(57) **ABSTRACT**

In an integrated circuit, a memory unit includes a first and a second data transfer interface. The first data interface services successive first accesses by a processor and subsystem of the IC, whereas the second data interface services second accesses by at least the processor in parallel. In one embodiment, the accesses are properly sequenced and responded to.

**RELATED APPLICATION**

[0001] This application claims priority to U.S. Provisional Application No. 60/272,439, entitled "MULTI-SERVICE PROCESSOR INCLUDING A MULTI-SERVICE BUS", filed Feb. 28, 2001, the specification of which is hereby fully incorporated by reference.

**BACKGROUND OF THE INVENTION**

[0002] 1. Field of the Invention

[0003] The present invention relates to the field of integrated circuit. More specifically, the present invention relates to inter-subsystem communication between subsystems on an integrated circuit device.

[0004] 2. Background Information

[0005] Advances in integrated circuit technology have led to the birth and proliferation of a wide variety of integrated circuits, including but not limited to application specific integrated circuits, micro-controllers, digital signal processors, general purpose microprocessors, and network processors. Recent advances have also led to the birth of what's known as "system on a chip" or SOC. Typically, a SOC includes multiple "tightly coupled" subsystems performing very different functions. These subsystems often have a need to communicate and cooperate with each other on a regular basis.

[0006] U.S. Pat. No. 6,122,690 discloses an on-chip bus architecture that is both processor independent and scalable. The '690 patent discloses a bus that uses "standardized" bus interfaces to couple functional blocks to the on-chip bus. The "standardized" bus interfaces include embodiments for bus master functional blocks, slave functional blocks, or either. The '690 bus suffers from at least one disadvantage in that it does not offer rich functionalities for prioritizing interactions or transactions between the subsystems, which are needed for a SOC with subsystems performing a wide range of very different functions.

[0007] Accordingly, a more flexible approach to facilitate inter-subsystem communication between subsystems on a chip is desired.

**BRIEF DESCRIPTION OF DRAWINGS**

[0008] The present invention will be described by way of exemplary embodiments, but not limitations, illustrated in the accompanying drawings in which like references denote similar elements, and in which:

[0009] **FIG. 1** illustrates an overview of a system on-chip including an on-chip bus and a number of subsystems coupled to the on-chip bus, in accordance with one embodiment;

[0010] **FIG. 2** illustrates the method of the present invention, in accordance with one embodiment;

[0011] **FIGS. 3a-3b** illustrate a request and a reply transaction between two subsystems, in accordance with one embodiment;

[0012] **FIG. 4** illustrates data transfer unit of **FIG. 1** in further detail, in accordance with one embodiment;

[0013] **FIGS. 5a-5b** illustrate the operational states and the transition rules for the state machines of **FIG. 4**, in accordance with one embodiment;

[0014] **FIGS. 6a-6c** are timing diagrams for practicing the present invention, in accordance with one implementation;

[0015] **FIG. 7** illustrates another overview of a system on-chip further including a data traffic router, in accordance with an alternate embodiment;

[0016] **FIG. 8** illustrates the data aspect of the data traffic router of **FIG. 7** in further details, in accordance with one embodiment; and

[0017] **FIG. 9** illustrates the control aspect of the data traffic router of **FIG. 7** in further details, in accordance with one embodiment;

[0018] **FIG. 10** illustrates another overview of a system on-chip further including a direct communication path between two subsystems, in accordance with an alternate embodiment; and

[0019] **FIG. 11** illustrates an exemplary subsystem having a first data transfer interface interfacing with the data traffic router, and a second data transfer interface interfacing with another subsystem directly, in accordance with one embodiment.

**DETAILED DESCRIPTION OF THE  
INVENTION**

[0020] The present invention includes interface units and operational methods for flexibly facilitating inter-subsystem communication between subsystems of a SOC. In the following description, various features and arrangements will be described, to provide a thorough understanding of the present invention. However, the present invention may be practiced without some of the specific details or with alternate features/arrangement. In other instances, well-known features are omitted or simplified in order not to obscure the present invention.

[0021] The description to follow repeatedly uses the phrase "in one embodiment", which ordinarily does not refer to the same embodiment, although it may. The terms "comprising", "having", "including" and the like, as used in the present application, including in the claims, are synonymous.

**Overview**

[0022] Referring now to **FIG. 1**, wherein a block diagram illustrating an overview of a SOC **100** with subsystems **102a-102d** incorporated with the teachings of the present invention for inter-subsystem communication, in accordance with one embodiment, is shown. As illustrated, for the embodiment, SOC **100** includes on-chip bus **104** and subsystems **102a-102d** coupled to each other through bus **104**. Moreover, each of subsystems **102a-102d** includes data transfer unit or interface (DTU) **108a-108d** incorporated with teachings of the present invention, correspondingly coupling the subsystems **102a-102d** to bus **104**. SOC **100** also includes arbiter **106**, which is also coupled to bus **104**.

[0023] In one embodiment, bus **104** includes a number of sets of request lines (one set per subsystem), a number of sets of grant lines (one set per subsystem), and a number of shared control and data/address lines. Included among the shared control lines is a first control line for a subsystem granted access to the bus (grantee subsystem, also referred to as the master subsystem) to assert a control signal to denote the beginning of a transaction cycle, and to de-assert the control signal to denote the end of the transaction cycle; and a second control line for a subsystem addressed by the grantee/master subsystem (also referred to as the slave subsystem) to assert a control signal to inform the grantee/master subsystem that the addressee/slave subsystem is busy (also referred to as “re-trying” the master system).

