(57) Sammendrag:
A programmable hair trimming system is disclosed, comprising a hair trimming device (2), an electromagnetic tracking system (1, 3, 4, 5, 6, 7, 10, 12) for detecting the position of the said hair trimming device (2) in relation to a client's head (30), a computer system (4, 5) for relating said position to a previously generated hair length profile data file (41) and dynamically adjusting the length regulation mechanism (18) of said hair trimming device (2) according to the hair trimmer position data (9) and the hair length profile data file (41), wherein the electromagnetic tracking system comprises electromagnetic field sources (1), electromagnetic field sensors (10) for detecting electromagnetic field properties (7) of the electromagnetic fields (6), and a computer system (4, 5) for determining the positions and orientations of the respective electromagnetic field sensors (10) relative to the electromagnetic field sources (1) from the detected electromagnetic field properties (7).

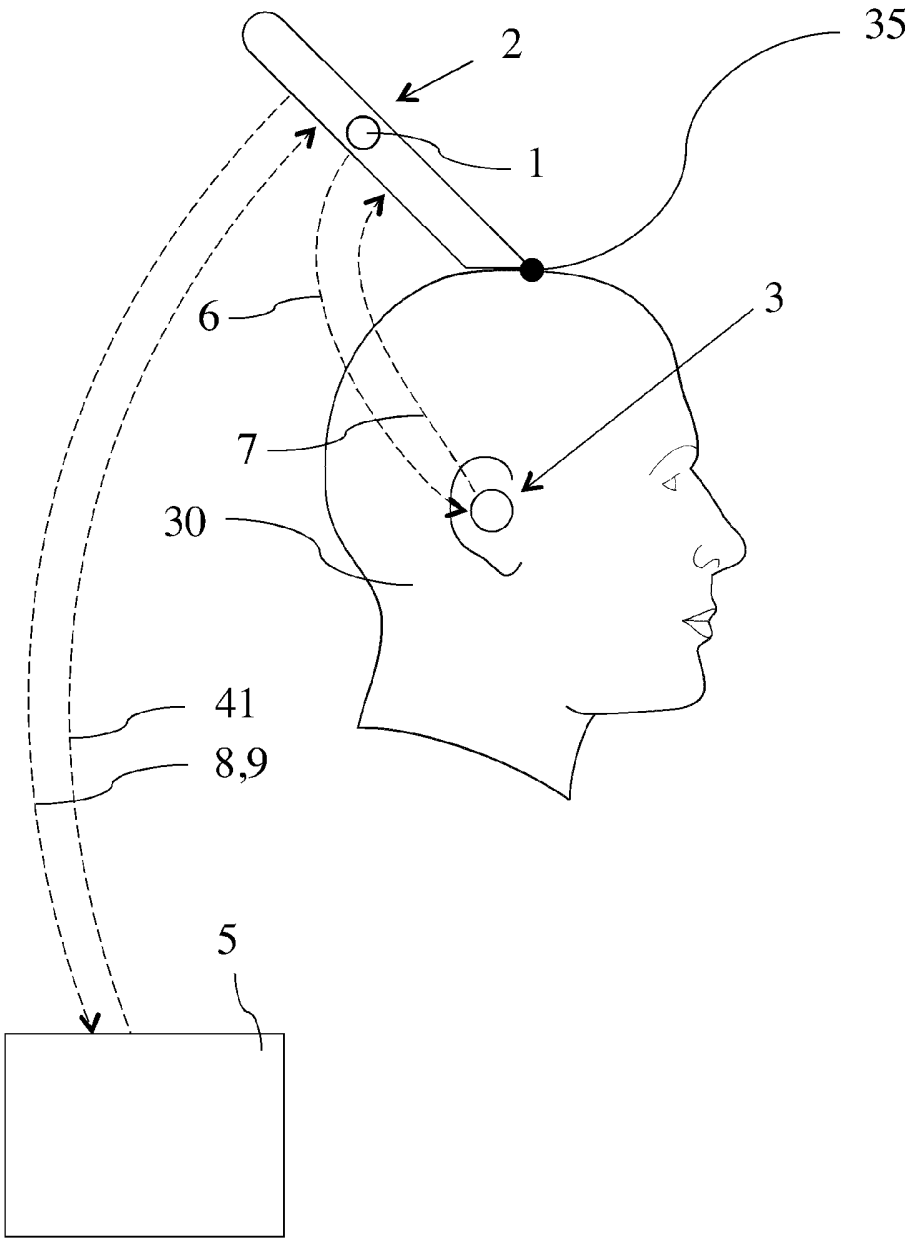
Fig. 1D



PROGRAMMABLE HAIR TRIMMING SYSTEM

The present invention relates to a hair trimming system, which can be programmed to adjust the hair trimming length according to a position of a hair trimming device in relation to the head of the person, whose hair is being trimmed.

