(57) **ABSTRACT**

Methods of depositing conformal aluminum nitride films on semiconductor substrates are provided. Disclosed methods involve (a) exposing a substrate to an aluminum-containing precursor, (b) purging the aluminum-containing precursor for a duration insufficient to remove substantially all of the aluminum-containing precursor in gas phase, (c) exposing the substrate to a nitrogen-containing precursor to form aluminum nitride, (d) purging the nitrogen-containing precursor, and (e) repeating (a) through (d). Increased growth rate and 100% step coverage and conformality are attained.

HIGH GROWTH RATE PROCESS FOR CONFORMAL ALUMINUM NITRIDE

CROSS-REFERENCE TO RELATED APPLICATION

[0001] This application is a continuation of and claims priority to U.S. patent application Ser. No. 14/183,287, filed Feb. 18, 2014, titled "HIGH GROWTH RATE PROCESS FOR CONFORMAL ALUMINUM NITRIDE," which is incorporated by reference herein in its entirety and for all purposes.

BACKGROUND

[0002] Various thin film layers for semiconductor devices may be deposited with atomic layer deposition (ALD) processes. However, existing ALD processes may not be suitable for depositing highly conformal dielectric films. For example, many existing ALD processes cannot offer a combination of high throughput (rapid deposition) and high conformality.

SUMMARY

[0003] Provided herein are methods of depositing conformal aluminum nitride and other materials such as other metal nitrides and metal oxides on semiconductor substrates.

[0004] One aspect involves a method of processing a semiconductor substrate having features in a reaction chamber. The method includes (a) exposing the substrate to an aluminum-containing precursor for a duration sufficient to substantially adsorb to a surface of the substrate; (b) purging the aluminum-containing precursor from the reaction chamber for a duration insufficient to remove substantially all of the aluminum-containing precursor from the gas phase; (c) exposing the substrate to a nitrogen-containing precursor for a duration sufficient to drive a thermally mediated reaction to form a layer of aluminum nitride on the surface of the substrate, such that the layer of aluminum nitride is substantially conformal to the substrate and has a thickness of about 1.5 Å or greater; (d) purging the nitrogen-containing precursor in gas phase from the reaction chamber; and (e) repeating (a) through (d). In some embodiments, the amount of aluminum nitride deposited during a cycle of (a) through (d) is at least about 2 Å. In some embodiments, the amount of aluminum nitride deposited during a cycle of (a) through (d) is at least about 5 Å. In some embodiments, the layer of aluminum-nitride has step coverage of at least about 80%. In various embodiments, the substrate is processed at a process temperature between about 250° C. and about 450° C. The substrate may be processed at a pressure between about 0.01 Torr and about 10 Torr.

[0005] In many embodiments, the aluminum-containing precursor is trimethylaluminum (TMA). In many embodiments, the nitrogen-containing precursor is ammonia (NH_3). In some embodiments, nitrogen (N_2) is flowed to purge the aluminum-containing precursor and is flowed to purge the nitrogen-containing precursor. In many embodiments, the aluminum-containing precursor is purged for about 2 seconds. In many embodiments, the substrate is exposed to the aluminum-containing precursor for about 7.5 seconds to about 30 seconds. In various embodiments, the ratio of the time the substrate is exposed to the aluminum-containing precursor to the time the aluminum-containing precursor is purged is between about 3.75:1 and about 15:1.

[0006] In some embodiments, the features of the substrate have aspect ratios of at least about 2:1. In some embodiments, the features of the substrate have openings of less than about 100 nm. In various embodiments, processing exhibits substantially no pattern loading.

[0007] Another aspect involves an apparatus for depositing a film on a substrate surface including a reaction chamber including a pedestal for holding the substrate, at least one outlet for coupling to a vacuum, one or more process gas inlets coupled to two or more precursor sources, and a controller for controlling operations in the apparatus. The controller includes machine-readable instructions for (a) introducing a first precursor into the reaction chamber for a duration sufficient to substantially adsorb the first precursor to the surface of the substrate; (b) purging the chamber for a duration insufficient to remove substantially all of the first precursor from gas phase; (c) introducing a second precursor to the reaction chamber for a duration sufficient to form a layer on the substrate surface, such that the layer is substantially conformal to the substrate and has a thickness of about 1.5 Å or greater; (d) purging the chamber for a duration sufficient to remove the second precursor from gas phase; and (e) repeating (a) through (d).

[0008] In some embodiments, the controller includes instructions for performing (a) for a time about 3.75 to about 15 times greater than the time for performing (b). In various embodiments, the instructions for introducing the first precursor include drawing the first precursor from the headspace of a reservoir of the first precursor to the chamber. In some embodiments, the instructions for introducing the first precursor also includes flowing a carrier gas with the first precursor downstream from the drawing of the first precursor from the headspace and upstream from the reaction chamber.

[0009] These and other aspects are described further below with reference to the drawings.

BRIEF DESCRIPTION OF THE DRAWINGS

[0010] FIG. **1** is a process flow diagram of a method of depositing aluminum nitride in accordance with disclosed embodiments.

[0011] FIG. **2** is a timing sequence diagram of pulses in accordance with disclosed embodiments.

[0012] FIGS. **3**A and **3**B are schematic illustrations of examples of a chamber for practicing various embodiments.

[0013] FIG. **4** is a schematic illustration of an example of an apparatus for practicing various embodiments.

[0014] FIGS. **5**, **6**A, **6**B, and **7** are images of deposited films in accordance with experiments of the disclosed embodiments.

DETAILED DESCRIPTION

[0015] In the following description, numerous specific details are set forth to provide a thorough understanding of the presented embodiments. The disclosed embodiments may be practiced without some or all of these specific details. In other instances, well-known process operations have not been described in detail to not unnecessarily obscure the disclosed embodiments. While the disclosed embodiments will be described in conjunction with the specific embodiments, it will be understood that it is not intended to limit the disclosed embodiments.

[0016] Manufacture of semiconductor devices typically involves depositing one or more thin films on a non-planar

structure in an integrated fabrication process. In some aspects of the integrated process, it may be useful to deposit thin films that conform to substrate topography. For example, some front-end-of-the-line processes may involve deposition of conformal films. Example substrates may include substrates with features having aspect ratios of at least about 2:1, or at least about 4:1, or at least about 6:1, or at least about 10:1. Examples of conformal films for front-end-of-line processes include hard masks, etch stops, and encapsulation layers. Front-end-of-line structures fabricated using such films include transistors (e.g., FinFETs) and metal-containing memory devices.