[0024] As a result of the facilities advantageously provided by DTU **108a-108d**, and the teachings incorporated in subsystem **102a-102d**, subsystems **102a-102d** are able to flexibly communicate and cooperate with each other, allowing subsystems **102a-102d** to handle a wide range of different functions having different needs. More specifically, as will be described in more detail below, in one embodiment, subsystems **102a-102d** communicate with each other via transactions conducted across bus **104**. Subsystems **102a-102d**, by virtue of the facilities advantageously provided by DTU **108a-108d**, are able to locally prioritize the order in which its transactions are to be serviced by the corresponding DTU **108a-108d** to arbitrate for access to bus **104**. Further, in one embodiment, by virtue of the architecture of the transactions, subsystems **102a-102d** are also able to flexibly control the priorities on which the corresponding DTU **108a-108d** are to use to arbitrate for bus **104** with other contending transactions of other subsystems **102a-102d**.

[0025] Arbiter **106** is employed to arbitrate access to bus **104**. That is, arbiter **106** is employed to determine which of the contending transactions on whose behalf the DTU **108a-108d** are requesting for access (through e.g. the request lines of the earlier described embodiment), are to be granted access to bus **104** (through e.g. the grant lines of the earlier described embodiment).

[0026] SOC **100** is intended to represent a broad range of SOC, including multi-service ASIC. In particular, in various embodiments, subsystems **102a-102d** may be one or more of a memory controller, a security engine, a voice processor, a collection of peripheral device controllers, a framer processor, and a network media access controller. Moreover, by virtue of the advantageous employment of DTU **108a-108d** to interface subsystems **102a-102d** to on-chip bus **104**, with DTU **108a-108d** and on-chip bus operating on the same clock speed, the core logic of subsystems **102a-102d** may operate in different clock speeds, including clock speeds that are different from the clock speed of non-chip bus **104** and DTU **108a-108d**. In one embodiment, one or more subsystems **102a-102d** may be a multi-function subsystems, in particular, with the functions identified by identifiers. Except for the teachings of the present invention incorporated into subsystems **102a-102d**, the exact constitution and the exact manner their core logic operate in providing the functions/services the subsystems are immaterial to the present invention. While for ease of understanding, SOC **100** is illustrated as having only four subsystems **102a-102d**, in practice, SOC **100** may have more or less subsystems. In particular, by virtue of the advantageous employment of DTU **108a-108d** to interface subsystems **102a-102d** to on-chip bus **104**, zero

or more selected ones of subsystems **102a-102d** may be removed, while other subsystems **102a-102d** may be flexibly added to SOC **100**.

[0027] Similarly, arbiter **106** may be any one of a number of bus arbiters known in the art. The facilities of DTU **108a-108d** and the teachings incorporated into the core logic of subsystems **102a-102d** to practice the present invention will be described in turn below.

#### Method

[0028] Referring now to FIG. 2, wherein a flow chart illustrating a method of the present invention, in accordance with one embodiment, is shown. As illustrated, in accordance with the present invention, subsystems **102a-102d** initiate transactions with one another, using the facilities of their corresponding DTU **108a-108d** to locally prioritize the order the transactions of the corresponding subsystems are to be serviced, for arbitration for access to bus **104**, block **202**.

[0029] Further, for the embodiment, for each transaction, each subsystem **102a-102d** also includes as part of the transaction the bus arbitration priority the corresponding DTU **108a-108d** is to use to arbitrate for access to bus **104**, when servicing the transaction in the prioritized manner.

[0030] In response, DTU **108a-108d** service the transactions of the respective subsystems **102a-102d** accordingly, and arbitrating for access to bus **104**, using the bus arbitration priorities included among the transactions. Arbiter **106** in turn grants accesses to bus **104** based on the bus arbitration priorities of the contending transactions, block **204**.

[0031] In one embodiment, arbiter **106** grants access strictly by the transaction priorities, e.g. in a three priority implementation, all high priority transactions will be granted access first, before the medium priority transactions are granted access, and finally the low priority transactions are granted access. In another embodiment, arbiter **106** further employs certain non-starvation techniques, to ensure the medium and/or low priority transactions will also be granted access to bus **104**. The non-starvation techniques may be any one of a number of such techniques known in the art.

[0032] Still referring to FIG. 2, once granted access to bus **104**, the grantee DTU **108\*** places the grantee transaction on bus **104** (through e.g. the shared data/address lines of the earlier described embodiment). In one embodiment, the transaction includes address of the targeted subsystem **102\***. In response, once placed onto bus **104**, the addressee subsystem **102\*** claims the transaction, and acknowledges the transaction, or if the subsystem **102\*** is busy, instructs the requesting subsystem **102\*** to retry later, block **206**. If acknowledgement is given and a reply is due (as in the case of a read request), the reply is later initiated as a reply transaction. In other words, for the embodiment, “read” transactions are accomplished in a “split” manner.

[0033] In the present application, for ease of designation, the trailing “\*” of a reference number denotes one of the instances of reference. For example, **108\*** means either **108a**, **108b**, **108c** or **108d**.

#### Exemplary Transaction Formats

[0034] FIGS. 3a-3b illustrate two exemplary transaction formats, a request format and a reply format, suitable for use

to practice the present invention, in accordance with one embodiment. As illustrated in FIG. 3a, exemplary request transaction 302 includes three parts, first header 301a, second header 301b, and optional data portion 312. First header 301a includes in particular, a command or request code 304, which for the embodiment, includes the bus arbitration priority, and address 306 of the target subsystem 102\*. The various subsystems 102a-102d of SOC 100 are assumed to be memory mapped. Arbitration is initiated by a DTU 108\* requesting arbiter 106 for access (through e.g. the earlier described subsystem based request lines), including with the request the included bus arbitration priority in the command portion 304 of first header 301a. Second header 301b includes an identifier identifying a function of the originating subsystem 102\*, allowing subsystem 102\* to be a multifunction subsystem and be able to associate transactions with the various functions. Second header 301b also includes size 310. For write transactions, size 310 denotes the size of the write data to follow (the "optional" data portion), in number of bytes. For read transactions, size 310 denotes the size of the data being accessed (i.e. read), also in number of bytes.

