Title

dslogit — Double-selection lasso logistic regression

Description	Quick start	Menu	Syntax
Options	Remarks and examples	Stored results	Methods and formulas
Reference	Also see		

Description

dslogit fits a lasso logistic regression model and reports odds ratios along with standard errors, test statistics, and confidence intervals for specified covariates of interest. The double-selection method is used to estimate effects for these variables and to select from potential control variables to be included in the model.

Quick start

Report an odds ratio from a logistic regression of y on d1, and include x1 to x100 as potential control variables to be selected by lassos

    dslogit y d1, controls(x1-x100)

Same as above, and estimate odds ratios for the levels of categorical d2

    dslogit y d1 i.d2, controls(x1-x100)

Use cross-validation (CV) instead of a plugin iterative formula to select the optimal λ^* in each lasso

    dslogit y d1 i.d2, controls(x1-x100) selection(cv)

Same as above, and set a random-number seed for reproducibility

    dslogit y d1 i.d2, controls(x1-x100) selection(cv) rseed(28)

Specify CV for the lasso for y only, with the stopping rule criterion turned off

    dslogit y d1 i.d2, controls(x1-x100) lasso(y, selection(cv), stop(0))

Same as above, but apply the option to the lassos for y, d1, and i.d2

    dslogit y d1 i.d2, controls(x1-x100) lasso(*, selection(cv), stop(0))

Compute lassos beyond the CV minimum to get full coefficient paths, knots, etc.

    dslogit y d1 i.d2, controls(x1-x100) lasso(*, selection(cv, alllambdas))

Syntax

> dslogit *depvar* *varsofinterest* $[$*if*$]$ $[$*in*$]$,
>
> <u>cont</u>rols($[$(*alwaysvars*)$]$ *othervars*) $[$*options*$]$

varsofinterest are variables for which coefficients and their standard errors are estimated.

options	Description
Model	
* <u>cont</u>rols($[$(*alwaysvars*)$]$ *othervars*)	*alwaysvars* and *othervars* make up the set of control variables; *alwaysvars* are always included; lassos choose whether to include or exclude *othervars*
selection(plugin)	use a plugin iterative formula to select an optimal value of the lasso penalty parameter λ^* for each lasso; the default
selection(cv)	use CV to select an optimal value of the lasso penalty parameter λ^* for each lasso
selection(adaptive)	use adaptive lasso to select an optimal value of the lasso penalty parameter λ^* for each lasso
selection(bic)	use BIC to select an optimal value of the lasso penalty parameter λ^* for each lasso
<u>sqrt</u>lasso	use square-root lassos for *varsofinterest*
<u>miss</u>ingok	after fitting lassos, ignore missing values in any *othervars* not selected, and include these observations in the final model
<u>off</u>set(*varname*)	include *varname* in the lasso and model for *depvar* with its coefficient constrained to be 1
SE/Robust	
vce(*vcetype*)	*vcetype* may be <u>rob</u>ust (the default), <u>clus</u>ter *clustvar*, or oim
Reporting	
level(*#*)	set confidence level; default is level(95)
or	report odds ratios; the default
coef	report estimated coefficients
display_options	control columns and column formats, row spacing, line width, display of omitted variables and base and empty cells, and factor-variable labeling
Optimization	
$[$no$]$log	display or suppress an iteration log
verbose	display a verbose iteration log
rseed(*#*)	set random-number seed
Advanced	
lasso(*varlist*, *lasso_options*)	specify options for the lassos for variables in *varlist*; may be repeated
sqrtlasso(*varlist*, *lasso_options*)	specify options for square-root lassos for variables in *varlist*; may be repeated

reestimate	refit the model after using [lassoselect](#) to select a different λ^*
<u>noh</u>eader	do not display the header on the coefficient table
<u>coefl</u>egend	display legend instead of statistics

*controls() is required.

varsofinterest, *alwaysvars*, and *othervars* may contain factor variables. Base levels of factor variables cannot be set for *alwaysvars* and *othervars*. See [U] **11.4.3 Factor variables**.

collect is allowed; see [U] **11.1.10 Prefix commands**.

reestimate, noheader, and coeflegend do not appear in the dialog box.

See [U] **20 Estimation and postestimation commands** for more capabilities of estimation commands.