Description of the related art

Hair trimming devices commercially available use either a replaceable or a manually adjustable comb unit in order to control the distance from the trimmer's cutting point to the client's head and thus the hair trimming length.

Using these devices, it is virtually impossible to create neither a smooth fading between different hair lengths, nor a repeatable end result if more than one length setting is applied. They have thus a limited use for other than short and even length haircuts, and, without a distance comb, for trimming off hair at a person's ears and neck area.

US patent No. US 3,413,985 describes a hair trimming system, in which the hair trimming length is adjusted according to the position of a hair trimming device relative to the head of the person, whose hair is being trimmed.

US patent application No. US 2010/0281636 describes a personal care system, in which the position and/or orientation of at least a part of a personal care product can be measured using different technologies.

It is an object for the present invention to provide a hair trimming system that can be used for a wider range of hairstyles by offering a pre-programmed and repeatable length-fading end result.

Brief description of the invention

The present invention relates to a programmable hair trimming system comprising a hair trimming device, an electromagnetic tracking system for detecting the position of the hair trimming device in relation to the head of a person on whom a hair trimming is being performed, a computer system for relating said position to a previously generated hair length profile data file regarding a number of position point trimming lengths and dynamically calculating local trimming lengths and dynamically adjusting the hair trimming length of said hair trimming device according to its present position and the hair length profile data file, wherein the electromagnetic tracking system comprises a number of electromagnetic field sources for emitting electromagnetic fields, a number of electromagnetic field sensors for detecting properties of the electromagnetic fields from the electromagnetic field sources, said electromagnetic field properties including at least the strengths of the electromagnetic fields at the place of the respective electromagnetic field sensor, and each of which electromagnetic field sensors comprises a transmitter for transmitting the detected electromagnetic field property data from the electromagnetic field sensors, and an embedded computer system for determining the positions and orientations of the respective electromagnetic field sensors relative to the electromagnetic field sources from the detected electromagnetic field properties.

The present invention differs from the disclosures of the above-mentioned US patent No. US 3,413,985 in that the position and orientation of the hair trimming device are detected using an electromagnetic tracking system configured as described here above.

This principle allows for 3D positioning with precision and price suitable for a consumer product, with small source and detector sizes suitable for being placed in a hair trimming device and a head tracking device.

This enables a user to perform a hair trimming with a pre-programmed and repeatable length-fading end result.

In an embodiment of the invention, said hair trimming device further comprises a number of electromagnetic field sources of the electromagnetic tracking system.

In another embodiment of the invention, said hair trimming system comprises a number of electromagnetic field sources of the electromagnetic tracking system, which are external to the hair trimming device, and wherein said hair trimming device further is arranged to detect electromagnetic field properties from the electromagnetic field sources of the electromagnetic tracking system by means of one or more electromagnetic field sensors of the electromagnetic tracking system and transmit data regarding said electromagnetic field properties, which electromagnetic field properties may be used to determine the position and orientation of the hair trimming device in relation to the electromagnetic field sources of the electromagnetic tracking system.

This layout allows for multiple electromagnetic field sources at various positions, thus allows for additional tracking precision.

In an embodiment of the invention, the hair trimming system further comprises a head tracking device, which is arranged to detect properties of an electromagnetic field from the electromagnetic field sources of the electromagnetic tracking system by means of electromagnetic field sensors of the electromagnetic tracking system, transmit data regarding said electromagnetic field properties, which may be used to determine the position and orientation of the head tracking device in relation to the electromagnetic field sources of the electromagnetic tracking system, receive and playback audio information and be placed in an ear of a person.

This allows a client on whom a hair trimming is being performed to move his head freely during a hair trimming session, while maintaining the position of said tracking device in relation to his hair in an area that does not interfere with the hair trimming being performed.

In an embodiment of the invention, said hair trimming device comprises an area dedicated for storing, charging and identifying a number of said head tracking devices.

This avoids the need for a separate charger for said head tracking devices, allows for integrated and hygienic storage for and transportation of said head tracking devices, and for automatic pairing of data transmitting hardware, i.e. bluetooth radios, between said devices.

In an embodiment of the invention, said hair trimming device comprises a fixed distance between its user grip area and its distance comb.

This layout allows the person who is holding said hair trimming device to focus on guiding the device on the surface on the client's head, while the hair trimming length adjustment is performed automatically by the motorized length regulation mechanism of the hair trimming device.

In an embodiment of the invention, said hair trimming system further comprises an embedded computer system, arranged to store hair length profile data, communicate with a head tracking device and an external computer system, calculate local trimming lengths and adjust the hair trimming length of the hair trimming device.

This allows for performing a hair trimming session using said hair trimming device and said head tracking device, without the use of an external computer system.