[0035] As illustrated in FIG. 3b, exemplary reply transaction 322 also includes three parts, first header 321a, second header 321b and data 332. First header 321a includes in particular, a command or request code 324, which includes the bus arbitration priority, identifier 328 which identifies the subsystem and its function, and low order byte of targeted address 326a of the replying subsystem 102\*. As alluded earlier, data 332 includes the data being accessed/read by the original read request. Again, arbitration is initiated by a DTU 108\* requesting arbiter 106 for access (through e.g. the earlier described subsystem based request lines), including with the request the included bus arbitration priority in the command portion 324 of first header 321a. Second header 321b includes the remaining high order bytes targeted address 326a of the replying subsystem 102\*. Accordingly, employment of these transaction formats enables a subsystem 102\* to communicate with another subsystem 102\* at any byte position, reducing the number of operations for unaligned data transfers.

[0036] In one embodiment, different commands are supported for "conventional" data versus control, and voice data. More specifically, for the embodiment, the commands supported are:

Command Code	Command	Description
000	Reserved	Reserved
001	DRead	Data Read Request
010	CRead	Control Read Request
011	VRead	Voice Read Request
100	DWrite	Data Write Request
101	CWrite	Control Write Request
110	VWrite	Voice Write Request
111	Reply	Read Reply

#### Data Transfer Units

[0037] FIG. 4 illustrates DTU 108\* in further details, in accordance with one embodiment. As illustrated, DTU 108\* includes a number of pairs of outbound and inbound trans-

action queues 402\* and 404\*, one pair each for each priority level. For example, in one embodiment where DTU 108\* supports three levels of priority, high, medium and low, DTU 108\* includes three pairs of outbound and inbound transaction queues 402a and 404a, 402b and 404b, and 402c and 404c, one each for the high, medium and low priorities. In another embodiment, DTU 108\* supports two levels of priority, high and low, DTU 108\* includes two pairs of outbound and inbound transaction queues 402a and 404a, and 402b and 404b, one each for the high and low priorities. Of course, in other embodiments, DTU 108\* may support more than three levels of priority or less than two levels of priority, i.e. no prioritization.

[0038] Additionally, DTU 108\* includes outbound transaction queue service state machine 406 and inbound transaction queue service state machine 408, coupled to the transaction queues 402\* and 404\* as shown. Outbound transaction queue service state machine 406 services, i.e. processes, the transactions placed into the outbound queues 402\* in order of the assigned priorities of the queues 402\* and 404\*, i.e. with the transactions queued in the highest priority queue being serviced first, then the transaction queued in the next highest priority queue next, and so forth.

[0039] For each of the transactions being serviced, outbound transaction queue service state machine 406 provides the control signals to the corresponding outbound queue 402\* to output on the subsystem's request lines, the included bus arbitration priority of the first header of the "oldest" (in turns of time queued) transaction of the queue 402\*, to arbitrate and compete for access to bus 104 with other contending transactions of other subsystems 102\*. Upon being granted access to bus; 104 (per the state of the subsystem's grant lines), for the embodiment, outbound transaction queue service state machine 406 provides the control signals to the queue 402\* to output the remainder of the transaction, e.g. for the earlier described transaction format, the first header, the second header and optionally, the trailing data.

[0040] Similarly, inbound transaction queue service state machine 408 provides the control signals to the corresponding inbound queue 402\* to claim a transaction on bus 104, if it is determined that the transaction is a new request transaction of the subsystem 102\* or a reply transaction to an earlier request transaction of the subsystem 102\*. Additionally, in one embodiment, if the claiming of a transaction changes the state of the queue 404\* from empty to non-empty, inbound transaction queue service state machine 408 also asserts a "non-empty" signal for the core logic (not shown) of the subsystem 102\*.

[0041] In due course, the core logic, in view of the "non-empty" signal, requests for the inbound transactions queued. In response, inbound transaction queue service state machine 408 provides the control signals to the highest priority non-empty inbound queue to cause the queue to output the "oldest" (in turns of time queued) transaction of the queue 404\*. If all inbound queues 404\* become empty after the output of the transaction, inbound transaction queue service state machine 408 de-asserts the "non-empty" signal for the core logic of the subsystem 102\*.

[0042] Thus, under the present invention, a core logic of a subsystem 102\* is not only able to influence the order its transactions are being granted access to bus 104, relatively

to transactions of other subsystems **102\***, through specification of the bus arbitration priorities in the transactions' headers, a core logic of a subsystem **102\***, by selectively placing transactions into the various outbound queues **402\*** of its DTU **108\***, may also utilize the facilities of DTU **108\*** to locally prioritize the order in which its transactions are to be serviced to arbitrate for access for bus **104**.

[0043] Queue pair **402\*** and **404\*** may be implemented via any one of a number of "queue" circuitry known in the art. Similarly, state machines **406-408**, to be described more fully below, may be implemented using any one of a number of programmable or combinatory circuitry known in the art. In one embodiment, assignment of priorities to the queues pairs **402\*** and **404\*** are made by programming a configuration register (not shown) of DTU **108\***. Likewise, such configuration register may be implemented in any one of a number of known techniques.