Options

> Model

controls([(*alwaysvars*)] *othervars*) specifies the set of control variables, which control for omitted variables. Control variables are also known as confounding variables. dslogit fits lassos for *depvar* and each of the *varsofinterest*. *alwaysvars* are variables that are always to be included in these lassos. *alwaysvars* are optional. *othervars* are variables that each lasso will choose to include or exclude. That is, each lasso will select a subset of *othervars*. The selected subset of *othervars* may differ across lassos. controls() is required.

selection(plugin | cv | adaptive | bic) specifies the selection method for choosing an optimal value of the lasso penalty parameter λ^* for each lasso or square-root lasso estimation. Separate lassos are estimated for *depvar* and each variable in *varsofinterest*. Specifying selection() changes the selection method for all of these lassos. You can specify different selection methods for different lassos using the option lasso() or sqrtlasso(). When lasso() or sqrtlasso() is used to specify a different selection method for the lassos of some variables, they override the global setting made using selection() for the specified variables.

    selection(plugin) is the default. It selects λ^* based on a "plugin" iterative formula dependent on the data. See [LASSO] **lasso options**.

    selection(cv) selects the λ^* that gives the minimum of the CV function. See [LASSO] **lasso options**.

    selection(adaptive) selects λ^* using the adaptive lasso selection method. It cannot be specified when sqrtlasso is specified. See [LASSO] **lasso options**.

    selection(bic) selects the λ^* that gives the minimum of the BIC function. See [LASSO] **lasso options**.

sqrtlasso specifies that square-root lassos be done rather than regular lassos for the *varsofinterest*. This option does not apply to *depvar*. Square-root lassos are linear models, and the lasso for *depvar* is always a logit lasso. The option lasso() can be used with sqrtlasso to specify that regular lasso be done for some variables, overriding the global sqrtlasso setting for these variables. See [LASSO] **lasso options**.

missingok specifies that, after fitting lassos, the estimation sample be redefined based on only the nonmissing observations of variables in the final model. In all cases, any observation with missing values for *depvar*, *varsofinterest*, *alwaysvars*, and *othervars* is omitted from the estimation sample for the lassos. By default, the same sample is used for calculation of the coefficients of the *varsofinterest* and their standard errors.

When `missingok` is specified, the initial estimation sample is the same as the default, but the sample used for the calculation of the coefficients of the *varsofinterest* can be larger. Now observations with missing values for any *othervars* not selected will be added to the estimation sample (provided there are no missing values for any of the variables in the final model).

`missingok` may produce more efficient estimates when data are missing completely at random. It does, however, have the consequence that estimation samples can change when selected variables differ in models fit using different selection methods. That is, when *othervars* contain missing values, the estimation sample for a model fit using the default `selection(plugin)` will likely differ from the estimation sample for a model fit using, for example, `selection(cv)`.

`offset(`*varname*`)` specifies that *varname* be included in the lasso and model for *depvar* with its coefficient constrained to be 1.

──────┤ SE/Robust ├──────

`vce(`*vcetype*`)` specifies the type of standard error reported, which includes types that are robust to some kinds of misspecification (`robust`), that allow for intragroup correlation (`vce(cluster` *clustvar*`)`), and that are derived from asymptotic theory (`vce(oim)`). See [R] *vce_option*.

When `vce(cluster` *clustvar*`)` is specified, all lassos also account for clustering. For each lasso, this affects how the log-likelihood function is computed and how the sample is split in cross-validation; see *Methods and formulas* in [LASSO] **lasso**. Specifying `vce(cluster` *clustvar*`)` may lead to different selected controls and therefore to different point estimates for your variable of interest when compared to the estimation that ignores clustering.

──────┤ Reporting ├──────

`level(#)`; see [R] **Estimation options**.

`or` reports the estimated coefficients transformed to odds ratios, that is, e^α. Standard errors and confidence intervals are similarly transformed. `or` is the default.

`coef` reports the estimated coefficients α rather than the odds ratios (e^α). This option affects how results are displayed, not how they are estimated. `coef` may be specified at estimation or when replaying previously estimated results.

display_options: `noci`, `nopvalues`, `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `nofvlabel`, `fvwrap(#)`, `fvwrapon(`*style*`)`, `cformat(`%*fmt*`)`, `pformat(`%*fmt*`)`, `sformat(`%*fmt*`)`, and `nolstretch`; see [R] **Estimation options**.

──────┤ Optimization ├──────

[`no`]`log` displays or suppresses a log showing the progress of the estimation. By default, one-line messages indicating when each lasso estimation begins are shown. Specify `verbose` to see a more detailed log.