In an embodiment of the invention, the data file format used for storing a hair length profile comprises a list of position points on a client's head with accompanying desired trimming lengths.

This allows for a small data file size that can easily be modified and stored, and for using a hair length profile data file on various compatible hair trimming systems.

In an embodiment of the invention, said hair length profile data file can be retrieved, modified, visualized and stored on an external computer system.

This allows a user to pre-program a desired hair length profile data file before a hair trimming session is initiated.

In an embodiment of the invention, the progress of an on-going hair trimming session can be monitored on a connected external computer system.

This allows for a user to identify which areas on a client's head that has been covered so far during the hair trimming session.

The drawing

In the following, a few embodiments of the invention are described and explained in more detail with reference to the drawing, where

fig. 1A illustrates schematically an overall system setup with a connected external computer system, and a system unit with an electromagnetic source according to an embodiment of the invention,

fig. 1B illustrates schematically an overall system setup with a system unit with an electromagnetic source and a computer system according to another embodiment of the invention,

fig. 1C illustrates schematically an overall system setup with a connected external computer system, and a hair trimming device with an embedded computer system unit according to another embodiment of the invention,

fig. 1D illustrates schematically an overall system setup with a hair trimming device with an integrated electromagnetic source according to another embodiment of the invention,

fig. 1E illustrates schematically a layout of an integrated system unit with an electromagnetic field source, a computer system, an interactive display and docking / charging areas for a hair trimming device and a head tracking device according to another embodiment of the invention,

fig. 2 illustrates schematically a head tracking device layout according to an embodiment of the invention,

fig. 3A illustrates schematically a hair trimming device layout with a fixed distance between a user grip area and a distance comb according to an embodiment of the invention,

fig. 3B illustrates schematically a hair trimming device layout with a fixed distance between a user grip area and a cutting point according to another embodiment of the invention,

fig. 3C illustrates schematically a hair trimming device layout with an integrated electromagnetic field source and a docking / charging area for a head tracking device according to another embodiment of the invention,

fig. 4A illustrates schematically a relationship between a coordinate system of an external electromagnetic field source, a head tracking device and a hair trimming device according to an embodiment of the invention,

fig. 4B illustrates schematically a relationship between a coordinate system of an electromagnetic field source inside a hair trimming device, and a head tracking device according to another embodiment of the invention,

fig. 5A illustrates schematically a longitude vector index of position point data with a 360° coordinate grid according to an embodiment of the invention,

fig. 5B/C illustrates schematically a latitude vector index of position point data with a 360° coordinate grid according to an embodiment of the invention,

fig. 6A illustrates schematically a placement of centred and symmetric position points according to an embodiment of the invention,

fig. 6B illustrates schematically calculated local trimming lengths between position point lengths according to an embodiment of the invention,

fig. 6C illustrates schematically calculated smooth Bézier local trimming lengths between position point lengths according to an embodiment of the invention,

fig. 6D illustrates schematically calculated linear local trimming lengths between position point lengths according to another embodiment of the invention,

fig. 7 illustrates schematically a calculation of the lower length limit for shorter adjacent hair in order to avoid longer hair being trimmed involuntarily at an offset position according to an embodiment of the invention,

fig. 8A illustrates schematically a primary hair area following potential movements of a client's head according to an embodiment of the invention,

fig. 8B illustrates schematically areas with different trimming lengths and their overlapping area when using interchangeable distance combs according to another embodiment of the invention,

fig. 8C illustrates schematically the start-up area where the hair trimming device is placed by the user before guiding the device into the primary hair area according to an embodiment of the invention,

fig. 8D illustrates schematically same-length contour lines according to an embodiment of the invention, and

fig. 9 illustrates schematically the modification of position point lengths on an external computer system according to an embodiment of the invention.

Detailed description of the invention

In the following descriptions, the term "user" describes the person holding and guiding the hair trimming device during a calibration and/or hair trimming session, and/or is operating an integrated and/or connected external computer system.
The term "client" describes the person on whom a hair trimming is being performed.
These can be multiple persons or a single person.

System layout:

Fig. 1A/1B/1C/1E illustrates an embodiment of the invention, where the position and orientation of both a client's head (30) and a hair trimming device (2) are monitored in relation to a number of electromagnetic field sources (1) placed next to the client.

The position and orientation of a client's head (30) is monitored using a head tracking device (3) with an integrated electromagnetic field sensor (10) detecting at least the strengths of the electromagnetic fields (6) generated by the electromagnetic field sources (1), said sensor (10) placed at a point on the client's head (30) that follows his potential movements during a hair trimming session without interfering with the hair trimming procedure.

In an embodiment of the invention, a head tracking device (3) is in a shape similar to small audio headsets, and is placed inside the client's ear, thus preventing it from moving and turning while in use.

