, see Temporary security credentials in IAM.

Forward access sessions for Amazon RDS

Supports forward access sessions: Yes.

When you use an IAM user or role to perform actions in AWS, you are considered a principal. When you use some services, you might perform an action that then initiates another action in a different service. FAS uses the permissions of the principal calling an AWS service, combined with the requesting AWS service to make requests to downstream services. FAS requests are only made when a service receives a request that requires interactions with other AWS services or resources to complete. In this case, you must have permissions to perform both actions. For policy details when making FAS requests, see Forward access sessions.

Service roles for Amazon RDS

Supports service roles: Yes.

A service role is an IAM role that a service assumes to perform actions on your behalf. An IAM administrator can create, modify, and delete a service role from within IAM. For more information, see Creating a role to delegate permissions to an AWS service in the *IAM User Guide*.

> **Warning**
>
> Changing the permissions for a service role might break Amazon RDS functionality. Edit service roles only when Amazon RDS provides guidance to do so.

Service-linked roles for Amazon RDS

Supports service-linked roles: Yes.

A service-linked role is a type of service role that is linked to an AWS service. The service can assume the role to perform an action on your behalf. Service-linked roles appear in your AWS account and are owned by the service. An IAM administrator can view, but not edit the permissions for service-linked roles.

For details about using Amazon RDS service-linked roles, see Using service-linked roles for Amazon RDS.

Identity-based policy examples for Amazon RDS

By default, permission sets and roles don't have permission to create or modify Amazon RDS resources. They also can't perform tasks using the AWS Management Console, AWS CLI, or AWS API. An administrator must create IAM policies that grant permission sets and roles permission to perform specific API operations on the specified resources they need. The administrator must then attach those policies to the permission sets or roles that require those permissions.

To learn how to create an IAM identity-based policy using these example JSON policy documents, see Creating policies on the JSON tab in the *IAM User Guide*.

Topics

- Permission policies to create, modify and, delete resources in Amazon RDS
- Example policies: Using condition keys
- Specifying conditions: Using custom tags

Policy best practices

Identity-based policies determine whether someone can create, access, or delete Amazon RDS resources in your account. These actions can incur costs for your AWS account. When you create or edit identity-based policies, follow these guidelines and recommendations:

- **Get started with AWS managed policies and move toward least-privilege permissions** – To get started granting permissions to your users and workloads, use the *AWS managed policies* that grant permissions for many common use cases. They are available in your AWS account. We recommend that you reduce permissions further by defining AWS customer managed policies that are specific to your use cases. For more information, see AWS managed policies or AWS managed policies for job functions in the *IAM User Guide*.
- **Apply least-privilege permissions** – When you set permissions with IAM policies, grant only the permissions required to perform a task. You do this by defining the actions that can be taken on specific resources under specific conditions, also known as *least-privilege permissions*. For more information about using IAM to apply permissions, see Policies and permissions in IAM in the *IAM User Guide*.
- **Use conditions in IAM policies to further restrict access** – You can add a condition to your policies to limit access to actions and resources. For example, you can write a policy condition to specify that all requests must be sent using SSL. You can also use conditions to grant access to service actions if they are used through a specific AWS service, such as AWS CloudFormation. For more information, see IAM JSON policy elements: Condition in the *IAM User Guide*.
- **Use IAM Access Analyzer to validate your IAM policies to ensure secure and functional permissions** – IAM Access Analyzer validates new and existing policies so that the policies adhere to the IAM policy language (JSON) and IAM best practices. IAM Access Analyzer provides more than 100 policy checks and actionable recommendations to help you author secure and functional policies. For more information, see IAM Access Analyzer policy validation in the *IAM User Guide*.
- **Require multi-factor authentication (MFA)** – If you have a scenario that requires IAM users or a root user in your AWS account, turn on MFA for additional security. To require MFA when API operations are called, add MFA conditions to your policies. For more information, see Configuring MFA-protected API access in the *IAM User Guide*.

For more information about best practices in IAM, see Security best practices in IAM in the *IAM User Guide*.

Using the Amazon RDS console

To access the Amazon RDS console, you must have a minimum set of permissions. These permissions must allow you to list and view details about the Amazon RDS resources in your AWS account. If you create an identity-based policy that is more restrictive than the minimum required permissions, the console won't function as intended for entities (users or roles) with that policy.

You don't need to allow minimum console permissions for users that are making calls only to the AWS CLI or the AWS API. Instead, allow access to only the actions that match the API operation that you're trying to perform.

To ensure that those entities can still use the Amazon RDS console, also attach the following AWS managed policy to the entities.

```
AmazonRDSReadOnlyAccess
```

For more information, see Adding permissions to a user in the *IAM User Guide*.

Permissions required to use the console

For a user to work with the console, that user must have a minimum set of permissions. These permissions allow the user to describe the Amazon RDS resources for their AWS account and to provide other related information, including Amazon EC2 security and network information.

If you create an IAM policy that is more restrictive than the minimum required permissions, the console doesn't function as intended for users with that IAM policy. To ensure that those users can still use the console, also attach the `AmazonRDSReadOnlyAccess` managed policy to the user, as described in Managing access using policies.

You don't need to allow minimum console permissions for users that are making calls only to the AWS CLI or the Amazon RDS API.

The following policy grants full access to all Amazon RDS resources for the root AWS account:

```
AmazonRDSFullAccess
```

Allow users to view their own permissions

This example shows how you might create a policy that allows IAM users to view the inline and managed policies that are attached to their user identity. This policy includes permissions to complete this action on the console or programmatically using the AWS CLI or AWS API.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "ViewOwnUserInfo",
            "Effect": "Allow",
            "Action": [
                "iam:GetUserPolicy",
                "iam:ListGroupsForUser",
                "iam:ListAttachedUserPolicies",
                "iam:ListUserPolicies",
                "iam:GetUser"
            ],
            "Resource": ["arn:aws:iam::*:user/${aws:username}"]
        },
        {
            "Sid": "NavigateInConsole",
            "Effect": "Allow",
            "Action": [
                "iam:GetGroupPolicy",
                "iam:GetPolicyVersion",
                "iam:GetPolicy",
                "iam:ListAttachedGroupPolicies",
                "iam:ListGroupPolicies",
                "iam:ListPolicyVersions",
                "iam:ListPolicies",
                "iam:ListUsers"
            ],
            "Resource": "*"
        }
    ]
}
```

Permission policies to create, modify and, delete resources in Amazon RDS

The following sections present examples of permission policies that grant and restrict access to resources:

Allow a user to create DB instances in an AWS account

The following is an example policy that allows the account with the ID `123456789012` to create DB instances for your AWS account. The policy requires that the name of the new DB instance begin with `test`. The new DB instance must also use the MySQL database engine and the `db.t2.micro` DB instance class. In addition, the new DB instance must use an option group and a DB parameter group that starts with `default`, and it must use the `default` subnet group.

```
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Sid": "AllowCreateDBInstanceOnly",
         "Effect": "Allow",
         "Action": [
            "rds:CreateDBInstance"
         ],
         "Resource": [
            "arn:aws:rds:*:123456789012:db:test*",
            "arn:aws:rds:*:123456789012:og:default*",
            "arn:aws:rds:*:123456789012:pg:default*",
            "arn:aws:rds:*:123456789012:subgrp:default"
         ],
         "Condition": {
            "StringEquals": {
               "rds:DatabaseEngine": "mysql",
               "rds:DatabaseClass": "db.t2.micro"
            }
         }
      }
   ]
}
```

The policy includes a single statement that specifies the following permissions for the user:

- The policy allows the account to create a DB instance using the CreateDBInstance API operation (this also applies to the create-db-instance AWS CLI command and the AWS Management Console).
- The `Resource` element specifies that the user can perform actions on or with resources. You specify resources using an Amazon Resources Name (ARN). This ARN includes the name of the service that the resource belongs to (`rds`), the AWS Region (* indicates any region in this

example), the AWS account number (123456789012 is the account number in this example), and the type of resource. For more information about creating ARNs, see Amazon Resource Names (ARNs) in Amazon RDS.

The Resource element in the example specifies the following policy constraints on resources for the user:

- The DB instance identifier for the new DB instance must begin with test (for example, testCustomerData1, test-region2-data).
- The option group for the new DB instance must begin with default.
- The DB parameter group for the new DB instance must begin with default.
- The subnet group for the new DB instance must be the default subnet group.

- The Condition element specifies that the DB engine must be MySQL and the DB instance class must be db.t2.micro. The Condition element specifies the conditions when a policy should take effect. You can add additional permissions or restrictions by using the Condition element. For more information about specifying conditions, see Policy condition keys for Amazon RDS. This example specifies the rds:DatabaseEngine and rds:DatabaseClass conditions. For information about the valid condition values for rds:DatabaseEngine, see the list under the Engine parameter in CreateDBInstance. For information about the valid condition values for rds:DatabaseClass, see Supported DB engines for DB instance classes .

The policy doesn't specify the Principal element because in an identity-based policy you don't specify the principal who gets the permission. When you attach policy to a user, the user is the implicit principal. When you attach a permission policy to an IAM role, the principal identified in the role's trust policy gets the permissions.

To see a list of Amazon RDS actions, see Actions Defined by Amazon RDS in the *Service Authorization Reference*.

Allow a user to perform any describe action on any RDS resource

The following permissions policy grants permissions to a user to run all of the actions that begin with Describe. These actions show information about an RDS resource, such as a DB instance. The wildcard character (*) in the Resource element indicates that the actions are allowed for all Amazon RDS resources owned by the account.

```
{
   "Version": "2012-10-17",
```

```
   "Statement": [
      {
         "Sid": "AllowRDSDescribe",
         "Effect": "Allow",
         "Action": "rds:Describe*",
         "Resource": "*"
      }
   ]
}
```

Allow a user to create a DB instance that uses the specified DB parameter group and subnet group

The following permissions policy grants permissions to allow a user to only create a DB instance that must use the mydbpg DB parameter group and the `mydbsubnetgroup` DB subnet group.

```
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Sid": "VisualEditor0",
         "Effect": "Allow",
         "Action": "rds:CreateDBInstance",
         "Resource": [
            "arn:aws:rds:*:*:pg:mydbpg",
            "arn:aws:rds:*:*:subgrp:mydbsubnetgroup"
         ]
      }
   ]
}
```

Grant permission for actions on a resource with a specific tag with two different values

You can use conditions in your identity-based policy to control access to Amazon RDS resources based on tags. The following policy allows permission to perform the `CreateDBSnapshot` API operation on DB instances with either the `stage` tag set to `development` or `test`.

```
{
   "Version":"2012-10-17",
   "Statement":[
      {
         "Sid":"AllowAnySnapshotName",
```

```
         "Effect":"Allow",
         "Action":[
            "rds:CreateDBSnapshot"
         ],
         "Resource":"arn:aws:rds:*:123456789012:snapshot:*"
      },
      {
         "Sid":"AllowDevTestToCreateSnapshot",
         "Effect":"Allow",
         "Action":[
            "rds:CreateDBSnapshot"
         ],
         "Resource":"arn:aws:rds:*:123456789012:db:*",
         "Condition":{
            "StringEquals":{
                "rds:db-tag/stage":[
                  "development",
                  "test"
               ]
            }
         }
      }
   ]
}
```

The following policy allows permission to perform the `ModifyDBInstance` API operation on DB instances with either the `stage` tag set to `development` or `test`.

```
{
   "Version":"2012-10-17",
   "Statement":[
      {
         "Sid":"AllowChangingParameterOptionSecurityGroups",
         "Effect":"Allow",
         "Action":[
            "rds:ModifyDBInstance"
         ],
         "Resource": [
            "arn:aws:rds:*:123456789012:pg:*",
            "arn:aws:rds:*:123456789012:secgrp:*",
            "arn:aws:rds:*:123456789012:og:*"
         ]
      },
```

```
      {
         "Sid":"AllowDevTestToModifyInstance",
         "Effect":"Allow",
         "Action":[
            "rds:ModifyDBInstance"
         ],
         "Resource":"arn:aws:rds:*:123456789012:db:*",
         "Condition":{
            "StringEquals":{
                "rds:db-tag/stage":[
                  "development",
                  "test"
               ]
            }
         }
      }
   ]
}
```

Prevent a user from deleting a DB instance

The following permissions policy grants permissions to prevent a user from deleting a specific DB instance. For example, you might want to deny the ability to delete your production DB instances to any user that is not an administrator.

```
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Sid": "DenyDelete1",
         "Effect": "Deny",
         "Action": "rds:DeleteDBInstance",
         "Resource": "arn:aws:rds:us-west-2:123456789012:db:my-mysql-instance"
      }
   ]
}
```

Deny all access to a resource

You can explicitly deny access to a resource. Deny policies take precedence over allow policies. The following policy explicitly denies a user the ability to manage a resource:

```
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Deny",
         "Action": "rds:*",
         "Resource": "arn:aws:rds:us-east-1:123456789012:db:mydb"
      }
   ]
}
```

Example policies: Using condition keys

Following are examples of how you can use condition keys in Amazon RDS IAM permissions policies.

Example 1: Grant permission to create a DB instance that uses a specific DB engine and isn't MultiAZ

The following policy uses an RDS condition key and allows a user to create only DB instances that use the MySQL database engine and don't use MultiAZ. The `Condition` element indicates the requirement that the database engine is MySQL.

```
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Sid": "AllowMySQLCreate",
         "Effect": "Allow",
         "Action": "rds:CreateDBInstance",
         "Resource": "*",
         "Condition": {
            "StringEquals": {
               "rds:DatabaseEngine": "mysql"
            },
            "Bool": {
               "rds:MultiAz": false
            }
         }
      }
   ]
}
```

Example 2: Explicitly deny permission to create DB instances for certain DB instance classes and create DB instances that use Provisioned IOPS

The following policy explicitly denies permission to create DB instances that use the DB instance classes `r3.8xlarge` and `m4.10xlarge`, which are the largest and most expensive DB instance classes. This policy also prevents users from creating DB instances that use Provisioned IOPS, which incurs an additional cost.

Explicitly denying permission supersedes any other permissions granted. This ensures that identities to not accidentally get permission that you never want to grant.

```
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Sid": "DenyLargeCreate",
         "Effect": "Deny",
         "Action": "rds:CreateDBInstance",
         "Resource": "*",
         "Condition": {
            "StringEquals": {
               "rds:DatabaseClass": [
                  "db.r3.8xlarge",
                  "db.m4.10xlarge"
               ]
            }
         }
      },
      {
         "Sid": "DenyPIOPSCreate",
         "Effect": "Deny",
         "Action": "rds:CreateDBInstance",
         "Resource": "*",
         "Condition": {
            "NumericNotEquals": {
               "rds:Piops": "0"
            }
         }
      }
   ]
}
```

Example 3: Limit the set of tag keys and values that can be used to tag a resource

The following policy uses an RDS condition key and allows the addition of a tag with the key `stage` to be added to a resource with the values `test`, `qa`, and `production`.

```
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": [
            "rds:AddTagsToResource",
            "rds:RemoveTagsFromResource"
         ],
         "Resource": "*",
         "Condition": {
            "streq": {
               "rds:req-tag/stage": [
                  "test",
                  "qa",
                  "production"
               ]
            }
         }
      }
   ]
}
```

Specifying conditions: Using custom tags

Amazon RDS supports specifying conditions in an IAM policy using custom tags.

For example, suppose that you add a tag named `environment` to your DB instances with values such as `beta`, `staging`, `production`, and so on. If you do, you can create a policy that restricts certain users to DB instances based on the `environment` tag value.

> **Note**
>
> Custom tag identifiers are case-sensitive.

The following table lists the RDS tag identifiers that you can use in a `Condition` element.

RDS tag identifier	Applies to
`db-tag`	DB instances, including read replicas
`snapshot-tag`	DB snapshots
`ri-tag`	Reserved DB instances
`og-tag`	DB option groups
`pg-tag`	DB parameter groups
`subgrp-tag`	DB subnet groups
`es-tag`	Event subscriptions
`cluster-tag`	DB clusters
`cluster-pg-tag`	DB cluster parameter groups
`cluster-snapshot-tag`	DB cluster snapshots

The syntax for a custom tag condition is as follows:

```
"Condition":{"StringEquals":{"rds:rds-tag-identifier/tag-name":
["value"]} }
```

For example, the following `Condition` element applies to DB instances with a tag named `environment` and a tag value of `production`.

```
"Condition":{"StringEquals":{"rds:db-tag/environment": ["production"]} }
```

For information about creating tags, see Tagging Amazon RDS resources.

Important

If you manage access to your RDS resources using tagging, we recommend that you secure access to the tags for your RDS resources. You can manage access to tags by creating policies for the `AddTagsToResource` and `RemoveTagsFromResource` actions.

For example, the following policy denies users the ability to add or remove tags for all resources. You can then create policies to allow specific users to add or remove tags.

```
{
   "Version":"2012-10-17",
   "Statement":[
      {
         "Sid":"DenyTagUpdates",
         "Effect":"Deny",
         "Action":[
            "rds:AddTagsToResource",
            "rds:RemoveTagsFromResource"
         ],
         "Resource":"*"
      }
   ]
}
```

To see a list of Amazon RDS actions, see Actions Defined by Amazon RDS in the *Service Authorization Reference*.

Example policies: Using custom tags

Following are examples of how you can use custom tags in Amazon RDS IAM permissions policies. For more information about adding tags to an Amazon RDS resource, see Amazon Resource Names (ARNs) in Amazon RDS.

Note

All examples use the us-west-2 region and contain fictitious account IDs.

Example 1: Grant permission for actions on a resource with a specific tag with two different values

The following policy allows permission to perform the `CreateDBSnapshot` API operation on DB instances with either the `stage` tag set to `development` or `test`.

```
{
```

```
   "Version":"2012-10-17",
   "Statement":[
      {
         "Sid":"AllowAnySnapshotName",
         "Effect":"Allow",
         "Action":[
            "rds:CreateDBSnapshot"
         ],
         "Resource":"arn:aws:rds:*:123456789012:snapshot:*"
      },
      {
         "Sid":"AllowDevTestToCreateSnapshot",
         "Effect":"Allow",
         "Action":[
            "rds:CreateDBSnapshot"
         ],
         "Resource":"arn:aws:rds:*:123456789012:db:*",
         "Condition":{
            "StringEquals":{
                "rds:db-tag/stage":[
                  "development",
                  "test"
               ]
            }
         }
      }
   ]
}
```

The following policy allows permission to perform the `ModifyDBInstance` API operation on DB instances with either the `stage` tag set to `development` or `test`.

```
{
   "Version":"2012-10-17",
   "Statement":[
      {
         "Sid":"AllowChangingParameterOptionSecurityGroups",
         "Effect":"Allow",
         "Action":[
            "rds:ModifyDBInstance"
         ],
         "Resource":" [
            "arn:aws:rds:*:123456789012:pg:*",
```

```
            "arn:aws:rds:*:123456789012:secgrp:*",
            "arn:aws:rds:*:123456789012:og:*"
         ]
      },
      {
         "Sid":"AllowDevTestToModifyInstance",
         "Effect":"Allow",
         "Action":[
            "rds:ModifyDBInstance"
         ],
         "Resource":"arn:aws:rds:*:123456789012:db:*",
         "Condition":{
            "StringEquals":{
                "rds:db-tag/stage":[
                  "development",
                  "test"
               ]
            }
         }
      }
   ]
}
```

Example 2: Explicitly deny permission to create a DB instance that uses specified DB parameter groups

The following policy explicitly denies permission to create a DB instance that uses DB parameter groups with specific tag values. You might apply this policy if you require that a specific customer-created DB parameter group always be used when creating DB instances. Policies that use `Deny` are most often used to restrict access that was granted by a broader policy.

Explicitly denying permission supersedes any other permissions granted. This ensures that identities to not accidentally get permission that you never want to grant.

```
{
   "Version":"2012-10-17",
   "Statement":[
      {
         "Sid":"DenyProductionCreate",
         "Effect":"Deny",
         "Action":"rds:CreateDBInstance",
```

```
         "Resource":"arn:aws:rds:*:123456789012:pg:*",
         "Condition":{
            "StringEquals":{
               "rds:pg-tag/usage":"prod"
            }
         }
      }
   ]
}
```

Example 3: Grant permission for actions on a DB instance with an instance name that is prefixed with a user name

The following policy allows permission to call any API (except to `AddTagsToResource` or `RemoveTagsFromResource`) on a DB instance that has a DB instance name that is prefixed with the user's name and that has a tag called `stage` equal to `devo` or that has no tag called `stage`.

The `Resource` line in the policy identifies a resource by its Amazon Resource Name (ARN). For more information about using ARNs with Amazon RDS resources, see Amazon Resource Names (ARNs) in Amazon RDS.

```
{
   "Version":"2012-10-17",
   "Statement":[
      {
         "Sid":"AllowFullDevAccessNoTags",
         "Effect":"Allow",
         "NotAction":[
            "rds:AddTagsToResource",
            "rds:RemoveTagsFromResource"
         ],
         "Resource":"arn:aws:rds:*:123456789012:db:${aws:username}*",
         "Condition":{
            "StringEqualsIfExists":{
               "rds:db-tag/stage":"devo"
            }
         }
      }
   ]
}
```

AWS managed policies for Amazon RDS

To add permissions to permission sets and roles, it's easier to use AWS managed policies than to write policies yourself. It takes time and expertise to create IAM customer managed policies that provide your team with only the permissions they need. To get started quickly, you can use our AWS managed policies. These policies cover common use cases and are available in your AWS account. For more information about AWS managed policies, see AWS managed policies in the *IAM User Guide*.

AWS services maintain and update AWS managed policies. You can't change the permissions in AWS managed policies. Services occasionally add additional permissions to an AWS managed policy to support new features. This type of update affects all identities (permission sets and roles) where the policy is attached. Services are most likely to update an AWS managed policy when a new feature is launched or when new operations become available. Services don't remove permissions from an AWS managed policy, so policy updates don't break your existing permissions.

Additionally, AWS supports managed policies for job functions that span multiple services. For example, the `ReadOnlyAccess` AWS managed policy provides read-only access to all AWS services and resources. When a service launches a new feature, AWS adds read-only permissions for new operations and resources. For a list and descriptions of job function policies, see AWS managed policies for job functions in the *IAM User Guide*.

Topics

- AWS managed policy: AmazonRDSBetaServiceRolePolicy

AWS managed policy: AmazonRDSReadOnlyAccess

This policy allows read-only access to Amazon RDS through the AWS Management Console.

Permissions details

This policy includes the following permissions:

- `rds` – Allows principals to describe Amazon RDS resources and list the tags for Amazon RDS resources.
- `cloudwatch` – Allows principals to get Amazon CloudWatch metric statistics.
- `ec2` – Allows principals to describe Availability Zones and networking resources.
- `logs` – Allows principals to describe CloudWatch Logs log streams of log groups, and get CloudWatch Logs log events.
- `devops-guru` – Allows principals to describe resources that have Amazon DevOps Guru coverage, which is specified either by CloudFormation stack names or resource tags.

For more information about this policy, including the JSON policy document, see AmazonRDSReadOnlyAccess in the *AWS Managed Policy Reference Guide*.

AWS managed policy: AmazonRDSFullAccess

This policy provides full access to Amazon RDS through the AWS Management Console.

Permissions details

This policy includes the following permissions:

- `rds` – Allows principals full access to Amazon RDS.
- `application-autoscaling` – Allows principals describe and manage Application Auto Scaling scaling targets and policies.
- `cloudwatch` – Allows principals get CloudWatch metric statics and manage CloudWatch alarms.
- `ec2` – Allows principals to describe Availability Zones and networking resources.
- `logs` – Allows principals to describe CloudWatch Logs log streams of log groups, and get CloudWatch Logs log events.

- `outposts` – Allows principals to get AWS Outposts instance types.
- `pi` – Allows principals to get Performance Insights metrics.
- `sns` – Allows principals to Amazon Simple Notification Service (Amazon SNS) subscriptions and topics, and to publish Amazon SNS messages.
- `devops-guru` – Allows principals to describe resources that have Amazon DevOps Guru coverage, which is specified either by CloudFormation stack names or resource tags.

For more information about this policy, including the JSON policy document, see AmazonRDSFullAccess in the *AWS Managed Policy Reference Guide*.

AWS managed policy: AmazonRDSDataFullAccess

This policy allows full access to use the Data API and the query editor on Aurora Serverless clusters in a specific AWS account. This policy allows the AWS account to get the value of a secret from AWS Secrets Manager.

You can attach the `AmazonRDSDataFullAccess` policy to your IAM identities.

Permissions details

This policy includes the following permissions:

- dbqms – Allows principals to access, create, delete, describe, and update queries. The Database Query Metadata Service (dbqms) is an internal-only service. It provides your recent and saved queries for the query editor on the AWS Management Console for multiple AWS services, including Amazon RDS.
- `rds-data` – Allows principals to run SQL statements on Aurora Serverless databases.
- `secretsmanager` – Allows principals to get the value of a secret from AWS Secrets Manager.

For more information about this policy, including the JSON policy document, see AmazonRDSDataFullAccess in the *AWS Managed Policy Reference Guide*.

AWS managed policy: AmazonRDSEnhancedMonitoringRole

This policy provides access to Amazon CloudWatch Logs for Amazon RDS Enhanced Monitoring.

Permissions details

This policy includes the following permissions:

- `logs` – Allows principals to create CloudWatch Logs log groups and retention policies, and to create and describe CloudWatch Logs log streams of log groups. It also allows principals to put and get CloudWatch Logs log events.

For more information about this policy, including the JSON policy document, see AmazonRDSEnhancedMonitoringRole in the *AWS Managed Policy Reference Guide*.

AWS managed policy: AmazonRDSPerformanceInsightsReadOnly

This policy provides read-only access to Amazon RDS Performance Insights for Amazon RDS DB instances and Amazon Aurora DB clusters.

This policy now includes `Sid` (statement ID) as an identifier for the policy statement.

Permissions details

This policy includes the following permissions:

- `rds` – Allows principals to describe Amazon RDS DB instances and Amazon Aurora DB clusters.
- `pi` – Allows principals make calls to the Amazon RDS Performance Insights API and access Performance Insights metrics.

For more information about this policy, including the JSON policy document, see AmazonRDSPerformanceInsightsReadOnly in the *AWS Managed Policy Reference Guide*.

AWS managed policy: AmazonRDSPerformanceInsightsFullAccess

This policy provides full access to Amazon RDS Performance Insights for Amazon RDS DB instances and Amazon Aurora DB clusters.

This policy now includes `Sid` (statement ID) as an identifier for the policy statement.

Permissions details

This policy includes the following permissions:

- `rds` – Allows principals to describe Amazon RDS DB instances and Amazon Aurora DB clusters.

- `pi` – Allows principals make calls to the Amazon RDS Performance Insights API, and create, view, and delete performance analysis reports.
- `cloudwatch` – Allows principals to list all the Amazon CloudWatch metrics, and get metric data and statistics.

For more information about this policy, including the JSON policy document, see AmazonRDSPerformanceInsightsFullAccess in the *AWS Managed Policy Reference Guide*.

AWS managed policy: AmazonRDSDirectoryServiceAccess

This policy allows Amazon RDS to make calls to the AWS Directory Service.

Permissions details

This policy includes the following permission:

- `ds` – Allows principals to describe AWS Directory Service directories and control authorization to AWS Directory Service directories.

For more information about this policy, including the JSON policy document, see AmazonRDSDirectoryServiceAccess in the *AWS Managed Policy Reference Guide*.

AWS managed policy: AmazonRDSServiceRolePolicy

You can't attach the `AmazonRDSServiceRolePolicy` policy to your IAM entities. This policy is attached to a service-linked role that allows Amazon RDS to perform actions on your behalf. For more information, see Service-linked role permissions for Amazon RDS.

AWS managed policy: AmazonRDSCustomServiceRolePolicy

You can't attach the `AmazonRDSCustomServiceRolePolicy` policy to your IAM entities. This policy is attached to a service-linked role that allows Amazon RDS to call AWS services on behalf of your RDS DB resources.

This policy includes the following permissions:

- `ec2` - Allows RDS Custom to perform backup operations on the DB instance that provides point-in-time restore capabilities.

- `secretsmanager` - Allows RDS Custom to manage DB instance specific secrets created by RDS Custom.
- `cloudwatch` - Allows RDS Custom to upload DB instance metrics and logs to CloudWatch through CloudWatch agent.
- `events`, `sqs` - Allows RDS Custom to send and receive status information about the DB instance.

For more information about this policy, including the JSON policy document, see AmazonRDSCustomServiceRolePolicy in the *AWS Managed Policy Reference Guide*.

AWS managed policy: AmazonRDSCustomInstanceProfileRolePolicy

You shouldn't attach `AmazonRDSCustomInstanceProfileRolePolicy` to your IAM entities. It should only be attached to an instance profile role that is used to grant permissions to your Amazon RDS Custom DB instance to perform various automation actions and database management tasks. Pass the instance profile as `custom-iam-instance-profile` parameter during the RDS Custom instance creation and RDS Custom associates this instance profile to your DB instance.

Permissions details

This policy includes the following permissions:

- `ssm`, `ssmmessages`, `ec2messages` - Allows RDS Custom to communicate, execute automation and maintain agents on the DB instance through Systems Manager.
- `ec2`, `s3` - Allows RDS Custom to perform backup operations on the DB instance that provides point-in-time restore capabilities.
- `secretsmanager` - Allows RDS Custom to manage DB instance specific secrets created by RDS Custom.
- `cloudwatch`, `logs` - Allows RDS Custom to upload DB instance metrics and logs to CloudWatch through CloudWatch agent.
- `events`, `sqs` - Allows RDS Custom to send and receive status information about the DB instance.
- `kms` - Allows RDS Custom to use an instance-specific KMS key to perform encryption of secrets and S3 objects that RDS Custom manages.

For more information about this policy, including the JSON policy document, see AmazonRDSCustomInstanceProfileRolePolicy in the *AWS Managed Policy Reference Guide*.

AWS managed policy: AmazonRDSPreviewServiceRolePolicy

You shouldn't attach `AmazonRDSPreviewServiceRolePolicy` to your IAM entities. This policy is attached to a service-linked role that allows Amazon RDS to call AWS services on behalf of your RDS DB resources. For more information, see Service-linked role for Amazon RDS Preview.

Permissions details

This policy includes the following permissions:

- `ec2` - Allows principals to describe Availability Zones and networking resources.
- `secretsmanager` – Allows principals to get the value of a secret from AWS Secrets Manager.
- `cloudwatch`, `logs` - Allows Amazon RDS to upload DB instance metrics and logs to CloudWatch through CloudWatch agent.

For more information about this policy, including the JSON policy document, see AmazonRDSDataFullAccess in the *AWS Managed Policy Reference Guide*.

AWS managed policy: AmazonRDSBetaServiceRolePolicy

You shouldn't attach `AmazonRDSBetaServiceRolePolicy` to your IAM entities. This policy is attached to a service-linked role that allows Amazon RDS to call AWS services on behalf of your RDS DB resources. For more information, see Service-linked role permissions for Amazon RDS Beta.

Permissions details

This policy includes the following permissions:

- `ec2` - Allows Amazon RDS to perform backup operations on the DB instance that provides point-in-time restore capabilities.
- `secretsmanager` - Allows Amazon RDS to manage DB instance specific secrets created by Amazon RDS.
- `cloudwatch`, `logs` - Allows Amazon RDS to upload DB instance metrics and logs to CloudWatch through CloudWatch agent.

For more information about this policy, including the JSON policy document, see AmazonRDSBetaServiceRolePolicy in the *AWS Managed Policy Reference Guide*.

Amazon RDS updates to AWS managed policies

View details about updates to AWS managed policies for Amazon RDS since this service began tracking these changes. For automatic alerts about changes to this page, subscribe to the RSS feed on the Amazon RDS Document history page.

Change	Description	Date
AWS managed policy: AmazonRDSPreviewServiceRolePolicy – Update to existing policy	Amazon RDS removed `sns:Publish` permission from the `AmazonRDSPreviewServiceRolePolicy` of the `AWSServiceRoleForRDSPreview` service-linked role. For more information, see AWS managed policy: AmazonRDSPreviewServiceRolePolicy.	August 7, 2024
AWS managed policy: AmazonRDSBetaServiceRolePolicy – Update to existing policy	Amazon RDS removed `sns:Publish` permission from the `AmazonRDSBetaServiceRolePolicy` of the `AWSServiceRoleForRDSBeta` service-linked role. For more information, see AWS managed policy: AmazonRDSBetaServiceRolePolicy.	August 7, 2024
Service-linked role permissions for Amazon RDS Custom – Update to existing policy	Amazon RDS added new permissions to the `AmazonRDSCustomServiceRolePolicy` of the `AWSServiceRoleForRDSCustom` service-linked role. The permissions allow	July 18, 2024

Change	Description	Date
	RDS Custom to communicate with Amazon RDS services in another AWS Region and copy EC2 images. For more information, see Service-linked role permissions for Amazon RDS Custom.	
AWS managed policy: AmazonRDSServiceRolePolicy – Update to existing policy	Amazon RDS removed `sns:Publish` permission from the `AmazonRDSServiceRolePolicy` of the `AWSServiceRoleForRDS` service-linked role. For more information, see AWS managed policy: AmazonRDSServiceRolePolicy.	July 2, 2024
Service-linked role permissions for Amazon RDS Custom – Update to existing policy	Amazon RDS added new permissions to the `AmazonRDSCustomServiceRolePolicy` of the `AWSServiceRoleForRDSCustom` service-linked role. This new permission allow RDS Custom to associate a service-role as an instance profile to an RDS Custom instance. For more information, see Service-linked role permissions for Amazon RDS Custom.	April 19, 2024

Change	Description	Date
AWS managed policies for Amazon RDS – Update to existing policy	Amazon RDS added a new permission to the `AmazonRDSCustomServiceRolePolicy` of the `AWSServiceRoleForRDSCustom` service-linked role to allow RDS Custom for SQL Server to modify the underlying database host instance type. RDS also added the `ec2:DescribeInstanceTypes` permission to get instance type information for database host. For more information, see AWS managed policies for Amazon RDS.	April 8, 2024
AWS managed policies for Amazon RDS – New policy	Amazon RDS added a new managed policy named `AmazonRDSCustomInstanceProfileRolePolicy` to allow RDS Custom to perform automation actions and database management tasks through an EC2 instance profile. For more information, see AWS managed policies for Amazon RDS.	February 27, 2024

Change	Description	Date
Service-linked role permissions for Amazon RDS – Update to an existing policy	Amazon RDS added new statement IDs to the `AmazonRDSServiceRolePolicy` of the `AWSServiceRoleForRDS` service-linked role. For more information, see Service-linked role permissions for Amazon RDS.	January 19, 2024
AWS managed policies for Amazon RDS – Update to existing policies	The `AmazonRDSPerformanceInsightsReadOnly` and `AmazonRDSPerformanceInsightsFullAccess` managed policies now includes `Sid` (statement ID) as an identifier in the policy statement. For more information, see AWS managed policy: AmazonRDSPerformanceInsightsReadOnly and AWS managed policy: AmazonRDSPerformanceInsightsFullAccess	October 23, 2023

Change	Description	Date
Service-linked role permissions for Amazon RDS – Update to an existing policy	Amazon RDS added new permissions to the `AmazonRDSCustomServiceRolePolicy` of the `AWSServiceRoleForRDSCustom` service-linked role. These new permissions allow RDS Custom for Oracle to create, modify, and delete EventBridge Managed Rules. For more information, see Service-linked role permissions for Amazon RDS Custom.	September 20, 2023
AWS managed policies for Amazon RDS – Update to existing policy	Amazon RDS added new permissions to `AmazonRDSFullAccess` managed policy. The permissions allow you to generate, view, and delete the performance analysis report for a time period. For more information about configuring access policies for Performance Insights, see Configuring access policies for Performance Insights	August 17, 2023

Change	Description	Date
AWS managed policies for Amazon RDS – New policy and update to existing policy	Amazon RDS added new permissions to `AmazonRDSPerformanceInsightsReadOnly` managed policy and a new managed policy named `AmazonRDSPerformanceInsightsFullAccess`. These permissions allow you to analyse the Performance Insights for a time period, view the analysis results along with the recommendations, and delete the reports. For more information about configuring access policies for Performance Insights, see Configuring access policies for Performance Insights	August 16, 2023
Service-linked role permissions for Amazon RDS – Update to an existing policy	Amazon RDS added new permissions to the `AmazonRDSCustomServiceRolePolicy` of the `AWSServiceRoleForRDSCustom` service-linked role. These new permissions allow RDS Custom for Oracle to use DB snapshots. For more information, see Service-linked role permissions for Amazon RDS Custom.	June 23, 2023

Change	Description	Date
Service-linked role permissions for Amazon RDS – Update to an existing policy	Amazon RDS added new permissions to the `AmazonRDSCustomServiceRolePolicy` of the `AWSServiceRoleForRDSCustom` service-linked role. These new permissions allow RDS Custom for Oracle to use DB snapshots. For more information, see Service-linked role permissions for Amazon RDS Custom.	June 23, 2023
Service-linked role permissions for Amazon RDS – Update to an existing policy	Amazon RDS added new permissions to the `AmazonRDSCustomServiceRolePolicy` of the `AWSServiceRoleForRDSCustom` service-linked role. These new permissions allow RDS Custom to create network interfaces. For more information, see Service-linked role permissions for Amazon RDS Custom.	May 30, 2023

Change	Description	Date
Service-linked role permissions for Amazon RDS – Update to an existing policy	Amazon RDS added new permissions to the `AmazonRDSCustomServiceRolePolicy` of the `AWSServiceRoleForRDSCustom` service-linked role. These new permissions allow RDS Custom to call Amazon EBS to check the storage quota. For more information, see Service-linked role permissions for Amazon RDS Custom.	April 18, 2023

Change	Description	Date
Service-linked role permissions for Amazon RDS – Update to an existing policy	Amazon RDS Custom added new permissions to the `AmazonRDSCustomServiceRolePolicy` of the `AWSServiceRoleForRDSCustom` service-linked role for integration with Amazon SQS. RDS Custom requires integration with Amazon SQS to create and manage SQS queues in the customer account. The SQS queue names follow the format `do-not-delete-rds-custom-[identifier]` and are tagged with `Amazon RDS Custom`. The permission for `ec2:CreateSnapshot` was also added to allow RDS Custom to create backups for volumes attached to the instance. For more information, see Service-linked role permissions for Amazon RDS Custom.	April 6, 2023

Change	Description	Date
AWS managed policies for Amazon RDS – Update to an existing policy	Amazon RDS added a new Amazon CloudWatch namespace `ListMetrics` to `AmazonRDSFullAccess` and `AmazonRDSReadOnlyAccess`. This namespace is required for Amazon RDS to list specific resource usage metrics. For more information, see Overview of managing access permissions to your CloudWatch resources in the *Amazon CloudWatch User Guide*.	April 4, 2023
AWS managed policies for Amazon RDS – Update to an existing policy	Amazon RDS added a new permission to `AmazonRDSFullAccess` and `AmazonRDSReadOnlyAccess` managed policies to allow the display of Amazon DevOps Guru findings in the RDS console. This permission is required to allow the display of DevOps Guru findings. For more information, see Amazon RDS updates to AWS managed policies.	March, 30 2023

Change	Description	Date
Service-linked role permissions for Amazon RDS – Update to an existing policy	Amazon RDS added new permissions to the `AmazonRDSServiceRolePolicy` of the `AWSServiceRoleForRDS` service-linked role for integration with AWS Secrets Manager. RDS requires integration with Secrets Manager for managing master user passwords in Secrets Manager. The secret uses a reserved naming convention and restricts customer updates. For more information, see Password management with Amazon RDS and AWS Secrets Manager.	December 22, 2022

Change	Description	Date
Service-linked role permissions for Amazon RDS – Update to an existing policy	Amazon RDS added new permissions to the `AmazonRDSCustomServiceRolePolicy` of the `AWSServiceRoleForRDSCustom` service-linked role. RDS Custom supports DB clusters. These new permissions in the policy allow RDS Custom to call AWS services on behalf of your DB clusters. For more information, see Service-linked role permissions for Amazon RDS Custom.	November 9, 2022

Change	Description	Date
Service-linked role permissions for Amazon RDS – Update to an existing policy	Amazon RDS added new permissions to the `AWSServiceRoleForRDS` service-linked role for integration with AWS Secrets Manager. Integration with Secrets Manager is required for SQL Server Reporting Services (SSRS) Email to function on RDS. SSRS Email creates a secret on behalf of the customer. The secret uses a reserved naming convention and restricts customer updates. For more information, see Using SSRS Email to send reports.	August 26, 2022

Change	Description	Date
Service-linked role permissions for Amazon RDS – Update to an existing policy	Amazon RDS added a new Amazon CloudWatch namespace to `AmazonRDSPreviewServiceRolePolicy` for `PutMetricData`. This namespace is required for Amazon RDS to publish resource usage metrics. For more information, see Using condition keys to limit access to CloudWatch namespaces in the *Amazon CloudWatch User Guide*.	June 7, 2022
Service-linked role permissions for Amazon RDS – Update to an existing policy	Amazon RDS added a new Amazon CloudWatch namespace to `AmazonRDSBetaServiceRolePolicy` for `PutMetricData`. This namespace is required for Amazon RDS to publish resource usage metrics. For more information, see Using condition keys to limit access to CloudWatch namespaces in the *Amazon CloudWatch User Guide*.	June 7, 2022

Change	Description	Date
Service-linked role permissions for Amazon RDS – Update to an existing policy	Amazon RDS added a new Amazon CloudWatch namespace to `AWSServiceRoleForRDS` for `PutMetricData` . This namespace is required for Amazon RDS to publish resource usage metrics. For more information, see Using condition keys to limit access to CloudWatch namespaces in the *Amazon CloudWatch User Guide*.	April 22, 2022
Service-linked role permissions for Amazon RDS – Update to an existing policy	Amazon RDS added new permissions to the `AWSServiceRoleForRDS` service-linked role to manage permissions for customer-owned IP pools and local gateway route tables (LGW-RTBs). These permissions are required for RDS on Outposts to perform Multi-AZ replication across the Outposts' local network. For more information, see Working with Multi-AZ deployments for Amazon RDS on AWS Outposts.	April 19, 2022

Change	Description	Date
Identity-based policies – Update to an existing policy	Amazon RDS added a new permission to the `AmazonRDSFullAccess` managed policy to describe permissions on LGW-RTBs. This permission is required to describe permissions for RDS on Outposts to perform Multi-AZ replication across the Outposts' local network. For more information, see Working with Multi-AZ deployments for Amazon RDS on AWS Outposts.	April 19, 2022
AWS managed policies for Amazon RDS – New policy	Amazon RDS added a new managed policy named `AmazonRDSPerformanceInsightsReadOnly` to allow Amazon RDS to call AWS services on behalf of your DB instances. For more information about configuring access policies for Performance Insights, see Configuring access policies for Performance Insights	March 10, 2022

Change	Description	Date
Service-linked role permissions for Amazon RDS – Update to an existing policy	Amazon RDS added new Amazon CloudWatch namespaces to `AWSServiceRoleForRDS` for `PutMetricData` . These namespaces are required for Amazon DocumentDB (with MongoDB compatibility) and Amazon Neptune to publish CloudWatch metrics. For more information, see Using condition keys to limit access to CloudWatch namespaces in the *Amazon CloudWatch User Guide*.	March 4, 2022
Service-linked role permissions for Amazon RDS Custom – New policy	Amazon RDS added a new service-linked role named `AWSServiceRoleForRDSCustom` to allow RDS Custom to call AWS services on behalf of your DB instances.	October 26, 2021
Amazon RDS started tracking changes	Amazon RDS started tracking changes for its AWS managed policies.	October 26, 2021

Preventing cross-service confused deputy problems

The *confused deputy problem* is a security issue where an entity that doesn't have permission to perform an action can coerce a more-privileged entity to perform the action. In AWS, cross-service impersonation can result in the confused deputy problem.

Cross-service impersonation can occur when one service (the *calling service*) calls another service (the *called service*). The calling service can be manipulated to use its permissions to act on another customer's resources in a way that it shouldn't have permission to access. To prevent this, AWS provides tools that can help you protect your data for all services with service principals that have been given access to resources in your account. For more information, see The confused deputy problem in the *IAM User Guide*.

To limit the permissions that Amazon RDS gives another service for a specific resource, we recommend using the `aws:SourceArn` and `aws:SourceAccount` global condition context keys in resource policies.

In some cases, the `aws:SourceArn` value doesn't contain the account ID, for example when you use the Amazon Resource Name (ARN) for an Amazon S3 bucket. In these cases, make sure to use both global condition context keys to limit permissions. In some cases, you use both global condition context keys and the `aws:SourceArn` value contains the account ID. In these cases, make sure that the `aws:SourceAccount` value and the account in the `aws:SourceArn` use the same account ID when they're used in the same policy statement. If you want only one resource to be associated with the cross-service access, use `aws:SourceArn`. If you want to allow any resource in the specified AWS account to be associated with the cross-service use, use `aws:SourceAccount`.

Make sure that the value of `aws:SourceArn` is an ARN for an Amazon RDS resource type. For more information, see Amazon Resource Names (ARNs) in Amazon RDS.

The most effective way to protect against the confused deputy problem is to use the `aws:SourceArn` global condition context key with the full ARN of the resource. In some cases, you might not know the full ARN of the resource or you might be specifying multiple resources. In these cases, use the `aws:SourceArn` global context condition key with wildcards (*) for the unknown portions of the ARN. An example is `arn:aws:rds:*:123456789012:*`.

The following example shows how you can use the `aws:SourceArn` and `aws:SourceAccount` global condition context keys in Amazon RDS to prevent the confused deputy problem.

```
{
  "Version": "2012-10-17",
  "Statement": {
    "Sid": "ConfusedDeputyPreventionExamplePolicy",
    "Effect": "Allow",
    "Principal": {
      "Service": "rds.amazonaws.com"
    },
    "Action": "sts:AssumeRole",
    "Condition": {
      "ArnLike": {
        "aws:SourceArn": "arn:aws:rds:us-east-1:123456789012:db:mydbinstance"
      },
      "StringEquals": {
        "aws:SourceAccount": "123456789012"
      }
    }
  }
}
```

For more examples of policies that use the `aws:SourceArn` and `aws:SourceAccount` global condition context keys, see the following sections:

- Granting permissions to publish notifications to an Amazon SNS topic
- Manually creating an IAM role for native backup and restore
- Setting up Windows Authentication for SQL Server DB instances
- Prerequisites for integrating RDS for SQL Server with S3
- Manually creating an IAM role for SQL Server Audit
- Configuring IAM permissions for RDS for Oracle integration with Amazon S3
- Setting up access to an Amazon S3 bucket (PostgreSQL import)
- Setting up access to an Amazon S3 bucket (PostgreSQL export)

IAM database authentication for MariaDB, MySQL, and PostgreSQL

You can authenticate to your DB instance using AWS Identity and Access Management (IAM) database authentication. IAM database authentication works with MariaDB, MySQL, and PostgreSQL. With this authentication method, you don't need to use a password when you connect to a DB instance. Instead, you use an authentication token.

An *authentication token* is a unique string of characters that Amazon RDS generates on request. Authentication tokens are generated using AWS Signature Version 4. Each token has a lifetime of 15 minutes. You don't need to store user credentials in the database, because authentication is managed externally using IAM. You can also still use standard database authentication. The token is only used for authentication and doesn't affect the session after it is established.

IAM database authentication provides the following benefits:

- Network traffic to and from the database is encrypted using Secure Socket Layer (SSL) or Transport Layer Security (TLS). For more information about using SSL/TLS with Amazon RDS, see Using SSL/TLS to encrypt a connection to a DB instance or cluster.
- You can use IAM to centrally manage access to your database resources, instead of managing access individually on each DB instance.
- For applications running on Amazon EC2, you can use profile credentials specific to your EC2 instance to access your database instead of a password, for greater security.

In general, consider using IAM database authentication when your applications create fewer than 200 connections per second, and you don't want to manage usernames and passwords directly in your application code.

The Amazon Web Services (AWS) JDBC Driver supports IAM database authentication. For more information, see AWS IAM Authentication Plugin in the Amazon Web Services (AWS) JDBC Driver GitHub repository.

The Amazon Web Services (AWS) Python Driver supports IAM database authentication. For more information, see AWS IAM Authentication Plugin in the Amazon Web Services (AWS) Python Driver GitHub repository.

- Limitations for IAM database authentication
- Recommendations for IAM database authentication
- Unsupported AWS global condition context keys
- Enabling and disabling IAM database authentication
- Creating and using an IAM policy for IAM database access
- Creating a database account using IAM authentication
- Connecting to your DB instance using IAM authentication

Region and version availability

Feature availability and support varies across specific versions of each database engine, and across AWS Regions. For more information on version and Region availability with Amazon RDS and IAM database authentication, see Supported Regions and DB engines for IAM database authentication in Amazon RDS.

CLI and SDK support

IAM database authentication is available for the AWS CLI and for the following language-specific AWS SDKs:

- AWS SDK for .NET
- AWS SDK for C++
- AWS SDK for Go
- AWS SDK for Java
- AWS SDK for JavaScript
- AWS SDK for PHP
- AWS SDK for Python (Boto3)
- AWS SDK for Ruby

Limitations for IAM database authentication

When using IAM database authentication, the following limitations apply:

- IAM database authentication throttles connections in the following scenarios:

- You exceed 20 connections per second using authentication tokens each signed by a different IAM identity.
- You exceed 200 connections per second using different authentication tokens.

  Connections that use the same authentication token are not throttled. We recommend that you reuse authentication tokens when possible.
- Currently, IAM database authentication doesn't support all global condition context keys.

  For more information about global condition context keys, see AWS global condition context keys in the *IAM User Guide*.
- For PostgreSQL, if the IAM role (`rds_iam`) is added to a user (including the RDS master user), IAM authentication takes precedence over password authentication, so the user must log in as an IAM user.
- For PostgreSQL, Amazon RDS does not support enabling both IAM and Kerberos authentication methods at the same time.
- For PostgreSQL, you cannot use IAM authentication to establish a replication connection.
- You cannot use a custom Route 53 DNS record instead of the DB instance endpoint to generate the authentication token.
- CloudWatch and CloudTrail don't log IAM authentication. These services do not track `generate-db-auth-token` API calls that authorize the IAM role to enable database connection.

Recommendations for IAM database authentication

We recommend the following when using IAM database authentication:

- Use IAM database authentication when your application requires fewer than 200 new IAM database authentication connections per second.

  The database engines that work with Amazon RDS don't impose any limits on authentication attempts per second. However, when you use IAM database authentication, your application must generate an authentication token. Your application then uses that token to connect to the DB instance. If you exceed the limit of maximum new connections per second, then the extra overhead of IAM database authentication can cause connection throttling.

  Consider using connection pooling in your applications to mitigate constant connection creation. This can reduce the overhead from IAM DB authentication and allow your applications to reuse

existing connections. Alternatively, consider using RDS Proxy for these use cases. RDS Proxy has additional costs. See RDS Proxy pricing.

- The size of an IAM database authentication token depends on many things including the number of IAM tags, IAM service policies, ARN lengths, as well as other IAM and database properties. The minimum size of this token is generally about 1 KB but can be larger. Since this token is used as the password in the connection string to the database using IAM authentication, you should ensure that your database driver (e.g., ODBC) and/or any tools do not limit or otherwise truncate this token due to its size. A truncated token will cause the authentication validation done by the database and IAM to fail.
- If you are using temporary credentials when creating an IAM database authentication token, the temporary credentials must still be valid when using the IAM database authentication token to make a connection request.

Unsupported AWS global condition context keys

IAM database authentication does not support the following subset of AWS global condition context keys.

- `aws:Referer`
- `aws:SourceIp`
- `aws:SourceVpc`
- `aws:SourceVpce`
- `aws:UserAgent`
- `aws:VpcSourceIp`

For more information, see AWS global condition context keys in the *IAM User Guide*.

Enabling and disabling IAM database authentication

By default, IAM database authentication is disabled on DB instances. You can enable or disable IAM database authentication using the AWS Management Console, AWS CLI, or the API.

You can enable IAM database authentication when you perform one of the following actions:

- To create a new DB instance with IAM database authentication enabled, see Creating an Amazon RDS DB instance.

- To modify a DB instance to enable IAM database authentication, see Modifying an Amazon RDS DB instance.
- To restore a DB instance from a snapshot with IAM database authentication enabled, see Restoring to a DB instance.
- To restore a DB instance to a point in time with IAM database authentication enabled, see Restoring a DB instance to a specified time.

IAM authentication for PostgreSQL DB instances requires that the SSL value be 1. You can't enable IAM authentication for a PostgreSQL DB instance if the SSL value is 0. You can't change the SSL value to 0 if IAM authentication is enabled for a PostgreSQL DB instance.

Console

Each creation or modification workflow has a **Database authentication** section, where you can enable or disable IAM database authentication. In that section, choose **Password and IAM database authentication** to enable IAM database authentication.

To enable or disable IAM database authentication for an existing DB instance

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.
3. Choose the DB instance that you want to modify.

   > **Note**
   >
   > Make sure that the DB instance is compatible with IAM authentication. Check the compatibility requirements in Region and version availability.

4. Choose **Modify**.
5. In the **Database authentication** section, choose **Password and IAM database authentication** to enable IAM database authentication. Choose **Password authentication** or **Password and Kerberos authentication** to disable IAM authentication.
6. Choose **Continue**.
7. To apply the changes immediately, choose **Immediately** in the **Scheduling of modifications** section.
8. Choose **Modify DB instance** .

AWS CLI

To create a new DB instance with IAM authentication by using the AWS CLI, use the `create-db-instance` command. Specify the `--enable-iam-database-authentication` option, as shown in the following example.

```
aws rds create-db-instance \
    --db-instance-identifier mydbinstance \
    --db-instance-class db.m3.medium \
    --engine MySQL \
    --allocated-storage 20 \
    --master-username masterawsuser \
    --manage-master-user-password \
    --enable-iam-database-authentication
```

To update an existing DB instance to have or not have IAM authentication, use the AWS CLI command `modify-db-instance`. Specify either the `--enable-iam-database-authentication` or `--no-enable-iam-database-authentication` option, as appropriate.

> **Note**
>
> Make sure that the DB instance is compatible with IAM authentication. Check the compatibility requirements in Region and version availability.

By default, Amazon RDS performs the modification during the next maintenance window. If you want to override this and enable IAM DB authentication as soon as possible, use the `--apply-immediately` parameter.

The following example shows how to immediately enable IAM authentication for an existing DB instance.

```
aws rds modify-db-instance \
    --db-instance-identifier mydbinstance \
    --apply-immediately \
    --enable-iam-database-authentication
```

If you are restoring a DB instance, use one of the following AWS CLI commands:

- `restore-db-instance-to-point-in-time`

- `restore-db-instance-from-db-snapshot`

The IAM database authentication setting defaults to that of the source snapshot. To change this setting, set the `--enable-iam-database-authentication` or `--no-enable-iam-database-authentication` option, as appropriate.

RDS API

To create a new DB instance with IAM authentication by using the API, use the API operation `CreateDBInstance`. Set the `EnableIAMDatabaseAuthentication` parameter to `true`.

To update an existing DB instance to have IAM authentication, use the API operation `ModifyDBInstance`. Set the `EnableIAMDatabaseAuthentication` parameter to `true` to enable IAM authentication, or `false` to disable it.

> **Note**
>
> Make sure that the DB instance is compatible with IAM authentication. Check the compatibility requirements in Region and version availability.

If you are restoring a DB instance, use one of the following API operations:

- `RestoreDBInstanceFromDBSnapshot`
- `RestoreDBInstanceToPointInTime`

The IAM database authentication setting defaults to that of the source snapshot. To change this setting, set the `EnableIAMDatabaseAuthentication` parameter to `true` to enable IAM authentication, or `false` to disable it.

Creating and using an IAM policy for IAM database access

To allow a user or role to connect to your DB instance, you must create an IAM policy. After that, you attach the policy to a permissions set or role.

> **Note**
>
> To learn more about IAM policies, see Identity and access management for Amazon RDS.

The following example policy allows a user to connect to a DB instance using IAM database authentication.