`verbose` displays a verbose log showing the iterations of each lasso estimation. This option is useful when doing `selection(cv)` or `selection(adaptive)`. It allows you to monitor the progress of the lasso estimations for these selection methods, which can be time consuming when there are many *othervars* specified in `controls()`.

`rseed(#)` sets the random-number seed. This option can be used to reproduce results for `selection(cv)` and `selection(adaptive)`. The default selection method `selection(plugin)` does not use random numbers. `rseed(#)` is equivalent to typing `set seed #` prior to running `dslogit`. See [R] **set seed**.

Advanced

lasso(*varlist*, *lasso_options*) lets you set different options for different lassos, or advanced options for all lassos. You specify a *varlist* followed by the options you want to apply to the lassos for these variables. *varlist* consists of one or more variables from *depvar* or *varsofinterest*. _all or * may be used to specify *depvar* and all *varsofinterest*. This option is repeatable as long as different variables are given in each specification. *lasso_options* are selection(...), grid(...), stop(#), toler-ance(#), dtolerance(#), and cvtolerance(#). When lasso(*varlist*, selection(...)) is specified, it overrides any global selection() option for the variables in *varlist*. It also overrides the global sqrtlasso option for these variables. See [LASSO] **lasso options**.

sqrtlasso(*varlist*, *lasso_options*) works like the option lasso(), except square-root lassos for the variables in *varlist* are done rather than regular lassos. *varlist* consists of one or more variables from *varsofinterest*. Square-root lassos are linear models, and this option cannot be used with *depvar*. This option is repeatable as long as different variables are given in each specification. *lasso_options* are selection(...), grid(...), stop(#), tolerance(#), dtolerance(#), and cvtolerance(#). When sqrtlasso(*varlist*, selection(...)) is specified, it overrides any global selection() option for the variables in *varlist*. See [LASSO] **lasso options**.

The following options are available with dslogit but are not shown in the dialog box:

reestimate is an advanced option that refits the dslogit model based on changes made to the underlying lassos using lassoselect. After running dslogit, you can select a different λ^* for one or more of the lassos estimated by dslogit. After selecting λ^*, you type dslogit, reestimate to refit the dslogit model based on the newly selected λ's.

reestimate may be combined only with reporting options.

noheader prevents the coefficient table header from being displayed.

coeflegend; see [R] **Estimation options**.

Remarks and examples

dslogit performs double-selection lasso logistic regression. This command estimates odds ratios, standard errors, and confidence intervals and performs tests for variables of interest while using lassos to select from among potential control variables.

The logistic regression model is

$$\Pr(y = 1|\mathbf{d}, \mathbf{x}) = \frac{\exp(\mathbf{d}\boldsymbol{\alpha}' + \mathbf{x}\boldsymbol{\beta}')}{1 + \exp(\mathbf{d}\boldsymbol{\alpha}' + \mathbf{x}\boldsymbol{\beta}')}$$

where $\mathbf{d}$ are the variables for which we wish to make inferences and $\mathbf{x}$ are the potential control variables from which the lassos select. dslogit estimates the $\boldsymbol{\alpha}$ coefficients and reports the corresponding odds ratios, e^{α}. However, double selection does not provide estimates of the coefficients on the control variables ($\boldsymbol{\beta}$) or their standard errors. No estimation results can be reported for $\boldsymbol{\beta}$.

For an introduction to the double-selection lasso method for inference, as well as the partialing-out and cross-fit partialing-out methods, see [LASSO] **Lasso inference intro**.

Examples that demonstrate how to use dslogit and the other lasso inference commands are presented in [LASSO] **Inference examples**. In particular, we recommend reading *1 Overview* for an introduction to the examples and to the vl command, which provides tools for working with the large lists of variables that are often included when using lassos methods. See *2 Fitting and interpreting inferential models* for comparisons of the different methods of fitting inferential models that are

available in Stata. Everything we say there about methods of selection is applicable to both linear and nonlinear models. See *3 Fitting logit inferential models to binary outcomes. What is different?* for examples and discussion specific to logistic regression models. The primary difference from linear models involves interpreting the results.

If you are interested in digging deeper into the lassos that are used to select controls, see *5 Exploring inferential model lassos* in [LASSO] **Inference examples**.