Parts that touch the client's ear channel can optionally be interchangeable for hygienic reasons in multiple user scenarios, and for adapting to different ear shapes.

The head tracking device (3) is powered by a battery (40) that can optionally be recharged while the device is placed in an integrated system unit (36) or a hair trimming device (2).

For increased precision, additional head tracking devices (3) can be used in the client's other ear and/or on the face area – nose, nasal bridge or in the upper mouth cavity (not shown).

The performance of the electromagnetic tracking system can be adapted to the desired precision by modifying the electromagnetic field source (1), the electromagnetic field sensor (10) and data calculation/transmission components.

The position and rotation of a hair trimming device (2) is simultaneously monitored using an electromagnetic field sensor (10) placed inside the hair trimming device (2).

The hair trimming device (2) can optionally be powered by a battery system (15) that can optionally be recharged while the device is placed in an integrated system unit (36).

The electromagnetic field property data (48) is transmitted, wired or wirelessly, from a head tracking device (3) and the hair trimming device (2) to an embedded computer system (4).

The embedded computer system (4) can be placed in either an integrated system unit (36), fig. 1A/1B/1E, or in the hair trimming device (2), fig. 1C/1D.

The distance and orientation of the two monitored devices (2, 3) in relation to the electromagnetic field source (1), together with previously generated data regarding the client's head shape, provides sufficient data for an

embedded computer system (4) to calculate the position of the hair trimming position reference point (35) in relation to the client's head (30).

This hair trimmer position data (9) is compared by the embedded computer system (4) to a previously generated hair length profile data file (41) that allows for the calculation of local trimming length (21) for any given point on the client's head (30).

The calculated local trimming length (21) is transmitted, wired or wirelessly, to the hair trimming device's (2) length regulation control system (11) and length regulation mechanism (18), which adjusts the hair trimming length accordingly.

In another embodiment of the invention, Fig. 1D, the position and orientation of a client's head (30) is monitored in relation to an electromagnetic field source (1) placed inside the hair trimming device (2).

The electromagnetic field property data (48) of the detected electromagnetic field (6) is transmitted, wired or wirelessly, from the head tracking device (3) to an embedded computer system (4), placed in either an integrated system unit (36) or in the hair trimming device (2).

The distance and orientation of the head tracking device (3) in relation to the hair trimming device's electromagnetic field source (1), together with previously generated data regarding the client's head shape, provides sufficient data for the embedded computer system (4) to calculate the position of the hair trimming position reference point (35) in relation to the client's head (30).

The invention is characterized by utilizing a general data file format and separate hair trimming hardware. This allows for the same data file to be used by hardware with various features, i.e. cutting point design, optional

vacuum, grid resolution, wired / wireless and trimming length adjusting mechanism design.

Head shape calibration procedure:

The hair trimming system can be adapted more precisely to the client's head (30) via an initial calibration procedure that generates a 3D representation of the client's head shape.

This once-per-client procedure can be performed using either a dedicated calibration device (not shown), alternatively by setting a hair trimming device (2) in a calibration mode with its trimmer motor (16) turned off.

The head shape calibration procedure can be performed using either an external computer system (5) or a computer system in an integrated system unit (36), hereafter called "the calibration system".

As the distance between the electromagnetic field source (1) or electromagnetic field sensor,(10) and the hair trimming position reference point (35) is programmed into the calibration system, these two components can be separately placed, fig. 4A/B.

At the beginning of the head shape calibration procedure, the system's head tracking device (3) is switched on and mounted on the client.

The hair trimming device (2) in calibration mode is placed by the user (42) at a number of random points on the client's head (30). The user (42) can optionally confirm the placement by pressing a button (not shown) on the handheld device.

The calibration system software provides the user (42) with a visual and/or acoustic feedback signal when a calibration point has been registered, and

can also optionally show the areas that the user (42) has covered so far and the areas where he still needs to position the hair trimming device (2) in calibration mode.

The calibration system indicates when the number of calibration points is sufficient for it to generate a smooth 3D representation of the shape of the client's head (30).

A similar calibration procedure can optionally be performed registering the hairlines of the clients's head (30) for greater precision in the following hair length profile creation and modification procedure.

The head shape and optional hairline calibration procedure can be repeated for multiple clients, and the result can be stored as individual head shape / hairline data files in an external computer system (5), and/or in the embedded computer system (4), and/or in a database accessible via connected computers i.e. the internet, and/or on local media i.e. USB memory devices, and/or portable devices such as mobile telephones.

Hair length profile (HLP) data file (41) creation and modification procedure:

The HLP data file (41) creation and modification procedure can be performed using an external computer system (5) and/or an embedded computer system (4) in an integrated system unit (36), hereafter called the "HLP modification system".

A HLP data file (41) contains a set of position points (20, 26), each with an accompanying trimming length between zero mm and a maximum length determined by a hair trimming device's adjustment travel length.