```
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": [
             "rds-db:connect"
         ],
         "Resource": [
             "arn:aws:rds-db:us-east-2:1234567890:dbuser:db-ABCDEFGHIJKL01234/db_user"
         ]
      }
   ]
}
```

Important

A user with administrator permissions can access DB instances without explicit permissions in an IAM policy. If you want to restrict administrator access to DB instances, you can create an IAM role with the appropriate, lesser privileged permissions and assign it to the administrator.

Note

Don't confuse the `rds-db:` prefix with other RDS API operation prefixes that begin with `rds:`. You use the `rds-db:` prefix and the `rds-db:connect` action only for IAM database authentication. They aren't valid in any other context.

The example policy includes a single statement with the following elements:

- `Effect` – Specify `Allow` to grant access to the DB instance. If you don't explicitly allow access, then access is denied by default.
- `Action` – Specify `rds-db:connect` to allow connections to the DB instance.

- `Resource` – Specify an Amazon Resource Name (ARN) that describes one database account in one DB instance. The ARN format is as follows.

```
arn:aws:rds-db:region:account-id:dbuser:DbiResourceId/db-user-name
```

In this format, replace the following:

- *`region`* is the AWS Region for the DB instance. In the example policy, the AWS Region is `us-east-2`.
- *`account-id`* is the AWS account number for the DB instance. In the example policy, the account number is `1234567890`. The user must be in the same account as the account for the DB instance.

  To perform cross-account access, create an IAM role with the policy shown above in the account for the DB instance and allow your other account to assume the role.
- *`DbiResourceId`* is the identifier for the DB instance. This identifier is unique to an AWS Region and never changes. In the example policy, the identifier is `db-ABCDEFGHIJKL01234`.

  To find a DB instance resource ID in the AWS Management Console for Amazon RDS, choose the DB instance to see its details. Then choose the **Configuration** tab. The **Resource ID** is shown in the **Configuration** section.

  Alternatively, you can use the AWS CLI command to list the identifiers and resource IDs for all of your DB instance in the current AWS Region, as shown following.

```
aws rds describe-db-instances --query "DBInstances[*].
[DBInstanceIdentifier,DbiResourceId]"
```

  If you are using Amazon Aurora, specify a `DbClusterResourceId` instead of a `DbiResourceId`. For more information, see Creating and using an IAM policy for IAM database access in the *Amazon Aurora User Guide*.

> **Note**
>
> If you are connecting to a database through RDS Proxy, specify the proxy resource ID, such as `prx-ABCDEFGHIJKL01234`. For information about using IAM database authentication with RDS Proxy, see Connecting to a proxy using IAM authentication.

- *`db-user-name`* is the name of the database account to associate with IAM authentication. In the example policy, the database account is `db_user`.

You can construct other ARNs to support various access patterns. The following policy allows access to two different database accounts in a DB instance.

```
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": [
             "rds-db:connect"
         ],
         "Resource": [
             "arn:aws:rds-db:us-east-2:123456789012:dbuser:db-ABCDEFGHIJKL01234/
jane_doe",
             "arn:aws:rds-db:us-east-2:123456789012:dbuser:db-ABCDEFGHIJKL01234/
mary_roe"
         ]
      }
   ]
}
```

The following policy uses the "*" character to match all DB instances and database accounts for a particular AWS account and AWS Region.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
```

```
            "Effect": "Allow",
            "Action": [
                "rds-db:connect"
            ],
            "Resource": [
                "arn:aws:rds-db:us-east-2:1234567890:dbuser:*/*"
            ]
        }
    ]
}
```

The following policy matches all of the DB instances for a particular AWS account and AWS Region. However, the policy only grants access to DB instances that have a `jane_doe` database account.

```
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": [
             "rds-db:connect"
         ],
         "Resource": [
             "arn:aws:rds-db:us-east-2:123456789012:dbuser:*/jane_doe"
         ]
      }
   ]
}
```

The user or role has access to only those databases that the database user does. For example, suppose that your DB instance has a database named *dev*, and another database named *test*. If the database user `jane_doe` has access only to *dev*, any users or roles that access that DB instance with the `jane_doe` user also have access only to *dev*. This access restriction is also true for other database objects, such as tables, views, and so on.

An administrator must create IAM policies that grant entities permission to perform specific API operations on the specified resources they need. The administrator must then attach those policies to the permission sets or roles that require those permissions. For examples of policies, see Identity-based policy examples for Amazon RDS.

Attaching an IAM policy to a permission set or role

After you create an IAM policy to allow database authentication, you need to attach the policy to a permission set or role. For a tutorial on this topic, see Create and attach your first customer managed policy in the *IAM User Guide*.

As you work through the tutorial, you can use one of the policy examples shown in this section as a starting point and tailor it to your needs. At the end of the tutorial, you have a permission set with an attached policy that can make use of the `rds-db:connect` action.

> **Note**
>
> You can map multiple permission sets or roles to the same database user account. For example, suppose that your IAM policy specified the following resource ARN.
>
> ```
> arn:aws:rds-db:us-east-2:123456789012:dbuser:db-12ABC34DEFG5HIJ6KLMNOP78QR/
> jane_doe
> ```
>
> If you attach the policy to *Jane*, *Bob*, and *Diego*, then each of those users can connect to the specified DB instance using the `jane_doe` database account.

Creating a database account using IAM authentication

With IAM database authentication, you don't need to assign database passwords to the user accounts you create. If you remove a user that is mapped to a database account, you should also remove the database account with the DROP USER statement.

> **Note**
>
> The user name used for IAM authentication must match the case of the user name in the database.

Topics

- Using IAM authentication with MariaDB and MySQL

- Using IAM authentication with PostgreSQL

Using IAM authentication with MariaDB and MySQL

With MariaDB and MySQL, authentication is handled by `AWSAuthenticationPlugin`—an AWS-provided plugin that works seamlessly with IAM to authenticate your users. Connect to the DB instance as the master user or a different user who can create users and grant privileges. After connecting, issue the `CREATE USER` statement, as shown in the following example.

```
CREATE USER 'jane_doe' IDENTIFIED WITH AWSAuthenticationPlugin AS 'RDS';
```

The `IDENTIFIED WITH` clause allows MariaDB and MySQL to use the `AWSAuthenticationPlugin` to authenticate the database account (`jane_doe`). The `AS 'RDS'` clause refers to the authentication method. Make sure the specified database user name is the same as a resource in the IAM policy for IAM database access. For more information, see Creating and using an IAM policy for IAM database access.

> **Note**
>
> If you see the following message, it means that the AWS-provided plugin is not available for the current DB instance.
> `ERROR 1524 (HY000): Plugin 'AWSAuthenticationPlugin' is not loaded`
> To troubleshoot this error, verify that you are using a supported configuration and that you have enabled IAM database authentication on your DB instance. For more information, see Region and version availability and Enabling and disabling IAM database authentication.

After you create an account using `AWSAuthenticationPlugin`, you manage it in the same way as other database accounts. For example, you can modify account privileges with `GRANT` and `REVOKE` statements, or modify various account attributes with the `ALTER USER` statement.

Database network traffic is encrypted using SSL/TLS when using IAM. To allow SSL connections, modify the user account with the following command.

```
ALTER USER 'jane_doe'@'%' REQUIRE SSL;
```

Using IAM authentication with PostgreSQL

To use IAM authentication with PostgreSQL, connect to the DB instance as the master user or a different user who can create users and grant privileges. After connecting, create database users and then grant them the `rds_iam` role as shown in the following example.

```
CREATE USER db_userx;
GRANT rds_iam TO db_userx;
```

Make sure the specified database user name is the same as a resource in the IAM policy for IAM database access. For more information, see Creating and using an IAM policy for IAM database access. You must grant the `rds_iam` role to use IAM authentication. You can use nested memberships or indirect grants of the role as well.

Connecting to your DB instance using IAM authentication

With IAM database authentication, you use an authentication token when you connect to your DB instance. An *authentication token* is a string of characters that you use instead of a password. After you generate an authentication token, it's valid for 15 minutes before it expires. If you try to connect using an expired token, the connection request is denied.

Every authentication token must be accompanied by a valid signature, using AWS signature version 4. (For more information, see Signature Version 4 signing process in the *AWS General Reference.*) The AWS CLI and an AWS SDK, such as the AWS SDK for Java or AWS SDK for Python (Boto3), can automatically sign each token you create.

You can use an authentication token when you connect to Amazon RDS from another AWS service, such as AWS Lambda. By using a token, you can avoid placing a password in your code. Alternatively, you can use an AWS SDK to programmatically create and programmatically sign an authentication token.

After you have a signed IAM authentication token, you can connect to an Amazon RDS DB instance. Following, you can find out how to do this using either a command line tool or an AWS SDK, such as the AWS SDK for Java or AWS SDK for Python (Boto3).

For more information, see the following blog posts:

- Use IAM authentication to connect with SQL Workbench/J to Aurora MySQL or Amazon RDS for MySQL

- Using IAM authentication to connect with pgAdmin Amazon Aurora PostgreSQL or Amazon RDS for PostgreSQL

Prerequisites

The following are prerequisites for connecting to your DB instance using IAM authentication:

- Enabling and disabling IAM database authentication
- Creating and using an IAM policy for IAM database access
- Creating a database account using IAM authentication

Topics

- Connecting to your DB instance using IAM authentication with the AWS drivers
- Connecting to your DB instance using IAM authentication from the command line: AWS CLI and mysql client
- Connecting to your DB instance using IAM authentication from the command line: AWS CLI and psql client
- Connecting to your DB instance using IAM authentication and the AWS SDK for .NET

- Connecting to your DB instance using IAM authentication and the AWS SDK for Java
- Connecting to your DB instance using IAM authentication and the AWS SDK for Python (Boto3)

Connecting to your DB instance using IAM authentication with the AWS drivers

The AWS suite of drivers has been designed to provide support for faster switchover and failover times, and authentication with AWS Secrets Manager, AWS Identity and Access Management (IAM), and Federated Identity. The AWS drivers rely on monitoring DB instance status and being aware of the instance topology to determine the new writer. This approach reduces switchover and failover times to single-digit seconds, compared to tens of seconds for open-source drivers.

For more information on the AWS drivers, see the corresponding language driver for your RDS for MariaDB, RDS for MySQL, or RDS for PostgreSQL DB instance.

> **Note**
>
> The only features supported for RDS for MariaDB are authentication with AWS Secrets Manager, AWS Identity and Access Management (IAM), and Federated Identity.

Connecting to your DB instance using IAM authentication from the command line: AWS CLI and mysql client

You can connect from the command line to an Amazon RDS DB instance with the AWS CLI and `mysql` command line tool as described following.

Prerequisites

The following are prerequisites for connecting to your DB instance using IAM authentication:

- Enabling and disabling IAM database authentication
- Creating and using an IAM policy for IAM database access
- Creating a database account using IAM authentication

> **Note**
>
> For information about connecting to your database using SQL Workbench/J with IAM authentication, see the blog post Use IAM authentication to connect with SQL Workbench/J to Aurora MySQL or Amazon RDS for MySQL.

Topics

- Generating an IAM authentication token
- Connecting to a DB instance

Generating an IAM authentication token

The following example shows how to get a signed authentication token using the AWS CLI.

```
aws rds generate-db-auth-token \
   --hostname rdsmysql.123456789012.us-west-2.rds.amazonaws.com \
```

```
  --port 3306 \
  --region us-west-2 \
  --username jane_doe
```

In the example, the parameters are as follows:

- `--hostname` – The host name of the DB instance that you want to access
- `--port` – The port number used for connecting to your DB instance
- `--region` – The AWS Region where the DB instance is running
- `--username` – The database account that you want to access

The first several characters of the token look like the following.

```
rdsmysql.123456789012.us-west-2.rds.amazonaws.com:3306/?
Action=connect&DBUser=jane_doe&X-Amz-Algorithm=AWS4-HMAC-SHA256&X-Amz-Expires=900...
```

> **Note**
>
> You cannot use a custom Route 53 DNS record instead of the DB instance endpoint to generate the authentication token.

Connecting to a DB instance

The general format for connecting is shown following.

```
mysql --host=hostName --port=portNumber --ssl-ca=full_path_to_ssl_certificate --enable-
cleartext-plugin --user=userName --password=authToken
```

The parameters are as follows:

- `--host` – The host name of the DB instance that you want to access
- `--port` – The port number used for connecting to your DB instance
- `--ssl-ca` – The full path to the SSL certificate file that contains the public key

  For more information about SSL/TLS support for MariaDB, see Using SSL/TLS with a MariaDB DB instance.

For more information about SSL/TLS support for MySQL, see Using SSL/TLS with a MySQL DB instance.

To download an SSL certificate, see Using SSL/TLS to encrypt a connection to a DB instance or cluster.

- `--enable-cleartext-plugin` – A value that specifies that `AWSAuthenticationPlugin` must be used for this connection

  If you are using a MariaDB client, the `--enable-cleartext-plugin` option isn't required.
- `--user` – The database account that you want to access
- `--password` – A signed IAM authentication token

The authentication token consists of several hundred characters. It can be unwieldy on the command line. One way to work around this is to save the token to an environment variable, and then use that variable when you connect. The following example shows one way to perform this workaround. In the example, */sample_dir/* is the full path to the SSL certificate file that contains the public key.

```
RDSHOST="mysqldb.123456789012.us-east-1.rds.amazonaws.com"
TOKEN="$(aws rds generate-db-auth-token --hostname $RDSHOST --port 3306 --region us-
west-2 --username jane_doe )"

mysql --host=$RDSHOST --port=3306 --ssl-ca=/sample_dir/global-bundle.pem --enable-
cleartext-plugin --user=jane_doe --password=$TOKEN
```

When you connect using `AWSAuthenticationPlugin`, the connection is secured using SSL. To verify this, type the following at the `mysql>` command prompt.

```
show status like 'Ssl%';
```

The following lines in the output show more details.

```
+---------------+-------------+
| Variable_name | Value
                                                                |
```

```
+---------------+-------------+
| ...           | ...
| Ssl_cipher    | AES256-SHA

                                                                  |
| ...           | ...
| Ssl_version   | TLSv1.1

                                                                  |
| ...           | ...
+-----------------------------+
```

If you want to connect to a DB instance through a proxy, see Connecting to a proxy using IAM authentication.

Connecting to your DB instance using IAM authentication from the command line: AWS CLI and psql client

You can connect from the command line to an Amazon RDS for PostgreSQL DB instance with the AWS CLI and psql command line tool as described following.

Prerequisites

The following are prerequisites for connecting to your DB instance using IAM authentication:

- Enabling and disabling IAM database authentication
- Creating and using an IAM policy for IAM database access
- Creating a database account using IAM authentication

> **Note**
>
> For information about connecting to your database using pgAdmin with IAM authentication, see the blog post Using IAM authentication to connect with pgAdmin Amazon Aurora PostgreSQL or Amazon RDS for PostgreSQL.

Topics

- Generating an IAM authentication token
- Connecting to an Amazon RDS PostgreSQL instance

Generating an IAM authentication token

The authentication token consists of several hundred characters so it can be unwieldy on the command line. One way to work around this is to save the token to an environment variable, and then use that variable when you connect. The following example shows how to use the AWS CLI to get a signed authentication token using the `generate-db-auth-token` command, and store it in a `PGPASSWORD` environment variable.

```
export RDSHOST="rdspostgres.123456789012.us-west-2.rds.amazonaws.com"
export PGPASSWORD="$(aws rds generate-db-auth-token --hostname $RDSHOST --port 5432 --
region us-west-2 --username jane_doe )"
```

In the example, the parameters to the `generate-db-auth-token` command are as follows:

- `--hostname` – The host name of the DB instance that you want to access
- `--port` – The port number used for connecting to your DB instance
- `--region` – The AWS Region where the DB instance is running
- `--username` – The database account that you want to access

The first several characters of the generated token look like the following.

```
rdspostgres.123456789012.us-west-2.rds.amazonaws.com:5432/?
Action=connect&DBUser=jane_doe&X-Amz-Algorithm=AWS4-HMAC-SHA256&X-Amz-Expires=900...
```

> **Note**
>
> You cannot use a custom Route 53 DNS record instead of the DB instance endpoint to generate the authentication token.

Connecting to an Amazon RDS PostgreSQL instance

The general format for using psql to connect is shown following.

```
psql "host=hostName port=portNumber sslmode=verify-full
 sslrootcert=full_path_to_ssl_certificate dbname=DBName user=userName
 password=authToken"
```

The parameters are as follows:

- `host` – The host name of the DB instance that you want to access
- `port` – The port number used for connecting to your DB instance
- `sslmode` – The SSL mode to use

  When you use `sslmode=verify-full`, the SSL connection verifies the DB instance endpoint against the endpoint in the SSL certificate.
- `sslrootcert` – The full path to the SSL certificate file that contains the public key

  For more information, see Using SSL with a PostgreSQL DB instance.

  To download an SSL certificate, see Using SSL/TLS to encrypt a connection to a DB instance or cluster.
- dbname – The database that you want to access
- `user` – The database account that you want to access
- `password` – A signed IAM authentication token

> **Note**
>
> You cannot use a custom Route 53 DNS record instead of the DB instance endpoint to generate the authentication token.

The following example shows using psql to connect. In the example, psql uses the environment variable RDSHOST for the host and the environment variable PGPASSWORD for the generated token. Also, */sample_dir/* is the full path to the SSL certificate file that contains the public key.

```
export RDSHOST="rdspostgres.123456789012.us-west-2.rds.amazonaws.com"
export PGPASSWORD="$(aws rds generate-db-auth-token --hostname $RDSHOST --port 5432 --
region us-west-2 --username jane_doe )"

psql "host=$RDSHOST port=5432 sslmode=verify-full sslrootcert=/sample_dir/global-
bundle.pem dbname=DBName user=jane_doe password=$PGPASSWORD"
```

If you want to connect to a DB instance through a proxy, see Connecting to a proxy using IAM authentication.

Connecting to your DB instance using IAM authentication and the AWS SDK for .NET

You can connect to an RDS for MariaDB, MySQL, or PostgreSQL DB instance with the AWS SDK for .NET as described following.

Prerequisites

The following are prerequisites for connecting to your DB instance using IAM authentication:

- Enabling and disabling IAM database authentication
- Creating and using an IAM policy for IAM database access
- Creating a database account using IAM authentication

Examples

The following code examples show how to generate an authentication token, and then use it to connect to a DB instance.

To run this code example, you need the AWS SDK for .NET, found on the AWS site. The `AWSSDK.CORE` and the `AWSSDK.RDS` packages are required. To connect to a DB instance, use the .NET database connector for the DB engine, such as MySqlConnector for MariaDB or MySQL, or Npgsql for PostgreSQL.

This code connects to a MariaDB or MySQL DB instance. Modify the values of the following variables as needed:

- `server` – The endpoint of the DB instance that you want to access
- `user` – The database account that you want to access
- `database` – The database that you want to access
- `port` – The port number used for connecting to your DB instance
- `SslMode` – The SSL mode to use

  When you use `SslMode=Required`, the SSL connection verifies the DB instance endpoint against the endpoint in the SSL certificate.
- `SslCa` – The full path to the SSL certificate for Amazon RDS

  To download a certificate, see Using SSL/TLS to encrypt a connection to a DB instance or cluster.

> **Note**
>
> You cannot use a custom Route 53 DNS record instead of the DB instance endpoint to generate the authentication token.

```
using System;
using System.Data;
using MySql.Data;
using MySql.Data.MySqlClient;
using Amazon;

namespace ubuntu
{
  class Program
  {
    static void Main(string[] args)
    {
      var pwd =
 Amazon.RDS.Util.RDSAuthTokenGenerator.GenerateAuthToken(RegionEndpoint.USEast1,
 "mysqldb.123456789012.us-east-1.rds.amazonaws.com", 3306, "jane_doe");
      // for debug only Console.Write("{0}\n", pwd);  //this verifies the token is
 generated

      MySqlConnection conn = new MySqlConnection($"server=mysqldb.123456789012.us-
east-1.rds.amazonaws.com;user=jane_doe;database=mydB;port=3306;password={pwd};SslMode=Required;
      conn.Open();

      // Define a query
      MySqlCommand sampleCommand = new MySqlCommand("SHOW DATABASES;", conn);

      // Execute a query
      MySqlDataReader mysqlDataRdr = sampleCommand.ExecuteReader();

      // Read all rows and output the first column in each row
      while (mysqlDataRdr.Read())
        Console.WriteLine(mysqlDataRdr[0]);

      mysqlDataRdr.Close();
      // Close connection
      conn.Close();
    }
```

```
  }
}
```

This code connects to a PostgreSQL DB instance.

Modify the values of the following variables as needed:

- `Server` – The endpoint of the DB instance that you want to access
- `User ID` – The database account that you want to access
- `Database` – The database that you want to access
- `Port` – The port number used for connecting to your DB instance
- `SSL Mode` – The SSL mode to use

  When you use `SSL Mode=Required`, the SSL connection verifies the DB instance endpoint against the endpoint in the SSL certificate.
- `Root Certificate` – The full path to the SSL certificate for Amazon RDS

  To download a certificate, see Using SSL/TLS to encrypt a connection to a DB instance or cluster.

> **Note**
>
> You cannot use a custom Route 53 DNS record instead of the DB instance endpoint to generate the authentication token.

```
using System;
using Npgsql;
using Amazon.RDS.Util;

namespace ConsoleApp1
{
    class Program
    {
        static void Main(string[] args)
        {
            var pwd =
 RDSAuthTokenGenerator.GenerateAuthToken("postgresmydb.123456789012.us-
east-1.rds.amazonaws.com", 5432, "jane_doe");
// for debug only Console.Write("{0}\n", pwd);  //this verifies the token is generated
```

```
            NpgsqlConnection conn = new
 NpgsqlConnection($"Server=postgresmydb.123456789012.us-east-1.rds.amazonaws.com;User
 Id=jane_doe;Password={pwd};Database=mydb;SSL Mode=Require;Root
 Certificate=full_path_to_ssl_certificate");
            conn.Open();

            // Define a query
                   NpgsqlCommand cmd = new NpgsqlCommand("select count(*) FROM
 pg_user", conn);

            // Execute a query
            NpgsqlDataReader dr = cmd.ExecuteReader();

            // Read all rows and output the first column in each row
            while (dr.Read())
                Console.Write("{0}\n", dr[0]);

            // Close connection
            conn.Close();
        }
    }
}
```

If you want to connect to a DB instance through a proxy, see Connecting to a proxy using IAM authentication.

Connecting to your DB instance using IAM authentication and the AWS SDK for Go

You can connect to an RDS for MariaDB, MySQL, or PostgreSQL DB instance with the AWS SDK for Go as described following.

Prerequisites

The following are prerequisites for connecting to your DB instance using IAM authentication:

- Enabling and disabling IAM database authentication
- Creating and using an IAM policy for IAM database access
- Creating a database account using IAM authentication

Examples

To run these code examples, you need the AWS SDK for Go, found on the AWS site.

Modify the values of the following variables as needed:

- `dbName` – The database that you want to access
- `dbUser` – The database account that you want to access
- `dbHost` – The endpoint of the DB instance that you want to access

> **Note**
>
> You cannot use a custom Route 53 DNS record instead of the DB instance endpoint to generate the authentication token.

- `dbPort` – The port number used for connecting to your DB instance
- `region` – The AWS Region where the DB instance is running

In addition, make sure the imported libraries in the sample code exist on your system.

> **Important**
>
> The examples in this section use the following code to provide credentials that access a database from a local environment:
> `creds := credentials.NewEnvCredentials()`
> If you are accessing a database from an AWS service, such as Amazon EC2 or Amazon ECS, you can replace the code with the following code:
> `sess := session.Must(session.NewSession())`
> `creds := sess.Config.Credentials`
> If you make this change, make sure you add the following import:
> `"github.com/aws/aws-sdk-go/aws/session"`

Connecting using IAM authentication and the AWS SDK for Go V2

You can connect to a DB instance using IAM authentication and the AWS SDK for Go V2.

The following code examples show how to generate an authentication token, and then use it to connect to a DB instance.

This code connects to a MariaDB or MySQL DB instance.

```
package main

import (
     "context"
     "database/sql"
     "fmt"

     "github.com/aws/aws-sdk-go-v2/config"
     "github.com/aws/aws-sdk-go-v2/feature/rds/auth"
     _ "github.com/go-sql-driver/mysql"
)

func main() {

     var dbName string = "DatabaseName"
     var dbUser string = "DatabaseUser"
     var dbHost string = "mysqldb.123456789012.us-east-1.rds.amazonaws.com"
     var dbPort int = 3306
     var dbEndpoint string = fmt.Sprintf("%s:%d", dbHost, dbPort)
     var region string = "us-east-1"

    cfg, err := config.LoadDefaultConfig(context.TODO())
    if err != nil {
     panic("configuration error: " + err.Error())
    }

    authenticationToken, err := auth.BuildAuthToken(
     context.TODO(), dbEndpoint, region, dbUser, cfg.Credentials)
    if err != nil {
     panic("failed to create authentication token: " + err.Error())
    }

    dsn := fmt.Sprintf("%s:%s@tcp(%s)/%s?tls=true&allowCleartextPasswords=true",
        dbUser, authenticationToken, dbEndpoint, dbName,
    )
```

```
    db, err := sql.Open("mysql", dsn)
    if err != nil {
        panic(err)
    }

    err = db.Ping()
    if err != nil {
        panic(err)
    }
}
```

This code connects to a PostgreSQL DB instance.

```
package main

import (
     "context"
     "database/sql"
     "fmt"

     "github.com/aws/aws-sdk-go-v2/config"
     "github.com/aws/aws-sdk-go-v2/feature/rds/auth"
     _ "github.com/lib/pq"
)

func main() {

     var dbName string = "DatabaseName"
     var dbUser string = "DatabaseUser"
     var dbHost string = "postgresmydb.123456789012.us-east-1.rds.amazonaws.com"
     var dbPort int = 5432
     var dbEndpoint string = fmt.Sprintf("%s:%d", dbHost, dbPort)
     var region string = "us-east-1"

    cfg, err := config.LoadDefaultConfig(context.TODO())
    if err != nil {
     panic("configuration error: " + err.Error())
    }

    authenticationToken, err := auth.BuildAuthToken(
     context.TODO(), dbEndpoint, region, dbUser, cfg.Credentials)
    if err != nil {
```

```
     panic("failed to create authentication token: " + err.Error())
    }

    dsn := fmt.Sprintf("host=%s port=%d user=%s password=%s dbname=%s",
        dbHost, dbPort, dbUser, authenticationToken, dbName,
    )

    db, err := sql.Open("postgres", dsn)
    if err != nil {
        panic(err)
    }

    err = db.Ping()
    if err != nil {
        panic(err)
    }
}
```

    err = db.Ping()
    if err != nil {
        panic(err)
    }
}
```

If you want to connect to a DB instance through a proxy, see Connecting to a proxy using IAM authentication.

Connecting to your DB instance using IAM authentication and the AWS SDK for Java

You can connect to an RDS for MariaDB, MySQL, or PostgreSQL DB instance with the AWS SDK for Java as described following.

Prerequisites

The following are prerequisites for connecting to your DB instance using IAM authentication:

- Enabling and disabling IAM database authentication
- Creating and using an IAM policy for IAM database access
- Creating a database account using IAM authentication

- Set up the AWS SDK for Java

For examples on how to use the SDK for Java 2.x, see Amazon RDS examples using SDK for Java 2.x.

Topics

- Generating an IAM authentication token
- Manually constructing an IAM authentication token
- Connecting to a DB instance

Generating an IAM authentication token

If you are writing programs using the AWS SDK for Java, you can get a signed authentication token using the `RdsIamAuthTokenGenerator` class. Using this class requires that you provide AWS credentials. To do this, you create an instance of the `DefaultAWSCredentialsProviderChain` class. `DefaultAWSCredentialsProviderChain` uses the first AWS access key and secret key that it finds in the default credential provider chain. For more information about AWS access keys, see Managing access keys for users.

> **Note**
>
> You cannot use a custom Route 53 DNS record instead of the DB instance endpoint to generate the authentication token.

After you create an instance of `RdsIamAuthTokenGenerator`, you can call the `getAuthToken` method to obtain a signed token. Provide the AWS Region, host name, port number, and user name. The following code example illustrates how to do this.

```
package com.amazonaws.codesamples;

import com.amazonaws.auth.DefaultAWSCredentialsProviderChain;
import com.amazonaws.services.rds.auth.GetIamAuthTokenRequest;
import com.amazonaws.services.rds.auth.RdsIamAuthTokenGenerator;

public class GenerateRDSAuthToken {

    public static void main(String[] args) {
```

```
     String region = "us-west-2";
     String hostname = "rdsmysql.123456789012.us-west-2.rds.amazonaws.com";
     String port = "3306";
     String username = "jane_doe";

     System.out.println(generateAuthToken(region, hostname, port, username));
    }

    static String generateAuthToken(String region, String hostName, String port, String
 username) {

     RdsIamAuthTokenGenerator generator = RdsIamAuthTokenGenerator.builder()
      .credentials(new DefaultAWSCredentialsProviderChain())
      .region(region)
      .build();

     String authToken = generator.getAuthToken(
      GetIamAuthTokenRequest.builder()
      .hostname(hostName)
      .port(Integer.parseInt(port))
      .userName(username)
      .build());

     return authToken;
    }

}
```

Manually constructing an IAM authentication token

In Java, the easiest way to generate an authentication token is to use `RdsIamAuthTokenGenerator`. This class creates an authentication token for you, and then signs it using AWS signature version 4. For more information, see Signature version 4 signing process in the *AWS General Reference.*

However, you can also construct and sign an authentication token manually, as shown in the following code example.

```
package com.amazonaws.codesamples;

import com.amazonaws.SdkClientException;
import com.amazonaws.auth.DefaultAWSCredentialsProviderChain;
```

```
import com.amazonaws.auth.SigningAlgorithm;
import com.amazonaws.util.BinaryUtils;
import org.apache.commons.lang3.StringUtils;

import javax.crypto.Mac;
import javax.crypto.spec.SecretKeySpec;
import java.nio.charset.Charset;
import java.security.MessageDigest;
import java.text.SimpleDateFormat;
import java.util.Date;
import java.util.SortedMap;
import java.util.TreeMap;

import static com.amazonaws.auth.internal.SignerConstants.AWS4_TERMINATOR;
import static com.amazonaws.util.StringUtils.UTF8;

public class CreateRDSAuthTokenManually {
    public static String httpMethod = "GET";
    public static String action = "connect";
    public static String canonicalURIParameter = "/";
    public static SortedMap<String, String> canonicalQueryParameters = new TreeMap();
    public static String payload = StringUtils.EMPTY;

```

```
        }
    }
}
```

Connecting to a DB instance

The following code example shows how to generate an authentication token, and then use it to connect to an instance running MariaDB or MySQL.

To run this code example, you need the AWS SDK for Java, found on the AWS site. In addition, you need the following:

- MySQL Connector/J. This code example was tested with `mysql-connector-java-5.1.33-bin.jar`.
- An intermediate certificate for Amazon RDS that is specific to an AWS Region. (For more information, see Using SSL/TLS to encrypt a connection to a DB instance or cluster.) At runtime, the class loader looks for the certificate in the same directory as this Java code example, so that the class loader can find it.
- Modify the values of the following variables as needed:
  - `RDS_INSTANCE_HOSTNAME` – The host name of the DB instance that you want to access.
  - `RDS_INSTANCE_PORT` – The port number used for connecting to your PostgreSQL DB instance.
  - `REGION_NAME` – The AWS Region where the DB instance is running.
  - `DB_USER` – The database account that you want to access.
  - `SSL_CERTIFICATE` – An SSL certificate for Amazon RDS that is specific to an AWS Region.

    To download a certificate for your AWS Region, see Using SSL/TLS to encrypt a connection to a DB instance or cluster. Place the SSL certificate in the same directory as this Java program file, so that the class loader can find the certificate at runtime.

This code example obtains AWS credentials from the default credential provider chain.

> **Note**
>
> Specify a password for `DEFAULT_KEY_STORE_PASSWORD` other than the prompt shown here as a security best practice.

If you want to connect to a DB instance through a proxy, see Connecting to a proxy using IAM authentication.

Connecting to your DB instance using IAM authentication and the AWS SDK for Python (Boto3)

You can connect to an RDS for MariaDB, MySQL, or PostgreSQL DB instance with the AWS SDK for Python (Boto3) as described following.

Prerequisites

The following are prerequisites for connecting to your DB instance using IAM authentication:

- Enabling and disabling IAM database authentication
- Creating and using an IAM policy for IAM database access
- Creating a database account using IAM authentication

In addition, make sure the imported libraries in the sample code exist on your system.

Examples

The code examples use profiles for shared credentials. For information about the specifying credentials, see Credentials in the AWS SDK for Python (Boto3) documentation.

The following code examples show how to generate an authentication token, and then use it to connect to a DB instance.

To run this code example, you need the AWS SDK for Python (Boto3), found on the AWS site.

Modify the values of the following variables as needed:

- `ENDPOINT` – The endpoint of the DB instance that you want to access
- `PORT` – The port number used for connecting to your DB instance
- `USER` – The database account that you want to access
- `REGION` – The AWS Region where the DB instance is running
- `DBNAME` – The database that you want to access
- `SSLCERTIFICATE` – The full path to the SSL certificate for Amazon RDS

  For `ssl_ca`, specify an SSL certificate. To download an SSL certificate, see Using SSL/TLS to encrypt a connection to a DB instance or cluster.

> **Note**
>
> You cannot use a custom Route 53 DNS record instead of the DB instance endpoint to generate the authentication token.

This code connects to a MariaDB or MySQL DB instance.

Before running this code, install the PyMySQL driver by following the instructions in the Python Package Index.

```
import pymysql
import sys
import boto3
import os

ENDPOINT="mysqldb.123456789012.us-east-1.rds.amazonaws.com"
PORT="3306"
USER="jane_doe"
REGION="us-east-1"
DBNAME="mydb"
os.environ['LIBMYSQL_ENABLE_CLEARTEXT_PLUGIN'] = '1'

#gets the credentials from .aws/credentials
```

```
session = boto3.Session(profile_name='default')
client = session.client('rds')

token = client.generate_db_auth_token(DBHostname=ENDPOINT, Port=PORT, DBUsername=USER,
 Region=REGION)

try:
    conn =
 pymysql.connect(auth_plugin_map={'mysql_clear_password':None},host=ENDPOINT,
 user=USER, password=token, port=PORT, database=DBNAME, ssl_ca='SSLCERTIFICATE',
 ssl_verify_identity=True)
    cur = conn.cursor()
    cur.execute("""SELECT now()""")
    query_results = cur.fetchall()
    print(query_results)
except Exception as e:
    print("Database connection failed due to {}".format(e))
```

This code connects to a PostgreSQL DB instance.

Before running this code, install `psycopg2` by following the instructions in Psycopg documentation.

```
import psycopg2
import sys
import boto3
import os

ENDPOINT="postgresmydb.123456789012.us-east-1.rds.amazonaws.com"
PORT="5432"
USER="jane_doe"
REGION="us-east-1"
DBNAME="mydb"

#gets the credentials from .aws/credentials
session = boto3.Session(profile_name='RDSCreds')
client = session.client('rds')

token = client.generate_db_auth_token(DBHostname=ENDPOINT, Port=PORT, DBUsername=USER,
 Region=REGION)
```

```
try:
    conn = psycopg2.connect(host=ENDPOINT, port=PORT, database=DBNAME, user=USER,
 password=token, sslrootcert="SSLCERTIFICATE")
    cur = conn.cursor()
    cur.execute("""SELECT now()""")
    query_results = cur.fetchall()
    print(query_results)
except Exception as e:
    print("Database connection failed due to {}".format(e))
```

If you want to connect to a DB instance through a proxy, see Connecting to a proxy using IAM authentication.

Troubleshooting Amazon RDS identity and access

Use the following information to help you diagnose and fix common issues that you might encounter when working with Amazon RDS and IAM.

Topics

- I'm not authorized to perform an action in Amazon RDS
- I'm not authorized to perform iam:PassRole
- I want to allow people outside of my AWS account to access my Amazon RDS resources

I'm not authorized to perform an action in Amazon RDS

If the AWS Management Console tells you that you're not authorized to perform an action, then you must contact your administrator for assistance. Your administrator is the person that provided you with your sign-in credentials.

The following example error occurs when the `mateojackson` user tries to use the console to view details about a *`widget`* but does not have `rds:`*`GetWidget`* permissions.

```
User: arn:aws:iam::123456789012:user/mateojackson is not authorized to perform:
 rds:GetWidget on resource: my-example-widget
```

In this case, Mateo asks his administrator to update his policies to allow him to access the *`my-example-widget`* resource using the `rds:`*`GetWidget`* action.

I'm not authorized to perform iam:PassRole

If you receive an error that you're not authorized to perform the `iam:PassRole` action, then you must contact your administrator for assistance. Your administrator is the person that provided you with your sign-in credentials. Ask that person to update your policies to allow you to pass a role to Amazon RDS.

Some AWS services allow you to pass an existing role to that service, instead of creating a new service role or service-linked role. To do this, you must have permissions to pass the role to the service.

The following example error occurs when a user named `marymajor` tries to use the console to perform an action in Amazon RDS. However, the action requires the service to have permissions granted by a service role. Mary does not have permissions to pass the role to the service.

```
User: arn:aws:iam::123456789012:user/marymajor is not authorized to perform:
 iam:PassRole
```

In this case, Mary asks her administrator to update her policies to allow her to perform the `iam:PassRole` action.

I want to allow people outside of my AWS account to access my Amazon RDS resources

You can create a role that users in other accounts or people outside of your organization can use to access your resources. You can specify who is trusted to assume the role. For services that support resource-based policies or access control lists (ACLs), you can use those policies to grant people access to your resources.

To learn more, consult the following:

- To learn whether Amazon RDS supports these features, see How Amazon RDS works with IAM.
- To learn how to provide access to your resources across AWS accounts that you own, see Providing access to an IAM user in another AWS account that you own in the *IAM User Guide*.
- To learn how to provide access to your resources to third-party AWS accounts, see Providing access to AWS accounts owned by third parties in the *IAM User Guide*.
- To learn how to provide access through identity federation, see Providing access to externally authenticated users (identity federation) in the *IAM User Guide*.

- To learn the difference between using roles and resource-based policies for cross-account access, see How IAM roles differ from resource-based policies in the *IAM User Guide*.

Logging and monitoring in Amazon RDS

Monitoring is an important part of maintaining the reliability, availability, and performance of Amazon RDS and your AWS solutions. You should collect monitoring data from all of the parts of your AWS solution so that you can more easily debug a multi-point failure if one occurs. AWS provides several tools for monitoring your Amazon RDS resources and responding to potential incidents:

Amazon CloudWatch Alarms

Using Amazon CloudWatch alarms, you watch a single metric over a time period that you specify. If the metric exceeds a given threshold, a notification is sent to an Amazon SNS topic or AWS Auto Scaling policy. CloudWatch alarms do not invoke actions because they are in a particular state. Rather the state must have changed and been maintained for a specified number of periods.

AWS CloudTrail Logs

CloudTrail provides a record of actions taken by a user, role, or an AWS service in Amazon RDS. CloudTrail captures all API calls for Amazon RDS as events, including calls from the console and from code calls to Amazon RDS API operations. Using the information collected by CloudTrail, you can determine the request that was made to Amazon RDS, the IP address from which the request was made, who made the request, when it was made, and additional details. For more information, see Monitoring Amazon RDS API calls in AWS CloudTrail.

Enhanced Monitoring

Amazon RDS provides metrics in real time for the operating system (OS) that your DB instance runs on. You can view the metrics for your DB instance using the console, or consume the Enhanced Monitoring JSON output from Amazon CloudWatch Logs in a monitoring system of your choice. For more information, see Monitoring OS metrics with Enhanced Monitoring.

Amazon RDS Performance Insights

Performance Insights expands on existing Amazon RDS monitoring features to illustrate your database's performance and help you analyze any issues that affect it. With the Performance Insights dashboard, you can visualize the database load and filter the load by waits, SQL

statements, hosts, or users. For more information, see Monitoring DB load with Performance Insights on Amazon RDS.

Database Logs

You can view, download, and watch database logs using the AWS Management Console, AWS CLI, or RDS API. For more information, see Monitoring Amazon RDS log files.

Amazon RDS Recommendations

Amazon RDS provides automated recommendations for database resources. These recommendations provide best practice guidance by analyzing DB instance configuration, usage, and performance data. For more information, see Recommendations from Amazon RDS.

Amazon RDS Event Notification

Amazon RDS uses the Amazon Simple Notification Service (Amazon SNS) to provide notification when an Amazon RDS event occurs. These notifications can be in any notification form supported by Amazon SNS for an AWS Region, such as an email, a text message, or a call to an HTTP endpoint. For more information, see Working with Amazon RDS event notification.

AWS Trusted Advisor

Trusted Advisor draws upon best practices learned from serving hundreds of thousands of AWS customers. Trusted Advisor inspects your AWS environment and then makes recommendations when opportunities exist to save money, improve system availability and performance, or help close security gaps. All AWS customers have access to five Trusted Advisor checks. Customers with a Business or Enterprise support plan can view all Trusted Advisor checks.

Trusted Advisor has the following Amazon RDS-related checks:

- Amazon RDS Idle DB Instances
- Amazon RDS Security Group Access Risk
- Amazon RDS Backups
- Amazon RDS Multi-AZ

For more information on these checks, see Trusted Advisor best practices (checks).

For more information about monitoring Amazon RDS, see Monitoring metrics in an Amazon RDS instance.

Compliance validation for Amazon RDS

Third-party auditors assess the security and compliance of Amazon RDS as part of multiple AWS compliance programs. These include SOC, PCI, FedRAMP, HIPAA, and others.

For a list of AWS services in scope of specific compliance programs, see AWS services in scope by compliance program. For general information, see AWS compliance programs.

You can download third-party audit reports using AWS Artifact. For more information, see Downloading reports in AWS Artifact.

Your compliance responsibility when using Amazon RDS is determined by the sensitivity of your data, your organization's compliance objectives, and applicable laws and regulations. AWS provides the following resources to help with compliance:

- Security and compliance quick start guides – These deployment guides discuss architectural considerations and provide steps for deploying security- and compliance-focused baseline environments on AWS.
- Architecting for HIPAA Security and Compliance on Amazon Web Services – This whitepaper describes how companies can use AWS to create HIPAA-compliant applications.
- AWS compliance resources – This collection of workbooks and guides that might apply to your industry and location.
- AWS Config – This AWS service assesses how well your resource configurations comply with internal practices, industry guidelines, and regulations.
- AWS Security Hub – This AWS service provides a comprehensive view of your security state within AWS. Security Hub uses security controls to evaluate your AWS resources and to check your compliance against security industry standards and best practices. For a list of supported services and controls, see Security Hub controls reference.

Resilience in Amazon RDS

The AWS global infrastructure is built around AWS Regions and Availability Zones. AWS Regions provide multiple physically separated and isolated Availability Zones, which are connected with low-latency, high-throughput, and highly redundant networking. With Availability Zones, you can design and operate applications and databases that automatically fail over between Availability Zones without interruption. Availability Zones are more highly available, fault tolerant, and scalable than traditional single or multiple data center infrastructures.

For more information about AWS Regions and Availability Zones, see AWS global infrastructure.

In addition to the AWS global infrastructure, Amazon RDS offers features to help support your data resiliency and backup needs.

Backup and restore

Amazon RDS creates and saves automated backups of your DB instance. Amazon RDS creates a storage volume snapshot of your DB instance, backing up the entire DB instance and not just individual databases.

Amazon RDS creates automated backups of your DB instance during the backup window of your DB instance. Amazon RDS saves the automated backups of your DB instance according to the backup retention period that you specify. If necessary, you can recover your database to any point in time during the backup retention period. You can also back up your DB instance manually, by manually creating a DB snapshot.

You can create a DB instance by restoring from this DB snapshot as a disaster recovery solution if the source DB instance fails.

For more information, see Backing up, restoring, and exporting data.

Replication

Amazon RDS uses the MariaDB, MySQL, Oracle, and PostgreSQL DB engines' built-in replication functionality to create a special type of DB instance called a read replica from a source DB instance. Updates made to the source DB instance are asynchronously copied to the read replica. You can reduce the load on your source DB instance by routing read queries from your applications to the read replica. Using read replicas, you can elastically scale out beyond the capacity constraints of a single DB instance for read-heavy database workloads. You can promote a read replica to a

standalone instance as a disaster recovery solution if the source DB instance fails. For some DB engines, Amazon RDS also supports other replication options.

For more information, see Working with DB instance read replicas.

Failover

Amazon RDS provides high availability and failover support for DB instances using Multi-AZ deployments. Amazon RDS uses several different technologies to provide failover support. Multi-AZ deployments for Oracle, PostgreSQL, MySQL, and MariaDB DB instances use Amazon's failover technology. SQL Server DB instances use SQL Server Database Mirroring (DBM).

For more information, see Configuring and managing a Multi-AZ deployment.

Infrastructure security in Amazon RDS

As a managed service, Amazon Relational Database Service is protected by AWS global network security. For information about AWS security services and how AWS protects infrastructure, see AWS Cloud Security. To design your AWS environment using the best practices for infrastructure security, see Infrastructure Protection in *Security Pillar AWS Well-Architected Framework*.

You use AWS published API calls to access Amazon RDS through the network. Clients must support the following:

- Transport Layer Security (TLS). We require TLS 1.2 and recommend TLS 1.3.
- Cipher suites with perfect forward secrecy (PFS) such as DHE (Ephemeral Diffie-Hellman) or ECDHE (Elliptic Curve Ephemeral Diffie-Hellman). Most modern systems such as Java 7 and later support these modes.

Additionally, requests must be signed by using an access key ID and a secret access key that is associated with an IAM principal. Or you can use the AWS Security Token Service (AWS STS) to generate temporary security credentials to sign requests.

In addition, Amazon RDS offers features to help support infrastructure security.

Security groups

Security groups control the access that traffic has in and out of a DB instance. By default, network access is turned off to a DB instance. You can specify rules in a security group that allow access from an IP address range, port, or security group. After ingress rules are configured, the same rules apply to all DB instances that are associated with that security group.

For more information, see Controlling access with security groups.

Public accessibility

When you launch a DB instance inside a virtual private cloud (VPC) based on the Amazon VPC service, you can turn on or off public accessibility for that DB instance. To designate whether the DB instance that you create has a DNS name that resolves to a public IP address, you use the *Public accessibility* parameter. By using this parameter, you can designate whether there is public access to the DB instance. You can modify a DB instance to turn on or off public accessibility by modifying the *Public accessibility* parameter.

For more information, see Hiding a DB instance in a VPC from the internet.

> **Note**
>
> If your DB instance is in a VPC but isn't publicly accessible, you can also use an AWS Site-to-Site VPN connection or an AWS Direct Connect connection to access it from a private network. For more information, see Internetwork traffic privacy.

Amazon RDS API and interface VPC endpoints (AWS PrivateLink)

You can establish a private connection between your VPC and Amazon RDS API endpoints by creating an *interface VPC endpoint*. Interface endpoints are powered by AWS PrivateLink.

AWS PrivateLink enables you to privately access Amazon RDS API operations without an internet gateway, NAT device, VPN connection, or AWS Direct Connect connection. DB instances in your VPC don't need public IP addresses to communicate with Amazon RDS API endpoints to launch, modify, or terminate DB instances. Your DB instances also don't need public IP addresses to use any of the available RDS API operations. Traffic between your VPC and Amazon RDS doesn't leave the Amazon network.

Each interface endpoint is represented by one or more elastic network interfaces in your subnets. For more information on elastic network interfaces, see Elastic network interfaces in the *Amazon EC2 User Guide.*

For more information about VPC endpoints, see Interface VPC endpoints (AWS PrivateLink) in the *Amazon VPC User Guide*. For more information about RDS API operations, see Amazon RDS API Reference.

You don't need an interface VPC endpoint to connect to a DB instance. For more information, see Scenarios for accessing a DB instance in a VPC.

Considerations for VPC endpoints

Before you set up an interface VPC endpoint for Amazon RDS API endpoints, ensure that you review Interface endpoint properties and limitations in the *Amazon VPC User Guide*.

All RDS API operations relevant to managing Amazon RDS resources are available from your VPC using AWS PrivateLink.

VPC endpoint policies are supported for RDS API endpoints. By default, full access to RDS API operations is allowed through the endpoint. For more information, see Controlling access to services with VPC endpoints in the *Amazon VPC User Guide*.

Availability

Amazon RDS API currently supports VPC endpoints in the following AWS Regions:

- US East (Ohio)
- US East (N. Virginia)
- US West (N. California)
- US West (Oregon)
- Africa (Cape Town)
- Asia Pacific (Hong Kong)
- Asia Pacific (Mumbai)
- Asia Pacific (Osaka)
- Asia Pacific (Seoul)
- Asia Pacific (Singapore)
- Asia Pacific (Sydney)
- Asia Pacific (Tokyo)
- Canada (Central)
- Canada West (Calgary)
- China (Beijing)
- China (Ningxia)
- Europe (Frankfurt)
- Europe (Zurich)
- Europe (Ireland)
- Europe (London)
- Europe (Paris)
- Europe (Stockholm)
- Europe (Milan)
- Israel (Tel Aviv)
- Middle East (Bahrain)
- South America (São Paulo)
- AWS GovCloud (US-East)
- AWS GovCloud (US-West)

Creating an interface VPC endpoint for Amazon RDS API

You can create a VPC endpoint for the Amazon RDS API using either the Amazon VPC console or the AWS Command Line Interface (AWS CLI). For more information, see Creating an interface endpoint in the *Amazon VPC User Guide*.

Create a VPC endpoint for Amazon RDS API using the service name `com.amazonaws.region.rds`.

Excluding AWS Regions in China, if you enable private DNS for the endpoint, you can make API requests to Amazon RDS with the VPC endpoint using its default DNS name for the AWS Region, for example `rds.us-east-1.amazonaws.com`. For the China (Beijing) and China (Ningxia) AWS Regions, you can make API requests with the VPC endpoint using `rds-api.cn-north-1.amazonaws.com.cn` and `rds-api.cn-northwest-1.amazonaws.com.cn`, respectively.

For more information, see Accessing a service through an interface endpoint in the *Amazon VPC User Guide*.

Creating a VPC endpoint policy for Amazon RDS API

You can attach an endpoint policy to your VPC endpoint that controls access to Amazon RDS API. The policy specifies the following information:

- The principal that can perform actions.
- The actions that can be performed.
- The resources on which actions can be performed.

For more information, see Controlling access to services with VPC endpoints in the *Amazon VPC User Guide*.

Example: VPC endpoint policy for Amazon RDS API actions

The following is an example of an endpoint policy for Amazon RDS API. When attached to an endpoint, this policy grants access to the listed Amazon RDS API actions for all principals on all resources.

```
{
   "Statement":[
      {
```

```
         "Principal":"*",
         "Effect":"Allow",
         "Action":[
            "rds:CreateDBInstance",
            "rds:ModifyDBInstance",
            "rds:CreateDBSnapshot"
         ],
         "Resource":"*"
      }
   ]
}
```

Example: VPC endpoint policy that denies all access from a specified AWS account

The following VPC endpoint policy denies AWS account 123456789012 all access to resources using the endpoint. The policy allows all actions from other accounts.