[0017] Atomic layer deposition (ALD) processes use surface-mediated deposition reactions to deposit films on a layer-by-layer basis. In one example of an ALD process, a substrate surface, including a population of surface active sites, is exposed to a gas phase distribution of a first precursor in a dose. Some molecules of this first precursor may form a condensed phase atop the substrate surface, including chemisorbed species and/or physisorbed molecules of the first precursor. The reactor is then evacuated to remove gas phase first precursor so that only adsorbed species remain. A second precursor may then be introduced to the reactor so that some of these molecules adsorb to the substrate surface. The reactor may then be evacuated again to remove unbound second precursor molecules. Thermal energy may activate surface reactions between the first and second precursors to form a film layer. In some processes, the second precursor reacts immediately with the adsorbed first precursor. In other embodiments, the second precursor reacts only after a source of activation is applied temporally. Additional ALD cycles may be used to build film thickness.

[0018] Conventional ALD processes such as the one described above form highly conformal films. Conformality of films is often measured by the step coverage. Step coverage may be calculated by comparing the average thickness of a deposited film on a bottom, sidewall, or top of a feature to the average thickness of a deposited film on a bottom, sidewall, or top of a feature. For example, step coverage may be calculated by dividing the average thickness of the deposited film on the sidewall by the average thickness of the deposited film at the top of the feature and multiplying it by 100 to obtain a percentage. Conventional ALD processes may deposit films with near 100% step coverage.

[0019] However, although deposited films are highly conformal, conventional ALD processes exhibit low deposition growth rate, such as, for example, between about 0.7 Å and 1.0 Å per cycle for deposition of aluminum nitride, or less than a monolayer deposited per cycle. A lower growth rate results in lower production efficiency and thus lower throughput.

[0020] Higher deposition growth rates are observed with chemical vapor deposition (CVD) and physical vapor deposition (PVD). However, in these processes, deposited films have low conformity with step coverage between about 50% and about 70%. Thus, existing processes fail to deposit conformal films that have both high growth rate and high conformality.

[0021] Provided herein are methods of depositing highly conformal thin films at a high growth rate. Methods involve a modified ALD method that combines CVD-like reactions with ALD surface reactions. CVD-like conditions are promoted with no significant loss of conformality. Methods may involve low purge to dose ratios and formation of the deposited film is driven largely on a thermal-mediated reaction and not a plasma-activated reaction. Deposited films may exhibit high growth rates about 4 to about 7 times greater than conventional ALD methods, which increases throughput and decreases cost of processing substrates. Methods also exhibit highly conformal deposited films, significantly greater than 70%, such as about 100% step coverage.

[0022] These methods may be performed to deposit films suitable for use as a conformal hardmask, an etch stop film, an encapsulation film, or one or more layers of a stack such as a gate, a memory stack (e.g., a magnetic RAM stack), or other suitable semiconductor device structures. In some cases, the deposited film encapsulates a gate structure including a gate electrode and/or gate dielectric. In some embodiments, the deposited film encapsulates a magnetic memory stack. Disclosed methods may be performed on substrates having "features" such as via or contact holes, which may be characterized by one or more of narrow and/or re-entrant openings, constrictions within the feature, and high aspect ratios. One example of a feature is a hole or via in a semiconductor substrate or a layer on the substrate. Another example is a trench in a substrate or layer. The substrate may be a silicon wafer, e.g., a 200-mm wafer, a 300-mm wafer, or a 450-mm wafer, including wafers having one or more layers of material, such as dielectric, conducting, or semi-conducting material deposited thereon. The feature may be formed in one or more of these layers. In some embodiments, the feature may have an aspect ratio of at least about 2:1, at least about 4:1, at least about 6:1, at least about 10:1, or higher. The feature may also have a dimension near the opening, e.g., an opening diameter or line width of between about 10 nm to 500 nm, for example between about 25 nm and about 300 nm. Disclosed methods may be performed on substrates with features having an opening less than about 150 nm. A feature via or trench may be referred to as an unfilled feature or a feature.

[0023] A feature that may have a re-entrant profile that narrows from the bottom, closed end, or interior of the feature to the feature opening. In various embodiments, the feature may have an under-layer, such as a barrier layer or adhesion layer. Non-limiting examples of under-layers include dielectric layers and conducting layers, e.g., silicon oxides, silicon nitrides, silicon carbides, metal oxides, metal nitrides, metal carbides, and metal layers. In certain embodiments, the under-layer may be titanium nitride (TiN), titanium metal (Ti), tungsten nitride (WN), titanium aluminide (TiAl), or a titanium oxide (TiO_x). In various embodiments, the under-layer may be a dielectric layer, such as an oxide or nitride or oxynitride. Examples of dielectric layers include silicon oxide, silicon nitride, silicon oxynitride, and others.

[0024] In many embodiments, the methods disclosed may be performed at a temperature between about 250° C. and about 450° C., or about 350° C. to about 400° C. In general, a higher deposition temperature results in a higher deposition rate. In various embodiments, the methods may be performed at a pressure of between about 0.01 Torr and about 10 Torr, or at a pressure of between about 0.1 Torr and about 1 Torr. A higher pressure results in a larger amount of reactant present in the deposition space, which may thereby increase the deposition rate. The methods described are dominantly driven by a thermal reaction process. In the following example, flow rates are provided for a 180 L chamber. In some cases, depending on the reactor configuration, the flow rates may be scaled to accommodate different volumes.

[0025] FIG. **1** is a process flow diagram of a method of depositing a thin conformal film in accordance with a certain embodiment. Note that the following chemistry presented is an example only to illustrate the disclosed embodiments. A substrate to be processed may be in a deposition chamber or deposition station. In operation **101**, a substrate is exposed to a first precursor—for example, an aluminum-containing precursor such as an organo-aluminum compound. In some embodiments, the aluminum-containing precursor is an alkyl-aluminum compound such as trimethylaluminum (TMA), or dimethylaluminum hydride. In some embodiments, the aluminum-containing precursor is an aluminum acetate, alkoxide, or aluminum halide. In many embodiments, the exposure time or duration is sufficient to form a substantially complete saturation or adsorption layer on the surface of the substrate. In certain embodiments, exposure time for this dose may be between about 5 seconds and about 60 seconds, e.g., between about 7.5 seconds and about 30 seconds. In certain embodiments, the flow rate of TMA may range from about 10 sccm to about 350 sccm. The process of contacting the substrate with reactant (e.g., aluminum-containing precursor) is sometimes referred to as "dosing."