#### State Machines

[0044] Referring now to FIGS. 5s and 5b wherein two state diagrams illustrating the operating states and transitional rules of state machines **406** and **408** respectively, in accordance with one embodiment, are shown. The embodiment assumes three pairs of queues **402a** and **404a**, **402b** and **404b**, and **402c** and **404c**, having three corresponding level of assign priorities, high, medium and low.

[0045] As illustrated in FIG. 5a, initially, for the embodiment, state machine **406** is in idle state **502**. If state machine **406** detects that the high priority queue **402a** is non-empty, it transitions to first arbitrate state **504**, and arbitrate for access to bus **104** for the "oldest" (in terms of time queued) transaction queued in the high priority queue **402a**. However, if while in idle state **502**, state machine **406** detects that the high priority queue **402a** is empty and the medium priority queue **402b** is not empty, it transitions to second arbitrate state **508**, and arbitrate for access to bus **104** for the "oldest" (in terms of time queued) transaction queued in the medium priority queue **402b**. Similarly, if while in idle state **502**, state machine **406** detects that both the high and medium priority queues **402a-402b** are empty, and the low priority queue **402c** is not empty, it transitions to third arbitrate state **512**, and arbitrate for access to bus **104** for the "oldest" (in terms of time queued) transaction queued in the low priority queue **402c**. If none of these transition conditions are detected, state machine **406** remains in idle state **502**.

[0046] Upon arbitrating for access to bus **104** for the "oldest" (in terms of time queued) transaction queued in the highest priority queue **402a** after entering first arbitrate state **504**, state machine **406** remains in first arbitrate state **504** until the bus access request is granted. At such time, it transitions to first placement state **506**, where it causes the granted transaction in the high priority queue **404a** to be placed onto bus **104**.

[0047] From first placement state **506**, state machine **406** returns to one of the three arbitrate states **504**, **508** and **512** or idle state **502**, depending on whether the high priority queue **402a** is empty, if yes, whether the medium priority queue **402b** is empty, and if yes, whether the low priority queue **402c** is also empty.

[0048] Similarly, upon arbitrating for access to bus **104** for the "oldest" (in terms of time queued) transaction queued in

the medium priority queue **402b** after entering second arbitrate state **508**, state machine **406** remains in second arbitrate state **508** until the bus access request is granted. At such time, it transitions to second placement state **510**, where it causes the granted transaction in medium priority queue **402b** to be placed onto bus **104**.

[0049] From second placement state **510**, state machine **406** returns to one of the three arbitrate states **504**, **508** and **512** or idle state **502**, depending on whether the high priority queue **402a** is empty, if yes, whether the medium priority queue **402b** is empty, and if yes, whether the low priority queue **402c** is also empty.

[0050] Likewise, upon arbitrating for access to bus **104** for the "oldest" (in terms of time queued) transaction queued in the low priority queue **402c**, state machine **406** remains in third arbitrate state **512** until the bus access request is granted. At such time, it transitions to third placement state **514**, where it causes the granted transaction in low priority queue **402c** to be placed onto bus **104**.

[0051] From third placement state **514**, state machine **406** returns to one of the three arbitrate states **504**, **508** and **512** or idle state **502**, depending on whether the high priority queue **402a** is empty, if yes, whether the medium priority queue **402b** is empty, and if yes, whether the low priority queue **402c** is also empty.

[0052] As illustrated in FIG. 5b, initially, for the embodiment, state machine **408** is also in idle state **602**. While at idle state **602**, if no transaction on bus **104** is addressed to the subsystem **102\*** (or one of the functions of the subsystem **102\***, in the case of a reply transaction), nor are there any pending request for data from the core logic of the subsystem **102\***, state machine **408** remains in idle state **602**.

[0053] However, if the presence of a transaction on bus **104** addressed to the subsystem **102\*** (or one of the functions of the subsystem **102\***, in the case of a reply transaction) is detected, state machine **408** transitions to claim state **604**, where it provides control signals to the appropriate queue **404\*** to claim the transaction, and acknowledges the transaction.

[0054] If claiming of the transaction changes the state of the queues from all empty to at least one queue not empty, state machine **408** transitions to the notify state **606**, in which it asserts the "non-empty" signal for the core logic of subsystem **102\***, as earlier described.

[0055] From notify state **606**, state machine **408** transitions to either claim state **604** if there is another transaction on bus **104** addressed to the subsystem **102\*** (or a function of the subsystem **102\***, in case of a reply), or output state **608**, if there is a pending request for data from the core logic of the subsystem **102\***. From output state **608**, state machine **408** either transitions to claim state **604** another transaction on bus **104** addressed to the subsystem **102\*** (or a function of the subsystem **102\***, in case of a reply) is detected, remains in output state **608** if there is no applicable transaction on bus **104**, but request for data from the core logic is outstanding, or returns to idle state **602**, if neither of those two conditions are true.

Bus Signals, Timing and Rules		
In one embodiment, the bus signals supported are as follows:		
Signal Name	Signal Width	Description
MSCLK	1	Bus Clock (e.g. 25–100 MHz)
MSRST	1	System Bus Reset
MSAD[31:0]	32	Address/Data (tri-state, bi-directional)
MSCYC	1	Shared among subsystems to denote master bus cycles
MSREQ[1:0]	pair for each subsystem	Bus request, 2 per subsystem to gain ownership of bus
MSGNT	# of subsystems	Bus grant-signifies subsystem own the bus
MSEL	1	Slave select-signifies subsystem has been selected (tri-state)
MSRDY	1	Master ready-signifies master data ready on the bus (tri-state)
MSBSY	1	Slave Busy-signifies selected device is busy (tri-state)
MSINT	# of subsystems	Interrupt request

[0056] In one embodiment, the request codes supported are as follows:

Req[1:0]	Request Type
00	Idle-no request
01	Low priority (“conventional” Data)
10	Medium priority (Control)
11	High priority (Voice and Replies)

[0057] FIGS. 6a-6c are three timing diagrams illustrating the timings of the various signals of the above described embodiment, for burst write timing, write followed by read timing and read followed by write timing (different subsystems) respectively.