The number of position points (20, 26) for a HLP data file (41) should be small enough to allow for smooth calculated local trimming lengths (21) ,

while maintaining the resolution needed for trimming length variation, preferably four to eight centred position points (20) and two to six pairs of symmetric position points (26).

The number of calculated steps between the positions (20, 26) can be adjusted by the HLP modification system with due respect for seamless steps, preferably not larger than one mm.

As a HLP data file (41) consists of said position points (20, 26) and accompanying position point trimming lengths (46), the software of the embedded computer system will be calculating the local trimming lengths (21), optimized for the precision of the length regulation mechanism (18) of its hair trimming device (2).

Each position point (20, 26) is characterized by its X coordinate, fig. 5A, and its Y coordinate, fig. 5B/C, which X and Y coordinates correspond to longitude and latitude coordinates, respectively, in the geographic coordinate system of a globe. A position point (20, 26) can thus be considered as a 3D vector direction with origin at a virtual centre inside a client's head (30).

The centred position points (20) all have an X value of 0° or 180°, while the symmetric position points (26) all have a mirrored twin point with similar Y value and an X value of three-hundred-and-sixty degrees minus the opposite point's X value. The symmetric position points (26) can optionally be replaced by individual position points (not shown) without a mirrored twin point on the opposite side of the client's head (30).

In an embodiment of the invention, the HLP modification system can present a number of default HLP data files (41) for the user (42) to choose from.

In another embodiment of the invention, the user (42) enters length values at a number of points on the client's head (30) into the HLP modification system. These values can be based on manually measured hair lengths on the client's head whilst having a desired hair length.

During this manual procedure, the HLP modification system can show to the user (42) where values need to be added in order to generate a HLP data file (41).

The HLP modification system can adapt the current HLP data file (41) to the previously performed registration of the client's head shape and optional hairline registration, and visualize the generated HLP data file (41) to the user (42).

The HLP modification system software allows the user (42) to modify the HLP data file (41) by selecting a position (20, 26) and then adjust its accompanying trimming length, fig. 9.

The length selectable at any position point (20, 26) is limited by the maximum travel distance of the length regulation mechanism (18) of the hair trimming device (2) to be used.

The limit for local length variation is given by the equation

$$Ly \geq sqr(Lx^2 - D^2)$$

where Ly is the minimum length of a hair at the distance D from a longer hair with the length Lx, fig. 7.

If the trimming length setting at Ly is shorter that given by said equation, longer Lx hair could be trimmed involuntarily at the Ly position.

The HLP modification system prevents the user (42) from adjusting a position point trimming length (46) with too much local variation according to said equation.

The length setting for the neck hair area (34) is automatically set to a similar length as at the closest position point (20, 26), as this area not necessarily follows the head tracking device (3) when the client's head (30) is moved / twisted / bend.

The fade shape between position points (20, 26) is by default adapted to a smooth Bézier curve connection angle (28), fig. 6C, and can be modified by the user (42) towards a sharp connection angle (29), fig. 6D.

When the user (42) has changed the trimming length at any position point (20, 26), the HLP modification system updates the HLP data file (41) by generating the calculated local trimming lengths (21) between the position point trimming lengths (46).

The user (42) can choose to modify any number of position points (20, 26).

The updated HLP data file (41) can be displayed by the HLP modification system by visualizing the position lengths (20, 26) and the calculated local trimming lengths (21) in a "hedgehog" style, and/or a terrain style with illustrated contour lines (23) with similar trimming length.

The updated HLP data file (41) can be illustrated by the HLP modification system by showing a number of hairstyles possible with the currently selected HLP data file (41).

The updated HLP data file (41) and potential hairstyles can be displayed by the HLP modification system in combination with a number of photographs

of the client's face, front and profile, visualized on a 3D head for a more realistic preview of the potential end result.

The updated HLP data file (41) can be stored in an external computer system (5), and/or in a database accessible via connected computers i.e. the internet, and/or on local media i.e. USB memory devices, and/or portable devices such as mobile telephones.

A number of HLP data files (41) can be stored in the embedded computer system (4) placed in either the hair trimming device (2) or the integrated system unit (36).

Hair trimming start-up procedure:

Prior to a trimming session, the user (42) selects which HLP data file (41) to use.

In an embodiment of the invention, the HLP data file (41) can be selected on an interactive display (17) on the hair trimming device (2) and/or on an interactive display (37) of an integrated system unit (36).

In another embodiment of the invention, the HLP data file (41) can be selected on an external computer system (5) connected to the trimming system.

In order to verify the placement and orientation of a head tracking device (3), and to verify that the HLP data file (41) selected is compatible with the current client's head (30), a start-up calibration procedure is performed by the user (42).

At the beginning of the start-up calibration procedure, the system's head tracking device (3) is switched on and mounted on the client's head (30).