[0026] In some embodiments, operation **101** may be performed by drawing TMA directly from the headspace of a source of TMA, which may be a reservoir of TMA, through a line connected to the deposition chamber where the substrate is located.

[0027] In some embodiments, operation **101** may be performed by inletting TMA from the headspace using a carrier gas introduced downstream of the TMA source into the chamber through the showerhead. The carrier gas may be downstream of the TMA source and upstream of the chamber or showerhead. In many embodiments, the carrier gas is an inert gas. In some embodiments, the carrier gas may be nitrogen (N_2), argon (Ar), hydrogen (H_2), or helium (He). In some embodiments, the flow rate of the carrier gas may be between about 50 sccm and about 1000 sccm. When a carrier gas is used to expose the substrate to TMA, the overall flow rate of TMA may be higher, such as between about 10 sccm and about 200 sccm of pure TMA vapor for a carrier gas flow between about 150 sccm and about 950 sccm. In some embodiments, the overall flow rate of TMA may be lower.

[0028] In operation **103**, the chamber or station is purged for a duration insufficient to completely purge the aluminum-containing precursor in the gas phase. In many embodiments, the chamber or station is purged by flowing a purge gas, such as, for example, nitrogen (N_2). In certain embodiments, the flow rate of the purge gas is between about 15 sccm and about 500 sccm. The purge gas is introduced after the flow of the first precursor is stopped. The purge time or duration of purge may be insufficient to completely purge the aluminum-containing precursor in the gas phase such that there is both surface adsorption from operation **101** as well as residual aluminum-containing precursor in the gas phase in the reaction space not on the surface of the substrate or loosely adhered to the substrate. In many embodiments, the purge time to dose time ratio, such as the operation **103** to operation **101** time ratio for example, may be between about 3:1 and about 20:1, e.g., between about 3.75:1 and about 15:1. In some embodiments, the purge time is less than about 5 seconds, e.g., between about 0.1 second and about 5 seconds, or about 2 seconds. In some embodiments, the purge in operation **103** may be accomplished by evacuating the reaction chamber.

[0029] In operation **105**, the substrate is exposed to a second precursor, or as an example, a nitrogen-containing precursor, for a duration sufficient to form a layer of, e.g., aluminum nitride by a thermal reaction on the surface of the substrate. In certain embodiments, the nitrogen-containing precursor is ammonia (NH_3). In many embodiments, the substrate is exposed to the nitrogen-containing precursor for a time between about 1 second and about 60 seconds, or about 2.5 seconds, or about 30 seconds. In various embodiments, the resulting aluminum nitride layer has a thickness about 1.5 Å or greater, typically greater than 3 Å/cycle. In some embodiments, the flow rate of the nitrogen-containing precursor may be between about 0.1 slm and about 20 slm (e.g., between about 1 slm and about 10 slm). In some embodiments, a carrier gas may be used during the exposure to the nitrogen-containing precursor. An example of a suitable carrier gas is nitrogen (N_2), and if nitrogen is used as a carrier gas and co-flowed with the nitrogen-containing precursor, the nitrogen may be flowed at a flow rate between about 500 sccm and 10 slm.

[0030] In operation **105**, the primary reaction is an ALD reaction on the surface such that surface-diffusion dominated kinetics occur to create a conformal aluminum nitride layer. Without being bound by a particular theory, at the same time, reactions in the gas phase, or gas-phase nucleation, occurs due to a CVD-like reaction that occurs between the residual aluminum-containing precursor remaining in gas phase after the purge in operation **103** and the nitrogen-containing precursor entering the reaction space. This may contribute to the increased growth rate in the thin, conformal film. The strong contribution of surface-diffusion dominated kinetics (associated with ALD) ensures preservation of conformality.

[0031] In operation **107**, the nitrogen-containing precursor is purged. In many embodiments, purging includes flowing a purge gas, such as, for example, nitrogen (N_2). In some embodiments, the purge gas is flowed between about 5 seconds to about 10 seconds, or about 6 seconds at a flow rate between about 0 sccm and about 10,000 sccm. This purge may be sufficient to remove substantially all of the remaining nitrogen-containing precursor in gas phase from the reaction space, or station, or chamber.

[0032] In operation **109**, workflow determines if the film has been deposited to an adequate thickness, and if so, then the method of depositing the film is complete. If the film has not yet been deposited to an adequate thickness, operations **101** through **107** are repeated until the film has been deposited to an adequate thickness.

[0033] The concept of a "cycle" is relevant to the discussion of various embodiments herein. Generally a cycle is the minimum set of operations required to perform a surface deposition reaction one time. The result of one cycle is production of at least a partial film layer on a substrate surface. Typically, a cycle will include only those steps necessary to deliver and adsorb each reactant to the substrate surface, and then react those adsorbed reactants to form the partial layer of film. Of course, the cycle may include certain ancillary steps such as sweeping one of the reactants or byproducts and/or treating the partial film as deposited. Generally, a cycle contains only one instance of a unique sequence of operations. As an example, a cycle may include the following operations: (i) delivery/adsorption of reactant A, (ii) sweep a portion of A out of the reaction chamber, (iii) delivery/adsorption of reactant

B under conditions sufficient to drive a reaction of A and B to form the partial film layer on the surface, and (iv) sweep B out of the reaction chamber.

[0034] Two deposition cycles of performing the method shown in FIG. **1** are depicted in the timing sequence **200** in FIG. **2**. In this sequence, a deposition cycle as shown in **210**A and **210**B includes exposure of a first precursor, a purge, exposure of a second precursor, and another purge. As shown, phases of exposure and purges occur from left to right in the timing scheme, and whether a gas is flowed or not is depicted by the lines on the sequence.

