Introduction: Uniform fungicide trials (UFT) were conducted over the last years (2018, 2019, and 2020) to compare the efficacy of Miravis Ace®, a new Succinate Dehydrogenase Inhibitor (SDHI; Adepidyn/Pydiflumetofen) + Demethylation Inhibitor (DMI; Propiconazole) fungicide, when applied at, before, or after anthesis, or sequentially with a DMI fungicide to that of a standard anthesis-only application of Prosaro® or Caramba®. Miravis Ace was recently labeled for management of diseases of wheat, barley, and other small grain crops, and preliminary results from a limited number of trials showed that when applied at early anthesis (Feekes 10.5.1) or within the first 6 days after anthesis (DAA), it was just as effective as Prosaro and Caramba (2,3). However, one of the primary questions addressed in the UFTs was whether Miravis Ace was just as effective when applied at Feekes 10.3 (early heading). If it is, this will extend the application window to as many as 10 days, allowing greater flexibility in terms of application timing. In addition, having a new, effective fungicide, particularly one of a different chemistry, and a wider application window will create opportunities for evaluating two-treatment fungicide programs for FHB and DON management. Several two-treatment programs were evaluated in this study. Results from the three years are summarized herein.

Materials and Methods: To accomplish the aforementioned objective, field experiments were conducted in 16 US wheat-growing states in 2018, 2019 and 2020. The standard protocol consisted of the application of fungicide treatments (**Table 1**) to plots of a susceptible cultivar. The experimental design was a randomized complete block, with at least 4 replicate blocks. In all experiments, plots were artificially inoculated with either *F. graminearum*-colonized grain spawn or a spore suspension of the fungus applied approximately 24-36 hours after anthesis. Plots were mist-

irrigated during and shortly after anthesis in some experiments to enhance inoculum production and infection. FHB index (IND) was rated or calculated as previously described (1) on 60-100 spikes per plot at approximately Feekes growth stage 11.2. Grain was harvested and samples were sent to a USWBSI-supported laboratory for mycotoxin analysis. Linear mixed models (multi-location) were fitted to the pooled arcsine square root-transformed IND and log-transformed DON data to evaluate treatment effects. Efficacy of fungicide treatment was estimated using percent reduction in IND and DON relative to the nontreated check.

Table 1. The following treatments were randomly assigned to experimental units. All fungicide treatments were applied along with a nonionic surfactant.

Treatment - product, rate, and timing	
Core	
1	Nontreated check
2	Prosaro at 6.5 fl oz/A at anthesis
3	Caramba at 13.5 fl oz/A at anthesis
4	Miravis Ace at 13.7 fl oz/A at Feekes 10.3
5	Miravis Ace at 13.7 fl oz/A at anthesis
6	Miravis Ace at 13.7 fl oz/A at anthesis followed by Prosaro at 6.5 fl oz/A 4-6 DAA
7	Miravis Ace at 13.7 fl oz/A at anthesis followed by Caramba at 13.5 fl oz/A 4-6 DAA
Optional	
8	Miravis Ace at 13.7 fl oz/A at anthesis followed by tebuconazole at 4 fl oz/A 4-6 DAA
9	Miravis Ace at 13.7 fl oz/A at 4-6 DAA

*DAA = days after anthesis

Results and Discussion: Mean Fusarium head blight index (IND) and deoxynivalenol (DON) contamination data from 47 and 31 environments (trial x state x year combinations) are summarized for different fungicide treatments in Figures 1 and 2, respectively. FHB IND ranged from 0 to 69% and DON from 0 to 39 ppm across environments. For both responses, the nontreated check has the highest means, whereas treatments that consisted of an early anthesis (Feekes 10.5.1) application of Miravis Ace followed by an application of Prosaro, Caramba, or tebuconazole at 4-6 DAA had the lowest means (**Fig. 1** and **2**).

FHB index: Means varied across 47 environments and among fungicide treatments, as shown by the distribution of data points around the median in Figure 1. All treatments resulted in significantly lower mean IND (on the arcsine square root-transformed scale) than the nontreated check (**Fig. 1A** and **2A**). Single fungicide treatments applied at anthesis reduced mean IND by 55 (Caramba), 56 (Prosaro), and 68% (Miravis Ace), relative to the nontreated check (**Fig. 2A**). A single application of Miravis Ace applied at early heading (Feekes 10.3) or 4-6 DAA reduced mean IND by 57 and 63%, respectively. The greatest reduction in mean IND were observed from the sequential applications of Miravis Ace and a DMI, with percent control ranging from 74 (Miravis Ace followed by Prosaro) to 83% (Miravis Ace followed by tebuconazole). Sequential treatments consisting of Miravis Ace followed by Prosaro is not significantly different (on the arcsine square root-transformed scale) from Miravis Ace followed by Caramba. Miravis Ace followed by Prosaro and Miravis Ace followed by tebuconazole were also not significantly different from each other.

Deoxynivalenol: All treatments resulted in significantly lower mean DON contamination of grain (on the transformed scale) than the nontreated check (**Fig. 1B** and **2B**). All treatments with an application at anthesis and/or within the first 6 DAA resulted in significantly lower mean DON than

the early heading application of Miravis Ace (**Fig 2B**). Among the treatments with a single application at anthesis, Miravis Ace resulted in the highest percent reduction in mean DON (46%), followed by Prosaro (35%) and Caramba (34%). Treatments with sequential applications of Miravis Ace followed by a DMI had lower mean DON (1.5 to 1.8 ppm) than a single application of Miravis Ace at early head emergence (4.0 ppm), anthesis (2.5 ppm), or post-anthesis (2.3 ppm). Relative to the check, sequential treatments reduced mean DON by 62 (Miravis Ace followed by Prosaro and by Caramba) and 69% (Miravis Ace followed by tebuconazole).

As additional data become available, a more complete set of analyses will be performed. However, the results summarized herein suggest that an application of Miravis Ace at Feekes 10.3 may suppress FHB IND to levels comparable to those achieved with an anthesis application, but such an early application is considerably less effective than a single anthesis or post-anthesis application in terms of DON suppression. More effective control is achieved when Miravis Ace is applied sequentially with a DMI fungicide.