The hair trimming device (2) with its trimmer motor (16) switched off is placed by the user (42) at a number of points on the client's head (30). The user (42) can optionally confirm the placement by pressing a button (not shown) on the hair trimming device (2).

The embedded computer system (4) gives the user (42) visual and/or acoustic feedback when a calibration point has been detected, after which the user (42) places the hair trimming device (2) at another random point on the client's head (30).

The user (42) can optionally follow the calibration procedure on an external computer system (5) or the interactive display (37) of the integrated system unit (36), which shows the areas where the user (42) so far has and still needs to position the hair trimming device (2) in calibration mode.

When sufficient points have been detected by the embedded computer system (4) to verify the compatibility between the client's head (30) and the HLP data file (41) as well as the placement and orientation of the head tracking device (3) in relation to the client's head (30), the user (42) is informed visually and/or acoustically by the embedded computer system (4), and the hair trimming can begin.

The trimmer motor (16) can optionally be prevented from being switched on until a start-up calibration is completed, or unless the hair trimming device (2) is set in a manual length regulation mode.

Hair trimming procedure:

The user (42) places the hair trimming device (2) in the start-up area (25) on the client's head (30), with contact detected by a pressure sensitive sensor in the hair trimming device (not shown). The hair trimming device (2) detects

and confirms the placement in the start-up area (25) as well as the trimmer/head contact via said pressure sensitive sensor, and starts the trimming motor (16) automatically.

During a hair trimming session, the user (42) guides the hair trimming device (2) on the surface of the client's head (30) in the same way, as he would use a commercially available hair trimming device.

The hair trimming procedure can be visualized using an external computer system (5) and/or an embedded computer system (4), hereafter called "the hair trimming visualization system".

The hair trimming visualization system can display the current position of the hair trimming position reference point (35) on the client's head (30), including a visualization of the area on the client's head (30) covered so far during the current session.

The hair trimming visualization system can show the user (42) to move the hair trimming device (2) perpendicular to contour lines (23) with the same trimming height, typically from a start-up area (25) towards the top of the client's head, in order to prevent that a hair trimming device (2) with a wide cutting point (22) trims off too much hair.

Information about i.e. the current hair trimming length, data signal strength and battery levels can be displayed on the interactive displays (17, 37).

If the system includes a head tracking device (3) that comprises an audio receiver (13) and loudspeaker (14), audio information regarding the current trimming length can optionally be provided to the client, which would be desirable if he is guiding the hair trimming device (2) himself, and/or if no hair trimming visualizing system is used during the trimming session.

If, for whatever reason, transmission of electromagnetic field property data (48) from an electromagnetic field sensor (10) to the embedded computer system (4) is interrupted, and/or the user (42) moves the hair trimming device (2) too fast for the embedded computer system (4) to calculate and transmit the current trimming length data (8) to the hair trimming device's (2) embedded length regulation control system (11), and/or the transmission of trimming length data (8) from the embedded computer system (4) to the hair trimming device (2) is interrupted, and/or the hair trimming device (2) is lifted from the client's head (30), then the trimmer motor (16) is automatically shuts off, and/or the length regulation mechanism (18) is set to its maximum trimming length.

In an embodiment of the invention, fig. 3A, the hair trimming device (2) has a fixed distance between its user grip area (24) and its distance comb (19), while the cutting point (22) of the hair trimming device (2) is moved up and down inside the distance comb (19) by the length regulation mechanism (18).

This allows the user (42) to focus on guiding the hair trimming device (2) on the surface of the client's head (30) without paying attention the automatically adjusted trimming length.

In order to minimize the size and weight of the moving parts, a heavy trimmer motor (16) should be at a fixed position inside the hair trimming device (2), and the length regulation mechanism (18) should only move a minimum of mass, including the cutting point (22).

In another embodiment of the invention, fig. 3B, a moveable distance comb (27) is used, whilst the cutting point (22) is fixed in the hair trimming device (2).

This is similar to the layout of most of today's commercially available hair trimmers, but also requires that the user (42) constantly applies both sufficient pressure on the client's head (30) in order to keep the moveable distance comb (27) touching the surface of client's head (30), and at the same time not using too much force that could prevent the moveable distance comb (27) from increasing the trimming distance.

Unless the electromagnetic field sensor (10) or electromagnetic field source (1) in the hair trimming device (2) is placed in a fixed relation to a moveable distance comb (27), the embedded computer system (4) compensates for the movement of the hair trimming position reference point (35) when the latter embodiment is implemented.

In an embodiment of the invention, the layout of the cutting point (22) mechanism is similar to hair trimming devices commercially available, with a horizontally moving shearing blade moving in parallel to a static blade.