[0058] In one embodiment, the maximum burst transfer size is 64-bytes of data (+8 bytes for the transaction header). The subsystems guarantee the burst transfer to be within a page. The slave devices would accept the maximum sized transfer (64 bytes +header) before generating the above described MSEL signal.

[0059] In one embodiment, each data transfer unit would permit only one Read request to be outstanding. If a Read request is pending, the subsystem would not accept requests from other masters until the reply to the outstanding Read request has been received. This advantageously prevents a deadlock condition. The subsystem may, however, continue to generate write requests.

[0060] In alternate embodiments, the present invention may be practiced with other approaches being employed to address these and other operational details.

#### Alternate Embodiment with Data Traffic Router

[0061] Referring now to FIG. 7, wherein another overview of SOC 100, including the employment of data traffic router 110, in accordance with another embodiment is shown. As will be described in more detail below, data traffic router 110 advantageously enables selected combinations of

the attached subsystems, such as subsystem A 102a, subsystem B 102b, subsystem C 102c, and the subsystem among subsystems D-G 102d-102g granted access to on-chip bus 104 to concurrently communicate with one another. For example, subsystem A 102a may be communicating with subsystem B 102b, while at the same time subsystem B 102b may be communicating with subsystem C 102c, subsystem C communicating with one of subsystem D-G 102d-102g having been granted access to on-chip bus 104, and so forth. Thus, data traffic router 110 is particularly useful for embodiments of SOC 100 where a subset of the subsystems 102a-102g has a relatively higher volume of communications with other subsystems. For example, in one embodiment of SOC 100 comprising a processor controlling the overall operation of SOC 100, an on-chip memory, and an external device controller having multiple external devices attached to them, these subsystems, i.e. the processor, the on-chip memory, and the external device controller all have relatively more communication needs than other subsystems 102\* of SOC 100.

#### Data Traffic Router

[0062] FIG. 8 illustrates the data paths 110a of data traffic router 110 in accordance with one embodiment. As illustrated, for the embodiment, multiplexor 802a is coupled to subsystem B 102b, subsystem C 102c and at any instance in time, one of subsystems D-G 102d-102g, the current grantee subsystem of on-chip bus 104, to select and output one of the outputs of these subsystems for subsystem A 102a. Similarly, multiplexor 802bis coupled to subsystem A 102a, subsystem C 102c and at any instance in time, one of subsystems D-G 102d-102g, the current grantee subsystem of on-chip bus 104, to select and output one of the outputs of these subsystems for subsystem B 102b. For the embodiment, multiplexor 802b may also select the output of subsystem B 102b and output it back for subsystem B 102b, thereby enabling two external devices attached to subsystem B 102b to communicate with one another.

[0063] In like manner, multiplexor 802c is coupled to subsystem A 102a, subsystem B 102b, and at any instance in time, one of subsystems D-G 102d-102g, grantee subsystem of on-chip bus 104, to select and output one of the outputs of these subsystems for subsystem C 102b, and multiplexor 802d is coupled to subsystem A 102a, subsystem B 102b, and subsystem C 802c to select and output one of the outputs of these subsystems for one of subsystem D-G 102d-102g, the current grantee subsystem of on-chip bus 104.

[0064] Thus, it can be seen by selectively configuring multiplexors 802a-802d, communications between a subset of selected combinations of subsystem A-G 102a-102g may be facilitated concurrently.

[0065] FIG. 9 illustrates the control aspect 110b of data traffic router 110, in accordance with one embodiment. As illustrated, for the embodiment, the control aspect 110b of data traffic router 110 includes configurator 902 and configuration states storage unit 904 coupled to one another. Further, configurator 902 is coupled to the various subsystems, i.e. subsystem A 102a, subsystem B 102b, subsystem C 102c, and in any instance in time, one of subsystems D-G 102d-102g, the grantee subsystem of on-chip bus 104, and receiving the outputs of these subsystems. More specifically, for the embodiment, recall, upon granted

access to on-chip bus **104**, each of these subsystems outputs the header of a transaction, which includes an address of the addressee subsystem, denoting the destination of the output.

[0066] Thus, based at least on the headers of the transactions, configurator **902** is able to discern the desired destinations of the outputs of the various subsystems. In response, configurator **902** generates and provides control signals to multiplexors **802a-802d** to configure multiplexors **802a-802d** to correspondingly select the appropriate inputs of the multiplexors **802a-802d** to provide the appropriate data paths for the data to reach the desired destinations, if configurator **902** is able to do so. That is, if the required multiplexors **802a-802d** have not already been configured to provide data paths for other communications first.

[0067] Thus, configurator **902** generates and provides control signals to multiplexors **802a-802d** to configure multiplexors **802a-802d** based at least in part on the current configuration states of multiplexors **802a-802d**. If a needed multiplexor is idle, and may be configured to provide the desired path. Configurator **902** generates and outputs the appropriate control signal for the multiplexor to configure the multiplexor to provide the appropriate path. Moreover, the new configuration state of the multiplexor is tracked and stored in configuration state storage unit **904** for use in subsequent configuration decisions. On the other hand, if the multiplexor is busy, that is it has already been configured to facilitate another communication, for the embodiment, configurator **902** notifies the subsystem accordingly. More specifically, for the embodiment, configurator **902** “retries” the subsystem, notifying the source subsystem that the destination subsystem is busy.