[0035] As an example, nitrogen (N_2) is flowed during the purge phase **240**A and **280**A in the deposition cycle **210**A, which corresponds with performing operation **103** and **107** in FIG. **1**, respectively. Nitrogen is also flowed during purge phase **240**B and **280**B in the deposition cycle **210**B, which corresponds with repeating operation **103** and **107** in FIG. **1**, respectively. As an example, TMA is shown as a gas flowed during the first precursor or TMA exposure phase **220**A in the deposition cycle **210**A, which corresponds with performing operation **101** in FIG. **1**. TMA is also flowed during TMA exposure phase **220**B in the deposition cycle **210**B, which corresponds with repeating operation **101** in FIG. **1**. Nitrogen or other carrier gas may be flowed together with the TMA, as illustrated in FIG. **2**. As an example, ammonia is shown as a gas flowed during the second precursor or ammonia exposure phase **260**A in the deposition cycle **210**A, which corresponds with performing operation **105** in FIG. **1**. Ammonia is also flowed during ammonia exposure phase **260**B in the deposition cycle **210**B, which corresponds with repeating operation **105** in FIG. **1**. It is noted here that after the first deposition cycle **210**A, the response to operation **109** in FIG. **1** is that the film has not been deposited to an adequate thickness, and thus operations **101** through **107** are repeated in the second deposition cycle **210**B.

[0036] For example, a "recipe" or single deposition cycle sequence may begin with exposure of TMA at a flow rate between about 10 sccm and 350 sccm with N_2 as a carrier gas flowed between about 15 sccm and 500 sccm for between about 7.5 seconds and about 30 seconds. Next, TMA flow may be turned off and nitrogen may continue to flow as a purge gas at a flow rate between about 0 sccm and about 10,000 sccm for about 2 seconds. Ammonia (NH_3) flow may then be turned on for ammonia exposure at a flow rate between about 1 slm and 10 slm with nitrogen as a carrier gas flowed between about 500 sccm and 10 slm for 30 seconds. Ammonia may then react with adsorbed and gas phase TMA to form an aluminum nitride film. Ammonia flow may then be turned off and nitrogen may continue to flow as a purge gas for about 6 seconds at a flow rate between about 0 sccm and about 10,000 sccm. This example deposition cycle may be performed at a pressure of about 0.1 Torr at a temperature between about 350° C. and about 400° C. A deposition cycle such as the one given here as an example may be repeated until the desired thickness of the film is deposited. For example, the aluminum nitride film may be deposited at a deposition rate of between about 2.5 Å and about 8 Å per cycle. The resulting aluminum nitride film may have step coverage of at least about 90% or about 100% and may depend on the number of deposition cycles performed.

[0037] Films deposited by methods disclosed herein may result in deposition rate or growth rate of about 1.5 Å to about 10 Å per cycle, or 2 Å to about 5 Å per cycle. In many embodiments, films deposited are highly conformal and exhibit step coverage at least about 80%, or at least about 90%, or at least about 99%, or about 100%. These levels of conformality and deposition rate are exhibited in features having high aspect ratios (e.g., about 1:2 or greater or about 1:6 or greater) and small size (e.g., openings of about 100 nm or smaller or about 60 nm or smaller). In many embodiments, the films deposited by methods disclosed herein result in little or no pattern loading, where pattern loading or "microloading" is defined as the tendency of a film to deposit differently the same wafer with different aspect ratios and different areal structure densities for the same deposition conditions.

[0038] In some embodiments, a plasma may be used. In embodiments where a plasma is used, the method may include (1) exposing a substrate to a metal-containing precursor (e.g., aluminum-containing precursor) for a duration sufficient to adsorb onto the surface of the substrate, (2) purging the metal-containing precursor for a duration insufficient to remove substantially all of the metal-containing precursor in gas phase, (3) exposing the substrate to a nitrogen- or oxygen-containing precursor while initiating a plasma to form a metal nitride or metal oxide film on the substrate, (4) purging the nitrogen-containing precursor from the gas phase, and (5) repeating (1) through (4). In certain embodiments, the metal-containing precursor is TMA. In some embodiments, the purging is performed by flowing a purge gas, such as, for example, nitrogen. In certain embodiments the nitrogen-containing precursor is ammonia. In many embodiments, radio frequency (RF) power of the plasma may be between about 13.56 MHz and about 40 MHz. For a 300 mm wafer, the RF power may range from about 0 kW per station to about 2.5 kW per station. In many embodiments, the plasma has a RF power density of between about 0 Watts/cm^2 and about 3.54 Watts/cm^2 of substrate. Examples of using a plasma in conformal film deposition (CFD) processes are provided in U.S. patent application Ser. No. 13/084,399, filed Apr. 11, 2011, and U.S. patent application Ser. No. 13/224,240, filed Sep. 1, 2011, which are incorporated herein by reference in their entireties.

[0039] The method shown in FIG. **1** may be practiced using other chemistries. Examples of a first precursor in operation **101** include metal-containing compounds such as aluminum-containing precursors such as an alkyl-aluminum compound such as trimethylaluminum (TMA), or dimethylaluminum hydride. In some embodiments, the aluminum-containing precursor is an aluminum acetate, alkoxide, or aluminum halide. In general, the metal containing precursors include organometallic compounds such as alkyl metal compounds as well as metal halides having a high vapor pressure under deposition conditions. Such compounds exist in a vapor state and are readily delivered to the substrate and adsorb thereon. Some methods described herein may be suitable for thermal ALD involving organometallic or halide precursors and ammonia/water (NH_3/H_2O) or ozone (O_3) as half reactants for a variety of metal systems. Examples of metal systems include titanium (Ti), hafnium (Hf), zirconium (Zr), manganese (Mn), tungsten (W), and tantalum (Ta). Examples of purge gases used in operations **103** and **107** include nitrogen (N_2), argon (Ar), helium (He), hydrogen (H_2), oxygen (O_2), and others. Examples of a second precursor in operation **105** include nitrogen-containing precursors, such as ammonia (NH_3), or tertbutylamine (TBA). Other examples of the second precursor include oxygen-containing precursors such as ozone (O_3), water vapor (H_2O), methanol (CH_4O), ethanol

(C_2H_6O), peroxides, and others. Examples of carrier gases that may flow with a precursor gas include argon (Ar), helium (He), and nitrogen (N_2).

