Ocean Sciences - February 24, 2010

An Argo mixed layer depth climatology

Main points:

- Constructed a global mixed layer depth (MLD) climatology using Argo profiles
- Calculated the MLDs with:
 - new hybrid algorithm (Holte and Talley, JAOT, 2009)
 - standard threshold method (de Boyer Montégut et al., 2004)
- New Argo climatology generally has shallower MLDs than de Boyer Montégut et al. climatology
- Provides global fields, as well as the ability to focus in on specific regions and times
- Climatology, MLD information for all Argo profiles, and a MATLAB version of the algorithm are available at <http://mixedlayer.ucsd.edu>

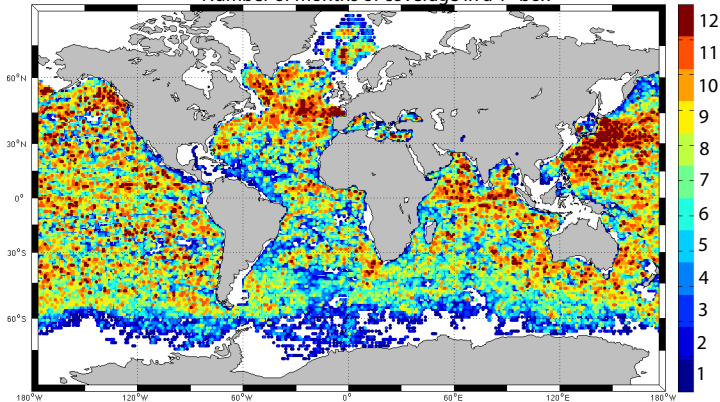

Argo

- Climatology currently includes more than 430,000 Argo real-time and delayed-mode temperature and potential density profiles
- Updated through November 2009

Argo

Number of months of coverage in a 1° box

- Coverage is sparse for a monthly climatology
- Number of profiles is increasing by nearly 100,000 profiles per year

Finding the MLD of Argo profiles

The MLD is calculated with two methods:

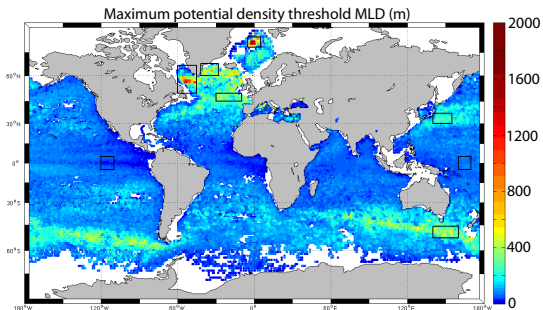

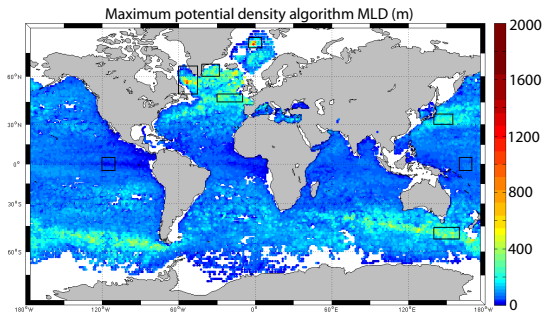

- Standard thresholds of 0.2°C and 0.03 kg m^{-3} (de Boyer Montégut et al., 2004)
- New hybrid algorithm (Holte and Talley, JAOT, 2009)

In this talk:

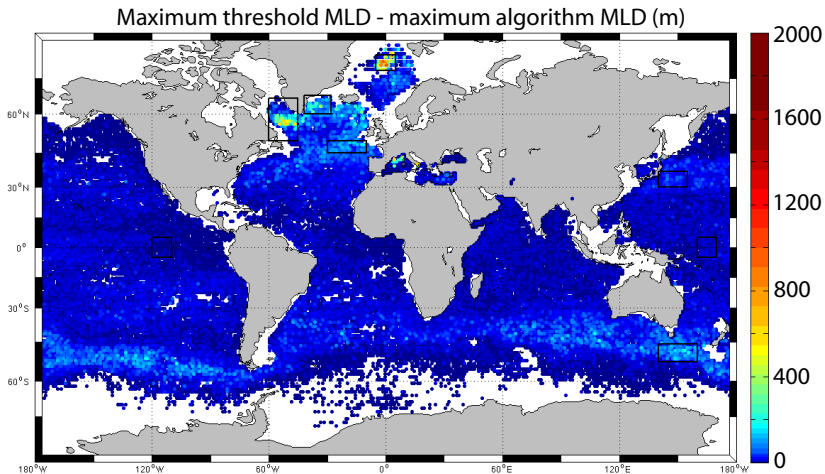

- Use potential density, but could do the same analysis for temperature profiles (and potentially add XBT profiles)
- Use a variable density threshold (density threshold is equivalent to a temperature change of -0.2°C , also from de Boyer Montégut et al., 2004)

Maximum MLDs

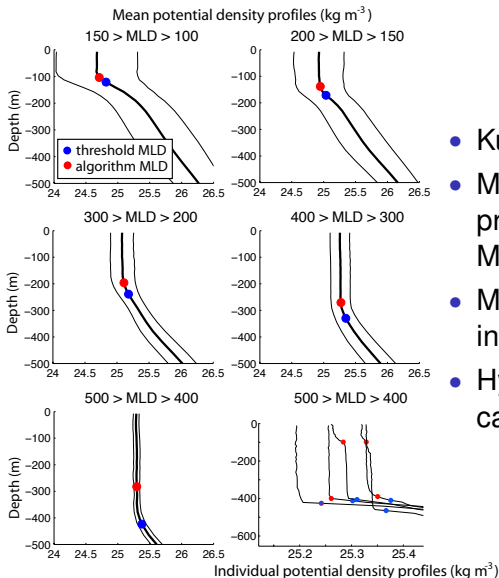

- Maximum MLD maps for the density algorithm (top) and threshold (bottom)
- Averaged in 1° bins
- Mean of the 5 maximum MLDs in each bin
- MLDs range from 0 to 2000 m