[0068] For the embodiment, as described earlier, upon granted access to on-chip bus **104**, each subsystem drives a control signal denoting the beginning of a transaction, and at the end of the transaction, deasserts the control signal, denoting the end of the transaction. Thus, responsive to the deassertion of the control signal denoting the end of the transaction, configurator **902** returns the corresponding multiplexor to the idle state, making the multiplexor available to be configured in a next cycle to facilitate another communication.

#### Subsystem Providing Multiple Access Paths-Memory

[0069] FIG. 10 illustrates yet another overview of SOC **100**, including a private/unshared access path between two most frequently communicated subsystems, in accordance with one embodiment. As illustrated, among the subsystems with relatively higher communication needs, such as subsystems A-C **102a-102c**, a couple of these subsystems have the highest need for timely high priority communications. Thus, it would be advantageous to provide a private/unshared communication link between these two most frequently communicated subsystems. Examples of two such subsystems are processor of SOC **100** responsible for controlling the overall operation of SOC **100**, and on-chip memory of SOC **100**.

[0070] FIG. 11 illustrates an exemplary memory subsystem equipped with multiple data transfer interfaces **1106a** and **1106b**, one data transfer interface **1106a** to operate and facilitate communication with other subsystems as earlier described, and another data transfer interface **1106b** to

operate and facilitate communication with the other most frequently communicated subsystem, such as the earlier described processor, in a complementary manner.

[0071] In addition to the two data transfer interfaces **1106a-1106b**, memory **1100** further includes memory array **1102**, a number of storage structures **1114-1118**, a number of multiplexors **1112a-1112c** and two control blocks **1104a-1104b**, coupled to each other as shown. First data transfer interface **1106a**, for the embodiment, includes two inbound queues **1108a** and **1108b** and an outbound queue **1110a**, whereas second data transfer interface **1106b** includes one each, an inbound queue **1108c** and an outbound queue **1110b**.

[0072] During operation, memory accesses from processor as well as other subsystems accessing memory **1100** in the earlier described manner are queued in inbound queues **1108a-1108b** in accordance with their priorities. However, super high priority memory accesses from processor accessing memory **1100** through the private non-shared communication link are queued in inbound queue **1108c**. Multiplexor **1112a** coupled to these queues **1108a-1108c**, under the control of access control **1104a**, selects memory accesses queued in these queues in order of their priorities and sequences the memory accesses into sequential storage structure **1114**. The sequenced memory accesses are released in turn, accessing memory array **1102**, and causing the data in the desired locations to be outputted.

[0073] In addition to controlling the operation of multiplexor **1112a** and sequential storage structure **1114**, for each memory access, access control **1104a** also causes the header of the reply transaction to the memory access be formed and staged in header storage structure **1116**. Output responses to memory accesses from memory array **1102** are stored in output storage structure **1118**.

[0074] Multiplexor **1112b** under the control of response control **1104b** selectively selects either headers queued in header storage structure **1116** and output data stored in output storage structure **1118**, and outputs them for multiplexor **1112c**. Multiplexor **1112c** in turn, under the control of response control **1104b** outputs the header/data to either outbound queue **1110a** or outbound queue **1110**.

[0075] Thus, it can be seen that memory **1110** is advantageously equipped to provide an additional private/unshared access path for a frequent access subsystem, such as a processor. Resultantly, inter-subsystem communication between subsystems of SOC **100** is further improved.

[0076] In various embodiments, to ensure data coherency, if subsystem A **102a** (e.g. a system processor) has been notified (e.g. via interrupt) by one of the subsystems **102\***, e.g. subsystem D **102d** (such as a network media access controller) of the fact that subsystem D **102d** has placed certain data into subsystem B **102b** (a memory unit), and subsystem A **102a** has a need to access the certain data, subsystem A **102a** would ensure the certain data have actually been placed into subsystem B **102b** (the memory unit) before accessing for that certain data through the direct unshared parallel access path. Subsystem A **102** (control processor) assumes that for efficiency of operation, subsystem D **102d** places the certain data in subsystem B **102b** (the memory unit) without requesting for confirmation, and notifies subsystem A **102a** upon initiating the placement

transaction. Thus, accessing the certain data via the unshared direct parallel access path immediately without the assurance may result in invalid data.

[0077] In one embodiment, subsystem A 102a (control processor) ensures that the certain data have actually been placed into subsystem B 102b (the memory unit) by first making “accesses” to subsystem B 102b (the memory unit) and subsystem D 102d via the shared access path, awaits for replies to these “accesses”, and defers making the access to subsystem B 102b (the memory unit) for the certain data via the unshared direct parallel access path until receiving the replies to these special “accesses”. The “accesses” to subsystem B 102b (the memory unit) and subsystem D 102d are made with appropriate priorities, equal to or less than the priority employed by subsystem D 102d in placing the certain data in subsystem B 102d (the memory unit). Accordingly, receipt of the replies by subsystem A 102a (control processor) ensures for subsystem A 102a that the certain data has indeed been placed into subsystem B 102b (the memory unit), by virtue of the manner transactions are processed through the respective DTU 108a-108d and 108d.

#### Conclusion and Epilogue

[0078] Thus, it can be seen from the above descriptions, an improved method and apparatus for inter-subsystem communication between subsystems of a SOC has been described. The novel scheme includes features incorporable in data transfer interfaces to facilitate additional private channels of communications between subsystems frequently communicate with one another. While the present invention has been described in terms of the foregoing embodiments, those skilled in the art will recognize that the invention is not limited to these embodiments. The present invention may be practiced with modification and alteration within the spirit and scope of the appended claims. Thus, the description is to be regarded as illustrative instead of restrictive on the present invention.