In another embodiment of the invention, the layout of the cutting point (22) contains a rotating cutting system, similar to other hair trimming devices commercially available, mostly with an integrated vacuum system.

In another embodiment of the invention, the hair trimming device (2) is connected to a vacuum unit (not shown) as applied by a number of commercially available hair trimming devices, which assists the distance comb (19, 27) in lifting the hair perpendicular to the client's head (30). This reduces the need for trimming the current area multiple times, as more hair is likely to be trimmed the first time the hair trimming device (2) is passing an area.

A connected vacuum unit could also remove trimmed-off hair and thus reduce the need for cleaning of both the hair trimming device (2) and the client afterwards.

The vacuum can be generated by an external system collecting the hair clippings, or a vacuum generator integrated in the hair trimming device (2) itself, including a reservoir for collecting hair clippings.

In another embodiment of the invention, a hair-thinning attachment (not shown) can be engaged at the cutting point (22), as applied by a number of commercially available hair trimming devices.

This hair-thinning attachment reduces the amount of hair that is caught at the cutting point (22), and thus provides an end result with a more fluffy and random appearance, which can be desirable for some clients.

As the optional hair trimming visualization system can display the area covered during the current trimming session, the user (42) can monitor which areas has been trimmed and/or thinned out so far during the current hair trimming / thinning session. This is especially useful when the user (42) and client is the same person.

In another embodiment of the invention, the distance comb (19) is interchangeable, thus making it possible for using the hair trimming system for hairstyles with longer lengths than the travel length of the length regulation mechanism (18).

I.e. if the length regulation mechanism (18) has a travel distance of thirty mm, one distance comb (19) could cover zero-to-thirty mm trimming lengths, and another could be used on twenty-to fifty mm lengths.

If these replaceable distance combs (19) are to be used during the same hair trimming session, an external computer system (5) can show the user which areas to trim with the current distance comb (19), fig. 8B. The hair trimming unit (2) will automatically shut off its trimmer motor (16), if the user

involuntarily moves a short length distance comb from its intended area (45) via an overlapping trimming length area (44) and into an area with longer hair (43).

In another embodiment of the invention, the user (42) can temporarily modify the selected HLP data file (41) by adjusting all position point trimming lengths (46) with a chosen percentage, i.e. plus/minus ten per cent, and/or a chosen distance, i.e. plus/minus two millimetres. The user (42) can also temporarily modify the selected HLP data file (41) by adding one or more ad-hoc position points and/or by modifying one or more position points (20, 26).

These temporary HLP data file (41) modifications can optionally be performed using the interactive display (17) on the hair trimming device (2).

In another embodiment of the invention, the user (42) can manually adjust the length regulation mechanism (18), and thus use the hair trimming device (2) as the manually adjustable hair trimming devices commercially available, without the need for additional hardware.

It should be noted that the described embodiments are exemplary only and are not in any way meant to limit the scope of protection, which is defined by the claims listed here below.

List of reference numbers

1. Electromagnetic field source
2. Hair trimming device
3. Head tracking device
4. Embedded computer system
5. External computer system
6. Electromagnetic field
7. Electromagnetic field property
8. Trimming length data
9. Hair trimmer position data
10. Electromagnetic field sensor
11. Length regulation control system
12. Electromagnetic field property transmitter
13. Audio receiver
14. Loudspeaker
15. Battery
16. Trimmer motor
17. Interactive display
18. Length regulation mechanism
19. Distance comb
20. Centred position point
21. Calculated local trimming length
22. Cutting point
23. Contour lines
24. User grip area
25. Start-up area
26. Symmetric position point
27. Moveable distance comb
28. Smooth Bézier curve connection angle
29. Sharp connection angle
30. Client's head

31. Static 3D coordinate system
32. Relative 3D coordinate system
33. Primary hair area
34. Neck hair area
35. Hair trimming position reference point
36. Integrated system unit
37. Interactive display
38. Hair trimming device docking / charging compartment
39. Head tracking device docking / charging compartment
40. Battery
41. Hair length profile data file
42. User of external computer system / hair trimming device
43. Longer hair area
44. Overlapping trimming length area
45. Shorter hair area
46. Position point trimming length
47. Calculated position point
48. Electromagnetic field property data