Apparatus

[0040] FIG. **3**A depicts a schematic illustration of an embodiment of an atomic layer deposition (ALD) process station **300** having a process chamber body **302** for maintaining a low-pressure environment. A plurality of ALD process stations **300** may be included in a common low pressure process tool environment. For example, FIG. **4** depicts an embodiment of a multi-station processing tool **400**. In some embodiments, one or more hardware parameters of ALD process station **300**, including those discussed in detail below, may be adjusted programmatically by one or more computer controllers **350**.

[0041] ALD process station **300** fluidly communicates with reactant delivery system **301***a* for delivering process gases to a distribution showerhead **306**. Reactant delivery system **301***a* includes a mixing vessel **304** for blending and/or conditioning process gases for delivery to showerhead **306**. One or more mixing vessel inlet valves **320** may control introduction of process gases to mixing vessel **304**.

[0042] FIG. **3**B depicts a schematic illustration of an alternative reactant delivery system **301***b* for delivering reactants to the showerhead **306**. Some reactants, such as trimethylaluminum (TMA), may be stored in liquid form prior to vaporization at and subsequent delivery to the process chamber body **302**. In FIG. **3**B, vapor of the process liquid contained in reservoir **370** may be drawn from the headspace **372** to a restrictor **362**, which may deliver reactants with the carrier gas to process chamber body **302**. The reservoir may include a gauge **365**. In some embodiments, a carrier gas may be upstream of the process liquid reservoir **370** such that the carrier gas pushes the vapor of the process liquid in reservoir **370** initially drawn from the headspace **372** through conduits to the restrictor **362** and subsequently to the chamber body **302**. In many embodiments, the carrier gas may first flow through a mass flow controller **360** before carrying vapor from headspace **372** to the restrictor **362**. In these embodiments where a carrier gas is used to push the vapor, the flow rate of the vapor into the chamber **302** may be higher than in embodiments where a carrier gas is not used and the vapor is drawn directly from the headspace **372**, to the mixing vessel **304**, and to the chamber body **302**.

[0043] As an example, the embodiment of FIG. **3**A includes a vaporization point **303** for vaporizing liquid reactant to be supplied to the mixing vessel **304**. In some embodiments, vaporization point **303** may be a heated vaporizer. The saturated reactant vapor produced from such vaporizers may condense in downstream delivery piping. Exposure of incompatible gases to the condensed reactant may create small particles. These small particles may clog piping, impede valve operation, contaminate substrates, etc. Some approaches to addressing these issues involve purging and/or evacuating the delivery piping to remove residual reactant. However, purging the delivery piping may increase process station cycle time, degrading process station throughput. Thus, in some embodiments, delivery piping downstream of vaporization point **303** may be heat traced. In some examples, mixing vessel **304** may also be heat traced. In one non-limiting example, piping downstream of vaporization point **303** has an increasing temperature profile extending from approximately 100° C. to approximately 150° C. at mixing vessel **304**.

[0044] In some embodiments, liquid precursor or liquid reactant may be vaporized at a liquid injector. For example, a liquid injector may inject pulses of a liquid reactant into a carrier gas stream upstream of the mixing vessel. In one embodiment, a liquid injector may vaporize the reactant by flashing the liquid from a higher pressure to a lower pressure. In another example, a liquid injector may atomize the liquid into dispersed microdroplets that are subsequently vaporized in a heated delivery pipe. Smaller droplets may vaporize faster than larger droplets, reducing a delay between liquid injection and complete vaporization. Faster vaporization may reduce a length of piping downstream from vaporization point **303**. In one scenario, a liquid injector may be mounted directly to mixing vessel **304**. In another scenario, a liquid injector may be mounted directly to showerhead **306**.

[0045] In some embodiments, a liquid flow controller (LFC) upstream of vaporization point **303** may be provided for controlling a mass flow of liquid for vaporization and delivery to process station **300**. For example, the LFC may include a thermal mass flow meter (MFM) located downstream of the LFC. A plunger valve of the LFC may then be adjusted responsive to feedback control signals provided by a proportional-integral-derivative (PID) controller in electrical communication with the MFM. However, it may take one second or more to stabilize liquid flow using feedback control. This may extend a time for dosing a liquid reactant. Thus, in some embodiments, the LFC may be dynamically switched between a feedback control mode and a direct control mode. In some embodiments, this may be performed by disabling a sense tube of the LFC and the PID controller.

[0046] Showerhead **306** distributes process gases toward substrate **312**. In the embodiment shown in FIG. **3**A, the substrate **312** is located beneath showerhead **306** and is shown resting on a pedestal **308**. Showerhead **306** may have any suitable shape, and may have any suitable number and arrangement of ports for distributing process gases to substrate **312**.

[0047] In some embodiments, a microvolume **307** is located beneath showerhead **306**. Practicing disclosed embodiments in a microvolume rather than in the entire volume of a process station may reduce reactant exposure and purge times, may reduce times for altering process conditions (e.g., pressure, temperature, etc.) may limit an exposure of process station robotics to process gases, etc. Example microvolume sizes include, but are not limited to, volumes between 0.1 liter and 2 liters. This also impacts productivity throughput. In some embodiments, the disclosed embodiments are not performed in a microvolume.

[0048] In some embodiments, pedestal **308** may be raised or lowered to expose substrate **312** to microvolume **307** and/or to vary a volume of microvolume **307**. For example, in a substrate transfer phase, pedestal **308** may be raised to position substrate **312** within microvolume **307**. In some embodiments, microvolume **307** may completely enclose substrate **312** as well as a portion of pedestal **308** to create a region of high flow impedance.

[0049] Optionally, pedestal **308** may be lowered and/or raised during portions the process to modulate process pressure, reactant concentration, etc., within microvolume **307**. In one scenario where process chamber body **302** remains at a base pressure during the process, lowering pedestal **308** may

allow microvolume **307** to be evacuated. Example ratios of microvolume to process chamber volume include, but are not limited to, volume ratios between 1:500 and 1:10. It will be appreciated that, in some embodiments, pedestal height may be adjusted programmatically by a suitable computer controller **350**.

[0050] In another scenario, adjusting a height of pedestal **308** may allow a plasma density to be varied during plasma activation and/or treatment cycles included in the process. At the conclusion of the process phase, pedestal **308** may be lowered during another substrate transfer phase to allow removal of substrate **312** from pedestal **308**.