```
{
  "Statement": [
    {
      "Action": "*",
      "Effect": "Allow",
      "Resource": "*",
      "Principal": "*"
    },
    {
      "Action": "*",
      "Effect": "Deny",
      "Resource": "*",
      "Principal": { "AWS": [ "123456789012" ] }
     }
   ]
}
```

Security best practices for Amazon RDS

Use AWS Identity and Access Management (IAM) accounts to control access to Amazon RDS API operations, especially operations that create, modify, or delete Amazon RDS resources. Such resources include DB instances, security groups, and parameter groups. Also use IAM to control actions that perform common administrative actions such as backing up and restoring DB instances.

- Create an individual user for each person who manages Amazon RDS resources, including yourself. Don't use AWS root credentials to manage Amazon RDS resources.
- Grant each user the minimum set of permissions required to perform his or her duties.
- Use IAM groups to effectively manage permissions for multiple users.
- Rotate your IAM credentials regularly.
- Configure AWS Secrets Manager to automatically rotate the secrets for Amazon RDS. For more information, see Rotating your AWS Secrets Manager secrets in the *AWS Secrets Manager User Guide*. You can also retrieve the credential from AWS Secrets Manager programmatically. For more information, see Retrieving the secret value in the *AWS Secrets Manager User Guide*.

For more information about Amazon RDS security, see Security in Amazon RDS. For more information about IAM, see AWS Identity and Access Management. For information on IAM best practices, see IAM best practices.

AWS Security Hub uses security controls to evaluate resource configurations and security standards to help you comply with various compliance frameworks. For more information about using Security Hub to evaluate RDS resources, see Amazon Relational Database Service controls in the AWS Security Hub User Guide.

You can monitor your usage of RDS as it relates to security best practices by using Security Hub. For more information, see What is AWS Security Hub?.

Use the AWS Management Console, the AWS CLI, or the RDS API to change the password for your master user. If you use another tool, such as a SQL client, to change the master user password, it might result in privileges being revoked for the user unintentionally.

Controlling access with security groups

VPC security groups control the access that traffic has in and out of a DB instance. By default, network access is turned off for a DB instance. You can specify rules in a security group that allow access from an IP address range, port, or security group. After ingress rules are configured, the same rules apply to all DB instances that are associated with that security group. You can specify up to 20 rules in a security group.

Overview of VPC security groups

Each VPC security group rule makes it possible for a specific source to access a DB instance in a VPC that is associated with that VPC security group. The source can be a range of addresses (for

example, 203.0.113.0/24), or another VPC security group. By specifying a VPC security group as the source, you allow incoming traffic from all instances (typically application servers) that use the source VPC security group. VPC security groups can have rules that govern both inbound and outbound traffic. However, the outbound traffic rules typically don't apply to DB instances. Outbound traffic rules apply only if the DB instance acts as a client. For example, outbound traffic rules apply to an Oracle DB instance with outbound database links. You must use the Amazon EC2 API or the **Security Group** option on the VPC console to create VPC security groups.

When you create rules for your VPC security group that allow access to the instances in your VPC, you must specify a port for each range of addresses that the rule allows access for. For example, if you want to turn on Secure Shell (SSH) access for instances in the VPC, create a rule allowing access to TCP port 22 for the specified range of addresses.

You can configure multiple VPC security groups that allow access to different ports for different instances in your VPC. For example, you can create a VPC security group that allows access to TCP port 80 for web servers in your VPC. You can then create another VPC security group that allows access to TCP port 3306 for RDS for MySQL DB instances in your VPC.

For more information on VPC security groups, see Security groups in the *Amazon Virtual Private Cloud User Guide*.

> **Note**
>
> If your DB instance is in a VPC but isn't publicly accessible, you can also use an AWS Site-to-Site VPN connection or an AWS Direct Connect connection to access it from a private network. For more information, see Internetwork traffic privacy.

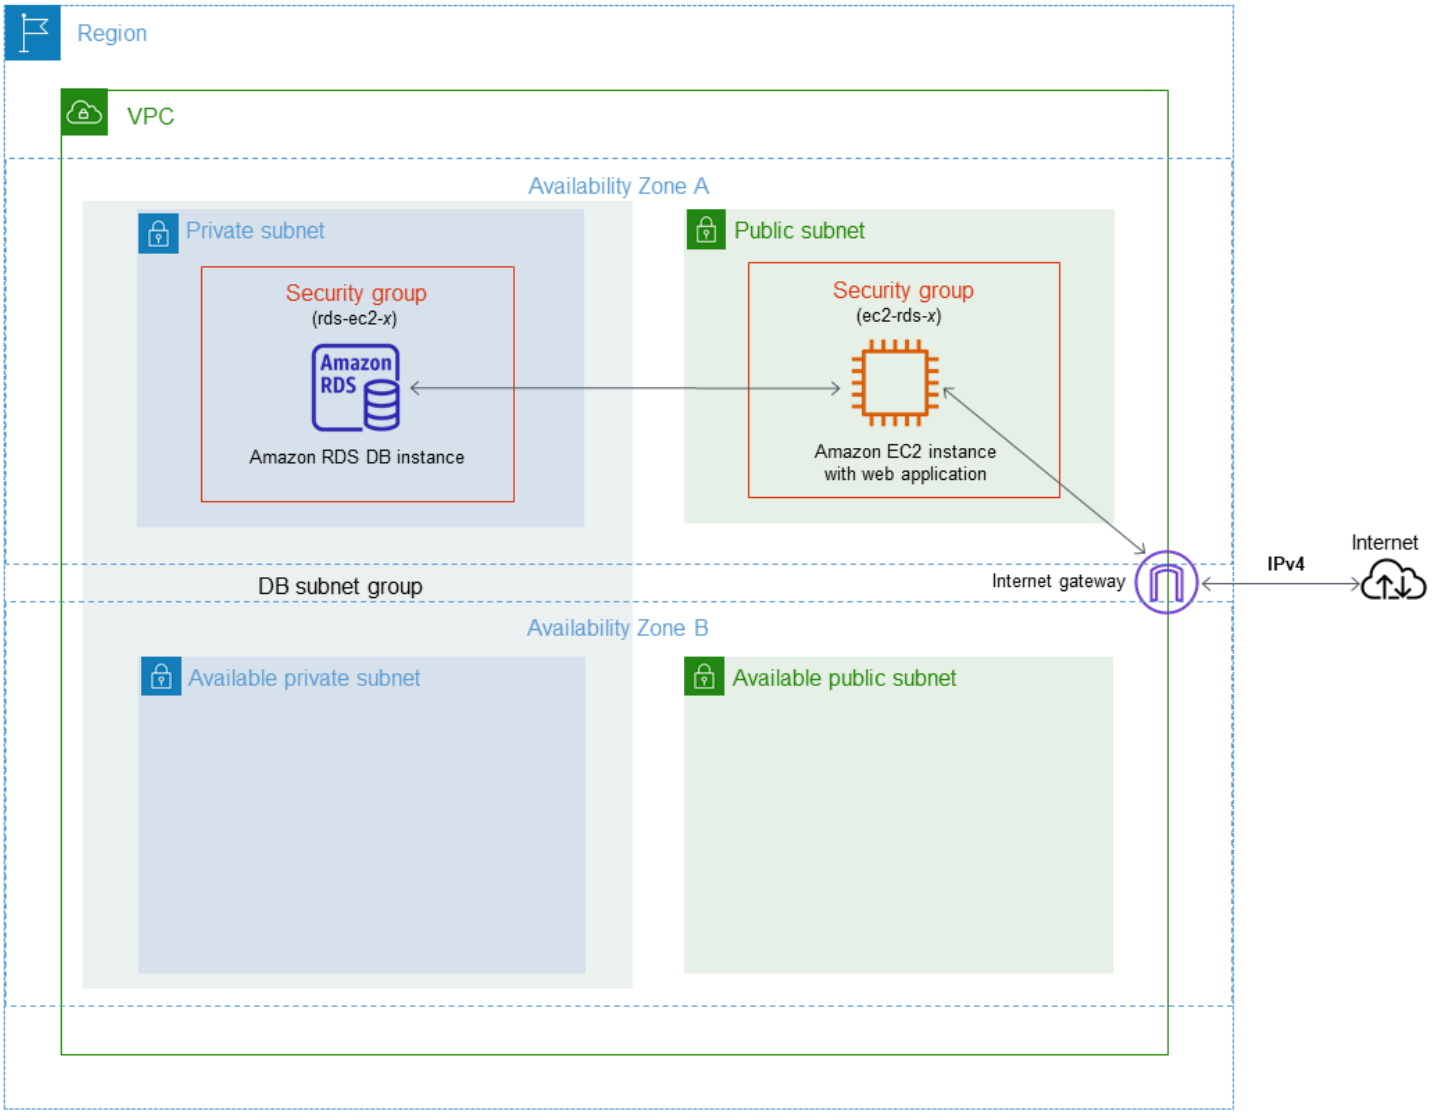
Security group scenario

A common use of a DB instance in a VPC is to share data with an application server running in an Amazon EC2 instance in the same VPC, which is accessed by a client application outside the VPC. For this scenario, you use the RDS and VPC pages on the AWS Management Console or the RDS and EC2 API operations to create the necessary instances and security groups:

1. Create a VPC security group (for example, `sg-0123ec2example`) and define inbound rules that use the IP addresses of the client application as the source. This security group allows your client application to connect to EC2 instances in a VPC that uses this security group.

2. Create an EC2 instance for the application and add the EC2 instance to the VPC security group (`sg-0123ec2example`) that you created in the previous step.
3. Create a second VPC security group (for example, `sg-6789rdsexample`) and create a new rule by specifying the VPC security group that you created in step 1 (`sg-0123ec2example`) as the source.
4. Create a new DB instance and add the DB instance to the VPC security group (`sg-6789rdsexample`) that you created in the previous step. When you create the DB instance, use the same port number as the one specified for the VPC security group (`sg-6789rdsexample`) rule that you created in step 3.

The following diagram shows this scenario.



For detailed instructions about configuring a VPC for this scenario, see Tutorial: Create a VPC for use with a DB instance (IPv4 only). For more information about using a VPC, see Amazon VPC and Amazon RDS.

Creating a VPC security group

You can create a VPC security group for a DB instance by using the VPC console. For information about creating a security group, see Provide access to your DB instance in your VPC by creating a security group and Security groups in the *Amazon Virtual Private Cloud User Guide*.

Associating a security group with a DB instance

You can associate a security group with a DB instance by using **Modify** on the RDS console, the `ModifyDBInstance` Amazon RDS API, or the `modify-db-instance` AWS CLI command.

The following CLI example associates a specific VPC security group and removes DB security groups from the DB instance

```
aws rds modify-db-instance --db-instance-identifier dbName --vpc-security-group-ids sg-ID
```

For information about modifying a DB instance, see Modifying an Amazon RDS DB instance. For security group considerations when you restore a DB instance from a DB snapshot, see Security group considerations.

> **Note**
>
> The RDS console displays different security group rule names for your database if the Port value is configured to a non-default value.

For RDS for Oracle DB instances, additional security groups can be associated by populating the security group options setting for the Oracle Enterprise Manager Database Express (OEM), Oracle Management Agent for Enterprise Manager Cloud Control (OEM Agent) and the Oracle Secure Sockets Layer options. In this case, both security groups associated with the DB instance and options settings apply to the DB instance. For more information about these option groups, see Oracle Enterprise Manager, Oracle Management Agent for Enterprise Manager Cloud Control, and Oracle Secure Sockets Layer.

Master user account privileges

When you create a new DB instance, the default master user that you use gets certain privileges for that DB instance. You can't change the master user name after the DB instance is created.

Important

We strongly recommend that you do not use the master user directly in your applications. Instead, adhere to the best practice of using a database user created with the minimal privileges required for your application.

Note

If you accidentally delete the permissions for the master user, you can restore them by modifying the DB instance and setting a new master user password. For more information about modifying a DB instance, see Modifying an Amazon RDS DB instance.

The following table shows the privileges and database roles the master user gets for each of the database engines.

Database engine	System privilege	Database role
RDS for Db2	The master user is assigned to the `masterdba` group and assigned the `master_user_role` . `SYSMON`, `DBADM` with `DATAACCESS` AND `ACCCESSCTRL` , `BINDADD`, `CONNECT`, `CREATETAB` , `CREATE_SECURE_OBJECT` , `EXPLAIN`, `IMPLICIT_SCHEMA` , `LOAD`, `SQLADM`, `WLMADM`	`DBA`, `DBA_RESTRICTED` , `DEVELOPER` , `ROLE_NULLID_PACKAGES` , `ROLE_PROCEDURES` , `ROLE_TABLESPACES` For more information, see Amazon RDS for Db2 default roles.
RDS for MariaDB	`SELECT`, `INSERT`, `UPDATE`, `DELETE`, `CREATE`, `DROP`, `RELOAD`, `PROCESS`, `REFERENCES` , `INDEX`, `ALTER`, `SHOW DATABASES` , `CREATE TEMPORARY`	—

Database engine	System privilege	Database role
	TABLES , LOCK TABLES, EXECUTE, REPLICATION CLIENT , CREATE VIEW, SHOW VIEW, CREATE ROUTINE, ALTER ROUTINE, CREATE USER, EVENT, TRIGGER, REPLICATION SLAVE	
RDS for MySQL 8.0.36 and higher	SELECT, INSERT, UPDATE, DELETE, CREATE, DROP, RELOAD, PROCESS, REFERENCES , INDEX, ALTER, SHOW DATABASES , CREATE TEMPORARY TABLES, LOCK TABLES, EXECUTE, REPLICATION SLAVE, REPLICATION CLIENT , CREATE VIEW, SHOW VIEW, CREATE ROUTINE, ALTER ROUTINE, CREATE USER, EVENT, TRIGGER, CREATE ROLE, DROP ROLE, APPLICATION_PASSWORD_ADMIN , ROLE_ADMIN , SET_USER_ID , XA_RECOVER_ADMIN	rds_superuser_role For more information about rds_superuser_role , see Role-based privilege model.
RDS for MySQL versions lower than 8.0.36	SELECT, INSERT, UPDATE, DELETE, CREATE, DROP, RELOAD, PROCESS, REFERENCES , INDEX, ALTER, SHOW DATABASES , CREATE TEMPORARY TABLES , LOCK TABLES, EXECUTE, REPLICATION CLIENT , CREATE VIEW, SHOW VIEW, CREATE ROUTINE, ALTER ROUTINE, CREATE USER, EVENT, TRIGGER, REPLICATION SLAVE	—

Database engine	System privilege	Database role
RDS for PostgreSQL	CREATE ROLE, CREATE DB, PASSWORD VALID UNTIL INFINITY, CREATE EXTENSION , ALTER EXTENSION , DROP EXTENSION , CREATE TABLESPACE , ALTER <OBJECT> OWNER, CHECKPOINT , PG_CANCEL_BACKEND( ) , PG_TERMINATE_BACKEND() , SELECT PG_STAT_REPLICATION , EXECUTE PG_STAT_STATEMENTS_RESET() , OWN POSTGRES_FDW_HANDLER() , OWN POSTGRES_FDW_VALIDATOR() , OWN POSTGRES_FDW , EXECUTE PG_BUFFERCACHE_PAGES() , SELECT PG_BUFFERCACHE	RDS_SUPERUSER For more information about RDS_SUPERUSER, see Understanding PostgreSQL roles and permissions.
RDS for Oracle	ADMINISTER DATABASE TRIGGER , ALTER DATABASE LINK, ALTER PUBLIC DATABASE LINK, AUDIT SYSTEM, CHANGE NOTIFICATION , DROP ANY DIRECTORY , EXEMPT ACCESS POLICY, EXEMPT IDENTITY POLICY, EXEMPT REDACTION POLICY, FLASHBACK ANY TABLE, GRANT ANY OBJECT PRIVILEGE , RESTRICTED SESSION , SELECT ANY TABLE, UNLIMITED TABLESPACE	DBA **Note** The DBA role is exempt from the following privileges: ALTER DATABASE, ALTER SYSTEM, CREATE ANY DIRECTORY , CREATE EXTERNAL JOB, CREATE PLUGGABLE DATABASE, GRANT ANY PRIVILEGE , GRANT ANY ROLE, READ ANY FILE GROUP

Database engine	System privilege	Database role
Amazon RDS for Microsoft SQL Server	ADMINISTER BULK OPERATIONS , ALTER ANY CONNECTION , ALTER ANY CREDENTIAL , ALTER ANY EVENT SESSION, ALTER ANY LINKED SERVER, ALTER ANY LOGIN, ALTER ANY SERVER AUDIT, ALTER ANY SERVER ROLE, ALTER SERVER STATE, ALTER TRACE, CONNECT SQL, CREATE ANY DATABASE, VIEW ANY DATABASE, VIEW ANY DEFINITION , VIEW SERVER STATE, ALTER ON ROLE SQLAgentOperatorRole	DB_OWNER (database-level role), PROCESSADMIN (server-level role), SETUPADMIN (server-level role), SQLAgentUserRole (database-level role)

Using service-linked roles for Amazon RDS

Amazon RDS uses AWS Identity and Access Management (IAM) service-linked roles. A service-linked role is a unique type of IAM role that is linked directly to Amazon RDS. Service-linked roles are predefined by Amazon RDS and include all the permissions that the service requires to call other AWS services on your behalf.

A service-linked role makes using Amazon RDS easier because you don't have to manually add the necessary permissions. Amazon RDS defines the permissions of its service-linked roles, and unless defined otherwise, only Amazon RDS can assume its roles. The defined permissions include the trust policy and the permissions policy, and that permissions policy cannot be attached to any other IAM entity.

You can delete the roles only after first deleting their related resources. This protects your Amazon RDS resources because you can't inadvertently remove permission to access the resources.

For information about other services that support service-linked roles, see AWS services that work with IAM and look for the services that have **Yes** in the **Service-Linked Role** column. Choose a **Yes** with a link to view the service-linked role documentation for that service.

Service-linked role permissions for Amazon RDS

Amazon RDS uses the service-linked role named AWSServiceRoleForRDS to allow Amazon RDS to call AWS services on behalf of your DB instances.

The AWSServiceRoleForRDS service-linked role trusts the following services to assume the role:

- `rds.amazonaws.com`

This service-linked role has a permissions policy attached to it called `AmazonRDSServiceRolePolicy` that grants it permissions to operate in your account.

For more information about this policy, including the JSON policy document, see AmazonRDSServiceRolePolicy in the *AWS Managed Policy Reference Guide*.

> **Note**
>
> You must configure permissions to allow an IAM entity (such as a user, group, or role) to create, edit, or delete a service-linked role. If you encounter the following error message:

Unable to create the resource. Verify that you have permission to create service linked role. Otherwise wait and try again later.
Make sure you have the following permissions enabled:

```
{
    "Action": "iam:CreateServiceLinkedRole",
    "Effect": "Allow",
    "Resource": "arn:aws:iam::*:role/aws-service-role/rds.amazonaws.com/
AWSServiceRoleForRDS",
    "Condition": {
        "StringLike": {
            "iam:AWSServiceName":"rds.amazonaws.com"
        }
    }
}
```

For more information, see Service-linked role permissions in the *IAM User Guide*.

Creating a service-linked role for Amazon RDS

You don't need to manually create a service-linked role. When you create a DB instance, Amazon RDS creates the service-linked role for you.

Important

If you were using the Amazon RDS service before December 1, 2017, when it began supporting service-linked roles, then Amazon RDS created the AWSServiceRoleForRDS role in your account. To learn more, see A new role appeared in my AWS account.

If you delete this service-linked role, and then need to create it again, you can use the same process to recreate the role in your account. When you create a DB instance, Amazon RDS creates the service-linked role for you again.

Editing a service-linked role for Amazon RDS

Amazon RDS does not allow you to edit the AWSServiceRoleForRDS service-linked role. After you create a service-linked role, you cannot change the name of the role because various entities

might reference the role. However, you can edit the description of the role using IAM. For more information, see Editing a service-linked role in the *IAM User Guide*.

Deleting a service-linked role for Amazon RDS

If you no longer need to use a feature or service that requires a service-linked role, we recommend that you delete that role. That way you don't have an unused entity that is not actively monitored or maintained. However, you must delete all of your DB instances before you can delete the service-linked role.

Cleaning up a service-linked role

Before you can use IAM to delete a service-linked role, you must first confirm that the role has no active sessions and remove any resources used by the role.

To check whether the service-linked role has an active session in the IAM console

1. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation pane of the IAM console, choose **Roles**. Then choose the name (not the check box) of the AWSServiceRoleForRDS role.
3. On the **Summary** page for the chosen role, choose the **Access Advisor** tab.
4. On the **Access Advisor** tab, review recent activity for the service-linked role.

> **Note**
>
> If you are unsure whether Amazon RDS is using the AWSServiceRoleForRDS role, you can try to delete the role. If the service is using the role, then the deletion fails and you can view the AWS Regions where the role is being used. If the role is being used, then you must wait for the session to end before you can delete the role. You cannot revoke the session for a service-linked role.

If you want to remove the AWSServiceRoleForRDS role, you must first delete *all* of your DB instances .

Deleting all of your instances

Use one of these procedures to delete each of your instances.

To delete an instance (console)

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.
3. Choose the instance that you want to delete.
4. For **Actions**, choose **Delete**.
5. If you are prompted for **Create final Snapshot?**, choose **Yes** or **No**.
6. If you chose **Yes** in the previous step, for **Final snapshot name** enter the name of your final snapshot.
7. Choose **Delete**.

To delete an instance (CLI)

See `delete-db-instance` in the *AWS CLI Command Reference*.

To delete an instance (API)

See `DeleteDBInstance` in the *Amazon RDS API Reference*.

You can use the IAM console, the IAM CLI, or the IAM API to delete the AWSServiceRoleForRDS service-linked role. For more information, see Deleting a service-linked role in the *IAM User Guide*.

Service-linked role permissions for Amazon RDS Custom

Amazon RDS Custom uses the service-linked role named `AWSServiceRoleForRDSCustom` to allow RDS Custom to call AWS services on behalf of your RDS DB resources.

The AWSServiceRoleForRDSCustom service-linked role trusts the following services to assume the role:

- `custom.rds.amazonaws.com`

This service-linked role has a permissions policy attached to it called `AmazonRDSCustomServiceRolePolicy` that grants it permissions to operate in your account.

Creating, editing, or deleting the service-linked role for RDS Custom works the same as for Amazon RDS. For more information, see AWS managed policy: AmazonRDSCustomServiceRolePolicy.

Note

You must configure permissions to allow an IAM entity (such as a user, group, or role) to create, edit, or delete a service-linked role. If you encounter the following error message: **Unable to create the resource. Verify that you have permission to create service linked role. Otherwise wait and try again later.**
Make sure you have the following permissions enabled:

```
{
    "Action": "iam:CreateServiceLinkedRole",
    "Effect": "Allow",
    "Resource": "arn:aws:iam::*:role/aws-service-role/custom.rds.amazonaws.com/
AmazonRDSCustomServiceRolePolicy",
    "Condition": {
        "StringLike": {
            "iam:AWSServiceName":"custom.rds.amazonaws.com"
        }
    }
}
```

For more information, see Service-linked role permissions in the *IAM User Guide*.

Service-linked role permissions for Amazon RDS Beta

Amazon RDS uses the service-linked role named `AWSServiceRoleForRDSBeta` to allow Amazon RDS to call AWS services on behalf of your RDS DB resources.

The AWSServiceRoleForRDSBeta service-linked role trusts the following services to assume the role:

- `rds.amazonaws.com`

This service-linked role has a permissions policy attached to it called `AmazonRDSBetaServiceRolePolicy` that grants it permissions to operate in your account. For more information, see AWS managed policy: AmazonRDSBetaServiceRolePolicy.

Note

You must configure permissions to allow an IAM entity (such as a user, group, or role) to create, edit, or delete a service-linked role. If you encounter the following error message: **Unable to create the resource. Verify that you have permission to create service linked role. Otherwise wait and try again later.**
Make sure you have the following permissions enabled:

```
{
    "Action": "iam:CreateServiceLinkedRole",
    "Effect": "Allow",
    "Resource": "arn:aws:iam::*:role/aws-service-role/custom.rds.amazonaws.com/
AmazonRDSBetaServiceRolePolicy",
    "Condition": {
        "StringLike": {
            "iam:AWSServiceName":"custom.rds.amazonaws.com"
        }
    }
}
```

For more information, see Service-linked role permissions in the *IAM User Guide*.

Service-linked role for Amazon RDS Preview

Amazon RDS uses the service-linked role named `AWSServiceRoleForRDSPreview` to allow Amazon RDS to call AWS services on behalf of your RDS DB resources.

The AWSServiceRoleForRDSPreview service-linked role trusts the following services to assume the role:

- `rds.amazonaws.com`

This service-linked role has a permissions policy attached to it called `AmazonRDSPreviewServiceRolePolicy` that grants it permissions to operate in your account. For more information, see AWS managed policy: AmazonRDSPreviewServiceRolePolicy.

Note

You must configure permissions to allow an IAM entity (such as a user, group, or role) to create, edit, or delete a service-linked role. If you encounter the following error message: **Unable to create the resource. Verify that you have permission to create service linked role. Otherwise wait and try again later.**
Make sure you have the following permissions enabled:

```
{
    "Action": "iam:CreateServiceLinkedRole",
    "Effect": "Allow",
    "Resource": "arn:aws:iam::*:role/aws-service-role/custom.rds.amazonaws.com/
AmazonRDSPreviewServiceRolePolicy",
    "Condition": {
        "StringLike": {
            "iam:AWSServiceName":"custom.rds.amazonaws.com"
        }
    }
}
```

For more information, see Service-linked role permissions in the *IAM User Guide*.

Amazon VPC and Amazon RDS

Amazon Virtual Private Cloud (Amazon VPC) makes it possible for you to launch AWS resources, such as Amazon RDS DB instances, into a virtual private cloud (VPC).

When you use a VPC, you have control over your virtual networking environment. You can choose your own IP address range, create subnets, and configure routing and access control lists. There is no additional cost to run your DB instance in a VPC.

Accounts have a default VPC. All new DB instances are created in the default VPC unless you specify otherwise.

Topics

Following, you can find a discussion about VPC functionality relevant to Amazon RDS DB instances. For more information about Amazon VPC, see Amazon VPC Getting Started Guide and Amazon VPC User Guide.

Working with a DB instance in a VPC

Your DB instance is in a virtual private cloud (VPC). A VPC is a virtual network that is logically isolated from other virtual networks in the AWS Cloud. Amazon VPC makes it possible for you to launch AWS resources, such as an Amazon RDS DB instance or Amazon EC2 instance, into a VPC. The VPC can either be a default VPC that comes with your account or one that you create. All VPCs are associated with your AWS account.

Your default VPC has three subnets that you can use to isolate resources inside the VPC. The default VPC also has an internet gateway that can be used to provide access to resources inside the VPC from outside the VPC.

For a list of scenarios involving Amazon RDS DB instances in a VPC and outside of a VPC, see Scenarios for accessing a DB instance in a VPC.

Topics

In the following tutorials, you can learn to create a VPC that you can use for a common Amazon RDS scenario:

Working with a DB instance in a VPC

Here are some tips on working with a DB instance in a VPC:

- Your VPC must have at least two subnets. These subnets must be in two different Availability Zones in the AWS Region where you want to deploy your DB instance. A *subnet* is a segment of a VPC's IP address range that you can specify and that you can use to group DB instances based on your security and operational needs.

  For Multi-AZ deployments, defining a subnet for two or more Availability Zones in an AWS Region allows Amazon RDS to create a new standby in another Availability Zone as needed. Make sure to do this even for Single-AZ deployments, just in case you want to convert them to Multi-AZ deployments at some point.

  > **Note**
  >
  > The DB subnet group for a Local Zone can have only one subnet.

- If you want your DB instance in the VPC to be publicly accessible, make sure to turn on the VPC attributes *DNS hostnames* and *DNS resolution*.
- Your VPC must have a DB subnet group that you create. You create a DB subnet group by specifying the subnets you created. Amazon RDS chooses a subnet and an IP address within that

subnet group to associate with your DB instance. The DB instance uses the Availability Zone that contains the subnet.

- Your VPC must have a VPC security group that allows access to the DB instance.

  For more information, see Scenarios for accessing a DB instance in a VPC.

- The CIDR blocks in each of your subnets must be large enough to accommodate spare IP addresses for Amazon RDS to use during maintenance activities, including failover and compute scaling. For example, a range such as 10.0.0.0/24 and 10.0.1.0/24 is typically large enough.

- A VPC can have an *instance tenancy* attribute of either *default* or *dedicated*. All default VPCs have the instance tenancy attribute set to default, and a default VPC can support any DB instance class.

  If you choose to have your DB instance in a dedicated VPC where the instance tenancy attribute is set to dedicated, the DB instance class of your DB instance must be one of the approved Amazon EC2 dedicated instance types. For example, the r5.large EC2 dedicated instance corresponds to the db.r5.large DB instance class. For information about instance tenancy in a VPC, see Dedicated instances in the *Amazon Elastic Compute Cloud User Guide*.

  For more information about the instance types that can be in a dedicated instance, see Amazon EC2 dedicated instances on the EC2 pricing page.

  > **Note**
  >
  > When you set the instance tenancy attribute to dedicated for a DB instance, it doesn't guarantee that the DB instance will run on a dedicated host.

- When an option group is assigned to a DB instance, it's associated with the DB instance's VPC. This linkage means that you can't use the option group assigned to a DB instance if you attempt to restore the DB instance into a different VPC.

- If you restore a DB instance into a different VPC, make sure to either assign the default option group to the DB instance, assign an option group that is linked to that VPC, or create a new option group and assign it to the DB instance. With persistent or permanent options, such as Oracle TDE, you must create a new option group that includes the persistent or permanent option when restoring a DB instance into a different VPC.

Working with DB subnet groups

Subnets are segments of a VPC's IP address range that you designate to group your resources based on security and operational needs. A *DB subnet group* is a collection of subnets (typically private) that you create in a VPC and that you then designate for your DB instances. By using a DB subnet group, you can specify a particular VPC when creating DB instances using the AWS CLI or RDS API. If you use the console, you can choose the VPC and subnet groups you want to use.

Each DB subnet group should have subnets in at least two Availability Zones in a given AWS Region. When creating a DB instance in a VPC, you choose a DB subnet group for it. From the DB subnet group, Amazon RDS chooses a subnet and an IP address within that subnet to associate with the DB instance. The DB uses the Availability Zone that contains the subnet.

If the primary DB instance of a Multi-AZ deployment fails, Amazon RDS can promote the corresponding standby and later create a new standby using an IP address of the subnet in one of the other Availability Zones.

The subnets in a DB subnet group are either public or private. The subnets are public or private, depending on the configuration that you set for their network access control lists (network ACLs) and routing tables. For a DB instance to be publicly accessible, all of the subnets in its DB subnet group must be public. If a subnet that's associated with a publicly accessible DB instance changes from public to private, it can affect DB instance availability.

To create a DB subnet group that supports dual-stack mode, make sure that each subnet that you add to the DB subnet group has an Internet Protocol version 6 (IPv6) CIDR block associated with it. For more information, see Amazon RDS IP addressing and Migrating to IPv6 in the *Amazon VPC User Guide.*

> **Note**
>
> The DB subnet group for a Local Zone can have only one subnet.

When Amazon RDS creates a DB instance in a VPC, it assigns a network interface to your DB instance by using an IP address from your DB subnet group. However, we strongly recommend that you use the Domain Name System (DNS) name to connect to your DB instance. We recommend this because the underlying IP address changes during failover.

> **Note**
>
> For each DB instance that you run in a VPC, make sure to reserve at least one address in each subnet in the DB subnet group for use by Amazon RDS for recovery actions.

Shared subnets

You can create a DB instance in a shared VPC.

Some considerations to keep in mind while using shared VPCs:

- You can move a DB instance from a shared VPC subnet to a non-shared VPC subnet and vice-versa.
- Participants in a shared VPC must create a security group in the VPC to allow them to create a DB instance.
- Owners and participants in a shared VPC can access the database by using SQL queries. However, only the creator of a resource can make any API calls on the resource.

Amazon RDS IP addressing

IP addresses enable resources in your VPC to communicate with each other, and with resources over the internet. Amazon RDS supports both IPv4 and IPv6 addressing protocols. By default, Amazon RDS and Amazon VPC use the IPv4 addressing protocol. You can't turn off this behavior. When you create a VPC, make sure to specify an IPv4 CIDR block (a range of private IPv4 addresses). You can optionally assign an IPv6 CIDR block to your VPC and subnets, and assign IPv6 addresses from that block to DB instances in your subnet.

Support for the IPv6 protocol expands the number of supported IP addresses. By using the IPv6 protocol, you ensure that you have sufficient available addresses for the future growth of the internet. New and existing RDS resources can use IPv4 and IPv6 addresses within your VPC. Configuring, securing, and translating network traffic between the two protocols used in different parts of an application can cause operational overhead. You can standardize on the IPv6 protocol for Amazon RDS resources to simplify your network configuration.

Topics

- IPv4 addresses

- IPv6 addresses
- Dual-stack mode

IPv4 addresses

When you create a VPC, you must specify a range of IPv4 addresses for the VPC in the form of a CIDR block, such as `10.0.0.0/16`. A *DB subnet group* defines the range of IP addresses in this CIDR block that a DB instance can use. These IP addresses can be private or public.

A private IPv4 address is an IP address that's not reachable over the internet. You can use private IPv4 addresses for communication between your DB instance and other resources, such as Amazon EC2 instances, in the same VPC. Each DB instance has a private IP address for communication in the VPC.

A public IP address is an IPv4 address that's reachable from the internet. You can use public addresses for communication between your DB instance and resources on the internet, such as a SQL client. You control whether your DB instance receives a public IP address.

For a tutorial that shows you how to create a VPC with only private IPv4 addresses that you can use for a common Amazon RDS scenario, see Tutorial: Create a VPC for use with a DB instance (IPv4 only).

IPv6 addresses

You can optionally associate an IPv6 CIDR block with your VPC and subnets, and assign IPv6 addresses from that block to the resources in your VPC. Each IPv6 address is globally unique.

The IPv6 CIDR block for your VPC is automatically assigned from Amazon's pool of IPv6 addresses. You can't choose the range yourself.

When connecting to an IPv6 address, make sure that the following conditions are met:

- The client is configured so that client to database traffic over IPv6 is allowed.
- RDS security groups used by the DB instance are configured correctly so that client to database traffic over IPv6 is allowed.
- The client operating system stack allows traffic on the IPv6 address, and operating system drivers and libraries are configured to choose the correct default DB instance endpoint (either IPv4 or IPv6).

For more information about IPv6, see IP Addressing in the *Amazon VPC User Guide*.

Dual-stack mode

When a DB instance can communicate over both the IPv4 and IPv6 addressing protocols, it's running in dual-stack mode. So, resources can communicate with the DB instance over IPv4, IPv6, or both. RDS disables Internet Gateway access for IPv6 endpoints of private dual-stack mode DB instances. RDS does this to ensure that your IPv6 endpoints are private and can only be accessed from within your VPC.

Topics

- Dual-stack mode and DB subnet groups
- Working with dual-stack mode DB instances
- Modifying IPv4-only DB instances to use dual-stack mode
- Region and version availability
- Limitations for dual-stack network DB instances

For a tutorial that shows you how to create a VPC with both IPv4 and IPv6 addresses that you can use for a common Amazon RDS scenario, see Tutorial: Create a VPC for use with a DB instance (dual-stack mode).

Dual-stack mode and DB subnet groups

To use dual-stack mode, make sure that each subnet in the DB subnet group that you associate with the DB instance has an IPv6 CIDR block associated with it. You can create a new DB subnet group or modify an existing DB subnet group to meet this requirement. After a DB instance is in dual-stack mode, clients can connect to it normally. Make sure that client security firewalls and RDS DB instance security groups are accurately configured to allow traffic over IPv6. To connect, clients use the DB instance's endpoint. Client applications can specify which protocol is preferred when connecting to a database. In dual-stack mode, the DB instance detects the client's preferred network protocol, either IPv4 or IPv6, and uses that protocol for the connection.

If a DB subnet group stops supporting dual-stack mode because of subnet deletion or CIDR disassociation, there's a risk of an incompatible network state for DB instances that are associated with the DB subnet group. Also, you can't use the DB subnet group when you create a new dual-stack mode DB instance.

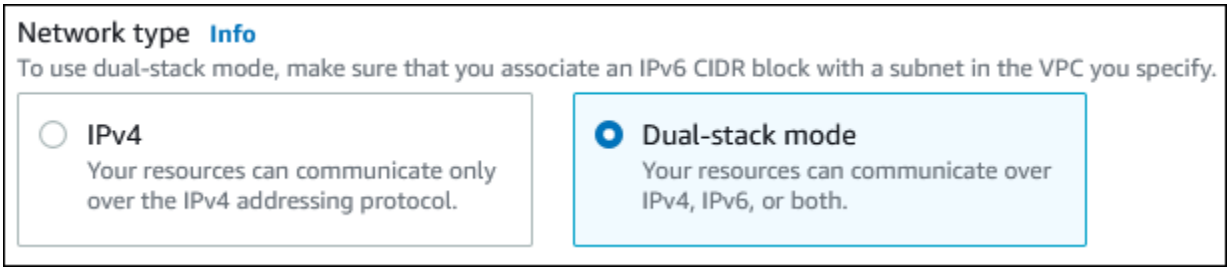
To determine whether a DB subnet group supports dual-stack mode by using the AWS Management Console, view the **Network type** on the details page of the DB subnet group. To determine whether a DB subnet group supports dual-stack mode by using the AWS CLI, run the describe-db-subnet-groups command and view `SupportedNetworkTypes` in the output.

Read replicas are treated as independent DB instances and can have a network type that's different from the primary DB instance. If you change the network type of a read replica's primary DB instance, the read replica isn't affected. When you are restoring a DB instance, you can restore it to any network type that's supported.

Working with dual-stack mode DB instances

When you create or modify a DB instance, you can specify dual-stack mode to allow your resources to communicate with your DB instance over IPv4, IPv6, or both.

When you use the AWS Management Console to create or modify a DB instance, you can specify dual-stack mode in the **Network type** section. The following image shows the **Network type** section in the console.



When you use the AWS CLI to create or modify a DB instance, set the `--network-type` option to `DUAL` to use dual-stack mode. When you use the RDS API to create or modify a DB instance, set the `NetworkType` parameter to `DUAL` to use dual-stack mode. When you are modifying the network type of a DB instance, downtime is possible. If dual-stack mode isn't supported by the specified DB engine version or DB subnet group, the `NetworkTypeNotSupported` error is returned.

For more information about creating a DB instance, see Creating an Amazon RDS DB instance. For more information about modifying a DB instance, see Modifying an Amazon RDS DB instance.

To determine whether a DB instance is in dual-stack mode by using the console, view the **Network type** on the **Connectivity & security** tab for the DB instance.

Modifying IPv4-only DB instances to use dual-stack mode

You can modify an IPv4-only DB instance to use dual-stack mode. To do so, change the network type of the DB instance. The modification might result in downtime.

It is recommended that you change the network type of your Amazon RDS DB instances during a maintenance window. Currently, setting the network type of new instances to dual-stack mode isn't supported. You can set network type manually by using the `modify-db-instance` command.

Before modifying a DB instance to use dual-stack mode, make sure that its DB subnet group supports dual-stack mode. If the DB subnet group associated with the DB instance doesn't support dual-stack mode, specify a different DB subnet group that supports it when you modify the DB instance. Modifying the DB subnet group of a DB instance can cause downtime.

If you modify the DB subnet group of a DB instance before you change the DB instance to use dual-stack mode, make sure that the DB subnet group is valid for the DB instance before and after the change.

For RDS for PostgreSQL, RDS for MySQL, RDS for Oracle, and RDS for MariaDB Single-AZ instances, we recommend that you run the modify-db-instance command with only the `--network-type` parameter set to `DUAL` to change the network to dual-stack mode. Adding other parameters along with the `--network-type` parameter in the same API call could result in downtime. To modify multiple parameters, ensure that the network type modification is successfully completed before sending another `modify-db-instance` request with other parameters.

Network type modifications for RDS for PostgreSQL, RDS for MySQL, RDS for Oracle, and RDS for MariaDB Multi-AZ DB instances cause a brief downtime and trigger a failover if you only use the `--network-type` parameter or if you combine parameters in a modify-db-instance command.

Network type modifications on RDS for SQL Server Single-AZ or Multi-AZ DB instances cause downtime if you only use the `--network-type` parameter or if you combine parameters in a `modify-db-instance` command. Network type modifications cause failover in an SQL Server Multi-AZ instance.

If you can't connect to the DB instance after the change, make sure that the client and database security firewalls and route tables are accurately configured to allow traffic to the database on the selected network (either IPv4 or IPv6). You might also need to modify operating system parameter, libraries, or drivers to connect using an IPv6 address.

When you modify a DB instance to use dual-stack mode, there can't be a pending change from a Single-AZ deployment to a Multi-AZ deployment, or from a Multi-AZ deployment to a Single-AZ deployment.

To modify an IPv4-only DB instance to use dual-stack mode

1. Modify a DB subnet group to support dual-stack mode, or create a DB subnet group that supports dual-stack mode:

   a. Associate an IPv6 CIDR block with your VPC.

      For instructions, see Add an IPv6 CIDR block to your VPC in the *Amazon VPC User Guide*.

   b. Attach the IPv6 CIDR block to all of the subnets in your the DB subnet group.

      For instructions, see Add an IPv6 CIDR block to your subnet in the *Amazon VPC User Guide*.

   c. Confirm that the DB subnet group supports dual-stack mode.

      If you are using the AWS Management Console, select the DB subnet group, and make sure that the **Supported network types** value is **Dual, IPv4**.

      If you are using the AWS CLI, run the describe-db-subnet-groups command, and make sure that the `SupportedNetworkType` value for the DB instance is `Dual, IPv4`.

2. Modify the security group associated with the DB instance to allow IPv6 connections to the database, or create a new security group that allows IPv6 connections.

   For instructions, see Security group rules in the *Amazon VPC User Guide*.

3. Modify the DB instance to support dual-stack mode. To do so, set the **Network type** to **Dual-stack mode**.

   If you are using the console, make sure that the following settings are correct:

   - **Network type** – **Dual-stack mode**

     
   - **DB subnet group** – The DB subnet group that you configured in a previous step
   - **Security group** – The security that you configured in a previous step

If you are using the AWS CLI, make sure that the following settings are correct:

- `--network-type` – `dual`
- `--db-subnet-group-name` – The DB subnet group that you configured in a previous step
- `--vpc-security-group-ids` – The VPC security group that you configured in a previous step

For example:

```
aws rds modify-db-instance --db-instance-identifier my-instance --network-type
 "DUAL"
```

4. Confirm that the DB instance supports dual-stack mode.

   If you are using the console, choose the **Connectivity & security** tab for the DB instance. On that tab, make sure that the **Network type** value is **Dual-stack mode**.

   If you are using the AWS CLI, run the describe-db-instances command, and make sure that the `NetworkType` value for the DB instance is `dual`.

   Run the `dig` command on the DB instance endpoint to identify the IPv6 address associated with it.

   ```
   dig db-instance-endpoint AAAA
   ```

   Use the DB instance endpoint, not the IPv6 address, to connect to the DB instance.

Region and version availability

Feature availability and support varies across specific versions of each database engine, and across AWS Regions. For more information on version and Region availability with dual-stack mode, see Supported Regions and DB engines for dual-stack mode in Amazon RDS.

Limitations for dual-stack network DB instances

The following limitations apply to dual-stack network DB instances:

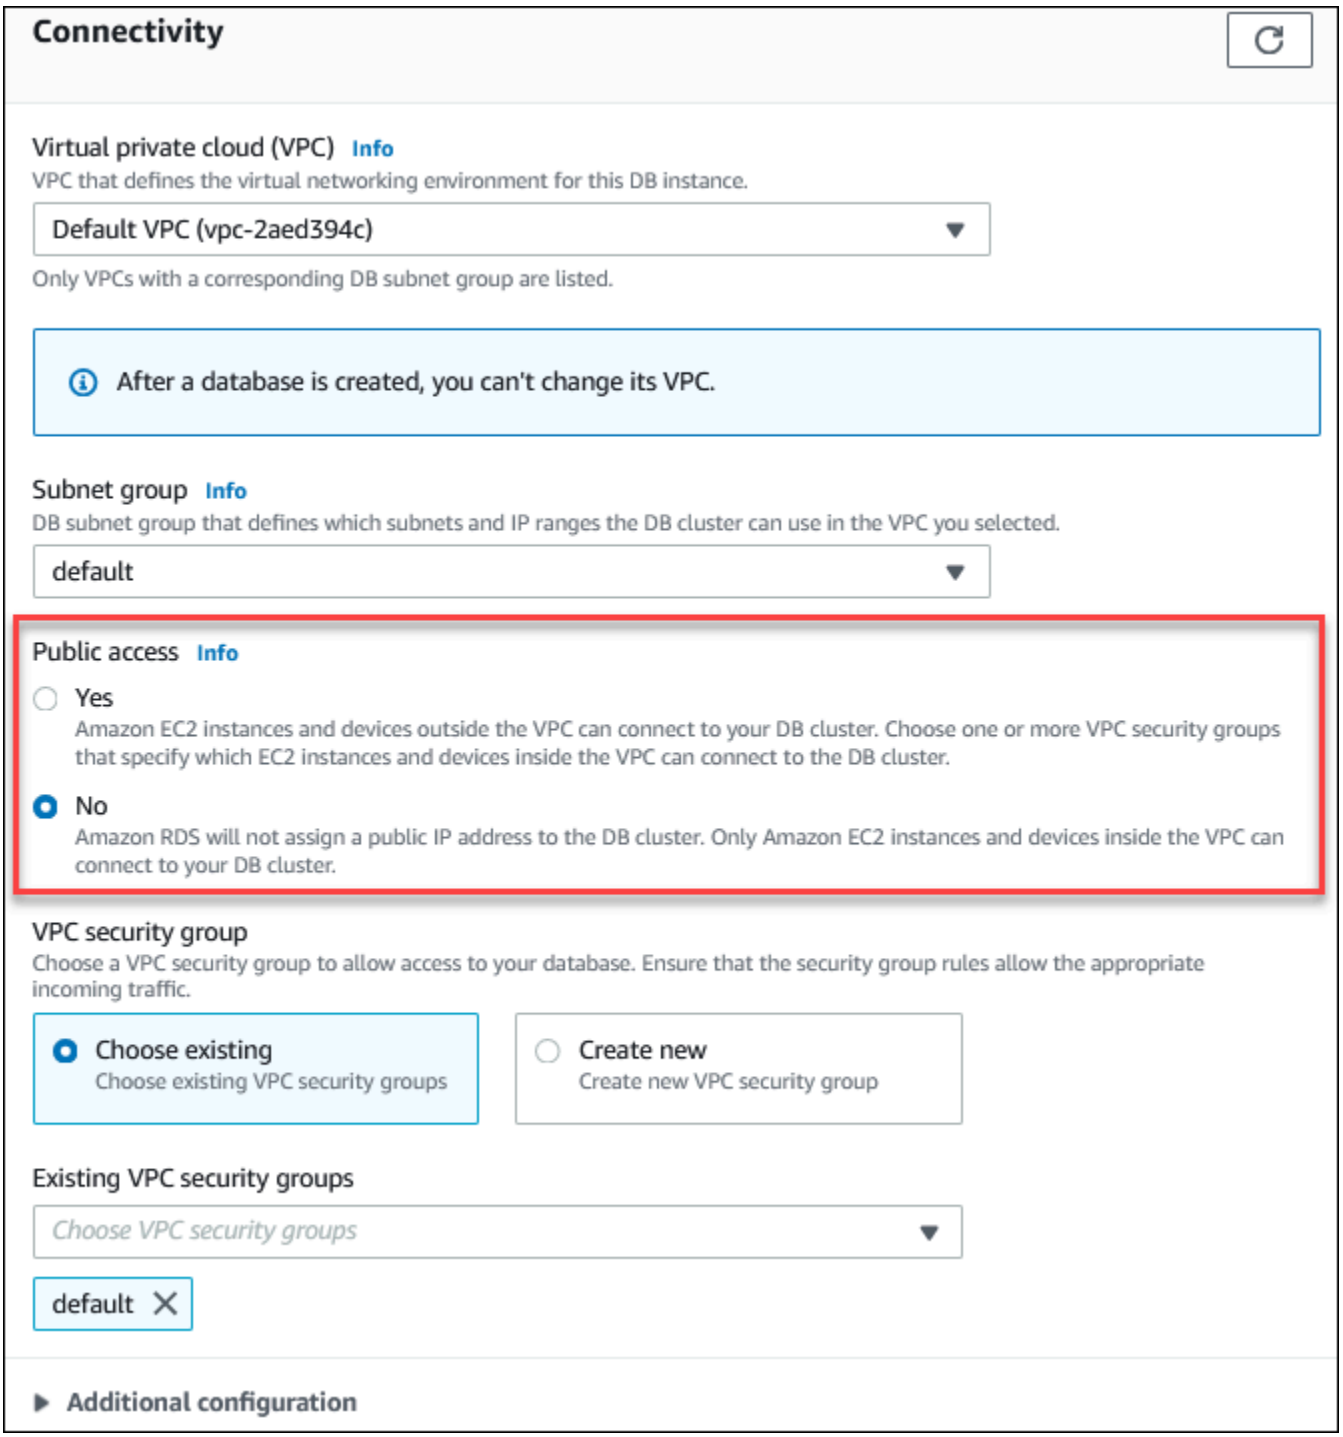
- DB instances can't use the IPv6 protocol exclusively. They can use IPv4 exclusively, or they can use the IPv4 and IPv6 protocol (dual-stack mode).
- Amazon RDS doesn't support native IPv6 subnets.
- DB instances that use dual-stack mode must be private. They can't be publicly accessible.
- Dual-stack mode doesn't support the db.m3 and db.r3 DB instance classes.
- For RDS for SQL Server, dual-stack mode DB instances that use Always On AGs availability group listener endpoints only present IPv4 addresses.
- You can't use RDS Proxy with dual-stack mode DB instances.
- You can't use dual-stack mode with RDS on AWS Outposts DB instances.
- You can't use dual-stack mode with DB instances in a Local Zone.

Hiding a DB instance in a VPC from the internet

One common Amazon RDS scenario is to have a VPC in which you have an EC2 instance with a public-facing web application and a DB instance with a database that isn't publicly accessible. For example, you can create a VPC that has a public subnet and a private subnet. Amazon EC2 instances that function as web servers can be deployed in the public subnet. The DB instances are deployed in the private subnet. In such a deployment, only the web servers have access to the DB instances. For an illustration of this scenario, see A DB instance in a VPC accessed by an EC2 instance in the same VPC.

When you launch a DB instance inside a VPC, the DB instance has a private IP address for traffic inside the VPC. This private IP address isn't publicly accessible. You can use the **Public access** option to designate whether the DB instance also has a public IP address in addition to the private IP address. If the DB instance is designated as publicly accessible, its DNS endpoint resolves to the private IP address from within the VPC. It resolves to the public IP address from outside of the VPC. Access to the DB instance is ultimately controlled by the security group it uses. That public access is not permitted if the security group assigned to the DB instance doesn't include inbound rules that permit it. In addition, for a DB instance to be publicly accessible, the subnets in its DB subnet group must have an internet gateway. For more information, see Can't connect to Amazon RDS DB instance

You can modify a DB instance to turn on or off public accessibility by modifying the **Public access** option. The following illustration shows the **Public access** option in the **Additional connectivity configuration** section. To set the option, open the **Additional connectivity configuration** section in the **Connectivity** section.



For information about modifying a DB instance to set the **Public access** option, see Modifying an Amazon RDS DB instance.

Creating a DB instance in a VPC

The following procedures help you create a DB instance in a VPC. To use the default VPC, you can begin with step 2, and use the VPC and DB subnet group have already been created for you. If you want to create an additional VPC, you can create a new VPC.

> **Note**
>
> If you want your DB instance in the VPC to be publicly accessible, you must update the DNS information for the VPC by enabling the VPC attributes *DNS hostnames* and *DNS resolution*. For information about updating the DNS information for a VPC instance, see Updating DNS support for your VPC.

Follow these steps to create a DB instance in a VPC:

- Step 1: Create a VPC
- Step 2: Create a DB subnet group
- Step 3: Create a VPC security group
- Step 4: Create a DB instance in the VPC

Step 1: Create a VPC

Create a VPC with subnets in at least two Availability Zones. You use these subnets when you create a DB subnet group. If you have a default VPC, a subnet is automatically created for you in each Availability Zone in the AWS Region.

For more information, see Create a VPC with private and public subnets, or see Create a VPC in the *Amazon VPC User Guide*.

Step 2: Create a DB subnet group

A DB subnet group is a collection of subnets (typically private) that you create for a VPC and that you then designate for your DB instances. A DB subnet group allows you to specify a particular VPC when you create DB instances using the AWS CLI or RDS API. If you use the console, you can just choose the VPC and subnets you want to use. Each DB subnet group must have at least one subnet in at least two Availability Zones in the AWS Region. As a best practice, each DB subnet group should have at least one subnet for every Availability Zone in the AWS Region.

For Multi-AZ deployments, defining a subnet for all Availability Zones in an AWS Region enables Amazon RDS to create a new standby replica in another Availability Zone if necessary. You can follow this best practice even for Single-AZ deployments, because you might convert them to Multi-AZ deployments in the future.

For a DB instance to be publicly accessible, the subnets in the DB subnet group must have an internet gateway. For more information about internet gateways for subnets, see Connect to the internet using an internet gateway in the *Amazon VPC User Guide*.

> **Note**
>
> The DB subnet group for a Local Zone can have only one subnet.

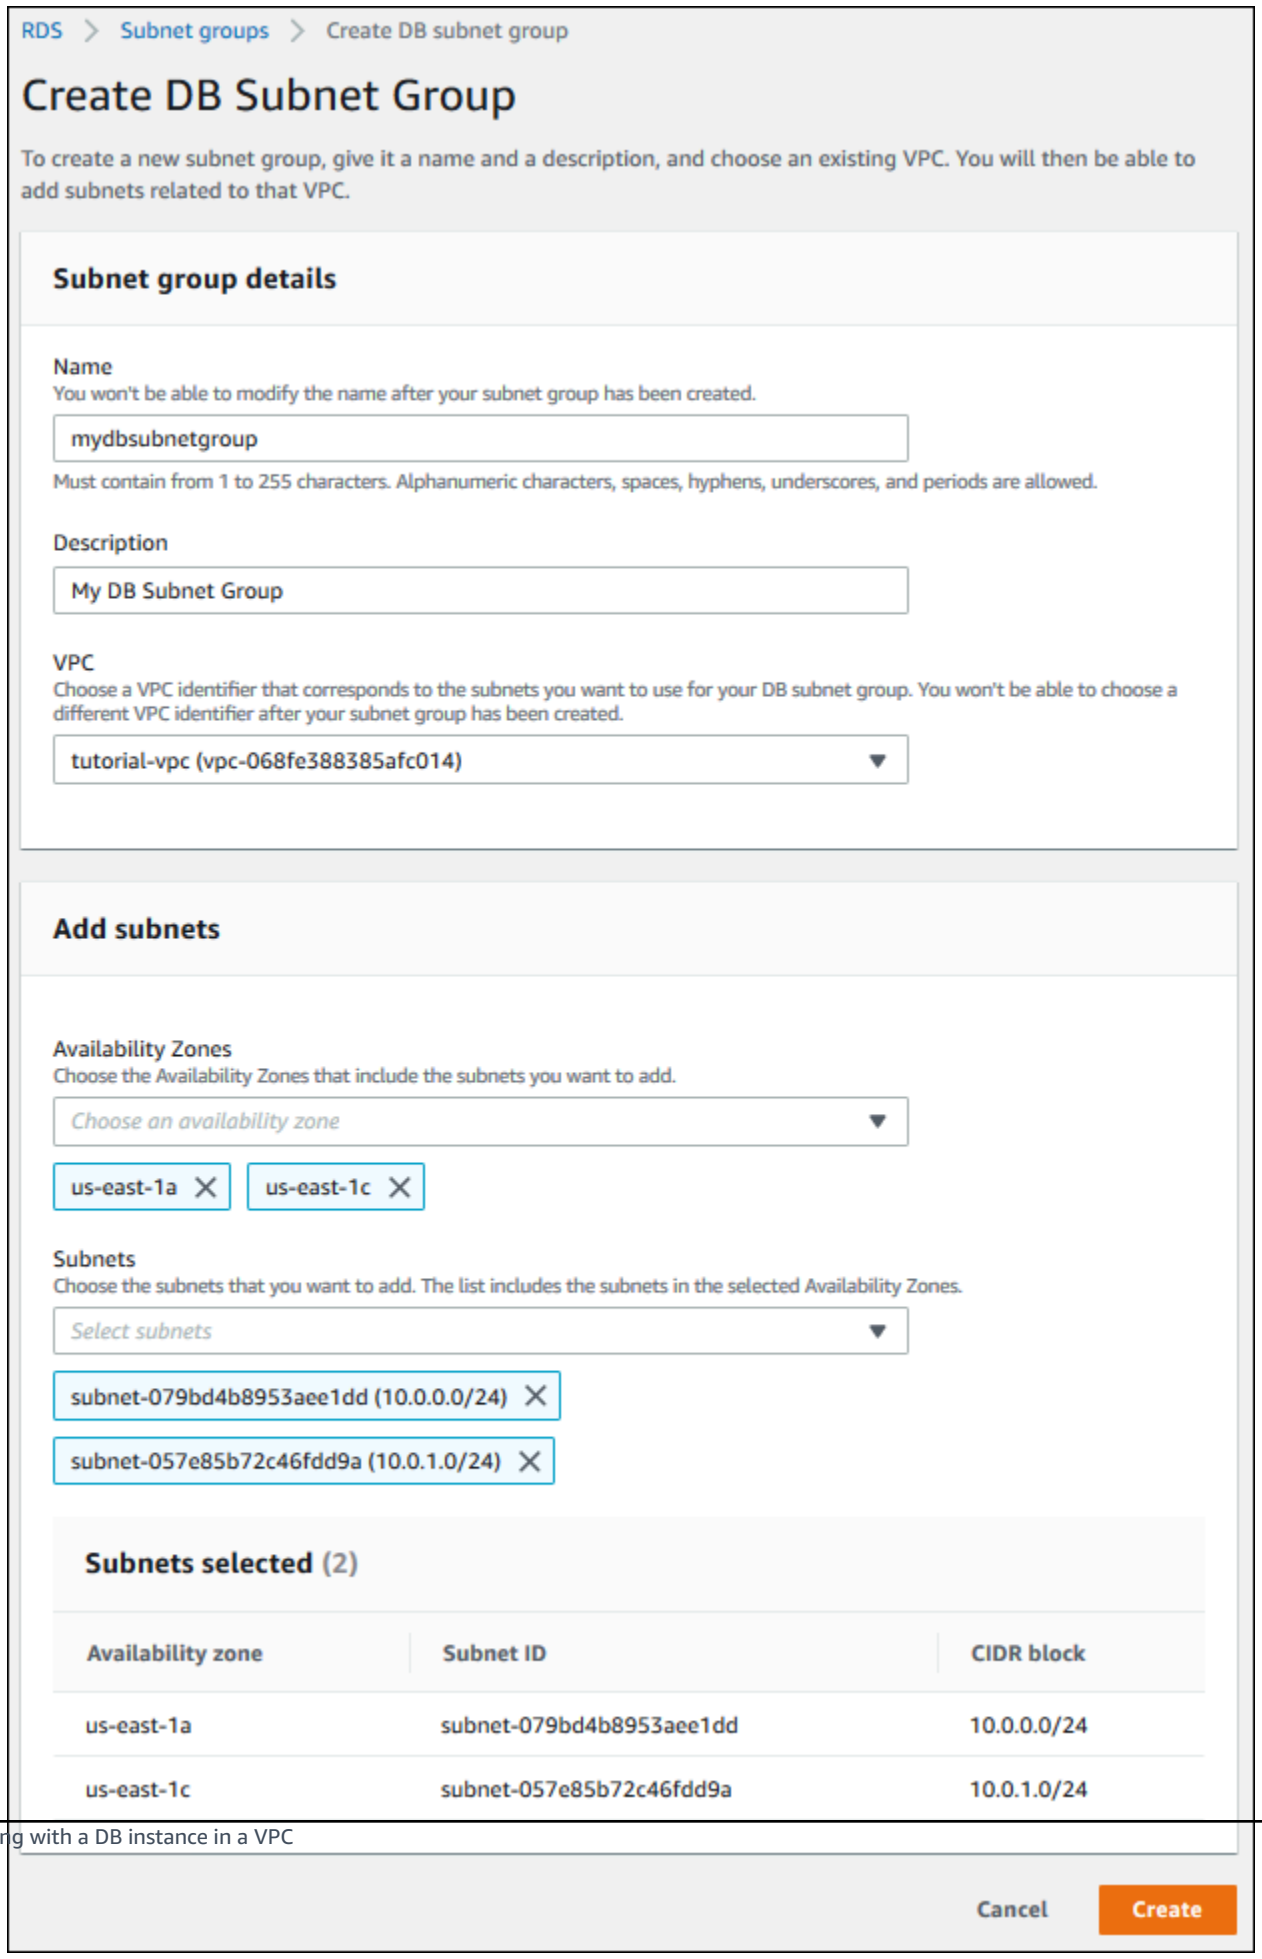
When you create a DB instance in a VPC, you can choose a DB subnet group. Amazon RDS chooses a subnet and an IP address within that subnet to associate with your DB instance. If no DB subnet groups exist, Amazon RDS creates a default subnet group when you create a DB instance. Amazon RDS creates and associates an Elastic Network Interface to your DB instance with that IP address. The DB instance uses the Availability Zone that contains the subnet.

For Multi-AZ deployments, defining a subnet for two or more Availability Zones in an AWS Region allows Amazon RDS to create a new standby in another Availability Zone should the need arise. You need to do this even For Single-AZ deployments, just in case you want to convert them to Multi-AZ deployments at some point.

In this step, you create a DB subnet group and add the subnets that you created for your VPC.

To create a DB subnet group

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Subnet groups**.
3. Choose **Create DB Subnet Group**.
4. For **Name**, type the name of your DB subnet group.
5. For **Description**, type a description for your DB subnet group.
6. For **VPC**, choose the default VPC or the VPC that you created.
7. In the **Add subnets** section, choose the Availability Zones that include the subnets from **Availability Zones**, and then choose the subnets from **Subnets**.



RDS > Subnet groups > Create DB subnet group
Create DB Subnet Group
To create a new subnet group, give it a name and a description, and choose an existing VPC. You will then be able to add subnets related to that VPC.
Subnet group details
Name
You won't be able to modify the name after your subnet group has been created.
mydbsubnetgroup
Must contain from 1 to 255 characters. Alphanumeric characters, spaces, hyphens, underscores, and periods are allowed.
Description
My DB Subnet Group
VPC
Choose a VPC identifier that corresponds to the subnets you want to use for your DB subnet group. You won't be able to choose a different VPC identifier after your subnet group has been created.

10.0.0.0/24
us-east-1c
subnet-057e85b72c46fdd9a
10.0.1.0/24
Cancel
Create

> **Note**
>
> If you have enabled a Local Zone, you can choose an Availability Zone group on the **Create DB subnet group** page. In this case, choose the **Availability Zone group**, **Availability Zones**, and **Subnets**.

8. Choose **Create**.

   Your new DB subnet group appears in the DB subnet groups list on the RDS console. You can choose the DB subnet group to see details, including all of the subnets associated with the group, in the details pane at the bottom of the window.

Step 3: Create a VPC security group

Before you create your DB instance, you can create a VPC security group to associate with your DB instance. If you don't create a VPC security group, you can use the default security group when you create a DB instance. For instructions on how to create a security group for your DB instance, see Create a VPC security group for a private DB instance, or see Control traffic to resources using security groups in the *Amazon VPC User Guide*.

Step 4: Create a DB instance in the VPC

In this step, you create a DB instance and use the VPC name, the DB subnet group, and the VPC security group you created in the previous steps.

> **Note**
>
> If you want your DB instance in the VPC to be publicly accessible, you must enable the VPC attributes *DNS hostnames* and *DNS resolution*. For more information, see DNS attributes for your VPC in the *Amazon VPC User Guide*.

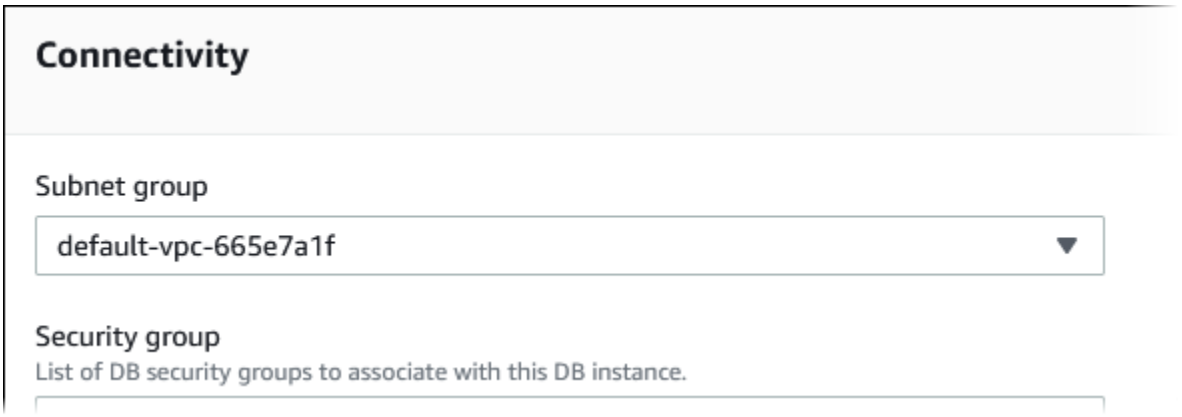
For details on how to create a DB instance, see Creating an Amazon RDS DB instance.

When prompted in the **Connectivity** section, enter the VPC name, the DB subnet group, and the VPC security group.

Updating the VPC for a DB instance

You can use the AWS Management Console to move your DB instance to a different VPC.

For information about modifying a DB instance, see Modifying an Amazon RDS DB instance. In the **Connectivity** section of the modify page, shown following, enter the new DB subnet group for **DB subnet group**. The new subnet group must be a subnet group in a new VPC.



You can't change the VPC for a DB instance if the following conditions apply:

- The DB instance is in multiple Availability Zones. You can convert the DB instance to a single Availability Zone, move it to a new VPC, and then convert it back to a Multi-AZ DB instance. For more information, see Configuring and managing a Multi-AZ deployment.
- The DB instance has one or more read replicas. You can remove the read replicas, move the DB instance to a new VPC, and then add the read replicas again. For more information, see Working with DB instance read replicas.
- The DB instance is a read replica. You can promote the read replica, and then move the standalone DB instance to a new VPC. For more information, see Promoting a read replica to be a standalone DB instance.
- The subnet group in the target VPC doesn't have subnets in the DB instance's the Availability Zone. You can add subnets in the DB instance's Availability Zone to the DB subnet group, and then move the DB instance to the new VPC. For more information, see Working with DB subnet groups.

Scenarios for accessing a DB instance in a VPC

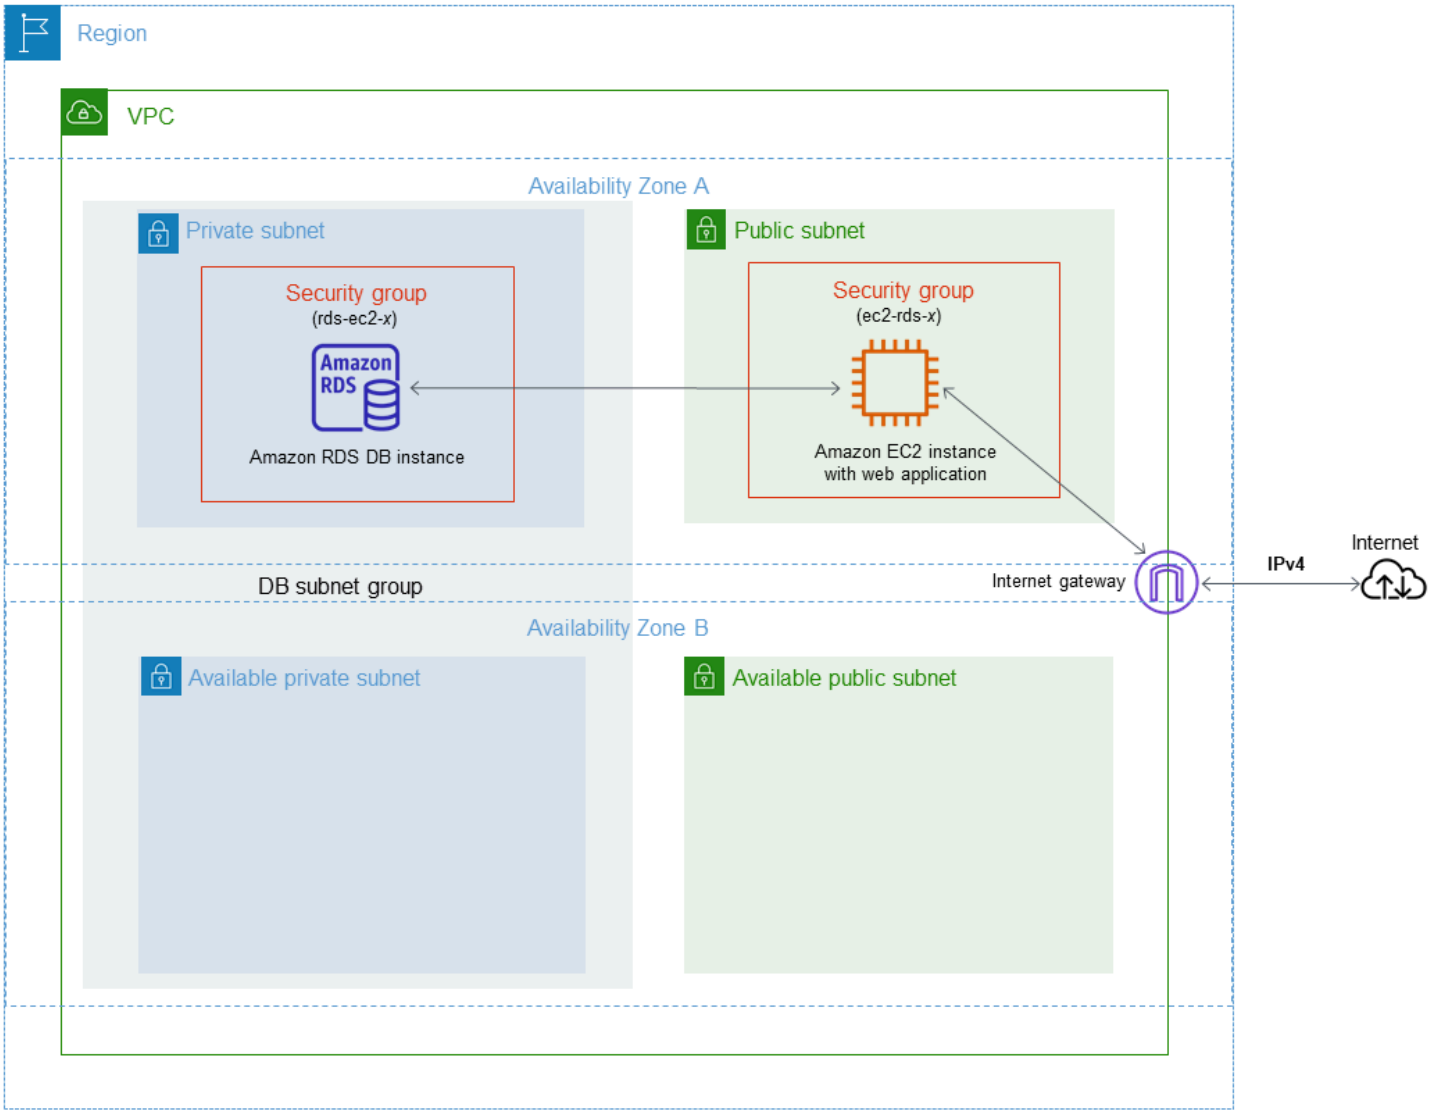
Amazon RDS supports the following scenarios for accessing a DB instance in a VPC:

- An EC2 instance in the same VPC
- An EC2 instance in a different VPC
- A client application through the internet
- A private network

A DB instance in a VPC accessed by an EC2 instance in the same VPC

A common use of a DB instance in a VPC is to share data with an application server that is running in an EC2 instance in the same VPC.

The following diagram shows this scenario.



The simplest way to manage access between EC2 instances and DB instances in the same VPC is to do the following:

- Create a VPC security group for your DB instances to be in. This security group can be used to restrict access to the DB instances. For example, you can create a custom rule for this security group. This might allow TCP access using the port that you assigned to the DB instance when you created it and an IP address you use to access the DB instance for development or other purposes.
- Create a VPC security group for your EC2 instances (web servers and clients) to be in. This security group can, if needed, allow access to the EC2 instance from the internet by using the VPC's routing table. For example, you can set rules on this security group to allow TCP access to the EC2 instance over port 22.
- Create custom rules in the security group for your DB instances that allow connections from the security group you created for your EC2 instances. These rules might allow any member of the security group to access the DB instances.

There is an additional public and private subnet in a separate Availability Zone. An RDS DB subnet group requires a subnet in at least two Availability Zones. The additional subnet makes it easy to switch to a Multi-AZ DB instance deployment in the future.

For a tutorial that shows you how to create a VPC with both public and private subnets for this scenario, see Tutorial: Create a VPC for use with a DB instance (IPv4 only).

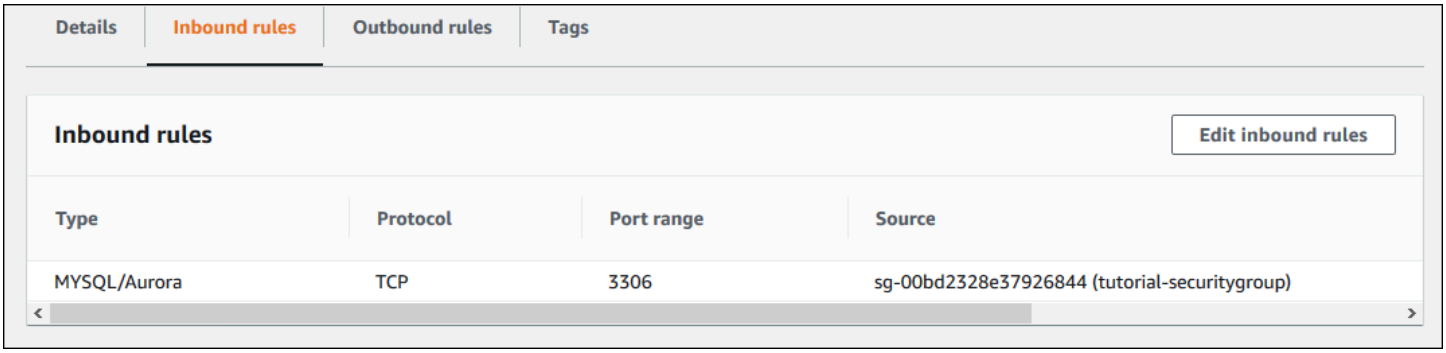
> **Tip**
>
> You can set up network connectivity between an Amazon EC2 instance and a DB instance automatically when you create the DB instance. For more information, see Configure automatic network connectivity with an EC2 instance.

To create a rule in a VPC security group that allows connections from another security group, do the following:

1. Sign in to the AWS Management Console and open the Amazon VPC console at https://console.aws.amazon.com/vpc.
2. In the navigation pane, choose **Security groups**.

3. Choose or create a security group for which you want to allow access to members of another security group. In the preceding scenario, this is the security group that you use for your DB instances. Choose the **Inbound rules** tab, and then choose **Edit inbound rules**.
4. On the **Edit inbound rules** page, choose **Add rule**.
5. For **Type**, choose the entry that corresponds to the port you used when you created your DB instance, such as **MYSQL/Aurora**.
6. In the **Source** box, start typing the ID of the security group, which lists the matching security groups. Choose the security group with members that you want to have access to the resources protected by this security group. In the scenario preceding, this is the security group that you use for your EC2 instance.
7. If required, repeat the steps for the TCP protocol by creating a rule with **All TCP** as the **Type** and your security group in the **Source** box. If you intend to use the UDP protocol, create a rule with **All UDP** as the **Type** and your security group in **Source**.
8. Choose **Save rules**.

The following screen shows an inbound rule with a security group for its source.

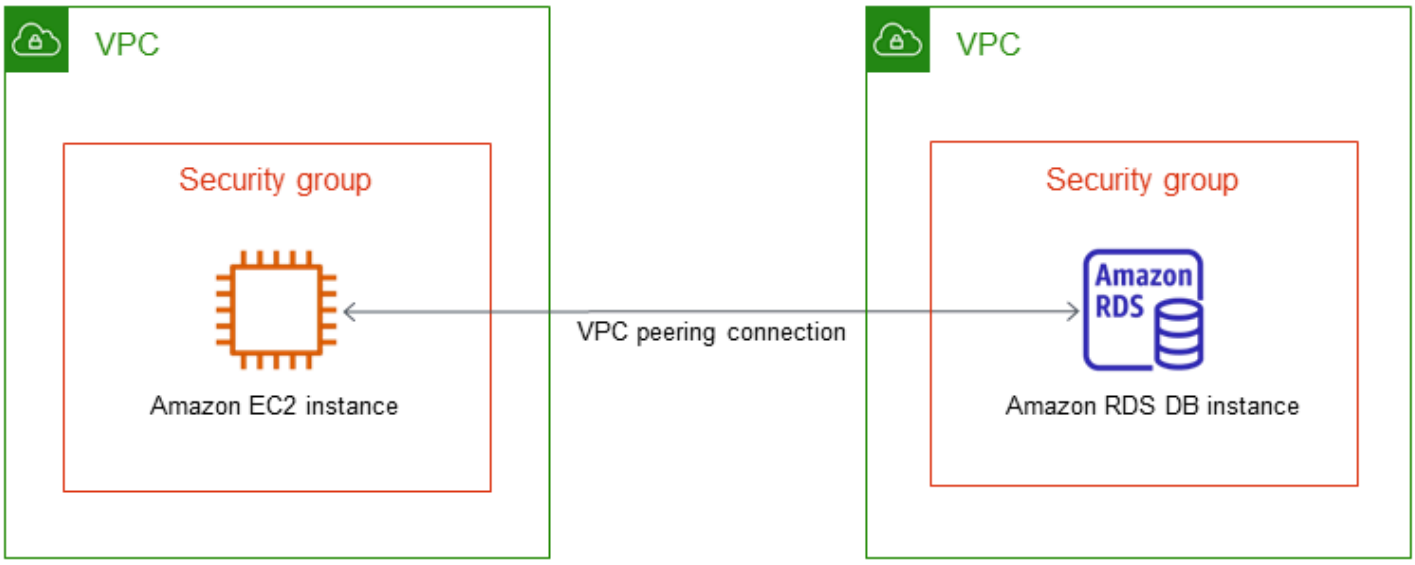


For more information about connecting to the DB instance from your EC2 instance, see Connecting to an Amazon RDS DB instance .

A DB instance in a VPC accessed by an EC2 instance in a different VPC

When your DB instances is in a different VPC from the EC2 instance you are using to access it, you can use VPC peering to access the DB instance.

The following diagram shows this scenario.

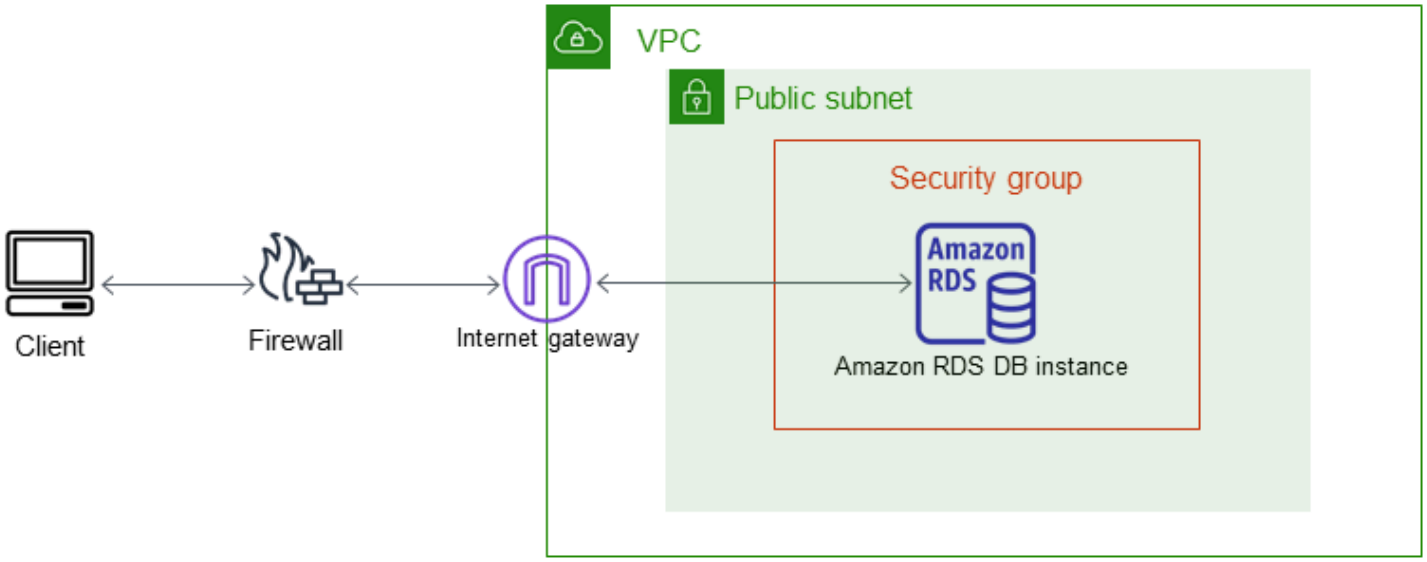


A VPC peering connection is a networking connection between two VPCs that enables you to route traffic between them using private IP addresses. Resources in either VPC can communicate with each other as if they are within the same network. You can create a VPC peering connection between your own VPCs, with a VPC in another AWS account, or with a VPC in a different AWS Region. To learn more about VPC peering, see VPC peering in the *Amazon Virtual Private Cloud User Guide*.

A DB instance in a VPC accessed by a client application through the internet

To access a DB instances in a VPC from a client application through the internet, you configure a VPC with a single public subnet, and an internet gateway to enable communication over the internet.

The following diagram shows this scenario.



We recommend the following configuration:

- A VPC of size /16 (for example CIDR: 10.0.0.0/16). This size provides 65,536 private IP addresses.
- A subnet of size /24 (for example CIDR: 10.0.0.0/24). This size provides 256 private IP addresses.
- An Amazon RDS DB instance that is associated with the VPC and the subnet. Amazon RDS assigns an IP address within the subnet to your DB instance.
- An internet gateway which connects the VPC to the internet and to other AWS products.
- A security group associated with the DB instance. The security group's inbound rules allow your client application to access to your DB instance.

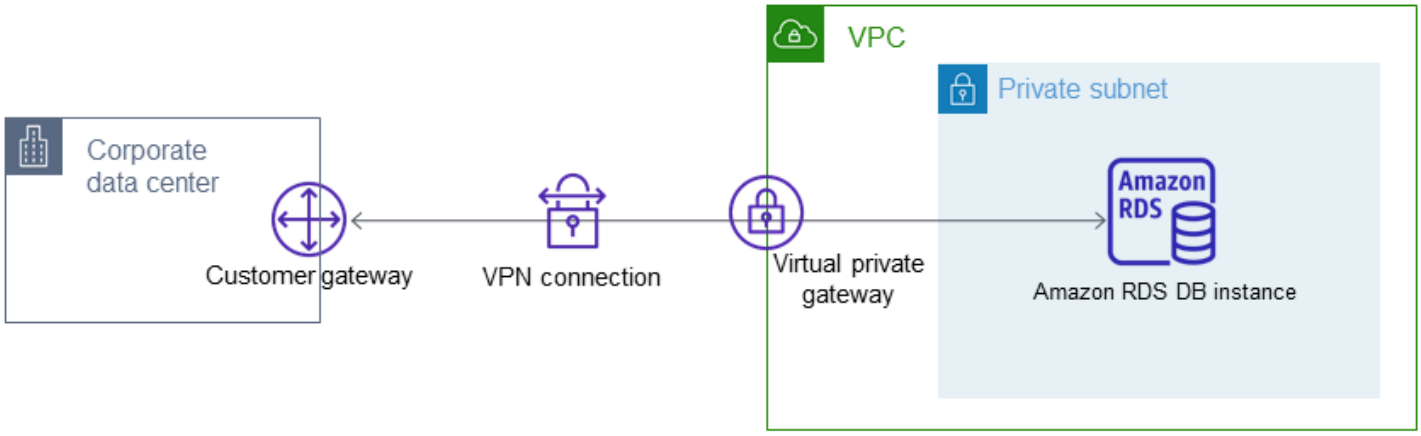
For information about creating a DB instances in a VPC, see Creating a DB instance in a VPC.

A DB instance in a VPC accessed by a private network

If your DB instance isn't publicly accessible, you have the following options for accessing it from a private network:

- An AWS Site-to-Site VPN connection. For more information, see What is AWS Site-to-Site VPN?
- An AWS Direct Connect connection. For more information, see What is AWS Direct Connect?
- An AWS Client VPN connection. For more information, see What is AWS Client VPN?

The following diagram shows a scenario with an AWS Site-to-Site VPN connection.

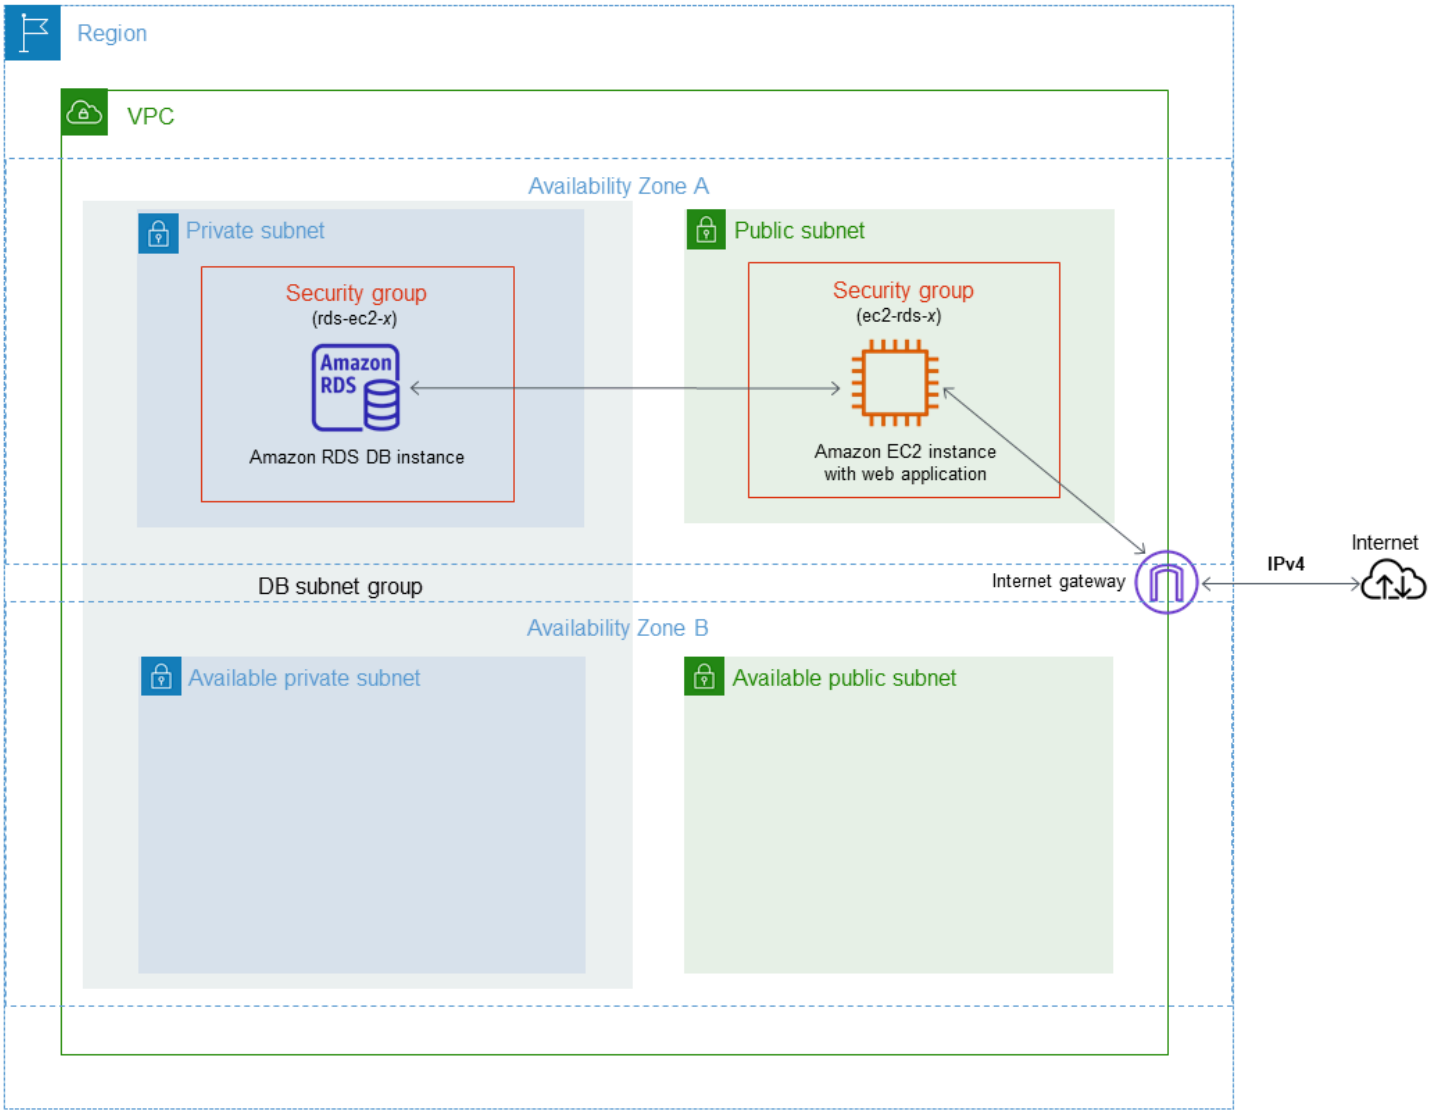


For more information, see Internetwork traffic privacy.

Tutorial: Create a VPC for use with a DB instance (IPv4 only)

A common scenario includes a DB instance in a virtual private cloud (VPC) based on the Amazon VPC service. This VPC shares data with a web server that is running in the same VPC. In this tutorial, you create the VPC for this scenario.

The following diagram shows this scenario. For information about other scenarios, see Scenarios for accessing a DB instance in a VPC.



Your DB instance needs to be available only to your web server, and not to the public internet. Thus, you create a VPC with both public and private subnets. The web server is hosted in the public subnet, so that it can reach the public internet. The DB instance is hosted in a private subnet. The web server can connect to the DB instance because it is hosted within the same VPC. But the DB instance isn't available to the public internet, providing greater security.

This tutorial configures an additional public and private subnet in a separate Availability Zone. These subnets aren't used by the tutorial. An RDS DB subnet group requires a subnet in at least two Availability Zones. The additional subnet makes it easier to switch to a Multi-AZ DB instance deployment in the future.

This tutorial describes configuring a VPC for Amazon RDS DB instances. For a tutorial that shows you how to create a web server for this VPC scenario, see Tutorial: Create a web server and an Amazon RDS DB instance. For more information about Amazon VPC, see Amazon VPC Getting Started Guide and Amazon VPC User Guide.

> **Tip**
>
> You can set up network connectivity between an Amazon EC2 instance and a DB instance automatically when you create the DB instance. The network configuration is similar to the one described in this tutorial. For more information, see Configure automatic network connectivity with an EC2 instance.

Create a VPC with private and public subnets

Use the following procedure to create a VPC with both public and private subnets.

To create a VPC and subnets

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the top-right corner of the AWS Management Console, choose the Region to create your VPC in. This example uses the US West (Oregon) Region.
3. In the upper-left corner, choose **VPC dashboard**. To begin creating a VPC, choose **Create VPC**.
4. For **Resources to create** under **VPC settings**, choose **VPC and more**.
5. For the **VPC settings**, set these values:

   - **Name tag auto-generation** – `tutorial`
   - **IPv4 CIDR block** – `10.0.0.0/16`
   - **IPv6 CIDR block** – **No IPv6 CIDR block**
   - **Tenancy** – **Default**
   - **Number of Availability Zones (AZs)** – **2**
   - **Customize AZs** – Keep the default values.

- **Number of public subnet** – **2**
- **Number of private subnets** – **2**
- **Customize subnets CIDR blocks** – Keep the default values.
- **NAT gateways ($)** – **None**
- **VPC endpoints** – **None**
- **DNS options** – Keep the default values.

> **Note**
>
> Amazon RDS requires at least two subnets in two different Availability Zones to support Multi-AZ DB instance deployments. This tutorial creates a Single-AZ deployment, but the requirement makes it easier to convert to a Multi-AZ DB instance deployment in the future.

6. Choose **Create VPC**.

Create a VPC security group for a public web server

Next, you create a security group for public access. To connect to public EC2 instances in your VPC, you add inbound rules to your VPC security group. These allow traffic to connect from the internet.

To create a VPC security group

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. Choose **VPC Dashboard**, choose **Security Groups**, and then choose **Create security group**.
3. On the **Create security group** page, set these values:
   - **Security group name: `tutorial-securitygroup`**
   - **Description: `Tutorial Security Group`**
   - **VPC:** Choose the VPC that you created earlier, for example: **vpc-*identifier* (tutorial-vpc)**
4. Add inbound rules to the security group.
   a. Determine the IP address to use to connect to EC2 instances in your VPC using Secure Shell (SSH). To determine your public IP address, in a different browser window or tab,

you can use the service at https://checkip.amazonaws.com. An example of an IP address is `203.0.113.25/32`.

In many cases, you might connect through an internet service provider (ISP) or from behind your firewall without a static IP address. If so, find the range of IP addresses used by client computers.

> **Warning**
>
> If you use `0.0.0.0/0` for SSH access, you make it possible for all IP addresses to access your public instances using SSH. This approach is acceptable for a short time in a test environment, but it's unsafe for production environments. In production, authorize only a specific IP address or range of addresses to access your instances using SSH.

b. In the **Inbound rules** section, choose **Add rule**.

c. Set the following values for your new inbound rule to allow SSH access to your Amazon EC2 instance. If you do this, you can connect to your Amazon EC2 instance to install the web server and other utilities. You also connect to your EC2 instance to upload content for your web server.

- **Type: SSH**
- **Source:** The IP address or range from Step a, for example: **`203.0.113.25/32`**.

d. Choose **Add rule**.

e. Set the following values for your new inbound rule to allow HTTP access to your web server:

- **Type: HTTP**
- **Source: `0.0.0.0/0`**

5. Choose **Create security group** to create the security group.

Note the security group ID because you need it later in this tutorial.

Create a VPC security group for a private DB instance

To keep your DB instance private, create a second security group for private access. To connect to private DB instancesin your VPC, you add inbound rules to your VPC security group that allow traffic from your web server only.

To create a VPC security group

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. Choose **VPC Dashboard**, choose **Security Groups**, and then choose **Create security group**.
3. On the **Create security group** page, set these values:
   - **Security group name: `tutorial-db-securitygroup`**
   - **Description: `Tutorial DB Instance Security Group`**
   - **VPC:** Choose the VPC that you created earlier, for example: **vpc-*identifier* (tutorial-vpc)**
4. Add inbound rules to the security group.
   a. In the **Inbound rules** section, choose **Add rule**.
   b. Set the following values for your new inbound rule to allow MySQL traffic on port 3306 from your Amazon EC2 instance. If you do this, you can connect from your web server to your DB instance. By doing so, you can store and retrieve data from your web application to your database.
      - **Type: `MySQL/Aurora`**
      - **Source:** The identifier of the **tutorial-securitygroup** security group that you created previously in this tutorial, for example: **sg-9edd5cfb**.
5. Choose **Create security group** to create the security group.

Create a DB subnet group

A *DB subnet group* is a collection of subnets that you create in a VPC and that you then designate for your DB instances. A DB subnet group makes it possible for you to specify a particular VPC when creating DB instances.

To create a DB subnet group

1. Identify the private subnets for your database in the VPC.

a. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.

b. Choose **VPC Dashboard**, and then choose **Subnets**.

c. Note the subnet IDs of the subnets named **tutorial-subnet-private1-us-west-2a** and **tutorial-subnet-private2-us-west-2b**.

   You need the subnet IDs when you create your DB subnet group.

2. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.

   Make sure that you connect to the Amazon RDS console, not to the Amazon VPC console.

3. In the navigation pane, choose **Subnet groups**.

4. Choose **Create DB subnet group**.

5. On the **Create DB subnet group** page, set these values in **Subnet group details**:

   - **Name: `tutorial-db-subnet-group`**
   - **Description: `Tutorial DB Subnet Group`**
   - **VPC: tutorial-vpc (vpc-*`identifier`*)**

6. In the **Add subnets** section, choose the **Availability Zones** and **Subnets**.

   For this tutorial, choose **us-west-2a** and **us-west-2b** for the **Availability Zones**. For **Subnets**, choose the private subnets you identified in the previous step.

7. Choose **Create**.

   Your new DB subnet group appears in the DB subnet groups list on the RDS console. You can choose the DB subnet group to see details in the details pane at the bottom of the window. These details include all of the subnets associated with the group.

> **Note**
>
> If you created this VPC to complete Tutorial: Create a web server and an Amazon RDS DB instance, create the DB instance by following the instructions in Create an Amazon RDS DB instance.

Deleting the VPC

After you create the VPC and other resources for this tutorial, you can delete them if they are no longer needed.

> **Note**
>
> If you added resources in the VPC that you created for this tutorial, you might need to delete these before you can delete the VPC. For example, these resources might include Amazon EC2 instances or Amazon RDS DB instances. For more information, see Delete your VPC in the *Amazon VPC User Guide*.

To delete a VPC and related resources

1. Delete the DB subnet group.
   a. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
   b. In the navigation pane, choose **Subnet groups**.
   c. Select the DB subnet group you want to delete, such as **tutorial-db-subnet-group**.
   d. Choose **Delete**, and then choose **Delete** in the confirmation window.
2. Note the VPC ID.
   a. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
   b. Choose **VPC Dashboard**, and then choose **VPCs**.
   c. In the list, identify the VPC that you created, such as **tutorial-vpc**.
   d. Note the **VPC ID** of the VPC that you created. You need the VPC ID in later steps.
3. Delete the security groups.
   a. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
   b. Choose **VPC Dashboard**, and then choose **Security Groups**.
   c. Select the security group for the Amazon RDS DB instance, such as **tutorial-db-securitygroup**.
   d. For **Actions**, choose **Delete security groups**, and then choose **Delete** on the confirmation page.

e. On the **Security Groups** page, select the security group for the Amazon EC2 instance, such as **tutorial-securitygroup**.

f. For **Actions**, choose **Delete security groups**, and then choose **Delete** on the confirmation page.

4. Delete the VPC.

a. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.

b. Choose **VPC Dashboard**, and then choose **VPCs**.

c. Select the VPC you want to delete, such as **tutorial-vpc**.

d. For **Actions**, choose **Delete VPC**.

The confirmation page shows other resources that are associated with the VPC that will also be deleted, including the subnets associated with it.

e. On the confirmation page, enter **`delete`**, and then choose **Delete**.

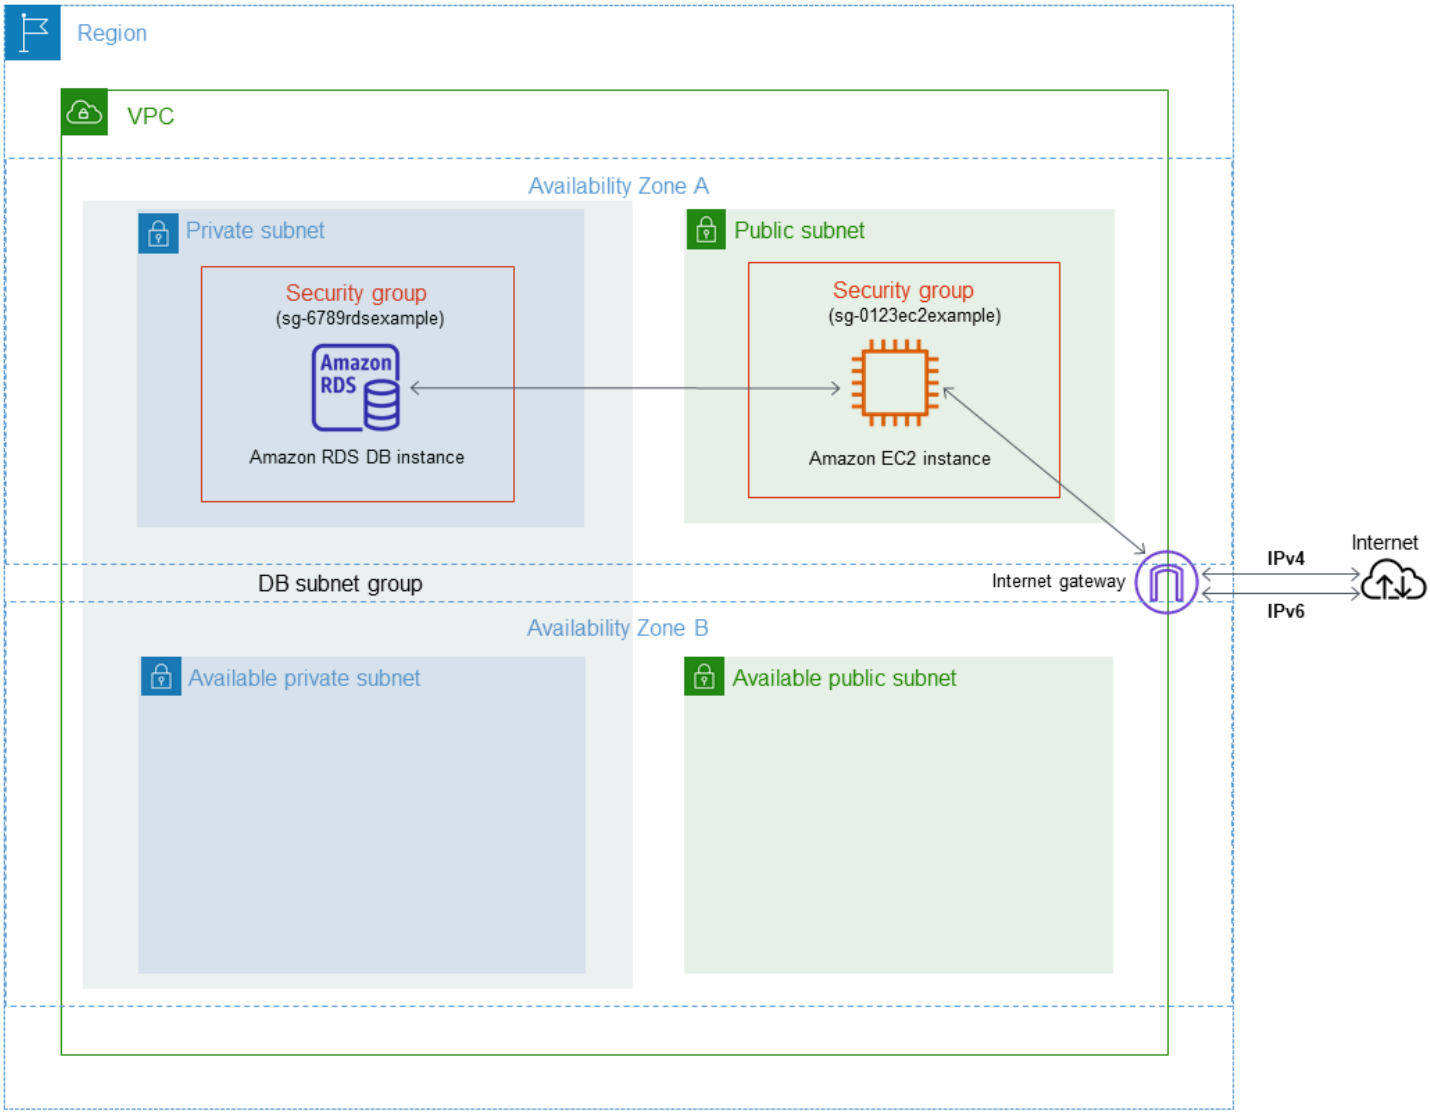
Tutorial: Create a VPC for use with a DB instance (dual-stack mode)

A common scenario includes a DB instance in a virtual private cloud (VPC) based on the Amazon VPC service. This VPC shares data with a public Amazon EC2 instance that is running in the same VPC.

In this tutorial, you create the VPC for this scenario that works with a database running in dual-stack mode. Dual-stack mode to enable connection over the IPv6 addressing protocol. For more information about IP addressing, see Amazon RDS IP addressing.

Dual-stack network instances are supported in most regions. For more information see Region and version availability. To see the limitations of dual-stack mode, see Limitations for dual-stack network DB instances.

The following diagram shows this scenario.



For information about other scenarios, see Scenarios for accessing a DB instance in a VPC.

Your DB instance needs to be available only to your Amazon EC2 instance, and not to the public internet. Thus, you create a VPC with both public and private subnets. The Amazon EC2 instance is hosted in the public subnet, so that it can reach the public internet. The DB instance is hosted in a private subnet. The Amazon EC2 instance can connect to the DB instance because it's hosted within the same VPC. However, the DB instance is not available to the public internet, providing greater security.

This tutorial configures an additional public and private subnet in a separate Availability Zone. These subnets aren't used by the tutorial. An RDS DB subnet group requires a subnet in at least two Availability Zones. The additional subnet makes it easy to switch to a Multi-AZ DB instance deployment in the future.

To create a DB instance that uses dual-stack mode, specify **Dual-stack mode** for the **Network type** setting. You can also modify a DB instance with the same setting. For more information, see Creating an Amazon RDS DB instance and Modifying an Amazon RDS DB instance.

This tutorial describes configuring a VPC for Amazon RDS DB instances. For more information about Amazon VPC, see Amazon VPC User Guide.

Create a VPC with private and public subnets

Use the following procedure to create a VPC with both public and private subnets.

To create a VPC and subnets

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the upper-right corner of the AWS Management Console, choose the Region to create your VPC in. This example uses the US East (Ohio) Region.
3. In the upper-left corner, choose **VPC dashboard**. To begin creating a VPC, choose **Create VPC**.
4. For **Resources to create** under **VPC settings**, choose **VPC and more**.
5. For the remaining **VPC settings**, set these values:

   - **Name tag auto-generation** – **`tutorial-dual-stack`**
   - **IPv4 CIDR block** – **`10.0.0.0/16`**
   - **IPv6 CIDR block** – **Amazon-provided IPv6 CIDR block**
   - **Tenancy** – **Default**
   - **Number of Availability Zones (AZs)** – **2**
   - **Customize AZs** – Keep the default values.
   - **Number of public subnet** – **2**
   - **Number of private subnets** – **2**
   - **Customize subnets CIDR blocks** – Keep the default values.
   - **NAT gateways ($)** – **None**
   - **Egress only internet gateway** – **No**
   - **VPC endpoints** – **None**
   - **DNS options** – Keep the default values.

> **Note**
>
> Amazon RDS requires at least two subnets in two different Availability Zones to support Multi-AZ DB instance deployments. This tutorial creates a Single-AZ deployment, but the requirement makes it easy to convert to a Multi-AZ DB instance deployment in the future.

6. Choose **Create VPC**.

Create a VPC security group for a public Amazon EC2 instance

Next, you create a security group for public access. To connect to public EC2 instances in your VPC, add inbound rules to your VPC security group that allow traffic to connect from the internet.

To create a VPC security group

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. Choose **VPC Dashboard**, choose **Security Groups**, and then choose **Create security group**.
3. On the **Create security group** page, set these values:
   - **Security group name: `tutorial-dual-stack-securitygroup`**
   - **Description: `Tutorial Dual-Stack Security Group`**
   - **VPC:** Choose the VPC that you created earlier, for example: **vpc-*identifier* (tutorial-dual-stack-vpc)**
4. Add inbound rules to the security group.
   a. Determine the IP address to use to connect to EC2 instances in your VPC using Secure Shell (SSH).

      An example of an Internet Protocol version 4 (IPv4) address is `203.0.113.25/32`. An example of an Internet Protocol version 6 (IPv6) address range is `2001:db8:1234:1a00::/64`.

      In many cases, you might connect through an internet service provider (ISP) or from behind your firewall without a static IP address. If so, find the range of IP addresses used by client computers.

> **Warning**
>
> If you use `0.0.0.0/0` for IPv4 or `::0` for IPv6, you make it possible for all IP addresses to access your public instances using SSH. This approach is acceptable for a short time in a test environment, but it's unsafe for production environments. In production, authorize only a specific IP address or range of addresses to access your instances.

b. In the **Inbound rules** section, choose **Add rule**.

c. Set the following values for your new inbound rule to allow Secure Shell (SSH) access to your Amazon EC2 instance. If you do this, you can connect to your EC2 instance to install SQL clients and other applications. Specify an IP address so you can access your EC2 instance:

- **Type: SSH**
- **Source:** The IP address or range from step a. An example of an IPv4 IP address is **`203.0.113.25/32`**. An example of an IPv6 IP address is **`2001:DB8::/32`**.

5. Choose **Create security group** to create the security group.

   Note the security group ID because you need it later in this tutorial.

Create a VPC security group for a private DB instance

To keep your DB instance private, create a second security group for private access. To connect to private DB instances in your VPC, add inbound rules to your VPC security group. These allow traffic from your Amazon EC2 instance only.

To create a VPC security group

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. Choose **VPC Dashboard**, choose **Security Groups**, and then choose **Create security group**.
3. On the **Create security group** page, set these values:

- **Security group name: `tutorial-dual-stack-db-securitygroup`**
- **Description: `Tutorial Dual-Stack DB Instance Security Group`**

- **VPC:** Choose the VPC that you created earlier, for example: **vpc-*identifier* (tutorial-dual-stack-vpc)**

4. Add inbound rules to the security group:

   a. In the **Inbound rules** section, choose **Add rule**.

   b. Set the following values for your new inbound rule to allow MySQL traffic on port 3306 from your Amazon EC2 instance. If you do, you can connect from your EC2 instance to your DB instance. Doing this means that you can send data from your EC2 instance to your database.

      - **Type: MySQL/Aurora**
      - **Source:** The identifier of the **tutorial-dual-stack-securitygroup** security group that you created previously in this tutorial, for example **sg-9edd5cfb**.

5. To create the security group, choose **Create security group**.

Create a DB subnet group

A *DB subnet group* is a collection of subnets that you create in a VPC and that you then designate for your DB instances. By using a DB subnet group, you can specify a particular VPC when creating DB instances. To create a DB subnet group that is DUAL compatible, all subnets must be DUAL compatible. To be DUAL compatible, a subnet must have an IPv6 CIDR associated with it.

To create a DB subnet group

1. Identify the private subnets for your database in the VPC.

   a. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.

   b. Choose **VPC Dashboard**, and then choose **Subnets**.

   c. Note the subnet IDs of the subnets named **tutorial-dual-stack-subnet-private1-us-west-2a** and **tutorial-dual-stack-subnet-private2-us-west-2b**.

      You will need the subnet IDs when you create your DB subnet group.

2. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.

   Make sure that you connect to the Amazon RDS console, not to the Amazon VPC console.

3. In the navigation pane, choose **Subnet groups**.

4. Choose **Create DB subnet group**.

5. On the **Create DB subnet group** page, set these values in **Subnet group details**:
   - **Name: `tutorial-dual-stack-db-subnet-group`**
   - **Description: `Tutorial Dual-Stack DB Subnet Group`**
   - **VPC: tutorial-dual-stack-vpc (vpc-*`identifier`*)**
6. In the **Add subnets** section, choose values for the **Availability Zones** and **Subnets** options.

   For this tutorial, choose **us-east-2a** and **us-east-2b** for the **Availability Zones**. For **Subnets**, choose the private subnets you identified in the previous step.
7. Choose **Create**.

Your new DB subnet group appears in the DB subnet groups list on the RDS console. You can choose the DB subnet group to see its details. These include the supported addressing protocols and all of the subnets associated with the group and the network type supported by the DB subnet group.

Create an Amazon EC2 instance in dual-stack mode

To create an Amazon EC2 instance, follow the instructions in Launch an instance using the new launch instance wizard in the *Amazon EC2 User Guide*.

On the **Configure Instance Details** page, set these values and keep the other values as their defaults:

- **Network** – Choose an existing VPC with both public and private subnets, such as **tutorial-dual-stack-vpc** (vpc-*`identifier`*) created in Create a VPC with private and public subnets.
- **Subnet** – Choose an existing public subnet, such as **subnet-*`identifier`* | tutorial-dual-stack-subnet-public1-us-east-2a | us-east-2a** created in Create a VPC security group for a public Amazon EC2 instance.
- **Auto-assign Public IP** – Choose **Enable**.
- **Auto-assign IPv6 IP** – Choose **Enable**.
- **Firewall (security groups)** – Choose **Select an existing security group**.
- **Common security groups** – Choose an existing security group, such as the `tutorial-securitygroup` created in Create a VPC security group for a public Amazon EC2 instance. Make sure that the security group that you choose includes inbound rules for Secure Shell (SSH) and HTTP access.

Create a DB instance in dual-stack mode

In this step, you create a DB instance that runs in dual-stack mode.

To create a DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the upper-right corner of the console, choose the AWS Region where you want to create the DB instance. This example uses the US East (Ohio) Region.
3. In the navigation pane, choose **Databases**.
4. Choose **Create database**.
5. On the **Create database** page, make sure that the **Standard create** option is chosen, and then choose the MySQL DB engine type.
6. In the **Connectivity** section, set these values:

   - **Network type** – Choose **Dual-stack mode**.

     
   - **Virtual private cloud (VPC)** – Choose an existing VPC with both public and private subnets, such as **tutorial-dual-stack-vpc** (vpc-*identifier*) created in Create a VPC with private and public subnets.

     The VPC must have subnets in different Availability Zones.

   - **DB subnet group** – Choose a DB subnet group for the VPC, such as **tutorial-dual-stack-db-subnet-group** created in Create a DB subnet group.
   - **Public access** – Choose **No**.
   - **VPC security group (firewall)** – Select **Choose existing**.
   - **Existing VPC security groups** – Choose an existing VPC security group that is configured for private access, such as **tutorial-dual-stack-db-securitygroup** created in Create a VPC security group for a private DB instance.

Remove other security groups, such as the default security group, by choosing the **X** associated with each.

- **Availability Zone** – Choose **us-west-2a**.

  To avoid cross-AZ traffic, make sure the DB instance and the EC2 instance are in the same Availability Zone.

7. For the remaining sections, specify your DB instance settings. For information about each setting, see Settings for DB instances.

Connect to your Amazon EC2 instance and DB instance

After you create your Amazon EC2 instance and DB instance in dual-stack mode, you can connect to each one using the IPv6 protocol. To connect to an Amazon EC2 instance using the IPv6 protocol, follow the instructions in Connect to your Linux instance in the *Amazon EC2 User Guide*.

To connect to your RDS for MySQL DB instance from the Amazon EC2 instance, follow the instructions in Connect to a MySQL DB instance.

Deleting the VPC

After you create the VPC and other resources for this tutorial, you can delete them if they are no longer needed.

If you added resources in the VPC that you created for this tutorial, you might need to delete these before you can delete the VPC. Examples of resources are Amazon EC2 instances or DB instances. For more information, see Delete your VPC in the *Amazon VPC User Guide*.

To delete a VPC and related resources

1. Delete the DB subnet group:

   a. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
   b. In the navigation pane, choose **Subnet groups**.
   c. Select the DB subnet group to delete, such as **tutorial-db-subnet-group**.
   d. Choose **Delete**, and then choose **Delete** in the confirmation window.
2. Note the VPC ID:

   a. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.

b. Choose **VPC Dashboard**, and then choose **VPCs**.

c. In the list, identify the VPC you created, such as **tutorial-dual-stack-vpc**.

d. Note the **VPC ID** value of the VPC that you created. You need this VPC ID in subsequent steps.

3. Delete the security groups:

a. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.

b. Choose **VPC Dashboard**, and then choose **Security Groups**.

c. Select the security group for the Amazon RDS DB instance, such as **tutorial-dual-stack-db-securitygroup**.

d. For **Actions**, choose **Delete security groups**, and then choose **Delete** on the confirmation page.

e. On the **Security Groups** page, select the security group for the Amazon EC2 instance, such as **tutorial-dual-stack-securitygroup**.

f. For **Actions**, choose **Delete security groups**, and then choose **Delete** on the confirmation page.

4. Delete the NAT gateway:

a. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.

b. Choose **VPC Dashboard**, and then choose **NAT Gateways**.

c. Select the NAT gateway of the VPC that you created. Use the VPC ID to identify the correct NAT gateway.

d. For **Actions**, choose **Delete NAT gateway**.

e. On the confirmation page, enter **`delete`**, and then choose **Delete**.

5. Delete the VPC:

a. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.

b. Choose **VPC Dashboard**, and then choose **VPCs**.

c. Select the VPC that you want to delete, such as **tutorial-dual-stack-vpc**.

d. For **Actions**, choose **Delete VPC**.

The confirmation page shows other resources that are associated with the VPC that will also be deleted, including the subnets associated with it.

e. On the confirmation page, enter **`delete`**, and then choose **Delete**.

6. Release the Elastic IP addresses:

    a. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
    b. Choose **EC2 Dashboard**, and then choose **Elastic IPs**.
    c. Select the Elastic IP address that you want to release.
    d. For **Actions**, choose **Release Elastic IP addresses**.
    e. On the confirmation page, choose **Release**.

Moving a DB instance not in a VPC into a VPC

Some legacy DB instances on the EC2-Classic platform are not in a VPC. If your DB instance is not in a VPC, you can use the AWS Management Console to easily move your DB instance into a VPC. Before you can move a DB instance not in a VPC, into a VPC, you must create the VPC.

EC2-Classic was retired on August 15, 2022. If you haven't migrated from EC2-Classic to a VPC, we recommend that you migrate as soon as possible. For more information, see Migrate from EC2-Classic to a VPC in the *Amazon EC2 User Guide* and the blog EC2-Classic Networking is Retiring – Here's How to Prepare.

Important

If you are a new Amazon RDS customer, if you have never created a DB instance before, or if you are creating a DB instance in an AWS Region you have not used before, in almost all cases you are on the *EC2-VPC* platform and have a default VPC. For information about working with DB instances in a VPC, see Working with a DB instance in a VPC.

Follow these steps to create a VPC for your DB instance.

- Step 1: Create a VPC
- Step 2: Create a DB subnet group
- Step 3: Create a VPC security group

After you create the VPC, follow these steps to move your DB instance into the VPC.

- Updating the VPC for a DB instance

We highly recommend that you create a backup of your DB instance immediately before the migration. Doing so ensures that you can restore the data if the migration fails. For more information, see Backing up, restoring, and exporting data.

The following are some limitations to moving your DB instance into the VPC.

- **Previous generation DB instance classes** – Previous generation DB instance classes might not be supported on the VPC platform. When moving a DB instance to a VPC, choose a db.m3 or db.r3 DB instance class. After you move the DB instance to a VPC, you can scale the DB instance to use a later DB instance class. For a full list of VPC supported instance classes, see Amazon RDS instance types.
- **Multi-AZ** – Moving a Multi-AZ DB instance not in a VPC into a VPC is not currently supported. To move your DB instance to a VPC, first modify the DB instance so that it is a single-AZ deployment. Change the **Multi-AZ deployment** setting to **No**. After you move the DB instance to a VPC, modify it again to make it a Multi-AZ deployment. For more information, see Modifying an Amazon RDS DB instance.
- **Read replicas** – Moving a DB instance with read replicas not in a VPC into a VPC is not currently supported. To move your DB instance to a VPC, first delete all of its read replicas. After you move the DB instance to a VPC, recreate the read replicas. For more information, see Working with DB instance read replicas.
- **Option groups** – If you move your DB instance to a VPC, and the DB instance is using a custom option group, change the option group that is associated with your DB instance. Option groups are platform-specific, and moving to a VPC is a change in platform. To use a custom option group in this case, assign the default VPC option group to the DB instance, assign an option group that is used by other DB instances in the VPC you are moving to, or create a new option group and assign it to the DB instance. For more information, see Working with option groups.

Alternatives for moving a DB instance not in a VPC into a VPC with minimal downtime

Using the following alternatives, you can move a DB instance not in a VPC into a VPC with minimal downtime. These alternatives cause minimum disruption to the source DB instance and allow it to serve user traffic during the migration. However, the time required to migrate to a VPC will vary based on the database size and the live workload characteristics.

- **AWS Database Migration Service (AWS DMS)** – AWS DMS enables the live migration of data while keeping the source DB instance fully operational, but it replicates only a limited set of DDL statements. AWS DMS doesn't propagate items such as indexes, users, privileges, stored procedures, and other database changes not directly related to table data. In addition, AWS DMS doesn't automatically use RDS snapshots for the initial DB instance creation, which can increase migration time. For more information, see AWS Database Migration Service.

- **DB snapshot restore or point-in-time recovery** – You can move a DB instance to a VPC by restoring a snapshot of the DB instance or by restoring a DB instance to a point in time. For more information, see Restoring to a DB instance and Restoring a DB instance to a specified time.

Quotas and constraints for Amazon RDS

Following, you can find a description of the resource quotas and naming constraints for Amazon RDS.

Topics

Quotas in Amazon RDS

Each AWS account has quotas, for each AWS Region, on the number of Amazon RDS resources that can be created. After a quota for a resource has been reached, additional calls to create that resource fail with an exception.

The following table lists the resources and their quotas per AWS Region.

Name	Default	Adjustable	Description
Authorizations per DB security group	Each supported Region: 20	No	Number of security group authorizations per DB security group
Custom engine versions	Each supported Region: 40	Yes	The maximum number of custom engine versions allowed in this account in the current Region
DB cluster parameter groups	Each supported Region: 50	No	The maximum number of DB cluster parameter groups
DB clusters	Each supported Region: 40	Yes	The maximum number of Aurora clusters allowed

Name	Default	Adjustable	Description
			in this account in the current Region
DB instances	Each supported Region: 40	Yes	The maximum number of DB instances allowed in this account in the current Region
DB subnet groups	Each supported Region: 50	Yes	The maximum number of DB subnet groups
Data API HTTP request body size	Each supported Region: 4 Megabytes	No	The maximum size allowed for the HTTP request body.
Data API maximum concurrent cluster-secret pairs	Each supported Region: 30	No	The maximum number of unique pairs of Aurora Serverless v1 DB clusters and secrets in concurrent Data API requests for this account in the current AWS Region.
Data API maximum concurrent requests	Each supported Region: 500	No	The maximum number of Data API requests to an Aurora Serverless v1 DB cluster that use the same secret and can be processed at the same time. Additional requests are queued and processed as in-process requests complete.

Name	Default	Adjustable	Description
Data API maximum result set size	Each supported Region: 1 Megabytes	No	The maximum size of the database result set that can be returned by the Data API.
Data API maximum size of JSON response string	Each supported Region: 10 Megabytes	No	The maximum size of the simplified JSON response string returned by the RDS Data API.
Data API requests per second	Each supported Region: 1,000 per second	No	The maximum number of requests to the Data API per second allowed for this account in the current AWS Region. This quota only applies to Amazon Aurora Serverless v1 clusters.
Event subscriptions	Each supported Region: 20	Yes	The maximum number of event subscriptions
IAM roles per DB cluster	Each supported Region: 5	Yes	The maximum number of IAM roles associated with a DB cluster
IAM roles per DB instance	Each supported Region: 5	Yes	The maximum number of IAM roles associated with a DB instance
Integrations	Each supported Region: 100	No	The maximum number of integrations allowed in this account in the current AWS Region

Name	Default	Adjustable	Description
Manual DB cluster snapshots	Each supported Region: 100	Yes	The maximum number of manual DB cluster snapshots
Manual DB instance snapshots	Each supported Region: 100	Yes	The maximum number of manual DB instance snapshots
Option groups	Each supported Region: 20	Yes	The maximum number of option groups
Parameter groups	Each supported Region: 50	Yes	The maximum number of parameter groups
Proxies	Each supported Region: 20	Yes	The maximum number of proxies allowed in this account in the current AWS Region
Read replicas per primary	Each supported Region: 15	Yes	The maximum number of read replicas per primary DB instance. This quota cant be adjusted for Amazon Aurora.
Reserved DB instances	Each supported Region: 40	Yes	The maximum number of reserved DB instances allowed in this account in the current AWS Region
Rules per security group	Each supported Region: 20	No	The maximum number of rules per DB security group
Security groups	Each supported Region: 25	Yes	The maximum number of DB security groups

Name	Default	Adjustable	Description
Security groups (VPC)	Each supported Region: 5	No	The maximum number of DB security groups per Amazon VPC
Subnets per DB subnet group	Each supported Region: 20	No	The maximum number of subnets per DB subnet group
Tags per resource	Each supported Region: 50	No	The maximum number of tags per Amazon RDS resource
Total storage for all DB instances	Each supported Region: 100,000 Gigabytes	Yes	The maximum total storage (in GB) on EBS volumes for all Amazon RDS DB instances added together. This quota does not apply to Amazon Aurora, which has a maximum cluster volume of 128 TiB for each DB cluster.

Note

By default, you can have up to a total of 40 DB instances. RDS DB instances, Aurora DB instances, Amazon Neptune instances, and Amazon DocumentDB instances apply to this quota.
The following limitations apply to the Amazon RDS DB instances:

- 10 for each SQL Server edition (Enterprise, Standard, Web, and Express) under the "license-included" model
- 10 for Oracle under the "license-included" model
- 40 for Db2 under the "bring-your-own-license" (BYOL) licensing model

- 40 for MySQL, MariaDB, or PostgreSQL
- 40 for Oracle under the "bring-your-own-license" (BYOL) licensing model

If your application requires more DB instances, you can request additional DB instances by opening the Service Quotas console. In the navigation pane, choose **AWS services**. Choose **Amazon Relational Database Service (Amazon RDS)**, choose a quota, and follow the directions to request a quota increase. For more information, see Requesting a quota increase in the *Service Quotas User Guide*.
For RDS for Oracle, the read replica limit is 5 per source database for each Region.
Backups managed by AWS Backup are considered manual DB snapshots, but don't count toward the manual snapshot quota. For information about AWS Backup, see the *AWS Backup Developer Guide*.

If you use any RDS API operations and exceed the default quota for the number of calls per second, the Amazon RDS API issues an error like the following one.

ClientError: An error occurred (ThrottlingException) when calling the *API_name* operation: Rate exceeded.

Here, reduce the number of calls per second. The quota is meant to cover most use cases. If higher quotas are needed, you can request a quota increase by using one of the following options:

- From the console, open the Service Quotas console.
- From the AWS CLI, use the request-service-quota-increase AWS CLI command.

For more information, see the *Service Quotas User Guide*.

Naming constraints in Amazon RDS

The naming constraints in Amazon RDS are as follows:

- DB instance identifier:
  - Must contain 1–63 alphanumeric characters or hyphens.
  - First character must be a letter.
  - Can't end with a hyphen or contain two consecutive hyphens.

- Must be unique for all DB instances per AWS account, per AWS Region.
- Initial database name:
  - Database name constraints differ for each database engine. For more information, see the available settings when creating each DB instance.
  - SQL Server – Create your databases after creating your DB instance.
- Master username – Master username constraints differ for each database engine. For more information, see the available settings when creating the DB instance.
- Master password:
  - The password for the database master user can include any printable ASCII character except /, ', ", @, or a space.

    For Oracle, & is an additional character limitation.
  - The password can contain the following number of printable ASCII characters depending on the DB engine:
    - Db2: 8–255
    - MariaDB and MySQL: 8–41
    - Oracle: 8–30
    - SQL Server and PostgreSQL: 8–128
- DB parameter group:
  - Must contain 1–255 alphanumeric characters.
  - First character must be a letter.
  - Hyphens are allowed, but the name cannot end with a hyphen or contain two consecutive hyphens.
- DB subnet group:
  - Must contain 1–255 characters.
  - Alphanumeric characters, spaces, hyphens, underscores, and periods are allowed.

Maximum number of database connections

The maximum number of simultaneous database connections varies by the DB engine type and the memory allocation for the DB instance class. The maximum number of connections is generally set in the parameter group associated with the DB instance. The exception is Microsoft SQL Server,

where it is set in the server properties for the DB instance in SQL Server Management Studio (SSMS).

Database connections consume memory. Setting one of these parameters too high can cause a low memory condition that might cause a DB instance to be placed in the **incompatible-parameters** status. For more information, see Diagnosing and resolving incompatible parameters status for a memory limit.

If your applications frequently open and close connections, or keep a large number of long-lived connections open, we recommend that you use Amazon RDS Proxy. RDS Proxy is a fully managed, highly available database proxy that uses connection pooling to share database connections securely and efficiently. To learn more about RDS Proxy, see Using Amazon RDS Proxy.

> **Note**
>
> For Oracle, you set the maximum number of user processes and user and system sessions. For Db2, you can't set maximum connections. The limit is 64000.

The following table shows information about the maximum database connections for different DB engines.

DB engine	Parameter	Allowed values	Default value	Description
MariaDB and MySQL	`max_connections`	1–100000	Default for all MariaDB and MySQL versions except for MariaDB version 10.5 and 10.6: {DBInstanceClassMemory/12582880} The formula is effectively equivalent to MB/12. Default for MariaDB version 10.5 and 10.6:	Number of simultaneous client connections allowed

DB engine	Parameter	Allowed values	Default value	Description
			LEAST({DBInstanceClassMemory/25165760},12000) The formula is effectively equivalent to MB/25. In either case, if the default value calculation results in a value greater than 16,000, Amazon RDS sets the limit to 16,000 for MariaDB and MySQL DB instances.	
Oracle	`processes`	80–20000	LEAST({DBInstanceClassMemory/9868951}, 20000)	User processes
Oracle	`sessions`	100–65535	Not applicable	User and system sessions
PostgreSQL	`max_connections`	6–8388607	LEAST({DBInstanceClassMemory/9531392}, 5000)	Maximum number of concurrent connections
SQL Server	`user connections`	0–32767	0 (unlimited)	Maximum number of concurrent connections. For more information, see Configure the user connections (server configuration option).

`DBInstanceClassMemory` is in bytes. For details about how this value is calculated, see Specifying DB parameters. Because of memory reserved for the operating system and RDS management processes, this memory size is smaller than the value in gibibytes (GiB) shown in Hardware specifications for DB instance classes.

For example, some DB instance classes have 8 GiB of memory, which is 8,589,934,592 bytes. For a MySQL DB instance running on a DB instance class with 8 GiB of memory, such as db.m7g.large, the equation that uses the total memory would be `8589934592/12582880=683`. However, the variable `DBInstanceClassMemory` automatically subtracts the amounts reserved to the operating system and the RDS processes that manage the DB instance. The remainder of the subtraction is then divided by 12,582,880. This calculation results in approximately 630 for the value of `max_connections` instead of 683. This value depends on the DB instance class and DB engine.

When a MariaDB or MySQL DB instance is running on a small DB instance class, such as db.t3.micro or db.t3.small, the total memory available is low. For these DB instance classes, RDS reserves a significant portion of the available memory, which affects the value `max_connections`. For example, the default maximum number of connections for a MySQL DB instance running on a db.t3.micro DB instance class is approximately 60. You can determine the `max_connections` value for your DB MariaDB or MySQL DB instance by connecting to it and running the following SQL command:

```
SHOW GLOBAL VARIABLES LIKE 'max_connections';
```

File size limits in Amazon RDS

File size limits apply to certain Amazon RDS DB instances. For more information, see the following engine-specific limits:

- MariaDB file size limits in Amazon RDS
- MySQL file size limits in Amazon RDS
- Oracle file size limits in Amazon RDS

Troubleshooting for Amazon RDS

Use the following sections to help troubleshoot problems you have with DB instances in Amazon RDS and Amazon Aurora.

Topics

For information about debugging problems using the Amazon RDS API, see Troubleshooting applications on Amazon RDS.

Can't connect to Amazon RDS DB instance

When you can't connect to a DB instance, the following are common causes:

- **Inbound rules** – The access rules enforced by your local firewall and the IP addresses authorized to access your DB instance might not match. The problem is most likely the inbound rules in your security group.

  By default, DB instances don't allow access. Access is granted through a security group associated with the VPC that allows traffic into and out of the DB instance. If necessary, add inbound and outbound rules for your particular situation to the security group. You can specify an IP address, a range of IP addresses, or another VPC security group.

> **Note**
>
> When adding a new inbound rule, you can choose **My IP** for **Source** to allow access to the DB instance from the IP address detected in your browser.

For more information about setting up security groups, see Provide access to your DB instance in your VPC by creating a security group.

> **Note**
>
> Client connections from IP addresses within the range 169.254.0.0/16 aren't permitted. This is the Automatic Private IP Addressing Range (APIPA), which is used for local-link addressing.

- **Public accessibility** – To connect to your DB instance from outside of the VPC, such as by using a client application, the instance must have a public IP address assigned to it.

  To make the instance publicly accessible, modify it and choose **Yes** under **Public accessibility**. For more information, see Hiding a DB instance in a VPC from the internet.
- **Port** – The port that you specified when you created the DB instance can't be used to send or receive communications due to your local firewall restrictions. To determine if your network allows the specified port to be used for inbound and outbound communication, check with your network administrator.
- **Availability** – For a newly created DB instance, the DB instance has a status of `creating` until the DB instance is ready to use. When the state changes to `available`, you can connect to the DB instance. Depending on the size of your DB instance, it can take up to 20 minutes before an instance is available.
- **Internet gateway** – For a DB instance to be publicly accessible, the subnets in its DB subnet group must have an internet gateway.

  To configure an internet gateway for a subnet

  1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
  2. In the navigation pane, choose **Databases**, and then choose the name of the DB instance.

3. In the **Connectivity & security** tab, write down the values of the VPC ID under **VPC** and the subnet ID under **Subnets**.
4. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
5. In the navigation pane, choose **Internet Gateways**. Verify that there is an internet gateway attached to your VPC. Otherwise, choose **Create Internet Gateway** to create an internet gateway. Select the internet gateway, and then choose **Attach to VPC** and follow the directions to attach it to your VPC.
6. In the navigation pane, choose **Subnets**, and then select your subnet.
7. On the **Route Table** tab, verify that there is a route with `0.0.0.0/0` as the destination and the internet gateway for your VPC as the target.

   If you're connecting to your instance using its IPv6 address, verify that there is a route for all IPv6 traffic (`::/0`) that points to the internet gateway. Otherwise, do the following:

   a. Choose the ID of the route table (rtb-*xxxxxxxx*) to navigate to the route table.

   b. On the **Routes** tab, choose **Edit routes**. Choose **Add route**, use `0.0.0.0/0` as the destination and the internet gateway as the target.

      For IPv6, choose **Add route**, use `::/0` as the destination and the internet gateway as the target.

   c. Choose **Save routes**.

   Also, if you are trying to connect to IPv6 endpoint, make sure that client IPv6 address range is authorized to connect to the DB instance.

For more information, see Working with a DB instance in a VPC.

For engine-specific connection issues, see the following topics:

- Troubleshooting connections to your SQL Server DB instance
- Troubleshooting connections to your Oracle DB instance
- Troubleshooting connections to your RDS for PostgreSQL instance
- Maximum MySQL and MariaDB connections

Testing a connection to a DB instance

You can test your connection to a DB instance using common Linux or Microsoft Windows tools.

From a Linux or Unix terminal, you can test the connection by entering the following. Replace *DB-instance-endpoint* with the endpoint and *port* with the port of your DB instance.

```
nc -zv DB-instance-endpoint port
```

For example, the following shows a sample command and the return value.

```
nc -zv postgresql1.c6c8mn7fake0.us-west-2.rds.amazonaws.com 8299

  Connection to postgresql1.c6c8mn7fake0.us-west-2.rds.amazonaws.com 8299 port [tcp/
vvr-data] succeeded!
```

Windows users can use Telnet to test the connection to a DB instance. Telnet actions aren't supported other than for testing the connection. If a connection is successful, the action returns no message. If a connection isn't successful, you receive an error message such as the following.

```
C:\>telnet sg-postgresql1.c6c8mntfake0.us-west-2.rds.amazonaws.com 819

  Connecting To sg-postgresql1.c6c8mntfake0.us-west-2.rds.amazonaws.com...Could not
 open
  connection to the host, on port 819: Connect failed
```

If Telnet actions return success, your security group is properly configured.

> **Note**
>
> Amazon RDS doesn't accept internet control message protocol (ICMP) traffic, including ping.

Troubleshooting connection authentication

In some cases, you can connect to your DB instance but you get authentication errors. In these cases, you might want to reset the master user password for the DB instance. You can do this by modifying the RDS instance.

For more information about modifying a DB instance, see Modifying an Amazon RDS DB instance.

Amazon RDS security issues

To avoid security issues, never use your AWS account root user email address and password for a user account. Best practice is to use your root user to create users and assign those to DB user accounts. You can also use your root user to create other user accounts, if necessary.

For information about creating users, see Creating an IAM user in your AWS account. For information about creating users in AWS IAM Identity Center, see Manage identities in IAM Identity Center.

Error message "failed to retrieve account attributes, certain console functions may be impaired."

You can get this error for several reasons. It might be because your account is missing permissions, or your account hasn't been properly set up. If your account is new, you might not have waited for the account to be ready. If this is an existing account, you might lack permissions in your access policies to perform certain actions such as creating a DB instance. To fix the issue, your administrator needs to provide the necessary roles to your account. For more information, see the IAM documentation.

Troubleshooting incompatible-network state

The incompatible-network state means that the database might still be accessible at the database level but you can't modify or reboot it.

Causes

The incompatible-network state of your DB instance could be a result of one of the following actions:

- Modifying the DB instance class.
- Modifying the DB instance to use Multi-AZ DB cluster deployment.
- Replacing a host due to a maintainence event.
- Launching a replacement DB instance.
- Restoring from a snapshot backup.

- Starting a DB instance that was stopped.

Resolution

Use start-db-instance command

To fix a database that is in an incompatible-network state, follow these instructions:

1. Open the https://console.aws.amazon.com/rds/ and choose **Databases** from the navigation pane.
2. Choose the DB instance that is in the incompatible-network state and note the DB instance identifier, VPC ID, and subnet IDs from the **Connectivity & Security** tab.
3. Use the AWS CLI to run the `start-db-instance` command. Specify the `--db-instance-identifier` value.

> **Note**
>
> Running this command when your database is in incompatible mode might cause some downtime.
> The `start-db-instance` command does not resolve this issue for RDS for SQL Server DB instances.

Your database status changes to **Available** if the command executes successfully.

If your database restarts, the DB instance might execute the last operation run on the instance before it was moved to incompatible-network state. This might move the instance back to the incompatible-network state.

If the `start-db-instance` command is unsuccessful or the instance moves back to incompatible-network state, open the **Databases** page in the RDS console and select the database. Navigate to the **Logs & events** section. The **Recent events** section displays further resolution steps to follow. The messages are classified as follows:

- **INTERNAL RESOURCE CHECK**: There might be issues with your internal resources.
- **DNS CHECK**: Check DNS resolution and hostnames for the VPC in the VPC console.
- **ENI CHECK**: The elastic network interface (ENI) for your database might not exist.

- **GATEWAY CHECK**: The internet gateway for your publicly available database is not attached to the VPC.
- **IP CHECK**: There are no free IP addresses in your subnets.
- **SECURITY GROUP CHECK**: There are no security groups associated with your database or the security groups are invalid.
- **SUBNET CHECK**: There are no valid subnets in your DB subnet group or there are issues with your subnet.
- **VPC CHECK**: The VPC associated with your database is invalid.

Perform point-in-time recovery

It is best practice to have a backup (snapshot or logical), in case your database enters incompatible-network state. See Introduction to backups. If you turned on automated backups, then temporarily stop any writes to the database and perform a point-in-time recovery.

> **Note**
>
> After an instance enters the incompatible-network state, the DB instance might not be accessible to perform a logical backup.

If you did't turn on automated backups, create a new DB instance. Then migrate the data using AWS Database Migration Service (AWS DMS), or by using a backup and restore tool.

If this does not resolve the issue, contact AWS Support for further assistance.

Resetting the DB instance owner password

If you get locked out of your DB instance, you can log in as the master user. Then you can reset the credentials for other administrative users or roles. If you can't log in as the master user, the AWS account owner can reset the master user password. For details of which administrative accounts or roles you might need to reset, see Master user account privileges.

You can change the DB instance password by using the Amazon RDS console, the AWS CLI command modify-db-instance, or by using the ModifyDBInstance API operation. For more information about modifying a DB instance, see Modifying an Amazon RDS DB instance.

Amazon RDS DB instance outage or reboot

A DB instance outage can occur when a DB instance is rebooted. It can also occur when the DB instance is put into a state that prevents access to it, and when the database is restarted. A reboot can occur when you manually reboot your DB instance. A reboot can also occur when you change a DB instance setting that requires a reboot before it can take effect.

A DB instance reboot occurs when you change a setting that requires a reboot, or when you manually cause a reboot. A reboot can occur immediately if you change a setting and request that the change take effect immediately. Or it can occur during the DB instance's maintenance window.

A DB instance reboot occurs immediately when one of the following occurs:

- You change the backup retention period for a DB instance from 0 to a nonzero value or from a nonzero value to 0. You then set **Apply Immediately** to `true`.
- You change the DB instance class, and **Apply Immediately** is set to `true`.
- You change the storage type from **Magnetic (Standard)** to **General Purpose (SSD**) or **Provisioned IOPS (SSD)**, or from **Provisioned IOPS (SSD)** or **General Purpose (SSD)** to **Magnetic (Standard)**.

A DB instance reboot occurs during the maintenance window when one of the following occurs:

- You change the backup retention period for a DB instance from 0 to a nonzero value or from a nonzero value to 0, and **Apply Immediately** is set to `false`.
- You change the DB instance class, and **Apply Immediately** is set to `false`.

When you change a static parameter in a DB parameter group, the change doesn't take effect until the DB instance associated with the parameter group is rebooted. The change requires a manual reboot. The DB instance isn't automatically rebooted during the maintenance window.

To see a table that shows DB instance actions and the effect that setting the **Apply Immediately** value has, see Modifying an Amazon RDS DB instance.

Amazon RDS DB parameter changes not taking effect

In some cases, you might change a parameter in a DB parameter group but don't see the changes take effect. If so, you likely need to reboot the DB instance associated with the DB parameter

group. When you change a dynamic parameter, the change takes effect immediately. When you change a static parameter, the change doesn't take effect until you reboot the DB instance associated with the parameter group.

You can reboot a DB instance using the RDS console. Or you can explicitly call the `RebootDBInstance` API operation. You can reboot without failover if the DB instance is in a Multi-AZ deployment. The requirement to reboot the associated DB instance after a static parameter change helps mitigate the risk of a parameter misconfiguration affecting an API call. An example of this is calling `ModifyDBInstance` to change the DB instance class. For more information, see Modifying parameters in a DB parameter group in Amazon RDS.

Amazon RDS DB instance running out of storage

If your DB instance runs out of storage space, it might no longer be available. We highly recommend that you constantly monitor the `FreeStorageSpace` metric published in CloudWatch to make sure that your DB instance has enough free storage space.

If your database instance runs out of storage, its status changes to `storage-full`. For example, a call to the `DescribeDBInstances` API operation for a DB instance that has used up its storage outputs the following.

```
aws rds describe-db-instances --db-instance-identifier mydbinstance

DBINSTANCE  mydbinstance  2009-12-22T23:06:11.915Z  db.m5.large  mysql8.0  50  sa
storage-full  mydbinstance.clla4j4jgyph.us-east-1.rds.amazonaws.com  3306
us-east-1b  3
 SECGROUP  default  active
 PARAMGRP  default.mysql8.0  in-sync
```

To recover from this scenario, add more storage space to your instance using the `ModifyDBInstance` API operation or the following AWS CLI command.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier mydbinstance \
    --allocated-storage 60 \
    --apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier mydbinstance ^
    --allocated-storage 60 ^
    --apply-immediately
```

```
DBINSTANCE  mydbinstance  2009-12-22T23:06:11.915Z  db.m5.large  mysql8.0  50  sa
storage-full  mydbinstance.clla4j4jgyph.us-east-1.rds.amazonaws.com  3306
us-east-1b  3  60
 SECGROUP  default  active
 PARAMGRP  default.mysql8.0  in-sync
```

Now, when you describe your DB instance, you see that your DB instance has `modifying` status, which indicates the storage is being scaled.

```
aws rds describe-db-instances --db-instance-identifier mydbinstance
```

```
DBINSTANCE  mydbinstance  2009-12-22T23:06:11.915Z  db.m5.large  mysql8.0  50  sa
modifying  mydbinstance.clla4j4jgyph.us-east-1.rds.amazonaws.com
3306  us-east-1b  3  60
 SECGROUP  default  active
 PARAMGRP  default.mysql8.0  in-sync
```

After storage scaling is complete, your DB instance status changes to `available`.

```
aws rds describe-db-instances --db-instance-identifier mydbinstance
```

```
DBINSTANCE  mydbinstance  2009-12-22T23:06:11.915Z  db.m5.large  mysql8.0  60  sa
available  mydbinstance.clla4j4jgyph.us-east-1.rds.amazonaws.com  3306
us-east-1b  3
 SECGROUP  default  active
 PARAMGRP  default.mysql8.0  in-sync
```

You can receive notifications when your storage space is exhausted using the `DescribeEvents` operation. For example, in this scenario, if you make a `DescribeEvents` call after these operations you see the following output.

```
aws rds describe-events --source-type db-instance --source-identifier mydbinstance
```

```
2009-12-22T23:44:14.374Z  mydbinstance  Allocated storage has been exhausted db-
instance
2009-12-23T00:14:02.737Z  mydbinstance  Applying modification to allocated storage db-
instance
2009-12-23T00:31:54.764Z  mydbinstance  Finished applying modification to allocated
 storage
```

Amazon RDS insufficient DB instance capacity

The `InsufficientDBInstanceCapacity` error can be returned when you try to create, start, or modify a DB instance. It can also be returned when you try to restore a DB instance from a DB snapshot. When this error is returned, a common cause is that the specific DB instance class isn't available in the requested Availability Zone. You can try one of the following to solve the problem:

- Retry the request with a different DB instance class.
- Retry the request with a different Availability Zone.
- Retry the request without specifying an explicit Availability Zone.

For information about troubleshooting instance capacity issues for Amazon EC2, see Insufficient instance capacity in the *Amazon EC2 User Guide*.

For information about modifying a DB instance, see Modifying an Amazon RDS DB instance.

Freeable memory issues in Amazon RDS

Freeable memory is the total random access memory (RAM) on a DB instance that can be made available to the database engine. It's the sum of the free operating-system (OS) memory and the available buffer and page cache memory. The database engine uses most of the memory on the host, but OS processes also use some RAM. Memory currently allocated to the database engine or used by OS processes isn't included in freeable memory. When the database engine is running out of memory, the DB instance can use the temporary space that is normally used for buffering and caching. As previously mentioned, this temporary space is included in freeable memory.

You use the `FreeableMemory` metric in Amazon CloudWatch to monitor the freeable memory. For more information, see Monitoring tools for Amazon RDS.

If your DB instance consistently runs low on freeable memory or uses swap space, consider scaling up to a larger DB instance class. For more information, see DB instance classes.

You can also change the memory settings. For example, on RDS for MySQL, you might adjust the size of the `innodb_buffer_pool_size` parameter. This parameter is set by default to 75 percent of physical memory. For more MySQL troubleshooting tips, see How can I troubleshoot low freeable memory in an Amazon RDS for MySQL database?

MySQL and MariaDB issues

You can diagnose and correct issues with MySQL and MariaDB DB instances.

Topics

- Maximum MySQL and MariaDB connections
- Diagnosing and resolving incompatible parameters status for a memory limit
- Diagnosing and resolving lag between read replicas
- Diagnosing and resolving a MySQL or MariaDB read replication failure
- Creating triggers with binary logging enabled requires SUPER privilege
- Diagnosing and resolving point-in-time restore failures
- Replication stopped error
- Read replica create fails or replication breaks with fatal error 1236

Maximum MySQL and MariaDB connections

The maximum number of connections allowed to an RDS for MySQL or RDS for MariaDB DB instance is based on the amount of memory available for its DB instance class. A DB instance class with more memory available results in a larger number of connections available. For more information on DB instance classes, see DB instance classes.

The connection limit for a DB instance is set by default to the maximum for the DB instance class. You can limit the number of concurrent connections to any value up to the maximum number of connections allowed. Use the `max_connections` parameter in the parameter group for the DB instance. For more information, see Maximum number of database connections and Parameter groups for Amazon RDS.

You can retrieve the maximum number of connections allowed for a MySQL or MariaDB DB instance by running the following query.

```
SELECT @@max_connections;
```

You can retrieve the number of active connections to a MySQL or MariaDB DB instance by running the following query.

```
SHOW STATUS WHERE `variable_name` = 'Threads_connected';
```

Diagnosing and resolving incompatible parameters status for a memory limit

A MariaDB or MySQL DB instance can be placed in **incompatible-parameters** status for a memory limit when the following conditions are met:

- The DB instance is restarted at least three times in one hour or at least five times in one day when the DB instance status is **Available**.
- An attempt to restart the DB instance fails because a maintenance action or monitoring process couldn't restart the DB instance.
- The potential memory usage of the DB instance exceeds 1.2 times the memory allocated to its DB instance class.

When a DB instance is restarted for the third time in one hour or for the fifth time in one day, it performs a check for memory usage. The check makes a calculation of the potential memory usage of the DB instance. The value returned by the calculation is the sum of the following values:

- **Value 1** – The sum of the following parameters:
  - `innodb_additional_mem_pool_size`
  - `innodb_buffer_pool_size`

    You can modify the value for `innodb_buffer_pool_size`. However, the value won't always match what you input. This mismatch occurs for several reasons. First, if the DB instance is a micro DB instance, then we override the default value and set it to 256 MB. For more information, see Overriding innodb_buffer_pool_size.

    Second, we make sure that 500 MB of memory is reserved on the DB instance for the host manager, the engine, the operating system, and the kernel.

    Last, we optimize `innodb_buffer_pool_size` by dividing it into units. The host manager rounds down to the closest multiple of those units. The units are calculated by multiplying

`innodb_buffer_pool_chunk_size` by `innodb_buffer_pool_instances`. For more information, see Configuring InnoDB Buffer Pool Size in the MySQL documentation.

The default for `innodb_buffer_pool_instances` is 8, unless `innodb_buffer_pool_size` is less than 1 GB. If `innodb_buffer_pool_size` is less than 1 GB, then the default for `innodb_buffer_pool_instances` is 1. The default for `innodb_buffer_pool_chunk_size` is 128 MB.

- `innodb_log_buffer_size`
- `key_buffer_size`
- `query_cache_size` (MySQL version 5.7 only)
- `tmp_table_size`

- **Value 2** – The `max_connections` parameter multiplied by the sum of the following parameters:
  - `binlog_cache_size`
  - `join_buffer_size`
  - `read_buffer_size`
  - `read_rnd_buffer_size`
  - `sort_buffer_size`
  - `thread_stack`
- **Value 3** – If the `performance_schema` parameter is enabled, then multiply the `max_connections` parameter by 429498.

  If the `performance_schema` parameter is disabled, then this value is zero.

So, the value returned by the calculation is the following:

```
Value 1 + Value 2 + Value 3
```

When this value exceeds 1.2 times the memory allocated to the DB instance class used by the DB instance, the DB instance is placed in **incompatible-parameters** status. For information about the memory allocated to DB instance classes, see Hardware specifications for DB instance classes.

The calculation multiplies the value of the `max_connections` parameter by the sum of several parameters. If the `max_connections` parameter is set to a large value, it might cause the check to return an inordinately high value for the potential memory usage of the DB instance. In this case, consider lowering the value of the `max_connections` parameter.

To resolve the problem, complete the following steps:

1. Adjust the memory parameters in the DB parameter group associated with the DB instance. Do so such that the potential memory usage is lower than 1.2 times the memory allocated to its DB instance class.

   For information about setting parameters, see Modifying parameters in a DB parameter group in Amazon RDS.
2. Restart the DB instance.

   For information about setting parameters, see Starting an Amazon RDS DB instance that was previously stopped.

Diagnosing and resolving lag between read replicas

After you create a MySQL or MariaDB read replica and the replica is available, Amazon RDS first replicates the changes made to the source DB instance from the time the read replica create operation started. During this phase, the replication lag time for the read replica is greater than 0. You can monitor this lag time in Amazon CloudWatch by viewing the Amazon RDS `ReplicaLag` metric.

The `ReplicaLag` metric reports the value of the `Seconds_Behind_Master` field of the MariaDB or MySQL `SHOW REPLICA STATUS` command. For more information, see SHOW REPLICA STATUS Statement in the MySQL documentation.

When the `ReplicaLag` metric reaches 0, the replica has caught up to the source DB instance. If the `ReplicaLag` metric returns -1, replication might not be active. To troubleshoot a replication error, see Diagnosing and resolving a MySQL or MariaDB read replication failure. A `ReplicaLag` value of -1 can also mean that the `Seconds_Behind_Master` value can't be determined or is `NULL`.

> **Note**
>
> Previous versions of MariaDB and MySQL used `SHOW SLAVE STATUS` instead of `SHOW REPLICA STATUS`. If you are using a MariaDB version before 10.5 or a MySQL version before 8.0.23, then use `SHOW SLAVE STATUS`.

The `ReplicaLag` metric returns -1 during a network outage or when a patch is applied during the maintenance window. In this case, wait for network connectivity to be restored or for the maintenance window to end before you check the `ReplicaLag` metric again.

The MySQL and MariaDB read replication technology is asynchronous. Thus, you can expect occasional increases for the `BinLogDiskUsage` metric on the source DB instance and for the `ReplicaLag` metric on the read replica. For example, consider a situation where a high volume of write operations to the source DB instance occur in parallel. At the same time, write operations to the read replica are serialized using a single I/O thread. Such a situation can lead to a lag between the source instance and read replica.

For more information about read replicas and MySQL, see Replication implementation details in the MySQL documentation. For more information about read replicas and MariaDB, see Replication overview in the MariaDB documentation.

You can reduce the lag between updates to a source DB instance and the subsequent updates to the read replica by doing the following:

- Set the DB instance class of the read replica to have a storage size comparable to that of the source DB instance.
- Make sure that parameter settings in the DB parameter groups used by the source DB instance and the read replica are compatible. For more information and an example, see the discussion of the `max_allowed_packet` parameter in the next section.
- Disable the query cache. For tables that are modified often, using the query cache can increase replica lag because the cache is locked and refreshed often. If this is the case, you might see less replica lag if you disable the query cache. You can disable the query cache by setting the `query_cache_type parameter` to 0 in the DB parameter group for the DB instance. For more information on the query cache, see Query cache configuration.
- Warm the buffer pool on the read replica for InnoDB for MySQL or MariaDB. For example, suppose that you have a small set of tables that are being updated often and you're using the InnoDB or XtraDB table schema. In this case, dump those tables on the read replica. Doing this causes the database engine to scan through the rows of those tables from the disk and then cache them in the buffer pool. This approach can reduce replica lag. The following shows an example.

  For Linux, macOS, or Unix:

```
PROMPT> mysqldump \
```

```
    -h <endpoint> \
    --port=<port> \
    -u=<username> \
    -p <password> \
    database_name table1 table2 > /dev/null
```

For Windows:

```
PROMPT> mysqldump ^
    -h <endpoint> ^
    --port=<port> ^
    -u=<username> ^
    -p <password> ^
    database_name table1 table2 > /dev/null
```

Diagnosing and resolving a MySQL or MariaDB read replication failure

Amazon RDS monitors the replication status of your read replicas. RDS updates the **Replication State** field of the read replica instance to `Error` if replication stops for any reason. You can review the details of the associated error thrown by the MySQL or MariaDB engines by viewing the **Replication Error** field. Events that indicate the status of the read replica are also generated, including RDS-EVENT-0045, RDS-EVENT-0046, and RDS-EVENT-0057. For more information about events and subscribing to events, see Working with Amazon RDS event notification. If a MySQL error message is returned, check the error in the MySQL error message documentation. If a MariaDB error message is returned, check the error in the MariaDB error message documentation.

Common situations that can cause replication errors include the following:

- The value for the `max_allowed_packet` parameter for a read replica is less than the `max_allowed_packet` parameter for the source DB instance.

  The `max_allowed_packet` parameter is a custom parameter that you can set in a DB parameter group. The `max_allowed_packet` parameter is used to specify the maximum size of data manipulation language (DML) that can be run on the database. In some cases, the `max_allowed_packet` value for the source DB instance might be larger than the `max_allowed_packet` value for the read replica. If so, the replication process can throw an error and stop replication. The most common error is `packet bigger than 'max_allowed_packet' bytes`. You can fix the error by having the source and read replica use DB parameter groups with the same `max_allowed_packet` parameter values.

- Writing to tables on a read replica. If you're creating indexes on a read replica, you need to have the `read_only` parameter set to *0* to create the indexes. If you're writing to tables on the read replica, it can break replication.
- Using a nontransactional storage engine such as MyISAM. Read replicas require a transactional storage engine. Replication is only supported for the following storage engines: InnoDB for MySQL or MariaDB.

  You can convert a MyISAM table to InnoDB with the following command:

  ```
  alter table <schema>.<table_name> engine=innodb;
  ```
- Using unsafe nondeterministic queries such as `SYSDATE()`. For more information, see Determination of safe and unsafe statements in binary logging in the MySQL documentation.

The following steps can help resolve your replication error:

- If you encounter a logical error and you can safely skip the error, follow the steps described in Skipping the current replication error. Your MySQL or MariaDB DB instance must be running a version that includes the `mysql_rds_skip_repl_error` procedure. For more information, see mysql.rds_skip_repl_error.
- If you encounter a binary log (binlog) position issue, you can change the replica replay position with the `mysql_rds_next_master_log` command. Your MySQL or MariaDB DB instance must be running a version that supports the `mysql_rds_next_master_log` command to change the replica replay position. For version information, see mysql.rds_next_master_log.
- You might encounter a temporary performance issue due to high DML load. If so, you can set the `innodb_flush_log_at_trx_commit` parameter to 2 in the DB parameter group on the read replica. Doing this can help the read replica catch up, though it temporarily reduces atomicity, consistency, isolation, and durability (ACID).
- You can delete the read replica and create an instance using the same DB instance identifier. If you do this, the endpoint remains the same as that of your old read replica.

If a replication error is fixed, the **Replication State** changes to **replicating**. For more information, see Troubleshooting a MySQL read replica problem.

Creating triggers with binary logging enabled requires SUPER privilege

When trying to create triggers in an RDS for MySQL or RDS for MariaDB DB instance, you might receive the following error.

```
"You do not have the SUPER privilege and binary logging is enabled"
```

To use triggers when binary logging is enabled requires the SUPER privilege, which is restricted for RDS for MySQL and RDS for MariaDB DB instances. You can create triggers when binary logging is enabled without the SUPER privilege by setting the `log_bin_trust_function_creators` parameter to true. To set the `log_bin_trust_function_creators` to true, create a new DB parameter group or modify an existing DB parameter group.

You can create a new DB parameter group so you can create triggers in your RDS for MySQL or RDS for MariaDB DB instance with binary logging enabled. To do so, use the following CLI commands. To modify an existing parameter group, start with step 2.

To create a new parameter group to allow triggers with binary logging enabled using the CLI

1. Create a new parameter group.

   For Linux, macOS, or Unix:

   ```
   aws rds create-db-parameter-group \
       --db-parameter-group-name allow-triggers \
       --db-parameter-group-family mysql8.0 \
       --description "parameter group allowing triggers"
   ```

   For Windows:

   ```
   aws rds create-db-parameter-group ^
       --db-parameter-group-name allow-triggers ^
       --db-parameter-group-family mysql8.0 ^
       --description "parameter group allowing triggers"
   ```

2. Modify the DB parameter group to allow triggers.

   For Linux, macOS, or Unix:

   ```
   aws rds modify-db-parameter-group \
   ```

```
    --db-parameter-group-name allow-triggers \
    --parameters "ParameterName=log_bin_trust_function_creators,
 ParameterValue=true, ApplyMethod=pending-reboot"
```

For Windows:

```
aws rds modify-db-parameter-group ^
    --db-parameter-group-name allow-triggers ^
    --parameters "ParameterName=log_bin_trust_function_creators,
 ParameterValue=true, ApplyMethod=pending-reboot"
```

3. Modify your DB instance to use the new DB parameter group.

   For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier mydbinstance \
    --db-parameter-group-name allow-triggers \
    --apply-immediately
```

   For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier mydbinstance ^
    --db-parameter-group-name allow-triggers ^
    --apply-immediately
```

4. For the changes to take effect, manually reboot the DB instance.

```
aws rds reboot-db-instance --db-instance-identifier mydbinstance
```

Diagnosing and resolving point-in-time restore failures

Restoring a DB instance that includes temporary tables

When attempting a point-in-time restore (PITR) of your MySQL or MariaDB DB instance, you might encounter the following error.

```
Database instance could not be restored because there has been incompatible database
 activity for restore
```

```
functionality. Common examples of incompatible activity include using temporary tables,
 in-memory tables,
or using MyISAM tables. In this case, use of Temporary table was detected.
```

PITR relies on both backup snapshots and binary logs (binlogs) from MySQL or MariaDB to restore your DB instance to a particular time. Temporary table information can be unreliable in binlogs and can cause a PITR failure. If you use temporary tables in your MySQL or MariaDB DB instance, you can decrease the possibility of a PITR failure by performing more frequent backups. A PITR failure is most probable in the time between a temporary table's creation and the next backup snapshot.

Restoring a DB instance that includes in-memory tables

You might encounter a problem when restoring a database that has in-memory tables. In-memory tables are purged during a restart. As a result, your in-memory tables might be empty after a reboot. We recommend that when you use in-memory tables, you architect your solution to handle empty tables in the event of a restart. If you're using in-memory tables with replicated DB instances, you might need to recreate the read replicas after a restart. This might be necessary if a read replica reboots and can't restore data from an empty in-memory table.

For more information about backups and PITR, see Introduction to backups and Restoring a DB instance to a specified time.

Replication stopped error

When you call the `mysql.rds_skip_repl_error` command, you might receive an error message stating that replication is down or disabled.

This error message appears because replication is stopped and can't be restarted.

If you need to skip a large number of errors, the replication lag can increase beyond the default retention period for binary log files. In this case, you might encounter a fatal error due to binary log files being purged before they have been replayed on the replica. This purge causes replication to stop, and you can no longer call the `mysql.rds_skip_repl_error` command to skip replication errors.

You can mitigate this issue by increasing the number of hours that binary log files are retained on your replication source. After you have increased the binlog retention time, you can restart replication and call the `mysql.rds_skip_repl_error` command as needed.

To set the binlog retention time, use the mysql.rds_set_configuration procedure. Specify a configuration parameter of 'binlog retention hours' along with the number of hours to retain

binlog files on the DB cluster, up to 720 (30 days). The following example sets the retention period for binlog files to 48 hours.

```
CALL mysql.rds_set_configuration('binlog retention hours', 48);
```

Read replica create fails or replication breaks with fatal error 1236

After changing default parameter values for a MySQL or MariaDB DB instance, you might encounter one of the following problems:

- You can't create a read replica for the DB instance.
- Replication fails with `fatal error 1236`.

Some default parameter values for MySQL and MariaDB DB instances help to make sure that the database is ACID compliant and read replicas are crash-safe. They do this by making sure that each commit is fully synchronized by writing the transaction to the binary log before it's committed. Changing these parameters from their default values to improve performance can cause replication to fail when a transaction hasn't been written to the binary log.

To resolve this issue, set the following parameter values:

- `sync_binlog = 1`
- `innodb_support_xa = 1`
- `innodb_flush_log_at_trx_commit = 1`

Can't set backup retention period to 0

There are several reasons why you might need to set the backup retention period to 0. For example, you can disable automatic backups immediately by setting the retention period to 0.

In some cases, you might set the value to 0 and receive a message saying that the retention period must be between 1 and 35. In these cases, check to make sure that you haven't set up a read replica for the instance. Read replicas require backups for managing read replica logs, and therefore you can't set a retention period of 0.

Amazon RDS API reference

In addition to the AWS Management Console and the AWS Command Line Interface (AWS CLI), Amazon RDS also provides an API. You can use the API to automate tasks for managing your DB instances and other objects in Amazon RDS.

- For an alphabetical list of API operations, see Actions.
- For an alphabetical list of data types, see Data types.
- For a list of common query parameters, see Common parameters.
- For descriptions of the error codes, see Common errors.

For more information about the AWS CLI, see AWS Command Line Interface reference for Amazon RDS.

Topics

Using the Query API

The following sections briefly discuss the parameters and request authentication used with the Query API.

For general information about how the Query API works, see Query requests in the *Amazon EC2 API Reference*.

Query parameters

HTTP Query-based requests are HTTP requests that use the HTTP verb GET or POST and a Query parameter named `Action`.

Each Query request must include some common parameters to handle authentication and selection of an action.

Some operations take lists of parameters. These lists are specified using the `param.`*n* notation. Values of *n* are integers starting from 1.

For information about Amazon RDS Regions and endpoints, go to Amazon Relational Database Service (RDS) in the Regions and Endpoints section of the *Amazon Web Services General Reference*.

Query request authentication

You can only send Query requests over HTTPS, and you must include a signature in every Query request. You must use either AWS signature version 4 or signature version 2. For more information, see Signature Version 4 signing process and Signature version 2 signing process.

Troubleshooting applications on Amazon RDS

Amazon RDS provides specific and descriptive errors to help you troubleshoot problems while interacting with the Amazon RDS API.

Topics

- Retrieving errors
- Troubleshooting tips

For information about troubleshooting for Amazon RDS DB instances, see Troubleshooting for Amazon RDS.

Retrieving errors

Typically, you want your application to check whether a request generated an error before you spend any time processing results. The easiest way to find out if an error occurred is to look for an `Error` node in the response from the Amazon RDS API.

XPath syntax provides a simple way to search for the presence of an `Error` node. It also provides a relatively easy way to retrieve the error code and message. The following code snippet uses Perl and the XML::XPath module to determine if an error occurred during a request. If an error occurred, the code prints the first error code and message in the response.

```
use XML::XPath;
    my $xp = XML::XPath->new(xml =>$response);
    if ( $xp->find("//Error") )
    {print "There was an error processing your request:\n", " Error code: ",
    $xp->findvalue("//Error[1]/Code"), "\n", " ",
    $xp->findvalue("//Error[1]/Message"), "\n\n"; }
```

Troubleshooting tips

We recommend the following processes to diagnose and resolve problems with the Amazon RDS API:

- Verify that Amazon RDS is operating normally in the AWS Region that you're targeting by checking http://status.aws.amazon.com.
- Check the structure of your request.

  Each Amazon RDS operation has a reference page in the *Amazon RDS API Reference*. Double-check that you are using parameters correctly. For ideas about what might be wrong, look at the sample requests or user scenarios to see if those examples do similar operations.
- Check AWS re:Post.

  Amazon RDS has a development community where you can search for solutions to problems others have experienced along the way. To view the topics, go to AWS re:Post.

Document history

Current API version: 2014-10-31

The following table describes important changes in each release of the *Amazon RDS User Guide* after May 2018. For notification about updates to this documentation, you can subscribe to an RSS feed.

> **Note**
>
> You can filter new Amazon RDS features on the What's New with Database? page. For **Products**, choose **Amazon RDS**. Then search using keywords such as **`RDS Proxy`** or **`Oracle 2023`**.