Maximum MLDs

- Algorithm MLD is always shallower
- Largest differences (>100 m) occur in deep and intermediate water formation regions

Kuroshio MLDs

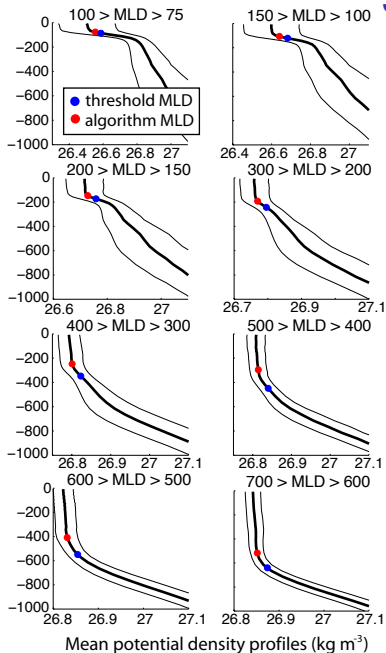

- Kuroshio region
- Mean potential density profiles binned by threshold MLD
- MLDs are the mean of the individual profile MLDs
- Hybrid algorithm more closely captures the mixed layer

Labrador Sea MLDs

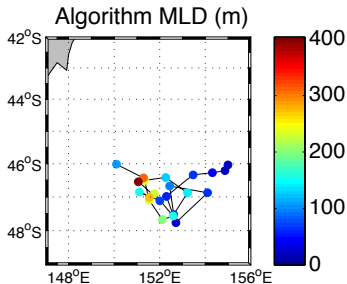

- Labrador Sea profiles grouped by threshold MLD
- Many of the threshold MLDs are too deep - threshold does not capture the finer mixed layer structure

Southern Ocean MLDs

- Southern Ocean region
- Mean potential density profiles binned by threshold MLD
- MLDs are the mean of the individual profile MLDs
- Hybrid algorithm more closely captures the mixed layer
- MLD difference between methods increases with MLD

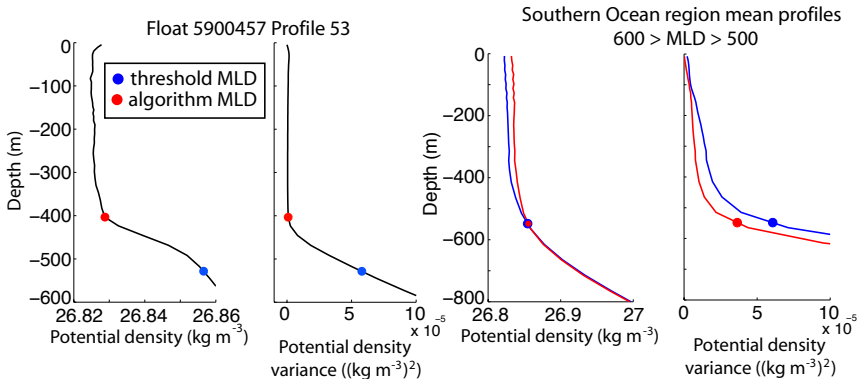

Southern Ocean MLDs

- Float 5900457 in the Southern Ocean region
- Collected 22 profiles from February to September 2005

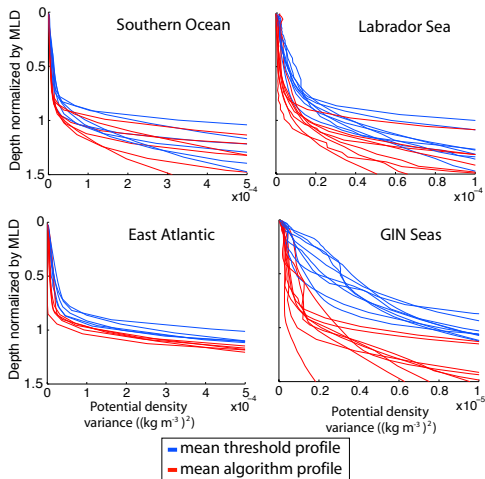

Southern Ocean MLDs

- The variance at each depth level is the cumulative variance in the profile to that depth
- Mean profiles binned by their respective MLDs
- Algorithm mean profile has lower variance - it is overestimating the MLD less than the threshold

Variance

- Mean potential density variance profiles for four regions
 - Profiles are binned according to algorithm and threshold MLDs
 - Depth is normalized by MLD
 - Variance increases as the MLD estimate extends past the actual mixed layer depth
-
- Hybrid algorithm generally has lower variance in the mixed layer - it is capturing the MLD more accurately

Global uses

- Zonal means of the maximum MLDs in 1° by 1° bins

Regional uses

- Subantarctic Mode Water in the southeast Indian Ocean (Southern Ocean region)
- Temperature-salinity properties of algorithm monthly maximum mixed layers

Summary

- We are producing a mixed layer depth (MLD) climatology with Argo. It provides MLDs and mixed layer properties calculated with standard threshold methods and with a new hybrid algorithm
- A seasonal climatology for most regions will be available soon
- Algorithm is more conservative than the threshold method - it tends to find shallower mixed layers
- Deep mixed layers only occur sporadically - the threshold methods make the mixed layer appear more uniformly deep
- The maximum MLDs found by the methods are similar, but the mean MLDs for the algorithm are generally shallower
- MLD data for all profiles and the algorithm MATLAB code are available at: **<http://mixedlayer.ucsd.edu>**