What is claimed is:

1. A memory unit for use in an integrated circuit (IC) comprising:

an array of memory cells;

a first data transfer interface coupled to the array of memory cells to provide a first access path for a selected one of a processor and a plurality of subsystems of the IC to access said array of memory cells;

a second data transfer interface coupled to the array of memory cells to provide a second access path for said processor to access said array of memory cells; and

a controller coupled to the array of memory cells and the first and second data transfer interfaces to control said array of memory cells and said first and second data transfer interfaces to facilitate concurrent accesses of said memory unit by said processor and said subsystems.

2. The memory unit of claim 1, wherein said first data transfer interface comprises

a first inbound queue coupled to said array of memory cells for queuing a first plurality of memory accesses of said processor and said subsystem of a first priority;

a second inbound queue coupled to said array of memory cells for queuing a second plurality of memory accesses of said processor and said subsystem of a second priority; and

an outbound queue coupled to said array of memory cells for queuing output responses to said first and second plurality of memory accesses of said processor and said subsystem of said first and second priorities accessed through said first and second inbound queues.

3. The memory unit of claim 1, wherein said second data transfer interface comprises

an inbound queue coupled to said array of memory cells for queuing a first plurality of memory accesses of said processor; and

an outbound queue coupled to said array of memory cells for queuing output responses to said first plurality of memory accesses of said processor.

4. The memory unit of claim 1, wherein said controller comprises

a sequential storage structure coupled to said array of memory cells;

a multiplexor coupled to inbound queues of said first and second data transfer units and said sequential storage structure to sequence memory accesses queued in said inbound queues into said sequential storage structure; and

a state machine coupled to said sequential storage structure, said multiplexor, and said inbound queues of said first and second data transfer units to control their operation.

5. The memory unit of claim 4, wherein said state machine controls said multiplexor to sequence memory accesses queued in said second data transfer interface into said sequential storage structure before sequencing any memory access queued in said first data transfer interface into said sequential storage structure.

6. The memory unit of claim 4, wherein said state machine controls said multiplexor to sequence memory accesses queued in inbound queues of said first data transfer interface into said sequential storage structure, in accordance with assigned priorities of said inbound queues.

7. The memory unit of claim 1, wherein said controller comprises

a first sequential storage structure to stage headers for output responses to memory accesses;

a second sequential storage structure coupled to said array of memory cells to stage output responses to memory accesses;

a first multiplexor coupled to said first and second sequential storage structures to selective output one of said staged headers of output responses to memory accesses and said staged output responses to memory accesses;

a second multiplexor coupled to said first multiplexor and outbound queues of said first and second data transfer units to selective output the selected output of said first multiplexor to a selected one of said outbound queues of said first and second data transfer unit; and

a state machine coupled to said first and second sequential storage structures, said first and second multiplexors,

and said outbound queues of said first and second data transfer units to control their operation.

**8.** In a memory unit of an integrated circuit (IC), a method of operation comprising:

queuing first memory accesses of a processor and a plurality of subsystems of the IC in inbound queues of a first data transfer interface;

queuing second memory accesses of the processor in an inbound queue of a second data transfer interface;

sequencing said first and second memory accesses into a single sequence of memory accesses; and

servicing said first and second memory accesses in accordance with their sequence order.

**9.** The method of claim 8, wherein said queuing of said first memory accesses of a processor and a plurality of subsystems of the IC in inbound queues of a first data transfer interface comprises queuing said first memory accesses into inbound queues of said first data transfer interface having associated priorities, in accordance with priorities of said first memory accesses.

**10.** The method of claim 8, wherein said sequencing comprises sequencing second memory accesses queued in said second data transfer interface before sequencing any memory access queued in said first data transfer interface.

**11.** The method of claim 8, wherein said sequencing comprises sequencing first memory accesses queued in inbound queues of said first data transfer interface, in accordance with assigned priorities of the inbound queues.

**12.** The method of claim 8, wherein said servicing comprises generating and queuing headers for output responses to said first and second memory accesses.

**13.** The method of claim 8, wherein said servicing comprises queuing output responses to said first and second memory accesses.

**14.** The method of claim 8, wherein said servicing comprises merging headers for output responses to said first and second memory accesses and output responses to said first and second memory accesses.

**15.** The method of claim 8, wherein said servicing comprises selectively outputting headers for output responses to said first and second memory accesses and output responses to said first and second memory accesses to a selected one of said first and said second data transfer interfaces.

**16.** An integrated circuit comprising:

a processor;

a plurality of subsystems; and

a memory unit coupled to said processor and said subsystems having at least a first access path to facilitate access by a selected one of said processor and said subsystem to access said memory unit and a second access path to facilitate access by said processor.

**17.** The integrated circuit of claim 16, wherein said memory unit comprises

an array of memory cells;

a first data transfer interface coupled to the array of memory cells to provide said first access path for said selected one of said processor and said subsystems;

a second data transfer interface coupled to the array of memory cells to provide said second access path for said processor; and

a controller coupled to the array of memory cells and the first and second data transfer interfaces to control said array of memory cells and said first and second data transfer interfaces.

**18.** The integrated circuit of claim 17, wherein said first data transfer interface comprises

a first inbound queue coupled to said array of memory cells for queuing a first plurality of memory accesses of said processor and said subsystem of a first priority;

a second inbound queue coupled to said array of memory cells for queuing a second plurality of memory accesses of said processor and said subsystem of a second priority; and

an outbound queue coupled to said array of memory cells for queuing output responses to said first and second plurality of memory accesses of said processor and said subsystem of said first and second priorities accessed through said first and second inbound queues.