Change	Description	Date
Zero-ETL integrations with Amazon Redshift generally available	Zero-ETL integrations make transactional data availabl e in Amazon Redshift within seconds of it being written to an RDS for MySQL DB instance. The feature is now generally available. For more information, see Working with Amazon RDS zero-ETL integrations with Amazon Redshift.	September 12, 2024
Amazon RDS supports MariaDB 10.11.9, 10.6.19, and 10.5.26	You can now create Amazon RDS DB instances running MariaDB version 10.11.9, 10.6.19, and 10.5.26. For more information, see MariaDB on Amazon RDS versions.	September 4, 2024

Amazon RDS for Oracle supports the OEM, OEMAGENT, and OLS options for the CDB architecture	You can now use Oracle Enterprise Manager and Oracle Label Security with RDS for Oracle CDB instances . For more information, see Oracle Enterprise Manager and Oracle Label Security.	September 4, 2024
RDS Custom for SQL Server is available in additional Regions	RDS Custom for SQL Server is now available in the US West (N. California) Region, Asia Pacific (Osaka) Region, and Europe (Paris) Region. For more information, see Supported Regions and DB engines for RDS Custom .	August 29, 2024
Amazon RDS Extended Support version 5.7.44-RDS.20240808 for RDS for MySQL	The RDS Extended Support version 5.7.44-RDS.20240808 is now available for RDS for MySQL. For more information, see Amazon RDS Extended Support versions for RDS for MySQL.	August 29, 2024
Amazon RDS is available in the Asia Pacific (Malaysia) Region	Amazon RDS is now available in the Asia Pacific (Malaysia) Region. For more information, see Regions and Availability Zones.	August 22, 2024
Amazon RDS supports MySQL 8.0.39	You can now create Amazon RDS DB instances running MySQL version 8.0.39. For more information, see MySQL on Amazon RDS versions.	August 12, 2024

Update to existing policy	Amazon RDS removed `sns:Publish` permission from the `AmazonRDSPreviewServiceRolePolicy` of the `AWSServiceRoleForRDSPreview` service-linked role. For more information, see Amazon RDS updates to AWS managed policies.	August 7, 2024
Update to existing policy	Amazon RDS removed `sns:Publish` permission from the `AmazonRDSBetaServiceRolePolicy` of the `AWSServiceRoleForRDSBeta` service-linked role. For more information, see Amazon RDS updates to AWS managed policies.	August 7, 2024
Amazon RDS supports MySQL 8.4 in the Database Preview environment	MySQL 8.4 is now available in the Database Preview environment in the US East (Ohio) AWS Region. For more information, see MySQL version 8.4 in the Database Preview environment.	August 1, 2024

Update to IAM service-linked role permissions	The `AmazonRDSCustomServiceRolePolicy` policy now grants additional permissions to communicate with Amazon RDS services in another AWS Region and copy EC2 images. For more information, see Amazon RDS updates to AWS managed policies.	July 18, 2024
Amazon RDS supports MariaDB 11.4 in the Database Preview environment	MariaDB 11.4 is now available in the Database Preview environment in the US East (Ohio) AWS Region. For more information, see MariaDB version 11.4 in the Database Preview environment.	July 18, 2024
AWS ODBC Driver for MySQL generally available	The Amazon Web Services (AWS) ODBC Driver for MySQL is a client driver designed for the high availability of RDS for MySQL. For more information, see Connecting to RDS for MySQL with the Amazon Web Services (AWS) ODBC Driver for MySQL.	July 18, 2024

Update to existing policy	Amazon RDS removed `sns:Publish` permission from the `AmazonRDSServiceRolePolicy` of the `AWSServiceRoleForRDS` service-linked role. For more information, see AWS managed policy: Amazon RDSServiceRolePolicy.	July 2, 2024
AWS Marketplace private offer for Db2	AWS Marketplace now supports private offers for a Db2 license through AWS Marketplace for Amazon RDS for Db2. For more information, see Obtaining a private offer.	July 1, 2024
Export Multi-AZ DB cluster snapshot data to Amazon S3	You can now export Multi-AZ DB cluster snapshot data to Amazon S3. For more information, see Exporting DB snapshot data to Amazon S3.	June 27, 2024
Amazon RDS for Oracle supports preconfigured r6i memory optimized instance classes	The db.r6i Oracle DB instance classes are optimized for workloads that require additional memory, storage, and I/O per vCPU. For example, db.r6i.8xlarge.tpc2.mem4x has multithreading turned on and provides 4 times as much memory as db.r6i.8xlarge. For more information, see RDS for Oracle instance classes.	June 21, 2024

Amazon RDS Extended Support version 5.7.44-RDS.20240529 for RDS for MySQL	The RDS Extended Support version 5.7.44-RDS.20240529 is now available for RDS for MySQL. For more information, see Amazon RDS Extended Support versions for RDS for MySQL.	June 20, 2024
Amazon RDS supports MySQL 8.0.37	You can now create Amazon RDS DB instances running MySQL version 8.0.37. For more information, see MySQL on Amazon RDS versions.	June 18, 2024
Amazon RDS supports MariaDB 10.11.8, 10.6.18, 10.5.25, and 10.4.34	You can now create Amazon RDS DB instances running MariaDB version 10.11.8, 10.6.18, 10.5.25, and 10.4.34. For more information, see MariaDB on Amazon RDS versions.	June 14, 2024
Amazon RDS is ending support for the db.m4, db.r4, and db.t2 DB instance classes	For the RDS for MariaDB, RDS for MySQL, and RDS for PostgreSQL DB engines, you can no longer create DB instances that use the db.m4, db.r4, and db.t2 instance classes. RDS is automatically upgrading existing DB instances that use these classes to a newer generation. For more information, see DB instance class types.	June 4, 2024

Multi-AZ DB clusters are available in additional AWS Regions	You can create Multi-AZ DB clusters in more AWS Regions. For a table that shows all supported Regions, see Supported Regions and DB engines for Multi-AZ DB clusters in Amazon RDS.	May 29, 2024
AWS Python Driver generally available	The Amazon Web Services (AWS) Python Driver is designed as an advanced Python wrapper. This wrapper is complementary to and extends the functionality of the open-source Psycopg driver. For more informati on, see Connecting to DB instances with the AWS drivers.	May 23, 2024
RDS Proxy is available in more Regions	RDS Proxy is now available in the Asia Pacific (Hyderaba d), Asia Pacific (Melbourne), Middle East (UAE), Israel (Tel Aviv), Canada West (Calgary) , and Europe (Zurich) regions. For more information about RDS Proxy, see Using Amazon RDS Proxy.	May 21, 2024
Db2 license through AWS Marketplace	With Db2 license through AWS Marketplace, you can now pay an hourly rate to subscribe to Db2 licenses for Amazon RDS for Db2. For more information, Amazon RDS for Db2 licensing options.	May 21, 2024

Amazon RDS supports fine-grained access for Performance Insights	You can now allow or deny access to individual dimensions in Performance Insights. This fine-grained access can be used for `GetResourceMetrics`, `DescribeDimensionKeys`, and `GetDimensionKeyDetails` actions. For more information, see Granting fine-grained access for Performance Insights.	May 21, 2024
Amazon RDS Extended Support versions for RDS for MySQL	You can view all releases of RDS Extended Support for RDS for MySQL versions. For more information, see Amazon RDS Extended Support versions for RDS for MySQL.	May 16, 2024
Amazon RDS supports MySQL 8.3 in the Database Preview environment	MySQL 8.3 is now available in the Database Preview environment in the US East (Ohio) AWS Region. For more information, see MySQL version 8.3 in the Database Preview environment.	April 30, 2024
Amazon RDS for Db2 supports time zones	RDS for Db2 now supports setting local time zones for new RDS for Db2 DB instances. For more information, see Local time zones for Amazon RDS for Db2 DB instances.	April 25, 2024

Update to IAM service-linked role permissions	The `AmazonRDSCustomServiceRolePolicy` policy now grants additional permissions to associate a service role as an instance profile to a RDS Custom instance. For more information, see Amazon RDS updates to AWS managed policies.	April 19, 2024
Amazon RDS for Oracle supports Oracle Data Guard switchover in all AWS Regions	You can now use Oracle Data Guard switchover in all supported Regions. For more information, see Overview of Oracle Data Guard switchover.	April 16, 2024
RDS Custom for Oracle supports Oracle Standard Edition 2	You can now create DB instances using Standard Edition 2 on Oracle Database 12c Release 1 (12.1), 12c Release 2 (12.2), 18c, and 19c. You can create both CDBs and non-CDBs. For more information, see Edition and licensing support for RDS Custom for Oracle.	April 11, 2024
Amazon RDS for Oracle supports Oracle APEX version 23.2.v1	You can use APEX 23.2.v1 with Oracle Database 19c and higher. For more information, see Oracle Application Express.	April 11, 2024

Update to RDS Custom service-linked role permissions	The `AmazonRDSCustomServiceRolePolicy` now grants additional permissions to allow RDS Custom for SQL Server to get EC2 instance type information and modify DB host instance type. For more information, Updates to AWS managed policies.	April 8, 2024
Amazon RDS Custom for Oracle supports the db.x2iezn DB instance class	You can now use the db.x2iezn instance class for RDS Custom for Oracle DB instances. For more information, see DB instance class support for RDS Custom for Oracle.	March 26, 2024
Amazon RDS supports the db.c6gd instance classes for Multi-AZ DB clusters	You can now use the db.c6gd instance classes for Multi-AZ DB cluster deployments. For more information, see Instance class availability for Multi-AZ DB clusters.	March 21, 2024

Amazon RDS Extended Support	Creating or restoring an RDS for MySQL 5.7 or RDS for PostgreSQL 11 database now automatically enrolls that database into Amazon RDS Extended Support so your existing applications continue to work as they are. You can opt out of RDS Extended Support to avoid charges after the RDS end of standard support date for your database engine. For more information, see Using Amazon RDS Extended Support.	March 21, 2024
RDS for Db2 integration with AWS License Manager	RDS for Db2 is now integrated with AWS License Manager. If you use the Bring Your Own License model, the AWS License Manager integration aids in monitoring your Db2 license usage within your organization. For more information, see Integrating with AWS License Manager.	March 20, 2024

CA certificate rotation for Multi-AZ DB clusters	You can now rotate the CA certificates for your Multi-AZ DB clusters. Consider using one of the new CA certificates rds-ca-rsa2048-g1, rds-ca-rsa4096-g1, or rds-ca-ecc384-g1. For more information, see Rotating your SSL/TLS certificate.	March 6, 2024
Amazon RDS supports io2 Block Express storage	You can now create RDS DB instances that use the io2 Block Express storage type. For more information, see io2 Block Express storage.	March 6, 2024
RDS Custom for SQL Server supports the db.r5b and db.x2iedn DB instance classes	You can now use the db.r5b and db.x2iedn instance classes for RDS Custom for SQL Server DB instances. For more information, see DB instance class support for RDS Custom for SQL Server.	March 4, 2024
RDS Custom for Oracle is available in the Middle East (UAE) Region	You can create RDS Custom for Oracle DB instances in the Middle East (UAE) Region. For a table that shows all supported AWS Regions, see Supported Regions and DB engines for RDS Custom for Oracle.	March 4, 2024

New AWS managed policy	Amazon RDS added a new managed policy named `AmazonRDSCustomInstanceProfileRolePolicy` to allow RDS Custom to perform automation actions and database management tasks through an EC2 instance profile. For more information, see Amazon RDS updates to AWS managed policies.	February 27, 2024
Amazon RDS supports MariaDB 10.11.7, 10.6.17, 10.5.24, and 10.4.33	You can now create Amazon RDS DB instances running MariaDB version 10.11.7, 10.6.17, 10.5.24, and 10.4.33. For more information, see MariaDB on Amazon RDS versions.	February 26, 2024
Amazon RDS Multi-AZ DB clusters support the Amazon EBS gp3 storage volume	Multi-AZ DB clusters now support gp3 SSD-based EBS volumes. For more information, see gp3 storage.	February 26, 2024
Amazon RDS support for AWS Secrets Manager in the Israel (Tel Aviv) Region	Amazon RDS supports Secrets Manager in the Israel (Tel Aviv) Region. For more information, see Password management with Amazon RDS and AWS Secrets Manager.	February 21, 2024

Amazon RDS for Db2 supports audit logging	RDS for Db2 now supports database-level audit logging. When you enable audit logging for an RDS for Db2 database, Amazon RDS records the database activity and stores the audit logs in Amazon S3. For more information, see Db2 audit logging.	February 15, 2024
Amazon RDS Extended Support	Amazon RDS now automatically enables Amazon RDS Extended Support when RDS for MySQL and RDS for PostgreSQL major engine versions in your DB instances and Multi-AZ DB clusters reach the RDS end of standard support date. For more information, see Using Amazon RDS Extended Support.	February 15, 2024
Amazon RDS supports MySQL 8.0.36	You can now create Amazon RDS DB instances running MySQL version 8.0.36. For more information, see MySQL on Amazon RDS versions.	February 12, 2024

Amazon RDS supports EBCDIC collation for RDS for Db2	You can now create Db2 databases that use EBCDIC collation sequences to sort content in the databases. For more information, see EBCDIC collation for Db2 databases on Amazon RDS.	January 29, 2024
Update to default CA Certificate	The default CA certificate is set to `rds-ca-rsa2048-g1`. For more information, see Using SSL/TLS to encrypt a connection to a DB instance.	January 26, 2024
Amazon RDS for PostgreSQL supports two new crates for PL/Rust, croaring-rs and num-bigint	You can use two new crates in Amazon RDS for PostgreSQL. For more information, see Using crates with PL/Rust.	January 24, 2024
Amazon RDS for PostgreSQL supports TLS version 1.3	You can use Transport Layer Security (TLS) version 1.3 in RDS for PostgreSQL. For more information, see Using SSL with a PostgreSQL DB instance.	January 24, 2024
RDS Custom for SQL Server supports Microsoft SQL Server 2022	You can now create RDS Custom for SQL Server DB instances that use SQL Server 2022. For more information, see Working with RDS Custom for SQL Server.	January 22, 2024

Update to AWS managed policy permissions	The `AmazonRDSServiceRolePolicy` of the `AWSServiceRoleForRDS` service-linked role has new statement IDs. For more information, see Amazon RDS updates to AWS managed policies.	January 19, 2024
RDS Custom for Oracle supports the Europe (Paris) Region	You can create RDS Custom for Oracle DB instances in the Europe (Paris) Region. For more information, see Supported Regions and DB engines for RDS Custom for Oracle.	January 18, 2024
Amazon RDS for MySQL supports multi-source replication	You can now use multi-source replication on RDS for MySQL DB instances. For more information, see Configuring multi-source replication on RDS for MySQL.	January 16, 2024
Amazon RDS supports MySQL 8.2 in the Database Preview environment	MySQL 8.2 is now available in the Database Preview environment in the US East (Ohio) AWS Region. For more information, see MySQL version 8.2 in the Database Preview environment.	January 11, 2024
RDS Proxy is available in the Europe (Spain) Region	RDS Proxy is now available in the Europe (Spain) region. For more information about RDS Proxy, see Using Amazon RDS Proxy.	January 8, 2024

Amazon RDS is available in the Canada West (Calgary) Region	Amazon RDS is now available in the Canada West (Calgary) Region. For more information, see Regions and Availability Zones.	December 20, 2023
Amazon RDS for Db2 supports 5,000 local users	You can now add up to 5,000 local users to an authorization list. For more information, see rdsadmin.add_user.	December 20, 2023
Amazon RDS supports viewing and responding to recommendations	Amazon RDS recommend ations now includes threshold based proactive and machine learning based reactive recommendations for RDS for PostgreSQL. For more information, see Recommend ations from Amazon RDS.	December 19, 2023
Amazon RDS supports MariaDB 10.11.6, 10.6.16, 10.5.23, and 10.4.32	You can now create Amazon RDS DB instances running MariaDB version 10.11.6, 10.6.16, 10.5.23, and 10.4.32. For more information, see MariaDB on Amazon RDS versions.	December 12, 2023

Amazon RDS introduces zero-ETL integrations with Amazon Redshift (preview)	Zero-ETL integrations provide a fully managed solution for making transactional data available in Amazon Redshift within seconds of it being written to an RDS for MySQL DB instance. For more information, see Working with Amazon RDS zero-ETL integrations with Amazon Redshift (preview).	November 28, 2023
Amazon RDS supports IBM Db2 database engines	You can now run IBM Db2 database engines in Amazon RDS. For more information, see Amazon RDS for Db2.	November 27, 2023
RDS for PostgreSQL supports major version upgrades to PostgreSQL 16.1 and minor version upgrades to 15.5, 14.10, 13.13, 12.17, and 11.22	With RDS for PostgreSQL, you can now upgrade the DB engine to major version 16.1 and minor version upgrades to 15.5, 14.10, 13.13, 12.17, and 11.22. For more information, see Upgrading the PostgreSQL DB engine for Amazon RDS.	November 17, 2023
RDS Custom for Oracle supports option groups	You can create or modify an option group and associate it with an RDS Custom for Oracle DB instance. The `Timezone` option is now supported. For more information, see Working with option groups in RDS Custom for Oracle.	November 17, 2023

Amazon RDS for MySQL supports the Group Replication plugin	You can now set up an active-active cluster with RDS for MySQL version 8.0.35 or higher DB instances by using the Group Replication plugin developed and maintained by the MySQL community. For more information, see Configuring active-active clusters for RDS for MySQL.	November 17, 2023
Amazon RDS Proxy supports RDS for PostgreSQL 16.1	You can now create proxies using RDS Proxy for RDS for PostgreSQL 16.1 DB instances. For more information, see Using Amazon RDS Proxy.	November 17, 2023
RDS Custom for SQL Server supports Microsoft SQL Server 2019 Developer edition	You can create RDS Custom for SQL Server DB instances that use SQL Server 2019 Developer edition. For more information, see Bring Your Own Media with RDS Custom for SQL Server.	November 16, 2023

Minor version upgrades of Multi-AZ DB clusters with minimal downtime	When you perform a minor version upgrade of a Multi-AZ DB cluster, Amazon RDS now upgrades the reader DB instances before the writer instance, thereby significantly reducing downtime. You can further reduce downtime to one second or less by using RDS Proxy. For more informati on, see Upgrading the engine version of a Multi-AZ DB cluster.	November 16, 2023
RDS for SQL Server supports Microsoft SQL Server 2022	You can now create RDS DB instances that use SQL Server 2022. For more informati on, see Microsoft SQL Server versions on Amazon RDS.	November 15, 2023
RDS for MySQL supports upgrading snapshots from version 5.7 to 8.0	You can now upgrade the engine version of an RDS for MySQL snapshot from version 5.7 to version 8.0. You can do so by using the AWS Management Console, or the `ModifyDBSnapshot` operation of the RDS API or AWS CLI. For more informat ion, see Upgrading a MySQL DB snapshot engine version.	November 15, 2023

RDS Custom for SQL Server supports point in time recovery of 1,0000 databases	You can now make up to 1,000 databases eligible for full backup and point in time recovery on your RDS Custom for SQL Server DB instance. For more information, see Restoring an RDS Custom for SQL Server instance to a point in time.	November 15, 2023
RDS Custom for SQL Server supports a using a Service Master Key	RDS Custom for SQL Server now supports using a Service Master Key (SMK). An SMK allows you to encrypt objects such as credentials, and use SQL Server features like TDE and column-encryption. For more information, see Using a Service Master Key with RDS Custom for SQL Server.	November 13, 2023
Amazon RDS supports MySQL 8.1 in the Database Preview environment	MySQL 8.1 is now available in the Database Preview environment in the US East (Ohio) AWS Region. For more information, see MySQL version 8.1 in the Database Preview environment.	November 10, 2023
RDS supports MySQL 8.0.35 and MySQL 5.7.44	You can now create Amazon RDS DB instances running MySQL version 8.0.35 and 5.7.44. For more information, see MySQL on Amazon RDS versions.	November 9, 2023

RDS Proxy supports Multi-AZ DB clusters	RDS Proxy now supports connecting to Multi-AZ DB clusters. For more informati on, see Working with Amazon RDS Proxy endpoints.	November 9, 2023
RDS Custom for Oracle is available in the AWS GovCloud (US) Regions	Amazon RDS is now available in the AWS GovCloud (US) Regions. For more informati on, see Supported Regions and DB engines for RDS Custom for Oracle.	November 9, 2023
Amazon RDS Optimized Writes supports the db.m5 DB instance class	Amazon RDS Optimized Writes now supports the db.m5 DB instance class. For more information, see Improving write performance with Amazon RDS Optimized Writes for MariaDB and Improving write performance with Amazon RDS Optimized Writes for MySQL.	November 9, 2023

Amazon RDS for Oracle supports the multi-tenant configuration of the CDB architecture	With the RDS for Oracle multi-tenant feature, RDS delivers a fully managed Oracle multitenant architecture and experience for your Oracle databases. You can use RDS APIs to create multiple PDBs, called *tenant databases*, in a CDB. RDS offers the multi-tenant configuration of the CDB architecture as an alternative to the legacy single-tenant configuration. For more information, see Multi-tenant configuration of the CDB architecture.	November 8, 2023
Amazon RDS exports Performance Insights metrics to Amazon CloudWatch	Performance Insights lets you export the preconfigured or custom metrics dashboards to Amazon CloudWatch. The exported metrics dashboards are available to view in the CloudWatch console. You can also export a selected Performance Insights metric widget and view the metrics data in the CloudWatch console. For more information, see Exporting Performance Insights metrics to CloudWatch.	November 8, 2023

Amazon RDS Custom for Oracle allows you to upgrade the operating system on a DB instance	You can now upgrade the database or operating system (OS) for an RDS Custom for Oracle DB instance using the CLI command `modify-db-instance`. For more information, see Upgrading a DB instance for Amazon RDS Custom for Oracle.	November 7, 2023
RDS Proxy supports Extended Protocol for RDS for PostgreSQL	You can now execute extended query protocols on an RDS for PostgreSQL DB instance. For more information, see Using Amazon RDS Proxy.	November 6, 2023
RDS for PostgreSQL support for RDS Blue/Green Deployments	You can now create a blue/green deployment from an RDS for PostgreSQL DB instance. For more information, see Using Amazon RDS Blue/Green Deployments for database updates.	October 26, 2023
Update to AWS managed policies	The `AmazonRDSPerformanceInsightsReadOnly` and `AmazonRDSPerformanceInsightsFullAccess` managed policies now includes `Sid` (statement ID) as an identifier in the policy statement. For more information, see Amazon RDS updates to AWS managed policies.	October 23, 2023

RDS Custom for Oracle supports the Europe (Milan) Region	For more information, see Supported Regions and DB engines for RDS Custom for Oracle.	October 23, 2023
Enable RDS Optimized Writes on existing databases	You can now enable RDS Optimized Writes on an existing DB instance even if it was created with an engine version, DB instance class, or file system config uration that doesn't support the feature. For more information, see Enabling RDS Optimized Writes on an existing database for RDS for MySQL, and Enabling RDS Optimized Writes on an existing database for RDS for MariaDB.	October 19, 2023
Amazon RDS supports using a dedicated log volume (DLV).	You can now use a dedicated log volume (DLV) with RDS for MariaDB, RDS for MySQL, and RDS for PostgreSQL. DLVs are ideal for databases with large allocated storage, high I/O per second (IOPS) requirements, or latency-s ensitive workloads. For more information, see Using a dedicated log volume (DLV).	October 17, 2023

Amazon RDS for PostgreSQL, MySQL, and MariaDB support new DB instance classes	You can create Amazon RDS DB instances running PostgreSQL, MySQL, and MariaDB that use the db.m6.in, db.m6idn, db.r6.in, and db.r6.idn DB instance classes. For more information, see Supported DB engines for all available DB instance classes.	October 12, 2023
Amazon RDS for PostgreSQL supports pgactive	The pgactive extension is available in Amazon RDS for PostgreSQL. For more information, see Using PostgreSQL extensions with Amazon RDS for PostgreSQL.	October 9, 2023
RDS Custom for Oracle is available in the Asia Pacific (Jakarta) Region	You can create RDS Custom for Oracle DB instances in the Asia Pacific (Jakarta) Region. For more information, see Supported Regions and DB engines for RDS Custom for Oracle.	October 5, 2023
RDS Custom for SQL Server supports new server-level collations	RDS Custom for SQL Server now supports a wide range of server collations, both in traditional and UTF-8 encoding, for the SQL_Latin, Japanese, German, and Arabic locales. For more information, see Collation and character support for RDS Custom for SQL Server DB instances.	September 26, 2023

Update to AWS managed policy permissions	The `AmazonRDSCustomServiceRolePolicy` of the `AWSServiceRoleForRDSCustom` service-linked role has new permissions that allow RDS Custom to create, modify, and delete EventBridge Managed Rules. For more information, see Amazon RDS updates to AWS managed policies.	September 20, 2023
Amazon RDS publishes Performance Insights counter metrics to Amazon CloudWatch	The **DB_PERF_INSIGHTS** metric math function in the CloudWatch console allows you to query Amazon RDS for Performance Insights counter metrics. For more information, see Creating CloudWatch alarms to monitor Amazon RDS.	September 20, 2023
Performance Insights supports digest-level statistics for SQL Server	When you use Performance Insights, you can view SQL statistics both at the statement and digest level for Amazon RDS for SQL Server. For more information, see Analyzing running queries in SQL Server.	September 18, 2023

Amazon RDS for PostgreSQL, MySQL, and MariaDB support the db.m6.id and db.r6.id DB instance class types	You can now create Amazon RDS DB instances running PostgreSQL, MySQL, and MariaDB that use the memory-optimized db.m6.id and db.r6.id DB instance class types. These types offer local NVMe-based SSD storage. For more information, see Supported DB engines for all available DB instance classes.	September 11, 2023
Major version upgrade support for RDS for PostgreSQL Multi-AZ DB clusters	You can now perform major version upgrades of your RDS for PostgreSQL Multi-AZ DB clusters. For more informati on, see Upgrading the engine version of a Multi-AZ DB cluster.	September 7, 2023
Amazon RDS supports MariaDB 10.11.5, 10.6.15, 10.5.22, and 10.4.31	You can now create Amazon RDS DB instances running MariaDB version 10.11.5, 10.6.15, 10.5.22, and 10.4.31. For more information, see MariaDB on Amazon RDS versions.	September 7, 2023

Amazon RDS Extended Support	Amazon RDS announces the upcoming ability to continue running RDS for MySQL and RDS for PostgreSQL major engine versions in your DB instances past the RDS end of standard support date. For more information, see Using Amazon RDS Extended Support.	September 1, 2023
RDS Custom supports starting and stopping an RDS Custom for SQL Server DB instance	RDS Custom now supports starting and stopping an RDS Custom for SQL Server DB instance. For more information, see Starting and stopping an RDS Custom for SQL Server DB instance.	August 31, 2023
Amazon RDS Optimized Writes supports the db.r5 DB instance class	Amazon RDS Optimized Writes now supports the db.r5 DB instance class. For more information, see Improving write performance with Amazon RDS Optimized Writes for MariaDB and Improving write performance with Amazon RDS Optimized Writes for MySQL.	August 31, 2023

Amazon RDS for Oracle supports timezone file autoupgrade for CDBs	With the `TIMEZONE_FILE_AUTOUPGRADE` option, you can upgrade the current time zone file to the latest version on your RDS for Oracle container database (CDB). For more information, see Oracle time zone file autoupgrade.	August 29, 2023
Amazon RDS Optimized Writes supports the db.m6g and db.m6i DB instance classes	Amazon RDS Optimized Writes now supports the db.m6g and db.m6i DB instance classes. For more information, see Improving write performance with Amazon RDS Optimized Writes for MariaDB and Improving write performance with Amazon RDS Optimized Writes for MySQL.	August 28, 2023
Amazon RDS supports MariaDB 10.11	You can now create Amazon RDS DB instances running MariaDB version 10.11. For more information, see MariaDB on Amazon RDS versions.	August 21, 2023

Update to AWS managed policy permissions	The `AmazonRDSCustomServiceRolePolicy` of the `AWSServiceRoleForRDSCustom` service-linked role has new permissions that allow RDS Custom to create network interfaces. For more information, see Amazon RDS updates to AWS managed policies.	August 18, 2023
Update to AWS managed policy permissions	The `AmazonRDSFullAccess` managed policy has new permissions that allows you to generate, view, and delete the performance analysis report for a time period. For more information, see Amazon RDS updates to AWS managed policies.	August 17, 2023
Update to AWS managed policy permissions	The addition of new permissions to `AmazonRDSPerformanceInsightsReadOnly` managed policy and addition of new managed policy `AmazonRDSPerformanceInsightsFullAccess` allows you generate a DB load analysis report for a time period. For more information, see Amazon RDS updates to AWS managed policies.	August 16, 2023

Amazon RDS supports performance analysis for a period of time	Performance Insights allows you to create and view performance analysis reports for a specific period of time. The report provides the insights identified and recommendations to resolve the performance issues. For more information, see Analyzing DB load for a period of time.	August 16, 2023
Amazon RDS Custom for Oracle supports the db.r5b and db.x2iedn DB instance classes	You can now use the db.r5b and db.x2iedn instance classes for RDS Custom for Oracle DB instances. For more information, see DB instance class support for RDS Custom for Oracle.	August 16, 2023
Amazon RDS Custom for Oracle supports the db.m6i, db.r6i, and db.t3 DB instance classes	You can now use the db.m6i, db.r6i, and db.t3 instance classes for RDS Custom for Oracle DB instances. For more information, see DB instance class support for RDS Custom for Oracle.	August 15, 2023
Amazon RDS for PostgreSQL now supports PostgreSQL version 16 Beta 3 in the database preview environment	PostgreSQL version 16 Beta 3 is now available in the database preview envir onment in the US East (Ohio) AWS Region. For more information, see Working with the database preview environment.	August 11, 2023

Amazon RDS supports MySQL 8.0.34 and 5.7.43	You can now create Amazon RDS DB instances running MySQL version 8.0.34 and 5.7.43. For more information, see MySQL on Amazon RDS versions.	August 9, 2023
RDS for SQL Server supports OS metrics view for the standby replica	You can now view OS metrics for standby replica for RDS for SQL Server. For more information, see Viewing OS metrics in the RDS console.	August 3, 2023
RDS for Oracle supports Oracle Data Guard for CDBs	RDS for Oracle supports Data Guard read replicas for Oracle Database 19c and 21c container databases (CDBs). You can create, manage, and promote read replicas in a CDB, just as you can in a non-CDB, using the existing RDS APIs. For more information, see Multitenant read replicas.	August 1, 2023
Amazon RDS is available in the Israel (Tel Aviv) Region	Amazon RDS is now available in the Israel (Tel Aviv) Region. For more information, see Regions and Availability Zones.	August 1, 2023
Amazon RDS supports Oracle APEX version 23.1.v1	You can use APEX 23.1.v1 with Oracle Database 19c and higher. For more information, see Oracle Application Express.	July 26, 2023

Amazon RDS Custom for Oracle supports a nondefault Oracle SID	When you create an RDS Custom for Oracle DB instance using Oracle Database 19c, you can specify a nondefault Oracle system identifier (Oracle SID). This value is also the name of the CDB. For more informati on, see Multitenant architect ure considerations .	July 21, 2023
RDS for SQL Server supports Self Managed Active Directory	You can now use Self Managed Active Directory to directly join your RDS for SQL Server DB instances to your Microsoft Active Directory (AD) domains. Self-mana ged AD domains can be on-premises or in the cloud. For more information, see Working with Self Managed Active Directory.	July 7, 2023
PostgreSQL logical replicati on support for Multi-AZ DB clusters	You can now use PostgreSQ L logical replication with your Multi-AZ DB cluster to replicate and synchronize individual tables rather than an entire database instance. For more information, see Using PostgreSQL logical replication with Multi-AZ DB clusters.	July 6, 2023

Amazon RDS for PostgreSQL now supports PostgreSQL version 16 Beta 2 in the database preview environment	PostgreSQL version 16 Beta 2 is now available in the database preview environment in the US East (Ohio) AWS Region. For more information, see Working with the database preview environment.	July 6, 2023
Update to AWS managed policy permissions	The `AmazonRDSCustomServiceRolePolicy` of the `AWSServiceRoleForRDSCustom` service-linked role has new permissions that allow RDS Custom for Oracle to use snapshots. For more information, see Amazon RDS updates to AWS managed policies.	June 23, 2023
RDS supports MariaDB 10.6.14, 10.5.21, and 10.4.30	You can now create Amazon RDS DB instances running MariaDB version 10.6.14, 10.5.21, and 10.4.30. For more information, see MariaDB on Amazon RDS versions.	June 22, 2023
RDS supports MySQL 8.0.33 and 5.7.42	You can now create Amazon RDS DB instances running MySQL version 8.0.33 and 5.7.42. For more information, see MySQL on Amazon RDS versions.	June 15, 2023

RDS supports MariaDB 10.6.13, 10.5.20, 10.4.29, and 10.3.39	You can now create Amazon RDS DB instances running MariaDB version 10.6.13, 10.5.20, 10.4.29, and 10.3.39. For more information, see MariaDB on Amazon RDS versions.	June 15, 2023
RDS for Oracle supports transportable tablespaces	You can migrate data from an on-premises Oracle database into an RDS for Oracle DB instance using transportable tablespaces. This technique doesn't require additional licensing and is the migration technique with the least downtime. For more information, see Migrating using Oracle transportable tablespaces.	June 15, 2023
Amazon RDS supports RDS Proxy with RDS for MariaDB version 10.6	You can now create an RDS Proxy with an RDS for MariaDB version 10.6 database. For more information about RDS Proxy, see Using Amazon RDS Proxy.	June 15, 2023
RDS Custom for SQL Server supports Bring Your Own Media (BYOM)	You can now create a Custom Engine Version (CEV) using your own SQL Server media. For more information, see Bring Your Own Media with RDS Custom for SQL Server.	June 8, 2023

RDS for Oracle can convert an Oracle Database 19c non-CDB to a CDB	If your DB instance runs Oracle Database 19c with the April 2021 or higher RU, you can convert a non-CDB to a CDB (container database) . After you convert the architecture, you can upgrade your 19c CDB to a 21c CDB. This step is necessary bec ause you can't upgrade your database and convert the architecture using a single command. For more informati on, see Converting an RDS for Oracle non-CDB into a CDB.	May 31, 2023
Multi-AZ DB clusters available in the China Regions	Multi-AZ DB clusters are now available in the AWS Regions China (Beijing) and China (Ningxia). For more informati on, see Supported Regions and DB engines for Multi-AZ DB clusters in Amazon RDS.	May 30, 2023
Amazon RDS Optimized Reads support for Multi-AZ DB clusters	Amazon RDS Optimized Reads now supports Multi-AZ DB clusters. For more information, see Improving query performance for RDS for MySQL with Amazon RDS Optimized Reads and Improving query performance for RDS for PostgreSQL with Amazon RDS Optimized Re ads.	May 30, 2023

RDS Custom for Oracle supports the Asia Pacific (Jakarta) Region	For more information, see Supported Regions and DB engines for RDS Custom for Oracle.	May 29, 2023
Create a DB instance read replica with a source RDS for PostgreSQL Multi-AZ DB cluster	You can now create a DB instance read replica with an RDS for PostgreSQL Multi-AZ DB cluster as the source. Previously, only RDS for MySQL was supported. For more information, see Creating a DB instance read replica from a Multi-AZ DB cluster.	May 24, 2023
Amazon RDS provides combined Performance Insights and CloudWatch metrics in the Performance Insights dashboard	Amazon RDS now provides a consolidated view of Performance Insights and CloudWatch metrics in the Performance Insights dash board. For more informati on, see Viewing combined metrics with the Performance Insights dashboard.	May 24, 2023

Amazon RDS Optimized Reads available in the China Regions	Amazon RDS Optimized Reads is now available in the AWS Regions China (Beijing) and China (Ningxia). For more information, see Improving query performance for RDS for MariaDB with Amazon RDS Optimized Reads and Improving query performance for RDS for MySQL with Amazon RDS Optimized Reads.	April 24, 2023
Amazon RDS support for AWS Secrets Manager in the China Regions	Amazon RDS supports Secrets Manager in the China (Beijing) and China (Ningxia) Regions. For more information, see Password management with Amazon RDS and AWS Secrets Manager.	April 20, 2023
RDS Custom for Oracle supports reuse of AMI IDs for new CEVs	When you create a custom engine version (CEV), RDS Custom for Oracle defaults to the most recent Amazon Machine Image (AMI) available. Now you can specify an AMI ID that was used in a previous CEV. For more information, see Creating a CEV.	April 19, 2023

Amazon RDS supports publishing events with tags to topic subscribers	Amazon RDS event notifications sent to Amazon Simple Notification Service (Amazon SNS) or Amazon EventBridge now contain event tags in the message body. These tags provide the resource data that was affected by the service event. For more information, see Amazon RDS event notification tags and attributes.	April 17, 2023
Purchase reserved instances for a Multi-AZ DB cluster	You can now purchase reserved DB instances for a Multi-AZ DB cluster. For more information, see Reserved DB instances for a Multi-AZ DB cluster.	April 12, 2023
Amazon RDS supports the db.m7g and db.r7g instance classes	You can now use the db.m7g and db.r7g instance classes for RDS for MySQL, RDS for MariaDB, and RDS for PostgreSQL DB instances. For more information, see Supported DB engines for DB instance classes.	April 12, 2023

Update to Amazon RDS Custom service-linked role permissions	The `AmazonRDSCustomServiceRolePolicy` now grants additional permissions to allow RDS Custom for SQL Server to use Amazon SQS and create snapshots. For more information, see Updates to AWS managed policies.	April 6, 2023
Migrate to an RDS for MySQL Multi-AZ DB cluster using a read replica	You can now use a read replica to migrate an RDS for MySQL Single-AZ deployment or Multi-AZ DB instance deployment to an RDS for MySQL Multi-AZ DB cluster deployment with reduced downtime. For more information, see Migrating to a Multi-AZ DB cluster using a read replica.	April 6, 2023
Create a DB instance read replica from a Multi-AZ DB cluster	You can now create a DB instance read replica from a Multi-AZ DB cluster in order to scale beyond the compute capacity of the source cluster. For more information, see Creating a DB instance read replica from a Multi-AZ DB cluster.	April 6, 2023

Amazon RDS Custom for SQL Server supports Multi-AZ	You can create a Multi-AZ deployment with RDS Custom for SQL Server. For more information, see Managing a Multi-AZ deployment for RDS Custom for SQL Server.	April 6, 2023
Update to AWS managed policy permissions	The `AmazonRDSFullAccess` and `AmazonRDSReadOnlyAccess` policies now grants additional permissions to allow the display of Amazon DevOps Guru findings in the RDS console. For more information, see Amazon RDS updates to AWS managed policies.	March 30, 2023
Amazon RDS supports Oracle APEX version 22.2.v1	You can use APEX 22.2.v1 with all supported versions of Oracle Database. For more information, see Oracle Application Express.	March 30, 2023

Amazon DevOps Guru available for RDS for PostgreSQL	RDS for PostgreSQL alerts you to recent anomalies detected by Amazon DevOps Guru. The database details page of the console alerts you to current and anomalies that occurred in the past 24 hours. DevOps Guru publishes proactive insights with recommendations to help address issues in your RDS for PostgreSQL databases before they are predicted to happen. For more information, see How DevOps Guru for RDS works.	March 30, 2023
RDS Custom supports the Amazon EBS gp3 storage volume	RDS Custom for Oracle and RDS Custom for SQL Server both support the io1, gp2, and gp3 SSD-based EBS volumes. For more informati on, see General requirements for RDS Custom for Oracle and General requirements for RDS Custom for SQL Server.	March 29, 2023

Update to AWS managed policy permissions	The `AmazonRDSFullAccess` and `AmazonRDSReadOnlyAccess` policies now grants additional permissions to Amazon CloudWatch. For more information, see Amazon RDS updates to AWS managed policies.	March 16, 2023
RDS Proxy is available in the China Regions	RDS Proxy is now available in the China (Beijing) and China (Ningxia) regions. For more information about RDS Proxy, see Using Amazon RDS Proxy.	March 15, 2023
RDS Proxy is available in the Asia Pacific (Jakarta) Region	RDS Proxy is now available in the Asia Pacific (Jakarta) Region. For more information about RDS Proxy, see Using Amazon RDS Proxy.	March 8, 2023
Amazon RDS Optimized Writes improves the performance of write transactions for RDS for MariaDB	You can improve the performance of write transactions for RDS for MariaDB DB instances with Amazon RDS Optimized Writes. For more information, see Improving write performance with Amazon RDS Optimized Writes for MariaDB.	March 7, 2023

Amazon RDS for PostgreSQL versions 15.2	New features in Amazon RDS for PostgreSQL 15.2 include the SQL standard "MERGE" command for conditional SQL queries, performance improvements for both in-memory and disk-based sorting, and support for two-phase commit and row/column filtering for logical replication.	February 27, 2023
RDS Custom for Oracle is available in the Canada (Central) Region and South America (São Paulo) Regions	For a table that shows all supported AWS Regions, see Supported Regions and DB engines for RDS Custom for Oracle.	February 22, 2023
Amazon RDS supports cross-Region automated backups for RDS for MariaDB and RDS for MySQL	You can now replicate DB snapshots and transaction logs between AWS Regions for RDS for MariaDB and RDS for MySQL DB instances. For more information, see Replicating automated backups to another AWS Region.	February 22, 2023

Amazon RDS for Oracle supports advance notice of automatic minor version upgrades	RDS notifies you in advance of the date when a new minor version of the RDS for Oracle engine will become available . RDS begins scheduling automatic minor version upgrades of your RDS for Oracle DB instances on the availability date. For more information, see Before an automatic minor version upgrade is scheduled.	February 21, 2023
Amazon RDS for SQL Server supports Database Activity Streams	You can now monitor a SQL Server DB instance using Database Activity Streams. A SQL Server database instance has the server audit which is managed by Amazon RDS. You can define the policies to record server events in the server audit specification. You can create a database audit specification and define the policies to record databa se events. The stream of activity is collected and transmitted to Amazon Kinesis. From Kinesis, you can monitor the activity stream for further analysis. For more information, see Monitoring Amazon RDS with Database Activity Streams.	February 15, 2023

RDS supports MySQL 8.0.32 and 5.7.41	You can now create Amazon RDS DB instances running MySQL version 8.0.32 and 5.7.41. For more information, see MySQL on Amazon RDS versions.	February 7, 2023
Amazon RDS for Oracle supports new cipher suites for SSL	If you run Oracle Database 19c or 21c, you can specify six new cipher suites in the SSL option for RDS for Oracle. These suites support FIPS and are FedRAMP-complaint. For more information, see Oracle Secure Sockets Layer.	February 3, 2023
Amazon RDS for Oracle supports new cipher suites for Oracle Enterprise Manager	You can use four new FedRAMP-compliant cipher suites for the OEM option. For more information, see Oracle Management Agent for Enterprise Manager Cloud Control.	February 3, 2023
RDS for Oracle supports Database Activity Streams in the Asia Pacific (Hyderabad), Europe (Spain), and Middle East (UAE) Regions	For more information, see Supported Regions and DB engines for database activity streams in Amazon RDS.	January 27, 2023

Migrate to an RDS for PostgreSQL Multi-AZ DB cluster using a read replica	By using a read replica, you can migrate an RDS for PostgreSQL Single-AZ deployment or Multi-AZ DB instance deployment to an RDS for PostgreSQL Multi-AZ DB cluster deployment with reduced downtime. For more information, see Migrating to a Multi-AZ DB cluster using a read replica.	January 23, 2023
Amazon RDS is available in the Asia Pacific (Melbourne) Region	Amazon RDS is now available in the Asia Pacific (Melbourne) Region. For more information, see Regions and Availability Zones.	January 23, 2023
RDS for MariaDB supports enforcing SSL/TLS connections	RDS for MariaDB now supports enforcing SSL/TLS connections by setting the `require_secure_transport` parameter to `ON`. For more information, see Requiring SSL/TLS for all connections to a MariaDB DB instance.	January 19, 2023
Amazon RDS Optimized Reads improves query performance for RDS for MariaDB	You can achieve faster query processing for RDS for MariaDB DB instances with Amazon RDS Optimized Reads. For more information, see Improving query performance for RDS for MariaDB with Amazon RDS Optimized Reads.	January 11, 2023

Restore a Multi-AZ DB cluster snapshot to a DB instance	You can now restore a Multi-AZ DB cluster snapshot to a Single-AZ deployment or Multi-AZ DB instance deployment. For more information, see Restoring from a Multi-AZ DB cluster snapshot to a DB instance.	January 10, 2023
Specify certificate authority (CA) during DB instance creation	You can now specify which CA to use for a DB instance's server certificate during DB instance creation. For more information, see Certificate authorities.	January 5, 2023
RDS Custom for SQL Server supports custom engine versions	A custom engine version (CEV) for RDS Custom for SQL Server is an Amazon Machine Image (AMI) with Microsoft SQL Server pre-installed. You choose an Amazon EC2 Windows AMI to use as a base image and can install other software on the operating system (OS). You can customize the configuration of the OS and SQL Server to meet your enterprise needs. For more information, see Working with custom engine versions for RDS Custom for SQL Server.	December 28, 2022

Use Amazon RDS Blue/Green Deployments available in additional AWS Regions	The Blue/Green Deployments feature is now available in the China (Beijing) and China (Ningxia) Regions. For more information, see Using Amazon RDS Blue/Green Deployments for database updates.	December 22, 2022
Update to IAM service-linked role permissions	The AmazonRDSServiceRolePolicy policy now grants additional permissions to AWS Secrets Manager. For more information, see Amazon RDS updates to AWS managed policies.	December 22, 2022
Amazon RDS supports renaming a Multi-AZ DB cluster	You can now rename a Multi-AZ DB cluster. For more information, see Renaming a Multi-AZ DB cluster.	December 22, 2022
Amazon RDS integrates with AWS Secrets Manager for password management	Amazon RDS can manage the master user password for a DB instance or Multi-AZ DB cluster in Secrets Manager. For more information, see Password management with Amazon RDS and AWS Secrets Manager.	December 22, 2022

Amazon RDS Optimized Writes supports the db.r6g and db.r6gd DB instance classes	Amazon RDS Optimized Writes now supports the db.r6g and db.r6gd DB instance classes. For more information, see Improving write performance with Amazon RDS Optimized Writes.	December 22, 2022
Amazon RDS Custom for Oracle supports new AWS Regions	You can create RDS Custom for Oracle DB instances in the Asia Pacific (Seoul) and Asia Pacific (Osaka) Regions. For more information, see Supported Regions and DB engines for RDS Custom for Oracle.	December 21, 2022
Amazon RDS on AWS Outposts supports read replicas	You can now create a read replica from an RDS on Outposts MySQL or PostgreSQL DB instance. For more information, see Creating read replicas for Amazon RDS on AWS Outposts.	December 19, 2022
RDS Custom for Oracle supports modifying the DB instance class	You can now change the instance class of your RDS Custom for Oracle DB instance. For more information, see Modifying your RDS Custom for Oracle DB instance.	December 16, 2022

RDS for MySQL and RDS for PostgreSQL support db.x2iedn DB instance classes	You can now use the db.x2iedn DB instance classes for RDS for MySQL and RDS for PostgreSQL DB instances . For more information, see Supported DB engines for DB instance classes.	December 14, 2022
Amazon RDS Optimized Writes supports db.x2iedn DB instance classes	Amazon RDS Optimized Writes now supports db.x2iedn DB instance classes. For more information, see Improving write performance with Amazon RDS Optimized Writes.	December 14, 2022
Amazon RDS supports copying DB option groups when copying DB snapshots	You can now copy an option group across AWS accounts as part of a snapshot copy request on RDS for Oracle databases. For more information, see Option group considerations.	December 13, 2022
Amazon RDS supports RDS Proxy with RDS for PostgreSQL version 14	You can now create an RDS Proxy with an RDS for PostgreSQL version 14 database. For more information about RDS Proxy, see Using Amazon RDS Proxy.	December 13, 2022

Amazon RDS for Oracle supports db.x2idn, db.x2iedn, and db.x2iezn instance classes	You can now use the db.x2idn, db.x2iedn, and db.x2iezn instance classes for Amazon RDS for Oracle DB instances. For more information, see Supported DB engines for DB instance classes and Supported RDS for Oracle instance classes.	December 12, 2022
RDS for PostgreSQL DB instances support Trusted Language Extensions for PostgreSQL	Trusted Language Extensions for PostgreSQL is an open source development kit that allows you to build high performance PostgreSQL extensions and safely run them on your RDS for PostgreSQL DB instance. For more information, see Working with Trusted Language Extensions for PostgreSQL.	November 30, 2022

Use Amazon RDS Blue/Green Deployments for database updates	You can make changes to a DB instance in a staging environment and test the changes without affecting your production DB instance. When you are ready, you can promote the staging environment to be the new production environment, with minimal downtime. For more information, see Using Amazon RDS Blue/Green Deployments for database updates.	November 27, 2022
Amazon RDS Optimized Writes improves the performance of write transactions for RDS for MySQL	You can improve the performance of write transactions for RDS for MySQL DB instances with Amazon RDS Optimized Writes. For more information, see Improving write performance with Amazon RDS Optimized Writes for MySQL.	November 27, 2022
Amazon RDS Optimized Reads improves query performance for RDS for MySQL	You can achieve faster query processing for RDS for MySQL DB instances with Amazon RDS Optimized Reads. For more information, see Improving query performance with Amazon RDS Optimized Reads.	November 27, 2022

Amazon RDS is available in the Asia Pacific (Hyderabad) Region	Amazon RDS is now available in the Asia Pacific (Hyderabad) Region. For more information, see Regions and Availability Zones.	November 22, 2022
RDS supports MariaDB 10.6.11, 10.5.18, 10.4.27, and 10.3.37	You can now create Amazon RDS DB instances running MariaDB versions 10.6.11, 10.5.18, 10.4.27, and 10.3.37. For more informati on, see MariaDB on Amazon RDS versions.	November 18, 2022
RDS Custom for Oracle supports setting nondefault installation parameters in a custom engine version (CEV)	When you create a CEV, you can set nondefault values for the Oracle base, Oracle home, UNIX user name and ID, and UNIX group name and ID. In this way, you gain more control over the database installation on your RDS Custom for Oracle DB instance. For more informati on, see Preparing the CEV manifest.	November 18, 2022
Amazon RDS supports Oracle APEX version 22.1.v1	You can use APEX 22.1.v1 with all supported versions of Oracle Database. For more information, see Oracle Application Express.	November 18, 2022

RDS for SQL Server supports cross-Region read replicas	You can now create a cross-Region read replica to enhance disaster recovery capability, reduce application read latency, and offload read workloads from the primary DB instance. For more information, see Creating a read replica in a different AWS Region.	November 16, 2022
Amazon RDS is available in the Europe (Spain) Region	Amazon RDS is now available in the Europe (Spain) Region. For more information, see Regions and Availability Zones.	November 16, 2022
RDS for SQL Server supports linked servers for Oracle database	You can now create a linked server to access external Oracle databases to read data and execute SQL commands. For more information, see Linked Servers with Oracle OLEDB with RDS for SQL Server.	November 15, 2022

RDS Custom for Oracle supports Oracle Multitenant	You can create an RDS Custom for Oracle DB instance as a container database (CDB). After creation, the CDB contains the CDB root, PDB seed, and one PDB. You can add more PDBs manually using Oracle SQL. For more information, see Overview of Amazon RDS Custom for Oracle architecture.	November 15, 2022
Amazon RDS for Oracle supports Amazon EFS integration	If you add the `EFS_INTEGRATION` option to your option group, you can transfer files between your RDS for Oracle DB instance and an Amazon EFS file system. For more information, see Amazon EFS.	November 15, 2022
RDS supports MySQL 8.0.31 and 5.7.40	You can now create Amazon RDS DB instances running MySQL version 8.0.31 and 5.7.40. For more information, see MySQL on Amazon RDS versions.	November 10, 2022
Amazon RDS is available in the Europe (Zurich) Region	Amazon RDS is now available in the Europe (Zurich) Region. For more information, see Regions and Availability Zones.	November 9, 2022

Access to transaction log backups is now available for RDS for SQL Server	You can now view and copy database transaction log backups to an Amazon S3 bucket. For more informati on, see Access to transaction log backups.	November 7, 2022
Multi-AZ DB clusters supported in additional AWS Regions	Multi-AZ DB clusters are now available in additional AWS Regions. For more information, see Supported Regions and DB engines for Multi-AZ DB clusters in Amazon RDS.	November 4, 2022
Amazon RDS supports gp3 storage	You can now create Amazon RDS DB instances that use Amazon EBS General Purpose SSD (gp3) storage volumes, which let you customize storage performan ce independently of storage capacity. For more informati on, see General Purpose SSD storage.	November 4, 2022
Amazon RDS supports a new event for operating system updates	Amazon RDS now supports a new DB instance event, RDS-EVENT-0230, under the event category of security patching. This new event alerts you when an operating system update is available for your DB instance. For more information, see Monitorin g Amazon RDS events and Working with operating system updates.	October 28, 2022

Amazon RDS for Oracle supports preconfigured r5b memory optimized instance classes	The db.r5b Oracle DB instance classes are optimized for workloads that require additional memory, storage, and I/O per vCPU. For example, db.r5b.4xlarge.tpc2.mem2x has multithreading turned on and provides twice as much memory as db.r5b.4xlarge. For more information, see RDS for Oracle instance classes.	October 27, 2022
Amazon RDS supports 15 read replicas for RDS for MariaDB, MySQL, and PostgreSQL DB instances	You can now create up to 15 read replicas for RDS for MariaDB, MySQL, and PostgreSQL DB instances. For more information about read replicas, see Working with read replicas.	October 20, 2022
Amazon RDS for PostgreSQL now supports PostgreSQL version 15 RC 3 in the database preview environment	PostgreSQL version 15 Beta 3 is now available in the database preview environment in the US East (Ohio) AWS Region. For more information, see Working with the database preview environment.	October 18, 2022

Amazon RDS supports automatically setting up connectivity between an RDS database and an EC2 instance	You can use the AWS Management Console to set up connectivity between an existing RDS DB instance or Multi-AZ DB cluster and an EC2 instance. For more information, see Connecting an EC2 instance and an RDS database automatically.	October 14, 2022
AWS JDBC Driver for PostgreSQL generally available	The AWS JDBC Driver for PostgreSQL is a client driver designed for RDS for PostgreSQL. The AWS JDBC Driver for PostgreSQL is now generally available. For more information, see Connecting with the AWS JDBC Driver for PostgreSQL.	October 6, 2022
Amazon RDS for Oracle supports Oracle APEX version 21.2.v1	APEX 21.2 includes patch 33420059. For more information, see APEX version requirements.	October 3, 2022
RDS supports MySQL 5.7.39	You can now create Amazon RDS DB instances running MySQL versions 5.7.39. For more information, see MySQL on Amazon RDS versions.	September 29, 2022

RDS supports MariaDB 10.6.10	You can now create Amazon RDS DB instances running MariaDB versions 10.6.10. For more information, see MariaDB on Amazon RDS versions.	September 29, 2022
RDS Proxy supports RDS for SQL Server	You can now create an RDS Proxy for an RDS DB instance that runs Microsoft SQL Server version 2014 or higher. For more information about RDS Proxy, see Using Amazon RDS Proxy.	September 19, 2022
RDS supports MariaDB 10.5.17, 10.4.26, and 10.3.36	You can now create Amazon RDS DB instances running MariaDB versions 10.5.17, 10.4.26, and 10.3.36. For more information, see MariaDB on Amazon RDS versions.	September 15, 2022

Amazon RDS for Oracle supports local instance storage for temporary data	You can now launch Amazon RDS for Oracle on Amazon EC2 db.r5d and db.m5d instance types with the temporary tablespace and Database Smart Flash Cache (the flash cache) configured to use an instance store. By storing temporary data locally, you can achieve lower read and write latencies when compared to standard storage based on Amazon EBS. For more information, see Storing temporary Oracle data in the instance store.	September 14, 2022
Performance Insights shows the top 25 SQL queries	In the Performance Insights dashboard, the **Top SQL** tab shows the 25 SQL queries that are contributing the most to DB load. For more information, see Overview of the Top SQL tab.	September 13, 2022
RDS supports MySQL 8.0.30	You can now create Amazon RDS DB instances running MySQL version 8.0.30. For more information, see MySQL on Amazon RDS versions.	September 9, 2022
Amazon RDS is available in the Middle East (UAE) Region	Amazon RDS is now available in the Middle East (UAE) Region. For more information, see Regions and Availability Zones.	August 30, 2022

Amazon RDS for SQL Server supports SSRS Email subscriptions	You can now use the SQL Server Reporting Services (SSRS) Email extension to send reports to users and subscribe to reports on the report server. For more information, see Support for SQL Server Reporting Services in RDS for SQL Server.	August 26, 2022
RDS for Oracle supports read replica backups	You can turn on automatic backups and create manual snapshots of RDS for Oracle replicas. For more information, see Working with RDS for Oracle replica backups.	August 23, 2022
RDS for Oracle supports Oracle Data Guard switchover	A switchover is a role reversal between a primary database and a mounted or open Oracle replica. During a switchover, the original primary database transitions to a standby role, while the original standby database transitions to the primary role. For more information, see Performing an Oracle Data Guard switchover.	August 23, 2022

Amazon RDS supports automatically setting up connectivity with an EC2 instance	When you create a DB instance or Multi-AZ DB cluster, you can use the AWS Management Console to s et up connectivity between an Amazon Elastic Compute Cloud instance and the new DB instance or DB c luster. For more informati on, see Configure automatic network connectivity with an EC2 instance for a new DB instance and Configure automatic network connectiv ity with an EC2 instance for a new DB cluster.	August 22, 2022
RDS Custom for Oracle supports promotion of Oracle replicas	If you use RDS Custom for Oracle, you can promote your managed Oracle replicas by using the `promote-read-replica` CLI command. Also, you can delete your primary DB instance, which causes RDS Custom for Oracle to promote your managed Oracle replicas to standalone instances. For more informati on, see Working with Oracle replicas for RDS Custom for Oracle.	August 5, 2022

RDS for MySQL supports enforcing SSL/TLS connections	RDS for MySQL now supports enforcing SSL/TLS connections by setting the `require_secure_transport` parameter to ON. For more information, see Requiring an SSL/TLS connection to a MySQL DB instance.	August 1, 2022
Amazon RDS has deprecated support for Oracle Database 12c Release 1 (12.1.0.2)	Support for version 12.1.0.2 is deprecated for both the BYOL and LI licensing models. On August 1, 2022, RDS for Oracle begins automatic upgrades of 12c Release 1 (12.1.0.2) DB instances and restored 12.1.0.2 snapshots to Oracle Database 19c. For more information, see the end of support timeline on AWS re:Post.	August 1, 2022
RDS Proxy supports RDS for MariaDB	You can now create an RDS Proxy for an RDS DB instance that runs MariaDB version 10.2, 10.3, 10.4, or 10.5. The MariaDB support is included under the MySQL engine family. For more information about RDS Proxy, see Using Amazon RDS Proxy.	July 26, 2022

RDS for MariaDB supports the db.r5b DB instance classes	You can now create RDS for MariaDB DB instances that use the db.r5b DB instance classes. For more information, Supported DB engines for DB instance classes.	July 25, 2022
RDS for Oracle supports modifying database activity streams	If you use RDS for Oracle, you can change the audit policy state of a database acti vity stream to either locked (default) or unlocked. Instead of stopping an activity stream, you can unlock its policy state, customize your audit policy, and then relock the policy state. For more information, see Modifying a database activity stream.	July 22, 2022
Performance Insights supports the Asia Pacific (Jakarta) Region	Formerly, you couldn't use Performance Insights in the Asia Pacific (Jakarta) Reg ion. This restriction has been removed. For more informati on, see Supported Regions and DB engines for Performan ce Insights in Amazon RDS.	July 21, 2022

Microsoft SQL Server 2012 has reached its end of support on Amazon RDS	Microsoft SQL Server 2012 has reached its end of support, coinciding with the Microsoft plan to end extended support for this version on July 12, 2022. Any existing Microsoft SQL Server 2012 instances are to be automatically upgraded to the latest minor version of Microsoft SQL Server 2014 starting on June 1, 2022. For more information, see Microsoft SQL Server 2012 support on Amazon RDS.	July 12, 2022
RDS supports MariaDB 10.6.8, 10.5.16, 10.4.25, 10.3.35, and 10.2.44	You can now create Amazon RDS DB instances running MariaDB versions 10.6.8, 10.5.16, 10.4.25, 10.3.35, and 10.2.44. For more information, see Supported MariaDB versions on Amazon RDS.	July 8, 2022

RDS Performance Insights supports additional retention periods	Previously, Performance Insights offered only two retention periods: 7 days (default) or 2 years (731 days). Now, if you need to retain your performance d ata for longer than 7 days, you can specify from 1–24 months. For more informat ion, see Pricing and data retention for Performance Insights.	July 1, 2022
RDS Custom supports the Asia Pacific (Mumbai) and Europe (London) Regions	You can create RDS Custom for Oracle and RDS Custom for SQL Server DB instances in two new AWS Regions: Asia Pacific (Mumbai) and Europe (London). For more informati on, see AWS Region support for RDS Custom for Oracle and AWS Region support for RDS Custom for SQL Server.	June 21, 2022
RDS Custom for Oracle supports Oracle Database 18c and 12c Release 2 (12.2)	You can now create a CEV for RDS Custom for Oracle using installation files for Oracle Database 18c and 12c Release 2 (12.2). You can use this these CEVs to create an RDS Custom for Oracle DB instance. For more informati on, see Working with custom engine versions for Amazon RDS Custom for Oracle.	June 21, 2022

Multi-AZ DB clusters support the db.m5d and db.r5d DB instance classes	You can now create Multi-AZ DB clusters that use the db.m5d and db.r5d DB instance classes. For more information, see Multi-AZ DB cluster deployments and DB instance class types.	June 21, 2022
Multi-AZ DB clusters available in additional AWS Regions	You can now create Multi-AZ DB clusters in the following Regions: Europe (Frankfurt) and Europe (Stockholm). For more information, see Multi-AZ DB cluster deployments.	June 21, 2022
RDS for Microsoft SQL Server supports migration of databases that use Transparent Data Encryption (TDE)	RDS for SQL Server now supports migrating Microsoft SQL Server databases with TDE turned on, using native backup and restore. For more information, see Support for Transparent Data Encryption in SQL Server.	June 14, 2022
Amazon RDS supports publishing events to encrypted Amazon SNS topics	Amazon RDS can now publish events to Amazon Simple Notification Service (Amazon SNS) topics that have server-side encryption (SSE) enabled, for additional protection of events that carry sensitive data. For more information, see Subscribing to Amazon RDS event notification.	June 1, 2022