Krav

1. Programmérbart hårklippersystem omfattende

en hårklipperenhed (2),

et system til elektromagnetisk sporing (1, 3, 4, 5, 6, 7, 10, 12) til detektering af positionen af et referencepunkt (35) på hårklipperenheden (2) i forhold til en persons hoved (30), på hvilket en hårklipning udføres,

et computersystem (4, 5) til

relatering af positionen af referencepunktet (35) til en på forhånd genereret hårlængdeprofil-datafil (41), der omfatter et antal positionspunkter (20, 26) på hovedet (30) med associerede positionspunktsklippelængder (46), og

dynamisk beregning af lokale klippelængder (21) mellem positionspunktsklippelængderne (46) og

dynamisk styring af en længdereguleringsmekanisme (18) på hårklipperenheden (2) i henhold til klippelængderne (21, 46),

hvor systemet til elektromagnetisk sporing omfatter

et antal elektromagnetiske feltkilder (1) til udsendelse af elektromagnetiske felter (6),

et antal elektromagnetiske feltsensorer (10) til detektering af egenskaber (7) for de elektromagnetiske felter (6) fra de

elektromagnetiske feltkilder (1), hvor de elektromagnetiske feltegenskaber (7) inkluderer i det mindste styrken af de elektromagnetiske felter (6) på den respektive elektromagnetiske feltsensors (10) placering, og hvor hver elektromagnetiske feltsensor (10) omfatter en transmitter (12) til transmission af detekterede elektromagnetiske feltegenskabsdata (48) fra de elektromagnetiske feltsensorer (10), og

et integreret computersystem (4) til bestemmelse af positionerne og orienteringerne af de respektive elektromagnetiske feltsensorer (10) i forhold til de elektromagnetiske feltkilder (1) ud fra de detekterede elektromagnetiske feltegenskaber (7).

2. Et hårklippersystem ifølge krav 1, hvor hårklipperenheden (2) yderligere omfatter et antal elektromagnetiske feltkilder (1) fra systemet til elektromagnetisk sporing.

3. Et hårklippersystem ifølge krav 1, hvor et antal elektromagnetiske feltkilder (1) fra systemet til elektromagnetisk sporing er anbragt eksternt i forhold til hårklipperenheden (2), og hvor hårklipperenheden (2) desuden er indrettet til at

- detektere et elektromagnetisk felt (6) fra de elektromagnetiske feltkilder (1) fra systemet til elektromagnetisk sporing ved hjælp af en eller flere elektromagnetiske feltsensorer (10) fra systemet til elektromagnetisk sporing,
- transmittere egenskabsdata (48) for det elektromagnetiske felt (6), hvilke egenskabsdata (48) kan anvendes til at bestemme positionen og orienteringen af hårklipperenheden (2) i forhold til de elektromagnetiske feltkilder (1) fra systemet til elektromagnetisk sporing.

4. Et hårklipper-system ifølge krav 2-3, hvor hårklippersystemet omfatter en hovedsporingsenhed (3), som er indrettet til at
   - detektere et elektromagnetisk felt (6) fra de elektromagnetiske feltkilder (1) fra systemet til elektromagnetisk sporing ved hjælp af elektromagnetiske feltsensorer (10) fra systemet til elektromagnetisk sporing,
   - transmittere egenskabsdata (48) for det elektromagnetiske felt (6), hvilke egenskabsdata (48) kan anvendes til at bestemme hovedsporingsenhedens (3) position og orientering i forhold til systemet til elektromagnetisk sporings elektromagnetiske feltkilder (1),
   - modtage og afspille lydinformation,
   - blive placeret i en persons øre.

5. Et hårklippersystem ifølge krav 2-4, hvor hårklipperenheden (2) yderligere omfatter et område (39) til opbevaring, opladning og identificering af et antal hovedsporingsenheder (3).

6. Et hårklippersystem ifølge krav 2-4, hvor hårklipperenheden (2) yderligere omfatter en fast afstand mellem dens brugergrebsområde (24) og dens afstandskam (19).

7. Et hårklippersystem ifølge et hvilket som helst af de foregående krav, hvor hårklippersystemet omfatter et integreret computersystem (4), indrettet til at
   - lagre en hårlængdeprofil-datafil (41),
   - modtage elektromagnetiske feltegenskabsdata (48) fra elektromagnetiske feltsensorer (10), der detekterer et elektromagnetisk felt (6),
   - beregne en klippelængde (21, 46) ud fra de lagrede og modtagne data,

- styre en længdereguleringsmekanisme (18) på en hårklipperenhed (2),
- transmittere information til en lydmodtager (13) i en hovedsporingsenhed (3),
- blive placeret i en hårklipperenhed (2),
- kommunikere med et eksternt computersystem (5).

8. Et hårklippersystem ifølge et hvilket som helst af de foregående krav, hvor hårlængdeprofil-datafilens (41) format indeholder en liste med individuelle positionspunkter (20, 26) på en klients hoved (30) med tilhørende klippelængder (46).

9. Et hårklippersystem ifølge krav 8, hvor et eksternt computersystem (5) er indrettet til at lade dets bruger hente, modificere, visualisere og lagre en hårlængdeprofil-datafil (41).

10. Et hårklippersystem ifølge et hvilket som helst af de foregående krav, hvor et eksternt computersystem (5) er indrettet til at lade dets bruger overvåge afviklingen af en hårklipning udført af et tilsluttet hårklippersystem.