**19.** The integrated circuit of claim 17, wherein said second data transfer interface comprises

an inbound queue coupled to said array of memory cells for queuing a first plurality of memory accesses of said processor; and

an outbound queue coupled to said array of memory cells for queuing output responses to said first plurality of memory accesses of said processor.

**20.** The integrated circuit of claim 17, wherein said controller comprises

a sequential storage structure coupled to said array of memory cells;

a multiplexor coupled to inbound queues of said first and second data transfer units and said sequential storage structure to sequence memory accesses queued in said inbound queues into said sequential storage structure; and

a state machine coupled to said sequential storage structure, said multiplexor, and said inbound queues of said first and second data transfer units to control their operation.

**21.** The integrated of claim 20, wherein said state machine controls said multiplexor to sequence memory accesses queued in said second data transfer interface into said sequential storage structure before sequencing any memory access queued in said first data transfer interface into said sequential storage structure.

**22.** The integrated circuit of claim 20, wherein said state machine controls said multiplexor to sequence memory accesses queued in inbound queues of said first data transfer interface into said sequential storage structure, in accordance with assigned priorities of said inbound queues.

**23.** The integrated circuit of claim 17, wherein said controller comprises

a first sequential storage structure to stage headers for output responses to memory accesses;

- a second sequential storage structure coupled to said array of memory cells to stage output responses to memory accesses;
- a first multiplexor coupled to said first and second sequential storage structures to selective output one of said staged headers of output responses to memory accesses and said staged output responses to memory accesses;
- a second multiplexor coupled to said first multiplexor and outbound queues of said first and second data transfer units to selective output the selected output of said first multiplexor to a selected one of said outbound queues of said first and second data transfer unit; and
- a state machine coupled to said first and second sequential storage structures, said first and second multiplexors, and said outbound queues of said first and second data transfer units to control their operation.
- 24.** The integrated circuit of claim 16, wherein said integrated circuit further comprises an on-chip bus to which said memory unit and at least a subset of said subsystems are attached.
- 25.** The integrated circuit of claim 16, wherein said integrated circuit further comprises a data traffic router to which said memory unit, said processor, and at least one of said subsystems is attached, said data traffic router facilitating concurrent communication between selected combinations of said memory unit, said processor and said at least one subsystem.
- 26.** The integrated circuit of claim 16, wherein each of said subsystems is a selected one of a security engine, a voice processor, a collection of peripheral device controllers, a framer processor, a network media access controller, and an external device controller.
- 27.** In an integrated circuit (IC), a method of operation comprising:
- a processor and a plurality of subsystem of the IC successively making first memory accesses of a memory unit of the IC via a first access path in turn;
  - the processor also successively making second memory accesses to said memory unit via a second access path in parallel; and
  - the memory unit servicing said first and second memory accesses made through said first and second access paths in parallel.
- 28.** The method of claim 27, wherein said servicing comprises
- queuing said first memory accesses of said processor and said plurality of subsystems of the IC in inbound queues of a first data transfer interface of said memory unit;
  - queuing said second memory accesses of the processor in an inbound queue of a second data transfer interface of said memory unit;
  - sequencing said first and second memory accesses into a single sequence of memory accesses; and
  - servicing said first and second memory accesses in accordance with their sequence order.
- 29.** The method of claim 28, wherein said queuing of said first memory accesses of said processor and said plurality of subsystems of the IC in inbound queues of a first data transfer interface comprises queuing said first memory accesses into inbound queues of said first data transfer interface having associated priorities, in accordance with priorities of said first memory accesses.
- 30.** The method of claim 28, wherein said sequencing comprises sequencing second memory accesses queued in said second data transfer interface before sequencing any memory access queued in said first data transfer interface.
- 31.** The method of claim 28, wherein said sequencing comprises sequencing first memory accesses queued in inbound queues of said first data transfer interface, in accordance with assigned priorities of the inbound queues.
- 32.** The method of claim 28, wherein said servicing comprises generating and queuing headers for output responses to said first and second memory accesses.
- 33.** The method of claim 28, wherein said servicing comprises queuing output responses to said first and second memory accesses.
- 34.** The method of claim 28, wherein said servicing comprises merging headers for output responses to said first and second memory accesses and output responses to said first and second memory accesses.
- 35.** The method of claim 28, wherein said servicing comprises selectively outputting headers for output responses to said first and second memory accesses and output responses to said first and second memory accesses to a selected one of said first and said second data transfer interfaces.
- 36.** The method of claim 27, wherein the method further comprises
- a first of said subsystem notifying said processor with respect to said first subsystem having placed a first data in said memory unit;
  - said processor making a first access of said first subsystem, and awaiting for a first reply to said first access of said first subsystem; and
  - said processor making a second access of said memory unit via said second access path for said first data placed into said memory unit by said first subsystem after at least receiving said first reply for said first access of said first subsystem.
- 37.** The method of claim 36, wherein the method further comprises
- said processor making a second access of said memory unit via said first access path, and awaiting for a second reply to said second access of said memory unit; and
  - said processor making said first access of said memory unit via said second access path for said first data placed into said memory unit by said first subsystem after also receiving said second reply for said second access of said memory unit.
- 38.** The method of claim 27, wherein the method further comprises
- a first of said subsystem notifying said processor with respect to said first subsystem having placed a first data in said memory unit;

said processor making a first access of said memory unit via said first access path, and awaiting for a first reply to said first access of said memory unit; and

said processor making a second access of said memory unit via said second access path for said first data

placed into said memory unit by said first subsystem after at least receiving said first reply for said first access of said memory unit.