RDS supports MySQL 5.7.38	You can now create Amazon RDS DB instances running MySQL version 5.7.38. For more information, see MySQL on Amazon RDS versions.	May 31, 2022
RDS for PostgreSQL supports cascading read replicas	You can now use cascading read replicas with RDS for PostgreSQL version 14.1 and higher releases. For more information, see Working with PostgreSQL read replicas in Amazon RDS.	May 4, 2022
Amazon RDS on AWS Outposts supports scale storage and autoscaling operations	You can now change the storage sizes of DB instances on your Outpost and use storage autoscaling. For more information, see Amazon RDS on AWS Outposts support for Amazon RDS features.	May 2, 2022
Multi-AZ DB clusters available in additional AWS Regions	You can now create Multi-AZ DB clusters in the following Regions: Asia Pacific (Singapore) and Asia Pacific (Sydney). For more informati on, see Multi-AZ DB cluster deployments.	April 29, 2022

Amazon RDS supports dual-stack mode	DB instances can now run in dual-stack mode. In dual-stack mode, resources can communicate with the DB instance over IPv4, IPv6, or both. For more informati on, see Amazon RDS IP addressing.	April 29, 2022
Amazon RDS publishes usage metrics to Amazon CloudWatc h	The `AWS/Usage` namespace in Amazon CloudWatch includes account-level usage metrics for your Amazon RDS service quotas. For more information, see Amazon CloudWatch usage metrics for Amazon RDS.	April 28, 2022
Amazon RDS for MySQL supports the db.m6i and db.r6i DB instance classes	You can now use the db.m6i and db.r6i DB instance classes for Amazon RDS DB instances running MySQL. For more information, see Supported DB engines for DB instance classes.	April 28, 2022
Amazon RDS for PostgreSQ L supports the db.m6i and db.r6i DB instance classes	You can now use the db.m6i and db.r6i DB instance classes for Amazon RDS DB instances running Postg reSQL. For more information, see Supported DB engines for DB instance classes.	April 27, 2022

Amazon RDS for MariaDB supports the db.m6i and db.r6i DB instance classes	You can now use the db.m6i and db.r6i DB instance classes for Amazon RDS DB instances running MariaDB. For more information, see Supported DB engines for DB instance classes.	April 26, 2022
Amazon RDS on AWS Outposts supports Multi-AZ deployments	You can now create a standby DB instance on a different Outpost. For more information, see Amazon RDS on AWS Outposts support for Amazon RDS features.	April 19, 2022
Amazon RDS for Oracle supports the db.m6i and db.r6i instance classes	If you run Oracle Database 19c, you can use the db.m6i and db.r6i instance classes. The db.m6i classes are general-purpose instance classes that are well suited for a broad range of workloads. For more information, see RDS for Oracle instance classes.	April 8, 2022
Amazon RDS for SQL Server supports SQL Server Agent job replication	When you turn on this feature, SQL Server Agent jobs created, modified, or deleted on the primary host are automatically synchronized to the secondary host in a Multi-AZ configuration. For more information, see Using SQL Server Agent.	April 7, 2022

Amazon RDS supports RDS Proxy with RDS for PostgreSQL version 13	You can now create an RDS Proxy with an RDS for PostgreSQL version 13 database. For more information about RDS Proxy, see Using Amazon RDS Proxy.	April 4, 2022
Amazon RDS plans to deprecate Oracle Database 12c	Oracle Database 12c is on a deprecation path. Oracle Corporation will no longer provide patches for Oracle Database 12c releases after the end-of-support dates. Amazon RDS plans to begin automatically upgrading Oracle Database 12c DB instances to Oracle Database 19c.	March 22, 2022
Amazon RDS for PostgreSQL Release Notes	There is now a separate guide for the Amazon RDS for PostgreSQL release notes. For more information, see *Amazon RDS for PostgreSQL Release Notes*.	March 22, 2022
Amazon RDS for Oracle Release Notes	There is now a separate guide for the Amazon RDS for Oracle release notes. For more information, see *Amazon RDS for Oracle Release Notes*.	March 22, 2022

Multi-AZ DB clusters available in additional AWS Regions	You can now create Multi-AZ DB clusters in the following Regions: US East (Ohio) and Asia Pacific (Tokyo). For more information, see Multi-AZ DB cluster deployments.	March 15, 2022
Amazon RDS for PostgreSQL versions 14.2, 13.6, 12.10, 11.15, and 10.20	RDS for PostgreSQL now supports versions 14.2, 13.6, 12.10, 11.15, and 10.20. Version 14.2 and 13.6 add support for two new foreign data wrappers. The `mysql_fdw` extension lets PostgreSQL work with data stored in MySQL, MariaDB, and Aurora MySQL databases. The `tds_fdw` extension lets PostgreSQL work with data stored in SQL Server databases. For more information, see Supported PostgreSQL database versions.	March 12, 2022
RDS supports MySQL 5.7.37	You can now create Amazon RDS DB instances running MySQL version 5.7.37. For more information, see MySQL on Amazon RDS versions.	March 11, 2022

Amazon RDS for SQL Server supports new DB instance classes	You can now create Amazon RDS DB instances running Microsoft SQL Server that use the db.m6i and db.r6i DB instance classes. For more information, see DB instance class support for Microsoft SQL Server.	March 9, 2022
Amazon RDS for Oracle supports Oracle Database 21c	You can now create Amazon RDS DB instances running Oracle Database 21c (21.0.0.0). This is the first Oracle Database release that supports only the multitena nt (CDB) architecture. For more information, see Oracle Database 21c with Amazon RDS.	March 7, 2022
RDS supports MariaDB 10.6.7, 10.5.15, 10.4.24, 10.3.34, and 10.2.43	You can now create Amazon RDS DB instances running MariaDB versions 10.6.7, 10.5.15, 10.4.24, 10.3.34, and 10.2.43. For more information, see MariaDB on Amazon RDS versions.	March 3, 2022
AWS JDBC Driver for MySQL generally available	The AWS JDBC Driver for MySQL is a client driver designed for RDS for MySQL. The AWS JDBC Driver for MySQL is now generally available. For more informat ion, see Connecting with the Amazon Web Services JDBC Driver for MySQL.	March 2, 2022

Multi-AZ DB clusters generally available	A Multi-AZ DB cluster deployment is a high availability deployment mode of Amazon RDS with two readable standby DB instances. Multi-AZ DB clusters are now generally available. For more information, see Multi-AZ DB cluster deployments.	March 1, 2022
RDS supports MySQL 8.0.28	You can now create Amazon RDS DB instances running MySQL version 8.0.28. For more information, see MySQL on Amazon RDS versions.	February 28, 2022
Amazon RDS for Oracle supports new settings for native network encryption (NNE)	To control whether clients can connect with non-secure encryption and checksumming methods, set `SQLNET.ALLOW_WEAK_CRYPTO_CLIENTS` and `SQLNET.ALLOW_WEAK_CRYPTO` in the NNE option. Examples of insecure methods include DES, 3DES, RC4, and MD5. For more information, see NNE option settings.	February 25, 2022

Amazon RDS for SQL Server supports Always On Availability Groups for Microsoft SQL Server 2017 Standard Edition	When you create a DB instance using the Multi-AZ configuration on SQL Server 2017 Standard Edition 14.00.3401.7 and higher versions, RDS automatically uses Availability Groups. For more information, see Multi-AZ deployments for Microsoft SQL Server.	February 18, 2022
RDS for Oracle supports Database Activity Streams in the Asia Pacific (Jakarta) Region	For more information, see Support for AWS Regions for database activity streams.	February 16, 2022
Amazon RDS Custom for Oracle support for Oracle Database 12.1	You can now create custom engine versions for RDS Custom for Oracle that use Oracle Database 12.1 Enterprise Edition. For more information, see Working with custom engine versions for Amazon RDS Custom for Oracle.	February 4, 2022
Amazon RDS for MariaDB supports a new major version	You can now create Amazon RDS DB instances running MariaDB version 10.6. For more information, see MariaDB 10.6 support on Amazon RDS.	February 3, 2022

Performance Insights supports plan capture for Oracle queries	The Performance Insights console supports a new plan dimension for top SQL. When you slice by plan, you can see which plans your top Oracle queries are using. If a query uses multiple plans, you can compare the plans side by side in the console and determine which plan is most efficient. You can also drill down to see which steps in a plan have the highest cost. For more information, see Analyzing Oracle execution plans using the Performance Insights dashboard.	January 27, 2022
Performance Insights supports new APIs	Performance Insights supports the following APIs: `GetResourceMetadata`, `ListAvailableResourceDimensions`, and `ListAvailableResourceMetrics`. For more information, see Retrieving metrics with the Performance Insights API in this manual and the *Amazon RDS Performance Insights API Reference*.	January 12, 2022

RDS Proxy supports events	RDS Proxy now generates events that you can subscribe to and view in CloudWatch Events or configure to send to Amazon EventBridge. For more information, see Working with RDS Proxy events.	January 11, 2022
Amazon RDS for SQL Server supports SSAS Multidimensional mode	RDS for SQL Server supports running SQL Server Analysis Services (SSAS) in Tabular or Multidimensional mode. For more information, see Support for SQL Server Analysis Services in RDS for SQL Server.	January 7, 2022
RDS Proxy available in additional AWS Regions	RDS Proxy is now available in the following Regions: Africa (Cape Town), Asia Pacific (Hong Kong), Asia Pacific (Osaka), Europe (Milan), Europe (Paris), Europe (Stockholm), Middle East (Bahrain), and South America (São Paulo). For more information about RDS Proxy, see Using Amazon RDS Proxy.	January 5, 2022
RDS supports MySQL 8.0.27	You can now create Amazon RDS DB instances running MySQL version 8.0.27. For more information, see MySQL on Amazon RDS versions.	December 21, 2021

Amazon RDS is available in the Asia Pacific (Jakarta) Region	Amazon RDS is now available in the Asia Pacific (Jakarta) Region. For more information, see Regions and Availability Zones.	December 13, 2021
Amazon RDS supports MariaDB 10.5.13, 10.4.22, 10.3.32, and 10.2.41	You can now create Amazon RDS DB instances running MariaDB versions 10.5.13, 10.4.22, 10.3.32, and 10.2.41. For more informati on, see MariaDB on Amazon RDS versions.	December 8, 2021
Amazon RDS Custom for SQL Server	Amazon RDS Custom is a managed database service for legacy, custom, and packaged applications that require access to the underlying operating system and database environment. With Amazon RDS Custom, you get the automation of Amazon RDS and the flexibili ty of Amazon EC2. For more information, see Working with Amazon RDS Custom.	December 1, 2021

Multi-AZ DB clusters (preview)	You can now create Multi-AZ DB clusters for RDS for MySQL and RDS for PostgreSQL. A Multi-AZ DB cluster deployment is a high availability deployment mode of Amazon RDS with two readable standby DB instances. Multi-AZ DB clusters are in preview. For more information, see Multi-AZ DB cluster deployments (preview).	November 23, 2021
Amazon RDS supports RDS Proxy with RDS for PostgreSQL version 12	You can now create an RDS Proxy with an RDS for PostgreSQL version 12 database. For more information about RDS Proxy, see Using Amazon RDS Proxy.	November 22, 2021
Amazon RDS on AWS Outposts supports local backups	You can store automated backups and manual snapshots in your AWS Region or locally on your Outpost. For more information, see Amazon RDS on AWS Outposts support for Amazon RDS features.	November 22, 2021
Amazon RDS support for cross-account AWS KMS keys	You can use a KMS key from a different AWS account for encryption when exporting DB snapshots to Amazon S3. For more information, see Exporting DB snapshot data to Amazon S3.	November 3, 2021

Amazon RDS on AWS Outposts supports publishing database engine logs to CloudWatch Logs	RDS on Outposts now supports publishing database engine logs to CloudWatch Logs. For more information, see Amazon RDS on AWS Outposts support for Amazon RDS features.	November 2, 2021
Amazon RDS Custom for Oracle	Amazon RDS Custom is a managed database service for legacy, custom, and packaged applications that require access to the underlying operating system and database environment. With Amazon RDS Custom, you get the automation of Amazon RDS and the flexibility of Amazon EC2. For more information, see Working with Amazon RDS Custom.	October 26, 2021
Support for delayed replication on for RDS for MySQL version 8.0	Starting with RDS for MySQL version 8.0.26, you can configure delayed replication for RDS for MySQL version 8.0 DB instances. For more information, see Configuring delayed replication with MySQL.	October 25, 2021
Support for MySQL 8.0.26	You can now create Amazon RDS DB instances running MySQL version 8.0.26. For more information, see MySQL on Amazon RDS versions.	October 25, 2021

Support for GTID-based replication for RDS for MySQL version 8.0	Starting with RDS for MySQL version 8.0.26, you can configure GTID-based re plication for RDS for MySQL version 8.0 DB instances. For more information, see Using GTID-based replication for RDS for MySQL.	October 25, 2021
Amazon RDS supports RDS Proxy with RDS for MySQL 8.0	You can now create an RDS Proxy for an RDS for MySQL 8.0 database instance. For more information, see Using Amazon RDS Proxy.	October 21, 2021
Amazon RDS on AWS Outposts supports additional RDS for MySQL versions	RDS on Outposts now supports RDS for MySQL versions 8.0.23 and 8.0.25. For more information, see Amazon RDS on AWS Outposts support for Amazon RDS features.	October 20, 2021
Amazon RDS for PostgreSQ L now supports PostgreSQ L version 14 RC 1 in the database preview environme nt	PostgreSQL version 14 RC 1 is now available in the database preview environment in the US East (Ohio) AWS Region. For more information, see Working with the database preview environment.	October 19, 2021

Amazon RDS supports Performance Insights in additional AWS Regions	Performance Insights is available in the Middle East (Bahrain), Africa (Cape Town), Europe (Milan), and Asia Pacific (Osaka) Regions. For more information, see Supported Regions and DB engines for Performance Insights in Amazon RDS.	October 5, 2021
Performance Insights supports digest-level statistics for Oracle	When you use Performance Insights, you can view SQL statistics both at the statement and digest level for Amazon RDS for Oracle. For more information, see Analyzing running queries in Oracle.	October 4, 2021
Amazon RDS on AWS Outposts supports additional RDS for PostgreSQL versions	RDS on Outposts now supports RDS for PostgreSQL versions 12.8 and 13.4. For more information, see Amazon RDS on AWS Outposts support for Amazon RDS features.	October 1, 2021
Amazon RDS supports Oracle APEX version 21.1.v1	You can use APEX 21.1.v1 with all supported versions of Oracle Database. For more information, see Oracle Application Express.	September 24, 2021

Amazon RDS for Oracle supports client-side encryption for NNE	When you configure NNE, you might want to avoid forcing encryption on the server side. For example, you might not want to force all client communications to use encryption because the server requires it. In this case, you can force encryption on the client side using the `SQLNET.*CLIENT` options. For more information, see Oracle native network encryption.	September 24, 2021
Amazon RDS for MySQL and RDS for PostgreSQL support new DB instance classes	You can now use the db.r5b, db.t4g, and db.x2g instance classes to create Amazon RDS DB instances running MySQL or PostgreSQL. For more information, see Supported DB engines for DB instance classes.	September 15, 2021
Amazon RDS for Microsoft SQL Server supports Java Database Connectivity (JDBC) with Microsoft Distributed Transaction Coordinator (MSDTC)	JDBC XA transactions are now supported with MSDTC for SQL Server 2017 version 14.00.3223.3 and higher, and SQL Server 2019. For more information, see Support for Microsoft Distributed Transaction Coordinator in RDS for SQL Server.	September 7, 2021

Amazon RDS supports MariaDB 10.5.12, 10.4.21, 10.3.31, and 10.2.40	You can now create Amazon RDS DB instances running MariaDB versions 10.5.12, 10.4.21, 10.3.31, and 10.2.40. For more informati on, see MariaDB on Amazon RDS versions.	September 2, 2021
Amazon RDS has ended support for Oracle Database 18c	You can create DB instances only for Oracle Database 12c and Oracle Database 19c. If you have Oracle Database 18c snapshots, upgrade them to a later release. For more information, see Upgrading an Oracle DB snapshot.	August 17, 2021
Amazon RDS for SQL Server supports automatic minor version upgrades	You can now have your RDS for SQL Server DB instances automatically upgraded to the latest minor version. For more information, see Upgrading the Microsoft SQL Server DB engine.	August 13, 2021
Amazon RDS for PostgreSQ L now supports PostgreSQ L version 14 beta 2 in the database preview environme nt	For more about PostgreSQ L version 14 beta 1, see PostgreSQL 14 beta 1 release notes. For more about PostgreSQL version 14 beta 2, see PostgreSQL 14 beta 2 release notes. For informati on on the Database Preview Environment, see Working with the database preview environment.	August 9, 2021

Amazon RDS supports RDS Proxy in a shared VPC	You can now create an RDS Proxy in a shared VPC. For more information about RDS Proxy, see "Managing Connections with Amazon RDS Proxy" in the Amazon RDS User Guide or the Aurora User Guide.	August 6, 2021
Amazon RDS supports MariaDB 10.2.39	You can now create Amazon RDS DB instances running MariaDB versions 10.2.39. For more information, see MariaDB on Amazon RDS versions.	August 4, 2021
Amazon RDS for Oracle adds the `TIMEZONE_FILE_AUTOUPGRADE` option	With this option, you can upgrade the current time zone file to the latest version on your Oracle DB instance. For more information, see Oracle time zone file autoupgrade.	July 30, 2021
Amazon RDS extends support for cross-Region automated backups	You can now replicate DB snapshots and transaction logs between more AWS Regions. For more information, see Replicating automated backups to another AWS Region.	July 19, 2021

Support for MySQL 5.7.34	You can now create Amazon RDS DB instances running MySQL version 5.7.34. For more information, see MySQL on Amazon RDS versions.	July 8, 2021
Amazon RDS on AWS Outposts supports additional RDS for PostgreSQL versions	RDS on Outposts now supports RDS for PostgreSQL versions 12.7 and 13.3. For more information, see Amazon RDS on AWS Outposts support for Amazon RDS features.	July 8, 2021
Amazon RDS for PostgreSQL supports oracle_fdw	You can now use the oracle_fdw extension to provide a foreign data wrapper for access to Oracle databases. For more information, see Accessing external data with the oracle_fdw extension.	July 8, 2021

Amazon RDS supports Oracle Management Agent (OMA) version 13.5	You can use Oracle Management Agent (OMA) version 13.5 with Oracle Enterprise Manager (OEM) Cloud Control 13c Release 5 and higher. Amazon RDS for Oracle installs OMA, which then communicates with your Oracle Management Service (OMS) to provide monitoring information. If you run OMS 13.5, you can manage databases by installing OMA 13.5. For more information, see Oracle Management Agent for Enterprise Manager Cloud Control.	July 7, 2021
Amazon RDS for Oracle supports downloading logs from Amazon S3	If archived redo logs aren't on your instance but are protected by your backup retention period, you can use `rdsadmin.rdsadmin_archive_log_download` to download them from Amazon S3. RDS for Oracle saves the logs to the `/rdsdbdata/log/arch` directory on your DB instance. For more information, see Downloading archived redo logs from Amazon S3.	July 2, 2021

Amazon RDS supports MariaDB 10.4.18 and 10.5.9	You can now create Amazon RDS DB instances running MariaDB versions 10.4.18 and 10.5.9. For more information, see MariaDB on Amazon RDS versions.	June 30, 2021
Amazon RDS for Oracle supports Database Activity Streams	You can now monitor an Oracle DB instance using Database Activity Streams. An Oracle database writes audit records to the unified audit trail. When you start a database activity stream on an Oracle DB instance, Amazon Kinesis streams all activities that match the Oracle Database audit policies. For more informati on, see Monitoring Amazon RDS with Database Activity Streams.	June 23, 2021
Amazon RDS for Oracle introduces memory optimized instance classes	New Oracle DB instance classes are optimized for workloads that require additional memory, storage, and I/O per vCPU. For more information, see RDS for Oracle instance classes.	June 23, 2021
Support for MySQL 8.0.25	You can now create Amazon RDS DB instances running MySQL version 8.0.25. For more information, see MySQL on Amazon RDS versions.	June 18, 2021

Amazon RDS on AWS Outposts supports additional RDS for PostgreSQL versions	RDS on Outposts now supports RDS for PostgreSQL versions 12.5, 12.6, 13.1, and 13.2. For more information, see Amazon RDS on AWS Outposts support for Amazon RDS features.	May 28, 2021
Amazon RDS supports MariaDB 10.2.37 and 10.3.28	You can now create Amazon RDS DB instances running MariaDB versions 10.2.37 and 10.3.28. For more information, see MariaDB on Amazon RDS versions.	May 27, 2021
Amazon RDS for Oracle supports multitenant container database (CDB)	A multitenant architecture enables an Oracle database to be a CDB. In Oracle Database 19c, your CDB can include a single PDB. The user experience with a PDB is mostly identical to the user experience with a non-CDB. For more information, see RDS for Oracle architecture.	May 25, 2021
Amazon RDS on AWS Outposts supports Amazon RDS for SQL Server	RDS on Outposts now supports Amazon RDS for SQL Server. For more information, see Amazon RDS on AWS Outposts support for Amazon RDS features.	May 11, 2021

Amazon RDS extends support for cross-Region automated backups	You can now configure Amazon RDS database instances running Microsoft SQL Server to replicate DB snapshots and transacti on logs to a different AWS Region. For more informati on, see Replicating automated backups to another AWS Region.	May 7, 2021
Amazon RDS supports cross-Region automated backups for encrypted DB instances	You can now replicate DB snapshots and transacti on logs to a different AWS Region for encrypted Amazon RDS database instances running Oracle or PostgreSQ L. For more information, see Replicating automated backups to another AWS Region.	May 3, 2021
Amazon RDS on AWS Outposts supports Amazon CloudWatch monitoring	RDS on Outposts now supports Amazon CloudWatc h monitoring. For more information, see Amazon RDS on AWS Outposts support for Amazon RDS features.	April 21, 2021
RDS for PostgreSQL supports AWS Lambda functions	You can now invoke AWS Lambda functions for your RDS for PostgreSQL DB instances. For more informati on, see Invoking an AWS Lambda function from an RDS for PostgreSQL DB instance.	April 13, 2021

RDS for SQL Server supports extended events	You can use SQL Server extended events to capture debugging and troublesh ooting information. For more information, see Using extended events with Amazon RDS for Microsoft SQL Server.	April 8, 2021
Support for MySQL 8.0.23, 5.7.33, and 5.6.51	You can now create Amazon RDS DB instances running MySQL version 8.0.23, 5.7.33, and 5.6.51. For more information, see MySQL on Amazon RDS versions.	March 31, 2021
Automatic rollback on failed Amazon RDS for MySQL upgrade	If a DB instance upgrade from MySQL version 5.7 to MySQL version 8.0 fails, Amazon RDS rolls back the changes performed for the upgrade automatic ally. After the rollback, the MySQL DB instance is running MySQL version 5.7. For more information, see Rollback after failure to upgrade from MySQL 5.7 to 8.0.	March 18, 2021
Amazon RDS supports cross-Region read replicas in opt-in Regions	You can now replicate DB instances to opt-in Regions. For more information, see Creating a read replica in a different AWS Region.	March 18, 2021

Amazon RDS plans to deprecate Oracle Database 18c	Oracle Database 18c (18.0.0.0) is on a deprecation path. Oracle Corporation will no longer provide patches for Oracle Database 18c after the end-of-support date. On July 1, 2021, Amazon RDS plans to begin automatically upgrading Oracle Database 18c instances to Oracle Database 19c. Before the automatic upgrades begin, we highly recommend that you manually upgrade your existing Oracle Database 18c instances to Oracle Database 19c. For more information, see Preparing for the automatic upgrade of Oracle Database 18c.	March 11, 2021
Amazon RDS has ended support for Oracle Database 11g	You can only create DB instances for Oracle Database 12c Release 1 (12.1.0.2) and later. If you have Oracle Database 11g snapshots, upgrade them to a later release. For more information, see Upgrading an Oracle DB snapshot.	March 11, 2021

Amazon RDS supports continuous backups of DB instances in AWS Backup	You can now create automated backups in AWS Backup and restore DB instances from these backups to a specified time. For more information, see Using AWS Backup to manage automated backups.	March 10, 2021
Amazon RDS supports Oracle Management Agent (OMA) version 13.4	You can use Oracle Management Agent (OMA) version 13.4 with Oracle Enterprise Manager (OEM) Cloud Control 13c Release 4 Update 9. Amazon RDS for Oracle installs OMA, which then communicates with your Oracle Management Service (OMS) to provide monitoring information. If you run OMS 13.4, you can manage databases by installing OMA 13.4. For more information, see Oracle Management Agent for Enterprise Manager Cloud Control.	March 10, 2021

RDS Proxy endpoint enhancements	You can create additional endpoints associated with each RDS proxy. Creating an endpoint in a different VPC enables cross-VPC access for the proxy. Proxies for Aurora MySQL clusters can also have read-only endpoints. These reader endpoints connect to reader DB instances in the clusters and can improve read scalability and availability for query-intensive applications. For more information about RDS Proxy, see "Managing Connections with Amazon RDS Proxy" in the Amazon RDS User Guide or the Aurora user guide.	March 8, 2021
Amazon RDS extends supports for cross-Region automated backups	You can now configure Amazon RDS database instances running PostgreSQL to replicate DB snapshots and transaction logs to a different AWS Region. For more information, see Replicating automated backups to another AWS Region.	March 8, 2021

Replication filters for Amazon RDS for MariaDB and MySQL supported in the China (Beijing) Region and China (Ningxia) Region	Replication filtering is now supported in the China (Beijing) Region and China (Ningxia) Region. For more information, see Configuring replication filters with MariaDB and Configuring replication filters with MySQL.	March 5, 2021
Amazon RDS supports cross-Region DB snapshot copy in opt-in Regions	You can now copy DB snapshots to and from opt-in AWS Regions. For more information, see Copying snapshots across AWS Regions.	March 4, 2021
Amazon RDS for SQL Server supports Always On Availability Groups for Standard Edition	When you create a DB instance using the Multi-AZ configuration on SQL Server 2019 for the Standard Edition database engine, RDS automatically uses Availability Groups. For more information, see Multi-AZ deployments for Microsoft SQL Server.	February 23, 2021

Amazon RDS for Oracle introduces advisor-related procedures	The `rdsadmin_util` package includes the procedures `advisor_task_set_parameter` , `advisor_task_drop` , and `dbms_stats_init` . You can use these procedures to modify, stop, and re-enable advisor tasks such as `AUTO_STATS_ADVISOR_TASK` . For more information, see Setting parameters for advisor tasks.	February 23, 2021
Amazon RDS provides failover reasons for Multi-AZ DB instances	You can now see more detailed explanations when a Multi-AZ DB instance fails over to a standby replica. For more information, see Failover process for Amazon RDS.	February 18, 2021
Amazon RDS extends support for exporting snapshots to Amazon S3	You can now export DB snapshot data to Amazon S3 in China. For more information, see Exporting DB snapshot data to Amazon S3.	February 17, 2021

Replication filters for Amazon RDS for MariaDB and MySQL	You can configure replication filters for MySQL and MariaDB instances. Replication filters specify which databases and tables are replicated in a read replica. You can create lists of databases and tables to include or exclude for each read replica. For more information, see Configuring replication filters with MariaDB and Configuring replication filters with MySQL.	February 12, 2021
RDS for Oracle supports APEX 20.2v1	You can use APEX 20.2.v1 with all supported versions of Oracle Database. For more information, see Oracle Application Express.	February 2, 2021
Amazon RDS for SQL Server supports local instance storage for the tempdb database	You can now launch Amazon RDS for SQL Server on Amazon EC2 db.r5d and db.m5d instance types with the tempdb database configured to use an instance store. By placing tempdb data files and log files locally, you can achieve lower read and write latencies when compared to standard storage based on Amazon EBS. For more information, see Instance store support for the tempdb database on Amazon RDS for SQL Server.	January 27, 2021

Amazon RDS for PostgreSQL supports pg_partman and pg_cron	Amazon RDS for PostgreSQL now supports the pg_partman and pg_cron extensions. For more information on the pg_partman extension, see Managing PostgreSQL partitions with the pg_partman extension. For more information on the pg_cron extension, see Scheduling maintenance with the PostgreSQL pg_cron extension.	January 12, 2021
Amazon RDS supports publishing the Oracle Management Agent log to Amazon CloudWatch Logs	The Oracle Management Agent log consists of emctl.log, emdctlj.log, gcagent.log, gcagent_errors.log, emagent.nohup, and secure.log. Amazon RDS publishes each of these logs as a separate CloudWatch log stream. For more information, see Publishing Oracle logs to Amazon CloudWatch Logs.	December 28, 2020
Amazon RDS on AWS Outposts supports additional database versions	RDS on Outposts now supports additional MySQL and PostgreSQL versions. For more information, see Amazon RDS on AWS Outposts support for Amazon RDS features.	December 23, 2020

Amazon RDS on AWS Outposts supports CoIPs	RDS on Outposts now supports customer-owned IP addresses (CoIPs). CoIPs provide local or external connectivity to resources in your Outpost subnets through your on-premises network. For more information, see Customer-owned IP addresses for RDS on Outposts.	December 22, 2020
Amazon RDS for Oracle plans upgrade of 11g BYOL instances to 19c	On January 4, 2021, we plan to begin automatically upgrading all editions of Oracle Database 11g instances on the Bring Your Own License (BYOL) model to Oracle Database 19c. All Oracle Database 11g instances, including reserved instances, will move to the latest available Release Update (RU). For more information, see Preparing for the automatic upgrade of Oracle Database 11g BYOL.	December 11, 2020

Amazon RDS supports replicating automated backups to another AWS Region	You can now configure your Amazon RDS database instances to replicate snapshots and transacti on logs to a destination AWS Region of your choice. For more information, see Replicating automated backups to another AWS Region.	December 4, 2020
Amazon RDS for Oracle and Microsoft SQL Server support a new DB instance class	You can now use the db.r5b instance class to create Amazon RDS DB instances running Oracle or SQL Server. For more information, see Supported DB engines for DB instance classes.	December 4, 2020
Support for MariaDB 10.2.32	You can now create Amazon RDS DB instances running MariaDB version 10.2.32. For more information, see MariaDB on Amazon RDS versions.	November 25, 2020
Amazon RDS for SQL Server supports the Microsoft Business Intelligence Suite on SQL Server 2019	You can now run SQL Server Analysis Services, SQL Server Integration Services, and SQL Server Reporting Services on DB instances using the latest major version. For more information, see Options for the Microsoft SQL Server database engine.	November 24, 2020

Amazon RDS for PostgreSQL version 13 in the database preview environment	Amazon RDS for PostgreSQL now supports PostgreSQL version 13 in the database preview environment. For more information, see PostgreSQL 13 versions.	November 24, 2020
Amazon RDS Performance Insights introduces new dimensions	You can group database load according to the dimension groups for database (PostgreSQL, MySQL, and MariaDB), application (PostgreSQL), and session type (PostgreSQL). Amazon RDS also supports the dimensions db.name (PostgreSQL, MySQL, and MariaDB), db.application.name (PostgreSQL), and db.session_type.name (PostgreSQL). For more information, see Top load table.	November 24, 2020
Amazon RDS for MariaDB supports a new major version	You can now create Amazon RDS DB instances running MariaDB version 10.5. For more information, see MariaDB on Amazon RDS versions.	November 23, 2020
Support for MySQL 5.6.49	You can now create Amazon RDS DB instances running MySQL version 5.6.49. For more information, see MySQL on Amazon RDS versions.	November 20, 2020

Support for MySQL 5.5.62	You can now create Amazon RDS DB instances running MySQL version 5.5.62. For more information, see MySQL on Amazon RDS versions.	November 20, 2020
Performance Insights supports analyzing statistics for running PostgreSQL queries	You can now analyze statistics for running queries with Performance Insights for PostgreSQL DB instances. For more information, see Statistics for PostgreSQL.	November 18, 2020
Amazon RDS extends support for storage autoscaling	You can now enable storage autoscaling when creating a read replica, restoring a DB instance to a specified time, or restoring a MySQL DB instance from an Amazon S3 backup. For more information, see Managing capacity automatically with Amazon RDS storage autoscaling.	November 18, 2020
Amazon RDS for SQL Server supports Database Mail	With Database Mail you can send email messages from your Amazon RDS for SQL Server database instance. After specifying the email recipients, you can add files or query results to the message you send. For more information, see Using Database Mail on Amazon RDS for SQL Server.	November 4, 2020

Support for MySQL 8.0.21	You can now create Amazon RDS DB instances running MySQL version 8.0.21. For more information, see MySQL on Amazon RDS versions.	October 22, 2020
Amazon RDS extends support for exporting snapshots to Amazon S3	You can now export DB snapshot data to Amazon S3 in all commercial AWS Regions. For more information, see Exporting DB snapshot data to Amazon S3.	October 22, 2020
Amazon RDS for PostgreSQL supports read replica upgrades	With Amazon RDS for PostgreSQL, when you do a major version upgrade of the primary DB instance, read replicas are also automatically upgraded. For more information, see Upgrading the PostgreSQL DB engine.	October 15, 2020
Amazon RDS for MariaDB, MySQL and PostgreSQL support the Graviton2 DB instance classes	You can now use the Graviton2 DB instance classes db.m6g.x and db.r6g.x to create Amazon RDS DB instances running MariaDB, MySQL or PostgreSQL. For more information, see Supported DB Engines for All Available DB instance Classes.	October 15, 2020

Amazon RDS for SQL Server supports upgrades to SQL Server 2019	You can upgrade your SQL Server DB instances to SQL Server 2019. For more information, see Upgrading the Microsoft SQL Server DB Engine.	October 6, 2020
Amazon RDS for Oracle supports specifying the national character set	The national character set, also called the NCHAR character set, is used in the NCHAR, NVARCHAR2 , and NCLOB data types. When you create a database, you can specify either AL16UTF16 (default) or UTF8 as the NCHAR character set. For more information, see Oracle character sets supported in Amazon RDS.	October 2, 2020
Support for MySQL 5.7.31	You can now create Amazon RDS DB instances running MySQL version 5.7.31. For more information, see MySQL on Amazon RDS versions.	October 1, 2020
Amazon RDS for PostgreSQL supports exporting data to Amazon S3	You can query data from a PostgreSQL DB instance and export it directly into files stored in an Amazon S3bucket. For more information, see Exporting data from an RDS for PostgreSQL DB instance to Amazon S3.	September 24, 2020

Amazon RDS for MySQL 8.0 supports Percona XtraBackup	You can now use Percona XtraBackup to restore a backup into an Amazon RDS for MySQL 8.0 DB instance. For more information, see Restoring a backup into a MySQL DB instance.	September 17, 2020
Amazon RDS for SQL Server supports native backup and restore on DB instances with read replicas	You can restore a SQL Server native backup onto a DB instance that has read replicas configured. For more information, see Importing and exporting SQL Server databases.	September 16, 2020
Amazon RDS for SQL Server supports additional time zones	You can match your DB instance time zone with your chosen time zone. For more information, see Local time zone for Microsoft SQL Server DB instances.	September 11, 2020
Amazon RDS for PostgreSQL version 13 beta 3 in the database preview environment	Amazon RDS for PostgreSQL now supports PostgreSQL Version 13 Beta 3 in the Database Preview Environment. For more information, see PostgreSQL 13 versions.	September 9, 2020

Amazon RDS for SQL Server supports trace flag 692	You can now use trace flag 692 as a startup parameter using DB parameter gro ups. Enabling this trace flag disables fast inserts while bulk loading data into heap or clustered indexes. For more information, see Disabling fast inserts during bulk loading.	August 27, 2020
Amazon RDS for SQL Server supports Microsoft SQL Server 2019	You can now create RDS DB instances that use SQL Server 2019. For more informati on, see Microsoft SQL Server versions on Amazon RDS.	August 26, 2020
RDS for Oracle supports mounted replica database	When creating or modifying an Oracle replica, you can place it in mounted mode. Because the replica database doesn't accept user connectio ns, it can't serve a read-only workload. The mounted replica deletes archived redo log files after it applies them. The primary use for mounted replicas is cross-Region disaster recovery. For more information, see Overview of Oracle replicas.	August 13, 2020

RDS for Oracle plans upgrade of 11g SE1 LI instances	On November 1, 2020, we plan to begin automatically upgrading Oracle Database 11g SE1 License Included (LI) instances to Oracle Database 19c for Amazon RDS for Oracle. All 11g instances, including reserved instances, will move to the latest available Oracle Release Update (RU). For more information, see Preparing for the automatic upgrade of Oracle Database 11g SE1.	July 31, 2020
Amazon RDS supports new Graviton2 DB instance classes in preview release for PostgreSQL and MySQL	You can now create Amazon RDS DB instances running PostgreSQL or MySQL that use the db.m6g.x and db.r6g.x DB instance classes. For more information, see Supported DB engines for all available DB instance classes.	July 30, 2020
RDS for Oracle supports APEX 20.1v1	You can use APEX 20.1v1 with all supported versions of Oracle Database. For more information, see Oracle application Express.	July 28, 2020
Support for MySQL 8.0.20	You can now create Amazon RDS DB instances running MySQL version 8.0.20. For more information, see MySQL on Amazon RDS versions.	July 23, 2020

Amazon RDS for MariaDB and MySQL support new DB instance classes	You can now create Amazon RDS DB instances running MariaDB and MySQL that use the db.m5.16xlarge, db.m5.8xlarge, db.r5.16x large, and db.r5.8xlarge DB instance classes. For more information, see Supported DB engines for all available DB instance classes.	July 23, 2020
RDS for SQL Server supports disabling old versions of TLS and ciphers	You can turn certain security protocols and ciphers on and off. For more information, see Configuring security protocols and ciphers.	July 21, 2020
RDS supports Oracle Spatial on SE2	You can use Oracle Spatial in Standard Edition 2 (SE2) for all versions of 12.2, 18c, and 19c. For more information, see Oracle Spatial.	July 9, 2020
Amazon RDS supports AWS PrivateLink	Amazon RDS now supports creating Amazon VPC endpoints for Amazon RDS API calls to keep traffic between applications and Amazon RDS in the AWS network. For more informat ion, see Amazon RDS and interface VPC endpoints (AWS PrivateLink).	July 9, 2020

Amazon RDS for PostgreSQL versions 9.4.x has reached its end of support.	Amazon RDS for PostgreSQL no longer supports versions 9.4.x. For supported versions, see Supported PostgreSQL database versions.	July 8, 2020
Support for MariaDB 10.3.23 and 10.4.13	You can now create Amazon RDS DB instances running MariaDB version 10.3.23 and 10.4.13. For more informati on, see MariaDB on Amazon RDS versions.	July 6, 2020
Amazon RDS on AWS Outposts	You can create Amazon RDS DB instances on AWS Outposts. For more informati on, see Working with Amazon RDS on AWS Outposts.	July 6, 2020
Amazon RDS for Oracle creates inventory files automatically	To open service requests for BYOL customers, Oracle Support requests inventory files generated by Opatch. Amazon RDS for Oracle automatically creates inventory files every hour in the BDUMP directory. For more information, see Accessing Opatch files.	July 6, 2020
Support for MySQL 5.7.30 and 5.6.48	You can now create Amazon RDS DB instances running MySQL version 5.7.30 and 5.6.48. For more information, see MySQL on Amazon RDS versions.	June 25, 2020

Amazon RDS for Oracle supports ADRCI	The Automatic Diagnostic Repository Command Interpreter (ADRCI) utility is an Oracle command-line tool that you use to manage diagnostic data. By using the functions in the Amazon RDS package `rdsadmin_adrci_util`, you can list and package problems and incidents, and also show trace files. For more information, see Common DBA diagnostic tasks for Oracle DB instances.	June 17, 2020
Support for MySQL 8.0.19	You can now create Amazon RDS DB instances running MySQL version 8.0.19. For more information, see MySQL on Amazon RDS versions.	June 2, 2020
MySQL 8.0 supports lower case table names	You can now set the `lower_case_table_names` parameter to 1 for Amazon RDS DB instances running MySQL version 8.0.19 and higher 8.0 versions. For more information, see MySQL parameter exceptions for Amazon RDS DB instances.	June 2, 2020

Amazon RDS for Microsoft SQL Server supports SQL Server Integration Services (SSIS)	SSIS is a platform for data integration and workflow applications. You can enable SSIS on existing or new DB instances. It's installed on the same DB instance as your database engine. For more information, see Support for SQL Server Integration Services in SQL Server.	May 19, 2020
Amazon RDS for Microsoft SQL Server supports SQL Server Reporting Services (SSRS)	SSRS is a server-based application used for report generation and distribution. You can enable SSRS on existing or new DB instances. It's installed on the same DB instance as your database engine. For more information, see Support for SQL Server Reporting Services in SQL Server.	May 15, 2020
Amazon RDS for Microsoft SQL Server supports S3 integration on Multi-AZ instances	You can now use Amazon S3 with SQL Server features such as bulk insert on Multi-AZ DB instances. For more information, see Integrating an Amazon RDS for SQL Server DB instance with Amazon S3.	May 15, 2020

Amazon RDS for Oracle supports purging the recycle bin	The `rdsadmin.rdsadmin_util.purge_dba_recyclebin` procedure purges the recycle bin. For more information, see Purging the recycle bin.	May 13, 2020
Amazon RDS for Oracle improves manageability of Automatic Workload Repository (AWR)	The `rdsadmin.rdsadmin_diagnostic_util` procedures generate AWR reports and extract AWR data into dump files. For more information, see Generating performance reports with Automatic Workload Repository (AWR).	May 13, 2020
Amazon RDS for Microsoft SQL Server supports Microsoft Distributed Transaction Coordinator (MSDTC)	Amazon RDS for SQL Server supports distributed transactions between hosts. For more information, see Support for Microsoft Distributed Transaction Coordinator in SQL Server.	May 4, 2020
Amazon RDS for Microsoft SQL Server supports new versions	You can now create Amazon RDS DB instances running SQL Server versions 2017 CU19 14.00.3281.6, 2016 SP2 CU11 13.00.5598.27, 2014 SP3 CU4 12.00.6329.1, and 2012 SP4 GDR 11.0.7493.4 for all editions. For more information, see Microsoft SQL Server versions on Amazon RDS.	April 28, 2020

Amazon RDS available in the Europe (Milan) Region	Amazon RDS is now available in the Europe (Milan) Region. For more information, see Regions and Availability Zones.	April 28, 2020
Amazon RDS support for Local Zones	You can now launch DB instances into a Local Zone subnet. For more informati on, see Regions, Availability Zones, and Local Zones.	April 23, 2020
Amazon RDS available in the Africa (Cape Town) Region	Amazon RDS is now available in the Africa (Cape Town) Region. For more information, see Regions and Availability Zones.	April 22, 2020
Amazon RDS for Microsoft SQL Server supports SQL Server Analysis Services (SSA S)	SSAS is an online analytical processing (OLAP) and data mining tool that is installed within SQL Server. You can enable SSAS on existing or new DB instances. It's installed on the same DB instance as your database engine. For more informat ion, see Support for SQL Server Analysis Services in SQL Server.	April 17, 2020

Amazon RDS proxy for PostgreSQL	Amazon RDS Proxy is now available for PostgreSQL. You can use RDS Proxy to reduce the overhead of connection management on your DB instance and also the chance of "too many connections" errors. The RDS Proxy is currently in public preview for PostgreSQL. For more information, see Managing connections with Amazon RDS proxy (preview).	April 8, 2020
Amazon RDS for Oracle supports Oracle APEX version 19.2.v1	Amazon RDS for Oracle now supports Oracle Application Express (APEX) version 19.2.v1. For more information, see Oracle application Express.	April 8, 2020
Amazon RDS for MariaDB supports a new major version	You can now create Amazon RDS DB instances running MariaDB version 10.4. For more information, see MariaDB on Amazon RDS versions.	April 6, 2020
Amazon RDS Performance Insights is available for Amazon RDS for MariaDB 10.4	Amazon RDS Performance Insights is now available for Amazon RDS for MariaDB version 10.4. For more information, see Using Amazon RDS performance insights.	April 6, 2020

Amazon RDS for PostgreSQL versions 9.3.x has reached its end of support	Amazon RDS for PostgreSQL no longer supports versions 9.3.x. For supported versions, see Supported PostgreSQL database versions.	April 3, 2020
Amazon RDS for Microsoft SQL Server supports read replicas	You can now create read replicas for SQL Server DB instances. For more informati on, see Working with read replicas.	April 3, 2020
Amazon RDS for Microsoft SQL Server supports multifile backups	You can now back up databases to multiple files using SQL Server native backup and restore. For more information, see Backing up a database.	April 2, 2020
Amazon RDS for Oracle integration with AWS License Manager	Amazon RDS for Oracle is now integrated with AWS License Manager. If you use the Bring Your Own License model, AWS License Manager integration makes it easier to monitor your Oracle license usage within your organizat ion. For more information, see Integrating with AWS License Manager.	March 23, 2020

Support for 64 TiB on db.r5 instances in Amazon RDS for MariaDB and MySQL	You can now create Amazon RDS DB instances for MariaDB and MySQL that use the db.r5 DB instance class with up to 64 TiB of storage. For more information, see Factors that affect storage performance.	March 18, 2020
Support for MySQL 8.0.17	You can now create Amazon RDS DB instances running MySQL version 8.0.17. For more information, see MySQL on Amazon RDS versions.	March 10, 2020
Amazon RDS Performance Insights is available for Amazon RDS for MySQL 8.0	Amazon RDS Performance Insights is now available for Amazon RDS for MySQL version 8.0.17 and higher 8.0 versions. For more information, see Using Amazon RDS performance insights.	March 10, 2020
Support for MySQL 5.6.46	You can now create Amazon RDS DB instances running MySQL version 5.6.46. For more information, see MySQL on Amazon RDS versions.	February 28, 2020

Amazon RDS Performance Insights is available for Amazon RDS for MariaDB 10.3	Amazon RDS Performance Insights is now available for Amazon RDS for MariaDB version 10.3.13 and higher 10.3 versions. For more information, see Using Amazon RDS performance insights.	February 26, 2020
Support for MySQL 5.7.28	You can now create Amazon RDS DB instances running MySQL version 5.7.28. For more information, see MySQL on Amazon RDS versions.	February 20, 2020
Support for MariaDB 10.3.20	You can now create Amazon RDS DB instances running MariaDB version 10.3.20. For more information, see MariaDB on Amazon RDS versions.	February 20, 2020
Amazon RDS for Microsoft SQL Server supports a new DB instance class	You can now create Amazon RDS DB instances running SQL Server that use the db.z1d DB instance class. For more information, see DB instance class support for Microsoft SQL Server.	February 19, 2020

Support for cross-account, cross-VPC Active Directory domains in Amazon RDS for SQL Server	Amazon RDS for Microsoft SQL Server now supports associating DB instances with Active Directory domains owned by different accounts and VPCs. For more information, see Using Windows authentication with a Microsoft SQL Server DB instance.	February 13, 2020
Oracle OLAP option	Amazon RDS for Oracle now supports the On-line Analytical Processing (OLAP) option for Oracle DB instances. You can use Oracle OLAP to analyze large amounts of data by creating dimensional objects and cubes in accordance with the OLAP standard. For more information, see Oracle OLAP.	February 13, 2020
FIPS 140-2 support for Oracle	Amazon RDS for Oracle supports the Federal Information Processing Standard Publication 140-2 (FIPS 140-2) for SSL/TLS connections. For more information, see FIPS support.	February 11, 2020

Amazon RDS for PostgreSQL supports new DB instance classes	You can now create Amazon RDS DB instances running PostgreSQL that use the db.m5.16xlarge, db.m5.8xlarge, db.r5.16xlarge, and db.r5.8xlarge DB instance classes. For more information, see Supported DB engines for all available DB instance classes.	February 11, 2020
Performance Insights supports analyzing statistics of running MariaDB and MySQL queries	You can now analyze statistics of running queries with Performance Insights for MariaDB and MySQL DB instances. For more information, see Analyzing statistics of running queries.	February 4, 2020
Support for exporting DB snapshot data to Amazon S3 for MariaDB, MySQL, and PostgreSQL	Amazon RDS supports exporting DB snapshot data to Amazon S3 for MariaDB, MySQL, and PostgreSQL. For more information, see Exporting DB snapshot data to Amazon S3.	January 23, 2020
Amazon RDS for MySQL supports Kerberos authentication	You can now use Kerberos authentication to authenticate users when they connect to your Amazon RDS for MySQL DB instances. For more information, see Using Kerberos authentication for MySQL.	January 21, 2020

Amazon RDS Performance Insights supports viewing more SQL text for Amazon RDS for Microsoft SQL Server	Amazon RDS Performance Insights now supports viewing more SQL text in the Performance Insights dashboard for Amazon RDS for Microsoft SQL Server DB instances. For more information, see Viewing more SQL text in the Performance Insights dashboard.	December 17, 2019
Amazon RDS proxy	You can reduce the overhead of connection management on your cluster, and reduce the chance of "too many connections" errors, by using the Amazon RDS Proxy. You associate each proxy with an RDS DB instance or Aurora DB cluster. Then you use the proxy endpoint in the connection string for your application. The Amazon RDS Proxy is currently in a public preview state. It supports the RDS for MySQL database engine. For more information, see Managing connections with Amazon RDS proxy (preview).	December 3, 2019

Amazon RDS on AWS Outposts (preview)	With Amazon RDS on AWS Outposts, you can create AWS-managed relational databases in your on-premises data centers. RDS on Outposts enables you to run RDS databases on AWS Outposts. For more information, see Amazon RDS on AWS Outposts (preview).	December 3, 2019
Amazon RDS for Oracle supports cross-region read replicas	Amazon RDS for Oracle now supports cross-region read replicas with Active Data Guard. For more information, see Working with read replicas and Working with Oracle read replicas.	November 26, 2019
Performance Insights supports analyzing statistics of running Oracle queries	You can now analyze statistics of running queries with Performance Insights for Oracle DB instances. For more information, see Analyzing statistics of running queries.	November 25, 2019
Amazon RDS for Microsoft SQL Server supports publishing logs to CloudWatch Logs	You can configure your Amazon RDS for SQL Server DB instance to publish log events directly to Amazon CloudWatch Logs. For more information, see Publishing SQL Server logs to Amazon CloudWatch Logs.	November 25, 2019

Amazon RDS for Microsoft SQL Server supports new DB instance classes	You can now create Amazon RDS DB instances running SQL Server that use the db.x1e and db.x1 DB instance classes. For more information, see DB instance class support for Microsoft SQL Server.	November 25, 2019
Amazon RDS for Microsoft SQL Server supports differential and log restores	You can restore differential backups and logs using SQL Server native backup and restore. For more information, see Using native backup and restore.	November 25, 2019
Multi-AZ supported on Amazon RDS for Microsoft SQL Server in new regions	Multi-AZ on SQL Server is now available in China, Middle East (Bahrain), and Europe (Stockholm). For more information, see Multi-AZ deployments for Microsoft SQL Server.	November 22, 2019
Amazon RDS for Microsoft SQL Server now supports bulk insert and S3 integration	You can transfer files between a SQL Server DB instance and an Amazon S3 bucket. Then you can use Amazon S3 with SQL Server features such as bulk insert. For more information, see Integrating an Amazon RDS for SQL Server DB instance with Amazon S3.	November 21, 2019

Performance Insights counters for Amazon RDS for Microsoft SQL Server	You can now add performance counters to your Performance Insights charts for Microsoft SQL Server DB instances. For more information, see Performance Insights counters for Amazon RDS for Microsoft SQL Server.	November 12, 2019
Amazon RDS for Microsoft SQL Server supports new DB instance class sizes	You can now create Amazon RDS DB instances running SQL Server that use the 8xlarge and 16xlarge instance sizes for the db.m5 and db.r5 DB instance classes. Instance sizes ranging from small to 2xlarge are now available for the db.t3 instance class. For more information, see DB instance class support for Microsoft SQL Server.	November 11, 2019
Support for PostgreSQL snapshot upgrades	If you have existing manual DB snapshots of your Amazon RDS PostgreSQL DB instances, you can now upgrade them to a later version of the PostgreSQL database engine. For more information, see Upgrading a PostgreSQL DB snapshot.	November 7, 2019

Amazon RDS for Oracle supports a new major version	You can now create Amazon RDS DB instances running Oracle Database 19c (19.0). For more information, see Oracle Database 19c with Amazon RDS.	November 7, 2019
Amazon RDS for PostgreSQL version 12.0 in the database preview environment	Amazon RDS for PostgreSQL now supports PostgreSQL Version 12.0 in the Database Preview Environment. For more information, see PostgreSQL version 12.0 in the database preview environment.	November 1, 2019
Amazon RDS for PostgreSQL supports Kerberos authentication	You can now use Kerberos authentication to authenticate users when they connect to your Amazon RDS DB instance running PostgreSQL. For more information, see Using Kerberos authentication with Amazon RDS for PostgreSQL.	October 28, 2019
OEM Management Agent database tasks for Oracle DB instances	Amazon RDS for Oracle DB instances now support procedures to invoke certain EMCTL commands on the Management Agent. For more information, see OEM agent database tasks.	October 24, 2019

Amazon RDS for PostgreSQL supports PostgreSQL transportable databases	PostgreSQL Transportable Databases provide an extremely fast method of migrating an RDS PostgreSQL database between two DB instances. For more information, see Transporting PostgreSQL databases between DB instances.	October 8, 2019
Amazon RDS for Oracle supports Kerberos authentication	You can now use Kerberos authentication to authenticate users when they connect to your Amazon RDS DB instance running Oracle. For more information, see Using Kerberos authentication with Amazon RDS for Oracle.	September 30, 2019
Amazon RDS for PostgreSQL version 12 beta 3 in the database preview environment	Amazon RDS for PostgreSQL now supports PostgreSQL Version 12 Beta 3 in the Database Preview Environment. For more information, see PostgreSQL version 12 beta 3 on Amazon RDS in the database preview environment.	August 28, 2019
Support for MySQL 8.0.16	You can now create Amazon RDS DB instances running MySQL version 8.0.16. For more information, see MySQL on Amazon RDS versions.	August 19, 2019

Amazon RDS for Oracle supports a new major version	You can now create Amazon RDS DB instances running Oracle Database 18c (18.0). For more information, see Oracle Database 18c with Amazon RDS.	August 15, 2019
Management Agent for OEM 13c release 3	Amazon RDS for Oracle DB instances now support the Management Agent for Oracle Enterprise Manager (OEM) Cloud Control 13c Release 3. For more information, see Oracle Management Agent for Enterprise Manager cloud control.	August 7, 2019
Amazon RDS for PostgreSQL version 12 beta 2 in the database preview environment	Amazon RDS for PostgreSQL now supports PostgreSQL Version 12 Beta 2 in the Database Preview Environment. For more information, see PostgreSQL version 12 beta 2 on Amazon RDS in the database preview environment.	August 6, 2019
Amazon RDS supports server collations for SQL Server	Amazon RDS for SQL Server supports a selection of collations for new DB instances. For more information, see Collations and character sets for Microsoft SQL Server.	July 29, 2019

Amazon RDS for Oracle supports Oracle APEX version 19.1.v1	Amazon RDS for Oracle now supports Oracle Application Express (APEX) version 19.1.v1. For more information, see Oracle application Express.	June 28, 2019
Amazon RDS for PostgreSQL version 13 beta 1 in the database preview environment	Amazon RDS for PostgreSQL now supports PostgreSQL Version 13 Beta 1 in the Database Preview Environment. For more information, see PostgreSQL 13 versions.	June 22, 2019
Amazon RDS storage autoscaling	Storage autoscaling for Amazon RDS DB instances enables Amazon RDS to automatically expand the storage associated with a DB instance to reduce the chance of out-of-space conditions. For information about storage autoscaling, see Working with storage for Amazon RDS DB instances.	June 20, 2019
Amazon RDS for Oracle supports db.z1d DB instance classes	You can now create Amazon RDS DB instances running Oracle that use the db.z1d DB instance classes. For more information, see DB instance class.	June 13, 2019

Amazon RDS Performance Insights supports viewing more SQL text for Amazon RDS for Oracle	Amazon RDS Performance Insights now supports viewing more SQL text in the Performance Insights dashboard for Amazon RDS for Oracle DB instances. For more information, see Viewing more SQL text in the Performance Insights dashboard.	June 10, 2019
Amazon RDS adds support native restores of SQL Server databases up to 16 TB	You can now do native restores of up to 16 TB from SQL Server to Amazon RDS. For more information, see Amazon RDS for SQL Server: Limitations and recommendations.	June 4, 2019
Amazon RDS adds support for Microsoft SQL Server audit	Using Amazon RDS for Microsoft SQL Server, you can audit server and database level events using SQL Server Audit, and view the results on your DB instance or send the audit log files directly to Amazon S3. For more information, see SQL Server Audit.	May 23, 2019