[0051] While the example microvolume variations described herein refer to a height-adjustable pedestal, it will be appreciated that, in some embodiments, a position of showerhead **306** may be adjusted relative to pedestal **308** to vary a volume of microvolume **307**. Further, it will be appreciated that a vertical position of pedestal **308** and/or showerhead **306** may be varied by any suitable mechanism within the scope of the present disclosure. In some embodiments, pedestal **308** may include a rotational axis for rotating an orientation of substrate **312**. It will be appreciated that, in some embodiments, one or more of these example adjustments may be performed programmatically by one or more suitable computer controllers **350**.

[0052] In some embodiments where plasma may be used as discussed above, showerhead **306** and pedestal **308** electrically communicate with a radio frequency (RF) power supply **314** and matching network **316** for powering a plasma. In some embodiments, the plasma energy may be controlled by controlling one or more of a process station pressure, a gas concentration, an RF source power, an RF source frequency, and a plasma power pulse timing. For example, RF power supply **314** and matching network **316** may be operated at any suitable power to form a plasma having a desired composition of radical species. Examples of suitable powers are included above. Likewise, RF power supply **314** may provide RF power of any suitable frequency. In some embodiments, RF power supply **314** may be configured to control high- and low-frequency RF power sources independently of one another. Example low-frequency RF frequencies may include, but are not limited to, frequencies between 50 kHz and 500 kHz. Example high-frequency RF frequencies may include, but are not limited to, frequencies between 1.8 MHz and 2.45 GHz. It will be appreciated that any suitable parameters may be modulated discretely or continuously to provide plasma energy for the surface reactions. In one non-limiting example, the plasma power may be intermittently pulsed to reduce ion bombardment with the substrate surface relative to continuously powered plasmas.

[0053] In some embodiments, the plasma may be monitored in-situ by one or more plasma monitors. In one scenario, plasma power may be monitored by one or more voltage, current sensors (e.g., VI probes). In another scenario, plasma density and/or process gas concentration may be measured by one or more optical emission spectroscopy sensors (OES). In some embodiments, one or more plasma parameters may be programmatically adjusted based on measurements from such in-situ plasma monitors. For example, an OES sensor may be used in a feedback loop for providing programmatic control of plasma power. It will be appreciated that, in some embodiments, other monitors may be used to monitor the plasma and other process characteristics. Such monitors may include, but are not limited to, infrared (IR) monitors, acoustic monitors, and pressure transducers.

[0054] In some embodiments, instructions for a controller **350** may be provided via input/output control (IOC) sequencing instructions. In one example, the instructions for setting conditions for a process phase may be included in a corresponding recipe phase of a process recipe. In some cases, process recipe phases may be sequentially arranged, so that all instructions for a process phase are executed concurrently with that process phase. In some embodiments, instructions for setting one or more reactor parameters may be included in a recipe phase. For example, a first recipe phase may include instructions for setting a flow rate of an inert and/or a reactant gas (e.g., the first precursor such as TMA), instructions for setting a flow rate of a carrier gas (such as nitrogen), and time delay instructions for the first recipe phase. A second, subsequent recipe phase may include instructions for modulating or stopping a flow rate of an inert and/or a reactant gas, and instructions for modulating a flow rate of a carrier or purge gas and time delay instructions for the second recipe phase. A third recipe phase may include instructions for setting a flow rate of an inert and/or reactant gas which may be the same as or different from the gas used in the first recipe phase (e.g., the second precursor such as ammonia), instructions for modulating a flow rate of a carrier gas, and time delay instructions for the third recipe phase. A fourth recipe phase may include instructions for modulating or stopping a flow rate of an inert and/or a reactant gas, instructions for modulating the flow rate of a carrier or purge gas, and time delay instructions for the fourth recipe phase. It will be appreciated that these recipe phases may be further subdivided and/or iterated in any suitable way within the scope of the present disclosure.

[0055] In some embodiments, pedestal **308** may be temperature controlled via heater **310**. Further, in some embodiments, pressure control for process station **300** may be provided by butterfly valve **318**. As shown in the embodiment of FIG. **3**, butterfly valve **318** throttles a vacuum provided by a downstream vacuum pump (not shown). However, in some embodiments, pressure control of process station **300** may also be adjusted by varying a flow rate of one or more gases introduced to the process station **300**.

[0056] As described above, one or more process stations may be included in a multi-station processing tool. FIG. **4** shows a schematic view of an embodiment of a multi-station processing tool **400** with an inbound load lock **402** and an outbound load lock **404**, either or both of which may comprise a remote plasma source. A robot **406**, at atmospheric pressure, is configured to move wafers from a cassette loaded through a pod **408** into inbound load lock **402** via an atmospheric port **410**. A wafer is placed by the robot **406** on a pedestal **412** in the inbound load lock **402**, the atmospheric port **410** is closed, and the load lock is pumped down. Where the inbound load lock **402** comprises a remote plasma source, the wafer may be exposed to a remote plasma treatment in the load lock prior to being introduced into a processing chamber **414**. Further, the wafer also may be heated in the inbound load lock **402** as well, for example, to remove moisture and adsorbed gases. Next, a chamber transport port **416** to processing chamber **414** is opened, and another robot (not shown) places the wafer into the reactor on a pedestal of a first station shown in the reactor for processing. While the embodiment depicted in FIG. **4** includes load locks, it will be appreciated that, in some embodiments, direct entry of a wafer into a process station may be provided.

[0057] The depicted processing chamber **414** comprises four process stations, numbered from **1** to **4** in the embodiment shown in FIG. **4**. Each station has a heated pedestal (shown at **418** for station **1**), and gas line inlets. It will be appreciated that in some embodiments, each process station may have different or multiple purposes. For example, in some embodiments, a process station may be switchable between an ALD and plasma-enhanced ALD process mode. Additionally or alternatively, in some embodiments, processing chamber **414** may include one or more matched pairs of ALD and plasma-enhanced ALD process stations. While the depicted processing chamber **414** comprises four stations, it will be understood that a processing chamber according to the present disclosure may have any suitable number of stations. For example, in some embodiments, a processing chamber may have five or more stations, while in other embodiments a processing chamber may have three or fewer stations.

