

BACKGROUND

We attempted to track disease vectors from their capture point to the point they acquired the disease. This was achieved using stable isotopes to identify D. citri sources of infection. Specifically, we nymph investigated the variability of nitrogen stable isotope ratios $^{15}N/^{14}N$ (expressed as $\delta^{15}N$) in citrus orchards with different fertilization management practices (organic versus conventional) and its correlation with the D. citri $\delta^{15}N$ values of the citrus pest, *Diaphorina citri*. adult **SOURCE OF PATHOGEN**

NEWLY INFECTED TREE

Citrus with HLB disease

HLB DISEASE

Tracing the origin of this pest in open field is crucial since the insect is a vector for the incurable and devastating citrus disease known as Huanglongbing (HLB).

THE STUDY

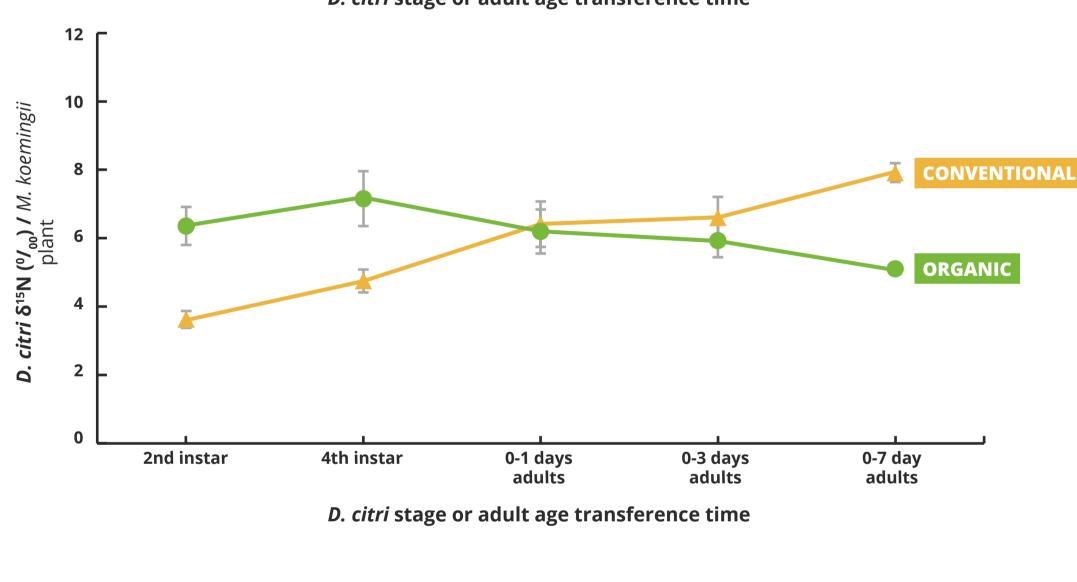

We hypothesized that the origin (natal tree) of the pest may be deduced by correlating the $\delta^{15}N$ values obtained from the young citrus leaves and the *D. citri* adults raised on them. Our study included:

Laboratory experiments to understand the acquisition and incorportation of the $\delta^{15}N$ values by *D. citri*.

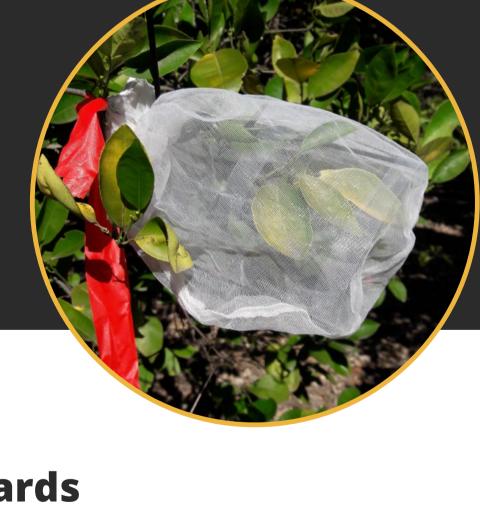

Average δ¹⁵N values (±SE) in leaf tissue from *M. koenigii* plants (with two fertilization regimes: conventional and organic) used to feed *D. citri*.

ORGANIC

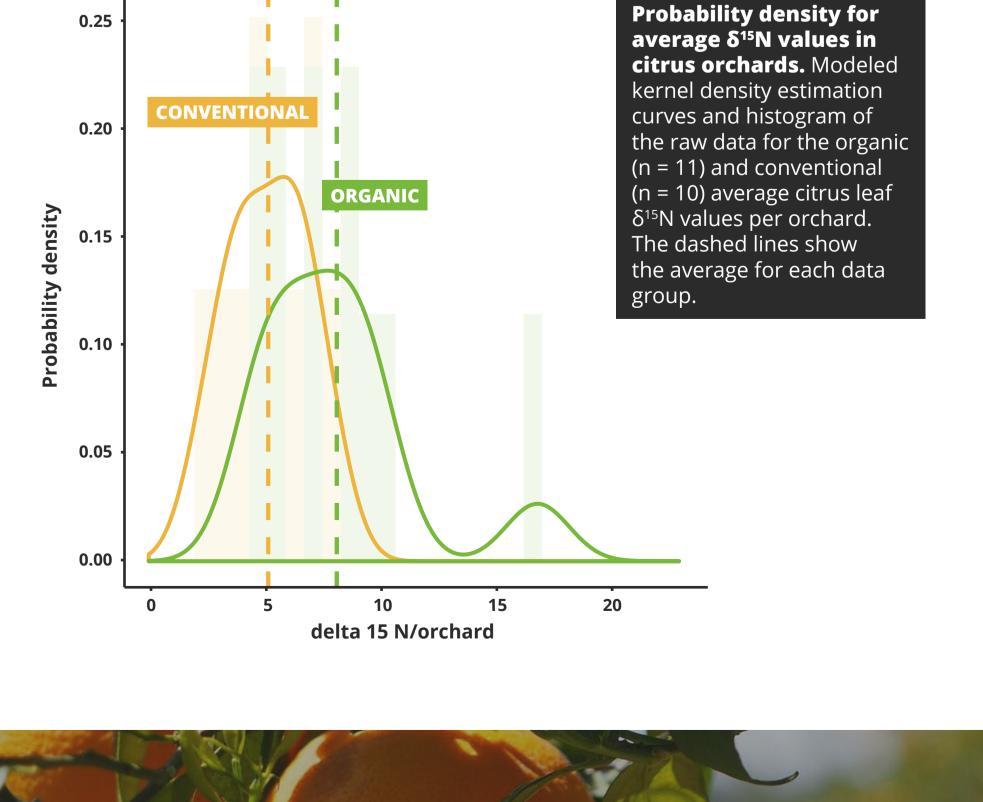

Average δ¹⁵N values (±SE) in *D. citri* adults raised on one plant fertilization regime and transferred, at various developmental stages, to plants with the opposite fertilization regime.

Confirming the positive correlation between the $\delta^{15}N$ values in the young citrus leaves and *D. citri*, by using exclusion bags in 4 orchards.

Field sampling in 21 citrus orchards from Southern California to study δ¹⁵N value variability in organic and conventional commercial citrus orchards.

CONCLUSION

Laboratory results suggest that the analysis of $\delta^{15}N$ values can be regarded as a useful method to trace the origin of the pest. However, the **high variability in nitrogen resources used by growers** in both fertilization management practices (especially in organic orchards) **makes this technique unfeasible in pinpointing the origin of** *D. citri* in citrus agroecosystems.