Improvements to Amazon RDS recommendations	Amazon RDS has improved its automated recommendations for database resources. For example, Amazon RDS now provides recommendations for database parameters. For more information, see Using Amazon RDS recommendations.	May 22, 2019
Support for more databases per DB instance for Amazon RDS for SQL Server	You can create up to 30 databases on each of your DB instances running Microsoft SQL Server. For more information, see Limits for Microsoft SQL Server DB instances.	May 21, 2019
Support for 64 TiB and 80k IOPS of storage for Amazon RDS for MariaDB, MySQL and PostgreSQL	You can now create Amazon RDS DB instances for MariaDB, MySQL and PostgreSQL with up to 64 TiB of storage and up to 80,000 provisioned IOPS. For more information, see DB instance storage.	May 20, 2019
Amazon RDS for MySQL supports upgrade prechecks	When you upgrade a DB instance from MySQL 5.7 to MySQL 8.0, Amazon RDS performs prechecks for incompatibilities. For more information, see Prechecks for upgrades from MySQL 5.7 to 8.0.	May 17, 2019

Support for the MySQL password validation plugin	You can now use the MySQL `validate_password` plugin for improved security of Amazon RDS for MySQL DB instances. For more information, see Using the Password Validation Plugin.	May 16, 2019
Performance Insights counters for Amazon RDS for Oracle	You can now add performance counters to your Performance Insights charts for Oracle DB instances. For more information, see Performance Insights counters for Amazon RDS for Oracle.	May 8, 2019
Support for per-second billing	Amazon RDS is now billed in 1-second increments in all AWS Regions except AWS GovCloud (US) for on-demand instances. For more information, see DB instance billing for Amazon RDS.	April 25, 2019
Support for importing data from Amazon S3 for Amazon RDS for PostgreSQL	You can now import data from Amazon S3 file into a table in an RDS PostgreSQL DB instance. For more information, see Importing Amazon S3 data into an RDS PostgreSQL DB instance.	April 24, 2019

Support for restoring 5.7 backups from Amazon S3	You can now create a backup of your MySQL version 5.7 database, store it on A mazon S3, and then restore the backup file onto a new Amazon RDS DB instance running MySQL. For more information, see Restoring a backup into a MySQL DB instance.	April 17, 2019
Support for multiple major version upgrades for Amazon RDS for PostgreSQL	With Amazon RDS for PostgreSQL, you can now choose from multiple major versions when you upgrade the DB engine. This feature enables you to skip ahead to a newer major version when you upgrade select PostgreSQ L engine versions. For more information, see Upgrading the PostgreSQL DB engine.	April 16, 2019
Support for 64 TiB of storage for Amazon RDS for Oracle	You can now create Amazon RDS DB instances for Oracle with up to 64 TiB of storage and up to 80,000 provisioned IOPS. For more information, see DB instance storage.	April 4, 2019
Support for MySQL 8.0.15	You can now create Amazon RDS DB instances running MySQL version 8.0.15. For more information, see MySQL on Amazon RDS versions.	April 3, 2019

Support for MariaDB 10.3.13	You can now create Amazon RDS DB instances running MariaDB version 10.3.13. For more information, see MariaDB on Amazon RDS versions.	April 3, 2019
Microsoft SQL Server 2008 R2 has reached its end of support on Amazon RDS	Microsoft SQL Server 2008 R2 has reached its end of support, coinciding with the Microsoft plan to end extended support for this version on July 9, 2019. Any existing Microsoft SQL Server 2008 R2 snapshots are to be automatically upgraded to the latest minor version of Microsoft SQL Server 2012 starting on June 1, 2019. For more information, see Microsoft SQL Server 2008 R2 support on Amazon RDS .	April 2, 2019
Always On availability groups supported in Microsoft SQL Server 2017	You can now use Always On Availability Groups in SQL Server 2017 Enterprise Edition 14.00.3049.1 or later. For more information, see Multi-AZ deployments for Microsoft SQL Server.	March 29, 2019

View volume metrics	You can now view metrics for the Amazon Elastic Block Store (Amazon EBS) volumes, which are the physical devices used for database and log storage. For more informati on, see Viewing Enhanced Monitoring.	March 20, 2019
Support for MySQL 5.7.25	You can now create Amazon RDS DB instances running MySQL version 5.7.25. For more information, see MySQL on Amazon RDS versions.	March 19, 2019
Amazon RDS for Oracle supports RMAN DBA tasks	Amazon RDS for Oracle now supports Oracle Recovery Manager (RMAN) DBA tasks, including RMAN backups. For more information, see Common DBA Recovery Manager (RMAN) tasks for Oracle DB instances.	March 14, 2019
Amazon RDS for PostgreSQL supports version 11.1	You can now create Amazon RDS DB instances running PostgreSQL version 11.1. For more information, see PostgreSQL version 11.1 on Amazon RDS.	March 12, 2019
Multiple-file restore is available in Amazon RDS for SQL Server	You can now restore from multiple files with Amazon RDS for SQL Server. For more information, see Restoring a database.	March 11, 2019

MariaDB 10.2.21	You can now create Amazon RDS DB instances running MariaDB version 10.2.21. For more information, see MariaDB on Amazon RDS versions.	March 11, 2019
Amazon RDS for Oracle supports read replicas	Amazon RDS for Oracle now supports read replicas with Active Data Guard. For more information, see Working with read replicas and Working with Oracle read replicas.	March 11, 2019
Amazon RDS Performance Insights is available for Amazon RDS for MariaDB	Amazon RDS Performance Insights is now available for Amazon RDS for MariaDB. For more information, see Using Amazon RDS Performance Insights.	March 11, 2019
MySQL 8.0.13 and 5.7.24	You can now create Amazon RDS DB instances running MySQL versions 8.0.13 and 5.7.24. For more information, see MySQL on Amazon RDS versions.	March 8, 2019
Amazon RDS Performance Insights is available for Amazon RDS for SQL Server	Amazon RDS Performance Insights is now available for Amazon RDS for SQL Server. For more information, see Using Amazon RDS Performance Insights.	March 4, 2019

Amazon RDS for Oracle supports Amazon S3 integration	You can now transfer files between an Amazon RDS for Oracle DB instance and an Amazon S3 bucket. For more information, see Integrating Amazon RDS for Oracle and Amazon S3.	February 26, 2019
Amazon RDS for MySQL and Amazon RDS for MariaDB support db.t3 DB instance classes	You can now create Amazon RDS DB instances running MySQL or MariaDB that use the db.t3 DB instance classes. For more information, see DB instance class.	February 20, 2019
Amazon RDS for MySQL and Amazon RDS for MariaDB support db.r5 DB instance classes	You can now create Amazon RDS DB instances running MySQL or MariaDB that use the db.r5 DB instance classes. For more information, see DB instance class.	February 20, 2019
Performance Insights counters for RDS for MySQL and PostgreSQL	You can now add performance counters to your Performance Insights charts for MySQL and PostgreSQL DB instances. For more information, see Performance Insights dashboard components.	February 19, 2019

Amazon RDS for PostgreSQL now supports adaptive autovacuum parameter tuning	Adaptive autovacuum parameter tuning with Amazon RDS for PostgreSQL helps prevent transaction ID wraparound by adjusting autovacuum parameter values automatically. For more information, see Reducing the likelihood of transaction ID wraparound.	February 12, 2019
Amazon RDS for Oracle supports Oracle APEX versions 18.1.v1 and 18.2.v1	Amazon RDS for Oracle now supports Oracle Application Express (APEX) versions 18.1.v1 and 18.2.v1. For more information, see Oracle application Express.	February 11, 2019
Amazon RDS Performance Insights supports viewing more SQL text for RDS for MySQL	Amazon RDS Performance Insights now supports viewing more SQL text in the Performance Insights dashboard for MySQL DB instances. For more information, see Viewing more SQL text in the Performance Insights dashboard.	February 6, 2019
Amazon RDS for PostgreSQL supports db.t3 DB instance classes	You can now create Amazon RDS DB instances running PostgreSQL that use the db.t3 DB instance classes. For more information, see DB instance class.	January 25, 2019

Amazon RDS for Oracle supports db.t3 DB instance classes	You can now create Amazon RDS DB instances running Oracle that use the db.t3 DB instance classes. For more information, see DB instance class.	January 25, 2019
Amazon RDS Performance Insights supports viewing more SQL text for Amazon RDS PostgreSQL	Amazon RDS Performance Insights now supports viewing more SQL text in the Performance Insights dashboard for Amazon RDS PostgreSQL DB instances. For more information, see Viewing more SQL text in the Performance Insights dashboard.	January 24, 2019
Amazon RDS for Oracle supports a new version of SQLT	Amazon RDS for Oracle now supports SQLT version 12.2.180725. For more information, see Oracle SQLT.	January 22, 2019
Amazon RDS for PostgreSQL supports db.r5 DB instance classes	You can now create Amazon RDS DB instances running PostgreSQL that use the db.r5 DB instance classes. For more information, see DB instance class.	December 19, 2018

Amazon RDS for PostgreSQL now supports restricted password management	Amazon RDS for PostgreSQL enables you to restrict who can manage user passwords and password expiration changes by using the parameter `rds.restrict_password_commands` and the role `rds_password`. For more information, see Restricting password management.	December 19, 2018
Amazon RDS for PostgreSQL supports uploading database logs to Amazon CloudWatch Logs	Amazon RDS for PostgreSQL supports uploading database logs to CloudWatch Logs. For more information, see Publishing PostgreSQL logs to CloudWatch Logs.	December 10, 2018
Amazon RDS for Oracle supports db.r5 DB instance classes	You can now create Amazon RDS DB instances running Oracle that use the db.r5 DB instance classes. For more information, see DB instance class.	November 20, 2018
Retain backups when deleting a DB instance	Amazon RDS supports retaining automated backups when you delete a DB instance. For more information, see Working with backups.	November 15, 2018

Amazon RDS for PostgreSQL supports db.m5 DB instance classes	You can now create Amazon RDS DB instances running PostgreSQL that use the db.m5 DB instance classes. For more information, see DB instance class.	November 15, 2018
Amazon RDS for Oracle supports a new major version	You can now create Amazon RDS DB instances running Oracle version 12.2.	November 13, 2018
Amazon RDS for SQL Server supports Always On	Amazon RDS for SQL Server supports Always On Availability Groups. For more information, see Multi-AZ deployments for Microsoft SQL Server.	November 8, 2018
Amazon RDS for PostgreSQL supports outbound network access using custom DNS servers	Amazon RDS for PostgreSQL supports outbound network access using custom DNS servers. For more informati on, see Using a custom DNS server for outbound network access.	November 8, 2018
Amazon RDS for MariaDB, MySQL, and PostgreSQL supports 32 TiB of storage	You can now create Amazon RDS DB instances with up to 32 TiB of storage for MySQL, MariaDB, and PostgreSQL. For more information, see DB instance storage.	November 7, 2018

Amazon RDS for Oracle supports extended data types	You can now enable extended data types on Amazon RDS DB instances running Oracle. With extended data types, the maximum size is 32,767 bytes for the VARCHAR2, NVARCHAR2, and RAW data types. For more information, see Using extended data types.	November 6, 2018
Amazon RDS for Oracle supports db.m5 DB instance classes	You can now create Amazon RDS DB instances running Oracle that use the db.m5 DB instance classes. For more information, see DB instance class.	November 2, 2018
Amazon RDS for Oracle migration from SE, SE1, or SE2 to EE	You can now migrate from any Oracle Database Standard Edition (SE, SE1, or SE2) to Oracle Database Enterprise Edition (EE). For more information, see Migrating between Oracle editions.	October 31, 2018
Amazon RDS can now stop Multi-AZ instances	Amazon RDS can now stop a DB instance that is part of a Multi-AZ deployment. Formerly, the stop instance feature had a limitation for multi-AZ instances. For more information, see Stopping an Amazon RDS DB instance temporarily.	October 29, 2018

Amazon RDS Performance Insights is available for Amazon RDS for Oracle	Amazon RDS Performance Insights is now available for Amazon RDS for Oracle. For more information, see Using Amazon RDS Performance Insights.	October 29, 2018
Amazon RDS for PostgreSQL supports PostgreSQL version 11 in the database preview environment	Amazon RDS for PostgreSQL now supports PostgreSQL version 11 in the Database Preview Environment. For more information, see PostgreSQL version 11 on Amazon RDS in the database preview environment.	October 25, 2018
MySQL supports a new major version	You can now create Amazon RDS DB instances running MySQL version 8.0. For more information, see MySQL on Amazon RDS versions.	October 23, 2018
MariaDB supports a new major version	You can now create Amazon RDS DB instances running MariaDB version 10.3. For more information, see MariaDB on Amazon RDS versions.	October 23, 2018
Amazon RDS for Oracle supports Oracle JVM	Amazon RDS for Oracle now supports the Oracle Java Virtual Machine (JVM) option. For more information, see Oracle Java virtual machine.	October 16, 2018

Custom parameter group for restore and point in time recovery	You can now specify a custom parameter group when you restore a snapshot or perform a point in time recovery operation. For more information, see Restoring from a DB snapshot and Restoring a DB instance to a specified time.	October 15, 2018
Amazon RDS for Oracle supports 32 TiB storage	You can now create Oracle RDS DB instances with up to 32 TiB of storage. For more information, see DB instance storage.	October 15, 2018
Amazon RDS for MySQL supports GTIDs	Amazon RDS for MySQL now supports global transaction identifiers (GTIDs), which are unique across all DB instances and in a replication configuration. For more information, see Using GTID-based replication for RDS for MySQL.	October 10, 2018
MySQL 5.7.23, 5.6.41, and 5.5.61	You can now create Amazon RDS DB instances running MySQL versions 5.7.23, 5.6.41, and 5.5.61. For more information, see MySQL on Amazon RDS versions.	October 8, 2018
Amazon RDS for Oracle supports a new version of SQLT	Amazon RDS for Oracle now supports SQLT version 12.2.180331. For more information, see Oracle SQLT.	October 4, 2018

Amazon RDS for PostgreSQL now supports IAM authentication	Amazon RDS for PostgreSQL now supports IAM authentication. For more information see IAM database authentication for MySQL and PostgreSQL.	September 27, 2018
You can enable deletion protection for your Amazon RDS DB instances	When you enable deletion protection for a DB instance, the database cannot be deleted by any user. For more information, see Deleting a DB instance.	September 26, 2018
Amazon RDS for MySQL and Amazon RDS for MariaDB support db.m5 DB instance classes	You can now create Amazon RDS DB instances running MySQL or MariaDB that use the db.m5 DB instance classes. For more information, see DB instance class.	September 18, 2018
Amazon RDS now supports upgrades to SQL Server 2017	You can upgrade your existing DB instance to SQL Server 2017 from any version except SQL Server 2008. To upgrade from SQL Server 2008, first upgrade to one of the other versions first. For information, see Upgrading the Microsoft SQL Server DB engine.	September 11, 2018

Amazon RDS for PostgreSQL now supports PostgreSQL version 11 beta 3 in the database preview environment	In this release, the Write-Ahead Log (WAL) segment size (wal_segment_size) is now set to 64MB. For more about PostgreSQL version 11 Beta 3, see PostgreSQL 11 beta 3 released. For information on the Database Preview Environment, see Working with the database preview environment.	September 7, 2018
Amazon Aurora User Guide	The *Amazon Aurora User Guide* describes all Amazon Aurora concepts and provides instructions on using the various features with both the console and the command line interface. The *Amazon RDS User Guide* now covers non-Aurora database engines.	August 31, 2018
Amazon RDS Performance Insights is available for RDS for MySQL	Amazon RDS Performance Insights is now available for RDS for MySQL. For more information, see Using Amazon RDS Performance Insights.	August 28, 2018
Aurora PostgreSQL-Compatible Edition now supports Aurora Auto Scaling	Auto Scaling of Aurora replicas is now available for Aurora PostgreSQL-Compatible Edition. For more information, see Amazon Aurora auto scaling with Aurora replicas.	August 16, 2018

Aurora Serverless for Aurora MySQL	Aurora Serverless is an on-demand, autoscaling configuration for Amazon Aurora. For more information, see Using Amazon Aurora Serverless.	August 9, 2018
MySQL 5.7.22 and 5.6.40	You can now create Amazon RDS DB instances running MySQL versions 5.7.22 and 5.6.40. For more information, see MySQL on Amazon RDS versions.	August 6, 2018
Aurora is now available in the China (Ningxia) region	Aurora MySQL and Aurora PostgreSQL are now available in the China (Ningxia) region. For more information, see Availability for Amazon Aurora MySQL and Availability for Amazon Aurora PostgreSQL.	August 6, 2018
Amazon RDS for MySQL supports delayed replication	Amazon RDS for MySQL now supports delayed replication as a strategy for disaster recovery. For more information, see Configuring delayed replication with MySQL.	August 6, 2018
Amazon RDS Performance Insights is available for Aurora MySQL	Amazon RDS Performance Insights is now available for Aurora MySQL. For more information, see Using Amazon RDS Performance Insights.	August 6, 2018

Amazon RDS Performance Insights integration with Amazon CloudWatch	Amazon RDS Performance Insights automatically publishes metrics to Amazon CloudWatch. For more information, see Performance Insights metrics published to CloudWatch.	August 6, 2018
Amazon RDS recommendations	Amazon RDS now provides automated recommendations for database resources. For more information, see Using Amazon RDS recommendations.	July 25, 2018
Incremental snapshot copies across AWS Regions	Amazon RDS supports incremental snapshot copies across AWS Regions for both unencrypted and encrypted instances. For more information, see Copying snapshots across AWS Regions.	July 24, 2018
Amazon RDS Performance Insights is available for Amazon RDS for PostgreSQL	Amazon RDS Performance Insights is now available for Amazon RDS for PostgreSQL. For more information, see Using Amazon RDS Performance Insights.	July 18, 2018
Amazon RDS for Oracle supports Oracle APEX version 5.1.4.v1	Amazon RDS for Oracle now supports Oracle Application Express (APEX) version 5.1.4.v1. For more information, see Oracle application Express.	July 10, 2018

Amazon RDS for Oracle supports publishing logs to Amazon CloudWatch Logs	Amazon RDS for Oracle now supports publishing alert, audit, trace, and listener log data to a log group in CloudWatch Logs. For more information, see Publishing Oracle logs to Amazon CloudWatch Logs.	July 9, 2018
MariaDB 10.2.15, 10.1.34, and 10.0.35	You can now create Amazon RDS DB instances running MariaDB versions 10.2.15, 10.1.34, and 10.0.35. For more information, see MariaDB on Amazon RDS versions.	July 5, 2018
Aurora PostgreSQL 1.2 is available and compatible with PostgreSQL 9.6.8	Aurora PostgreSQL 1.2 is now available and is compatible with PostgreSQL 9.6.8. For more information, see Version 1.2.	June 27, 2018
Read replicas for Amazon RDS PostgreSQL support Multi-AZ deployments	RDS read replicas in Amazon RDS PostgreSQL now support multiple Availability Zones. For more information, see Working with PostgreSQL read replicas.	June 25, 2018

Performance Insights available for Aurora PostgreSQL	Performance Insights is generally available for Aurora PostgreSQL, with support for extended retention of performance data. For more information, see Using Amazon RDS performance insights.	June 21, 2018
Aurora PostgreSQL available in western US (northern California) region	Aurora PostgreSQL is now available in the western United States (Northern Cal ifornia) region. For more information, see Availability for Amazon Aurora PostgreSQ L.	June 11, 2018
Amazon RDS for Oracle now supports CPU configuration	Amazon RDS for Oracle supports configuring the number of CPU cores and the number of threads for each core for the processor of a DB instance class. For more information, see Configuri ng the processor of the DB instance class.	June 5, 2018

Earlier updates

The following table describes the important changes in each release of the *Amazon RDS User Guide* before June 2018.

Change	Description	Date changed
Amazon RDS for PostgreSQL now supports PostgreSQL Version 11 Beta 1 in the Database Preview Environment	PostgreSQL version 11 Beta 1 contains several improvements that are described in PostgreSQL 11 beta 1 released! For information on the Database Preview Environment, see Working with the Database Preview environment.	May 31, 2018
Amazon RDS for Oracle now supports TLS versions 1.0 and 1.2	Amazon RDS for Oracle supports Transport Layer Security (TLS) versions 1.0 and 1.2. For more information, see TLS versions for the Oracle SSL option.	May 30, 2018
Aurora MySQL supports publishing logs to Amazon CloudWatch Logs	Aurora MySQL now supports publishing general, slow, audit, and error log data to a log group in CloudWatch Logs. For more information, see Publishing Aurora MySQL to CloudWatch Logs.	May 23, 2018
Database Preview Environment for Amazon RDS PostgreSQL	You can now launch a new instance of Amazon RDS PostgreSQL in a preview mode. For more information about the Database Preview Environment see, Working with the Database Preview environment.	May 22, 2018
Amazon RDS for Oracle DB instances support new DB instance classes	Oracle DB instances now support the db.x1e and db.x1 DB instance classes. For more information, see DB instance classes and RDS for Oracle DB instance classes.	May 22, 2018
Amazon RDS PostgreSQL now supports	You can now use postgres_fdw to connect to a remote server from a read replica. For more information see, Using the postgres_fdw extension to access external data.	May 17, 2018

Change	Description	Date changed
postgres_fdw on a read replica.		
Amazon RDS for Oracle now supports setting sqlnet.ora parameters	You can now set sqlnet.ora parameters with Amazon RDS for Oracle. For more information, see Modifying connection properties using sqlnet.ora parameters.	May 10, 2018
Aurora PostgreSQL available in Asia Pacific (Seoul) region.	Aurora PostgreSQL is now available in the Asia Pacific (Seoul) region. For more information, see Availability for Amazon Aurora PostgreSQL.	May 9, 2018
Aurora MySQL supports backtracking	Aurora MySQL now supports "rewinding" a DB cluster to a specific time, without restoring data from a backup. For more information, see Backtracking an Aurora DB cluster.	May 9, 2018
Aurora MySQL supports encrypted migration and replication from external MySQL	Aurora MySQL now supports encrypted migration and replication from an external MySQL database. For more information, see Migrating data from an external MySQL database to an Amazon Aurora MySQL DB cluster and Replication between Aurora and MySQL or between Aurora and another Aurora DB cluster.	April 25, 2018
Aurora PostgreSQL-Compatible Edition support for the Copy-on-Write protocol.	You can now clone databases in an Aurora PostgreSQL database cluster. For more information see, Cloning databases in an Aurora DB cluster.	April 10, 2018

Change	Description	Date changed
MariaDB 10.2.12, 10.1.31, and 10.0.34	You can now create Amazon RDS DB instances running MariaDB versions 10.2.12, 10.1.31, and 10.0.34. For more information, see MariaDB on Amazon RDS versions.	March 21, 2018
Aurora PostgreSQL Support for new regions	Aurora PostgreSQL is now available in the EU (London) and Asia Pacific (Singapore) regions. For more information, see Availability for Amazon Aurora PostgreSQL.	March 13, 2018
MySQL 5.7.21, 5.6.39, and 5.5.59	You can now create Amazon RDS DB instances running MySQL versions 5.7.21, 5.6.39, and 5.5.59. For more information, see MySQL on Amazon RDS versions.	March 9, 2018
Amazon RDS for Oracle now supports Oracle REST Data Services	Amazon RDS for Oracle supports Oracle REST Data Services as part of the APEX option. For more information, see Oracle Application Express (APEX).	March 9, 2018
Amazon Aurora MySQL-Compatible Edition available in new AWS Region	Aurora MySQL is now available in the Asia Pacific (Singapore) region. For the complete list of AWS Regions for Aurora MySQL, see Availability for Amazon Aurora MySQL.	March 6, 2018
Amazon RDS DB instances running Microsoft SQL Server support change data capture (CDC)	DB instances running Amazon RDS for Microsoft SQL Server now support change data capture (CDC). For more information, see Change data capture support for Microsoft SQL Server DB instances.	February 6, 2018

Change	Description	Date changed
Aurora MySQL supports a new major version	You can now create Aurora MySQL DB clusters running MySQL version 5.7. For more information, see Amazon Aurora MySQL database engine updates 2018-02-06.	February 6, 2018
Publish MySQL and MariaDB logs to Amazon CloudWatch Logs	You can now publish MySQL and MariaDB log data to CloudWatch Logs. For more information, see Publishing MySQL logs to Amazon CloudWatch Logs and Publishing MariaDB logs to Amazon CloudWatch Logs.	January 17, 2018
Multi-AZ support for read replicas	You can now create a read replica as a Multi-AZ DB instance. Amazon RDS creates a standby of your replica in another Availability Zone for failover support for the replica. Creating your read replica as a Multi-AZ DB instance is independent of whether the source database is a Multi-AZ DB instance. For more information, see Working with DB instance read replicas.	January 11, 2018
Amazon RDS for MariaDB supports a new major version	You can now create Amazon RDS DB instances running MariaDB version 10.2. For more information, see MariaDB 10.2 support on Amazon RDS.	January 3, 2018
Amazon Aurora PostgreSQL-Compatible Edition available in new AWS Region	Aurora PostgreSQL is now available in the EU (Paris) region. For the complete list of AWS Regions for Aurora PostgreSQL, see Availability for Amazon Aurora PostgreSQL.	December 22, 2017
Aurora PostgreSQL supports new instance types	Aurora PostgreSQL now supports new instance types. For the complete list of instance types, see Choosing the DB instance class.	December 20, 2017

Change	Description	Date changed
Amazon Aurora MySQL-Com patible Edition available in new AWS Region	Aurora MySQL is now available in the EU (Paris) region. For the complete list of AWS Regions for Aurora MySQL, see Availability for Amazon Aurora MySQL.	December 18, 2017
Aurora MySQL supports hash joins	This feature can improve query performance when you need to join a large amount of data by using an equijoin. For more information, see Working with hash joins in Aurora MySQL.	December 11, 2017
Aurora MySQL supports native functions to invoke AWS Lambda fun ctions	You can call the native functions `lambda_sync` and `lambda_async` when you use Aurora MySQL. For more information, see Invoking a Lambda function from an Amazon Aurora MySQL DB cluster.	December 11, 2017
Added Aurora PostgreSQL HIPAA eligibility	Aurora PostgreSQL now supports building HIPAA compliant applications. For more information, see Working with Amazon Aurora PostgreSQL.	December 6, 2017
Additional AWS Regions available for Amazon Aurora with PostgreSQL compatibility	Amazon Aurora with PostgreSQL compatibility is now available in four new AWS Regions. For more information, see Availability for Amazon Aurora PostgreSQL.	November 22, 2017
Modify storage for Amazon RDS DB instances running Microsoft SQL Server	You can now modify the storage of your Amazon RDS DB instances running SQL Server. For more informati on, see Modifying an Amazon RDS DB instance.	November 21, 2017

Change	Description	Date changed
Amazon RDS supports 16 TiB storage for Linux-based engines	You can now create MySQL, MariaDB, PostgreSQL, and Oracle RDS DB instances with up to 16 TiB of storage. For more information, see Amazon RDS DB instance storage.	November 21, 2017
Amazon RDS supports fast scale up of storage	You can now add storage to MySQL, MariaDB, PostgreSQL, and Oracle RDS DB instances in a few minutes. For more information, see Amazon RDS DB instance storage.	November 21, 2017
Amazon RDS supports MariaDB versions 10.1.26 and 10.0.32	You can now create Amazon RDS DB instances running MariaDB versions 10.1.26 and 10.0.32. For more information, see MariaDB on Amazon RDS versions.	November 20, 2017
Amazon RDS for Microsoft SQL Server now supports new DB instance classes	You can now create Amazon RDS DB instances running SQL Server that use the db.r4 and db.m4.16xlarge DB instance classes. For more information, see DB instance class support for Microsoft SQL Server.	November 20, 2017
Amazon RDS for MySQL and MariaDB now supports new DB instance classes	You can now create Amazon RDS DB instances running MySQL and MariaDB that use the db.r4, db.m4.16xlarge, db.t2.xlarge, and db.t2.2xlarge DB instance classes. For more information, see DB instance classes.	November 20, 2017
SQL Server 2017	You can now create Amazon RDS DB instances running Microsoft SQL Server 2017. You can also create DB instances running SQL Server 2016 SP1 CU5. For more information, see Amazon RDS for Microsoft SQL Server.	November 17, 2017

Change	Description	Date changed
Restore MySQL backups from Amazon S3	You can now create a backup of your on-premises database, store it on Amazon S3, and then restore the backup file onto a new Amazon RDS DB instance running MySQL. For more information, see Restoring a backup into a MySQL DB instance.	November 17, 2017
Auto Scaling with Aurora Replicas	Amazon Aurora MySQL now supports Aurora Auto Scaling. Aurora Auto Scaling dynamically adjusts the number of Aurora Replicas based on increases or decreases in connectivity or workload. For more information, see Amazon Aurora Auto Scaling with Aurora replicas.	November 17, 2017
Oracle default edition support	Amazon RDS for Oracle DB instances now supports setting the default edition for the DB instance. For more information, see Setting the default edition for a DB instance.	November 3, 2017
Oracle DB instance file validation	Amazon RDS for Oracle DB instances now supports validating DB instance files with the Oracle Recovery Manager (RMAN) logical validation utility. For more information, see Validating database files in RDS for Oracle .	November 3, 2017
Management Agent for OEM 13c	Amazon RDS for Oracle DB instances now support the Management Agent for Oracle Enterprise Manager (OEM) Cloud Control 13c. For more information, see Oracle Management Agent for Enterprise Manager Cloud Control.	November 1, 2017
Storage reconfiguration for Microsoft SQL Server snapshots	You can now reconfigure the storage when you restore a snapshot to an Amazon RDS DB instance running Microsoft SQL Server. For more information, see Restoring to a DB instance.	October 26, 2017

Change	Description	Date changed
Asynchronous key prefetch for Aurora MySQL-Compatible Edition	Asynchronous key prefetch (AKP) improves the performance of noncached index joins, by prefetching keys in memory ahead of when they are needed. For more information, see Working with asynchronous key prefetch in Amazon Aurora.	October 26, 2017
MySQL 5.7.19, 5.6.37, and 5.5.57	You can now create Amazon RDS DB instances running MySQL versions 5.7.19, 5.6.37, and 5.5.57. For more information, see MySQL on Amazon RDS versions.	October 25, 2017
General availability of Amazon Aurora with PostgreSQL compatibility	Amazon Aurora with PostgreSQL compatibility makes it simple and cost-effective to set up, operate, and scale your new and existing PostgreSQL deployments, thus freeing you to focus on your business and applications. For more information, see Working with Amazon Aurora PostgreSQL.	October 24, 2017
Amazon RDS for Oracle DB instances support new DB instance classes	Amazon RDS for Oracle DB instances now support memory optimized next generation (db.r4) instance classes. Amazon RDS for Oracle DB instances also now support the following new current generation instance classes: db.m4.16xlarge, db.t2.xlarge, and db.t2.2xlarge. For more information, see DB instance classes and RDS for Oracle DB instance classes.	October 23, 2017

Change	Description	Date changed
New feature	Your new and existing Reserved Instances can now cover multiple sizes in the same DB instance class. Size-flexible reserved instances are available for DB instances with the same AWS Region, database engine, and instance family, and across AZ configuration. Size-flexible reserved instances are available for the following database engines: Amazon Aurora, MariaDB, MySQL, Oracle (Bring Your Own License), PostgreSQL. For more information, see Size-flexible reserved DB instances.	October 11, 2017
New feature	You can now use the Oracle SQLT option to tune a SQL statement for optimal performance. For more information, see Oracle SQLT.	September 22, 2017
New feature	If you have existing manual DB snapshots of your Amazon RDS for Oracle DB instances, you can now upgrade them to a later version of the Oracle database engine. For more information, see Upgrading an Oracle DB snapshot.	September 20, 2017
New feature	You can now use Oracle Spatial to store, retrieve, update, and query spatial data in your Amazon RDS DB instances running Oracle. For more information, see Oracle Spatial.	September 15, 2017
New feature	You can now use Oracle Locator to support internet and wireless service-based applications and partner-based GIS solutions with your Amazon RDS DB instances running Oracle. For more information, see Oracle Locator.	September 15, 2017
New feature	You can now use Oracle Multimedia to store, manage, and retrieve images, audio, video, and other heterogeneous media data in your Amazon RDS DB instances running Oracle.	September 15, 2017

Change	Description	Date changed
New feature	You can now export audit logs from your Amazon Aurora MySQL DB clusters to Amazon CloudWatch Logs. For more information, see Publishing Aurora MySQL logs to Amazon CloudWatch Logs.	September 14, 2017
New feature	Amazon RDS now supports multiple versions of Oracle Application Express (APEX) for your DB instances running Oracle. For more information, see Oracle Application Express (APEX).	September 13, 2017
New feature	You can now use Amazon Aurora to migrate an unencrypted or encrypted DB snapshot or MySQL DB instance to an encrypted Aurora MySQL DB cluster. For more information, see Migrating an RDS for MySQL snapshot to Aurora and Migrating data from a MySQL DB instance to an Amazon Aurora MySQL DB cluster by using an Aurora read replica.	September 5, 2017
New feature	You can use Amazon RDS for Microsoft SQL Server databases to build HIPAA-compliant applications. For more information, see Compliance program support for Microsoft SQL Server DB instances.	August 31, 2017
New feature	You can now use Amazon RDS for MariaDB databases to build HIPAA-compliant applications. For more information, see Amazon RDS for MariaDB.	August 31, 2017
New feature	You can now create Amazon RDS DB instances running Microsoft SQL Server with allocated storage up to 16 TiB, and Provisioned IOPS to storage ranges of 1:1–50:1. For more information, see Amazon RDS DB instance storage.	August 22, 2017

Change	Description	Date changed
New feature	You can now use Multi-AZ deployments for DB instances running Microsoft SQL Server in the EU (Frankfurt) region. For more information, see Multi-AZ deployments for Amazon RDS for Microsoft SQL Server.	August 3, 2017
New feature	You can now create Amazon RDS DB instances running MariaDB versions 10.1.23 and 10.0.31. For more information, see MariaDB on Amazon RDS versions.	July 17, 2017
New feature	Amazon RDS now supports Microsoft SQL Server Enterprise Edition with the License Included model in all AWS Regions. For more information, see Licensing Microsoft SQL Server on Amazon RDS.	July 13, 2017
New feature	Amazon RDS for Oracle now supports Linux kernel huge pages for increased database scalability. The use of huge pages results in smaller page tables and less CPU time spent on memory managemen t, increasing the performance of large database instances. You can use huge pages with your Amazon RDS DB instances running all editions of Oracle ver sions 12.1.0.2 and 11.2.0.4. For more information, see Turning on HugePages for an RDS for Oracle instance.	July 7, 2017
New feature	Updated to support encryption at rest (EAR) for db.t2.small and db.t2.medium DB instance classes for all non-Aurora DB engines. For more information, see Availability of Amazon RDS encryption.	June 27, 2017
New feature	Updated to support Amazon Aurora in the Europe (Frankfurt) region. For more information, see Availability for Amazon Aurora MySQL.	June 16, 2017

Change	Description	Date changed
New feature	You can now specify an option group when you copy a DB snapshot across AWS regions. For more information, see Option group considerations.	June 12, 2017
New feature	You can now copy DB snapshots created from specialized DB instances across AWS regions. You can copy snapshots from DB instances that use Oracle TDE, Microsoft SQL Server TDE, and Microsoft SQL Server Multi-AZ with Mirroring. For more information, see Copying a DB snapshot.	June 12, 2017
New feature	Amazon Aurora now allows you to quickly and cost-effectively copy all of your databases in an Amazon Aurora DB cluster. For more information, see Cloning databases in an Aurora DB cluster.	June 12, 2017
New feature	Amazon RDS now supports Microsoft SQL Server 2016 SP1 CU2. For more information, see Amazon RDS for Microsoft SQL Server.	June 7, 2017
Preview	Public preview of Amazon Aurora with PostgreSQL Compatibility. For more information, see Working with Amazon Aurora PostgreSQL.	April 19, 2017
New feature	Amazon Aurora now allows you to run an ALTER TABLE *tbl_name* ADD COLUMN *col_name column_definition* operation nearly instantaneously. The operation completes without requiring the table to be copied and without materially impacting other DML statements. For more information, see Altering tables in Amazon Aurora using fast DDL.	April 5, 2017
New feature	We have added a new monitoring command, SHOW VOLUME STATUS, to display the number of nodes and disks in a volume. For more information, see Displaying volume status for an Aurora DB cluster.	April 5, 2017

Change	Description	Date changed
New feature	You can now use your own custom logic in your custom password verification functions for Oracle on Amazon RDS. For more information, see Creating custom functions to verify passwords.	March 21, 2017
New feature	You can now access your online and archived redo log files on your Oracle DB instances on Amazon RDS. For more information, see Accessing online and archived redo logs.	March 21, 2017
New feature	You can now copy both encrypted and unencrypted DB cluster snapshots between accounts in the same region. For more information, see Copying a DB cluster snapshot across accounts.	March 7, 2017
New feature	You can now share encrypted DB cluster snapshots between accounts in the same region. For more information, see Sharing a DB cluster snapshot.	March 7, 2017
New feature	You can now replicate encrypted Amazon Aurora MySQL DB clusters to create cross-region Aurora Replicas. For more information, see Replicating Aurora MySQL DB clusters across AWS Regions.	March 7, 2017
New feature	You can now require that all connections to your DB instance running Microsoft SQL Server use Secure Sockets Layer (SSL). For more information, see Using SSL with a Microsoft SQL Server DB instance.	February 27, 2017
New feature	You can now set your local time zone to one of 15 additional time zones. For more information, see Supported time zones.	February 27, 2017

Change	Description	Date changed
New feature	You can now use the Amazon RDS procedure `msdb.dbo.rds_shrink_tempdbfile` to shrink the tempdb database on your DB instances running Microsoft SQL Server. For more information, see Shrinking the tempdb database.	February 17, 2017
New feature	You can now compress your backup file when you export your Enterprise and Standard Edition Microsoft SQL Server database from an Amazon RDS DB instance to Amazon S3. For more information, see Compressing backup files.	February 17, 2017
New feature	Amazon RDS now supports custom DNS servers to resolve DNS names used in outbound network access on your DB instances running Oracle. For more information, see Setting up a custom DNS server.	January 26, 2017
New feature	Amazon RDS now supports creating an encrypted read replica in another region. For more information, see Creating a read replica in a different AWS Region and CreateDBInstanceReadReplica.	January 23, 2017
New feature	Amazon RDS now supports upgrading a MySQL DB snapshot from MySQL 5.1 to MySQL 5.5.	January 20, 2017
New feature	Amazon RDS now supports copying an encrypted DB snapshot to another region for the MariaDB, MySQL, Oracle, PostgreSQL, and Microsoft SQL Server database engines. For more information, see Copying a DB snapshot and CopyDBSnapshot.	December 20, 2016

Change	Description	Date changed
New feature	Amazon Aurora MySQL now supports spatial indexing. Spatial indexing improves query performance on large datasets for queries that use spatial data. For more information, see Amazon Aurora MySQL and spatial data.	December 14, 2016
New feature	Amazon RDS now supports outbound network access on your DB instances running Oracle. You can use utl_http, utl_tcp, and utl_smtp to connect from your DB instance to the network. For more information, see Configuring UTL_HTTP access using certificates and an Oracle wallet.	December 5, 2016
New feature	Amazon RDS has retired support for MySQL version 5.1. However, you can restore existing MySQL 5.1 snapshots to a MySQL 5.5 instance. For more information, see Supported storage engines for RDS for MySQL.	November 15, 2016
New feature	Amazon RDS now supports Microsoft SQL Server 2016 RTM CU2. For more information, see Amazon RDS for Microsoft SQL Server.	November 4, 2016
New feature	Amazon RDS now supports major version upgrades for DB instances running Oracle. You can now upgrade your Oracle DB instances from 11g to 12c. For more information, see Upgrading the RDS for Oracle DB engine.	November 2, 2016
New feature	You can now create DB instances running Microsoft SQL Server 2014 Enterprise Edition. Amazon RDS now supports SQL Server 2014 SP2 for all editions and all regions. For more information, see Amazon RDS for Microsoft SQL Server.	October 25, 2016

Change	Description	Date changed
New feature	Amazon Aurora MySQL now integrates with other AWS services: You can load text or XML data into a table from an Amazon S3 bucket, or invoke an AWS Lambda function from database code. For more information, see Integrating Aurora MySQL with other AWS services.	October 18, 2016
New feature	You can now access the tempdb database on your Amazon RDS DB instances running Microsoft SQL Server. You can access the tempdb database by using Transact-SQL through Microsoft SQL Server Management Studio (SSMS), or any other standard SQL client application. For more information, see Accessing the tempdb database on Microsoft SQL Server DB instances on Amazon RDS.	September 29, 2016
New feature	You can now use the UTL_MAIL package with your Amazon RDS DB instances running Oracle. For more information, see Oracle UTL_MAIL.	September 20, 2016
New features	You can now set the time zone of your new Microsoft SQL Server DB instances to a local time zone, to match the time zone of your applications. For more information, see Local time zone for Microsoft SQL Server DB instances.	September 19, 2016
New feature	You can now use the Oracle Label Security option to control access to individual table rows in your Amazon RDS DB instances running Oracle Database 12c. With Oracle Label Security, you can enforce regulatory compliance with a policy-based administration model, and ensure that an access to sensitive data is restricted to only users with the appropriate clearance level. For more information, see Oracle Label Security.	September 8, 2016

Change	Description	Date changed
New feature	You can now connect to an Amazon Aurora DB cluster using the reader endpoint, which load-balances connections across the Aurora Replicas that are available in the DB cluster. As clients request new connections to the reader endpoint, Aurora distributes the connection requests among the Aurora Replicas in the DB cluster. This functionality can help balance your read workload across multiple Aurora Replicas in your DB cluster. For more information, see Amazon Aurora endpoints.	September 8, 2016
New feature	You can now support the Oracle Enterprise Manager Cloud Control on your Amazon RDS DB instances running Oracle. You can enable the Management Agent on your DB instances, and share data with your Oracle Management Service (OMS). For more information, see Oracle Management Agent for Enterprise Manager Cloud Control.	September 1, 2016
New feature	This release adds support to get an ARN for a resource. For more information, see Getting an existing ARN for Amazon RDS.	August 23, 2016
New feature	You can now assign up to 50 tags for each Amazon RDS resource, for managing your resources and tracking costs. For more information, see Tagging Amazon RDS resources.	August 19, 2016

Change	Description	Date changed
New feature	Amazon RDS now supports the License Included model for Oracle Standard Edition Two. For more information, see Creating an Amazon RDS DB instance. You can now change the license model of your Amazon RDS DB instances running Microsoft SQL Server and Oracle. For more information, see Licensing Microsoft SQL Server on Amazon RDS and RDS for Oracle licensing options.	August 5, 2016
New feature	Amazon RDS now supports native backup and restore for Microsoft SQL Server databases using full backup files (.bak files). You can now easily migrate SQL Server databases to Amazon RDS, and import and export databases in a single, easily-portable file, using Amazon S3 for storage, and AWS KMS for encryption. For more information, see Importing and exporting SQL Server databases using native backup and restore.	July 27, 2016
New feature	You can now copy the source files from a MySQL database to an Amazon Simple Storage Service (Amazon S3) bucket, and then restore an Amazon Aurora DB cluster from those files. This option can be considerably faster than migrating data using `mysqldump` . For more information, see Migrating data from an external MySQL database to an Aurora MySQL DB cluster.	July 20, 2016

Change	Description	Date changed
New feature	You can now restore an unencrypted Amazon Aurora DB cluster snapshot to create an encrypted Amazon Aurora DB cluster by including an AWS Key Management Service (AWS KMS) encryption key during the restore operation. For more information, see Encrypting Amazon RDS resources.	June 30, 2016
New feature	You can use the Oracle Repository Creation Utility (RCU) to create a repository on Amazon RDS for Oracle. For more information, see Using the Oracle Repository Creation Utility on RDS for Oracle .	June 17, 2016
New feature	Adds support for PostgreSQL cross-region read replicas. For more information, see Creating a read replica in a different AWS Region.	June 16, 2016
New feature	You can now use the AWS Management Console to easily add Multi-AZ with Mirroring to a Microsoft SQL Server DB instance. For more information, see Adding Multi-AZ to a Microsoft SQL Server DB instance.	June 9, 2016
New feature	You can now use Multi-AZ Deployments Using SQL Server Mirroring in the following additional regions: Asia Pacific (Sydney), Asia Pacific (Tokyo), and South America (São Paulo). For more information, see Multi-AZ deployments for Amazon RDS for Microsoft SQL Server.	June 9, 2016
New feature	Updated to support MariaDB version 10.1. For more information, see Amazon RDS for MariaDB.	June 1, 2016
New feature	Updated to support Amazon Aurora cross-region DB clusters that are read replicas. For more informati on, see Replicating Aurora MySQL DB clusters across AWS Regions.	June 1, 2016

Change	Description	Date changed
New feature	Enhanced Monitoring is now available for Oracle DB instances. For more information, see Monitoring OS metrics with Enhanced Monitoring and Modifying an Amazon RDS DB instance.	May 27, 2016
New feature	Updated to support manual snapshot sharing for Amazon Aurora DB cluster snapshots. For more information, see Sharing a DB cluster snapshot.	May 18, 2016
New feature	You can now use the MariaDB Audit Plugin to log database activity on MariaDB and MySQL database instances. For more information, see Options for MariaDB database engine and Options for MySQL DB instances.	April 27, 2016
New feature	In-place, major version upgrades are now available for upgrading from MySQL version 5.6 to version 5.7. For more information, see Upgrading the MySQL DB engine.	April 26, 2016
New feature	Enhanced Monitoring is now available for Microsoft SQL Server DB instances. For more information, see Monitoring OS metrics with Enhanced Monitoring.	April 22, 2016
New feature	Updated to provide an Amazon Aurora **Clusters** view in the Amazon RDS console. For more information, see Viewing an Aurora DB cluster.	April 1, 2016
New feature	Updated to support SQL Server Multi-AZ with mirroring in the Asia Pacific (Seoul) region. For more information, see Multi-AZ deployments for Amazon RDS for Microsoft SQL Server.	March 31, 2016

Change	Description	Date changed
New feature	Updated to support Amazon Aurora Multi-AZ with mirroring in the Asia Pacific (Seoul) region. For more information, see Availability for Amazon Aurora MySQL.	March 31, 2016
New feature	PostgreSQL DB instances have the ability to require connections to use SSL. For more information, see Using SSL with a PostgreSQL DB instance.	March 25, 2016
New feature	Enhanced Monitoring is now available for PostgreSQL DB instances. For more information, see Monitoring OS metrics with Enhanced Monitoring.	March 25, 2016
New feature	Microsoft SQL Server DB instances can now use Windows Authentication for user authentication. For more information, see Working with AWS Managed Active Directory with RDS for SQL Server.	March 23, 2016
New feature	Enhanced Monitoring is now available in the Asia Pacific (Seoul) region. For more information, see Monitoring OS metrics with Enhanced Monitoring.	March 16, 2016
New feature	You can now customize the order in which Aurora Replicas are promoted to primary instance during a failover. For more information, see Fault tolerance for an Aurora DB cluster.	March 14, 2016
New feature	Updated to support encryption when migrating to an Aurora DB cluster. For more information, see Migrating data to an Aurora DB cluster.	March 2, 2016
New feature	Updated to support local time zone for Aurora DB clusters. For more information, see Local time zone for Aurora DB clusters.	March 1, 2016
New feature	Updated to add support for MySQL version 5.7 for current generation Amazon RDS DB instance classes.	February 22, 2016

Change	Description	Date changed
New feature	Updated to support *db.r3* and *db.t2* DB instance classes in the AWS GovCloud (US-West) region.	February 11, 2016
New feature	Updated to support encrypting copies of DB snapshots and sharing encrypted DB snapshots. For more information, see Copying a DB snapshot and Sharing a DB snapshot.	February 11, 2016
New feature	Updated to support Amazon Aurora in the Asia Pacific (Sydney) region. For more information, see Availability for Amazon Aurora MySQL.	February 11, 2016
New feature	Updated to support SSL for Oracle DB instances. For more information, see Using SSL with an RDS for Oracle DB instance.	February 9, 2016
New feature	Updated to support local time zone for MySQL and MariaDB DB instances. For more information, see Local time zone for MySQL DB instances and Local time zone for MariaDB DB instances.	December 21, 2015
New feature	Updated to support Enhanced Monitoring of OS metrics for MySQL and MariaDB instances and Aurora DB clusters. For more information, see Viewing metrics in the Amazon RDS console.	December 18, 2015
New feature	Updated to support db.t2, db.r3, and db.m4 DB instance classes for MySQL version 5.5. For more information, see DB instance classes.	December 4, 2015
New feature	Updated to support modifying the database port for an existing DB instance.	December 3, 2015
New feature	Updated to support major version upgrades of the database engine for PostgreSQL instances. For more information, see Upgrading the PostgreSQL DB engine for Amazon RDS.	November 19, 2015

Change	Description	Date changed
New feature	Updated to support modifying the public accessibi lity of an existing DB instance. Updated to support db.m4 standard DB instance classes.	November 11, 2015
New feature	Updated to support manual DB snapshot sharing. For more information, see Sharing a DB snapshot.	October 28, 2015
New feature	Updated to support Microsoft SQL Server 2014 for the Web, Express, and Standard editions.	October 26, 2015
New feature	Updated to support the MySQL-based MariaDB database engine. For more information, see Amazon RDS for MariaDB.	October 7, 2015
New feature	Updated to support Amazon Aurora in the Asia Pacific (Tokyo) region. For more information, see Availabil ity for Amazon Aurora MySQL.	October 7, 2015
New feature	Updated to support db.t2 burst-capable DB instance classes for all DB engines and the addition of the db.t2.large DB instance class. For more information, see DB instance classes.	September 25, 2015
New feature	Updated to support Oracle DB instances on R3 and T2 DB instance classes. For more information, see DB instance classes.	August 5, 2015
New feature	Microsoft SQL Server Enterprise Edition is now available with the License Included service model. For more information, see Licensing Microsoft SQL Server on Amazon RDS.	July 29, 2015
New feature	Amazon Aurora has officially released. The Amazon Aurora DB engine supports multiple DB instances in a DB cluster. For detailed information, see What is Amazon Aurora?.	July 27, 2015

Change	Description	Date changed
New feature	Updated to support copying tags to DB snapshots.	July 20, 2015
New feature	Updated to support increases in storage size for all DB engines and an increase in Provisioned IOPS for SQL Server.	June 18, 2015
New feature	Updated options for reserved DB instances.	June 15, 2015
New feature	Updated to support using Amazon CloudHSM with Oracle DB instances using TDE.	January 8, 2015
New feature	Updated to support encrypting data at rest and new API version 2014-10-31.	January 6, 2015
New feature	Updated to include the new Amazon DB engine: Aurora. The Amazon Aurora DB engine supports multiple DB instances in a DB cluster. Amazon Aurora is currently in preview release and is subject to change. For detailed information, see What is Amazon Aurora?.	November 12, 2014
New feature	Updated to support PostgreSQL read replicas.	November 10, 2014
New API and features	Updated to support the GP2 storage type and new API version 2014-09-01. Updated to support the ability to copy an existing option or parameter group to create a new option or parameter group.	October 7, 2014
New feature	Updated to support InnoDB Cache Warming for DB instances running MySQL version 5.6.19 and later.	September 3, 2014
New feature	Updated to support SSL certificate verification when connecting to MySQL version 5.6, SQL Server, and PostgreSQL database engines.	August 5, 2014

Change	Description	Date changed
New feature	Updated to support the db.t2 burstable DB instance classes.	August 4, 2014
New feature	Updated to support the db.r3 memory optimized DB instance classes for use with the MySQL (version 5.6), SQL Server, and PostgreSQL database engines.	May 28, 2014
New feature	Updated to support SQL Server Multi-AZ deployments using SQL Server Mirroring.	May 19, 2014
New feature	Updated to support upgrades from MySQL version 5.5 to version 5.6.	April 23, 2014
New feature	Updated to support Oracle GoldenGate.	April 3, 2014
New feature	Updated to support the M3 DB instance classes.	February 20, 2014
New feature	Updated to support the Oracle Timezone option.	January 13, 2014
New feature	Updated to support replication between MySQL DB instances in different regions.	November 26, 2013
New feature	Updated to support the PostgreSQL DB engine.	November 14, 2013
New feature	Updated to support SQL Server transparent data encryption (TDE).	November 7, 2013
New API and new feature	Updated to support cross region DB snapshot copies; new API version, 2013-09-09.	October 31, 2013
New features	Updated to support Oracle Statspack.	September 26, 2013
New features	Updated to support using replication to import or export data between instances of MySQL running in Amazon RDS and instances of MySQL running on-premises or on Amazon EC2.	September 5, 2013

Change	Description	Date changed
New features	Updated to support the db.cr1.8xlarge DB instance class for MySQL 5.6.	September 4, 2013
New feature	Updated to support replication of read replicas.	August 28, 2013
New feature	Updated to support parallel read replica creation.	July 22, 2013
New feature	Updated to support fine-grained permissions and tagging for all Amazon RDS resources.	July 8, 2013
New feature	Updated to support MySQL 5.6 for new instances , including support for the MySQL 5.6 memcached interface and binary log access.	July 1, 2013
New feature	Updated to support major version upgrades from MySQL 5.1 to MySQL 5.5.	June 20, 2013
New feature	Updated DB parameter groups to allow expressions for parameter values.	June 20, 2013
New API and new feature	Updated to support read replica status; new API version, 2013-05-15.	May 23, 2013
New features	Updated to support Oracle Advanced Security features for native network encryption and Oracle Transparent Data Encryption.	April 18, 2013
New features	Updated to support major version upgrades for SQL Server and additional functionality for Provisioned IOPS.	March 13, 2013
New feature	Updated to support VPC By Default for RDS.	March 11, 2013
New API and feature	Updated to support log access; new API version 20 13-02-12	March 4, 2013
New feature	Updated to support RDS event notification subscri ptions.	February 4, 2013

Change	Description	Date changed
New API and feature	Updated to support DB instance renaming and the migration of DB security group members in a VPC to a VPC security group.	January 14, 2013
New feature	Updated for AWS GovCloud (US-West) support.	December 17, 2012
New feature	Updated to support m1.medium and m1.xlarge DB instance classes.	November 6, 2012
New feature	Updated to support read replica promotion.	October 11, 2012
New feature	Updated to support SSL in Microsoft SQL Server DB instances.	October 10, 2012
New feature	Updated to support Oracle micro DB instances.	September 27, 2012
New feature	Updated to support SQL Server 2012.	September 26, 2012
New API and feature	Updated to support provisioned IOPS. API version 2012-09-17.	September 25, 2012
New features	Updated for SQL Server support for DB instances in VPC and Oracle support for Data Pump.	September 13, 2012
New feature	Updated for support for SQL Server Agent.	August 22, 2012
New feature	Updated for support for tagging of DB instances.	August 21, 2012
New features	Updated for support for Oracle APEX and XML DB, Oracle time zones, and Oracle DB instances in a VPC.	August 16, 2012
New features	Updated for support for SQL Server Database Engine Tuning Advisor and Oracle DB instances in VPC.	July 18, 2012

Change	Description	Date changed
New feature	Updated for support for option groups and first option, Oracle Enterprise Manager Database Control.	May 29, 2012
New feature	Updated for support for read replicas in Amazon Virtual Private Cloud.	May 17, 2012
New feature	Updated for Microsoft SQL Server support.	May 8, 2012
New features	Updated for support for forced failover, Multi-AZ deployment of Oracle DB instances, and nondefault character sets for Oracle DB Instances.	May 2, 2012
New feature	Updated for Amazon Virtual Private Cloud (VPC) Support.	February 13, 2012
Updated content	Updated for new Reserved Instance types.	December 19, 2011
New feature	Updated for Oracle engine support.	May 23, 2011
Updated content	Console updates.	May 13, 2011
Updated content	Edited content for shortened backup and maintenance windows.	February 28, 2011
New feature	Added support for MySQL 5.5.	January 31, 2011
New feature	Added support for read replicas.	October 4, 2010
New feature	Added support for AWS Identity and Access Management (IAM).	September 2, 2010
New feature	Added DB engine Version Management.	August 16, 2010
New feature	Added Reserved DB instances.	August 16, 2010
New Feature	Amazon RDS now supports SSL connections to your DB instances.	June 28, 2010

Change	Description	Date changed
New Guide	This is the first release of the Amazon RDS User Guide.	June 7, 2010

AWS Glossary

For the latest AWS terminology, see the AWS glossary in the *AWS Glossary Reference*.