[0058] FIG. **4** depicts an embodiment of a wafer handling system **490** for transferring wafers within processing chamber **414**. In some embodiments, wafer handling system **490** may transfer wafers between various process stations and/or between a process station and a load lock. It will be appreciated that any suitable wafer handling system may be employed. Non-limiting examples include wafer carousels and wafer handling robots. FIG. **4** also depicts an embodiment of a system controller **450** employed to control process conditions and hardware states of process tool **400**. System controller **450** may include one or more memory devices **456**, one or more mass storage devices **454**, and one or more processors **452**. Processor **452** may include a CPU or computer, analog and/or digital input/output connections, stepper motor controller boards, etc.

[0059] In some embodiments, system controller **450** controls all of the activities of process tool **400**. System controller **450** executes system control software **458** stored in mass storage device **454**, loaded into memory device **456**, and executed on processor **452**. Alternatively, the control logic may be hard coded in the controller **450**. Applications Specific Integrated Circuits, Programmable Logic Devices (e.g., field-programmable gate arrays, or FPGAs) and the like may be used for these purposes. In the following discussion, wherever "software" or "code" is used, functionally comparable hard coded logic may be used in its place. System control software **458** may include instructions for controlling the timing, mixture of gases, amount of sub-saturated gas flow, chamber and/or station pressure, chamber and/or station temperature, wafer temperature, target power levels, RF power levels, substrate pedestal, chuck and/or susceptor position, and other parameters of a particular process performed by process tool **400**. System control software **458** may be configured in any suitable way. For example, various process tool component subroutines or control objects may be written to control operation of the process tool components necessary to carry out various process tool processes. System control software **458** may be coded in any suitable computer readable programming language.

[0060] In some embodiments, system control software **458** may include input/output control (IOC) sequencing instructions for controlling the various parameters described above. Other computer software and/or programs stored on mass storage device **454** and/or memory device **456** associated with system controller **450** may be employed in some embodiments. Examples of programs or sections of programs for this purpose include a substrate positioning program, a process gas control program, a pressure control program, a heater control program, and a plasma control program.

[0061] A substrate positioning program may include program code for process tool components that are used to load the substrate onto pedestal **418** and to control the spacing between the substrate and other parts of process tool **400**.

[0062] A process gas control program may include code for controlling gas composition (e.g., TMA, ammonia, and purge gases as described herein) and flow rates and optionally for flowing gas into one or more process stations prior to deposition in order to stabilize the pressure in the process station. A pressure control program may include code for controlling the pressure in the process station by regulating, for example, a throttle valve in the exhaust system of the process station, a gas flow into the process station, etc.

[0063] A heater control program may include code for controlling the current to a heating unit that is used to heat the substrate. Alternatively, the heater control program may control delivery of a heat transfer gas (such as helium) to the substrate.

[0064] A plasma control program may include code for setting RF power levels applied to the process electrodes in one or more process stations in accordance with the embodiments herein.

[0065] A pressure control program may include code for maintaining the pressure in the reaction chamber in accordance with the embodiments herein.

[0066] In some embodiments, there may be a user interface associated with system controller **450**. The user interface may include a display screen, graphical software displays of the apparatus and/or process conditions, and user input devices such as pointing devices, keyboards, touch screens, microphones, etc.

[0067] In some embodiments, parameters adjusted by system controller **450** may relate to process conditions. Non-limiting examples include process gas composition and flow rates, temperature, pressure, plasma conditions (such as RF bias power levels), etc. These parameters may be provided to the user in the form of a recipe, which may be entered utilizing the user interface.

[0068] Signals for monitoring the process may be provided by analog and/or digital input connections of system controller **450** from various process tool sensors. The signals for controlling the process may be output on the analog and digital output connections of process tool **400**. Non-limiting examples of process tool sensors that may be monitored include mass flow controllers, pressure sensors (such as manometers), thermocouples, etc. Appropriately programmed feedback and control algorithms may be used with data from these sensors to maintain process conditions.

[0069] System controller **450** may provide program instructions for implementing the above-described deposition processes. The program instructions may control a variety of process parameters, such as DC power level, RF bias power level, pressure, temperature, etc. The instructions may control the parameters to operate in-situ deposition of film stacks according to various embodiments described herein.

[0070] The system controller will typically include one or more memory devices and one or more processors configured to execute the instructions so that the apparatus will perform a method in accordance with the present invention. Machine-readable media containing instructions for controlling process operations in accordance with the present invention may be coupled to the system controller.

[0071] An appropriate apparatus for performing the methods disclosed herein is further discussed and described in U.S. patent application Ser. No. 13/084,399, filed Apr. 11, 2011, and titled "PLASMA ACTIVATED CONFORMAL FILM DEPOSITION"; and Ser. No. 13/084,305, filed Apr. 11, 2011, and titled "SILICON NITRIDE FILMS AND METHODS," each of which is incorporated herein in its entireties.

[0072] The apparatus/process described herein may be used in conjunction with lithographic patterning tools or processes, for example, for the fabrication or manufacture of semiconductor devices, displays, LEDs, photovoltaic panels and the like. Typically, though not necessarily, such tools/processes will be used or conducted together in a common fabrication facility. Lithographic patterning of a film typically includes some or all of the following operations, each operation enabled with a number of possible tools: (1) application of photoresist on a workpiece, i.e., substrate, using a spin-on or spray-on tool; (2) curing of photoresist using a hot plate or furnace or UV curing tool; (3) exposing the photoresist to visible or UV or x-ray light with a tool such as a wafer stepper; (4) developing the resist so as to selectively remove resist and thereby pattern it using a tool such as a wet bench; (5) transferring the resist pattern into an underlying film or workpiece by using a dry or plasma-assisted etching tool; and (6) removing the resist using a tool such as an RF or microwave plasma resist stripper.

EXPERIMENTAL

Experiment 1

[0073] An experiment was conducted to evaluate step coverage of features deposited using methods of the disclosed embodiments. In this experiment, an aluminum nitride layer was deposited on a metal dielectric substrate with features at 350° C. and 0.1 Torr using cycles of a 7.5-second exposure of trimethylaluminum (TMA), a 2-second purge, a 30-second exposure of ammonia (NH_3), and a 6-second purge. The reaction was entirely thermal and no plasma was initiated.

[0074] The results of the measurements and calculations of step coverage are shown in Table 1 below.