Stored results

dslogit stores the following in e():

Scalars
e(N)	number of observations
e(N_clust)	number of clusters
e(k_varsofinterest)	number of variables of interest
e(k_controls)	number of potential control variables
e(k_controls_sel)	number of selected control variables
e(df)	degrees of freedom for test of variables of interest
e(chi2)	χ^2
e(p)	*p*-value for test of variables of interest
e(rank)	rank of e(V)

Macros
e(cmd)	dslogit
e(cmdline)	command as typed
e(depvar)	name of dependent variable
e(lasso_depvars)	names of dependent variables for all lassos
e(varsofinterest)	variables of interest
e(controls)	potential control variables
e(controls_sel)	selected control variables
e(model)	logit
e(title)	title in estimation output
e(offset)	linear offset variable
e(clustvar)	name of cluster variable
e(chi2type)	Wald; type of χ^2 test
e(vce)	*vcetype* specified in vce()
e(vcetype)	title used to label Std. err.
e(rngstate)	random-number state used
e(properties)	b V
e(predict)	program used to implement predict
e(select_cmd)	program used to implement lassoselect
e(marginsnotok)	predictions disallowed by margins
e(asbalanced)	factor variables fvset as asbalanced
e(asobserved)	factor variables fvset as asobserved

Matrices
e(b)	coefficient vector
e(V)	variance–covariance matrix of the estimators

Functions
e(sample)	marks estimation sample

In addition to the above, the following is stored in r():

Matrices
r(table)	matrix containing the coefficients with their standard errors, test statistics, *p*-values, and confidence intervals

Note that results stored in r() are updated when the command is replayed and will be replaced when any r-class command is run after the estimation command.

Methods and formulas

dslogit implements double-selection lasso logit regression (DSLLR) as described in Belloni, Chernozhukov, and Wei (2016, table 2 and sec. 2.1). The regression model is

$$\mathbf{E}[y|\mathbf{d}, \mathbf{x}] = G(\mathbf{d}\boldsymbol{\alpha}' + \beta_0 + \mathbf{x}\boldsymbol{\beta}')$$

where $G(a) = \exp(a)/\{1 + \exp(a)\}$, $\mathbf{d}$ contains the J covariates of interest, and $\mathbf{x}$ contains the p controls. The number of covariates in $\mathbf{d}$ must be small and fixed. The number of controls in $\mathbf{x}$ can be large and, in theory, can grow with the sample size; however, the number of nonzero elements in $\boldsymbol{\beta}$ must not be too large, which is to say that the model must be sparse.

DSLLR algorithm

1. Perform a logit lasso of y on $\mathbf{d}$ and $\mathbf{x}$, and denote the selected controls by $\widetilde{\mathbf{x}}$.

   This logit lasso can choose the lasso penalty parameter (λ^*) using the plugin estimator, adaptive lasso, or CV. The plugin value is the default.

2. Fit a logit regression of y on $\mathbf{d}$ and $\widetilde{\mathbf{x}}$, denoting the estimated coefficient vectors by $\widetilde{\boldsymbol{\alpha}}$ and $\widetilde{\boldsymbol{\beta}}$, respectively.

3. Let $w_i = G'(\mathbf{d}_i\widetilde{\boldsymbol{\alpha}}' + \widetilde{\mathbf{x}}_i\widetilde{\boldsymbol{\beta}}')$ be the ith observation of the predicted value of the derivative of $G(\cdot)$.

4. For $j = 1, \ldots, J$, perform a linear lasso of d_j on $\mathbf{x}$ using observation-level weights w_i, and denote the selected controls by $\check{\mathbf{x}}_j$.

   Each of these lassos can choose the lasso penalty parameter (λ_j^*) using one of the plugin estimators for a linear lasso, adaptive lasso, or CV. The heteroskedastic plugin estimator for the linear lasso is the default.

5. Let $\widehat{\mathbf{x}}$ be the distinct variables from the union of the variables in $\check{\mathbf{x}}_1, \ldots, \check{\mathbf{x}}_J$, and $\widetilde{\mathbf{x}}$.

6. Fit a logit regression of y on $\mathbf{d}$ and $\widehat{\mathbf{x}}$, denoting the estimated coefficient vectors by $\widehat{\boldsymbol{\alpha}}$ and $\widehat{\boldsymbol{\beta}}$, respectively.

7. Store the point estimates $\widehat{\boldsymbol{\alpha}}$ in e(b) and their variance estimates (VCE) in e(V).

   Option vce(robust), the robust estimator of the VCE for a logistic regression, is the default. Specify option vce(oim) to get the OIM estimator of the VCE.

See *Methods and formulas* in [LASSO] **lasso** for details on how the lassos in steps 1 and 4 choose their penalty parameter (λ^*).