TABLE 1

Step Coverage				
Sidewall (avg, nm)	Top (avg, nm)	Bottom (avg, nm)	Step Coverage Sidewall/Top (%)	Step Coverage Sidewall/Bottom (%)
20.09	19.97	19.43	100.6%	102.8%

[0075] FIG. **5** is an image of the deposited aluminum nitride film on the substrate. The average deposition rate of aluminum nitride was about 3.3 Å per cycle and 100% conformality was achieved.

Experiment 2

[0076] An experiment was conducted to evaluate whether there was pattern loading as a result of practicing the disclosed embodiments. In this experiment, an aluminum nitride layer was deposited on a metal dielectric substrate with features at 350° C. and 0.1 Torr using cycles of a 7.5-second exposure of trimethylaluminum (TMA), a 2-second purge, a 30-second exposure of ammonia (NH_3), and a 6-second purge. The reaction was entirely thermal and no plasma was initiated. Experiments were conducted on substrates with an aspect ratio of 2.5:1 and 6:1, and a field or blanket substrate. The results of the measurements and calculations of step coverage are shown in Table 2 below.

TABLE 2

Pattern Loading				
Feature Aspect Ratio	Top (avg, nm)	Sidewall (avg, nm)	Bottom (avg, nm)	Step Coverage (Sidewall/Top %)
Field	19.14	—	—	—
2.5:1	19.97	20.09	19.43	100.6%
6:1	18.99	19.30	19.13	102%

[0077] FIG. **5** is an image of the deposited aluminum nitride film on the 2.5:1 aspect ratio features. FIG. **6**A is an image of the deposited aluminum nitride film on the 6:1 aspect ratio features. FIG. **6**B depicts an image of the deposited aluminum nitride film on the field substrate. Layers deposited using disclosed embodiments were still conformal for features with an aspect ratio of up to about 1:6 and no pattern loading effect was observed.

Experiment 3

[0078] An experiment was conducted to evaluate film quality of deposited films in accordance with various embodiments. In this experiment, an aluminum nitride layer was deposited on a metal dielectric substrate with features at 350° C. and 0.1 Torr using cycles of a 7.5-second exposure of trimethylaluminum (TMA), a 2-second purge, a 30-second exposure of ammonia (NH_3), and a 6-second purge. The reaction was entirely thermal and no plasma was initiated. FIG. **5** is an image of the deposited aluminum nitride film before the wet etch test or dip.

[0079] The substrate was then subject to an SC2 wet etch test using a standard clean solution at 50° C. for a 25-second dip. The composition of the SC2 standard etchant/clean solution includes HCl, H_2O_2, and H_2O in a 1:1:5 composition ratio. The results of the measurements and calculations of step coverage are shown in Table 3 below.

TABLE 3

Film Quality			
	Thickness (pre-dip)	Thickness (post-dip)	Etch Rate (Å/min)
Sidewall (avg, Å)	200.9	179.7	51
Top (avg, Å)	199.7	177.8	53
Bottom (avg, Å)	194.3	173.5	50

[0080] FIG. **7** is an image of the etched aluminum nitride film after the wet etch test. As shown the etch was uniform throughout the surface of the features. The calculated sidewall to top etch rate ratio was about 0.97. The film quality was comparable to that of conventional ALD. Even after the wet etch dip, the step coverage of the deposited film was still about 100%, thereby indicating that the film etches uniformly and etch rate is consistent over the deposited film. The results also show that the quality of the film on the sidewall is equivalent to the quality of the film in the field regions at the top and bottom of the structure despite having CVD-like reactions

during deposition. This suggests that the film quality generated at the surface and the gas phase are equivalent or similar.

CONCLUSION

[0081] Although the foregoing embodiments have been described in some detail for purposes of clarity of understanding, it will be apparent that certain changes and modifications may be practiced within the scope of the appended claims. It should be noted that there are many alternative ways of implementing the processes, systems and apparatus of the present embodiments. Accordingly, the present embodiments are to be considered as illustrative and not restrictive, and the embodiments are not to be limited to the details given herein.

What is claimed is:

1. A method of processing a semiconductor substrate having features in a reaction chamber, the method comprising:

(a) exposing the substrate to a metal-containing precursor for a duration sufficient to substantially adsorb to a surface of the substrate, the metal-containing precursor comprising a metal selected from the group consisting of titanium, hafnium, zirconium, manganese, tungsten, and tantalum;

(b) purging the metal-containing precursor from the reaction chamber for a duration insufficient to remove substantially all of the metal-containing precursor from the gas phase;

(c) exposing the substrate to a nitrogen-containing precursor for a duration sufficient to drive a thermally mediated reaction to form a layer of metal nitride on the surface of the substrate, wherein the layer of metal nitride is substantially conformal to the substrate and has a thickness of about 1.5 Å or greater;

(d) purging the nitrogen-containing precursor in gas phase from the reaction chamber; and

(e) repeating (a) through (d).

2. The method of claim **1**, wherein the layer of metal nitride has step coverage of at least about 80%.

3. The method of claim **1**, wherein the substrate is processed at a process temperature between about 250° C. and about 450° C.

4. The method of claim **1**, wherein the substrate is processed at a pressure between about 0.01 Torr and about 10 Torr.

5. The method of claim **1**, wherein the nitrogen-containing precursor is ammonia (NH_3).

6. The method of claim **1**, wherein purging the metal-containing precursor further comprises flowing nitrogen (N_2) and purging the nitrogen-containing precursor further comprises flowing nitrogen (N_2).

7. The method of claim **1**, wherein the metal-containing precursor is purged for about 2 seconds.

8. The method of claim **1**, wherein the substrate is exposed to the metal-containing precursor for about 7.5 seconds to about 30 seconds.

9. The method of claim **1**, wherein the ratio of the time the substrate is exposed to the metal-containing precursor to the time the metal-containing precursor is purged is between about 3.75:1 and about 15:1.

10. The method of claim **1**, wherein processing exhibits substantially no pattern loading.

11. The method of claim **1**, wherein the amount of metal nitride deposited during a cycle of (a) through (d) is at least about 2 Å.

12. The method of claim **1**, wherein the amount of metal nitride deposited during a cycle of (a) through (d) is at least about 5 Å.

13. The method of claim **1**, wherein the features of the substrate have aspect ratios of at least about 2:1.

14. The method of claim **1**, wherein the features of the substrate have openings of less than about 100 nm.
